We are disappointed bighorn sheep were given little consideration in the forest plan. Memoranda dated Feb 15, 1989, Feb 14, 1994 and April 18, 1995 to the Forest Service from the Wyoming Game and Fish Department and a letter dated Nov 6, 1995 from Grand Teton National Park stressed concerns about bighorn sheep winter range and domestic sheep grazing. At the Forest Service plan revision meeting on Jan 16, 1992, bighorn sheep were discussed as a possible management indicator species. Problems identified for this herd at this meeting included disease transmission from domestic sheep and loss of winter range due to plant succession and fire suppression.

The draft plan should include a forest-wide standard protecting crucial bighorn sheep winter range, and we also recommend historic bighorn sheep winter range be included in the winter range prescription. Bighorn sheep ranges located in Teton, Darby, Fox and Phillips Canyons, Rendezvous Peak, and Bitch Creek also need to be addressed in the forest plan. The standard should include recreation and travel constraints for these areas.

9 Disease Transmission From Domestic to Wild Sheep Scientific data indicate the single most important and ominous threat to the continued existence of the Teton bighorn sheep herd is the potential for a complete herd die-off resulting from a disease transmission from domestic sheep. The cause and effect relationship between bighorn die-offs and contact with domestic sheep is well known. The Forest Service's environmental assessment on the Moose Creek Sheep and Goat Allotment Grazing Permit renewal states "of 38 recorded die-offs of bighorn sheep from 1905 to the present, (at least) 23 were known to have been caused by contact with domestic sheep."

This well-documented relationship forms the basis for accepted and formalized management guidelines, recommendations, and practices at the domestic sheep/bighorn sheep interface. One such formal guideline, produced by and for the Forest Service (Suminski 1991) suggests establishing a buffer zone between domestic sheep and bighorn use areas to prevent transmission of fatal diseases, and recommends no trailing of domestic sheep occur within at least 2 miles of occupied bighorn ranges. This document also cites a 1981 letter from the Forest Service Chief to Regional Foresters stating "appropriate caution should be exercised to prevent contact between domestic sheep and bighorn sheep." Similar guidelines formulated by the Bureau of Land Management, and in consensus with the American Sheep Industry Association, the Western Association of Fish and Wildlife Agencies, and several bighorn sheep specialists and organizations (18 June 1992 memo from Director of the Bureau of Land Management) state a) domestic sheep grazing and trailing should be discouraged in the vicinity of bighorn sheep range, b) bighorn sheep and domestic sheep should be spatially separated to discourage the possibility of coming into physical contact with each other, and c) buffer strips (up to 9 miles wide depending on local conditions and management options) surrounding bighorn sheep habitat should be encouraged.

The Wyoming Game & Fish Department strongly recommends the Forest Service follow management strategies outlined by Suminski (1991). In particular, we emphasize implementation of management strategies 1, 2, 3, 5, 7, 8, 10. We also strongly encourage

implementation of a minimum of a two mile "buffer zone" between occupied bighorn sheep habitat and domestic sheep grazing

10 Recreation Under the recreation discussion (p III-17), a goal to minimize winter recreation impacts on wintering wildlife is included. We recommend standards and guidelines be developed and enforced to help achieve this goal

11 Lion Range Subsection (p III-47) Plans for this subsection have a wildlife objective to improve big game winter range. However moose and bighorn sheep winter ranges have been overlooked. This should be corrected. The Forest Service should also include standards and guidelines to address this objective

12 Designated Wilderness (pp III-57 - III-65) Bighorn sheep population indices indicate a declining population. We recommend the Forest Service include a goal in this section to maintain habitat for a viable bighorn sheep population, and give bighorn sheep priority over other wilderness uses. Bighorn sheep should also be included as one of the species (grizzly bears, harlequin ducks, and peregrine falcons) in all opportunity classes. No new trails or campsites should be allowed in bighorn sheep habitat

13 Management Prescription 2.7 (p III-92) This section should have a standard to limit outfitter special use permits from Dec 1 to April 30 to protect big game on crucial winter ranges. To minimize disturbance in elk security areas and protect habitat effectiveness all-terrain vehicles should not be allowed for game retrieval in any prescription

14 Timber Harvest, Palisades Ranger District Timber harvest on the Palisades Ranger District in Wyoming should only occur after development of a comprehensive cumulative impacts analysis that evaluates impacts to old growth and wildlife, and reviews public access to areas that winter big game species. Absence of protection for mule deer and elk crucial winter ranges on the Palisades Ranger District is of great concern. The environmental impact statement as well as the Standards and Guidelines should incorporate language that identifies and protects crucial mule deer and elk winter ranges

15 Management Implementation Draft standards and guidelines contain no specific language directing the Targhee National Forest to implement certain management practices, including prescribed burns, certain standards or activities specified for allotments, data collection to monitor allotment management plans, etc. We recommend the documents incorporate language stipulating compulsory management actions which are designed to repair, upgrade, or enhance watersheds and ecosystems

16 Elk Cover and Forage No elk cover/forage relationship guidelines (i.e. sight distance requirements logging impacts, and elk vulnerability guidelines) or habitat effectiveness guidelines are included in this plan revision. Guidelines should be developed and incorporated as standards especially in prescription areas considered as contributing to the suitable timber base and allowable sale quotient

17 Monitoring Programs Monitoring programs to identify current status of the forest plan relative to goals have not been included. The Forest Service should identify accomplishments, and future management directions

18 Outfitter and Guide Standards No outfitter and guide standards and guidelines were included. The Forest Service should provide these standards to allow for public review

19 Range of Natural Variability Many of the vegetation and habitat objectives are too ambiguously worded to accommodate management within the "range of natural variability". We understand the range of natural variability analysis study is not complete, and we have not had the opportunity to review this technique. Without specific range of natural variability criteria, we cannot determine wildlife impacts of an range of natural variability-driven forest objective. For example, if canopy in a lodgepole pine fire discriminates varies from 10% to 90%, how can we determine impacts on a threatened and endangered species? The range of natural variability analysis should be reviewed by the scientific community for accuracy and applicability in natural resource management prior to utilization in this revised plan

20 Riparian habitat Logging in contiguous areas should be conducted in a manner which improves streambank conditions. All previous discussions about riparian habitats have been omitted from the current description of the preferred alternative. These discussions should be re-instated

In our review of the riparian section prior to its omission, a written standard implied that population reductions were an appropriate solution in areas where wildlife use exceeds standards or guidelines for forage removal and streambank trampling. Livestock grazing standards and guidelines are generally based on vegetation and soil conditions within allotments, but the wildlife grazing standard is not tied to a specific area. More specific criteria should be developed to characterize what constitutes wildlife overutilization

21 Timber Harvest near Aquatic Systems The Wyoming Game & Fish Department does not support clearcutting within 100 feet of any water body, or cutting up to 50% of a timbered shoreline (lentic or lotic). To protect wildlife resources and minimize habitat degradation via erosion and other factors, a vegetative buffer strip managed for individual tree removal only (selective harvest) should be maintained for lakes, streams, wetlands, and impoundments. A wider buffer is necessary for areas with steep slopes or erodible soils

22 Biodiversity Several standards related to biodiversity have been changed to guidelines. We believe indicator species should remain as standards to assess habitat and species diversity. Without such standards, habitat management will become inconsistent and potentially conflict with Forest Service goals. Also no objectives are specifically tied to maintaining vegetative diversity as it pertains to old growth

23 Forest-wide Forage Utilization Standards The Wyoming Game & Fish Department does not believe the forest-wide forage utilization standards and guidelines are adequate to protect important habitats and areas susceptible to overgrazing. We believe qualified Forest Service personnel should periodically monitor all stocked ranges to determine forage utilization and to record damage to riparian communities and other sensitive habitats. We suggest the Forest Service also maintain written documentation of compliance for each allotment management plan. Upon completion of the new forest plan, an updated allotment management plan should be prepared for each allotment that will continue to be grazed by domestic stock. Also, all criteria designated under allotment management planning should be designated as standards, not guidelines. We recommend wording on pages III-20-III-22 be changed to read that data will be collected not should be collected, along riparian areas, to monitor livestock trampling and distribution.

24 State Wildlife Objectives The revised plan should incorporate wildlife objectives of the States of Wyoming and Idaho. State objectives are not based upon managing habitat to accommodate only "minimum viable populations". A "minimum viable population" is merely that needed to maintain genetic diversity. A population kept at that level would neither support sport hunting nor offer sufficient viewing opportunities to satisfy the non-consumptive public. Population objectives of the respective states should become forest-wide goals.

25 Old Growth We do not understand why old growth prescriptions managed or unmanaged, were not delineated in the Wyoming portion of the Targhee National Forest. Omission of old growth management from preferred Alternative 3-M is inappropriate. The National Forest Management Act requires no conversions of forest cover types yet restocking of spruce-fir and Douglas fir types is often difficult to nearly impossible. Therefore, conversions to lodgepole pine are inevitable. If old growth is reduced or lost, how will the new plan propose to replace it? Timber harvest in spruce-fir or Douglas fir types should only occur when there is evidence the site will naturally regenerate within the designated 5 year period. Also, standards and guidelines as well as specific goals for maintenance of old growth should be developed and enforced.

We recommend the Targhee National Forest also conduct an accurate inventory of old growth timber on the Forest by watershed or timber management unit and identify provisions for determining how large an area (watershed diversity unit cutting unit) must be maintained in order to accommodate 100 acres of old growth. For example will 5,000 or 500 contiguous acres be required to maintain 100 acres of old growth? One hundred acres of old growth within a specified area appears insufficient to maintain old growth habitat functions and dependent wildlife species. Much of the language in this revision is unclear regarding old growth management. Specific management criteria should be developed.

The revised plan also makes no provisions to increase old growth habitat without undergoing a forest plan amendment. This seems inconsistent with the flexibility the

tumber and range programs have to enlarge a timber sale area or increase the stocking levels of livestock with only minor National Environmental Policy Act documentation. The same guidelines should also apply to increasing old growth acreage.

26 Mountain Goats No management considerations are provided for mountain goats in the Wyoming portion of the revised plan. However, many mountain goats summer in Wyoming. Depending on livestock stocking rates, and distribution and length of domestic grazing in the high elevation cirque basins, domestic grazing can have a considerable impact on mountain goat summer range. We recommend the Forest Service evaluate all domestic sheep allotments that overlap occupied mountain goat habitat for impacts to high elevation cirque basin habitats and mountain goats. Goals and objectives of both the Idaho and Wyoming state wildlife management agencies should also be considered in the forest plan implementation process.

27 Protection of Big Game Winter Ranges The statement "Motorized access is managed or restricted to provide security for winter elk and deer" may be insufficient to provide adequate protection for important and crucial big game winter ranges. The Forest Service should prohibit motorized access in core areas of winter ranges that are crucial to the winter survival of big game.

28 Grizzly Bear Habitat In prescription area 2.6 to 2.6.5, grizzly bear habitat - Situation I, the Forest Service has designated the suitable timber base as part of the allowable sale quotient. If the Forest Service is interested in recovery of the grizzly bear on the Targhee National Forest, these areas should be considered for exclusion from the suitable timber base and allowable sale quotient.

29 Limited Access in Big Game Security Areas No specific definition is provided for "limited" access. If a primary goal is to maintain big game security habitat "limited" access should be more specifically defined and should include "prohibited" where warranted. Words such as "limited" or "restricted" are nebulous and promote ambiguity (reference snowmobile hill climb issue near Afton where the word "restricted" was used by the Forest Service). When areas are managed for "wildlife protection" or "wildlife values" and other resource uses are permitted (e.g. timber harvesting, grazing, off road vehicle use, etc.), wildlife values are ultimately compromised. The Forest Service should add a provision to prohibit motorized activities if they conflict with the primary goal of providing and protecting big game habitat. Motorized vehicle use should occur only on designated routes and only in those areas that do not conflict with big game security. Goals for timber management should consider big game security habitat.

30 Livestock Management Livestock grazing in areas where the goal is to protect big game security habitat can be incompatible due to the impacts of domestic animals on these habitat types. It is essential that management of livestock on important big game ranges assures the maintenance or improvement of habitat conditions for wildlife.

31 Water Developments for Livestock Water developments should be prohibited in areas that will dramatically affect the quality and quantity of forage for wildlife and which would adversely impact the distribution of big game

32 Range Management Standards In each prescription area, range management forest-wide forage utilization standards apply. However, the revised plan does not define these standards. The Forest Service should list these standards, especially for high value wildlife habitats and/or areas susceptible to domestic livestock overgrazing

33 Allotment Management Plan Integrated Ecosystem Management Process Additional standards should be implemented through the allotment management plan integrated ecosystem management process. We recommend the following additions

a Management should maintain or improve edge, edge contrast, food, and cover on all rangelands and shrublands to provide wildlife habitat

b On seasonally important big game range, management techniques that will maintain or improve key forage species in grass, forb, and shrub communities should be prescribed

c On mixed grass/forb/shrub range, a desired forb and shrub composition should be identified by the Forest Service wildlife biologist and used to assist in developing an integrated range/wildlife condition class objective. On mixed range, a forb component should comprise at least 10 percent, with a shrub component at least 30 percent of mixed vegetation cover

d Conflicts between livestock grazing and habitat conservation need to be identified for all riparian, aquatic and wetland habitats. Methods for conflict resolution should be developed

34 Goshawk Nest Surveys Effective protection of goshawks and goshawk nests cannot be achieved without adequate surveys. Surveys should be conducted for any activity which may disturb this species

35 Wildlife Surveys We recommend mandatory surveys for important wildlife and habitats prior to any project or activity that could significantly disrupt these important wildlife species or their habitats. We suggest forest-wide standards and guidelines require surveys to locate raptor nests, threatened and endangered species, candidate species, State priority species, caves, wetlands, etc

36 Sensitive Species The only sensitive species for which measurable standards are defined is the goshawk. The Targhee National Forest standards, guidelines, and prescriptions do not adequately deal with objectives for managing old growth habitat for pine martens, great gray owls, or cavity nesting birds, or habitats for bald eagles, peregrine falcons, or trumpeter swans. We suggest adding a goal to provide habitat to support existing populations and distribution of nongame birds and mammals listed as

species of special concern (Wyoming) or sensitive species by state agencies and the Targhee National Forest

37 Bald Eagles The revised plan states that in occupied nesting zones and primary use areas, human activity will be "minimized" (p III-11). However, where possible, human activity should be prohibited if nest success is a goal. Additionally, historic levels of livestock use are permitted near bald eagle nests as long as no adverse impacts occur related to this activity. "Adverse impacts" should be defined to avoid any misunderstanding of what constitutes an adverse impact

38 Peregrine Falcons All known peregrine falcon nest sites/cliffs should be protected from human activity. Timber sale and mineral extraction activities should not occur within the buffer defined by the peregrine falcon recovery plan or current U.S. Fish and Wildlife Service recommendations for known peregrine falcon nest sites. This stipulation should also be a standard, not a guideline

39 Use of Toxicants We recommend toxicants (including M-44s) be restricted on the Targhee National Forest. In adopting a new management system based on enhancing biological diversity, using toxicants on National Forest System lands to kill wildlife would be a contradiction to the ecosystem approach of land management. Furthermore, in areas that are or may be occupied by grizzly bears or other threatened or endangered species, the use of toxicants on the Targhee National Forest may violate the Endangered Species Act

40 Livestock Pastures The Forest Service has designated as a standard that all administrative sites will comply with forest-wide standards and guidelines for livestock pastures. However, no other livestock pastures are required to meet this compliance. The Forest Service should clarify this discrepancy, and justify management of select livestock pastures by guidelines rather than standards

41 Livestock Conversions Livestock conversions should be considered only after a cumulative impacts analysis is completed to determine what impacts such a conversion will have on wildlife, range resources, vegetation communities, watershed function, recreation (i.e. hunting, hiking, etc.) and soil maintenance and stability

42 Range Improvements In addition to the criteria listed on page III-22, another criterion should be added stating range improvements (i.e. fence construction, water developments, livestock type conversions, etc.) will avoid adversely affecting local wildlife. Emphasis should be placed on improvements that benefit both livestock distribution and wildlife

43 Designation of Natural Resources Goal statements on page III-20 imply wildlife is not a basic natural resource found on the Targhee National Forest. The Wyoming Game & Fish Department strongly disagrees with this implication. Many native wildlife species have evolved and coexisted for thousands of years within the Targhee Forest. Wildlife is one of the basic resources. We believe forage production for

basic natural resources, including wildlife, should be considered before other consumptive uses

44 Maximum Utilization Levels Most maximum utilization levels in Table 1 (p III-21) appear overestimated. We are unaware of any scientific literature supporting utilization levels at 40%/4" stubble height for grasses and 50%/3" stubble height for herbaceous upland species for season-long and rotation grazing of unsatisfactory ranges. In many cases, upland ranges in unsatisfactory condition do not recover to satisfactory condition after several years of complete rest. The preponderance of current scientific literature recommends much more conservative utilization levels. Utilization recommendations for sagebrush grasslands, coniferous forests, and mountain shrubs range from 30-40% (Holechek 1988). Root growth is significantly reduced at levels exceeding 50% leaf removal; and 60% leaf volume removal results in 50% root growth stoppage (Dietz 1989). Dietz (1989) reports 20 to 50% of the total root system of grasses is lost annually. These roots must be replaced if the plant is to remain healthy and productive. Utilization rates in Table 1 are consistently 5 to 10% higher than levels recommended in the scientific literature. This table should be modified unless the Forest can provide a scientific basis (literature, etc.) for the recommended utilization levels. Application of generic utilization levels to all shrubs is inappropriate. While many species of shrubs can withstand 50-60% utilization (i.e. willows, rabbitbrushes), others (i.e. antelope bitterbrush, sagebrush, mountain mahogany) should not receive more than 20-25% use.

45 Riparian Forage Utilization Riparian rangeland maximum utilization levels identified in the revised plan (p III-21) are excessive according to current scientific literature. The Forest Service Intermountain Research Station publication by Clary and Webster (1989) provides an excellent review of recommendations for grazing intermountain riparian areas and should be consulted for developing standards and guidelines. Clary and Webster recommend that "residual stubble or regrowth should be at least 4 to 6 inches in height to provide sufficient herbaceous vigor, maintenance, bank protection, and sediment entrapment". Moreover, these utilization guides are based on "use in pastures in good to high ecological status". Degraded riparian areas may require complete rest to initiate the recovery process. The required rest period may range from 1 to 15 years. Knopf and Cannon (1982) concluded that 10 to 12 years was not sufficient time for a riparian willow community to recover from a history of excessive grazing. Others recommend 35-45% utilization on excellent condition meadows and down to 20-30% on meadows in poor condition (Ratliff et al. 1987, Platts 1982). Meyers (1989) reported additional stubble height, such as 6 inches or more, may be necessary to protect riparian ecosystem functions.

Allowable utilization levels identified in the revised plan for use of unsatisfactory riparian areas range to 4" stubble height. This is contrary to current scientific literature. This section also allows or exceeds the minimum stubble height recommended by current literature for each category, including 2" stubble heights for Kentucky bluegrass areas. Riparian sites dominated by Kentucky bluegrass are usually a result of historic and present overgrazing by livestock and the characteristic of site conversions. Allowing for

continued utilization at the 2" stubble height level will never allow for re-establishment of native species capable of restoring proper watershed functions. We recommend that all stubble heights be increased to 5" and 6" for satisfactory and unsatisfactory conditions, respectively, unless the Forest Service can provide scientific documentation to support the levels in the revised plan.

46 Allotment Management Planning Goals for allotment management planning state the Forest Service wishes to "Achieve or maintain rangeland in satisfactory condition which is defined as 1) having a resource value rating of 50 or above for vegetation." A resource value rating of 50 places a rangeland site in "fair" condition. This designation results in a "satisfactory" condition from a Forest Service range management perspective. The Wyoming Game & Fish Department does not consider "fair" and "satisfactory" as equivalent range conditions for wildlife habitat. We recommend goals for resource value rating scores should be greater than 50, which would place rangelands in Good or Excellent condition ratings.

47 Allotment Management Planning The allotment management planning section appears fairly intensive and inclusive. However, given current budget and personnel restrictions, it is unlikely the Forest Service can implement allotment management planning at the levels prescribed in the revised plan on all allotments. To compensate, utilization levels may be used to evaluate range condition. As previously discussed, we believe the proposed utilization levels are too high and are not supported by scientific literature. Utilization levels should be more conservative and specific relative to vegetative species and location.

48 Resource Value Ratings We recommend more emphasis be given to maintaining or improving resource value ratings for rangelands and less on utilization levels, unless the Forest Service makes utilization levels more specific relative to species and site. Resource value ratings compare current range conditions to potential natural vegetation. This is consistent with the ecological approach to resource management which the Forest Service is taking.

49 Fire and Fuels Management We recommend the following be incorporated into standards and guidelines for fire and fuels management:

a Change the goal to "To provide well-planned and executed fire management programs that mimic natural fire regimes, are efficient, and are responsive to land and resource management goals and objectives."

b Add to the standards and guidelines information and education section "prepare and make available to the public informational and educational materials addressing fire behavior, effects, and natural role in ecosystem management."

50 Management Prescriptions (p III-56) We recommend the Targhee National Forest develop a management prescription for those avian species dependent on forested

habitat for population viability. These species include, but are not limited to northern goshawk, boreal owl, great gray owl, northern pygmy-owl, northern saw-whet owl, Lewis' woodpecker, three-toed woodpecker, Williamson's sapsucker, and black-backed woodpecker. A management prescription should also be developed for the common loon because existing breeding habitat within the Targhee National Forest is important to the continued nesting success of this small population. Any management prescriptions for the common loon within Wyoming should be coordinated with wildlife and fisheries personnel in our Jackson regional office, and non-game personnel in our Lander regional office.

51 Ecological Component (p II-2) To the sentence "Native plant and animal species are favored and habitats are managed with the goal of delisting threatened and endangered", we suggest adding "and preventing new listing of threatened and endangered species."

52 Caves, Standards and Guidelines (p III-5) Abandoned mines are a significant component of bat habitat. Over one-half of 118 underground features surveyed in Wyoming occupied by bats were abandoned mines (Friday and Luce 1996). If abandoned mines occur on the Targhee National Forest, they should be protected as bat habitat and given the same management consideration as caves. All underground features on the Targhee National Forest should be considered habitat for Townsend's big-eared bat and other Wyoming Game and Fish Department bat species of special concern until surveys have been conducted. We suggest the Forest Service standards and guidelines for bat management include the following provisions:

- a) Subsection 1 Due to potential disturbance, logging, road construction and other uses of heavy equipment should be prohibited above any cave or abandoned mine known or suspected to be bat habitat until season of bat use is well documented. Seasonal restrictions should be applied as necessary where caves or abandoned mines are known to be occupied by bats.
- b) Subsection 2 Direction and amount of air flow are significant components of bat habitat and are affected by standing timber near cave or abandoned mine entrances. We recommend a buffer zone for timber harvests with a minimum of 500 feet horizontal radius around all bat roosts.
- c) Human disturbance to roosting bat colonies can have significant negative impacts on populations. Disturbance can be direct (vandalism or intentional disturbance), or indirect (walking through an occupied cave or abandoned mine), resulting in roost abandonment or death of wintering bats. We recommend logging roads be planned to avoid improving access to caves and abandoned mines used by bats during any season of the year.
- d) Spotted bat and Townsend's big-eared bat objective (p III-16) Man-made underground habitat should be described as either an abandoned mine adit or abandoned mine shaft. Adit refers to a horizontal feature and shaft to a vertical

feature. The spotted bat is rarely associated with caves and abandoned mines instead occupying cracks in sheer rock walls and other habitat associated with canyons. Therefore, the Targhee National Forest should remove this species from all discussions related to caves and abandoned mines.

e) The Targhee National Forest should recognize management activities may impact bat habitat other than caves and abandoned mines. For example, snags may be an important component of habitat for forest dwelling species including Townsend's big-eared bat.

f) Management Prescriptions (pp III-56 and V) For all management prescriptions, the Targhee National Forest should work with the respective state wildlife agencies to verify cave and abandoned mine locations and conduct bat surveys. Long-term monitoring of populations and distribution should also be conducted.

53 Access, Standards and Guidelines (p III-16) Roads should be dosed and/or use restricted to meet the guidelines of the Interagency Grizzly Bear Committee grizzly bear/motorized access management recommendations. All potential off-highway vehicle use should be incorporated in the analysis of road density to determine impacts on habitat security and effectiveness, including the proposed use in the Wyoming portion of the Island Park Madison Plateau and Teton Range Subsections. The Madison Plateau and Teton Range Subsections should be managed to meet the goals for grizzly bear habitat security. A moratorium on new road construction should be considered in Management Situation I and II grizzly bear habitat.

54 Wilderness We support the goals, objectives, standards and guidelines for designated wilderness opportunity classes I, II, and III wilderness study areas, wild rivers, and scenic rivers, except as noted in our aquatic comments. In addition, phasing out any domestic sheep grazing adjacent to wilderness areas will reduce the likelihood of conflicts with grizzly bears that might primarily use the recovery zone. This would help protect resident grizzlies within the zone.

55 Carcass Removal (Section 2.6.5, p III-91) The Forest Service states disposal of livestock carcasses includes burying greater than 2 feet under the ground. This will do nothing to prevent a grizzly from obtaining the carcass and possibly coming into conflict with other livestock in the area. Removal of the carcasses or complete incineration is the only alternative that will prevent a bear from using the carcass. Grazing permits should include specific language to assure guidelines for minimizing grizzly bear-livestock conflicts are met.

56 Garbage Storage (Section 2.6.5, p III-91) Garbage storage should meet the same requirements as other attractants in grizzly bear areas. Guidelines for hanging food, etc. should include the definition "a minimum of 10 feet off the ground and 4 feet from any vertical supporting structure."

DRAFT ENVIRONMENTAL IMPACT STATEMENT

57 Small Mammals (pp III-30 and IV-18) The list of wildlife management indicator species is incomplete without inclusion of any small mammal species. We recommend inclusion of at least two small mammals as indicators of riparian condition, possibly the water vole, snowshoe hare, western jumping mouse, or vagrant shrew. The snowshoe hare is also an indicator of forest successional stage and condition of the conifer forest. Presence or absence of the hare is also an indicator of the potential for existence of lynx and fisher, and whether or not habitat management to favor these species should be considered. Red-backed vole and northern flying squirrel could also be considered indicators of the condition of conifer habitats.

58 Lynx and Wolverine Lynx and wolverine are forest carnivores for which Draft Conservation Strategies, including habitat management guidelines, have been prepared. We recommend these guidelines be consulted during finalization of habitat management priorities for the various segments of the Targhee National Forest.

59 Cumulative Impacts Analysis We believe the draft environmental impact statement's cumulative impacts analyses are incomplete. The analyses should consider historic, ongoing, and proposed livestock grazing, timber harvest, road development and use, recreational use, water developments, oil and gas developments, recreation, etc., and include impacts to wildlife, forest, riparian habitats, old growth, succession, soil, watershed, rangeland condition, and other resources.

Aquatic Considerations

Upon review of the most recent version of this document, we became aware that most all of our previous aquatic comments were not addressed. Hence, we are resubmitting them here.

DRAFT ENVIRONMENTAL IMPACT STATEMENT

Page III-20, Table III-4, Fish-bearing Streams. Neither the text nor the table indicate the type fish considered for this classification. Although most of the fish-bearing streams on the Forest contain only trout, several contain only nongame fish species. As written, the table suggests this category includes all stream with any species of fish. While we have no problems with this grouping, some readers may be misled or confused and think this includes only streams supporting trout. We suggest a footnote be added to the table to clarify this.

Page III-20, Table III-4, Teton Range Subsection. It is unclear in both the text and table how the Desired Vegetation Condition for the Teton Range subsection was determined considering Aquatic Habitat Condition and Trend and Vegetation Seral Stage and Trend are listed as unknown. We suggest the document be modified to either explain how the numbers were obtained or changed to an unknown status.

Page IV-18, Wildlife Associated With Aquatic Ecosystems. This section makes no mention of impacts to any fish species which seems inappropriate given the ability of fish community structure and abundance to reflect watershed and riparian conditions. We

suggest this resource element be included in this part of the document by including cutthroat trout habitat

DRAFT TARGHEE FOREST PLAN REVISION

Page III-7. Biological Elements, Goals #3. Although all of the streams on the Forest in Wyoming flow into Idaho, they are still under the jurisdiction of the State of Wyoming until they exit the state. This section seems to address only streams that are presently impacted and where water quality improvements are desired. We suggest modifying this passage to indicate water quality would be maintained or improved to meet respective state water quality standards.

Page III-7. Standards and Guidelines. This section makes no mention of the need to secure protective minimum fishery pools in new, enlarged or retrofitted reservoirs. Though the Forest must recognize legitimate water rights and the authority of respective states to administer those rights, minimum pools for fisheries are an important opportunity for maximizing public benefits and realizing multiple use goals. We suggest another Guideline be added to this section in which the document conveys the desire to maximize multiple uses of water by requiring all new water storage facilities to include minimum fishery pools and encouraging existing facilities to consider water management strategies and/or design alternatives that maintain or improve reservoir fishery values whenever special use permits are reissued.

Both of the elements of this section make reference to "Forest-specified instream flows". Because Wyoming has enacted legislation that allows the state to acquire instream flows, we suggest these elements be modified to say "State and/or Forest-specified instream flows".

Page III-15. Wildlife, Objectives - Common Loon Habitat. Implementing a management prescription could unnecessarily inhibit angler activity, especially at Fish Lake. It is our understanding from discussions with Department wildlife biologists that loons occupying this habitat have successfully hatched young in recent years. The current use of this area by the public does not appear to have impacted loons. We suggest this information be addressed in the development of future management prescriptions or plans, and that continuation of reasonable angler access to this water receive a high priority. Further, we suggest any management decisions for this area be coordinated with wildlife and fisheries personnel in our Jackson regional office, and non-game personnel in our Lander regional office.

Page III-25. Timber Management, Standards and Guidelines - Logging Systems. We suggest the following best management practices be included in the final document:

- a) Buffer zones of undisturbed vegetation should be left along each side of standing waters and water courses to minimize sedimentation and direct fish habitat

impacts. Factors such as slope, stream channel stability and fish habitat should be considered when determining appropriate buffer zone width.

- b) Surface disturbing activities in areas with slopes greater than 40 percent are a special concern because of potential problems with soil stability. Special technical consideration should be given to the proposed activities in these areas including coordination with Wyoming Game and Fish Department fisheries personnel in Jackson for activities within Wyoming.
- c) A specific skid pattern design should be developed and strictly followed to avoid sedimentation to stream channels downstream from project areas. In certain areas, felling trees toward a predetermined skid area (felling to the lead) may be appropriate. In areas with important fisheries and where slopes are greater than 40%, winching logs directly out of sensitive areas (end-liming) should be implemented.

Page III-58. Designated Wilderness - Opportunity Class 1, Objective 1. The State of Wyoming currently has a fishery management plan for wilderness fisheries. Because this is a state jurisdictional responsibility, we suggest the Forest Service recognize this and simply refer to the State's document within their forest plan.

Page III-59. Designated Wilderness - Opportunity Class 1, Biological Elements, Fish and Other Aquatic Resources. The reference that "Fish stocking for recreational purposes is permitted with species native to the Wilderness" seems inappropriate. Fish Lake is the only water so managed in Opportunity Class I and, as such, has been and will continue to be stocked with brook trout to provide a recreational fishery. This is a "grand-fathered" activity with enactment of the Wyoming Wilderness Act (1984) and we have no plans to cease stocking this water in the near future, and will stock species we deem most appropriate. We recommend the present verbiage be modified to more accurately reflect states' rights to stock fish in waters contained in this jurisdiction.

Page III-76. Minerals/Geology. We suggest the following best management practice be incorporated into the document: No pollutants (topsoil, silt, sand, gravel, solid wastes, slash, debris or chemicals) should be stored or deposited within the active flood plain, in areas immediately adjacent to riparian areas or in natural drainages (draws, land surface depressions or other areas where overland flow could concentrate materials and carry pollutants directly into surface waters).

Page III-96. Aquatic Influence Zone, Standards and Guidelines - Boundary Widths of Water Types by Subsections. We support the general goal of ecosystem management as portrayed in this document. In this regard, we believe all perennial streams, whether fish bearing or not, would have the same approximate sediment carrying capacity and should have the same protective buffer requirements.

RE: Comments on Draft Forest Plan Revision and Draft Environmental Impact Statement

Dear Mr Reese

Comments on the draft forest plan revision and the draft environmental impact statement follow. This review and comments are limited to the evaluation of aquatic and riparian resources, the potential effects of different forest alternatives on water quality, and a comparison of proposed actions with State of Idaho water quality requirements and policies.

General Comment on both documents The Forest Leadership and Interdisciplinary Teams have done good jobs of summarizing and presenting a tremendous amount of information in a generally accessible and understandable manner. Alternatives were clearly described, the consequences of different actions, and the balancing of issues were presented clearly. The public and agency participation opportunities through distribution of the plan, mailings, ads, and the public meetings were thorough.

The key issues and indicators seem appropriate. The analysis is responsive to earlier concerns that DEQ raised about riparian protection.

Comments on the Draft Environmental Impact Statement (DEIS):

General comment EISs often contain separate volumes to present data and a detailed analysis of key issues. Information on ecological processes, riparian and water indicators, was not presented and summarized so that I could independently review the data and draw my own conclusions. Instead, in many areas only the project teams' conclusions were presented (e.g. aquatic connectivity, riparian condition, water quality). Either the data relied upon for developing these alternatives should be added to the final EIS as a separate volume, or, if it is reported elsewhere, it should be cited in the final EIS.

Specific comments (by page numbers)

II-18 Aquatic connectivity This would seem to be a useful indicator of ecosystem patterns, however, I could find no further discussion of how this was measured, critical values, or differences in significance of different systems. The range in the different alternatives of 342,000 acres to 793,000 acres of aquatic zones where connectivity would be maintained seems huge. I did not locate any discussion of why maintaining connectivity in 448,000 acres of aquatic zone was the preferred choice.

II-19 Riparian and Water Indicators The table indicates that under the preferred alternative, stream miles with adequate habitat conditions for cutthroat trout streams would decline from existing conditions (97 to 83 stream miles), but stream miles with improved conditions for other fish-bearing streams (no cutthroat) would greatly increase. Is this a mistake? Proposing to lower water quality from existing conditions by allowing habitat impairment, a component of water quality, is generally prohibited under Idaho's antidegradation policy (Idaho Code 39-3603). Doing so for a species in decline would be additionally unwise.

On this comparison of alternatives, I did not locate any discussion why the conditions of key indicators in the preferred alternative were the preferable conditions. For example, are their estimated thresholds of minimum stream miles with adequate habitat to fully support cutthroat trout populations? Rephrasing this question in the jargon of the Idaho Code, will the minimum conditions necessary to fully support beneficial uses be maintained by the preferred alternative? This type of analysis should be attempted and presented in the environmental impact statement. Instead, the analyses of the comparisons of alternatives seem to be limited to split-the-difference approaches between the extreme alternatives of maximum Forest exploitation and maximum Forest preservation.

III-1 Affected environment A fundamental inadequacy of this environmental impact statement is the omission of maps or figures to compare the affected environment to the proposed actions. At least a few key maps showing the distribution of key indicators on the forest in a format that is readily comparable to the (excellent) maps of the draft forest plan revision are needed. The ecosystem approach promoted in these documents is based in part on analyses of important ecosystem processes and patterns. The patterns relied upon are generally spatial patterns. Spatial information has to be spatially illustrated; tabular presentations do not present the essential information. The many tables comparing total acres of vegetative cover, aquatic zones, riparian areas in desired or impaired conditions are incomprehensible without some illustration of the distribution and location of these indicators. Since these tables appear to have been generated from a geographical information system type database, I presume that this spatial information is also reasonably available.

At the minimum, the following should be illustrated with enough detail to reasonably compare the effects of the proposed action to the affected environment. If the information can be legibly

2

presented at the same scale as the maps of the draft forest plan revision, this would be most readily compared to the proposed action. Otherwise, presenting at the subsection level would be appropriate since that is how the tabular and narrative analysis is broken down. Regardless, existing conditions of key indicators or other spatial data that were relied upon to adopt the proposed action must be presented. The following should be included in the revised presentation:

- 1 Aquatic zones (connectivity of these zones is relied upon as a key indicator; which zones are disconnected now?),
- 2 Riparian areas meeting, moving toward, and not meeting, the desired vegetative conditions (This is a key issue, and since some 2500 acres of degraded riparian zone are predicted not to improve under the proposed action, the locations and patterns of these areas should be shown too), and
- 3 Locations of cutthroat and other fish-bearing streams with the areas that meet and do not meet the riparian habitat indicators (residual vegetation stubble heights). Further, I could not locate any discussion of how the "hydraulic green line" criteria were derived. To avoid appearing arbitrary, this (and the basis for all key indicators) should be described.

III-22 Water quality-channel stability "Channel stability ranges from fair to good." This general assessment, which is repeated for all the subsections, is so vague that it is meaningless. Are the conditions related to grazing or other anthropogenic reasons? Where are the problem areas? Will the proposed revision improve these conditions? How were these conclusions developed? No data is presented or cited. If it is unpublished Forest data, then if the data are relied upon to select the proposed action, it needs to be presented in the analysis (with a map). How was the data developed? Cite the reference for the methods and briefly summarize them here. If the citation is not to a published journal or widely available government report, the methods should be completely described in an appendix.

III-23 Typo Temperatures listed are in °C, not °F.

III-24-25 Madison Plateau This section describes water quality problems but I could not locate any discussion of how the proposed action will affect these conditions. "Standards and guidelines will not be able to mitigate impacts acceptable levels. Current conditions do not reflect watershed objectives. Turbidity increases, sometimes significantly [in Moose Creek], during and after rainstorms." However, the later discussions of this area do not address how these water quality problems will be addressed (page 5-3-5 on Map 10 for the preferred alternative 3-M).

III-26, Third full paragraph "Idaho DEQ sampled several streams in 1994. Conclusions cannot be drawn from their data, however." What is that statement supposed to mean? Does it mean that the interdisciplinary team could not conclude anything from a set of raw data points considered out of context? It reads like an unnecessary swipe. These streams were sampled as part of DEQ's Beneficial Use Reconnaissance Project (BURP). These data have not yet been interpreted and reported out by DEQ. The results of the first three years (1994-1996) of the

3

program are scheduled to be analyzed during the fall quarter of CY96 and will be reported out in early 1997. We have sampled many streams throughout the Targhee in addition to the ones listed in this paragraph.

I request you either change this "conclusions cannot be drawn from their data" statement as follows:

1. If we can provide a reduced and interpreted data set to you in time for the FEIS, report that, or
2. Change the statement along the lines of "Idaho DEQ Brockman Creeks. However, at writing, the data had not been interpreted and conclusions from the data could not yet be drawn for this DEIS."

III-27 It's a lot further than 48 miles from the Medicine Lodge - Beaver/Camas hydrologic sinks to the Thousand Springs area.

IV-17, Fifth full paragraph (Hydrologic Effects) Researchers have shown. These are significant findings but no citation is given. TNF data? Needs a source if it is to be relied upon.

Comments on the draft Forest Plan Revision (DFPR)

III-2 Forest Standards and Guidelines for Ecological Processes and Biodiversity. The aquatic environment is completely left out of this discussion. Biodiversity is not just important in terrestrial ecology. Biodiversity is one element considered in whether beneficial uses for aquatic life are fully supported in Idaho water bodies.

III-6,7 Aquatic, riparian resources, and watersheds. The listed goals are appropriate but incomplete. Habitat conditions and inventory needs are solely described for cutthroats. What about waters that either currently do not or never supported cutthroat? A more general goal of maintaining natural conditions for aquatic life, or to fully support attainable beneficial uses would be appropriate for the non-cutthroat trout streams.

III-95 Goals. "Riparian, wetland, and aquatic ecosystems are managed to promote their health and function with the range of variation, where feasible." I could not locate a discussion of what is intended by this disclaimer. It is broad enough that, liberally applied, it could negate all protections. Does it mean where feasible due to natural conditions, feasibility due to other desired forest uses? Needs a definition.

III-132 Area 5 3 5. The discussion of this area does not address how water quality problems on the Madison Plateau will be addressed (see earlier comment on EIS).

V-9 Aquatic/Riparian Monitoring Verification of water quality limited streams. I recommend that this section be significantly revised. First, a significant difficulty for the authors of this section is that the State standards for water quality are likely to change over the 10-15 year life of

this plan. Secondly, DEQ, the state water quality agency, has not yet published procedures for evaluating whether waters are impaired as required by Idaho's new (1995) water quality law, Idaho Code 39-3601 *et seq*. Thus, I suggest starting out with a disclaimer that monitoring to determine compliance with state standards will change as the science and the standards change over the life of the plan. However, this section follows such guidance as was available at writing (this line could go in many places in the plan).

Indicators. The indicator data collected should be usable with state guidelines for assessing beneficial uses. For "water quality limited" streams to be delisted, they must be monitored to determine if beneficial uses are fully supported. "In making such determinations, the director shall compare the physical, chemical, and biological measures of the water body in question with the reference stream or conditions appropriate to the land type, land uses, and geophysical features of the water body in question." (Idaho Code 39-3606). DEQ is approaching these requirements by comparing macroinvertebrate, fish (and potentially algal) communities in streams to reference conditions as the primary measures. Secondly, if data for parameters which have numerical standards are available, the data would be compared against these standards to determine whether these standards are met (i.e. chemical or physical integrity).

Method - Idaho's beneficial use reconnaissance program protocols are not mentioned. While, these be controversial, they are so far the only available protocol directed toward verification of "water quality limited" streams and should be included if the focus of this monitoring is as stated, verification of "water quality limited" waters. Our protocols are derived from attempts to define and measure biological integrity, as described by Karr (1991), EPA (1994), and many others. These references may provide useful thoughts on the water quality sections of the plan and could be provided if desired.

V-10 ***Note. For streams which remain on the Forest's "water quality limited" list, additional restriction on forest activities which generate nonpoint source pollutants could be imposed. Changes in best management practices (BMPs) for nonpoint sources that are deemed necessary shall be made to protect beneficial uses (Idaho Code 39-3610 and 3611). Depending on the significance of the water quality problems on a water body, the "total maximum daily load" or equivalent process may be required. This involves:

1. Completing an inventory of all point and nonpoint sources of the identified pollutants,
2. Conducting an analysis of why current control strategies are not effective in assuring fully support of designated beneficial uses,
3. Completing a plan to monitor and evaluate progress toward meeting water quality standards and to ascertain when designated beneficial uses will be fully supported,
4. Developing pollution control strategies for both point sources and nonpoint sources for reducing those sources of pollution, and,

5 Identifying the period of time necessary to achieve full support of designated beneficial uses (Idaho Code 39-3610 and 3611)

V-10 BMP Monitoring Idaho Code 39-3610 generally requires BMPs as the legal remedy for addressing "water quality limited" streams in addition to other requirements for BMPs to be installed and maintained. What does "Priority 3" mean for monitoring? Lowest priority? Will it happen? A statement describing what is meant by these priorities is needed.

I hope these comments are helpful with your forest planning effort. Please call me if you need further information or clarification of these comments, State of Idaho water quality standards, or any other items.

Sincerely,

Christopher A. Mebane

س. ج. ر. ب. ر. س.
م. ج. ر. ب. ر. س.

Dear Mr. Reese:

The Idaho Department of Parks and Recreation Trails Program has reviewed the Draft Forest Plan Revision for the Targhee National Forest and the Draft Environmental Impact Statement Forest Plan Revision for the Targhee National Forest. Our program appreciates the Targhee National Forest's effort in putting this plan together. The extensive public involvement and the wide range of alternatives reflect this effort.

After reviewing the document, the Trails Program staff projects that the selected alternative, 3M, will provide inadequate trail opportunities and doesn't represent the wishes of the citizens most affected by the Forest Plan Revision. This was reflected by a referendum vote. On May 27, 1996, the voters of Fremont, Madison, Teton, and Lemhi, by a super majority, selected Alternative 2 as the best response to their needs. The results were as follows: Fremont County--86% in favor, Madison County--76% in favor, Teton County--70% in favor, and Lemhi County--78% in favor. The Targhee National Forest should seriously consider these results, since the overwhelming majority of these citizens do not favor the selected alternative 3M.

The Draft Environmental Impact Statement Forest Plan Revision for the Targhee National Forest (DEIS) has numerous misstatements. The first is found on page I-8 under Key Issue 3 Security for Elk. The statement "Observations and studies by the Idaho Fish and Game Department, University of Idaho, and Forest Service scientists have determined that as motorized road and trail densities increase, elk security declines" is false. The Targhee National Forest is using unsupported conclusions when it makes this statement. Our program has reviewed all the studies that the Targhee National Forest used for Security for Elk and Elk Habitat Effectiveness. None of the studies show how the motorized trail densities effect Elk Security or Elk Habitat Effectiveness (EHE). Until such a study is undertaken, the Targhee National Forest shouldn't state that scientists have determined that as motorized trail densities increase, elk security declines. Our Trails Program staff strongly recommends that throughout the Forest Plan Revision and the Draft EIS, the Targhee National Forest do not compare road and trail densities as if they are equal to each other.

There is also new information regarding the effects motorized use has on elk habitat effectiveness and elk vulnerability. Our program reviewed the Draft Interagency Guidelines for Managing Elk Habitats and Populations on USFS Lands in Central Idaho. This document does not equate motorized trails as having the same effects as motorized roads. In addition, the document also states "Similarly, roads and trails restricted to all motorized vehicles during the

summer and hunting seasons also decrease EHE and increase elk vulnerability by making elk habitat more accessible to humans using nonmotorized methods of travel, like hiking and pack stock. With that reasoning, the revision could include restrictions on non-motorized use to increase elk security, however, we don't believe that restrictions on nonmotorized use is necessary either.

Our Trails Program staff supports road and trail closures for wildlife protection when scientific facts support the reasoning for the closure. Extrapolating vehicle use on roads regarding the impact on Elk Vulnerability (EV) to trail bikes on trails is hypothetical at best. Presently, there is no data that supports motorized trail density having the same or similar effect on elk as open road density. Comparing a road bed with cuts and fills, roadside vegetative removal, and sight distances to trail tread with minimal cuts and fills, minimal impact on trailside vegetation, and minimal sight distances is not comparable. Road density in EHE and elk vulnerability should not include motorized trail density as a part of the formula.

The department has data that shows in Hunting Unit #39, which has some of the heaviest OHV recreation and motorized trail densities in Idaho, elk harvested from 1980 to 1989 during the general elk hunt steadily increased from 100 in 1980 to almost 600 in 1989. The primary result of this increased harvest was the increased herd size. While the herd size was increasing, so was OHV use. Also, Hunting Unit #43 on the Fairfield Ranger District is one of the highest trail bike use areas in the state and it is still the number one producing controlled elk hunt in Idaho. Elk vulnerability due to hunting pressure does not significantly decrease with elimination of trail bikes from an area. The Idaho Department of Fish and Game's 1988 Deer/Elk Rifle Hunting Study shows that only 1% of hunters use trail bikes to hunt. That still leaves 99% of the hunters in an area.

What data do you use to address the effects of trails open to trail bike use on elk numbers in any elk range as it relates to EHE? Does reduction in EHE because of trail bike use significantly affect carrying capacity, conception rates, or calf or adult elk survival? Elk Calf Response to Simulated Noise Disturbance in Southeast Idaho, Journal of Wildlife Management, 49(4) 926-930, showed there was no significant difference in calf survival between harassed and unharassed calves. The disturbance factor in this case was a simulated mine disturbance that occurred every two days from June 4 to July 15. How can singling out occasional trail bike traffic have a measurable effect on calf survival?

The Trails Program staff also has a problem with the way the alternatives were presented regarding elk security. On page II-5, when analyzing Alternative 2, the draft EIS states, "The 72% of the Forest meeting state elk vulnerability standards is a 30 percentage points increase over the existing level of 42%, probably resulting in a potential for a slightly lower proportion of bulls to be harvested during the general hunting season." Then on page II-9, when analyzing Alternative 3M, the draft EIS states, "The 91% of the Forest meeting state elk vulnerability standards is more than twice over the existing level of 42%, thereby greatly improving elk security." Why does Alternative 2 only probably slightly improve elk security with a 1/3 increase when Alternative 3M greatly improves elk security with a 1/2 increase? What are your standards for greatly improves and slightly improves, and how were these numbers determined? How can the Targhee National Forest make the statement that a 30% increase would probably only slightly improve elk security and then turn around and say that a 49% increase greatly improves elk security?

When discussing elk security and elk vulnerability, it is very important to note that 90% of bull elk mortality is caused by hunters. The Targhee National Forest can't control the number of hunters, that is the job of the State Fish and Game Department. If the Targhee is serious about increasing elk security, it could recommend to Fish and Game that long general seasons be shortened or eliminated or that a permit system be implemented as well as implemented road closures. This would be a better way to control mortality.

On page II-6, under the issue Access, the draft EIS states, "Winter OHV access would be increased with an additional 210 miles of groomed trails for snowmobiles for a total of 666 miles." The county snowmobile programs in the Targhee National Forest currently have a difficult time grooming all the trails they presently have. Without additional funding sources, grooming of additional snowmobile trails can not happen.

Our program strongly disagrees with the restrictions on snowmobile use within the Bear Management Units (BHU). Cross-country snowmobile access would be restricted from December 15 to April 1 in all BHU's. This restriction is excessive and is the result of an out-of-court settlement between your Forest and the Greater Yellowstone Coalition. Your own draft EIS shows that in 1994, the Greater Yellowstone area was exceeding grizzly bear population recovery goals. If these restrictions are implemented, it is very likely that snowmobilers will appeal the plan on this basis and take it to court if necessary. Although we are not wildlife biologists, it appears there is no need to restrict snowmobile access from December 15 to April 1. Our program would support allowing snowmobiles from November 15 to June 1. A better and more effective method exists. Instead of restricting use over a wide area, use should only be restricted around the den sites.

Our program disagrees with the statement on page IV-39, "Some of the impacts to trails such as rutting or displacement of soils, being caused by OHV use would also be removed." Rutting or displacement of soils on trails is caused by the design and maintenance of the trail, not the type of use on it. Some non-motorized trails in the Selway-Bitterroot Wilderness, as well as other areas that have never had OHV use on them, have as many as three parallel trails rutted 2 to 3 feet deep. We also disagree with the statement on the same page, "Much of the cross-country travel that is presently occurring would be eliminated by Alternatives 3-6." Alternative 2 will also eliminate cross-country travel. The statement should reflect this. Overall, restricting use to designated routes will not work unless there is proper signing of the area and user education. If this plan is going to work, the Targhee National Forest will have to invest time and money into making designated routes work. Just putting designated routes on a travel map won't work.

Our program disagrees with the statement on page IV-50, "Those alternatives with fewer miles of road and trail open for motorized use would likely see increased concentrations of motorized use on miles remaining open, reductions in recreation dependent on motorized use, increases in nonmotorized recreation or some combination thereof." The Targhee National Forest has no way of proving whether motorized recreation would decrease or nonmotorized recreation would increase. Perhaps both would decrease, since our department's Trail Ranger program and motorized users would be unable to maintain trails that were formally open to motorized use.

That concludes our comments on the Draft Environmental Impact Statement Forest Plan Revision for the Targhee National Forest. We encourage you to make changes to the unsupported conclusions made in the document.

Our program also has several comments regarding the Draft Forest Plan Revision for the Targhee National Forest. We appreciate the effort that your forest put together in writing the revision. It was one of the easier forest plans that our program has reviewed and an improvement in organization over the last Forest Plan.

On page III-17, under Objectives-Winter Recreation, the first objective states, "Establish a linear capacity for two-way snowmobile trails for purposes of safety and quality of the recreation experience." We strongly encourage the Targhee National Forest to consult with our department and the county snowmobile programs on this issue. Establishing a linear capacity for two-way snowmobile trails involves several factors, ones in which our department has 22 years of experience.

On Page III-18, under Standards and Guidelines - OHV, Standard #4 states, "No motorized vehicles > 50 inches wide are allowed on trails unless the trails are specifically designed for such vehicles." This standard fails to address ATV use on single track trails. Does the Targhee National Forest plan to make every single track trail open to ATV use? Our program strongly recommends that this standard be changed to only allow 2 wheeled motorized vehicles on trails unless the trails are specifically designed for such vehicles. When ATVs are allowed on single track trails, the wheels being too wide for the trail tread, they ride on the cut bank or on top of the fill. After considerable use, the narrow trail is broken down and severely damaged.

Examples of this can be found throughout the forest. Recently, our staff examined the effects of ATV use on the Pass Creek Trail #18045. The ATVs have broken down the trail tread and, in one section, completely left the trail for approximately 1/2 mile to avoid a steep sidehill. In order to get around this sidehill, ATV users have climbed straight up the mountain and then straight down again. This action is causing resource damage because the trail was not built to ATV specifications, and the forest failed to close this trail to ATV use.

This plan needs to address ATV use. Our registration figures show that ATV use is growing faster than trail bike use. If land managers are going to protect their single track trail resource, they need to provide opportunities for ATV users. Our program offers the Off-Road Motor Vehicle Fund and the National Recreation Trails Fund, which can help you build those ATV opportunities. As a general rule, our Trails Program staff opposes the conversion of single track trail into ATV trails because of the outcry from both nonmotorized users and trail bike users. Old roads or some suitable trails could be designated for ATV use but not all trails.

In the Desired Future Condition for the Lemhi/Medicine Lodge subsection, the Recreation Objective needs to be expanded. The subsection should set an objective to preserve single track trails and another objective to create more ATV opportunities. The benches along the Lemhi's with the numerous jeep roads have a good opportunity to provide a quality ATV riding opportunity in the spring and early summer. Our program suggests that you work cooperatively with the BLM and the Salmon/Challis National Forest on developing a loop from Big Eightmile Canyon to Spring Mountain Canyon on the north side of the Lemhi's and from North Canyon to Warm Creek on the south side of the Lemhi's.

The Centennial Subsection, the Island Park Subsection, and the Madison Plateau Subsection all have had varying degrees of roading in the past. Now many of these roads are being proposed for removal from the inventory. We suggest that when it does not conflict with other resource objectives, ATV opportunities be developed with these old roads.

On page III-49, under the Desired Future Condition for the Big Hole/Palshades subsection, the revision states, "The subsection will be managed to provide high quality motorized recreation opportunities both summer and winter with a signed system of roads and trails for OHV and full-sized vehicles while protecting resources." While this is an admirable desired future condition, it ignores the fact that this subsection also provides quality nonmotorized recreation opportunities in the Big Holes and the Palshades mountain ranges. Our department suggests that this statement be revised to read as follows, "The subsection will be managed to provide high quality recreation opportunities both summer and winter with a signed system of roads and trails for OHV, nonmotorized use and full-sized vehicles while protecting resources."

On page III-53, under the Desired Future Condition for the Caribou subsection, the DFC states, "This subsection will be managed to provide high quality non-motorized and dispersed camping recreation opportunities." This statement leaves out motorized use, which this area currently provides and will provide in the future.

Our program also reviewed the management prescriptions for Alternative 3M. Every one of these prescriptions has the problem of equating motorized trails as the same as an open road. We have previously on pages 1-3 of this letter stated our objection to this process and proved why it is pseudoscience. Through this process, the Targhee Forest has eliminated some important trails to trail bike riders in the Big Holes, Caribou, and Lemhi subsections.

One of the major problems with your elk habitat effectiveness analysis and elk vulnerability analysis is that the Targhee Forest assumed that if a road or trail was open to motorized use, then it was used more than twice per week by motorized users. If an open motorized route is counted in the elk vulnerability analysis, then why are some of these routes disappearing because of a lack of use? Examples of these trails are the lower trail of Pass Creek on the Lemhi Ranger District and the North Fork of Pine Creek trail (that runs on the ridge that divides North Pine Creek and West Pine Creek) in the Big Hole Range.

The Targhee National Forest should not abandon any trails, unless it has contacted the volunteer trail maintenance groups or our Trail Ranger Program. First. Many of these routes could continue to receive use and maintenance under these programs.

All snowmobile seasonal restrictions in the Targhee Forest Plan should allow snowmobiling from November 15 to June 1 for the reasons stated earlier on page 3. Eastern Idaho has the largest concentration of snowmobiles in Idaho and some of the longest snowmobiling seasons in the state. If the Targhee National Forest is going to provide adequate snowmobile opportunities for these users, then snowmobiling should be allowed from November 15 to June 1.

Our program also reviewed the Chapter V Monitoring and Evaluation. On page V-17, under Recreation, impacts to on-trail and off-trail soils and vegetation the trail, not the use, is the main cause of erosion. If you close an improperly designed trail to all uses, it would still erode unless rehabilitation work was done.

The frequency of monitoring is inadequate in 5-10% of the system trail areas (60-120 miles). If more of the Targhee National Forest staff had the capability to ride trail bikes, the Targhee National Forest could easily monitor close to 100% of the trail system annually in areas open to motorized use. To give one example, our program did a rail-trail survey of 900 miles statewide with one staff person in only three weeks.

We also have some concerns over the Monitoring Item - Effectiveness of Road and Trail Closures on pages V-23 and V-24. We strongly agree that this item does need to be monitored, but involving user groups with this item could significantly decrease your precision and reliability if a certain user group wants to eliminate another user group from an area or start user conflict. We strongly suggest that this remain the responsibility of the Forest Service. This information should also be made public.

Our Trails Program staff does not agree that your Monitoring Item - Achievement of standards in prescription areas for Total Motorized Access Route Density and Open Road and Open Motorized Trail Route Density, has high precision. According to your own definition of a open road or trail, the route must be open to motorized use and must have more than 1 to 2 motorized vehicle trips per week for the majority of the weeks for the spring/summer/fall period. This very low use should not even be of concern. The largest problem with this method is that it underestimates elk habitat effectiveness and elk vulnerability, which is unfair to motorized users. There are many open roads and trails on the Targhee National Forest which have less than 1 to 2 motorized vehicle trips per week for the majority of the weeks for the spring/summer/fall period. The Targhee National Forest has no scientific proof that any motorized trail or road has more than 1 to 2 trips per week unless counters with cameras are installed on every motorized route on the Targhee National Forest. With only six cameras, and hundreds of roads and trails, there is no way that this monitoring item will work with accurate precision.

PHILIP E. BATT
GOVERNOR
KARL J. DREHER
DIRECTOR

The Idaho Department of Parks and Recreation ORMV Program has invested significant resources in the Targhee National Forest, under the recommendation of the ORMV Advisory Committee. The users represented by this committee expect that their investment will ensure the maximum availability of resources for their use. We feel that the partnership of the Idaho Department of Parks and Recreation ORMV Program providing facilities and the Forest Service providing the resource base will give the user an excellent return on his/her fees.

In conclusion, our Trails Program staff encourages the Targhee National Forest to change its selected alternative from 3M to 2 and make the suggested recommended changes. We appreciate the opportunity to be involved in the planning process and look forward to working with the Targhee National Forest in the future.

Sincerely,

Chuck Wells
Trails Program Supervisor

Dear Mr Reese

We have reviewed the Draft Forest Plan and supporting documentation for the Targhee National Forest. The amount of effort and time devoted to its preparation is apparent. We are submitting the following comments concerning water resource management within the Forest.

The Idaho Water Resource Board completed a plan for the Henrys Fork basin in 1992. Through this effort the Board designated several streams within the Targhee as Natural or Recreational Rivers. These designations prohibit certain stream channel alteration activities below the high water mark. We urge you to ensure that the Henrys Fork Plan, and the state river protection designations, are recognized in the Forest Plan.

The Water Resource Board is currently preparing a comprehensive state water plan for the South Fork Snake planning area. A draft plan is expected in September 1996. This plan will likely designate additional stream reaches for protection as state Natural or Recreational Rivers.

We note that the Draft Forest Plan recommends Wild and Scenic suitability studies for the South Fork Snake, Fall River, Henrys Fork and Warm River. These rivers are either currently designated, or are being recommended for designation as state Natural or Recreational Rivers through the Water Resource Board's planning process. The Board does not support federal Wild and Scenic River designations on streams that are already designated under the state system.

Re Comments on Draft Forest Plan Revision--Targhee National Forest Research Natural
Areas

Dear Mr Reese

I appreciate the opportunity to comment on the Targhee National Forest Draft Forest Plan
Revision (Forest Plan) These comments are specifically directed to the research natural areas
Forest Plan prescription, they complement comments submitted for the Idaho Department of
Fish and Game by Don E Wright, Regional Supervisor, Upper Snake Region These
comments are arranged in a manner parallel to the structure of the Forest Plan

Management Area Description

Proposed and established research natural areas on Targhee National Forest (the Forest) need
to be identified by name The specific objectives and a brief description of the biological and
physical values of each area should be included in the research natural areas management area
description

While the Forest Plan provides Forest-wide management standards and guidelines, the site
specific management prescription for each research natural area is specifically stated in the
Establishment Record for each individual research natural area on the Forest This
relationship between the Forest Plan and the Establishment Record should be described in the
management area description

The statement "Livestock grazing may occur if not detrimental to the ecological processes of
the area" is not consistent with Forest Service Manual (FSM) policy and needs to be modified

I suggest the following language:

Unless specifically stated in the Establishment Record, commercial and domestic livestock grazing are prohibited in these areas.

Prescription Goal and Objective

An important objective of the national research natural area network (and similar public and private natural areas) is to preserve a *wide spectrum* of pristine representative areas that typify *important* forest, shrubland, grassland, and alpine situations (FSM 4063.02). The selection and establishment of research natural areas are part of the *continuing land and resource management planning process* for National Forest System lands (FSM 4063.03, Regional Guide for the Intermountain Region). Research natural areas should be selected to represent ecological conditions *needed to complete* the natural area system (FSM 4063.2).

Based on these fundamental policy guidelines, the goal and objective statements for the research natural area management prescription must be expanded. The goal statement should contain language concerning representation of the spectrum of natural forest, shrubland and grassland plant communities present on the Forest and the fish and wildlife habitats that these plant communities represent. I suggest the following language:

Maintain a series of specially designated areas that provide representation of the spectrum of important terrestrial and aquatic ecosystems on the Forest. Protect and maintain these areas so that ecological processes prevail in the development of ecosystem composition and structure.

The objective statement should reference an administrative process whereby research natural area needs within the region and on the Forest are recognized and whereby new candidate areas identified to fill these needs are evaluated. This statement should be added as a third objective for the management prescription. As an example of how this might read, I offer the following language:

During project planning, identify areas that provide high-quality representation of the important terrestrial and/or aquatic ecosystems on the Forest. In cooperation with the Intermountain Research Station and the State Natural Heritage Program (Idaho Conservation Data Center, Idaho Department of Fish and Game) assess the value of these areas for their contribution to the national research natural area network. When areas are identified that provide needed terrestrial and/or aquatic components for biological diversity, recommend these

areas to the Regional Research Natural Area Committee for consideration of research natural area designation.

The revised goal and objective statements should be linked in the Forest Plan to (1) a presentation of the natural forest, shrubland and grassland plant communities present on the Forest, and (2) an assessment of the conservation status of these elements of biological diversity. This information is currently available in a format that could be incorporated into the Forest Plan (Rust 1995¹).

Standards and Guidelines

The standards and guidelines section should be modified to be consistent with FSM policy guidelines. The Forest Plan standards and guidelines should reference the Establishment Record as the source for specific management prescriptions for each respective research natural area. The standards and guidelines should state that management activities that fall outside the direction provided in the Establishment Record must be approved by the Station Director, Intermountain Research Station.

Ecological Processes, Fire/Fuels An objective of the research natural area Forest Plan prescription is to maintain ecological processes in high-quality, representative natural areas. Fire plays an important functional role in many of these ecosystems. Prescribed fire may be needed to maintain ecological processes in research natural areas. The current statement concerning prescribed fire use (page III-73) should be modified to reference the Establishment Record or fire management plan for the area, perhaps as follows:

In accordance with the Establishment Record, prescribed fire (management ignited and natural ignited) may be used to maintain fire-dependent ecological processes and to provide a natural range of fuels, understory vegetation, and successional stages. Where specific direction is not provided or modification is needed, prescribed fire management plans should be developed and approved by the Station Director.

Physical Elements, Soil and Water The draft language in the Physical Elements, Soil and Water, Standards and Guidelines is not consistent with national and regional objectives for

¹ Rust, S. K. 1995. Framework for representativeness assessment of research natural areas on National Forest System lands in Idaho. Unpublished report prepared for USDA Forest Service Northern Region, Intermountain Region and Intermountain Research Station Conservation Data Center, Idaho Department of Fish and Game, Boise. 65 p.

Mr Jerry Reese
June 27, 1996
Page 4

research natural areas I am particularly concerned about the language pertaining to burned area emergency rehabilitation Please change this language to read as follows.

Burned area emergency rehabilitation will only be permitted in research natural areas under the incident-specific approval of the Station Director Plans for the emergency rehabilitation of research natural areas will be developed in prescribed fire management plans

Similar comments also apply to the other three guidelines identified in the Physical Elements, Soil and Water section Restoration and rehabilitation management activities in research natural areas must all be approved by the Station Director

Biological Elements In the Biological Elements Standards and Guidelines section, "exist/evolve" should be replaced with "exist/develop "

Forest Use and Occupation. Access The standards and guidelines identified in the Forest Plan should assure attainment of management prescription goals and objectives Recreational use of research natural areas raises paradoxical issues While it is desirable for forest users to experience the value of areas designated to preserve and maintain pristine, representative natural conditions, this use is, in itself, a powerful, insidious threat to the perpetuity of this exact value (the experience of pristine naturalness) An adaptive management strategy similar to the Limits of Acceptable Change approach implemented in many wilderness areas may be appropriate for the management of recreation use of research natural areas

To effectively achieve the goal stated for the Research Natural Areas prescription, the standards and guidelines need to establish more exacting side boards on recreational use of research natural areas Horse and pack stock use should be limited to (road and) trail travel Research natural areas should be closed to *all* motorized use - winter and summer, trailed and off-trail

Forest Use and Occupation. Recreation In order to effectively attain the prescription goal of "maintain the natural processes inherent in each research natural area," the management prescription cannot provide the "semi-primitive motorized" recreational opportunity spectrum The ROS classification for the prescription should be appropriately stated as "primitive "

Range The draft Forest Plan language is inconsistent with FSM policy I suggest the following language

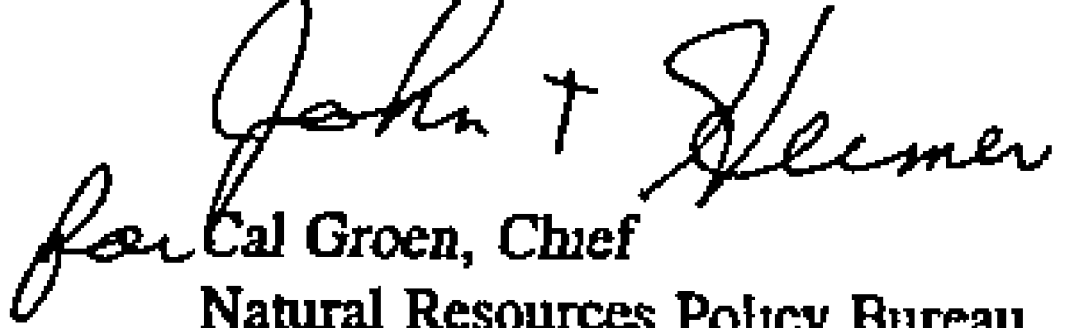

Mr Jerry Reese
June 27, 1996
Page 5

Prohibit commercial and recreational livestock grazing unless the Establishment Record specifically states that livestock grazing is needed to achieve the objectives for the research natural area

Draft EIS

Over the past decades several research natural areas have been proposed for establishment To clarify the disposition of these proposals, the specific reasons for dropping further consideration of research natural areas previously proposed should be addressed in the environmental impact statement

The effects of managing for the maintenance of biological diversity through the research natural area management prescription need to be disclosed in the Forest Plan environmental impact statement

Sincerely,

for Cal Groen, Chief

Subject: Targhee Forest Draft Plan Revision (DFPR) and Draft Environmental Impact Statement (DEIS)

Dear Jerry

The Idaho Department of Fish and Game (IDFG) commends the Targhee National Forest (TNF or Forest) on your perseverance in designing proposed remedies for problems on the Forest and re-directing Forest activities to accommodate changes that have occurred since adoption of the current Land Management Plan.

We commend the TNF's goals to improve riparian conditions, establish a comprehensive access management plan, protect roadless areas, provide habitat to support T & E and sensitive species, conduct timber harvest within sustainable levels, and provide recreational opportunities on the Forest.

We appreciate the Forest's acknowledgment that big game hunting is a valuable Forest resource and the TNF is responsible to provide habitat to support the fish and wildlife goals of the State of Idaho.

Many TNF proposals in the Draft Plan Revision are excellent, and could contribute to this Forest's recovery from more than two decades of road building and logging above sustained yield. In previous letters and in the comments provided below, we have identified Plan Revision deficiencies that we believe may prevent attainment of the Forest's goals and objectives. The Idaho Department of Fish and Game has the statutory mandate to preserve, protect, perpetuate, and manage the fish and wildlife resources of the State of Idaho. It is under that authority and responsibility that we offer these comments. It is our intention to assist you with meeting the goals of the Forest Service and the State of Idaho.

I GENERAL COMMENTS

A. Standards, Guidelines, and Objectives

These are the foundation of explicit Forest Service guidance for management on the ground over the next 10 to 15 years. We consider standards and guidelines to be the primary product of more than 5 years of planning.

Standards in the DFPR will require TNF compliance unless the Plan is amended. We view standards as a disclosed commitment to the public for the 10 to 15 year plan period. The DFPR proposes to address many crucial management needs with guidelines, which may be waived under a wide range of circumstances. We believe a vast majority of the guidelines in the DFPR should be changed to standards, to convey the commitment of the Forest Service to implement the intended management direction.

We recommend that standards and guidelines be clearly written to explicitly convey to the public the Forest's intended management. There are an unbelievable number of exceptions written into standards and guidelines. They are filled with phrases such as "should", "generally", "usually", "strive to maintain", "as it becomes practical to do so", "if possible", "if feasible", "unless otherwise specified in the management direction", etc. These phrases clearly indicate either a lack of Forest commitment to implement the standard or guideline, or a lack of belief that compliance is feasible.

Equally troubling are the large number of important standards and guidelines that imply a specific action will be taken, but include in the statement such phrases as "where ground verified", "where there is potential for damage", "where data shows", etc. This language is clearly included to provide an exception for compliance whenever there is a lack of data to demonstrate the need for compliance. Given the lack of budgetary and monitoring assurance to meet these types of requirements within standards and guidelines, it appears likely that the implied action may not occur. These types of standards and guidelines are a meaningful disclosure to the public of intended Forest management only if there is assurance of funding to collect the necessary information for the Forest to act, consistent with the identified language.

The DFPR also contains a large number of standards and guidelines that more closely meet the Forest Service definition of goals or objectives. There are also a large number of objectives that are neither measurable, nor followed by standards and guidelines that provide assurance the proposed objective will be met.

B Planning Process

We suggest the Forest Service never again use a general planning process similar to that used for this Plan Revision. We believe a productive Forest planning process that utilizes the best available science, while incorporating public input, would be to conduct the following activities in chronological order.

1. Complete a scientific analysis of the current management situation. This would be done in cooperation with state and federal fish and wildlife agencies, Indian tribes, and other appropriate agencies.
2. Conduct public scoping to determine needs for management changes and recommendations for additional analyses and information summaries.
3. Complete scientific analyses of alternative methods to achieve the recommended changes (desired future condition) on the Forest. This would be done in cooperation with state and federal wildlife agencies, Indian tribes, and other appropriate agencies. Legal constraints on all alternatives would be identified.
4. Present scientifically-based alternatives for Forest management to the public. This would address public desires for management direction within the range of legal constraints.

The activities recommended above were vigorously requested throughout the TNF Plan Revision process by the agencies and the public. Contrary to this, the TNF established from the beginning an adversarial atmosphere in which public meetings became dominated by discussions of whether or not many federal laws and nationwide Forest Service policies would be applied to TNF management. For the first 2 to 3 years of this planning, the TNF committed to simply listening to the public, during the time when agencies and the public were imploring the TNF to provide scientific information and side-boards (e.g., legal constraints) to positively focus, and limit, the public debate. The result of this strategy was that after nearly 4 years of Citizens Involvement Group debate, about half of the draft Forest-wide standards and guidelines were deleted from the Plan.

During the first 4 years of planning, agency representatives were informed by the TNF that we held the same status as individual citizens, despite the fact we represented large constituencies (states of Idaho, Wyoming, or United States) that had provided us legal mandates to achieve. Particularly frustrating to state and federal agencies was being told the goals and objectives we were mandated to achieve on Forest Service land would be implemented on the TNF only if we could obtain consensus from the diverse individuals in the Citizens Involvement Group. In

the middle of the planning period, the TNF erroneously cited the Federal Advisory Committee Act as a legal constraint preventing coordination with us as an agency, and limiting coordination with us under the same legal constraints as coordinating with private citizens.

This process has been very disappointing to the agencies as well as the public. However, one of our greatest concerns is the apparent lack of effective consultation and coordination between the planning team and TNF District biologists. It does not appear the significant field-level knowledge of District biologists has been incorporated into the DFPR or DEIS. We recommend the Forest Service evaluate the TNF planning process prior to revising plans on other Forests.

II. SPECIFIC COMMENTS

A+ Big Game Management

The current TNF Land Management Plan designated elk as an indicator species for monitoring condition and trend of general forested habitat. It should be noted this indicator species is assumed to represent other species sensitive to human disturbance and affected by general forested habitat.

1. Need For Change

We recommend the first ecological component (DFPR II-3) be restated as "Manage to improve elk security." Both elk vulnerability and elk habitat effectiveness should be addressed. Two key elements of elk/hunting management are overlooked several times in the DFPR and DEIS: 1) the fact that Forest management affects hunter density and distribution, by affecting animal numbers and distribution and the quality of the hunting experience, and 2) the importance of managing for sufficiently high levels of elk habitat effectiveness such that big game remain on Forest lands and are therefore available to the hunting public of Idaho, rather than being driven into refuge areas (such as Yellowstone National Park and Harriman State Park) or across state borders to more secure habitat.

An example of these impacts occurred from the 1980's to the present when most of the elk, deer, and hunters abandoned the lodgepole salvage area. Surviving big game moved either into refuges or more secure habitat elsewhere. The highest hunter densities on the Forest now occur in the portions of the Island Park subsection that have adequate access restrictions and elk security cover.

Several times in the DFPR and DEIS, reference is made to "the elk population", usually to assert that "it" is at an all-time high. In numerous letters, meetings, and

a two-day workshop, we educated the TNF that elk sub-populations summering on the Targhee National Forest and elk populations that visibly gather on winter ranges are not one and the same. For example, the Sand Creek winter range supports animals from 3 states and at least 2 refuges. During the summer and hunting season, the TNF supports a portion of that herd, the portion critical to general elk hunting on the TNF in Idaho.

We also note that the DEIS does not report our radio-telemetry study, which estimated that the portion of the ~~east~~ east of highway 20 and north of Robinson Creek, which previously summered about 30% of the Sand Creek elk herd, was supporting only 1 to 2% of that herd by the time we began appealing timber sales in 1991.

For an analysis of quantity and quality of big game hunting on most of the TNF, some of the least useful data are the size and bull:cow composition of herds on the winter range. The most important factors for elk hunters to hunt on the Forest in Idaho are 1) the numbers of elk on the Forest during hunting season, and 2) the proportion of total bulls on the Forest comprised of mature branch-antlered bulls. These mature bulls are critical for reproductive success, calf survival, hunting quality, and the hoped-for re-establishment of general bull elk hunting on the Forest.

The Plan Revision need for change relative to elk is that available information indicated numbers of elk summering on the Forest were decreasing, the proportion of the population summering in refuges was increasing, and vulnerability of bulls to hunting harvest was so high that to meet the biological and public desire objectives for the population required implementing spike-only regulations.

The above information is on file at the TNF supervisor's office. Regardless, after 5+ years of interagency coordination on this subject, the preliminary DEIS environmental consequences section stated "From information that the Forest has been able to analyze, the current summer elk populations on the Forest are at record all-time highs." To our knowledge, other than contributing to our study (which showed a radically reduced summer population in the study area), the Forest collected no data on summer populations, and no data are presented in these documents to support the statement. Even if it were true, it ignores the greater importance of herd composition and the population being well-distributed.

It is shallow and misleading to summarize the elk situation on the TNF only in terms of winter population size off the Forest. A credible evaluation of big game and hunting requires analysis of habitat quality and population size and spacial and temporal distribution of animals, herd composition, vulnerability to harvest, productivity, calf/fawn survival, quality of the hunting experience, and amount of hunting opportunity.

5

It is also important to note that the current Forest Plan uses elk as an indicator species to represent general forested habitat. A significant, measurable reduction in elk security, and the observed elk response to those impacts, should be assumed to indicate that similar impacts were occurring for other Forest wildlife species that are sensitive to the impacts of extensive logging and human disturbance.

2. State of Idaho Elk Hunting Objectives

The elk hunting objectives presented in the DEIS (III-40) should be completed by adding the following after the respective bull:cow ratio:

For Ready Access units: "... with 40% of bulls branch-antlered, and maintain the percentage of yearling bulls in the antlered segment of the harvest at or below 50% and the percentage of mature bulls [having at least 6 points on one antler] at or above 10%."

For Front Range units: "... with 50% of bulls branch-antlered, and maintain the percentage of yearling bulls in the antlered segment of the harvest at or below 35% and the percentage of mature bulls (having at least 6 points on one antler) at or above 20%."

We are intensely dismayed that the TNF has refused to properly depict the very objectives the TNF agreed to incorporate in the Plan. These objectives are published in the IDFG 5-year Elk Plan. We also provided the objectives to the TNF by letters and meetings during the 1992 to 1995 planning period, by letter of November 15, 1995 (review of preliminary DFPR and DEIS to identify major problems), and by personal contact during spring, 1996. The TNF's obvious reluctance to correct the documents makes us distrustful. We are forced to speculate that a loop-hole is being crafted so the TNF can argue at a later date that access restrictions are not necessary and/or permitted game retrieval (see below) is not affecting elk vulnerability. We consider the TNF failure to accurately state the agreed-upon elk objectives to be a breach of faith, and it reduced our ability to support the DFPR preferred alternative during the public review period.

3. Game Retrieval

We strongly recommend deleting the game retrieval guideline from all management prescriptions.

During coordination meetings over the last 4 years, the TNF agreed that analyses and proposals for elk habitat management would be jointly developed by an interagency / tribal elk work group. The Forest also agreed to adopt the elk objectives of the State of Idaho. Neither we, nor the team, agreed to propose permitted game retrieval. The issue was discussed in meetings and workshops.

6

and we conveyed the following to the Forest, while explaining our opposition to the game retrieval proposal

- 1 Game retrieval is a significant variable in predicting elk vulnerability
- 2 It was not included in the study that developed the elk vulnerability model the team agreed to apply to the Targhee Forest
- 3 Game retrieval may negate and/or invalidate the significant progress that access restrictions are predicted to provide toward meeting elk vulnerability objectives
- 4 Eighty-five percent of 3,300 Idaho elk and deer hunters surveyed reported that encountering motorized vehicles off roads detracted from their hunting experience, and the highest ranked factor affecting hunt quality was encountering motorized vehicles off roads (McLaughlin et al. 1989) These findings were the same when analyzed at both the state-wide and regional (eastern Idaho) level
- 5 Considering archery antelope and spring black bear seasons, big game hunting occurs over a 10-month period, during which TNF offices would have to be open to dispense permits during evenings and weekends, to avoid waste of game,
- 6 The game retrieval exemption would create a major new administrative and enforcement burden for the TNF, and serious enforcement and public relations problems for IDFG
- 7 There is no reasonable or acceptable method to permit individual access behind closures that effectively restrict general public access. Assuming keys to gates would not be distributed to permit holders, options discussed to date by the TNF include a) installing new gates with openings 50 inches wide, presumably to be passed through only by permitted off-highway vehicles, and b) instructing permit holders to pioneer routes around otherwise effective closures. Either way, demand for closed road maintenance (downed log removal, etc.) will increase, and enforcement problems will increase.
- 8 Other state wildlife agencies and Forests are dissatisfied with the effects of game retrieval.

During public meetings, the TNF stated that permitted game retrieval would be proposed as an experiment to be closely monitored. A specific monitoring plan is neither proposed in the Plan nor apparently planned for in future budgets. The only

planned link we can speculate between this experiment and monitoring would be for the TNF to examine how well elk vulnerability objectives stated in the DEIS are being achieved. As long as the TNF will only include in the DEIS one of the four State of Idaho objectives for elk vulnerability (namely, bull:cow ratio on winter range), monitoring could be virtually worthless on most of the Forest. For the reason, see our comments under Needs For Change above.

4. Crucial Deer and Elk Winter Range =

a Winter Motorized Access

The TNF agreed on a delineation of crucial mid- to late-winter range for elk and deer. This is depicted on DFPR map no. 24. The TNF acknowledges these crucial winter ranges are the areas considered to be the determining factor in a population's ability to maintain itself at a certain level over the long term [DFPR III-92].

Available scientific literature and professional opinion clearly indicates that protection from disturbance during winter (primarily motorized disturbance) is a critical factor affecting individual survival and recruitment rates. However, DEIS table IV-6 indicates that alternative 3-M would permit cross-county snowmachine use on 66% of the crucial winter range, while also permitting designated motorized routes through all winter ranges.

The area proposed for winter range prescription 2.7 is even smaller than the area mapped by the TNF as crucial winter range under the current Land Management Plan.

The public lands coordinator of the largest snowmachine advocacy group in eastern Idaho indicated to IDFG staff and the Post-Register newspaper that they expected and preferred to be excluded from crucial big game winter ranges, both for the good of the animals and the image of the snowmachine users.

TNF research clearly indicates that snowmachine use is dramatically increasing (5 to 10% per year) on the Forest, and it is acknowledged in the DEIS that increasing development on adjacent private lands will increase the importance of TNF lands for winter range. Therefore, protection from motorized disturbance will become even more crucial for minimizing big game depredations on private property during winter and for maintaining current size of the public's deer, elk, and moose herds.

Given the above, we do not understand the rationale for the TNF's proposal to permit cross-country snowmachine use on 66% of crucial winter range, either from a biological or recreational perspective.

We recommend that all of the delineated crucial deer and elk winter range be protected from cross-country snowmachine use

If this protection is provided under management prescription 2.7, we recommend allowable summer motorized route densities ≤ 1 mile per square mile for those areas providing crucial winter range and summer habitat for deer or elk.

We recommend that areas of crucial winter range currently closed to snowmachines remain closed under the plan revision. The Palisades/South Fork Snake River and Kelly Canyon-Hawley areas are examples of areas that should remain closed to winter motorized cross-country use

b Winter Range Habitat:

The DFPR and DEIS make several references to improving habitat for big game on winter ranges through timber harvest prescriptions. However, specific habitat needs of wintering big game are not disclosed, nor are the proposals to supposedly improve winter habitat quality. We recommend this aspect of ecosystem management either be fully disclosed and justified by scientific evidence, or it be deleted from the plan until sufficient information is available to demonstrate a wildlife need for timber harvest on winter range.

Alternative 3-M does not adequately protect crucial deer and elk winter range areas and moose winter habitat along the South Fork Snake River and adjacent to Palisades Reservoir. In addition to cross-country snowmachine use being permitted, a significant portion of the area is proposed for management under a timber prescription that emphasizes extensive timber management under urban interface objectives.

Perhaps very narrow strips of fuel removal are justified adjacent to summer homes. However, the South Fork / Palisades Reservoir area is some of the best wildlife habitat remaining on the TNF. We recommend it be protected from extensive timber harvest and any road construction (including temporary roads), to protect valuable wildlife habitat. We recommend protection of a buffer strip extending one mile from the water's edge, giving emphasis to protection of old-growth Douglas-fir, Englemann spruce, and cottonwoods.

5. Elk Habitat Effectiveness

We recommend adding a wildlife standard to maintain an elk habitat effectiveness (EHE) value of at least 0.6 in each subwatershed (approx. 2,000 to 6,000 acres). This would provide an essential threshold indicator for elk and other wildlife species that require security cover and are sensitive to human disturbance during summer. Although moderately good to excellent elk summer habitat generally has EHE values

≥ 0.7 to 0.8, setting a minimum of 0.6 would assist meeting desired future conditions for well-distributed populations of wildlife sensitive to summer motorized travel disturbance.

6. Additional Access Management Issues

a Forest Use and Occupation, Access

The access goal (DFPR III-16) is not clear. What is meant by "emphasized"? Does this imply road density standards would be de-emphasized in all other areas? We recommend adding "big game summer range" and "big game winter range" to any list prioritizing or emphasizing implementation of motorized access targets.

Objective 2. We recommend revising as follows: Decrease elk vulnerability, increase elk habitat effectiveness, and increase grizzly bear security through effective road, trail, and cross-country motorized closures.

Objective 4. We recommend replacing "road density" with "motorized access". This objective should include time-specific statements for implementing the proposed motorized access plan. The need for implementing an improved motorized access plan is acknowledged to be perhaps the most important need for change in the plan revision. Therefore, it deserves a commitment to rapid, time-specific targets for implementation.

We recommend including a standard to implement the motorized access plan immediately upon signing of the record of decision, by approving and publishing the new travel plan for each district.

We recommend implementing construction of effective motorized road and trail closures on the ground within one year of the record of decision, and completing implementation within three years of that date.

We recommend the access program be adequately funded in annual budgets. As correctly stated in the DFPR Needs for Change, "The accelerated timber harvest over the past decade has created many roads, and clearcutting in the lodgepole pine component has reduced cover. This combination resulted in high vulnerability for elk" It is apparent that the purpose of revised motorized access standards is to mitigate for past roading and logging on the Forest. Therefore, we recommend funding and implementing the access plan as a project that stands on its own. We do not believe it is appropriate 1) to plan that implementation of this program will occur only (or mostly) as part of new timber sales in the future, or 2) to consider that implementation of this program (which is mitigation for past impacts) will be mitigation for future impacts of new timber sales.

b Forest Use and Occupation, Access Management Cumulative Effects

The DEIS (IV-39) states the following "A secondary effect of decreasing motorized access areas could be reduction of hunting and fishing opportunities. This may not be too significant except in alternatives 5 and 6." Although this may be correct for the physically challenged hunter, a more fair and balanced analysis would be to include the many increased or maintained hunting, fishing, and other recreational opportunities that will likely occur when the currently very high motorized access on the Forest is reduced.

The TNF predicts virtually no beneficial effects on fish, wildlife, water quality, recreation, or the local economy expected to result from the proposed access management program. This is a significant oversight in the DFPR and DEIS, and results in the appearance of an analysis prejudiced against wildlife and nonmotorized recreation and programmed to invite opposition or failure.

c Access Standards and Guidelines:

We recommend prohibiting cross-country snowmachine use in big game hunt areas during open seasons. This type of activity can cause undesirable rapid movement of animals to winter range and the perception of unethical hunting.

The conflicts we have identified include areas in the Palisades/Big Holes subsection.

7. Mountain Goat / Domestic Sheep Conflicts

Conflicts between mountain goats and domestic sheep have not been adequately addressed in the DFPR or DEIS. We are concerned about 1) the long-term impacts of the Palisades mountain goat herds being displaced to winter range by domestic sheep during summer months, and 2) the potential for disease transmission from domestic sheep to mountain goats.

High cirque basins are prime summer habitat for goats, which respond to grazing disturbance from sheep by moving onto poor condition winter range far sooner than under natural conditions. The most important basins where conflicts have occurred are Neeley Cove, the heads of Canyon Creek, Waterfall Canyon, Little Horn, and Hell's Hole, and the ridge between the heads of Waterfall Canyon and Little Elk Creek.

When domestic sheep and mountain goats share habitat, there is a threat of disease transmission from the sheep to the mountain goats. Although we are not aware of significant levels of disease in the goats at this time, other herds have suffered die-offs, and the threat of a similar situation exists in the Palisades area.

B. Wolvernes

In the past, a general lack of information on wolverine habitat and life history requirements has resulted in little management attention to potential land use impacts on wolvernes. A U.S. Forest Service / Idaho Department of Fish and Game cooperative study of wolvernes was recently completed in central Idaho (Copeland 1996). A primary finding of this research concerned impacts of human winter recreational activities on wolverne natal denning and kit rearing success. Consideration of these findings relative to the Forest Plan Revision, and adjustment of winter access management, appear to be necessary for wolverne presence and perpetuation on the Targhee Forest.

Female wolvernes den from late February to early March. Idaho wolvernes denned in high-elevation subalpine cirque basins, locating the den beneath the snow in the tunnels and chambers associated with big-boulder talus. Females may move the kits several times prior to weaning, which occurs when kits are 9 to 10 weeks old. The Idaho study found females sensitive to human activity near the dens. In 2 cases, human disturbance near maternal dens resulted in den abandonment by females and kits. Sensitivity to human presence near dens has also been documented in wolverne studies in Finland (Pulliainen 1968) and Norway (Myrberget 1968). Female offspring normally remain near their natal area at reproductive maturation, establishing their home range near that of their mother.

The subalpine cirque habitats selected by Idaho wolvernes for denning habitat are often preferred winter recreation sites for backcountry skiing and snowmachining. Human activities in these habitats during the denning and kit rearing period displace wolvernes into suboptimal denning sites, which may decrease reproductive success and kit survival. Persistent or traditional winter recreational use of denning habitat will remove habitat from potential use by wolvernes, thereby restricting normal population maintenance and growth processes.

Sites selected for natal and maternal dens by central Idaho wolvernes were specific to 4 habitat criteria:

- 1 Dens were situated above 8,000 feet in elevation. (This criterion identifies the demarcation between mid-elevation montane coniferous forest, primarily spruce-fir/lodgepole pine forest, and subalpine-alpine habitats. Although this elevational demarcation may vary throughout the wolverne's regional distribution, it is likely applicable within the Targhee National Forest.)
- 2 Within a north-northeast aspect range of $\geq 320^\circ$ to $\leq 130^\circ$.
- 3 Zero vegetative overstory - select for bare-exposed rock cover type.

4 Concave physiographic landscape feature of glacial cirque

High-elevation subalpine habitats provide seclusion and reduce vulnerability to kit predation prior to weaning. Boulder caves beneath deep snows likely provide a stable thermal environment for the protection and rearing of kits. Northeastly aspects and glacial cirques provide persistent snow coverage and den stability to the mid-May weaning period.

The above criteria could be readily adapted to GIS for development of a Forest-wide predicted wolverine denning habitat map coverage. Management to protect and perpetuate wolverines would exclude human recreational activities within an 8 km buffer of predicted wolverine denning habitat from January 1 to May 31. Recreational activities outside the restricted period would be managed for minimum intensity (e.g., skier/snowmachiner quotas, weekend closures).

The wolverine is identified as a management indicator species in 4 of 7 subunits described in the DEIS. The TNF may provide a critical link between Montana, central Idaho, and Wyoming wolverine populations. Protection of denning habitat may be critical for maintenance of this link and the health of the wolverine population throughout the ecosystem. Increased popularity of winter recreational activities will result in higher human densities within traditional winter sports areas. Technological improvements in winter sports equipment will enable recreationists to travel farther into backcountry environments. Historical winter recreation may have eliminated potential wolverine denning habitat from availability to parturient female wolverines.

C. Wildlife Surveys

We recommend mandatory surveys for important wildlife and habitats prior to any project or activity that could cause a significant impact. We recommend a forest-wide standard to require surveys to locate raptor nests, threatened and endangered species, candidate species, sensitive species, state species of special concern, caves, wetlands, etc.

D. Bats and Caves

We recommend that all abandoned mines on the TNF be protected as bat habitat and given the same management considerations as natural caves. We recommend that standards for bat management include the following provisions:

1. Due to potential disturbance, prohibit the use of heavy equipment above any cave or abandoned mine known or suspected to be bat habitat. Identify

season of bat use, and apply seasonal restrictions on nearby disturbance as necessary to protect caves or abandoned mines inhabited by bats.

2. Provide a buffer zone of 500-foot radius around all bat roosts, in order to not adversely impact direction and amount of air flow near cave mouths.

3. In order to minimize human disturbance of caves, do not improve access to caves.

E. Forest-wide Forage Utilization Standards

We do not believe the forest-wide forage utilization standards and guidelines are adequate to protect important habitats and areas susceptible to overgrazing. We are not aware of any scientific literature, nor is any presented in the DFPR or DEIS, that supports the levels proposed in Alternative 3-M. Utilization rates in Table 1 are 5 to 10% higher than recommended in the scientific literature. We recommend either reducing proposed utilization to levels supported by scientific literature, or providing site-specific evidence that the proposed levels will meet water quality, watershed, fisheries, and sagebrush-grassland ecosystem objectives.

F. Water Quality/Fisheries

1. Aquatic Influence Zone (AIZ)

a. Riparian Forage Utilization

We do not believe these standards, and the associated monitoring plan, will result in meeting the stated desired future condition of riparian/aquatic areas. Improving riparian areas and fisheries habitat is presented as one of the most important needs for change to achieve the Forest's Desired Future Condition. In most riparian situations, far greater riparian vegetation is present outside the hydric greenline (HGL) than is present between the line and the water's edge. When sediments are transported during high-water events, the entire riparian area is critical for flood velocity reduction and sediment filtration, not just the "belt of riparian vegetation found closest to the water's edge" (Glossary definition of HGL). We understand the TNF's working definition for HGL area is the strip of vegetation \leq the width of a researcher's foot adjacent to open water.

Scientific literature does not support the contention that a 4-inch residual stubble height at the water's edge and a 3-inch stubble height in all of the riparian area except at the water's edge is sufficient to provide either maintenance or improvement of degraded riparian habitat. Although the standard is proposed to be

monitored at the end of the grazing period, there is no provision within the DFPR that ensures adequate additional growth of stubble will occur between the end of the grazing period and the end of the growing season. The monitoring plan fails to ensure that riparian monitoring will either 1) be adequately funded, or 2) dictate when livestock are to be removed from riparian areas

The stubble height standard is not adequate to protect riparian vegetation, water quality, or the many species which are dependent upon riparian vegetation for forage, nesting cover, hiding cover, or other biological needs. The DEIS (IV-7) acknowledges that permitting this level of utilization will slow the rate of improvement of riparian areas that do not currently meet the desired condition

It is very important to note that monitoring of the HGL requires a water's edge. Therefore, even if it is adequately funded, no monitoring would occur in seeps, bogs, wet meadows, cottonwood forests, or other wetlands that do not have observable standing water at the end of the grazing period. These types of areas provide habitat values, and contribute to biodiversity, far greater than their relative occurrence on the Forest

The best available science regarding residual stubble height indicates a minimum of 4 to 6 inches needs to be retained over the entire riparian area. Even that is reported to maintain riparian health only on satisfactory or better range. Greater protection would be needed to improve the condition of unsatisfactory riparian pastures. The Forest Service's own research (Clary and Webster 1989) appears to be the best available science on this subject. It has not been superseded by other research or Forest Service policies to date. As such, Clary and Webster's riparian grazing standards should be implemented as standards for entire aquatic influence zones.

For the protection and perpetuation of cutthroat trout on the TNF, we recommend a minimum 6 inch stubble height for existing and potential cutthroat trout habitat, and for streams that affect cutthroat trout habitat in a watershed

We disagree with the TNF considering stubble height to be the only indicator of riparian health affected by grazing. In addition to an objective to establish a stream bank stability standard (DFPR III-21), other indicators such as plant density, plant composition, and litter should be used with standards assigned to each criterion

DFPR range objective number 4 states that a stream bank stability standard will be established within 5 years. It is noteworthy that the Forest Planning Team had this same objective 5 years ago, with a plan to have it completed for the Forest Plan Revision. Stream bank management and monitoring plans have already been developed on other Forests in the region. We recommend the TNF adapt one of those systems within a more aggressive time-frame such as 2 years

b. Monitoring

Monitoring is proposed to occur only at the hydric greenline. With the hydric greenline including only inches of the total riparian area, the vast majority of riparian vegetation will not be monitored for stubble height. We recommend that riparian grazing standards be monitored across riparian areas, not just at the water's edge

We also recommend that riparian area monitoring be assigned to the Priority 3 group, to ensure that stated grazing standards are met.

c. Cross-country Motorized Access:

We disagree that riparian desired future conditions will be met with essentially unregulated cross-country motorized access. This proposal (DFPR III-98) permits motorized vehicles of all sizes to travel cross-country in wetlands and riparian areas and across streams, provided the recreator is accessing a picnic or camping site

We recommend the TNF at least propose to 1) set a maximum distance that vehicles are allowed to travel cross-country from open roads and trails (other Forests set a 300-foot maximum), and 2) prohibit motorized vehicle crossings of streams and wetlands other than on system roads and trails (see Salmon NF travel plan restrictions).

In addition to the ALL, our comments and recommendations for stream and wetland protection also apply to prescriptions 4.3, 5.1.3(a), 5.1.4(a and c), 5.2.1, and 5.2.2.

d. Timber Harvest

In the DFPR and DEIS, the TNF asserts several times that unscheduled timber harvest may be necessary within the AIZ to meet riparian objectives and/or maintain ecological health. The argument that unscheduled timber harvest is necessary to restore or improve riparian "health" is one of the most disturbing contentions in the documents

We are not aware of any credible scientific research indicating that timber removal has improved riparian values relative to fish and wildlife habitat, biodiversity, streambank stability, sediment filtering, woody debris recruitment, groundwater recharge, flood desynchronization, or any value we would associate with riparian health. The vegetative removal and physical impacts associated with harvest have primarily negative consequences for riparian areas. We feel certain that the Forest does not have sufficient data from controlled silvicultural experiments to support this management proposal. Once such data are available, and are coupled with the final results of the landscape-level vegetation studies currently underway on the

Forest, this proposal can be reevaluated. If these proposals remain in the final Plan, more details must be provided as to exactly what set of circumstances would lead the Forest to propose commercial salvage, fuelwood cutting, or other manipulations.

2. Water Quality Limited Stream Segments

The Forest is correct in noting that stream segments listed as water quality limited under section 303(d) of the Clean Water Act (CWA) must have special BMP's and pollutant limits established" (DEIS III-22). However, it is unclear in the DFPR and DEIS how the Forest intends to meet its legal obligations under the federal Clean Water Act, State of Idaho Water Quality Standards, and NFMA requirements in managing water quality limited segments (WQLSs). The NFMA requires the Forest Service to comply with state and federal water quality requirements. NFMA regulations direct forest plans to provide for "compliance with requirements of the Clean Water Act, the Safe Drinking Water Act, and all substantive procedural requirements of Federal, State and local government bodies" (36C.F.R section 219.23(d)).

Currently, state water quality standards are not being met in 25 or more WQLSs located on the TNF (Appendix "C", 1994 Sec. 303(d) list for the State of Idaho, US EPA, Region 10). Inclusion on the WQLSs list means that a stream has already been degraded to the point of failing to support beneficial uses. The TNF acknowledges that Alternative 3-M will only "result in a moderate rate of recovery of degraded habitats ..." (DEIS IV-18).

State of Idaho water quality code provides that "existing beneficial uses of the waters of the state will be protected" (IDAPA 16.01 02050, 02 c.) Furthermore, the state's water quality standards prohibit sediment transport and deposition in "quantities that impair beneficial uses." Virtually all of the WQLSs on the Forest are on the 303(d) list because of sediment. In light of their existing degraded status, it appears the Forest Service may not permit additional loadings of pollutants (primarily sediment) to these streams.

The DFPR and DEIS appear deficient with respect to WQLSs. First, the impacts of Forest Service permitted activities are not disclosed or quantified for WQLSs, in terms of pollutants or beneficial uses. The Forest needs to address and disclose predicted impacts, and discuss how they will affect other related resources, such as fisheries, aquatic resources, T&E species, sensitive species, etc.

Secondly, the CWA prohibits deliberate violation of state water quality standards. "Each department, agency, or instrumentality of the executive [branch] ...shall be subject to, and comply with, all Federal, State, interstate, and local requirements, administrative authority, and process and sanctions respecting the control and

abatement of water pollution" (33 U.S.C. section 1323(a)).

Moreover, Idaho promulgated its antidegradation standard specifically to prevent further degradation of already-impaired stream segments: "...existing instream water uses shall be maintained and protected" (See IDAPA 16.01.02051,01). State antidegradation policies, at a minimum, shall prohibit "further water quality degradation which would interfere with or become injurious to existing instream water uses" (See 40 C.F.R. section 35.1550(e)).

It appears that until water quality standards are attained and beneficial uses restored on WQLSs, the Forest Service may not permit any project that further degrades these streams until "total maximum daily loads" (TMDLs) have been developed. Where water quality standards have not been attained for listed WQLSs, discharges are only permitted where the cumulative effect of all discharges will assure the attainment of water quality standards. (See 33U.S.C section 1313(d)(4)(A)).

G. Wild, Scenic, and Recreational Eligible Rivers

The Wild and Scenic Rivers Act of 1968 was intended to assure unimpaired flows and to preserve the outstanding scenic, recreational, geological, fish and wildlife, historic, and cultural values of stream reaches. The DEIS reports that 249 miles of rivers and streams were determined to be eligible, but that suitability studies have not been completed.

We recommend the TNF reevaluate eligibility based on the results of State of Idaho Comprehensive Basin Plans for the Henrys Fork and South Fork Snake River. The South Fork basin planning included a scientific evaluation of river and stream segments possessing outstanding fish and wildlife, scenic, and/or recreational values. The evaluation was reviewed and approved by a citizens' advisory group comprised of water managers, irrigators, local landowners, outfitters, sportsmen group members, and elected officials. Resource and land management agencies provided technical assistance to the group. The study determined that outstanding resources occurred on a far greater number and length of rivers and streams than the TNF's evaluation.

The State Basin Plan for the Henrys Fork was completed in 1992, and will be reviewed within 3 years. It appears appropriate that Forest Service wild and scenic river planning should take into consideration the Comprehensive Basin Plans of the state of Idaho.

Given that suitability evaluations by the TNF will take several years to complete, we recommend the Plan Revision ensure protection of the outstanding characteristics

of all eligible segments until the suitability studies are completed,

We recommend the Plan Revision clearly ensure the South Fork is managed in compliance with fish and wildlife and habitat provisions of the 1991 Snake River Activity/Operations Plan. We recommend the TNF respond to provisions of the Activity/Operations Plan and reduce grazing/riparian habitat conflicts on Forest Service land, as well as preventing trespass grazing on BLM land.

H. Biodiversity

1. Roadless Areas

Currently existing roadless areas provide crucial habitat for rare species and species sensitive to human disturbance. They provide a critical contribution to maintenance of biodiversity on the Forest. Existing roadless areas provide important habitat that, if protected, could contribute to meeting desired future conditions for 6 of the Forest's 7 "key indicators" identified as the purpose and need for a Forest Plan revision: Patch Size (these areas provide the large patch sizes that occur naturally), Riparian, Elk Security, Grizzly Bear, Access, and Roadless Area Management.

The roadless area analysis and presentation is unclear and confusing. The preliminary DEIS reported 879,000 acres of roadless areas exist on the Forest. The TNF roadless area process paper reported the existence of 871,000 acres of roadless areas. Then the DEIS reported 841,000 acres for existing roadless. Alternative 3-M is depicted in Table II-1 as protecting only 772,000 acres as roadless areas. Due to the changing numbers, it is unclear whether the TNF proposes to reduce roadless acreage on the Targhee by 69,000 or 107,000 acres. Regardless, the TNF's proposal appears contradictory to the desired future condition stated in the DEIS: "Roadless characteristics are preserved in existing roadless areas and proposed wilderness" (DFPR II-2).

We recommend this roadless management indicator be more clearly depicted by presenting acreages and maps showing existing delineated roadless areas and roadless areas proposed in the preferred alternative.

We believe a comprehensive analysis of the key indicators of biodiversity would clearly demonstrate the critical importance of roadless areas for the maintenance of fish and wildlife species that are rare and/or sensitive to human disturbance. Scientific literature indicates the most crucial component of biodiversity is number of species present with at least a viable population size. Most threatened, endangered, rare, and sensitive species of the intermountain west depend on extensive blocks of habitat relatively free from human disturbance. For many of those species, their future survival depends on protection of linkage habitat between those blocks of habitat.

19

The value of roadless areas for fish and wildlife is indicated by one of the key conclusions in the Columbia River Basin Landscape Ecology Assessment (November, 1995): "Across BLM and Forest Service lands of the basin, as well as on other ownerships, there has been a substantial decrease from historic to current of: net primary productivity, native grasslands, shrublands, riparian channel and bank conditions, old forest multi-layer, old forest single layer, scattered residual large trees, large snags, and tree species that are resistant to insects, disease, stress, and fire mortality. In contrast, there has been a substantial increase from historic to current conditions of: water balance stress, exotic and noxious plants, range, woodlands, mid seral forests, forest canopy closure/density, small diameter trees, small snags, tree species susceptible to insect and disease, fire intensity, costs of fire suppression, fatalities and accidents related to fire suppression hazards, bare soil, and erosion rates. The decreases and increases are highest in human influenced management classes (areas with roads and time/grazing emphasis) as compared to naturally influenced management classes (areas without roads and wilderness/semi-primitive emphasis)."

We recommend full protection of the roadless characteristics of existing roadless areas on the Targhee Forest.

2. Rare Plant Communities

a. Wetlands,

Wetland plant communities are recognized as being extremely valuable for biodiversity, far in excess of their relative occurrence on the landscape. The Conservation Strategy for Henrys Fork Basin Wetlands (Jankovsky-Jones 1996) was completed very recently. It includes information and recommendations regarding the status and management of rare plant species and rare plant communities occurring in basin wetlands.

We recommend the TNF review this publication, and include in the Plan Revision standards that will fully protect the unique values of the identified significant sites.

b. Old-growth Forest.

We are unaware of any credible scientific evidence that justifies the TNF grouping into one age-class the broad range of "mature" to old-growth, especially considering the Forest's broad definition of "mature" forest. In fact, there is abundant scientific literature demonstrating the unique fish, wildlife, and ecosystem values of genuine old-growth forest. Identification, and planned protection, of old-growth forest on the TNF appears to be crucial under any analysis of biodiversity on the Forest.

20

3. Sagebrush-Grassland Habitat

TNF sagebrush-grassland objectives and standards are estimated to result during the next decade in 20,755 acres of sagebrush being burned, 500 acres sprayed, and 1,300 acres rotobeat (DEIS IV-23). Many factors are adversely affecting sage grouse habitat in the general area, including extensive conversions and reductions in sagebrush on lands adjacent to the TNF. This has caused significant habitat reductions and fragmentation. Research also indicates that adequate cover and height of residual herbaceous cover is significantly correlated to nesting success (Connelly, et al. 1991; Gregg, et al. 1994).

Sage grouse populations in eastern Idaho are currently in a precipitous decline. Studies by several entities, including the Forest, are currently being conducted to address this problem. Until the causes of the problem are better understood, we recommend using extreme caution with any treatments that reduce or fragment sagebrush habitat.

Sage grouse are an excellent indicator species for the sagebrush-grassland guild of wildlife species, due to being dependent on sagebrush-grassland habitat for their survival. The long-term declining trend monitored for sage grouse should be considered to indicate similar trends for other wildlife species dependent on sagebrush-grasslands.

In order to reverse the declining trend for sage grouse, we recommend the following habitat treatment standards [Draft Idaho Sage Grouse Management Plan 1996-2000].

Vegetation manipulation (fire, herbicide, and mechanical treatments)

Low precipitation areas (< 11 inches)

No treatments in sage grouse habitat for 5 years

Higher precipitation areas (> 11 inches)

Allow treatments only if sagebrush canopy coverage (CC) is > 25%

Allow treatments only if < 500 acres and > 1.6 miles from existing treatments with < 15% CC

Do not reduce average sagebrush CC in herbicide or mechanically treated areas to < 15% CC in winter, brooding, or nesting habitats.

Grazing management

To improve spring breeding habitat, manage for a healthy understory of

21

perennial grasses and forbs and fall stubble height of ≥ 7 inches.

To improve brood rearing habitat, manage to produce a fall stubble height of ≥ 4 inches.

Fire management and fire rehabilitation

Make protection of important sage grouse habitat a priority for wildfire suppression

Include sagebrush, forbs, and native grasses in fire rehabilitation seeding mixtures.

I. Ecosystem Management

1. Forested Habitat

In our opinion, the single most glaring flaw in the DFPR and associated DEIS analysis is proposing unlimited allowance of Forest vegetation manipulation under the guise of ecosystem management, while providing virtually no analysis of the potential environmental consequences of what could be an extensive logging program.

Management indicators are displayed and analyzed throughout the DECS with logging effects based solely on scheduled timber harvest on suited lands. There is no quantitative disclosure of, or limits to, logging and other projects that are expected to occur as "unscheduled" projects and/or on unsuited lands. The Forest's study of range of natural variability is not complete for the sagebrush-grassland ecosystem, yet the DEIS states to the nearest acre the projects planned for the next decade. Why no similar treatment of the forested component of ecosystem management? There is already one written ecosystem management proposal to log (in the next decade) 7.2 million board feet of mature Douglas-fir and mixed coniferous forest, directly affecting 2,876 acres, on only 3 of 5 subwatersheds in the Camas Creek watershed (only one of 45 watersheds on the Forest). The TNF has stated these aspen enhancement treatments need to be very large in scale, partly in order to continue livestock grazing in the treatment areas. The DEIS (Alt 3-M) analyzes 37 million board feet of scheduled timber harvest on an estimated 11,430 acres over the next decade. The DEIS does not disclose or analyze the fact that the TNF intends to conduct timber harvest on tens of thousands of acres in the name of aspen enhancement and other ecosystem management.

The DFPR Biodiversity Objective No. 5 is to treat aspen plant communities, but no

22

standards, guidelines, or other information is presented for reviewers to understand or analyze the scope of potential impacts that implementing this objective may cause

Extensive aspen enhancement and other ecosystem management should either be disclosed and analyzed in this EIS, or it should not be permitted until analyzed in its own EIS. Habitat manipulation across entire landscapes appears to be a major federal action worthy of environmental analysis.

We recommend that ecosystem management utilizing timber harvest not be included as part of the Plan Revision until the TNF landscape / range of natural variability analysis is completed and reviewed by the scientific community, the TNF has developed appropriate management strategies, and the process has been subjected to thorough public review and comment.

2. Ecosystem Management Summary

We have reviewed the ecosystem management section of the June 20, 1996 letter from the Greater Yellowstone Coalition (GYC) to you regarding the Draft Plan Revision and DEIS. The analysis and summary of scientific literature and other information presented in their section on Applying Ecosystem Management to the Forest Plan Revision appears to be accurate and reflective of our opinions on the subject. Their analysis (and associated recommendations) incorporated the opinions of numerous research and management professionals from both outside and within the Forest Service. We agree with the concerns expressed and support the recommendations presented in the Applying Ecosystem Management to the Forest Plan Revision section of GYC's comment letter.

J. Monitoring / Budgets

These sections are critical for 1) indicating whether action items in the Plan Revision will be implemented, and 2) conducting an analysis of TNF management impacts on Forest resources. A determination that the Plan Revision will not cause significant environmental impacts should require assurance that 1) planned fish, wildlife, and habitat enhancement projects will be conducted, and 2) authorized actions that may adversely affect natural resources will be effectively monitored.

The proposed plan does not adequately provide that assurance. Given the uncertainty of future budgets, we recommend a stated percentage of funding be allocated to the TNF programs (timber, range, fish and wildlife, recreation, etc.) if equitably allocated, the programs could be implemented at rates that complement each other. This could prevent limited budgets from being used to fund some programs at high levels while sacrificing necessary monitoring and mitigation for the

23

traditionally under funded programs of fish, wildlife, soils, and watersheds

K Attitudes, Beliefs, and Values

We will have considerable difficulty working effectively with the Targhee National Forest until readjustment of the attitude of Plan Revision authors conveyed by the following statement in the DEIS, p IV-50 'As the numbers assigned to the alternatives increase, the alternatives move consistently toward Less accommodation of those who feel the Forest's resources should be used for the benefit of humans.' This clearly conveys the authors' opinions that 1) the Targhee Forest does not consider fish, wildlife, hunting, fishing, water quality, outfitting, recreation, visual aesthetics, etc to be Forest resources and 2) anyone who benefits from those is not human.

In fact, recent public opinion surveys by both the State of Idaho and the U S Forest Service indicate a large majority of Idahoans and Americans support the protection of fish, wildlife, and habitat, and the recreational opportunity those natural resources provide.

In closing, we hope you will utilize our comments during formulation of the final Plan and EIS. If the Targhee Forest requires any additional information or clarification to implement our recommendations, my staff and I are available to answer questions or provide the necessary assistance. Literature references are available on request.

Sincerely,

Don E. Wright

Mr Jerry Reese Forest Supervisor Targhee National Forest P.O. Box 208 St Anthony, ID 83445

Dear Jerry:

Many of my constituent have raised concerns regarding the Draft Forest Plan Revision for the Targhee National Forest I am in receipt of the Draft and am currently reviewing the alternatives outlined in the Draft Environmental Impact Statement

Thank you for your efforts in educating me and my staff on this proposal I appreciate your efforts to educate and involve the public in the development of the various alternatives and request that this effort continue.

Notwithstanding my appreciation of your help, I must bring to your attention concerns raised by my constituents regarding the potential road closings in the preferred alternative Idahoans rely on many different methods of transportation to experience and enjoy outdoor Idaho I am concerned that the preferred alternative will severely impact the multiple-use industry as well as motorized access and recreational use to the very people who choose to live in Idaho. In addition to this concern, many constituents have contacted me regarding reduction in AUM units, potential wilderness designation and reduced elk hunting areas

I request that in your evaluation of the forest plan revision alternatives you take into consideration the economic and recreational needs of the affected communities and those who frequent this area I am concerned that the preferred alternative does not adequately address the concerns raised in this letter. I look forward to working with you to produce a forest plan that fits the needs of all involved

Sincerely,

Michael D. Crapo Member of Congress

RECEIVED
JUL 10 1996

Jerry Reese, Forest Supervisor
Targhee National Forest
P O Box 208
St Anthony, ID 83445

Dear Supervisor Reese

Thank you for the opportunity to comment on the draft Environmental Impact Statement and draft management plan revision for the Targhee National Forest. I appreciate the time you have taken to brief my staff and provide information that I've requested.

The Targhee Forest Plan revision is very important to Idahoans and others who use the forest and to the local communities which depend on goods and services flowing from the forest. The draft plan signals some major changes in philosophy which have caused many constituents to contact me. As I have indicated to you, I am concerned about certain provisions contained in Alternative 3M, the preferred alternative in the DEIS.

Obviously, there are many other aspects of the proposed plan which I find suitable and in accord with my views about national forest management. I commend you and the planning team for your effort in reaching this stage of the planning process.

Based on my comments which follow, I am asking that you seriously consider making critical changes before adopting a final forest plan. I cannot support Alternative 3M as currently formulated. I strongly support Alternative 2, as modified by Citizens for a User-Friendly Forest. Following are the concerns I have with the DEIS in general, and Alternative 3M in particular.

Goshawk

The DEIS places undue significance on preservation of goshawk habitat. The Goshawk is doing quite well on the Targhee with 49 pairs identified. This species has never been listed as threatened or endangered under the Endangered Species Act. Moreover, the U.S. Fish & Wildlife Service has even dropped it from the ESA candidate list. In fact, USF&W recently pared its candidate list in Idaho by 107 plant and animal species.

Based on the USF&W decision, I suggest the Targhee NF re-evaluate the role of sensitive species in its forest plan revision. Information you sent me indicates the plan revision placed a strong reliance on the fact that the candidate list on the Targhee NF increased from 12 to 47 species since the current forest plan was adopted. That is the reason given for proposing new and more restrictive standards, guidelines and constraints for (former) candidate species like the goshawk. Reason follows that restrictions on other national forest uses could be greatly reduced, now that the number of candidate species are even fewer than when the current plan was prepared.

The Forest Service has made a practice of classifying candidate species as sensitive species for purposes of the National Forest Management Act. Now that there remain only 4 Idaho species on the candidate list, and the goshawk is not one of them, I suggest you re-examine the prominence you have given to habitat constraints related to sensitive species. Since all DEIS alternatives include an extensive network of goshawk habitat which constrains other activities, I would expect to see substantial relief from constraints in the final forest plan based on a re-evaluation of the goshawk.

Hydrologic Disturbance Constraint

I believe the 30 percent cap placed on watershed disturbance is too restrictive in several respects. In your model, any forest stand which has been harvested and regenerated triggers the cap until the young trees reach a size of 4-5 inches in diameter [late sapling stage]. This approximates a 20 year recovery period in your assumptions.

My understanding of watershed recovery is that the preponderance of effects, such as runoff and sedimentation, can be expected to have dissipated within about 10 years after regeneration is established. Your criteria may be unnecessarily restrictive, especially in the relatively dry and gentle terrain in lodgepole pine forests.

There is something unsettling about leaving unmanaged for a decade 70 percent of your lodgepole pine stands, all of which are at or nearing maturity. We can predict with some certainty that much of the untouched lodgepole forest will deteriorate and burn while the hydrologic disturbance constraint holds management in abeyance. I don't find that an acceptable alternative. I recommend that added flexibility for vegetative management and timber harvest be built into your plan, particularly in lodgepole types.

Also, I wonder whether your DEIS has properly assessed the risks and costs of fighting wildfire which might have been prevented through vegetative management. The risk of hydrologic disturbance from wildfire must be examined in the same light as

the risk from timber harvest. If the risks are similar, then the difference may be that harvesting creates jobs and income while suppressing fire creates a huge drain on the federal and state treasuries.

Elk Vulnerability Model

As I understand it, the elk vulnerability model is a device to limit motorized access and thereby control hunting pressure. If it were applied only during the hunting season, I could at least understand the rationale.

However, it appears that Alternative 3M proposes to apply it year-round, causing a tremendous reduction in motorized recreation opportunities. The mileage of official and unofficial OHV trails would decline drastically. The miles of system roads and two-track roads to be closed numbers 828. Bear in mind these would not be the first closures on the Targhee NF. Over a thousand miles of roads and trails have already been gated and closed under the existing plan. The cumulative effect would be devastating to motorized recreation users.

The need for these reductions is not immediately obvious. The Analysis of the Management Situation documents increased deer, elk and bear populations. Summer habitat is not a limiting factor for these species, and elk, in particular, are at or near record levels. Winter habitat is a critical factor for elk, and it is dealt with in other provisions of Alternative 3M.

I suggest that the elk vulnerability model be applied as a temporary measure only during the elk hunting season. Its use at other times of the year cannot be justified, at least: not at the same standard of a maximum one mile of road/trail per square mile. This added flexibility would fit the circumstances to a greater degree and would relieve the Forest Service of the need to make extensive trail and road closures except where some other problem, such as severe erosion, is documented and cannot be repaired.

Plateau Bear Management Unit (BMU)

After having examined a number of issues related to the Plateau BMU over the past few years, I have come to the conclusion that it is such poor grizzly habitat that it should never have been included as part of the grizzly recovery zone. It should be dropped since it is ignored by the bears and a source of continuing strife for my constituents.

On a scale of 0 to 1 reflecting the quality of grizzly bear habitat, the Plateau BMU rates only 0.8 - by far the lowest rating of any BMU. Now, Alternative 3M worsens an already illogical land allocation by proposing extraordinary land use restrictions to see whether, in the next ten to fifteen years, grizzlies can be lured into using the Plateau BMU. Alternative

3

3M calls for new, protected core areas within the Plateau BMU as an enticement to the bears. At the same time, human use is discouraged, motorized trails and roads are closed, timber harvest is virtually eliminated, several sheep grazing allotments are cancelled and spring cross-country snowmobiling is prohibited.

All this mayhem is proposed as a ten to fifteen year experiment to see if a female grizzly with cubs can be tempted to use this sub-par habitat. The Plateau BMU is not needed. The grizzly population is doing well enough throughout the rest of the recovery zone to warrant delisting. None of these proposals in the Plateau BMU should be enacted in the final plan. If this is an example of the over-reaching land use regulations which will be necessary to obtain clearance from the USF&W, then I am afraid my position against further grizzly introduction in Idaho will harden considerably. I will communicate my position in a separate letter to USF&W.

Seasonal Cross-Country Travel Snowmobile Closure

The proposed new snowmobile cross-country closure in all bear management units from April 1 to December 15 each year is not necessary and should not be included in the final plan. This proposal is a classic example of over-regulation to achieve an objective. The objective is to protect grizzly leaving their dens far lower elevations in the spring.

The cross-country closure would cover 431,000 acres of prime spring riding terrain. On the one hand, the Forest Service cites this type of recreation opportunity as needed to serve a growing constituency in the future, but on the other hand, the agency incrementally eliminates such opportunities with proposals like this, and proposals for wilderness additions.

As I understand it, there are very few known grizzly denning sites anywhere on the Targhee NF, and there has never been a recorded case of snowmobile conflict with a bear. Protection of bears leaving dens could be accomplished with much more site-specific and time-specific measures rather than the wholesale prohibition which is proposed.

Allowable Sale Quantity

The Targhee National Forest makes an unfortunate statement by proposing an ASQ of only 3.7 million board feet of timber harvest from 487,000 acres of suitable forest land in the preferred alternative. This is an embarrassingly small volume from such an extensive and productive land base.

This suitable forest land base currently holds 1.6 billion board feet of merchantable timber which is growing at the rate of 54 MMBF per year. Yet, the Targhee NF proposes to harvest only 3.7 MMBF per year - only 7 percent of the net annual growth on

4

merchantable trees

The public has become much more concerned about sustainable forestry in recent years, and rightfully so. Table IV-19 reveals that the Long Term Sustained Yield (LTSY) capacity of the suitable lands in the preferred alternative is 27.6 MMBF. Even that figure is only half of actual net growth, and it seems suspiciously low given the net growth data. However, even then, the ASQ is not calculated on this LTSY figure. The LTSY's in Table IV-19 were all substantially reduced by a method of field validation which is not revealed in the DEIS. The LTSY for Alternative 3M was reduced to 14.9 MMBF by a process which is not documented in the DEIS and not available for comment by the public. Subsequently, the ASQ's in Table IV-21 were built from the lower LTSY figures.

The data and how it has been used to calculate ASQ raise serious questions. Given the standing volume and the solid growth rate (which doesn't even account for growth on young timber stands), it appears the LTSY should be higher. Beyond that, it is not clear how the FORPLAN results for LTSY were field-validated. Some downward adjustment of ASQ is appropriate to account for on-ground conditions which aren't reflected in the model, but a 50 percent reduction as we see occurring in the preferred alternative seems excessive. Such a large adjustment calls into question formulation of the model in the first place.

The Targhee NF should be able to support a far larger annual timber harvest on a sustainable basis than is documented in the DEIS. I am asking that you re-examine your data and your process for arriving at LTSY and the proposed ASQ.

Setting those matters aside, timber harvest on the Targhee NF would not even reach the LTSY level until the sixth decade in Alternative 3M. In Alternative 2 the LTSY would not be reached until the ninth decade. Obviously, the ASQ has been severely capped by the various constraints discussed in my comments. It is my sincere hope that a re-examination of the constraints, as I have suggested above, would point the way toward a higher and more credible timber output in this plan period. That end could be partly met by pulling more harvest volume into the first decade of the plan so as to create a smoother transition toward LTSY in future decades.

Community Needs

In my view, insufficient attention has been paid in the DEIS to the economic needs of the local community and to the possibility of offering a timber sale program which would sustain the local forest products industry at its current level (about 20 MMBF). The preferred alternative will supply only 21 percent of the local demand for forest products, though it has the potential to

5

do far more. It appears that one constraint is piled on another, and when all is said and done, only a tiny amount of timber harvest is found to be permissible, irrespective of the very clear and forceful statement of needs being voiced by several counties and the communities which are inseparable from the Targhee National Forest.

The voices of these governments and citizens were heard through the unusual step they took to place a ballot initiative in local elections amounting to a referendum on forest plan alternatives. That referendum soundly rejected the preferred alternative and endorsed Alternative 2. It is my opinion that the best decisions on land management matters are likely to result from a broad-based consensus of local participants. In this case, the local citizens and communities have spoken, and I hope the Targhee NF has listened and will act accordingly in the final plan revision.

Finally, I note that a selection criterion designed to meet the needs of the local communities appears nowhere among the priorities used to select the preferred alternative. Instead, the most important criterion in the selection was assigned to "Ecological process and patterns as measured by patch size limitations." Only an insider would understand what this means. Perhaps in the selection of the final forest plan, the needs of people could be given more prominence.

Summary

In summary, I've related a number of my concerns and I ask that you consider them in drafting your final documents. The revision of the forest plan is a complex undertaking with many legitimate forces at play, and I commend you and the Forest Planning Team for your sincere efforts to follow the science, and yet, reach an appropriate balance where you have discretion to do so.

This public comment period on the DEIS is the appropriate time to question application of the science and make needed changes in the flow of products and opportunities which the draft plan proposes. I am pleased to be able to offer my views and comments, and if any questions arise, I would be happy to discuss them further with you.

Sincerely,

LARRY E. CRAIG
United States Senator

RE TARGHEE FOREST PLAN REVISION (3M)

I write in opposition to the proposed Targhee Forest Plan Revision

1. The decision is skewed toward environmental factors. There are no decision criteria to evaluate loss of jobs and diminished revenue return to local economies. Economic and social effects are basically ignored in 3M.
2. The grizzly bear strategy is a flawed strategy with no scientific basis.
3. A proposed additional 125,000 acres of wilderness is just another "land grab".
4. Further reduction of grazing and logging does not produce long-term forest health and development. "No use" does not automatically translate into "wise use".
5. Ecosystem management is a vague, undefined concept whose only purpose is to further bind local control with federal control.
5. In the matter of road closure, closing roads without action by the county commissioners will violate RS 2477 and state law.

On April 9 at a meeting in Idaho Falls called by the Fremont Commissioners to discuss your proposed revision, you indicated in response to my question that the current plan was working well enough, but that a lawsuit settled with an environmental group directed further downsizing of activity on the Targhee.

Furthermore, those of us who have submitted to this process time after time after time, are fully aware that USFS alternatives align themselves into the good, the bad and the ugly. We know we aren't going to get the "good", we certainly don't want the "ugly", so process of elimination leaves us with the "bad" (3M). This is not acceptable.

Page 2
Mr Jerry Reese
Targhee Forest Plan Revision

The CUFF alternative is at least livable for now, even though the whittling will continue. With no other sensible alternative available and with no chance of leaving well enough alone, I support the CUFF alternative.

With CUFF we can make some progress. Things will get worse at a slower rate!

Sincerely,

Lenore Hardy Barrett

RECEIVED
JUN 26 1996

Dear Mr. Reese:

Thank you for the opportunity to comment on the draft Targhee Forest Plan. At the outset I want to express my opposition to the Forest Service's preferred Alternative 3H and give my support to the CUFF Alternative 2. Details of my position follow.

First, let me say that as a State Senator from District 27, I represent the people of Madison County and six precincts in Fremont County including Island Park. In the May 28th Primary election a nonbinding referendum was on the ballot giving voters an opportunity to choose between Alternative 3H and the CUFF Alternative 2. The voters in District 27 chose CUFF Alternative 2 by a 3-1 margin as did the voters in the other counties. I urge you to follow the will of the people in this very important matter instead of bowing to pressure from special interest groups such as the Yellowstone Coalition.

I believe the referendum says to the Forest Service that the people are pretty well pleased with past management of the Targhee National Forest. The bug-killed lodgepole pine needed to be harvested, the numbers of elk have increased dramatically, prime trout fishing streams have been protected by the State, snow machining and other recreational opportunities have been greatly improved and trout fishing in the region's rivers and streams is unsurpassed. Counties have benefitted from Forest Service payments.

But the proposed Targhee Forest Plan Alternative 3M places severe restrictions on the use of the Targhee National Forest by the public by reducing timber harvest far below a sustainable yield

by 125,000 acres. The people want less government control in their lives not more regulations!

It has been said, and I've heard you agree, that the Targhee Forest Plan Alternatives are being driven by grizzly bear recovery goals. But those goals make little sense along the west boundary of Yellowstone Park because studies show it is not good grizzly bear habitat and few bears have been observed in the area. There have been very few grizzly bear sightings in the Plateau BHN in Yellowstone Park even though timber harvesting, grazing, snow machining and ORV use are prohibited. Why then should grizzly bear recovery drive the planning process? I can tell you this, the Idaho Legislature and most of the citizens of Idaho are opposed to grizzly bear reintroduction in central Idaho and they are equally opposed to their introduction into the Island Park area.

Finally, you should know that although the Idaho Legislature cannot submit a resolution to you by June 27, 1996, there will likely be one forthcoming in early 1997. I can assure you that such a resolution will support a Targhee Forest Plan that closely follows the CUFF Alternative 2 Plan.

Sincerely,

Robert R. Lee

Dear Jerry

I have been hearing from many of my constituents and others expressing frustration, deep concern and down right anger over the preferred alternative 3 M Forest Plan being proposed. You of course are hearing from these same folks plus many others

I will not rehearse the reasons of concern in this letter as you no doubt have them memorized from all you have been hearing and reading

Let me just say, that in spite of the constraints that you are operating under, such as the Grizzly Bear issue, the 3 M plan seems to go way beyond the mark and I hope you will adopt a plan closer to the CUFF Alternative 2

Sincerely,

Golden C Linford
Representative Dist 27

Mr. Jerry Reese
Forest Supervisor, Targhee N.F.
P.O. Box 208
St. Anthony, ID 83445

Dear Jerry:

Over the past few weeks I have received a considerable number of letters relative to the "3M Targhee Forest Plan Revision." All of these letter express strong opposition.

The most significant opposition has come from those who represent the vast majority of the citizens on a local level...The County Commissioners, elected by the voice of the people.

Letters to me indicate that the County Commissioners of Eastern Idaho unanimously reject the Forest Service Alternative 3M Plan.

The County Commissioners recommend a similar plan to the "CUFF Alternative 2"...one that harvest about 20 MMBF per year, leaves grazing at the existing level, leaves most of the areas open to summer cross-country motorized use that are open now, and one that does not restrict cross-country snowmobile use after April 1. We also object to more areas recommended as wilderness! We have 4 million acres of wilderness in Idaho, more than any other state besides Alaska and California, and there are 6 million acres of designated wilderness in the Greater Yellowstone Region. That is enough!"

I strongly believe, as did the Founding Fathers, that the further government is from the people (either in distance of ideology), the more absurd are its regulations and decrees.

In our representative system of government, how can you overlook the officials elected who are closest to the people?

Sincerely,

Max C. Mortensen, Representative, District 28

Whereas environmentally appropriate management practices are in the best interests
of the resource industries and the multiple use concept

THEREFORE BE IT RESOLVED that the Idaho Republican Party supports
environmentally sound development and management of our natural resources

6 Proposed Forest Revision Plan

Whereas the Tarheel Forest Plan Revision currently proposed by the Tarheel
Forest will reduce travel, reduce timber harvest below sustainable levels, gradually reduce
(eliminate) grazing, institute ecosystem management, expand grizzly bear habitat,
increase wilderness designation and have a negative fiscal impact on local
economies and local governments, and

Whereas Congress passed a Revised Statute 2477 to allow public access across
public domain lands before these lands became national forest and closing them
without action by the County Commissioners will violate state law, and

Whereas the Tarheel approach to address ecosystem management is a vague,
undefined concept that will elude any meaningful contribution to the process other
than pseudo-science, conflict and confusion, and

Whereas the additional 125,000 acres recommended for wilderness is neither
needed nor justified, and

Whereas the "grizzly bear strategy" is a flawed term for "land grab" with no
scientific basis, and

Whereas PILT payments will be substantially reduced, and

Whereas NEPA procedures are only nominally adhered to, and

Whereas three counties within the Tarheel National Forest overwhelmingly voted
against the Forest Service's plan in an advisory election in May, and

Whereas a less disagreeable alternative is proposed by local resource users,
including a group called Citizens for a User-Friendly Forest (CUFF),

THEREFORE BE IT RESOLVED that the Idaho Republican Party officially
 comment in opposition to the Proposed Forest Revision Plan (3M) and direct this
 opposition to Jerry Reese, Forest Supervisor, Targhee National Forest, P O Box
 208, St Anthony, Idaho 83445, and
 BE IT FURTHER RESOLVED that this opposition be directed to the Secretary of
 Agriculture, the Idaho Congressional Delegation, the Governor of Idaho and the
 Idaho State Land Board

We have voiced opinions and concerns from time to time and attended some of the meetings
 for the Targhee Forest 10 year plan. We would like to make the following comments on the
 Draft Proposal. The 10-year plan has used much information that was derived from
 "Impian" economic model. This model has used information for jobs, income,
 etc. which has been used over a region-wide basis or the upper South-east Idaho area that
 the Targhee Forest lies in. In Clark County, we have found first of all that the "Impian"
 model is quite flawed and we are extremely wary of any numbers or trends that are
 predicted from the use of Impian generated data. We have found gross mistakes in the
 information generated for us by the University of Idaho, Agriculture Economic Dept. when
 Impian was used. We complained and still, nobody has given us a good reason why the
 numbers on cattle feedlot operations are 40-50 times the employment for range-fed cattle
 operations in Clark County. Dale Pekar did better than anyone else by far. He's the
 sharpest person we've found on explaining Impian so far. But the numbers are still wrong.
 Not only are we being viewed with poor numbers, but we've been thrown in with the entire
 "ecosystem" as everyone likes to put it. These are separate counties and for good reason.
 Were not like West Yellowstone or Driggs and we will not be thrown in on a regional basis
 when our economies are at stake. We don't get the hundreds of thousands of tourists, nor
 do we want them! PILT payments are made on a county-to-county basis and we are
 penalized by our low population, so at least give us the same treatment now.

The closure of roads and restriction of travel has adversely affected our historical custom
 and culture. We want mountains and valleys protected, not closed and padlocked. We
 have, as a county filed RS-2477 right-of-way, and those seem to be lost in the shuffle or
 else covered up by a big cat. We cannot believe that the Fish and Game has the Forest
 Service doing their "dirty work," that is trying to give some protection to the game while
 they continue to sell more licenses, extend seasons, and do nothing themselves to control
 pressure on the animals. Road restrictions and closures alone will not work! On the
 grazing issue, we need to recognize the grazing as a useful tool in fire suppression and
 maintenance of our plant communities. We also need to recognize grazing as part of the
 heritage (custom and culture) and the economic importance to Clark County, whether of not
 the rest of Southeastern Idaho counties care about it. The value added to Clark County (and
 others) is VERY significant, especially when you have over 100,000 AUMS and a value of
 \$1040 per annual unit per year established by the IRS. We are also opposed to any
 reduction in the amount of mineral entry lands available. This may be one of the most

RE Comments on the Forest Plan Revision

June 19 1996

Dear Mr Reese

The City of Island Park Planning and Zoning Commission has proposed the following policy which will probably become part of the Fremont County Comprehensive Plan in the near future

Nonregulatory strategies B

"The City of Island Park should work with Fremont County, the Targhee National Forest, and the Idaho Department of Lands to promote public acquisition of environmentally sensitive lands via exchange for national forest or state lands that can appropriately be managed as private forest or grazing lands, or developed" [Fremont County Comprehensive Plan, page 30 of proposal]

Please note that in the existing Fremont County Comprehensive Plan, Policy 5 [page 11], it states.

"It shall be Fremont County's policy to encourage land exchanges that place stream and lakeshore corridors, wetlands, wildlife habitat, and other critical areas in public ownership, while placing state and federal lands that are suitable for development in private ownership. The county also recognizes the possibility that state lands may be leased or sold for development. Development resulting from state or federal land exchanges, leases, or sales must comply with this plan and the *Fremont County Development Code*. This policy does not apply to land exchanges between public agencies, for instance an exchange between the Bureau of Land Management and the Idaho Department of Lands."

We would request that the Forest recognize this policy in the Forest Plan Revision and include similar language in the Plan. This could be a way of increasing critical winter

MADISON COUNTY

PO BOX 389
REXBURG IDAHO
83440

3-PP-Reserv
102 - Madison County

wildlife range critical wetlands, and other items of concern in the Plan. On the other hand, forest land that adjoins the Commercial Nodes being created in Island Park by the city and county planning and zoning commissions might become available to increase the area of these nodes while preventing "strip" development. Commercial development is necessary to provide the goods and services needed by the growing population of Island Park, but it must be kept orderly and concentrated to maintain the appealing character of Island Park.

Respectfully submitted,

Mahlon Hiestand, M.D., Chair
City of Island Park Planning & Zoning Commission

JUNE 24, 1996

RECEIVED
JUN 25 1996

JERRYB REESE
FOREST SUPERVISOR
TARGHEE NATIONAL FOREST
P.O. BOX 208
ST. ANTHONY, IDAHO 83445

Dear Jerry

Thank you for the opportunity to comment on the Draft Revised Forestland the Draft Environmental Impact Statement. The following are the comments of the Madison County Commission, representing the majority of the residents of Madison County.

During the Primary Election, the Madison County Commission conducted a straw poll on two alternatives, the results of this poll were:

CUFF (Citizens for a User Friendly Forest) ALTERNATIVE 2	2442
TARGHEE FOREST ALTERNATIVE 3M	783
Ballots where the voters declined to participate	487

A copy of this ballot is attached to this comment letter.

We believe that the message from this poll is very clear, that the residents of Madison County are definitely in favor of more access, timber cutting, grazing, and accessibility to the Targhee Forest.

We recognize 86.5 MMBF ASQ established in the current plan was not sustainable however we feel that a realistic environmental analysis under the guidelines of NEPA and NFMA should recognize an ASQ of 20 MMBF per year. The Range of the ASQ in the seven alternatives evaluated is from a low of 0 MMBF to a high of 6 MMBF. For all practical purposes this range is the same. None of these alternatives would sustain a viable timber industry in southeastern Idaho which has a economic

effect on our community as a whole

Security for elk is a key indicator in the Targhee Plan. The Forest Service essentially agreed to meet the goals of the Idaho Fish and Game Department without the consideration of other multiple uses and the resulting economic effect. We feel that agreeing to meet the goals of a single agency without consideration of multiple uses is a violation of the Forest Service multiple-use mandate. This agreement has resulted in a dramatic reduction in the ASQ as well as access. We believe that these goals are unsubstantiated due to the increase in the elk population over the last 10 years. The number of elk counted on the winter range in 1996 is more than what the winter range can support in a typical heavy snow year. The Elk numbers have increased substantially in those years when cover was at a minimum. As long as the numbers of elk remain high the argument for limited access and 50 to 60% of the water shed set aside for cover is a moot point!

The indicator for grizzly bear management uses open road and motorized trail route densities as the basis for eliminating all of these forms of access.

We believe that the agreement on management is counter to the best available scientific evidence. (Intervenors Reply to Plaintiffs' and Federal Defendants', United States District Court, Case No. 93-303-E-HLR)

1. The Ban of commercial timber harvesting will not accomplish the goal of grizzly bear recovery in the Greater Yellowstone Ecosystem.

2. The major cause of mortality to the Grizzly Bear population is access to BMUs by humans with firearms.

3. Commercial timber harvesting does not by itself reduce the amount of food and cover habitat to prevent the MI recovery goals of the Grizzly Bear Recovery Plan as set forth by the Interagency Grizzly Bear Study Team.

4. The use of the Plateau by the grizzly bear is questionable even under the terms of the settlement and the Plateau management strategy.

5. Research has shown that when the grizzly comes out of hibernation that there is little if any food in the upper elevations. This forces the bear to lower elevations where there is a vegetation base. Limiting access to these upper elevations for snowmobilers where the bear can not exist is not warranted.

With the revisions of Range Management Plans over the last 20 years the Range on the Targhee Forest is in better condition than it had been in 50 years. Further reductions in Grazing are unwarranted and are solely the political agenda of self-serving parties. We believe that there should be no further reduction.

We believe that the Economic Analysis is inadequate, doesn't take into consideration the effect of the decisions that have been made since 1985, the closure of four major sawmills and loss of almost all timber cutting jobs. In their analysis they refer to the increase in tourism to make up for the loss of these jobs, but the seven proposals severely limits the access to the forest for all motorized transportation. If people don't have access to recreate they will take those tourist dollars somewhere else.

The residents of Madison County have made it clear that they believe that the proposed alternatives are too restrictive and limit access to the forest. They believe that the DEIS and the Draft Forest Plan has been prepared for political purposes, bowing to those who threaten to sue, ignoring the best available science.

Therefore we as commissioners of Madison County request that an alternative be considered that is based upon science, considers the Unique ecosystem of the Targhee National Forest, and displays the economic consequences of the other seven alternatives. We recognize that a supplemental Environmental Impact Statement will be necessary for consideration of this alternative. But we believe that this will be best for all of those that are involved in the process.

RESPECTFULLY YOURS

GERALD LEE JEPPESEN (CHAIRMAN)

RECEIVED
JUN 27 1998

Dear Mr Reese

The Mayor and the members of the Irwin City Council appreciate the informational efforts of the Targhee National Forest. Our city periodically receives up-to-date accounts of projects and other efforts taking place on nearby public lands. As part of that continual process, we appreciate the opportunity to comment in writing on the **Draft Environmental Impact Statement and Forest Plan Revision** for the Targhee National Forest. The City of Irwin would acknowledge that the Palisades Ranger District is of immediate concern while policies throughout the forest also affect our "city impact" area.

The City is in agreement that a new plan is desired for managing these public lands. The old Forest Plan of 1985 is now outdated and the reasons thus delineated in Chapter 1 of the Draft Environmental Impact Statement. The National Forest Management Act (NFMA) of 1976 is an example of a good law. It requires 10 year, integrated land management plans for all National Forests with public involvement and comment.

Controversy is certainly generated with any proposed change and particularly so when governmental jurisdictions are involved. The City of Irwin has thus received various "points-of-view" from different "special interest" groups regarding the forest plan. The greatest concerns seem to be centered with **Key Issue 5 Access** and **Key Issue 7 Timber Harvest**.

Discussion of the Alternative Continuum has been narrowed in public comments to the preferred **Alternative 3-M** (Proposed Programmatic Action and Preferred Alternative) and **Alternative 2** as promoted by the Citizens for a User Friendly Forest (CUFF) and the Blue Ribbon Coalition. The City of Irwin would ask that all comments received from the public be reviewed and incorporated where possible. With that idea, the City of Irwin would support a **Final Environmental Impact Statement and Forest Plan** for the Targhee National Forest that finds middle ground between **Alternative 3-M** and **Alternative 2**.

Other comments concerning the proposed actions follow

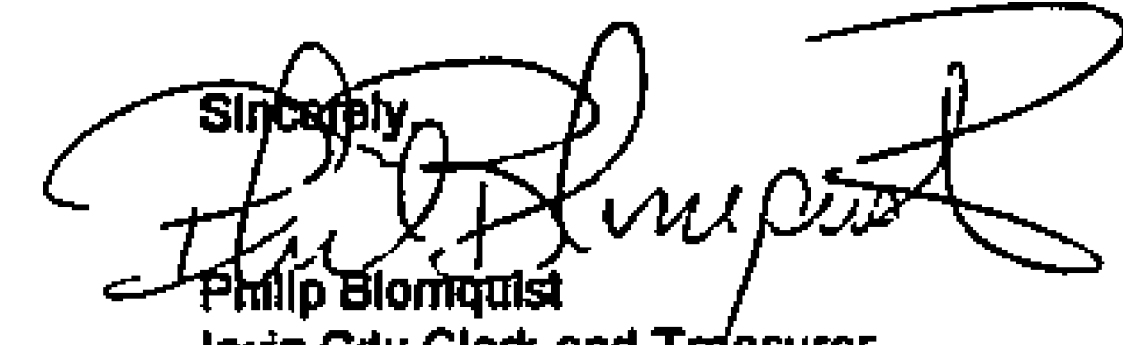

The Targhee National Forest is somewhat unique in that logging has occurred beyond sustainable levels for many years. The 1998 Forest Plan must address this issue. While we agree that allowable cuts are necessary, these must be reviewed to also address local economic concerns. In some cases, these drastic reductions in board feet will allow increased logging in future years. The City of Irwin supports this management strategy.

Stubble height is another concern addressed by several residents in Irwin. We agree recovery rates in grazing allotments should be measured. The 1985 plan used a two to three inch stubble height which will be changed to four inches in the 1998 plan. We support this change. The 1998 revision also allows managers to impose a six-inch stubble height if necessary in some riparian units. If this management criteria is selected, it should be employed only in an extreme scenario. Other measures for rate of recovery should be explored.

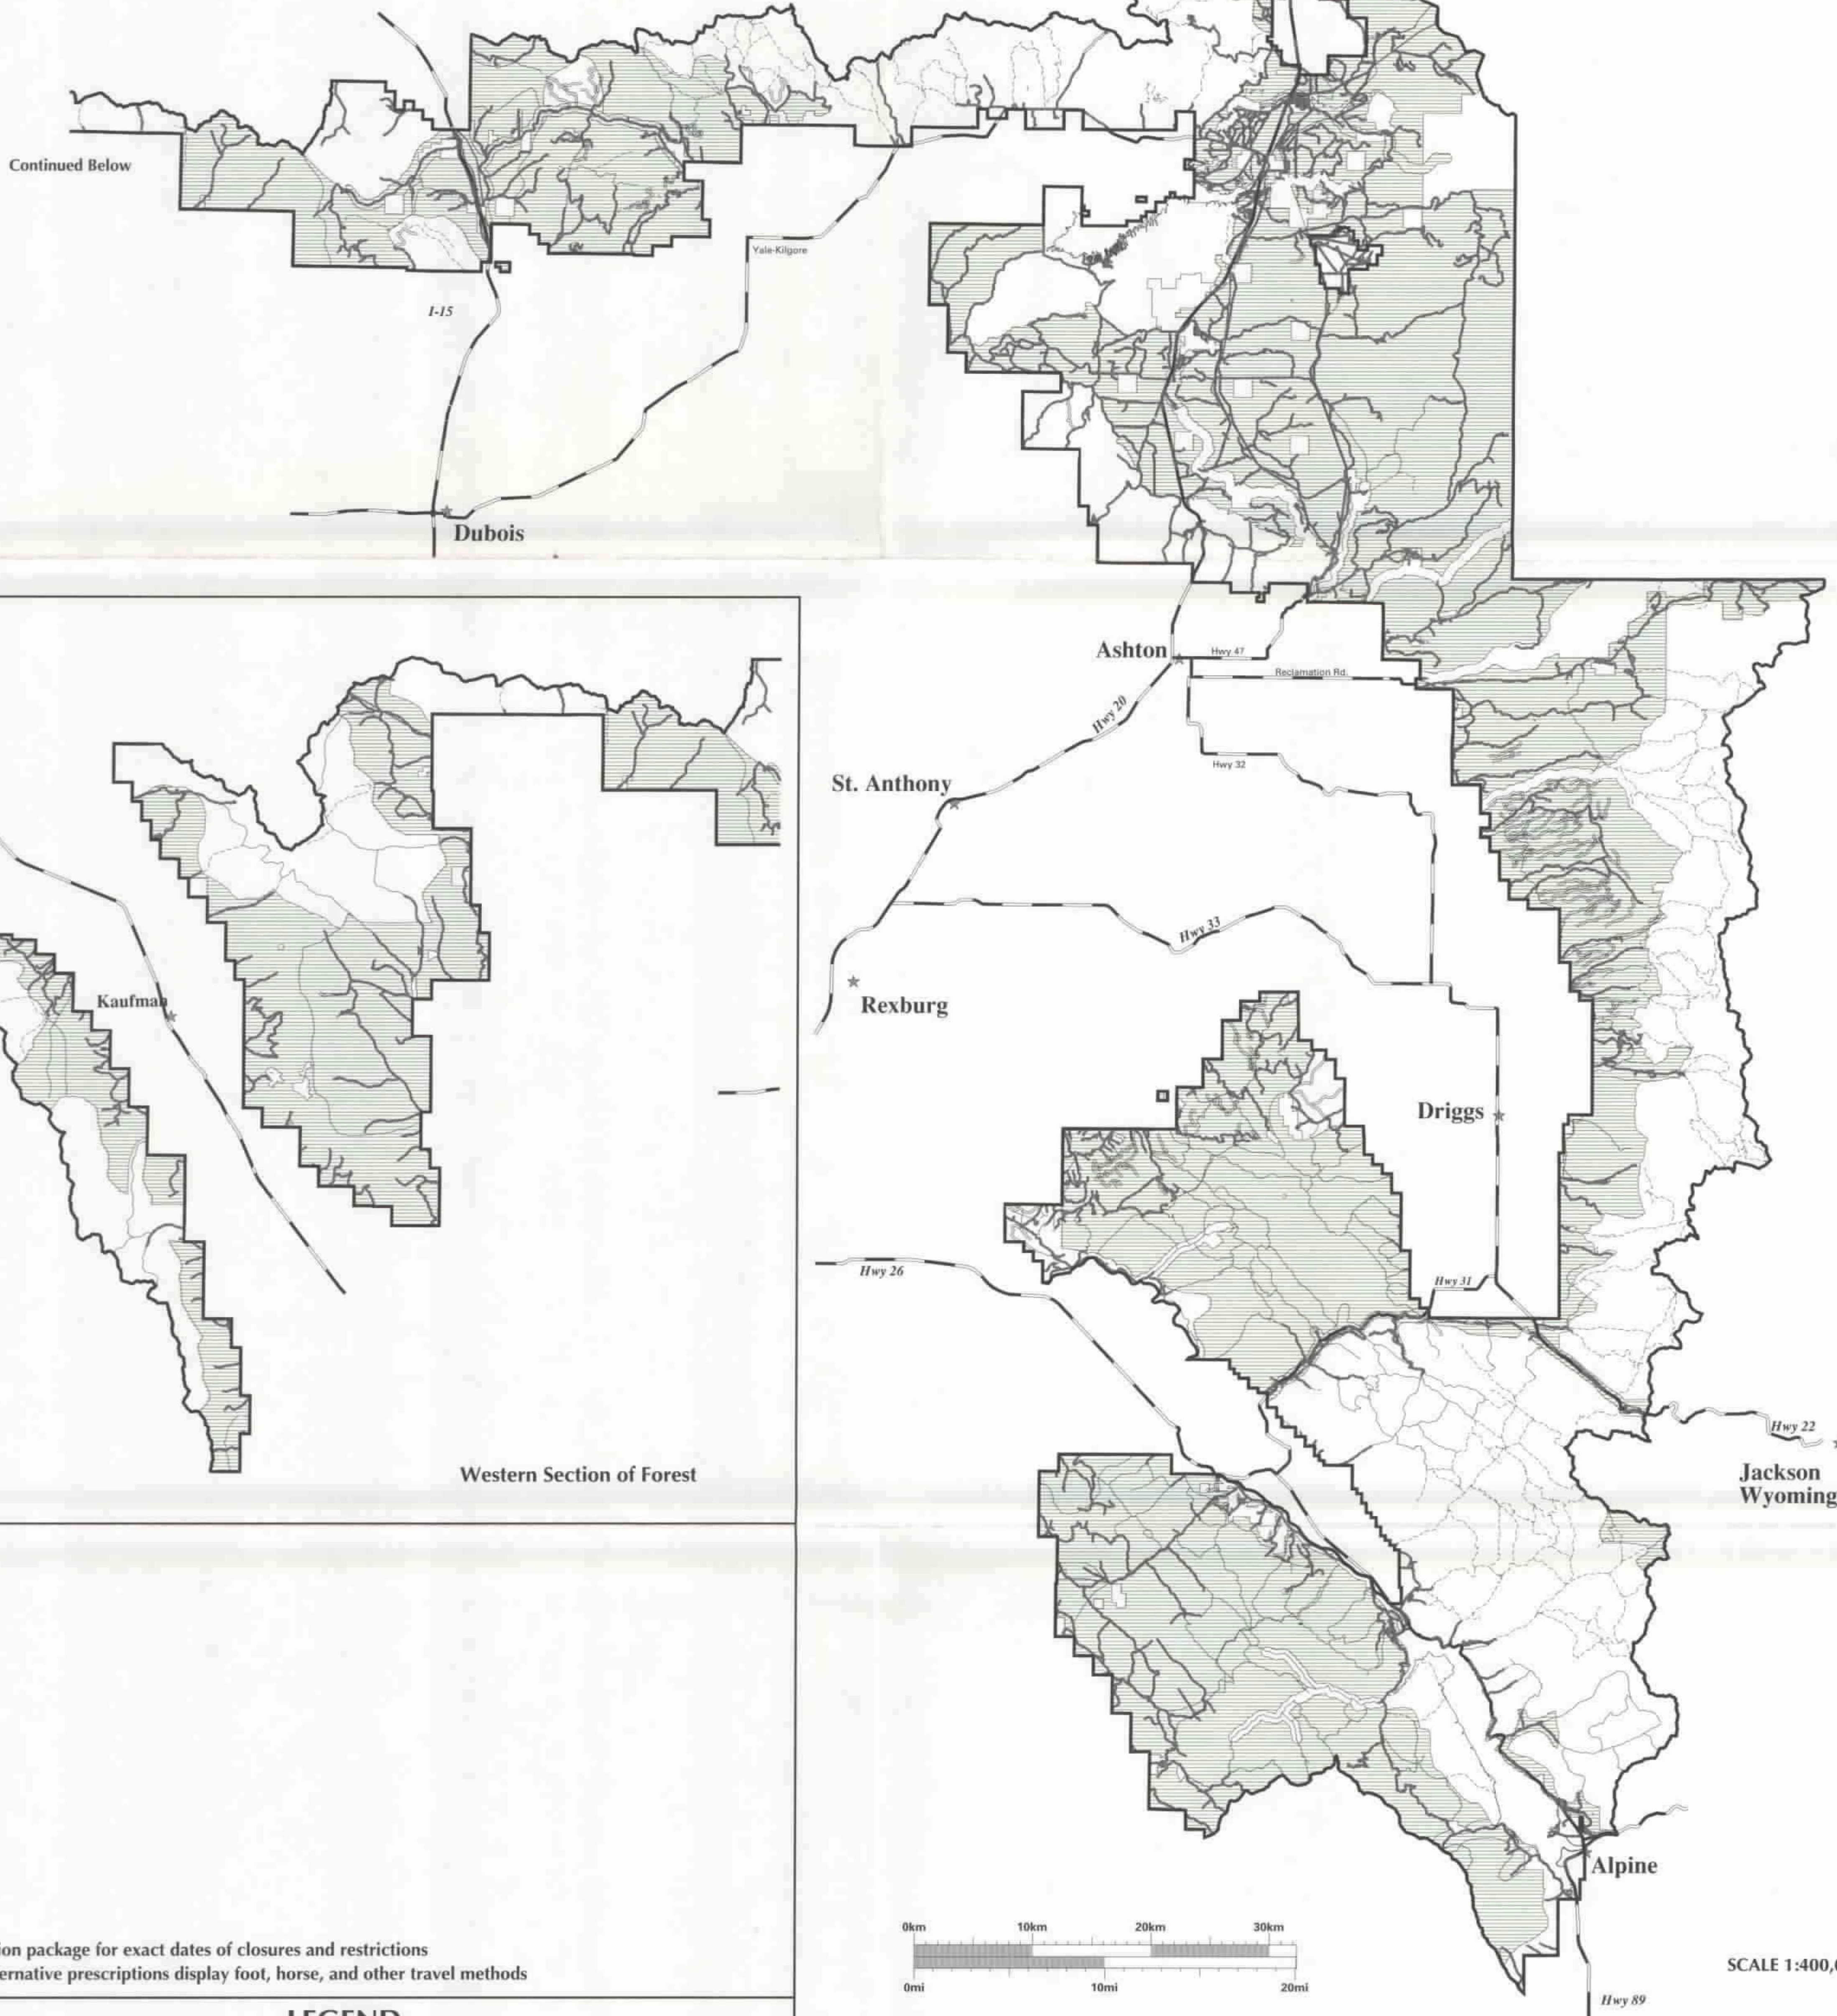

The City of Irwin concurs with habitat protection for the native cutthroat trout. The fine-spotted cutthroat is valuable in the Palisades region both for aesthetic and economic reasons.

Access to the Forest road system needs to be carefully reviewed. While certain road closures are a benefit to wildlife, they have constantly been abused in the past. The 1985 plan closed 1600 miles of primarily timber access roads. Many of these road closures have unfortunately been ignored by the public. More education and public involvement is needed to determine the extent of road closures. Restricting ORVs to certain roads, trails and off-road areas seems reasonable.

The new plan calls for an increase in groomed snowmobile trails. The 1998 plan would designate 658 miles of groomed winter trails. The 1985 plan had only 450 miles. We support the increase.

Sincerely,

Philip Blomquist
Irwin City Clerk and Treasurer

This Revised Forest Plan was prepared according to Secretary of Agriculture regulations (36 CFR 219), which are based on the Forest and Rangeland Renewable Resources Planning Act (RPA) as amended by the National Forest Management Act of 1976 (NFMA). This Revised Forest Plan was developed in accordance with regulations (40 CFR 1500) for implementing the National Environmental Policy Act (NEPA). A detailed Environmental Impact Statement (EIS) has been prepared as required by NEPA and 36 CFR 219.

If any particular provision of this Revised Plan, or the application of the action to any person or circumstances, is found to be invalid, the remainder of the proposed action and the application of that provision to other persons or circumstances shall not be affected.

The United States Department of Agriculture (USDA) prohibits discrimination in its programs on the basis of race, color, national origin, sex, religion, age, disability, political beliefs, and marital or familial status. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (braille, large print, audiotape, etc.) should contact the USDA Office of Communications at (202) 720-2791.

To file a complaint, write the Secretary of Agriculture, U S Department of Agriculture, Washington, D C 20250, or call 1-800-245-6340 (voice) or (202) 720-1127 (TDD). USDA is an equal opportunity employer.

**Revised Forest Plan
Introduction**

CHAPTER I

FOREST PLAN REVISION INTRODUCTION

PURPOSE OF THE LAND AND RESOURCE MANAGEMENT PLAN (FOREST PLAN REVISION)

This Revised Forest Plan (Revision, or Plan) guides all natural resource management activities and establishes management standards for the Targhee National Forest (hereinafter referred to as "the Forest") The Revision embodies the provisions of the Forest and Rangeland Renewable Resources Planning Act (RPA) as amended by the National Forest Management Act (NFMA), Endangered Species Act (ESA), and other guiding documents The forestwide standards and guidelines, subsection direction and management prescriptions state the Revision's management direction, however, the project outputs, services, and rates of implementation are dependent on the annual budgeting process

The Forest Plan will be revised every 10-15 years, or sooner should conditions or demands significantly change

Development of the Revision occurs within the overall framework of both National and Regional Planning The Revision and accompanying Environmental Impact Statement (EIS) are "tiered to the Intermountain Regional Guide Regional planning is a two-way street that helps convey direction from National to the Forest level, and helps transmit information from the Forest to the National level The Regional Guide establishes standards and guidelines, and resolves Regional issues

During the Revision process, alternatives were developed, analyzed, compared, and a preferred alternative selected This Revision is based on the "selected alternative" displayed in the accompanying Environmental Impact Statement (EIS) The planning process and analysis procedures used in developing this Revised Plan, as well as the other management alternatives that were considered, are described or referenced in the EIS In the development of the alternatives, estimates were made based on broad averages, as to the various activities and resulting outputs of implementing that alternative These estimates were used to compare alternatives and to arrive at the preferred alternative Actual outputs may vary slightly from those displayed in the preferred alternative, however, the intent of the preferred alternative will be met

Revised Forest Plan direction serves as an "umbrella" for the environmental analysis for proposed projects at the Forest and Ranger District levels Future environmental analyses for those projects will refer to this Plan, the accompanying EIS, and related documents wherever possible (the travel plan will be implemented by a separate decision based on the EIS associated with this Plan) Analysis and decision documents will be developed for project level activities not specifically described in this Plan and will concentrate on issues unique to the project

Landscape or watershed analysis is one means of implementing Revised Forest Plan direction It is not a process independent of the Plan, but fits under the Plan "umbrella" This process evaluates ecological, social, and economic conditions—present and historical—at a geographic scale between the entire Targhee National Forest and a much smaller individual project area It generally assesses conditions at a watershed (such as Camas Creek) or subsection (such as Centennial Mountains) scale This assessment precedes analysis and decision-making on individual project proposals in the landscape analysis area Subsequent site-specific project analyses use the broader scale analysis to set the context for the proposed activities and their anticipated results

Most projects will not be preceded by a landscape analysis because it is an intense analysis process. However, landscape analysis may be helpful for

- identifying and evaluating ecosystems in properly functioning condition and systems at risk,
- providing baseline data and information for project planning,
- understanding the role of historical processes and patterns within which current management actions can take place,
- identifying priorities for project proposals,
- predicting cumulative environmental effects beyond the project area, and,
- integrating individual project outcomes into the larger ecological landscape

The Revision does not give specific "how-to's" for project implementation. Many implementation plans will be developed during the life of the plan that will provide this operational direction. These plans will be adapted as new scientific principles and methods become available to improve resource management activities. The Revision contains detailed guidance for implementing travel management plan maps for all Districts on the Forest. A fire management plan for the Jedediah Smith Wilderness will be completed shortly which outlines operational direction for that portion of the Forest.

The Revision replaces previous resource management plans. Upon final approval of the Revision, all Forest activities, including budget proposals, will conform to it. All permits, contracts, and other uses of Forest lands must also conform with the Revision. Some existing permits and leases are already committed. In this case, existing contracts will remain in effect until they can be adjusted to accommodate Revision direction.

REVISION STRUCTURE

The Revision provides the long-term direction for managing the Forest. When implemented it will achieve the desired condition for the Forest.

The Revised Forest Plan is organized into five chapters and one appendix.

Chapter I Forest Plan Revision Introduction

Discusses the general purpose of the Plan, the relationship of the Plan to other documents, and the Plan structure. Includes a brief description of the Forest.

Chapter II Summary of the Analysis of the Management Situation (AMS)

Summarizes the key information contained in the AMS and describes the need to revise the original Targhee National Forest Land Management Plan. Presents the Desired Future Condition for the Forest.

Chapter III Management Direction

Presents the forestwide management direction, descriptions and direction for ecological subsections, and lists the management prescriptions. Collectively these represent direction for management of the Forest.

Chapter IV Implementation of the Plan

Displays the timber activity schedule contemplated to meet the Desired Future Conditions (DFC) set forth in the EIS.

Chapter V Monitoring and Evaluation

Shows how the Forest will monitor compliance with, and performance of, critical standards and guidelines in the Revision. In this sense it is a part of a larger range of project level monitoring activities which take place on the Forest

LOCATION OF THE FOREST

The Forest contains approximately 1,789,000 acres of National Forest System land located in south-east Idaho and western Wyoming. Parts of the Forest lie in the Idaho counties of Bonneville, Butte, Clark, Fremont, Jefferson, Lemhi, Madison, Teton, and the Wyoming counties of Lincoln and Teton. The Forest is bordered on the east by Yellowstone and Grand Teton National Parks and the Bridger-Teton National Forest, on the south by the Caribou National Forest, on the west by the Challis and Salmon National Forests, and on the north by the Beaverhead and Gallatin National Forests. Figures I-1 and I-2 display the location of the Forest on a National and local scale.

The Forest has five administrative Districts

District	Net Acres
Dubois D-1	449,416
Island Park D-2	285,712
Ashton D-3	347,130
Palisades D-4	442,447
Teton Basin D-5	264,341

The Forest Supervisor's office is located in St. Anthony, Idaho

Chapter

Summary of the Analysis of the Management Situation

CHAPTER II

SUMMARY OF THE ANALYSIS OF THE MANAGEMENT SITUATION

Introduction

This chapter summarizes the key information contained in the Analysis of the Management Situation (AMS) and describes the need to revise the Targhee National Forest Land Management Plan

Purpose of Preparing an AMS

As part of the Revision process an AMS was completed in 1992 (USDA Forest Service, Targhee National Forest, 1992) A comprehensive review of the existing Plan identified changed conditions and new information, including new public issues and changed public attitudes and awareness, which affected the appropriateness of continuing with the management direction in the Plan The AMS is on file at the Targhee Supervisor's Office This analysis 1) described the present Forest condition, 2) defined the progress that has been made in implementing the Plan with respect to accomplishment of goals and objectives set forth in the Plan, and 3) showed how effective standards and guides were in achieving the desired future conditions described in the Plan Process papers provide additional information These are listed in the literature cited section of this document

Primary Emphasis of the Plan

A primary goal of the existing Plan was to harvest and reforest the thousands of acres of lodgepole pine that had been killed or damaged by the mountain pine beetle To achieve this goal, species/product mix objectives were established Concerning species mix, about ten percent of the acres harvested were to be Douglas-fir and about 90 percent lodgepole pine Another objective was to provide a product mix that was 40 percent sawtimber and 60 percent other products, such as posts, poles and firewood A third objective limited the percent or number of acres within each Management Area that would be harvested

Results of Monitoring

Monitoring indicated the volume of timber actually harvested, for both lodgepole pine and Douglas-fir, was near planned levels This volume was taken from 58 percent of the acres originally considered for harvest

It was expected that the Allowable Sale Quantity (ASQ) would be reached while operating within standards and guidelines The Forest began to experience difficulty in achieving this level of outputs within these constraints Agency direction states that ASQ will be adjusted if standards and guidelines cannot be met

The species mix objective was achieved, with the total harvest consisting of 11 percent Douglas-fir and 89 percent lodgepole pine The product mix objective was not met The product mix was 76 percent sawtimber and 24 percent other products This exceeded the 20 percent variance set forth in the Plan

Habitat effectiveness for big game and grizzly bear was reduced through increases in road density and reduction of forest cover Some degraded riparian habitats showed improvement as a result of implementing the standards and guidelines in the original Plan

The number of plant and animal species on the Forest listed as threatened or endangered has increased by one with the recent discovery on the Forest of the Ute ladies'-tresses, a threatened species of orchid. Bald eagles (threatened) and peregrine falcons (endangered) have reached recovery levels on the Forest and there is a need to address long-term management needs for these species. The number of plant and animal species on the Forest which are listed as sensitive by the Intermountain Region of the Forest Service has increased as more information on occurrence and habitat needs has become available.

Public Interaction and DFC

Social needs and desires have changed. This is evidenced by the comments received in scoping for individual projects, public meetings, and the number of administrative appeals and lawsuits that challenged the application of Forest management. The proposals most frequently challenged after 1991 were timber harvests. Issues centered on impacts to wildlife and, to a lesser extent, recreation and scenic values.

The original Forest Plan was designed by focusing primarily on capabilities of the land to produce commodities such as timber or livestock forage. The advent of ecosystem management (EM) requires that the Forest be managed for sustainability of all ecosystem components, some of which were not adequately addressed in the original Plan.

Public comments and ideas received through scoping identified new public expectations as to what uses and benefits the Forest should provide. The new Desired Future Condition (DFC) which emerged could not be achieved under the original Plan direction. It is described below.

Desired Future Condition for Ecosystem Processes and Patterns

A mosaic of age classes and types of vegetation are sustained through time and exist across the landscape. Natural disturbances such as insects, disease, and fires continue their natural roles in ecosystem. The Forest functions as an integral part of the Greater Yellowstone Ecosystem as well as adjacent systems sustaining habitat and conditions necessary for free movement of wildlife.

Desired Future Condition for Biological and Physical Resources

Riparian zones (aquatic influence zones) are healthy and productive. Aquatic systems are allowed to function naturally while protecting flows for downstream consumptive uses. Riparian area integrity contributes to productive fisheries and excellent water quality. Native plant and animal species are favored over undesirable nonnative species and sustained populations of all native and desirable species thrive. Habitat conditions contribute toward the recovery of threatened, endangered and sensitive species.

Desired Future Condition for Forest Use and Occupation

Growing and diverse recreational, cultural, visual, historical, and prehistoric management, interpretive and spiritual needs are accommodated based on the capability of the ecosystem to sustain these uses. Recreation use is managed to minimize conflicts between incompatible uses and provide high levels of satisfaction. Year-round human access is managed to provide both motorized and nonmotorized recreation opportunities. A system of trails and support facilities exist which are compatible with resource capabilities. Roadless characteristics are preserved in the proposed wilderness areas and in existing wildernesses.

Desired Future Condition for Production of Commodity Resources

Commodity production, such as timber, firewood, mining, livestock forage, or outfitting and guide services are conducted at sustainable levels and maintain the capability of the land to produce an even flow and variety of goods and services for present and future generations. Timber harvest, prescribed fires and livestock grazing are tools used to achieve desired ecological vegetation conditions. Forest products are provided to sustain social and economic values and needs of the local communities within limits which maintain ecosystem health.

New Information

Another reason for embarking on the Revision was the need to review and incorporate new knowledge and techniques to improve sustainability of ecosystems. Recent studies and publications indicate, for example, that road density plays a more crucial role in habitat management for elk and grizzly bears than was assumed in the original Plan. Much work has been done to develop standards for nesting and foraging habitat for goshawks and other raptors. EM efforts analyzing fish habitat in the Upper Columbia River Basin have suggested new ways of managing fisheries and aquatic ecosystems. These findings and other information have been reviewed for their applicability to habitat management on the Forest and incorporated where appropriate.

Need for Change

The original Targhee Forest Plan, approved in 1985, emphasized an extensive salvage and reforestation program of dead lodgepole killed by a massive mountain pine beetle epidemic over the previous 30 years. This rate of salvage caused, in effect, a departure from a sustained yield of timber harvest and could not be continued beyond the first decade (1985-1995) in an environmentally sound manner. Monitoring of activities during this time showed it was increasingly difficult to meet the standards and guidelines in the 1985 Plan. New information on resource needs and various management practices became evident during this time, and by 1990 it was apparent that a full revision was needed. More specific needs for change are as follows:

- The salvage program has ended. Use of the many roads built during salvage operations by increasing numbers of people is causing unwanted effects to wildlife, riparian areas, and soil productivity.
- The need to review and incorporate new knowledge and techniques continues, especially in wildlife habitat management. For example, recent studies indicate motorized road and trail densities play a crucial role in availability of suitable habitat for elk and grizzly bears. Standards for management activities near nesting and foraging habitat for goshawks and other raptors are needed to protect these crucial areas. Results of studies analyzing fish habitat in the Upper Columbia River Basin are pointing out new ways to manage fisheries. Some of these findings have widespread implications that the revision process was intended to address.
- Although much of the lodgepole pine component on the Forest has been salvaged, there is still a need to use timber harvest as a tool to reach ecosystem objectives, supply a variety of timber products for local use, deter other epidemics like the mountain pine beetle outbreak, and manage the potential for a devastating wildfire, like the Yellowstone Wildfires of 1988.

Chapter

Forestwide Standards and Guidelines, Subsection Direction, and Management Prescriptions

**CHAPTER III
FORESTWIDE STANDARDS AND GUIDELINES,
SUBSECTION DIRECTION, AND PRESCRIPTIONS FOR
IMPLEMENTING THE SELECTED ALTERNATIVE.**

INTRODUCTION	III-2
PART 1 - FORESTWIDE STANDARDS AND GUIDELINES	1114
PART 2 - SUBSECTION DESCRIPTIONS AND DIRECTION	111-34
PART 3 - MANAGEMENT PRESCRIPTIONS	111-65

CHAPTER III - INTRODUCTION

This chapter provides management direction for the Forest for the next 10 to 15 years. This direction takes several forms and is applied at three geographic levels.

Desired Future Conditions (DFCs) are broad target conditions envisioned for the Forest or various resources at some point in the future. They may or may not be totally achieved during the life of the Revised Plan, but they serve to indicate the direction in which management should proceed.

Goal - a concise statement that describes a DFC which normally is expressed in broad, general terms that are timeless, in that there is no specific date by which each goal is to be achieved.

Objective - a concise, typically time-specific statement of a condition, outcome, or purpose. Objectives are often measurable planned results that respond to goals.

Standard - a condition of land, normally a maximum or minimum condition, that is measurable. A standard can also be expressed as a constraint on management activities or practices. Standards are established on a forestwide, subsection, and management prescription area basis to promote achievement of the DFC and objectives. Deviation from compliance with a standard requires a Forest Plan amendment (except for emergency situations as explained below). (USDA Forest Service, 1993)

Guideline - a preferred or advisable course of action that is generally expected to be carried out. Deviation from compliance with a guideline does not require a Forest Plan amendment, but the rationale for such a deviation shall be documented in the project decision document. Guidelines are established on a forestwide, subsection, and management prescription area basis to promote achievement of the desired future condition and objectives in an operationally flexible manner that responds to such variations as changing site conditions or changed management circumstances. (USDA Forest Service, 1993)

If the wording of an item appears to conflict with its label, the label shall prevail ("S" for standard, "G" for guideline).

Direction in the form of goals, objectives, standards and guidelines is prescribed at three different geographic levels in the Revised Plan. This direction is described in the following three parts of this chapter.

Part 1 -- Forestwide Standards and Guidelines. Direction is provided for individual and collective resources. This applies forestwide unless otherwise stated in subsequent parts of the chapter. Forestwide direction is organized into five components which are consistent with descriptions in the Final EIS for this Revised Plan. These components are Ecological Processes and Patterns, Biological Elements, Physical Elements, Forest Use and Occupation, and Production of Commodity Resources.

Part 2 -- Subsection Direction. This part of the chapter describes the Forest in terms of seven large geographic units, or ecological subsections. This provides a locational perspective to overall management direction. Conditions in each subsection are briefly described and broad DFCs are presented. These are followed by goals, objectives, standards and guidelines as applicable.

Part 3 -- Management Prescriptions. An array of different management regimes are presented here which have been applied to various parts of the Forest to address specific management needs or public desires. The 45 prescriptions are organized in categories and presented in a sequence allowing progressively more active management. Prescriptions beginning with a "1" provide direction

for areas managed as wilderness, wilderness study areas or recommended wilderness, while series "8" prescriptions give direction for areas managed for concentrated development such as ski areas or utility corridors. All prescriptions are organized according to the five components used in the Final EIS and forestwide direction.

In the event of conflicting direction for a given area of the Forest, the direction stated under the applicable prescription shall prevail, with few exceptions. Where prescription direction is superseded by Forestwide or subsection direction, this is explicitly stated in those parts of the chapter.

INTRODUCTION

The forestwide standards and guidelines are organized by ecological groupings, as shown in the table of contents. The standards and guidelines in this section of the document are common to the entire Forest. Forestwide goals and (in some cases) objectives are provided for each resource area and/or activity. Following the goals and objectives, the specific standards and guidelines are presented. A standard is identified with an (S), and a guideline is identified with a (G). A diligent effort has been made to make these goals and objectives, and standards and guidelines specific to the Forest. This set of standards and guidelines is the result of many suggested changes made by our publics and employees.

The existing body of national direction for managing a National Forest remains in effect. The standards and guidelines presented herein provide direction more specific to the needs of the Targhee. A summary of national program and regional policy and goals can be found in Appendix A. The direction from the references cited in Appendix A is incorporated herein as additional forestwide direction.

If an emergency event occurs on the Forest, deviation from these standards and guidelines may occur in order to protect human life, property values and structures, and forest resources. Activities in response to emergency events include such things as law enforcement, search and rescue, and fire.

ECOLOGICAL PROCESSES AND PATTERNS

Properly Functioning Condition (PFC)

✓ Goals - PFC

- 1 Ecosystems and their components are maintained in properly functioning condition: dynamic and resilient to disturbances to structure, composition, and processes at appropriate landscape scales. Ecosystems are not at risk for disturbances that have the potential to degrade them beyond the point of resiliency and sustainability.
- 2 Ecological systems at risk are identified and prioritized for management action.
- 3 In assessing properly functioning condition, the biological and physical, social, and economic components of ecosystems are considered.
- 4 Management strategies are used to maintain or restore ecological integrity, productivity and sustainability over time.
- 5 Biodiversity is maintained or enhanced by managing as much as possible for a diverse array of habitats tied to natural occurrence and distribution of plant communities.
- 6 Adaptive management strategies are used to gain understanding during project implementation and make adjustments to maintain and restore properly functioning condition.

/Objective - PFC

- 1 Within three years, complete a PFC assessment within a selected subsection.

Standards and Guidelines - PFC

- 1 During landscape or watershed analyses, identify ecosystems in properly functioning condition and those at risk (G).

2 Where appropriate, during project planning and implementation, identify and prioritize systems at risk for corrective treatment or action (G)

Insects and Disease

Goal

Insects and disease are allowed to play their natural role in ecosystem dynamics to the extent compatible with other resource objectives

Fire

Goals

- 1 Identify the historic role of fire and restore fire as an ecological process, where appropriate to achieve multiple-use and ecosystem management objectives
2. Prescribed fire and managed natural fire is used to achieve desirable soil and habitat characteristics, improve forest health, and create or maintain diversity in vegetative structure, composition, and patterns as described in PFC analysis
- 3 Suppress fire in a safe, cost effective manner where necessary to protect human life and safety, developments, structures, and sensitive resource values
- 4 Fuel accumulations are reduced and managed within their historic range

Objectives

- 1 By 2007, develop at least one fire management plan for a priority area within each of the seven subsections
- 2 By 2005, initiate a program to burn a minimum 2,000 acres annually for habitat improvement, fuels management, and forest health, consistent with approved fire management plans

Standards and Guidelines

When feasible and appropriate, use prescribed burning to dispose of slash in order to return the inorganic and organic chemicals in the foliage and small woody material to the soil, to reduce fire hazard and to provide seed beds for natural regeneration (G)

PHYSICAL ELEMENTS

Soils

Goal

Long-term soil productivity is sustained by retaining fine organic matter and woody residue on activity areas

Standards and Guidelines - Soil Quality (applicable only to current activity areas)/Forested Ecosystems

- 1 Fine Organic Matter Generally strive to maintain fine organic matter over at least 50 percent of

the area. The preference is for fine organic matter to be undisturbed, but if disturbed, it should be of sufficient quantity and quality to avoid detrimental nutrient cycle deficits. If the soil and potential natural community are not capable of producing fine organic matter over 50 percent of the area, adjust minimum amounts to reflect potential soil and vegetation capability (G)

2 Woody Residue Requirements for Materials three inches in Diameter or larger. Sustain site productivity by providing the following minimum amounts of woody residue dispersed on the site (G)

WOODY RESIDUE REQUIREMENT FOR WOODY MATERIALS >= 3 INCHES IN DIAMETER		
Woody Residue Minimum Requirement (tons/acre) 1/	Forest Habitat Type	
3-5	Limber pine/curl-leaf mountain mahogany (Pifi/Cele) Douglas-fir/common juniper (Psmc/Juco)	Douglas-fir/mountain snowberry (Psmc/Syor) Lodgepole pine/heartleaf arnica (Pinc/Arco)
5-10	Douglas-fir/ninebark (Psmc/Phma) Douglas-fir/mountain maple (Psmc/Acgl) Douglas-fir/blue huckleberry (Psmc/Vagl) Douglas-fir/grouse whorleberry (Psmc/Vasc) Douglas-fir/common snowberry (Psmc/Syal) Douglas-fir/white spirea (Psmc/Spbe) Douglas-fir/pine grass (Psmc/Caru) Alpine fir/white spirea (Abla/Spbe)	Alpine fir/pine grass (Abla/Caru) Alpine fir/heartleaf arnica (Abla/Arco) Whitebark pine/ross sedge (Pial/Caro) Lodgepole pine/blue huckleberry (Pico/Vagl) Lodgepole pine/grouse whorleberry (Pico/Vasc) Lodgepole pine/white spirea (Pico/Spbe) Lodgepole pine/pine grass (Pico/Caru) Lodgepole pine/elk sedge (Pico/Cage)
10-15	Douglas-fir/mountain sweetroot (Psmc/Osch) Engelman spruce/softleaved sedge (Pien/Cadi) Alpine fir/ninebark (Abla/Phma) Alpine fir/blue huckleberry (Abla/Vagl) Alpine fir/grouse whortleberry (Abla/Vasc)	Alpine fir/mountain arnica (Abla/Arta) Alpine fir/common snowberry (Abla/Syal) Alpine fir/western meadow-rue (Abla/Thoc) Alpine fir/oregon grape (Abla/Bere)
15-20	Engelman spruce/sweetscented bedstraw (Pien/Gatr)	Alpine fir/baneberry (Alba/Acru) Alpine fir/mountain sweetroot (Abla/Osch)

3 During site preparation treatments, strive to avoid disturbing concentrated areas of soil wood (G)

Standards and Guidelines - Slope Stability for Mineral Activities

1 In areas of high mass instability, that have been ground verified, occupancy shall not be allowed (S)

2 In areas identified as having moderate instability, and that are ground verified, occupancy may be allowed provided it can be shown the project design can prevent unacceptable resource damage (G)

Caves

Standards and Guidelines

1 Restrict logging, road construction, and other uses of heavy equipment above or in the vicinity of a cave with a thin roof, or the course of such a cave, if there is a potential for damage (G)

2 Retain vegetation in the vicinity of a cave or cave course if it is required to protect the cave's microenvironment (habitat, climate, vegetation, etc) (G)

3 Fell trees away from the cave and its course if timber harvesting is permitted in the vicinity of a cave (G)

4 Cave entrances will not be altered or used as disposal sites for slash or other refuse and no action will be taken to prevent or hinder ingress or egress of cave-dependent wildlife Gating of cave entrances will be allowed as long as physical alteration of the entrance is not needed to construct the gate Wilderness values will also be considered prior to installing such structures (S)

5 Management activities will not be permitted within any area draining into a cave if they are likely to affect the cave ecosystem through sedimentation, soil sterilization, the addition of nutrients or other chemicals (including pesticides, herbicides, and fertilizers) or by changing the cave's natural hydrology (S)

6 Do not allow alteration of natural surface drainage into or away from caves (S)

Lands

Goals

1 A well planned system of reliable and technically feasible energy corridors are provided to serve existing and future regional and local energy needs, compatible with other resource needs and objectives These corridors may be either designated (prescription 8 1) or nondesignated (other prescriptions)

2 The National Forest System lands set aside for utility corridors are minimized to reduce fragmentation and minimize acres allocated for that use

Objective

Remove utility facilities located in avoidance or exclusion areas as it becomes practical to do so

Standards and Guidelines

Allow for essential access for repair and maintenance of facilities within energy corridors (S)

Avoid parallel corridors Consolidate facilities within existing energy corridors where feasible (G)

Bury new lines and upgrades/replacements when feasible (G)

Proponents of new facilities within existing corridors, and new corridor routes, must demonstrate clearly that the proposal is in the public interest, and that no other reasonable alternative exists to public land routing (G)

Minerals

Goal

Implement leasing decisions including identification of lands available for leasing made in the Forest Oil and Gas Leasing EIS and its associated Record of Decision

Standards and Guidelines - Locatable and Mineral Materials

1 Common Minerals Give priority to use of currently developed common mineral (natural gravel and hard rock) material sources over undeveloped sources Exceptions should be made when existing

sources are unable to economically supply the quality and quantity of material needed or when conflicts with other resource uses are found to be unacceptable (G)

2 The Forest is open to exploration and development and production of locatable, leasable, and mineral material resources unless otherwise specified in the management prescriptions (S)

3 Oil and gas pipelines and other related utilities should share utility corridors except as needed to meet other resource objectives (G)

BIOLOGICAL ELEMENTS

Fisheries, Water, and Riparian Resources

Goals

1 Maintain or improve water quality to meet water quality standards for the States of Idaho and Wyoming

2 Water quality will improve on stream segments on the Forest identified by the States of Idaho and Wyoming as having water quality concerns and they are removed from the Water Quality Limited list

3 Maintain or restore water quality, to a degree that provides for stable and productive riparian and aquatic ecosystems

4 Maintain or restore stream channel integrity, channel processes, and the sediment regime (including the elements of timing, volume, and character of sediment input and transport) under which the riparian and aquatic ecosystems naturally developed

5 Maintain or restore instream flows to support healthy riparian and aquatic habitats, the stability and effective function of stream channels, and the ability to route discharges

6 Maintain or restore the natural timing and variability of the water table elevation in meadows and wetlands

7 Maintain or restore the diversity and productivity of native and desirable nonnative plant communities in riparian zones.

8 Maintain or restore riparian vegetation to

A Provide an amount and distribution of large woody debris characteristic of natural aquatic and riparian ecosystems,

B Provide adequate summer and winter thermal regulation within the riparian and aquatic zones,

C Help achieve rates of surface erosion, bank erosion, and channel migration characteristic of those under which the communities developed naturally

9 Maintain or restore aquatic habitats necessary to support overall biodiversity, including unique genetic fish stocks such as native cutthroat trout that evolved within the specific geo-climatic regions

10 Maintain or restore habitat to support populations of well-distributed native and desired nonnative plant, vertebrate, and invertebrate populations that contribute to the viability of riparian-dependent communities

11 Wherever possible, secure water rights for maintenance of riparian and aquatic habitat, under State appropriative law, State reserved rights (in Wyoming), and Federal reserved rights

12 Focus maintenance and restoration efforts, where needed, within inventoried hydrologically disturbed watersheds

13 Participate in cooperative river basin planning efforts. Coordinate management activities to be consistent with the results of these efforts including the Henry's Fork Basin Plan and the South Fork Snake Basin Plan

Objectives

1 By 2007, complete watershed improvement needs backlog in the Lemhi/Medicine Lodge, Big Hole Mountains, and Caribou Range Mountains Subsections. Verify watershed improvement needs identified in the Teton Basin Study. Inventory watershed improvement needs on the Centennial Mountains, Madison-Pitchstone Plateaus, and Teton Range Subsections

2 Within two years after the ROD is signed, coordinate with the States of Idaho and Wyoming to 1) reassess the health of native cutthroat trout populations within the Lemhi/Medicine Lodge, Centennial Mountains, Island Park, Madison-Pitchstone Plateaus, and Teton Range Subsections, 2) use this information to further define species recovery needs and opportunities and to evaluate the effectiveness of the Native Trout Watersheds, and 3) determine which subwatersheds (drainages) within Native Trout Watersheds are vital to native cutthroat trout recovery. The designated Native Trout Watersheds on the Forest are Elk Creek (003), Palisades Creek (004), Rainey Creek (005), Pine Creek (006), Heise (007), Henry's Fork Headwaters (008), Robinson Creek (013), Trail Creek (017), Mahogany Creek (022), Moody Creek (024), Bitch Creek (032), Burns-Pat Canyon (035), McCoy-Jensen Creeks (036), Elk-Bear Creeks (037), Fall Creek (038), Prichard Creek (039), and Brockman Creek (040)

3 Within four years after the ROD is signed, coordinate with the States of Idaho and Wyoming to 1) reassess the health of native cutthroat trout populations within the Big Hole Mountains and Caribou Range Mountains Subsections, 2) use this information to further define species recovery needs and opportunities, and 3) determine which subwatersheds (drainages) within designated Native Trout Watersheds are nonessential to native cutthroat trout recovery

4 Coordinate with sub-basin assessments for implementation of State water quality standards (Total Maximum Daily Loads, TMDLs)

Standard and Guideline - Watershed, General

Not more than 30 percent of any of the principal watersheds and their subwatersheds should be in a hydrologically disturbed condition at any one time (G)

Standards and Guidelines - Fisheries and Other Aquatic Resources

1 New special use permits or new Forest Service projects involving instream facilities (exclusive of facilities retrofitted to existing dams) must maintain minimum instream flows as specified by the Forest or State and, on fish-bearing streams provide for fish passage and include screening devices to prevent accidental loss of fish (S)

2 When reauthorizing existing special use permits or existing Forest Service projects involving instream facilities (exclusive of facilities retrofitted to existing dams), where feasible, provide for minimum instream flows as specified by the Forest or State and, on fish-bearing streams, where feasible, provide for fish passage and include screening devices to prevent accidental loss of fish (G)

For guidelines 3, 4, and 5, refer to the following discussion and Table

The following table describes expected values for specific habitat features which are reflective of good fisheries habitat conditions and are also indicators of ecosystem health. It is intended to guide management of native cutthroat trout habitats. Although individual habitat features will be measured at the stream reach scale, the criteria for meeting the expected values apply at the watershed scale, generally for third- to sixth-order streams. These expected values are based on the best available information including INFISH. They are intended as a starting point and can be refined later, based on field analysis or literature review, to better reflect conditions that are attainable in a particular watershed or stream reach.

EXPECTED VALUES FOR HEALTHY NATIVE FISH HABITAT CONDITIONS AT THE WATERSHED SCALE	
Habitat Feature	Expected Value
Pool Frequency (all systems)	At least 1 pool per length of stream equal to 5-7 times the channel width
Water Temperature	Within spawning habitats 13 C or less with a maximum daily average no greater than 9 C ^{1/} Within adult holding habitat 16 C with a maximum daily average no greater than 12 C
Large Woody Debris (forested systems)	> 20 pieces per mile ^{2/}
Bank Stability (nonforested systems)	> 80 percent
Lower Bank Angle (nonforested systems)	> 75 percent of banks with < 90 degree angle
Width/Depth Ratio (all systems)	Must be suitable for the Rosgentype of the given stream reach ^{3/}
<p>^{1/} This criterion applies to the period of time from spawning to emergence. In lieu of site-specific information, use March 1 to September 15</p> <p>^{2/} Criteria must meet R1/R4 stream inventory procedures</p> <p>^{3/} Rosgentype refers to a stream classification system which categorizes streams based on entrenchment, gradient, width to depth ratio, sinuosity, and channel materials</p>	

3 Within subwatersheds occupied by native cutthroat trout or designated as vital to meeting recovery goals, avoid management activities that are found, through interdisciplinary site-specific analysis, to either reduce habitat features below the expected values described above or retard the rate of recovery of degraded habitat features (G)

4 Emphasize watershed analysis or site-specific analysis to more accurately define fisheries habitat features when planning or conducting management activities within Native Trout Watersheds (G)

5 Values for fish habitat features may be adjusted based on field analysis or literature review. A clear rationale supporting the adjustment must be documented (G)

Vegetation

Goals

- 1 Maintain and restore healthy, diverse forested and nonforested ecosystems through time, including appropriate components of dead and down woody material
- 2 Use vegetation management to achieve a broad array of multiple-use and ecosystem management objectives, including maintenance, improvement, and restoration of
 - forest health,
 - scenic viewsheds and corridors,
 - wildlife habitat effectiveness and quality,
 - hazardous fuels reduction,
 - biological diversity of plant and animal communities,
 - riparian and watershed health and function,
 - vegetation structure, composition, and distribution in larger landscapes

Objectives

- 1 By 2007, identify properly functioning condition (PFC) and systems at risk for forested landscapes
- 2 Within five years, complete a properly functioning condition assessment for the lodgepole pine community type and develop long term vegetation and density management strategies to reduce the risk of a future catastrophic bark beetle epidemic

Standards and Guidelines

- 1 Where appropriate, use methods of vegetation treatment that emulate natural ecological processes to maintain or restore properly functioning ecosystems (G)
- 2 Forest vegetation manipulation on lands not included in the ASQ will be accomplished to meet the individual management prescription direction. Production of wood products will not be the primary consideration. Harvest will be accomplished with sufficient mitigation to protect and maintain soil, wildlife, visual, and aquatic resources (S)
- 3 Vegetation manipulation may include mechanical treatments, commercial or noncommercial timber harvest of wood products, prescribed fire, or other appropriate methods (G)
- 4 Vegetation manipulation through timber harvest on lands not included in the ASQ will not exceed 20 million board feet (MMBF) per decade (S)
- 5 Treat aspen plant communities to reduce encroaching conifers and maintain a balance of age classes for these communities (G)
- 6 Old Growth and Late Seral Forest Stages
 - A In each principal watershed, the combination of old growth and late seral forest stage acres will be 20 percent or more of the forested acres. Where it exists, at least half of this (ten percent of the forested acres) should meet old growth characteristics (G)
 - 1 For aspen and conifer forest types, acres classified as old growth and late seral should be in blocks over 300 acres in size (a block can consist of a combination of old growth and late successional forest types) (G)

Within these blocks

- a Maintain 80 percent or greater primary cavity nesting species habitat capability (see Wildlife Standards and Guidelines - Snag/Cavity Nesting Habitat) (G)
 - b Maintain the wildlife dead and down woody material guidelines (see Wildlife Standards and Guidelines - 1 Dead and Down Material) (G)
 - c Silvicultural techniques may be used to maintain or improve old growth and late successional characteristics (G)
- 2 If a catastrophic event (such as fire) reduces the acres of old growth and late seral forest below 20 percent of the forested acres in a principal watershed, identify replacement forested acres to achieve the 20 percent. When necessary, use silvicultural techniques to promote old growth and late seral characteristics in the replacement acres (G)
- 3 Use the definition of old growth characteristics by forest type found in "Characteristics of Old-Growth Forests in the Intermountain Region" (USDA Forest Service 1993) (S)
- 4 Use the definition of late seral stages by forest type in the table below (G)

LATE SERAL (SUCCESSIONAL) STAGES					
		Dominant	Live	Overstory	Trees
Forest	Type	Age	Trees/Acre	DBH(IN)	
Lodgepole	Pine	100+	40+	9+	
Douglas-fir		140+	25+	14+	
Mixed	Conifer	100+	40+	12+	
Spruce/Fir		110+	20+	12+	
Aspen		60+	20+	10+	
Cottonwood		50+	--	--	

- 7 Conduct vegetation manipulations in a cost effective manner. Manipulations should emphasize desired ecological and multiple-use outcomes over being above cost (G)
- 8 Maintain, and where possible, increase unique or difficult-to-replace elements or habitats such as whitebark pine, and areas of high species diversity, such as aspen, riparian zones, etc (G)
- 9 Do not conduct management activities which alter canopy vegetation within 400 feet of a Natural Resources Conservation Service (NRCS) snow measuring site without first contacting NRCS. Legal locations of these sites are in the Forest Geographic Information System (GIS) (S)
- 10 Sagebrush/grassland habitats. Within big sagebrush (*Artemisia tridentata* & varieties)/grassland habitats strive for canopy coverage distributions on a subwatershed basis (generally 2,000 to 6,000 acres in size) of (G)
- Less than five percent of a subwatershed in a less than five percent canopy coverage class
 - Seventy-five percent of a subwatershed in a well distributed mosaic of canopy coverage ranging from 5-30 percent
 - Twenty percent of a subwatershed in a greater than 30 percent canopy coverage class

Goals - Plant Species Diversity

- 1 Preserve unique formations within a landscape (such as cliffs, bogs, seeps, talus slopes, warm or alkaline springs, pot holes, and rock outcroppings) that provide habitat to plant species not common to the overall landscape and contribute to the species diversity within the landscape
- 2 Provide necessary protection and management to conserve listed threatened, endangered and sensitive plant species.

Standards and Guidelines - Plant Species Diversity

- 1 Native plant species from genetically local sources will be used to the extent practicable for erosion control, fire rehabilitation, riparian restoration, forage enhancement, road right-of-way seeding, and other revegetation projects (G)
2. Areas planned for nonnative seedings or plantings of nonnative woody species need to be evaluated to determine the impacts to the native flora within the analysis area and habitats adjacent to it (G)
- 3 Introduced species should be utilized in project seedings where native species would not meet the objectives of erosion control, such as in high **use** or impact areas, and where the effects on local, native flora is minimal, sites that are currently dominated by introduced species and **use** of nonnative species has not degraded the adjacent native flora; and sites where the management objective is to utilize nonnative species in one area to prevent degradation of other natural areas. (G)
- 4 Information on the presence of listed threatened, endangered or sensitive plant species will be included in all assessments for vegetation and/or ground disturbing management activities. Appropriate protection and mitigation measures will be applied to the management activities (S)

Objectives - Ute Ladies' Tresses (*Spiranthes diluvialis*)

- 1 Map suitable habitat (generally within wetland/riparian/floodplain areas below 7,000 feet elevation) on the Forest within three years of implementation of the ROD
- 2 Complete intensive surveys of suitable habitat to document presence of plants within five years of implementation of the ROD

Standards and Guidelines - Ute Ladies' Tresses (*Spiranthes diluvialis*)

- 1 For known populations within livestock grazing allotments, provide appropriate protection, particularly during the flowering and seed-set periods (generally August and September) (S)
- 2 Allow no ground disturbing activities or changes in hydrology within occupied habitat without review by botanist and interdisciplinary team (S)

Goals - Special Forest Products

- 1 Establish guidelines for commercial harvesting of special forest product species
- 2 Provide for the historical, cultural, and recreational **uses**, as well as rights and privileges afforded Native Americans under treaties and agreements, before commercial **uses** of special forest products are allowed

Wildlife ✓

Goals

- 1 Wildlife biodiversity is maintained or enhanced by managing for a diverse array of habitats and distribution of plant communities
- 2 Provide habitat to support the wildlife and hunting goals of the States of Idaho and Wyoming

Standards and Guidelines - General Habitat

1 Dead and Down Material

(Note These requirements are interrelated with the woody residue requirements and are not cumulative to those requirements)

A On at least 60 percent of the forested acres of each analysis area an average of 21 logs per acre should be left consisting of logs in decomposition classes 1, 2 and 3 where they exist (USFS, 1979) (G) (Note unmanaged stands or stands where management did not include the removal or piling of down material, meet forestwide standards and guidelines for down woody material)

When this amount of down material is not present on at least 60 percent of the forested acres in an analysis area, an average of **42** logs per acre should be left in all activity areas (harvest units) consisting of logs in all decomposition classes where they exist Fewer logs may be left if fuel loading would exceed 25 tons per acre (G)

1 Logs should be at least seven inches in diameter at the small end, be at least 20 feet long, and have a volume of at least ten cubic feet (e.g., a log averaging 9.5 inches in diameter and 20 feet long) (G)

a Smaller size logs may only be used in meeting this volume criteria if the area is incapable of producing larger trees, or the stand is too young to produce these trees In these cases, logs representing the largest tree diameter class present in the stand should be retained and at least 200 cubic feet (approximately 2.3 tons) per acre of down logs shall be retained

b For every area two-acre area in an activity area, a minimum of two logs should be left, where they exist, to maintain distribution of down woody material

2 Winter Feeding of Big Game Allow no new permanent feed grounds for wintering big game animals (S)

3 Animal Damage management will be conducted in compliance with the 1996 "APHIS-ADC Predator Damage Management in Southern Idaho" Decision Notice and FONSI, selected alternative "Current Program with Livestock Protection Collar" (S)

a Annual ADC work plans will be prepared using the 1990 Targhee National Forest "Forest-Wide Predator Control Environmental Assessment" as a framework for conducting predator control activities on the Forest Deviations from the direction in the 1990 EA will be considered when necessary to deal with particular problem animals (G)

b Problem wolves will be managed according to the Nonessential Experimental Population for Gray Wolves Final Rule (USDI, 1994b) (S)

c Problem grizzly bears will be addressed according to the Interagency Grizzly Bear Committee nuisance bear guidelines (IGBC, 1994) (S)

d Use of toxicants will not be allowed on the Forest (S)

Objective - Snag/Cavity Nesting Habitat

Determine the biological potential for cavity nesting habitat on a watershed basis to enable management of some areas at higher levels of biological potential and some at lower levels of biological potential and meet the overall management prescription objectives

Standards and Guidelines - Snag/Cavity Nesting Habitat

1 Retain snags within all management prescription areas allowing timber harvest (refer to the following Tables 1 & 2 for snag requirements of cavity nesting species, refer to the wildlife standards and guidelines in each management prescription for the specific biological potential to be achieved) (G)

Table 1 Snag requirements for 100 percent biological potential for woodpecker populations

Species	Range in Snag DBH (inches)	Range in Snag Height (feet)	No of Snags per 100 Forested Acres for 100 Percent Biological Potential			
			Aspen	Cottonwood	Doug-fir Spruce/Fir	Lodgepole
Lewis's Woodpecker	12 to 27	5 to 170	101	101	101	NA
Yellow-bellied Sapsucker	9 to 47	15+	150	150	150	150
Williamson's Sapsucker	12 to 37	15+	NA	NA	150	150
Downy Woodpecker	6 to 14	6 to 50	300	300	300	300
Hairy Woodpecker	9 to 29	15+	180	180	180	180
Three-toed Woodpecker	7 to 19	15+	59	NA	59	59
Black-backed Woodpecker	8 to 17	6+	NA	NA	59	59
Northern Flicker	10 to 51	6+	38	38	38	38
Total Hard Snags per 100 acres			828	769	1037	936
NA indicates the species does not use this forest type						

Table 2 Snag requirements for maintaining various percentages of biological potential for woodpecker populations (refer to Table 1 for snag dbh, snag height, and individual species requirements)

Percent of Biological Potential	Number of Hard Snags per 100 Forested Acres			
	Aspen	Cottonwood	Doug-fir Spruce/Fir	Lodgepole
100	828	769	1037	936
80	662	615	830	749
60	497	461	622	562
40	331	308	415	374
20	166	154	207	187

2 Retain live trees for future snag recruitment using the following guidelines to achieve various percentages of biological potential (G)

Percent of Biological Potential	Number of Live Trees per Forested Acre				
	>= 10 in dbh	>= 7 0-9 9 in dbh	>= 5 0-6 9 in dbh	< 5 0 in dbh	Total Tree/Acre
100	8	5	5	7	25
80	6	4	4	6	20
60	5	3	3	4	15
40	3	2	2	3	10
20	2	1	1	1	5

3 In analysis areas where snag numbers are low (at or approaching management minimums), no dead standing trees should be harvested (G)

4 Public workforce and contractor safety will be considered and provided for in selecting the arrangement of retained snags and trees (S)

Goals - Grizzly Bear Habitat

- 1 Habitat conditions will be sufficient to sustain a recovered population of grizzly bears
- 2 Allow for unhindered movement of bears (continuity with Yellowstone National Park and adjacent bear management units)

Objectives - Grizzly Bear Habitat

- 1 Meet recovery criteria in the current Grizzly Bear Recovery Plan
- 2 Implement guidelines developed by the Interagency Grizzly Bear Committee
- 3 Provide safe, secure sites for nuisance bears as defined by Interagency Grizzly Bear Guidelines

4 Achieve the road density standards in the Bear Management Units (BMUs) within three years of the implementation of the ROD in coordination with USFWS and State Wildlife agencies

5 Develop fire management plans for each of the Bear Management Units (BMUs) to address wildfires and prescribed fires, as follows

- Bechler-Teton BMU -- within two years of the Record of Decision (ROD) for the Revised Plan,
- Plateau BMU -- within four years of the ROD,
- Henrys Lake BMU -- by 2003

Standards and Guidelines - Grizzly Bear Habitat

1 The grizzly bear education program will focus on residents in residential and summer home areas, developed recreation site users, wilderness users, hunters, outfitters and guides, and permittees (G)

2 Those areas shown as Management Situation 3 (MS3) habitat on Map #5 of the 1985 Forest Plan will continue to be managed as MS3 habitat (S)

Goals - Bald Eagle Habitat

Habitat conditions will be sufficient to sustain a recovered bald eagle population

Objectives - Bald Eagle Habitat

- 1 Continue current nest location and productivity monitoring
- 2 Identify bald eagle wintering and migration habitat and identify appropriate management needs
 - For the Henry's Fork watershed, within three years of the ROD for the Revision
 - For the South Fork of the Snake, by the year 2003

Standards and Guidelines - Bald Eagle Habitat

1 In Occupied Nesting Zones (Zone I) and Primary Use Areas (Zone II) apply the following

A Minimize all human activities from February 1 to August 1 (G)

B No new roads in Zone I (S) Avoid building new roads in Zone II (G)

C Manage human use on existing roads at levels which do not adversely affect use and productivity of the nest site (G)

D No new developed recreation sites or facilities in Zone I (S) Avoid building new recreation sites or facilities in Zone II (G)

E Manage existing recreation use at levels which do not adversely affect use and productivity of the nest site (S)

F Use the "No Surface Occupancy" stipulation for all minerals activities (S)

G If eagles choose to establish new nest sites and use areas in an area already receiving human use, the human activities may be restricted or modified Expanded human activity, however, should be discouraged (G)

H Use silvicultural techniques which maintain or promote mature and old growth timber stand characteristics in both the short and long term, but reduce the risks of insects and disease epidemics (S)

I Vegetation management can only occur between September 1 and January 31 (S)

J Use "control" as the appropriate suppression response for wildfires to minimize loss of habitat (G)

K Prohibit new structures that have the potential to cause direct mortality to bald eagles (e.g. power lines) (S)

L Permit historic levels of livestock use as long as no adverse impacts (such as abandonment of nest territory or reproduction failures) occur related to this activity. Manage livestock to allow successful reproduction of cottonwood where applicable (G)

M Prohibit wildlife management or predator control activity with the potential to cause mortality to bald eagles (such as exposed traps) (S)

2 Within Home Ranges (Zone III) follow existing site-specific management plans (when they exist) for each bald eagle territory, or Zone III management direction in the Bald Eagle Management Plan for the Greater Yellowstone Area when site-specific management plans do not exist (S)

3 Within Zones I, II, and III, prohibit all **use** of herbicides and pesticides which cause egg shell thinning as determined by EPA labeling (S)

4 Recreation activities and developments will be designed to minimize conflicts with bald eagle wintering and migration habitat (G)

5 New roads and trails will be located to avoid bald eagle wintering and migration habitat. Where these areas cannot be avoided the roads and trails will be designed and located to minimize impacts to eagles (G)

Objective - Gray Wolf Habitat

All wolves found in the wild on the Forest will be considered nonessential experimental animals as defined in the FEIS for The Reintroduction of Gray Wolves to Yellowstone National Park and Central Idaho (USDI Fish and Wildlife Service 1994 a and b)

Standards and Guidelines - Gray Wolf Habitat

1 Restrict intrusive human disturbances (motorized access, vegetation management, livestock grazing, etc.) within one mile around active den sites and rendezvous sites between April 1 and June 30, when there are five or fewer breeding pairs of wolves in the Yellowstone Nonessential Experimental Population Area (applies to the portion of the Forest east of Interstate 15) or the Central Idaho Nonessential Experimental Population Area (applies to the portion of the Forest west of Interstate 15). After six or more breeding pairs become established in each experimented population Area, land-use restrictions will not be needed (USDI Fish and Wildlife Service 1994 a and b) (S)

2 The ability of individuals holding grazing permits on public land to harass adult wolves in an opportunistic, noninjurious manner will become part of their permit conditions so it is clearly understood exactly what can occur. There is a seven day reporting requirement (USDI Fish and Wildlife Service 1994 a and b) (S)

3 The following conditions and criteria will apply in determining the problem status of wolves (USDI Fish and Wildlife Service 1994 a and b) (S)

A Wounded livestock or some remains of a livestock carcass must be present with clear evidence that wolves were responsible for the damage and there must be a reason to believe that additional losses would occur if the problem wolf or wolves were not controlled. Such evidence is essential since wolves may simply feed on carrion they have found while not being responsible for the kill.

B Artificial or intentional feeding of wolves must not have occurred. Livestock carcasses not properly disposed of in an area where depredations have occurred will be considered attractants. Removal or resolution of such attractants must accompany any control action. Livestock carrion or carcasses not being used as bait in an authorized control action (by agencies) must be removed, burned, treated with an acceptable chemical repellent, or otherwise rendered such that the carcass(es) will not attract wolves using methods approved by the District Ranger.

C Animal husbandry practices previously identified in existing approved Allotment Management Plans and annual operating plans for allotments must have been followed.

4 If additional livestock depredations are likely, proper animal husbandry practices are employed (proper disposal of livestock carcasses, etc.), artificial feeding does not take place, and AMPs are followed, the Forest may implement procedures to harass, capture, move, or kill wolves that attacked livestock (defined as cattle, sheep, horses, or mules only) on National Forest land (G). Prior to the establishment of six breeding pairs, depredating females and their pups will be captured and released at or near the site of capture, one time prior to October 1. If depredations continue, or if six packs are present, females and their pups will be removed (USDI Fish and Wildlife Service 1994 a and b) (S)

Goal - Peregrine Falcon Habitat

Plan project activities to avoid adverse impacts to falcons and their habitats.

Standards and Guidelines - Peregrine Falcon Habitat

1 For proposed projects within two miles of known falcon nests consider such items as 1) human activities (aircraft, ground and water transportation, high noise levels, and permanent facilities) which could cause disturbance to nesting pairs and young during the nesting period March 15 to July 31, 2) activities or habitat alterations which could adversely affect prey availability (G)

2 Within 15 miles of all known nest sites, prohibit all use of herbicides and pesticides which cause egg shell thinning as determined by risk assessment (USDA-Forest Service, September 1992) (S)

3 Restrict climbing and other human disturbances from March 15 through July 31 to avoid adverse impacts at known falcon nest sites (S)

Objective - Wolverine Habitat

Within two years of the ROD complete a GIS inventory to identify potential wolverine natal den sites. Within 4 years of the ROD, survey all potential wolverine natal den sites to document wolverine presence.

Goal - Goshawk Habitat

Provide suitable habitat conditions for known active and historic goshawk nesting territories.

Standard and Guideline - Goshawk Habitat

Management standards and guidelines for all forest types within active and historic goshawk nesting territories follow

Attribute	Nest Area	Post-Fledging Family Area	Foraging Area
Number of areas (S)	1	1	1
Size of each area (acres) (S)	>= 200 acres	>= 400	>= 5,400
Size-Class Distribution for forested acres (%) (G)			
nonstocked/seedling	0	<= 20	<= 20
sapling	0	<= 20	<= 20
pole	0	<= 20	<= 20
mature/old growth ^{1/}	100	>= 40	>= 40
Rotation age (years) (G)	--	60 to 240	60 to 240
Maximum created opening (acres) (G)	0	<= 40	<= 40
Snags and Reserve Trees ^{2/} (G)	>= 60% unless specified higher in prescription	>= 60% unless specified higher in prescription	>= 60% unless specified higher in prescription
Downed logs (average/acre) (G)	Forestwide S&Gs	Forestwide S&Gs	Forestwide S&Gs
Management Season (S)	Oct-Feb	Oct-Feb	Year-long
Thinning (G)	Non-uniform ^{3/}	Non-uniform	by silvicultural prescription
Open Road Density ^{4/} (G)	No new system roads	No new system roads	<= Management Rx Density
^{1/} Mature and old growth canopy closure for nest sites and post-fledging family areas should range between 75-100 percent (G) ^{2/} Refer to previous section on snag/cavity nesting habitat for explanation of biological potential ^{3/} Maximize diversity of structure ^{4/} Open roads in goshawk territories will be given priority for closure to meet management prescription road density standards. First priority will be to close roads in nest areas, second priority in post-fledging family areas, third priority in foraging areas. Where possible, open road density should be zero in the nest areas and the post-fledging family areas			

Standard and Guideline - Flammulated Owl Habitat

Do not allow timber or firewood harvest activities within a 30-acre area around all known flammulated owl active and historic nest sites (S)

Standards and Guidelines - Boreal Owl Habitat

1 Do not allow timber or firewood harvest activities within a 30-acre area around all known boreal owl active and historic nest sites (S)

- 2 Maintain over 40 percent of the forested acres in late seral age classes within a 3,600-acre area around all known boreal owl nest sites (G)

Standards and Guidelines - Great Gray Owl Habitat

- 1 Do not allow timber or firewood harvest activities within a 20-acre area around all known great gray owl active and historic nest sites. Vegetation manipulation does not include tree planting (S)
- 2 Maintain over 40 percent of the forested acres in late seral age classes within a 1,600-acre area around all known great gray owl nest sites (S)
- 3 Restrict the use of strychnine poison to control pocket gophers within a 1/2-mile buffer around all known active great gray owl nest sites (G)

Goals - Trumpeter Swan Habitat

- 1 Maintain habitat to support ten breeding pairs or more on the Forest
- 2 Protect emergent vegetation along shorelines. Maintain riparian vegetation in desired vegetative condition

Standards and Guidelines - Trumpeter Swan Habitat

- 1 Maintain suitable trumpeter swan nesting habitat conditions including (but not limited to) the following lakes and ponds: Boundary Pond, Swan Lake, Lily Pond, Hatchery Butte, Railroad Pond, Mesa Marsh, Bear Lake, Upper Goose Lake, Long Meadows, Thompson Hole, Twin Lakes, Chain Lakes, Widgit Lake, Rock Lake, Indian Lake, Putney Meadows, Unnamed Pond (Sec 19, T9N, R46E) (S)
- 2 Change livestock grazing through management or fencing when grazing is adversely affecting trumpeter swan use or productivity (G)
- 3 No vegetation management will occur within 300 feet of the lake or pond shoreline unless necessary to improve riparian habitat conditions favorable for trumpeter swans. Management may occur after the swans have left the lake or pond (S)
- 4 Maintain constant water levels, allow no drawdowns from May 1 to September 30 when not in conflict with preexisting water rights (G)
- 5 Do not take any recreation management actions that would encourage dispersed recreation activity at these lakes and ponds. Close these areas to recreation activity if this activity is adversely affecting trumpeter swan use or productivity (G)
- 6 Implement habitat improvement projects at these lakes and ponds, such as dredging to maintain proper water depths and aquatic vegetation control (G)

Goal - Spotted Frog Habitat

Maintain riparian vegetation in desired vegetation condition

Goals - Common Loon Habitat

- 1 Evaluate the potential to provide and maintain suitable breeding habitat for common loons at these sites: Indian Lake, Thompson Hole, Bergman Reservoir, Junco lake, Fish Lake, Loon Lake, Moose Lake, unnamed pond (Sec 9, T47N, R118W)

2 Develop common loon management plans for the above sites if the evaluation indicates there is potential to provide and maintain suitable breeding habitat

Standard and Guideline - Harlequin Duck Habitat

Avoid establishing new trails, new roads, or new recreation facilities within 300 feet (on each side) of any stream reach with documented harlequin duck breeding activity (G)

Objective - Spotted Bat and Western Big-eared Bat Habitat

Develop management plans for any caves, mine shafts, and other suitable habitats where these bat species are known to be present

FOREST USE AND OCCUPATION

~~Access~~

Goals

- 1 The Forest road and trail system is cost effective and integrates human needs with those of other resource values, particularly grizzly bear, elk, and native cutthroat trout
- 2 Elk vulnerability is decreased and grizzly bear security is increased
- 3 Native cutthroat trout habitat is restored through effective road closures, obliterations, reclamations, redesign, and improved maintenance practices

Objective

Motorized access standards in each management prescription will be achieved as soon as practicable

- 1 Within three years of the ROD for BMUs
- 2 By the year 2007 for all other areas

Standards and Guidelines

1 Road Closure

A Road closures will be located and designed to effectively control motorized use (S)

B Restrict or reclaim roads not needed for future management as determined in site-specific analysis, at the end of project use Consider historic recreation use before closure (G)

2 Administrative Use on Restricted Roads and Trails and in Restricted Areas

A The Open Road and Open Motorized Trail Route Density (OROMTRD) Standards prescribed for each prescription area do not restrict responses to emergency events to protect human life, property values and structures, and forest resources Responses to emergency events include law enforcement, search and rescue, and fire suppression (S)

B Prudent cross-country motorized access is allowed to implement projects consistent with prescription objectives, in all prescription areas except for grizzly bear core areas and designated

wilderness Administrative uses including but not limited to planned project work such as firewood harvest, timber sales, tree planting, prescribed burns, wildland survey or fish and wildlife habitat improvements on restricted roads, trails or areas will only be allowed under the following conditions

- 1 Any motorized vehicle access on a restricted road or trail or in a restricted area will be for official administrative business only and must be approved by the District Ranger
- 2 When motorized vehicle access on a restricted road or trail or area is necessary, a sign will be posted while project work is being accomplished
- 3 Motorized vehicle access on a restricted road or trail or area will be allowed by permit under the following conditions when approved by the Forest Supervisor or District Ranger
 - a Project work is one mile or 30 minutes walk or greater
 - b Equipment is being used that is unreasonable to carry to the project work site
 - c Contract inspectors working with contractors who have motorized equipment and vehicles which are necessary for the contract work

This direction (in item 2 B above) supersedes direction in access tables for individual prescriptions (S)

C Needs for motorized cross-country administrative access will be presented and considered in analysis documents for proposals including, but not limited to prescribed burning, fish and wildlife habitat improvement, timber sales, and personal use firewood harvest The proposal will limit access to that reasonably needed to conduct the project Prudent cross-country access to implement these projects may be allowed consistent with project-level NEPA decisions and prescription objectives in all prescription areas except for grizzly bear core areas and designated wilderness This direction supersedes direction in access tables for individual prescriptions (S)

D During the big game hunting seasons, persons with disabilities may be permitted to use motorized vehicles, if needed for mobility, on restricted roads and trails which are designated for such use, with an authorized motor vehicle hunting permit issued by the district ranger These persons must have a Disabled Hunting Permit issued from the State Fish and Game Departments (G)

3 Figures appearing in the access tables for individual prescriptions represent direction for those prescription areas If no figure appears refer to the following direction (S)

	Henry's Lake BMU Subunit 1	Henry's Lake BMU Subunit 2	Plateau BMU	Bechler-Teton BMU
TMARD	1.0 MI/SQ MI	1	1	1
OROMTRD	0.6 MI/SQ MI	0.6	0.6	0.6
Henry's Lake 1 - The Targhee National Forest portion of the Henry's Lake 1 subunit, excluding Management Situation 3 (MS3) habitat Henry's Lake 2 - The Targhee NF portion of the Henry's Lake 2 subunit Plateau BMU - The Targhee NF portion of this Bear Management Unit (BMU), excluding MS3 habitat Bechler/Teton BMU - The Targhee NF portion of this BMU				

The access density measurements TMARD and OROMTRD are defined in the Glossary Access densities are based on open and restricted roads and trails

4 Travel Plan

The Forest travel plan was developed from individual prescription access tables and the elk and deer winter range map. The following application dates were developed to respond to local resource and travel conditions. This direction supplements and is to be used in conjunction with the applicable direction in individual prescription access tables.

A Snow-Free Season - The snow-free season direction takes effect yearly in the spring as local conditions become suitable to support wheeled vehicle traffic on roads and trails without damage. Where legally permitted, snowmachines may use designated roads and trails shown on the travel plan as open to motorized use. Cross-country snowmachine travel is allowed only where the snow-free season direction allows cross-country motorized travel after June 1 except in Prescription 5 1 4 (c) (S).

B Snow Season - The snow season direction takes effect yearly on Thanksgiving Day. Where legally permitted, snowmachine travel is allowed consistent with the travel plan map. Cross-country snowmachine travel is permitted from Thanksgiving Day through June 1 except on the Palisades Ranger District which permits said usage from December 15 through June 1 and except in (inventoried) winter range as shown on Forest Plan Map #24. Cross-country snowmachine travel is allowed in Prescription area 5 1 4 (c) (Big Bend Ridge) from January 1 until April 30 (S).

Recreation

Goals - Winter Recreation

- 1 Provide a quality winter recreation experience while minimizing conflicts between motorized and nonmotorized use and wintering big game
- 2 Establish a linear capacity for two-way snowmachine trails for purposes of safety and quality of the recreation experience
- 3 Provide networks of marked, designated, and groomed snowmachine, cross-country ski, and other winter travel routes and trailhead facilities
- 4 Provide winter recreation user information to educate users of wildlife needs and promote backcountry safety
- 5 Promote opportunities for backcountry winter recreation

Objective - Winter Recreation

Within three years, establish by prescription, travel plan designation or other method a few nonmotorized winter recreation activity areas with easy access for users such as telemark skiers, snowshoers, and snowboarders. Conform to results anticipated from the Greater Yellowstone Winter Visitor Use Management (GYWNUM) Assessment currently underway.

Standards and Guidelines - Winter Recreation

- 1 Develop or provide trailhead facilities to match the desired trail capacity. These facilities may be public or private depending on location (G)
- 2 Management of winter trails should be done where feasible by cooperative agreements with agencies and groups (G)

a 3 Snowmachine, snowshoes, and dogsleds are prohibited within designated groomed cross-country ski trails. Snowmachines and dogsleds are prohibited within designated cross-country ski areas. (S)

4 Those areas mapped as winter range on the Revised Forest Plan elk and deer winter range map are closed to cross-country snowmachine travel. This direction supersedes direction in access tables for individual prescriptions. (S)

Goal - Visual Quality

Manage the visual landscape in accordance with the planned visual quality objective, as mapped in the Geographic Information System.

Standards and Guidelines - Visual Quality

1 Following timber harvest in lodgepole pine, dispose of slash not needed to meet other resource objectives by a combination of piling, firewood gathering, and burning in areas up to 200-250 feet on either side of primary travelways, trails, and use areas which have high public concern for scenic quality as soon after harvest as possible. (G)

2 Following timber harvest in lodgepole pine, dispose of slash not needed to meet other resource objectives by piling, firewood gathering, or burning for 150-200 feet on either side of roads, trails, and areas which have moderate public concern for scenic quality. (G)

Goal - OHV

Provide a network of OHV trails while minimizing the effects of OHV use on soils, wildlife and other users.

Standards and Guidelines - OHV

1 Discourage OHV use on slopes greater than 40 percent, except on designated routes and except for snowmachine use. Roads and trails, however, may cross slopes that exceed 40 percent. (G)

2 Areas with slopes of 25-40 percent may require travel restrictions if soil erosion factors warrant them. (G)

3 Restrict OHV use on identified areas of unstable soils (except for snowmobiles). (G)

4 No motorized vehicles over 50 inches wide are allowed on trails unless the trails are specifically designed for such vehicles. (S)

Goal - Developed Facilities

Maintain or slightly increase the Forest's developed site capacity in accordance with the CIP (Capital Improvement Projects) Implementation Schedule.

Standards and Guidelines - Developed Facilities

1 Expand existing developed facilities to meet public needs. (G)

2 Phase out low use developments that have high operation and maintenance (O&M) costs consistently exceeding \$1.50 per persons-at-one-time (PAOT) per day. (G)

3 Rehabilitate or provide heavy maintenance to facilities in Maintenance Class Two (MC 2) and Maintenance Class Three (MC 3) which cannot be brought up to Maintenance Class One (MC 1) through general maintenance (G)

4 Developed facilities receiving heaviest use should receive first priority for maintenance (G)

5 Facilities that cannot be maintained to acceptable health and safety requirements will be closed until they can be brought up to standard (S)

Objective - Dispersed Recreation Use

By 2007, address soil, water, and vegetation impacts to maintain the desirable recreation setting on approximately 100 campsite areas of the 300 identified dispersed recreation sites on the Forest, which are in greatest need of monitoring. These sites would have limited developed facilities.

Standards and Guidelines - Dispersed Recreation Use

1 Unless otherwise posted, motorized access is allowed for parking and dispersed camping within 300 feet of roads and trails which are open for motorized use. This direction supersedes direction in individual prescriptions, except no motorized use is permitted within designated wilderness. (S)

2 Wilderness, recommended wilderness, and roadless areas dispersed campsites should be managed according to the Frissell Condition Classification System. Actions (close, protect, or restore) should be taken to restore campsites that do not meet Class three or better. (G)

3 Dispersed campsite conditions on the remainder of the Forest should have no more than 15 percent of an activity area in a detrimentally disturbed soil condition, as described in the Dispersed Camping Protocol (Process Paper X). (G)

4 Low-development-level facilities should be provided at undeveloped concentrated-use areas to prevent resource damage and protect public health and safety. (G)

Goal - Trails

1 Trails for motorized/mechanized use would be sufficient to sustain use over long periods of time and minimize requirements for maintenance or reconstruction. These conditions would be achieved within subsections in the following sequence: Big Hole Mountains, Caribou Range Mountains, Lemhi-Medicine Lodge, Centennial Mountains, Madison-Pitchstone Plateaus, Island Park, and Teton Range.

2 Trails for nonmotorized/mechanized use would be sufficient to sustain use over long periods of time with minimal requirements for maintenance or reconstruction. These conditions would be achieved within subsections in the following sequence: Teton Range, Big Hole Mountains, Centennial Mountains, and Caribou Range Mountains.

Objective - Trails

Complete an interdisciplinary review of five-ten percent of the system trails each year to determine rehabilitation needs.

Objective - Outfitters and Guides

Establish use capacities using the process outlined in the AMS for outfitter and guide recreation opportunities prior to issuing new permits.

Standard and Guideline - Outfitters and Guides

Outfitter and guide facilities in dispersed nonwilderness areas should be built in less-frequented areas and be temporary. To prevent unacceptable resource damage or sanitation problems, facilities may be allowed at more heavily used locations. Only essential facilities should be provided at commercial outfitter camps in accordance with Greater Yellowstone Area Outfitter Policy camp standards (G)

Wilderness

The following goals, standards and guidelines apply to all congressionally designated wilderness on the Forest Presently that includes the Jedediah Smith and Winegar Hole Wildernesses

Goal

Achieve desirable wilderness conditions for the Jedediah Smith and Winegar Hole Wildernesses as specified in the management prescriptions. The Wilderness Implementation Schedules and a Monitoring Action Plan will guide implementation using the Limits of Acceptable Change (LAC) process

Standards and Guidelines

- 1 Outfitter/Guide - Allow no new outfitter camps (for hunters, anglers, etc) until studies have been completed to determine site suitability and carrying capacity (S)
- 2 Recreation - ROS Manage for a primitive to semi-primitive nonmotorized classification (G)
- 3 Recreation - VQO Manage for preservation (S)

Tribal Coordination

Standard

Forest consultation procedures and intergovernment agreements with the tribes to guide future cooperative efforts will comply with the protocols set forth in the National Resource Book on American Indian and Alaska Native Relations Working Draft 1995 or its successor (S)

PRODUCTION OF COMMODITY RESOURCES

Range

Goals

- 1 Upland and riparian plant communities meet Desired Vegetation Conditions (DVCs) for site-specific areas
- 2 Domestic livestock grazing is managed to promote the desired conditions of various resources including maintenance of adequate plant and litter ground cover, nutrient recycling, forage for wildlife species, seed production, and the restoration and maintenance of riparian communities

Objectives

- 1 By 2007, improve the ecological status of 1,200 acres of riparian habitat currently reported as not meeting Desired Vegetation Condition (DVC) to meeting or moving toward DVC
- 2 By 2007, improve 26,400 acres of uplands (nonriparian and nontimber plant communities) currently reported as not meeting Desired Vegetation Condition (DVC) to meeting or moving toward DVC
- 3 By 2007, implement grazing systems or Allotment Management Plans (AMPs) designed to meet Range Goals 1 and 2 above on all grazing allotments
- 4 Establish utilization levels for key browse and grass species in either the Allotment Management Plan or the Annual Operating Plan for allotments within elk and deer winter ranges

Standards and Guidelines

1 Upland Forage Utilization

Apply upland forage utilization levels to all allotments and/or management areas as shown in Table 1, unless determined otherwise through the interdisciplinary team process. These figures provide for maximum utilization levels regardless of which species of animal uses the forage or browse. These utilization guidelines apply to native and desirable nonnative vegetation as recorded at the end of the grazing period (G)

Table 1 Upland Rangeland Ecosystems - Percent Forage Utilization of Current Years Growth 1/				
	Season-long Grazing		Rotation Grazing	
	Unsatisfactory Range Condition	Satisfactory Range Condition	Unsatisfactory Range Condition	Satisfactory Range Condition
Grasses and Herbaceous Species	35%	45%	45%	55%
Shrubs	25%	35%	35%	35%

1/ The figures shown represent the best estimate of acceptable use levels which will provide for maintenance or improvement of these ecosystems. They shall be used as maximum use levels unless there is site-specific information to show that these levels are incorrect. Percent use is based on a dry weight percentage.

2 Riparian Forage Utilization

A Riparian Woody Plant Utilization No more than 30 percent use on riparian woody plant species (current year's growth) is allowed. Thirty percent is the maximum allowed use as recorded at the end of the grazing period (S)

B Riparian Vegetation Stubble Height Standard (these apply to all grazing systems) (S)

1 At the HGL, there will be at least four inches of stubble height remaining on key species at the end of the grazing period, unless determined otherwise through the interdisciplinary team process. This standard applies to key species of native and desirable nonnative hydric vegetation.

2 Away from the HGL, at least three inches of stubble will be left on the remainder of the key riparian species at the end of the grazing period, unless determined otherwise through the interdisciplinary team process

3 Allotment Management Planning (AMP)

A Salt should be placed greater than **1/4** mile from water, or as far from water as practicable Salting should be designed to avoid conflicts with aspen regeneration, conifer plantations, and system trails (G)

B Allow no livestock grazing before seed set of the second growing season after prescribed or natural fires and rangeland planting or seeding (G)

C Allow livestock conversions based only on resource capability (such as topography, water distribution, vegetation, wildlife, and recreation), and management objectives and not solely based on the desires of the permittee (G)

1 Conversions may be made in accordance with an AMP, and current range analysis, only after all necessary range improvements structures are in place (G)

2 All range improvements necessary for the conversion will be financed and constructed by the permittee Construction will be in accordance with Forest Service standards (S)

3 Do not convert from a cattle allotment to a sheep allotment within bighorn sheep habitat or in grizzly bear management prescriptions (S)

4 All proposed livestock conversions will be evaluated through the interdisciplinary process Only those conversions meeting Forest Plan objectives and desired vegetation conditions will be approved (S)

D Forest Service administrative site livestock pastures will comply with the forestwide standards and guidelines for forage utilization and riparian management (S)

E All structural improvements directly required to implement the AMP will be installed and financed whereby the Forest Service provides approximately 50 percent of the cost and the permittee provides the remaining 50 percent (G)

F Permittees are allowed motorized access to maintain facilities AMPs and Annual Operating Plans will include direction that motorized access must be less than two vehicles per week (This permitted access is not included in the OROMTRD) (S)

G In Idaho, follow the "Memorandum of Understanding Between the National Forests in Southern Idaho and the Idaho State Historic Preservation Officer Regarding Rangeland Management Activities" (February 1996) In Wyoming, follow the process outlined in the National Programmatic Agreement, Option 2 (Criteria and standards for independent management) until a memorandum of agreement is developed between southern Idaho Forests and the Wyoming State Historic Preservation Office (S)

H Monitor heritage resource sites on grazing allotments in Wyoming, and in Idaho consistent with the Heritage Resource Monitoring Plan for Southern Idaho Forests (S)

I Within subwatersheds occupied by native cutthroat trout or designated as vital to meeting recovery goals, identify areas where livestock grazing is causing fisheries habitat conditions to fall below or retard the rate of recovery toward the values described in the table, "Expected Values for Healthy Fish Habitat Conditions" in standards and guidelines for Fisheries and Other Aquatic Resources Include specific remedial actions in the AMP or Annual Operating Plan Progress toward meeting these expected values should be monitored and grazing systems adjusted, as necessary (G)

J All grazing allotments will be managed at FRES (Forest Range Environmental Study) management strategies A, B, C, or D with exceptions as noted in individual prescriptions (1 1 6, 1 1 7, 1 1 8, 2 2, 2 4, 2 5, 4 2) (G)

Timber Management

Goal - General

Silvicultural techniques will be used as a tool to manage or manipulate vegetation for the purpose of achieving Forest Plan resource objectives Emphasis will be placed on restoration of ecological function, structure and composition

Standards and Guidelines

1 ASQ (Allowable Sale Quantity)

A Estimates of ASQ and long-term sustained yield timber supply capacity are themselves based on estimates of volume available on timbered acres scheduled for harvest Total harvested acres for the decade may vary and will depend on site-specific project implementation to meet plan goals and objectives (G)

B ASQ will not exceed 80 million board feet (MMBF) for the plan decade (S)

C ASQ will not exceed 80 million board feet for outyear decades until this Plan is revised or amended (S)

D On suited lands within five-series prescriptions, roadless areas and areas with slopes between 40 and 60 percent are in a noninterchangeable component (NIC) (S)

2 Rotation Age Guideline Following are the earliest rotation ages of each species group beginning at culmination of mean annual increment (G)

Species	Earliest Rotation Age (years)
Douglas-fir	100
Mixed Conifer 1/	80
Spruce-fir	100
Aspen	60

1/ Includes both MX (DF/LP) and MX3 (DF/LP with ES/AF)

3 Minimum Stocking Guideline Following is the minimum stocking which should occur before an area can be certified as stocked (G)

Species	Minimum Stocking	Percent of Area Meeting Minimum Stocking
Lodgepole Pine	170	70
Douglas-fir	140	70
Mixed Conifer 2/	200	70
Spruce-fir	200	70
Aspen	300	70

1/ Aspen counts toward stocking
 2/ Includes both MX (DF/LP) and MX3 (DF/LP with ES/AF)

Goal - Slash Treatment

1 Fuel loading on activity areas meets site productivity objectives for wildlife and fire

Guideline- Slash Treatment

SLASH TREATMENT FOR FUELS < 3 INCHES IN DIAMETER (G)		
redicted and existing fuel loading under 3 inches diameter 1/	Minimum Treatment 2/	Maximum Fuel Patch size
Under 5 Tons/Acre	No treatment necessary for fire hazard reduction	160 ac under 40% slope 100 ac over 40% slope
to 10 Tons/Acre	Lop or crush to Regional Lopping Specifications	80 ac < 40% 40 ac > 40%
11 - 25 Tons/Acre	Alternatives	
	1 Reduce single entry loading to 10 tons/ac or less by multiple entry thinnings Follow lopping stds above according to loading	Single entry loading < 5 Ton/Ac , use above stds for < 5 tons Loading 5-10 use above std for 5-10 T/Ac
	2 Reduce slash < 3 in to < 5 tons per ac by burning or chipping	160 Ac < 40% 100 Ac > 40%
	3 Reduce loading of lopped or crushed fuel < 3 in to 5- 10 ton per acre by burning or chipping	80 Ac < 40% 40 Ac > 40%
	4 Rehabilitate by piling, burning, and reforestation	160 Ac < 40% 100 Ac > 40%
	5 No treatment	N/A
1/ When down woody fuels constitute 30% or more of the total loading under 3 inches, the values in this column may be increased by 3 tons per acre 2/ Make sure mechanical treatments meet forestwide soils standards		

Objective - Size of Harvest Units and Adjacent Leave **Blocks/Strips**

Design timber management projects to simulate natural patch sizes, patch shapes, connectivity, and species composition and age class diversity

Standard and Guideline

Created Opening. A harvested area of commercial forest land will not be considered a created opening for silvicultural purposes when stocking surveys indicate that minimum stocking is achieved and at least seven feet high. When other resource management considerations (such as wildlife habitat, watershed needs, or visual requirements) prevail, a created opening will no longer be considered an opening when the vegetation in it meets a particular management objective stated in the applicable management prescription (S)

Standards and Guidelines - Logging Systems

1 Slopes 40 percent or less will normally be harvested using ground-based logging equipment (tractors, rubber-tired skidders, low ground pressure equipment, etc.) Slopes greater than 40 percent, but less than 60 percent, will normally be harvested using advanced logging systems like shortspan cable systems, longspan cable systems, or aerial systems (G)

2 Rutting in skid trails should not exceed six to eight inches in depth (wet condition) over more than ten percent of a designated skid trail system. No yarding operations should take place when ground conditions are wet enough that there is a risk of such rutting (G)

Goals - Fuelwood

- 1 A sustainable level of fuelwood is made available
- 2 Conduct inventory for better determining the sustainable level of fuelwood

Standards and Guidelines - Fuelwood

- 1 Allow permitted fuelwood gathering in designated areas only (S)
- 2 Select designated fuelwood areas that have an excess of dead and down woody material which is in excess of that required for ecological function, structure and composition (G)

Goals - Precommercial Thinning

- 1 Thinning results in restoration of ecological structure, function and composition
- 2 Mimic tree densities and patch sizes occurring under natural conditions over a landscape
- 3 Provide for a variety of future resource products

Chapter III - Part 2

Subsection Descriptions and Direction

CHAPTER III - PART 2

SUBSECTION DESCRIPTIONS AND DIRECTION

About This Part

Working guidelines for ecosystem management state that effects of proposed actions should be considered at several geographic scales including one scale larger and one smaller than that at which the action is proposed (USDA Forest Service, June 1994). Based on a larger national mapping effort it was determined that the Forest wholly or partially overlays seven large ecological units, or subsections, which were delineated using physiographic parameters. Using this approach resource conditions can be viewed at a scale between the larger forest and the smaller prescription area levels. These subsections are numbered and named as follows:

- M332Ek - Lemhi/Medicine Lodge (subsection comprising two noncontiguous parts)
- M332Ea - Centennial Mountains
- M331Aa - Island Park
- M331Ab - Madison-Pitchstone Plateaus
- M331Db - Teton Range
- M331Dk - Big Hole Mountains
- M331Di - Caribou Range Mountains

In this part of the Revised Plan lands in each of these subsections are described. Desired Future Conditions (DFCs), goals, objectives and standards and guidelines for management in each subsection may also be presented.

Figure III-1 displays the locations of these seven subsections. Figure 1112 shows the boundaries of the principal watersheds on the Forest and their relation to the subsections. Figures III-3 through III-9 display the individual subsections. A listing shows the management prescriptions applied within each, and the total acres of each prescription area. More information on these prescriptions including the management direction they provide is given in the third part of this chapter.

Further Information

The ECOMAP unit of the Forest Service has developed a National Hierarchical Framework of Ecological Units to improve consistency in developing and sharing resource data and information at multiple geographic scales and across administrative and jurisdictional boundaries.

An Ecological Unit is defined as "A mapped landscape unit designed to meet management objectives, comprised of one or more ecological types" (FSM 2060 05). These ecological units are designed to exhibit similar patterns in potential natural communities, soils, hydrologic function, landform and topography, lithologies, climate, air quality, and natural processes for cycling plant biomass and nutrients.

As of this writing, ECOMAP has described four levels in the National Hierarchy of Ecological Units: Domains, Divisions, Provinces, and Sections. A map of the United States (1:7,500,000 scale) displays these four levels. The land area of the Forest falls within three of those sections. The National Hierarchical Framework of Ecological Units is shown in Figure III-1 in its particular application to the Forest, as adjusted by Revision and Ecological Unit Inventory personnel.

Domain - Described by broad climatic zones or groups. The Forest is within the Dry Domain (which covers most of the Intermountain Region). This is an area of water deficit where the potential annual water losses through evaporation exceed annual water gains through precipitation.

Division - Described by regional climatic types, vegetation affinities, and soil order The Forest is within the Temperate Steppe Regime Mountains Division (M330)

Province - Described by potential natural vegetation, highlands or mountains with complex vertical climate-vegetation-soilzonation The Forest is within two Provinces

M331 - Southern Rocky Mtn Steppe - Open Woodland - Coniferous Forest - Alpine Meadow

M332 - Middle Rocky Mtn Steppe - Coniferous Forest - Alpine Meadow

Sections - Described by geomorphic province, geologic age, stratigraphy, lithology, regional climatic data, phases of soil orders, suborders or great groups, potential natural vegetation (PNV), potential natural communities (PNC) The Forest lies within three Sections

M331A - Yellowstone Highlands Section

M331D - Overthrust Mountains Section

M332E - Beaverhead Mountains Section

Delineation of ecological subsections was done by Targhee National Forest personnel under direction provided by ECOMAP Subsections are described by geomorphic process, surficial geology, lithology, phases of soil orders, suborders or great groups, subregional climatic data, PNC - formation or series The Forest lies within seven subsections

Subsection Overlay on the Targhee National Forest and the Surrounding Area

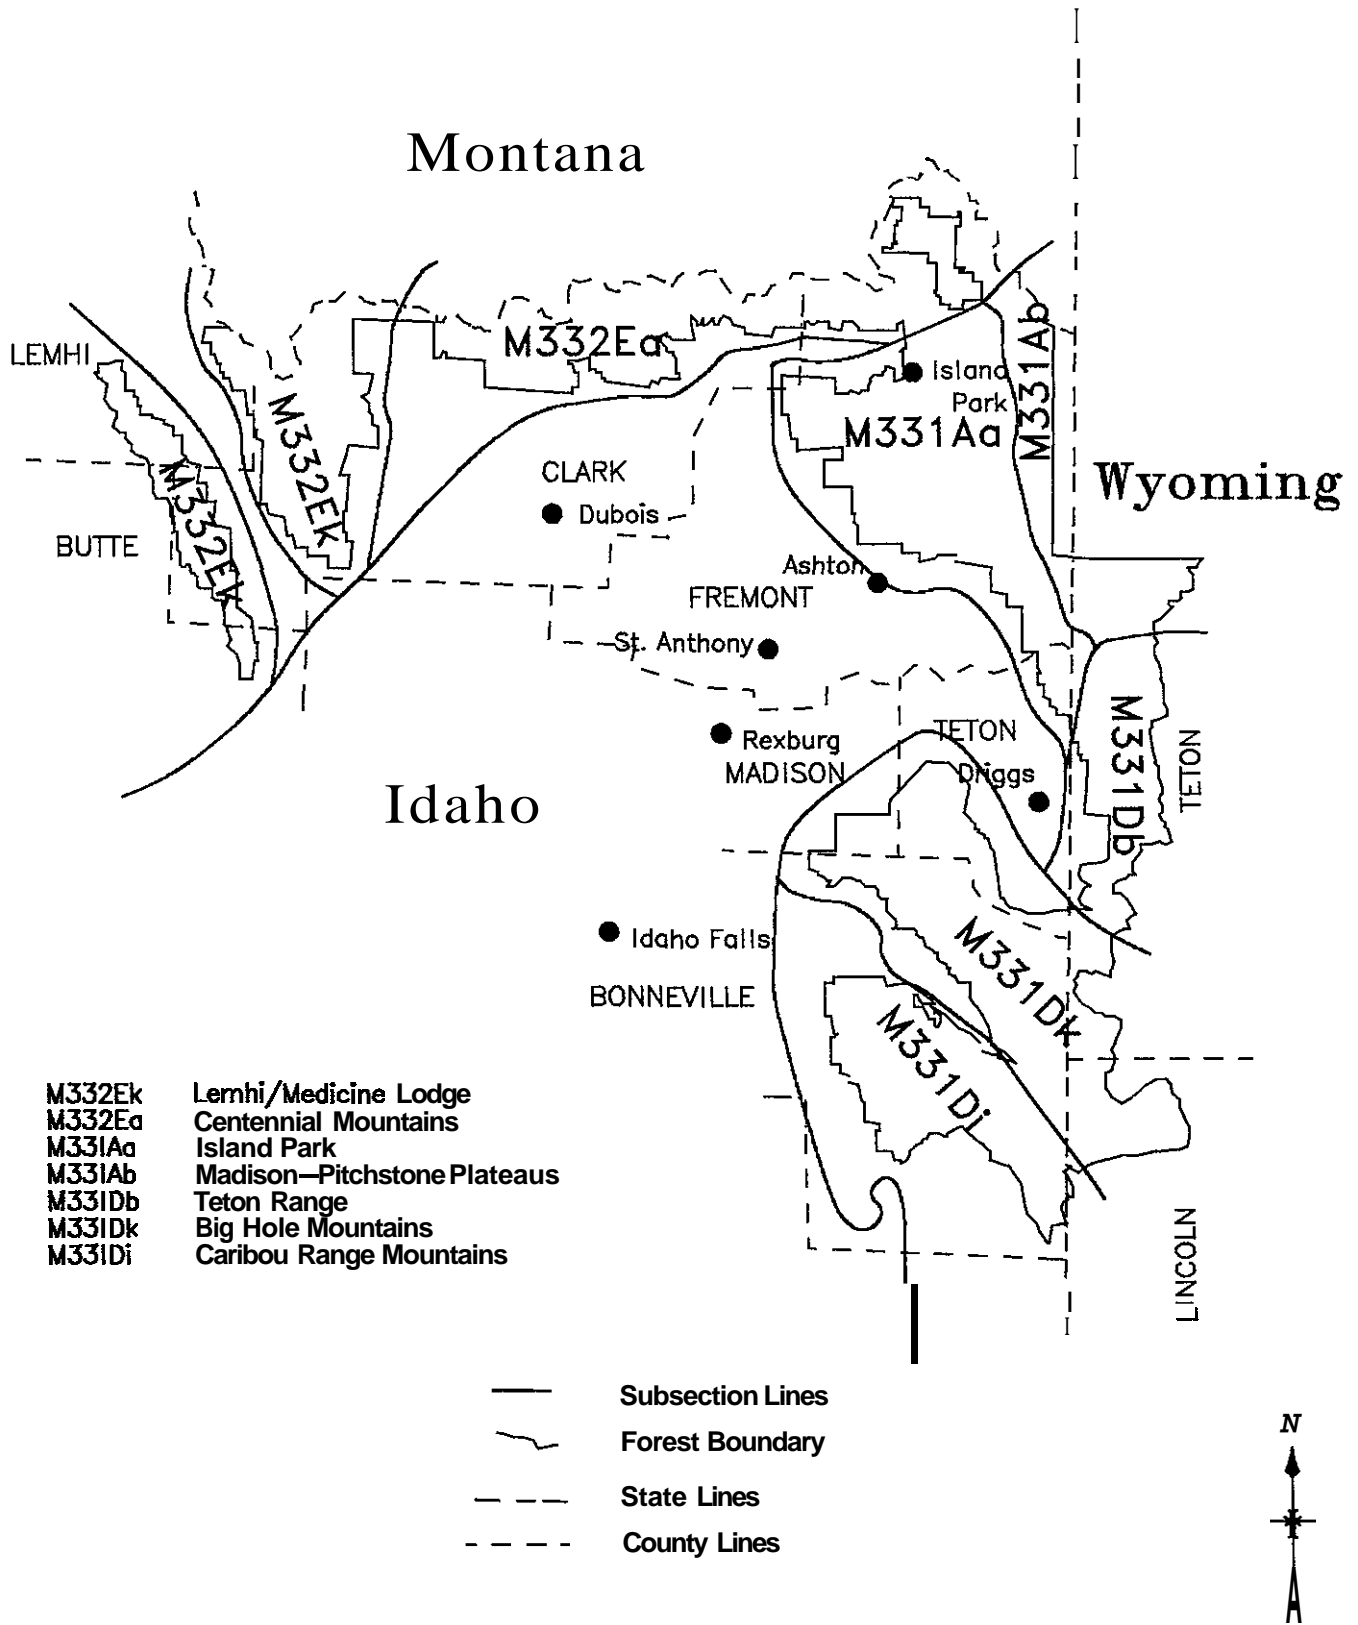

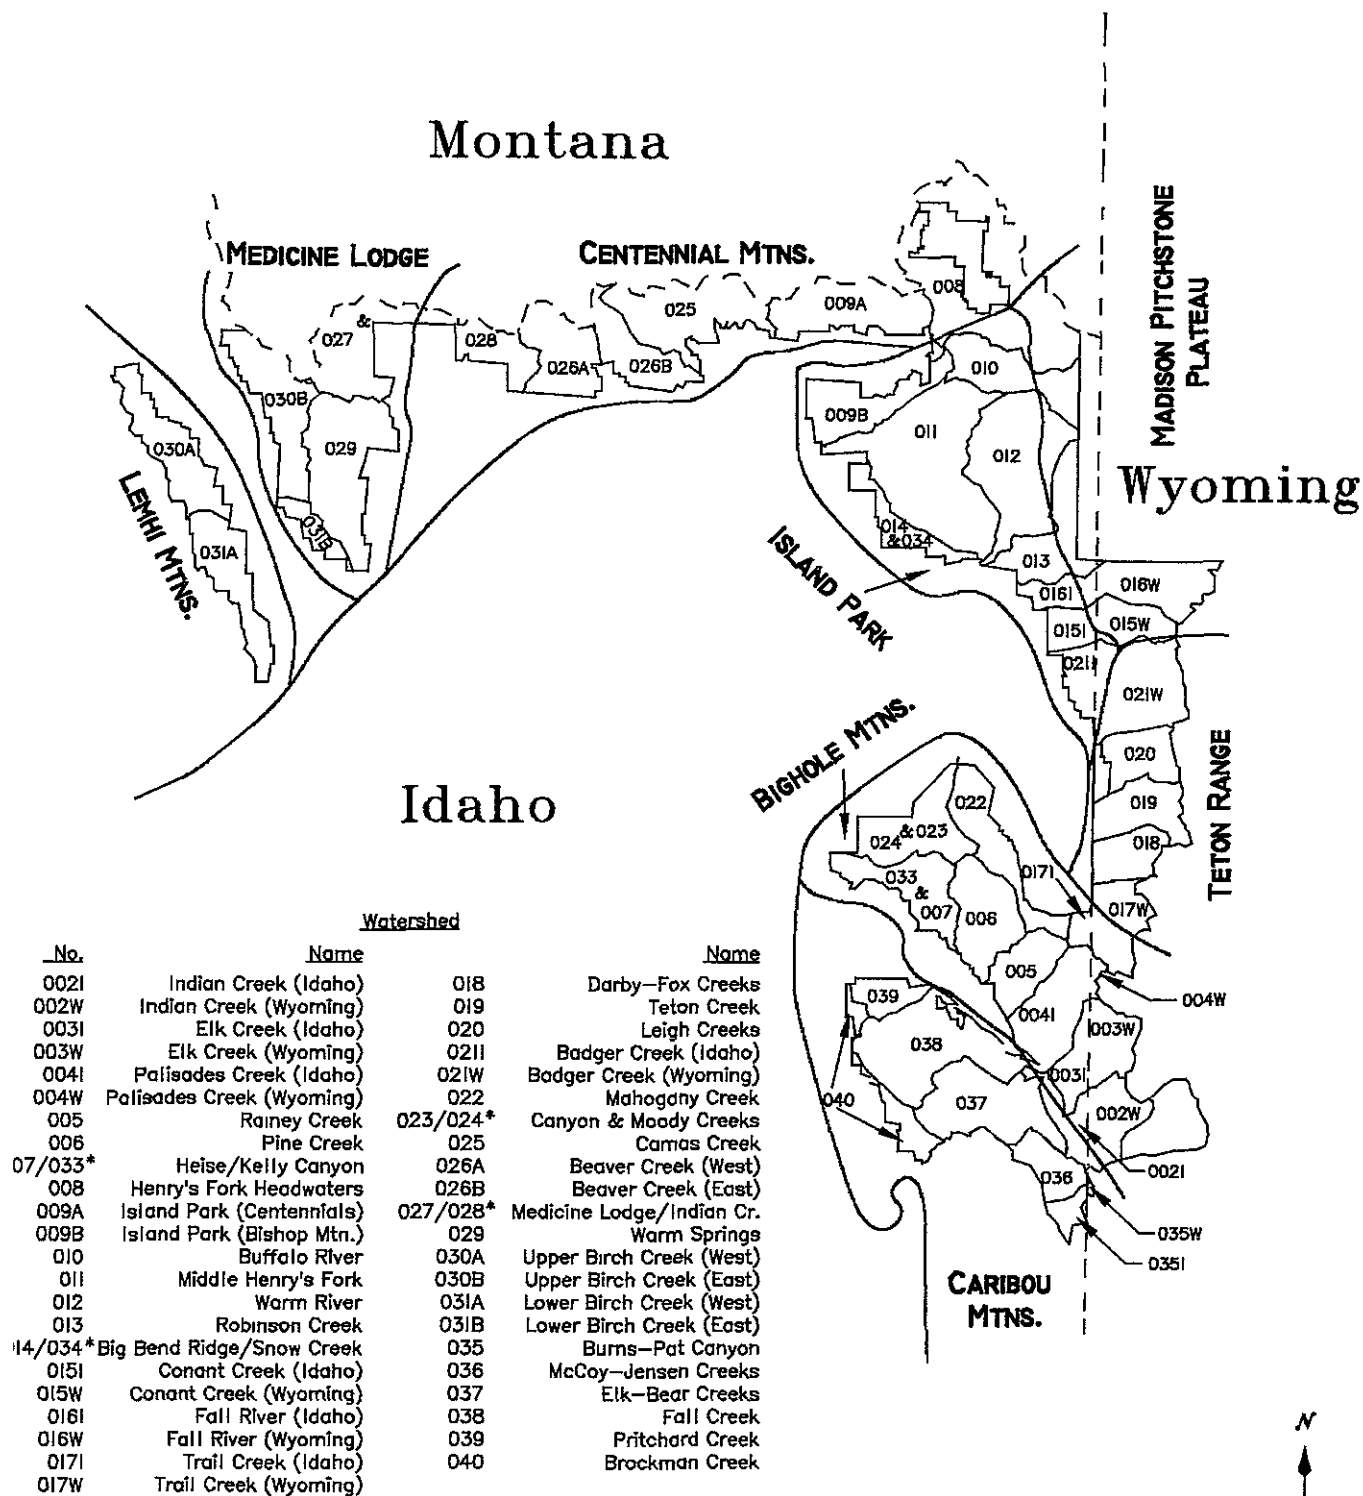

Figure III-1

Targhee National Forest Principal Watersheds

Note.

* Both used for watershed analysis in EIS, combined for elk habitat analysis as shown on Forest Plan Map 22.

Not To Scale

Figure III-2

LEMHI/MEDICINE LODGE SUBSECTION (M332Ek)

SETTING

This subsection includes the Lemhi Mountains and the Medicine Lodge/Beaverhead Mountains. A variety of vegetation exists with forested communities dominated by Douglas-fir and limber pine. Sagebrush/bunchgrass and mountain mahogany communities are common at lower elevations and on strong southerly exposures. Limber pine communities and alpine meadows exist at the high elevations. This subsection is rich in mining history with old mining sites and remnants of town sites. In the Birch Creek Valley four preserved brick adobe charcoal kilns remain of sixteen originally built to furnish charcoal to the Nicholia Mine. This area contains some of the most significant Native American sites on the Forest, as well as a segment of the Continental Divide National Scenic Trail, two recommended wildernesses (Diamond Peak and Italian Peaks) and most big game species found on the Forest.

About 37 percent of this subsection is forested, this is more forest land than occurred historically. Information from the early 1900s indicates that in some areas Douglas-fir has recently established itself on lands formerly dominated by grasses and sagebrush. Some riparian communities also appear to have more conifers than they did historically.

Approximately 90 percent of the forested land is in a mature age class, indicating a lack of age class diversity in the subsection. With 90 percent of the forests in Douglas-fir there is also a lack of tree species diversity. Many of the Douglas-fir stands are densely stocked. The uniformity of tree species and age classes, as well as the dense stocking, make this area's forests more susceptible to ecosystem disturbances such as insects, diseases and large fires. An example of the latter was the Gallagher Peak Fire which burned 37,230 acres in 1979. This was the largest fire in the last twenty years on the Forest.

Aspen forest acreage in this subsection has declined since the early twentieth century due to fire suppression. This is of concern since aspen provides important habitat for many wildlife species. It is also an important factor in the scenic beauty of the Forest.

Existing biological potential for woodpeckers is 26 to 34 percent. This indicates that larger size snags are not abundant or well distributed in this subsection at this time, even though a very high percentage of the forests are in mature and older successional stages.

Figure III-3 displays this subsection along with the major prescription areas.

DESIRED FUTURE CONDITION

This area provides quality motorized and nonmotorized dispersed recreation, livestock forage, and elk and deer winter range. Big game hunting is an important recreational activity.

Italian Peaks is managed as a recommended wilderness. Diamond Peak Roadless Area is also managed as a recommended wilderness. Except for the Eightmile-Pass Creek corridor, the rest of this roadless area would remain roadless.

GOALS AND OBJECTIVES

Goal - Properly Functioning Condition

Manage where possible for a diverse array of habitats tied to the natural occurrence and distribution of plant communities. Regenerate and maintain plant associations in properly functioning condition.

Objectives - Fisheries, Water and Riparian Resources

1. Improve stream channel stability ratings to good or excellent by 2007 on Divide Creek.

Lemhi/Medicine Lodge Subsection (M332Ek)

RX	Lemhi Mtns. acres	Med. Lodge acres	TOTAL acres

Figure 111-3

2 By 2007, reassess conditions on Webber Creek to determine needs for channel stability improvement

Goal - Recreation

Provide increased designated motorized road and trail access in a managed low impact method

Goal - Heritage Resources

Provide opportunities for scientific studies of significant archaeological sites

Objective - Range

Within three years of signing the ROD, assess opportunities to modify grazing allotment boundaries and permits to more effectively use natural barriers, change grazing patterns, adjust seasons of use, administratively close some additional areas, etc , to further separate winter domestic sheep grazing in the Medicine Lodge portion of the subsection from bighorn sheep

STANDARDS AND GUIDELINES

Recreation

Restrict motorized use to designated routes only, except for snowmobiles (G)

Range ✓

1 To better manage bighorn sheep habitat, the Kelly Canyon and Snakey Canyon winter sheep allotments in the Medicine Lodge portion of the subsection, on the Dubois Ranger District, will be phased out on an opportunity basis (Process Papers L and N) In addition, the winter sheep grazing permit will be phased out on the Nicholia-Chandler S&G allotment An opportunity is defined as a suitable or favorable time to abolish or close an allotment because of nonuse violations, term permit waivers where the permit is waived back to the government, resource protection, or permit actions resulting in cancellation of the permit If opportunities do not arise, then efforts will be made to relocate or accommodate sheep to other areas When all winter sheep allotments in that portion of the subsection have been vacated, they will be closed The intent of not closing these individual allotments as they become vacated is to provide an opportunity to minimize conflicts between domestic and bighorn sheep (S)

2 On the Medicine Lodge portion of the Dubois Ranger District, the sheep grazing permit on the Willow Creek S&G allotment will be closed immediately to grazing for watershed protection (S)

CENTENNIAL MOUNTAINS SUBSECTION (M332Ea)

SETTING

This subsection covers the Centennial Mountains between the east fork of Irving Creek on the west and Reas Pass to the east. The Centennials, which form part of the Continental Divide, are a scenic mountain range with high mountain meadows scattered among spruce/fir and Douglas-fir forests. At lower elevations sagebrush/grasslands grade into Douglas-fir and lodgepole pine forests. The recommended Lionhead wilderness, in the northeast portion of the subsection, abuts existing and recommended wilderness in Montana. The major travel corridors are Highways 20 and 87, and a portion of Interstate 15. The Yale-Kilgore road is a secondary travel route connecting Island Park to Kilgore and Dubois. In the northeast portion of the subsection is Henry's Lake, a world-renowned fishery. Segments of the Continental Divide National Scenic Trail, the Nez Perce National Historic Trail and the Two Top National Recreation (snowmobile) Trail lie within this subsection.

This subsection is dominated by sagebrush/grasslands and Douglas-fir communities, some of which have seen substantial timber management activities. Forested communities cover 71 percent of the subsection. Approximately 51 percent of the forested acres are Douglas-fir. Lodgepole pine (21 percent) is found in pockets on low productivity soils. Mixed lodgepole pine/Douglas-fir (13 percent) and other mixed conifers (ten percent) are also well represented. Species such as Douglas-fir and subalpine fir are becoming established as stands move toward later seral stages through succession. Aspen comprises four percent of the forested acres, which is less than was historically present. Fire suppression has allowed conifers to take over areas that were previously rangeland, tall forb communities, and aspen. Conifers have also encroached into riparian areas.

Mature forests make up 79 percent of the forested acres, indicating a lack of diversity in age classes. Existing biological potential for larger woodpeckers is 33 to 52 percent. Larger size snags are not abundant or well distributed in this subsection. Severe fires, insects and diseases are concerns in this subsection, mainly because of the large component of mature forests. The wildland/urban interface has significantly increased due to the development of the private lands within the forest protection boundary. This increases the risk of a fire spreading between the forest and private lands.

The subsection contains portions of two subunits within the Henry's Lake Bear Management Unit.

Figure III-4 displays this subsection along with the major prescription areas.

DESIRED FUTURE CONDITION

This subsection is one of the most diverse and complex subsections on the Forest. It offers the greatest opportunity to move the landscape toward properly functioning condition while reducing the risk of catastrophic events.

The Lionhead Roadless Area will provide access for snowmobiles. Its core area is recommended for wilderness designation.

Any activities will need to address concerns associated with grizzly bear and big game habitat management as well as reducing the risks of insects, disease and fire to Forest resource values and adjacent lands.

Centennial Mountains Subsection (M332Ea)

RX	TOTAL	RX	TOTAL acres

Figure III-4

GOALS AND OBJECTIVES

Goal - Properly Functioning Condition

Move the spatial distribution patterns and ages of vegetation toward sustainable conditions

Objective - Properly Functioning Condition

By 2007, develop a fire plan which allows for prescribed natural and management ignited fire, where compatible with other resource objectives

Objective - Fisheries, Water and Riparian Resources

Improve stream channel stability ratings to good or excellent by 2007 on Allan Canyon Creek, McGarry Canyon Creek, Moose Creek, Dairy Creek, Long Creek, E Rattlesnake Creek, E Three-mile Creek and W Dry Creek

STANDARDS AND GUIDELINES

Lands (Special Uses)

The Leon Petersen cabin and associated facilities will be managed as an isolated cabin. Follow provisions in Special Use Permit (11/25/96) that allow continued use as an isolated cabin until December 31, 2017. The permit will not be renewed or extended beyond December 31, 2017, at which time the cabin and associated facilities will be removed from National Forest System lands and the site restored to Forest Service specification. All costs for facility removal and site restoration will be the responsibility of the permit holder (S)

Range

1 To better manage grizzly bear habitat, all sheep allotments on the Island Park Ranger District will be phased out on an opportunity basis (Process Papers L and N). These allotments are the Blue Creek, Carrot-Taylor, Coffee Pot, Hotel Creek, Icehouse-Willow, Myers Creek, Sawtell Creek, Snyder Creek, and West Lake S&G allotments. Domestic sheep grazing within the grizzly bear recovery area will be managed according to Management Situation 2 guidelines and will be phased out on an opportunity basis. When all sheep allotments in the portion of the subsection within the grizzly bear recovery area have been vacated, all of the allotments will be closed in that portion of the subsection. The intent of not closing these individual allotments as they are vacated is to provide an opportunity to minimize conflicts between grizzly bears and domestic sheep in the event of an encounter with grizzlies on sheep allotments (S)

A Opportunities to vacate an allotment include such events as nonuse violations, term permit waivers where the permit is waived back to the government, resource protection, or permit actions resulting in cancellation of the permit. If opportunities do not arise, then efforts will be made to relocate or accommodate sheep to other areas

B Vacated allotments in these areas will be made available as needed to resolve grizzly bear/sheep conflicts in other sheep allotments in Situation 2 habitat

2 On the Dubois Ranger District portion of this subsection, the Huntley Canyon S&G allotment will be closed immediately for watershed protection (S)

3 On the Island Park Ranger District portion of this subsection, the Reas Pass, Dry Creek and Jesse Creek S&G allotments will be closed immediately to better manage grizzly bear habitat (S)

ISLAND PARK SUBSECTION (M331Aa)

SETTING

This subsection includes the west half of Island Park, Ashton, and the north dissected tablelands portion of Teton Basin Ranger Districts (Jackpine Loop). The dominant landscape feature of this subsection is a large volcanic caldera. Highway 20 is the only major highway that travels through this subsection. Among the many scenic attractions are Upper and Lower Mesa Falls, the last major undisturbed falls on the Columbia River system. The Mesa Falls Scenic Byway, established in 1989, provides motorists with an impressive view of the Teton Mountain Range and accesses a summer interpretive site along the two falls.

The Island Park subsection offers excellent trout fishing at Island Park Reservoir and along the Henry's Fork, Buffalo River, Warm River, Fall River and Bitch Creek. The Island Park subsection is also known nationally for its many snowmobile and cross-country ski trails. The significant influx of summer and year-round residents to private lands adjacent to the Forest in recent years is expected to continue. This urban interface is a growing concern for the Forest. The area shows signs of large scale timber harvesting due to salvage efforts following the mountain pine beetle epidemics in the 1960s and 1970s. Harriman State Park lies in the heart of the Harriman Wildlife Refuge, with 16,000 acres of forest, meadows, lakes and streams.

A small portion of the Winegar Hole recommended wilderness lies along the eastern border of this subsection. The Big Springs National Recreation (water) Trail and segments of the Nez Perce National Historic Trail lie within this subsection.

The landscape is dominated by forested cover types, which blanket 93 percent of the area. Forested areas are primarily lodgepole pine types (70 percent) that contain small pockets of aspen, sagebrush/grass, grass meadows and mountain brush. Douglas-fir (ten percent) and mixed lodgepole pine/Douglas-fir (15 percent) cover types provide some diversity in the area. Lodgepole pine occupies the floor of the Island Park Caldera and Douglas-fir cover types are concentrated on the caldera rim. On the caldera rim, aspen and sagebrush areas are being encroached upon by Douglas-fir as the process of succession continues.

Currently 61 percent of the forests are in a mature or older age class which provide suitable nesting sites for a variety of bird species. Since 93 percent of this subsection is forested, creation of young forest age classes probably increases the amount of suitable foraging habitat. Currently 26 percent of the forested acres are in nonstocked and seedling conditions which provide foraging habitat.

Salvage harvesting has shifted 35 percent of the forested acres into the nonstocked, seedling and sapling classes. Active management of aspen, as well as aspen sprouting in lodgepole pine clearcuts, has moved 34 percent of the aspen into these young classes. Other cover types are concentrated in the mature age group.

Mature Douglas-fir on the caldera rim experienced outbreaks of spruce budworm and Douglas-fir beetle in the past decade. These have now subsided, but could easily recur given the mature condition of the Douglas-fir and the presence of multiple-storied stands. Due to fuel reductions and young age classes associated with timber harvest, fire is less of a concern here than in most other subsections.

Figure III-5 displays this subsection along with the major prescription areas.

Island Park Subsection (M331Aa)

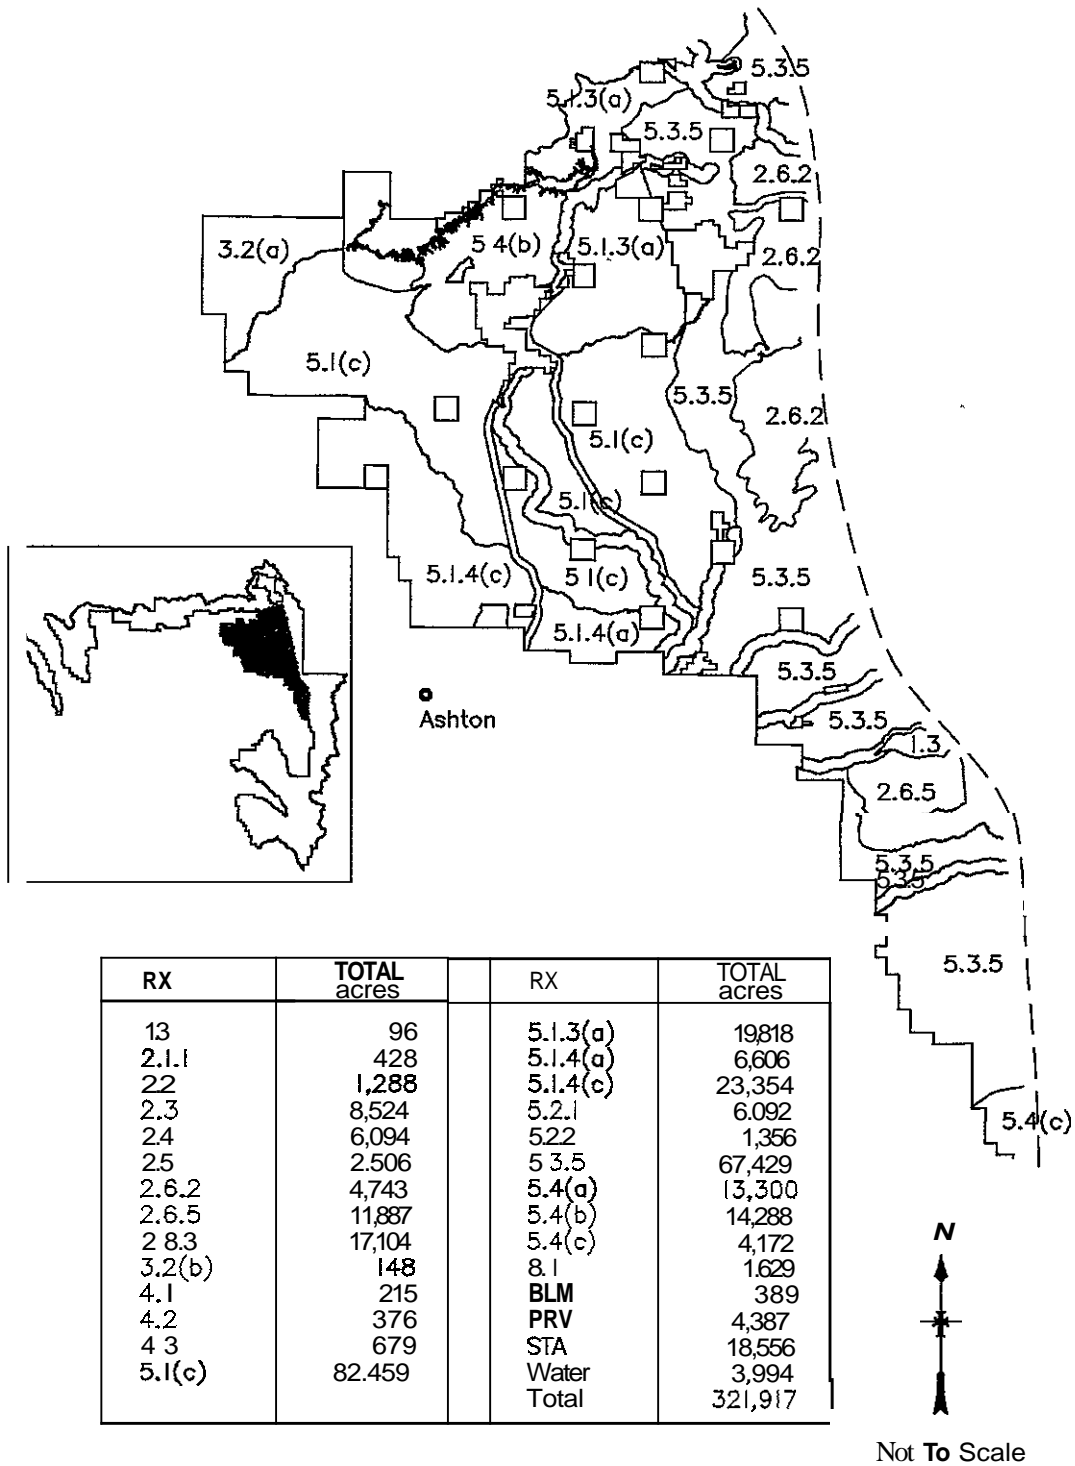

Figure 111-5

DESIRED FUTURE CONDITION

Important Forestwide objectives in this subsection focus on grizzly bear habitat management and elk. Road closures and vegetation treatments aimed at improving cover and maintaining forest health are opportunities to achieve these objectives.

This area will have improved recreation access and quality, particularly on the Highway 47-Mesa Falls Scenic Byway and for snowmobile use linked to West Yellowstone.

GOALS AND OBJECTIVES

Goal - Properly Functioning Condition

Move toward patch sizes that better reflect historical patterns and frequencies of disturbance. Manage forest structure to reflect historic patterns as they are determined.

Goal - Fire

Use management-ignited fire where possible to meet resource objectives.

Goal - Recreation

Maintain visual quality and visitor interpretation facilities along the Highway 47 Mesa Falls Scenic Byway.

STANDARDS AND GUIDELINES

Waterfowl Nesting Areas

The Goose Neck Bay area on Island Park Reservoir is closed to motorized vehicle use April 1 to June 15, and open to motorized vehicle use the remainder of the year. (S)

Range

On the Ashton Ranger District portion of this subsection, the Fish Creek, Partridge Creek, Trail Canyon and Black Mountain S&G allotments will be closed immediately to grazing to better manage grizzly bear habitat. (S)

MADISON-PITCHSTONE PLATEAUS SUBSECTION (M331Ab)

SETTING

The largest portion of the Madison Plateau subsection lies within Yellowstone National Park. The portion on the Forest is managed by the Island Park and Ashton Ranger Districts next to Yellowstone National Park. The Ashton-Flagg Ranch Road and Fish Creek Road are the major access routes through the area. Grassy Lake, a 320-acre artificial lake, as well as other lakes and streams in the area, are popular fishing areas and are accessed by the Ashton-Flagg Ranch road. Several organized youth camps fall within this subsection. The Cave Falls road is the only motorized access to the southwest portion of Yellowstone Park. Segments of the Continental Divide National Scenic Trail and the Two Top National Recreation (snowmobile) Trail lie within this subsection.

Forests comprise 97 percent of the area. Lodgepole pine is the most common forest cover type (76 percent), with mixed stands of lodgepole pine and Douglas-fir making up the remaining forested area (24 percent). Relatively minor amounts of aspen and various mixed conifers provide some diversity. The southern portion of the subsection is unique in that there are many wet meadows and small lakes intermingled with the forests.

The 1988 North Fork Fire scorched 17,700 acres in the northern part of this subsection, stimulating aspen suckering in numerous locations. This fire event and past timber harvesting primarily in the north half of the subsection have shifted 39 percent of the lodgepole pine into the nonstocked, seedling and sapling age classes. Active management of aspen has also provided some age class diversity. Due to fuel reductions and young age classes resulting from these disturbances, fire is less of a concern here than in many other areas. However, conditions in the southern portion of the Madison subsection are presenting some fire risks as aspen and lodgepole pine stands convert to Douglas-fir through succession. Mature subalpine fir and Douglas-fir in this southern area experienced outbreaks of western balsam bark beetle and Douglas-fir beetle in the past decade. These conditions have subsided, but could easily recur since vegetation conditions have not changed.

Currently 63 percent of the forests are in a mature or older age classes and provide suitable nesting sites for various bird species. Currently 23 percent of the forested acres are in nonstocked and seedling conditions which provide foraging habitat.

The two designated wildernesses on the Forest lie wholly or partially within this subsection. The Jedediah Smith Wilderness (123,451 acres) is mostly in the Teton Range subsection with the balance in the Madison Plateau subsection. The Winegar Hole Wilderness (10,715 acres) is totally within the Madison Plateau subsection. Winegar Hole is largely primitive with very little use. This is mostly due to access difficulty, since there are only four miles of trail in the area. Use of this area is mostly for hunting big game. The Jedediah Smith is intensively used in the summer with approximately 60,000 visits (hiking, backpacking and horseback riding). This is a spectacular mountainous area on the west slope of the famous Teton Mountain Range. These wildernesses are two of twelve designated in the Greater Yellowstone Area which total 3.8 million acres. An area in this subsection in Idaho adjoining Wyoming's Winegar Hole Wilderness is recommended for wilderness designation.

Figure III-6 displays this subsection along with the major prescription areas.

DESIRED FUTURE CONDITION

This subsection will contribute toward grizzly bear and elk habitat management objectives, and provide primitive to semi-primitive recreation opportunities. Vegetation management may be used to reduce threats to remaining habitat from fire, insects and disease. Roads will be closed to improve security for grizzly bears and other wildlife.

Madison–Pitchstone Plateaus Subsection (M331Ab)

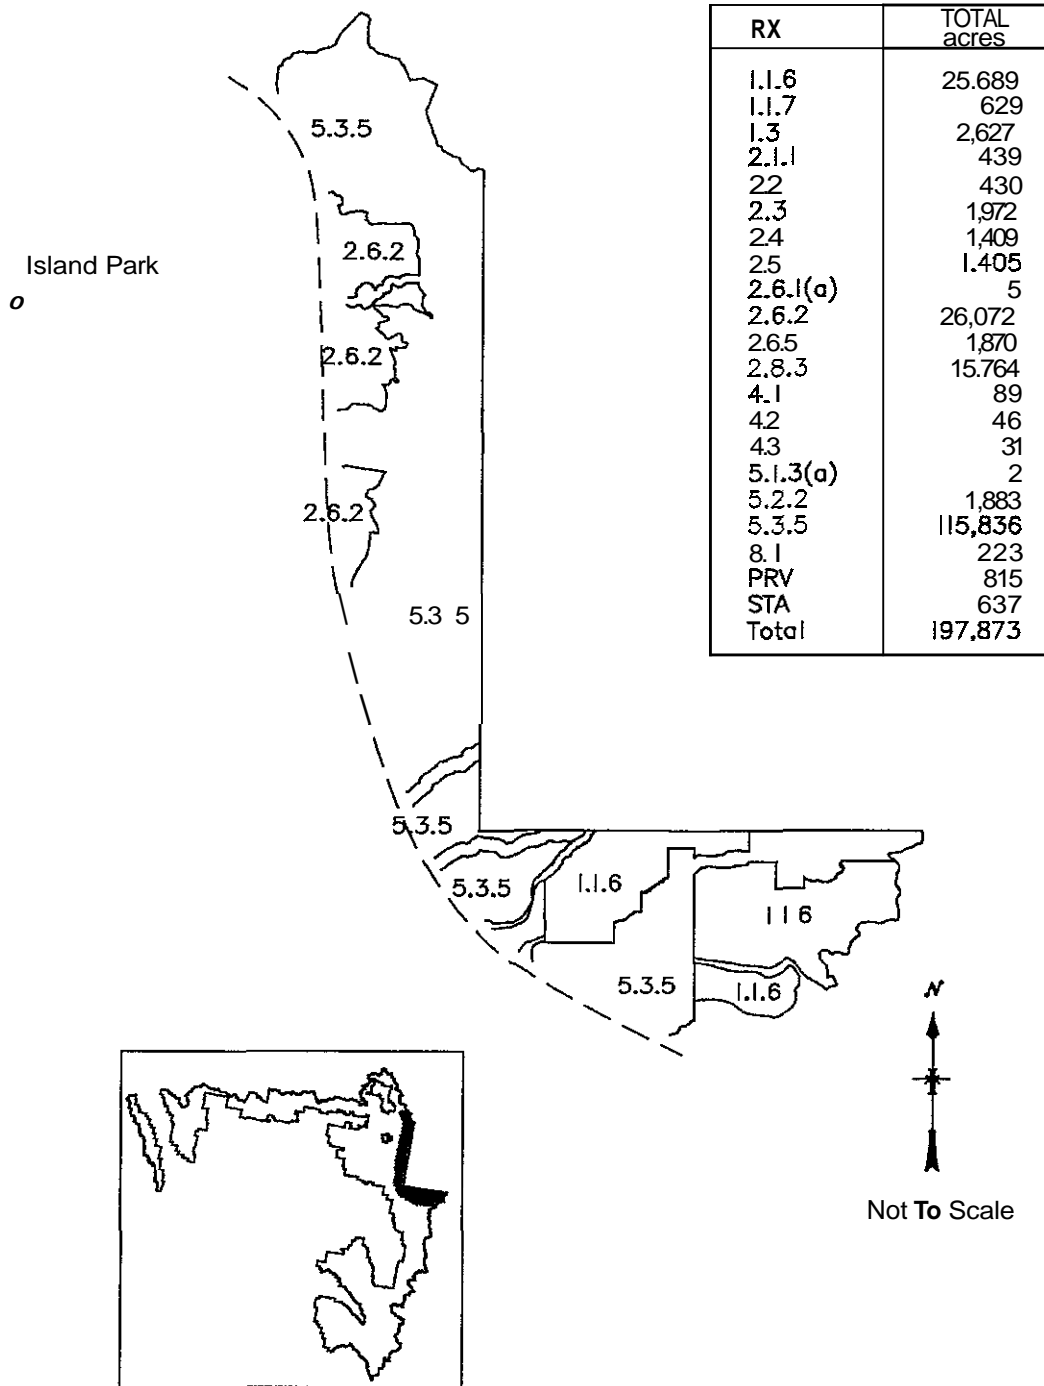

Figure 111-6

GOALS AND OBJECTIVES

Goal - Properly Functioning Condition

Move the area toward its properly functioning condition with a full mix of age classes, larger patch sizes and connectivity between stands

Goal - Fire

Use management-ignited and natural fire to meet resource objectives Comply with the Jedediah Smith Wilderness Fire Management Plan

Goal - Fisheries, Water and Riparian Resources

Effective rehabilitation of the North Fork Fire burn area to stabilize slopes and reduce sediment delivery to streams

TETON RANGE SUBSECTION (M331Db)

SETTING

This area encompasses the Teton Mountains, bounded on the north by South Boone Creek, on the south by Highway 22, on the west by the Teton Basin and on the east by Jackson Hole in Wyoming. The Teton Range is a spectacular line of high peaks rising abruptly along the east side of the Teton Basin. The landscape is a diverse mix of forested and open vegetation. The Jedediah Smith Wilderness traverses the upper portions of the west slopes of the Teton Mountains. The Grand Targhee Ski and Summer Resort is a major tourist destination. Two permitted organized youth camps operate within the subsection. This area is known for its many backcountry trail systems, which are accessible by horse or foot.

The landscape is a diverse mix of forested (57 percent) and open (43 percent) community types. Forest tree species include Douglas-fir, lodgepole pine and mixed conifers. Lodgepole is mixed with Douglas-fir in 31 percent of the forested area, indicating that the pine is converting to Douglas-fir through succession. Open Douglas-fir forests, mountain brush, aspen, and sagebrush pockets are found predominantly on south and west aspects. Aspen is being encroached upon by conifers as succession proceeds, and the amount of aspen has declined compared with historic levels due to fire suppression. Upper elevations are characterized by dense mixed conifer forests, open grass/forb meadows, and talus slopes. Conifers are moving into riparian areas and mountain meadows due to fire suppression.

Since much of the Teton Range subsection is designated wilderness, timber harvest has been limited. Due to this fact and long-term fire suppression only one percent of the forested acres is in the nonstocked, seedling or sapling age classes. The preponderance of mature and older forests (97 percent of total) make this area suitable habitat for species such as marten and owls that prefer late-seral-stage forests. Conversely the lack of fire has contributed to a decline in habitat for bighorn sheep and promoted susceptibility of the forested lands to insect infestations, diseases and large-scale fires. In recent years the western balsam bark beetle has been active in the subalpine fir. The Douglas-fir beetle has killed pockets of Douglas-fir in the past decade, but beetle populations have declined since 1992.

The Jedediah Smith Wilderness (123,451 acres) is mostly in the Teton Range subsection with the balance in the Madison Plateau subsection. The Jedediah Smith is intensively used yearlong with approximately 60,000 visits per year. Some of this use is shared with Grand Teton National Park, lying immediately to the east across the Teton Crest.

The Bechler-Teton Bear Management Unit is also partially within the subsection. In addition to grizzly bears, peregrine falcon, bighorn sheep and many big game species inhabit the area.

Teton Valley has been experiencing a development boom recently and urban interface is a growing concern for the Forest.

Figure III-7 displays this subsection along with the major prescription areas.

DESIRED FUTURE CONDITION

The Teton Range subsection is dominated by the lands inside the Jedediah Smith Wilderness. Over 73 percent of the subsection is wilderness where the focus is to provide quality wilderness experiences. The description of the potential experience is described in Prescriptions 1.1.6, 1.1.7 and 1.1.8.

The subsection includes the Grand Targhee Ski and Summer Resort, which will be managed to provide a safe and enjoyable recreation experience.

Teton Range Subsection (M33 1Db)

+
↓
Not To Scale

Figure III-7

The subsection includes the Bechler - Teton Bear Management Unit. This area will experience little vegetation treatment in the near future while providing a high degree of security for grizzly bear.

The remaining lands in the subsection will provide for motorized recreation while improving big game winter range. These will be managed to reduce or eliminate conflicts with adjacent wilderness.

Of critical importance to this subsection is the high amount of mature and overmature vegetation. To achieve the desired vegetation conditions for all of the management prescriptions will require careful fire management since little of this area will be available for silviculture treatment.

GOALS AND OBJECTIVES

✓ Thru 57

Objective - Fire

By 2007 complete a fire management plan for the Teton Range subsection which will include opportunities for improving bighorn sheep habitat.

Objective - Fisheries, Water and Riparian Resources

Improve stream channel stability ratings to good or excellent by 2007 where natural conditions allow on Teton Creek, N Leigh, S Leigh, Moose Creek, Trail Creek, Fox Creek, and Kiln Creek where instability is management-caused.

Goals - Wildlife

1. Maintain or improve big game winter range.
2. Coordinate with Grand Teton National Park and the Wyoming Game and Fish Department in the management of the bighorn sheep population and habitat.
3. Provide for recreational activity while maintaining the integrity of crucial wildlife habitats.
4. Work with the Intermountain Research Station to establish a research project to study the effects of recreation on bighorn sheep in the Teton Range subsection.

Goal - Recreation

Provide for a variety of opportunities including motorized, nonmotorized, developed and dispersed recreation uses.

Goal - Roadless

Maintain remaining roadless areas in their roadless condition.

Objective - Range

Within three years of signing the ROD, assess opportunities to modify grazing allotment boundaries and permits to more effectively use natural barriers, change grazing patterns, adjust seasons of use, administratively close some additional areas, etc., to further separate domestic sheep from bighorn sheep.

STANDARDS AND GUIDELINES

Recreation

Manage the development of the Grand Targhee Ski and Summer Resort within the intent of the 1994 Master Development Plan Final Environmental Impact Statement and according to the Master Plan approved April 27, 1995 (G).

Wilderness

Implement the Jedediah Smith Wilderness Fire Management Plan (G)

Range

- 1 Domestic sheep grazing within the grizzly bear recovery area will be managed according to Management Situation 2 guidelines (S)
- 2 To better manage grizzly bear and bighorn sheep habitat, all sheep allotments in the Teton Range Subsection on the Teton Basin Ranger District will be phased out on an opportunity basis (Process Papers L and N) These allotments are the Moose Creek, Canyon Badlands, Dry Basin, Badger Twin, and Green Mountain S&G allotments Opportunities to vacate an allotment include such events as nonuse violations, term permit waivers where the permit is waived back to the government, resource protection, or permit actions resulting in cancellation of the permit If opportunities do not arise, then efforts will be made to relocate or accommodate sheep to other areas Vacated allotments in these areas will be made available as needed to resolve conflicts between grizzly bears and domestic sheep in other sheep allotments in Situation 2 habitat (S)
- 3 When all sheep allotments in the portion of the subsection within the grizzly bear recovery area have been vacated, they will be closed Likewise, when all sheep allotments in bighorn sheep habitat have been vacated, they will be closed The intent of not closing these individual allotments as they become vacated is to provide an opportunity to minimize conflicts between domestic sheep and bighorn sheep or grizzly bears (S)
- 4 The range direction in the Revised Forest Plan for the Targhee National Forest applies to the grazing activities (allotment/permit administration, forage utilization direction, AMP development, etc) for that portion of the Moose Creek S&G allotment on the Bridger-Teton National Forest (S)

BIG HOLE MOUNTAINS SUBSECTION (M331Dk)

SETTING

This subsection includes all National Forest System lands between Highway 33 in Idaho and Highway 22 in Wyoming on the north and the South Fork of the Snake River to the south. Several major highways provide access. Idaho Highways 26, 31 and 33, and Highway 22 in Wyoming. Highway 31 is a State Scenic Byway over Pine Creek Pass. Vegetation consists of mountain brush, grass/forb openings, aspen, and forests of Douglas-fir and lodgepole pine. The area has a variety of recreational opportunities including Kelly Canyon Ski Resort, Kelly Canyon Nordic Ski trails, Palisades backcountry, and trail motorbike riding. Palisades Reservoir and its many boat ramps are used by water sports enthusiasts. The Palisades Creek National Recreation Trail lies within this subsection.

Several utility corridors (electrical transmission lines) are located in this subsection. Most follow the highway system and are visible from the highway but do not dominate the landscape. Maintenance work and line upgrades can be seen along these highways. Additional power line needs have been identified and are expected in the near future within or next to these existing corridors.

There is increasing development of summer homes and year-round residences adjacent to the Forest boundary. It is possible that some inholdings within the Forest boundary may also see development in the near future.

The landscape is a mixture of vegetation community types. Some 65 percent of the landscape is forested and 35 percent is nonforested. The most common forest type is mixed lodgepole pine and Douglas-fir, comprising 47 percent of the forested acres. Aspen, pure Douglas-fir and pure lodgepole pine each account for roughly 15 percent of the forest. Mountain mahogany is found on south slopes and hawthorne, chokecherry, serviceberry, antelope bitterbrush and Rocky Mountain maple on various slopes and aspects depending on elevation. Grass/forb meadows and sagebrush are also common.

The northwestern boundary of the subsection extends into the cottonwood river bottom type along the Snake River. There is concern about the lack of cottonwood regeneration along the Snake River, due to a lack of historic river flood levels. A high-density bald eagle population inhabits this area.

Currently 95 percent of the subsection is in a mature age class which provides suitable habitat for a variety of interior wildlife species. This creates hazards for large fires, insect infestations and disease problems. In the north end of the subsection Douglas-fir beetle and western balsam bark beetle caused damage in the late 1980s and early 1990s; this tapered off in 1994. Insect information is not available for the southern portion. Due to fire suppression and lack of disturbance over the years, conifers have encroached into some sites that were historically nonforested. This has reduced overall vegetative diversity in the subsection. Only four percent of the forested stands are in the nonstocked, seedling or sapling age category. These are concentrated in the north end of the subsection where timber harvest has occurred. Most of the shrublands are also in late age classes or seral stages.

The Wyoming portion of the Palisades Roadless Area was designated by Congress as a Wilderness Study Area in 1984. The Study Area contains 132,000 acres, of which over 79,800 acres are administered by the Bridger-Teton National Forest. Some 110,520 acres of this roadless area in Idaho are recommended as wilderness but have had no congressional action taken on them.

Figure 1118 displays this subsection along with the major prescription areas.

Big Hole Mountains Subsection (M331Dk)

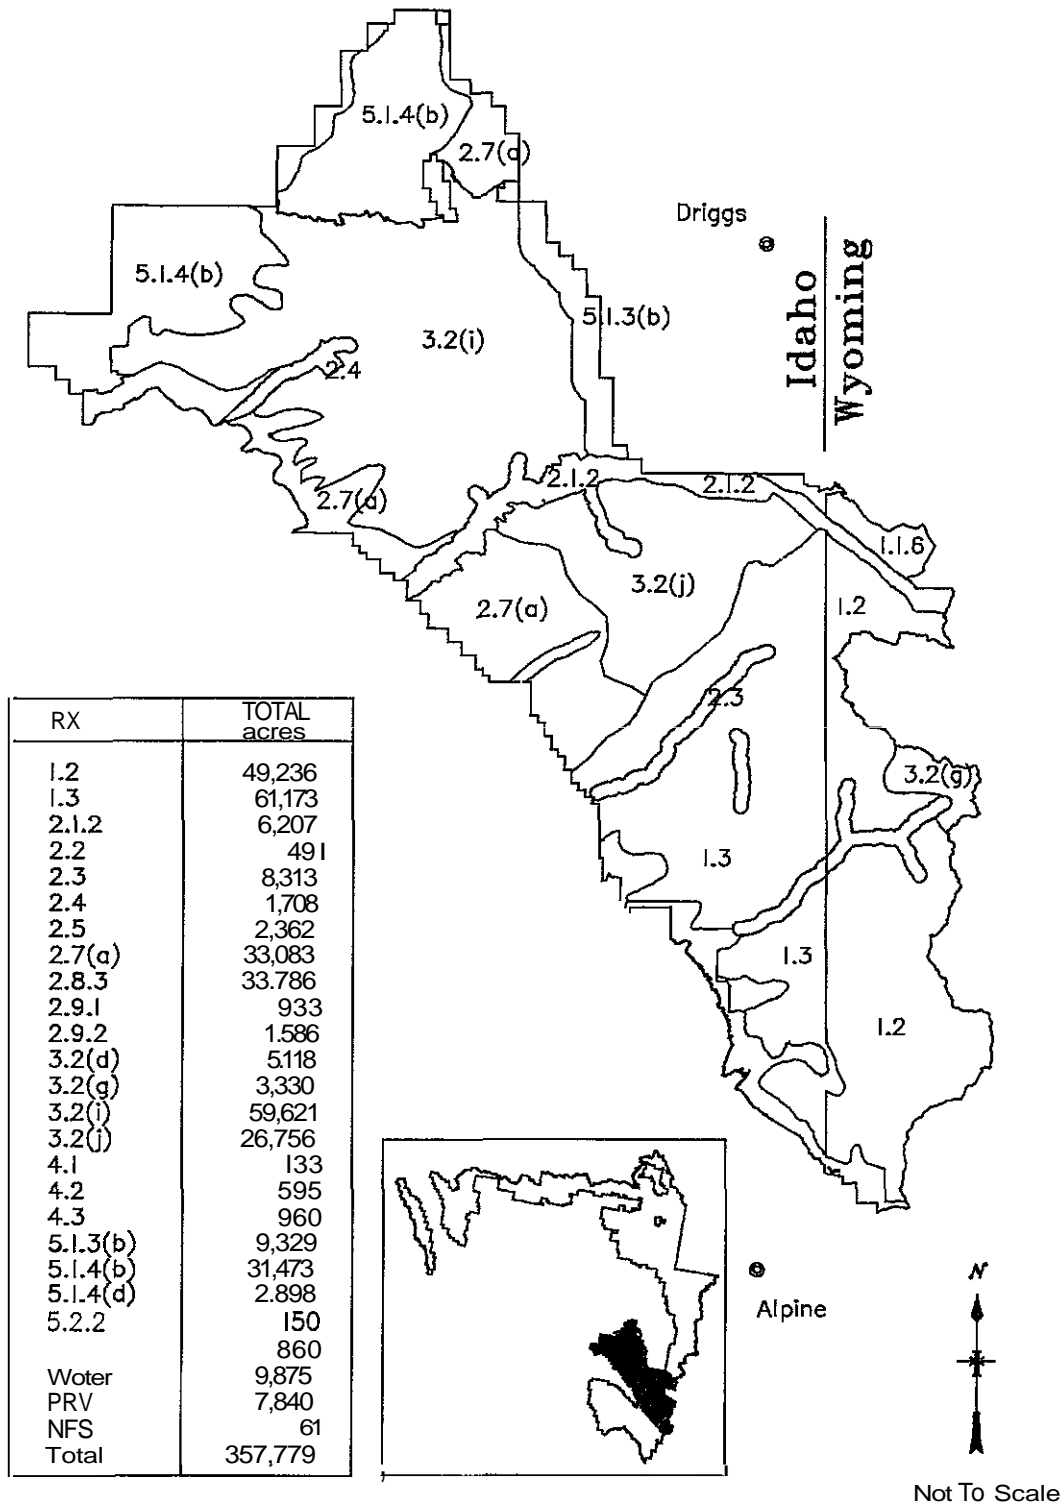

Figure 111-8

DESIRED FUTURE CONDITION

This subsection will provide a diverse range of recreation opportunities at different locations within the subsection

The Big Hole portion of the subsection will provide a wide variety of resources and recreation opportunities. This area will provide quality motorized recreation opportunity with a signed system of roads and trails for motorized use. Resource protection will be accomplished by restricting motorized use to designated routes and by locating routes along planned and selected routes.

The Palisades portion of the subsection will provide more primitive motorized and nonmotorized recreation opportunities. Emphasis will be placed on quality backcountry experience for these uses along appropriate designated trails. The Forest recommends the Idaho portion of the Palisades roadless area for wilderness designation. The Wyoming portion is managed as a wilderness study area according to existing legislation.

On lands suitable for timber harvest (mostly on the northern part of the Big Holes) the risks from insect and disease attack will be reduced using timber management while improving big game security and summer range. Prescribed fire will be used on the remainder of the subsection to improve ecosystem health and wildlife winter ranges.

The recreational use on the South Fork of the Snake River will continue but be balanced with the needs of wildlife. Management for bald eagle recovery will continue.

Much of this subsection is made up of inventoried roadless areas. With the exception of the north end of the Big Holes, most of that area is in the Garns Mountain and Palisades Roadless Areas. These areas are typified by steep mountain ranges where little development opportunity is expected.

GOALS AND OBJECTIVES

Goal - Properly Functioning Condition

Continue cooperation with other agencies in conducting research and implementing management actions to regenerate cottonwood along the South Fork of the Snake River.

Objective - Properly Functioning Condition

By 2007, develop a fire management plan which considers summer home development and risk around the Palisades Reservoir.

Goal - Fisheries, Water and Riparian Resources

Channel stability would be rated at good to excellent for individual streams.

Objective - Fisheries, Water and Riparian Resources

Improve stream channel stability ratings to good or excellent by 2007 where natural conditions allow on South Fork, Packsaddle, Horseshoe, Superior, North Fork Mahogany, Main Mahogany, Henderson, Patterson, and Murphy Creeks.

Goal - Wildlife

Provide for recreational activity while maintaining the integrity of crucial wildlife habitats such as winter range.

Goals - Recreation

1. Continue to place emphasis on winter recreation for the Big Hole portion of the subsection by continuing a grooming program for snowmachines, which is orientated towards family opportunities, continuing to work with user groups for cross-country skiing opportunities in the Kelly area.

2 Continue to improve the quality of the summer time OHV use in the Big Hole area and protect resource values by locating and maintaining trails on suitable locations

Goal - Visuals

Manage the Pine Creek Scenic Byway (Highway 31) and Highway 22 over Teton Pass for visual quality allowing needs of the utility corridor

Objective - Heritage Resources

Complete heritage resources inventory of this subsection by 2007

Goals - Roadless

1 In recommended wilderness, protect roadless area values to ensure wilderness characteristics are maintained

2 In all other areas, continue to protect resource values

Goal - Range

Continue to recognize the value of grazing on the Kelly Ski hill for forage control and fire protection. Grazing timing and duration will continue to be coordinated between grazing permittees, ski hill permittee and the Forest Service

STANDARDS AND GUIDELINES

Lands (Special Uses)

The Therold Buckland isolated cabin will continue as a life tenure permit and will not be transferred. Upon the expiration of the permit, the cabin will be evaluated and its historical qualifications determined. If the cabin is found to have historic value, it may be moved from the site, or the Forest may issue a special use permit to a Historical Association for maintenance of the cabin if warranted. If no historical value is found the cabin will be removed (S)

Old Growth Habitat

✓ Within one mile of the Palisades Reservoir and the South Fork of the Snake River, emphasis will be given to managing old growth Douglas-fir, spruce and cottonwood habitats for wildlife species (G)

Access

In the Table Rock area, the OROMTRD standard of < 2.0 mi/sq mi does not apply (S)

Range

The range direction in the Targhee Land Management Plan applies to the grazing activities (allotment/permit administration, forage utilization S&Gs, AMP development, etc) for that portion of Targhee National Forest lands administered by the Bridger-Teton National Forest, above Alpine Junction. Those lands are the Big Basin/South Elk S&G, South Indian/Cottonwood Creek S&G, Spencer/Wolf S&G, Grand Canyon S&G, and the Dog Creek S&G allotments (S)

CARIBOU RANGE MOUNTAINS SUBSECTION (M331D1)

SETTING

This subsection is the portion of the Caribou National Forest administered by the Targhee. It lies south of the South Fork of the Snake River. Steep mountain slopes and canyons dominate the landscape. The Palisades Reservoir is shared between this subsection and the Big Hole/Palisades subsection. Vegetation forms a patchwork of sagebrush/grass openings, aspen, and mixed Douglas-fir/lodgepole pine forests. Recreation use is very similar to that in the Big Hole/Palisades subsection with high mountain trails, motorized use on trails, and backcountry use as well as hunting, fishing and water sports on the reservoir and the Snake River. There are several summer home divisions and two organizational camps. Forest lands are visible from U.S. Highway 26, the major travel corridor between Idaho Falls, Idaho and Jackson, Wyoming. Very little logging has taken place in the past. Both cattle and sheep grazing occur.

One utility corridor (electrical transmission line) is located in this subsection. It is visible from the Fall Creek road but does not dominate the landscape. Maintenance work and line upgrades can be seen from travel routes.

The Caribou subsection is 60 percent forested and 40 percent nonforested. The primary forest types are aspen (31 percent) and mixed lodgepole and Douglas-fir (47 percent). The interspersed forests with sagebrush, grass/forb meadows and mountain brush provides for good diversity of plant species. The northeastern boundary area of the subsection includes cottonwood river bottom forests along the Snake River.

Age class diversity is limited. Some limited timber management has occurred in the lodgepole pine/Douglas-fir type. Almost no harvesting has taken place in the Engelmann spruce/subalpine fir type. Some 99 percent of the conifer forests are in mature or older seral stages. Douglas-fir is becoming more predominant as it encroaches on stands of lodgepole pine, aspen or shrubs. Evidence of insect attacks is readily visible in the Douglas-fir type and is increasing each year. It is likely that there is more Douglas-fir here now, and less aspen, lodgepole pine and shrubland, than existed historically. Fires have been suppressed for many years. Because stands are scattered and difficult to access, this condition is likely to persist. Treatment opportunities center around prescribed burns and limited vegetation treatment where access is more easily obtained.

Most of the shrublands are also in late seral stages. Consequently, risks of large fires, insects and disease outbreaks is high. Insect attacks in recent years have been similar to those in the Big Hole/Palisades subsection. The Snake River cottonwood stands are also predominately in the mature age class due to lack of disturbance, which they need in order to regenerate. Historic disturbance patterns consisting of periodic flooding have been interrupted since placement of the Palisades Dam.

Establishing natural regeneration of both Douglas-fir and lodgepole pine following harvest has been a problem in this subsection, and most sites have required planting.

Much of this subsection is made up of five inventoried roadless areas. Bear Creek is the largest inventoried area. Development or evidence of humans is easier to see in these roadless areas than in the Big Hole Mountains subsection. The size of the roadless areas and intrusions from motorized-use roads limit their wilderness characteristics.

Figure III-9 displays this subsection along with the major prescription areas.

Caribou Range Mountains Subsection (M331Di)

Figure III-9

DESIRED FUTURE CONDITION

Recreation will emphasize dispersed recreation opportunities, and semi-primitive backcountry experiences while providing high-quality motorized use on designated trail systems

The recreational use around Palisades Reservoir and the South Fork of the Snake River will continue but be balanced with the needs of wildlife and other resources

On lands suitable for timber harvest silvicultural management will reduce the risks of insect and disease attack while improving big game winter range conditions. Prescribed fire and some vegetation manipulation will be used on the remainder of the subsection where access permits to help restore and maintain a healthy ecosystem

Quality range management practices will continue on this subsection. High valued big game winter range in the Fall Creek area will be maintained or improved

GOALS AND OBJECTIVES

Goals - Properly Functioning Condition,

- 1 Continue cooperation with other agencies in conducting research and implementing management actions to regenerate cottonwood along the South Fork of the Snake River
- 2 Develop a fire management plan which allows for natural fire and which considers summer home development and risk around the Palisades Reservoir

Goals - Recreation

- 1 Improve the quality of summertime OHV use in this subsection and protect resource values by locating and maintaining trails at suitable locations
- 2 Emphasize winter recreation by allowing continued grooming of snow machine trails oriented towards family opportunities, and providing shelter facilities (warming huts)

Objective - Heritage Resources

Complete heritage resource inventory of this subsection by 2007

Goal - Roadless

Protect resource values on lands managed with a nonwilderness emphasis

STANDARDS AND GUIDELINES

Old Growth Habitat

Within one mile of the Palisades Reservoir and the South Fork of the Snake River, emphasis will be given to managing old growth Douglas-fir, spruce and cottonwood habitats for wildlife species (G)

Access - Alpine Wetland Area

This area is located near the Salt River on the Palisades Reservoir. It is closed to cross-country travel except on designated routes for all wheeled vehicles and snow machines (S)

Range

On the Palisades Ranger District, the Garden-Pritchard S&G allotment will be closed immediately to grazing for watershed protection (S)

INTRODUCTION

A management prescription is a composite of the specific multiple-use direction applicable to all or part of a management area that generally includes, but is not limited to, goals, objectives, standards and guidelines, and probable management practices

The terms goals, objectives, standards and guidelines were defined in the Introduction of this Chapter. The goals, objectives, standards and guidelines in this section are specific to each management prescription.

Most management prescriptions have a motorized access density standard established. Roads or trails are frequently used as a convenient geographic feature to identify management prescription area boundaries. When roads or trails are used to identify a management prescription area boundary where the TMARD (Total Motorized Access Route Density) or OROMTRD (Open Road and Open Motorized Trail Route Density) is 0.0 miles/square mile, the road or trail miles are not counted in the TMARD or OROMTRD for that particular prescription area. The road and trail miles are included in the TMARD and OROMTRD calculations in the adjacent management prescription areas. The road and trail miles are included when calculating environmental effects, such as elk vulnerability, grizzly bear cumulative effects, etc.

All areas of the Forest are allocated to one prescription area. For those areas where two management intents overlap one prescription was identified to prevail over the other. In cases where research natural areas (Prescription 2.2) or eligible wild (2.3), scenic (2.4) or recreational (2.5) rivers lie within designated wilderness (1.1.6, 1.1.7 or 1.1.8), the wilderness prescription prevails. Where any of those four prescriptions lie within a wilderness study area (1.2) or recommended wilderness (1.3), they prevail over the wilderness study area or recommended wilderness prescription. Direction on prevalence of the aquatic influence zone (Prescription 2.8.3) is given in the description of that item.

1.1.6 DESIGNATED WILDERNESS - OPPORTUNITY CLASS I

Description

This prescription applies to the Winegar Hole Wilderness and portions of the Jedediah Smith Wilderness.

The effects of human activities are not noticeable to most visitors. Camping activities are not evident, although facilities such as bearproof storage boxes may be present to assist recovery of listed threatened or endangered species. User-created routes and nonsystem trails may exist but they appear as game trails and are not shown on maps or trail guides.

Opportunities exist for individuals or small groups to experience a high quality wilderness-dependent educational experience. A low level of recreation use occurs in these remote areas which often contain rugged terrain. There is a lack of system trails, a lack of signing, and information about the area is not distributed. Trailhead facilities for these areas are minimally developed to encourage low levels of use. There is a low level of outfitter/guide use.

Low use levels allow for meeting the user's expectations of finding a recreation or wilderness experience with a high degree of solitude. Signs of the user's passing are not evident. Opportunity for discovery may exist.

Refer to the "Monitoring Plan" and the "Jedediah Smith Wilderness Environmental Assessment for Forest Plan Amendment Process Paper" for detailed descriptions of opportunity classes (I, II, III) and use levels.

This prescription meets the Interagency Grizzly Bear Committee definition for core areas

Goals

- 1 The maintenance of the natural diversity of wildlife species is given the highest priority and is dominant over other uses. There is no great alteration of wildlife behavior or use of crucial habitat by wildlife as a result of human activities.
- 2 Human activities are managed so there is no appreciable modification of natural succession. Any vegetation loss resulting from camping recovers within one growing season.
- 3 There is no measurable downward trend in plant species composition and plant diversity due to livestock grazing. Utilization levels are compatible with maintaining or enhancing ecological condition. The range is managed so that plant communities are at or trending towards potential natural community status except where natural disturbance, and not livestock or recreation use, determines the lower seral condition.
- 4 There are outstanding opportunities for solitude, self-reliance, and challenge. Users do not normally see or hear other users.
- 5 A very minor amount of human-caused bare soil persists from year-to-year in localized areas. No great human-caused soil erosion occurs.
- 6 Opportunities are provided for research that do not require permanent instrumentation or direct contact with visitors in the Wilderness.
- 7 Manage as trailless areas. Any existing trails will be abandoned and allowed to regress to a natural state unless needed to prevent resource damage.
- 8 Manage for a low level of outfitter/guide use.

Objectives

- 1 Coordinate with the Wyoming Game and Fish Department to prepare a wilderness fishery management plan within five years of implementation of the ROD, with consideration of the State's existing fishery management plan for wilderness fisheries.
- 2 Implement a wilderness education program for all users, which could include yearly contacts with local schools, yearly programs with organizational camps, information available at Forest and District offices for distribution to the public, periodic contacts at trailheads by Forest Service personnel with wilderness users, ethics orientation for wilderness use presented to permittees and Forest Service personnel, and information about grizzly bears.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is as follows:

Within the grizzly bear recovery zone, the Interagency Grizzly Bear Guidelines for Management Situation 1 habitat apply to this management prescription, except that livestock grazing in existing Management Situation 2 habitat will continue to be managed under Management Situation 2 guidelines. (S)

Ecological Processes and Patterns

Fire/Fuels

Natural and manager-ignited fires will be allowed to burn under predetermined prescriptive

conditions as described in wilderness fire management action plans (G)

Biological Elements

Fisheries, Water and Riparian Resources

1 Fish stocking for recreational fishing is permitted with species native to the Wilderness in waters previously stocked (prior to wilderness designation) by the Game and Fish Department (G)

2 Fish stocking for reestablishment of native species may occur (G)

Forest Use and Occupation

Access (S) - 1 1 6

Season	Type of Access	Cross-County Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian	Yes	No
	Horse/Pack Stock	Yes	No
	Mtn Bike/Mechanized	No	No
Snow free Seasons	Motorized, <50" wide	No	No
	Motorized, >50" wide	No	No
	OROMTRD 2/	N/A	0.0 mi/sq mi
Snow Seasons	Winter Nonmotorized	Yes	No
	Snowmachine	No	No

1/ These areas are managed as trailless, there are no maintained trails. Motorized use is prohibited, except for emergencies or valid uses specified in the law

2/ OROMTRD= Open road and open motorized trail route density includes all open roads and open motorized trails (See Roads in Glossary for more information)

Recreation

Dispersed - No dispersed facilities are provided, except facilities may be present for recovery of listed threatened and endangered species. Existing bearproof food storage boxes in Opportunity Class I zones installed prior to 1993 may remain, but no additional boxes or other facilities will be installed in these areas (S)

- No signing (S)

- No distribution of information about these areas (S)

ROS - Manage for a primitive classification (S)

VQO - Manage for a preservation classification (S)

Heritage Resources

Evaluate and protect these resources in the context of a setting where there is little public visibility (G)

Production of Commodity Resources

Range

Manage allotments at FRES levels A, B, or C (G)

1.1.7 DESIGNATED WILDERNESS - OPPORTUNITY CLASS II

Description

This prescription applies to portions of Jedediah Smith Wilderness

The effects of human activities are somewhat evident to visitors. Camping activities are set back from trails and water. Trail treads are evident but the trail may be brushy and its location blends well with the natural topography. Trails are maintained to protect the resource.

Opportunities exist for individuals and moderate sized groups to experience a quality wilderness-related educational experience.

A moderate level of recreation use occurs. Bridges generally are not provided except where needed for resource protection. Directional and resource protection signs may be provided. Campsite facilities such as bearproof food boxes may be present for recovery of listed threatened and endangered species. Trailheads used by those accessing these areas contain bulletin boards and may provide undeveloped areas for overnight camping. There may be a high level of outfitter/guide use.

There is a moderate to high opportunity for solitude during July-September. Opportunities for solitude are high at other times. Users may experience a moderate degree of self-reliance and challenge. Users normally do not see other users but may occasionally hear other groups.

Moderate use levels may result in other users seeing or hearing some evidence of recreational activities. Fixed anchors at rappel stations, impacts on approach and descent routes, and some protection left by previous parties notifies users that others have gone before.

Refer to Chapter V and the "Jedediah Smith Wilderness Environmental Assessment for Forest Plan Amendment Process Paper" for detailed descriptions of opportunity classes (I, II, III) and use levels.

This prescription meets the Interagency Grizzly Bear Committee definition for core areas.

Goals

1. The maintenance of the natural diversity of wildlife species is given high priority. There is no displacement of wildlife during critical periods (winter and birthing), and only temporary displacement during noncritical periods.
2. Human activities are managed so there is only limited modification of natural succession at campsites, trails, and grazed areas. Some vegetation loss persists from year-to-year at identified campsites.
3. There is no measurable downward trend in plant species composition and plant diversity due to livestock grazing. Utilization levels are compatible with maintaining or enhancing ecological condition. The range is managed so that plant communities are at or trending towards potential natural community status except where natural disturbance, and not livestock use or recreation use, determines the lower seral condition.
4. Some bare soil persists from year-to-year due to human activities. Human-caused soil erosion may occur.
5. Research opportunities may include a minor amount of instrumentation and only occasional contact with visitors.

Objectives

In addition to Objectives 1 and 2 in prescription 1 1 6, also add the following

Install signs at wilderness trailheads advising users they may encounter a variety of other legitimate wilderness uses including sheep and cattle grazing, llama trekking, etc

Standards and Guidelines

Forestwide standards and guidelines apply Additional direction for this prescription is listed below

Within the grizzly bear recovery zone, the Interagency Grizzly Bear Guidelines for Management Situation 1 habitat apply to this management prescription, except that livestock grazing in existing Management Situation 2 habitat will continue to be managed under Management Situation 2 guidelines

Ecological Processes and Patterns

Fire/Fuels

Natural and manager-ignited fires will be allowed to burn under predetermined prescriptive conditions as described in the Wilderness Fire Management Action Plan (G)

Biological Elements

Fisheries, Water and Riparian Resources

Same as 1 1 6 Designated Wilderness

Wildlife

Grizzly Bear - In the event future trails or campsites are developed within the grizzly bear recovery zone, avoid locations within 1/2-mile of key habitat areas such as white bark pine stands, huckleberry patches, riparian areas and wet meadows, avalanche chutes, seasonal insect feeding sites (G)

Harlequin Duck - Avoid locating new trails or campsites within 300 feet of streams which provide harlequin duck habitat (G)

Forest Use and Occupation

Access (S) - 1 1 7

Season	Type of Access	Cross-country Travel	Road and Trail Travel ^{1/}
Snow free Seasons	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	No	No
Snow free Seasons	Motorized, <50" wide	No	No
	Motorized, >50" wide	No	No
	OROMTRD2/	N/A	0 0 m/sq mi
Snow Seasons	Winter Nonmotorized	Yes	Yes
	Snowmachine	No	No

Recreation

Dispersed - Additional food storage boxes may be provided in Opportunity Class II zones for protection of the grizzly bear (G)

Directional and resource protection signs may be provided (G)

Trails/Bridges - Trails have evident tread but may be brushy Bridges generally are not provided except where needed for resource protection (G)

ROS - Manage for a primitive to semi-primitive nonmotorized classification (G)

VQO - Manage for a preservation classification (S)

Heritage Resources

Evaluate and protect these resources in the context of a setting where there is some public visibility (G)

Production of Commodity Resources

Range

Same as 1 1 6 Designated Wilderness

1.1.8 DESIGNATED WILDERNESS - OPPORTUNITY CLASS III

Description

This prescription applies to areas of the Jedediah Smith Wilderness

The effects of human activities are evident to most visitors but blend in with the natural setting Camping is set back from trails and water Trail treads are very evident

Opportunities exist for individuals and large groups to experience a quality wilderness educational experience

Recreation use is relatively high Bridges are provided where needed for resource protection or visitor safety Directional, informational and regulatory signs may be provided Campsite facilities such as bear proof food boxes may be present for recovery of listed threatened and endangered species Trailheads used by those accessing these areas may contain information stations, undeveloped and developed areas for overnight camping and stock facilities There may be a moderate level of outfitter/guide use

There is a low to moderate opportunity for solitude during July-September Opportunities are high at other times Users may experience a low to moderate degree of challenge and self reliance Users may see or hear other groups especially during July-September

High use levels at peak times may result in other users seeing and hearing other visitors Visitors may encounter other groups, which may slow their progress and may impact their solitude expectations Fixed anchors at rappel sites are evident Approach and descent trails are evident, and their impacts are managed to control erosion Fixed protection anchors on climbs may be evident to hikers at the base of cliffs, but not those on system trails

Refer to Chapter V and the "Jedediah Smith Wilderness Environmental Assessment for Forest Plan Amendment Process Paper" for detailed descriptions of opportunity classes (I, II, III) and use levels

Goals

- 1 The maintenance of the natural diversity of wildlife species is given high priority but does not dominate other uses except where measures are needed to recover listed threatened and endangered species. Temporary displacement of non-TES species may occur except on crucial ranges but there is no permanent displacement. Some habituation of species may be evident.
- 2 Human activities are managed so that modification of natural succession only occurs at campsites, trails, and grazed areas. Moderate vegetation loss persists from year-to-year at identified campsites.
- 3 There is no measurable downward trend in plant species composition and plant diversity due to livestock grazing. Utilization levels are compatible with maintaining or enhancing ecological condition. The range is managed so that plant communities are at or trending towards potential natural community status except where natural disturbance, and not livestock or recreation use, determines the lower seral condition.
- 4 A moderate amount of bare soil may persist from year-to-year due to human activities. A moderate amount of human-caused soil erosion may occur.
- 5 Research opportunities may include some instrumentation and moderate contact with visitors.
- 6 Manage for a moderate level of outfitter/guide use.

Objectives

Same as Prescription 1 1 7

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Within the grizzly bear recovery zone, the Interagency Grizzly Bear Guidelines for Management Situation 1 habitat apply to this management prescription, except that livestock grazing in existing Management Situation 2 habitat will continue to be managed under Management Situation 2 guidelines.

Ecological Processes and Patterns

Fire/Fuels

Natural and manager-ignited fires will be allowed to burn under predetermined prescriptive conditions as described in the Wilderness Fire Management Action Plan (G)

Biological Elements

Fisheries, Water, and Riparian Resources

1 Stocking of native and nonnative fish is permitted only in waters previously stocked by Game and Fish Department (S)

2 Fish stocking for reestablishment of native species may occur (G)

Wildlife

Grizzly Bear- In the event future trails or campsites are developed within the grizzly bear recovery zone, avoid locations within 1/2-mile of key habitat areas such as white bark pine stands, huckleberry patches, riparian areas and wet meadows, avalanche chutes, and seasonal insect feeding sites (G)

Harlequin Duck - Avoid locating new trails or campsites within 300 feet of streams which provide harlequin duck habitat (G)

Forest Use and Occupation

Access (S)- 1 1 8

Season	Type of Access	Cross-Country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	No	No
Snow free Seasons	Motorized, <50" wide	No	No
	Motorized, >50" wide	No	No
	ROMTRD 2/	N/A	0.0 mi/sq mi
Snow Seasons	Winter Nonmotorized	Yes	Yes
	Snowmachine	No	No

1/ Individual roads and trails are designated open or closed in the Forest Plan Travel Maps. Motorized users may use roads, except for emergencies or valid uses specified in the law (FSM 2326 03)

2/ ROMTRD = Road and Motorized Trail route density includes all open roads and open motorized trails. (See Roads in Glossary for more information)

Recreation

Dispersed - Bear proof food storage boxes may be provided in Opportunity Class III zones for protection of the grizzly bear (G)

Directional, informational, regulatory and resource protection signs may be provided (G)

Trails/Bridges - Trails are well defined and brushed out. Bridges are provided where needed for resource protection and visitor safety (G)

ROS - Manage for a primitive to semi-primitive nonmotorized classification (G)

VQO - Manage for a preservation classification (S)

Heritage Resources

Evaluate, protect and interpret these resources in the context of a setting where there is moderate human influence and public visibility (G)

Production of Commodity Resources

Range

Same as 1 1 6 Designated Wilderness Opportunity Class I

1.2 WILDERNESS STUDY AREA

Description

This prescription applies to the Wyoming portion of the Palisades and Teton Basin Ranger Districts, which was designated as a Wilderness Study Area by the Wyoming Wilderness Act of 1984

The 1984 Act provided the area be administered to "maintain its present existing wilderness character and potential for inclusion in the National Wilderness Preservation System" (AMS, Roadless Areas, Page 7) The Act provided that oil and gas exploration and development be allowed in accordance with laws and regulations generally applicable to nonwilderness lands in the National Forest system, and that snowmobiling should continue to be allowed in the same manner and degree as was occurring prior to the date of enactment of the Act

This is a mostly pristine area where little sign exists of people away from trails or camping areas. They are undeveloped lands retaining their primeval character and influence, and are managed so as to preserve their natural condition. They generally appear to have been affected primarily by the forces of nature and therefore offer an excellent opportunity for solitude or a primitive and unconfined type of recreation. Occasionally, however, a visitor may see effects of human activity such as primitive campsites, rustic bridges, trails, signs, or primitive roads. A visitor may also encounter livestock, mining, or a snowmobile.

You may find areas of the forest where recent burns, insect activity, or blowdowns dominate the landscape. You would not expect to encounter very much motorized equipment, except snowmobiles.

This prescription meets the Interagency Grizzly Bear Committee definition for core areas.

Goals

1. Protect and perpetuate wilderness character.
2. Insects and disease are allowed to play, as nearly as possible, their natural ecological role in the environment.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes and Patterns

Insects and Disease

Insect and plant disease epidemics may be controlled to prevent unacceptable damage to resources on adjacent lands or an unnatural loss to the Wilderness Study Area resource due to exotic pests (G)

Fire/Fuels

Minimum Impact Suppression Tactics (MIST) will be employed to the maximum extent possible (G)

Allow prescribed fires from both natural and management-ignition when they meet the objectives of the Wilderness Study Area (G)

Physical Elements

Soil and Water

Watershed restoration will be done primarily where deteriorated soil or hydrologic conditions are caused by humans, or where their influences create a serious threat or loss of the Wilderness Study Area values (G)

Promote natural healing where a definite hazard to life or property or important environmental qualities outside and within the Wilderness Study Area are not imminent, or where natural vegetation would return in a reasonable time (G)

Use indigenous species to reestablish vegetation as the first choice. Where native species are unlikely to succeed, use appropriate self-extirpating naturalized species (G)

Permit emergency burned area rehabilitation only if necessary to prevent an unnatural loss of wilderness-like resources or to protect life, property, and other resource values outside the Wilderness Study Area (S)

Maintenance or reconstruction of existing water development structures is allowed if it does not change the location, size, or type, or which does not increase the storage capacity of a reservoir (G)

Minerals/Geology

Locatable - Withdraw from mineral entry, or remove from mineral entry through the notation rule, subject to valid existing rights (G)

Mineral Material - This area is not available for mineral material entry (S)

Biological Elements

Fisheries, Water and Riparian Resources

Fish stocking of native and nonnative species is allowed where it existed prior to establishment of the Wilderness Study Area (G)

Wildlife

Reintroduce wildlife species only if the species was once indigenous to the area and was eliminated by human-induced events (S)

Allow wildlife habitat manipulation only if (S)

- 1 The condition needing change is a result of abnormal human influence
- 2 The project can be accomplished with assurance that there will be no serious or lasting damage to wilderness characteristics
- 3 There is reasonable assurance that the project will accomplish the desired objectives

Forest Use and Occupation

Access (S) - 1 2

Season	Type of Access	Cross-country Travel	Road and Trail Travel 1/
Snow free Season	Pedestrian Horse/Pack Stock Mtn Bike/Mechanized	Yes Yes Yes	Yes Yes Yes
Snow free Season	Motorized, <50" wide Motorized, >50" wide OROMTRD3/	No 2/ No 2/ N/A	Yes No 2/ 0.2 mi/sq mi
Snow Seasons	Winter Nonmotorized Snowmachine	Yes Yes	Yes Yes
<p>1/ individual roads and trails are designated open or closed in the Forest Plan Travel Maps</p> <p>2/ Motorized use is prohibited, except for emergencies or valid uses specified in the law</p> <p>3/ OROMTRD = Open road and open motorized trail mute density includes all open roads and open motorized trails (See Roads in Glossary for more information)</p>			

Trails and bridges are constructed/maintained to accommodate heavy foot and horse traffic (G)

Roads

Roads are allowed only to the extent they already exist (S)

Recreation

ROS - Manage for primitive or semi-primitive nonmotorized classification (G)

VQO - Manage for a preservation classification (S)

Heritage Resources

Remove structures that do not qualify for the National Register of Historic Places, or allow them to deteriorate naturally unless they are (G)

- 1 Deemed necessary to support public purposes of the Wilderness Study Area, or
- 2 Serve administration purposes

Interpretation of cultural resources located in the Wilderness Study Area shall be done outside the area (S)

Production of Commodity Resources

Timber

Trees may be cut only for valid mining claims under specific conditions, when emergency conditions such as fire, insect and disease arise, for protecting public safety, or when administrative use make it necessary (G)

1.3 RECOMMENDED WILDERNESS

Description

This prescription applies to areas that are recommended for addition to the Wilderness Preservation System. They will be managed in their present condition (including existing trail use and snowmachine use, as long as existing uses will not degrade the character of the resources) until Congress takes action on that recommendation. In the Lionhead area and the Winegar Hole Addition, this management prescription meets the Interagency Grizzly Bear Committee criteria for grizzly bear core areas (IGBC Task Force Report July 1994).

These are mostly pristine areas of the Forest where you find little sign of people away from trails or camping areas. They are undeveloped lands retaining their natural condition. They generally appear to have been affected primarily by the forces of nature and therefore offer an excellent opportunity for solitude or a primitive and unconfined type of recreation. Occasionally, however, a visitor may see effects of human activity such as primitive campsites, rustic bridges, trails, signs or primitive roads. A visitor may also encounter livestock or mining activity.

You may also find areas of the forest where recent burns, insect activity, or blowdowns dominate the landscape. You may encounter mechanized equipment on designated trails during the summer or snow-machine use during the winter.

Goals

Protect and perpetuate wilderness character

In the Lionhead area and Winegar Hole Addition, maintain grizzly bear core area attributes as defined in the IGBC Task Force Report, July 1994.

Objective

Within the grizzly bear recovery zone, an active education program will be implemented each year, including patrols during the fall hunt.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

In the Lionhead area and Winegar Hole Addition, the Interagency Grizzly Bear Guidelines for Management Situation 1 habitat apply to this management prescription.

The standards and guidelines for this prescription are the same as 1.2 (Wilderness Study) except as follows:

Forest Use and Occupation

Access (S) - 1 3

Season	Type of Access	Cross-Country Travel	Road and Trail Travel 1/

Recreation

- 1 Developed- Developed, hardened campsites are generally not allowed (G)
- 2 Existing hell-skiing operations which **do** not degrade wilderness values may continue (G)

2.1.1 SPECIAL MANAGEMENT AREAS

Description

This management prescription applies to areas with unique cultural, geologic, botanical, or zoological resource values, and sites which are listed or eligible for the National Register of Historic Places

Vegetation will vary depending on the objectives of each special area A mix of age class distributions, openings, and horizontal/vertical diversity may be present In general, vegetation will appear natural in the special management areas, however, exceptions may exist for some areas, and some human-caused vegetation manipulation will occur depending on the objectives of each special area

Facilities may or may not be present to manage the special areas. Access will range from black top roads, to trails, to no access at all. Administrative sites could have a variety of facilities such as buildings, roads, trails, microwave towers, boat ramps and pasture for the livestock used by Forest Service personnel to manage the Forest.

The amount of human activity apparent in special areas will vary, depending upon the management objectives of each area.

Special management areas may provide some forage for livestock. Timber harvest may be rare or not at all. Restricted livestock grazing and timber activities can be expected to provide additional protection to the special values in the area. Surface facilities for leasable minerals, such as oil and gas, will not be found within a special management area. To protect the values within a special management area, restrictions can be expected for valid existing rights to develop locatable minerals, such as precious metals and high value industrial minerals.

Because of the unique characteristics of these special management areas, these lands may provide economic opportunities for outfitter and guides, educational opportunities for the public and research opportunities for resource managers and academia. These areas will provide a spectrum of recreational opportunities from developed sites containing comfort facilities and visitor centers in a natural setting to sites with no access at all in a pristine setting.

Goal

- 1 Manage and protect the unique cultural, historic, botanical, geological, and/or zoological resources
- 2 Maintain or enhance the inherent values associated with each special interest area
- 3 Allow insects and disease to play their natural role in ecological succession, except where resource values will be adversely affected
- 4 Maintain or enhance the inherent wildlife habitat values associated with each special management area

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Within the grizzly bear recovery zone, the Interagency Grizzly Bear Guidelines for Management Situation 1 habitat apply to this management prescription (S)

Ecological Processes and Patterns

Fire/Fuels

Prescribed fire, utilizing both management-ignited and natural ignitions, may be used to maintain fire-dependent characteristics of the area (G)

Physical Elements

Soil and Water

Watershed restoration will be done primarily where deteriorated soil or hydrologic conditions are caused by humans (G)

Promote natural healing where natural vegetation would return in a reasonable time (G)

Use indigenous or appropriate naturalized species to reestablish vegetation where there is no reasonable expectation of natural healing (G)

Permit emergency burned area rehabilitation only if necessary to prevent an unnatural loss of resources (S)

Lands

Establish exterior boundaries of sites when necessary for protection (G)

Minerals/Geology

Same as 1 2 Wilderness Study Area

Forest Use and Occupation

Access (S) - 2 1 1

Season	Type of Access	Cross-Country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian Horse/Pack Stock Mtn Bike/Mechanized	Yes 2/ Yes 2/ No	Yes Yes Yes
Snow free Seasons	Motorized, <50" wide Motorized, >50" wide OROMTRD3/	No No N/A	Yes Yes <= 10 mi/sq mi
Snow Seasons	Winter Nonmotorized Snowmachine	Yes 2/ Yes 2/	Yes Yes

Roads

New road construction may occur if needed to meet the management objectives for the special management area (G)

Recreation

Dispersed - Minimal recreation facilities may be provided (such as trails, board walks, toilets, etc) Generally, such recreation facilities are not encouraged, and are only provided to protect resource values (G)

ROS - Primitive to roaded natural (G)

VQO - Retention to partial retention (G)

Heritage Resource

Multiple user interpretive sites may be provided Avoid indoor interpretive sites unless warranted by special circumstances (G)

Production of Commodity Resources

Range

Livestock grazing and associated developments (such as fencing) are permissible as long as they do not adversely affect the unique resources of the special management area (G)

Timber

These areas are removed from the suitable timber base. They do not contribute to the ASQ (S)

Generally, no timber harvesting will be allowed in special management areas. Exceptions to this may occur on a site-specific basis for such things as public safety, visual quality, long term maintenance of vegetation conditions, etc (G)

2.1.2 VISUAL QUALITY MAINTENANCE

Description

This prescription emphasizes maintaining the existing visual quality within major travel corridors with high quality natural vistas, while allowing livestock production, and other compatible commodity outputs. There is no scheduled timber harvesting.

Overall you may notice signs of people camping by the roadside. The main road system is paved or gravel-surfaced and well maintained, with gentle grades well suited for sedan travel. Vistas of the surrounding areas provide a variety of high quality views.

The roadside area is dominated by a wide variety of vegetation and landscape forms (e.g. mountain peaks, valleys, meadows, streams, etc.) that are easily observed from natural vistas and natural openings along the road. Occasionally, a few older cut areas show tree seedlings, saplings and poles up to 35 feet tall and have a less-disturbed appearing forest floor. Scattered dead trees are seen throughout the forest, but generally it appears healthy and vigorous.

If you watch for wildlife, you may occasionally see an elk, deer or moose in a natural opening or alongside the road, but generally these are hidden from view by the trees. During the summer and fall, you may encounter cattle or sheep grazing in openings. Signs of intensive management practices, such as burning, spraying, seeding, fences, water developments and gates are normally visually compatible.

Nonmotorized activities, such as hiking, biking or horseback riding may originate from trail or road points along the main road. Some roads and nearby areas are available for year-around snowmobile, motorcycle, and 4 wheel-drive vehicle use.

Goals

- 1 Manage these travel corridors to protect their natural visual quality
- 2 Manage these lands in an environmentally sensitive manner to promote the production of noncommodity resources at varying levels, and limited commodity production
- 3 Manage these lands to provide various dispersed recreational opportunities
- 4 Maintain stand vigor by controlling tree density

Standards and Guidelines

Forestwide standards and guidelines apply. The Standards and Guidelines are the same as 5.2.2 except as shown below.

Forest Use and Occupation

Access (S) - 2.1.2

Season	Type of Access	Cross-Country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
Snow free Seasons	Motorized, <50" wide	No	Yes
	Motorized, >50" wide	No	Yes
	OROMTRD 3/	N/A	2/
Snow Seasons	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes
1/ individual roads and trails are designated open or closed in the Forest Plan Travel Maps			
2/ OROMTRD= Open road and open motorized trail. Mute density does not apply to this prescription area.			

Production of Commodity Resources

Timber

These areas are removed from the suitable timber base. They do not contribute to the ASQ (S).

2.2 RESEARCH NATURAL AREAS

Description

These management prescription areas are important ecological or natural areas established for nonmanipulative research, education, and to maintain natural diversity on National Forest system lands. They also may assist in carrying out provisions of special acts, such as the Endangered Species Act and the monitoring provisions of the National Forest Management Act.

These areas are good examples of physical or biological units in which current natural conditions are maintained insofar as possible. These conditions are ordinarily achieved by allowing natural, physical and biological processes to prevail without human intervention.

Nonmanipulative research activities occur in these areas. Some scientific instrumentation may be present. Since these areas are also used for education purposes, occasional groups of people may be present observing and being instructed about the area.

Generally, there are no developed facilities on site. Interpretation of special features will generally be done off site. A road or trail may be present to provide access primarily for research and education purposes. Recreation use is not promoted in these areas, and may be reduced or eliminated if adverse impacts are occurring.

There are nine established **RNAs** on the Targhee National Forest, as follows

Area Name	Year Established	Location	Size Acres	Area Features
Meadow Canyon'	1981	Dubois R D	3880	Alpine Tundra, Rare Plants 1/
Copper Mountain	1987	Dubois R D	550	Alpine Grassland
Thurman Creek	1991	Island Park R D	330	Spring Fed Streams
Moose Creek Plateau	1991	island Park R D	440	Obsidian Sands, Lodgepole Pine 2/
Willow Creek	1987	Ashton R D	1100	Aspen, Lumber Pine, Mtn Maple
Webber Creek	1988	Dubois R D	2245	High Mtn Grassland 1/
Burns Canyon	1996	Palisades R D	490	Sub-alpine Fir/ Ninebark Habitat 3/
Targhee Creek	1996	island Park R D	2640	Wet Meadows, Lakes, Alpine & Subalpine Ecosystems 1/, 2/
Sheep Mountain **	1996	Dubois R D	1542	Alpine Vegetation

This prescription meets the Interagency Grizzly Bear Committee definition for core areas

Goals

- 1 Maintain specially designated areas that provide representation of important terrestrial and aquatic ecosystems on the Forest
- 2 Protect and maintain these areas so that ecological processes prevail in the development of ecosystem composition and structure

Objective

By 2007, in cooperation with the Intermountain Research Station, develop a research plan and monitoring plan for each research natural area

Standards and Guidelines

Forestwide standards and guidelines apply Additional direction for this prescription is listed as follows

Within the grizzly bear recovery zone, the Interagency Grizzly Bear Guidelines for Management Situation 1 habitat apply to this management prescription (S)

Physical Elements

Minerals/Geology

Locatable - Withdraw from mineral entry, or remove from mineral entry through the notation rule, subject to valid existing rights (S)

Mineral Material - This area is not available for mineral material entry (S)

Forest Use and Occupation

Access (S) - 2 2

Season	Type of Access	Cross-Country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian Horse/Pack Stock Mtn Bike/Mechanized	Yes 2/ Yes 2/ No	Yes Yes Yes
Snow free Seasons	Motorized. <50" wide Motorized. >50" wide OROMTRD 3/	No No N/A	Yes Yes 3/
Snow Seasons	Winter Nonmotorized Snowmachine	Yes 2/ Yes 2/	Yes Yes

Recreation

No bear baiting (S)

2.3 ELIGIBLE WILD RIVER

Description

The purpose of this prescription is to maintain and protect the free-flowing character and the "outstandingly remarkable" values which qualify the river to be considered eligible as a Wild River in the National Wild and Scenic Rivers System pending a suitability determination. This prescription shall also be applied to a river determined to be suitable as a Wild River and to a river designated as a Wild River until such time as a Wild River Management Plan can be adopted. In Targhee Creek, this management prescription meets the Interagency Grizzly Bear Committee criteria for grizzly bear core areas (IGBC Task Force Report July 1994).

Wild Rivers are intended to remain as a "vestige of primitive America" with the river corridor, within at least 1/4-mile of the ordinary high water mark on each side of the river, essentially natural and unmodified. Management maintains or improves this undeveloped character, and prevents the degradation or loss of the fish and wildlife, scenic, recreational, cultural, historic, ecologic, or other values which are determined to be outstandingly remarkable. This management prescription provides recreation opportunities that afford a high degree of independence, closeness to nature and self-reliance in an unmodified natural setting.

A few inconspicuous roads and/or motorized trails may lead to the boundary of the river area. This will not disqualify a river segment from study for wild river classification. Motorized travel on land or water could be permitted but is generally not compatible with this prescription. Most existing intrusions of roads and motorized trails would be recommended for restriction or obliteration if designated by Congress.

Interaction between users is infrequent and evidence of resource management activities and other

users is minimal. Motorized use within the area is generally not compatible with this designation. Access is usually cross-country or on constructed trails.

The forest presents a natural appearance. A variety of forest successional stages may be present, ranging from areas with recent wildfires to old growth habitat. Firewood is available for camping, but is not available for home use. Outfitter and guiding activity may be present. Domestic livestock grazing may be present in some areas, and you may see limited range improvements such as fencing. A variety of nonforested rangeland successional stages may be present.

Eligible wild river segments are as follows:

RIVER	INVENTORIED TRIBUTARIES	LOCATION	LENGTH OF SEGMENT (miles)
Robinson Creek	None	From the Yellowstone N.P. boundary to Warm River	12.00
Targhee Creek	West and East Forks of Targhee Creek	Unnamed lake north of Edwards Lake to the boundary with the State section (within recommended wilderness)	12.50 includes tributaries
Henry's Fork of the Snake	None	Riverside Campground to 11.4 mile upstream from Mesa Falls, 11.4 mile downstream from Mesa Falls to Warm River	19.00
Waterfall Canyon	None	From the waterfall to Upper Palisades Lake (within recommended wilderness)	2.00
Palisades Creek	None	From the confluence of the north Fork of Palisades Creek and Corral Canyon to Palisades Campground (within recommended wilderness)	9.00
Darby Creek	North and South Forks of Darby Creek	From the source in the Darby Badlands to the boundary of the Jedediah Smith Wilderness	7.10
North Fork of Teton Creek	South and Roaring Forks of Teton Creek		
Bitch Creek	North and South Bitch Creek	From the source of the North and South Forks in the Jedediah Smith Wilderness to the forest boundary	28.00
Big Elk Creek	North, South and Siddoway Forks	Main stem and the lower two miles of each of the three forks (partly within recommended wilderness)	12.00

Goals

Maintain and protect the free flowing character and the outstandingly remarkable values of the river and corridor which qualify it as a wild river.

In Targhee Creek, maintain grizzly bear core area attributes as defined in the IGBC Task Force Report, July 1994.

Objective

Insects and disease are allowed to play, as nearly as possible, their ecological role in the environment

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below

In Targhee Creek and Robinson Creek, the Interagency Grizzly Bear Guidelines for Management Situation 1 habitat apply to this management prescription

In Bitch Creek, the Interagency Grizzly Bear Guidelines for Management Situation 1 habitat apply, except that livestock grazing in Management Situation 2 (MS2) habitat will continue to be managed under MS2 guidelines (S)

Ecological Processes and Patterns

Insects and Disease

Insect and plant disease epidemics may be controlled to prevent unacceptable damage to resources on adjacent lands or an unnatural loss to the wild river resource due to exotic pests (G)

When control is necessary, it shall be carried out by measures that have the least adverse impact on the wild river resource and are compatible with wild river management objectives (S)

Fire/Fuels

Employ Minimum Impact Suppression Tactics to the maximum extent possible (G)

Physical Elements

Soil and Water

Watershed restoration will be done primarily where deteriorated soil or hydrologic conditions are caused by humans or their influences create a serious threat or loss of outstandingly remarkable river resource values (G)

Promote natural healing where a definite hazard to life or property or important environmental qualities outside and within this prescription area are not imminent, or where natural vegetation would return in a reasonable time (G)

Use indigenous or appropriate naturalized species to reestablish vegetation where there is no reasonable expectation of natural healing (S)

Permit emergency burned area rehabilitation only if necessary to prevent an unnatural loss of outstandingly remarkable river resource values, or to protect life, property, and other resource values outside the area (S)

Minerals/Geology

Locatable - These areas are recommended for withdrawal from mineral activity, or, should be removed from mineral entry through the Notation Rule, subject to valid existing rights. For valid existing claims, design mineral exploration, and development activities to be compatible with this prescription. Apply the following management practices to reduce resource impacts (G)

- 1 Design mineral management activities to maintain the present and continued productivity of fish habitat

- 2 Take maximum advantage of topographic and vegetation screening when locating mining facilities and equipment
- 3 Haul away, bury, burn, or scatter vegetation removed from the project area when vegetation is located adjacent to sensitive travel routes
- 4 Minimize the scale of spoil/disposal areas in relation to the surrounding landscape as seen from sensitive viewpoints
- 5 Use colors that simulate those found in the characteristic landscape. Avoid use of reflective materials in project facilities
- 6 Apply timing restrictions to instream construction as needed to protect fisheries habitat and mitigate adverse disturbance of stream sediments
- 7 Use sedimentation traps as needed to mitigate adverse stream sedimentation and meet State and Federal water quality regulations
- 8 Design reclamation plans so minerals activities leave a natural appearing condition
- 9 Shape landform modifications to simulate naturally occurring forms
- 10 Revegetate disturbed areas in accordance with project plans

Mineral Material -These areas are not available for mineral material entry (S)

Biological Elements

Fisheries, Water and Riparian Resources

Fish habitat will exist/evolve with natural ecological processes. Fish habitat manipulation can only occur if (S)

- 1 The condition needing change is a result of abnormal human influence
- 2 The project can be accomplished with assurance that there will be no serious or lasting damage to wild river values
- 3 There is reasonable assurance that the project will accomplish the desired objectives

Fish stocking of non-native species is allowed where it existed prior to establishment of the Wild River (S)

Wildlife

Reintroduce wildlife species only if the species was once indigenous to the area and was eliminated by human-induced events (S)

Wildlife habitat will exist/evolve with natural ecological processes. Wildlife habitat manipulation can only occur if (S)

- 1 The condition needing change is a result of abnormal human influence
- 2 The project can be accomplished with assurance that there will be no serious or lasting damage to outstandingly remarkable river values
- 3 There is reasonable assurance that the project will accomplish the desired objectives

Forest Use and Occupation

Access (S) - 2 3

Season	Type of Access	Cross-country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	NO	Yes
Snow free Seasons	Motorized. <50" wide	No	No 2/
	Motorized. >50" wide	No	No 2/
	OROMTRD 3/	N/A	0.0 miles/mi 3/
Snow Seasons 4/	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes

1/ individual roads and trails are designated open in the Forest Plan Travel Maps

2/ This use may be allowed where currently existing and it does not degrade the outstandingly remarkable river values

3/ OROMTRD = Open road and open motorized trail route density includes all open roads and open motorized trails. Some open roads and motorized trails may currently exist, most of these intrusions would be recommended for restriction or obliteration if designated by Congress (See Roads in Glossary for more information)

4/ Within grizzly bear BMUs, site-specific restrictions on winter recreation activity (such as area closures, timing restrictions, etc) will be imposed to resolve human-grizzly bear conflicts

Roads

No new roads may be constructed that would change or modify the classification for which the river was designated (S)

Recreation

Dispersed - Recreation facilities will be of a very primitive nature, using a pack-it-in, pack-it-out philosophy (G)

ROS - Primitive to semi-primitive nonmotorized (G)

VQO - Retention (S)

Heritage Resource

Remove structures that do not qualify for the National Register, or allow them to deteriorate naturally unless they are (G)

1 Deemed necessary to support public purposes of wild rivers, or

2 Serve administration purposes

Interpretation of heritage resources located in wild river corridors shall be done outside the corridor (S)

Outfitter/Guide

Permanent caches or nonnative improvements are not allowed unless they existed prior to the establishment of the wild river and have not been phased out. Upon designation of a Wild River, any existing caches will be phased out within two years (S)

Production of Commodity Resources

Range

Minimize conflicts with recreation use (G)

Range developments (water tanks, fences, etc) that do not detract from the overall objectives of the area are acceptable (G)

Timber

Lands are removed from the suitable timber base They do not contribute to the ASQ (S)

Cutting of trees will not be allowed except when needed in association with a primitive recreation experience (such as clearing for trails and protection of users) or to protect the environment (such as control of fire) (G)

2.4 ELIGIBLE SCENIC RIVER

Description

The purpose of this prescription is to maintain and protect the free-flowing character and the "outstandingly remarkable" values which qualify the river to be considered eligible as a Scenic River in the National Wild and Scenic Rivers System pending a suitability determination This prescription shall also be applied to a river determined to be suitable as a Scenic River and to a river designated as a Scenic River until such time as a Scenic River Management Plan can be adopted.

Proposed Scenic Rivers are managed to protect and enhance the outstandingly remarkable fish and wildlife, scenic, recreational, historic, cultural or other values identified for the river, within, as a minimum, 1/4-mile of the ordinary high water mark on each side of the river Moderate levels of existing development, including roads which cross the river but are generally screened from the river banks, are allowed New development and uses must not degrade the values which qualify the river for consideration as eligible Recreation facilities of a rustic design, including boat access, cabins, access roads leading to the river and trails are appropriate The area is managed to provide a waterway and associated shorelines where activities are not visually evident to the casual observer The Scenic River management prescription may provide recreation opportunities which meet high expectations for scenic quality associated with an essentially natural appearing environment and a free-flowing river

Administrative and recreation facilities are screened from the river Nonrecreation special use structures may occur if they meet visual quality objectives and do not degrade the outstandingly remarkable values Recreation facilities are designed to be compatible with the visual quality objectives of the river and corridor Recreation opportunities range from roaded natural to primitive Outfitter and guiding activity may be present

No development of hydroelectric power facilities is permitted New structures that would have a direct adverse effect on river values are not authorized

Lands are open to mineral entry subject to regulations prescribed by the Secretary of Agriculture to protect the free-flowing character and outstandingly remarkable values of the river Existing and new activity must minimize surface disturbance, sedimentation, air pollution, visual impairment, and meet applicable State Water Quality Standards Reasonable access is permitted

Fish and wildlife habitat improvement may occur and is designed to be visually compatible with the scenic qualities of the river and corridor

Roads are generally screened from the river and infrequent road and trail crossings (bridges) may be present. Trails paralleling the river are acceptable.

Domestic livestock grazing may be present in some areas. Range improvements may occur and are designed to be visually compatible with the scenic qualities of the river and corridor.

Forested lands are classified as unsuitable, no scheduled timber harvesting is allowed. Personal use wood cutting is compatible with this land use designation provided that management objectives are met.

Eligible scenic river segments are as follows:

RIVER	INVENTORIED TRIBUTARIES	LOCATION	LENGTH OF SEGMENT (miles)
Buffalo River	None	Buffalo River Springs to the confluence with Elk Creek	5.00
Henry's Fork of the Snake	None	Coffeepot Campground to McCrea's Bridge	4.50
Henry's Fork of the Snake	None	Island Park Dam to Box Canyon Summer Homes	3.00
Henry's Fork of the Snake	None	North boundary of Harriman Park to Pinehaven Subdivision	8.20
Henry's Fork of the Snake	None	From Mesa Falls 1/4 mile upstream and downstream	0.50
Warm River	None	Warm River Springs to the confluence with the Henry's Fork	9.00
Fall River	None	From the Yellowstone Park boundary to the National Forest boundary	11.50
Burns Creek	None	Just west of Crystal Lake to the trailhead	5.00
Big Elk Creek	None	First mile main stem	1.00
Bear Creek	North Fork and Deadman Creek	Main stem west of Palisades reservoir and the two forks	15.00

Goal

Maintain and protect the free-flowing character and the outstandingly remarkable values of the river and corridor which qualify it as a Scenic River.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

In Fall River, the Interagency Grizzly Bear Guidelines for Management Situation 1 habitat apply to this prescription (S).

For those segments of Warm River and Buffalo River lying within the grizzly bear recovery zone, the Interagency Grizzly Bear Guidelines for Management Situation 1 apply to this prescription (S).

Ecological Processes and Patterns

Insects and Disease

Allow sanitation and salvage of infested timber as long as such practices are carried out in such a way that there is no substantial adverse effect on the river and its immediate environment (G)

Fire/Fuels

Same as 2 3 Eligible Wild River

Physical Elements

Soil and Water

Same as 2 3 Eligible Wild River

Lands

Same as 2 3 Eligible Wild River

Minerals/Geology

Same as 2 3 Eligible Wild River

Biological Elements

Fisheries, Water and Riparian Resources

Fish stocking of non-native species is allowed (S)

Wildlife

Same as 2 3 Eligible Wild River

Forest Use and Occupation

Access (S) - 2 4

Season	Type of Access	Cross-Country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
Snow free Seasons	Motorized, <50" wide	No	Yes 2/
	Motorized, >50" wide	No	Yes 2/
	OROMTRD 3/	N/A	3/
Snow Seasons 4/	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes

1/ Individual roads and trails are designated open or closed in the Forest Plan Travel Maps

2/ Motorized use is allowed unless it needs to be prohibited or restricted to protect the river values

3/ OROMTRD= Open road and open motorized trail route density does not apply to this prescription area

4/ Within grizzly bear **BMUs**, site-specific restrictions on winter recreation activity (such as area closures, timing restrictions, etc) will be imposed to resolve human-grizzly bear conflicts

Roads

No new roads may be constructed or road improvements made that would change or modify the classification for which the river was designated (S)

Recreation

Dispersed- Comfort and convenience facilities, such as fireboxes and shelters may be provided as necessary within the river area. These should harmonize with the surroundings and be managed so they do not adversely affect spawning grounds (G)

Maintain existing dispersed campsites that do not degrade the outstandingly remarkable values (G)

Trails - Trails and bridges paralleling or crossing the river are acceptable, provided VQO and ROS objectives for the river and corridor are maintained (G)

No new trails may be constructed or trail improvements made that would change or modify the classification for which the river was designated (S)

ROS - Primitive to semi-primitive motorized (G)

VQO - Retention (S)

Outfitter/Guide

Permanent caches or improvements are allowed if they meet the visual quality management objectives for the river and corridor and are within the Greater Yellowstone Area Outfitter Plan (G)

Production of Commodity Resources

Range

Range management is permitted to the extent it is currently practiced and does not degrade river values (G)

Range developments (water tanks, fences, etc) that do not detract from the overall objectives of the area are acceptable (G)

Manage allotments at FRES levels B, C, or D (G)

Timber

Lands are not included in the suitable timber base. They do not contribute toward the ASQ (S)

Personal use wood cutting is allowed with restrictions to protect the outstanding remarkable values (G)

2.5 ELIGIBLE RECREATION RIVER

Description

The purpose of this prescription is to maintain and protect the essentially free-flowing character and the outstandingly remarkable values which qualify the river to be considered eligible as a Recreational River in the National Wild and Scenic Rivers System pending a suitability determination. This prescription shall also be applied to a river determined to be suitable as a Recreation River and to a river designated as a Recreation River until such time as a Recreation River Management Plan can be adopted.

Proposed Recreational Rivers are managed to protect the outstandingly remarkable fish and wildlife, scenic, recreational, historic, cultural or other values identified for the river, within, as a minimum, 1/4 mile of the ordinary high water mark on each side of the river. The area may include significant human development, residences, roads and highways, and minor existing modifications to the waterway, including diversion dams. Major water resource projects are not authorized. The area may include landscapes in a variety of visual conditions. Activities and structures may be dominant in some areas, but harmonize and blend with the generally natural-appearing environment to provide a pleasing setting for recreation activities. This management area prescription may provide recreation opportunities where the interaction between users may be moderate-to-high with evidence of current and past use prevalent. Roads are designed for conventional motorized vehicles. Facilities may exist for boat or aircraft use.

Allowed motorized use within the area may include boats, aircraft, snowmachines, construction and maintenance of needed facilities. Motorized land travel for recreation purposes may be restricted. All scheduled resource management activities are integrated in such a way that the recreation and water quality values remain paramount.

Administrative and recreation facilities are located and designed to complement and facilitate area management. Recreation opportunities range from semi-primitive nonmotorized to rural. Outfitter and guiding activity may be present.

To the extent of Forest Service authority, no development of hydroelectric power facilities is permitted. New structures that would have a direct adverse effect on river values are not authorized.

Lands are open to mineral entry subject to regulations prescribed by the Secretary of Agriculture. Existing and new activity must minimize surface disturbance, sedimentation, air pollution, visual impairment, and meet applicable State Water Quality Standards. Reasonable access is permitted.

Forested lands are classified as unsuitable, no scheduled timber harvesting is allowed. Personal use woodcutting is compatible with this land use designation provided that management objectives are met.

Design and location of roads and facilities provide for conventional motorized use. User safety and opportunities for nonmotorized recreation activities may be provided by restricting motorized use to designated routes and areas. Both motorized and nonmotorized trail opportunities may be provided.

Fish projects may be identified and implemented which create or improve fishing opportunity. Wildlife habitat emphasis is on maintaining healthy and productive habitat conditions for indigenous species and improving wildlife viewing opportunities.

Domestic livestock grazing may be present in some areas. Range improvements may occur and are designed to be compatible with the recreational qualities of the river and corridor.

Eligible Recreation River segments are as follows

RIVER	INVENTORIED TRIBUTARIES	LOCATION	LENGTH OF SEGMENT (miles)
Buffalo River	None	Confluence with Elk Creek to the backwaters of Pond's power dam	2 00
Henry's Fork of the Snake	Henry's Lake Outlet, Moose Creek	Big Springs to Coffeepot Campground, Outlet from Forest boundary to junction with Big Springs outflow. Moose Creek from source to junction with Henry's Fork	19 4 includes pail of Outlet and Moose Cr
Henry's Fork of the Snake	None	Box Canyon Summer Homes to the North boundary of Harriman State Park	1 80
Henry's Fork of the Snake	None	Pinehaven Subdivision to Riverside Campground	3 00
Pine Creek	West, North Pine Creek	Tie Canyon SW to Forest boundary	7 5

Consider the use of indigenous or appropriate naturalized species to reestablish vegetation where there is no reasonable expectation of natural healing (G)

Permit emergency burned area rehabilitation only if necessary to prevent an unnatural loss of Recreational River resource values, or to protect life, property, and other resource values outside the area (S)

Lands

Same as 2 3 Eligible Wild River

Minerals/Geology

Same as in 2 3 Eligible Wild River

Biological Elements

Fisheries, Water and Riparian Resources

Fish stocking of non-native species is allowed (S)

Wildlife

Same as 2 3 Eligible Wild River

Forest Use and Occupation

Access (S) - 2 5

Season	Type of Access	Cross-country Travel	Road and Trail Travel 1/
Snow tree Seasons	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes

	MotORIZED, >50" wide	No	Yes 2/
	OROMTRD 3/	N/A	3/
Snow Seasons 4/	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes

Recreation

Dispersed - All forms of recreation facilities may be provided, such as boat access points, trails, toilets, fire rings, grills, garbage collection, etc. Facilities are designed to be compatible with the ROS and VQO of the river and corridor and should be managed so they do not adversely affect spawning grounds (G)

Close the Henrys Fork of the Snake River from its headwaters at Big Springs downstream to the Big Springs boat launch, to all human entry including rafting, innertubing, swimming, wading, fishing and other motorized and nonmotorized activities, to protect fish habitat and other resource values (S)

Trails - Trails and bridges paralleling or crossing the river are acceptable, provided VQO and ROS objectives for the river and corridor are maintained (G)

- Both motorized and nonmotorized trail opportunities may exist (G)
- New trails could be constructed on one or both river banks. There can be several bridge crossings and numerous river access points (G)

ROS - Semi-primitive nonmotorized to urban (G)

VQO - Partial retention VQO in the foreground as seen from the river, roads, trails and recreational facilities (S)

- Modification to maximum modification for all other areas within the corridor (G)

Outfitter/Guide

Permanent caches or improvements are allowed if they meet the visual quality management objectives for the river and corridor and are within the Greater Yellowstone Area Outfitter Plan (G)

Production of Commodity Resources

Range

Range developments (water tanks, fences, etc) that do not detract from the overall objectives of the area are acceptable (G)

Manage allotments at FRES levels B, C, or D (G)

Timber

Lands are not included in the suitable timber base. They do not contribute to the ASQ (S)

Personal use wood cutting is allowed with restrictions to protect the outstandingly remarkable values (G)

2.6.1 (a) GRIZZLY BEAR HABITAT (NO ASQ, NO CROSS-COUNTRY, NO SHEEP)

Same as 5 3 5 except

Forest Use and Occupation

Access (S) - 2 6 1 (a)

Season	Type of Access	Crosscountry Travel	Road and Trail Travel 1/

Production of Commodity Resources

Range

No domestic sheep grazing is allowed (S)

Timber

Lands are not included in the suitable timber base They do not contribute to the ASQ (S)

2.6.2 GRIZZLY BEAR CORE AREA

Description

The core area is defined as an area that provides a predictable refuge in space and time for a bear population segment or family unit This area is consistently available for use by wary bears while activities occur elsewhere The core area contains moderate to high quality bear foods, provides predictable and consistently available space to meet seasonal bear habitat needs, and achieves the lowest mortality risk possible due to human activities for a period not less than 11 years Management activities shall follow established rules The primary emphasis for this area is on providing secure habitat for grizzly bears

This is a refugium of high quality habitat available to bears where management activities do not occur during the period bears are active Habitat conditions provide space that is consistently available and

predictably locatable to bears. This area provides a portion of the foraging requirement for a reproductive female and a female's offspring for spring, summer, and fall foraging away from human activities. Secure habitat exists, and mortality risk to bears is low.

This prescription meets the Interagency Grizzly Bear Committee definition for core areas.

Goals

1. Insects and diseases are allowed to play their natural role in ecosystem development.
2. Any nonfederal lands within this area will be a high priority for acquisition.
3. Manage dispersed recreation to minimize grizzly conflicts with humans.

Objective

A fire management plan will be developed (and will be coordinated with any adjacent wilderness fire plans) to address wildfires.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

The Interagency Grizzly Bear Guidelines for Management Situation 1 Habitat apply to this management prescription.

Ecological Processes and Patterns

Fire/Fuels

No prescribed fire is allowed (S)

In the event of a fire that warrants suppression, only minimum impact suppression techniques will be allowed (S)

Physical Elements

Minerals/Geology

Same as 2-3 Eligible Wild River

Biological Elements

Wildlife

No wildlife habitat improvement projects are allowed (S)

Forest Use and Occupation

Access (S) - 2 6 2

Season	Type of Access	Crosscountry Travel	Road and Trail Travel 1/

	Motorized, >50" wide	NO	NO
	TMARD 2/	N/A	
	OROMTRD 2/	N/A	0.0 mi/sq mi
Snow Seasons 3/	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes

31 Within grizzly bear BMUs, site-specific restrictions on winter recreation activity (such as area closures, limiting restrictions, etc.) will be imposed to resolve human-grizzly bear conflicts

Roads

Construct no new roads (S)

Recreation

Special Uses - No special uses are allowed from April 1 to December 15 (S)

Trails - Construct no new trails (S)

ROS - Primitive to semi-primitive nonmotorized (G)

VQO - Retention (S)

Heritage Resource

No new interpretation/enhancement of cultural sites (S)

Outfitter/Guide

No outfitter and guide permits are allowed from April 1 to December 15 (S)

Production of Commodity Resources

Range

No livestock grazing permits of any kind are allowed (S)

Timber

Lands are not included in the suitable timber base. They do not contribute to the ASQ (S)

No vegetation management of any kind will occur (S)

2.6.5 GRIZZLY BEAR SECURITY AREA

Description

This area is consistently available for use by wary bears while activities occur elsewhere. This area contains moderate to high quality bear foods, provides predictable and consistently available space to meet seasonal bear habitat needs, and achieves the lowest mortality risk possible due to human activities for a period not less than the planning period. Management activities shall follow established rules. Emphasis for this area is on providing secure habitat for grizzly bears.

This is an area of high quality habitat available to bears where management activities are limited during the period bears are active. Habitat conditions provide space that is consistently available and predictably locatable to bears. This area provides a portion of the foraging requirement for a reproductive female and offspring for spring, summer, and fall foraging.

This prescription meets the Interagency Grizzly Bear Committee definition for core areas.

Goals

1. Insects and diseases are allowed to play their natural role in ecosystem development.
2. Any nonfederal lands within this area will be a high priority for acquisition.
3. Activities which adversely affect grizzly bear populations and/or their habitat will not be allowed.
4. Manage dispersed recreation to minimize grizzly conflicts with humans.

Standards and Guidelines

The Interagency Grizzly Bear Guidelines for Management Situation 1 habitat apply to this management prescription, except that livestock grazing in existing Management Situation 2 habitat will continue to be managed under Management Situation 2 guidelines.

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes and Patterns

Fire/Fuels

Prescribed fire is allowed to maintain or improve grizzly bear habitat (G).

Physical Elements

Minerals/Geology

Same as 2.3 Eligible Wild River.

Biological Elements

Wildlife

1. Inventory, monitoring, and short duration activities such as trail maintenance, spraying weeds, range maintenance activities, wildlife habitat improvement, etc., should be concentrated in time and space (G).

2. Wildlife habitat improvement projects are permitted which maintain grizzly bear habitat (G).

Forest Use and Occupation
Access (S) - 2 6 5

Season	Type of Access	Cross-Country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian Horse/Pack Stock	Yes Yes Yes	Yes Yes Yes
Snow free Seasons	Motorized, <50" wide TMAARD 2/ OROMTRD 2/	No N/A N/A	No No 00 m/sq m R
Snow Seasons 3/	Winter Nonmotorized Snowmachine	Yes Yes	Yes Yes

1/ Individual roads and trails are designated open or closed in the Forest Plan Travel Maps

2/ TMAARD = Total motorized access route density includes all open and restricted roads and motorized trails (See Roads in Glossary for more information) Unless a figure is specified here, this is calculated on a BMLU or subunit basis Please refer to the Forestwide standards and guidelines for Access

OROMTRD = Open road and open motorized trail route density includes all open roads and open motorized trails (see Roads in Glossary for more information) Unless a figure is specified here, this is calculated on a BMLU or subunit basis Please refer to the Forestwide standards and guidelines for Access

Two roads are designated open through this prescription area the Ashton/Flag Ranch Road (#261) and the Jackass Loop Road (#264)

3/ Within grizzly bear BMLUs site-specific restrictions on winter recreation activity (such as area closures, timing restrictions, etc) will be imposed to resolve human-grizzly bear conflicts

Roads
Same as 2 6 2 Grizzly Bear Core Area

Recreation
Special Uses

1 No new special uses are allowed from April 1 to December 15 (S)

2 Existing special use permits may be transferred (G)

Trails - Construct no new trails (relocating existing trails to maintain or improve habitat is permitted) (S)

ROS - Primitive to semi-primitive motorized (G)

VGO - Retention (S)

Heritage Resource

Same as 2 6 2 Grizzly Bear Core Area

Outfitter/Guide

No new outfitter and guide permits are allowed from April 1 to December 15 (S)

Production of Commodity Resources

Range

Forestwide standards and guidelines apply for the management of domestic sheep grazing in Management Situation 2 grizzly bear habitat (G)

Cattle grazing is allowed Allotment Management Plan will specify measures to meet agency grizzly goals and objectives (S)

Permittee's full compliance in meeting grizzly bear management goals and objectives for grizzly bear habitat will be a condition of the permit In addition, the following will be required (S)

1 Temporary cessation or modification of permitted livestock grazing activities will occur to resolve grizzly bear conflicts with humans or livestock

2 Livestock carcasses will be disposed of or rendered unattractive to bear within **24** hours after they are discovered Disposal may include removing the carcass from the area, burning, using an acceptable chemical repellent, or other methods approved by the District Ranger Disposal shall be in accordance with other governing agencies (such as the Wyoming Game and Fish Department) in order to determine cause of death for reimbursement purposes

3 Human food, refuse, and prepared livestock/pet foods associated with the livestock operation will be made unavailable to grizzlies through proper storage, handling, and disposal Proper storage includes a) inside a bearproof container, b) suspended horizontally from adjacent posts or trees, c) stored in a hard-sided vehicle or trailer, or d) other methods approved by the District Ranger The exception is when the food is being eaten or prepared for eating, or when food and similar organic matter is being transported Unburned human foods, garbage or other refuse will be carried off the Forest as often as practical

4 High quality food production areas for grizzlies such as wet alpine and subalpine meadows, stream bottoms, aspen groves, and other riparian areas will receive special grazing direction such as light, once-over grazing, special utilization standards, or complete closure These sites and their corresponding direction will be identified in the Annual Operating Plan

5 Livestock depredation believed to be associated with bears will be reported within **24** hours after they are discovered to the District Ranger and the proper State agencies

6 Any observation of grizzly bear or grizzly bear sign will be reported to the District Ranger as soon as practical

7 Any action taken by the permittee or their agents which violates the Endangered Species Act will be grounds for cancellation of their grazing permit

Timber

Lands are not included in the suitable timber base They do not contribute to the ASQ (S)

No firewood harvest is allowed other than for dispersed camping (S)

2.7 (a-b) ELK & DEER WINTER RANGE

Description

This management prescription emphasizes management actions and resource conditions which provide quality elk and deer winter habitat. Habitats are managed for multiple land use benefits, to the extent these land uses are compatible with maintaining or improving elk and deer winter habitat.

These areas are "crucial mid-to-late" natural winter ranges for deer and elk. These are the winter range areas which are considered to be the determining factor in a population's ability to maintain itself at a certain level over the long term. Moose, antelope and bighorn sheep may also be present.

Vegetation management occurs to maintain or improve winter habitat conditions. Winter range forage is abundant, includes a good mixture of grasses, forbs, and shrubs, and is well distributed throughout the area. Cover is maintained and well distributed.

Access is managed or restricted to provide security for wintering elk and deer. Area closures are emphasized where terrain and vegetation allow OHV use, with motorized use occurring only on designated routes.

Livestock grazing, timber management, recreation, and other resource management activities can occur as long as desired vegetation range conditions are being maintained.

Goals

- 1 Provide quality elk and deer winter range
- 2 Minimize forage use conflicts between big game and livestock on the winter range
- 3 Forested vegetation is managed to maintain or improve cover *or* forage conditions needed for wintering deer and elk
- 4 Nonforested vegetation is managed to maintain or improve forage production needed for wintering deer and elk
- 5 Minimize human disturbance to wintering big game animals

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed as follows:

Ecological Processes and Patterns

Fire/Fuels

Prescribed fire is allowed to maintain or improve winter habitat and enhance ecological conditions (G)

Forest Use and Occupation

Access (S) - 2 7 (a)

Season	Type of Access	Cross-Country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian Horse/Pack Stock Mtn Bike/Mechanized	Yes 2/ Yes 2/ Yes 2/	Yes Yes Yes
Snow free Seasons	Motorized, <50" wide Motorized, >50" wide OROMTRD 31	No No N/A	Yes Yes <= 2 0 mi/sq mi
Snow Seasons	Winter Nonmotorized Snowmachine	No NO	Yes 41 Yes 41

Access (S) - 2 7 (b)

Season	Type of Access	Cross-country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian Horse/Pack Stock Mtn Bike/Mechanized	Yes Yes Yes	Yes Yes Yes
Snow free Seasons	Motorized, <50" wide Motorized, >50" wide OROMTRD 2/	No No N/A	Yes Yes <= 2 0 mi/sq mi 2/
Snow Seasons	Winter Nonmotorized Snowmachine	Yes No	Yes Yes 31
<p>1/ Individual roads and trails are designated open or closed in the Forest Plan Travel Maps</p> <p>2/ OROMTRD = Open road and open motorized trail route density includes all open roads and open motorized trails (See Roads in Glossary for more information)</p> <p>In 2 7 (b) Prescription areas <= 4 0 sq mi in size, OROMTRD does not apply</p> <p>31 Snowmachine use will be restricted to 50 feet on either side of a designated road or trail</p>			

Recreation

Dispersed- Manage recreation sites to maintain winter habitat conditions Minimal recreation facilities may be provided (such as hitch rack, rudimentary toilets, etc) Generally, recreation facilities are not encouraged (G)

ROS - Semi-primitive nonmotorized to roaded natural (G)

VQO - Retention to modification (G)

Heritage Resource

No new interpretation/enhancement of cultural sites (S)

Production of Commodity Resources

Timber

These areas are not part of the suitable timber base They are not part of the **ASQ** (S)

2.8.3 AQUATIC INFLUENCE ZONE

Description

This prescription applies to the aquatic influence zone associated with lakes, reservoirs, ponds, perennial and intermittent streams, and wetlands (such as wet meadows, springs, seeps, and bogs) These areas control the hydrologic, geomorphic, and ecological processes that shape the various water types mentioned above and directly affect aquatic life They also provide unique habitat characteristics which are important to those plant and animal species which rely on aquatic, wetland, or riparian ecosystems for all or a portion of their life cycle Many such habitats are locally rare or are sensitive to disturbance (such as fens and thermal springs) Overall, these areas serve as important reservoirs of biodiversity, critical linkages for the interchange of plant and animal genetic material, specialized areas of nutrient cycling and freshwater filtration, storage, and transport, and are important to water quality

Management emphasis is directed at the application of ecological knowledge to restore and maintain the health of these areas in ways that also produce desired resource values, products, protection, restoration, enhancement, interpretation, and appreciation of these areas

These aquatic influence zones provide a high level of aquatic protection and maintain ecological functions (e.g., sediment transport, microclimate control, nutrient regulation, and connectivity within the watershed) and processes (e.g., stream channel formation, plant community development, recruitment of organic material including large wood, and hydrologic cycles) necessary for the restoration and maintenance of habitat for aquatic and riparian dependent organisms They also maintain future management options

This management prescription is defined on the ground using boundary widths which may vary by water type, and geographic characteristics The actual boundaries of the aquatic influence zone, as determined by a person having current knowledge of fluvial geomorphology, of stream-riparian ecology, or both, could be narrower or wider than the prescribed boundary widths

The five basic water types found on the Forest are

- 1 Fish-bearing Stream Reaches,
- 2 Perennial Non-fish-bearing Stream Reaches,
- 3 Lakes,

4 Reservoirs, Ponds and Wetlands Greater Than One Acre,

5 Intermittent Streams, and Wetlands Less Than One Acre

In cases of overlap, this prescription prevails over all other prescriptions except the following

Designated Wilderness - Opportunity Class I (Prescription 1 1 6)

Designated Wilderness - Opportunity Class II (1 1 7)

Designated Wilderness - Opportunity Class III (1 1 8)

Wilderness Study Area (I 2)

Recommended Wilderness (1 3)

Special Management Areas (2 1 1)

Research Natural Areas (2 2)

Eligible Wild River (2.3)

Eligible Scenic River (2 4)

Eligible Recreation River (2 5)

South Fork Eligible Scenic River (2 9 1)

South Fork Eligible Recreation River (2 9 2)

Developed Recreation Sites (4 1)

Special Use Permit Recreation Sites (4 2)

Dispersed Camping Management (4 3)

Concentrated Development Areas (8 1)

Where this prescription area runs through areas which meet the IGBC definition for core areas, this prescription area also meets the IGBC definition for core areas

Goals

- 1 Minimize adverse effects to aquatic and riparian dependent species from past, existing and proposed management activities
- 2 Allow endemic levels of insects and disease to play their natural role in ecological succession, compatible with other resource objectives
- 3 Manage wood residue (natural and human-made), including fuelwood, to maintain or restore ecological health and function
- 4 Coordinate with Idaho Fish and Game, Wyoming Game and Fish, and other interested individuals or groups, to identify and evaluate potential beaver reintroduction sites Support reintroductions into areas that would benefit from beaver activity and where conflicts with other uses have been resolved

Objective

- 1 Within five years of the Record of Decision, all existing roads, trails, culverts, fords and stream crossings within these lands will be inventoried and evaluated as to whether they meet management prescription goals Those that do not meet management prescription goals will be scheduled for restoration or obliteration

Standards and Guidelines

Forestwide standards and guidelines apply Riparian forage utilization standards are found in the forest-wide standards and guidelines for Range Additional direction for this prescription is listed below

Boundary widths for the five water types apply until a site-specific analysis is completed The slope

distances specified for boundary widths in the five water types will vary by ecological subsection. Following are the slope distances of boundary widths, in feet, by ecological subsection (G)

BOUNDARY WIDTHS OF WATER TYPES, BY SUBSECTIONS

Water Type			
	3,4	2	1,5,6,7
Fish-bearing Stream Reaches 1/	150	200	300
Perennial Nonfish-bearing Stream Reaches 1/	75	75	150
Lakes 2/	150	200	300
Reservoirs, Ponds, Wetlands Greater Than One Acre 3/	75	75	150
Intermittent Streams, Wetlands Less Than One Acre 4/	75	75	100
<p>1/ The boundary width is the slope distance on both sides of the stream, in feet, measured from the edge of the stream, or the area from the edge of the active stream channel to the outer edges of the riparian vegetation, whichever is greater</p> <p>2/ The boundary width is the slope distance specified, in feet, measured from the high water mark of the lake, or the area from the high mark of the lake to the outer edge of the riparian vegetation or seasonally saturated soil, whichever is greater</p> <p>3/ The boundary width is the slope distance specified, in feet, measured from the edge of the body of water (edge is defined as the maximum pool elevation of the water body), or the wetland area to the outer edges of the riparian vegetation, whichever is greater</p> <p>4/ The boundary width is the slope distance on both sides of the intermittent stream, in feet, measured from the edge of the stream, or the wetland area to the outer edges of the riparian vegetation, whichever is greater</p>			

Ecological Processes and Patterns

Insects and Disease

Where catastrophic insect and disease damage results in degraded riparian conditions, unscheduled timber harvest (salvage and commercial fuelwood cutting) is allowed where needed to attain the goals of this management prescription providing other goals of this management prescription are not adversely affected (G)

Fire/Fuels

Avoid locating bases, camps, helibases, staging areas, helispots, hazardous material storage facilities, and other centers for incident activities within these lands. If the only suitable location for such activities is within this area, an exception may be granted following a review and recommendation by a resource advisor. The resource advisor will prescribe the location, use conditions, and rehabilitation requirements (G)

Avoid application of chemical retardant, foam, or additives in these areas. Exceptions may be warranted in situations where overriding safety concerns exist, or following a review and recommendation by a resource advisor, when an escape would cause more long-term damage (G)

Prescribed fire activities on adjacent lands must be compatible with management prescription goals. (S)

Use minimum impact suppression methods (G)

Physical Elements

Lands

Avoid locating utility corridors and their access roads in these lands whenever possible (G)

Minerals/Geology

Adequate reclamation plans and bonds are required in mining plans of operation. These bonds must cover the full costs of removing facilities, equipment, and materials, recontouring disturbed areas to near pre-mining topography, isolating and neutralizing or removing toxic or potentially toxic materials, salvaging and replacing topsoil, and preparing seedbeds and revegetating to meet management prescription goals (S)

Do not locate permanent structures or facilities within these lands (S)

Do not locate waste dumps, leaching pads, and other facilities within these lands where other alternatives are available. If no other alternative exists, ensure that safeguards are in place to prevent release or drainage of toxic or other hazardous materials onto these lands (S)

Do not allow debris, overburden, and other materials associated with mining activities to be placed within these lands if other alternatives are available. If no alternative is available, place them outside the active floodplain and outside the Stream Protection Zones defined by the state. In either case, place them in such a manner as to prevent their entry by erosion, high water, or other means into stream channels (S)

Discourage mineral material extraction (subject to valid permitted rights, or where permitted by plans of operation) (G)

Plans of operation will be consistent to the fullest extent possible with management prescription goals (G)

Biological Elements

Wildlife

Strive to maintain dead and defective tree habitat at a level capable of supporting 100 percent potential populations of the management indicator species for primary cavity excavators. (G)

Forest Use and Occupation

Access (S) - 2 8 3

Season	Type of Access	Cross-Country Travel 2/	Road and Trail Travel 1/
Snow free Seasons	Pedestnan	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
Snow free Seasons	Motonzed, <50" wide	No	Yes
	Motonzed, >50" wide	No	Yes
	OROMTRD 3/	NA	3/
Snow Seasons 4/	Winter Nonmotonzed	Yes	Yes
	Snowmachine	Yes	Yes

1/ Individual roads and trails are designated open or closed in the Forest Plan Travel Maps

2/ When cross-country travel is found to result in soil displacement in excess of 15 percent of an activity area, or alternation of natural stream channel morphology, reduce impacts through education, use limits, more intensive maintenance, facility modification, and/or closures

3/ OROMTRD= Open road and open motonzed trail route density includes all open roads and open motorized trails. The acres in this prescription area and the OROMTRD will be included in the calculations with the acres and OROMTRD in adjacent upland prescription areas (See Roads in Glossary for more information)

4/ Within grizzly bear BMUs, site-specific restrictions on winter recreation activity (such as area closures, timing restrictions, etc) will be imposed to resolve human-grizzly bear conflicts

Containers holding more than five gallons of spare vehicle fuel should be stored outside the AIZ or stored in such a way as to prevent leakage into riparian areas. Vehicle refueling should be done in a way that avoids contamination of water bodies (G)

Roads and Trails

No new roads, trails, or landings will be constructed within these lands until appropriate standards for construction, maintenance, and operations are in place (G)

Improve, seasonally close, close, relocate and stabilize, or obliterate roads and trails that have been identified as posing a high risk of causing unnaturally high levels of sediment input or are known to be doing so. Action to be taken will be determined based on travel management needs, terrain, the need for the road or trail, the potential environmental impacts, and resource priorities (G)

Roads and trails or sections of them that have been identified as inhibiting riparian, wetland or aquatic ecosystem processes and/or functions (e.g., plant community development, sediment transport, and stream channel development) will be improved, relocated, or obliterated. The decision to improve, relocate, or obliterate will be based on the potential environmental impact, the ecological condition of the riparian, wetland and aquatic resources affected, and the need for the road or trail (G)

Culverts and stream crossings found to pose a risk to riparian, wetland or aquatic conditions will be improved to accommodate at least a 50-year flood, including associated bedload and debris (G)

New stream crossings will be constructed and maintained to prevent diversion of streamflow out of the channel and down the road in case of failure. In locations found to have high potential for failure, the roadway will be hardened to further lessen the chance of roadway failure or severe erosion should the crossing overtop (G)

Constructed temporary stream crossings, such as log and culvert installations, may be allowed if temporary crossings will be constructed and used in such a way as to minimize sediment input and to provide for fish passage. They will be maintained during use and removed and rehabilitated as soon as they are no longer needed (G)

Construct, reconstruct, and maintain all road and trail crossings of streams which currently or historically bear fish to provide for fish passage. Exceptions are allowed where it is necessary to restrict fish movements in order to protect native or desirable nonnative fish populations (G)

Conserve surfacing materials and protect riparian resources, by properly maintaining roads and avoiding side casting during road maintenance activities (G)

Recreation and Outfitter/Guide

When dispersed recreation is found to result in soil disturbance in excess of 15 percent of an activity area, or alteration of natural stream channel morphology, address impacts through education, use limits, more intensive maintenance, facility modification, and /or closures (G)

Recreational grazing must meet range standards for utilization of riparian vegetation (S)

Permitted stock holding, watering, and handling facilities within riparian vegetation (may not include the entire AIZ boundary) are allowed only if appropriate mitigation measures are implemented to reduce negative impacts (S)

ROS - Primitive to urban (G)

VQO - Retention to modification (G)

Production of Commodity Resources

Range

Incorporate into AMPs, objectives for attainment of desired vegetation conditions for riparian plant community seral stage development and stream channel condition (G)

Proposed livestock watering facilities, corrals, and holding pastures within these lands are allowed only if appropriate mitigation measures are implemented to reduce negative impacts (S)

Existing livestock watering facilities, corrals, and holding pastures within these lands are allowed at permit issuance only if mitigation measures are implemented to reduce negative impacts (G)

Timber

These lands are not included in the suitable timber base. They are not part of the ASQ (S)

Where needed to attain management prescription goals, design silvicultural prescriptions and allow prescribed burning and stocking control, as well as the reestablishment and culturing of stands to attain desired vegetation characteristics (G)

Mechanized treatment of wood residue is minimized (G)

Burning of mechanized treated wood residues within the bankfull channel is prohibited (S)

Where catastrophic events such as fire or windstorms result in degraded riparian conditions, unscheduled timber harvest (salvage and commercial fuelwood cutting) may be selected as the most desirable management practice (G)

2.9.1 SOUTH FORK ELIGIBLE SCENIC RIVER

Description

This prescription applies to the portion of the South Fork of the Snake River that has been determined to be an eligible scenic river, consisting of the water surface, islands, sand bars, riparian vegetation, and adjacent uplands from Conant Valley powerline downstream to Riley Diversion (17 miles)

Within this corridor are campgrounds, picnic sites, boating sites/ramps, and other facilities such as trailheads, scenic and wildlife viewing areas, fishing access points and inventoried National Forest recreationsites selected for potential development. Development ranges from native material roads and campsites, with nonflush toilets, to a high degree of site modification with comfort and convenience facilities including paved roads, water systems, flush toilets, and boat launches.

Overall, you notice signs of people, generally oriented toward water use. Drifting downstream in a boat, you notice roads, buildings, picnic tables, camping spots and, occasionally, people fishing along the river bank. You hear sounds of vehicles and other human activity. You will see powerlines across the river from time to time. Other stretches of river have few roads or developments and provide a relatively quiet, peaceful, natural setting.

As you float you often see stands of cottonwood, most of them mature. In and around these cottonwood stands you may see bald eagles or peregrine falcon perched in trees, or great blue heron on the ground. During the winter you may see elk, moose, and deer on adjacent slopes.

During the summer, livestock may be seen grazing next to the river and on nearby slopes.

The management direction contained in the Snake River Activity/Operations Plan, as developed between the U S Forest Service and the Bureau of Land Management and signed in February 1991, applies to this area. This management direction will be adjusted (if necessary) to reflect direction from the required suitability study.

Goals

1. Maintain the river's scenic values.
2. Maintain or enhance critical nesting, foraging and wintering areas for bald eagles, maintain big game winter range and improve unsatisfactory big game habitat. Maintain heron rookeries and improve goose nesting opportunities.

Standards and Guidelines

Manage this area according to the standards and guidelines established in the Snake River Activity/Operations Plan (U S Forest Service & Bureau of Land Management, February 1991), except for the direction shown below (S).

Physical Elements

- Minerals/Geology
Same as 2.3 Eligible Wild River

Forest Use and Occupation

Access (S) - 2 9 1

Season	Type of Access	Cross-Country Travel	Road and Trail Travel 1/

2/ OROMTRD= Open road and open motorized trail route density does not apply to this prescription area			

2.9.2 SOUTH FORK ELIGIBLE RECREATION RIVER

Description

This prescription applies to the portion of the South Fork of the Snake River that has been determined to **be** an eligible recreation river, consisting of the water surface, islands, sand bars, riparian vegetation, and adjacent uplands

The rest of the description is the same as the scenic portion of the river (2 9 I)

Goals

Goals are the same as the scenic portion except

Maintain the river's recreation values, from Palisades Dam to Conant Valley powerline, some 165 miles

Standards and Guidelines

Same as 2 9 1 S Fork Eligible Scenic River

3.1.1 (a) NONMOTORIZED

Description

This management prescription identifies areas where semi-primitive nonmotorized recreation **use**, like hiking and horseback riding, will occur during the summer months. The experience is similar to a primitive experience, but does allow some motorized use, like chainsaws for summer trail maintenance, snowmachines during the winter, and helicopters. Groomed snowmachine trails are not allowed.

These areas are accessible by trails or cross-country, you find no usable roads. All-terrain vehicles and motorcycles cannot use the area. Encounters with other people diminish as you move away from nearby roads and trailheads. Generally, you experience a backcountry setting with a high likelihood of solitude. However, you may occasionally meet large groups.

You may find oversnow vehicles, helicopter use, stock tanks, or fences. Otherwise, the forest generally presents a natural appearance. A variety of forest seral stages may be present, ranging from areas with recent wildfires to old growth habitat. Firewood is available for camping, but is not generally available for home use. Outfitter and guiding activity may be present. Domestic livestock grazing may be present in some areas, and you may see range improvements such as fencing and stock tanks. A variety of nonforested rangeland seral stages may be present.

Goals

1. Maintain or enhance semi-primitive nonmotorized dispersed recreation opportunities outside of the winter season.
2. Prescribed natural fire and manager-ignited fire will be managed to maintain fire's ecological role and to enhance habitat.
3. Allow insects and disease to play their natural role in ecological succession, compatible with other resource objectives.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes and Patterns

Fire/Fuels

The emphasis will be on prescribed natural fire whenever conditions permit. (G)

Employ Minimum Impact Suppression Tactics (MIST) to the maximum extent possible. (G)

Physical Elements

Soil and Water

Watershed restoration will be done primarily where deteriorated soil or hydrologic conditions are caused by humans or their influences create a serious threat or loss of resource values. (G)

Promote natural healing where a definite hazard to life or property or important environmental qualities outside and within this prescription area are not imminent, or where natural vegetation would return in a reasonable time. (G)

6

Use indigenous or appropriate naturalized species to reestablish vegetation where there is no reasonable expectation of natural healing (G)

Permit emergency burned area rehabilitation only if necessary to prevent an unnatural loss of semi-primitive nonmotorized resources or to protect life, property, and other resource values outside the area (S)

Minerals/Geology

Same as 1 2 Wilderness Study Area

Forest Use and Occupation

Access (S) - 3 1 1 (a)

Season	Type of Access	Cross-country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
Snow free Seasons	Motorized, <50" wide	No	No 2/
	Motorized, >50" wide	No	No 2/
	OROMTRD 3/	N/A	0 0 mi/sq mi 3/
Snow Seasons	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes

1/ Individual roads and trails are designated open or closed in the Forest Plan Travel Maps

2/ Motorized use is not allowed, except that motorized equipment is allowed for trail construction/maintenance. Motorized transport of Forest Service employees is not allowed except on contracts where motorized maintenance equipment is being used.

YOROMTRD = Open road and open motorized trail route density includes all open roads and open motorized trails (See Roads in Glossary for more information)

Roads

Existing system or nonsystem roads will be closed as soon as practicable (S)

No new road construction (S)

Recreation

Dispersed- Minimal recreation facilities may be provided (such as hitch rack, rudimentary toilets, etc) not to exceed Development Level I (see Glossary) Generally, recreation facilities are not encouraged (G)

High impact campsites should be restored to meet Frissell Condition Class 3 (see Glossary) (G)

Trails - Trails and bridges are constructed/maintained to a level to accommodate heavy foot and horse traffic, where allowed (G)

- Motorized/mechanized trail maintenance and construction equipment may be used (G)

ROS - Primitive to semi-primitive nonmotorized (G)

VQO - Retention to partial retention (G)

Production of Commodity Resources

Range

Livestock Grazing - Range developments (water tanks, fences, etc) that do not detract from the overall objectives of the area are acceptable (S)

Timber

These areas are removed from the suitable timber base They do not contribute to the ASQ (S)

No timber harvesting, except for 'minor' forest products such as camp firewood, posts and poles for fencing on Forest only, administrative use, etc Harvesting does not trigger the need for reforestation Chainsaws are allowed (S)

3.1.2 NONMOTORIZED

Description

This management prescription identifies areas where semi-primitive nonmotorized recreation use, like hiking and horseback riding, will occur during the summer months The experience is similar to a primitive experience, but does allow some motorized use, like chainsaws for summer trail maintenance, snowmachines during the winter, and helicopters Groomed snowmachine trails are not allowed

This management prescription meets the Interagency Grizzly Bear Committee criteria for grizzly bear core areas (IGBC Task Force Report, July 1994)

These areas are accessible by trails or cross-country, you find no usable roads All-terrain vehicles and motorcycles cannot use the area Encounters with other people diminish as you move away from nearby roads and trailheads Generally, you experience a backcountry setting with a high likelihood of solitude However, you may meet large groups occasionally

You may find oversnow vehicles, helicopter use, stock tanks, and fences Otherwise, the forest presents a natural appearance. A variety of forest successional stages may be present, ranging from areas with recent wildfires to old growth habitat Firewood is available for camping, but is not available generally for home use Outfitter and guiding activity may be present Domestic sheep grazing is greatly reduced or absent to provide better management in grizzly bear habitat Cattle grazing may be present in some areas, and you may see range improvements such as fencing and stock tanks A variety of nonforested rangeland successional stages may be present

Goals

- 1 Maintain or enhance semi-primitive nonmotorized dispersed recreation opportunities outside of the winter season
- 2 Maintain grizzly bear core area attributes as defined in the IGBC Task Force Report, July 1994

Standards and Guidelines

Forestwide standards and guidelines apply Within the grizzly bear recovery zone, the Interagency Grizzly Bear Guidelines for Management Situation 1 habitat apply to this management prescription, except that livestock grazing in existing Management Situation 2 habitat will continue to be managed under Management Situation 2 guidelines Additional direction for this prescription is listed below

Ecological Processes and Patterns

Insects and Disease

Allow insects and disease to play their natural role in ecological succession, compatible with other resource objectives (G)

Fire/Fuels

Wildfire will be managed using the appropriate suppression response. The emphasis will be on prescribed natural fire whenever conditions permit (S)

Employ Minimum Impact Suppression Tactics (MIST) to the maximum extent possible (G)

Use management-ignited fire to maintain fire's ecological role and to enhance habitat (G)

Physical Elements

Soil and Water

Watershed restoration will be done primarily where deteriorated soil or hydrologic conditions are caused by humans or their influences create a serious threat or **loss** of resource values (G)

Promote natural healing where a definite hazard to life or property or important environmental qualities outside this prescription area are not imminent, or where natural vegetation would return in a reasonable time (G)

Use indigenous or appropriate naturalized species to reestablish vegetation where there is no reasonable expectation of natural healing (S)

Permit emergency burned area rehabilitation only if necessary to prevent an unnatural loss of semi-primitive nonmotorized resources or to protect life, property, and other resource values outside and within the area (G)

Minerals/Geology

All operating plans and special use permits will specify measures to meet grizzly bear management goals and objectives for grizzly bear habitat. The following will be required (S)

- 1 Temporary cessation or modification of permitted activities will occur to resolve grizzly bear conflicts
- 2 Human food, refuse, and prepared livestock/pet foods associated with the permitted activity will be made unavailable to grizzlies through proper storage, handling, and disposal. Proper storage includes a) inside a bearproof container, b) suspended horizontally from adjacent posts or trees, c) stored in a hard-sided vehicle or trailer, or d) other methods approved by the District Ranger. The exception is when the food is being eaten or prepared for eating, or when food and similar organic matter is being transported. Unburned human foods, garbage or other refuse will be carried off the forest as often as practical.
- 3 Any observation of grizzly bear or grizzly bear sign will be reported to the District Ranger as soon as practical.
- 4 Access roads that are not open on the travel plan will be low standard roads and gated to allow access only to the operators. Nonwinter motorized use behind locked gates is authorized only for permitted activities.

Forest Use and Occupation

Access (S) - 3 1 2

Season	Type of Access	Cross-Country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
Snow free Seasons	Motorized, <50" wide	NO	No 2/
	Motorized, >50" wide	NO	No 21
	TMARO 3/	N/A	
	OROMTRD 3/	N/A	0.0 m/sq mi
Snow Seasons 4/	Winter ** motorized	Yes	Yes
	Snowmachine	Yes	Yes

1/ Individual roads and trails are designated open or closed in the Forest Plan Travel Maps

21 Motorized use is not allowed, except that motorized equipment is allowed for trail construction/maintenance. Motorized transport of Forest Service employees is not allowed except on contracts where motorized maintenance equipment is being used.

3/ TMARO = Total motorized access route density includes all open and restricted roads and motorized trails (See Roads in Glossary for more information). Unless a figure is specified here, this is calculated on a BMU or subunit basis. Please refer to the Forestwide standards and guidelines for Access.

OROMTRD = Open road and open motorized trail route density includes all open roads and open motorized trails (See Roads in Glossary for more information). Unless a figure is specified here, this is calculated on a EMU or subunit basis. Please refer to the Forestwide standards and guidelines for Access.

4/ Within grizzly bear BMUs, site-specific restrictions on winter recreation activity (such as area closures, timing restrictions, etc.) will be imposed to resolve human-grizzly bear conflicts.

Roads

Construct no new roads (S)

Recreation

Dispersed - Minimal recreation facilities may be provided (such as hitch rack, rudimentary toilets, etc.) not to exceed Development Level I. Generally, recreation facilities are not encouraged (G)

High impact campsites should be restored to meet Frissell Condition Class 3 (G)

Trails - Trails and bridges are constructed/maintained to a level to accommodate heavy foot and horse traffic, where allowed (S)

Motorized/mechanized trail maintenance and construction equipment may be used (G)

ROS - Primitive to semi-primitive nonmotorized (S)

VQO - Preservation to partial retention (G)

Production of Commodity Resources

Range

Forestwide standards and guidelines apply for the management of domestic sheep grazing in Management Situation 2 grizzly bear habitat (G)

Cattle grazing is allowed (S)

Allotment Management Plans will specify measures to meet agency grizzly goals and objectives (S)

Permittee's full cooperation in meeting grizzly bear management goals and objectives for Situation 2 grizzly bear habitat will be a condition of the permit. In addition, the following will be required (S)

- a Temporary cessation or modification of permitted livestock grazing activities may occur to resolve grizzly bear conflicts with humans or livestock
- b Livestock carcasses will be disposed of or rendered unattractive to bear within 24 hours after they are discovered. Methods may include removing the carcass from the area, burning, using an acceptable chemical repellent, or others approved by the District Ranger. Disposal shall be in accordance with other governing agencies (such as the Wyoming Game and Fish Department) in order to determine cause of death for reimbursement purposes
- c Human food, refuse, and prepared livestock/pet foods associated with the livestock operation will be made unavailable to grizzlies through proper storage, handling, and disposal. Proper storage includes a) inside a bearproof container, b) suspended horizontally between adjacent posts or trees, c) stored in a hard-sided vehicle or trailer, or d) other methods approved by the District Ranger. The exception is when the food is being eaten or prepared for eating, or when food and similar organic matter is being transported
- d High quality food production areas for grizzlies such as wet alpine and subalpine meadows, stream bottoms, aspen groves, and other riparian areas will receive special grazing direction such as light, once-over grazing, special utilization standards, or complete closure. These sites and their corresponding direction will be identified in the Annual Plan of Use
- e Livestock depredation believed to be associated with bears will be reported within 24 hours after they are discovered to the District Ranger and the proper State agencies
- f Any observation of grizzly bear or grizzly bear sign will be reported to the District Ranger as soon as practical
- g Any action taken by the permittee or their agents which violates the Endangered Species Act will be grounds for cancellation of their grazing permit

Range developments (water tanks, fences, etc.) that do not detract from the overall objectives of the area are acceptable (S)

Timber

These areas are removed from the suitable timber base. They are not part of the ASQ (S)

No timber harvesting, except for 'minor' forest products such as camp firewood, posts and poles for fencing on Forest only, administrative use, etc. Harvesting does not trigger the need for reforestation. Chainsaws are allowed (S)

3.2 (b,c,d,g,i,j) SEMI-PRIMITIVE MOTORIZED

Description

This management prescription identifies areas with a semi-primitive backcountry recreation experience, associated with some motorized vehicle use. These areas are accessible by roads and trails. Cross-country motorized vehicle use is only allowed in prescription areas 3.2 (b) and 3.2 (f). Roads and trails are designed and maintained to allow easy passage. You will find occasional to frequent encounters with trail users. You may meet large groups occasionally.

Generally, the forest presents a natural appearance. A variety of forest successional stages may be present, ranging from areas with recent wildfires to late successional habitat. Firewood is available for camping and home use. Outfitter and guiding activity may be present. Domestic livestock grazing may be present in some areas, and you may see range improvements such as fencing and stock tanks. A variety of nonforested rangeland successional stages may be present.

Goals

1. Maintain or enhance semi-primitive motorized dispersed recreation opportunities.
2. Prescribed natural fire and management-ignited fire will be managed to maintain fire's ecological role and to enhance habitat.

Standards and Guidelines

Within the grizzly bear recovery zone, the Interagency Grizzly Bear Guidelines for Management Situation 1 habitat apply to management prescription 3.2 (c), except that livestock grazing in existing Management Situation 2 habitat will continue to be managed under Management Situation 2 guidelines.

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes and Patterns

Insects and Disease

Allow insects and disease to play their natural role in ecological succession (G)

Fire/Fuels

The emphasis will be on prescribed natural fire whenever conditions permit (G)

Employ Minimum Impact Suppression Tactics (MIST) to the maximum extent possible (G)

Physical Elements

Minerals/Geology

All operating plans and special use permits will specify measures to meet grizzly bear management goals and objectives for grizzly bear habitat. The following will be required (S)

1. Temporary cessation or modification of permitted activities will occur to resolve grizzly bear conflicts.

2. Human food, refuse, and prepared livestock/pet foods associated with the permitted activity will be made unavailable to grizzlies through proper storage, handling, and disposal. Proper storage includes a) inside a bearproof container, b) suspended horizontally from

adjacent posts or trees, c) stored in a hard-sided vehicle or trailer, or d) other methods approved by the District Ranger. The exception is when the food is being eaten or prepared for eating, or when food and similar organic matter is being transported. Unburned human foods, garbage or other refuse will be carried off the forest as often as practical.

3 Any observation of grizzly bear or grizzly bear sign will be reported to the District Ranger as soon as practical.

4 Access roads that are not open on the travel plan will be low standard roads and gated to allow access only to the operators. Nonwinter motorized use behind locked gates is authorized only for permitted activities.

Biological Elements

Wildlife

Maintain snags at 60 percent of biological potential for woodpeckers (G)

Forest Use and Occupation

Access (S) - 3 2 (b)

Season	Type of Access	Cross Country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestnan Horse/Pack Stock Mtn Bike/Mechanized	Yes Yes Yes	Yes Yes Yes

Snow Seasons	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes

1/ Individual roads and trails are designated open or closed in the Forest Plan Travel Maps

2/ OROMTRD = Open road and open motorized trail route density includes all open roads and open motorized trails (See Roads in Glossary for more information)

Access (S) - 3 2 (j)

Season	Type of Access	Cross-country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
Snow free Seasons	Motorized, <50" wide	No	Yes
	Motorized, >50" wide	No	Yes
	OROMTRD 2/	N/A	<= 0.5 mi/sq mi 2/
Snow Seasons	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes
1/ individual roads and trails are designated open or closed in the Forest Plan Travel Maps			
2/ OROMTRD= Open road and open motorized trail route density includes all open roads and open motorized trails (See Roads in Glossary for more information)			

Roads

Generally, construct no new roads (G)

Recreation

Dispersed- Dispersed recreation facilities may be provided to reduce adverse resource impacts at heavily used sites (G)

- Development level shall not exceed Level 2 for developed recreation sites (see Glossary) (S)

- High impact campsites should be restored to meet Frissell Condition Class 3 (see Glossary) (G)

Trails - Trails and bridges are constructed/maintained to a level to accommodate heavy foot, horse, and motorized vehicle traffic, where allowed (G)

ROS - Semi-primitive nonmotorized and roaded natural (G)

VQO - Retention to partial retention (G)

Production of Commodity Resources

Range

Range developments (water tanks, fences, etc) that do not detract from the overall objectives of the area are acceptable (G)

Forestwide standards and guidelines apply for the management of domestic sheep grazing in Management Situation 2 grizzly bear habitat (3 2 (c), 3 2 (g)) (G)

Timber

These areas are removed from the suitable timber base They are not part of the ASQ (S)

Timber management is allowed for such products as camp firewood, home use firewood, posts and poles for fencing on Forest, Christmas trees, wildlife habitat, administrative use, etc Harvesting generally does not trigger the need for reforestation (G)

Commercial post and pole sales are allowed provided no new temporary or system road construction occurs (G)

4.1 DEVELOPED RECREATION SITES

Description

This prescription applies to existing campgrounds, picnic areas, boating sites/ramps, and other facilities such as trailheads, snow parks, scenic and wildlife viewing areas, fishing access points, and inventoried National Forest recreation sites selected for potential development located throughout the Targhee National Forest. Development ranges from native material roads and campsites, with nonflush toilets, to a high degree of site modification with comfort and convenience facilities including paved roads, water systems, mobility impaired access, flush toilets and boat launches. (See Developed Recreation Sites - Development Scales 1-5 in the Glossary)

Overall, you find many signs of people. You see little or no evidence of resource development except for recreation. Picnic tables, roads, buildings, and camping spots are obvious. You often hear sounds of vehicles and other human activity. Signs advise that off-highway vehicle use is not allowed except to enter and depart the site on roads.

You can gather down firewood for camping, but you cannot gather it for home use. Access to fishing may be rather easy if the facility is near a stream or river, but the fishing may be less satisfactory than in more remote areas.

You generally will not find livestock within campgrounds, but they may be visible nearby. Signs and sounds of logging may also be apparent from time to time.

Wildlife, in the form of chipmunks, squirrels, birds, and occasional big game may be seen.

Generally you will find a variety of vegetation conditions from sagebrush to forested land within these areas. The forest cover will vary from mature trees to young seedling and sapling trees. The forest will generally be in a healthy, vigorous condition to provide for safety and provide for a friendly, relaxed outdoor experience. The area around the campground will generally exhibit a variety of visual conditions, depending on past insect, disease, and fire activity and management's response to those disturbances.

Goals

- 1 Provide for a variety of concentrated public recreation uses in a roaded-natural setting based on the character of the areas and visitors' needs
- 2 Protect and enhance a natural appearing environment within and adjacent to the existing sites to the extent possible while maintaining the existing array of developed recreation sites
- 3 Promote wildlife viewing opportunities when compatible with developed recreation use
- 4 Provide an appropriate mix of reservation and nonreservation sites in campgrounds
- 5 Provide short trails to facilities and opportunities for interpretation
- 6 Manage aspen for its value in providing seasonal color

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes and Patterns

Insects and Disease

Control insects and disease consistent with recreational objectives (S)

Fire/Fuels

All wildfires that threaten these areas will be aggressively suppressed (S)

Prescribed fire generally will not apply here. It may be used, however, to obtain natural regeneration in preference to soil-disturbing techniques (G)

Natural fuels will be reduced or otherwise treated so the potential fireline intensities will not exceed 100 BTU per second per foot on 90 percent of the days during the regular fire season (Burning Index < 40) (G)

Physical Elements

Soil and Water

Where standards are not being met, actively rehabilitate these areas. Use rehabilitation techniques that do not detract from the recreation opportunity (S)

Avoid new construction on unstable or highly erosive soil (G)

On new developments provide adequate vegetation filters to maintain and/or enhance riparian-dependent resources (G)

Lands

Corridor rights-of-way should avoid campgrounds and other facilities (G)

Minerals/Geology

Same as 1.2 Wilderness Study Area

Biological Elements

Wildlife

Animal Damage Control - Animal damage control generally will not be done on these sites because of potential conflicts with recreation users and their pets, except for control of problem bears, beavers, porcupines, etc (G)

Forest Use and Occupation

Access (S) - 4.1

Season	Type of Access	Cross-County Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian	Yes	Yes
	Horse/Pack Stock	No	Yes
	Mtn Bike/Mechanized	No	Yes
Snow free Seasons	Motorized, <50" wide	No	Yes 2/
	Motorized, >50" wide	No	Yes 2/
	OROMTRD 3/	N/A	N/A
Snow Seasons	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes

1/ Individual roads and trails are designated open or closed in the Forest Plan Travel Maps

2/ Motorized use is allowed only on existing roads and is limited to entering, leaving, and visiting other sites within the facility

3/ OROMTRD = Open road and open motorized trail route density includes all open roads and open motorized trails (See Roads in Glossary for more information)

Recreation

Developed

Campgrounds and picnic areas that have a seasonal use level of 40 percent or higher should be managed at the Standard Service Level (see Glossary) (G)

Campgrounds and picnic areas that have a season-long use level of 20 to 40 percent should be managed at less than the Standard Service Level (G)

Those with less than 20 percent average season-long use may require closure of sites first and then, if needed, closure of the entire facility (G)

Trailhead facilities adjacent to designated wilderness will be developed to a level appropriate to the adjacent wilderness management prescription (G)

Development Level Developed sites should be built, improved, and maintained in accordance with the established Recreation Opportunity Spectrum (ROS) classification for the management prescription area and the development standards as follows (G)

ROS Class	Site Development Scale
Primitive	None
Semi-primitive Nonmotorized	Not to exceed 1
Semi-primitive Motorized	Not to exceed 2
Roaded Natural	Not to exceed 3
Urban	Not to exceed 4

ROS - Semi-primitive motorized to urban (G)

VQO - Manage for a full range from retention to modification. Facilities are often evident but harmonize and blend with the natural setting (G)

Production of Commodity Resources

Range

Grazing at trailheads, boatramps, picnic areas, etc. may be allowed when developments or recreation use is not adversely affected (G)

Timber

Developed recreation sites are removed from the suitable timber base. These lands do not contribute to the ASQ (S)

4.2 SPECIAL USE PERMIT RECREATION SITES

Description

This prescription applies to ski areas, resorts, summer home sites and organization camps (such as Boy Scouts and Girl Scouts of America) that are allowed under a special use permit.

The emphasis is on providing privately operated types of recreation on National Forest land for large concentrated groups of people. Overall, you find many signs of people. You see little or no evidence of resource development except for recreation. Cabins and buildings used by permittees are visible but blend into the surroundings. Roads are generally gravelled, but may be paved in higher use areas. OHV use is limited to entry and departure routes and for administrative purposes. In some areas you may see extensive development associated with ski areas or resorts—for example, buildings, ski lifts, maintenance equipment, etc. Many pedestrians and cars may be seen in these areas.

You generally will not find livestock within these areas, but they may be visible nearby. Signs and sounds of logging may also be apparent from time to time.

Wildlife, in the form of chipmunks, squirrels, birds, and occasional big game may be seen.

Generally you will find a variety of vegetation conditions from sagebrush to forested land within these areas. The forest cover will vary from mature trees to young seedling and sapling trees. The forest will generally be in a healthy, vigorous condition to provide for safety and provide for a friendly, relaxed outdoor experience. The area around the special use facility will generally exhibit a variety of visual conditions, depending on past insect, disease, and fire activity and management's response to those disturbances.

Goals

- 1 Provide for privately operated recreation **use**
- 2 Protect and enhance a natural appearing environment to the extent possible while providing for private and group recreation opportunities
- 3 Strive to incorporate opportunities for watchable wildlife

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes and Patterns

Insects and Disease

Control insects and disease consistent with visual objectives (S)

Fire/Fuels

All wildfires that threaten these areas will be aggressively suppressed (S)

Prescribed fire generally will not apply here. It may be used, however, to achieve resource objectives (G)

Natural fuels will be reduced or otherwise treated so the potential fireline intensities will not exceed 100 BTU per second per foot on 90 percent of the days during the regular fire season (Burning Index < 40) (G)

Physical Elements

Soil and Water

Use rehabilitation techniques that do not detract from the recreation opportunity (G)

Avoid new construction on unstable or highly erosive soils (G)

On new developments provide adequate vegetation filters to maintain and/or enhance riparian-dependent resources (G)

Lands

Corridor rights-of-way will avoid summer homes and group facilities (G)

Continue existing recreation residence permits under specific subsection direction and the following conditions for specific areas

a) Implement the Big Springs Summer Home Agreement (S)

b) New recreation residence tracts (summer homes) will not be established. No new residences will be permitted on vacant lots that are no longer leased unless necessary to replace lots damaged by landslides at the Hoffman site or to implement the Big Springs court order (S)

Do not consider Buffalo, Moose Creek, and Big Springs summer home areas for land exchange (S)

Minerals/Geology

Locatable- Withdraw from mineral entry, or remove from mineral entry through the notation rule, subject to valid existing rights (G)

Mineral Material - No entry for mineral materials (S)

Biological Elements

Wildlife

Projects that allow selected wildlife species to be more visible to recreation users may be allowed when compatible with special use permit recreation sites (G)

Animal Damage Control - Animal damage control generally will not be done on these sites because of potential conflicts with recreation users and their pets, except for control of problem bears, beavers, porcupines, etc (G)

Plants

Projects or events that focus on the identification and/or uses of plants are allowed where compatible with special use permits and the activities do not degrade the vegetation at the facility (G)

Forest Use and Occupation

Access (S) - 4 2

Season	Type of Access	Cross-country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian Horse/Pack Stock Mtn Bike/Mechanized	Yes No 2/ No	Yes Yes Yes
Snow free Seasons	Motonzed, <50" wide Motorized, >50" wide OROMTRD 4/	No No N/A	Yes 3/ Yes 3/ not applicable
Snow Seasons	Winter Nonmotorized Snowmachine	Yes Yes 5/	Yes Yes 5/

Recreation

Developed - Natural vegetation should be favored around facilities However, mowing natural vegetation around facilities may be allowed (G)

Trails - Trails may be allowed for the convenience of people using these sites (G)

Short trails are allowed which provide access to facilities and opportunities for interpretation (G)

ROS - Roaded natural to urban (G)

VQO - Manage for a full range from partial retention to maximum modification Facilities are often evident. but harmonize and blend with the natural setting (G)

Production of Commodity Resources

Range

Unless grazing activities are needed to meet recreation objectives, or unless authorized by special use or grazing permit, grazing of recreation stock and other livestock will not be allowed in special use recreation sites (G)

Grazing activities may be allowed in and around facilities designed for livestock use (G)

Timber

Developed recreation sites are removed from the suitable timber base. These lands do not contribute to the ASQ (S)

All vegetation treatment options are available, but only as required to meet specific recreation objectives (G)

Stipulate removal of unsafe and/or dead trees in the special use permit. Native species may be planted to provide cover when naturally-occurring vegetation is inadequate (G)

4.3 DISPERSED CAMPING MANAGEMENT

Description

The purpose of this prescription is to maintain a quality dispersed recreation experience for the public and still protect other resource values that occur in the same area. This prescription applies to highly attractive and desirable, heavy summer use areas such as around lakes or reservoirs, along roads and streams, or at trailheads where there are multiple campsites accessed by conventional wheeled vehicles (> 50" wide) or boats. Included would be heavy use areas where dispersed camping occurs in potential conflict with other resources or where site damage is occurring or likely to occur.

While dispersed recreation is the main theme, protecting the resource values of the area is also critical. Therefore this prescription is intended to create a balance between the users and the resource they came to enjoy. This prescription is intended to be applied in those areas where special concerns or consideration must be given to dispersed recreation use in order to maintain the recreation opportunities.

This prescription includes areas not considered developed, but which are used by the public on a reoccurring basis. They include sites where developed status does not fit, but use by the public is more than occasional use during the recreation use period. These sites may have some limited developed facilities which may include one or two, but not the majority of the following: fire-rings, tables, toilet facilities, signs, and/or water. These sites are not fee areas and have very limited capital investment.

Management emphasis is directed at managing dispersed or undeveloped type camping opportunities, such that other resources are not unacceptably affected. Minor development is allowed to protect the site or prevent resource damage, but development should not put sites into a developed site management emphasis. Restrictions may be placed on camping locations to allow used areas to recover or to protect natural resources.

Goals

- 1 Provide facilities to a level only to meet resource protection needs
- 2 Provide a balance between recreation use and other resource needs so that the resources which provide attractions to the area are protected to a point they continue to be important recreational attractions
- 3 Maintain or improve the quality of the dispersed camping sites that now exist in the area
- 4 Avoid allowing heavy buildup of fuels in these areas to reduce risk of accidental fire ignition

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes and Patterns

Fire/Fuels

Avoid application of chemical retardant, foam, or additives in these areas. Exceptions may be warranted in situations where overriding safety situations exist, or following a review and recommendation by a resource advisor, when an escape would cause more long-term damage. (G)

Use minimum impact suppression methods. (G)

Physical Elements

Minerals/Geology

Adequate reclamation plans and bonds are required in mining plans of operation. These bonds include costs of removing facilities, equipment, and materials, recontouring disturbed areas to near pre-mining topography, isolating and neutralizing or removing toxic or potentially toxic materials, salvaging and replacing topsoil, and preparing seedbeds and revegetating to meet management prescription goals. (G)

Avoid locating permanent structures or facilities within these lands. Limit road construction to the minimum necessary for the approved activity. (G)

Avoid locating waste dumps, leaching pads, and other facilities within these lands or within the viewshed where other alternatives are available. If no other alternative exists, ensure that visual mitigation such as screening is in place to prevent degradation of visual quality on these lands. (G)

For leasable minerals, avoid surface occupancy for exploration and development activities where leases do not already exist. (G)

Mineral material extraction should be discouraged (subject to valid permitted rights, or permitted plans of operation as allowed by Law). (G)

Forest Use and Occupation

Access (S) - 4 3

Season	Type of Access	Cross-country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
Snow free Seasons	Motorized, <50" wide	No 2/	Yes
	Motorized, >50" wide	No 2/	Yes
	OROMTRD 3/	N/A	N/A
Snow Seasons	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes

Roads and Trails

No new roads, trails, or landings will be constructed within these lands until appropriate standards for construction, maintenance, and operations are in place (G)

Improve, seasonally close, close, relocate and stabilize, or obliterate roads and trails (or sections of them) that have been identified as posing a high risk of causing unnaturally high levels of sediment input into fish spawning areas. Action to be taken will be determined based upon travel management needs, terrain, the need for the road or trail, and resource priorities (G)

Roads and trails that have been identified as inhibiting riparian, wetland or aquatic ecosystem processes and/or functions (e.g., plant community development, sediment transport, and stream channel development) will be improved, relocated, or obliterated. The decision to improve, relocate, or obliterate will be based on the potential environmental impact, the ecological condition of the riparian, wetland and aquatic resources affected, and the need for the road or trail (G)

Culverts and stream crossings found to pose a risk to riparian, wetland or aquatic conditions will be improved to accommodate at least a 50-year flood, including associated bedload and debris (G)

New stream crossings will be constructed and maintained to prevent diversion of streamflow out of the channel and down the road in case of failure(s). In locations found to have high potential for failure, the roadway will be hardened to further lessen the chance of roadway failure or severe erosion should the crossing overtop (G)

Constructed temporary stream crossings, such as log and culvert installations, may be allowed. Temporary crossings will be constructed and used in such a way as to minimize sediment input and to provide for fish passage. They will be maintained during use and removed and rehabilitated as soon as they are no longer needed (G)

Construct, reconstruct, and maintain all road crossings of streams which currently or historically bear fish to provide for fish passage. Exceptions are allowed where it is necessary to restrict fish movements in order to protect native or desirable nonnative fish populations (G)

Conserve surfacing materials and riparian and other resources by properly maintaining roads and avoiding sidecasting during road maintenance activities (G)

Recreation and Outfitter/Guide

When dispersed recreation is found to result in soil displacement in excess of 15 percent of an activity area (e.g., aquatic influence zone, riparian areas, dispersed campsites, etc.), or alteration of natural stream channel morphology, address impacts through education, use limits, more intensive maintenance, facility modification, and/or closures (G)

Recreational grazing must meet range standards for utilization of riparian vegetation (S)

Permitted stock holding, watering, and handling facilities within riparian vegetation (does not include the entire aquatic influence zone) are only allowed if appropriate and mitigation measures are implemented to reduce negative impacts (S)

Road surfacing or hardening should be encouraged in areas of high use and evident resource damage. Both parking location and access roads should be considered (G)

Fire circles created by the public, should not exceed one per site. Where more than one circle is inventoried, action should be taken to reduce the number to one. Action could include education, signing, facility installation closure order, surfacing, etc. Restrictions to require use of fire pans or contained fires may be necessary and should be considered in the area management plan (G)

Boat launching along streams, river sections, lakes or reservoirs should be restricted to developed sites or if no sites exist, consideration should be made to develop a facility to meet the public needs (G)

For all groups in excess of 20 persons, the site should have toilet facilities. Where facilities do not exist, portable toilet units should be provided by groups of 20 or more persons (G)

When portable toilet units are used, they shall be placed away from water and must be packed out when use has ended (S)

Solid waste disposal will be accomplished using the Pack In-Pack Out program (G)

ROS - Primitive to urban (G)

VQO - Retention to modification (G)

Production of Commodity Resources

Range

Incorporate into AMPs, objectives for attainment of site-specific DFCs for riparian or wetland plant community seral stage development and stream channel condition (G)

Proposed livestock watering facilities, corrals, and holding pastures within these lands are allowed only if appropriate, and mitigation measures are implemented to reduce negative impacts (S)

Existing livestock watering facilities, corrals, and holding pastures within these areas are allowed at permit issuance only if mitigation measures are implemented to reduce negative impacts (G)

Salting sites should be placed 1/4 mile from dispersed sites (G)

Timber

These lands are not included in the suitable timber base. They are not part of the ASQ (S)

Where needed to attain management prescription goals, design silvicultural prescriptions and allow prescribed burning and stocking control, as well as the reestablishment and culturing of stands to attain desired vegetation characteristics (G)

5.1 (c) TIMBER MANAGEMENT

Description

The emphasis is on scheduled wood-fiber production and use, on livestock production, and on other compatible commodity outputs, and consideration for long-term forest health

Overall, you notice many signs of people. You see a fairly extensive roading system and timber harvest activity in some areas. The main road system is gravel-surfaced and well maintained, with gentle grades well suited for sedan travel. You may see timber harvest equipment on roadsides and meet logging traffic along the roadway. You will see other people driving for pleasure or hauling out a load of firewood. Driving a sedan you can travel about two-thirds of the main road system. About one-third of the main road system is closed for wildlife security or roadway protection.

You notice frequent low-standard branch roads with native and gravel surfaces. Most of these low-standard roads are closed annually or seasonally to vehicle access. Some branch roads remain open for public access, for commodity production and for Forest Service administration.

The forest is a mosaic of different sizes, ages and heights. Older, taller trees tend to dominate the landscape, but openings with smaller trees are obvious. Recently cut areas show tree stumps, slash and disturbed soil. Recently cut areas have a partial canopy of older trees. Older clearcut areas have seedlings, saplings, poles, and older trees up to 35 feet tall and have a less disturbed appearing forest floor. Dead trees from the mountain pine beetle infestation are seen in older stands and scattered throughout the rest of the forest.

Firewood is available in designated areas, by permit, from live and dead trees, designated aspen areas, and from slash and logs decked for that purpose.

If you watch wildlife, you will see a variety of species, particularly those which prefer young seral stages of forest vegetation to those which prefer later stages. Elk and deer numbers have generally increased somewhat in recent years. However, in areas of active timber harvest activity, some elk and other big-game species may have been displaced to areas with greater security. Because of the setting, outfitted hunting may not be as common as it is in less-developed areas.

During the summer and fall you encounter cattle or sheep and notice signs of intensive management practices, such as burning, spraying, seeding, fences, cattleguards, water developments and gates. You see some cattle within streamside riparian areas and on nearby slopes. Away from the streams, you see scattered groups of livestock. You may find traffic delays when livestock is being moved.

You find such nonmotorized activities as hiking, biking and horseback riding along roads closed to vehicle traffic. Some roads and areas are available for snowmobile, motorcycle, and 4-wheel-drive vehicle use.

Goals

- 1 Manage lands to promote the production of commodity and noncommodity resources
- 2 Establish fire protection objectives for the area and desired fuel conditions

3 Fire management strategies emphasize preservation and protection of timber and range values scheduled for current use

4 Effectively control insects and disease and sustain forest growth

5 Provide a wide array of dispersed recreation opportunities

Standards and Guidelines

Forestwide standards and guidelines apply Additional direction for this prescription is listed below

Ecological Processes and Patterns

Insects and Disease

Practices to prevent or control insects and disease through direct control or silvicultural practices may be considered (G)

Fire/Fuels

Wildfires will normally be suppressed using control strategies during the fire season Pre- and post-fire season strategies may include containment, confinement, or control (G)

Prescribed fire may be used to reduce fuel loading, obtain natural regeneration; improve livestock forage conditions, for wildlife habitat improvement, and for other purposes that meet the needs of this prescription (G)

Biological Elements

Wildlife

Maintain snag habitat at greater than 40 percent of the biological potential for woodpeckers (G)

Forest Use and Occupation

Access (S) - 5 1 (c)

Season	Type of Access	Cross-Country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Nonmechanized	Yes	Yes
Snow free Seasons	Motorized, <50" wide	No	Yes
	Motorized, >50" wide	No	Yes
	OROMTRD 2/	N/A	<= 1.5 mi /sq mi
Snow Seasons	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes

ROS- Recreation is managed to provide a combination of semi-primitive nonmotorized to roaded natural opportunities (G)

VQO - The VQO is generally Partial Retention to Modification. In visually sensitive foreground areas, the VQO is Retention (G)

Production of Commodity Resources

Range

Livestock grazing may be allowed on transitory forage produced following timber harvest where and when that use will not conflict with regeneration efforts or other concerns (G)

Timber

Lands are included in the suitable timber base. They contribute toward the **ASQ** (S)

Regeneration systems should rely on natural regeneration to the greatest extent possible (G)

Reforested sites may be protected from rodent and livestock damage to encourage the greatest possible survival and growth over time, consistent with other resource needs (G)

Harvest and treatment residues should be made available for firewood and other products in a manner compatible with site preparation, productivity, and restocking requirements. Designated aspen areas should be made available for firewood (G)

5.1.3 (a-b) TIMBER MANAGEMENT (NO CLEARCUTTING, URBAN INTERFACE FUELS MANAGEMENT)

The purpose of this prescription is to allow timber management with no clearcutting, and to allow **fuels** management within and adjacent to urban areas of the Forest.

Description

The emphasis is on scheduled wood-fiber production and use, on fuels management within and adjacent to urban areas of the Forest, on livestock production, and on other compatible commodity outputs, with consideration for long-term forest health.

Overall, one would notice the same conditions as in Management Prescription 5.1 (b) and (c).

Goal

Manage vegetation and fuels to minimize fire risk for urban facilities within the interface.

Standards and Guidelines

Forestwide standards and guidelines apply. The same standards and guidelines apply as 5.1 except

Forest Use and Occupation

Access (S) - 5 1 3 (a)

Production of Commodity Resources

Timber

No clearcutting is allowed in this prescription area (S)

5.1.4 (a-d) TIMBER MANAGEMENT (BIG GAME SECURITY EMPHASIS)

The purpose of this prescription is to provide commodity resource development with special emphasis on big game security

Description

The emphasis is on scheduled wood-fiber production and use, big game security, other compatible commodity outputs, and consideration for long-term forest health. It combines the forested security block emphasis of 5.4 with cross-country motorized use allowed in 5.1, but restricts that motorized use during the big game hunts.

This management prescription emphasizes management actions and resource conditions which provide increased security for big game species, and hunting opportunities with limited access. Habitats are managed for multiple land use benefits, but these are managed over time and space to provide security and cover for hunted big game species.

Spring, summer, and fall forage is abundant and well distributed throughout the area. Hiding and thermal cover is abundant and in large patches to provide security for big game throughout the spring, summer, and fall seasons. Big game movements and migrations are facilitated due to well distributed forage and cover.

Timber management emphasizes providing a variety of forested seral stages, with large blocks of forested vegetation providing hiding cover. Security areas are provided adjacent to areas where timber harvesting is occurring.

Motorized access is managed to provide big game security. You notice frequent low-standard branch roads with native and gravel surfaces. Most of these low-standard roads are closed annually or seasonally to vehicle access. Some branch roads remain open for public access, for commodity production and for Forest Service administration.

Hiking off-road conditions, forest stand conditions, ability to view wildlife, presence of cattle and sheep, and nonmotorized activities are the same as 5.1.

Goals

1. Protect the long-term productivity of the land and meet areawide standards that protect resource values such as fisheries, water quality, wildlife habitat (including big game security areas) and visual quality.
2. Manage for big game security in greater than 250 acre forested blocks.

Standards and Guidelines

Forestwide standards and guidelines apply. The same standards and guidelines apply as 5.1 except'

Forest Use and Occupation

Access (S) - 5 1 4 (a)

Season	Type of Access	Cross-Country Travel	Road and Trail Travel 1/

Production of Commodity Resources

Timber

Manage for big game cover in forested blocks over 250 acres in **size** (a forested block is defined as adjacent stands of sapling, pole, mature and old growth trees) **(S)**

For the forested component within the prescription area, no more than 20 percent of the acres will be in a created opening at any point in time (a created opening is defined as a) clearcuts (nonstocked and seedling stages), b) seed cuts of a shelterwood (nonstocked and seedling stages), or c) group selection (nonstocked and seedling stages) (S)

Naturally occurring forested blocks **less** than 250 acres in size, may have 20 acre harvest units, with no more than 20 percent of the block in the created opening category at one time (G)

For scheduling harvest activity areas, big game security areas will be provided Security should provide the following conditions

- 1 Security areas will be greater than 250 acres in size, or depending on the size of the timber sale area boundary, as large as necessary to meet big game security needs (G)
- 2 Within the security area, OROMTRD must be < the density established for this management prescription (S)
- 3 No timber harvesting activity or similar type of disturbance activity (i.e. involving heavy equipment, noise, concentrated human activity) can occur within the security area during the time it is designated as a security area while the adjacent timber harvesting activity is occurring (S)

5.2.1 VISUAL QUALITY IMPROVEMENT

Description

This prescription emphasizes improving or maintaining visual opportunities for visitors along major travel corridors through heavily timbered areas, while allowing livestock production, timber harvest, and other compatible commodity outputs. The purpose of this prescription is to maintain or create openings in timber stands to provide scenic vistas.

Overall you may notice signs of people camping by the roadside or as part of a commercial timber harvest.

As you drive, you see occasional timber harvest activity in some areas. The main road system is paved or gravel-surfaced and well maintained, with gentle grades suited for sedan travel. Clearcuts and harvest areas have been designed and located to provide vistas of the surrounding area.

There will be occasional places to pull off the road and have a picnic, read an interpretive sign or photograph a pleasing landscape.

The road side area is dominated by a mix of older stands of trees, young stands, and created openings to provide scenic vistas. A few areas show tree stumps, hand-piled slash, and disturbed soil. Occasionally, older cut areas show tree seedlings, saplings and poles up to 35 feet tall and have a less-disturbed appearing forest floor. Scattered dead trees are seen throughout the forest, but generally it appears healthy and vigorous.

If you watch for wildlife, you may occasionally see an elk, deer or moose in a natural opening or alongside the road, but generally they are hidden from view by the trees. During the summer and fall, you may encounter cattle or sheep grazing in openings. Signs of intensive management practices, such as burning, spraying, seeding, fences, water developments and gates are normally visually compatible.

Nonmotorized activities, such as hiking, biking or horseback riding may originate from trail or road points along the main road. Some roads and nearby areas are available for year-around snowmobile, motorcycle, and 4 wheel-drive vehicle use.

Goals

1. Manage these major travel corridors to improve or maintain their visual quality.
2. Manage these lands in an environmentally sensitive manner to promote the production of commodity and noncommodity resources at varying levels through a variety of silvicultural prescriptions.
3. Establish fire protection objectives for the area and desired fuel conditions.
4. Fire management strategies emphasize preservation and protection of timber and range values scheduled for current use.
5. Effectively control the insects and disease and sustain forest growth.
6. Provide a wide array of dispersed recreation facilities.

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes and Patterns

Insects and Disease

Practices to prevent or control insects and disease through direct control or silvicultural practices may be considered (G)

Fire/Fuels

Wildfires will normally be suppressed using control strategies during the fire season. Pre- and post-fire season strategies may include containment, confinement, or control (G)

Prescribed fire may be used to reduce fuel loading, obtain natural regeneration, improve livestock forage conditions, improve wildlife habitat, and for other purposes that meet the needs of this prescription (G)

Biological Elements

Wildlife

Maintain snag habitat at 40 percent or greater of the biological potential for woodpeckers (G)

Forest Use and Occupation

Access (S) - 5 2 1

Season	Type of Access	Cross-country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
Snow free Seasons	Motorized, <50" wide	Yes	Yes
	Motorized, >50" wide	Yes	Yes
	OROMTRD 2/	N/A	N/A
Snow Seasons	Winter Nonmotorized Snowmachine	Yes	Yes
		Yes	Yes

Roads

Management of the area does not require an extensive road system, and will consist of short spurs from the main travel routes (G)

Recreation

Trails - Motorized trails should be developed using primarily local roads and trails not being actively used for commodity recovery (G)

ROS - Recreation is managed to provide a combination of semi-primitive nonmotorized to roaded natural opportunities (G)

VQO - The Visual Quality Objective (VQO) is Retention to Maximum Modification (G)

Production of Commodity Resources

Range

Livestock grazing may be allowed on transitory forage produced following timber harvest where and when that use will not conflict with regeneration efforts or other concerns (G)

Timber

Lands are included in the suitable timber base They contribute toward the ASQ (S)

Any silvicultural system may be used, depending on the visual quality that is being emphasized (G)

Regeneration systems should rely on natural regeneration to the greatest extent possible (G)

Reforested sites may be protected from rodent and livestock damage to encourage the greatest possible growth over time, consistent with other resource needs (G)

Maximum created opening size could be 40 acres, but will generally be 1 to five acres in size to create scenic vistas (G)

Harvest and treatment residues should be made available for firewood and other products in a manner compatible with the visual quality objective. Designated aspen areas should be made available for firewood to ensure the color provided by these stands is maintained over time. (G)

5.2.2 VISUAL QUALITY MAINTENANCE

Description

This prescription emphasizes maintaining the existing visual quality within major travel corridors with high quality natural vistas, while allowing livestock production, limited timber harvest, and other compatible commodity outputs.

Overall you may notice signs of people camping by the roadside. Signs of commercial timber harvesting will generally not be evident.

The natural vistas include a wide variety of vegetation and landscape forms (mountain peaks, valleys, meadows, streams, etc.) easily observed from openings along the road. Occasionally, older cut areas show tree seedlings, saplings and poles up to 35 feet tall and have a less-disturbed appearing forest floor. Scattered dead trees are seen throughout the forest, but generally it appears healthy and vigorous.

If you watch for wildlife, you may occasionally see an elk, deer or moose in a natural opening or alongside the road, but generally they are hidden from view by the trees. During the summer and fall, you may encounter cattle or sheep grazing in openings. Signs of intensive management practices, such as burning, spraying, seeding, fences, water developments and gates are normally visually compatible.

Nonmotorized activities, such as hiking, biking or horseback riding may originate from trail or road points along the main road. Some roads and nearby areas are available for year-around snowmobile, motorcycle, and 4 wheel-drive vehicle use.

Other signs of activity are the same as 5.2.1.

Goals

1. Manage these travel corridors to protect their visual quality.
2. Silvicultural practices are designed to emphasize or maintain visual quality of the area.

Standards and Guidelines

Forestwide standards and guidelines apply. The standards and guidelines are the same as 5.2.1 except.

Biological Elements

Wildlife

No assigned snag habitat biological potential for woodpeckers.

Forest Use and Occupation

Access (S) - 5 2 2

Season	Type of Access	Cross-County Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
Snow free Seasons	Motonzed, <50" wide	Yes 2/	Yes
	Motorized, >50" wide	Yes 2/	Yes
	OROMTRD 3/	N/A	N/A
Snow Seasons	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes
1/ individual roads and trails are designated open or closed in the Forest Plan Travel Maps			
2/ Allowed unless visual features are degraded by disturbances to vegetation or soils Where this prescription is used in the Centennial sub-section, cross-country motorized travel is prohibited in the snow free seasons			
3/ OROMTRD = Open road and open motorized trail route density does not apply to this prescription area			

Recreation

VQO - The Visual Quality Objective (VQO) is Retention to Partial Retention (G)

Production of Commodity Resources

Range

Livestock grazing may be allowed on transitory forage produced following timber harvest where and when that use will not conflict with regeneration efforts or other concerns (G)

Timber

Lands are included in the suitable timber base They contribute to the ASQ (S)

Regeneration systems should rely on natural regeneration to the greatest extent possible (G)

Reforested sites may be protected from rodent and livestock damage to encourage the greatest possible survival and growth over time, consistent with other resource needs (G)

Maximum created opening size shall generally be less than five acres (G)

Harvest and treatment residues should be made available for firewood and other products in a manner compatible with the visual quality objective Designated aspen areas should be made available for firewood to ensure the color provided by these stands is maintained over time (G)

5.3.5 GRIZZLY BEAR HABITAT (NIC FOR ASQ, NO CROSS-COUNTRY, PHASE OUT SHEEP)

Description

This management prescription emphasizes a high degree of security and resource conditions which contribute toward the conservation and recovery of the grizzly bear, and benefits to other wildlife Habi-

tats will be managed to meet the goals of grizzly bear recovery Other uses may be allowed when compatible with these goals

Grizzly habitat maintenance and improvement, and grizzly-human conflict minimization will receive the highest management priority Management decisions will favor the needs of the grizzly bear when grizzly habitat and other land use values compete Land uses which can affect grizzlies and/or their habitat will be made compatible with grizzly needs or such uses will be disallowed or eliminated Grizzly-human conflicts will be resolved in favor of grizzlies unless the bear involved is determined to be a nuisance bear (IGBC, 1986)

The abundance and distribution of natural food sources (such as huckleberry habitats, whitebark pine, etc) are maintained or improved by natural events such as fire and insect disturbances, or by designed vegetation management activities A variety of forested seral stages are present, and are the result of natural disturbances such as fire and insects or by designed vegetation management activities Habitat conditions which contribute to the movement of bears to adjacent bear management units are maintained Human activities are managed or restricted so that human conflicts with grizzlies are unlikely, this includes restricting human activities and generally reduced public access

Goals

- 1 Make nonfederal lands within this area a high priority for acquisition
- 2 Maintain grizzly bear security through a low density of open, motorized roads and trails.
- 3 Manage recreation to minimize grizzly conflicts with humans
- 4 Wildlife habitat improvement projects will maintain or improve grizzly bear habitat Vegetation manipulation to improve grizzly bear habitat includes treatment to maintain long term ecosystem vegetation patterns

Objective

By 1998, develop a fire management plan for this prescription area

Standards and Guidelines

Forestwide standards and guidelines apply Additional direction for this prescription is listed below

The Interagency Grizzly Bear Guidelines for Management Situation 1 habitat apply to this management prescription, except that livestock grazing in existing Management Situation 2 habitat will continue to be managed under Management Situation 2 guidelines

Ecological Processes and Patterns

Effects of proposals will be analyzed at multiple scales Analysis areas will follow ecological boundaries, watersheds, and topographic breaks Cumulative effects will be analyzed on no less than a BMU subunit scale (G)

Insects and Disease

Insects and disease are allowed to play their natural role in ecosystem development, unless this conflicts with the maintenance of grizzly bear habitat (G)

Fire/Fuels

Prescribed fire is allowed to maintain or improve grizzly habitat (G)

Physical Elements

Minerals/Geology

All operating plans and special use permits will specify measures to meet grizzly bear management goals and objectives for grizzly bear habitat. The following will be required (S)

- 1 Temporary cessation or modification of permitted activities will occur to resolve grizzly bear conflicts
- 2 Human food, refuse, and prepared livestock/pet foods associated with the permitted activity will be made unavailable to grizzlies through proper storage, handling, and disposal. Proper storage includes a) inside a bearproof container, b) suspended horizontally from adjacent posts or trees, c) stored in a hard-sided vehicle or trailer, or d) other methods approved by the District Ranger. The exception is when the food is being eaten or prepared for eating, or when food and similar organic matter is being transported. Unburned human foods, garbage or other refuse will be carried off the forest as often as practical
- 3 Any observation of grizzly bear or grizzly bear sign will be reported to the District Ranger as soon as practical
- 4 Access roads that are not open on the travel plan will be low standard roads and gated to allow access only to the operators. Nonwinter motorized use behind locked gates is authorized only for permitted activities

Biological Elements

Wildlife

Maintain snag habitat at greater than 60 percent of the biological potential for woodpeckers (G)

Environmental analysis areas (for NEPA purposes) will be at least 7,000 acres in size (G)

Long-term activities, for purposes of this prescription, are those activities which may last more than one field season, or may be expected to recur in different areas year after year. They may occur over a larger geographic area than short-term activities. These include timber sales, firewood harvesting, prescribed burns, road reclaiming, tree thinning, and trail construction

Long-term activities must be concentrated in activity areas on an annual basis between April 1 and September 15. Each activity area shall not exceed 7,000 acres in size (S)

Long-term activities should be concentrated in space and be of as short a duration as is practical (G)

Long-term activity areas should generally follow ecological boundaries, watersheds and topographic breaks. Activity areas should be distributed such that no less than 7,000 acres lie between them (G)

Short-term activities, for purposes of this prescription, are those activities that are typically accomplished within one field season and will not necessarily recur on an annual basis. These activities generally occur over a more limited spatial extent than long-term activities. These include tree planting, trail maintenance, spraying weeds, and range maintenance activities

Inventory, monitoring, and short-term activities should be concentrated in time and space (G)

Short-term management activities should be planned to be concentrated in one consecutive 30-day period. Exceptions should be implemented over as short a duration as is practical (G)

Management activities may take place during winter (December 15 to April 1) and shall be addressed on a case-by-case basis. The primary concern during the winter will be the changes the activity may have on habitat quality and quantity (G)

Administrative Responsibilities- Emergency cessation or modification of activities will occur when those activities are in conflict with grizzly bear management objectives. Scheduled activities will not occur during the season of bear use in areas where foraging opportunities are limited in their availability, in area, or time (S)

Forest Use and Occupation

Access (S) - 5 3 5

Season	Type of Access	Cross-Country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian Horse/Pack Stack Mtn Bike/Mechanized	Yes Yes Yes	Yes Yes Yes
Snow free Seasons	Motorized, <50" wide Motorized, >50" wide TMARD 2/ OROMTRD 2/	No No N/A N/A	Yes Yes
Snow Seasons 3/	Winter Nonmotorized Snowmachine	Yes Yes	Yes Yes

Roads

New or relocated roads should meet the following guidelines (G)

- 1 Avoid high quality (such as whitebark pine habitat) grizzly bear habitat
- 2 Minimize sight lines on temporary roads and skid trails
- 3 Revegetate temporary roads following use
- 4 Follow minimum required construction standards

Motorized administrative use on restricted roads and restricted motorized trails by personnel of resource management agencies is acceptable at low intensity levels as defined in existing cumulative effects analysis models. This includes contractors and permittees in addition to agency employees. (See Roads and Trails in the Glossary for definitions) (S)

Recreation

Special Uses - Special Use Activities which adversely affect grizzly bear populations or their habitat will not be permitted (S)

Trails - New or relocated trails will meet the following

- 1 Avoid high quality grizzly bear habitat (G)
- 2 Locate so as to minimize the risk of human/bear interactions (for example, do not place trails along roaring streams where bears cannot hear humans approaching) (G)

ROS - Primitive to semi-primitive motorized (G)

VQO - Retention to partial retention (G)

Heritage Resource

No new interpretation/enhancement of cultural sites (S)

Production of Commodity Resources

Range

Forestwide standards and guidelines apply for the management of domestic sheep grazing in Management Situation 2 grizzly bear habitat (G)

Cattle grazing is allowed Allotment Management Plans will specify measures to meet agency grizzly goals and objectives (S)

Permittee's full compliance in meeting grizzly bear management goals and objectives for grizzly bear habitat will be a condition of the permit In addition, the following will be required (S)

- 1 Temporary cessation or modification of permitted livestock grazing activities will occur to resolve grizzly bear conflicts with humans or livestock
- 2 Livestock carcasses will be disposed of or rendered unattractive to bear within 24 hours after they are discovered Disposal may include removing the carcass from the area, burning, using an acceptable chemical repellent, or other methods approved by the District Ranger Disposal shall be in accordance with other governing agencies such as the Wyoming Game and Fish Department in order to determine cause of death for reimbursement purposes
- 3 Human food, refuse, and prepared livestock/pet foods associated with the livestock operation will be made unavailable to grizzlies through proper storage, handling, and disposal Proper storage includes a) inside a bearproof container, b) suspended horizontally from adjacent posts or trees, c) stored in a hard-sided vehicle or trailer, or d) other methods approved by the District Ranger The exception is when the food is being eaten or prepared for eating, or when food and similar organic matter is being transported Unburned human foods, garbage or other refuse will be carried off the Forest as often as practical
- 4 High quality food production areas for grizzlies (wet alpine and subalpine meadows, stream bottoms, aspen groves, and other riparian areas) will receive special grazing direction such as light, once-over grazing, special utilization standards, or complete closure These sites and their corresponding direction will be identified in the Annual Operating Plan
- 5 Livestock depredation believed to be associated with bears will be reported within 24 hours after they are discovered to the District Ranger and the proper State agencies

6 Any observation of grizzly bear or grizzly bear sign will be reported to the District Ranger as soon as practical

7 Any action taken by the permittee or their agents which violates the Endangered Species Act will be grounds for cancellation of their grazing permit

Timber

These lands are included in the suitable timber base They contribute toward the ASQ, but are a NIC (S)

There will be no vegetation manipulation in riparian areas in the spring or in whitebark pine areas in the fall (except in years of poor cone crops) (G)

Scarification is limited to 15 percent or less of an area where soil disturbance impedes the reestablishment of grizzly bear foods (for example where berry producing shrubs are present such as blue huckleberry, mountain ash, chokecherry, buffaloberry, grouse whortleberry, etc , where wet site species are present such as horsetail, cow parsnip, camas, wet-site carex spp , etc) (S)

Scarification of elk sedge (*Carex geyeri*) and Ross's sedge (*Carex rossii*) is allowed at levels above 15 percent since these species readily reestablish following scarification (G)

Cover - Maintain greater than 70 percent of the forested acres in each analysis area in vegetation that provides security cover for the grizzly bear Where security cover is below 70 percent, no treatments are allowed which would further reduce the number of acres meeting security cover (S)

Security cover is defined as forested acres (all tree species) which have not been managed or burned in the last 20 years, and managed or burned forested areas within the last 20 years which meet the following criteria. (G)

Overstory Basal Area of trees 5 0"+	Understory Trees/ac 0-4 9" and 7'+	Acreage Multiplier
130+ sq ft per acre	250+	1 0 (Good)
80-129 sq ft per acre	150-249	0 7 (Medium)
30-79 sq ft per acre	50-149	0 4 (Poor)

The overstory and understory categories for security cover are to be considered separately A stand having either 130 sq ft of basal area per acre or 250 understory trees per acre over seven ft tall would meet the requirements for full security cover Both live and dead tree basal areas are used for overstory calculations (S)

Maintain greater than 20 percent thermal cover in each analysis area Where thermal cover is below 20 percent, no treatments are allowed which would further reduce the number of acres meeting thermal cover criteria Thermal cover is defined as forest stands with over 80 sa ft of basal area per acre (live and dead trees), greater than 45 percent canopy closure, and trees over 40 feet tall (S)

For created openings maximum distance to security cover should be 300 feet (G)

Created openings will be located at least 1,500 feet from open roads. A clearcut and seedtree cut result in created openings. Final removal of a shelterwood or an overstory removal result in a created opening if the stand is less than seven feet tall or less than stocking standards. (S)

No new created openings are allowed adjacent to existing openings (including meadows and created openings). Maintenance of natural openings is allowed. (S)

Leave strips between openings will be the larger of 600 feet or 3 times the sight distance (the distance needed to hide 90 percent of a grizzly bear). (S)

Dead & Down Component - If available, leave at least two pieces per acre over 12 inches in diameter. Woody material should be in various stages of decay if possible. If a treatment area is below forestwide standards, use the treatment to increase down woody material to recommended amounts. (Note: This requirement accrues toward the requirements in the forestwide standards and guidelines. It is not cumulative to them.) (G)

Security Areas - Maintain a minimum 7,000 acre security area adjacent to each timber sale area. (S)

Security areas must provide the following conditions. (S)

1. Within the security area, TMARD and OROMTRD must be less than or equal to the density established for the BMU (see forestwide standards and guidelines, Access)
2. Within the security area, security cover must be greater than or equal to the amount established for this management prescription
3. No timber harvesting activity or similar type of disturbance activity can occur within the security area during the time it is designated as a security area

5.4 (a,b,c) ELK SUMMER RANGE

Description

This management prescription emphasizes management actions and resource conditions which provide increased security for elk, and hunting opportunities with limited access. Habitats are managed for multiple land use benefits, but these uses are managed over time and space to provide security and cover for elk. These habitat conditions are also favorable for many other wildlife species.

Spring, summer, and fall forage is abundant and well distributed throughout the area. Hiding and thermal cover is abundant and in large patches to provide security for elk throughout the spring, summer, and fall seasons. Elk movements and migrations are facilitated due to well distributed forage and cover.

Timber management emphasizes providing a variety of forested age classes, with large blocks of forested vegetation providing hiding cover. Security areas are provided adjacent to areas where timber harvesting is occurring.

Motorized access is managed to provide security for elk. Motorized summer **use** will occur only on designated routes.

Livestock grazing exists in some areas, forage utilization, water developments, grazing systems, and other livestock management actions are managed to be compatible with elk habitat needs.

Dispersed recreation, mining activity, and other multiple uses are managed in time and space to help provide security habitat for elk

Goals

- 1 Provide elk security areas while allowing for other resource activities
- 2 Utilize silvicultural techniques which prevent or lessen insect and disease epidemics to maintain cover values for elk

Standards and Guidelines

Forestwide standards and guidelines apply Additional direction for this prescription is listed below

Ecological Processes and Patterns

Fire/Fuels

Use prescribed fire to improve forage production, assist in forest regeneration and enhance ecological conditions (G)

Biological Elements

Wildlife

Maintain snag habitat at greater than 60 percent of the biological potential for woodpeckers (G)

Forest Use and Occupation

Access (S) - 5 4 (a)

Season	Type of Access	Cross-country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/mechanized	No	Yes
Snow free Seasons	Motorized, <50" wide	No	Yes
	Motorized, >50" wide	No	Yes
	OROMTRD 2/	N/A	<= 1 0 milesq mi
Snow Seasons	Winter Nonmotorized Snowmachine	Yes	Yes
		Yes	Yes

Season	Type of Access	Cross-County Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian	Yes	Yes

	Snowmachine	Yes	Yes

1/ Individual roads and trails are designated open or closed in the Forest Plan Travel Maps

ZOROMTRD = Open road and open motorized trail route density includes all open roads and open motorized trails (See Roads in Glossary for more information)

Recreation

ROS - Primitive to urban (G)

VQO - Retention to partial retention (G)

Production of Commodity Resources

Timber

These lands are part of the suitable timber base. They contribute toward the ASQ (S)

Manage for elk cover in forested blocks greater than 250 acres (a forested block is defined as adjacent stands of saplings, pole, mature and old growth trees) (S)

For the forested component within the prescription area, no more than 20 percent of the acres will be in a created opening at any point in time (a created opening is defined as a) clearcuts (nonstocked and seedling stages), b) seed cuts of a shelterwood (nonstocked and seedling stages), or c) group selection (nonstocked and seedling stages) (S)

Naturally occurring forested blocks less than 250 acres in size, may have 20 acre harvest units, with no more than 20 percent of the block in the created opening category at one time (G)

Adjacent to harvest activity areas, big game security areas will be provided Security areas must provide the following conditions (S)

- 1 Security areas will be greater than 250 acres in size, or as large as the timber sale area boundary, whichever is greater
- 2 Within the security area, OROMTRD must be < the density established for this management prescription
- 3 No timber harvesting activity or similar type of disturbance activity can occur within the security area during the time it is designated as a security area

6.1 (b) RANGE MANAGEMENT

Description

The purpose of this management prescription is to achieve and maintain healthy nonforested rangelands for livestock forage production and good watershed condition

Forage is provided on a sustained-yield basis that protects rangeland values, including domestic livestock grazing and wildlife habitat Cattle, sheep, horses, and perhaps other domestic livestock can often be seen Important seasonal ranges for big game animals exist in many of these areas Not all areas are grazed by domestic livestock, some areas may be reserved for wildlife and watershed restoration work Range improvements such as fencing, corrals, and water developments are present Roads, trails, and stock driveways exist, as needed, to provide access for livestock management Vegetation manipulation (with the use of fire, mechanical means, or herbicides) may occur to achieve or maintain healthy rangeland conditions A variety of rangeland vegetation successional stages can be observed Herders, range riders, camps, and transport vehicles may be seen at various times and places Dispersed recreation activity generally occurs throughout these areas

Goal

Provide forage on a sustained-yield basis that protects rangeland values, including domestic livestock grazing, and wildlife habitat

Standards and Guidelines

Forestwide standards and guidelines apply Additional direction for this prescription is listed as follows

Ecological Processes and Patterns

Fire/Fuels

Prescribed fire is allowed to achieve desired forage or ecological condition (G)

Forest Use and Occupation

Access (S) - 6 1 (b)

Season	Type of Access	Cross-County Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
Snow free Seasons	Motorized, <50" wide	No	Yes
	Motorized, >50" wide	No	Yes
	OROMTRD 2/	N/A	<= 2 m/sq mi 2/
Snow Seasons	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes

1/ Individual roads and trails are designated open or closed in the Forest Plan Travel Maps

2/ OROMTRD = Open road and open motorized trail route density includes all open roads and open motorized trails (See Roads in Glossary for more information)

In 6 1 (b) Prescription areas <= 4 0 sq mi in size. OROMTRD does not apply

Recreation

Dispersed- Limited recreation facilities, which are not detrimental to intensive range management, and other resources may be provided in this prescription (G)

Opportunities may exist for some interpretative signs for public education (G)

ROS - Semi-primitive nonmotorized to roaded natural (G)

VQO - Retention to modification (G)

Outfitter/Guide

Outfitter/Guide stock are allowed, AUMs are specified in outfitter/guide permits and Rangeland Project Decisions (RPDs) (G)

Production of Commodity Resources

Timber

These areas are removed from the suitable timber base They are not part of the ASQ (S)

Timber may be harvested to improve wildlife habitat and to provide miscellaneous products (such as posts & poles, firewood, etc) as long as the harvest does not trigger the need for reforestation (G)

8.1 CONCENTRATED DEVELOPMENT AREAS

Description

This prescription applies to all existing concentrated developments including active mines, borrow pits, gravel pits, electronic sites, utility corridors (electric transmission lines of 50 Kv or greater, and major natural gas conduits), and administrative sites (including guard stations and rental cabins). Concentrated development is normally small, but may be extensive on occasion. A wide variety of vegetation and landtypes may be present. This category is often surrounded by other management areas.

These are generally highly developed areas with much evidence of people, structures, roads, and often disturbed ground. High noise levels sometimes emanate from these sites due to the use of heavy equipment or blasting at various times. Other sites are collections of buildings and storage structures from which the administration of the National Forest is carried out. Some closed gates and restrictions on travel may be present in order to protect equipment and developments.

Goal

Allow concentrated development in small areas for mineral development and infrastructure needs.

Objectives

1. Restrict development of concentrated development sites to the smallest area possible.
2. Obtain materials from commercial sources or borrow sites identified in the Forest "Compendium for Material Sources".

Standards and Guidelines

Forestwide standards and guidelines apply. Additional direction for this prescription is listed below.

Ecological Processes and Patterns

Insects and Disease

Attempt to control epidemics at small outbreak sizes. Salvage of dead and dying trees of commercial value is possible. (G)

Fire/Fuels

All wildfire will be aggressively suppressed. (S)

Physical Elements

Lands

Energy/utility corridors will be no more than 600 feet in width. (S)

Forest Use and Occupation

Access (S) - 8 1

Season	Type of Access	Cross-country Travel	Road and Trail Travel 1/
Snow free Seasons	Pedestrian	Yes	Yes
	Horse/Pack Stock	Yes	Yes
	Mtn Bike/Mechanized	Yes	Yes
Snow free Seasons	Motorized. <50" wide	No 2/	Yes
	Motorized. >50" wide	No 2/	Yes
	OROMTRD 31	N/A	N/A
Snow Season	Winter Nonmotorized	Yes	Yes
	Snowmachine	Yes	Yes

Recreation

Dispersed - Do not encourage use of areas in proximity to these sites (G)

Trails - Protect existing trails and wherever possible avoid development of trails in or near concentrated development sites Where feasible move existing trails away from these areas (G)

ROS - Semi-primitive nonmotorized to urban (G)

VQO - The Visual Quality Objective (VQO) is generally Partial Retention to Maximum Modification (G)

Production of Commodity Resources

Timber

These lands are removed from the suitable timber base They do not contribute to the ASQ (S)

Chapter

IV

Implementation

CHAPTER IV FOREST TIMBER SCHEDULE

The following tables display the timber sale program by watershed over the first ten years of this revised forest plan. Volumes are in MMBF. Miles of road construction is based on an estimate of 0.23 miles per MMBF. Miles of road reconstruction is based on an estimate of 0.15 miles per MMBF.

The figures in these tables represent our best estimate as to how the ASQ will be achieved. These estimates will change as new information becomes available, and as site-specific analysis for individual projects reveals the need for adjustments. Some of these sales may not occur at all, other sales not identified herein may occur.

The lands described in the following table are in the noninterchangeable component on ASQ lands. Figures represent a proportion of the average annual ASQ.

LANDS	VOLUME (MMBF)
	2.0 MMBF
Roadless areas/steep slopes	0.0 MMBF
Roadless areas/no steep slopes	1.1 MMBF
Steep slopes	0.1 MMBF
TOTAL NIC	3.2 MMBF

The roadless areas which may be entered for timber harvest over the next decade are:

- Garfield Mountain
- Mount Jefferson
- Pole Creek
- Caribou Creek
- Bear Creek
- Garns Mountain
- West Slope Tetons

Chapter

Monitoring and Evaluation

CHAPTER V

MONITORING AND EVALUATION

INTRODUCTION

In the preceding chapters of the Revision, the Forest Service identified general management direction in terms of goals and objectives and commitments to carry out that direction. Monitoring and evaluation provides an opportunity for the agency to demonstrate how it is complying with the standards and guidelines, and whether or not the standards and guidelines are performing in the predicted manner. In essence, it answers the question, "Are we doing what we said we would do?", and "Are the assumptions on which we based decisions and allocations correct?"

A monitoring and evaluation plan is required by Forest Service planning regulations, which stipulate a report will be issued at the midpoint of the planning cycle. The Forest will issue a monitoring report annually to demonstrate progress toward meeting goals and objectives, and to identify as early as possible any needed changes to the Revised Forest Plan.

RELATIONSHIP TO OTHER MONITORING ACTIVITIES

This plan shows how the Forest will monitor compliance with, and performance of, standards and guidelines and assumptions in the Revision. The monitoring activities listed in this plan are only a part of a larger range of monitoring activities which take place on the Forest.

Monitoring requirements are often determined in planning and analysis which support specific projects (known as the NEPA process). Though these monitoring activities are conducted independently of Revision monitoring, there will often be an overlap between the two in that project monitoring can give some indication of how Revision standards and guidelines are working, or accomplishment of Revision goals and objectives. Monitoring of randomly-selected projects for compliance with Revision standards and guides is also conducted.

The Forest conducts some monitoring which is required by law or regulation and which may not necessarily demonstrate how the Revision is working. An example of this type of monitoring is regeneration surveys which are done in timber harvest units. Additionally, some contract administration provides information on how Revision goals and objectives are being met, and provides information on compliance with standards and guides.

The research branch of the Forest Service conducts a wide range of trials and experiments to determine the causes of resource problems, or to improve resource management. The results of these scientifically-rigorous experiments are documented in research technical reports and serve to validate current goals, objectives, standards and guidelines, or to recommend changes to them. This type of monitoring is crucial to the Forest's adaptive management approach.

Collectively, all of the above-mentioned efforts, and other day-to-day work not discussed here, comprises a large body of monitoring work of which Revision monitoring is an important part. While not all of the items monitored by these other efforts are expressly listed in the Revision Monitoring Plan, they often overlap and are closely related.

TYPES OF MONITORING

Three types of monitoring can assess performance of the Revision. The three types of monitoring are implementation, effectiveness and validation.

Implementation monitoring answers the question, "Are projects and activities being implemented in compliance with the standards and guidelines?" Implementation monitoring forms the basis for the other types of monitoring, since those cannot be conducted unless projects and activities comply with Revision standards and guidelines. Thus this monitoring type may be the most important of the three types, and needs to be conducted most often.

Effectiveness monitoring answers the question, "Is implementation of the standards and guidelines giving us the results we expected?" Effectiveness monitoring often means quantitatively assessing the effects of management actions. Since this may require quite a bit of data, effectiveness monitoring is generally conducted on a limited basis and deals with sensitive areas and activities that pose higher risks of adverse effects on Forest resources, or addresses items of high public interest. Once the question of whether effects are as expected is answered, then implementation monitoring is sufficient.

Validation monitoring answers the questions, "Are these results what we really want? Are there better ways to meet the Revision goals and objectives?" Validation monitoring is usually conducted when there is reason to question basic assumptions or coefficients, such as when these are not reasonably supported by existing research. Validation monitoring focuses on items of strong public interest, agency concern, diversity of opinion, or that have the potential to be unduly lax or restrictive. This type of monitoring may require a partnership with the Research branch and long-term investigations. Once an item is validated, as with effectiveness monitoring, then implementation monitoring is sufficient.

ITEMS TO BE MONITORED

To maximize the efficiency of the overall monitoring effort, the Forest has focused on certain critical items, identified partners, and will measure as many items as possible with the least number of indicators. The items selected for Revision monitoring met these important criteria, among others:

- critical planning assumptions
- activities with the greatest risk to resources
- most potentially constraining on outputs

The items are listed in brief in the accompanying Monitoring Item Summary, and in greater detail in the individual Monitoring Item Descriptions on the following pages.

MONITORING AND THE BUDGET

The monitoring program outlined here is the optimal level, assuming the Revision is fully funded. It is unlikely that annual budgets will fully fund the monitoring effort shown here. Priorities for the annual monitoring effort will be based on annual budgets and program direction, and on the priority of the item, in descending order, from Forest Priority Group 1 to Forest Priority Group 3.

In order to maximize efficiency and promote cooperation, the Forest will seek to develop monitoring partnerships with federal and state agencies and other entities as appropriate, to further shared goals and carry out agency responsibilities.

The cost of annually monitoring the items in Priority Groups 1, 2 and 3 is as follows:

Priority Group	Cost for Entire Group
1 (27 items):	between \$283,525 and \$285,525;
2 (6 items):	between \$76,690 and \$86,690;
3 (12 items):	between \$100,800 and \$115,300;
Total Program Cost (45 items):	between \$461,015 and \$487,515.

MONITORING ITEM SUMMARY

Monitoring Item	Forest Priority Group	Page
PHYSICAL ELEMENTS		
Air Quality		
Long-term Visual Range in Class I and II Airsheds	3	V-6
Soils		
Hydrologic Disturbance in Watersheds	2	V-7
Woody Residue Needs for Soil and Wildlife	1	V-7
Detrimental Soil Disturbance	2	V-9
Fine Organic Matter Retention	3	V-9
BIOLOGICAL ELEMENTS		
Fisheries, Water and Riparian Resources		
Improvement of WQL Streams	1	V-11
Application of BMPs	3	V-11
Native Cutthroat Trout Habitat Features	1	V-12
Vegetation

Vegetation Structure, Composition and Distribution of Sagebrush/Grassland Habitats	3	V-15
Wildlife		
Cavity Nesters	1	V-16
Standing Dead Tree Habitat	3	V-17
Grizzly Bear Population	1	V-18
Grizzly Bear Habitat Improvement	1	V-19
Bald Eagle Nesting Population	1	V-20
Gray Wolf Population	1	V-21
Peregrine Falcon Nesting Population	1	V-22
Furbearer Population Trends	1	V-23
Goshawk Population Trends	1	V-24
Forest Owl Population	1	V-25
Trumpeter Swan Nesting Population	1	V-26
Spotted Frog Population	1	V-27
Common Loon Population	1	V-28
Harlequin Duck Population	1	V-29
Elk Vulnerability and Elk Habitat Effectiveness	1	V-30
Red Squirrel Population	1	V-31
FOREST USE AND OCCUPATION		
Forest Users		
User Satisfaction	2	V-32
Forest Operation		
Budget	1	V-33

Recreation		
Seasonal Trail Use Impacts to Soil and Vegetation	2	V-33
Recreation/Wildlife Conflicts	2	V-34
Dispersed Campsite Soil Displacement	3	V-35
Jedediah Smith Wilderness LAC	3	V-35
Roads and Trails Access		
Authorized Use Level	2	V-39
Road Closure Effectiveness	1	V-39
Achievement of Road Density Standards	1	V-41
PRODUCTION OF COMMODITY RESOURCES		
Range		
Streambank Disturbance/Stubble Height/ Channel Stability	1	V-42
Riparian Forage Utilization Within Key Areas	1	V-42
Upland Forage Utilization Within Key Areas	3	V-43
Riparian and Upland Long-Term Trend in Benchmarks	3	V-44
Timber		
Changes to Land Suitability	1	V-44
Maximum Created Opening Size	3	V-45
Security Cover Retention	3	V-46
Large Forested Block Retention	3	V-46

HOW THE MONITORING INFORMATION WILL BE USED

The results of annual monitoring activities will be evaluated to either verify the propriety of current actions, standards and guidelines, or to determine the need to change them. This evaluation will be assembled into an annual report and made available to Forest stakeholders.

Based on the information in the annual report the Forest will identify any changes needed to actions, standards or guidelines. Depending on the magnitude of the change required the Forest may choose to amend the Revised Plan through either the minor (nonsignificant) or major (significant) amendment processes. If the changes needed are of such a large magnitude that it is not feasible to amend the Plan, a Revision may be called for. Through the constant updating of direction due to yearly monitoring or advances in knowledge the Forest will strive to minimize the need to revise the Plan.

The monitoring item descriptions contain certain information in a standard format, which is briefly explained below:

Monitoring Item - The subject of the monitoring. This can often be tied back to a particular standard or guideline in the Revised Plan.

Type of Monitoring - Implementation, Effectiveness or Validation. The item may address more than one type of monitoring, such as effectiveness and validation.

Priority - The relative importance assigned to the item by the Forest leadership team, with one being highest priority and three the lowest.

Where Applies - Shows areas of the Forest where the monitoring would be conducted.

Indicator - Describes the parameter(s) that will be used to show compliance or change. For example, trails meeting acceptable standards could be measured in miles, areas meeting standards for down woody residue might be measured in acres, and so on.

Method - Explains how the monitoring will be conducted. For example, line transects could be used to monitor vegetation conditions, user surveys could be used to monitor recreation use and experience, and so on. If partnerships can be developed for doing the monitoring, that might be explained here.

Expected Precision and Reliability

- **Precision** - Shows how correct the monitoring result can be expected to be. For methods which allow scientifically replicable measurements these may be expressed in terms of how closely the estimate approaches the average of a cluster of sample values. For methods which are less scientifically rigorous precision may be expressed in terms of high, medium (or moderate) and low.

- **Reliability** - Measures the confidence which may be placed in the correctness of the estimate. Reliability may be expressed in terms of high, medium (or moderate) and low.

Tolerance or Variability Indicating Action - Explains the point at which management review or corrective action will be taken.

Frequency of Monitoring - Shows how often the monitoring will be conducted.

Lead Responsibility - Designates Forest personnel accountable for conducting the monitoring.

Estimated Annual Cost - Gives an estimate of the yearly cost to the Forest to conduct the monitoring.

MONITORING AND EVALUATION STRATEGY
Monitoring Item Description

PHYSICAL ELEMENTS

Air Quality

Monitoring Item - Long-term Visual Range in Class I and Class II Airsheds

Type of Monitoring - Implementation The standards have not been quantified so there is also a need to establish a baseline

Priority - Forest Priority Group 3

Where Applies - Monitoring should be conducted in designated wilderness on the Forest, and other nonwilderness areas upwind from and adjacent to Class I airsheds and Class II wilderness airsheds managed by other entities

Indicator - *Visibility in miles*

Method - The following methods will be used

1 Mounted, timed-exposure camera(s) established at fixed photopoint(s) The exposures should be evaluated periodically by density-monitoring devices in addition to ocular means

2 Aerosol particle evaluation, to supplement information gathered by photographic means on days not meeting visual standards These devices gather and evaluate information at the site only, not at remote locations on the visual evaluation track, and can help determine the particulate components of air not meeting standards to help discover the cause

There appears to be ample opportunity for partnerships in this effort Other federal agencies such as the Environmental Protection Agency, the U S Fish and Wildlife Service, and the National Park Service are already engaged in efforts of this type The adjacent national parks, especially Grand Teton National Park, have been conducting some of this type of monitoring for some time, most recently in conjunction with their own prescribed burning activities which have increased since the 1988 Yellowstone fires Within the Forest Service, the Bridger-Teton National Forest has conducted air quality monitoring for years in connection with oil and gas development activities The Rocky Mountain Regional Office and Rocky Mountain Research Station both have shown interest in, and have expertise in, air quality monitoring

Expected Precision and Reliability

- Precision - High
- Reliability - High

Tolerance or Variability Indicating Action - Reference standards

Frequency of Monitoring - This will depend on local activities Initially the frequency should be higher, until a baseline is established, perhaps at intervals of two to three times a week After ambient conditions are determined, frequency could be relaxed and targeted toward times when conditions exceed naturally-occurring ambient conditions, or the Forest is planning and conducting activities which threaten to exceed standards

Lead Responsibility - The Forest fire management group

Estimated Annual Cost

Installation of camera	\$2,000 per unit, or \$200/year
Annual operation and evaluation cost	\$1,500 per unit
Installation of aerosol monitoring unit	\$5,000 per unit, or \$500/year
Annual operation and evaluation cost	\$1,500 per unit

TOTAL COST \$3,700/year

Soils

Monitoring Item - Hydrologic Disturbance in Watersheds

Type of Monitoring - Implementation, Validation Designed to measure implementation of the standard and verify its applicability

Priority - Forest Priority Group 2

Where Applies - Watersheds 10, 11 and 12 (currently at or above the 30 percent level), and watersheds 13 and 25 (which are approaching the 30 percent level)

Indicator - Bank instability (natural versus management-induced) along representative stream reaches within the above-mentioned watersheds

Method - Rosgen stream-typing and Intermountain Region streambank stability ratings

Expected Precision and Reliability

- Precision - Moderate
- Reliability - Moderate

Tolerance or Variability Indicating Action - Determine if bank instability is occurring within the watersheds currently exceeding the 30 percent guideline Determine the sufficiency of the 30 percent guideline

Frequency of Monitoring - Annually, until the 30 percent figure is validated or changed by appropriate study

Lead Responsibility - The forest soil scientist will coordinate an integrated effort by watershed specialists and aquatic scientists

Estimated Annual Cost - \$4,500

Monitoring Item - Woody Residue Needs for Soil and Wildlife ✓

Type of Monitoring - Effectiveness/Validation

Priority - Forest Priority Group 1

Where Applies - Subsection, Watershed, Stand (~25 acres), Site

Indicator -

1 Size class, length, composition class to meet standards

1 logs of > 7" diameter @ small end and > 20' length

2 number of logs per acre consisting of logs in appropriate decomposition classes as shown in the Forestwide S&Gs for soil and wildlife

2 Acre/acres (patch) dependent upon analysis approach, and area size, species or life form (such as cavity-nesters) of interest

3 Distribution/condition/availability

1 stand

2 subwatershed or watershed

3 landscape (incl species type and sere(s))

4 subsection

4 Follow requirements for woody residue and dead and down material in the Forestwide S&Gs

Method - Sampling in project or analysis areas by subsection by watershed/subwatershed, by type, elevation, and soil productivity class (integrated resource inventory)

Also, follow procedures such as those outlined within "Guidelines for Sampling Some Physical Conditions of Surface Soils", by Steve Howes, John Hazard, and J Michael Geist, Pacific Northwest Region, July 1983 (R6-RWM-146-1983) Sampling would be on line transects

Role of partners will depend on the availability of funds and relation of partner skills to task needs

Expected Precision and Reliability

- Precision - Variable by type but generally high

- Reliability - High

Tolerance or Variability Indicating Action - Changes in management will be necessary when

A Baseline studies (inventory) refine dead/down needs in varied forest types for species needs,

B Monitoring of projects and comparison of results among treated areas demonstrate that current guidelines are in need of change

Measures and need for change in both (A) and (B) should be determined through evaluations of site, stand and landscape conditions coupled with baseline forestwide (systematic) species inventories and improved knowledge of regional life history characteristics and requirements for various species of wildlife that use dead and down logs

Frequency of Monitoring - (Soils) Prior to and following project analyses for each subsection Analyses and evaluations should include site, stand and landscape conditions For soils, monitoring would be conducted annually, until an adequate determination can be made for ground-disturbing resource management practices

Lead Responsibility - (Soils) Monitoring teams including soils, vegetation and wildlife/ecology specialists

Estimated Annual Cost - Will vary by the number of projects anticipated and planned to affect the distribution and abundance of dead and down material. Per analysis and project costs will vary, but will likely range from \$2,000 to \$4,000, depending on size of analysis area and levels of previous and expected disturbance. Costs do not include baseline inventories nor NEPA preparation.

Monitoring Item - Detrimental Soil Disturbance

Type of Monitoring - Implementation and Effectiveness

Priority - Forest Priority Group 2

Where Applies - Forestwide (select representative sites where various land treatments have occurred)

Indicator - At least 85 percent of the total area within an activity area must have soil in satisfactory condition, or, no more than 15 percent of an activity area may have detrimentally-disturbed soil. Detrimen- tally-disturbed soil is soil that has been displaced, compacted, puddled, or severely burned.

Method - Follow procedures such as those outlined in "Guidelines for Sampling Some Physical Condi- tions of Surface Soils", by Steve Howes, John Hazard, and J. Michael Geist, Pacific Northwest Region, July 1983 (R6-RWM-146-1983). Sampling would be done on line transects.

Expected Precision and Reliability

- Precision - Moderately high
- Reliability - Moderately high

Tolerance or Variability Indicating Action - For those resource practices consistently exceeding the 15 percent threshold, determine if techniques can be improved or another method found. Evaluate areas with greater than 15 percent soil disturbance for rehabilitation opportunities.

Frequency of Monitoring - Annually, until an adequate determination can be made for various resource practices that are ground-disturbing.

Lead Responsibility - Forest or District soil scientist

Estimated Annual Cost - \$5,000

Monitoring Item - Fine Organic Matter Retention

Type of Monitoring - Implementation and Effectiveness

Priority - Forest Priority Group 3

Where Applies - Forestwide (select representative sites, or habitat types, where various land treatments have occurred)

Indicator - At least 50 percent (evenly distributed) of the total area within an activity area must retain its fine organic matter (duff layer plus materials less than 3-inches in diameter) within forested ecosystems,

provide for a minimum of 65 percent ground cover (plants, litter and rock - greater than 3/4-inch in diameter) on rangeland ecosystems, or, in both ecosystems, an equivalent percentage if the site cannot naturally attain the minimum percentages mentioned above

Method - Follow procedures such as those outlined within "Guidelines for Sampling Some Physical Conditions of Surface Soils" by Steve Howes, John Hazard, and J Michael Geist, Pacific Northwest Region, July 1983, (R6-RWM-146-1983) Sampling would consist of line transects and 1/10th acre plots

Expected Precision and Reliability

- Precision - Moderately high to high
- Reliability - Moderately high to high

Tolerance or Variability Indicating Action - For those resource practices consistently exceeding the threshold, determine if techniques can be improved or another method found Evaluate areas exceeding the standard for rehabilitation opportunities

Frequency of Monitoring - Annually, until an adequate determination can be made for various ground-disturbing resource management practices

Lead Responsibility - Forest or District soil scientist

Estimated Annual Cost - \$1,000

BIOLOGICAL ELEMENTS

Fisheries, Water and Riparian Resources

Monitoring Item - Improvement of Water Quality Limited Streams

Type of Monitoring - Validation This monitoring should answer the question, Is water quality in these streams at the point where they can be delisted?

Priority - Forest Priority Group 1

Where Applies - First on streams listed as Water Quality Limited, and then, if necessary, monitoring will be extended to their tributaries and watersheds This item will follow updates to the State WQL lists

Indicator - Depends on the reason for listing, e g , on streams listed for nutrient concerns, nitrate + nitrite and orthophosphate are used as indicators If monitoring of streams for the specific compound or component turns up concerns, monitoring would be extended to find the source of the concern

Method - Approved protocols for the constituent of concern Procedures include those used by Idaho DWR - Division of Environmental Quality (BURP Methods), methods approved for the State of Wyoming, the U S Geological Survey, or in publications such as "Monitoring Protocols to Evaluate Water Quality Effects of Grazing Management on Western Rangeland Streams" by Stephen Bauer and Timothy Burton, October 1993 (EPA 910/R-93-017) Methods will change as water quality standards and assessment procedures change

Expected Precision and Reliability

- Precision - Depends on the parameter/constituent being measured (e g , nutrients may be in mg/l, but sediment measurements vary widely)
- Reliability - if conditions remain constant, should be able to reproduce Some constituents, though, vary with streamflow There are some things that are difficult to reproduce when dealing with a fluid medium

Tolerance or Variability Indicating Action - When it can be reliably determined that water quality standards are being violated, or that the stream cannot be removed from the WQL list because of deteriorated conditions

Frequency of Monitoring - Depends on the constituent being monitored Generally, one can expect to have to visit sites several times during the summer

Lead Responsibility - Forest hydrologist

Estimated Annual Cost - Monitoring all WQL streams has an estimated annual cost of approximately \$15,000 This would include a full-time person to do the monitoring at the GS-5 level

Monitoring Item - Application of Best Management Practices (BMPs)

Type of Monitoring - Implementation and Effectiveness Measures whether BMPs related to maintaining and improving water quality are being applied

Priority - Forest Priority Group 3

Where Applies - Project areas where BMP's are applied (such as timber sale areas, new roads, etc)

Indicator - Variable, depending upon the BMP which was applied

Method - For implementation monitoring, reviews would be conducted of projects by teams including the project planner, administrator, and interested specialists For effectiveness monitoring, water quality, soil characteristics (such as erosion), and fish habitat would be monitored for selected projects

Expected Precision and Reliability

- Precision - Variable, depending on the project and the impacts being measured
- Reliability - Results should be reasonably reproducible, unless conditions change between monitoring times

Tolerance or Variability Indicating Action - If BMP's are not being applied in situations which call for their use, a review would be conducted to determine the reasons If instream beneficial uses may be put at risk, or if unacceptable soil degradation is occurring, a review would be conducted to determine the reasons

Frequency of Monitoring -

Implementation monitoring: Once after projects are finished

Effectiveness monitoring Variable Water quality monitoring might be conducted several times per year Monitoring for changes in soils, fish habitat or channel condition may be conducted once per year

Lead Responsibility - Soil scientist, fisheries biologist, hydrologist

Estimated Annual Cost - Average cost would be between \$2,000 and \$10,000 per year, depending on what is being monitored

Monitoring Item - Native Cutthroat Trout Habitat Features ✓

Type of Monitoring - Validation Test the following critical planning assumptions 1) the "expected values" for water temperature and width/depth ratio, for a given Rosgen stream type, represent good habitat conditions for native cutthroat trout at the watershed scale, and 2) these conditions are attainable

Priority - Forest Priority Group 1 Monitoring needed to meet a Forest Plan objective Relates to many Forest Plan goals and provides a basis by which several guidelines were developed Monitoring needed to validate the "expected values" for water temperature and width/depth ratio because they are not strongly supported by site specific research There is strong public interest and agency concern over fisheries guidelines which may be unduly restrictive or lax

Where Applies - Within Native Trout Watersheds (17 identified at present)

Indicator - Number of Native Trout watersheds in which correlations have been completed

Method - Protocol to be determined

Phase 1 Within all Native Trout Watersheds, assess the population status of native cutthroat trout populations as to presence/absence, relative abundance, presence of other salmonid species, and

level of hybridization Survey techniques will employ snorkeling and electro-fishing

Phase 2 Where populations of native cutthroat trout exist, measure and record values for all of the six habitat features, including Rosgen stream type

Phase 3 Compare, at the watershed scale, the recorded values for water temperature and width/depth ratio to the "expected values "

Expected Precision and Reliability

- Precision - To be determined
- Reliability - At least 80 percent

Tolerance or Variability Indicating Action

Water temperature 1) meet State water quality standards, and 2) two degrees C above values in the table needed to meet biological requirements for native cutthroat trout

Width/depth ratio a factor of one

Frequency of Monitoring - Survey one time

Lead Responsibility - Forest Fisheries Biologist

Estimated Annual Cost - Monitoring costs could be incurred over a 2-5 year period Total cost is \$71,000 (assuming no cost-share above existing partnerships)

Year 1 \$ 9,000 (lower Henry's Fork drainage)

Year 2 \$26,000 (Teton drainages)

Year 3 \$36,000 (South Fork drainages)

Vegetation

Monitoring Item - Timber Volume Removed from Unsuitable and Suitable-Unscheduled (U/S-U) Lands

Type of Monitoring - Implementation

Priority - Forest Priority Group 1

Where Applies - Applies to harvest on lands not calculated in the Allowable Sale Quantity (ASQ)

Indicator - Million Board Feet (MMBF) for the Revised Plan initial decade

Method - Review project-level NEPA analysis for identification of U/S-U lands proposed for vegetation manipulation by timber harvest District timber sale project personnel include summary of cutting units on U/S-U lands and volume to be harvested with the Gate 3 Appraisal package submitted to the Contracting Officer for contract preparation

Expected Precision and Reliability

- Precision - High

- Reliability - High

Tolerance or Variability Indicating Action - U/S-U harvested volume exceeding 20 MMBF before completion of the Revised Plan initial decade

Frequency of Monitoring - Annually

Lead Responsibility - Forest Timber Contracting Officer and District Timber Sale project personnel

Annual Estimated Cost - \$1,000

Monitoring Item - Pest Increase in Managed Stands

Type of Monitoring - Effectiveness Detects increases in insect and disease attacks in vegetation polygons after management activities

Priority - Forest Priority Group 1 (required by regulation)

Where Applies - Forestwide where management activities have altered vegetation

Indicator - An increase in insect and/or disease activity as plotted on annual aerial survey maps

Method - Forest silviculturist will review the annual aerial survey maps issued by Forest Service Pest Management branch, paying special attention to any increased incidence of pest activity in recent activity areas

Expected Precision and Reliability

- Precision - Moderate to High
- Reliability - Moderate to High

Tolerance or Variability Indicating Action - Significant pest activity noted in or near recent activity areas in any given year, or low-level recurring pest activity noted over several years, will be cause for visiting the sites to determine whether the pest activity is occurring within recently-treated areas Further action will be taken as needed

Frequency of Monitoring - Annually

Lead Responsibility - Forest Silviculturist

Annual Estimated Cost - GS-12 @ \$200/day for three days per year = \$600

Monitoring Item - Ute Ladies'-Tresses Populations

Type of Monitoring - Effectiveness/Validation Designed to assess the effectiveness of standards and guidelines for livestock grazing and other activities for protection of this plant and its habitat

Priority - Forest Priority Group 1

Where Applies - Applies in occupied habitat and habitat suitable for the occurrence of this plant

Indicators -

- 1) Population trend as indicated by population size, condition or structure, in permanently marked or unmarked areas
- 2) Documented habitat changes as indicated by parameters such as hydrology, riparian successional stages, presence or absence of noxious weeds, etc

Method - To measure population trends, the size and condition of populations will be quantitatively monitored in marked and unmarked areas. In marked areas a permanently marked grid system will be used. Unmarked areas will be monitored using methods such as belt transects, quadrats or well-defined unmarked areas.

Habitat changes will be mapped and documented. In known population areas human activities will be recorded which have been or may be defined as threats to the species and its habitat.

Expected Precision and Reliability

- Precision - Generally high
- Reliability - Generally high if methods are applied correctly and data interpreted appropriately

Tolerance or Variability Indicating Action - Ute ladies'-tresses populations fluctuate with respect to the number of individuals flowering from year to year. In general, a sustained downward trend in population numbers would indicate a need for action.

Frequency of Monitoring - At least once a year during flowering and seed-set periods (generally August and September)

Lead Responsibility - Native plant program manager. State fish and game departments and other agencies will be invited to become involved as much as possible.

Annual Estimated Cost - \$1,500

Monitoring Item - Vegetation Structure, Composition, and Distribution of Sagebrush/Grassland Habitats

Type of Monitoring - Implementation

Priority - Forest Priority Group 3

Where Applies - Watersheds and subwatersheds

Indicator - Big sagebrush (*Artemisia tridentata*) canopy cover age distribution across a subwatershed or watershed

Method - Ocular estimate or Line Intercept Method for Crown Canopy Cover, described in the Forest Service Handbook 2209 21, Ch 44 51

Expected Precision and Reliability

- Precision - High
- Reliability - Moderate

Tolerance or Variability Indicating Action - When sagebrush/grassland habitat conditions are not within Forestwide S&Gs (vegetation)

Frequency of Monitoring - As needed

Lead Responsibility - District Rangeland Management Specialist

Estimated Annual Cost

One GS-9 @ \$175 00/day for 35 days = \$6,125/year

Wildlife ✓

Monitoring Item - Cavity Nesters

Thru V-31

Type of Monitoring - Effectiveness and/or Validation Designed to measure population trends of primary cavity nesting species and relationships to habitat changes

Priority - Forest Priority Group 1

Where Applies - Monitoring emphasis will be in the 5 x x series management prescriptions which allow timber harvesting Other management prescriptions will be monitored on an as needed basis depending on human activities and natural events such as fires

Indicator -

Population trend Birds per transect and/or birds per point

Habitat changes Percent biological potential (snags per 100 forested acres) as identified in the Forestwide S&Gs and the 5 x x series management prescriptions

Method -

Population trend Point count surveys following methods which have been used in the Neotropical Migratory Landbird Monitoring Project in the Big Hole Mountains (Kliene 1996) A minimum of 24 transects, with 10 to 15 point count stations per transect, distributed within the 5 x x series management prescriptions Surveys should be done in March and April, prior to the start of incubation Don't use playback calls

Habitat changes Documentation of changes in percent biological potential (snags per 100 forested acres) Several data sources could be used which include the following stand exam surveys, permanent forest inventory plots, and a methodology recently developed at the University of Idaho using variable length and width transects

Expected Precision and Reliability

- Precision - Moderate to High
- Reliability - Moderate to High

Tolerance or Variability Indicating Action -

Population trend Population trends are expected to be variable from year to year and are affected by habitat changes, weather conditions, predation, etc A declining trend for at least four years in a row would be an indication for action

Habitat changes Percent biological potential below that specified for a management prescription

Frequency of Monitoring - Annually

Lead Responsibility - Targhee National Forest State Fish and Game Departments and other agencies will be involved as much as possible

Estimated Annual Cost - \$3,800 (24 days at \$160/day/person)
 3,960 (vehicle expense, equipment, etc)
 800 (record keeping/report writing)
 \$8,600

Monitoring Item - Standing Dead Tree Habitat

Type of Monitoring - Effectiveness/Validation Determines degree to which wildlife requirements are met by standing dead and replacement green trees

Priority - Forest Priority Group 3

Where Applies - Subsection, Watershed, Stand (~25 acres), Site

Indicators -

- A diameter
- B tree species
- C tree height
- D composition (dead tree hardness/class)
- E number and dispersion of dead standing and replacement trees (dispersion refers to the evenness and clumpiness of dead and green replacement trees)

Factors to be considered include but are not limited to

- A Forest inventories for species that use dead standing trees
- B Number of species, species group or life form (e.g. cavity nesters, forest raptors, songbirds, furbearers) with potential to occur according to species distribution and available habitat characteristics (Note Guidelines do not assume that requirements for one species meet the needs for another where overlap in size and placement characteristics exist)
- C Size of female home range and breeding area requirements with representative habitat characteristics for successful breeding and fledging of young according to species of interest or concern
- D Existing landscape, stand, and site conditions and characteristics within analysis and treatment areas as determined by inventories prior to project implementation
- E Distribution/condition/availability
 - 1 stand
 - 2 subwatershed or watershed
 - 3 landscape (incl species type and sere(s))
 - 4 subsection

F Distribution of natural opening sizes, shapes and structural characteristics of forest seres comparing natural disturbance types to human-induced

G Occurrence and distribution of forest types and effective conditions at landscape, stand and site relative to potential for species occurrence, distribution and reproduction

Method - Systematic sampling in project or analysis areas by subsection by watershed/subwatershed, forest type, elevation, and soil productivity class (IRI inventory) Role of partners will be systematic inventories of habitat conditions and species occurrences prior to and after vegetation treatments

Expected Precision and Reliability

- Precision - Variable by species and forest (condition, characteristics) type but generally high
- Reliability - High

Tolerance or Variability Indicating Action - Changes in management will be necessary as

A Baseline studies (inventory) refine or replace dead standing and green replacement trees in varied forest types and conditions for species needs,

B Monitoring of projects and comparison of results among treated areas demonstrate that current guidelines are in need of change

Measures and need for change in both (A) and (B) should be determined through evaluations of site, stand and landscape conditions coupled with baseline forestwide (systematic) species inventories and improved knowledge of regional life history characteristics and requirements for various species of wildlife that use dead standing and green replacement trees

Frequency of Monitoring - Prior to and following project analyses for each subsection Analyses and evaluations should include site, stand and landscape conditions

Lead Responsibility - Forest wildlife biologist

Estimated Annual Cost - Will vary by the number of projects anticipated and planned to affect the distribution and abundance of dead and down material Per analysis and project costs will vary, but will likely range from \$1500 to \$3000 depending on size of analysis area, levels of previous disturbance, and expected disturbance Costs do not include baseline inventories nor NEPA preparation

Monitoring Item - Grizzly Bear Population

Type of Monitoring - Effectiveness and/or Validation Designed to measure grizzly bear population and relationship to habitat changes

Priority - Forest Priority Group 1

Where Applies - Grizzly Bear BMU's and Subunits

Indicator -

Population trend Population trends are developed for the entire Yellowstone recovery area, and are computed from several components of the grizzly bear population which include the following annual unduplicated sightings of females with cubs, distribution of females with cubs, total known mortality, total female mortality

Habitat changes Habitat changes are analyzed with the grizzly bear cumulative effects model (CEM), and include changes in vegetation (fires, timber harvesting, etc), road and trail access (also called linear activities), developed sites such as campgrounds, resorts, etc (also called point activities), and dispersed recreation such as hunting, berry picking, etc (also called dispersed activities)

Method -

Population trend In cooperation with the USFWS and Interagency Study Team, report all verified sightings of grizzly bears (especially sows with cubs) and all verified mortalities

Habitat changes Within the BMU's and Subunits, Ranger Districts will annually update information on vegetation, linear features, point activities, and dispersed activities This information will be maintained in the GIS database in the Supervisor's Office.

Expected Precision and Reliability

- Precision - Moderate for population trends (it is difficult to observe bears and verify all reported sightings) High for habitat changes
- Reliability - Moderate for population trends (it is difficult to observe bears and verify all reported sightings) High for habitat changes

Tolerance or Variability Indicating Action - Failure to meet the recovery targets as outlined in the Grizzly Bear Recovery Plan (this applies to the entire GYA recovery zone) Failure to meet the Forest Plan S&Gs for the BMU/Subunits on the Targhee National Forest

Frequency of Monitoring - Annually

Lead Responsibility - Population trend monitoring has been lead by the Interagency Grizzly Bear Study Team and the USFWS, Ranger Districts and the Supervisor's Office provide verified sighting information to the Study Team and USFWS Habitat monitoring is done by the Ranger Districts and Supervisor's Office

Estimated Annual Cost - \$19,200 (120 days at \$160/day (30 days/RD & SO))
8,550 (vehicle expense, equipment, etc)
800 (record keeping/report writing)
\$28,550

Monitoring Item - Grizzly Bear Habitat Improvement

Type of Monitoring - Implementation, Effectiveness Measures improvement in the quality of grizzly bear habitat on the Forest, and the contribution of the Forest to total grizzly bear habitat quality in the Greater Yellowstone Area

Priority - Forest Priority Group 1

Where Applies - Applies to all prescription areas within designated Bear Management Units (BMU's) on the Forest

Indicator - The primary indicators of trend in grizzly bear habitat are habitat effectiveness, habitat value, and bear displacement These three are described in detail in the documentation for the grizzly bear cumulative effects model (IGBC 1990)

In addition to the above, indicators will be used from the Interagency Grizzly Bear Committee Taskforce Report on Motorized Access Management (IGBC 1994)

Method - Each management unit of the Greater Yellowstone Area, including the Targhee National Forest, will annually submit data on changes in road and trail access, and vegetation, to the USDA-Forest Service Intermountain Regional Office. That office will compile the data, develop a data set fixed in time, and issue this in electronic digital form (CD-ROM). This data will then be forwarded to individual management units for on-site use and runs.

On the Targhee National Forest, individual ranger districts will track changes in road and trail access and vegetation. These will be submitted to the Forest GIS shop for assembly into a Forest data package.

Expected Precision and Reliability

- Precision - Very high
- Reliability - Results will be reproducible with the same data set

Tolerance or Variability Indicating Action - Refer to the item on achievement of road density standards

Frequency of Monitoring - Annually

Lead Responsibility - Forest wildlife biologist

Estimated Annual Cost - On each of the three ranger districts with grizzly bear habitat, one person (GS-9 wildlife biologist) will need two weeks to put together the input data required. On receipt of the CD-ROM data from the Regional Office, the Forest GIS shop will need one person (GS-7 tech) for one day to run the cumulative effects model on each of the seven subunits.

GS-9 biologist 3 districts, two weeks each @ \$150/day	\$4,500
GS-7 GIS technician 7 subunits, one day each @ \$110/day	\$ 770
TOTAL	\$5,270

Monitoring Item - Bald Eagle Nesting Population

Type of Monitoring - Effectiveness and/or Validation Measures the nesting population of bald eagles and its relationship to habitat changes

Priority - Forest Priority Group 1

Where Applies - All bald eagle nesting territories

Indicator -

Population trends Occupancy and productivity of all bald eagle nesting territories

Habitat changes Changes in vegetation within nesting territories, changes in human activities within nesting territories

Method -

Population trends Standard monitoring of occupancy and productivity which has been done for more than a decade

Habitat changes Documentation and mapping of vegetation changes within nesting territories using the forest GIS database Documentation of changes in human activities within nesting territories, which may include recreation use (boating, floating, fishing, etc), motorized access, construction activities, etc

Past monitoring has been a cooperative effort with the Idaho Department of Fish and Game, BLM, U S Fish and Wildlife Service, Forest Service, and some private individuals It is expected that this cooperation will continue in the future

Expected Precision and Reliability

- Precision - High for population trends and vegetation changes Moderate to high for human activities
- Reliability - High for population trends and vegetation changes Moderate to high for human activities

Tolerance or Variability Indicating Action - Failure of an adult pair to occupy a nesting territory more than two years in a row Data on productivity shows that spring weather has a great influence on productivity Therefore, reductions in productivity must indicate factors other than spring weather are responsible for reduced productivity

Frequency of Monitoring - Annually

Lead Responsibility - Coordinated by the Forest wildlife biologist

Estimated Annual Cost - \$16,000

Monitoring Item - Gray Wolf Population

Type of Monitoring - Effectiveness and/or Validation Designed to measure gray wolf population and relationship to habitat changes

Priority - Forest Priority Group 1

Where Applies - Forestwide

Indicator -

Population trend Number of wolf packs, reproduction, movements, and mortality are being monitored

Habitat changes Intrusive human disturbances within one mile around active den sites and rendezvous sites between April 1 and June 30, when there are five or fewer breeding pairs of wolves in each experimental population area Forestwide standards for livestock grazing and gray wolves

Method -

Population trend In cooperation with the USFWS and monitoring teams, report all verified sightings of gray wolves (especially evidence of packs)

Habitat changes Within one mile of active den sites and rendezvous sites, restrict intrusive human disturbances between April 1 and June 30, when there are five or fewer breeding pairs of

wolves in each experimental population area Increase monitoring of livestock allotments where wolf packs have established

Expected Precision and Reliability

- Precision - High
- Reliability - High

Tolerance or Variability Indicating Action - Failure to implement the Revision S&Gs for gray wolves

Frequency of Monitoring - Annually

Lead Responsibility - Habitat monitoring is done by the Ranger Districts and Supervisor's Office, and coordinated by the Forest biologist Population trend monitoring has been lead by the USFWS and wolf monitoring teams Ranger Districts and the Supervisor's Office provide verified sighting information to the USFWS

Estimated Annual Cost - \$8,000 (50 days at \$160/day)
 2,000 (vehicle expense, equipment, etc)
 800 (record keeping/report writing)
 \$10,800

Monitoring Item - Peregrine Falcon Nesting Population

Type of Monitoring - Effectiveness and/or Validation Designed to measure the peregrine falcon nesting population and relationship to habitat changes

Priority - Forest Priority Group 1

Where Applies - All peregrine falcon nest sites and territories

Indicator -

Population trend Occupancy and productivity of all peregrine falcon nest sites and territories

Habitat changes The primary concern is human activity, such as rock climbing, at known nest sites In the past, use of pesticides which caused egg shell thinning was the primary concern Human activities and use of pesticides will be the main habitat changes monitored General habitat conditions and changes within the foraging area will also be monitored

Method -

Population trend Standard monitoring of occupancy and productivity which has been done for more than a decade

Habitat changes Periodic visits to nest sites to document changes in human activities If necessary, cameras could be established to document human activity at nest sites Documentation of the use of pesticides Documentation of general habitat changes through tracking of proposed project activities and GIS databases

Past monitoring has been a cooperative effort with the Idaho Department of Fish and Game, BLM, U S Fish and Wildlife Service, Forest Service, and some private individuals It is expected that this cooperation will continue in the future

Expected Precision and Reliability

- Precision - High for population trends Moderate to high for human activities
- Reliability - High for population trends Moderate to high for human activities

Tolerance or Variability Indicating Action - Peregrine falcon nest sites may not be occupied or produce young every year Nest sites may also change over time A nest site not occupied for more than two consecutive years may indicate the need to assess needed management actions

Frequency of Monitoring - Annually

Lead Responsibility - Forest biologist

Estimated Annual Cost - \$4,800 (30 days at \$160/day)
 1,200 (vehicle expense, equipment, etc)
 800 (record keeping/report writing)
 \$6,800

Monitoring Item - Furbearer Population Trends

Type of Monitoring - Effectiveness and/or Validation Measures the population trends of marten, fisher, wolverine, and relationships to habitat changes

Priority - Forest Priority Group 1

Where Applies - Ecological subsections of the Forest

Indicator -

Population trend travel distance per encounter of tracks or other sign, (example 1 43 marten tracks or sign per mile)

Habitat changes documented changes in important habitat parameters such as forest seral stages, dead and downed woody debris, motorized access, etc

Method -

Population trend Winter track/sign surveys following procedures developed by Dr Steve Minta in the Western Yellowstone Forest Carnivore Project Briefly a minimum of three sampling units of four square miles in each ecological subsection, with 8 to 10 linear miles of snowmachine routes in each sampling unit Each sampling unit should be sampled 3 times during the winter period Specific protocol is documented in Western Yellowstone Forest Carnivore Project Study

Since wolverine and fisher are extremely rare, additional monitoring using the following techniques may be used

A Scent stations with cameras and/or track recording,

B Surveys of natal denning areas in boulder fields (for wolverine),

C All observations from reputable sources will be recorded and maintained in District and Forest databases

Habitat changes Documentation and mapping of changes in forest seral stages (timber harvest, fires, etc) in the Forest GIS database Documentation of changes in motorized access (see road and trail access monitoring items) Loss of dead and downed woody debris due to firewood gathering, timber harvesting, etc

Expected Precision and Reliability

- Precision - Moderate to High
- Reliability - Moderate to High

Tolerance or Variability Indicating Action - Furbearer populations will fluctuate naturally due to a variety of factors such as weather, prey abundance, trapping pressure (martens), etc Populations are expected to change due to programmed management actions like timber harvesting, as predicted in the FEIS Therefore a sustained downward trend for at least four sampling winters which is greater than expected from programmed management actions will trigger management review

Frequency of Monitoring - At least half of the ecological subsections each winter

Lead Responsibility - Forest wildlife biologist State Fish and Game Departments and other agencies will be involved as much as possible

Estimated Annual Cost - \$18,000

Monitoring Item - Goshawk Population Trends

Type of Monitoring - Effectiveness and/or Validation Designed to measure population trends of goshawks and relationships to habitat changes

Priority - Forest Priority Group 1

Where Applies - Forestwide

Indicator -

Population trend adult occupancy of known goshawk nesting territories

Habitat changes documented changes in important habitat parameters identified in the Forestwide S&Gs within known goshawk nesting territories

Method -

Population trend Random sampling of adult occupancy at a minimum of 15 goshawk nesting territories each year Sampling can occur during April (no taped calls), and June 10-30 (using taped calls) More than one trip to each territory may be needed to accurately assess adult occupancy Alternate nest sites must be checked

In addition to random sampling, all verified observations of adult occupancy in territories will be recorded All new verified territories will be added to the forestwide database

Habitat changes Documentation and mapping of changes in habitat conditions identified in the Forestwide S&Gs within active and historic nest territories, using the forest GIS database

Expected Precision and Reliability

- Precision - Moderate to High
- Reliability - Moderate to High

Tolerance or Variability Indicating Action - Habitat changes which exceed the Forestwide goshawk S&Gs Goshawk territories are not always occupied every year. However, overtime, a stable population should revolve around some average occupancy rate. A sustained downward trend of adult occupancy for at least four years may indicate a need for action.

Frequency of Monitoring - Annually

Lead Responsibility - Targhee National Forest, State Fish and Game Departments and other agencies will be involved as much as possible.

Estimated Annual Cost -
\$7,200 (1 person for 45 days at \$160/day)
4,550 (vehicle expense, equipment, etc.)
800 (record keeping/report writing)
\$12,550

Monitoring Item - Forest Owl Population

Type of Monitoring - Effectiveness and/or Validation. Designed to measure population trends of boreal, great gray and flammulated owls, and relationships to habitat changes.

Priority - Forest Priority Group 1

Where Applies - Ecological subsections of the forest

Indicator -

Population trend: Travel distance per encounter of calling adults (example: 0.5 boreal owl or great gray owl encounters per ten miles)

Habitat changes: Documented changes in important habitat parameters such as forest seral stages, dead and downed woody debris, etc., within active and historic nesting territories.

Method -

Population trend: A minimum of ten miles of calling transects within each ecological subsection (70 miles total) conducted each year. Briefly, Boreal owls can be surveyed from about February through April, great gray owls from March through May, and flammulated owls during May. Follow standard survey/calling protocol which has been used on the forest for owl surveys for the past several years. About four miles of transect can be done in one night by one team.

In addition to the survey routes, all verified observations of boreal, great gray, and flammulated owls during the nesting and brooding/rearing seasons will be recorded and maintained in a forest database.

Habitat changes: Documentation and mapping of changes in forest seral stages (due to timber harvest, fires, etc.) within active and historic nest territories, using the forest GIS database. Loss of dead and downed woody debris due to firewood gathering, timber harvesting, etc.

Expected Precision and Reliability

- Precision - Moderate to High
- Reliability - Moderate to High

Tolerance or Variability Indicating Action - Forest owl populations will fluctuate naturally due to a variety of factors such as weather, prey abundance, etc. Forestwide S&Gs were developed to maintain suitable habitat conditions in known territories. Therefore a sustained downward trend for at least four sampling years which can be correlated with changes in habitat conditions due to vegetation management or natural events such as fire will trigger management review.

Frequency of Monitoring - Annually

Lead Responsibility - Forest biologist. State Fish and Game Departments and other agencies will be involved as much as possible.

Estimated Annual Cost - \$5,760 (2 person teams/18 days at \$160/day/person)
 4,520 (vehicle expense, equipment, etc)
 800 (record keeping/report writing)
 \$11,080

Monitoring Item - Trumpeter Swan Nesting Population

Type of Monitoring - Effectiveness and/or Validation. Designed to measure nesting populations and relationship to habitat changes.

Priority - Forest Priority Group 1

Where Applies - Trumpeter swan nesting habitat, highest priority will be the ponds and lakes identified in the Forestwide S&Gs.

Indicator -

Population trend. Occupancy of suitable nesting habitat and productivity of swan pairs using suitable nesting habitat.

Habitat changes. Changes in riparian and aquatic habitat within or adjacent to suitable nesting habitat, changes in human activities within or adjacent to suitable nesting habitat.

Method -

Population trend. Standard monitoring of occupancy and productivity which has been done for more than a decade. Emphasis will be on those sites listed in the trumpeter swan Forestwide S&Gs.

Habitat changes. Documentation and mapping of riparian and aquatic vegetation changes at suitable nesting ponds and lakes. Documentation of changes in water depths. Documentation of changes in human activities at suitable nesting ponds and lakes, which may include recreations use, motorized access, livestock grazing, etc.

Expected Precision and Reliability

- Precision - High for population trends. Moderate to high for habitat changes.

- Reliability - High for population trends Moderate to high for habitat changes

Tolerance or Variability Indicating Action - From 1982 to 1996, the number of sites occupied by pairs has ranged from 7 to 17 Only one site has been occupied by a swan pair all 15 years, and only one site has been occupied by a swan pair 14 out of the 15 years Total young observed has ranged between 3 and 16 for the 15 years of data The recent work to move swans to new areas may have resulted in reduced pairs using suitable habitat on the forest We therefore expect a lot of variability between years However, a downward trend in the number of pairs and/or productivity for more than four years in a row would indicate that some management action may be necessary

Frequency of Monitoring - Annually

Lead Responsibility - Forest biologist Ranger Districts will gather data, in cooperation with the State Fish and Game Departments and the U S Fish and Wildlife Service (Red Rock Lakes National Wildlife Refuge)

Estimated Annual Cost -	\$3,200 (20 days at \$160/day)
	1,000 (vehicle expense, equipment, etc)
	800 (record keeping/report writing)
	\$5,000

Monitoring Item - Spotted Frog Population

Type of Monitoring - Effectiveness and/or Validation Designed to measure populations of frogs and relationship to habitat changes

Priority - Forest Priority Group 1

Where Applies - Spotted frog habitat, which is riparian and wetland areas on the northern portions of the Forest

Indicator -

Population trend Occupancy at documented sites and relative abundance at those sites

Habitat changes Changes in riparian and aquatic habitat conditions within or adjacent to documented sites, changes in human activities within or adjacent to documented sites

Method -

Population trend The Forest and Idaho State University recently completed a survey of spotted frogs on the forest Sites with spotted frogs were documented, and a relative estimate of the frog population observed at each site was made Each year, random sampling of occupancy and relative abundance will be done at a minimum of 15 sites, using the same techniques and procedures as used by Idaho State University In addition to resurveying known sites, new sites with spotted frogs will be added to the data base, and included in the survey program

Habitat changes Spotted frog habitat is to be managed according to Rx 2 8 3 and Forestwide S&Gs for Fisheries, Water and Riparian Resources As spotted frog sites are surveyed each year, documentation will be done on the habitat conditions and adherence to the management direction Conditions will be compared with descriptions from the Idaho State University survey reports

Expected Precision and Reliability

- Precision - Moderate for population trends Moderate to high for habitat changes
- Reliability - Moderate for population trends Moderate to high for habitat changes

Tolerance or Variability Indicating Action - The survey results from Idaho State University indicate that spotted frog distribution and abundance is highly variable between years, and is strongly influenced by moisture and water We expect survey results to be variable A consistent decline in the relative abundance of frogs at a majority of the survey sites, and a downward trend in riparian habitat conditions, would indicate that some management action may be necessary

Frequency of Monitoring - Annually

Lead Responsibility - Forest biologist will coordinate work by district personnel Other agencies and institutions will be involved as much as possible

Estimated Annual Cost - \$4,000 (25 days at \$160/day)
 1,000 (vehicle expense, equipment, etc)
 800 (record keeping/report writing)
 \$5,800

Monitoring Item - Common Loon Population

Type of Monitoring - Effectiveness and/or Validation Designed to measure populations of common loons and relationship to habitat changes

Priority - Forest Priority Group 1

Where Applies - Suitable common loon nesting and brood rearing habitat identified in Process Paper D Additional sites may be added when new information documents that new sites are suitable

Indicator -

Population trend Occupancy at documented sites and productivity of breeding pairs at those sites

Habitat changes Changes in riparian and aquatic habitat conditions within or adjacent to documented sites, changes in human activities within or adjacent to documented sites

Method -

Population trend Annually document the presence of common loons at the sites listed in Process Paper D Several visits should be made to each site during the nesting and brood rearing seasons to document the presence of young

Habitat changes Common loon habitat is to be managed according to prescription 2 8 3 and Forestwide S&Gs for Fisheries, Water and Riparian Resources As common loon sites are surveyed each year, habitat conditions and adherence to the management direction will be documented

Expected Precision and Reliability

- Precision - High for population trends Moderate to high for habitat changes

- Reliability - High for population trends Moderate to high for habitat changes

Tolerance or Variability Indicating Action - Successful reproduction by common loons has been documented at only three sites Our data indicates that occupancy by pairs and successful reproduction does not occur every year at these sites The Forest Plan has two objectives for common loons One objective is to evaluate the potential to provide and maintain suitable breeding habitat The second objective is to develop common loon management plans for suitable sites if the evaluation indicates there is potential to provide and maintain suitable breeding habitat While these objectives are being accomplished, we want to maintain existing habitat conditions and existing levels of common loon pairs

Frequency of Monitoring - Annually

Lead Responsibility - Forest biologist and Ranger Districts Other agencies and institutions will be involved whenever possible

Estimated Annual Cost - \$1,600 (10 days at \$160/day)
 400 (vehicle expense, equipment, etc)
 400 (record keeping/report writing)
 \$2,400

Monitoring Item - Harlequin Duck Population

Type of Monitoring - Effectiveness and/or Validation Designed to measure populations of harlequin ducks and relationship to habitat changes

Priority - Forest Priority Group 1

Where Applies - Suitable harlequin duck nesting and brood rearing habitat identified in Process Paper D Additional sites may be added when new information documents that new sites are suitable

Indicator -

Population trend Occupancy at documented sites and productivity of breeding pairs at those sites

Habitat changes Changes in riparian and aquatic habitat conditions within or adjacent to documented sites, changes in human activities within or adjacent to documented sites

Method -

Population trend Annually document the presence of harlequin ducks at the sites listed in Process Paper D Several visits should be made to each site during the nesting and brood rearing seasons to document the presence of young

Habitat changes Harlequin duck habitat is to be managed according to Rx 2 8 3 and Forestwide S&Gs for Fisheries, Water and Riparian Resources, and Forestwide S&Gs for harlequin ducks As harlequin duck sites are surveyed each year, documentation will be done on the habitat conditions and adherence to the management directions

Expected Precision and Reliability

- Precision - Moderate for population trends Moderate to high for habitat changes
- Reliability - Moderate for population trends Moderate to high for habitat changes

Tolerance or Variability Indicating Action - Successful reproduction by harlequin ducks has been documented at only three sites. Our data indicates that occupancy by pairs and successful reproduction does not occur every year at these sites. If harlequin duck presence is to be maintained on the forest, existing habitat conditions and existing levels of harlequin duck pairs must be maintained. Any decline in existing habitat conditions may indicate the need for action.

Frequency of Monitoring - Annually

Lead Responsibility - Forest biologist will coordinate work by district personnel. Other agencies and institutions will be involved as much as possible.

Estimated Annual Cost - \$3,200 (20 days at \$160/day)
 800 (vehicle expense, equipment, etc)
 800 (record keeping/report writing)
 \$4,800

Monitoring Item - Elk Vulnerability and Elk Habitat Effectiveness

Type of Monitoring - Effectiveness and/or Validation

Priority - Forest Priority Group 1

Where Applies - Forestwide

Indicator -

Population trend: Percent bull elk mortality during the general elk hunting seasons

Habitat changes: Open road and open motorized trail route density (OROMTRD), cross-country OHV use, hiding cover

Method -

Population trend: Percent bull elk mortality is gathered by the State Fish and Game Departments

Habitat changes: OROMTRD is covered in the Road and Trail Access monitoring. Cross-country OHV use will be monitored during the fall general elk seasons with the help of the State Fish and Game Departments. Cover analysis will be updated using the Forest GIS vegetation database to account for natural disturbances (such as fire) and management activities (such as timber harvesting)

Expected Precision and Reliability

- Precision - High
- Reliability - High

Tolerance or Variability Indicating Action - Failure to implement the Revision S&Gs for OROMTRD, cross-country OHV travel, and timber harvesting

Frequency of Monitoring - Annually

Lead Responsibility - Forest biologist compiles data. Percent bull elk mortality is done by the State Fish

and Game Departments Ranger Districts and the Supervisor's Office have the lead on OROMTRD, cross-country OHV travel, and cover analysis

Estimated Annual Cost - \$9,600 (60 days at \$160/day)
 2,400 (vehicle expense, equipment, etc)
 800 (record keeping/report writing)
 \$12,800

Monitoring Item - Red Squirrel Population

Type of Monitoring - Effectiveness and/or Validation Designed to measure population trends of red squirrels and relationship to habitat changes

Priority - Forest Priority Group 1

Where Applies - Grizzly bear BMU's and subunits

Indicator -

Population trend Densities of active squirrel middens

Habitat changes Cone producing conifer stands, with emphasis on cone producing whitebark pine

Method -

Population trend Follow methodology described by David J Mattson and Daniel P Reinhart in "Indicators of Red Squirrel (*Tamiasciurus hudsonicus*) Abundance in the Whitebark Pine Zone," Great Basin Naturalist 56(3) 272-275 (1996)

Habitat changes Documentation and mapping of changes in forest seral stages (due to timber harvest, fires, etc) within grizzly bear BMU's and subunits, using the Forest GIS database

Expected Precision and Reliability

- Precision - Moderate to high
- Reliability - Moderate to high

Tolerance or Variability Indicating Action - Red squirrel populations will fluctuate with natural fluctuations in cone crops due to weather and other variables and disturbances which replace cone bearing age trees such as fire and timber harvesting. The management objective is to maintain red squirrel populations wherever suitable habitat occurs. Therefore, a population decline in suitable habitat that cannot be correlated with natural fluctuations in cone crops may indicate action is needed

Frequency of Monitoring - Annually

Lead Responsibility - Forest biologist

Estimated Annual Cost - \$12,800 (2 person teams/40 days at \$160/day)
 2,000 (vehicle expense, equipment, etc)
 800 (record keeping/report writing)
 \$15,600

FOREST USE AND OCCUPATION

Forest Users

Monitoring Item - User Satisfaction

Type of Monitoring - Implementation, Effectiveness Designed to measure forest customer satisfaction with the direction, progress, and administration of the Revision

Priority - Forest Priority Group 2

Where Applies - Forestwide

Indicator - Comments, both written and oral, approving or disapproving of the direction of Forest management and the rate of progress in implementing it

Method - Forest User mailing lists would be used to periodically build random samples Individuals and groups on this list would then be sampled using methods such as phone surveys or mailings These samples would be conducted by organizations or academic institutions with sampling expertise, under contract to the Forest Informal, optional, person-to-person user surveys would be conducted of trail users, campers, and sport recreationists by field-going Forest personnel Records and notes would be kept of public meetings held by the Forest Forest employees would be encouraged to record and submit informal notes of opinions and suggestions of friends and family for consideration by the Forest

Expected Precision and Reliability

- Precision - Samples designed with statistical principles could be quite accurate Otherwise it would still provide a reasonable indication to managers
- Reliability - The results should be reasonably reproducible

Tolerance or Variability Indicating Action - This would have to determined by Forest line officers based on the issue

Frequency of Monitoring - Annually or as needed

Lead Responsibility - Forest Public Affairs Officer

Estimated Annual Cost - Working with a survey organization would require three weeks per year for the Public Affairs Officer Helping to assess the surveys would require GS-9 employees To conduct field surveys of recreationists would require two weeks for two GS-9 employees

Contract to conduct phone sample	\$3,000
GS12 PAO, three weeks @ \$1,000/wk	\$3,000
GS9 45 hours at \$18/hr	\$ 810
GS9 (field survey), 4 wks @ \$18/hr	\$2,880
TOTAL	\$9,690

Forest Operation

Monitoring Item - Budget

Type of Monitoring - Implementation and Effectiveness

Priority - Forest Priority Group 1 Required by regulation at 36 CFR 219 12(K)(3)

Where Applies - Forestwide

Indicator - Forest budget adjusted for the effects of inflation

Method - Convert annual budget figures to the same basis as the Revision's projected budget Compare the results

Expected Precision and Reliability

- Precision - High
- Reliability - High

Tolerance or Variability Indicating Action - +/- 25 percent of projected budget

Frequency of Monitoring - Every five years

Lead Responsibility - Forest Budget and Finance Officer

Annual Estimated Cost - \$1,000 every five years

Recreation

Monitoring Item - Seasonal Trail Use Impacts to Soil and Vegetation

Type of Monitoring - Implementation and Effectiveness Designed to measure the impacts to on-trail and off-trail soils and vegetation from impacts from hiking, horse use and OHV use, for compliance with the 15 percent soil disturbance policy

Priority - Forest Priority Group 2

Where Applies - System trail and off-trail areas

Indicator - Soil displacement on the trail or within the adjacent meadow or basin area

Method - Visual and photo documentation and trail condition surveys

Expected Precision and Reliability

- Precision - 60-75 percent
- Reliability - 60-75 percent

Tolerance or Variability Indicating Action - When condition surveys show that use is impacting the trail tread or adjacent soils and vegetation such that significant resource damage, health, and safety, or trail maintenance are at risk

Frequency of Monitoring - Annually on approximately 5-10 percent of the system trail areas (60-120 miles) and adjacent off-trail areas (Priority areas initially are the Big Hole Mountains, Madison-Pitchstone Plateaus, Caribou Range Mountains and Lemhi-Medicine Lodge subsections)

Lead Responsibility - Recreation and Engineering Staffs

Estimated Annual Cost - \$25,000-35,000

Monitoring Item - Recreation/Wildlife Conflicts

Type of Monitoring - Implementation and Effectiveness Designed to measure conflicts between all forms of recreation and wildlife

Priority - Forest Priority Group 2

Where Applies - Forestwide

Indicator - Number of violations of closure areas, observed wildlife disturbances, and diminishing wildlife populations or signs of stress

Method - Field and aerial observations, photography This item will depend partially on the results of monitoring of the effectiveness of road closures, which is another Priority Group 2 item

It is expected that partnerships can be developed with state game and fish agencies, State recreation agencies, other agencies and possibly recreation user groups to monitor this item

Expected Precision and Reliability

- Precision - 50-75 percent
- Reliability - 50-75 percent

Tolerance or Variability Indicating Action - When evaluation of wildlife populations indicates they are beginning to falter or seek out other areas for security and solitude, then an evaluation of recreation use levels will take place Evaluation of other uses of the area may also be appropriate

Frequency of Monitoring -

- Winter, in prescription areas emphasizing winter range values weekly in 10 percent of winter range per year for 3-4 months,
- Summer, in prescription areas emphasizing big game security or summer range values weekly for 3 to 4 months, especially in the early summer

Lead Responsibility - District Rangers

Estimated Annual Cost - \$30,000

Monitoring Item - Dispersed Campsite Soil Displacement

Type of Monitoring - Implementation, Effectiveness Designed to measure soil displacement in heavy-use dispersed campsites, for compliance with the 15 percent soil disturbance policy

Priority - Forest Priority Group 3

Where Applies - 4 3 prescription areas

Indicator - Displaced soil

Method - Frissell Condition Class method

Expected Precision and Reliability

- Precision - 75 percent+
- Reliability - Very Good, 75 percent+

Tolerance or Variability Indicating Action - Significant or consistent violation of the 15 percent soil disturbance policy in 4 3 prescription areas will be cause to reexamine campsite use This may also trigger validation monitoring of the propriety of applying the policy in these areas

Frequency of Monitoring - Annually, within approximately 10 percent of the one hundred 4 3 prescription areas (Lemhi-Medicine Lodge and Caribou Range Mountains subsections will receive top priority for this monitoring initially)

Lead Responsibility - Forest Recreation Staff

Estimated Annual Cost - \$40,000

Monitoring Item - Jedediah Smith Wilderness LAC

Type of Monitoring - Implementation and Effectiveness Designed to measure impacts from wilderness use on wilderness quality (from the Limits of Acceptable Change planning process for the Jedediah Smith Wilderness)

Priority - Forest Priority Group 3

Where Applies - Jedediah Smith Wilderness

Indicator - See The Jedediah Smith monitoring plan which follows

Method - See The Jedediah Smith plan which follows

Expected Precision and Reliability

- Precision - 75 percent
- Reliability - 75 percent

Tolerance or Variability Indicating Action - If it is determined that impacts from use of the Wilderness are exceeding those limits shown, then an evaluation will be made of the possible causes and potential remediations identified

Frequency of Monitoring - Annually

Lead Responsibility - Teton Basin Ranger District, and Forest Recreation Staff

Estimated Annual Cost - \$15,000-20,000

Jedediah Smith Wilderness Monitoring Plan - Further Details

INDICATORS AND STANDARDS

Indicators and standards will be monitored yearly and may require adjustment if on site administration indicates resources or social conditions are deteriorating beyond an acceptable level. These measurements relate only within each specific zone of the Wilderness and not all of one type of zone lumped together. In other words, for Class 1, if the standard is exceeded in a particular Class 1 zone, then management action will be taken. Following each indicator is a list of management actions which could be used to bring the indicator back to the identified standard for its class. The order of the actions shown does not indicate priority.

Indicator #1	Standards			
	Class 1	Class 2	Class 3	Issues 1/
Number of occupied campsites users may see from their site	0	2	3	1, 2, 4

Possible Management Actions - If number of visible campsites is approaching or exceeds standards

- 1 Remove campsite(s) and restore the area to as near natural condition as possible
- 2 Relocate campsite(s) to more suitable location and restore to as near natural condition as possible
- 3 Talk with users and suggest other camping possibilities

Indicator #2	Standards			
	Class 1	Class 2	Class 3	Issues 1/
Condition of individual campsites	vegetation flattened, not permanently injured	vegetation worn away at center of activity	vegetation lost around center of activity	1, 2, 5

Possible Management Actions - If condition of campsite is approaching or exceeds standards

- 1 Rehabilitate the site, sign it for restoration, and/or close it
- 2 Talk with users about minimum impact camping techniques
- 3 Relocate site to a more durable location and restore the vacated campsite to as near natural condition as possible
- 4 Visit local schools, organizational groups to discuss wilderness ethics, regulations, minimum impact practices

Indicator #3	Standards			
	Class 1	Class 2	Class 3	Issues 1/
Condition of user-created routes and trail segments	game trail	18" to 42" wide, brush, rock, litter present	42" wide, brushed out along edge	1, 2, 4

Possible Management Actions - If user-created route or trail is approaching or exceeds standard

- 1 Talk with users about trail conditions and experiences
- 2 Ensure trail crews and maintenance volunteers are aware of standards and do not exceed them
- 3 Rehabilitate trail sections that exceed standards
- 4 Relocate trail segments to more suitable locations
- 5 Encourage use on other trails
- 6 Limit number of users on trail
- 7 Visit local schools, organizational groups to discuss wilderness ethics, regulations, minimum impact practices

Indicator #4	Standards			
	Class 1	Class 2	Class 3	Issues 1/
Number of encounters per mile with other parties along a user-created route or trail	0*	3*	5*	1, 2, 3, 4, 5
* Encounters may be higher within first mile of trail from trailhead				

Possible Management Actions - If number of encounters is approaching or exceeds standards

- 1 Encourage users to vary starting times
- 2 Lower party size and stock limits
- 3 Monitor user acceptance of trail use levels
- 4 Encourage users to go to other places

Indicator #5	Standards			
	Class 1	Class 2	Class 3	Issues 1/
Number of substantiated complaints about outfitters and grazing permittees from the public and other permittees	2	5	10	3, 5

Possible Management Actions - If the number of complaints concerning permittees is approaching or exceeds standards

- 1 Increase permit administration on the ground
- 2 Require wilderness ethics education as a condition of permit issuance
- 3 Restrict the number of permits issued
- 4 Bring parties together to discuss issue(s)

Indicator #6	Standards			
	Class 1	Class 2	Class 3	Issues 1/
Number of violations of regulations by type	5	10	15	1, 3, 5
1/ See process paper for Jedediah Smith Wilderness				

Possible Management Actions - If the number of violations is approaching or exceeding standards

- 1 Increase presence of uniformed Forest Service personnel
- 2 Visit local schools, organizational groups to discuss wilderness ethics, regulations, minimum impact camping techniques
- 3 Review regulations for appropriateness
- 4 Increase posting of regulations at trailheads

MONITORING

Air Quality

- 1 Monitor acid deposition in Wilderness lakes Specifically, Two Island Lake is extremely sensitive to acid deposition, and Middle Granite Lake is more typical of Wilderness lakes with some buffering capacity Reference for more information the water quality survey conducted in 1992 by personnel from the Targhee and Bridger-Teton National Forests
- 2 Monitor visual air quality by means such as periodic photography Consider establishing a monitoring station at the Grand Targhee ski area or other location which would permit observation of air quality in both the Wilderness and Grand Teton National Park

Wildlife

- 1 Monitor human/grizzly interactions (confrontations and movements) to determine any change in the known range of the bear, and which management actions are needed if any
- 2 Monitor grizzly bear activity and movement relevant to domestic sheep grazing to determine which management actions are needed if any
- 3 Continue annual population censusing of bighorn sheep including lamb survival and ram harvest (Wyoming Game and Fish Department)

Cultural Resources

Monitor cultural resource sites in high public use areas annually to assess potential and actual effects Formulate mitigations in conjunction with the Wyoming State Historic Preservation Officer when effects are adverse

Roads and Trails Access

Monitoring Item - Authorized Use Level

Type of Monitoring - Implementation Designed to measure the amount of authorized motorized use on closed roads and trails, to determine if a route or area is effectively open

Priority - Forest Priority Group 2

Where Applies - This item is most important in prescriptions which feature the following

- * elk and deer habitat values—5 1 4, 5 4, 2 7,
- * grizzly bear habitat values—5 3 5, 2 6 1, 2 6 2, 2 6 5,

Indicator - The number of motorized trips per week per route

Method - The districts will keep a record of administrative motorized use allowed on each route by date. This record could be maintained by the district ranger, and could be supported by an entry of dates and trips made per road, returned gate permits, or other means. At reporting time this record would be totalled and an evaluation made as to whether or not the number of trips throughout the summer effectively opened the road. Those roads opened would be noted to the GIS shop.

Expected Precision and Reliability

- Precision - Precision could be high depending on the accuracy of the record keeping
- Reliability - The results would be wholly dependent on the records kept

Tolerance or Variability Indicating Action - Reference prescription standards

Frequency of Monitoring - Annually

Lead Responsibility - The district ranger would keep records of allowed entries onto closed routes for administrative purposes, and evaluate the data. The Forest GIS shop would display any resultant roads which are effectively opened.

Estimated Annual Cost

- * Two days per district per GS-9 biologist 5 (\$450)
- * Two days for one GS-5 GIS technician \$240

TOTAL \$2,500

Monitoring Item - Road Closure Effectiveness ✓

Thru V-41

Type of Monitoring - Effectiveness Designed to measure the effectiveness of road and trail closures

Priority - Forest Priority Group 1

Where Applies - This item is most important in prescriptions which feature the following

- * elk and deer habitat values—5 1 4, 5 4, 2 7,
- * grizzly bear habitat values—5 3 5, 2 6 1, 2 6 2, 2 6 5,

- * any 1-series prescriptions where motorized use exceeds prescription limits,
- * those areas where roads and/or trails were closed to stop direct resource damage

Indicator - The units of measure to be used are

- * direct encounter of a prohibited use in a restricted area,
- * evidence of prohibited use such as tire tracks

Method - Several methods would be used, in a rough stratified sampling approach. Visual checks of access points to closed road systems would be performed. Ocular check information from incidental employee observations would also be used. On the basis of evidence such as use encounters or tire tracks, roads would be placed into strata of confirmed-use, suspected-use and no-use. Each of these strata would then be sampled with mounted cameras activated by motion sensors. Although we might not be able to obtain a scientifically- valid number of samples due to cost, the data would help to refine our estimates of use and target areas of greatest concern.

There is an opportunity to develop partnerships with several entities, including state fish and game departments and the U S Fish and Wildlife Service. It is possible that user groups would be interested in assisting with this as well, though this would have to be done as appropriate.

Expected Precision and Reliability

- Precision - We can measure presence or absence of prohibited use with some accuracy. We will not be able to measure the number of offenses accurately.
- Reliability - Evidence of recent use at one point in time should be reliable. This data cannot be used reliably by itself to judge the frequency of prior use or predict future use since this will depend to some extent on the individual violators. The data could be entered into a predictive model if one is available and accepted.

Tolerance or Variability Indicating Action - Reference the standards in the Roads section of the Forest-wide Standards and Guidelines. Briefly, the point at which some action would be required is when use exceeds 1-2 trips per week during the majority of the weeks during the spring/summer/fall period.

Frequency of Monitoring - The visual checks would be performed three times during the spring/summer/fall seasons, to incorporate at least one holiday weekend and the fall hunting season. Due to the limited number of cameras and personnel costs, we may wish to target only one or two districts per year, or only portions of certain districts. Complete Forest coverage would take several years.

Lead Responsibility - Forest law enforcement officer

Estimated Annual Cost - Assume we will monitor one district per year. Assume one GS-5 tech can visually monitor ten roads per day, or thirty roads per sampling round of three days. Assume one GS-9 camera tech can install, monitor and remove six cameras (six roads) per one-week sampling round. Also assume we will purchase two camera units @ \$800 (the Forest wildlife shop already has 4-6 of these, but some need repairs). Then

For visual checks

- * One GS-5 tech twice per summer @ three days \$ 750,
- * Rental vehicle @ \$15/day \$ 90,

For camera confirmations

- * two new camera units amortized over ten years \$ 160/year,
- * install and read cameras-one week per sampling round three times per summer for one GS-9 @ \$700/week \$2,100,

* materials/incidentals-mounting hardware, film, developing of film, incidental repairs \$ 500,
 Analysis/evaluation - one GS11 for one week \$ 800

TOTAL \$4,400/year

Monitoring Item - Achievement of Road Density Standards

Type of Monitoring - Implementation monitoring Designed to measure the achievement of standards in prescription areas for Total Motorized Access Route Density (TMARD), and Open Road and Open Motorized Trail Route Density (OROMTRD)

Priority - Forest Priority Group 1

Where Applies - This item is most important in prescriptions which feature the following

- * elk and deer habitat values-5 1 4, 5 4, 2 7,
- * grizzly bear habitat values-5 3 5, 2 6 1, 2 6 2, 2 6 5,

Indicator - Miles per square mile of open roads and open motorized trails (for OROMTRD), and open and restricted roads and motorized trails (for TMARD)

Method - The method is explained in more detail in the Forestwide standards and guides for access The Forest geographic information system (GIS) and associated database will be used Highlights of the method include

- * annually update the transportation database with road and trail closures and other pertinent data,
- * GIS calculate the contiguous area of each prescription polygon,
- * calculate the miles of routes that are open and seasonally open, and total these,
- * moving-window technology will be used

No partners in this effort were identified

Expected Precision and Reliability

- Precision - High
- Reliability - High

Tolerance or Variability Indicating Action - Progress in achieving the TMARD and OROMTRD standards should follow an established activity schedule based on plan goals and objectives At the end of the specified time period the standards should be met If the standards are not met by the end of the time period a management review should be conducted to determine the cause

Frequency of Monitoring - Annually

Lead Responsibility - The district ranger will annually forward accomplishments toward meeting standards, and other pertinent data, to the Forest engineer The GIS shop will do the calculations and produce the report

Estimated Annual Cost - One GS-7 biologist for two days on each district - 2 (\$180) (5)
 One GS-5 GIS technician for one week per district - 5 (\$600)
 TOTAL \$4,800

PRODUCTION OF COMMODITY RESOURCES

Range

Monitoring Item - Streambank Disturbance/Stubble Height/Channel Stability

Type of Monitoring - Validation

Priority - Forest Priority Group 1

Where Applies - At any one of the 100 established correlation plot sites across the Forest

Indicator - Percent of streambank disturbance in relation to stubble height and how these parameters relate to channel stability

Method - Targhee Monitoring Protocol

Expected Precision and Reliability

- Precision - High
- Reliability - High

Tolerance or Variability Indicating Action - To be determined

Frequency of Monitoring - At various times throughout the field season for a five-year time period

Lead Responsibility - Forest range and watershed staffs, and district rangeland management specialists

Estimated Annual Cost - Each year, 150* percent of the plots will be monitored for trampling and stubble height. Fifty percent will be monitored for stream channel stability

1 day/plot x 150* plots x \$175/day (GS-9) =	\$26,250
55 days (50 field, 5 office) x \$200/day (GS-11) =	\$11,000
Total	\$37,250

* 150 plot readings per year, of the 100 plots, some will be read twice

Monitoring Item - Riparian Forage Utilization Within Key Areas

Type of Monitoring - Implementation

Priority - Forest Priority Group 1

Where Applies - Key areas in grazing allotments

Indicator - Stubble height of key species in the hydric greenline and AIZ, percent utilization of browse in the entire key area, and soil disturbance levels in the AIZ

Method - Targhee Monitoring Protocol

Expected Precision and Reliability

- Precision - Moderate
- Reliability - Moderate

Tolerance or Variability Indicating Action - When the stubble height is more than one inch below allowable use levels or when browse use is more than 10 percent above proper use

Frequency of Monitoring - At least once a year on units within priority allotments and additional readings if time allows

Lead Responsibility - District Rangeland Management Specialist

Estimated Annual Cost - One-third of all allotments on each District will be monitored yearly 1 GS-9 @ \$175 00/day Each priority allotment will require one trip per unit Since the allotments have an average of five units each, it will total five days per priority allotment One-third of 154 allotments = 51

$$\begin{array}{r} (\$175\ 00) (5) = 875 \\ 51 \\ \hline - - - - - \$44,625\ \text{yearly} \end{array}$$

Monitoring Item - Upland Forage Utilization Within Key Areas

Type of Monitoring - Implementation

Priority - Forest Priority Group 3

Where Applies - Key areas within grazing allotments These sites will be used in areas where upland forage is limiting

Indicator - Percent utilization of key species and soil disturbance in key areas

Method - Targhee Monitoring Protocol

Expected Precision and Reliability

- Precision - Moderate
- Reliability - Moderate

Tolerance or Variability Indicating Action - When the utilization is ten percent above proper use

Frequency of Monitoring - Once a year on units within priority allotments and additional readings if time allows

Lead Responsibility - District Rangeland Management Specialist

Estimated Annual Cost - Upland use will be monitored on one-third of the allotments on each district One GS-9 at \$175 00/day Average allotment requires 2 days per year One-third of 154 allotments = 51

$$\begin{array}{r} (\$175\ 00) (2) = 350\ 00 \\ 51 \\ \hline \$17,850\ 00\ \text{yearly Forestwide} \end{array}$$

Monitoring Item - Riparian and Upland Long-Term Trend in Benchmarks

Type of Monitoring - Implementation

Priority - Forest Priority Group 3

Where Applies - There should be at least one benchmark in each dominant ecological type unit within an area of interest

Indicator - Acres of riparian and uplands meeting or moving toward DVC's (range objectives 1 and 2)

Method - Targhee Monitoring Protocol

Expected Precision and Reliability

- Precision - High
- Reliability - High

Tolerance or Variability Indicating Action - When less than ten percent of the acres identified in range objectives 1 and 2 have improved each year

Frequency of Monitoring - Every five years

Lead Responsibility - District Rangeland Management Specialist

Estimated Annual Cost - One GS-9 @ \$175 00/day, 5 days per study (3 field, 2 office days) 35 ecological types x 2 sites/type = 105 Benchmark sites Ten percent of Benchmarks monitored annually = 11 Benchmarks/year

$$\begin{aligned}(11 \text{ sites})(5 \text{ days/site}) &= 55 \text{ days} \\ (\$175/\text{per day})(55\text{days}) &= \$9,625\end{aligned}$$

Timber

Monitoring Item - Changes to Land Suitability

Type of Monitoring - Validation of tentative suitability assessment made in the Revised Plan

Priority - Forest Priority Group 1

Where Applies - Applies primarily to lands in 5-series prescriptions, but could involve the review of projects anywhere on the Forest

Indicator - Change in total acreage in tentatively suited and unsuited lands using the criteria in the regulations and directives system

Method - Review project-level NEPA analyses for site-level confirmations of LMP tentative suitability calls Changes to initial calls on either suited or unsuited lands would be documented on a hardcopy map maintained in the planning shop This map would aggregate changes from various documents Changes to the Forest tentatively suited land base could be entered into the Forest GIS

Expected Precision and Reliability

- Precision - Site-specific analysis should give a precise description of true conditions
- Reliability - Using given parameters such as slope percent and soil stability, results should be reliable and reproducible

Tolerance or Variability Indicating Action - A significant overall change in tentatively suitable acres could trigger a revision of the ASQ

Frequency of Monitoring - Annually

Lead Responsibility - The Forest planning shop would aggregate the findings Project ID teams would do the individual analyses

Estimated Annual Cost - \$1,000

Monitoring Item - Maximum Created Opening Size

Type of Monitoring - Implementation

Priority - Forest Priority Group 3

Where Applies - This item needs to be monitored in the following prescription areas

- Rx 5 2 1 - generally 1 to 5 acres, but less than 40,
- Rx 5 2 2, 2 1 2 - generally less than 5 acres,
- Rx 5 3 5, 2 6 1 (a) - less than 6 5 acres,
- Rx 5 4 (some areas) - 20 acres or less,

Indicator - Size of created openings, in acres

Method - Compliance with the standard would be described in environmental documents

Expected Precision and Reliability

- Precision - High
- Reliability - High

Tolerance or Variability Indicating Action - Proposals to exceed the respective area standard would need to be sound and ecologically-based, and would require a Forest Plan amendment. If a trend is seen in legitimate proposals to exceed the respective standards the standards would need to be reviewed.

Frequency of Monitoring - In each decision document, where vegetation management is selected

Lead Responsibility - IDT leader and line officer

Estimated Annual Cost - \$1000 per year, primarily in incidental GIS and other analysis costs to display compliance with the standard

Monitoring Item - Security Cover Retention

Type of Monitoring - Implementation and effectiveness Designed to measure compliance with the standard governing security cover retained for grizzly bears in vegetation management projects

Priority - Forest Priority Group 3

Where Applies - This item must be monitored in the following prescription areas

5 3 5, 2 6 1 (a) - 70 percent

Indicator - Percent cover in area (see prescriptions for specifics)

Method - Environmental analysis and documentation for specific project proposals will display compliance with the respective standards. See prescriptions

Expected Precision and Reliability

- Precision - High
- Reliability - High

Tolerance or Variability Indicating Action - Proposals to exceed the standard will require a Revision amendment If a trend is seen toward exceeding the standard in soundly-based ecological management proposals the standard will need to be reviewed This may involve reopening formal consultation

Frequency of Monitoring - Every decision document selecting vegetation management in BMU's

Lead Responsibility - IDT leaders, District Biologists, line officers

Estimated Annual Cost - \$2000, primarily in incidental GIS and other analysis costs to display compliance with the standard If the information required to demonstrate security cover is not found in the Forest data base, then field survey may be required

Monitoring Item - Large Forested Block Retention

Type of Monitoring - Implementation Designed to measure retention of 250-acre forested blocks where required

Priority - Forest Priority Group 3

Where Applies - This applies to prescription areas 5 1 4 (c) and 5 4 (a-c)

Indicator - Size of forested blocks within project areas

Method - Timber sale environmental documents will disclose compliance with this measure Additionally, follow-up activity reviews should review effectiveness of treatments

Expected Precision and Reliability

- Precision - High
- Reliability - High

Tolerance or Variability Indicating Action - Any proposal to violate the standard requires a Revision amendment. If a trend develops of proposals citing ecologically-sound reasons to amend the Plan or change the standard, the standard needs to be reviewed

Frequency of Monitoring - With every decision document selecting a vegetation management alternative

Lead Responsibility - IDT leaders and line officers

Estimated Annual Cost - \$1,000, primarily in incidental costs of GIS or other analysis to demonstrate compliance with the standard

Appendix

National Direction Relevant to Land and Resource Management

APPENDIX A
NATIONAL DIRECTION RELEVANT TO LAND AND RESOURCE MANAGEMENT
(BASED ON FSM OBJECTIVE STATEMENTS)

Agency policy articulated in the Forest Service directives system (Forest Service Manual and Handbook) is hereby incorporated in its entirety as direction in this Revised Forest Plan. Some of the more commonly referenced objectives are found at the following locations:

American Indians * 1563
Noxious Weed Management * 2080
Solid Waste Management * 2130 2
Pesticide Management * 2150 2
Energy Management * 2170 2

Range Management * 2202 1
Grazing and Livestock Use Permit System * 2230 2
Range Improvements * 2240 2
Structural Range Improvement * 2242 02
Maintenance of Improvement * 2244 02
Range Improvement Investment * 2246 02

Recreation * 2302
National Wilderness Preservation System * 2320 2
Recreation in Wilderness * 2323 11
Range in Wilderness * 2323 21
Wildlife and Fish Management in Wilderness * 2323 31
Stocking Methods *2323 34b
Stocking Policy *2323 34c
Soil and Water in Wilderness *2323 41
Forest Cover in Wilderness * 2323 51

BEST MANAGEMENT PRACTICES FOR IDAHO AND WYOMING

Idaho

The Administrative Rules of the Idaho Department of Health and Welfare, Water Quality and Wastewater Treatment (IDAPA 16, Title 01, Chapter 02, February 20, 1996) lists documents that contain approved Best Management Practices. On page 71 (IDAPA 16 01 02,350 03) these documents are listed and include:

Idaho Forest Practices Rules as adopted by Board of Land Commissioners

Idaho Department of Health and Welfare (IDHW) Rules, Title 1, Chapter 6, "Rules Governing Solid Waste Management"

IDHW Rules, Title 1, Chapter 3, "Rules Governing Subsurface and Individual Sewage Disposal Systems"

"Rules and Minimum Standards for Stream-channel Alterations" as adopted by the Board of Water Resources

"Rules Governing Exploration and Surface Mining Operations in Idaho" as adopted by the Board of Land Commissioners

"Rules Governing Placer and Dredge Mining in Idaho" as adopted by the Board of Land Commissioners

Wyoming

Grazing Draft BMPs have been developed (dated February 1996), but the State is currently working on a responsiveness summary, so the BMPs have not been certified yet (personal communication with Beth Pratt, Wyoming DEQ, November 26, 1996)

Hydrologic Modifications These BMPs have been certified by DEQ and the governor of Wyoming

Silviculture These measures include BMPs for roads. They have been certified by DEQ and the governor of Wyoming

Oil and Gas Exploration and Production, Mineral Extraction, Highway Construction, Underground Storage Tanks These activities are covered by site regulatory programs, and so BMPs will not be developed for them

Subject: Biological Opinion for the Targhee National Forest Plan Revision
1-4-97-F-2 File # 116 0020

Dear Mr. Reese:

This letter transmits the U.S. Fish and Wildlife Service final biological opinion (opinion) on the proposed Targhee National Forest Plan Revision (Revision).

This opinion was prepared in response to your November 12, 1996, request to initiate formal consultation under section 7 of the Endangered Species Act of 1973, as amended. Your letter was received by this office on November 13, 1996. The Service reviewed the Revision in accordance with the Section 7 Interagency Cooperation Regulations (50 CFR 402, FR 51(106):19957-19963). This opinion refers only to the potential effects of implementing the Revision on the grizzly bear.

If you have any questions concerning this opinion, please contact Mike Donahoo of the Service Eastern Idaho Field Office at (208)233-8550.

Sincerely,

Supervisor, Snake River Basin Office

Final Biological Opinion for the Targhee National Forest Plan Revision

The U S Fish and Wildlife Service (Service) has reviewed the proposed Targhee National Forest Plan Revision and preferred alternative, Alternative 3-M (Revision), for the Targhee National Forest (Forest) in eastern Idaho and northwestern Wyoming. Your letter dated November 12, 1996, requesting formal consultation was received November 13, 1996. This document represents the Service's biological opinion on the effects of that action on threatened grizzly bear (*Ursus arctos horribilis*), bald eagle (*Haliaeetus leucocephalus*), Ute Ladies'-tresses (*Spiranthes diluvialis*), the endangered peregrine falcon (*Falco peregrinus*), and the experimental, non-essential population of gray wolf (*Canis lupus*) in accordance with section 7 of the Endangered Species Act (Act) of 1973, as amended (16 U S C 1531 et seq.)

This biological opinion addresses only the potential effects of the proposed Revision on the threatened grizzly bear (*Ursus arctos horribilis*) in the Greater Yellowstone Ecosystem (GYE). The Service has reviewed the biological assessments prepared for the proposed Revision and concurs with the Forest determinations that the Revision, as proposed, may affect but is not likely to adversely affect the threatened bald eagle (*Haliaeetus leucocephalus*), Ute Ladies'-tresses (*Spiranthes diluvialis*), and the endangered peregrine falcon (*Falco peregrinus*). The Service concurs that the project will not jeopardize the continued existence of the experimental, non-essential population of gray wolf (*Canis lupus*), the entire Forest is within the boundaries of the Yellowstone and Central Idaho Nonessential Experimental Areas.

This biological opinion is based on information provided in the November 12, 1996, biological assessment and updates as received, the March 19, 1997 letter from the Forest Supervisor, the January 1996 draft Forest Plan Revision and draft Environmental Impact Statement for the Forest Plan Revision, and the January 1994 and April 1995, biological opinions for the "Management Direction for the Grizzly Bear on the Portion of the Plateau Bear Management Unit" (Strategy). It is also based on other actions that have been consulted on since completion of and including the June 1984 biological opinion, consultation on the 1985 Forest Land Management Plan (LMP), current Cumulative Effects Model information, information in office files, discussions with others, including Forest biologists and administrators knowledgeable of the area and species, and from information obtained from field investigations. A complete administrative record of this consultation is on file in the Service's Eastern Idaho Field Office in Pocatello, Idaho.

CONSULTATION HISTORY

The listing of the grizzly bear as threatened in 1975 required Federal agencies under the conditions of sections 7(a)(1) and 7(a)(2) of the Endangered Species Act (Act) to (1) utilize their authorities to carry out conservation programs for listed species, (2) ensure that their activities not jeopardize the continued existence of a listed species, and (3) ensure that their activities or programs not result in the destruction or adverse modification of critical habitat.

Formal consultation between the Forest and the Service concerning the grizzly bear occurred during development of the existing LMP. The Reasonable and Prudent Measures for the 1985 Biological Opinion issued by the Service for the LMP required security areas for grizzly bears.

(USDI 1984) Other informal and formal consultations between the Service and Forest, including biological opinions for the Management Direction for the Grizzly Bear on the Portion of the Plateau Bear Management Unit on February 22, 1994, and April 20, 1995 (USDI 1994, 1995), have developed and incorporated into the existing LMP, management standards and guidelines for listed species within which LMP activities are conducted. These standards and guidelines were developed for the grizzly bear because of evidence that impacts to the bears occurred as a result of logging, roads, recreation, mining, grazing, etc.

In the 1994 biological opinion on the Strategy, core areas were delineated for the Plateau Bear Management Unit (BMU) Subunits 1 and 2 to address the issue of habitat security needs of the grizzly bear. The geographic boundaries included sufficient territory to provide for a female grizzly bear with young, but did not strictly meet the Interagency Grizzly Bear Committee (IGBC) definition for core because of road densities and lack of security cover. Plans were in place to begin developing core and security areas for the Bechler-Teton BMU. The process was changed to focus on the Revision in an effort to address all of the remaining BMU's at one time.

The final report for the Henry's Lake and Plateau BMU habitat evaluation and grizzly bear presence study (IGBC 1994a) noted there was a management strategy that had been developed for the area by the Service and the Forest. The report states, "If this strategy were implemented it would greatly improve habitat effectiveness and security within the subunits (IGBC 1994a)." The management strategy is part of the biological opinion for the "Grizzly Bear Management Strategy for the Portion of the Plateau Bear Management Unit on the Targhee National Forest" also referenced as the "Strategy". This management strategy underwent formal consultation and was being implemented for the Plateau BMU Subunits 1 and 2 when the Forest suspended implementation of road closures to focus on the Revision. A few additional miles of were restricted on an interim basis through formal consultation and the entire road density and closure issue was incorporated into the Revision process (USDI 1995).

The original Grizzly Bear Management Guidelines for the Greater Yellowstone Area (USDA and USDI 1979) referenced in the existing Forest Plan were revised in 1986 by the IGBC (1986). The Service's biological opinion on the revised Guidelines states "It is our biological opinion that implementation of the Guidance for Management Involving Grizzly Bears in the Greater Yellowstone Area will promote the conservation of the grizzly bear" (USDI 1986 in IGBC 1986). The Guidelines include a plan for determining when a grizzly bear is considered a "nuisance" and delineate an action plan in case of human-grizzly conflicts.

The IGBC, of which the Forest and Service are members, appointed an Access Committee for the GYE (Access Committee) and a cumulative effects model (CEM) team to develop standard access definitions and implement a unified CEM across the GYE. Specific objectives for each team are referenced in the list of definitions. Information from the IGBC Access Committee and the CEM outputs are intended to be used together in preparation of Geographic Information System (GIS) based maps for analyzing impacts of human activities in grizzly bear habitat.

The proposed Revision is being prepared to comply with the National Forest Management Act (NFMA) of 1976 which directs the Forest to review and/or update forest plans every ten to fifteen years or more frequently when resource and management conditions change significantly. The existing management plan was finalized in 1985 and this is the first revision of the plan (USDA 1996a). The Revision includes the provisions of the Resources Planning Act as amended by the NFMA, the Endangered Species Act of 1973, as amended, and other guiding documents.

Description of the Proposed Action

The Forest contains approximately 1,810,000 acres of National Forest System land located in southeast Idaho and northwestern Wyoming. Parts of the Forest lie in the Idaho counties of Bonneville, Butte, Clark, Fremont, Jefferson, Lemhi, Madison, Teton, and in the Wyoming counties of Lincoln and Teton. The Forest is bordered on the east by Yellowstone and Grand Teton National Parks and the Bridger-Teton National Forest, on the south by the Caribou National Forest, on the west by the Salmon/Challis National Forest, and on the north by the Beaverhead and Gallatin National Forests (Figure 1).

The Forest will emphasize actions which contribute toward conservation and recovery of the bear within areas identified in the Grizzly Bear Recovery Plan. Objectives are to maintain and enhance habitat and to minimize potential for grizzly-human conflicts. The Forest will manage habitats essential to bear recovery for multiple land use benefits, to the extent these land uses are compatible with the goal of grizzly bear recovery. Land uses which cannot be made compatible with the goal of grizzly recovery, and are under Forest Service control, will be redirected or discontinued (IGBC 1986).

The Forest-wide Standards and Guidelines, Subsection Direction, and Prescriptions for Implementing the Preferred Alternative further define the proposed goals and objectives for grizzly bear habitat in the Revision as follows:

Goals

1. Habitat conditions will be sufficient to sustain a recovered population of grizzly bears.
2. Allow for unhindered movement of bears (continuity with Yellowstone National Park and adjacent bear management units).

Objectives

1. Meet recovery criteria in the Grizzly Bear Recovery Plan.
2. Implement guidelines developed by the IGBC.
3. Provide safe, secure sites for relocation of nuisance bears.

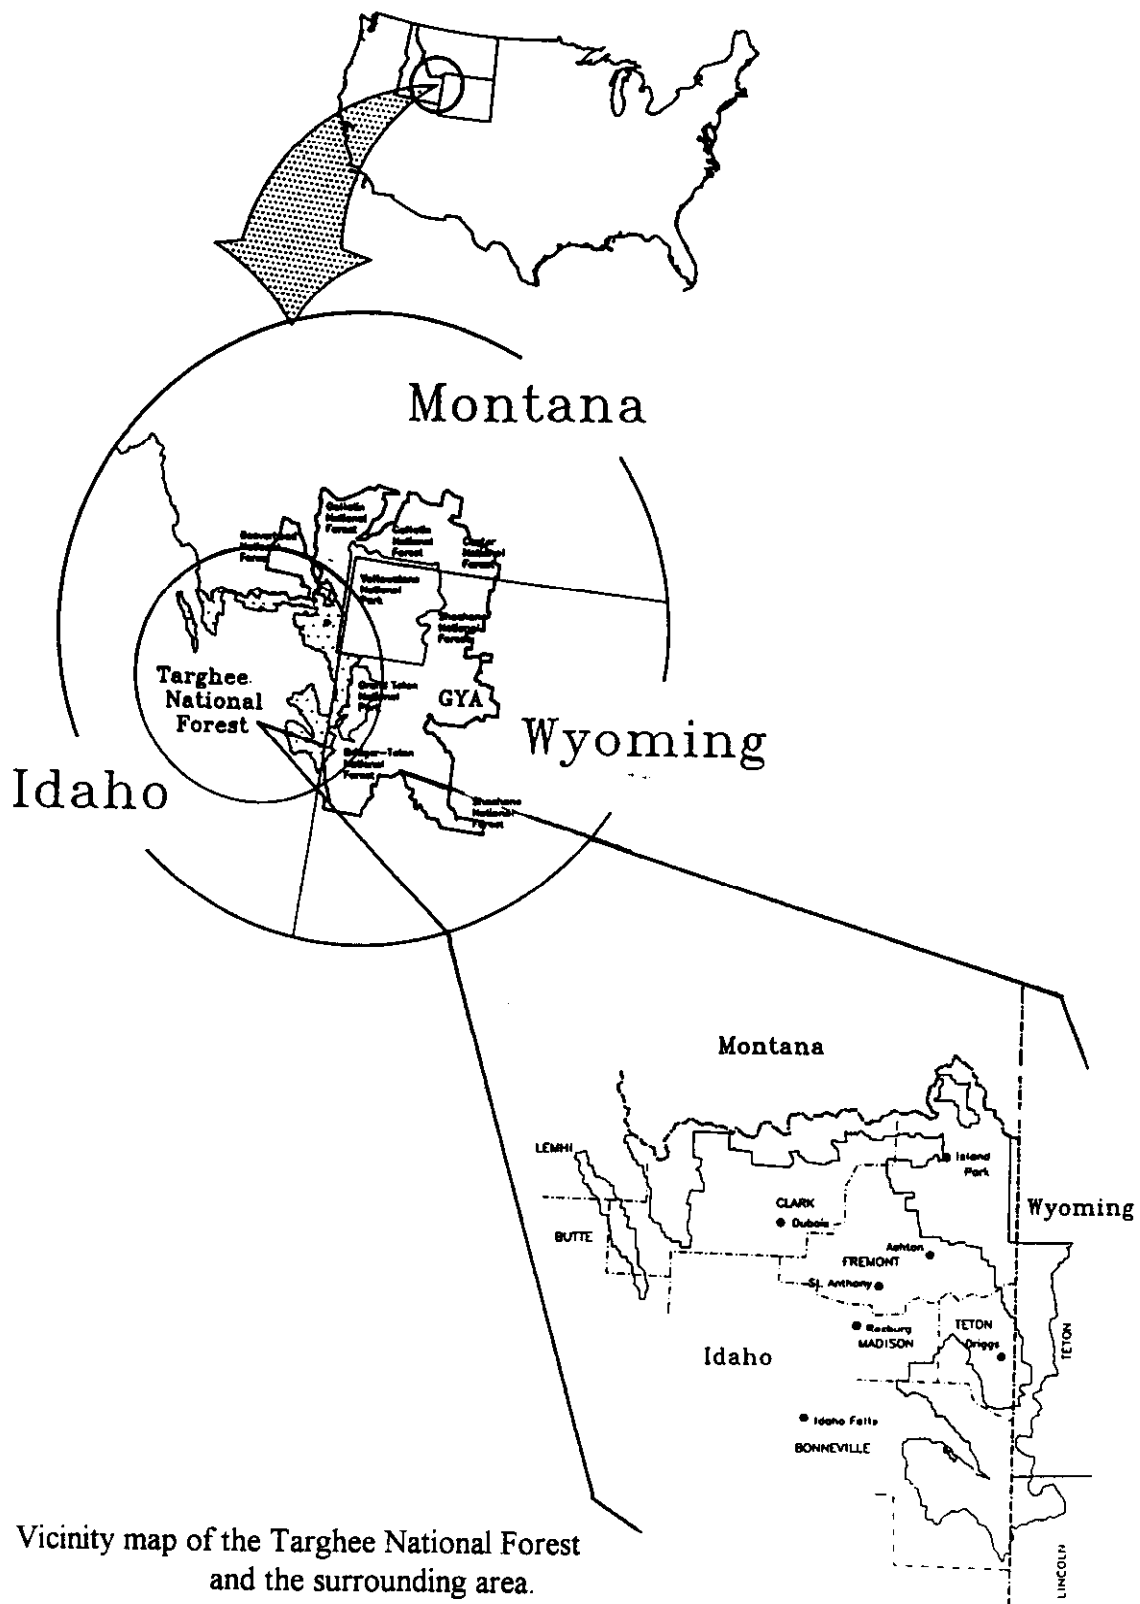

Figure 1. Vicinity map of the Targhee National Forest and the surrounding area.

- 4 Implement the road density standards in the BMU's within 3 years of signing the Record of Decision in coordination with the U S Fish and Wildlife Service and State wildlife agencies

Standard and Guideline

The grizzly bear education program will focus on residents in residential and summer home areas, developed recreation site users, wilderness users, and hunters

The Revision incorporates the following portions of the proposed IGBC Conservation Strategy for grizzly bear and grizzly bear habitat management into the Forest wide Goals, Objectives, and Standards and Guidelines

- 1 All Management Situation (MS) 2 habitat within the BMU subunits will receive the same emphasis for grizzly bear management as the MS-1 habitat, except livestock grazing in existing MS-2 habitat will continue to be managed under MS-2 guidelines Livestock grazing will be managed under MS-2 guidelines to allow for the proposed phase out, on an opportunity basis, of sheep allotments
- 2 Proposed timber harvesting activities will be strictly controlled in the BMU's as described in Management Prescription 5 3 5 Proposed timber harvest levels from the BMU's are a noninterchangeable component (NIC) of the allowable sale quantity (ASQ) and will not include designated core areas
- 3 Two Records of Decisions (ROD) will be signed, one to put into effect the Forest-wide Standards, Guidelines, Goals and Objectives, including the open and total route density standards The second ROD will implement the site specific Travel Plan that shows which areas, roads, and trails will be open to motorized use On-the-ground signing necessary to enforce the Travel Plan will be completed in 1997, the actual on-the-ground restrictions will be completed by the close of 1999 for all of the BMU's (USDA 1997a)
- 4 Total motorized access density (total route density) is reduced from existing levels to meet Forest wide standards of ≤ 1.0 mile per square mile (mi /sq mi)
- 5 Open road and open motorized trail route densities (open route density) are reduced from existing levels to meet Forest-wide standards of ≤ 0.6 mi /sq mi
- 6 Acres in each BMU which are designated core areas are increased from existing levels
- 7 Remaining domestic sheep grazing allotments are to be phased out on an opportunity basis
- 8 Cross-country off-highway vehicle (OHV) travel is eliminated, except in the MS-3

areas, which amounts to about 4 percent of the Forest acres within the BMU's

9 The MS-3 habitat in Henry's Lake Subunit 1 and those areas shown as MS-3 habitat on Map #5 of the 1985 Forest Plan, are managed as an area where grizzly bear presence is discouraged because of high human use and developments

The Revision will guide all natural resource management activities, establish management standards for the Forest, and serve as an "umbrella" for the environmental analysis of proposed projects at the Forest and District levels. Future environmental analysis documented in environmental assessments and environmental impact statements will refer to the Revision. Environmental assessments will be developed for project level activities not specifically described in the Revision and will concentrate on issues specific to the project (USDA 1996)

The Revision replaces previous resource management plans and generally incorporates conditions from previous actions that have undergone section 7 consultation. Upon final approval of the Revision, all Forest activities will conform to it. All permits, contracts, and other uses of Forest lands must also conform to the proposed Revision. The Forest has selected a preferred alternative, Alternative 3-M, for the Revision and prepared a Draft Environmental Impact Statement (DEIS). The Service has reviewed the DEIS and the biological assessments from the Forest that address the effects of the preferred alternative on the grizzly bear.

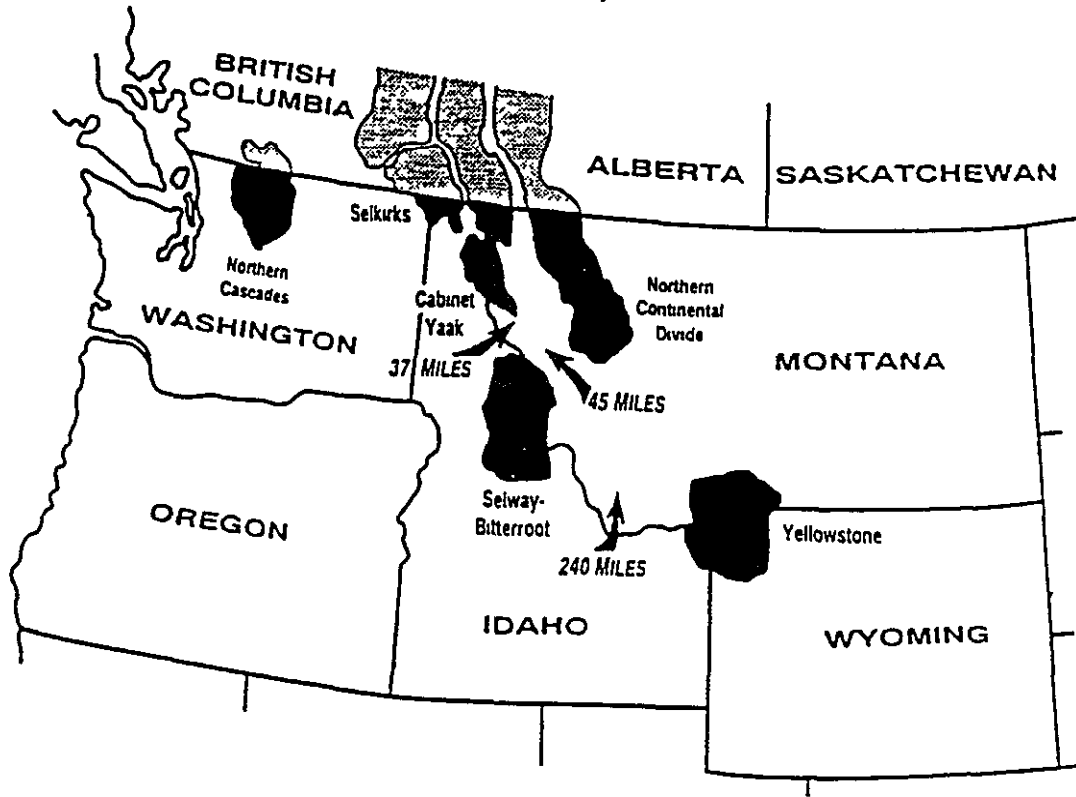

Status of the Species/Environmental Baseline

The grizzly bear (*Ursus arctos horribilis*) was classified as threatened on July 28, 1975. The grizzly bear was originally distributed in various habitats throughout western North America from Central Mexico to the Arctic Ocean. Current distribution is reduced to less than 2 percent of its former range south of Canada. In the conterminous 48 States, only 5 areas in mountainous regions, national parks, and wilderness areas of Washington, Idaho, Montana, and Wyoming (Hoak et al. 1981, Servheen 1985) currently contain either self-perpetuating or remnant populations of grizzly bears (Figure 2).

The GYE grizzly bear recovery zone contains over 9,500 square miles of grizzly bear habitat. Grizzly bear management areas transcend Federal, State, private, and corporate ownership. The GYE includes Yellowstone and Grand Teton National Parks, parts of 5 national forests (the Targhee, Bridger-Teton, Teton, Gallatin, Shoshone, and Custer), Bureau of Land Management lands, and isolated parcels of State and private lands in the areas surrounding the publicly administered lands.

The Grizzly Bear Recovery Plan (Recovery Plan) specifies occupancy targets for female grizzly bears with young (cubs, yearlings, or 2-year olds) as a running six-year average (USDI 1993) in

Figure 2. Present grizzly bear ecosystems in the conterminous 48 States, 1990 (the San Juan Mountains area of Colorado is not shown). (USDI 1993)

each BMU in the GYE. Distribution of reproducing females may provide evidence of adequate habitat management, because it is assumed that successful reproduction is an indicator of habitat sufficiency. Adequate distribution of family groups indicates future occupancy of these areas because grizzly bear offspring, especially female offspring, tend to establish home ranges within or near the home range of their mother after weaning (USDI 1993, 1993a).

Recovery for the GYE population depends upon verifying that the population meets the criteria for a recovered population. It is important to recognize that one of the primary recovery objectives is to identify specific management measures needed to remove population and habitat limiting factors so the populations will increase and sustain themselves at levels identified in the recovery goals. Providing secure habitat for grizzly bears, especially adult females, is a high priority in MS-1 habitat. Monitoring data from 1987 through 1996 indicate the Recovery Plan population recovery parameters for the numbers of females with cubs and numbers of BMU's with family groups are being met. The average annual known human-caused grizzly bear mortalities and female mortality limits are close to being met (IGBC 1996).

The environmental baseline of the Forest has changed considerably since the 1985 Forest Plan was prepared. Extensive management activities including timber harvest and road construction have reduced vegetative cover, lowered food values, and created a vast road network across the Forest. These values are portrayed in CEM outputs for habitat value and effectiveness (HV and HE) as determined by the Forest (USDA 1997). In some portions of the BMU's, the lack of suitable habitat away from human access is continuing to displace grizzly bears from the area and induce various stress-related behavioral adaptations and habitat modifications, including

- 1 avoidance/displacement of grizzly bears away from roads and road activity,
- 2 changes in grizzly bear behavior, especially habituation, as well as breeding, feeding, reproduction, shelter, and travel, due to ongoing contact with roads and human activities conducted along roads,
- 3 habitat loss, modification, and fragmentation due to roads and road construction, including vegetative and topographic disturbances, and
- 4 direct mortality from road kills, legal and illegal harvest, and other factors resulting from increased human-bear encounters (IGBC 1987)

The GYE grizzly bear recovery zone has been subdivided into smaller units to facilitate both the assessment of projects and recovery of the species. Eighteen BMU's have been formally delineated in the GYE (Figure 3)

These BMU's are designed to

- 1 assess the effects of existing and proposed activities on grizzly bear habitat without having the effects diluted by consideration of too large an area,
- 2 address unique habitat characteristics and bear activity/use patterns,
- 3 identify contiguous complexes of habitat which meet yearlong needs of the grizzly bear, and
- 4 establish priorities for areas where land use management needs would require cumulative effects assessment (USDA et al 1990)

BMU's have been further divided into smaller units, termed subunits. The rationale for defining subunits are the same as described above for the BMU. The BMU or subunit provides the basic scale for project impact analysis (USDA et al 1990). The Forest has three BMU's divided into 4 subunits, they are the Henry's Lake BMU with subunits 1 and 2, the Plateau BMU with subunits 1 and 2, and the Bechler-Teton BMU.

Existing Conditions by Bear Management Unit

The Service used the figures for "acres and percent of areas" as presented and updated in Table 4a of the biological assessment for the grizzly bear to evaluate the existing conditions of the BMU's (see Table 1).

The IGBC Access Committee addressed the need for secure habitat for grizzly bears through the definition of a core area in a BMU. The Forest has expanded the definition of core area to include their own terms of "designated and undesignated" core. Core areas provide important habitat needs for grizzly bears and "(r)esearchers and managers throughout the recovery zones agree that core areas, areas free of motorized access during the non-denning period, are an important component of adult females that have successfully reared and weaned offspring" (IGBC 1994).

A study to evaluate habitat and grizzly bear presence in the Henry's Lake BMU and to finalize the requirements for occupancy by female grizzly bears in the Plateau BMU, was begun in March of 1993 and completed in the fall of 1994 (IGBC 1994a). The study concluded the habitat and habitat effectiveness values for the Henry's Lake BMU were of moderate value. It was not expected that a female grizzly bear with young would occupy the area on a yearlong basis, however, because the BMU was too small in size and the 9 sheep allotments in the area pose a significant mortality risk.

The report recommended adding the Madison Subunit 2, some of which is on the Gallatin N F in Montana, to the Henry's Lake BMU. This would increase the size of the BMU and provide a more ecologically based area for a female with young. This recommendation was implemented in 1994 with the acceptance of the report by the IGBC. The entire BMU, according to the latest

Table 1 Existing Habitat Components for the Targhee N F Bear Management Units

Habitat Component	HL #1	HL #2	PBMU #1	PBMU #2	B-T

figures, encompasses approximately 226,415 acres (128,515 acres in Subunit 1 and 97,900 acres in Subunit 2) of MS-1, 2 and 3 habitat

The study also concluded the existing habitat values for the Plateau BMU were moderate, however, it was not expected that a female grizzly bear with young would occupy the area on a yearlong basis. The reason for this conclusion is that habitat effectiveness is low and there is a 51 percent reduction of the current habitat value. The reduction in habitat value and high mortality risk to grizzly bears is due to the high road densities and human use of the existing road network (IGBC 1994a). Similar results were obtained for the Moose Creek/Pitchstone portion of the Plateau BMU Subunit 2. The study team recommended the Forest improve habitat effectiveness in both areas by implementing access management measures approved by the IGBC in July 1994. The team, in speaking of Subunit 1, further stated, "With improved habitat effectiveness occupancy should be expected. Continued monitoring for evidence of reproducing females is recommended" (IGBC 1994a).

Table 1 shows the acres of MS-1, 2, and 3 habitat, the core areas (designated and undesignated), the open and total route densities, snowmachine and off-highway vehicle (OHV) use, sheep and cattle allotments, and the habitat effectiveness and habitat value ratings for each BMU.

Henry's Lake BMU, Subunits 1 and 2

The Henry's Lake Subunit 1 covers about 128,515 acres [201 square miles (sq mi)], with approximately 93,345 acres (146 sq mi) on the Forest. The Centennial Mountains form part of the Continental Divide and border the BMU on the north. The mountain range contains high mountain meadows scattered through spruce fir and Douglas-fir forests and at lower elevations sagebrush/grasslands transition into Douglas-fir and lodgepole pine forests. Other vegetation communities found in the area include aspen, some whitebark pine, mountain brush, and herbaceous types, both upland and riparian. Less than 2 percent of the riparian vegetation in the BMU is not meeting the desired vegetation condition for lands open to grazing. The MS-3 portion of this subunit (18,669 acres) is dominated by the world famous Henry's Lake (6,672 acres) and the Henry's Lake Flat area. From 1959 to 1986 this subunit has had fewer sightings of grizzly bears than any of the other BMU's (Orme and Williams 1986). Since 1986 there has only been 1 grizzly bear sighted in the area.

Henry's Lake BMU Subunit 2 covers approximately 97,944 acres (153 sq mi) of which 38 percent [37,350 acres (58 sq mi)] are in Idaho on the Forest, the remainder is in Montana, primarily on the Gallatin National Forest. Vegetation habitat types and conditions are similar in Subunits 1 and 2. The entire Subunit 2 on the Forest is classified as MS-1 habitat. This Subunit has the second highest number of grizzly bear sightings from 1959 to 1986 (Orme and Williams 1986) when compared to the other BMU's. Eight grizzly bear sightings have been recorded, in addition to numerous recorded observations of a radio collared bear since 1986.

Plateau BMU, Subunits 1 and 2

The Plateau BMU, Subunit 1, covers about 87,177 acres (136 sq mi) in Idaho, approximately 83,690 acres (131 sq mi) is on the Forest along the southwestern edge of the Yellowstone National Park. The landscape is dominated by lodgepole pine with small pockets of Douglas fir, whitebark pine, spruce fir, aspen, sagebrush/grass, grass meadows, and mountain brush. Approximately 19 percent of the area has high berry-producing shrubs in the understory, an important food source for grizzly bears. Within the Subunit there are 86,124 acres of forested lands on which timber harvest has occurred on 33,502 acres (38.9 percent), the 1988 North Fork Fire burned approximately 17,700 acres (20.6 percent) in the Subunit. The Forest has determined there are no designated core areas in this Subunit, however, they have identified 45,643 acres of undesignated core area. The determination is based on the IGBC definition of core area and because this Subunit is so highly roaded, the Forest indicates the area has no designated core habitat. The 1994 biological assessment and opinion on the Strategy identified core areas for Subunits 1 and 2. These areas are included in the "undesignated" area and are treated as core areas under the existing LMP.

Between 1959 and 1984 several more human caused grizzly bear mortalities occurred than were noted in the biological assessment report (Craighead et al 1988). These occurred in and around Reas Pass where sheep were being grazed, in the Island Park area around cabins, and along the southern boundary of the BMU. The bears may or may not have lived in the BMU but, from the mortality locations, it is apparent they traveled across the area. Displacement of grizzly bears has occurred and continues to occur across the BMU because of the degraded condition of the environmental baseline. Since 1986 there have been 5 sightings in the Subunit and many recorded observations of a radio collared male grizzly bear.

Plateau BMU, Subunit 2 is directly south of Plateau BMU Subunit 1, and the 28 percent of the unit that is on the Forest covers 76,090 acres (119 sq mi). The landscape is dominated by lodgepole pine with pockets of whitebark pine, Douglas fir, aspen, sagebrush/grass, grass meadows, and mountain brush. The entire area is classified as MS-2 habitat. There are no designated core areas, however, undesignated core areas cover 28,616 acres. Recorded grizzly bear observations and mortalities from 1959 to the present indicate bears have used the area. The last recorded sighting of a female grizzly with cubs was in 1994.

Extensive areas in Plateau BMU Subunits 1 and 2 that have flat terrain were recently clear-cut and are close to either open or closed roads. These areas are used by OHVs since there are currently no OHV restrictions in the Plateau BMU, except in the North Fork Fire portion of the Island Park District (USDA Forest Travel Plan Map 1994). Standard OHV closures and the existing road closures with gates are often ineffective at excluding motorized vehicles, especially motorcycles and other OHVs, and will not significantly reduce the mortality risk to the grizzly bear (USDI 1994). Also, due to the terrain in the area, enforcement of road closures in the BMU is difficult without intense monitoring of gate conditions and barrier effectiveness.

From 1975 to 1991, many new roads were constructed, extensive volumes of timber were sold by the Forest (Figure 4), and large areas were clear-cut to remove the "bug" infected trees in this

Figure 4 Timber volumes sold on the Targhee National Forest between 1975 and 1995

subunit This action also removed security cover for the grizzly bear and displaced animals into less desirable habitat and in some cases may have lead to confrontations with humans, resulting in permanent removal of the bear The lack of occupancy of the BMU from 1985 to the present has been caused in part by the displacement of grizzly bears away from areas with high human access via roads

The Bechler-Teton BMU

The Bechler-Teton BMU covers about 191,340 acres (299 sq mi) and 189,433 acres (99 percent/ 296 sq mi) is administered by the Forest Service This BMU joins the extreme southwest corner and southern boundary of Yellowstone National Park and extends along the western edge of the Grand Teton National Park The BMU includes the Winegar Hole and Jedediah Smith Wilderness areas which cover about 34 percent (65,165 acres) of the area The landscape is similar to the other BMU's with large stands of lodgepole pine interspersed with aspen, Douglas fir, sagebrush/grass, grass meadows, riparian habitat, and mountain brush

This BMU has the highest numbers of sightings of grizzly bears of all of the BMU's on the Forest There have been more grizzly bear mortalities in this BMU than the others (Craighead 1988), however, there have been no bear mortalities from 1983 to the present There have been two documented grizzly bear/sheep conflicts in the past During 1996 a female grizzly bear and her cubs were moved to another area off the Forest due to a bear/sheep encounter The incident occurred in MS-2 habitat on a sheep allotment within 2 or 3 miles of MS-1 habitat

EFFECTS OF THE PROPOSED ACTION

General Effects of the Proposed Action

Habitat security conditions cannot be defined entirely by motorized access route density Other factors such as vegetation (food, cover), concentrated human use locations (towns, summer homes, campgrounds), heavily used non-motorized trails, and areas of high levels of dispersed human use will also influence the effectiveness of habitat security in an area Motorized access routes and the human use associated with these routes, however, are one of the most easily defined and measurable factors to evaluate Motorized access is also one of the more influential parameters affecting habitat security Timber harvest, other human activities, and impacts associated with roads and increased road densities have had a major influence on grizzly bear population and habitat use patterns in numerous widespread areas (Tracy 1977, Schallenberger and Jonkel 1980, Jonkel et al 1981, Brannon 1984 Manley and Mace 1992, Mace and Manley 1993)

The concepts of precise open and total motorized access density to assess and manage the effects of roads on grizzly bear habitat has received widespread acceptance by public land and wildlife managers and biologists The IGBC Roads Taskforce (1994) advocated the concepts of open and total motorized access density management and core habitat Using definitions provided by the

IGBC Taskforce, the GYE Access Committee is currently developing the recommended levels at which open and total motorized route density and core area in grizzly bear habitat should be managed. The GYE Access Committee is using the most current computer models to determine access standards, however, the final recommendations are not yet available. In the interim, the Forest Service is using the IGBC Access Committee recommended definitions for open, restricted, and closed roads and trails and methods of identifying existing and potential core habitat to address access management in the Revision. When the final recommendations are presented, the Forest will evaluate the access management conditions via CEM and incorporate changes as needed to comply with the findings.

Mortality - Mortalities are the most serious consequences of roads in grizzly habitat. Research has confirmed that grizzlies experience increased vulnerability to legal harvest and poaching (direct mortality) as a consequence of increased road access by humans (Schallenberger 1980, Zager 1980, McLellan and Mace 1985, Aune and Kasworm 1989). McLellan and Mace (1985) found that a disproportionate number of mortalities occurred near roads. Aune and Kasworm (1989) reported 63 percent of known human-caused grizzly deaths on the east front of the Rocky Mountains occurred within 1 kilometer (km) of roads including 10 of 11 known female grizzly deaths. In the GYE, Mattson and Knight (1991) reported areas impacted by secondary roads and major developments were most lethal to bears. In Montana, Dood et al (1986) reported 48 percent of all known nonhunting mortalities during 1967-1986 occurred within 1 mile of roads.

Increased human access into grizzly bear habitat also increases grizzly habituation to humans, which increases the potential for human-bear conflicts. Habituated bears are those that have lost their natural wariness of humans and generally experience higher mortality rates than bears that are not habituated. Continued exposure to human presence, activity, noise, etc. without negative consequences results in habituation. Habituated bears often end up obtaining human food or garbage and become involved in nuisance bear incidents, become threats to human life or property, and are eventually destroyed or removed from the population through management actions. Habituated bears are also more vulnerable to illegal killing because of their increased exposure to people.

Mortality rates that result from roads are unevenly distributed between different ages and sexes. In the GYE subadult males and adult females with young are more likely to be found near roads during years of low whitebark pine seed availability (Blanchard 1990). Mattson et al (1987) reported that subadults were most often located near roads, perhaps displaced into roaded, marginal habitat by dominant bears. Females with cubs avoid adult males because males have been known to kill cubs (McLellan and Shackleton 1988). Habitat near roads may be selected by females with cubs and yearlings because this habitat is unoccupied by male grizzly bears. In addition, these cohorts have higher energy demands so they may need the additional native or non-native foods that lie near roads despite the risk of encountering humans.

Displacement - In addition to mortality, roads cause displacement of grizzlies from roads and surrounding habitat (Lloyd and Fleck 1977, Schallenberger and Jonkel 1980, Brannon 1984, Aune

and Kasworm 1989, Manley and Mace 1992, Mace and Manley 1993) Aune and Stivers (1985) reported that bears avoided roads and surrounding corridors even when the area contained preferred habitat for breeding, feeding, shelter, and reproduction. Areas in the Northern Continental Divide Ecosystem show radio-instrumented grizzlies may have avoided harvested stands (less than 30 years old) during "all" seasons (USDA 1993)

Mattson et al (1987) found that individual age and sex classes of bears were impacted differently by roads. Zager (1980) stated that the avoidance of roads by females with cubs was a major concern. Some subadult bears, perhaps displaced into roaded, marginal habitat by dominant bears, become habituated, thus becoming more vulnerable to illegal kills and conflict with people, which may result in removal of bears through management action. Mattson et al (1992) reported wary bears consistently avoid areas within 2 km of major roads and 4 km of major developments or townsites. Such animals are unlikely to change this avoidance behavior even after road closures and the lack of negative reinforcement. The general relationship of roads and grizzly bear under-utilization of habitat as described in these studies is applicable to the GYE. The lack of or low level of occupancy in the BMU's on the Forest has been caused, in part, by the displacement of grizzly bears away from areas with high human access via roads, this is especially true in the Plateau BMU.

Based on the available information, the Service believes the use of important low elevation spring habitat, such as riparian areas, is very limited in many areas of the BMU's on the Forest. This is the result of the high road densities, timber harvest, and human encroachment of the low elevation habitat areas. When roads are located in important habitats such as riparian zones, scrub/shrub areas, and timber cover areas, habitat loss through avoidance behavior can be significant because bears cannot use the resources in these areas (USDI 1993), thus, normal behavioral patterns are significantly modified and bears are injured.

Aune and Kasworm (1989) and McLellan (1989) showed that female cubs generally establish their home range within or have a significant overlap with their mother's home range, while males generally disperse from their mother's home range. Long-term displacement of a female from a portion of her home range may result in that area being lost to female bears because her offspring have no chance to learn the foraging opportunities in areas no longer used. Research by Mace and Jonkel (1980) showed monitored grizzlies were displaced from a drainage during the time logging was occurring, and as a result, normal behavior was significantly altered. If timber harvesting occurs in a drainage for extended periods of time, historical bear use of the area may be lost, particularly to female bears.

The end result of displacement is direct or indirect mortality. Based on the preceding discussion, the Service concludes that it is likely some individual bears will not select home ranges which include low elevation habitats that are highly roaded on the Forest, but those that do will suffer higher risks of human-caused mortality.

Habitat Fragmentation - As human populations and roads increase in bear habitat, bear

populations become fragmented. As fragmented populations become smaller and more isolated, they become vulnerable to extinction, especially when human-induced mortality pressures continue. Habitat fragmentation is particularly important to the survival of large carnivores, such as grizzly bears, which have great metabolic demands, require large home ranges, and wide vegetative and topographic habitat diversity (Servheen 1986). Their low densities, low reproductive rate, individualistic behavior, and association with riparian habitat, an area also used extensively by humans, require careful management involving all the principles of island population management and conservation biology (USDI 1993).

Mobility is an important aspect of grizzly bear behavioral patterns (Quimby and Snarski 1974). Movements of grizzly bears may exceed 60 air miles, and their home ranges can encompass 1,000 to 1,500 square miles, thus, space is essential to bears. With a wide-ranging species like the grizzly bear, large expanses of unfragmented areas defined as MS-1 and MS-2 habitat are essential for feeding, breeding, sheltering, traveling, and other essential behavioral patterns (USDI 1993). Grizzly bear habitat on the Forest, particularly on the Plateau BMU, has been fragmented by management activities during the past 20 years. The fragmented habitat has reduced the quantity of available habitat for grizzly bears which has contributed to conditions that could reduce grizzly bear survival and reproduction in the BMU's on the Forest.

Security Habitat - Grizzlies know no competitors that restrict their use of habitat except man, and it appears that they have not evolved behavioral adaptations to contend with the scope of current human influences. Grizzly bear populations require a level of safety from human depredation and competitive use of habitat such as roading, logging, mining, human settlement, grazing, and recreation. Competitive use of habitat encompasses all factors that lead eventually to increased negative impact of human activity on grizzly populations. The density and management of roads is one of the most powerful tools available to balance the needs of people with the needs of bears (USDI 1993).

The Service believes security habitat is important to grizzlies and should be one of the basic considerations in grizzly bear management. However, at this time no absolute criteria are available for identifying grizzly bear security areas. Research has shown, in some cases, grizzly bears and elk react in a similar manner to logging and roads. Most elk studies indicate full utilization of available elk habitat does not occur where security is inadequate. Based on scientific literature, the Service concludes grizzly bear security needs are vital to maintaining healthy, viable populations just as they are for elk. Certain security measures most often used in elk management may also be appropriate for grizzly bear management. Security has been recognized as a requirement for elk during the period of active logging in a timber sale. However, additional research has made it clear security is a continuing requirement in all elk habitats, whether logging is in progress or not. More important, security has been recognized as a requirement which is not necessarily satisfied simply because hiding cover is maintained at a minimum level. In many situations, space may be as important as hiding cover in establishing security values. The quantity of security habitat on the Forest has been reduced during the past 20 years due to road construction associated with resource extraction activities and subsequent human access into

previously inaccessible areas used by grizzly bears

Based on the above information, the Service concludes the environmental baseline for the Forest is resulting in the following effects to grizzly bears

- 1 Increased risk of direct mortality to grizzly bears because of high road densities due to human use of roads and the visual access provided by roadways through the forest environment,
- 2 High risk of increased habituation of grizzly bears to human activities along roads and in association with summer home developments by some bears thereby increasing the mortality risk of these bears,
- 3 Displacement from critical, seasonally important feeding sites (i.e., spring and fall ranges) which actually kills or injures bears by significantly impairing essential behavior patterns such as foraging, breeding, travel and sheltering,
- 4 Habitat fragmentation which actually kills or injures bears by significantly impairing essential behavior patterns by displacing bears from important constituent habitat elements including food, cover, solitude, and space,
- 5 Loss of habitat needed for security which results in actual injury or death of grizzly bears

Specific Effects of the Proposed Action

Habitat effectiveness on the Forest is essential to the recovery of grizzly bears in the GYE. The Forest administers approximately 485,308 acres (758 sq mi) of land covering three BMU's within the GYE Recovery Zone on the Forest. Under the existing Forest Plan the Forest has designated 35.8 percent of the land as MS-1 habitat, 59.2 percent MS-2 habitat, and 5 percent as MS-3 habitat as defined in the IGBC Guidelines (USDA 1985). The Revision proposes to set into action a series of changes in management to recover and protect the habitat in the BMU's, thereby increasing the probability that the area can support a resident family unit of grizzly bears. Existing habitat conditions in portions of some of the BMU's on the Forest, as described in the environmental baseline section, are such that occupancy by a grizzly bear family unit is highly improbable because of past habitat manipulations and high road densities. Without a change in Forest management actions, road densities would remain at high levels and other habitat conditions related to food and cover resources in the BMU's would continue to decline. The Revision seeks to reverse the decline in grizzly bear habitat components and restore grizzly use, while addressing the multiple use obligations mandated by various existing laws, regulations, and directives the Forest must operate under.

The desired future conditions for BMU's on the Forest aim at providing habitat conditions for

resident free-ranging grizzly bears (including family groups or population segments) throughout suitable habitat in each unit. This condition would be achieved by providing seasonal foraging needs, free-ranging movement and dispersal of resident grizzly bears, and minimizing mortality risks due to human-bear conflicts. Available habitat, secure space, and a diversity of habitats, to the extent they naturally occur within each BMU, are key components of the desired future condition. Established core and security areas and the protection they provide are, in the short and long-term, designed to be predictable in space and time and of sufficient size to provide for occupancy by a bear or bears. These areas delineate the highest quality habitat to meet the seasonal needs of grizzly bears, allow for the exchange to and from "source" areas of known, consistent bear use, and provide connectivity to adjacent BMU's in the GYE. In this condition the BMU's administered by the Forest should be capable of fully contributing to grizzly bear conservation and recovery.

The Forest-wide actions and the specific management prescriptions incorporate scientifically based management actions, recovery goals from the Recovery Plan, IGBC guidelines for access management as they currently exist and direction to implement additional guidelines as they are developed, and reasonable and prudent measures and recommended actions from consultations on past project activities in addition to those of this biological opinion for each BMU.

Table 2 shows the desired future condition of the Forest with respect to acres of MS-1, 2, and 3 habitat, core areas (designated and undesignated), open and total route densities, snowmachine and OHV use, sheep and cattle allotments, and habitat effectiveness and habitat value ratings for each BMU. The signing of the Record of Decision (ROD) for the Revision will put into effect the Forest-wide Standards, Guidelines, Goals and Objectives, including the open and total route density standards. A second ROD will be signed at the same time to "implement the site specific Travel Plan that shows which areas, roads and trails will be open to motorized use. The Travel Plan will implement the road density standards on-the-ground" (USDA 1997a). The on-the-ground signing necessary to enforce the Travel Plan will be completed in 1997. By the end of calendar year 1999 the actual on-the-ground restrictions will be in place in all of the BMU's.

CUMULATIVE EFFECTS

Cumulative effects include the effects of future State, local, or private actions that are reasonably certain to occur in the action area considered in this biological opinion. Future Federal actions are not considered in this section because they require separate consultation pursuant to section 7 of the Act.

Within the GYE, actions on private lands, such as summer and residential homes and recreational development, logging, road building, and livestock grazing will continue to contribute to mortality risk and habitat degradation and loss. Year-long distribution of visitors and types of recreational pursuits in the GYE have changed from seasonal peaks, mainly spring, summer and fall, to year-round activity. All of these activities may affect the ability of grizzly bears to adequately utilize important habitats in the GYE.

Table 2 Habitat Components for the Targhee N F Bear Management Units, Alternative 3-M

Habitat Component	HL #1	HL #2	PBMU #1	PBMU #2	B - T	
N F Acres	93,345	37,350	87,177	76,090	191,346	
Total Acres in BMU	128,515	97,944	183,203	275,708	341,894	
Designated Core Area	28,490	15,491	17,581	16,131	80,238

HE/HV Index	0.68	0.67	0.58	0.56	0.72	

Cumulative effects from the proposed action on the Forest include the continued use of private lands around and within the BMU's. The associated loss of grizzly bear habitat, as a result of human access, is anticipated to continue. Habitat fragmentation and loss of habitat would be expected to continue as secondary development from increasing recreational use of the BMU's will create a demand for new public services and facilities. Population pressures from private residential development are increasing in eastern Idaho (USDA 1996a) and are expected to continue in the future. Increasing human occupancy in and adjacent to the BMU's emphasizes the importance of managing human access on adjacent public lands. Residential and recreation homesites are increasing in eastern Idaho. Human development in low elevation areas has, and will continue to have, a cumulative impact on grizzly bears through loss of habitat and continued displacement due to human disturbance. The Revision includes standards and guidelines that stipulate Forest activities not increase total or open motorized access densities in the BMU's above 0.6 mi²/sq. mi. open route density, and 1.0 mi²/sq. mi. total route density. Existing core and security areas established from previous consultations will remain in place on the Plateau BMU. Additional delineations for designated and undesignated core areas have been established for the Bechler-Teton BMU. The management prescription for nonmotorized recreation within the Henry's Lake BMU will meet and maintain IGBC Roads Taskforce criteria for grizzly bear core areas. The Service believes adverse cumulative effects to bears will continue as a consequence of non-Federal actions on private lands. However, according to the proposed Revision, Forest actions would not contribute to, and in certain areas may alleviate, the impacts of some of these adverse effects.

The Service did not identify any other future state or private activities in the GYE that are reasonably certain to occur within the action area that would contribute as cumulative effects to the proposed action. State and private activities outside of the Forest will not influence the determination in this biological opinion because implementation of the proposed action would not change the impact these other activities may have on the grizzly bear in the GYE.

CONCLUSION

After reviewing the current status of the grizzly bear (*Ursus arctos horribilis*), the environmental baseline for the Forest, the effects of the Revision preferred alternative, Alternative 3-M, and the cumulative effects, it is the Service's biological opinion that implementation of the Revision, Alternative 3-M, as proposed, is not likely to jeopardize the continued existence of the GYE grizzly bear population. No critical habitat has been designated for this species, therefore, none will be affected.

INCIDENTAL TAKE STATEMENT

Section 9 of the Act, and Federal regulation pursuant to section 4(d) of the Act, prohibit the take of endangered and threatened species, respectively, without a special exemption. Take is defined as harass, harm, pursue, hunt, shoot, wound, kill, capture, or collect or attempt to engage in any such conduct. Harm is further defined by the Service to include significant habitat modification or

degradation that results in death or injury to listed species by significantly impairing behavioral patterns, including breeding, feeding or sheltering. Harass is defined by the Service as actions that create the likelihood of injury to a listed species to such an extent as to significantly disrupt normal behavior patterns which include, but are not limited to, breeding, feeding or sheltering. Incidental take is defined as take that is incidental to, and not the purpose of, carrying out an otherwise lawful activity. Under the terms of section 7(b)(4) and section 7(o)(2), taking that is incidental to and not intended as part of the agency action is not considered to be a prohibited taking under the Act provided that such taking is in compliance with this incidental take statement.

The measures described below are non-discretionary, and must be undertaken by the agency so they become binding conditions of any grant or permit issued to an applicant, as appropriate, in order for the exemption in section 7(o)(2) to apply. The Forest has a continuing duty to regulate the activity covered by this incidental take statement. If the Forest (1) fails to require an applicant to adhere to the terms and conditions of the incidental take statement through enforceable terms that are added to the permit or grant document, and/or (2) fails to retain oversight to ensure compliance with these terms and conditions, the protective coverage of section 7(o)(2) may lapse.

A special regulation for the grizzly bear pursuant to section 4(d) of the Act provides that no person shall take a grizzly bear in the 48 conterminous states, with certain specified exceptions [50 CFR 17.40(b)].

Amount or Extent of Take

The Service anticipates that use of the open and total route system on the Forest will increase as recreation use increases during this cycle of the Revision process. Therefore, based on the most current biological information, the Service believes that until open and total route densities meet IGBC and the Revision standards, and habitat conditions for grizzly bear feeding, breeding, travel and sheltering are increased, take, direct and indirect, will continue at the present level. The Service believes the level of access and lack of cover in the BMU's is an indicator of the level of take, direct and indirect, that may be occurring.

It is the opinion of the Service that the current level of incidental take associated with the existing use is not at a level that is likely to jeopardize the recovery and survival of the grizzly bear population in the GYE. This is based in part, on the fact that measured population parameters have met established recovery plan levels, with the exception of mortality of female grizzly bears across the GYE during the last 2 years. However, the Service anticipates that the direct and indirect effects of implementing the Revision will not reduce the level of take until the access management plan is completed. The level of "take" may be in the form of direct take, as a result of illegal killing or human-grizzly bear conflicts, or in the form of indirect take such as harm resulting from displacement of grizzly bears from important habitats. The best scientific and commercial data available are not sufficient to enable the Service to quantify a specific amount of incidental take for the Revision. The effects of the Revision are largely unquantifiable in the short

term and may be measurable only as long-term effects on the species' habitat and population levels. Without additional information and analysis that are currently unavailable, we must designate the anticipated level of incidental take for the Revision as **unquantifiable**.

However, the Service believes the level of human-grizzly bear conflict is an indicator of the level of take occurring and provides an early warning of changes in the level of take. Therefore, within the BMU's, all human-grizzly bear conflicts will be handled according to the IGBC Nuisance Grizzly Bear Guidelines and the Forest will immediately reinstate consultation on the Revision. Any incidents that occur outside the BMUs should also be handled according to the IGBC Nuisance Grizzly Bear Guidelines. The Forest should immediately contact the Service to discuss the conditions surrounding the incident and the possible need to reinstate consultation on the Revision. Problem bears translocated onto the Forest from other areas of the ecosystem under the direction of the IGBC Nuisance Grizzly Bear Guidelines would not cause reinstatement of consultation. However, the Forest should immediately contact the Service to discuss the conditions surrounding the incident.

Effect of the Take

In the accompanying biological opinion, the Service determined that this level of anticipated take is not likely to result in jeopardy to the species. There is no critical habitat designated, therefore, none will be affected.

Reasonable and Prudent Measures

The Service believes the following reasonable and prudent measures are necessary and appropriate to minimize take of the grizzly bear on the Forest:

- 1 Effectively implement and complete an open and total motorized route management program for roads and trails on the Forest by the end of calendar year 1999 that will contribute to the conservation, survival and recovery of the grizzly bear in the GYE as described in Section V of the Revision and the March 19, 1997, letter from the Forest.
- 2 The Forest shall implement and comply with monitoring and reporting procedures that allow the Forest and the Service to keep up-to-date on the status of access density and other management activities on the Forest as described in Section V of the Revision and the March 19, 1997, letter from the Forest.
- 3 Where wilderness lands occur, the Forest should, in coordination with the Idaho Department of Fish and Game and the Service, ensure that the "secure habitat" contains seasonal habitat in approximately the same proportion to its availability across the BMU as currently designated through management prescriptions for wilderness and adjacent lands.
- 4 The Forest shall implement an information program that provides the public with

accurate and accessible information regarding the biological basis for and the resulting effects of the Revision to adequately minimize take of grizzly bears

Terms and Conditions

In order to be exempt from the prohibitions of section 9 of the Act, the Forest must comply with the following terms and conditions, which implement the reasonable and prudent measures described above. These terms and conditions are non-discretionary.

1. The Forest will, by the end of calendar year 1999, have in place in each BMU or subunit a precise open motorized route standard not to exceed 0.6 mi/sq mi and a precise total route density standard not to exceed 1.0 mi/sq mi. Forest activities that involve new road or motorized trail construction should be designed to improve, or at a minimum, designed so as not to increase existing open and/or total motorized route densities within a BMU or subunit above these levels.

2. The Forest shall adopt the open and total motorized route density recommendations of the IGBC Access Committee and implement these recommended levels of motorized access on areas of the Forest that are in the GYE Recovery Zone. This includes, but is not confined to, site specific restrictions (such as area closures, timing restrictions, etc.) on recreation and other activities to resolve human-grizzly bear conflicts, revision of access density standards, and use of CEM to refine core and security area percentages. However, the final IGBC access standards are not yet available, therefore, upon their completion, the Forest will contact the Service and jointly develop a time frame for implementation and attainment of the standards.

Until the standards are available, the Forest will ensure the above effective access restrictions are in place in the BMU's by the close of 1999 as described in the Travel Plan, Section V of the Revision and the March 19, 1997, letter from the Forest. At the end of 5 years from the date the ROD is signed, routes to be restricted that are in close proximity to, but outside the BMU's, will be effectively restricted according to the Revision standards and guidelines.

3. The Forest shall submit an annual report to the Service in December of each year. The report shall detail the progress in achieving the open and total route densities and core area criteria in the BMU's and subunits, including but not limited to listing road and trail closures and the number, location, and kinds of incidents and/or activities that occurred on closed roads and trails. The report to the Service should also document the duration, location, and type of activities proposed to take place in each BMU or subunit during the next activity season. The Forest will provide information to the Service on efforts taken to ensure that core areas contain seasonal habitat approximately proportional to its availability in the BMU and BMU Subunits.

The Service will use these reports to ascertain whether sufficient progress is being made toward realizing the Forest's 1999 and overall Revision objectives. Within 90 days after meeting the open and total road motorized access densities and core area requirements in each BMU or subunit, the Forest shall provide the Service with a final report for the BMU or subunit detailing all activities undertaken in association with the terms and conditions of this biological opinion.

4 Within one year of issuance of the Revision, the Forest will develop and implement a public information program on the positive effects of road closures for fish and wildlife, water quality, and other Forest resources. The effort should focus on both information that is available and relevant at a local, district level and on information pertinent to a more broad-based Forest level approach. The public should be provided a thorough and understandable analysis of existing road densities and future road densities resulting from implementation of the Revision. The net reduction in open motorized access density and the remaining opportunities for motorized public access, timber extraction, recreation, and other Forest uses should be emphasized.

5 In conjunction with implementation of the Travel Plan Standards and Guidelines of the Revision, the Forest should include the following:

A As management recommendations are developed by the GYE Access Committee, the CEM moving windows analysis or most current up-to-date scientific methodology should be used to evaluate and monitor the habitat effectiveness and value across each BMU or subunit. The information will be used by the Forest and the Service to evaluate and update management actions and recommendations for the Forest.

B The IGBC Access Committee definitions make allowances for the occurrence of restricted roads within core areas. Although restricted roads in core areas must be effectively blocked in such a way to prevent motorized access, the presence of a roadbed within a core area increases the potential for illegal motorized use. Effective road closures require effective monitoring of the closures. The Service supports the Forest monitoring efforts and encourages the use of records of violations in closure areas to monitor effectiveness of closures and focus remedial efforts on those areas where the highest incidents of trespass occur.

C Road reclamation should be emphasized in core areas. The number of restricted roads which are still available for use in core areas should be minimized.

D Roads constructed or reconstructed for timber sale purposes should be single purpose roads according to the IGBC Guidelines. New roads or road reconstruction should be of minimum design specifications and placed on the landscape to reduce costs and facilitate reclamation of the roads after the timber

sale is completed

CONSERVATION RECOMMENDATIONS

Sections 2(c) and 7(a)(1) of the Act direct Federal agencies to use their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on listed species or critical habitat, to help implement recovery plans, or to develop information. The recommendations provided here relate only to the proposed Revision and do not necessarily represent complete fulfillment of the Forest section 7(a)(1) responsibility for the grizzly bear.

1. Motorized access management is only one of several factors influencing grizzly bear habitat and grizzly bear security. The presence of attractants is a major factor leading to food conditioning and habituation and the eventual direct mortality or management removal of grizzly bears. The Service supports the continuing efforts to implement the food storage order for the Forest within the BMU's. To further address security for grizzly bears and safety for recreationists outside of the BMU's, the Service recommends the Forest develop and implement a range of alternative food storage options Forest-wide to accommodate a variety of Forest user groups. The Service encourages the implementation of these orders at the earliest date possible.

2. All travel routes scheduled to be restricted outside the BMU's, but on the remaining areas of the Forest will be effectively restricted 10 years from the date the ROD is signed.

In order for the Service to be kept informed of actions minimizing or avoiding adverse effects or benefitting listed species or their habitats, the Service requests notification of the implementation of any conservation recommendations.

REINITIATION NOTICE

This concludes formal consultation on the actions outlined in your November 1996, request for consultation and subsequent updates. As provided in 50 CFR §402.16, reinitiation of consultation is required when discretionary Federal agency involvement or control over the action has been retained (or is authorized by law) and if (1) the amount or extent of incidental take is exceeded (as discussed under the "Incidental Take Statement" section of this opinion, the Service believes this limit is exceeded if a human-grizzly bear incident occurs in a BMU), (2) new information reveals effects of the Forest action that may affect listed species or habitat in a manner or to an extent not considered in this opinion, (3) the action is subsequently modified in a manner that causes an effect to the listed species or habitat not considered in this opinion, or (4) a new species is listed or critical habitat designated that may be affected by the action. In instances where the amount or extent of incidental take is exceeded, any operations causing such take must cease pending reinitiation.

DEFINITIONS

Cummulative Effects Model (CEM) for IGBC

CEM is intended to 1) quantify individual and collective effects of land uses and activities in space and through time, and 2) provide an analytic tool for evaluating alternative land use scenarios relative to grizzly bear recovery goals and objectives (USDA et al 1990)

Access Committee for IGBC

The Access Committee is to 1) establish standardized definitions for roads, i.e., open road reclaimed road, etc., 2) standardize methods to measure road densities and define the analysis areas within which density should be measured, and 3) assure that developed definitions and procedures interface with the existing unified cumulative effects model (IGBC 1994)

Grizzly Bear Recovery Plan Objectives

A recovered population is defined as one that

- 1 can sustain the existing level of known and estimated unknown, unreported human-caused mortality that exists in the GYE, and
- 2 is well distributed throughout the recovery zone in the GYE

Recovery parameters for the GYE are as follows

- 1 15 females with cubs over a running 6-year average both inside the recovery zone and within a 10 mile area immediately surrounding the recovery zone,
- 2 16 of 18 BMU's occupied by females with young from a running 6-year sum of observations with no two adjacent BMU's unoccupied,
- 3 known, human-caused mortality not to exceed 4% of the minimum population estimates based on the most recent three-year sum of females with cubs, and
- 4 no more than 30% of known, human-caused mortality shall be females

IGBC Core Area and Forest Designated and Undesignated Core Area

Core area criteria include the following

- 1 No motorized use of roads and trails during the non-denning period Within the core

area, restricted roads require closure devices that are permanent such as tank traps, large boulders, dense vegetation, etc

- 2 No roads or trails that receive non-motorized, high intensity use as defined in established cumulative effects activity definitions
- 3 Minimum of 0.3 miles from any open road or motorized trail This will be accomplished by buffering all open roads and open motorized trails
- 4 Consideration should be given, when information is available, to ensure the core area(s) meet seasonal bear habitat needs by assuring that spring, summer, fall, and denning habitat within the core areas are representative of these seasonal habitats in the entire analysis area
- 5 Once core areas become established and effective, these areas should remain in place for at least 10 years This duration is based upon the generation time for a female grizzly bear or the time it takes a female grizzly bear to replace herself

The Forest Service has expanded the definition of core area to include the terms "designated and undesignated"

Designated core areas are those areas which meet all of the core area criteria and their boundaries are mapped with a management prescription

Undesignated core areas are those areas which meet all of the core area criteria, but their boundaries are not mapped with a management prescription There is concern since undesignated core areas are not mapped, they may not be established and effective for at least 10 years, therefore, criteria number 5 may not be fully guaranteed in all cases However, undesignated core areas have existed in some areas for many decades, and they may exist into the future for a decade or more For however long they exist, they do provide some habitat benefit to the bear

IGBC Management Situation (MS)

MS-1 areas are those which contain grizzly population centers and/or habitat that is needed for the survival and recovery of the species The needs of the grizzly bear will be given priority over other management considerations Land uses which can affect grizzly bears and/or their habitat will be made compatible with grizzly needs or such uses will be disallowed or eliminated

MS-2 areas are those that do not contain grizzly population centers although grizzlies do occur, and highly suitable habitat components do not generally occur The needs of the grizzly bear will be given consideration where feasible Management would accommodate

grizzly populations and/or habitat use if feasible, but not to the extent of exclusion of other land uses. Human-bear conflict minimization will be given high priority.

MS-3 areas contain no suitable habitat for grizzlies and their presence is possible but infrequent. Grizzly use of such areas will be discouraged. Management within these areas will encourage measures that minimize the potential for human-bear conflict. Examples include towns or other residential areas, established campgrounds, or highways.

IGBC Total and Open Road and Motorized Trail Route Density

Total Motorized Access Route Density - includes all open and restricted roads and motorized trails. Density is displayed as a percentage of the analysis area in a defined density category. Example 20% >2.0 miles per square mile.

Open Road and Open Motorized Trail Route Density - includes all open roads and open motorized trails. Density is displayed as a percentage of the analysis area in a defined density category. Density is a single cumulative total of open roads and open motorized trails.

Percentage of Analysis Area in Core Area(s) - percentage of the analysis area that meets core area criteria. Minimum size and connectivity of patches will be established at the recovery zone level. It is recommended that the minimum size for the core area(s) be that area necessary to support a female grizzly bear for 24 hours of foraging.

Habitat Value

Habitat value (HV) is a measure of the amount and quantity of vegetative and non-vegetative habitat currently in the unit. While HV does not explicitly include human activity, the effects of past activity in the landscape, such as roads, implicitly affects both the vegetative (e.g. habitat type, cover type, and successional stage) and non-vegetative (e.g. ungulate range use) components of grizzly bear habitat (IGBC 1994a).

Habitat value is a relative figure representing the inherent quality of an area to support grizzly bears (USDA et al. 1990).

Habitat Effectiveness

Habitat effectiveness (HE) is the habitat value after discounting for current human activity. Each activity has a zone of influence and a set of dates over which it occurs. The impact of an activity depends upon its level of use and the surrounding security cover. An activity may therefore have high impact during one season and no impact during another. Activities located outside the BMU boundary may have zones of influence extending into the boundary area (IGBC 1994a).

Habitat effectiveness is the product of the values from the habitat routine and disturbance routine calculations, and reflects the area's actual ability to support bears given the quality of habitat and the type of human disturbance imposed upon the area (USDA et al 1990)

Management Prescription 5 3 5 Description

This management prescription emphasizes a high degree of security and resource conditions which contribute toward the conservation and recovery of the grizzly bear, and benefits to other wildlife. Habitats will be managed to meet the goals of grizzly bear recovery. Other uses may be allowed when compatible with these goals.

Grizzly habitat maintenance and improvement, and grizzly-human conflict minimization will receive the highest management priority. Management decisions will favor the needs of the grizzly bear when grizzly habitat and other land use values compete. Land uses which can affect grizzlies and/or their habitat will be made compatible with grizzly needs or such uses will be disallowed or eliminated. Grizzly-human conflicts will be resolved in favor of grizzlies unless the bear involved is determined to be a nuisance bear (IGBC 1986)

The abundance and distribution of natural food sources (such as huckleberry habitats, whitebark pine, etc) are maintained or improved by natural events such as fire and insect disturbances, or by designed vegetation management activities. A variety of forested successional stages are present, and are the result of natural disturbances such as fire and insects or by designed vegetation management activities. Habitat conditions which contribute to the movement of bears to adjacent bear management units are maintained. Human activities are managed or restricted so that human conflicts with grizzlies are unlikely, this includes restricting human activities and generally reduced public access.

Objectives

- 1 Any nonfederal lands within this area will be a high priority for acquisition
- 2 Maintain grizzly bear security through a low density of open, motorized roads and trails
- 3 Manage recreation to minimize grizzly conflicts with humans
- 4 Domestic sheep grazing will be phased out over time, on an opportunity basis
- 5 Wildlife habitat improvement projects will maintain or improve grizzly bear habitat. Vegetation manipulation to improve grizzly bear habitat includes treatment to maintain long term ecosystem vegetation patterns

6 Effects analysis will be analyzed at multiple scales. Analysis areas will follow ecological boundaries, watersheds, and topographic breaks. Cumulative effects will be analyzed on no less than a *BMU* subunit scale.

Standards and Guidelines

Forestwide standards and guidelines apply. The Interagency Grizzly Bear Guidelines for Management Situation 1 habitat apply to this management prescription, except that livestock grazing in existing Management Situation 2 habitat will continue to be managed under Management Situation 2 guidelines.

GLOSSARY

-A-

Abiotic - Nonliving substances or environmental factors.

Accelerated Soil Erosion - Erosion much more rapid than normal, natural, geological erosion; primarily a result of the influence of the activities of man, animals, or catastrophic events.

Acceptable Storage/Acceptably Stored - (a) stored in a bear resistant container or; (b) stored in a closed vehicle constructed of solid, nonpliable material or; (c) suspended at least 10 feet clear of the ground at all points and 4 feet horizontally from any supporting tree or pole.

Acre-foot - A measure of water or sediment volume equal to the amount which would cover an area of one acre to a depth of one foot (325,851 gallons).

Active Nest Site - See Nest Site.

Activity Area - (regarding soil disturbance) A land area impacted by a management activity, excluding specified transportation facilities, dedicated trails, mining excavations, and dumps. Activity areas include harvest units within timber sale areas, prescribed burn areas, and grazing areas within range allotments. Riparian and other environmentally sensitive areas may be monitored and evaluated as individual activity areas.

Activity Area - (regarding wildlife habitat management for grizzly bear and other wildlife species) A geographic area in which activities are conducted. Refers primarily to long-term activities as described in Prescription 5.3.5. A geographic area delineation which reasonable encompasses and supports the primary and immediate effects of the management action which is carried out within it as measured in time and space.

Adaptation - A change in either the genetic makeup or behavior of an organism that enhances its ability to cope with or survive in its environment.

Adaptive Management - A type of natural resource management that implies making decisions as part of an ongoing process. Monitoring the results of

actions will provide a flow of information that may indicate the need to change a course of action. Scientific findings and the needs of society may also indicate the need to adapt resource management to new information.

Adaptive Planning - A strategy whereby planning efforts are directed towards meeting temporary crises which arise in response to changing conditions.

Aerial Logging - Removing logs from a timber harvest area by helicopter. Fewer roads are required, so the impact to an area is minimized.

Affected Environment - The natural environment that exists at the present time in an area being analyzed.

Afforestation - The establishment of a forest cover on areas not previously forested.

Age Class - An age grouping of trees according to an interval of years, usually 20 years. A single age class would have trees that are within 20 years of the same age, such as 1-20 years or 21-40 years and so on.

Air Pollution - The undesirable addition to the atmosphere of substances (gases, liquids, or solid particles) that are either foreign to or are in quantities exceeding their natural concentrations.

Air Quality - The composition of air with respect to quantities of pollution therein; used most frequently in connection with "standards" of maximum acceptable pollutant concentrations.

Air Shed - A collection of geographic areas that because of topography, climate and meteorology share the same air mass.

Allocation - The assignment of management practices to specific land areas to achieve established goals and objectives; for example the allocation of a wilderness management zone to an opportunity class.

Allotment (range allotment) - The area designated for use by a prescribed number of livestock for a prescribed period of time. Though an entire Ranger District may be divided into allotments, all

land may not be grazed, because other uses, such as recreation or tree plantings, may be more important at a given time

Allotment Management Plan (AMP) - A document that specifies the program of action needed to reach a given set of objectives for a livestock allotment. It is prepared in consultation with the permittee(s) involved and prescribes the manner and extent to which the permittee's livestock operations will be conducted in order to meet multiple use, sustained yield, economic, and other needs and objectives as determined for the lands involved. It describes the type, location, ownership, and specifications for the range improvements in place or to be installed and maintained on the lands to meet the livestock grazing and other objectives for the land. It contains such other provisions relating to the permittee's livestock management responsibilities and other objectives as may be prescribed by the Forest Service.

Allowable Sale Quantity (ASQ) - The amount of chargeable timber volume which can be sold from a plan area for a decade. The volume sold from suitable lands cannot exceed the allowable sale quantity standard established for the plan area. Each forest plan which provides for a timber sale program must establish a standard setting the allowable sale quantity. The allowable quantity is a ceiling, it is not a future sale level projection or target and does not reflect all of the factors that may influence future sale levels. This quantity may be expressed on an annual basis as the "average annual allowable sale quantity."

Allowable Use - The degree of utilization considered desirable and attainable on various specific parts of an allotment considering the present nature and condition of the resource, management objectives, and level of management.

All-Aged Stand - A portion of a forest or a stand that contains trees of all, or almost all, age classes.

All Terrain Vehicle (ATV) - A type of off-highway vehicle 50 inches or less in width, having an unladen dry weight of 700 pounds or less, traveling on three or more low pressure tires, having a seat designed to be straddled by the operator and designed for or capable of travel over unimproved terrain.

Alternative - One of several policies, plans or projects proposed for decision making.

AMP - Allotment Management Plan

Analysis - A detailed examination of anything complex in order to understand its nature or determine its essential features.

Analysis Area - A geographic area used for environmental analysis. Analysis areas will vary in size, depending on the type of activity and/or project being analyzed, and the associated issues, concerns and opportunities.

Animal Carcass - The dead body or parts thereof, of any mammal, bird, or fish, including domestic livestock.

Animal Unit (AU) - Considered to be one mature dry cow of approximately 1000 pounds based upon an average daily forage consumption of 26 pounds dry matter per day.

Animal Unit Conversion Factor - A numerical figure expressing the forage requirements of a particular kind or class of animal relative to the requirement for an animal unit. A conversion factor is satisfactory with respect to the amount of forage required to maintain an animal, but may not be applicable in determining stocking rates for range use for particular kinds or classes of animals because of different grazing preferences.

Animal Unit Month (AUM) - The amount of feed or forage required by an animal unit for 1 month. Each wildlife species will utilize some fraction of this as follows: Elk = 7, Deer = 3, and Antelope = 3.

Annual Operating Plan - The yearly annual plan of use for livestock grazing activities on an allotment. The annual operating plan prescribes the annual actions that are necessary to implement and comply with the AMP and/or Forest Land Management Plan goals, objectives, standards and guidelines. It clearly specifies the permittee's obligations as well as those of the Forest Service for the current year. It is the working agreement with the permittee for carrying out the management action prescribed for that year. The term Annual Operating Plan is synonymous with the term Annual Plan of Use.

Annual Plan of Use - See Annual Operating Plan.

Anthropogenic - Involving the impact of humans on natural systems.

Apparent Trend - An estimate of trend drawn from the presence or absence of indicators noted or measured during a onetime observation. Conclusion drawn from such a method can be borne out or refuted only by making additional observations or measurements over time. Apparent trend is described in the same terms as measured trend except that when no trend is apparent it shall be described as "not apparent."

Appeal - A request to a higher ranking Forest Service official for review of and relief from a written decision.

Appropriate Suppression Response - The planned strategy for wildfire suppression action, in terms of kind, amount and timing, which most efficiently meets fire management direction under current and expected burning conditions. The response may range from a strategy of prompt control to one of containment, confinement or surveillance.

Aquatic Connectivity - The level of connection between aquatic habitat patches. Aquatic ecosystems and species coevolved to function within certain limits of connectivity. When aquatic habitat patches are fragmented beyond natural limits, the key ecological linkages between the biological (aquatic biota, soil microbes, riparian plants) and physical (water, parent material, gradient) elements are weakened and result in reduced aquatic ecosystem health.

Aquatic Ecosystem - Any body of water, such as streams, lakes, or springs, and all organisms and nonliving components within it, functioning as a natural system and interacting with associated terrestrial ecosystems.

Aquatic Influence Zone (AIZ) - Used in the context of a land management prescription, the area encompassing aquatic and riparian ecosystems and adjacent lands which directly affect the hydrologic, geomorphic, and ecological processes controlling aquatic and riparian ecosystem health and function.

Aquatic Macroinvertebrates - Invertebrates living within aquatic systems that are large enough to be seen with the naked eye, i.e. most aquatic insects.

Aquifer - A water-bearing geologic formation or structure that transmits water.

Artificial Regeneration - Replacement of forest stands by planting young trees or applying seed (direct seeding).

Aspect - The direction a slope faces. A hillside facing east has an eastern aspect.

ASQ - Allowable Sale Quantity.

Assessment - The Renewable Resource Assessment required by the Forest and Rangeland Renewable Resources Planning Act (RPA).

Associated Species - A species found to be numerically more abundant in a particular forest successional stage as compared to other stages.

Association - Any assemblage of populations living in a prescribed area or physical habitat. A loosely organized unit to the extent that it has characteristics additional to its individual components.

ATV - All Terrain Vehicle.

AUM - Animal Unit Month.

Avoidance Areas - Areas having one or more physical, environmental, institutional or statutory impediments to corridor designation. These are two types of avoidance areas.

Discretionary - areas that may be crossed by corridors only if necessary and reasonable mitigation or avoidance of significant impacts can be obtained.

Nondiscretionary - areas that may not be crossed by corridors unless authorized by the appropriate official (for example, Governor, President, etc.).

-B-

BA - Biological Assessment.

Background - The visible terrain beyond the foreground and middleground where individual trees are not visible but are blended into the total fabric of the stand. (See "Foreground" and "Middleground").

Background Level (Background, Natural Background) - The ever-present environmental conditions or effects above which a phenomenon must manifest itself in order to be detected.

Bald Eagle Occupied Nesting Zone (Zone I) - The area within a 400 m (1312 ft) radius of an occupied nest, or where monitoring data is sufficient, it is the distance at which the presence of humans first causes significant stress or behavior that results in inattentiveness to young or eggs

Bald Eagle Primary Use Area (Zone II) - The area within an 800 m (2625 ft) radius of the active nest and of all known alternative nests, or where monitoring data is sufficient, the area where over 75% of the adults foraging and loafing activity occurs during the nesting season (excluding Zone I) The area could be discontinuous if movement data indicate the need

Bald Eagle Home Range (Zone III) - Includes all potential foraging habitat along rivers and streams within 4 Km (2.5 mi) of Zone I areas, which is not included in Zones I or II The zone will include a 400 m (1312 ft) buffer along the potential foraging habitat

Bark Beetle - An insect that bores through the bark of trees to eat the inner bark and lay its eggs Bark beetles and associated fungi are important killers of forest trees

Basal Area - 1 The area of the cross section of a tree stem, including the bark, generally at breast height (4.5 feet [1.4 m] above the ground) 2 The total area of ground covered by trees measured at breast height 3 The actual surface area of soil covered or occupied by a plant measured close to the ground (basal cover, ground cover)

Base Sale Schedule - A timber sale schedule formulated on the basis that the quantity of timber planned for sale and harvest for any future decade is equal to or greater than the planned sale and harvest for the preceding decade and that this planned sale and harvest for any decade is not greater than the long-term sustained-yield capacity This definition expresses the principle of nondeclining flow

BE - Biological Evaluation

Bear Management Units (BMUs) - Eighteen land units delineated within the Yellowstone Grizzly Bear Recovery Zone These units are approved by the IGBC for grizzly bear population and habitat analysis There are three bear management units which encompass portions of the Targhee National Forest

Bear Management Unit Subunits - Smaller divisions of BMUs approved by the IGBC for additional habitat and population analysis

Bear Resistant Container - A securable container constructed of solid nonpliable material capable of withstanding 200 foot-pounds of energy (using the approved bear-resistant container impact testing machine) When secured and under stress the container will not have any cracks, openings, or hinges that would allow a bear to gain entry by biting or pulling with its claws Wood containers are not considered bear-resistant unless they are reinforced with metal

Benchmark - (1) A permanent reference point (2) In range monitoring, it is used as a point where changes in vegetation through time are measured

Best Management Practices (BMPs) - Practices which have been designed to prevent or reduce the amount of nonpoint pollution, to a level compatible with State water quality standards and quality goals These practices may be determined by the State, the Forest, a designated area wide planning agency, or on a project level basis Also referred to as Soil and Water Conservation Practices (SWCPs)

Big Game - Those species of large mammals normally managed for sport hunting

Biodegradable - Chemicals or substances which can be readily broken down into their component parts by biological action

Biodiversity - See Biological Diversity

Biological - Relating to, or affecting life and living organisms

Biological Assessment (BA) - A document that reviews and evaluates proposed actions of Federal agencies for possible effects on any species listed, or proposed to be listed, as threatened or endangered, and their designated or proposed critical habitat

Biological Control - The use of natural means to control pests Examples include introduced or naturally occurring predators such as wasps, or hormones that inhibit the reproduction of pests Biological controls can sometimes be alternatives to mechanical or chemical means

Biological Diversity - The distribution and abundance of different plant and animal species and communities within an area. Biodiversity can be defined as the number of different items and their relative frequency. Diversity can occur on the genetic, species, ecosystem and landscape levels.

Biological Evaluation (BE) - A document that reviews all Forest Service planned, funded, executed, or permitted programs and activities for possible effects on endangered, threatened, proposed, or sensitive plant and animal species.

Biological Potential - The maximum possible resource output limited only by inherent physical and biological characteristics.

Biomass - The total weight of the living organisms in some biological system.

Biosphere - That part of the earth's crust, waters and surrounding air-layer which is inhabited by living organisms.

Biota - The plants and animals of an area, taken collectively.

Biotic - Pertaining to life or living organisms.

Biotic Climax - A climax caused by a permanent influence or culmination of influences from one or more kinds of organisms, including humans. See Climax.

Biotic Community - See Community.

Biotic Diversity - See Biodiversity.

BMP - Best Management Practices.

Board Foot - The amount of wood equivalent to a piece 1 foot long by 1 foot wide by 1 inch thick. Generally, five board feet log measure is approximately equivalent to 1 cubic foot of round wood.

Bog - An inadequately drained area rich in plant residues, usually acid in reaction, frequently surrounding a body of open water, and having a characteristic flora.

Broadcast Burn - Allowing a prescribed fire to burn over a designated area within well-defined boundaries for reduction of fuel hazard, improve forage for wildlife and livestock, or encourage successful regeneration of trees.

Browse - Twigs, leaves and young shoots of trees and shrubs that animals eat. Browse is often used to refer to the shrubs eaten by big game, such as elk and deer.

Brush - Stands of shrubby, woody plants or low growing trees.

Buffer - A designated land or water area, along the perimeter of some feature (e.g., a stream), whose use is regulated so as to resist, absorb or preclude unwanted effects to the protected feature.

Buffer Strip - A protective area adjacent to an area requiring special attention or protection.

Burning Index (BI) - A number related to the contribution of fire behavior to the effort of containing a fire. BI is represented in NFDRS by a calculation of flame length in feet multiplied by 10.

BURP - Beneficial Use Reconnaissance Project. It includes methods used by Idaho DEQ to measure water quality, beneficial use status and attainability, and general stream health.

-C-

C&H Allotment - A cattle and horse allotment.

Cable Logging - Logging that involves the transport of logs from stump to collection points by means of suspended steel cables. Cable logging reduces the need for the construction of logging roads.

Candidate Species - A species being considered for Federal listing as a threatened or endangered species.

Canopy - The more or less continuous cover of branches and foliage formed collectively by the crown of adjacent trees and other woody growth. It usually refers to the uppermost layer of foliage, but it can be used to describe lower layers in a multi-storied forest.

Canopy Closure - The degree to which the collective forest canopy, as projected onto the surface, occupies or covers that surface, the degree to which the sunlight is blocked or the sky obscured.

Canopy Cover - The percentage of ground covered by a vertical projection of the outermost pe-

rimeter of the natural spread of foliage of plants. Small openings within the canopy are included. The sum of canopy cover of several species may exceed 100 percent. (Syn: crown cover)

Capability - The potential of an area of land to produce resources, supply goods and services, and allow resource uses under an assumed set of management practices and at a given level of management intensity. Capability depends upon current conditions and site conditions such as climate, slope, landform, soils and geology, as well as the application of management practices, such as silviculture or protection from fire, insects and disease.

Capability for Livestock Grazing - Refers to the ability (given physical, biological, and technological feasibility) of land to produce forage resources that can be grazed by domestic or wild ungulates. Areas designated as "open" to domestic livestock grazing have the potential to produce resources, supply goods and services, and allow resource uses under an assumed management intensity. Capability depends upon factors such as soils, slope, landform, etc.

Carnivore - A flesh eating organism.

Carrying Capacity - The number of organisms that the resources of a habitat can support. Usually used with respect to specific species even though the carrying capacity of a habitat depends on the interactions of both its abiotic and biotic components.

Catastrophic Condition - A significant change in forest conditions on the area that affects Forest Plan resource management objectives and their projected and scheduled outputs, uses, costs, and effects on local communities and environmental quality.

Catastrophic Event - A large-scale, high-intensity natural disturbance that occurs infrequently.

Cavity - The hollow excavated in trees by birds or other natural phenomena, used for roosting and reproduction by many birds and mammals.

CEM - Cumulative Effects Model (Bear)

Channel - A natural or artificial conduit which periodically or continuously contains moving water, such as a stream. A channel has defined bed and banks.

Chargeable Volume - All volume included in the growth and yield projections for the selected management prescriptions used to arrive at the allowable sale quantity, based on regional utilization standards.

Chemical Control - The use of chemical pesticides and herbicides to control pests and undesirable plant species.

Class I Areas (Airsheds) - An area designated for the most stringent degree of air quality protection by the Clean Air Act. Included are National parks established before August 1977 and wildernesses designated by the 1964 Wilderness Act. Increases in sulfur dioxide and particulate matter concentrations in ambient air are strictly regulated to protect visibility.

Class II Areas (Airsheds) - The level of air quality protection assigned to areas other than Class I Areas.

Class of Livestock - Age and/or sex group of a kind of livestock. (compare to class of animal)

Classification - The systematic grouping (and naming) of entities based on shared characteristics.

Clean Air Act - Public Law 84-159 as amended. Section 309 of 42 U.S.C. 7609 provides authority for the Environmental Protection Agency to review other agency environmental impact statements.

Clearcutting - A method of regenerating an even-aged stand in which a new age class develops in a fully-exposed microclimate after removal, in a single cutting, of all trees in the previous stand.

Clearcutting with Reserves Regeneration Method - A variant of the Clearcutting Method in which varying numbers of reserve trees are not cut to attain goals other than regeneration. The method normally creates a two-aged stand.

Climate - The average course or condition of the weather at a particular place over a period of many years as exhibited in extremes, means, ranges and seasonal distributions.

Climax - The culminating stage in plant succession for a given site where the vegetation has reached a highly stable condition.

Climax Community - The final stage in plant succession for a site. Its nature is determined largely by the climate and soil of a region. Absent disturbance, the climax community develops and maintains itself in steady state conditions.

Climax Species - Species that are self-perpetuating in the absence of disturbance.

Climax Vegetation - The pattern or complex of climax communities in a landscape corresponding to the pattern of environmental gradients or habitats.

Closed Allotment/Area - An allotment or area where livestock grazing is not permitted.

Coarse-filter Analysis - An analysis of aggregates of elements such as cover type or plant community.

Coarse Filter Management - Land management that addresses the needs of all associated species, communities, environments, and ecological processes in a land area. (See fine filter management.)

Collector Roads - Roads that serve small land areas and are usually connected to a Forest System Road, a county road, or a state highway.

Commercial Forest Land - Forest land that is producing or is capable of producing crops of industrial wood and (a) has not been withdrawn by Congress, the Secretary, or the Chief, (b) existing technology and knowledge is available to ensure timber production without irreversible damage to soils productivity, or watershed conditions, and (c) existing technology and knowledge, as reflected in current research and experience, provides reasonable assurance that adequate restocking can be attained within 5 years after final harvesting.

Commercial Thinning - Selective cutting in immature stands in which all or part of the felled trees are extracted for useful products and designed to improve the quality and growth of the remaining trees.

Commodity - A resource product for which a monetary value has been established.

Common Variety Mineral - (also called salable mineral) In general, common variety mineral ma-

terials occur widely and have a low unit value. These include common varieties of sand, gravel, cinders, stone, pumice, clay and other similar materials. Defined in the Materials Act of 1947 and Public Law 167 of 1955, these minerals are sold rather than located or leased. Their disposal is totally at the discretion of the Forest Service.

Community - All of the organisms inhabiting a common environment and interacting with one another, or an association of interacting populations usually defined by the nature of their interaction in the place in which they live.

Community Cohesion - The degree of unity and cooperation within a community in working toward shared goals and solutions to problems. Used in the context of human relationships.

Community Stability - A community's capacity to handle change without major hardships or disruptions to component groups or institutions. Measurement of community stability requires identification of the type and rate of proposed change and an assessment of the community's capacity to accommodate that level of change.

Community Type - An aggregation of all plant communities distinguished by floristic and structural similarities in both overstory and undergrowth layers. A unit of vegetation within a classification.

Compartment - A unit of forested land, usually between 1,000 and 3,000 acres in size, defined by natural and man-made features and used to facilitate timber planning.

Competition - The general struggle for existence and dominance in which living organisms compete for a limited supply of the necessities of life.

Composition - What an ecosystem is composed of. Composition could include water, minerals, trees, snags, wildlife, soil, microorganisms, and certain plant species that comprise a biotic community or other ecological unit.

Concern - (Also management concern) An issue, problem or condition which constrains the range of management practices identified by the Forest Service in the planning process.

Confine - To limit fire spread within a predetermined area principally by use of natural or precon-

structured barriers or environmental conditions. Suppression action may be minimal and limited to surveillance under appropriate conditions

Conifer - A tree, usually evergreen, that produces cones, such as a pine, spruce, or fir tree

Connected Actions - Closely related actions which automatically trigger other actions, cannot proceed unless other actions are taken previously or simultaneously, or are interdependent parts of a larger action and depend on the larger action for justification

Connectivity (of habitats) - The linkage of similar but separated vegetation stands by patches, corridors or "stepping stones" of like vegetation. This term can also refer to the degree to which similar habitats are linked

Connectivity - The condition in which the spatial arrangement of land or water habitats allows biological and ecological processes to function across the landscape. Connectivity is the opposite of fragmentation

Conservation - The careful protection, utilization and planned management of natural resources to prevent their depletion, exploitation, destruction, waste or neglect

Consistency - The degree to which all resource plans and permits, contracts and other instruments for the use and occupancy of National Forest System land adhere to Forest Plan direction

Constraint - A limitation, action which cannot be taken or must be taken

Consumer Organism - An organism which ingests other organisms or existing organic matter

Consumptive Use - A use of resources that reduces the supply, such as logging and mining (See also nonconsumptive use)

Contain - To surround a fire, and any spot fires therefrom, with control lines as needed, which can reasonably be expected to check the fire's spread under prevailing and predicted conditions

Contingency Plan - A plan for providing timely recognition of approaching critical fire situations, priority setting, and deployment of forces and other action to resolve those situations

Continuous Grazing System - Unrestricted grazing throughout the entire grazing season every year

Contour - A line drawn on a map connecting points of the same elevation

Contrast - The degree to which adjacent landscape elements differ from each other, with respect to species composition and physical attributes

Control - To complete the control line around a fire, any spot fires therefrom, and any interior islands to be saved, burn out any unburned area adjacent to the fire side of the control line, and cool down all hot spots that are immediate threats to the control line, until the line can reasonably be expected to hold under foreseeable conditions

Coordinated Resource Management (CRM) - The process whereby various user groups are involved in discussion of alternative resource uses and collectively diagnose management problems, establish goals and objectives, and evaluate multiple use resource management

Core Area - A term used to describe a component of grizzly bear habitat. Core areas are free of motorized access during the nondenning period. Core areas must meet the following criteria

No motorized use of roads and trails during the nondenning period. Within the core area, restricted roads require closure devices that are permanent such as tank traps, large boulders, dense vegetation, etc

No roads or trails that receive nonmotorized, high intensity use as defined in established cumulative effects activity definitions

Minimum of 3 miles from any open road or motorized trail. This will be accomplished by buffering all open roads and open motorized trails

Consideration should be given to ensure that the core areas meet seasonal bear habitat needs by assuring that spring, summer, fall and denning habitat within the core areas are representative of these seasonal habitats in the entire analysis area

Once core areas become established and effective, these areas should remain in place

for at least 10 years. This duration is based upon the generation time for a female grizzly bear or the time it takes a female grizzly bear to replace herself.

Corridor - A linear strip of land managed for specific vegetational and other (roads) characteristics to allow the movement of species between areas of suitable habitat. The landscape elements that connect similar patches through a dissimilar matrix or an aggregation of dissimilar patches.

Cost-efficiency - The usefulness of specified inputs (costs) to produce specified outputs (benefits). In measuring cost efficiency, some outputs, including environmental, economic, or social impacts, are not assigned monetary values but are achieved at specified levels in the least cost manner. Cost efficiency is usually measured using present net value, although use of benefit-cost ratios and rates-of-return may be appropriate.

Council on Environmental Quality (CEQ) - The Council issues regulations binding on all federal agencies, to implement the procedural provisions of the National Environmental Policy Act. The regulations address the administration of the NEPA process, including preparation of Environmental Impact Statements (EIS) for major federal actions which significantly affect the quality of the human environment.

Cover - Any feature that conceals wildlife or fish. Cover may be dead or live vegetation, boulders, or undercut streambanks. Animals use cover to escape from predators, to rest or to feed.

Cover Class - Represents a percentage range for a fixed area covered by the crowns of plants. It is measured as a vertical projection of the outermost portion of the foliage. Cover Class A = <40% canopy cover, Cover Class B = 40-60% canopy cover, Cover Class C = >60% canopy cover.

Cover-forage Ratio - The ratio of hiding cover to foraging areas for wildlife species.

Cover, Percent - The area covered by the combined aerial parts of plants and vegetative ground cover expressed as a percent of the total area.

Cover Type (forested cover type) - Stands of vegetation that are distinguished by the existing dominant or codominant plant canopies. The as-

pen cover type contains plants distinct from the pinyon-juniper cover type.

Created Opening - An opening in the forest cover (nonstocked and seedling stages) created by the application of even-aged silvicultural practices (clearcuts, seed cuts of a shelterwood, or group selection), and nonstocked and seedling stages following natural or prescribed fire.

Critical Area - A portion of rangeland which has a critical issue related to it, such as a threatened or endangered or sensitive species, a high use recreation area, or a key wildlife habitat. The area serves as a monitoring and evaluation site for the critical issue.

Critical Habitat - Specific area occupied by threatened or endangered species, on which are found those physical and/or biological features that are essential to the conservation of the species.

Crop Tree - A tree that forms, or is selected to form, a component of the final stand, specifically, one selected to be carried through to maturity. Also known as a final crop tree or growing stock tree.

Crown - The upper part of a tree or other woody plant carrying the main branch system and foliage above a more or less clean stem.

Crown Closure - See cover class.

Crown Cover - The amount of canopy provided by branches and foliage of trees, shrubs, and herbs in a plant community. May be specified by species, growth form or collectively.

Crown Fire - A fire that advances from top to top of trees or shrubs more or less independently of the surface fire. Sometimes crown fires are classed as either running or dependent, to distinguish the degree of independence from the surface fire.

Crown Height - The distance from the ground to the base of the crown of a tree.

CU Allotment - An allotment grazed by both sheep and cattle (common use).

Culmination of Mean Annual Increment - For a tree or stand of trees, the age at which the average annual increment is greatest. It coincides precisely with the age at which the current annual increment just equals the mean annual increment of

the stand and thereby define the rotation of a fully stocked stand that yields the maximum volume growth

Cultural Resource - The remains of sites, structures, or objects used by humans in the past - historical or archaeological

Cultural Sensitivity - Refers to the likelihood of encountering significant cultural volumes (quantity and/or quality) that may affect and may be affected by ground-disturbing activities

Cumulative Actions - Actions which when viewed with other proposed actions have cumulatively significant impacts

Cumulative Effects or Impacts - The impact on the environment which results from the incremental impact of an action when added to other past, present and reasonably foreseeable future actions regardless of what agency or person undertakes such other action. Cumulative effects or impacts can result from individually minor but collectively significant actions taking place over a period of time

Cumulative Effects Analysis - An analysis of the cumulative effects

Cutting Cycle - The planned lapse of time between successive cuttings in a stand

Cutting Method - Describes cuttings used either to help reproduce forest stands (reproduction or harvest cuttings) or to maintain their vigor and desired composition and structure in terms of tree species, ages, and size classes (intermediate cuttings)

Cycling - One of the ways functions are described, resources which are transported within the system (such as animal migration, nutrient cycling in a forest stand, snow melt becoming part of the surface or groundwater flow)

-D-

Data - Any measurements, facts, evidence or observations reduced to a recorded and retrievable format

DB - Database

DBH - Diameter at Breast Height

Decomposer - An organism, usually a bacterium or fungus, that breaks down the bodies or parts of dead plants and animals into simpler compounds

Decomposition - The process of separating into constituent parts, elements, or simpler organic and inorganic compounds. In biological systems, a process usually accomplished by fungi and bacteria

Decomposition Class - Any of five stages of decomposition of logs left in the forest, stages range from essentially sound to almost total decomposition (See table at end of glossary for additional information)

Defoliation - The removal of leaves from plants, especially by herbicides or plant eating animals

Density - Numbers of individuals or stems per unit area (Density does not equate to any kind of cover measurement)

Departure - A timber sale schedule that deviates from the principle of nondeclining flow by exhibiting a planned decrease in the sale schedule at any time during the planning horizon. A departure is characterized by a temporary increase, usually in the beginning decade(s) of the planning horizon, over the base sale schedule originally established. This increase does not impair the future attainment of the long-term sustained yield capacity

Dependent Species - A species for which a habitat element (for example, snags) is deemed essential for the species to occur regularly or to reproduce

Desirable Plant Species - Species which contribute to the management objectives

Desired Condition (DC) - A portrayal of land or resource conditions which are expected to result if planning goals and objectives are fully achieved

Desired Future Condition (DFC) - A description of the cumulative results of implementing the goals expressed in the Forest Plan

Desired Future Vegetation - The future state of the plant community on a site or an ecological unit which meets forest plan or other management objectives

Desired Plant Community - A plant community which produces the kind, proportion, and amount of vegetation necessary for meeting or exceeding the Forest Land Management Plan or Allotment Management Plan objectives established for an ecological type(s). The desired plant community must be consistent with the type's capability to produce the desired vegetation through management, land treatment, or a combination of the two. The desired plant community must conserve to the extent practicable the long-term potential of the site to produce vegetation, and produce in the short-term those combinations of desired goods and services.

Desired Soil Protection - Desired soil quality standards which meet forest plan or other management objectives for maintaining soil productivity potential, including thresholds for soil cover, erosion, compaction and soil displacement.

Desired Vegetation Condition (DVC) - For both riparian areas and nonforested uplands is defined as The specific future condition of rangeland vegetation and other resources such as aquatic habitat and water quality that meet management objectives as identified in the Forest Plan, Allotment Management Plans, or other documents. Additional clarification can be found in the nonforested vegetation sections of Chapters 3 and 4 of the EIS.

Detrimental Compaction - See Soil section of glossary.

Detrimental Displacement - See Soil section of glossary.

Detrimental Disturbance - See Soil section of glossary.

Detrimental Puddling - See Soil section of glossary.

Developed Recreation Sites - Relatively small, distinctly defined and developed areas where facilities are provided for concentrated public use, (for example, campgrounds, picnic areas, and swimming areas). These areas have more than \$50,000 of investment and two or more developed facilities are present.

Development Scale - The following scale describes facility development levels for dispersed and developed recreation sites.

1- Minimum site modification. Rustic or rudimentary improvements designed for protection of the site rather than comfort of the users. Use of synthetic materials excluded. Minimum controls are subtle. No obvious regimentation. Spacing informal and extended to minimize contacts between users. Motorized access not provided or permitted.

2- Little site modification. Rustic or rudimentary improvements designed primarily for protection of the site rather than the comfort of the users. Use of synthetic materials avoided. Minimum controls are subtle. Little obvious regimentation. Spacing informal and extended to minimize contacts between users. Motorized access provided or permitted. Primary access over primitive roads. Interpretive services informal, almost subliminal.

3- Site modification moderate. Facilities about equal for protection of site and comfort of users. Contemporary/rustic design of improvements is usually based on use of native materials. Inconspicuous vehicular traffic controls usually provided. Roads may be hard surfaced and trails formalized. Development density about 3 family units per acre. Primary access may be over high standard roads. Interpretive services informal, but generally direct.

4- Site heavily modified. Some facilities designed strictly for comfort and convenience of users. Luxury facilities not provided. Facility design may incorporate synthetic materials. Extensive use of artificial surfacing of roads and trails. Vehicular traffic control usually obvious. Primary access usually over paved roads. Development density 3-5 family units per acre. Plant materials usually native. Interpretive services often formal or structured.

5- High degree of site modification. Facilities mostly designed for comfort and convenience of users and usually include flush toilets, may include showers, bathhouses, laundry facilities, and electrical hookups. Synthetic materials commonly used. Formal walks or surfaced trails. Regimentation of users is obvious. Access usually by high-speed highways. Development density 5 or more family units per acre. Plant materials may be foreign to the environment. Formal interpretive services usually available. Designs formalized and architecture may be contemporary. Mowed lawns and clipped shrubs not unusual.

DFC - Desired Future Condition

Diameter at Breast Height (DBH) - The diameter of a tree measured 4 feet 6 inches (1.4 m) above the ground

Direct Effect - An effect that is caused by an action and occurs in [generally] the same time and place as the action

Discount Rate - An interest rate that represents the cost or time value of money in determining the present value of future costs and benefits. A "real" discount rate is one adjusted to exclude the effects of inflation

Discounting - An adjustment, using a discount rate, for the value of money over time so that costs and benefits occurring in the future are reduced to a common time, usually the present, for comparison

Dispersal - The movement of plants and animals away from their point of origin to another location where they subsequently get established and produce offspring

Dispersed Recreation - Recreational activities that do not require developed facilities. These include hiking, fishing, hunting, biking, camping at undeveloped campsites, etc

Dispersed Recreation Sites - Relatively small, undeveloped areas where public recreation use occurs. These areas have less than \$50,000 of investment in facilities such as toilets, tables, fencing, etc. These sites are generally adjacent to roads or trails and are used for dispersed recreation activities, such as camping, fishing, hunting, hiking, etc

Dispersion - To spread out the impacts of timber harvest by distributing harvest units more or less uniformly throughout a drainage

Distinctive (Class A) landscape - Areas where features of landform, vegetation patterns, water forms, and rock formations are of unusual or outstanding visual quality

Disturbance - Any event such as a forest fire or insect infestation that alters the structure, composition, or function of an ecosystem

Disturbed Soil - see Soil Disturbance

Diversity - The distribution and abundance of different plant and animal communities and species within the area covered by a land and resource management plan. See also Biological Diversity, Edge, and Horizontal Diversity

Dominant - A taxon or group of taxa which by their collective size, mass, or numbers exert the most influence on community composition and form

Drainage - A large area mostly bounded by ridges, encompassing part, most or all of a watershed

Drought Index - A number representing net effect of evaporation, transpiration, and precipitation in producing cumulative moisture depletion in deep duff or upper soil layers

Durability - The ability of resources to tolerate sustained use, without degradation of the resource base (i.e., productivity or quality)

Dwarf Mistletoe (*Arceuthobium spp.*) - Parasitic, seedbearing plants that attack most western conifers. Infected trees can be recognized by presence of witches' brooms, cankers, swellings, and other abnormalities. Economic losses can be heavy, as damage results in smaller trees, lower timber quality, and increased mortality

-E-

EA - Environmental Assessment

Early Forest Succession - The biotic (or life) community that develops immediately following the removal or destruction of vegetation in an area. For instance, grasses may be the first plants to grow in an area that was burned, followed by forbs and shrubs

Ecocentric - A conservation strategy that focuses on providing habitat patterns that are manifestations of ecological processes operating at several scales

Also, a philosophical viewpoint which emphasizes the maintenance of natural systems at the expense of commodity production and other human uses. The goal of this philosophy is to permit natural ecological processes to operate as freely as possible,

because wild land values for society ultimately depend on the retention of naturalness

Ecoclass - Classification system for the biological and earth sciences based on linking together existing disciplinary classifications of the major ecosystem components

Ecological Approach - A natural resource planning and management method that assures consideration of the relationship among all organisms (including humans) and their environment

Ecology - The interrelationships of living things to one another and to their environment, or the study of these interrelationships

ECOMAP - The name given to the Forest Service workgroup that developed the National Hierarchy of Ecological Units for the United States

Economic impacts -

direct economic impact - Effects caused directly by forest product harvest or processing or by forest uses

indirect economic impact - Effects that occur when supporting industries sell goods or services to directly affected industries

induced economic impact - Effects that occur when employees or owners of directly or indirectly affected industries spend their income within the economy

Ecoregion - A continuous geographic area over which the macroclimate is sufficiently uniform to permit development of similar ecosystems on sites with similar properties. Ecoregions contain multiple landscapes with different spatial patterns of ecosystems

Ecosystem - An arrangement of living and nonliving things and the forces that move among them. Living things include plants and animals. Nonliving parts of ecosystems may be rocks and minerals. Weather and wildfire are two of the forces that act within ecosystems

Ecosystem Composition - The constituent elements of an ecosystem

Ecosystem Function - The processes through which the constituent living and nonliving elements

of ecosystems change and interact, including biogeochemical processes and succession

Ecosystem Health - Ecosystems at any temporal or spatial scale are "healthy" when they are dynamic and resilient to perturbations to structures, compositions and processes of their biological or physical components

Ecosystem Management - The use of an ecological approach to blend social, physical, economic and biological needs and values to provide productive, healthy ecosystems

Ecosystem Pattern - The structure that results from the distribution of organisms in, and their interaction with their environment. Includes zonation, stratification, activity or periodicity, food-webs, reproductive, social and stochastic

Ecosystem Resilience - The tendency of an ecosystem to return after a disturbance to its former structure and function

Ecosystem Resistance - The tendency of an ecosystem to remain unchanged in the face of a disturbance

Ecosystem Restoration - Returning an ecosystem from a nonsustainable to a sustainable condition

Ecosystem Stability - The degree to which an ecosystem is resistant and/or resilient to disturbances

Ecosystem Structure - The spatial arrangement of the living and nonliving elements of an ecosystem

Ecosystem Sustainability - The ability to sustain diversity, productivity, resilience to stress, health, renewability, and/or yields of desired values, resource uses, products, or services from an ecosystem while maintaining its integrity over time

Edge - The margin where two or more vegetation patches meet, such as a meadow opening next to a mature forest stand, or a Douglas-fir stand next to an aspen stand

Edge Effect - The increased richness of plants and animals resulting from the mixing of two communities where they join

Effects - The environmental consequences of a proposed action. Included are direct effects, which are caused by the action and occur at the same time and place, and indirect effects, which are caused by the action and are later in time or further removed in distance, but which are still reasonably foreseeable. Indirect effects may include growth inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air, water and other natural systems, including ecosystems.

Effects and impacts as used in this statement are synonymous. Effects include ecological (such as the effects on natural resources and on the components, structures and functioning of affected ecosystems), aesthetic quality, historic, cultural, economic, social or health whether direct, indirect or cumulative. Effects may also include those resulting from actions that may have both beneficial and detrimental effects, even if on balance the agency believes that the effects will be beneficial.

EHE - Elk Habitat Effectiveness

EIS - Environmental Impact Statement

Elk Habitat Effectiveness (EHE) - A measure of the quality of an area for elk during the spring/summer/fall seasons. Two habitat parameters are considered to be most important for EHE: 1) motorized road and trail densities (measured in miles/square mile), 2) elk hiding cover (measured as a percentage of an area in cover).

Elk Hiding Cover - Vegetation capable of hiding 90 percent of a standing adult elk from the view of a human at a distance equal to or less than 200 feet.

Elk Vulnerability (EV) - The percent mortality of bull elk during the fall general rifle hunting season. Two parameters are considered to be most important for EV: 1) hunter densities (measured in hunter-days/square mile), 2) motorized road and trail densities (measured in miles/square mile).

Emergent Vegetation - Plants rooted in shallow water and having most of the vegetative growth above water.

Emission - A release of air contaminants into the outdoor atmosphere.

Endangered Species - Any species of animal or plant that is in danger of extinction throughout all or a significant portion of its range. Plant or animal species identified (listed) by the Secretary of the Interior as endangered in accordance with the 1973 Endangered Species Act.

Endangered Species Act - Public Law 93-205 (16 U.S.C. 1531-1536, 1538-1540). Cited as the Endangered Species Act of 1973. The Act requires consultation with U.S. Fish and Wildlife Service if practices on National Forest System lands may impact a threatened or endangered species (plant or animal).

Endemic - Native to, and restricted in distribution to, a defined area. (Not epidemic).

Environment - The complex of climatic, soil and biotic factors that act upon and influence an ecosystem. The complex of these factors which make up the immediate habitat of an organism.

Environmental Analysis - An analysis of alternative actions and their predictable long and short-term environmental effects. Environmental analyses include physical, biological, social and economic factors.

Environmental Assessment (EA) - A document providing evidence and analysis relating to a proposed action by a Federal Agency. It establishes whether an environmental impact statement (EIS) must be written, or a finding of no significant impact (FONSI) will be issued. It includes the proposed action and alternatives, and evaluates their potential environmental impacts.

Environmental Impact Statement (EIS) - A statement of the environmental effects of a proposed action and alternatives to it. It is required for major Federal actions under Section 102 of the National Environmental Policy Act (NEPA) and released to the public and other agencies for comment and review. It is a formal document that must follow the requirements of NEPA, the Council on Environmental Quality (CEQ) guidelines, and directives of the agency responsible for the project proposal.

Ephemeral Streams - Streams that flow only as the direct result of rainfall or snowmelt. They have no permanent flow.

Erosion - The wearing away of the land surface by wind, water, ice or gravity.

ESA - Endangered Species Act

Escaped Fire - A fire which has exceeded, or is anticipated to exceed, initial attack capabilities or the fire management direction or prescription

EV - Elk Vulnerability

Even-aged Forest - A forest stand comprising trees with less than a 20-year difference in age

Even-aged Management - Timber management actions that result in the creation of a stand of trees in which the trees are essentially the same age. Clearcut, shelterwood, or seed tree cutting methods produce even-aged stands

Even-aged Stand - A portion of a forest or a stand composed of trees having no, or relatively small, differences in age, although differences of as much as 30 percent are admissible in rotations greater than 100 years

Even-aged System - A silvicultural system that produces stands in which all trees are about the same age, that is, the difference in age between trees forming the main crown canopy level will usually not exceed 20 percent of the rotation length

EWU - Ecological Water Unit

Exclusion Areas - Areas having a statutory prohibition to rights-of-way for lineal facilities or corridor designation

Extensive Management - The practice of forestry on a basis of low operating and investment costs per acre. Also known as extensive forestry

Extinct - A species is extinct when it no longer exists

Extinction - The process which results in the complete elimination of a species leaving no living descendants. Extinctions may be local or global

Eyrie - A ledge along a cliff used for nesting peregrine falcons

sanitary landfills, dams, bridges and communication systems

Fauna - The animal life of an area

Felling - Cutting down trees

Fen - Low peaty land covered wholly or partly with water

Final Cut - The removal of the last seed bearers or shelter trees after regeneration of new trees has been established in a stand being managed under the shelterwood system of silviculture

Final Removal - Removal of all remaining overstory trees to release an adequately stocked salvageable understory

Final Removal Cut - A type of cut that releases established regeneration from competition with seed trees under the seed tree and shelterwood regeneration methods. Reserve trees may or may not be retained

Fine Fuels - Fast drying fuels such as grass, leaves, draped pine needles, and small twigs that when dry ignite readily. Fine fuels are considered 1 hour timelag fuels (see timelag definition)

Fine Organic Matter - Organic material on top of mineral soil consisting of fallen vegetative matter in various stages of decomposition. Specifically referred to as horizons in soil descriptions. Fine organic matter includes woody material up to 3 inches in diameter

Fines - Waterborn particles the size of silt and clay

Fire - The rapid, persistent chemical reaction of a fuel and oxygen that releases heat, light and unburned particulate (smoke)

Fire Ecology - Area of study addressing the relationships among fire, the environment, and living organisms

Fire Frequency - The number of wildland fires started in a given area over a given time

Fire Group - A collection of similar habitat types and their associated fire ecology

Fire Hazard - A fuel complex, defined by volume, type condition, arrangement, and location, that

-F-

Facilities - Physical infrastructure such as administrative buildings, water and sanitation systems,

determines the degree of ease of ignition and of resistance to control

Fire Management - All activities required for the protection from fire of burnable wildland values and the use of fire to meet land management goals and objectives

Fire Management Area - One or more parcels of land having a common set of fire management objectives

Fire Occurrence - Number of fires per unit time in a specified area

Fire Regime - The characteristic frequency, extent, intensity, severity and seasonality of fires in an ecosystem

Fire Risk - The chance of fire starting, as affected by the nature and incidence of causative agents, an element of the fire danger in any area

Fire Suppression - All work and activities associated with fire extinguishing operations beginning with discovery and continuing until the fire is completely extinguished

Fireline Intensity - The amount of heat released in BTUs per foot of fire front per second Related to the difficulty of containment of a fire

Fish - Any of numerous cold-blooded aquatic vertebrates having fins, gills and a streamlined body

Fish-bearing Stream Reaches - Those portions of streams and rivers that support fish of any species during all, or a portion of, their life cycle

Fisheries Habitat Streams, lakes, and reservoirs that support fish, or have the potential to support fish

Floodplain - The lowland and relatively flat area adjoining waters including, at a minimum, the area subject to a one percent or greater chance of flooding in any given year (100-year recurrence)

Flora - The plant life of an area

Fluvial - Of or relating to rivers and streams

FOIA - Freedom of Information Act

Food Chain - A series of spatially associated species, each of which lives as a predator, parasite or absorber of the next lower species down in the series

FOR - FORPLAN or FORPLAN Alternative

Forage - All browse and herbaceous foods that are available to grazing animals It may be grazed or harvested for feeding

Forb - A broadleaf plant that has little or no woody material in it

Foreground - The part of a scene or landscape that is nearest to the viewer

Forest - An ecosystem characterized by a more or less dense and extensive tree cover Usually supporting or capable of supporting forests at a density of 10 percent crown closure or more

Forest and Rangeland Renewable Resources Planning Act (RPA) (1974) - Public Law 93-378 (16 U S C 1600-1614) This act requires the development of long term strategies for the management and inventory of the renewable forest and range resources of National Forest System lands

Forest Health - A measure of the robustness of forest ecosystems Aspects of forest health include biological diversity, soil, air, and water productivity, natural disturbances, and the capacity of the forest to provide a sustained flow of goods and services for people

Forest Land - See "Timber Classification "

Forest Plan - Source of management direction for an individual National Forest unit Specifies allowable activities, minimum requirements, expected outputs and land use allocations for a 10 to 15-year period

Forest Roads and Trails - A legal term for Forest roads or trails that are under the jurisdiction of the Forest Service

Forest Structure - Often divided into four conceptual aspects age, species composition, horizontal or mosaic pattern, and vertical

Forest Supervisor - The official responsible for administering National Forest System lands on an

administrative unit, usually one or more National Forests The Forest Supervisor reports to the Regional Forester

Forest Trees - Woody plants having a well-developed stem and usually more than 12 feet in height at maturity

Forest Type - A descriptive concept used to differentiate groups of stands of similar character of development and species composition from other groups of stands

FORPLAN - A linear programming-based forest planning model This model allows the user to find the combination of activities and outputs that will maximize or minimize the desired objective, subject to constraints (Schuster and others, 1993)

Fragile - Those land or water areas containing ecosystems, possibly but not necessarily rare, that are sensitive to external stimuli which may disturb their balance, especially in an irreversible direction

Fragmentation - The splitting or isolating of patches of similar habitat, typically forest cover, but including other types of habitat Habitat can be fragmented naturally or from forest management activities, such as clearcut logging

Freedom of Information Act (FOIA) (1966) - Public Law 93-502 (5 U S C 552) The act provides public access to records of the agencies and departments of the Executive Branch of the U S government

Frequency - A quantitative expression of the presence or absence of individuals of a species in a population

FRES - Forest Range Environmental Study (See Process Paper K)

Frissell Condition Classes - A classification system which rates the degree of person-caused change that a wilderness, dispersed campsite or concentrated-use area has undergone There are five classes as follows

Frissell Condition Class 1 - Visible Indicators Ground vegetation flattened, but not permanently injured Minimal physical change except for possibly a simple rock fireplace

Frissell Condition Class 2 - Visible Indicators Ground vegetation worn away around fireplace or center of activity

Frissell Condition Class 3 - Visible Indicators Ground vegetation lost on most of the site, but humus and litter still present in all but a few areas

Frissell Condition Class 4 - Visible Indicators Bare mineral soil widespread Tree roots exposed on the surface

Frissell Condition Class 5 - Visible Indicators Soil erosion obvious Trees reduced in vigor or dead

FSRAMIS - Forest Service Range Management Information System

Fuel Loading - The dry weight of fuels in a given area, usually expressed in tons per acre Fuel loading may be referenced to fuel size and may include total biomass

Fuel Management - The treatment of fuels that would otherwise interfere with effective fire management or control For instance, prescribed fire can reduce the amount of fuels that accumulate on the forest floor before the fuels become so heavy that a natural wildfire in the area would be explosive and impossible to control

Fuel Model - Simulated fuel complex for which all fuel descriptors required for the solution of a mathematical rate of spread model have been specified

Fuel Moisture Content - The quantity of moisture in fuel expressed as a percentage of the weight when thoroughly dried at 212 degrees F

Fuels - Plants and woody vegetation, both living and dead, that are capable of burning

Fuelwood - Wood that is round, split, or sawn and/or otherwise generally refuse material cut into short lengths or chipped for burning

Function - All the processes within an ecosystem through which the elements interact, such as succession, the food chain, fire, weather, and the hydrologic cycle

Functional Planning - Planning which focuses on a single aspect or resource of a total complex

Grazing Season - The season of use specified on the grazing permit for a specific allotment

-G-

Game Species - Any species of wildlife or fish that is harvested according to prescribed limits and seasons

Grazing System - A specialization of grazing management which defines systematically recurring periods of grazing and deferment for two or more pastures or management units. Includes deferred, intermittent, deferred-rotation, and short-duration grazing systems

Geographic Information System (GIS) - A set of procedures and computer hardware and software for organizing, storing, retrieving, analyzing, and displaying data that includes a geographic position component

Greater Yellowstone Area - A term for the 117-million-acre area made up of parts of six National Forests and two National Parks in northwest Wyoming, eastern Idaho, and southwest Montana

Ghost Road - See Nonsystem Road

GIS - Geographic Information Systems

Greenline - The first perennial vegetation from the waters edge. Riparian areas that are in late seral status with stable stream banks will exhibit a continuous line of vegetation at the bankfull discharge level. Rocky stream types may have a significant amount of rock causing breaks in the vegetation. This rock is considered part of the green line. Other breaks may occur in the first perennial band of vegetation (watercourses or bare ground). The amounts of these (perennial vegetation, rock, and bare ground) should be recorded

Goal - A concise statement that describes a desired condition to be achieved sometime in the future. It is normally expressed in broad, general terms and may not have a specific date for accomplishment

Goods and Services - The various outputs, including on-site users, produced from forest and rangeland resources

Grizzly Bear Security Cover - Forested areas (all tree species) which have not been managed or burned in the last 20 years, and forested areas managed or burned within the last 20 years which meet the following criteria

Grassland - Plant communities whose potential natural and dominant vegetation is comprised of grasses and grasslike plants

The overstory and understory categories are to be considered separately. A stand having either 130 sq ft of basal area per acre or 250 understory trees per acre over 7 ft tall would meet the requirements for full security cover. Both live and dead tree basal areas were used for overstory calculations

Grasslike Plant - A plant of the Cyperaceae or Juncaceae families which vegetatively resembles a true grass of the Gramineae family

Grazing - Consumption of forage by animals

Grazing Formula - The specific order of grazing or sequence within a grazing system

Ground Cover - Material covering the land surface. It may include live vegetation, standing dead vegetation, litter, cobble, gravel, stones and bedrock. Ground cover plus bare ground would total 100 percent of the area evaluated

Grazing Period - The period of time livestock use a specific pasture or unit within a grazing allotment, as identified in the yearly Annual Operating Plan or Allotment Management Plan. The end of the grazing period will not coincide with the end of the grazing season, unless that pasture or unit is grazed last. There is usually more than one grazing unit or pasture in an allotment. The grazing period for a pasture or unit usually changes from year to year as a result of rotation grazing systems

Ground Fire - A fire that burns along the forest floor and does not burn in the crowns of mature trees

Ground Water - The supply of fresh water under the earth's surface in an aquifer or in the soil

Group Selection - A method of tree harvest in which trees are removed periodically in small groups. This silvicultural treatment results in small openings that form mosaics of age class groups in the forest.

Group Selection Regeneration Method - A method of regenerating uneven-aged stands in which trees are cut, and new age classes are established, in small groups.

Growing Stock Trees - Live trees, meeting specified standards of quality or vigor, included in growth and yield projections to arrive at the allowable sale quantity.

Guideline - In Forest Plans, guidelines represent a preferred or advisable course of action that is generally expected to be carried out. Deviation from compliance with a guideline does not require a Forest Plan amendment, but the rationale for such a deviation shall be documented in the project decision document.

Guilds - A group of organisms that share a common food resource.

-H-

Habitat - The area where a plant or animal lives and grows under natural conditions.

Habitat Capability - The ability of a land area or plant community to support a given species of wildlife.

Habitat Diversity - The number of different types of habitat within a given area.

Habitat Type - An aggregation of all land areas capable of supporting similar plant communities at climax (Pflister and other, 1977).

Hard Snag - See Snag-hard.

Harvest Activity - In timber management, a reference to a specific type of cut applied under a regeneration or intermediate treatment method. Refer to FSH 2409 14, Chapter 78 for valid values.

Harvest Cutting - The felling of the final crop of trees either in a single cutting or in a series of regeneration cuttings. Generally, the removal of fi-

nancially or physically mature trees, in contrast to cuttings that remove immature trees. Also referred to as main felling and major harvest.

Harvesting - A loose term for the removal of natural resource for human use or consumption.

Hawksworth Classes - A six-class dwarf mistletoe rating system useful to (1) quantify the degree of infection so that stand management priorities can be established, (2) aid quantification and estimation of growth loss and mortality, (3) help define which trees are suitable for seed trees, and (4) help quantify the mistletoe-infection hazard of overstory trees or stands to understory stands.

For this system the live crown is divided into thirds, and each third is rated as 0, no mistletoe, 1, light mistletoe (less than half of the branches infected), and 2, heavy mistletoe (more than half of the branches infected). The ratings of each third are added to obtain a total for the tree. For example, a tree heavily infected in the lower third of the crown, lightly infected in the middle third, and not infected in the upper third, would be a Class 3. A tree heavily infected in each third would be a Class 6. The system is simple to use, and different observers tend to rate an infected tree similarly.

Healthy Ecosystem - An ecosystem in which structure and functions allow the maintenance of the desired condition of biological diversity, biotic integrity, and ecological processes over time.

Herb - Any flowering plant except those developing persistent woody stems above ground.

Herbivore - Any animal (mammal, bird, insect, etc.) that consumes living plants or their parts.

HGL - Hydric Greenline.

Hiding Cover - Vegetation or other surface characteristics (rocks, downed logs, etc.) that will hide 90% of an animal from the view of a human at some distance that varies by species. For deer and elk that distance is 200 feet.

Hierarchical - A type of classification technique whose successively lower level units must fit entirely within the separate units delineated by the next higher level in that system.

Hierarchical Approach - An analysis approach

accounting for differences in space and time (USDA Forest Service 1994)

Historic Nest Site - See Nest Site

Historical Variation - See Variability, Range of

Home Range - The area in which an animal conducts its activities during a defined period of time

Horizontal Diversity - The distribution and abundance of plant and animal communities or different stages of plant succession across an area of land. The greater the numbers of communities in a given area, the higher the degree of horizontal diversity

Human Dimension - An integral component of ecosystem management that recognizes people are part of ecosystems, that people's pursuits of past, present, and future desires, needs, and values (including perceptions, beliefs, attitudes, and behaviors) have and will continue to influence ecosystems, and that ecosystem management must include consideration of the physical, emotional, mental, spiritual, social, cultural, and economic well-being of people and communities

Human Impact or Influence - A disturbance or change in ecosystem composition, structure, or function caused by humans

Hydric Greenline - A belt of perennial riparian vegetation found closest to the water's edge. It is the area where recovery of riparian and aquatic ecosystems is first expressed and, therefore, can be monitored to test the impacts of livestock grazing. It is also the area which approximates the geographic elevation of the active floodplain, a feature otherwise difficult to locate

Hydric Soil - A soil that is saturated, flooded, or ponded long enough during the growing season to develop anaerobic conditions that favor the growth and regeneration of hydrophytic vegetation

Hydrologic Cycle - Also called the water cycle, this is the process of water evaporating, condensing, falling to the ground as precipitation, and returning to the ocean as runoff

Hydrologically Disturbed Condition - Changes in natural canopy cover (vegetation removal) or a change in surface soil characteristics (such as compaction) that may alter natural streamflow quanti-

ties and character. Acres of vegetation within a watershed that are in a non-stocked, seedling, sapling, or first entry category, acres in roads, acres from other types of mechanical treatments (e.g., roto-beat acres within the sagebrush ecosystem), and burned acres are included in the calculation of hydrologically disturbed area

Hydrologically Recovered Condition - Vegetative life form where natural canopy coverage is achieved and subsequent streamflow quantities and character (timing and amount) reflect more natural conditions. Within the forested ecosystem this equates roughly with the sapling/early pole life form. This life form is achieved at approximately 20 to 30 years of age, depending upon cover type and inherent site productivity potentials

Hydrology - The science dealing with the study of water on the surface of the land, in the soil and underlying rocks and in the atmosphere

-I-

Idaho and Wyoming Species of Concern - Plant or animal species which are officially listed by state agencies due to concerns for habitats and/or populations

Igneous Rock - Rocks formed when high temperature, molten mineral matter cooled and solidified

Implementation Schedules - The schedules of projects and specific actions to implement a Land and Resource Management Plan. Implementation schedules are normally revised annually. They include site-specific actions, responsibilities and target dates

Improvement Cutting - The elimination or suppression of less valuable trees in favor of more valuable trees, typically in a mixed, uneven-aged forest

Increaser - Plant species of the original vegetation that increase in relative amount, at least for a time, under overuse

Index - A number derived from a formula to characterize a complex set of information

Indicator - An organism or an ecologic community that is so strictly associated with particular environmental conditions, that its presence (or ab-

sence) is a fairly certain sign or symptom of the existence of these conditions

Indicator Species - A plant or animal species adapted to a particular kind of environment. Its presence is sufficient indication that specific habitat conditions are also present

Indigenous Species - Any species of flora or fauna that naturally occurs in an area and that was not introduced by man

Indirect Effect - Those effects occurring at a later time or distance from the triggering action

Individual (Single) Tree Selection - The removal of individual trees from certain size and age classes over an entire stand area. Regeneration is mainly natural, and an uneven-aged stand is maintained

Individual Tree Selection Cutting - An uneven-aged cutting method in which selected trees from specified size or age classes are removed over the entire stand area to meet a predetermined goal of size or age distribution and species composition in the remaining stand

Infrastructure - The foundation (transportation, communications, utilities, schools, etc.) underlying an area's economy

Input - Broadly referring to anything that is taken in by or enters into the workings of a system

Insect Pests - Any of a variety of insects that can impact forest health by damaging or killing trees. Insect population levels may also affect other forest resources and activities like wildlife habitat, visual quality and fire management. Some of the important insects in the Intermountain Region include Douglas-fir beetle (*Dendroctonus pseudotsugae*), Douglas-fir tussock moth (*Orgyia pseudotsugata*), Fir engraver (*Scolytus ventralis*), Mountain pine beetle (*Dendroctonus ponderosae*), Spruce beetle (*Dendroctonus rufipennis*), Western balsam bark beetle (*Dryocoetes confusus*) and Western spruce budworm (*Choristoneura occidentalis*)

Instream Flows - The minimum water volume (cubic feet per second) in each stream necessary to meet seasonal streamflow requirements for maintaining aquatic ecosystems, visual quality, recreational opportunities, and other uses

Integrated Pest Management (IPM) - A process for selecting strategies to regulate forest pests in which all aspects of a pest-host system are considered, including the impact of the unregulated pest population to resources, alternative regulation strategies, and benefit/cost estimates of these alternative strategies

Integrated Resource Management - A management strategy which emphasizes no resource element to the exclusion or violation of the minimum legal standards of others

Interdisciplinary Team (IDT) - A team of individuals with skills from different disciplines that focuses on the same task or project

Intermediate Cut - The removal of trees from a stand sometime between the beginning or formation of the stand and the regeneration cut. Types of intermediate cuts include thinning, release, and improvement cuttings

Intermittent Stream - A stream that flows only at certain times of the year when it receives water, usually from a surface source such as melting snow. These streams have a defined bed and banks

Intermountain Region - The fourth of nine geographical regions of the United States designated by the Forest Service for administrative purposes. Headquartered in Ogden, Utah, the Intermountain Region oversees administration of National Forests in Utah, Nevada, Southern Idaho and Southwestern Wyoming

Invader - Plant species that were absent in the original vegetation and will invade under disturbance or continued overuse

Inventoried Roadless Area - (West of the 100th meridian) An area which meets the statutory definition of wilderness, does not contain improved roads maintained for travel by standard passenger-type vehicles, and meets one or more of the following criteria

- Contains 5,000 acres or more
- Contains less than 5,000 acres, but

- Due to physiography or vegetation, is manageable in a natural condition
- Is a self-contained ecosystem such as an island

- Is contiguous to existing wilderness, primitive area, Administration-endorsed wilderness, or roadless area in other Federal ownership, regardless of size

Inventoried Roadless Area - (East of the 100th meridian) An area which contains no more than a half mile of improved road for each 1,000 acres, in which the road is under Forest Service jurisdiction and

- The land is regaining a natural, untrammelled appearance
- Improvements existing in the area are being affected by the forces of nature rather than humans and are disappearing or muted
- The area has existing or attainable National Forest System ownership patterns, both surface and subsurface, that could ensure perpetuation of identified wilderness values
- The location of the area is conducive to the perpetuation of wilderness values, considering the relationship of the area to sources of noise, air and water pollution and other unsightly conditions that would have an effect on the wilderness experience

Inventory - The gathering of data for future use Also, a collection of such data

Inversion - A condition in which air temperatures increase rather than decrease with increasing elevation in the atmosphere A rising air mass in the atmosphere is inhibited by this stratification, allowing for pollutants to be trapped near the surface

Irretrievable - Applies to losses of production, harvest or commitment of renewable natural resources For example, some or all of the timber production from an area is irretrievably lost during the time an area is used as a winter sports site If the use is changed, timber production can be resumed The production lost is irretrievable, but the action is not irreversible

Irreversible - Applies primarily to the loss or commitment of nonrenewable resources, such as minerals or cultural resources, or to those that are renewable only over long time spans, such as soil productivity Irreversible also includes loss of future options

Issue - A point, matter or question of public discussion or interest to be addressed or decided through the planning process

Preliminary issue is an issue identified early in the scoping phase and is sometimes referred to as a tentative issue

Significant issue is an issue within the scope of the proposed action which is used to formulate alternatives in an Environmental Analysis (EA) or Environmental Impact Statement (EIS)

-K-

Key Area - A relatively small portion of rangeland which because of its location, grazing or browsing value, and/or use, serves as a monitoring and evaluation site (A key area guides the general management of the entire area of which it is a part, and will reflect the overall acceptability of current grazing management over the range)

Key Species - (1) Forage species whose use serves as an indicator to the degree of use of associated species (2) Those species which must, because of their importance, be considered in the management program

Key Summer Range - The portion of a wildlife species' summer range that is essential for the animal's pre, post, and reproduction cycles Deer require "fawning areas" where does give birth and hide their fawns for an essential period of time in the spring

Key Winter Range - That portion of range where big game animals find food and cover during severe winter weather

Kind of Livestock - Species of animal

-L-

LAC - Limits of Acceptable Change

Ladder Fuels - Vegetation located below the crown level of forest trees which can carry fire from the forest floor to tree crowns Ladder fuels may be low-growing tree branches, shrubs, or smaller trees

Land - A term denoting the entire complex of surface and near-surface attributes of the solid portion of the surface of the earth which are significant to mankind

Land Class - The topographic relief of a unit of land Land classes are separated by slope This

coincides with the timber inventory process. The three land classes used in the Forest Plan are defined by the following slope ranges: 0 to 40%, 41-60%, and greater than 60%.

Landform - Any physical, recognizable form or feature of the earth's surface having a characteristic shape and produced by natural causes.

Landscape - A large land area composed of interacting ecosystems that are repeated due to factors such as geology, soils, climate, and human impacts. Landscapes are often used for coarse grain analysis.

Landscape Ecology - The body of knowledge pertaining to the ecological effects of spatial patterns in ecosystems.

Landtype - A group of defined and named taxonomic soil units occurring together in an individual and characteristic pattern over a geographic region.

Land Unit - One of the hierarchy levels used for project planning, encompassing one to tens of acres.

Land Use Allocation - In land management planning, the committing of a given area of land or resources to one or more specific uses such as to campgrounds, wilderness, etc.

Large Woody Debris - Organic materials such as plant stems and branches with a diameter greater than 3 inches. Included are both natural materials and management induced post-harvest slash. Large trees, or parts of them, that accumulate in streams or other water bodies. This material is important for aquatic habitat and stream channel stability, and in maintenance of on-site productivity.

Late-Successional Forests - Forest seral stages that include mature and old-growth age classes.

Leasable Mineral - Leasable minerals are hard-rock and liquid minerals that are subject to exploration and development under leases, permits, and licenses under the Mineral Leasing Act of 1920 and several other subsequent Acts. Oil, gas, coal and phosphates have been the most sought-after leasable minerals on the Forest, along with the geothermal resource. The Forest Service decides which lands are available for leasing and under what

conditions these lands are leased. The BLM decides whether or not to offer for lease the lands authorized by the Forest Service.

Legal Notice - A notice of a decision which can be appealed that is published in the Federal Register or in the legal notice section of a newspaper of general circulation.

Lentic - Relating to, or living in, still waters (as lakes, ponds and swamps).

Limiting Factor - Any environmental factor whose presence, absence or abundance is the main factor restricting the distribution numbers or condition of an organism.

Limits of Acceptable Change (LAC) - A planning framework that establishes explicit measures of the acceptable and appropriate resource and social conditions in wilderness settings as well as the appropriate management strategies for maintaining or achieving those desired conditions.

Line Officer - The official (District Ranger, Forest Supervisor, Regional Forester, etc.) having authority for a specific district, forest, region, etc.

Litter (forest litter) - The freshly fallen or only slightly decomposed plant material on the forest floor. This layer includes foliage, bark fragments, twigs, flowers and fruit.

Locatable Mineral - In general, locatable minerals are hardrock minerals which are mined and processed for the recovery of metals, or mineral which are "valuable" in the economic sense. Examples which occur on the Forest include gold, silver, lead, copper and opal. Citizens rights to exploration and access are granted under the General Mining Law of 1872. By agreement with the BLM the Forest Service administers locatable mining activities on Forest lands.

Logging Residues - The residue left on the ground after timber cutting. It includes unused logs, uprooted stumps, broken branches, bark, and leaves. Certain amounts of "slash" provide important ecosystem roles, such as soil protection, nutrient cycling, and wildlife habitat.

Long-term Sustained Yield Capacity (LTSYC) - The highest uniform wood yield from lands being managed for timber production that may be sus-

tained, under a specified management intensity, consistent with multiple-use objectives

LTSL - Less-Than-Standard Service Level

LTSYC - Long-term Sustained Yield Capacity

-M-

M - Thousand Five thousand board feet of timber can be expressed as 5M board feet

MAI - Mean Annual Increment

Maintenance Class - In facilities management a method of classifying existing facility needs for budget purposes and others

Maintenance Class 1, Satisfactory Facility is safe and sanitary Annual maintenance will not exceed 10 percent of replacement cost

Maintenance Class 2, Substandard Facility is safe and sanitary, although substandard as to type, construction standard, or not in keeping with planned experience-level for the site Annual maintenance will not exceed 10 percent of current replacement cost of standard type facility May be scheduled for eventual elimination or replacement but will serve intended purpose for next 3-5 years

Maintenance Class 3, Heavy Maintenance Facility unsafe or otherwise unsatisfactory May be put back in good condition at a cost not to exceed 50 percent of current replacement of like kind facility

Maintenance Class 4, Replacement Facility unsafe or otherwise unsatisfactory To put back in good condition would cost more than 50 percent of the replacement cost Replace with like kind and standard of facility Cost includes both removal of old facility and replacement

Manage - To treat with care, handle or direct with skill

Management Action - Any activity undertaken as part of the administration of the National Forest

Management Area - Units of land small enough for Districts and the public to characterize and develop issues for, but large enough to provide for

management flexibility A desired future condition developed for the management area describes and will assist in achieving the shared land expectations

Management Concern - An issue, problem or a condition which constrains the range of management practices identified by the Forest Service in the planning process

Management Direction - A statement of multiple-use and other goals and objectives, the associated management prescriptions, and standards and guidelines for attaining them

Management Ignition - A fire started by a scheduled, deliberate management action

Management Indicator Species - A wildlife species whose population and trend in a certain habitat type indicates the population and trend of other species that are dependent upon the same habitat

Management Intensity - A management practice or combination of management practices and associated costs designed to obtain different levels of goods and services

Management Practice - A specific activity, measure, course of action or treatment

Management Prescription - Management practices and intensity selected and scheduled for application on a specific area to attain multiple-use and other goals and objectives

Management Situation 1 - Population and habitat conditions The area contains grizzly population centers (areas key to the survival of grizzly where seasonal or yearlong grizzly activity, under natural, free-ranging conditions is common) and habitat components needed for the survival and recovery of the species or a segment of its population The probability is very great that major Federal activities or programs may affect (have direct or indirect relationships to the conservation and recovery of) the grizzly (IGBC, 1986)

Management Situation 2 - Population and habitat conditions Current information indicates that the area lacks distinct population centers, highly suitable habitat does not generally occur, although some grizzly habitat components exist and grizzlies may be present occasionally Habitat re-

sources in Management Situation 2 either are unnecessary for survival and recovery of the species, or the need has not yet been determined but habitat resources may be necessary. Certain management actions are necessary. The status of such areas is subject to review and change according to demonstrated grizzly population and habitat needs. Major Federal activities may affect the conservation of the grizzly bear primarily in that they may contribute toward (a) human-caused bear mortalities or (b) long-term displacement where the zone of influence could affect habitat use in Management Situation 1 (IGBC, 1986)

Management Situation 3 - Population and habitat conditions. Grizzly presence is possible but infrequent. Developments, such as campgrounds, resorts, or other high human use associated facilities, and human presence result in conditions which make grizzly presence untenable for humans and/or grizzlies. There is a high probability that major Federal activities or programs may affect the species' conservation and recovery (IGBC, 1986)

Market-Value Outputs - Goods and services valued in terms of what people are willing to pay for them rather than go without, as evidenced by market transactions

Mass Movement/Wasting - The downslope movement of large masses of earth material by the force of gravity. Also called a landslide or earthflow

Mature Forest - Trees that have attained full development, especially height, and are in full seed production

Mature Timber - Generally used in an economic sense to indicate that a forest has attained harvest age

Maximum Modification - See "Visual Quality Objectives"

MBF - Thousand board feet (See board feet)

Mean Annual Increment - The average yearly growth of trees in a stand over a period of years, usually expressed in annual cubic feet of growth per acre

Mean Annual Increment of Growth - The total increase in size or volume of individual trees. Or, it can refer to the increase in size and volume of a

stand of trees at a particular age, divided by that age in years

Mean Fire Interval - Arithmetic average of all fire intervals determined in years, in a designated area during a specified time period. The size of the area and the time period must be specified

Microclimate - The climate of a small site. It may differ from the climate of the larger area due to aspect, tree cover (or the absence of tree cover), or exposure to winds

Microhabitat - A restricted set of distinctive environmental conditions for a small habitat, such as the area under a log

Microsite - A localized area in which environmental conditions differ in a significant or important way from those of the region outside the area

Middleground - A term used in the management of visual resources, or scenery. It refers to the visible terrain beyond the foreground where individual trees are still visible but do not stand out distinctly from the stand

Mineral Soil - Soil that consists mainly of inorganic material, such as weathered rock, rather than organic matter. Any soil composed chiefly of mineral matter (sand, silt, clay, rocks, etc.)

Minimum Impact Suppression Tactics (MIST) - In wildland firefighting, a concept employing the minimum amount of forces needed to effectively achieve fire management protection objectives consistent with land and resource management objectives. Derives from a sensitivity to the impacts of suppression tactics and their long-term effects in areas such as wilderness with special values. Can feature a range of suppression and support actions to minimize impacts to these values, and special rehabilitation measures

Minimum Streamflow - A specified minimum level of flow through a channel that must be maintained by the users of the stream for biological, physical, or other purposes

MIS - Management Indicator Species

MIST - Minimum Impact Suppression Tactics

Mitigate/mitigation - To lessen the severity. Actions taken to avoid, minimize or rectify the impact of a land management practice

Mixed Stand - A stand of trees in which less than 80 percent of the trees in the main crown canopy are of a single species

MM - Million

MMBF - Million board feet (See board feet)

Modification - A visual quality objective, management activities may visually dominate the original characteristic landscape, but they must borrow from naturally established form, line, color or texture so that the activity blends with the surrounding area

Monitoring - The determination of how well project or plan objectives have been met and how closely management practices should be adjusted (See adaptive management)

Mortality - The volume in trees that were merchantable and have died within a specified period of time. The term mortality can also refer to the rate of death of a species in a given population or community

Mountain Pine Beetle - A tiny black beetle, *Dendroctonus ponderosae*, ranging from 1/8 to 1/4-inch in size, that bores through a pine tree's bark to feed in the phloem layer in the inner bark. Such feeding by large numbers of beetles girdles and kills the tree. The beetle also carries the blue stain fungus that clogs the trees water transport system

Multiple-Use - The management of all the various renewable surface resources of National Forest System lands for a variety of purposes such as recreation, range, timber, wildlife and fish habitat, and watershed

Municipal Supply Watershed - A watershed that serves a public water system as defined in Public Law 93-523 (Safe Drinking Water Act), or as defined in State safe drinking water regulations. The definition does not include communities served by a well or confined ground water unaffected by Forest Service activities

National Environmental Policy Act (NEPA) (1970) - Public Law 91-190 (42 U S C 4321-4347, parts) The basic national charter for the protection of the environment. It establishes policy, sets goals and provides means for carrying out the policy. The NEPA process helps public officials make decisions that are based on understanding of environmental consequences, and take actions that protect, restore, and enhance the environment

National Forest Management Act (NFMA) (1976) - Public Law 94-588 (16 U S C 1600-1614 and others) This act amended the Forest and Rangeland Renewable Resources Planning Act of 1974, and lays out the process for developing, adopting and revising land and resource management plans for National Forest System lands

National Forest System (NFS) Lands - Federal lands that have been designated by Executive Order or statute as National Forests, National Grasslands, Purchase Units, and other lands under the administration of the Forest Service, including Experimental Areas and Bankhead-Jones Title III lands

Native - Species indigenous to an area of consideration

Native Organisms - Animals or plants which originated in the area in which they are found, i.e., were not introduced and naturally occur in the area

Native Species - Any species of flora or fauna that naturally occurs in the United States and that was not introduced by humans

Native Trout Watersheds - Those primary watersheds identified as containing contiguous well connected subwatersheds with high aquatic integrity and population strongholds of native cutthroat trout or have the capability to achieve this condition through recovery efforts. They have been determined to be necessary for species recovery. Of the 39 primary watersheds on the Forest, 17 have been designated: Elk Creek (003), Palisades Creek (004), Rainey Creek (005), Pine Creek (006), Heise (007), Henry's Fork Headwaters (008), Robinson Creek (013), Trail Creek (017), Mahogany Creek (022), Moody Creek (024), Bitch Creek (032), Burns-Pat Canyon (035), McCoy-Jensen Creeks (036), Elk-Bear Creeks (037), Fall Creek (038), Pritchard Creek (039), and Brockman Creek (040)

Additional fish population and habitat inventory and analysis will be conducted in the future and will provide the basis for determining the capability of these Native Trout Watersheds in meeting recovery goals. Based on this information, specific subwatersheds will be designated for maintenance or recovery efforts and others may be designated as not vital to recovery goals. Additional Native Trout Watersheds may be designated, or existing Native Trout Watersheds may be deleted.

Natural - Existing in, or formed by, nature, not artificial.

Natural Barrier - A natural feature, such as a dense stand of trees or downfall, that will restrict animal travel.

Natural Catastrophic Condition - A significant change in forest conditions in the planning area that affects Forest Plan resource management objectives and their projected and scheduled outputs, uses, costs, and impacts on local communities and environmental quality.

Natural Ignition - A fire started at random by natural causes.

Natural Range of Variability - See Variability, Range of.

Natural Regeneration - Renewal of a tree crop by self-sown seed or from sprouts.

Natural Resource - A feature of the natural environment that is of value in serving human needs.

Naturalized Species - Introduced or alien (not native) species that are now permanently established and reproducing spontaneously (without human fostering).

Nest Site - The location of nest structures used by birds for incubating and hatching eggs.

a) Active Nest Site - The location of nest structures which have been used within a current year or one year previous.

b) Historic Nest Site - The location of nest structures which are known to have been used, but not within 2 years. Historic nest sites must be documented in Forest or District databases to be subject to standards and guidelines.

Nest Survey - A way to estimate the size of a bird population by counting the number of nests in a given area.

Net Public Benefits - An expression used to signify the overall long-term value to the Nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs) whether they can be quantitatively valued or not. Net public benefits are measured by both quantitative and qualitative criteria rather than a single measure or index. The maximization of net public benefits to be derived from management of units of the National Forest System is consistent with the principle of multiple-use and sustained-yield.

NFRS - National Forest recreation sites that have been inventoried.

No Action Alternative - The most likely condition expected to exist in the future if management practices continue unchanged.

Nonchargeable Volume - All volume not included in the growth and yield projections for the selected management prescriptions used to arrive at the allowable sale quantity.

Noncommercial Vegetation Treatment - The removal of trees for reasons other than timber production.

Nonconsumptive Use - The use of a resource that does not reduce its supply, for example, nonconsumptive uses of water include hydroelectric power generation, boating, swimming and fishing.

Noncontinuous Grazing System - Rotational and repeated seasonal grazing systems.

Nondeclining Flow - See base sale schedule.

Nondegradation - A policy of not allowing resources to deteriorate any further than what exists at a chosen point in time. The objective is to either maintain the status quo, or to improve resource conditions.

Nonforest Land - See "Timber Classification."

Nongame - Species of animals not managed for sport hunting.

Noninterchangeable Component (NIC) - A portion of the allowable sale quantity (ASQ) which cannot be substituted for from other areas or species types. Volume programmed from a NIC will not be replaced by volume from other NICs. The volume in the NICs are mutually exclusive.

Nonmarket-Valued Outputs - Goods and services not generally traded in the marketplace, but valued in terms of what reasonable people would be willing to pay for them rather than to do without them. Those obtaining the actual outputs do not necessarily pay what they would be willing to pay for them.

Nonnative Species - A species introduced into an ecosystem through human activities.

Nonpoint Source Pollution - Pollution whose source is not specific in location. The sources of discharge are dispersed, not well-defined, or constant. Examples include sediments from logging activities, and runoff from agricultural chemicals.

Nonrenewable Resource - A resource whose total quantity does not increase measurably over time, so that each use of the resource diminishes the supply.

Notice of Intent - A notice printed in the Federal Register announcing that an Environmental Impact Statement (EIS) will be prepared.

Noxious Plant - A plant recognized by law as being especially undesirable, troublesome, and difficult to control.

Noxious Weed - See Noxious plant.

NTU - Nephelometric Turbidity Units.

Nutrient Cycle - The circulation of chemical elements and compounds, such as carbon and nitrogen, in specific pathways from the nonliving parts of ecosystems into the organic substances of the living parts of ecosystems, and then back again to the nonliving parts of the ecosystem. For example, nitrogen in wood is returned to the soil as the dead tree decays, the nitrogen again becomes available to living organisms in the soil, and upon their death, the nitrogen is available to plants growing in that soil.

Nutrient Cycling - The assimilation of an element by organisms and its release in a reusable inorganic form.

Objective - A clear and quantifiable statement of planned results to be achieved within a stated time period. Something aimed at or striven for within a predetermined time period. An objective must be achievable, be measurable, have a stated time period for completion, be quantifiable, be clear, and its results must be described.

Off-Highway Vehicle (OHV) - Any of a class of vehicles, regardless of width, weight or number of wheels, designed for or capable of travel over unimproved terrain. Snowmobiles, all terrain vehicles, high clearance four-wheel-drive pickups, and trail bikes and motorcycles are all off-highway vehicles.

OHV - Off-Highway Vehicle.

Old Growth - Terrestrial ecosystems characterized by vegetation of, and associated animals requiring, the most mature seral stages. Old growth forests contain trees normally beyond the age of optimum maturity for economic harvest. The precise definition of old growth varies with the tree species comprising the stand.

Opportunities - Ways to address or resolve public issues or management concerns in the land and resource management planning process.

Opportunity Class - In the Limits of Acceptable Change wilderness planning method, opportunity classes represent the desired conditions management would attempt to achieve and maintain over the planning period.

Optimum - A level of production that is consistent with other resource requirements as constrained by environmental, social, and economically sound conditions.

Organism - A plant or animal.

OROMTRD (Open Road and Open Motorized Trail Route Density) - See definition under Roads.

Output - One of the ways functions are described, resources which leave a system, such as, animals migrating out of an area, mass erosion, removal of commercial timber from an area, etc.

Overmature Timber - Trees that have obtained full development, particularly in height, and are declining in vigor, health, and soundness.

Overstory - The upper canopy or canopies of plants Usually refers to trees, tall shrubs, and vines

Overstory Removal - The final harvest cut of the shelterwood method in which overstory trees are removed releasing the established regeneration

-P-

Packing - A temporary influx of organisms of various sex and age classes into remaining suitable habitat as previously available habitat is changed to unsuitable conditions

PAOT - Persons-At-One-Time

Parasites - Organisms that absorb nutrients from the body fluids of living hosts Parasites may be fungal, bacterial, plant or animal, (examples include the braconid wasp that parasitizes the fir engraver beetle, or dwarf mistletoe)

Parent Material - The unconsolidated and more or less chemically weathered, mineral or organic matter from which soils developed by soil-forming processes

Partial Retention - A visual quality objective which, in general, means human activities may be evident, but must remain subordinate to the characteristic landscape

Particulates - Small particles suspended in the air and generally considered pollutants

Partnership - A cooperative, working relationship between the Forest Service and individuals, corporations, organizations or public agencies to pool financial and human resources to complete projects on National Forest System lands

Patch - A small (20-60 acres) part of the forest An area of vegetation that is internally homogeneous, differing from what surrounds it (matrix)

Patch Cut - A clearcut that creates small openings in a stand of trees, usually between 1 and 20 acres in size

Payment in Lieu of Taxes (PILT) - Payments to local or State governments based on ownership of Federal land and not directly dependent on production of outputs or receipt sharing Specifically, includes payments made under the payments in

Lieu of Taxes Act of 1976 by U S Department of the Interior

Payments to Local Government - The portion of receipts derived from Forest Service resource management that is distributed to State and county governments such as the Forest Service 25 percent fund payments

Percent Use - The percentage of current year's forage production that is consumed or destroyed by grazing animals May refer to a single species or to the vegetation as a whole

Percolation - Downward flow or infiltration of water through the pores or spaces of rock or soil

Perennial Streams - Streams that flow continuously throughout most years These streams have defined bed and banks

Permitted Grazing - Grazing on a National Forest range allotment under the terms of a grazing permit

Personal Use - Normally used to describe the type of permit issued for removal of wood products (firewood, posts, poles, and Christmas trees) from National Forest System land when the product is for home use and not to be resold for profit

Persons-At-One-Time (PAOT) - A recreation capacity measurement term indicating the number of people who can use a facility or area at one time

Planning - The act of deciding in advance, what to do A dynamic problem solving effort used to guide future actions and decisions

Planning Area - The area covered by a Regional Guide or Forest Plan

Planning Period - One decade The time interval within the planning horizon that is used to show incremental changes in yields, costs, effects, and benefits

Planning Regulations - The regulations at 36 CFR 219 implementing NFMA which guide land and resource management planning on the National Forests

Plant Association - A potential natural plant community of definite floristic composition and uniform appearance See Association

Plantation - Clearcut harvested area that has regenerated with natural and/or planted seedlings

Plant Community - An aggregation of plants that are similar in species composition and structure, and occupy similar habitats over the landscape
See Community

Plant Vigor - Plant health

PM-10 - Smoke and debris particles with an aerodynamic diameter smaller than or equal to a nominal ten micrometers

PNV - Present Net Value or Potential Natural Vegetation

Pole Timber - Trees of at least 3.0 inches DBH, but smaller than 8.0 inches DBH, (except lodgepole pine and aspen which includes trees less than 7.0 inches DBH)

Policy - A guiding principle which is based on a specific decision or set of decisions

Pollution - The presence of matter or energy whose nature, location or quantity produces undesired environmental effects

Porosity - Pertaining to landscapes, the density of a particular type of patch within a matrix. Porous landscapes have many small patches of similar type contained within the matrix

Potential Natural Community (PNC) - (nonforested vegetation) - The biotic community that would become established on an ecological type if all successional sequences were completed without interference by man under the present environmental conditions. Natural disturbances, such as drought, floods, wildfire, grazing by native fauna, insects, and disease, are inherent in its development. The Potential Natural Community (PNC) may include acclimatized or naturalized nonnative species

The similarity between the present plant community and the PNC is the seral stage, and can be expressed as a percentage. PNC is the ecological status of vegetation that ranges from 86% - 100% of the Potential Natural Community

Potential Vegetation - Vegetation that would develop if all successional sequences were completed under present site conditions

Practicable - When funding is obtained or a project is initiated

Practice (Also Management Practice) - A specific activity, measure, course of action, or treatment

Precommercial Thinning - Removal of trees from a young stand to promote increased growth on the remaining stems and maintain a specific stocking or stand density range, controlling species composition and stand quality through selection of trees that are to remain in the stand

Predator - An animal (rarely a plant) that kills and eats animals. Sometimes used in the sense of an insect consuming a seed

Preparatory Cut - The removal of trees near the end of a rotation, which opens the canopy and enables the crowns of residual trees to enlarge, to improve conditions for seed production and natural regeneration. Typically done in the shelterwood system

Prescribed Fire - Controlled application of fire to wildland fuels in either their natural or modified state, under specified environmental conditions which allow fire to be confined to a predetermined area and at the same time to produce the intensity of heat and rate of spread required to attain planned resource management objectives

Prescribed Fire or Burn - A wildland fire ignited by humans under pre-planned, specified conditions, to accomplish specific, planned resource management objectives. This practice is common in California and is also known as "controlled burning"

Prescribed Natural Fire - A wildland fire ignited by natural sources such as lightning or volcanism. These fires are allowed to burn in designated areas under carefully established conditions to provide for safety and fire control. If these conditions are exceeded, or predicted to worsen, a fire is reclassified as a wildfire and suppressed

Prescription - A set of management practices selected to accomplish specific land and resource management objectives

Present Net Value - The difference between the discounted value (benefits) of all outputs to which monetary values or established market prices are

assigned and the total discounted costs of managing the planning area

Preservation - See "Visual Quality Objectives "

Presuppression - Activities organized in advance of fire occurrence to assure effective suppression action

Prey - Animals eaten by predators

Primary Succession - The concept in which there is a sequence of vegetation development initiated on newly formed soils or upon surfaces exposed for the first time (as by landslides) which have never previously supported vegetation

Primitive ROS (Recreation Opportunity Spectrum) - A classification of wilderness and recreation opportunity It is characterized by an essentially unmodified environment, where trails may be present but structures are rare, and, where it is highly probable to be isolated from the sights and sounds of people (See ROS)

Principal Watersheds - The National Forest System watersheds used for purposes of project and Forest planning

Probability of Ignition - A rating of the probability that a firebrand (glowing or flaming) will cause a fire, provided it lands on receptive fuels It is calculated from air temperature, fuel shading, and fuel moisture

Production - The generation or "manufacturing" of resources within a system (such as, plant growth, animal reproduction, snags falling and becoming down woody material)

Productive - The ability of an area to provide goods and services and to sustain ecological values

Productivity - The amount of material (wood, forage, meat, etc) yielded by an ecosystem, or its inherent potential to yield such material

Program - When capitalized, the Renewable Resource Program required by the RPA Generally, sets of activities or projects with specific objectives, defined in terms of specific results and responsibility for accomplishment

Project - A single activity or an integrated group of activities designed to accomplish a specific on-the-

ground purpose or result

Properly Functioning Condition - Ecosystems at any temporal or spatial scale that are dynamic and resilient to disturbance to structure, composition, and processes of their biological and physical components

Proposal - A proposal exists at the stage in the development of an action when an agency is actively preparing to make a decision on one or more alternative means of accomplishing a goal and the effects can be meaningfully evaluated

Proposed Action - A proposal by the Forest Service to authorize, recommend or implement an action

Province - The third-highest level in the National Hierarchical Framework of Ecological Units developed by ECOMAP See also Chapter III, Part 2

Public Issue - A subject or question of widespread public interest relating to management of the National Forest System or one of its units

Public Land - Land for which title and control rests with a government - federal, state, regional, county or municipal

Public Participation - Generally, collaboration by the public at large in Forest Service planning and decision making Can be facilitated by meetings, conferences, seminars, workshops or tours, and can take the form of written or oral comments or responses or other such contributions

Purpose and Need - The underlying reason(s) to which the agency is responding in generating a proposed action

-R-

Range (of a species) - The area or region over which an organism occurs

Range - Land on which the principal natural plant cover is native grasses, forbs, and shrubs available as forage for big game and livestock

Range Allotment - An area designated for the use of a prescribed number and kind of livestock under one management plan

Range Analysis - Systematic acquisition and evaluation of rangeland resources data for allotment management and overall land management planning

Range Inspection - A field inspection of rangeland to determine if the forest plan standards and guides, the allotment management plan goals and objectives, and the grazing permit requirements are being met and followed

Range of Natural Variability - See Variability, Range of

Rangeland - All land producing or capable of producing native vegetation, and lands that have been revegetated naturally or artificially. Includes all grasslands, shrublands, and those forest lands which will continually or periodically, naturally or through management, support an understory of herbaceous or shrubby vegetation

Rangeland Condition - The state of vegetation, soil cover, and soils in relation to a standard or ideal for a particular ecological type. (See satisfactory rangeland and unsatisfactory rangeland condition)

Range Management - The art and science of planning and directing range use intended to yield the sustained maximum animal production and perpetuation of the natural resources

Range of Variability (Natural Variability, Historical Variability) - See Variability, Range of

Ranger District - The administrative subunit of a National Forest that is supervised by a District Ranger who reports directly to the Forest Supervisor

Raptor - A bird of prey, primarily meat eating birds with strong hooked bills and sharp talons. Includes but is not limited to members of the Strigidae (Owls), Cathartidae (New World Vultures), Accipitridae (Hawks and Eagles), Falconidae (Falcons), and Laniidae (Shrikes)

RARE II - Roadless Area Review and Evaluation. The national inventory of roadless and undeveloped areas within the National Forests and Grasslands

Reach - A continuous unbroken stretch of a stream, with homogeneous characteristics

Real Dollar Value - A monetary value that compensates for the effects of inflation

Recharge - The addition of water to ground water by natural or artificial processes

Record of Decision - An official document in which a deciding official states the alternative that will be implemented from a prepared EIS

Recovery - The achievement of viable populations of threatened or endangered plant or animal species

Recreation Capacity - The number of people that can take advantage of any supply of recreation opportunity at any one time without substantially diminishing the quality of the experience sought after

Recreation Opportunity Class or Spectrum (ROS) - A system categorizing land areas by settings and probable or desired recreation experiences. Six categories have been defined as follows

Primitive (P or Class I) Very high probability of experiencing solitude, freedom, closeness to nature, tranquility, self-reliance, challenge and risk. Unmodified natural or natural appearing environment. Very low interaction between users. Minimal evidence of other users. Restrictions and controls not evident after entry. Access and travel is nonmotorized on trails or cross country. No vegetation alterations. Access for people with disabilities can be most difficult and very challenging. No site modifications for facilities. Interpretation through self-discovery. No on-site facilities. No facilities for user comfort. Rustic and rudimentary ones for site protection only. Use undimensioned native materials. (USDA Forest Service 1994)

Semi-Primitive Nonmotorized (SPNM or Class II) High probability of experiencing solitude, closeness to nature, tranquility, self-reliance, challenge and risk. Natural appearing environment. Low interaction between users. Some evidence of other users. Minimum of subtle on-site controls. Access and travel is nonmotorized on trails, some primitive roads or cross country. Vegetation alterations sanitation salvage to very small units in size and number, widely dispersed and not evident. Access for

people with disabilities is difficult and challenging. Rustic and rudimentary facilities primarily for site protection. No evidence of synthetic materials. Use undimensioned native materials. Interpretation through self-discovery. Some use of maps, brochures, and guidebooks. No on-site facilities.

Semi-primitive Motorized (SPM or Class III)

Moderate probability of experiencing solitude, closeness to nature, tranquility. High degree of self-reliance, challenge and risk in using motorized equipment. Predominantly natural appearing environment. Low concentration of users but often evidence of others on trails. Minimum on-site controls and restrictions present but subtle. Vegetation alterations very small in size and number, widely dispersed and visually subordinate. Access for people with disabilities is difficult and challenging. Rustic and rudimentary facilities primarily for site protection. No evidence of synthetic materials. Use undimensioned native materials. Interpretation through very limited on-site facilities. Use of maps, brochures and guidebooks.

Roaded Natural (RN or Class IV) Opportunity to affiliate with other users in developed sites but with some chance of privacy. Self-reliance on outdoor skill of only moderate importance. Little challenge and risk. Mostly natural appearing environment as viewed from sensitive roads and trails. Interaction between users at camp sites is of moderate importance. Some obvious on-site controls of users. Access and travel is conventional motorized including sedan, trailers, RV's and some motor homes. Vegetation alterations done to maintain desired visual and recreational characteristics. Access for people with disabilities is of only moderate challenge. Rustic facilities providing some comfort for the user as well as site protection. Use native materials but with more refinement in design. Synthetic materials should not be evident. Moderate site modification for facilities. Interpretation through simple wayside exhibits. Use native-like materials with some refinement in design. Some casual interpretation by forest staff.

Rural (R or Class V) Opportunity to observe and affiliate with other users is important as is convenience of facilities. Self-reliance on

outdoor skills of little importance. Little challenge and risk except for activities such as downhill skiing. Natural environment is culturally modified yet attractive. Backdrop may range from alterations not obvious to dominant. Interactions between users may be high as is evidence of other users. Obvious and prevalent on-site controls. Access and travel facilities are for individual intensified motorized use. Access for people with disabilities is easy and meets ADAAG standards. Some facilities designed primarily for user comfort and convenience. Some synthetic but harmonious materials may be incorporated. Design may be more complex and refined. Moderate to heavy site modification. Interpretation through more complex wayside exhibits including small lighted structures. Interpretive facilities such as kiosks and portals may be staffed part-time.

Urban (U or Class VI) Opportunity to observe and affiliate with other users is very important as is convenience of facilities and recreation opportunities. Outdoor skills, risk, and challenge are unimportant except for competitive sports. Urbanized environment with dominant structures, traffic lights and paved streets. May have natural appearing backdrop. Recreation places may be city parks and large resorts. Interaction between large numbers of users is high. Intensive on-site controls are numerous. Access and travel facilities are highly intense, motorized and often with mass transit supplements. Vegetation is planted and maintained. Access for people with disabilities is easy and meets ADAAG standards. Facilities mostly designed for user comfort and convenience. Synthetic materials are commonly used. Facility design may be highly complex and refined but in harmony or complimentary to the site. Heavy site modifications for facilities. Interpretation through very sophisticated exhibits in staffed visitor centers, wayside exhibits, etc.

Recreation Visitor Day (RVD) - Twelve visitor hours, which may be aggregated continuously, intermittently, or simultaneously by one or more persons.

Recruitment - The addition to a population from all causes, including reproduction, immigration and stocking.

Reforestation - The natural or artificial restocking of an area with forest trees

Regeneration - The renewal of a tree crop, whether by natural or artificial means. Also, the young crop itself, which commonly is referred to as reproduction

Regeneration Method - A harvest method by which a new age class is created. The major methods are clearcutting, seed-tree, shelterwood, selection, and coppice regeneration methods and their variants

Regional Forester - The official of the USDA Forest Service responsible for administering an entire region of the Forest Service

Regulations - A set of directions drafted to implement a law or laws. Generally refers to the Code of Federal Regulations, Title 36, Chapter II, which covers management of the Forest Service

Rehabilitation - A short-term management activity used to return visual impacts in the natural setting to a desired visual quality

Release - Freeing trees from competition for light, water, and nutrients by removing or reducing the vegetation growth that is overtopping or closely surrounding them

Release Cutting - Removal of competing vegetation to allow desired tree species to grow

Release Treatment - A treatment designed to free young trees from undesirable, usually overtopping, competing vegetation. Treatments include liberation, cleaning, and weeding

Removal Cut - The removal of the last seed bearers or shelter trees after regeneration is established

Renewable Resource - Resources whose total physical quantity is replenished over time and thus can sustain some rate of consumption

Repeated Seasonal Grazing - A situation in which a pasture is grazed at the same time each year

Research Natural Area (RNA) - Lands that are protected for the purpose of maintaining biological diversity, conducting nonmanipulative research and monitoring, and promoting education

Reserve Trees - Trees deliberately retained in a stand for a specific resource use

Resident Fish - Fish that are not migratory and complete their entire life cycle in fresh water

Resource - A broad term denoting anything that is useful for something

Resource Value - The value of an ecosystem for a particular use or benefit on an ecological type. This value may be expressed as the value amount or as a relative rating, when compared to the maximum value for an ecological type

Responsible Official - The Forest Service employee who has been delegated the authority to carry out a specific planned action

Restoration - Actions taken to modify an ecosystem in whole or in part to achieve a desired condition

Restoration Ecology - The study of recreating entire communities of organisms closely modeled after communities that occur naturally

Retention - A visual quality objective whose guidelines stipulate that management activities are not visually evident, and activities repeat form, line, color, and texture characteristics found in the landscape

Revalidation - Pertaining to prescribed natural fire, the daily certification by the approving line officer that the fire is within prescription and will remain in prescription through the ensuing 24-hour period, given reasonably foreseeable weather conditions and fire behavior

Revegetation - The reestablishment and development of a plant cover by either natural or artificial means, such as reseeding

Right-of-Way - An accurately located strip of land with defined width, point of beginning, and point of ending. Within this area the user has authority to conduct operations approved or granted by the landowner in an authorizing document, such as a permit, easement, lease, license, or Memorandum of Understanding (MOU)

Riparian - Of, on, or relating to the bank of a natural course of water

Riparian Area - Areas adjacent to water and composed of vegetation communities dependent on water near the ground surface. Associated with lakes, reservoirs, potholes, springs, bogs, wet meadows, and ephemeral, intermittent, or perennial streams.

Risk - Refers to situations in which the outcome is not certain, but the chance of system degradation beyond the point of resiliency and sustainability can be estimated.

RNA - Research Natural Area

Road - A created or evolved travel route greater than 500 feet long (minimum inventory standard for the Forest Service Route Management System), which is reasonably and prudently drivable with a conventional passenger car or pickup (vehicles greater than 50 inches wide and having a dry weight of 600 pounds or more).

System Road/Managed Road A road which is part of the official Forest Transportation Management System, these roads usually have a number and a name and are usually on the Forest travel plan maps.

Nonsystem Road (Unmanaged Road or Ghost Road) A road which is not part of the official Forest Transportation Management System, these roads usually do not have a number or a name and they are not on the Forest travel plan maps.

Open Road/Motorized Road Any road without restriction on motorized vehicle use.

Restricted Road Any road on which motorized vehicle use is restricted seasonally or yearlong by physical obstruction (generally gated), and on which motorized vehicle use is legally restricted. Motorized administrative use by personnel of resource management agencies is acceptable at low intensity levels as defined in existing cumulative effects analysis models. This includes contractors and permittees in addition to agency employees.

Reclaimed/Obliterated Road Any road which has been treated in such a manner so as to no longer function as a road or trail. This can be accomplished through one or a combination of several means including recontouring to original slope, placement of logging, road, or forest

debris, planting of shrubs or trees, etc.

TMARD (Total Motorized Access Route Density) Includes all open and restricted roads and open and restricted motorized trails. Density may be displayed as follows: 1) Density (miles/square mile) for an analysis area (such as a watershed or a management prescription area); 2) Density as a percentage of the analysis area in a defined density category (example: 20% > 2.0 miles per square mile).

Calculating TMARD for Grizzly Bear Management Units. Follow the procedures outlined in the Interagency Grizzly Bear Committee Taskforce Report - Grizzly Bear/Motorized Access Management, Final, approved by the IGBC, July 21, 1994.

OROMTRD (Open Road and Open Motorized Trail Route Density): Includes all open roads and open motorized trails. Density may be displayed as follows: 1) Density (miles/square mile) for an analysis area (such as a watershed or a management prescription area); 2) Density as a percentage of the analysis area in a defined density category (example: 20% > 2.0 miles per square mile).

A. Calculating OROMTRD for elk habitat effectiveness (the spring/summer/fall period, but not including the general big game rifle seasons).

1. OROMTRD will be calculated on the basis of principal watersheds. The area in square miles of each principal watershed will be calculated, and the miles of open roads and open trails within that principal watershed will also be calculated to determine the OROMTRD (expressed as miles/square mile). The acreage and road and trail mileage included in the calculation will include all acres (NF and private) within the principal watershed.

a. Open roads include (a) all system (managed) roads which are open for motorized use on the Forest Plan Travel Maps, plus (b) all system (managed) and nonsystem (unmanaged) roads which have more than 1 to 2 motorized vehicle trips per week for the majority of the weeks.

during the spring/summer/fall period, even if they are designated closed on the Forest Plan Travel Maps, plus (c) all highways and county roads and private roads which are open for motorized use

b Open motorized trails include (a) all system (managed) trails which are open for motorized use on the Forest Plan Travel Maps, plus (b) all system (managed) and nonsystem (unmanaged) trails which have more than 1 or 2 motorized vehicle trips per week for the majority of the weeks during the spring/summer/fall period, even if they are designated closed on the Forest Plan Travel Maps

c Open roads and open motorized trails which are on the boundary of principal watersheds will be calculated as having one-half the total mileage of that road or trail in each of the watersheds it separates. Open roads and open motorized trails which form the Forest boundary will likewise have one-half of that boundary mileage counted as occurring within the Forest

B Calculating OROMTRD for elk vulnerability (the general big game rifle seasons)

1 OROMTRD will be calculated on the basis of principal watersheds. The area in square miles of each principal watershed will be calculated. The miles of open roads and open motorized trails within the principal watershed will also be calculated. In addition, "infinitely open areas" will be determined and included in the calculation using a factor of 6 miles of open road per square mile of infinitely open area. Open road and open motorized trail density will be expressed as miles/square mile. The acreage and road and trail mileage included in the calculation will include all acres (NF and private) within a principal watershed

a Open roads include (a) all system (managed) roads which are open for

motorized use on the Forest Plan Travel Maps during the general big game rifle seasons, plus (b) all system (managed) and nonsystem (unmanaged) roads which have motorized vehicle use during the general big game rifle seasons, even if they are designated closed on the Forest Plan Travel Maps, plus (c) all highways and county roads and private roads which are open for motorized use during the general big game rifle seasons

b Open motorized trails includes (a) all system (managed) trails which are open for motorized use on the Forest Plan Travel Maps during the general big game rifle seasons, plus (b) all system (managed) and nonsystem (unmanaged) trails which have motorized vehicle use during the general big game rifle seasons, even if they are designated closed on the Forest Plan Travel Maps

c Infinitely open areas include areas which have terrain and vegetation which allow OHV use and they are not closed to OHV use on the Forest Plan Travel Maps during the general big game hunting seasons. Calculate the total square miles for these areas, and use a factor of 6 miles of open road for each square mile of area

d Open roads and open motorized trails which are on the boundary of principal watersheds will be calculated as having one-half the total mileage of that road or trail in each of the watersheds it separates. Open roads and open motorized trails which form the Forest boundary will likewise have one-half of that boundary mileage counted as occurring within the Forest

C Calculating OROMTRD for Management Prescription Areas. Follow the same procedure as for elk habitat effectiveness, except the boundaries will be contiguous management prescription areas (and in some cases adjacent management

prescription areas as directed in the management prescriptions)

D Calculating OROMTRD for Grizzly Bear Management Units Follow the procedures outlined in the Interagency Grizzly Bear Committee Taskforce Report - Grizzly Bear/ Motorized Access Management, Final, approved by the IGBC, July 21, 1994

Roadless Areas - Areas of National Forest land which qualify for placement on the inventory of potential wilderness if, in addition to meeting the statutory definition of wilderness, they meet one or more of the following criteria

- 1 They contain 5,000 acres or more
- 2 They contain less than 5,000 acres but
 - a Due to physiography of vegetation, they are manageable in their natural condition
 - b They are self-contained ecosystems such as an island
 - c They are contiguous to existing wilderness, primitive areas, Administration- endorsed wilderness, or roadless areas in other Federal ownership, regardless of their size
- 3 They do not contain improved roads maintained for travel by standard passenger-type vehicles, except as permitted in areas east of the 100th meridian

ROD - Record of Decision

ROS - Recreation Opportunity Spectrum

Rosgen Channel Types - A classification system developed by Dave Rosgen which places stream reaches into categories based on physical characteristics This system is useful in comparing the existing classification (condition) of a stream to its natural potential

Rotation - The number of years required to establish (including the regeneration period) and grow timber crops to a specific condition or maturity for regeneration harvest Selected management prescriptions in the forest plan provide the basis for the rotation age

Rotational Grazing System - A livestock grazing system under which animals are moved from pasture to pasture on a scheduled basis

RPA - The Forest and Rangeland Renewable Resources Planning Act of 1974 Also refers to the National Assessment and Recommended Program developed to fulfill the requirements of this Act

RPA Assessment - An analysis of present and anticipated uses, demand for, and supply of renewable resources The Assessment is prepared every 10 years in response to the Forest and Rangeland Renewable Resources Planning Act

Runoff - The portion of precipitation that flows over the land surface or in open channels

RVD - Recreation Visitor Day

RVR - Resource Value Rating

-S-

S&G Allotment - A sheep and goat allotment

Salable Mineral - See Common Variety Mineral

Sale Schedule - The quantity of timber planned for sale by time period from the area of suitable land covered by a forest plan The first period, usually a decade, of the selected sale schedule provides the allowable sale quantity Future periods are shown to establish that long-term sustained yield will be achieved and maintained

Salvage Cutting - See Salvage Harvest

Salvage Harvest - Harvest of trees that are dead, dying, or deteriorating because they are overmature or have been materially damaged by fire, wind, insects, fungi, or other injurious agents before the wood becomes unmerchantable

Sanitation Cutting - See Sanitation Harvest

Sanitation Harvest - The harvest of dead, damaged or susceptible trees done primarily to prevent the spread of pests or disease and to promote forest health

Sapling - A young tree larger than a seedling but smaller than a pole Size is within the range of 1 0 to 2 9 inches DBH

Satisfactory Condition - (nonforested vegetation) - Vegetation that is meeting Desired Vegetation Conditions (DVC)

Sawtimber - Trees of a given diameter at breast height or larger that can be made into lumber For lodgepole, this minimum diameter is 7 0 inches, for Douglas-fir, it is 8 0 inches

Scoping - The ongoing process to determine public opinion, receive comments and suggestions, and determine issues during the environmental analysis process It may involve public meetings, telephone conversations or letters

SDI - Stand Density Index

Second Growth - Forest growth that was established after some kind of interference with the previous forest crop, such as cutting, fire, or insect attack

Security Cover - See Grizzly Bear Security Cover

Sediment - Solid material, both mineral and organic, transported from its site of origin by air, water, gravity or ice

Sedimentation - The action or process of forming or depositing excessive amounts of sediment

Seed Cut - Timber harvest designed to prepare the seed bed and create a new age class in an even-aged or two-aged stand under the Seed-Tree or Shelterwood Regeneration Method Reserve trees may or may not be retained

Seedling - A young tree less than 1 0 inches DBH

Seed Tree Cutting - An even-aged cutting method in which most of the mature timber from an area is removed in one cut except for a small number of desirable trees retained to provide seed or shelter for regeneration

Seed Tree Harvest - Removal of the mature timber crop from an area in one cut, except for a small number of seed bearers

Seed Tree Regeneration Method - A method of regenerating a stand in which a new age class develops from seeds that germinate in a fully-exposed microenvironment after removal of the previous stand, except for a small number of trees left to

provide seed This method creates an even-aged stand

Selection - See "Group Selection" and "Individual (Single) Tree Selection"

Selection Cutting - The annual or periodic removal of trees (particularly mature trees), individually or in small groups, from an uneven-aged forest, to realize the yield and to maintain age stratification

Selection System - An uneven-aged silvicultural system in which trees are removed individually or in groups, from a large area on a set temporal cycle

Sensitive Species - Those species that are recognized by the U S Forest Service as needing special management considerations

Sensitivity Level - A particular degree of measure of viewer interest in scenic qualities of the landscape Three sensitivity levels are employed, each identifying a different level of user concern for the visual environment

Level 1 - Highest Sensitivity

Level 2 - Average Sensitivity

Level 3 - Lowest Sensitivity

Seral - A plant or animal community that is transitional If left alone, the seral stage will give way to another plant or animal community that represents a further stage of succession

Seral Stage - Any of a series of relatively transitional planned communities that develop during ecological succession from bare ground to the climax stage. There are five stages

Early seral stage - (forested vegetation) - The period from disturbance to crown closure of conifer stands managed under the current forest management regime Grass, herbs, or brush are plentiful

(nonforested vegetation) - The developmental stage of an existing plant community in progression toward a Potential Natural Community (PNC) Early seral stage is the ecological status of vegetation that ranges from 0-39% of the Potential Natural Community

Mid seral stage - (forested vegetation) - The period in the life of a forest stand from crown closure to first merchantability usually ages 15-

40 Due to stand density, brush, grass, or herbs rapidly decrease in the stand. Hiding cover may be present

(nonforested vegetation) - The developmental stage of an existing plant community in progression toward a Potential Natural Community (PNC). Mid seral stage is the ecological status of vegetation that ranges from 40% - 59% of the Potential Natural Community

Late seral stage - (forested vegetation) - The period in the life of a forest stand from first merchantability to culmination of mean annual increment. This is under a regime including commercial thinning, or to 100 years of age, depending on wildlife habitat needs. During this period, stand diversity is minimal, except that conifer mortality rates will be fairly rapid. Hiding and thermal cover may be present. Forage is minimal

(nonforested vegetation) - The developmental stage of an existing plant community in progression toward a Potential Natural Community (PNC). Late seral stage is the ecological status of vegetation that ranges from 60% - 85% of the Potential Natural Community

Mature seral stage - The period in the life of a forest stand from culmination of mean annual increment to an old-growth stage or to 200 years. This is a time of gradually increasing stand diversity. Hiding cover, thermal cover, and some forage may be present

Old-growth seral stage - This stage constitutes the potential plant community capable of existing on a site given the frequency of natural disturbance events. For forest communities this stage exists from approximately age 200 until when stand replacement occurs and secondary succession begins again. Depending on fire frequency and intensity, old growth forests may have different structures, species composition, and age distributions. In forests with longer periods between natural disturbance, the forest structure will be more even-aged at late mature or early old-growth stages

Sere - See Seral Stage

Series - An aggregation of taxonomically related plant associations which take the name of (climatic) climax species that dominate, or have the potential to dominate, the principal vegetative layer in a

time frame appropriate to the vegetative or taxonomic group under consideration

Severely Burned - Soil organic matter and nutrient loss as a result of having been burned over. Severely burned is detrimental if it adversely affects site productivity or hydrologic function

Shade-Tolerant Plants - Plants that grow well in shade

Shelterwood Regeneration Method - A method of regenerating a stand in which a new age class develops beneath the partially-shaded microenvironment provided by the residual trees. The method creates an even-aged stand

Shelterwood Removal Cut - A type of cut that releases established regeneration from competition with seed trees while retaining some trees needed for shelter under the Shelterwood Regeneration Method. Reserve trees may or may not be retained

Shrub - A plant that has persistent, woody stems and a relatively low growth habit, and that generally produces several basal shoots instead of a single bole. It differs from a tree by its low stature and nonarborescent form

Sight Distance - The distance at which 90 percent or more of a deer or elk is hidden from an observer. Hiding cover exists when 90 percent or more of a standing deer or elk is hidden at a distance of 200 feet or less

Significance - As used in NEPA, requires consideration of both context and intensity. (See regulations at 40 CFR 1508.27)

Silvicultural System - The planned process whereby a stand is tended, harvested, and re-established. The system name is based on the number of age classes, and/or the regeneration method used

Silviculture - The art and science that promotes the growth of single trees and the forest as a biological unit to meet management objectives

Single-Tree Selection - See "Individual (Single) Tree Selection"

Site - A small area or parcel of land considered in terms of its environment

Site Development Scale - See Development Scale

Site Preparation - The general term for removing unwanted vegetation, slash, roots, and stones from a site before reforestation. Naturally occurring wild-fire, as well as prescribed fire can prepare a site for natural regeneration

Site Productivity - Production capability of specific areas of land

Size Class - One of the intervals of tree stem diameters used to classify timber in the Forest Plan data base. See Seedling, Sapling, Pole Timber, and Sawtimber

Skidding - Hauling logs by sliding, not on wheels, from stump to a collection point

Skid Trail - Narrow path on which logging equipment travels when moving logs from the forest to a designated landing location

SL - Standard Service Level

Slash - The residue left on the ground after timber cutting and/or as a result of storm, fire, or other damage. Includes unused logs, uprooted stumps, broken or uprooted stems, branches, twigs, leaves, bark and chips

Slope Distance - The physical measured distance on the slope (not horizontal distance)

Small Game - Birds and small mammals typically hunted or trapped

Snag - A standing dead tree greater than 20 feet tall from which the leaves and most of the limbs have fallen (USDA Forest Service 1979). Or, for wildlife habitat, a standing dead or partly dead tree at least 6 inches dbh and at least 5 feet tall (this definition is based on minimum dbh and height of trees used by primary cavity nesting species)

Snag-hard - Composed of sound wood, especially on the outside

Snag-soft - In advanced stages of decay and deterioration both inside and outside

Snowmachine - Any motorized vehicle which is used for over snow travel

Soil - The unconsolidated mineral material on the immediate surface of the earth that serves as a natural medium for the growth of land plants

Soil and Water Conservation Practices (SWCPs) - See Best Management Practice

Soil Cover - Ground cover consisting of vegetation, litter, and rock fragments larger than three-fourths inch in diameter in contact with the soil. Also, perennial canopy cover that is within 3 to 30 feet of the ground

Soil Disturbance - The effect upon soil of having been displaced, compacted, puddled, or severely burned. Any of these disturbances which adversely affect hydrologic function or site productivity are termed detrimental

Detrimental Displacement - The loss of either two inches or one-half of the humus-enriched top soil (A-horizon), or both, from an area of one square meter or larger

Detrimental Compaction/Puddling: Decreases in soil porosity by 10 percent or more from undisturbed values, or doubling of the soil strength, in any two-inch increment in the top foot of soil

Soil Hydrologic Function - The inherent capacity of a soil to take up, retain and transmit water

Soil Organic Matter - The organic fraction of soil. Includes plant, animal and microbial residues, fresh and at all stages of decomposition, and the relatively resistant soil humus

Soil Productivity - The capacity of a soil to produce a specific crop. Productivity depends on adequate moisture and soil nutrients, as well as favorable climate

Soil Puddling - Puddling is generally evaluated at the mineral soil surface. Infiltration and permeability are affected by detrimental soil puddling. Visual indicators of detrimental puddling include clearly identifiable ruts with berms or hoof prints in mineral soil, or in an Oa horizon of an organic soil

Soil Quality - Long term soil productivity and soil hydrologic function

Soil Survey - The systematic examination of soils in the field and laboratory, including description,

classification, interpretation of productivity and mapping

Soil Wood - Woody debris, larger than 3 inches in diameter, that is incorporated into the soil surface layers

Spatial Scale - The level of resolution in space perceived or considered

Special Forest Products - Nontimber renewable plant products (such as mushrooms, berries, flowers, etc)

Special Use Permit - A permit issued to an individual or group by the USDA Forest Service for use of National Forest System land for a special purpose. Examples of permitted activities could include a Boy Scout Jamboree or a mountain bike race

Species - A fundamental category of plant or animal classification

Species Composition - The proportions of various plant or animal species in relation to the total on a given area. Plant species may be expressed in terms of cover, density, weight, and so on

Stand - A community of trees or other vegetation sufficiently uniform in composition, constitution, age, spatial arrangement or condition to be distinguishable from adjacent communities and so form a silvicultural or management entity

Stand Exam - The activity of looking at a stand in the field to obtain measure of stand conditions, physical site factors, and other environmental data to help determine future management of the stand

Stand Replacement Fire - Fire which kills all or most living overstory trees in a forest and initiates regrowth at an earlier seral stage

Standard - A measurable constraint on management activities or practices often expressed as a maximum or minimum. Deviation from compliance with a standard requires a Forest Plan amendment

Standard Service Level (SL) - Management level designed to enhance the recreation experience, ensure public safety, correct resource damage, and maximize the longevity and serviceability of recreation facilities

Standards and Guidelines - Requirements found in a Forest Plan which impose limits on natural resource management activities, generally for environmental protection. See Chapter III

State Air Quality Regulations - The legal base for control of air pollution sources in a State. Prescribed burning is generally covered under these regulations

State Implementation Plan - A State plan that covers implementation, maintenance, and enforcement of primary and secondary standards in each air quality control Region, pursuant to section 110 of the Clean Air Act

Stocked Stand - A stand is certified as stocked when there are 140-300 established trees per acre, depending on species, over 70% of the stand five years after a regeneration cut. See FWSG for timber

Stocking - A measure of the proportion of the area in a stand actually occupied by trees, expressed in terms of stocked quadrats or percent of canopy closure (as distinct from stand density)

Stocking Level - (Timber management) The number of trees in an area as compared to the number of trees desired. (Livestock grazing) The area of land allotted to each animal unit for the entire grazing period. Usually expressed as a ratio

Storage - A description of resources which are conserved within a system such as, sediments and water retained in wetlands, or carbon and other nutrient storage in down woody material

Stream Reach - A segment of stream with similar characteristics

Structure - How the parts of ecosystems are arranged, both horizontally and vertically. Vegetation patches, edge, canopy layers, snags, down wood, steep canyons, rocks in streams, and roads may be arranged in some pattern or mosaic, or the structure may be totally random

Subregion - One of the hierarchy levels used for RPA assessments and statewide planning encompassing hundreds to thousands of square miles

Subsection - An ecological unit of land that has uniform climatic and geologic characteristics

Seven subsections have been delineated within the Targhee National Forest

Subwatershed - A drainage delineated for one of the streams within a National Forest System (NFS) watershed, often to analyze the effects of a proposed action. The subwatershed chosen for analysis may depend on the size and anticipated effects of a proposal

Succession - The natural replacement, in time, of one plant community by another. Conditions of the prior plant community (or successional or seral stage) create conditions that are favorable for the establishment of the next stage

Succession, Plant - The process of vegetation development whereby an area is successively occupied by different plant communities of higher ecological order

Successional Stage - See Seral Stage

Suitability - The appropriateness of applying certain management practices to a particular area of land, as determined by an analysis of the economic and environmental consequences and the opportunity cost of uses foregone

Suitability for Livestock Grazing - The appropriateness of applying livestock grazing practices to a particular area of land (grazing allotment), as determined by an analysis of the economic and environmental consequences and the alternative uses foregone. A unit of land may be suitable for a variety of individual or combined management practices

Suitability for Timber Production - The appropriateness of commercial timber management on a given land area. Timber harvest, other than salvage sales or sales to protect other multiple-use values, cannot occur on lands not suited for timber production

Suitable Forest Land - See Timber Classification

Suitable Habitat - The biological and physical components necessary to meet some or all of the life needs of a species

Suitable Range - Rangeland that is accessible and used by grazing animals, that produces forage or has inherent forage producing capabilities, and that

can be grazed on a sustained yield basis under reasonable management goals

Suppression - The action of extinguishing or confining a fire

Surface Resources - Renewable resources that are on the surface of the earth, such as timber and forage, in contrast to ground water and minerals which are located beneath the surface

Sustainability - The ability of an ecosystem to maintain ecological processes and functions, biological diversity, and productivity over time

Sustainable - For a renewable resource, the capacity to produce continuously at a given intensity of management

Sustainable Development - The use of land and water to sustain production indefinitely without environmental deterioration, ideally without loss of native biodiversity

Sustainable Ecosystem Management - Management directed towards developing or maintaining a synergistic complex of plants and animals which can be perpetuated indefinitely

Sustained-Yield - The yield of a renewable resource which can be produced continuously at a given intensity of management

Swing Allotment - A vacant allotment open to grazing that can be temporarily grazed by an existing forest livestock grazing permittee whose existing authorized allotment is not available in whole or part. Nonforest permittees are not allowed to use swing allotments. Cattle are not allowed to use swing sheep allotments and sheep are not allowed to use swing cattle allotments

Systems at Risk - Ecosystems which demonstrate a potential for loss of resilience or sustainability if disturbed

-T-

Target - A National Forest's annual goal for accomplishment for natural resource programs. Targets represent the commitment of the Forest Service to Congress to accomplish the work Congress has funded, and are often used as a measure of the agency's performance

Temporary Roads - Roads other than specified which are constructed by the purchaser for the purpose of harvesting included timber. A timber sale road is a temporary road when it is the purchaser's road. It is not needed by anyone else for any reason. The purchaser develops it, maintains it, and eliminates its function as a road when it has served its purpose. If the Forest Service access needs are only short-term, such as for post-sale work or fuelwood access, the road will be specified in the timber sale contract. The Forest Service will then be responsible for eliminating its function as a road when it has served its purpose.

Tentatively Suitable Forest Land - See Timber Classification

Thermal Cover - Cover used by animals to moderate the effects of weather and provide protection from heat or cold. Thermal cover requirements vary with species and the prevailing climate.

Thinning - An intermediate cutting made in an immature stand primarily to maintain or accelerate diameter increment, enhance forest health or recover mortality, and also to improve the average form of the remaining trees without permanently breaking the canopy.

Threatened Species - Any species listed in the Federal Register under terms of the Endangered Species Act which is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range.

Timber Base - The lands within the Forest which are capable, available and suited for timber production.

Timber Classification - In forest planning, the disaggregation of forested lands into strata to aid in the development of management alternatives. The strata are based on the ability of the land to produce commercial timber, and are as follows:

Forest Land - Land at least 10 percent occupied by forest trees of any size or formerly having had such tree cover and not currently developed for nonforest use. Lands developed for nonforest use include areas for crops, improved pasture, residential, or administrative areas, improved roads of any width and adjoining road clearing and powerline clearing of any width. The term occupancy when used to define forest

land will be measured by canopy cover of live forest trees at maturity. The minimum area for classification of forest land is 1 acre. Unimproved roads, trails, streams and clearings in forest areas are classified as forest if they are less than 120 feet in width.

Nonforest Land - Lands never having or incapable of having greater than 10 percent of the area occupied by forest trees and lands formerly forested and currently developed for nonforest use.

Suitable (Suited) Forest Land - Tentatively suitable forest lands selected for management for timber production on a regulated basis in a Forest Plan.

Tentatively Suitable (Commercial) Forest Land - Forest Land which is producing or is capable of producing crops of industrial wood and for which (1) a withdrawal has not been entered by Congress, the Secretary of Agriculture or the Chief of the Forest Service (for example, as designated wilderness), (2) technology and knowledge exists to ensure timber production without irreversible damage to soil productivity or watershed condition, (3) technology and knowledge exists, and is reflected in current research and experience, to reasonably assure that the lands can be adequately restocked (regenerated) within five years after final harvest, and (4) adequate information is available to project responses to timber management activities.

Unsuitable (Unsuited) Forest Land - Land not scheduled (designated) for timber management in the Forest Plan. May be tentatively suitable land on which timber management is inconsistent with or not cost-efficient in meeting Forest Plan multiple-use objectives or management requirements, or land not found tentatively suitable for timber production.

Timber Harvest Schedule - See "Sale Schedule"

Timber Production - The purposeful growing, tending, harvesting, and regeneration of regulated crops of trees for cutting into logs, bolts, or other round sections for industrial or consumer use. For purposes of forest planning, timber production does not include fuelwood or harvests from unsuitable lands.

Timber Sale Program Quantity (TSPQ) - The volume of timber planned for sale during the first decade of the planning horizon. It includes the allowable sale quantity (chargeable volume) and any additional material (nonchargeable volume) planned for sale. The timber sale program quantity usually is expressed as an annual average for the first decade.

Timber Stand Improvement (TSI) - Measures such as thinning, pruning, release cutting, prescribed fire, girdling, weeding, or poisoning of unwanted trees aimed at improving growing conditions of the remaining trees.

Timelag - In fire planning an indication of the rate at which dead fuel gains or loses moisture due to changes in its environment. The time necessary for a fuel particle to gain or lose approximately 63 percent of the difference between its initial moisture content and its equilibrium moisture content. Fuels are usually grouped into the following groups:

Classification	Diameter (Inches)
1 hour	0-1/4
10 hour	1/4-1
100 hour	1-3
1,000 hour	3-8

TMARD (Total Motorized Access Route Density) - See definition under Roads.

TMDL - From the Clean Water Act, Total Maximum Daily Load. TMDLs for given pollutants may be assigned to Water Quality Limited streams.

Tractor Logging - A logging method that uses tractors to carry or drag logs from the stump to a collection point.

Trail - Any created or evolved travel (access) route that does not qualify as a road. Used for both motorized and nonmotorized modes of travel. For motorized travel, trails are generally routes for vehicles less than 50 inches wide and which have a dry weight of 600 pounds or less. Trails are not reasonably and prudently drivable with a conventional passenger car or pickup.

System Trail/Managed Trail - A trail which is part of the official Forest Transportation Management System. These trails usually have a number and a name, they are usually on the Forest travel plan maps.

Nonsystem Trail/Unmanaged Trail/Ghost Trail - A trail which is not part of the official Forest Transportation Management System. These trails usually do not have a number or a name, they are not on the Forest travel plan maps.

Open Motorized Trail - A trail without restriction on motorized use and used by motorized vehicles. Trails used by 3-wheelers, 4-wheelers, and motorized trail bikes are examples of this type of access route.

Restricted Motorized Trail - A trail on which motorized use is legally restricted seasonally or yearlong. Motorized administrative use by personnel of resource management agencies is acceptable at low intensity levels as defined in existing cumulative effects analysis models. This includes contractors and permittees in addition to agency employees.

Trail Maintenance - There are five levels of trail maintenance which are defined as follows:

Level I - Trails maintained for primitive experience level. Custodial care only. No tread maintenance. Drainage functional and not likely to fail. Trail sides not brushed but tread is kept passable. Small slides may remain except for those with erosion potential. Structures maintained as needed. Signing may be deferred.

Level II - Trails maintained for near-primitive experience level. Tread maintained for public safety. Logs or similar rustic structures may be provided at stream crossing. Drainage same as Level I. Signing at a minimum level commensurate with level of trail use.

Level III - Trails maintained for intermediate experience level. Tread maintained for public safety and user convenience. Drainage same as Level I. Trail sides brushed out at policy standards. Signing same as Level II.

Level IV - Trails maintained at relatively high standards to provide for public safety and convenience. Tread relatively smooth, firm and may require stabilization. Signing at high level, all other elements same as Level III. These trails are generally maintained for family or senior citizen use.

Level V Trails maintained for high use and experience levels, including special purposes such as VIS trails, bicycle trails, trails to major vista points, trails for persons with disabilities, etc. Basic care same as Level IV but patching of paved tread may be needed annually. Trail sides maintained to meet high visual quality standards by brushing and cleanup of debris beyond the trail limits. Vistas are maintained.

Transportation Analysis - A systematic analysis conducted to determine the transportation facilities and management needed to meet land and resource management objectives.

Transportation System or Network - All existing and proposed roads, trails, airfields, and other transportation facilities wholly or partly within or adjacent to and serving the National Forests and other areas administered by the Forest Service or intermingled private lands.

Treatment Area - The specific site location of a resource improvement activity.

Tree Opening - An opening in the forest cover created by even-aged silvicultural practices.

TSI - Timber Stand Improvement

TTS - Tentative Timber Suitability

-U-

Underburn - A surface fire that can consume ground vegetation and "ladder" fuels.

Understory - The trees and woody shrubs growing beneath the overstory in a stand of trees.

Uneven-aged - The condition of a forest, crop, or stand composed of intermingling trees that differ markedly in age. In practice a minimum age difference of 25 percent of the length of the rotation usually is used.

Uneven-aged Management - Actions that maintain a forest or stand of trees composed of intermingled trees that differ markedly in age. Cutting methods that develop and maintain uneven-aged stands are single-tree selection and group selection.

Uneven-aged Stand - A stand of trees of three or more distinct age classes, either intimately mixed or in small groups.

Uneven-aged System - A planned sequence of treatments designed to maintain and regenerate a stand with three or more age classes (see Individual Tree Selection, and Group Selection Regeneration Methods).

Unregulated Harvest - Timber harvest that is not part of the allowable sale quantity (ASQ). Can include the removal of cull or dead material or non-commercial species. Also includes volume removed from unsuitable areas for research, to meet objectives other than timber production (such as wildlife habitat improvement), or to improve administrative sites such as campgrounds.

Unsatisfactory Condition - (nonforested vegetation) - Vegetation that is not meeting Desired Vegetation Conditions (DVC).

Unsuitable Forest Land (Not Suited) - See Timber Classification.

Unsuitable Range - Rangeland that should not be grazed by livestock because of physical or biological limitations.

Use, allowable - An estimate of proper range use by grazing animals. Also, the amount of forage planned to be used to accelerate range rehabilitation.

Utility and Transportation Corridors - A strip of land, up to approximately 600 feet in width, designated for the transportation of energy, commodities, and communications by railroad, State highway, electrical power transmission (66 KV and above), oil and gas and coal slurry pipelines 10 inches in diameter or larger, and telecommunication cable and electronic sites for interstate use. Routes conducting minor amounts of power for short distances, such as short feeder lines from small power projects including geothermal or wind, or to serve customer subservice substations along the line, are not designated corridors.

-V-

Vacant Allotment - An allotment for which a livestock grazing permit has not been issued. The allotment may or may not be available for grazing.

Variability, Range of (Natural, Historic) - The spectrum of conditions possible in ecosystem composition, structure and function considering both temporal and spatial factors. The natural range of the spatial, structural, compositional and temporal characteristics of ecosystem elements specified to represent "natural" conditions. The flux in composition, structure, and function of an ecosystem over the long term in a landscape.

Vegetation - Collectively, the plants growing in a given area.

Vegetation Management - Activities designed primarily to promote the health of forest vegetation for multiple-use purposes.

Vegetation Type - A plant community with distinguishable characteristics. See Cover Type.

Vegetative Structural Stage - A method of describing the growth stages of a stand of living trees. It is based on tree size (DBH = diameter at breast height) and total canopy cover. The stages are Grass/forb/shrub (VSS 1) = 0-1 inch DBH, Seedling/sapling (VSS 2) = 1-5 inches DBH, Young Forest (VSS 3) = 5-12 inches DBH, Mid-aged Forest (VSS 4) = 12-18 inches DBH, Mature Forest (VSS 5) = 18-24 inches DBH; Old Forest (VSS 6) = 24+ inches DBH.

Viable Population - A number of individuals of a species sufficient to ensure the long-term existence of the species in natural, self-sustaining populations adequately distributed throughout their region.

Viewshed - An expansive landscape or panoramic vista seen from a specific viewpoint, such as a road.

Vigor - The relative robustness of a plant in comparison to other individuals of the same species. It is reflected primarily by the size of the plant and its parts in relation to its age and the environment in which it is growing.

Visual Quality Objectives (VQO's) - In forest planning, a set of measurable goals for the management of visual resources. Used to measure the amount of visual contrast with the natural landscape caused by human activities. The following are VQOs.

Preservation - Ecological change only here.

Retention - Human activities should not be evident to the casual Forest visitor.

Partial Retention - Human activity may be evident but must remain subordinate to the characteristic landscape.

Modification - Human activity may dominate the characteristic landscape but must, at the same time, follow naturally established form, line, color, and texture. The activity should appear as a natural occurrence when viewed in foreground or middleground.

Maximum Modification - Human activity may dominate the characteristic landscape but should appear as a natural occurrence when viewed as background.

Visual Resource - A part of the landscape important for its scenic quality. It may include a composite of terrain, geologic features, or vegetation.

-W-

Watershed - The area of land above a given point on a stream that contributes water to the streamflow at that point. Also the land that contributes water to a lake or reservoir.

Watershed Improvement Needs (WIN) Inventory - A broad reconnaissance inventory oriented primarily to problem identification rather than specific project design. Forms the basis for identifying potential soil and water resource restoration project areas and assigning priority for detailed planning and treatment.

Watershed Information System (WIS) - Inventory of Forest Service water rights and uses. The inventory includes such information as location of water right or use, the amounts of water involved, status of the use or right, purpose, etc.

Water Table - The upper surface of groundwater. Below it, the soil is saturated with water.

Water Yield - The runoff from a watershed, including groundwater outflow.

Weeding - In timber management, a release treatment in stands of sapling stage or younger that

eliminates or suppresses undesirable vegetation regardless of crown position

Wet Areas - These sites, often occurring at the heads of drainages, may be wet sedge meadows, bogs, or seeps. Often referred to as "moist sites," they are very important components of elk summer range

Wetlands - Areas that are inundated by surface or ground water with a frequency sufficient, under normal circumstances, to support a prevalence of vegetative or aquatic life that requires saturated or seasonally saturated soil conditions for growth and reproduction. Wetlands include wet meadows, springs, seeps, bogs, etc

Wild and Scenic Rivers - Rivers and their immediate environs that are managed to be unpolluted and free of impoundments and diversions. Designated by Congress pursuant to the Wild and Scenic Rivers Act

Wilderness - Areas designated by congressional action pursuant to the Wilderness Act that are managed for primeval characteristics, solitude or unconfined primitive recreation, natural conditions and where the imprint of man is substantially unnoticeable

Wilderness Act (1964) - Public Law 88-577 (16 U.S.C. 1131-1136). The Wilderness Act allows preservation of designated areas of federal land under the National Wilderness Preservation System for the benefit of present and future generations. The land must be primarily affected by the forces of nature (not man), have outstanding opportunities for solitude or primitive recreation, be at least 5000 acres in size, and may also contain ecological, geological, or other features of scientific, educational, scenic, or historical value

Wildfire - Any wildland fire not designated and managed as a prescribed fire within an approved prescription and occurring in natural fuels

Wildlife - All undomesticated mammals, birds, reptiles and amphibians living in a natural environment. Does not include feral animals, such as wild horses and burros

Wildlife Habitat Diversity - The distribution and abundance of different plant and animal communities and species within a specific area

WINI - Watershed Improvement Needs Inventory

Windthrow - Trees that have been uprooted by the wind

WIS - Watershed Information System

Wood Fiber Production - The growing, tending, harvesting and regeneration of harvestable trees

Woody Plant - Perennial plants that have stems consisting of wood (shrubs, trees, and vines)

Woody Residue/Residue - Organic materials such as plant stems and branches having a minimum diameter of three inches (small end). Included are both natural materials and materials remaining after timber harvest (slash)

WQL - Water Quality Limited. Water bodies listed by EPA as not meeting State water quality standards. They are to be monitored to determine if water quality standards are, or are not, being met. On those not meeting water quality standards, TMDLs may be assigned

-X-

Xeric - Refers to a habitat characterized by dry soil conditions

-Y-

Yield - The amount of forest produce that may be harvested periodically from a specified area in accordance with the objectives of management

-Z-

ZOI (Zone of Influence) - The area influenced by Forest Service management activities

Zoning - The demarcation of a planning area into zones, usually accompanied by the establishment of regulations to govern the types of activities and uses within each zone

Zoological Area - A protective area designated for its authentic, significant and interesting evidence of important animals, animal groups and animal communities

Decomposition Class (cont)

Log Characteristics	Log decomposition class				
	1	2	3	4	5
Bark	intact	intact	trace	absent	absent
Twigs < 3 cm	present	absent	absent	absent	absent
Texture	intact	intact to partly soft	hard, large pieces	small, soft, blocky pieces	soft and powdery
Shape	round	round	round	round to oval	oval
Color of wood	original color	original color	original color to faded	light brown to faded brown or yellowish	faded to light yellow or gray
Portion of log on ground	log elevated on support points	log elevated on support points but sagging slightly	log is sagging near ground	all of log on ground	all of log on ground

INTRODUCTION

The Targhee National Forest covers approximately 1.8 million acres (this includes the portion of the *Caribou National Forest* which is administered by the Targhee). The majority of the Forest lies in eastern Idaho and the remainder in western Wyoming. Situated next to Yellowstone and Grand Teton National Parks, the Forest lies almost entirely within the Greater Yellowstone Ecosystem.

The Forest serves as a home for many plant and animal species. It also offers a wide range of recreation opportunities year-round, as well as a unique setting for a diversified local economy. The Targhee Forest personnel anticipate that over the next decade, more people will discover the Targhee and compete for its resources and services.

Vicinity Map of Targhee National Forest on a National Scale

The Decision - An Overview

This document presents my decision for a Revised Land and Resource Management Plan (Revised Plan or Revised Forest Plan) for the Targhee National Forest. It explains the reasons I have selected the Preferred Alternative 3M, as presented in the Final Environmental Impact Statement (EIS). Alternative 3M is the basis for the Revised Forest Plan which will guide the management activities for the Targhee National Forest for the next 10 to 15 years.

We are embracing the concept of adaptive management in this Revised Forest Plan. From a strategic perspective, this means that

- We will adjust our management if our strategies do not move us toward the achievement of the Revised Plan Desired Future Conditions, Goals and Objectives. New information will be incorporated as it becomes available.
- We will make decisions that leave future generations with as many options as possible.

Alternative 3M, as modified from the Draft EIS in response to public comment, responds to the issues in a reasoned, deliberate, comprehensive and equitable manner. I have selected Alternative 3M because it best meets the needs for change, positions the Forest Team to address the seven key issues in a balanced way and also addresses the other factors common to all alternatives in the Final EIS. Key features of Alternative 3M are (details provided in Chapter II of the FEIS)

- 1) Ecosystem Sustainability will be increased by allowing silvicultural treatments on 45,200 acres where forest structure can be maintained or improved during the next decade. Prescribed fire will also be allowed where appropriate to maintain or improve ecosystem health on 1,750,000 acres,
- 2) Desired Vegetative Conditions within aquatic influence zones will be improved by managing approximately 512,000 acres to promote health and function of riparian, wetland and aquatic ecosystems, ✓
- 3) Elk Security will be increased and, as a result 89 percent of the Forest will meet the state elk vulnerability threshold,
- 4) Grizzly Bear Habitat will be improved by managing almost 476,600 acres (Targhee portion within Grizzly Bear Recovery Zone) in a comprehensive strategy that provides "core" areas to ensure grizzly security and which reduces road and trail densities to the level needed to allow grizzly occupancy. Timing and other mitigation measures are applied to human activities within the recovery zone.
- 5) Reasonable access to the Forest by roads and trails open for motorized use will be provided on a system of designated routes. However, motorized road and trail density will be reduced to achieve the road density standards for each management prescription area. This means that during the next decade, 20 percent (408 miles) of roads will be closed and 30 percent (233 miles) of motorized trails will be closed. Acres currently available for off-highway vehicle use will be reduced by 90 percent, to about 121,000 acres. These changes are necessary to improve elk security, improve grizzly bear habitat and prevent other resource damage.

6) Roadless Areas - 106,000 acres will be recommended to Congress for wilderness designation in addition to the 65,000 acres already recommended, for a total of 171,000 acres. With the current 134,166 acres designated as wilderness, and the 49,300 acres designated as a wilderness study area (the Targhee portion of the Palisades Roadless Area), a total of almost 354,500 acres will be managed to retain the wilderness character until Congress takes legislative action on the wilderness issue.

7) Timber Harvest is allowed at a sustainable level, not to exceed 80 MMBF for the decade. An estimated 20,520 acres of forest land suitable for timber production will be harvested. The use of timber harvest as a tool to meet ecosystem health objectives will also be allowed on forest land unsuited for timber production. This harvest will not exceed 20 MMBF for the decade.

The balance of these key issues is weighed within the capabilities of the land and Alternative 3M provides for sustainable ecosystems across the Forest. The reasons to support these statements are discussed in full in the "Reasons for the Decision" section that follows the description of all "Alternatives Considered."

The Forest Team will implement a monitoring and evaluation strategy to improve our understanding of ecosystems and our use of management activities to achieve ecosystem objectives. We also want to test our assumptions made during this analysis, to be able to adjust our management as needed. We have learned much from our monitoring efforts of the 1985 Targhee Forest Plan and now have a better idea of what needs to be monitored to assure we are moving toward our desired future conditions. It was the evaluation of past monitoring that identified the needs for change which began this revision process.

Monitoring and evaluation will be given a high priority as implementation work plans are developed each year. In the Monitoring and Evaluation Plan (Chapter V of the Revised Plan), I have prioritized the monitoring items into three categories. First priorities are

- critical planning assumptions,
- activities with the greatest risk to resources,
- standards and guidelines that are potentially the most constraining on resource outputs

Monitoring of the first priorities is mandatory. Monitoring of second and third priorities will occur as funds are available. The Forest Team will develop monitoring partnerships with Federal, State, local and other agencies to further shared goals.

The sections of this record that follow include the needs for change and desired future conditions, public participation and the revision process, alternatives considered, the environmentally preferable alternative, reasons for the decision with comparisons of the 1985 Plan, changes made between draft and final EISs and responses of the alternatives to the key issues, findings required by other laws, implementation, and appeal.

NEED FOR CHANGE AND DESIRED FUTURE CONDITIONS

A Revised Plan for the Targhee National Forest, as well as each Forest in the National Forest System, is required by the rules implementing the Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA), as amended by the National Forest Management Act of 1976 (NFMA). The purpose of a revised plan is to respond to the needs for change identified from the monitoring of the 1985 Plan and continue to provide multiple-use and sustained yield of goods and services from National Forest System lands in an environmentally sound manner. NFMA implementing regulations (36 CFR 219.10(g)) require a forest plan be revised on a 10 to 15 year schedule. This decision will remain in effect until this Revised Plan is revised, no later than 2012. In the final EIS, a 50-year planning period is used to project the environmental effects of alternative choices beyond the first decade for economic and timber harvest only. Short-term opportunities, problems, or conflicts may arise in managing the Forest that were not anticipated in the Revised Plan. When this occurs, the Plan can be adjusted through rescheduling activities, amendment, or revision.

The original Targhee Forest Plan, approved in 1985, emphasized an extensive salvage and reforestation program of dead lodgepole killed by a massive mountain pine beetle epidemic over the previous 30 years. This rate of salvage caused, in effect, a departure from a sustained yield of timber harvest and could not be continued beyond the first decade (1985 - 1995) in an environmentally sound manner. Monitoring of activities during this time showed it was increasingly difficult to meet the standards and guidelines in the 1985 Plan. New information on resource needs and various management practices became evident during this time, and by 1990 it was apparent that a full revision was needed. More specific needs for change are as follows:

- The salvage program has ended. Use of the many roads built during salvage operations by increasing numbers of people is causing unwanted effects to wildlife, riparian areas, and soil productivity.
- The need to review and incorporate new knowledge and techniques continues, especially in wildlife habitat management. For example, recent studies indicate motorized road and trail densities play a crucial role in availability of suitable habitat for elk and grizzly bears. Standards for management activities near nesting and foraging habitat for goshawks and other raptors are needed to protect these crucial areas. Results of studies analyzing fish habitat in the Upper Columbia River Basin are pointing out new ways to manage fisheries. Some of these findings have widespread implications that the revision process was intended to address.
- Although much of the lodgepole pine component on the Forest has been salvaged, there is still a need to use timber harvest as a tool to reach ecosystem objectives, supply a variety of timber products for local use, deter other epidemics like the mountain pine beetle outbreak, and manage the potential for a devastating wildfire, like the Yellowstone Wildfires of 1988.

Based on public, other resource management agencies, and Forest Service employee participation between 1991-1994, a set of goal statements emerged that collectively represent what ideal conditions would be for the Targhee National Forest. These statements, called "Desired Future Conditions for the Year 2007" are the foundation for the goals, objectives, standards and guidelines developed in the Revised Forest Plan. They have changed from the desired future conditions described in the 1985 Plan, reflecting changes in conditions and values of the local communities and knowledge gained over the decade. These titles of the desired future conditions also show how the analysis and documents are organized, and are described as follows:

Ecosystem Processes and Patterns Desired Future Conditions:

A mosaic of age classes and types of vegetation are sustained through time and exist across the landscape. Natural disturbances such as insects, disease and fires continue their natural roles in the ecosystem. The Forest functions as an integral part of the Greater Yellowstone Ecosystem as well as adjacent systems, sustaining habitat and conditions necessary for free movement of wildlife.

Biological and Physical Desired Future Conditions:

Riparian zones (aquatic influence zones) are healthy and productive. Aquatic systems are allowed to function naturally while protecting flows for downstream consumptive uses. Riparian area integrity contributes to productive fisheries and excellent water quality. Native plant and animal species are favored over undesirable non-native species and sustained populations of all native and desirable species thrive. Habitat conditions contribute toward the recovery of threatened, endangered and sensitive species.

Forest Use and Occupation Desired Future Conditions:

Growing and diverse recreational, cultural, visual, historical, and prehistoric management, interpretive, and spiritual needs are accommodated based on the capability of the ecosystem to sustain these uses. Recreation use is managed to minimize conflicts between incompatible uses and provide high levels of satisfaction. Year-round human access is managed to provide both motorized and nonmotorized opportunities. A system of trails and support facilities exist which are compatible with resource capabilities. Roadless characteristics are preserved in the recommended wilderness areas and in existing wildernesses.

Production of Commodity Resources Desired Future Conditions:

try count
① →

Commodity production, such as timber, firewood, mining, livestock forage, or outfitting and guide services are conducted at sustainable levels and maintain the capability of the land to produce an even flow and variety of goods and services for present and future generations. Timber harvest, prescribed fires and livestock grazing are tools used to achieve desired ecological vegetation conditions. Forest products are provided to sustain social and economic values and needs of the local communities within limits which maintain ecosystem health.

PUBLIC PARTICIPATION AND THE REVISION PROCESS

The Targhee National Forest Team conducted an extensive public involvement process that continues. The revision process began in December, 1990 when a notice of intent to prepare an environmental impact statement (EIS) was issued in the Federal Register. The notice of intent announced our interest in identifying changed conditions and need to revise the 1985 Plan. We held an initial set of public meetings in 1991 in the six communities where Forest offices are located.

The Revision effort included involvement, coordination, and comments from federal, state and local agencies and the Shoshone-Bannock Tribes. Some participants included the State of Idaho (Fish and Game, Parks and Recreation), State of Wyoming Game and Fish, the U.S. Fish and Wildlife Service, Yellowstone and Grand Teton National Parks. Representatives of county and city governments were involved along with the Henry's Fork Watershed Council, the Shoshone-Bannock Tribal Council and tribal members. The Forest Team kept the public informed of revision progress through a series of newsletters and news releases. Our mailing list includes more than 3,500 persons and organizations.

A series of public meetings and field trips was held between October 1991 and January 1994 (13 total) to determine the public's vision regarding what the Targhee National Forest should look like, and what uses they desired. This vision became the desired future conditions described above, and are the basis for the goals and objectives developed for the Revised Plan. The interaction also worked to improve communication, provide opportunity for mutual problem solving and increased understanding among the public, government agencies, tribal nations, and Forest personnel.

The public and Forest staff identified issues and concerns that evolved into the seven key issues, and over 70 additional sub-issues. Alternative management strategies for the Targhee National Forest were developed in response to the seven key issues. The environmental effects on the sub-issues were analyzed and are summarized in the EIS. The public reviewed the preliminary alternatives at work sessions beginning in May 1994. In June 1995, two meetings focused solely on the access issue, specifically which roads and trails were proposed open for motorized use in each of the six alternatives.

After publication of the draft EIS and draft Revised Forest Plan in February 1996, the Forest Team held another series of public meetings beginning in March and continuing through June. At these meetings, Forest personnel answered questions, displayed how the Preferred Alternative 3M responded to the seven key issues, compared the differences in Forest management from the 1985 Plan to the preferred alternative, and discussed the proposed changes in access, which was the most controversial issue. Forest personnel held numerous meetings with interest groups (such as conservation and preservation, motorized and nonmotorized recreation users, timber industry, and others).

Six of the nine counties of the sixth district of elected officials in southeast Idaho chose to put two alternatives on an "advisory referendum" on the May 1996 primary ballot. Citizens were asked to vote on four issues. Ballot results indicated that the people who voted wanted more motorized access and more focus on commodity uses, and less attention to wildlife needs that impact motorized access. Not all issues addressed in the EIS were on the ballot.

The public comment period on the draft documents stretched from February 27 to June 27, 1996. We received 2,168 individual responses in the form of letters, petitions, and postcards. The Forest Team responded to each substantive comment in the Final EIS, Appendix A. The Forest Team also made many changes as a result of these comments, including additional analysis and refinement of the Selected Alternative 3M.

Public involvement and discussions continue. The Targhee Forest staff listened to all points of view and incorporated many suggestions. I am confident it is evident that the staff has listened, and that public involvement in this process has strengthened the Revised Plan. Appendix A in the Final EIS summarizes the public comments and is larger than the Revised Plan because we responded directly to every substantive comment. The Revised Plan reflects the fact that we considered public comments, although we did not make every change suggested by the public. Often comments were mutually exclusive. For example, some people want a particular area to remain roadless and others want that area available for motorized recreation activities. In making this kind of trade-off decision, I have looked at the broader picture and reached a balance I believe is workable.

Planning Records

With all of the above collaboration with the public and other agencies and expertise from many Forest Service employees, an Interdisciplinary Team followed a revision process, completed the environmental analyses (summarized in the final EIS) and developed the Revised Plan from the Selected Alternative 3M. The Team has provided detailed explanations of the analysis and results of each revision process.

step in the process planning records. The final EIS includes references to the detailed planning records on file in the Forest Service office in St. Anthony, Idaho. These records can be reviewed at

Forest Supervisor's Office
Targhee National Forest
420 N. Bridge St.
St. Anthony, ID 83445

ALTERNATIVES CONSIDERED

A brief description of the of the alternatives considered in this analysis follows. Important points in the development of each alternative include

- The range of alternatives responds to the concerns and issues raised by the public, not on predetermined or unrealistic outputs
- All alternatives include the principles of multiple-use, sustained yield, and ecosystem management
- All alternatives share a set of basic goals and standards and guidelines which insure protection of Forest resources and compliance with applicable laws
- All alternatives, except the No Action, Alternative 1, achieve the purpose and need for a revised Forest Plan, based on the needs for change discussed previously
- All alternatives meet the management requirements of 36 CFR 219.17, and other legal and regulatory requirements

Objectives Shared by All Alternatives

All alternatives will meet the following objectives established in the Intermountain Regional Guide

- ~~Protect the basic soil, air and water resources.~~
- Provide for multiple uses and sustainability in an environmentally acceptable manner
- Provide for a quality of life through management of ecosystems
- Provide for scenic quality and a range of recreation opportunities that respond to our customers and local communities
- Emphasize cooperation with individuals, organizations, and other agencies in coordination of planning and project implementation
- Promote rural development opportunities
- In cooperation with other landowners, strive for improved landownership and access patterns, to the mutual benefit of both public and private landowners
- Improve the financial efficiency of all programs and projects

Alternative Descriptions

The Forest Team analyzed seven alternatives in detail. Alternative 1 is the No Action Alternative, or a continuation of management under the 1985 Plan. As the numbers increase from Alternatives 2-6, they generally move consistently toward the following

- Greater protection of wildlife habitat
- Greater protection of riparian areas
- More protection in Bear Management Units
- More security for elk
- More nonmotorized, dispersed recreation opportunities
- More recommended wilderness
- Less cross-country motorized use
- Fewer open motorized roads and trails
- Reduced livestock grazing and timber harvest
- Fewer lasting visual impacts from management activities

Alternative 1 (No Action)

The purpose of the No Action alternative is to show the current level of goods and services expected to be provided in the future if management of the Targhee National Forest were to continue under the 1985 Forest Plan. The 1985 plan has been updated with 24 non-significant amendments, requirements of court orders for grizzly bear habitat management, and changes needed to address habitat for new sensitive wildlife species in the last 10 years.

Timber harvest occurs at a high level within the management requirements for threatened and sensitive wildlife species like grizzly bears and goshawks. Vehicle access is slightly reduced over recent levels due to the requirements of the Interagency Grizzly Bear Committee Task Force Report, Grizzly Bear/Motorized Access Management, July 1994. Cross-country, motorized use in summer and winter would continue near recent levels. Grazing continues at current levels. Riparian, wildlife and recreation values are emphasized in specific areas of the Forest, consistent with the 1985 Plan. Alternative 1 recommends portions of the Lionhead, Italian Peaks and Winegar Hole roadless areas for wilderness designation. Legislative action is still needed to make these recommendations, the same as 1985, permanent.

Alternative 2

The purpose of this alternative is to resolve the key issues by emphasizing cross-country winter access and timber production, while adding more restrictions to summer cross-country access. Use of motorized vehicles to retrieve hunted game is allowed on 58 percent of the Forest. Timber harvest occurs at the highest levels within the management direction required to maintain threatened, endangered and sensitive species habitat. Grazing continues at current levels. Vehicle access is slightly reduced from recent levels to meet Interagency Grizzly Bear Committee (IGBC) Guidelines. Riparian, wildlife and heritage resource values are emphasized in specific areas of the Forest. Alternative 2 does not recommend any wilderness designation.

Alternative 3

This alternative responds to the key issues by emphasizing management of wildlife habitat and sustaining timber harvest levels within wildlife constraints. Grizzly bear recovery is enhanced with a reduction in motorized use allowed in each bear management unit (BMU). Grazing allotments continue at current levels and a larger percentage of riparian areas meet the desired vegetative condition. Cross-country summer motorized vehicle use is restricted to specific areas. Lionhead, Palisades and Italian Peaks, plus the Idaho portion adjacent to the Winegar Hole wilderness are recommended for wilderness designation.

Alternative 3M

This is the alternative which emphasizes wildlife habitat management and provides more core areas for grizzly bears. Motorized access, timber harvest levels and livestock grazing are all reduced. Cutthroat trout are further protected with increased vegetation requirements along streams. Cross-country, summer, motorized vehicle use is restricted to specific areas. Lionhead, Palisades, a portion of Diamond Peak and Italian Peaks, plus the Idaho portion adjacent to the Winegar Hole wilderness are recommended for wilderness designation.

Alternative 4

This alternative emphasizes watershed and wildlife habitat improvement and a reduction in timber harvest. Riparian areas have increased emphasis. Motorized access is restricted to designated routes and more roads are closed in BMUs than in previous alternatives. Lionhead, Palisades and Italian Peaks, plus the Idaho portion adjacent to the Winegar Hole wilderness and another 14,000 acres of presently roadless areas are recommended for wilderness designation.

Alternative 5

This alternative addresses the key issues by reducing resource management by people and reducing human disturbances of wildlife and riparian habitat. Motorized access is restricted to designated routes and more roads are closed in BMUs than in previous alternatives. Lionhead, Palisades and Italian Peaks, plus the Idaho portion adjacent to the Winegar Hole wilderness and another 100,000 acres of presently roadless areas are recommended for wilderness designation.

Alternative 6

This alternative meets the needs for change and addresses the key issues by de-emphasizing resource management by people and reducing human disturbance of wildlife and riparian habitat to the lowest level in all the alternatives. Timber harvest is not scheduled. All access is strongly restricted to designated routes and more roads and trails are closed to reduce human disturbances than in any previous alternative. Lionhead, Palisades and Italian Peaks, plus the Idaho portion adjacent to the Winegar Hole wilderness and another 340,000 acres of presently roadless areas are recommended for wilderness designation. Almost all the existing roadless areas retain their roadless characteristics.

REASONS FOR THE DECISION

My decision is to approve the Revised Forest Plan for the Targhee National Forest which accompanies the Final Environmental Impact Statement (EIS). I have made this decision after fully reviewing and understanding the alternatives and environmental consequences. Alternative 3M provides for

- healthy riparian areas by specifying management standards to restore systems within aquatic influence zones,
- improved elk security by decreasing the densities of roads and trails open for use,
- quality grizzly bear habitat to meet recovery goals by designating core habitat areas and restricting some activities by their season of use,
- a balanced mix of motorized and nonmotorized access by designating roads and restricting some activities by their season of use,
- retaining the roadless character of most existing roadless areas by using a management prescription (Category 3) that protects the roadless character of these areas for recreation use and future options,
- recommend high-quality areas as additions to the wilderness system,
- a flow of goods and services to help maintain local economies and lifestyles

The Forest Supervisor determined the major public issues, management concerns, and resource use and development opportunities that are addressed in this revision process, as set forth in the planning regulations (36 CFR 219.12(b)). During the revision process, I made several trips to the Targhee Forest, including meetings and field trips with the public and Forest Team. The Forest Team also made several trips to the Regional Office to brief my office on developments and progress.

Alternative 3M is the result of the alternative development and public involvement stages of the Forest Plan Revision process. Important considerations to protect the environment that have influenced my decision include

- Protection of the basic resources (air, soil, and water), as mandated by our agency's mission, vision and guiding principles, are provided for with the management standards and guidelines and monitoring items
- The local and national people who use the Targhee National Forest, the communities they live in, and the relationship of the Forest Service with people and local communities
- Economics and the role the Targhee National Forest plays in local, regional and national economies
- Science, both social and biological as it applies to the management of National Forests, and because people are an integral part of ecosystems and this Revised Plan

- The role of the Targhee National Forest to provide multiple use opportunities in the Greater Yellowstone Ecosystem
- The role of fire in ecosystem dynamics
- The plans and policies of other government agencies (local, state, tribal and national), especially Snake River Activity Operations Plan
- The Forest Plan Revision considered and appropriately included existing scientific literature, including appropriate parts of the *Interior Columbia Basin Ecosystem Management Project* scientific assessment (see References Cited in the FEIS)
- The applicable laws and policies that govern the development of a Forest Plan and for management of National Forest lands Endangered Species Act, Clean Water Act

The environmental consequences and cumulative effects of these factors are disclosed in the Final EIS, Chapter IV by alternative. Details of the analysis completed can be found in the process papers

Components of the Decision and Comparison to the 1985 Plan

This decision is accompanied by the necessary supporting analysis and disclosure, summarized in the Final EIS, required by the National Environmental Policy Act (NEPA) and its implementing regulations (40 CFR 1500) Also incorporated are the requirements of the National Forest Management Act (NFMA) and its implementing regulations (36 CFR 219) The six components of the decision made in every forest plan are

- 1. The establishment of forestwide goals and objectives.**
- 2. The establishment of forestwide standards and guidelines**
- 3. The establishment of management area direction.**
- 4. The designation of suitable timber land and establishment of an allowable sale quantity**
- 5. The establishment of monitoring and evaluation requirements.**
- 6. Recommendations for Wilderness and Wild & Scenic Rivers.**

The descriptions that follow explain what these decisions mean for the Revised Targhee Forest Plan, and how they differ from the decisions made in the 1985 Plan

1. The establishment of forestwide goals and objectives.

Goals and objectives are described in Chapter III of the Revised Plan Goals are concise statements that describe a portion of the desired future condition (discussed previously) in broad terms that are timeless Objectives are more concise, usually time-specific statements of a condition, outcome or purpose necessary to accomplish during this next decade to move toward reaching a certain goal and achieving the desired future conditions on the Targhee National Forest Many of the goals are similar to the 1985 Plan, as the overall desired conditions for many resources have not changed New goals have been added where we have learned from our activities and are beginning to understand how ecosystems function

Some specific examples of these are described under goals for properly functioning condition of ecological processes and patterns (Revised Plan, p III-4)

2. The establishment of forestwide standards and guidelines.

There are changes in the standards and guidelines from the 1985 Plan, particularly the forestwide standards and guidelines. As we learned from implementation of the 1985 Plan, we have incorporated more resource protection standards and guidelines for management activities that will be implemented to achieve the objectives and goals, and move the forest conditions toward the desired future. Standards and guidelines are also in Chapter III of the Revised Plan. Some of these standards and guidelines apply forestwide and others apply to specific areas of the forest.

3. The establishment of management area direction.

Land allocations have been decided by assigning a management prescription to each area of the Targhee National Forest. These prescriptions contain the goals, objectives, standards and guidelines to be used when any management activities are to occur on a particular piece of ground. The prescriptions are permissive in that they allow certain activities to occur and prohibit or restrict other activities, but they do not require management actions to take place.

The Revised Plan includes 45 separate management prescriptions to address specific needs or desired uses on a particular piece of ground. These management prescriptions have been grouped into geographic units called subsections to provide a locational perspective to the overall management direction. These subsections are much larger than the management areas used in the 1985, as there were 22 management areas and now there are seven subsections. I think this broader geographic grouping will help us better understand processes and patterns and how our activities affect the ecosystems.

Again found in Chapter III of the Revised Plan, these management prescriptions guide future management activities within each specific area. The basic categories for prescriptions are consistent with categories used in the Interior Columbia River Basin Ecosystem Management Project. The same basic categories will be used in future Forest Plan Revisions in the Intermountain Region, and are briefly described here including the acres allocated to each management prescription category for Alternative 3M.

Table ROD-2 Description of Management Prescription Categories		
Management Category	Acres	Percent of total Forest area
1 - Wilderness, Wilderness Study Areas and Recommended Wilderness	337,846	19
2 - Special Management Areas, Maintenance of Visual Quality, Research Natural Areas, Eligible Wild, Scenic & Recreation Rivers, Grizzly Bear Habitat, Elk and Deer Winter Range, Aquatic Influence Zones, South Fork of the Snake River	437,335	24
3 - Semi-private Nonmotorized Recreation and Motorized Backcountry Rec	242,165	14
4 - Developed and Special Use Permit Recreation Sites, Dispersed Camping Management	8,103	0.40
5 - Lands Suitable for Timber Management with General, Urban Interface, Big Game Security, Visual Quality Improvement and Maintenance, Grizzly Bear Habitat, Elk and Deer Summer Range Emphases	601,559	33.60
6 - Non-forested Rangeland	157,385	9
7 - not used because this group of management prescriptions do not fit any management situations on the Forest	-	-
8 - Concentrated Development Areas	4,639	0

4. The designation of suitable timber land and establishment of the allowable sale quantity (ASQ). Designation of lands suitable for grazing and browsing. The identification of lands suitable and available for Oil and Gas Leasing.

There are 703,100 acres of tentatively suitable timber land on the Forest. In Alternative 3M, 465,000 acres are suitable for timber management and the allowable sale quantity is 80 Million Board Feet (MMBF) for the next decade. There are more acres in Category 5 prescription areas than what is considered suitable (601,559 compared to 465,000) because prescription areas are typically large, contiguous areas and inclusions of unsuitable land were not identified at the Forest scale. Land suitability will be evaluated on a site-specific basis. Fewer acres are identified as suitable for timber management than in the 1985 Plan because more recent inventories and subsequent improvement in mapping capabilities show about 290,000 more acres of non-forested land than the information used in the 1985 analysis. A further explanation of this can be found in the Final EIS (Chapter III) and in Process Paper C. After additional analysis between the Draft and Final EISs, some areas on the forest were added or deleted from the suitable timber land with no net change in the acres suitable for timber harvest.

The allowable sale quantity of 80 MMBF for the decade is an upper limit of harvest that can occur within the management direction in the Revised Targhee Plan. An estimated 32 MMBF of this will come from components of the Forest that have slopes greater than 40 percent, grizzly bear habitat areas (Prescription 5.3.5) or roadless areas. Any volume harvested from these areas is intended to be counted as a non-interchangeable component of the allowable sale quantity. This means that if the maximum 32 MMBF does not come from these components, it need not be replaced by timber volume from the

Table ROD-3 Acreage by Management Category, Ownership or Other Management Within Forest Boundary

3 2 (d)	Semi-Primitive Motorized	5,118		State	25,702
3 2 (g)	Semi-Primitive Motorized	49,821		TOTAL ACRES	1,906,303

general suitable timber lands on the Forest. The specific breakdown of these non-interchangeable components is:

- slopes greater than 40 percent (maximum 0.7 MMBF for the decade),
- roadless areas within the Category 5 management prescription (maximum 11.3 MMBF for the decade),
- grizzly bear habitat within Category 5 management prescription (maximum 19.85 MMBF for the decade),

During implementation of the Revised Plan, all timber harvest will be analyzed on a site-specific basis.

Determination of land suitable for livestock grazing is another important consideration in this decision. Alternative 3M has 1,026,000 acres of suitable rangelands. These rangelands will continue to meet the needs of livestock permittees and grazing will continue to be a valued use of resources on the Targhee National Forest. The amount of suitable rangelands in Alternative 3M is slightly lower than in the 1985 Plan but will accommodate current livestock use.

With an emphasis on effective range management, monitoring and more clearly measurable standards and guidelines in the Revised Forest Plan, existing unsatisfactory rangeland conditions will improve. The quality of the rangelands in satisfactory condition will be maintained, as will the habitat for healthy herds of elk, deer and bighorn sheep. Integrated with this are the forestwide objectives to maintain and improve fish habitat, particularly cutthroat trout, protect and improve riparian areas and wetlands, and meet grizzly bear recovery goals.

The determination of areas available for oil and gas leasing and identification of protection clauses for leased areas will be disclosed in a separate analysis. The Draft EIS for this oil and gas leasing was issued for public comment October 1996, and a Final EIS is due to be released August, 1997. A decision on areas available for oil and gas leasing will be made when the Final EIS has been completed.

5. The establishment of requirements for monitoring and evaluation.

This decision component provides a basis for periodic determination and evaluation of the effects of management practices. While the 1985 Plan also included monitoring items, we have learned much about what is useful monitoring, and what we can afford. The monitoring described in Chapter V of the Revised Forest Plan will ensure this management strategy works over the long-term. Forest staff developed a Monitoring Plan that identifies the minimum legal requirements for monitoring and other requirements that are important. Many of these monitoring items resulted from concerns expressed by the public. I have prioritized items into three categories. First priorities are mandatory to accomplish. Second and Third priorities will be accomplished as funds and partnerships are available.

6. Recommendations for Wilderness and Wild, Scenic and Recreation Rivers.

This component of the decision considers any recommendations for additions to the National Wilderness Preservation System. The 1985 Plan recommended portions of three roadless areas (65,000 acres) be added to the three existing congressionally designated areas (2 wilderness, 1 wilderness study area) on the Targhee National Forest. My decision in the Revised Forest Plan retains these recommendations and adds an additional 106,000 acres of quality roadless area to be considered for addition to the Wilderness System by the US Congress. This helps balance the variety of goods, services and uses on the Targhee National Forest and leaves options available for future generations.

The other part of this decision component is determination of eligibility for inclusion in the Wild, Scenic and Recreation River System. A 1994 update to the inventory determined about 245.5 miles of rivers and streams were eligible to be included in the River System. This is only a minor change to the eligibility determinations identified in the DEIS. One creek was dropped from consideration after an analysis determined it did not have "outstandingly remarkable" qualities. A summary can be found in the Final EIS (Chapter IV) and details are covered in the Wild, Scenic and Recreational Rivers Eligibility Determination Process Paper R.

Comparison of Alternatives' Response to the Key Issues and Changes Made in response to Other Decision Factors

Resolution of key issues was achieved by the emphasis placed on each decision component described previously (establishment of goals, objectives, standards and guidelines, management area direction, suitable timber, rangeland, and allowable sale quantity, monitoring and evaluation requirements; and wilderness and wild & scenic river recommendations). The alternatives varied in their ability to resolve each issue. A comparison of the differences among the alternatives I considered, and changes made in response to the comments on the draft documents follows.

Key Issue 1: Sustainability, Fire and Natural Disturbances

A variety of management approaches to sustaining ecosystems are available for use. Of primary concern are the use of fire and timber harvest in relation to their effects on the health of the forest structure and composition. The key indicators for this issue are acres where forest structure and composition is maintained or improved and acres where prescribed fire is allowed.

The alternatives varied in how many acres would be silviculturally treated to improve structure and composition, and where prescribed burning would be allowed. Alternatives 1, 2 and 3 improved structure and composition on the most acres, near 60,000 for the decade for Alternative 2 and 50,000 for Alternatives 1 and 3. Alternative 3M improved sustainability on almost 45,000 acres. Alternatives 4 is around 40,000 and Alternative 5 around 30,000 acres, and Alternative 6 improved the fewest acres at 20,000.

The range of acres where prescribed burning would be allowed varied less among the alternatives. Alternatives 1 allows prescribed burning on about 1,630,000 acres for the first decade, while the rest of the alternatives allowed prescribed burning on just over 1,750,000 acres.

Public comments to the draft documents included some that disagreed with the Forest Team's approach for range of natural variability, sustainability, patch size, succession, old growth, use or non-use of natural disturbances (fire, insects), forest health, viability and biodiversity. Many disliked our ecosystem

management definition or requested more clarification and monitoring. The Forest Team was challenged on the use of ecosystem management as being simply an opportunity to harvest more timber. Some wanted more scientific studies prior to adoption of the Final Plan, especially related to Yellowstone National Park and the Interior Columbia Basin Ecosystem Management Project.

I have modified Alternative 3M since the draft documents and changed the emphasis on identifying the range of natural variation. Many people thought the objective was to duplicate historical vegetation patterns, although this was not the case. I added forestwide standards and guidelines to identify ecosystems that are functioning properly and those that are at risk. Management activities will prioritize the "at risk" ecosystem for treatment to bring these back into proper functioning condition. I intend to limit harvest to 20 million board feet (20 MMBF) for the decade on those lands that were not identified as suitable for timber management. Such harvest would only be done to foster proper functioning condition like removing conifers from sagebrush grass ecosystems.

Some additional sites in the Henry's Fork Basin which represent good examples of ecosystems functioning properly were added as Special Management Areas. These will serve as barometers for other systems within the basin.

Other changes included placing more emphasis on the use of prescribed fire and managed natural fire to achieve desired soil and habitat characteristics, improve forest health, and create or maintain diversity in vegetative structure, composition and patterns. Additional objectives were added to develop Fire Management Plans throughout the Forest.

Key Issue 2: Riparian

Although riparian areas constitute less than five percent of the total land base, they are the most productive areas in terms of plant and animal species diversity and consumptive use. A healthy riparian area indicates that most, if not all, of the water and soil components are also healthy.

The number of acres meeting the desired vegetation conditions for riparian areas was used as the key indicator for this issue.

Alternative 1 has just under 19,000 acres meeting the desired riparian conditions by the end of the decade. Alternatives 2, 3, and 3M have about 20,000 acres meeting the desired conditions. Alternatives 4, 5, and 6 would have the most acres meeting the desired vegetation conditions in riparian areas, just over 21,000 acres.

The primary concerns about riparian areas are the amount of vegetation which would be retained after grazing and other activities in riparian areas, primarily the height of the vegetation stubble remaining after grazing, concern over enforcement and monitoring of the standards, recreational use within the riparian areas, especially the allowance for camping and motorized use within 300 feet of the road, water quality limited streams, and interpretations of what management activities are allowed in these areas. Some people wanted more protection, monitoring and standards for fisheries, especially for native cutthroat trout, while others thought the management direction was too constraining on uses.

No changes were made to the height of vegetation stubble remaining after grazing activities because this standard is necessary to protect streambanks and to provide for a moderate rate of recovery of degraded riparian and aquatic systems together with a moderately high level of fisheries habitat quality. Additional objectives, standards and guidelines to address native cutthroat trout watershed were developed and added to the final Revised Plan. These include objectives to coordinate with the states of Idaho and Wyoming to

- 1) re-assess the health of native cutthroat trout populations within all seven subsections on the Forest,
- 2) use this information to further define species recovery needs and opportunities and to evaluate the effectiveness of the Native Trout Watersheds, and
- 3) determine which subwatersheds (drainages) within designated Native Trout Watersheds are non-essential to native trout recovery

Additional guidelines, modeled after the Inland Native Fish Strategy (INFISH) of June 1995 were added to meet the recovery objectives for native cutthroat trout. It is important to note that we intend to manage all native trout, fine spotted and Yellowstone, as sensitive, and site-specific impacts will be analyzed in a biological evaluation for each project affecting native trout habitat.

Key Issue 3: Security for Elk

Security for elk was chosen as a key issue relating to future hunting conditions and opportunities and cooperative relations with fish and game departments. Observations and studies by agency and university scientists determined that as motorized road and trail densities increase, elk security declines. Portions of the Forest have high densities of trails and roads open to motorized use due to the extensive road building associated with the salvage of dead lodgepole pine. The percent of the Targhee Forest meeting the Idaho state elk vulnerability thresholds (measured by miles of open roads and open motorized trails) was used as the key indicator.

Alternative 1 provides the least security for elk, with 62 percent of the Forest meeting the state vulnerability thresholds. Alternative 2 is at 76 percent and Alternative 3 at 83 percent. Alternatives 3M and 4 are approximately at 89 percent. Alternatives 5 and 6 provide the most security for elk, with 95 percent of the Forest meeting the state vulnerability thresholds.

Many of the letters on this issue cited a variety of studies supporting or not supporting our road density standards, and our findings on the impacts of people and motorized use on wildlife. Strong feelings were expressed supporting or not supporting the use of off-highway vehicles because of wildlife hunting and viewing opportunities.

Overall, the open motorized road and trail density standards did not change from the draft documents. These density standards make the Forest road and trail system cost effective by requiring low-use roads to be closed, resulting in fewer miles to maintain. Access needs by people are integrated with other resource values, including elk, grizzly bear and native cutthroat trout. Public comments were used to identify specific motorized roads and trails which could be opened and still meet standards. The miles of open motorized roads and trails increased between Draft and Final by approximately 20 miles. The decision on exactly which roads will remain open will be made by Supervisor Reese as one of his first implementation decisions for the Revised Plan.

Key Issue 4: Grizzly Bear Management

Portions of the Forest are within the Yellowstone Grizzly Bear Ecosystem which has been divided into Bear Management Units (BMUs) by the Interagency Grizzly Bear Committee (IGBC) that developed the Grizzly Bear Recovery Plan (Managing motorized access is one of the most influential parameters affecting grizzly bear habitat security). We now have better information on effective management of roads, timber and human activities in grizzly bear habitat. Miles of open roads and open motorized trails were used as the key indicator for grizzly bear management units.

Alternatives 1 and 2 provide the least grizzly bear habitat security with the greatest road densities in the bear management units (BMU), ranging from 42 miles per square mile in the Henry's BMU to 137 miles in the Plateau BMU. Alternatives 3 and 3M range between 40 miles per square mile in the Henry's BMU to 85 miles in the Plateau BMU. Alternatives 4, 5 and 6 have the most bear habitat security, ranging from 35 miles per square mile in the Henry's BMU to 74 miles in the Plateau BMU (Table ROD-1).

Management of grizzly bear habitat was one issue emphasized by local National Forest users. A meeting against any management for the grizzly bear was held in St. Anthony, ID, because some people thought the Forest Team had exceeded measures needed to protect the bear. Other groups supported our strategy for grizzly bear management or wanted more protection with even lower open motorized road and trail densities, and more core areas set aside.

The Endangered Species' Act requires certain elements for our grizzly bear strategy. We did note the public comments received, however, few changes were made except for the snowmobile change which is discussed later. The Final Revised Plan is consistent with the biological opinion of the US Fish and Wildlife Service. The objective to phase out sheep grazing in the BMUs as opportunities arise (such as when a sheep allotment permit expires) remains as it was in the draft documents, to reduce the chances of sheep and grizzly bear conflicts. The reduction sustained as a result of this phase out amounts to approximately 4,000 animal unit months (AUMs) on nine allotments, or about three percent of the permitted AUMs currently allowed on the Targhee National Forest. Some modifications were made to the standards and guidelines in the grizzly bear habitat prescription, in addition to the snowmobile changes listed under sub-issues, to clarify management practices and allow as much flexibility as is possible under the existing situations.

Key Issue 5: Access

Recreational motorized use has increased over the last decade. The 1985 Plan allowed cross-country motorized travel across much of the Forest and did not establish road density standards. Road closures provide more protection and fewer impacts on wildlife, threatened, endangered, and sensitive species, soils and water, and fisheries, less visual, garbage and noise pollution, reduced maintenance, and more nonmotorized opportunities for escape and solitude. Open roads and trails allow more access for hunting, fishing, berry-picking, developed camping, hiking and other recreational pursuits, increased opportunities for sight-seeing, challenging cross country travel for off-highway vehicles, and greater access for persons with disabilities and the elderly. The key indicators for access are the total miles of roads and open trails available for motorized use on the Forest.

Alternatives 1 and 2 provide the most open roads and trails, about 2,500 - 2,300 miles available for motorized use. Alternatives 3 and 3M provide slightly fewer open roads and trails, at 2,000 - 2,100 miles. Alternatives 4, 5 and 6 reduce the open roads and trails the most, with about 1,800 to 1,500 to 1,300 miles available for motorized use, respectively.

Motorized access is the most controversial of the seven key issues. Many people in the local area thought too many roads and trails were being proposed for closure, especially in grizzly bear and elk country, and too many restrictions on motorized use overall were considered in the draft documents. A few motorized recreation user groups wanted us to use studies that were being used on other Idaho forests which do not equate road use at the same level as trail use. After reviewing these comments, we completed this analysis and a comparison is shown in Chapter IV of the EIS. Other letters strongly suggested that we needed to decrease the miles of roads and trails that are open for use, and establish better enforcement because many of the existing closures are ineffective (based on the Road Scholar study). Our analysis methods were questioned, particularly the accuracy of the road inventory (inventory process is summarized in the Access Appendix C in the Final EIS).

Between the draft and final EISs we reviewed our inventory and found that the number of roads and trails that currently exist was less than what was displayed in the draft EIS, this figure has been corrected in the final EIS. The Forest Team made additional changes in response to public comments including restricting cross-country snowmobile access on all areas mapped as winter range on map #24 in the final EIS map packet, and making some minor changes in open road and trail density standards in the Palisades/Big Hole area. Overall there was an increase in the miles of roads and trails open for motorized use.

I am deciding to specify the maximum allowable road densities (miles of roads and trails open for motorized use per square mile) by the management prescriptions area described previously. Forest Supervisor Reese will decide which roads will be open to achieve these road density standards as one of his first implementation decisions. This discussion will be based on the analysis shown in Appendix C of the Final EIS and will be made shortly after the decision made here.

Key Issue 6: Management of Roadless Areas

As motorized recreation demands increased, public debate increased over whether or not the Forest should maintain the roadless character of the remaining roadless areas. Recommending more acres be congressionally designated as wilderness ensures protection from resource uses and national recognition of wilderness character. Allowing areas to remain roadless, but not as recommended wilderness, keeps more options available for the future. Fewer acres recommended for wilderness could allow more motorized access for recreation, oil and gas, timber and other industries.

Alternative 2 recommends the no roadless acres be added to the wilderness system and Alternative 6 recommends the most at 465,000 acres. Alternative 1 maintains the areas recommended in the 1985 Plan (65,000 acres).

Alternatives 3, 3M, 4 and 5 recommend increasing amounts, 125,000 to 171,000 to 139,000 to 226,000 acres, respectively.

This issue generated the most comments on the draft EIS and draft Revised Plan. Many comments either wanted more wilderness or less. Other letters addressed concerns for continued motorized use in roadless areas and areas recommended for wilderness, especially cross-country use. We were asked to prepare a supplemental draft EIS because some people thought our analysis was flawed. In the letters that supported more wilderness, people listed specific roadless areas they wanted to be recommended for wilderness. The draft documents were updated to reflect the most recent information and did not find a significant change in the results of the analysis, so no supplement was prepared.

Based on a review of roadless areas, the Alternative 3M recommends a moderate 171,000 acres be included in the wilderness system by legislative action, about 46,000 more acres than were analyzed in the draft EIS for Alternative 3M. The Diamond Peak roadless area has been added as recommended wilderness, based on its high wilderness capability rating.

There is a demand for backcountry recreation, both motorized and nonmotorized experiences and we have more management options available to satisfy that demand in a non-wilderness setting. The option is also preserved to include these areas in future wilderness recommendations with designation now of the semi-primitive management prescription. Alternative 3M allocates about 240,000 acres of roadless areas on the Targhee National Forest to a Semi-Primitive Motorized or Non-Motorized Management Prescription. These areas will remain roadless during the next decade.

Key Issue 7: Timber Harvest

Higher levels of timber harvest aid the local economy, better maintain the 25 percent payments to local governments, maximize the removal of the remaining dead or mature wood and assist in faster regeneration of the fire-dependent lodgepole pine. A reduction in timber harvest results in fewer impacts from motorized trail and road uses on wildlife, riparian areas, soils and water, aesthetics and other resources. In the past decade, large scale salvage of dead and dying lodgepole pine timber was conducted at levels that could not be sustained. Since the harvest of dead timber has largely been completed, we are now in a rest and recovery mode until higher levels of timber harvest can be sustained.

The alternatives ranged from 130 MMBF for the decade in Alternative 2 to 110 MMBF in Alternatives 1 and 3. Alternatives 3M, 4 and 5 go 80 MMBF to 40 MMBF respectively. Alternative 6 would have no harvest during the next decade.

	Exist Level	Alt #1	Alt #2	Alt #3	Alt #3-M	Alt #4	Alt #5	Alt #6
ASQ volume (MMBF/year)	60 Potential Yield	11	13	11	8	6	4	0

This issue drew major disagreement by those who commented on timber harvest. A local organized group called CUFF (Citizens For A User Friendly Forest), congressionals, legislators, county commissioners and many locals wanted more allowable sale quantity (ASQ), comments said the allowable sale quantity should be between 8 MMBF and 20 MMBF when specific numbers were used. Environmental groups wanted us to retain the ASQ of 3.7 MMBF as proposed in the DEIS, with more proposed wilderness and no below cost timber sales. A few people who commented wanted more firewood, especially for businesses.

Letters from some local elected officials in the Upper Snake River Valley, expressed concern over the future of the timber industry in the Upper Snake River Valley. They asked us to take another look at how various constraints on the suitable timber acres were applied in our analysis in the DEIS, and to select an alternative that assures a sustainable level of harvest but accomplishes harvest in an environmentally sound and aesthetically pleasing way.

Between the draft and final EIS, we found the model that estimates ASQ had been constrained more than necessary to model the effects of standards and guidelines, particularly the constraint on acres hydrologically disturbed in a watershed and the constraint to meet goshawk habitat needs. The limits on which acres could be available for harvest and meet the management direction for each alternative had been applied too narrowly. The model was changed, resulting in almost twice as many acres available for harvest in the next decade. This increase in acres also results in about twice as much timber volume estimated to be available. These changes are proportionately the same for all alternatives considered in the draft EIS. This re-analysis is summarized in Chapters II and IV of the final EIS. Details can be found in Process Paper B.

Although the acres available for timber harvest and corresponding volume estimates doubled from those disclosed in the draft EIS, the percent of the total forested acres that are proposed for treatment changed from about 1.0 to 1.5 percent, while the percent of tentatively suitable acres changed from 1.5 percent proposed in the draft EIS to approximately 3.0 in the final EIS. It was because of the comments received on the draft EIS that the change was made. Because the change is in how the management direction was modelled, and not a substantial change in the proposed action, I determined this was not significant new information that would require preparation of a supplemental draft EIS. The changes are proportionately the same for all alternatives considered, so the comparison of the effects is still proportionally the same as displayed in the draft EIS. In addition, the small percentage change in the forested acres treated did not significantly change the environmental effects displayed in the draft EIS.

The salvage operations of the 1980s, combined with the Endangered Species Act, the Grizzly Bear Recovery Plan and Guidelines, ecosystem management principles, the reduced availability of dead lodgepole, increased knowledge about the impacts of motorized use of roads and trails upon the Forest's resources, and other factors described in the final EIS, result in a reduced availability of timber for harvest for the next decade, when compared to the 860 MMBF allowed in the 1985 Plan for the past decade. This is why the allowable sale quantity has been calculated at 80 MMBF for the next 10 years in the selected Alternative 3M. The amount of firewood estimated to be available in the next decade is 38 MMBF.

Other Decision Factors

The following issues are important, but the key indicators did not vary much among the alternatives considered. An overview of the response to the comments received is given here. I encourage readers to review Appendix A of the final EIS where detailed responses to all substantive issues posed by those who commented on the draft documents can be found.

Old Growth

As described in the Final EIS, there are several reasons why responsible management should include retaining old growth forest areas. Of concern is how much old growth occurs on the Forest, how much land to retain in an old growth stage, and what constitutes old growth.

To respond to public comments, an analysis of 412 permanent forest inventory plots was completed to assess what percentage of the forested acres meet the old growth characteristics as described in the Intermountain Region Old Growth publication (see Process Paper D). Several guidelines were added to the final Revised Plan that apply to the management and retention of old growth and late seral forested areas. These include management direction for the retention of coarse woody debris and the inventory

and assessment of old growth and late seral forest stages during project planning. Identification of replacement forested acres to provide future old growth areas is planned in case a catastrophic event reduces the level of old growth below the minimum amount desired in a watershed.

Winter Range

Winter range for deer and elk is an integral part of the Targhee National Forest. Several people who commented stated that cross country snowmobiling should be restricted in winter range. Some letters requested crucial winter range for moose be designated.

The Forest staff met with representatives from both Idaho and Wyoming State Fish and Game Departments and agreed on the boundaries of crucial winter range on the Forest. Motorized cross country snowmobile restrictions were applied to these areas. I have included these refinements in Alternative 3M. They are displayed on map #24 of the final EIS map package.

Goshawks

Goshawks are a sensitive species that use much of the Forest for nesting and foraging. We received letters stating the guidelines in the Draft Plan were too restrictive and not restrictive enough, and that we should use or not use the southwest guidelines developed to provide for goshawk habitat.

Following re-analysis of the guidelines, additional literature review and examination of forest inventory data, I have decided to keep the guidelines in the final Revised Plan essentially the same as in the draft. I did make some minor changes in snag numbers and management opportunities within goshawk territories. These are patterned after the Southwest guidelines and meet goshawk habitat needs in all alternatives.

Bighorn Sheep

Maintaining historical habitat for bighorn sheep and preventing potential conflicts between domestic sheep and bighorn sheep was of considerable concern to some local biologists. Concerns included disease transfer potential, recreational use levels and lack of prescribed fire as a management tool to maintain historic ranges.

A task group composed of Forest personnel reviewed current literature, mapped bighorn sheep locations in relation to domestic sheep allotments and conducted telephone conversations with veterinarians with experience in this subject. Current restrictions within allotment management plans in bighorn sheep habitat areas reduce risk of disease transmission to low levels. However, some risk of disease transmission exists wherever bighorn sheep can come in nose to nose contact with domestic sheep.

Therefore, based on this additional review, I have decided to phase out domestic sheep grazing on an opportunity basis. This means that as sheep grazing permits expire, they will not be renewed in areas of the forest that currently support populations of bighorn sheep. This reduction amounts to approximately 2,600 AUMs on five allotments and one permit. There are two allotments within both grizzly bear and bighorn sheep habitat that will also be phased out on an opportunity basis and this reduction is about 1,800 AUMs.

Motorized Game Retrieval

Many comments on this issue opposed motorized game retrieval for similar reasons as some Forest employees. They are difficult to enforce, favoritism is perceived for hunters with off-highway vehicles, and obtaining the required permit is impractical in most situations. I have decided not to include this concept in the final Revised Plan.

Snowmobiling and Heliskiing

Many comments (over 500 letters were received before the official comment period began) opposed restricting snowmachines to designated trails in the grizzly bear units before Dec 15 and after April 1. Some groups wanted unrestricted cross-country snowmobile use, except in winter range, while others wanted no snowmachines, heliskiing, or any motorized use in roadless areas proposed as wilderness. Heliskiing companies and patrons want to be allowed to use roadless areas that are proposed for wilderness, especially in the Palisades area.

To address the issue a Forest task group reviewed data between draft and final documents to determine the average grizzly denning time for the area, location of dens (including an analysis done with information available on the geographic information system (GIS) to identify areas of high denning potential), and the number of conflicts that have been recorded between grizzly bears and snowmachines.

Based on this analysis, I have deleted the seasonal cross-country snowmobile restriction from all grizzly bear management prescriptions and replaced it with a standard to develop site-specific restrictions to resolve potential conflicts with grizzly bears during their denning time. I did this because we are not aware of any recent conflicts, and most of the area in question is not particularly desirable grizzly bear denning habitat. Desirable denning habitat is usually on steep slopes in timbered areas, typically not the area where most cross-country snowmobile use occurs. Problems identified can be addressed with site-specific analysis and restrictions as necessary. The US Fish and Wildlife Service concurred with this analysis in their Biological Opinion.

Centennial Mountain Range

Several comments opposed vegetation management in this area, particularly timber removal of Douglas-fir to regenerate decadent aspen. A large number of comments recommended this area be preserved as a wildlife corridor (primarily for grizzly bears and wolves) between Yellowstone National Park and other Montana, Wyoming and Idaho roadless areas. The Greater Yellowstone Coalition and many of their members submitted a new management prescription for the Centennial range to address this concern.

Habitat connectivity is important. After comparing the Grizzly Bear Recovery Plan with Alternative 3M, I conclude the activities that could occur in the Centennials will maintain this area as a potential linkage zone. The Recovery Plan also says that management prescriptions to maintain linkage potential should be similar to big game summer range prescriptions that address access management. The management prescriptions applied to this area in Alternative 3M address habitat connectivity by providing appropriate road density standards and maintaining ecosystem compositions to provide wildlife security cover. Except for some minor boundary refinements because of the updated roadless inventory, I have decided to keep the management prescriptions for the Centennial Mountain Range the same as those disclosed in the draft EIS.

Native American Treaty Rights

Government to government consultation was conducted with the Shoshone-Bannock Tribe on both the draft and final Revised Plan. We received formal substantive comments from the Shoshone-Bannock Tribe on the draft documents. Most of the comments were critical of the consideration given to Native American treaty rights. Forest personnel and Tribal members have different interpretations. The Tribes interpret their legal right to hunt, to include fishing and gathering and harvest of wood products owned by the Federal government. Following a review of the Fort Bridger Treaty and the relevant case law, it has been determined that the treaty rights do not encompass the gathering of wood products. No changes were made from the draft documents to address the gathering of wood products, and the Revised Plan does not infringe on Native American Treaty Rights.

Other comments received from the Shoshone-Bannock Tribe concerned access, cultural resource sites on grazing allotments and planning. A forestwide standard has been added to the final Revised Plan to address Tribal coordination. Procedures were also added to assure protection of cultural resources on grazing allotments.

Interior Columbia Basin Ecosystem Management Project

Some public comments questioned the relationship of the Revision with the Interior Columbia Basin Ecosystem Management Project science and EIS efforts. The Revision included appropriate parts of the scientific assessment. The Upper Columbia River Basin EIS decisions will not cover the Targhee National Forest.

FINDINGS REQUIRED BY OTHER LAWS

I have considered the multitude of statutes governing management of the Targhee National Forest and believe Alternative 3M is the best possible approach to harmonizing the current statutory duties of the Forest Service. Specific findings follow.

The Targhee Revised Plan is in compliance with the Clean Water Act because of the conclusions presented in Chapter IV, water quality section of the FEIS.

The Targhee Revised Plan is in compliance with the National Historic Preservation Act because of the conclusions presented in Chapter IV, Heritage Resource section of the FEIS.

The Targhee Revised Plan is in compliance with the Endangered Species Act and the US Fish and Wildlife Service Biological Opinion because of the conclusions presented in Chapter IV, Wildlife section of the FEIS. The US Fish and Wildlife Service (Service) has determined that the Revised Forest Plan may affect but is not likely to adversely affect the threatened bald eagle, Ute ladies'-tresses and the endangered peregrine falcon. The Service concurs that the Revised Forest Plan will not jeopardize the continued existence of the experimental, non-essential population of gray wolf. The Service has also determined that the implementation of the Revised Forest Plan is not likely to jeopardize the continued existence of the Greater Yellowstone Ecosystem grizzly bear population. No critical habitat has been designated for the grizzly bear, therefore, none will be affected.

~~The Targhee Revised Plan is in compliance with the Clean Air Standards because of the conclusions presented in Chapter IV, Air Resources section of the FEIS.~~

The Environmentally Preferred Alternative

Although Alternative 6 would allow the fewest ground disturbing activities, I am identifying the selected Alternative 3M as environmentally preferable based on the following interpretation of the law and agency policy.

Regulations implementing the National Environmental Policy Act (NEPA) require agencies to specify the alternative or alternatives which were considered to be environmentally preferable (40 CFR 1505.2(b)). Forest Service policy further defines environmentally preferable as an alternative that best meets the goals of section 101 of NEPA. Ordinarily this is the alternative that causes the least damage to the biological and physical environment and best protects, preserves, and enhances historical, cultural, and natural resources. In some cases there may be more than one environmentally preferable alternative (FSH 1909.15-05).

Section 101 of NEPA declares national environmental policy, calling on federal, state and local governments and the public to create and maintain conditions under which humans and nature can exist in productive harmony. This broad policy is further defined in six goals.

(1) fulfill the responsibilities of each generation as trustee of the environment for succeeding generations,

(2) assure for all Americans safe, healthful, productive, and aesthetically and culturally pleasing surroundings,

(3) attain the widest range of beneficial uses of the environment without degradation, risk to health or safety, or other undesirable and unintended consequences,

(4) preserve important historic, cultural, and natural aspects of our national heritage and maintain wherever possible an environment which supports diversity and variety of individual choice,

(5) achieve a balance between population and resource use which will permit high standards of living and a wide sharing of life's amenities, and

(6) enhance the quality of renewable resources and approach the maximum attainable recycling of depletable resources

The goals of Section 101 are similar to the principles of ecosystem management and of this Revised Plan, calling for sustainable and balanced use, and provision for future generations. Section 101 does not call for the exclusion of Americans from use of their natural resources, but does demand that such uses avoid degradation of the environment. Alternative 3M best meets the goals of Section 101 of NEPA. By this standard, the selected Alternative 3M is the environmentally preferable alternative for the Revised Targhee Forest Plan.

IMPLEMENTATION

The Forest Supervisor will accomplish many management activities to implement the Revised Forest Plan. Unlike the programmatic decisions listed above, these activities are site-specific and require analysis and disclosure of the activity's effects under the National Environmental Policy Act (NEPA). These site-specific analyses will be done during implementation of the Revised Forest Plan.

Forest plans are permissive in that they allow, but do not mandate, certain activities to occur. Site-specific analysis of proposed activities will determine what can be accomplished. The outputs specified in the Revised Plan are estimates and projections based on available information, inventory data and assumptions.

All activities, many of which are interdependent, may be affected by annual budgets. The Revised Plan is implemented through various site-specific projects such as wildlife habitat improvements, campground development, road building and timber sales. Budget allocations for any given year may require re-scheduling projects. However, the desired future conditions, goals, objectives, standards and guidelines and management prescriptions described in the Revised Plan may not change unless the Plan is amended. If, over time, funds received are significantly different from those necessary to implement the Revised Plan, the Plan may need to be amended. This would likely reflect different outputs and environmental conditions from those disclosed in this revision analysis.

Implementation of this decision will occur 30 days following publication of the notice of this decision in the Federal Register. Resource plans, permits, contracts, and other instruments, when necessary, shall be revised as soon as practicable to incorporate the revised management direction.

As one of the first steps to implement this Revised Plan, the Targhee National Forest Supervisor will issue a separate Record of Decision for Travel Management that designates which roads and trails are open for motorized use. I am deciding now which standards, by management prescription area, apply to meet the desired open road and trail densities.

The proposed open motorized roads and trails are displayed on summer and winter access maps for Alternative 3M. A separate Travel Plan map will be available when Supervisor Reese makes his implementation decision.

APPEAL

This decision is subject to appeal pursuant to the provisions of 36 CFR 217. A written notice of appeal must be filed within 90 days following the date of publication of this decision in the Federal Register. The appeal must be filed with the reviewing officer.

Chief, USDA - Forest Service
14th and Independence, SW
201 14th Street
Washington, DC 20250

A copy of the appeal must simultaneously be sent to the deciding officer.

Regional Forester, Intermountain Region
USDA - Forest Service
324 25th Street
Ogden, UT 84401

Notice of appeal must include sufficient narrative evidence and argument to show why this decision should be changed or reversed (36 CFR 217.9). Requests to stay approval of the Revised Forest Plan will not be granted (36 CFR 217.10(a)).

Decisions on site-specific projects are not made in this Revised Forest Plan. Final decisions on proposed projects will be made after site-specific analysis and documentation in compliance with NEPA, and are subject to appeal at that time. Recommended wilderness designations contained in the Revised Forest Plan are nonbinding recommendations and not a decision within the context of appeal regulation and are not subject to appeal (36 CFR 217.4(4)).

More information on the final EIS and Revised Forest Plan may be obtained by contacting the Targhee National Forest Supervisor in St. Anthony, ID. Reviewers are encouraged to check with the Forest Supervisor on the Revised Forest Plan decisions before submitting appeals to determine if concerns or misunderstandings can be clarified or resolved.

Forest Supervisor, Targhee National Forest
USDA - Forest Service
420 N. Bridge Street
St. Anthony, ID 83445

CONCLUSION

I am pleased to announce this decision and bring the Forest Plan Revision to its beginning. This Revised Forest Plan is a framework for the present and a positive direction for the future. Now is the challenge before us all to work together, the public, Forest Service, ranchers, conservationists, preservationists, snowmobilers, campers, hunters, timber industry, and all of the others who have an interest in Forest management. Together, we must overcome the challenges, realize the opportunities, and achieve the goals and objectives of this Forest Plan.

We are committed to the philosophy of adaptive management as we work together to implement this Plan. We will monitor our activities, the condition of the land as projects are completed, the products produced, and the effectiveness of the resource protection measures included in the Revised Plan. Most importantly, this Plan is our commitment to the future to ensure healthy, resilient ecosystems for the next generation.

DALE N. BOSWORTH

Dear Participant.

Enclosed is a copy of the Draft Environmental Impact Statement (DEIS) for the Targhee National Forest Open Road and Open Motorized Trail Analysis. The primary purpose of the DEIS is to outline the proposed management of summer motorized travel on the Forest and consider alternatives to that proposal. The decision and management direction from the Final EIS for this process will be used to implement a new Travel Plan on the Forest in the summer of 1999.

I appreciate the comments many of you have provided which have been considered and used as we developed this analysis and documentation. The analysis in this DEIS is based on much of the analysis in the 1997 Revised Forest Plan FEIS, and references are provided to that FEIS. Copies of the Revised Forest Plan FEIS are available upon request.

Your review and comments on this DEIS are important to the analysis process. In your review, I encourage you to pay particular attention to concerns you may have raised earlier, to see if the analysis is responsive. Comments on the DEIS should be as specific as possible and must be received no later than February 1, 1999.

It would be helpful to know the reasons for your comments to help us make better, informed decisions. Positive comments about portions that are acceptable to you would also be appreciated. After the comment period ends, the comments will be analyzed and the Final EIS and Record of Decision will be prepared and issued.

You can also find the document on the Internet at <http://www.fs.fed.us/tnf/> and comments can be sent by e-mail to pcomment/r4_targhee@fs.fed.us

If you have questions or comments, please contact me or Alan Silker, Recreation Staff, at P O Box 208, St Anthony, ID 83445 or call (208) 624-3151

Sincerely,

JERRY B. REESE
Forest Supervisor

ABSTRACT This Draft Environmental Impact Statement (DEIS) documents the analysis of four alternatives, which were developed for possible management of summer motorized road and trail travel on the 18 million acres administered by the Targhee National Forest. Alternatives analyzed in detail are identified as 1M, 3M(+), 3M, and 3M(-). Alternative 3M(+) is identified as the preferred alternative.

The alternative ultimately chosen may change based on input from the public, other agencies, and this agency's own internal deliberation process. That alternative, selected by the Forest Supervisor, will be published in a Final EIS, and will become the basis for the Forest Travel Plan to be issued in the summer of 1999.

Date of transmission of this DEIS to the Environmental Protection Agency (EPA) and the public is November 20, 1998. Send comments regarding this DEIS to the Forest Supervisor, Targhee National Forest, at the above address by February 1, 1999. The comment period for this DEIS will be 60 days from the date the EPA publishes the Notice of Availability in the Federal Register.

Reviewers should provide the Forest Service with their comments during the review period of the draft environmental impact statement. This will enable the Forest Service to analyze and respond to the comments at one time and to use information acquired in the preparation of the final environmental impact statement, thus avoiding undue delay in the decisionmaking process. Reviewers have an obligation to structure their participation in the National Environmental Policy Act process so that it is meaningful and alerts the agency to the reviewers' position and contentions. Vermont Yankee Nuclear Power Corp v NRDC, 435 U.S. 519, 553 (1978). Environmental objections that could have been raised at the draft stage may be waived if not raised until after completion of the final environmental impact statement. City of Angoon v Hodel (9th Circuit, 1986) and Wisconsin Heritages, Inc v Harris, 490 F. Supp. 1334, 1338 (E.D. Wis. 1980). Comments on the draft environmental impact statement

should be specific and should address the adequacy of the statement and the merits of the alternatives discussed (40 CFR 1503.3)

To assist the Forest Service in identifying and considering issues and concerns on the proposed action, comments on the DEIS should be as specific as possible. It is also helpful if comments refer to specific pages or chapters of the DEIS. Comments may also address the adequacy of the DEIS or the merits of the alternatives formulated and discussed in the DEIS. Reviewers may wish to refer to the Council on Environmental Quality Regulations for implementing and procedural provisions of the National Environmental Policy Act at 40 CFR 1503.3 in addressing these points.

Please note that comments on the DEIS will be regarded as public information.

The U.S. Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, gender, religion, age, disability, political beliefs, sexual orientation, and marital or family status. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact USDA's TARGET Center at 202-720-2600 (voice and TDD).

To file a complaint of discrimination, write USDA, Director, Office of Civil Rights, Room 326-W, Whitten Building, 14th and Independence Avenue, SW, Washington, DC 20250-9410 or call (202) 720-5964 (voice or TDD). USDA is an equal opportunity provider and employer.

Summary

SUMMARY OF THE DRAFT ENVIRONMENTAL IMPACT STATEMENT FOR THE TARGHEE FOREST - OPEN ROAD AND MOTORIZED TRAIL ANALYSIS (Motorized Road and Trail Travel Plan)

NOTE to READERS Please refer to the 1997 Revised Forest Plan for a "Glossary" of terms used in this document

INTRODUCTION

The purpose of this document is to consider alternatives for and disclose the environmental effects of a Forest Travel Plan that will implement the 1997 Revised Forest Plan direction for the Targhee National Forest. The purpose of this Travel Plan is to offer a balanced network of summer motorized roads and trails that meet the Forest's transportation needs and the open motorized road and trail route density standards in the Revised Forest Plan. The need for this analysis and decision was directed by the Regional Forester in his 4/15/97 Record of Decision for the Revised Forest Plan (ROD - pages 22 and 30). This is one of the first steps needed to meet the objectives in the Revised Forest Plan and move the Targhee National Forest toward the desired future conditions of that Plan. In accordance with the Regional Forester's direction, no decision contained in the Revised Forest Plan will be changed, reversed, or superceded by the decision that will result from this analysis. Therefore, it should be understood that winter travel and summer, cross-country travel as decided in the Revised Forest Plan will also be displayed in the final Travel Plan along with the open roads and trails determined from this analysis.

The Forest Supervisor will decide which combination of roads and trails will be open for summer motorized use to remain within the density standards specified by management prescriptions in the Revised Forest Plan. This Draft Environmental Impact statement (DEIS) will summarize and review the previous (1997) open motorized road and trail decision and consider alternative actions that would remain within the direction of the Revised Forest Plan and respond to the issues raised. The analysis in this DEIS is based on much of the analysis in the 1997 Revised Forest Plan (RFP) Final Environmental Impact Statement (FEIS), and references that document. Throughout this DEIS, references to the RFP-FEIS will be indicated by (RFP-FEIS, page x,y,z). Copies of the RFP-FEIS are available from the Targhee National Forest Supervisor's Office.

LOCATION AND SETTING

The Targhee National Forest (hereinafter usually referred to as "the Forest") is an administrative unit of the US Department of Agriculture, Forest Service. The Forest lies almost entirely within the "Greater Yellowstone Area" (GYA). The Forest encompasses approximately 1.8 million acres. Established by President Theodore Roosevelt in 1908, the Forest is named in honor of a Bannock Indian warrior. The Shoshone-Bannock Tribe has ancestral Treaty Rights to uses of the Forest. The Forest Supervisor's Office is located in St. Anthony, Idaho, with District offices located in Dubois, Island Park, Ashton, Idaho Falls, and Driggs, Idaho. The Forest is bordered by six other National Forests (NF). This DEIS addresses travel on the Targhee National Forest and the portions of the Bridger-Teton and Caribou National Forests administered by the Targhee Forest.

The majority of the Forest lies in eastern Idaho, and the remainder in western Wyoming (Figure S-1). Situated next to Yellowstone National Park (the Park) and Grand Teton National Park (GTNP), the Forest is home to a diverse number of wildlife and fish (including Threatened and Endangered species), and contains two designated wildernesses, scenic panoramas and intensively managed forest lands (RFP-FEIS, p. I-1-2).

**Vicinity Map of Targhee National Forest
on a National Scale**

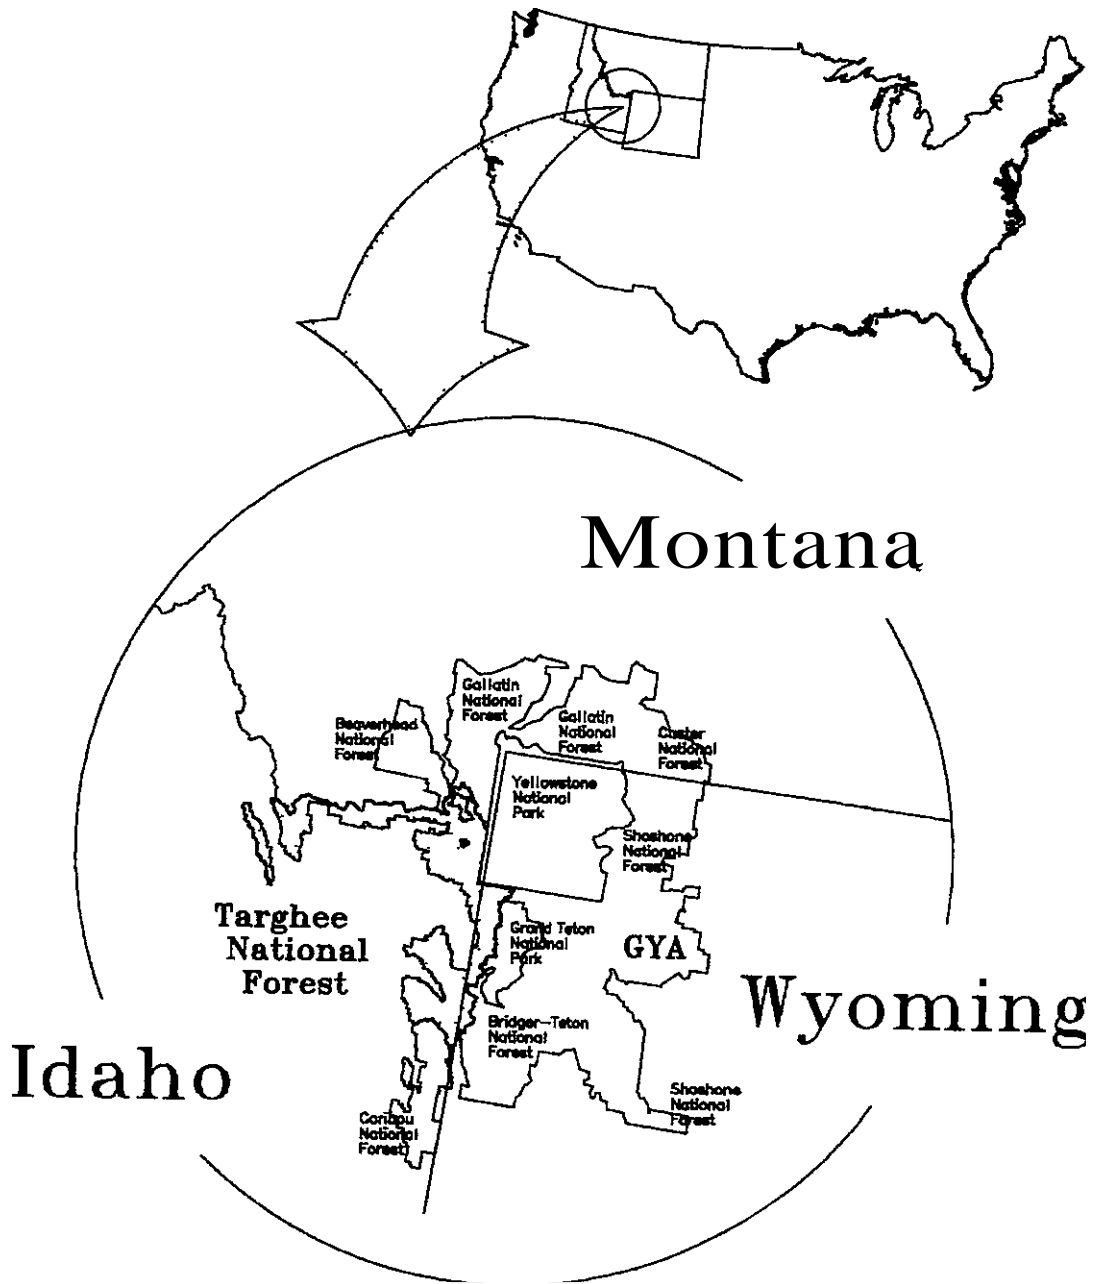

Figure I-1

ISSUES

The key issues identified through scoping are summarized as follows

- Adverse effects of specific roads and trails open for summer motorized travel on wildlife and fisheries (cutthroat trout) and their habitat, on roadless areas and recommended wilderness, and on water quality These specific roads and trails were identified on an overlay of the 1997 Travel Plan map for reference in the analysis These maps are on file in the Forest Supervisor's Office in the analysis records
 - Adverse effects of specific closed roads and trails on recreational and other access opportunities These specific roads and trails were identified on the same map overlays as described above for use in this analysis
- Revised Statute 2477 (RS 2477) road access This issue involves potential access rights the Counties may have on roads and trails that may have existed prior to the establishment of the Forest The assertions by the Counties that were available were mapped (see map #1 in map packet) for consideration in this analysis

The following public comments were also received and considered They were addressed in the Revised Forest Plan analysis, or are considered procedural comments and therefore will not be directly addressed in this analysis

- A broad, programmatic document was used to make site-specific decisions on road closures
- No new roads should be built, and existing roads should be decommissioned and rehabilitated
- Existing trails should not be reconstructed for OHV (<50") use
 - Accessibility needs to be addressed better for the less-abled
- Range of alternatives considered in the Revised Forest Plan FEIS and Travel Plan RODs was not adequate, and road density factors used were too constraining, or not constraining enough
- Appendix C Update and Draft Travel Plan need to be available for public review and comment

ALTERNATIVES CONSIDERED

Based on available data, public issues and the Final EIS for the Revised Forest Plan, four alternatives were considered and analyzed in detail Alternative 3M presented below is the same alternative as considered in the Revised Forest Plan FEIS (pages 11-34 and II-7-8) and in the ROD for the 1997 Open Road and Open Motorized Trail Travel Plan (ROD - page 4) Three new alternatives (3M+, 3M-, and 1M) have been created based on issues described previously, which resulted from consideration of public issues and appeals These issues were mapped as stated in Chapter 1-Issues, and these overlay maps are on file in the Forest Supervisor's Office These working maps are available for review Alternatives 3M(+) and 3M(-) are in response to specific public issues and appeals and, represent minor additions (+) or deletions (-) to the 3M alternative Alternative 1M is the existing situation as modified by the Regional Forester's remand. These alternatives only address summer access for roads and trails, since winter travel and summer cross-country access were already decided in the Revised Forest Plan

The four alternatives considered are briefly described as follows

- Alternative 1(M) - "No Action" - This alternative is based on the existing situation This alternative would leave the open, motorized roads and trails of the 1994/96 Travel Plans (old brown maps) in place for all of the Forest outside the bear management units (BMUs) Inside the BMUs, (see Figure III-6 in RFP-FEIS, page 11155) travel would be according to the Revised Forest Plan (Alternative 3M) Forest-wide, summer, cross-country travel would also be according to the Revised Forest Plan (Alternative 3M) This alternative is displayed on the summer transportation map (map #2) Approximately 2,077 miles of open, motorized road, 51 miles of seasonally restricted road, 467 miles of decommissioned roads, and 725 miles of open, motorized trail are included in this alternative (Table S-1) Appendix C(M) to this DEIS describes which roads and trails remain

open to motorized use and the reasons why routes were selected as open or closed. This alternative would not be consistent with the Revised Forest Plan and would require a plan amendment to the open road and open motorized trail density standards to be implemented. Its purpose here is to provide a baseline to compare site-specific effects with the other alternatives being considered.

- **Alternative 3M** - This alternative is the 1997 Travel Plan (summer - roads, trails and cross-country travel) as displayed by the summer Transportation Plan (map #3 - see map packet) for Alternative 3M in the Revised Forest Plan FEIS. This alternative has 1,617 miles of open, motorized road, 62 miles of seasonally restricted road, 939 miles of decommissioned roads, and 511 miles of open, motorized trail. Appendix C (1998 Update) and C(M) to this DEIS describes which roads and trails remain open to motorized use and the reasons why roads were selected as open or closed for each alternative. The 1997 Appendix C Update and the roads and trails GIS data layer were corrected (Appendix C-1998 Update) to delete duplicate segments, and to make other minor edits. These corrections resulted in approximately 40 miles of additional road inventory. It was discovered during this analysis, that road density for this alternative was below densities allowed for some prescription areas and lower than calculated in the RFP-FEIS. This is mostly due to GIS query data errors. It is also partially due to topography limitations and the design of prescription densities being just an initial goal to guide planning. During mapping of the alternative there was also a conscious effort to leave room for management flexibility, e.g. - by not pushing elk vulnerability to the limit.
- **Alternative 3M(+)** - **PREFERRED ALTERNATIVE** - This alternative includes additional open roads and trails to those in Alternative 3M, but is still within the road density standards of 3M as decided in the Revised Forest Plan. Alternative 3M(+) is displayed on Summer Transportation map #4. As noted in Alternative 3M, it was discovered in this analysis that road density of 3M was below the level allowed for some of the prescription areas. Therefore, roads and trails were added in this alternative to respond to some of the specific requests in public comment and appeal records as noted on the overlay maps (appeals) and RS 2477 maps.

The roads and trails added are shown in green on Map #4 in the map packet. This alternative has 1,672 miles of open, motorized road, 70 miles of seasonally restricted road, 984 miles of decommissioned roads, and 536 miles of open, motorized trail. Appendix C(M) to this DEIS describes which roads and trails remain open to motorized use and the reasons why routes were selected as open or closed. The total miles of open, motorized roads and trails in this alternative are similar to Alternative 3 in the Plan Revision FEIS, but the open roads and trails are in different locations. Summer, cross-country travel would be the same as Alternative 3M from the Revised Forest Plan.

This alternative has the same prescription areas as Alternative 3M, and road densities are within the prescription (Rx) density allowed, except as shown in Table S-2. Implementation of a new Travel Plan under this preferred Alternative (3M+) requires a minor amendment to the 1997 Forest Plan revision to cover the following, specific road density changes (Table S-2) for individual prescription areas which would vary from the Forest Plan prescription Access Tables (OROMTRD allowed).

All of the densities and associated motorized routes in Table S-2 were shown and approved in the Revised Forest Plan (Alternative 3M) Transportation Plan Map #11, except the Moody Creek road (80251). The Moody Creek change is in response to an RS 2477 assertion. Motorized use was approved by the RFP-FEIS in Indian Creek and was intended to be unrestricted as shown in the RFP-DEIS footnote, but when the footnote was prepared for the RFP-FEIS, an incorrect OROMTRD of 0.2 miles per square miles was put in the footnote to the Access Table. The working copy of the OROMTRD density map dated December, 1997 actually showed a density of 0.5 miles and all of the motorized routes in that density were displayed in the Transportation Plan for Alternative 3M.

Many of the variances occur to accommodate roads running along or through small prescription areas (approximately 5 square miles or less) which are affected disproportionately by their presence.

Table S -1 Comparison of Environmental Effects by Key Issue Indicators

Indicator	Issue	Alt 1(M)	Alt 3M(+)	Alt 3M	Alt 3M(-)
ROADS (miles)	Access				
Open		2,077	1,672	1,617	1,613

	Indian Cr	1 2	0 2	0 5	Access Table error - RFP
	Sheep Cr	3 2(d)	1 0	1 8	Small Rx area
	Poker Peak	3 1 1(a)	0 0	0 1	Adjacent road

A Travel Plan (map and Restriction Order) would be developed and implemented using the same format as the 1997 Travel Plan Map. The Travel Plan would include the details from the Transportation Plan (map #4 of map packet) for this alternative along with the 1998 Travel Plan Addendum (Appendix A), and road, trail, and cross-country matrices. This procedure will be followed using the appropriate data and maps for any alternative selected in the final EIS.

- **Alternative 3M(-)** - This alternative has slightly fewer open roads/trails than Alternative 3M. This alternative is essentially the same as Alternative 3M, but with the reduction of specific open roads and trails as requested in public comment and appeal records. Roads and trails were eliminated in response to some of the specific requests noted on the overlay maps described previously in the issues analysis. The roads and trails eliminated are shown in red on map #5 in the map packet. This alternative has the same prescription areas as Alternative 3M and 3M(+), but road densities are lower in several prescription areas than in Alternative 3M. This alternative is similar to Alternative 4 in the Plan Revision FEIS in total open motorized roads and trails, but the roads and trails are in different locations. Summer, cross-country travel is the same as Alternative 3M from the Revised Forest Plan. The Transportation Plan for this alternative is enclosed in the map packet for this DEIS as map #5. This alternative has 1,613 miles of open, motorized road, 62 miles of seasonally restricted roads, 989 miles of decommissioned roads, and 454 miles of open, motorized trail. Appendix C(M) to this DEIS describes which roads and trails remain open to motorized use and the reasons why routes were selected as open or closed.

ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED STUDY

Other alternatives were considered that would address additional requests for opening or closing road and trail segments beyond the maximum road density or significantly below the density allowed for prescriptions. The formal administrative appeal requests and public comments were mapped and reviewed for alternative consideration and development as described in the issues analysis and Alternatives 3M(+) and 3M(-) above. Our analysis of these options was found to match the same range of alternatives considered in the Revised Forest Plan FEIS. For example, an alternative with more open roads and trails than 3M is represented by Alternatives 1, 2, and 3 of that FEIS. An alternative with fewer open roads and trails would be represented by Alternatives 4, 5, and 6. Since an infinite array of alternatives could be constructed from issues indicated by the comments and appeals, and since

that array has already been considered in the previous FEIS, it would not be helpful to reconstruct those alternatives in this analysis

Furthermore, any alternative with a higher road/trail density than allowed by the Revised Forest Plan prescription direction would be outside the standards established in the Revised Forest Plan and contrary to the Purpose and Need for this decision. The scope of this analysis is limited to alternatives that meet the open road and open motorized trail density standards decided in the recently revised Forest Plan, as directed by the Regional Forester (remand letter of 1/14/98). Because these density standards have recently been decided, whether they should be adjusted is not ripe for decision at this time. Effectiveness monitoring is a requirement of the Revised Forest Plan. An evaluation of the effectiveness of these road density standards will be made at appropriate intervals in the annual monitoring plan report.

ANALYSIS AND CONCLUSIONS

As indicated in the Alternative 3M description, the 1997 Appendix C was updated for the seven alternatives originally considered in the Revised Forest Plan to show reasons roads and trails were open or closed. This analysis formed the basis for a new Appendix C(M) which was developed to analyze the four alternatives for this EIS. Each road and trail was considered and reasons for open or closed status were documented for each specific road or trail for each alternative. This resource analysis is further documented in each resource consequences section in Chapter IV of this EIS.

The consequences analysis indicates that the Preferred Alternative (3M+) has slightly higher impact potential than Alternative 3M as described in the Revised Forest Plan. Alternative 3M(+) addresses some of the RS 2477 assertions and other specific open road concerns. However, the analysis indicates this alternative will still not have significant effects on soil, vegetation, water quality, or fish habitat except in minor, localized areas. The analysis also indicates that potential effects of motorized road and trail density on grizzly bear and elk habitat will be within one or two percent change of the levels determined in the Revised Forest Plan FEIS (RFP-FEIS).

Chapter

Purpose and Need for a Travel Plan Revision

CHAPTER I

PURPOSE AND NEED

READER'S GUIDE - In this chapter you will find:

- BACKGROUND INFORMATION
- LOCATION AND SETTING
- PURPOSE AND NEED

NOTE to READERS Please refer to the 1997 Revised Forest Plan for a "Glossary" of terms used in this document

BACKGROUND INFORMATION

On April 15, 1997, the Intermountain Regional Forester issued a Record of Decision (ROD) for the 1997 Revised Forest Plan for the Targhee National Forest. This Revised Forest Plan contained travel management direction in the form of winter and summer Transportation Plans (open, motorized roads and trails) and management prescription direction for road density and cross-country travel. During the summer of 1997 a final Travel Map was prepared to represent this management direction and specifically to disclose which roads and trails would be open for motorized use to meet the road density standards specified in the Revised Forest Plan. The 1997 Travel Map was approved by a Record of Decision (ROD) signed August 15, 1997, by Targhee Forest Supervisor, Jerry Reese.

The August 15, 1997 decision for the Travel Map was appealed to the Regional Forester by individuals and groups representing both sides of the issues. Most of the appeals resulted from issuance of an "Updated Appendix C - Summer and Winter Access", which displayed the roads and trails to remain open to motorized travel. The same list of roads and trails was included as the original "Appendix C" in the RFP-FEIS. This Appendix C Update contained minor edits and revisions that were done to correct duplications of listings and to delete or add minor road segments in the Transportation Plan Map for Alternative 3-M (selected alternative) in the Plan Revision Final Environmental Impact Statement (FEIS). This update did not change the road and trail data or maps that were used in that analysis. On January 14, 1998, the Intermountain Regional Forester reversed (remand letter of 1/14/98) the Travel Map decision and directed that a supplemental environmental analysis be prepared and disclosed. The basis for his appeal decision was

- Some procedural requirements for public involvement had not been fully met, specifically, some people may not have understood the decision to be made in the Travel Map and may not have had adequate opportunity to review and comment on the site-specific actions indicated in the Appendix C Update (1997 Travel Plan ROD)
- The roles of the counties and the Forest Service in management of roads with RS 2477 assertions were not completely assessed and analyzed

This DEIS is tiered to and will refer to and incorporate much of the analysis from the 1997 Revised Forest Plan FEIS. This DEIS will also document subsequent analysis concerning affected environment and environmental consequences of alternatives developed in response to comments and issues presented by interested public and agencies.

LOCATION AND SETTING

The Targhee National Forest (hereinafter usually referred to as "the Forest") is an administrative unit of the U.S. Department of Agriculture, Forest Service. The Forest lies almost entirely within the "Greater Yellowstone Area" (GYA). The Forest encompasses approximately 1.8 million acres. Established by President Theodore Roosevelt in 1908, the Forest is named in honor of a Bannock Indian warrior. The Shoshone-Bannock Tribe has ancestral Treaty Rights to uses of the Forest. The Forest Supervisor's Office is located in St. Anthony, Idaho, with District offices located in Dubois, Island Park, Ashton, Idaho Falls, and Driggs, Idaho. The Forest is bordered by six other National Forests.

(NF) This DEIS addresses travel on the Targhee National Forest and the portions of the Bridger-Teton and Caribou National Forests administered by the Targhee Forest

The majority of the Forest lies in eastern Idaho, and the remainder in western Wyoming (Figure I-1) Situated next to Yellowstone National Park (the Park) and Grand Teton National Park (GTNP), the Forest is home to a diverse number of wildlife and fish (including Threatened and Endangered species), and contains two designated wildernesses, scenic panoramas and intensively managed forest lands (RFP-FEIS, p I-1-2)

on a National Scale**

Figure I-1

PURPOSE AND NEED

Introduction

The purpose of this document is to consider alternatives for and disclose the environmental effects of a Forest Travel Plan that will implement the 1997 Revised Forest Plan direction. The purpose of this Travel Plan is to offer a balanced network of motorized road and trails that meet the Forest's transportation needs and the open motorized road and trail route density standards in the Revised Forest Plan. The need for this analysis and decision was directed by the Regional Forester in his 4/15/97 Record of Decision for the Revised Forest Plan (ROD - pages 22 and 30). This is one of the first steps needed desired future conditions of that Plan. In accordance with the Regional Forester's direction, no decision contained in the Revised Forest Plan will be changed, reversed, or superceded by the decision that will result from this analysis. Therefore, winter travel and summer, cross-country travel as decided in the Revised Forest Plan will also be displayed in the final Travel Plan along with the open roads and trails determined from this analysis.

The Forest Supervisor will decide which combination of roads and trails will be open for summer motorized use to remain within the density standards specified by management prescriptions in the Revised Forest Plan. This document will summarize and review the previous open motorized road and trail decision and consider alternative actions that would remain within the (1997) direction of the Revised Forest Plan and respond to the issues raised.

Issues

In an effort to obtain public comments and concerns, news releases were sent to area newspapers and media on February 6, and April 1, 1998. An analysis process information letter was also mailed March 24, 1998 to the approximately 1200 appellants of the 1997 Travel Pan ROD. In response to these information releases and the Notice of Intent filed in the Federal Register (March 24, 1998), we received 40 letters providing comments and suggestions for consideration in this analysis. We have summarized those comments into the following ~~issue~~ topics.

- Adverse effects of specific roads and trails open for summer motorized travel on wildlife and fisheries (cutthroat trout) and their habitat, on roadless areas and recommended wilderness, and on water quality. These specific roads and trails were identified on an overlay of the 1997 Travel Plan map for reference in the analysis. These maps are on file in the Forest Supervisor's Office in the analysis records.
- Adverse effects of specific closed roads and trails on recreational and other access opportunities. These specific roads and trails were identified on the same map overlays as described above for use in this analysis.
- RS 2477 road access. This issue involves potential access rights the Counties may have on roads and trails that may have existed prior to the establishment of the Forest. The assertions by the Counties available were mapped (see map #1 in map packet) for consideration in this analysis.

The following public comments were **also** received and considered. They were addressed in the Revised Forest Plan analysis, or are considered procedural comments and therefore will not be directly addressed in this analysis.

- A broad, programmatic document was used to make site-specific decisions on road closures.
- No new roads should be built, and existing roads should be decommissioned and rehabilitated.
- Existing trails should not be reconstructed for OHV (<50") use.
- Accessibility needs to be addressed better for the less-abled.
- Range of alternatives considered in the Revised Forest Plan FEIS and Travel Plan RODs was not adequate, and road density factors used were too constraining, or not constraining enough.

- Appendix C Update and Draft Travel Plan need to be available for public review and comment

We have reviewed all of the approximately 1,200 appeals received on the 8/15/97 Travel Plan Decision. As indicated in the issues above, we also mapped all of the requests for opening or closing roads and trails as contained in the appeals and public comments on this DEIS. The resulting overlay maps highlight existing roads and trails that were previously considered in Alternatives 1 through 6 for the Revised Forest Plan. The Revised Forest Plan scoping and issue analysis (RFP-FEIS, pages I-5-11), as well as public comments on that EIS, considered almost identical summer transportation plan maps and Appendix C analysis as contained in this new DEIS.

The public involvement Process Paper A from the RFP-FEIS is incorporated by reference. It summarizes the early public involvement efforts in the Forest Plan revision process from 1990 through 1995, until the release of the RFP-DEIS. Throughout that process roads and access were significant issues. The public involvement discussion in RFP "Appendix A, Response to Public Comments, Volume 1," is also incorporated by reference. That discussion details the extensive public involvement during the draft RFP review.

The issues concerning motorized travel and access from the Revised Forest Plan FEIS analysis were considered in relation to public issues identified from comments concerning development of this DEIS. This current analysis of specific road and trail issues indicates existence of the same polarization concerning access issues as identified during the original public scoping processes for the Revised Forest Plan.

In the Forest Plan appeals, many of the roads to be closed or decommissioned by the Revised Forest Plan, were requested to be left open, and many of the roads and trails to be left open were requested to be closed. Public comments received concerning opening or closing roads were summarized into the issue topics identified previously. The displays (map overlays) of these appeal and public comment issues are on file in the Forest Supervisor's Office and are available for review upon request. These overlay maps were used as the basis for developing new Alternatives 3M(+) and 3M(-) as described in the following alternatives section.

Chapter

Alternatives Including the Proposed Programmatic Action (Preferred Alternative)

CHAPTER II

ALTERNATIVES INCLUDING THE PREFERRED ALTERNATIVE

READERS GUIDE - In this chapter **you** will find:

- ALTERNATIVES CONSIDERED
- ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED STUDY

NOTE to READERS Please refer to the 1997 Revised Forest Plan for a "Glossary" of terms used in this document

ALTERNATIVES CONSIDERED

Based on available data, public issues and the Final EIS for the Revised Forest Plan, four alternatives were considered and analyzed in detail. Alternative 3M presented below is the same alternative as selected in the Revised Forest Plan FEIS (pages 11-34 and 11-7-8) and in the 1997 ROD for the Open Road and Open Motorized Trail Travel Plan (ROD - page 4)

Three new alternatives (3M+, 3M- and 1M) have been created based on issues described in Chapter I which resulted from consideration of public comments and appeals. Alternatives 3M(+) and 3M(-) are in response to specific public issues and appeals and represent minor additions (+) or deletions (-) to the 3M Alternative. These issues were mapped as stated in Chapter 1 and these overlay maps are on file in the Forest Supervisor's Office. These working maps are available for review. Alternative 1M is the existing situation as modified by the Regional Forester's remand. For a complete analysis and discussion of each alternative and its consequences, see Table 11-1 and Chapter IV of this FEIS, and Appendix C (1998 Update) and Appendix C(M) Appendix C (1998 Update) is the same as Appendix C in the 1997 Travel Plan ROD, except that the 1997 forms have been updated by deleting the rows with "strikeovers" and by adding ratings in the blanks to show reasons why every road was left open, or closed. Appendix C (1998 Update) has been provided as a bridge between the 1997 version and the new Appendix C(M). Appendix C(M) was developed by using ratings from Alternative 3M from the 1998 Update and by adding ratings for the three new alternatives considered.

These alternatives only address summer access for roads and trails because winter travel and summer cross-country access were already decided in the Revised Forest Plan. It should also be understood that cleanup of GIS layers resulted in slight changes in existing road and trail totals, and thus in representation of Alternative 3M from the RFP-FEIS. Also, it is not possible to have all totals for the alternatives presented here match exactly due to difficulties with the GIS layer overlays as data queries are created. Small segments of roads and trails exist or are created during the overlay process that cannot be accounted for or made to match. These discrepancies are minor and the data used was the best available from any source.

It should also be noted that more miles of road show on each alternative map referenced below than in Alternative 1 - existing situation (map #2, RFP-FEIS) for the Revised Forest Plan, because the yearlong restricted roads were not shown on the RFP-FEIS maps.

The four alternatives considered are briefly described as follows:

- Alternative 1(M) - "No Action" - This alternative is based on the existing situation. This alternative would leave the open, motorized roads and trails of the 1994/96 Travel Plans (old brown maps) in place for all of the Forest outside the bear management units (BMU's). Inside the BMU's, travel would be according to the Revised Forest Plan (Alternative 3M). Location of the BMUs is displayed in Figure III-6 in the RFP-FEIS, page 111-55. Forest-wide, summer, cross-country travel would also be according to the Revised Forest Plan (Alternative 3M). This alternative is displayed on the summer transportation map (map #2). Approximately 2,077 miles of open, motorized road, 51 miles of seasonally restricted road, 467 miles of decommissioned roads, and 725 miles of open, motorized trail are included in this alternative (Table 11-1). Appendix C(M) to this DEIS describes which roads and trails remain open to motorized use and the reasons why routes were selected as open or closed. This alternative would not be consistent with the Revised Forest Plan.

and would require a plan amendment to the open road and open motorized trail density standards. Its purpose here is to provide a baseline to compare site-specific effects with the other alternatives being considered.

- **Alternative 3M** - This alternative is the 1997 Travel Plan (proposed action) from the Revised Forest Plan FEIS (summer - roads, trails and cross-country travel) as displayed by the summer Transportation Plan (map #3 - see map packet) for Alternative 3M in the Revised Forest Plan FEIS. This alternative has 1,617 miles of open, motorized road, 62 miles of seasonally restricted road, 939 miles of decommissioned roads, and 511 miles of open, motorized trail. Appendix C (1998 Update) and C(M) to this DEIS describes which roads and trails remain open to motorized use and the reasons why roads were selected as open or closed for each alternative. The 1997 Appendix C Update and the roads and trails GIS data layer were corrected (Appendix C-1998 Update) to delete duplicate segments, and to make other minor edits. These corrections resulted in approximately 40 miles of additional road inventory. It was discovered during this analysis, that road density for this alternative was below densities allowed for some prescription areas and lower than calculated in the RFP-FEIS. This is mostly due to GIS query data errors. It is also partially due to topography limitations and the design of prescription densities being just an initial goal to guide planning. During mapping of the alternative there was also a conscious effort to leave room for management flexibility, e.g. - by not pushing elk vulnerability to the limit.
- **Alternative 3M(+)** - **PREFERRED ALTERNATIVE** - This alternative includes additional open roads and trails to those in Alternative 3M, but is still within the road density standards of 3M as decided in the Revised Forest Plan. Alternative 3M(+) is displayed on Summer Transportation map #4. As noted in Alternative 3M, it was discovered in this analysis that road density of 3M was below the level allowed for some of the prescription areas. Therefore, roads and trails were added in this alternative to respond to some of the specific requests in public comment and appeal records as noted on the overlay maps and RS 2477 maps.

The roads and trails added are shown in green on Map #4 in the map packet. This alternative has 1,672 miles of open, motorized road, 70 miles of seasonally restricted road, 984 miles of decommissioned roads, and 536 miles of open, motorized trail. Appendix C(M) to this DEIS describes which roads and trails remain open to motorized use and the reasons why routes were selected as open or closed. The total miles of open, motorized roads and trails in this alternative are similar to Alternative 3 in the Plan Revision FEIS, but the open roads and trails are in different locations. Summer, cross-country travel would be the same as Alternative 3M from the Revised Forest Plan.

This alternative has the same prescription areas as Alternative 3M, and road densities are within the prescription (Rx) density allowed, except as shown in Table 11-2. Implementation of a new Travel Plan under this preferred Alternative (3M+) requires a minor amendment to the 1997 Forest Plan revision to cover the following, specific road density changes (Table 11-2) for individual prescription areas which would vary from the Forest Plan prescription Access Tables (OROMTRD allowed).

All of the densities and associated motorized routes in Table 11-2 were established and approved in the Revised Forest Plan (Alternative 3M) Transportation Plan Map #11, except the Moody Creek road (80251). The Moody Creek change is in response to an RS 2477 assertion. Motorized use was approved by the RFP-FEIS in Indian Creek and was intended to be unrestricted as shown in the RFP-DEIS footnote, but when the footnote was prepared for the RFP-FEE, an incorrect OROMTRD of 0.2 miles per square miles was put in the footnote to the Access Table. The working copy of the OROMTRD density map dated December, 1997 actually showed a density of 0.5 miles and all of the motorized routes in that density were displayed in the Transportation Plan for Alternative 3M.

Many of the variances occur to accommodate roads running along or through small prescription areas (approximately 5 square miles or less) which are affected disproportionately by their presence.

Table II -1 Comparison of Environmental Effects by Key Issue Indicators

Indicator	Issue	Alt 1(M)	Alt 3M(+)	Alt 3M	Alt 3M(-)
ROADS (miles)	Access				
Open		2,077	1,672	1,617	1,613
Seasonal Restriction		51	70	62	62
Yearlong Restriction		399	289	303	303
Decomm in BMU's		467	466	463	465
Decomm outside BMU's		0	473	521	524
Total Miles		2,994	2,970	2,966	2,967
TRAILS (miles)	Access				
Open		725	536	511	454
Seasonal Restricted		0	0	0	0
Yearlong Restricted		651	862	879	933
Total Miles		1,376	1,398	1,390	1,387
Total Miles Rds/Trs		4,370	4,368	4,356	4,354
Miles of motorized rd/tr de-commissioned & reclaimed	Soil and water quality	467	473	521	989
Miles of motorized rd/tr on unstable soils	Soil and water quality	1,297	950	916	860
Miles of motorized rd/tr in AIZ	Soil and water quality	863	702	677	642
Number of rd/tr stream crossings	Water quality and fisheries	4,248	3,263	3,153	2,988
Miles of rd/tr in cutthroat AIZ	Cutthroat trout habitat	220	196	189	174
Number of rd/tr stream crossings in cutthroat AIZ	Cutthroat trout habitat	618	610	595	545
OROMTRD (mi/sq mi)	Grizzly habitat				
Henrys BMU - Sub 1		0.59	0.60	0.61	0.60
Henrys BMU - Sub 2		0.52	0.52	0.52	0.52
Plateau BMU - Sub 1		0.61	0.61	0.61	0.61

Elk Vulnerability 1/	Wildlife effects	85	90	91	91
Miles of motorized rd/tr in roadless	Potential impact on roadless or on wilderness designa-	776	548	520	469

1/ Percent of Forest meeting State Fish and Game agency goals or thresholds for elk vulnerability

Table 112 Proposed Minor Forest Plan Amendment for Prescription Road Densities

DISTRICT	AREA NAME/	Rx	RD DENSITY of Forest Plan	PROPOSED RD DENSITY	REASONS DENSITY EXCEEDED
Dubois	Eightmile	3 1 1(a)	0 0	0 1	Existing road
	Spring Mtn Cyn	3 2(g)	1 0	1 1	Existing road
Island Park	E Lionhead	1.3	0 0	0 1	Small Rx area
Palisades	Palisades Cr	1.3	0 0	0 1	Indian Cr trails *approved in RFP
	Kelly Cyn	5 1 4(d)	1 5	2 2	Small Rx area
	Moody Cr	5 1 4(b)	1 5	1 6	RS 2477
	Indian Cr	1 2	0 2	0 5	Access Table error - RFP
	Sheep Cr	3 2(d)	1 0	1 8	Small Rx area
	Poker Peak	3 1 1(a)	0 0	0 1	Adjacent road

A Travel Plan (map and Restriction Order) would be developed and implemented using the same format as the 1997 Travel Plan Map. The Travel Plan would include the details from the Transportation Plan (map #4 of map packet) for this alternative along with the 1998 Travel Plan Addendum (Appendix A), and road, trail, and cross-country matrices. This procedure will be followed using the appropriate data and maps for any alternative selected in the FEIS.

- **Alternative 3M(-)** - This alternative has slightly fewer open roads/trails than Alternative 3M. This alternative is essentially the same as Alternative 3M, but with the reduction of specific open roads and trails as requested in public comment and appeal records. Roads and trails were eliminated in response to some of the specific requests noted on the overlay maps described previously in the issues analysis. The roads and trails eliminated are shown in red on map #5 in the map packet. This alternative has the same prescription areas as Alternative 3M and 3M(+), but road densities are lower in several prescription areas than in Alternative 3M. This alternative is similar to Alternative 4 in the Plan Revision FEIS in total open motorized roads and trails, but the roads and trails are in different locations. Summer, cross-country travel is the same as Alternative 3M from the Revised Forest Plan. The Transportation Plan for this alternative is enclosed in the map packet for this DEIS as map #5. This alternative has 1,613 miles of open, motorized road, 62 miles of seasonally restricted roads, 989 miles of decommissioned roads, and 454 miles of open, motorized trail. Appendix C(M) to this DEIS describes which roads and trails remain open to motorized use and the reasons why routes were selected as open or closed.

ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED STUDY

Other alternatives were considered that would address additional requests for opening or closing road and trail segments beyond the maximum road density or significantly below the density allowed for prescriptions. The formal administrative appeal requests and public comments were mapped and reviewed for alternative consideration and development as described in the issues analysis and Alternatives 3M(+) and 3M(-) above. Our analysis of these options was found to match the same range of alternatives considered in the Revised Forest Plan FEIS. For example, an alternative with more open roads and trails than 3M is represented by Alternatives 1, 2, and 3 of that FEIS. An alternative with fewer open roads and trails would be represented by Alternatives 4, 5, and 6. Since an infinite array of alternatives could be constructed from issues indicated by the comments and appeals, and since

that array has already been considered in the previous FEIS, it would not be helpful to reconstruct those alternatives in this analysis

Furthermore, any alternative with a higher road/trail density than allowed by the Revised Forest Plan prescription direction would be outside the standards established in the Revised Forest Plan and contrary to the Purpose and Need for this decision. The scope of this analysis is limited to alternatives that meet the open road and open motorized trail density standards decided in the recently revised Forest Plan, as directed by the Regional Forester (remand letter of **1/14/98**). Because these density standards have recently been decided, whether they should be adjusted is not ripe for decision at this time. Effectiveness monitoring is a requirement of the Revised Forest Plan. An evaluation of the effectiveness of these road density standards will be made at appropriate intervals in the annual monitoring plan report.

Chapter

Affected Environment

CHAPTER III

AFFECTED ENVIRONMENT

READERS GUIDE - In this chapter you will find:

A description of the following components of the Forest

- INTRODUCTION TO ECOSYSTEM MANAGEMENT
- PHYSICAL ELEMENTS OF THE ENVIRONMENT
- BIOLOGICAL ELEMENTS OF THE ENVIRONMENT
- FOREST USE AND OCCUPATION
- PRODUCTION OF COMMODITY RESOURCES

This chapter describes the existing environment that will be affected by implementation of any of the alternatives. It describes the existing physical, biological and social environment of the Forest and the surrounding area. Most of the following information is a summary of the information contained in the 1997 Revised Forest Plan FEIS (pages III-1 through III-100). References to the Plan Revision FEIS, will be shown throughout this document as (RFP-FEIS, page x,y,z). In some cases, a topic or resource summary is not presented in detail, because the topic is not relevant to the issues or alternative analysis. In these cases, a reference to the resource topic location in the RFP-FEIS is all that is provided. We have also added some new information to update the status of resource conditions.

NOTE to READERS: Please refer to the 1997 Revised Forest Plan for a "Glossary" of terms used in this document.

INTRODUCTION TO ECOSYSTEM MANAGEMENT

Principles

In recent years the Forest Service has embraced the concept of Ecosystem Management (EM). This is an approach to natural resource management that strives to ensure healthy, productive, sustainable ecosystems by blending the needs of people (e.g. - roads and trails as discussed in this EIS) and environmental values in a given area such as the Forest. An ecosystem is a complex system of living and nonliving components that interact and change continually. Healthy ecosystems (Glossary - RFP-FEIS, page G-19) are those that are in Properly Functioning Condition (PFC). Ecosystems that are in PFC display resilience to disturbance to the structure, composition and process of their biological and physical components. They retain all of their parts and functions for future generations even though vegetation patterns, human uses or other conditions may change. Understanding ecological processes (fire and other natural disturbances) and how these processes shaped vegetation patterns over time in a landscape are important steps towards implementing EM.

The Targhee Forest remains committed to ecosystem management principles as outlined in the Revised Forest Plan and as analyzed in the FEIS for that Plan. Those processes and principles include adaptive management, PFC, range of variability (ROV), use of geographic scales (ecological units known as subsections), and ecological processes and patterns including succession, fire, insects and disease, vegetation types, connectivity, etc. (RFP-FEIS- pages III-1-17).

One change in condition is the approval of the Fire Management Plan for the Jedediah Smith Wilderness which was implemented with the Revised Forest Plan approval in 1997. Since that time, one fire was approved for management in the summer of 1997. It burned **less** than one tenth of an acre.

Subsections

Many resources are described in this chapter using the ecological units known as subsections. These units exhibit unique patterns in soils, landform, topography and potential natural vegetation, among

other characteristics The Forest encompasses part or all of the following seven subsections (RFP-FEIS-Figure III-1, page III-3)

- Lemhi/Medicine Lodge
- Centennial Mountains
 - Island Park
- Madison-Pitchstone Plateaus
- Teton Range
- Big Hole Mountains
 - Caribou Range Mountains

PHYSICAL ELEMENTS OF THE ENVIRONMENT

Soils and Geology

Soils and geology are described (RFP-FEIS, pages 111-17-19) and summarized for each ecological subsection as follows

Lemhi/Medicine Lodge - This subsection consists of fault block mountains, which exhibit a northwest-southeast trend. The dominant rock types are limestone and sandstone. The landscape is dissected by parallel drainage systems.

Soils on these landscapes are greater than 60 inches to bedrock, having gravelly, medium textured surface layers and extremely gravelly, medium textured subsurface layers. These soils have a low to moderate inherent fertility, are droughty, are high in carbonates and have a high erosion hazard.

The principal management activities affecting soil quality are roads, grazing concerns along incised drainages and OHV use. Secondary management activities affecting soil quality include water developments and mining impacts which have not been reclaimed.

Centennial Mountains - This subsection consists of a fault block mountain range, which exhibits an east-west trend along the Continental Divide. The dominant rock types are rhyolite, sandstone and shale. The landscape is dissected by dendritic and parallel drainage systems.

Soils on these landscapes are greater than 60 inches to bedrock, having nongravelly to gravelly medium to medium-fine textured surface layers and gravelly to extremely stony medium to medium-fine subsurface layers. These soils have a moderate to moderately high inherent fertility, are susceptible to compaction and puddling, have a moderate to high erosion hazard, exhibit plant competition concerns and demonstrate slumping hazards on mountain side-slopes and escarpments at higher elevations.

Principal management activities that are concerns affecting soil quality include roads and OHV use, dispersed recreation impacts, grazing concerns along drainages and water developments. Secondary management activities that are affecting soil quality include mining impacts which have not been reclaimed, past timber/firewood harvest which have resulted in roads, compaction, organic matter removal or displacement and loss of woody residue.

Island Park - The Island Park Caldera was formed by the collapse of a large rhyolite shield volcano. After the collapsing of the caldera, volcanic activity continued, resulting in basalt flows covering much of the caldera floor. The entire subsection has been overlain by wind blown silts (loess). The dominant rock types are rhyolite and basalt. The landscape is dissected by dendritic and parallel drainage systems on the caldera rim and associated tablelands. The caldera floor has very little dissection.

Soils on these landscapes are greater than 60 inches to bedrock, having nongravelly to gravelly medium textured surface layers and medium fine to extremely cobbly medium textured

subsurface layers. These soils have a moderately low to moderate inherent fertility. Soils on the caldera floor have plant competition concerns on deeper soils, reforestation concerns on more shallow soils, and a moderate susceptibility to compaction. Soils on the caldera rim have a moderate susceptibility to compaction, moderate to high erosion hazard, low bearing strength and plant competition concerns.

Principal management activities affecting soil quality (caldera rim) are roads, OHV use, and extensive past ~~timber~~/firewood harvest which have resulted in roads, compaction, organic matter removal or displacement and loss of woody residue. Principal management activities (caldera floor) are the same as for the rim, plus dispersed recreation, which is especially heavy near summer home areas, and grazing along certain riparian areas and meadow complexes.

Madison-Pitchstone Plateaus - This subsection consists of a large consolidated ash flow that came out of the Park and overtopped the east rim of the Island Park Caldera. The landscape is dissected by dendritic and parallel drainage systems.

The soils in the northern part are greater than 60 inches to bedrock, having medium textured surface layers and stratified gravelly coarse textured to extremely gravelly coarse textured subsurface layers. The soils in the southern part are greater than 60 inches to bedrock, having gravelly medium textured surface layers and very gravelly to extremely cobbly medium textured subsurface layers. These soils have a moderately low inherent fertility, are droughty and have windthrow hazards. They are highly erodible if the subsoil is exposed, as it is in the northern part of this subsection due to the North Fork Fire.

Principal management activities affecting soil quality include roads and OHV use, dispersed recreation, effects associated with timber harvest which have resulted in roads, compaction, organic matter removal or displacement and loss of woody residue.

Teton Ranae - This subsection includes a north-south trending mountain range. The dominant rock types are granite, limestone, sandstone, dolomite, slate, gneiss and quartzite. The landscape is dissected by parallel drainage systems.

This subsection consists of two primary landscape settings. These include foothills on lower to mid elevations and mountain side-slopes at mid to high elevations. Soils on these landscapes are 40 to greater than 60 inches to bedrock, having nongravelly to very gravelly medium textured surface layers and gravelly to extremely stony medium textured subsurface layers. These soils have low to moderately low inherent fertility, low to moderate compaction hazard, moderate to high erosion hazard, reforestation concerns and low to high mass instability hazards.

Principal management activities affecting soil quality include roads, grazing along drainages, OHV use and dispersed recreation. Secondary management activities affecting soil quality include the effects of timber harvest which have resulted in road construction, compaction, organic matter removal or displacement and loss of woody residue.

Bia Hole Mountains - This subsection consists of a mountain range of multiple, parallel overthrusts (faults) and benches of mixed rocks and eolian material that have been modified by thrust faulting.

Soils on these landscapes are greater than 60 inches to bedrock, having gravelly medium textured surface layers and very gravelly moderately coarse to moderately fine textured subsurface layers. These soils have a moderate to high inherent fertility, moderate compaction and rutting hazard, moderate to high erosion hazard, moderate to high slumping and earth-flow hazard, plant competition concerns and areas of low bearing strength.

Principal management activities affecting soil quality are roads, OHV use, dispersed recreation and grazing along drainages. Secondary management activities affecting soil quality include erosion along sheep driveways, effects resulting from timber harvest and big game feeding areas along Rainey Creek.

Caribou Ranae Mountains - The Caribou Range Mountains Subsection is a southeast to northwest trending overthrust (multiple faults) mountain range. The northeast side of the range is moderate relief mountains on mixed sediments. The southwest side of the range is low relief foothills and basins on fine-textured marine sediments. The dominant rock types are a mix of sedimentary materials with a loess influence. The landscape is dissected by dendritic drainage systems.

Soils on these landscapes are greater than 60 inches to bedrock, having medium textured surface layers and moderately-coarse to fine textured subsurface layers. These soils have a moderate to high inherent fertility, moderate compaction and rutting hazard, moderate to high erosion hazard, moderate to high slumping and earthflow hazard, plant competition concerns and areas of low bearing strength.

Principal management activities affecting soil quality include roads, OHV use, dispersed recreation and grazing along drainages. Secondary management activities affecting soil quality includes erosion along sheep driveways and effects from timber harvest.

Air Quality (see RFP-FEIS, page III-20)

Caves (see RFP-FEIS, page III-20)

Lands (see RFP-FEIS, page 111-20)

Minerals (see RFP-FEIS, page 111-22-23)

BIOLOGICAL ELEMENTS OF THE ENVIRONMENT

This section is divided into various types of ecosystems so that the relationships between biological elements within the same system can be better understood. Aquatic, riparian and terrestrial ecosystems (upland forested and upland nonforested) will be considered.

Riparian and Aquatic Ecosystems

Riparian

Riparian areas lie adjacent to water and are composed of vegetation communities influenced by water (RFP-FEIS, page 111-23-25).

Grazing is considered to have shifted the species composition on 8,988 acres (32 percent) of riparian communities across the forest. Under current range management, 5,338 of these acres are moving toward higher ecological conditions with increasing plant biodiversity. Some 3,650 acres are remaining in less stable, lower ecological conditions, with lower plant diversity (Table III-6, RFP-FEIS, page 111-24). Where grazing decreases species diversity, shallow, fine-rooted species such as Kentucky bluegrass (*Poa pratensis*) become dominant and replace the deeper, thicker-rooted native herbaceous species, thus decreasing streambank stability. Specific riparian conditions are presented by subsection as follows.

Lemhi/Medicine Lodge - The principal ecological concern affecting riparian quality in this subsection is that upland vegetation has expanded into riparian zones due to past over-utilization and/or a drop in the water table levels. A secondary ecological concern affecting riparian quality in this subsection is that within some riparian areas willows are dying out and are not being regenerated.

Principal management influences affecting riparian quality include past overuse by ungulates (domestic and wild), dispersed recreation, OHV use and roads in or adjacent to riparian areas and associated stream crossings.

Centennial Mountains - Principal ecological concerns affecting riparian quality include the expansion of upland vegetation into riparian zones due to past over-utilization and/or a drop in the water table levels and some areas of fine-textured subsoils which have a moderate to high slumping potential. A secondary ecological concern affecting riparian quality is that within some riparian areas, willows are dying out and are not being regenerated.

Principal management concerns affecting riparian quality are overuse in some areas by ungulates (domestic and wild), dispersed recreation, OHV use and roads in or adjacent to riparian areas and associated stream crossings. Secondary management concerns affecting riparian quality include past mining sites that have not been rehabilitated, past timber harvest that left inadequate buffers and fuel wood gathering.

Island Park - The principal ecological concern affecting riparian quality is that there are areas where willows are dying out and are not being regenerated.

Principal management concerns affecting riparian quality include high use recreation areas (including summer home, dispersed and developed recreation areas), OHV use, roads in or adjacent to riparian areas and associated stream crossings, past timber harvest which left inadequate buffers and fuelwood gathering. A secondary management concern affecting riparian quality is overuse in some areas by ungulates (domestic and wild).

Madison-Pitchstone Plateaus - The principal ecological concern affecting riparian quality is in the area of the North Fork Burn. Principal management concerns affecting riparian quality include dispersed recreation, OHV use, roads in or adjacent to riparian areas and associated stream crossings, past timber harvest which left inadequate buffers and fuelwood gathering. A secondary management activity affecting riparian quality is overuse in some areas by ungulates (domestic and wild).

Teton Ranae - The principal ecological concern affecting riparian quality is mass wasting.

Principal management activities affecting riparian quality include high levels of dispersed recreation, horse and OHV use, trails in close proximity to or within riparian areas and associated crossings, isolated areas of overuse by ungulates (domestic and wild), roads in or adjacent to riparian areas and associated stream crossings. Secondary management activities affecting riparian quality include past timber harvest which left inadequate buffers and fuelwood gathering.

Bia Hole Mountains - The principal ecological concern affecting riparian quality is mass wasting.

Principal management activities affecting riparian quality include high levels of dispersed recreation, horse and OHV use, trails in close proximity to or within riparian areas and associated crossings and areas of overuse by ungulates (domestic and wild). Secondary management activities affecting riparian quality include sheep driveways, past timber harvest which left inadequate buffers, fuelwood gathering and IDFG feed grounds in Lower Rainey Creek.

Caribou Ranae Mountains - The principal ecological concern affecting riparian quality is mass wasting.

Principal management activities affecting riparian quality include high levels of dispersed recreation, OHV use, trails in close proximity to or within riparian areas and associated crossings, areas of overuse by ungulates (domestic and wild), sheep driveways and roads in and adjacent to riparian areas and associated crossings.

Water

It is important to determine which streams are naturally "unstable" (i.e., dynamic) due to landforms, bed and bank materials, etc. and which ones have instability induced by management practices. An attempt is made in the text to make this determination where possible (RFP-FEIS, page III-26-31).

Water Yield - Total annual water yield on the Forest is about 1.4 million acre-feet. Water is lost or used in many ways, including evaporation, infiltration, use by plants and animals and diversion from stream channels. Because of these and many other factors, the amount of water reaching the Forest boundary will be less than what is produced.

Water Quality - The biggest pollutant on the Forest is excess sediment, derived from within-channel erosion and upland erosion reaching stream channels. The main source of management-produced sediment is roads, specifically those segments within riparian areas, including stream crossings.

Forest roads generally contribute an estimated 85 to 90 percent of the management-produced sediment reaching streams in disturbed Forest land (Burroughs 1990 - RFP-FEIS, page R-2) Currently there are 2,957 stream crossings and 323 miles of road in Aquatic influence Zones (AIZs) on all lands within the Forest boundary (including inholdings) The amount of water meeting State water quality goals on the Forest is unknown Idaho Code Section 39-3601 et seq (effective July 1, 1995) approved adoption of new water quality standards Streams targeted for the new regulations are those listed as Water Quality Limited (WQL) under section 303(d) of the Clean Water Act

The Forest is in the process of validating WQL streams to determine where we have water quality concerns, and if they exist, to find the source of the concerns Many of the water bodies currently listed have very limited data, so there is a great deal of speculation as to whether they should remain listed Until we can verify the condition of these streams, particularly the condition of fish habitat and fish populations, the Forest is employing especially stringent management requirements in the WQL watersheds We have begun baseline monitoring in at least one WQL watershed where new management activities are planned Impacts to WQL streams are analyzed at the project level, where site-specific BMPs can be tailored to a given situation Specific subsection conditions for stream channels and water quality are summarized as follows

Lemhi/Medicine Lodge - Major streams in this subsection are Medicine Lodge Creek and its tributaries There are many perennial streams that have their headwaters in the Bitterroot and Beaverhead Ranges, that eventually flow through broad valleys Channel stability ranges from fair (-) to good (+) This subsection has generally declining trends in channel stability, sometimes even where grazing has been excluded

Idaho DEQ sampled sites on streams in this subsection to assess changes in water quality from management On Irving, Edie and Fritz Creeks, water quality was similar above and below where forest management was occurring All sites showed impacts from grazing at the time of the survey

Centennial Mountains - Streams having headwaters along the front of the Centennial Mountains generally flow south and their water comes from both snowmelt and spring sources

Channel stability ratings generally range from fair (-) to good (+) with stable or declining trends throughout most of the subsection The only standout is a poor rating on part of West Dry Creek, though there is no apparent management related reason Some portions of the Henry's Fork Headwaters rated as excellent The most frequent management problems are livestock damage and roads

Sampling at Big Springs in 1994 found water quality to be excellent and water temperatures consistently low Monitoring by the State of Idaho in the Henry's Fork headwaters showed limited impacts to beneficial uses

Island Park - Many streams here show a strong influence from groundwater, having relatively low variation in flow throughout the year

Channel stability ratings range from fair (-) to excellent Management impacts stem from roads, livestock and recreation, which vary in significance in different places The Buffalo River was sampled in the late 1970s and water quality was found to be good

Madison-Pitchstone Plateaus - Surface drainage here is not very well-developed, due to the underlying volcanic rocks which allow more water to percolate than to run off. These streams originate in or near the Park and exhibit strong groundwater influence

Channel stability ranges from fair (+) to excellent The North Fork Fire in 1988 caused major changes in channel stability to Moose Creek Road systems were a watershed concern in this area even before the fire After the fire, erosion from uplands accelerated due to loss of vegetation and burning effects on soils, which caused more water to run off slopes

Five of the streams in the subsection (Rock, Robinson, Fish and Porcupine Creeks and Warm River) had been named by Idaho as Stream Segments of Concern before this designation was eliminated in 1995 Water quality has been generally good on these streams

Teton Ranae - Streams in this subsection originate along the west slope of the Teton Mountains. They are steep, dynamic and characterized by coarse substrate (up to boulders in size) due to the proximity of this material to the stream channel. Glaciation has been an important influence on stream systems here.

Channel stability ranges from fair (-) to good (+). Impacts to channels stem mostly from natural causes such as avalanche debris, unstable bank materials and failed beaver dams. Localized management effects are related to roads, recreation and livestock.

Bia Hole Mountains - Streams here contribute to either the Teton River or the South Fork Snake River. They are generally confined within steep-sided valleys or canyons, and are high-energy systems, able to move a considerable amount of sediment. Snowmelt is important in these streams, so they have high spring peak flows which later drop to their late summer levels.

Channel stability ranges from poor to good (+). Impacts exist in most drainages from recreation **use**, especially trails along the streams and dispersed camping. Management impacts associated with cattle and roads are also very common.

In-depth water quality sampling was conducted on Big Elk Creek in the late 1970s. Water temperatures were consistently good, and turbidity was consistently low. Little Elk Creek was sampled once, and had readings similar to Big Elk. In general, it appears that stream channel stability is a concern in many places, but (based on available data) water quality impacts are not evident.

Caribou Ranae Mountains - Geology has played an important role in this subsection. The underlying geology of folded and faulted sedimentary rocks has produced perpendicular drainages, and the streams follow the weaknesses in the rocks.

All reaches rated from fair (-) to good (+) in channel stability. Grazing, powerline clearing, roads in riparian areas and heavy recreational use are all listed as problems in the Fall Creek drainage. Most streams here have not been surveyed.

Idaho DEQ sampled several streams in 1994, Antelope, Sawmill, Lava, Hell, Willow and Brockman Creeks. Conclusions have not yet been drawn from their data regarding support of beneficial uses.

Fisheries

Streams delineated as "fish-bearing" are those stream segments that are used by any fish species to satisfy all or a portion of its requirements such as spawning, rearing of young, adult feeding and winter survival. Of the 39 primary watersheds on the Forest, 17 have been designated as native trout watersheds, Elk Creek (003), Palisades Creek (004), Rainey Creek (005), Pine Creek (006), Heise (007), Henry's Fork Headwaters (008), Robinson Creek (013), Trail Creek (017), Mahogany Creek (022), Moody Creek (024), Bitch Creek (032), Burns-Pat Canyon (035), McCoy-Jensen Creeks (036), Elk-Bear Creeks (037), Fall Creek (038), Prichard Creek (039) and Brockman Creek (040) (RFP-FEIS, page 111-31-34).

The land area immediately surrounding the various water bodies is referred to as the aquatic influence zone (**AIZ**). These zones control the biological diversity and integrity of the aquatic environment. It is within these zones that the ecological functions and processes necessary for the maintenance of healthy fisheries habitat take place. Aquatic habitat conditions are expressed in terms of water quality, quantity, and timing of flow, conditions within the stream channel (pools, woody material, etc), and health of associated plant communities. Since the hydrologic, geomorphic and ecological processes that shape the various water types differ by hydrologic unit, the sensitivity of fisheries habitat to disturbances also varies by hydrologic unit. Human-induced disturbances within the AIZ, including stream-flow diversion, livestock grazing, road construction, timber harvesting, and recreation use can disrupt natural processes and functions. Where these are intense or prolonged, fisheries distribution, abundance and productivity can be impaired.

A complete list of the fish species on the Forest by hydrologic unit is shown in Table III-8 of the RFP-FEIS (page 111-32). Descriptions of the condition and trends of aquatic and riparian habitats are shown in Table III-6 of the RFP-FEIS (page 111-24).

Yellowstone cutthroat trout (large-spotted and fine-spotted form) is selected to represent the many species of fish occupying the Forest. This species requires high water quality and high habitat diversity for survival. Since these conditions are indicative of healthy aquatic ecosystems, with associated healthy riparian plant communities and functioning watersheds, it is assumed that by providing for these habitat needs, the habitat needs of all other aquatic life would be provided as well.

Birch, Medicine Lodge and Beaver-Camas Hydrologic Units - Fish populations within the Birch, Crooked, Medicine Lodge and Beaver-Camas Creek systems are now physically and genetically isolated from the Snake River system and from each other.

Fish-bearing streams on Forest lands are small, steep to moderate-gradient and fed by snowmelt runoff and baseflow from groundwater sources. The natural capabilities of this area to produce abundant or diverse fisheries resources is relatively limited. Specific conditions are presented by following hydrologic units.

Upper Henry's Hydrologic Unit - All drainages flow into Henry's Lake or the Henry's Fork of the Snake River above the confluence of Fall River. Spring-fed creeks provide an environment capable of producing abundant aquatic insect and plant biomass. Where fisheries life history requirements are met, these streams are among the most productive trout fisheries in the world.

Fisheries resources in this hydrologic area are very productive and varied. Duck and Targhee Creeks are important economically and scientifically as they provide key spawning habitats for the Henry's Lake native cutthroat trout fisheries and associated Idaho Fish and Game managed hatchery.

Lower Henry's Hydrologic Unit - All drainages flow into the Henry's Fork of the Snake River near the confluence of Falls River. The fisheries resources of importance within this area are primarily small headwater streams and alpine lakes spread across a small portion of the landscape.

Teton Hydrologic Unit - This area drains the western aspect of the Tetons and the northern aspect of the Big Hole Mountains. Fish-bearing streams originating in the Teton Mountains are steep, dynamic and strewn with large boulders. Stream channels developed from the sediment and rock that was delivered through glaciation. Within the Big Hole Mountains, fish-bearing streams are relatively small, moderate-gradient and fed by snowmelt runoff and baseflow from groundwater sources.

Palisades Hydrologic Unit - All drainages originate along the south aspect of the Big Hole Mountains and the north aspect of the Caribou Mountains and are tributary to the South Fork of the Snake River.

The fisheries resources found here are very productive and varied. Many of the streams flowing into Palisades Reservoir, and Palisades, Rainey, Pine and Burns Creeks, provide key spawning and rearing habitats for the native cutthroat trout fisheries.

Cutthroat Trout

Cutthroat trout is a sensitive species and has been selected as a management indicator. Table 1119 of the RFP-FEIS (page 111-34) illustrates cutthroat trout population status and distribution on the Forest by hydrologic unit. Yellowstone cutthroat trout currently occupy 41 percent of their historic habitat. Within Idaho, approximately 45 percent of the historic habitat is presently occupied. German brown, rainbow, and brook trout have been stocked into many drainages and compete with cutthroat trout. Table III-8 of the RFP-FEIS (page 111-32) shows rainbow trout have been introduced into every hydrologic unit on the Forest and have hybridized with cutthroat trout, causing genetic contamination of cutthroat trout populations, and threatening their long-term survival.

Wildlife Associated with Aquatic and Riparian Habitats

Wildlife management indicator species include bald eagles, trumpeter swans, spotted frogs, common loons and harlequin ducks. Table III-10 in the RFP-FEIS (page 111-35) illustrates the distribution of these species and their habitats by subsection. A brief overview of these species and habitats follows. Additional information is available in the RFP-FEIS (pages 111-34-39) and Process Paper D.

Bald Eagle

Southeast Idaho and Forest Overview - The data we compiled on bald eagle nesting populations in southeast Idaho dates back to 1972. In 1972, there was one recorded bald eagle nest along the South Fork of the Snake River, which was not on the Forest. As of 1998, total known nesting territories in southeast Idaho numbered 47. The first recorded bald eagle nest on the Forest occurred in 1975 along the Palisades Reservoir. From 1975 to 1998, the bald eagle nesting populations on the Forest increased to 19 nesting pairs.

Bald Eagle Recovery Plan - The Forest is within the "Greater Yellowstone Bald Eagle Management Zone" as outlined in the Pacific States Bald Eagle Recovery Plan (USFWS 1986 - RFP-FEIS, page R-16). All of the Recovery Plan goals have been exceeded with the current bald eagle populations.

Trumpeter Swan

From less than 200 birds in 1930, the Rocky Mountain Population (RMP) increased to about 2,500 birds by 1996, the highest in over a century (Maj and Shea 1996 - RFP-FEIS, page R-8). About 80 percent of the RMP winters in southeast Idaho along the Henry's Fork of the Snake and southeast Montana along the Madison River.

For the period 1982 to 1994, 31 lakes and ponds on the Forest have been used at least during one or more summers, 17 of these 31 have had at least one nesting attempt, 13 of these 31 have successfully produced young during one or more years (RFP-FEIS, page 111-36-37).

Spotted Frog

We do not know and are not able to provide a spotted frog population estimate for the Forest. An amphibian survey conducted on the Forest in 1992 and 1993 provides an overview on the distribution of spotted frogs on the Forest (Clark and Peterson 1994 - RFP-FEIS, page R-3). This amphibian survey documented spotted frogs at 51 sites, distributed within five subsections.

Common Loon

Common loon abundance on the Forest is highest during spring and fall migrations. Common loons have been documented using four reservoirs, nine lakes and an unnamed pond within five subsections (RFP-FEIS, page 111-38).

The following lakes and ponds within the Island Park and Madison-Pitchstone Plateaus subsections have been identified as capable of providing suitable breeding habitat for common loons: Loon Lake, Moose Lake, Indian Lake, Thompson Hole, Junco Lake, Fish Lake, Bergman Reservoir and an unnamed pond. Only Indian Lake, Thompson Hole and Bergman Reservoir have documented nesting and rearing of young.

Harlequin Duck

Harlequin ducks have been observed along four creeks within three subsections on the Forest: Big Elk Creek, Teton Creek, Darby Creek and McCoy Creek. Successful reproduction has been documented at Big Elk Creek, Teton Creek and Darby Creek. One to two pairs have been documented along each creek, therefore we estimate the breeding population on the Forest to be between three and six pairs. However, not all streams with potential suitable habitat have been surveyed, so this is considered a minimum estimate of breeding pairs (RFP-FEIS, page 111-38-39).

Harlequin ducks are only present on the Forest during the nesting and brood-rearing seasons, they migrate to the coasts of Oregon and Washington to winter.

TERRESTRIAL ECOSYSTEMS

Upland Forested Ecosystems (see RFP-FEIS, page 111-39)

TES and Biodiversity Indicator Plant Species

Fifteen sensitive plant species and one threatened plant species (RFP-FEIS, page 111-42) are currently listed on the Forest TES plant species list (Process Paper F - RFP-FEIS) and occur in a broad range of habitats (Table III-11 - RFP-FEE, page 111-43). Twenty-two rare Idaho and Wyoming plant species occur on the Forest and are indicator of biodiversity and unique habitats on the Forest (Process Paper G - RFP-FEIS).

One sensitive plant species, *Astragalus paysonii*, occurs in forest ecosystems of lodgepole pine and mixed Douglas-fir/lodgepole pine communities. The plant is found in disturbed or open areas in mature stands or in early seral lodgepole pine stands following fire. Fire suppression has been identified as a cause of decline of this species over its range (Fertig et al. 1993 - RFP-FEE, page R-4). Currently, there is one known location for the species on lands managed by the Forest within the Caribou Range Mountains subsection.

One threatened plant species (Table 111-11 - RFP-FEIS, page III-43) is known to exist on the Forest. Listed in 1992 and discovered on the Forest in 1996, Ute ladies'-tresses (*Spiranthes diluvialis*) occurs on the Palisades Ranger District along the South Fork of the Snake River. The species is suspected to occur elsewhere on the Forest within riparian and wetland habitats below 7,000 foot elevation.

Upland Nonforested Ecosystems

Herbaceous and shrub ecosystems dominate the landscape in the Lemhi/Medicine Lodge Subsection and are significant in the Centennial, Big Hole Mountains and Caribou Range Mountains Subsections (RFP-FEIS, page 111-42).

Fire suppression has modified the historical 10-25 year frequency of fire in the low to mid elevation areas. Fire suppression coupled with grazing and drought cycles has increased shrub canopy cover and decreased herbaceous species composition within the sagebrush/grass and mountain brush community types.

Noxious Weeds (see RFP-FEE, page 111-46)

Wildlife Associated with Terrestrial Habitats

Wildlife management indicator species include, elk, gray wolf, grizzly bear, primary cavity nesting species (eight species), northern goshawk, red squirrel and peregrine falcon. Table 111-16 (RFP-FEIS, page III-50) illustrates their distribution by subsection. A brief overview of these species and habitats follows. Additional information for these species and other wildlife species is available in the (RFP-FEIS, pages III-47-50) and Process Paper D.

Elk Populations

We do not know the total population of elk which use the Forest (RFP-FEIS, page 111-47). The number of elk changes with seasons. Elk populations are lowest during the winter period because they migrate to lower elevation winter ranges. Many of the winter ranges occur off Forest lands. Elk populations on the Forest are highest during the spring, summer and fall periods, as elk migrate back from winter range areas. Some elk migrate through the Forest and summer in the Park.

For the Idaho Game Management Units which encompass the Forest (Figure 111-4, RFP-FEIS, page III-48), elk populations have sustained annual harvests which have ranged between 940 to 3,111 animals harvested between 1979 to 1995. Elk harvests have shown a general increasing trend from 1979 to the present. The average annual harvest for the period 1979 to 1995 was 1,915 animals.

For the Wyoming Elk Hunt Areas which encompass the Forest (Figure 111-4, RFP-FEIS, page III-48), elk populations have sustained annual elk harvests which have ranged between 66 to 205 animals harvested for the years 1979 to 1995. Elk harvests have shown a general increasing trend from 1979 to the present. The average annual harvest for the period 1979 to 1995 was 134 animals.

Age and sex composition data reported for elk populations on or adjacent to the Forest range from 29 to 53 calves per 100 cows, and the mid to low teens to 22 bulls per 100 cows (USDI Fish and Wildlife Service 1994 - RFP-FEIS, page R-15) Using an average age and sex composition of 40 calves per 100 cows and 20 bulls per 100 cows, the pre-harvest elk population to sustain the average elk harvests from 1979 to 1995 is calculated to be 10,250 animals (the post harvest elk population would be 8,201) This is considered a minimum population estimate because it does not include the need to account for animals dying from natural causes and unreported wounding losses

Elk Vulnerability (EV)

At the present time, 48 percent of the Forest meets State Fish and Game thresholds for EV (RFP-FEIS, page 111-49)

Elk Habitat Effectiveness (EHE)

EHE is defined as the percentage of available habitat that is usable by elk outside the hunting season (RFP-FEIS, page 111-49).

An EHE of 100 percent (usually displayed as 1.0) would require no motorized roads and trails within a watershed, and 50 to 60 percent of the watershed being in hiding cover The existing values for EHE range from a low of 0.46 in a portion of the Centennial Mountains to a high of 0.74 in the Madison-Pitchstone Plateaus Subsection just south of the Park, an average Forest-wide EHE value is 0.57

Elk & Deer Winter Range

Generally, elk and deer winter range are those areas at lower elevations with lower snow accumulations, used by elk and deer during the winter months (Lyon and Christensen 1992, RFP-FEIS, page R-7) Map number 24 (RFP-FEIS map packet) displays these winter ranges on the Forest There are 313,825 acres of crucial mid-to-late elk and deer winter range on the Forest. Currently, 78 percent of the winter range acres are meeting DVCs for condition, 13 percent of the winter range acres are improving and moving toward DVCs, and 9 percent of the winter range acres are not improving

All elk and deer winter range is closed to cross-country snowmachine use (RFP-FEIS, page IV-30)

There is one feed ground for wintering elk and deer on the Forest, this is in Rainey Creek, within the South Fork/Palisades winter range area The number of animals fed at this site varies each winter, primarily based on the severity of the winter Because of recent documentation of the disease brucellosis, the State Fish and Game Department is considering other management options to winter feeding

Grizzly Bear Population

Portions of the Forest are within the Yellowstone Grizzly Bear Ecosystem (YGBE), (RFP-FEIS, page 111-53) The YGBE has been divided into Bear Management Units (BMUs) Portions of the Forest are within the following BMUs Henry's Lake (Subunits 1 and 2), Plateau (Subunits 1 and 2), and Bechler/Teton (Figure III-6 - RFP-FEIS, page 111-55)

The following are recovery goals for the YGBE (U S Fish and Wildlife Service 1993, RFP-FEIS, pages 111-53-54)

"Fifteen females with cubs over a running 6-year average both inside the recovery zone and within a 10-mile area immediately surrounding the recovery zone, 16 of 18 BMUs occupied by females with young from a running 6-year sum of observations, no two adjacent BMUs shall be unoccupied, and known, human-caused mortality not to exceed 4 percent of the population estimate based on the most recent 3-year sum of females with cubs Furthermore, no more than 30 percent of this 4 percent mortality limit shall be females These mortality limits cannot be exceeded during any two consecutive years for recovery to be achieved"

As of 1997, the status of the grizzly bear population in relation to the recovery goals was as follows

- The running 6-year average for unduplicated females with cubs was 24.0, compared to the recovery goal of 15

- Average annual human-caused mortality was 8.7 bears, compared to the recovery goal mortality limit which is to be < 10.5 bears (< 4 percent mortality limit of the population estimate).
- Average annual human-caused female mortality was 3.5 bears, compared to the recovery goal mortality limit which is to be < 3.2 bears (< 30 percent of the total known mortalities)
- The distribution of females with young was 18 of 18 BMUs, compared to the recovery goal of 16 of 18 BMU's

Gray Wolf Populations and Habitat

Possible sightings of gray wolves have occurred on the Forest and are summarized in the AMS and Process Paper D. There have been no reported sightings of packs or evidence of successful breeding (RFP-FEIS, page III-60-61)

The portion of the Forest west of Interstate 15 is within the Central Idaho Nonessential Experimental Population Area. The portion of the Forest east of Interstate 15 is within the Yellowstone Nonessential Experimental Area (Figure 111-7, RFP-FEIS, page III-59). All wolves found in the wild within the boundaries of these management areas, after the first wolf releases, will be considered nonessential experimental animals (USDI Fish and Wildlife Service 1994a and b, RFP-FEIS, page III-60)

This gray wolf reintroduction does not conflict with existing or anticipated Federal agency actions or traditional public uses of park lands, wilderness areas or surrounding lands (USDI Fish and Wildlife Service 1994b). Land use restrictions may be temporarily used by land or resource managers to control intrusive human disturbance, primarily around active den sites between April 1 and June 30, when there are five or fewer breeding pairs of wolves in a recovery area. After six or more breeding pairs become established in a recovery area, land-use restrictions would not be needed (USDI Fish and Wildlife Service 1994a)

Wolf recovery will not result in wolf travel corridors or linkage zones being established. The size and proximity of the areas where wolves will be managed for recovery are large enough, close enough and have enough public land between them that additional areas (travel corridors) are not required in the foreseeable future to maintain a viable wolf population after the three subpopulations become established (USDI Fish and Wildlife Service 1994a)

Primary Cavity Nester Populations (see RFP-FEIS, Daae 111-61)

Primary Cavity Nester Habitat (see RFP-FEIS, Daae III-62)

Forest Owl Populations (see RFP-FEIS, Daae 111-62)

Furbearer Populations (see RFP-FEIS, Daae III-63)

Canada Lynx

Lynx habitat in the western mountains consists primarily of two structurally different forest types occurring at opposite ends of the stand age gradient. Lynx require early seral forests that contain high numbers of prey (especially snowshoe hares) for foraging and late seral forests that contain cover for kittens (especially deadfalls) and for denning. Intermediate seral stages may serve as travel cover for lynx, but function primarily to provide connectivity within a forest landscape. Although such habitats are not required by lynx, they fill in the gaps between foraging and denning habitat within a landscape mosaic of forest seral types.

According to a recent report (USFWS, 1998), lynx were distributed throughout northern Idaho in the early 1940s. This report indicates the only documented reports of lynx on the Targhee National Forest have occurred on the Wyoming portion in the Palisades Mountains. However, in 1993, 1997 and 1998, lynx tracks were documented in the Centennial Mountains subsection in four watersheds (TNF files)

Northern Goshawk Populations (see RFP-FEIS, Daae III-65)

Red Squirrel Populations and Habitat (see RFP-FEIS, Daae III-67)

Peregrine Falcon Populations

The Forest is within the American Peregrine Falcon Recovery Plan • Rocky Mountain/Southwest Population (USDI Fish and Wildlife Service 1977/revised 1984, RFP-FEIS, page R-16) The objectives for the Recovery Plan are a minimum of 183 breeding pairs with the following distribution Arizona-46, Colorado-31, Idaho-17, Montana-20, Nebraska-1, New Mexico-23, North Dakota-1, South Dakota-1, Texas-8, Utah-21 and Wyoming-14 (RFP-FEIS, page 111-67)

At the present time, there are 575 known peregrine falcon pairs within the area covered by the Recovery Plan, surpassing the recovery objective by 392 pairs (Robert Mesta, personal communication, 1998)

In 1998, there were seven occupied peregrine falcon eyries on or adjacent to the Forest

The current population and reproductive levels has been sufficient to support considerable population growth which exceeds recover goals At this time, the U S Fish and Wildlife Service has proposed to remove the American peregrine falcon from the list of endangered and threatened wildlife (USDI Fish and Wildlife Service 1998)

Biahorn Sheep Populations and Habitat (see RFP-FEIS, page III-69)

Neotropical Migratory Bird Populations and Habitat (see RFP-FEIS, Daae III-70)

Predator Control (see RFP-FEIS, Daae III-70)

Unique Ecosystems

Research Natural Areas (RNAs) (see RFP-FEIS, Daae III-71)

FOREST USE AND OCCUPATION

Access Management

Road System

The Forest road system provides access for recreation, industry and administration (RFP-FEIS, page 111-73-74) Land transportation by motorized vehicles is the principle means of travel on the Forest Seven major highways run through the Forest and all primary access begins from one of these highways Average daily traffic counts collected by the Idaho State Highways Department (Gillespie 1994, RFP-FEIS, page R-4) suggest the heaviest traffic occurs on the highways between Idaho Falls and the northeast part of the Forest (Figure 111-8, RFP-FEIS, page 111-72) Many of the Forest's roads were constructed in the mid-1970's as part of the timber salvage program and provided access to recreationists, firewood gatherers and hunters The roads have also proved useful for fire suppression activities Forest-wide there are 2,077 miles of open roads In addition, motorized use is restricted on some roads as follows 51 miles of roads have seasonal restrictions, 399 miles of roads have year-long restrictions (Table 11-1) Approximately 85 percent of the 467 miles of roads inside the grizzly bear management units have been decommissioned during the summer of 1998

The Forest road system is essentially in good shape, with annual maintenance on arterial and collector roads and some local roads depending on resources needs and funding available Further information on the Forest Development Road System can be found in the Transportation section of the AMS

The current road system has created resource conflicts with wildlife, fish and watershed resources Road restrictions or decommissioning have been requested by agencies and individuals to reduce resource conflicts Law enforcement problems have also increased over the years due to the need to enforce restrictions

The Forest has begun restricting and/or reclaiming roads to reduce resource conflicts Many of the local spur roads built during the salvage program are now restricted Motorized use was restricted on 377 miles of road from 1981-1991 and on an additional 1,245 miles in 1992-1993

There are approximately 2,994 miles of existing roads Of this total, only 2,077 miles are open Of these open roads, 10 percent are classified as arterials They are often two-lane and paved or have a

good gravel surface and can handle unrestricted traffic at moderate speeds. Branching from the arterial roads are the collectors. Collector roads are medium standard roads that constitute about 25 percent of the mileage in the transportation system. Collector roads are stable enough for most traffic during normal season of use. Small single-lane roads, known as local roads, are found throughout the Forest and make up 65 percent of the road system. These minimum standard roads provide access for specific purposes, such as harvesting timber, maintaining electronic communication sites or reaching a trailhead. They allow limited passing, but the road conditions require that vehicles move slowly. Many of the local roads are currently closed to vehicular traffic much of the time.

Two-track roads exist that are referred to as low standard roads (sometimes called "ghost roads"). These isolated roads were not designed or maintained for public use, they are created by repeated use by the public. Some vehicles cannot travel on these roads. Road surfaces are generally rough and irregular with no drainage. Some of these roads are closed to motorized use.

Concern has been expressed by County officials of several counties regarding Revised Statute (RS) 2477 roads and trails under the 1866 Act. The intent of requirements under this Act have not yet been clarified by additional legislation or Forest Service policy. During the last year, County representatives have prepared lists and maps displaying RS 2477 assertions for roads and trails they believe were in existence (as required by the law) prior to the establishment of the Forest. These RS 2477 assertions are on file in the Forest Supervisor's Office, and the routes are displayed in Map #1 (map packet).

The National Forest Scenic Byways Program was developed to increase public awareness and understanding of the National Forest and State activities and recreation opportunities. Presently there are two Scenic Byways that pass through the Forest, the Mesa Falls and Teton Scenic Byways. The Mesa Falls Scenic Byway follows old State Highway 47 from Ashton to where it ties back to US Highway 20. About 20 of the total 29 miles are located on the Forest. The Teton Scenic Byway Route travels east from Idaho Falls to Swan Valley along Highway 26, then north to Victor on Highway 31, from Victor to Teton on Highway 33 to the intersection of Highway 32, and then to Ashton on Highway 32.

The Forest has been working with the Federal Highway Administration on improving Forest Highways. Funding provided by the Federal Highways Administration allows the Forest to make improvements on roads which normally could not be made. Roads that are identified for improvements are required to accommodate current conditions and impending future growth and road uses. Without improvements, the highways cannot satisfy current and future traffic demands, safety requirements, Forest Service land and resource management objectives and maintenance capabilities of the various agencies.

The roads that have been slated for improvement and the expected year for reconstruction are Forest Highway number 62, Mesa Falls (1999-2000), Forest Highway number 76, Fred's Mountain or Grand Targhee road (1999-2000), and part of the Yale-Kilgore road (est 2000).

Summer Access for Off-Highway Vehicles (OHV)

Approximately seven percent of the Forest (121,000 acres) is currently open for summer cross-country motorized and mechanized vehicle access (RFP-FEIS, page 11-20, Alternative 3M data). There are currently 2,077 miles of open road and 725 miles of open trail useable by OHV's due to the Regional Forester's remand direction to return to 1997 open road conditions. The Forest conducted an analysis of motorized access and road/trail density in the spring of 1995 and again in 1998 to accurately inventory these opportunities. The analysis is documented in Appendix C - 1998 Update.

There are very few trails designed specifically for motorized OHVs or mountain bikes, although some are suitable in their present condition. The Forest is currently reconstructing four to six miles of trail each year for motorized use. There is a significant increase in demand for such opportunities. Both types of use are increasing at a rate of five to ten percent per year on the Forest and adjacent lands. The highest concentration of these activities is in the Big Hole and Caribou Range Mountains Subsections, where there is significant use by motorcycles and mountain bikes. There are currently moderate conflicts arising between two-wheel and four-wheel OHV users which are making planning for reconstruction somewhat difficult. As noted in the Soil and Riparian section, there are areas of concern for OHV effects on soil and vegetation. Although there are a few areas of new OHV hill-climbs occurring,

there are no serious adverse consequences as a result of OHV use. However, it is possible that motorized use is affecting some big game wildlife habitat potential or vulnerability to hunting pressure. Also, some conflict between OHV users and hunters is now being experienced.

Winter Access (see RFP-FEIS, page III-75)

Many snowmachines currently use roads in the winter which are open for summer, motorized travel.

WILDERNESS AND RECREATION RESOURCES

Recreation, tourism and National Forest use are important to the area economy (RFP-FEIS, page III-75-81). The Idaho Department of Commerce estimates that tourism in Idaho is a two billion dollar industry, with 23 million visitors each year. The visitors to the Forest may account for over 10 percent of this industry. Table 111-26 in the RFP-FEIS (page 111-76) displays current recreation and wilderness information by ecological subsection.

Wilderness and Recommended Wilderness

There are currently two designated wilderness areas on the Forest. These are the Jedediah Smith Wilderness (123,451 acres) and the Winegar Hole Wilderness (10,715 acres). The Jedediah Smith is mostly in the Teton Range Subsection with the balance in the Madison-Pitchstone Plateaus Subsection. Winegar Hole is totally within the Madison-Pitchstone Plateaus Subsection. Winegar Hole is largely primitive with very little recreational use. This is mostly due to access difficulty, since there are only four miles of trail in the area. Use of this area is mostly for hunting big game.

The Jedediah Smith is intensively used in the summer with approximately 60,000 visits for hiking, backpacking and horseback riding. This is a spectacular mountainous area on the west slope of the famous Teton Mountain Range. These wilderness areas are two of twelve designated in the GYA which total 3.8 million acres, and provide significant areas of biodiversity important to the GYE.

The Wyoming portion of the Palisades Roadless Area was designated by Congress as a Wilderness Study Area in 1984. The Study Area contains approximately 129,100 acres. Of these acres, over 79,800 are administered by the Bridger-Teton N.F. and 49,300 acres are administered by the Forest. In addition, there are 110,520 acres of this roadless area in Idaho which have had no action taken on them. However, a large part of the Palisades Roadless area was recommended for wilderness designation in the 1997 Revised Forest Plan. The studies on the Wyoming portion have not been conducted. Much of the Palisades Roadless area is under special use permit for heli-skiing operations which have been in existence for over 15 years. This heli-skiing operation is a recreational business operating out of Jackson, Wyoming. The Palisades area is also used by a large number of snowmobilers, except in the steep, avalanche prone areas.

Portions of Diamond Peak, Italian Peak, Lionhead, and Winegar Hole and Palisades Roadless Areas (171,000 acres) were recommended for wilderness consideration in the 1997 Revised Forest Plan, but no legislative action has been taken to date.

Roadless Areas

There are 16 areas on the Forest which qualify as roadless or roadless adjacent to designated wilderness. These areas are described in the Process Paper Q and Forest Plan map number 25 (RFP-FEIS). These areas total about 841,000 acres. This acreage is approximately 30,000 acres less than the 1993 inventory. This is due to improved calculation from computer digitizing the area boundaries. The new roadless area acreages are shown in the Rating of Wilderness Characteristics Factors Table in Process Paper Q (RFP-FEIS). Within these roadless areas, some 243,000 acres are closed to summer OHV use. The majority of the roadless acres are contained in the Lemhi/Medicine Lodge, Centennial Mountains, Big Hole Mountains and Caribou Range Mountains Subsections. The 1993 roadless inventory showed a net increase in qualifying acres over the inventory in the 1985 Forest Plan. This is because several of the roading and timber harvest projects proposed in that Plan were never completed. These areas were added to the previously inventoried areas. In contrast, the Signal Peak, Warm River South and East and Moody Creek areas incurred enough development to require them to be removed from the inventory. In 1990, the Centennial Mountains Wilderness Suitability Study EIS (Mt. Jefferson) was completed and none of the Forest portion was recommended.

wilderness The Mt Jefferson area was thereby released for management according to the 1985 Forest Plan direction

There is an existing appeal settlement agreement with the Caribou N F concerning Bear Creek and Caribou City roadless areas on that Forest The agreement states that no timber entry is scheduled before the year 2000 and that none will be made

Wild, Scenic and Recreational Rivers (see RFP-FEIS, page 111-77)

Visual Resources

The Forest has some very unique and outstanding scenery It encompasses peaks over 10,000 feet, arid lands, timbered highlands, lakes and waterfalls During the past decade, the greatest change in visual resources occurred among the vast expanses of mature lodgepole pine found in the Madison-Pitchstone Plateaus and Island Park Subsections Large portions of this mature timber were clearcut Some of this timber harvest occurred near major travel routes and use areas such as campgrounds, resorts, summer home areas and private lands This changed many of the solid timbered areas to open meadow-like mosaics of scattered timber stands Even though this was a drastic change from the past, it also provided variety in terms of scenic views and vistas In some instances, this type of harvest enhanced areas from a visual standpoint

Developed Recreation Sites (see RFP-FEIS, page III-78)

Dispersed Recreation

The largest number of dispersed activity and camping sites are in the Caribou Range and western Centennial Mountains Subsections as shown in Table 111-26 (RFP-FEIS, page 111-76) The next largest numbers of sites are in the Lemhi/Medicine Lodge and Big Hole Mountains Subsections These sites receive approximately 1,147,000 visits and result in 992,000 RVDs annually Dispersed sites have few or no structural facilities for recreation They are used for general camping and to provide access to fishing, hunting, OHV areas and trails Some of these sites have received increased use and as a result, have increased the number of camping spots, such as at Horseshoe Lake which has increased from three to seven sites in the last decade Many dispersed activity uses are increasing at a rate of approximately four percent

The capacity in PAOT of these sites is greater than the developed sites on the Forest There are 106 heavy use dispersed sites on the Forest, and some of these dispersed campsites are showing damage to vegetation and soils Field reviews during the summer of 1996 and 1997 indicate a few of these sites are in need of management actions to stabilize or minimize such impacts Monitoring studies during the summer of 1997 indicate that only a small percentage of these dispersed campsites have soil disturbance in excess of the Forest-wide soil standard in the Revised Forest Plan These more disturbed sites have had management action recommendations developed that will be implemented on a trial basis over the next few years

Outfitters and Guides (see RFP-FEIS, page 111-79)

Special Uses (see RFP-FEIS, page 111-79)

ECONOMIC AND SOCIAL ENVIRONMENT

The area primarily affected by the Forest in terms of economic and social concerns comprises Bonneville, Clark, Fremont, Jefferson, Madison and Teton counties in Idaho (RFP-FEIS, page 111-79-92) Together these counties make up the great majority of the Forest's total administrative area and account for the largest part of Forest-related employment, personal income and payments to local governments These counties are recognized as being the Area of Primary Forest Economic Influence (APFEI) (Table 111-27 - RFP-FEIS, page III-80) Information for the Shoshone-Bannock reservation at Fort Hall is also provided

Some observations can be readily made Bonneville county has the highest median household income and the highest incidence of college graduates Clark county has the highest incidence of Social Security recipients Fort Hall's median household income is somehow comparable to the counties listed and yet its unemployment rate seems inconsistently high This may be the result of having more

wage-earners per household and/or some distortion in the estimate of unemployment Fremont county's high rate of unemployment was possibly associated with timber harvests which were declining from peak levels Jefferson county had the highest incidence of owner-occupied housing units and high school graduates Because most of these counties have very small populations, statistics must be thought through Teton county's infant death rate for instance, actually reflects the death of only a single infant Teton county has the highest rate of heating with wood and the lowest unemployment rate

The Forest is of lesser economic importance to other area counties including Teton and Lincoln counties in Wyoming and the Idaho counties of Bannock, Bingham, Butte and Lemhi Bannock and Bingham counties have no lands administered by the Forest The Forest does manage significant amounts of land in Butte, Lemhi, Lincoln, and Teton (Wyoming) counties However, management of the Forest as depicted in the various alternatives under consideration is not expected to have significant effects on these counties Even though these counties are not included in the APFEI they still have important links to the Forest The Grand Targhee Ski Resort, for instance, is located in Teton County, Wyoming It is an important source of income and employment Services and supplies for the facility must come through Teton County, Idaho, however

People from outside this area also have strong ties to the Forest Besides Idaho, Wyoming and Montana the Forest receives many visitors from Utah, California, and the rest of the nation The designation of an area of influence does not diminish the interests others have in the area or the attention paid to their input

Most of the area's population lives in cities like Idaho Falls, Blackfoot and Rexburg The area's population is relatively small and concentrated in Bonneville County which contains Idaho Falls, the area's largest city with a population in excess of 42,000 It regularly ranks as Idaho's second- or third-largest city

Perhaps the most striking characteristic of the area's population is the growth that has occurred in Bonneville and Madison counties during recent decades, and Teton county in recent years Since 1950 the population within the APFEI has more than doubled, from 63,334 in 1950 to 137,991 in 1994 (REIS 1996, RFP-FEIS, page R-9) Bonneville and Madison counties have increased over 2.5 times during that same period Teton county's population has increased by more than six percent annually from 1990 to 1995 Available information indicates this population growth is traditional (based on employment growth), rather than being the cause of employment growth (Taylor and Fletcher 1995, RFP-FEIS, page R-11)

Employment and Income (see RFP-FEIS, page 111-81)

Payments to Local Governments (see RFP-FEIS, page 111-84)

Amenity Interests

Many people in the area, and outside the area, enjoy the Forest for the recreational opportunities it provides, for the scenic vistas it offers, for its aesthetic values, for its importance to wildlife and fish and for the contributions it makes to the greater ecosystem Interests include those associated with the effects of clearcutting on the visual landscape and on area plants, fish, and wildlife, spiritual concerns, land ethics, and environmental concerns in general

Tribal Interests

The Forest lies within the aboriginal territory of the Shoshone-Bannock Tribes The Tribes collectively comprise a single, federally recognized Indian tribe with a governing body, the Fort Hall Business Council, which is duly recognized by the Secretary of the Interior Tribal members are successors-in-interest of Indian signatories to the Fort Bridger Treaty In part, that treaty led to the creation of the Fort Hall Indian Reservation in the Idaho Territory as a permanent tribal homeland The 544,000-acre reservation lies generally between Blackfoot and American Falls, Idaho

Article 4 of said treaty secured for the Tribes in perpetuity the continuation of a wide variety of "use rights" to off-Reservation lands More specifically, by virtue of Article 4 of the treaty, the Tribes expressly reserved the right to hunt on the unoccupied lands of the United States so long as game

may be found thereon" including such lands owned by the federal government outside the boundaries of the Reservation. The courts decided in the Tinno decision (State v Tinno 1972) that the right to hunt also included a right to fish (Shoshone-Bannock Tribes 1992b, RFP-FEIS, page R-10). Hanes (1995, RFP-FEIS, page R-5) observed, "The court agreed that the Indian peoples expected rights to harvest food on the unsettled lands as a means of subsistence and an integral part of their way of life."

The Tribes have historically used the Forest for hunting, fishing and gathering. American Indians historically used at least 838 species of plants on the Forest, covering virtually every type of plant community. These activities are important economically as well as socially and culturally. Part of the economic importance to the Tribes lies in their use of hunted meat to provide food for the elderly and the disabled. "The philosophy and management direction from the Tribes has always been for subsistence hunting and this is reflected in the Tribes Big Game Regulations," (Shoshone-Bannock Tribes 1992a, RFP-FEIS, page R-10).

Rights to believe, express, and exercise traditional religions are protected by various federal laws, including the American Indian Religious Freedom Act of 1978. This includes, but is not limited to, access to sites, the use and possession of sacred objects and the freedom to worship through ceremonial and traditional rites. Additionally, rights reserved under treaty may possess an inherent measure of resource protection (U.S. v. Washington (759 F.2d 1353, 1985) in Shoshone-Bannock Tribes 1992b).

The Forest has worked with representatives of the Tribes to coordinate the Revision with them. Representatives of the Tribes have stressed the following points:

- Treaties are the supreme law of the land (U.S. Constitution, Article 6, Clause 2). Treaty rights cannot be negotiated at the Department level of the United States government. Consultations with the Tribes are on a government-to-government basis.
- The multiple jurisdictions they have to work with make any attempts at working with the Forest an extremely frustrating exercise. Their territory lies within the boundaries of many National Forests, on lands administered by the Bureau of Land Management, on state lands and on lands privately held. This complicates even relatively simple matters like interpretive signs.
- The processes the Forest uses to handle archaeological sites and cultural values do not fully address the Tribes' concerns. It is important to protect sites, to keep them unpublished and to recognize that providing access to sites invites vandalism. It is important for the Forest to consult with the Tribes on a case-by-case basis when providing protection to sites. It is important that vandalism of sites be vigorously prosecuted to serve as a deterrent.
- The Revision must recognize the sacredness of the land, need for protection, obligation to consult with the Tribes as outlined in the American Indian Religious Freedom Act, the NEPA and NFMA, and many aspects of reserved rights including, but not limited to, the priority nature of rights reserved under the treaty, as well as an inherent measure of resource protection to satisfy these rights.
- The Forest must be recognized for its religious and spiritual significance to the Tribes. That significance is not limited to vision quest sites or traditional camp sites. The Forest and even the lands beyond its borders are important in their entirety. As with many other religions, tribal members are not free to share all the dimensions of their faith.

The Tribes also have a significant economic interest in the Forest. These include subsistence activities like hunting, fishing and gathering. They also include important aspects of Tribal life like sharing the fruits of the land. Riverine ecosystems are important to the Tribes not only for their resources but also for the role they play in the Tribes' religion. The Forest will continue to work and coordinate with the Tribes.

Heritage Resources

Heritage resources are described for each of the subsections as follows:

Lemhi/Medicine Lodge - This area contains over 200 heritage resources of predominately American Indian sites including habitation sites and rock art

Centennial Mountains - The Centennial Mountains contain the highest frequency of heritage resource sites on the Forest. Over 400 heritage resources of predominately American Indian sites have been identified

Island Park - Heritage resources in the Island Park area are primarily related to the Tie Hack Period (cutting trees for railroad ties) and early Forest Service history. The 140 sites identified are composed primarily of tie hack camps associated with the Yellowstone Railroad, Forest Service administrative sites such as guard stations, ranger stations, fire lookouts and recreational cabins dating to the early 1900s

Madison-Pitchstone Plateaus - The Madison-Pitchstone Plateaus contains one of the lowest frequencies of heritage resource sites on the Forest. Relatively extensive inventory has identified only 25 sites

Teton Range - The Teton Range has high frequencies of American Indian sites in the upper reaches of the drainages. Over 79 heritage resource sites have been identified

Big Hole Mountains - This area contains over 100 heritage resource sites with most sites located along the northwestern edge of the Big Hole Mountains

Caribou Range Mountains - The Caribou Range is one of the least inventoried areas of the Forest, however, 50 heritage resources have been identified

Quality of Life

The Center for Business Research and Science (CBRS) and the Center for Rural Economic Development (CRED) of Idaho State University have conducted recent surveys of Quality of Life perceptions among area residents in Fremont County and the City of Idaho Falls. These two areas are vastly different in terms of population, income structure, employment opportunities and other demographic characteristics. In both surveys, many of the questions relate to concerns people have with regard to their everyday lives - things like shopping and local government services. The amount of information presented which relates to the Forest is limited. The surveys do provide some insight into how area residents perceive their living environments.

The Center for Business Research and Science (CBRS) and the Center for Rural Economic Development (CRED) of Idaho State University have conducted surveys of Quality of Life perceptions among area residents in Fremont County and the City of Idaho Falls. The amount of information presented which relates to the Forest is limited.

Fremont County respondents were most satisfied with Air Quality and Open Spaces and Green Spaces and least satisfied with Employment Opportunities and the Availability of Retail Shopping. Forty-three percent felt that Tourism was the type of ideal business they would like to see locate in Fremont County. Some 34 percent felt the same way about General Manufacturing. The most important factors in determining Quality of Life were Employment Opportunities, Level of Individual Well-Being, and Public Education. (CBRS, CRED a and b)

City of Idaho Falls respondents identified a Low Local Tax Rate, Medical Services, and Salary and Wage Levels as favorable characteristics of their community. When faced with making choices, people preferred to Limit Economic and Population Growth (32 percent) and Increase Taxes and the Local Cost of Living (31 percent). Their least desirable courses of action were to Permit Degrading of the Environment (30 percent) and Increase Taxes and the Local Cost of Living (27 percent). (CBRS)

Minorities and Women (see RFP-FEIS, page 111-92)

Coordination with Other Agencies (see RFP-FEIS, page 111-92)

PRODUCTION OF COMMODITY RESOURCES

Timber

The amount of forested land by species group, age class and subsection on the Forest was displayed in Table 1113 in the RFP-FEIS (page III-12)

Table 11133 in the RFP-FEIS (page 111-93) displays the average mature volume of saw timber growing on the Forest by species and subsection

Tentatively Suitable Forest Land (see RFP-FEIS, page III-93)

Future Supply and Demand (see RFP-FEIS, page III-97)

Reforestation/Timber Stand Improvement (see RFP-FEIS, page III-98)

LIVESTOCK GRAZING

Livestock Grazing

Livestock grazing has been a use of both forested and non-forested plan communities throughout the Forest since before 1900 (RFP-FEIS, page III-98-100). Approximately 73 percent (1,371,066) of the 1.87 million acres under Forest grazing administration are identified as being in grazing allotments. Of these acres, about 782,005 (53 percent) are capable for livestock grazing. Approximately 496,049 acres (27 percent) are presently closed to grazing. There are 145 allotments (76 cattle and 69 sheep) on the Forest where livestock grazing occurs, of which 109 have AMPs.

As documented in the Annual Operating Plans and/or the Allotment Management Plans, all of the allotments open to grazing have grazing systems in place which implement various grazing strategies. These plans include grazing utilization standards that implement direction from the Revised Forest Plan (page 111-29).

The current permitted livestock use reported on the Forest is 148,775 AUMs. Permitted livestock consists of 22,066 cattle and 71,985 sheep. Currently 182 permittees hold 277 grazing permits which authorize grazing on the Forest. Presently, based on 1993 data, the numbers of livestock actually using the forest are 20,362 cattle for 84,212 AUMs and 54,478 sheep for 44,006 AUMs.

To better manage livestock, many structural improvements have been constructed using equal (50 percent Forest Service and 50 percent permittee) contributions from the Forest Service and the grazing permittees. These improvements include 563 miles of fence, 670 water developments, 72.5 miles of pipeline, 8 wells, 16 corrals, 7 stock bridges, 2 herder cabins, 74 cattleguards, and 25 miles of stock trail. The Forest portion of these improvements is generated from grazing receipts (range betterment funds) and usually is in the form of materials and supplies. Range improvement structures are maintained by the grazing permittees.

Chapter

IV

Environmental Consequences

CHAPTER IV

ENVIRONMENTAL CONSEQUENCES

READER'S GUIDE - In this chapter you will find.

A description of the consequences of implementing the alternatives with respect to the following components and key issues

- **ECOSYSTEM MANAGEMENT**
- **PHYSICAL ELEMENTS OF THE ENVIRONMENT**
- **BIOLOGICAL ELEMENTS OF THE ENVIRONMENT**
- **FOREST USE AND OCCUPATION**
- **PRODUCTION OF COMMODITY RESOURCES**
- **IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES**

The consequences are described in some or all of the following terms - Consequences Common to All Alternatives, Consequences Which Vary by Alternatives, and Cumulative Effects

NOTE to READERS Please refer to the 1997 Revised Forest Plan for a "Glossary" of terms used in this document

ECOSYSTEM MANAGEMENT

The RFP-FEIS, pages IV-1 through IV-12 describes the ecological processes and patterns which would result from management actions of the Revised Forest Plan Road and trail transportation management were also considered during that analysis, and management goals and objectives and standards and guidelines were developed to minimize environmental consequences of motorized travel

PHYSICAL ELEMENTS

Soils and Geology

Indicators

- 1 Road and trail acres removed from productive land base
- 2 Miles of roads and trails transecting soil types having mass stability concerns
- 3 Acres placed back into productive land base

Consequences Common to All Alternatives - Soil disturbance from dispersed camping and OHV use will continue to be a challenge to soil quality management. Demand for these uses will continue to escalate with corresponding concerns

Consequences Which *Vary by Alternative* -

Land removed from the productive land base, due to roads and trails, would be greatest under Alternative 1M - approximately 9,120 acres (Table IV-1) or roughly 5 percent of the Forest's land base Of these acres, approximately 1,527 acres (17 percent) would naturally recover over the long-term due to having year-long restrictions

Alternative 3M(+) would result in approximately 7,389 acres removed from the productive land base or roughly 4 percent of the Forest's land base Of these acres, approximately 1,184 acres (16 percent) would naturally recover over the long-term due to having year-long restrictions Alternative 3M would result in approximately 7,215 acres removed from productive land, or 5 percent of the Forest's land base Of these acres, approximately 1,237 acres (17 percent) would naturally recover over the long-term due to having year-long restrictions Alternative 3M(-) would have the fewest acres

removed from the productive land base - approximately 7,200 acres. Of these, approximately 1,248 acres (17 percent) would naturally recover over the long-term due to having year-long restrictions. These lands (minus the acres with year-long restrictions in the long-term) would be effectively removed from the Forest's total productive land base for the life of the road and trail and would be susceptible to erosion and subsequent sedimentation. A high percentage of these acres occur within the Aquatic Influence Zones (AIZs), thus having a short delivery distance to a stream channel. One objective under the watershed activity schedule is to inventory roads, trails, culverts, fords and stream crossings within the AIZ's by the year 2007. This inventory will identify problem areas and suggest remedial actions (RFP-FEIS page IV-13-14).

Table IV-1 Alternative Effects on Soils and Productivity

Alternative	1M	3M(+)	3M	3M(-)
Acres removed from productivity for short-term	9,120	7,389	7,320	7,200
Acres removed from productivity for long-term	7,593	6,025	5,978	5,952
Miles of roads/trails on unstable soils	1,297	950	916	860
Miles of roads/trails on unstable soils >40 percent	900	644	614	570
Acres back in productivity short-term	1,635	3,287	3,444	3,462
Acres back in productivity long-term	3,161	4,470	4,681	4,709

Thus, in the short-term the ranking (greatest to least) of Alternatives that would remove acres from the productive land base would be 1M, 3M(+), 3M, and 3M(-). In the long-term (taking into consideration the recovery of year-long restricted access routes) the ranking of acres removed from productivity (greatest to least) would also be 1M, 3M(+), 3M, and 3M(-).

Miles of roads/trails transecting soil types having mass instability concerns would be greatest under Alternative 1M, approximately 1,297 miles of which 900 miles (69 percent) occur on slopes over 40 percent. None of the roads planned for decommissioning¹ under this alternative would occur on soils where mass instability is a concern, 44 percent (41 of the 93 miles) of the roads on soils having mass instability concerns and that have slopes over 40 percent would have year-long restrictions. Alternative 3M(+) would result in approximately 950 miles of roads on unstable soils, of which 644 miles (68 percent) occur on slopes over 40 percent. Approximately 61 percent (104 of the 171 miles) of the roads on soils having mass instability concerns and that have slopes over 40 percent would be decommissioned. In addition, 50 percent (29 of 58 miles) of the roads on soils having mass instability concerns and that have slopes over 40 percent would have year-long restrictions. Alternative 3M would result in approximately 916 miles of which 614 (67 percent) occur on slopes over 40 percent. Approximately 62 percent (121 of the 195 miles) of the roads on soils having mass instability concerns and that have slopes over 40 percent would be decommissioned. In addition, 48 percent (30 of

¹ Decommissioned Road: Any road which has been treated in such a manner so as to no longer function as a road or trail for summer restricted use. This can be accomplished through one or a combination of several means including recontouring to original slope, placement of logging, deadfall piles, planting of shrubs, etc. See Appendix B of the DEIS for a list of locations on the Forest.

62 miles) of the roads on soils having mass instability concerns and that have slopes over 40 percent would have year-long restrictions. Alternative 3M(-) would result in approximately 860 miles of which 570 miles (66 percent) occur on slopes over 40 percent. Approximately 61 percent (120 of the 196 miles) of the roads on soils having mass instability concerns and that have slopes over 40 percent would be decommissioned. In addition, 50 percent (31 of 62 miles) of the roads on soils having mass instability concerns and that have slopes over 40 percent would have year-long restrictions.

Thus, in both the short and long-term the ranking of Alternatives having the greatest to least potential effect on mass instability concerns would be 1M, 3M(+), 3M, and 3M(-).

Acres placed back into productivity (stabilized and revegetated) through road reclamation/ decommissioning would be ranked (greatest to least) 3M(-), 3M, 3M(+), and 1M. This would occur in the short-term with active road decommissioning and reclamation. Taking into account long-term recovery resulting from roads having year-long restrictions (these would recover with time) the ranking (greatest to least) would be 3M(-) - 4,709 acres, 3M - 4,681 acres, 3M(+) - 4,470 acres, and 1M - 3,161 acres. Decommissioned roads would have a lower inherent site productivity than adjacent undisturbed sites but overall benefits from decommissioning and year-long closures is beneficial to soil and watershed conditions.

Overall, in ranking the alternatives as to their benefits to soil productivity and soil hydrologic function (soil quality) the ranking (most beneficial to least beneficial) would be 3M(-), 3M, 3M(+), and 1M. This is mainly because of the potentials associated with roads on soils having mass instability concerns, especially on slopes that are over 40 percent and due to short and long-term reclamation differences. The difference between Alternatives on acres taken out or placed back into productivity are fairly close and thus do not play as significant a role in making this determination of ranking Alternatives.

Cumulative Effects - Effects indicated above and for all foreseeable projects would be very similar to those stated in the RFP-FEIS and including those for cross-country travel, since there is no change in cross-country from that indicated by the Revised Forest Plan. Overall, soil quality on the Forest should improve over the existing situation under all alternatives (RFP-FEE, page IV-15). This effect is due to the decommissioning and reclamation and yearlong restrictions of roads which will allow for recovery of soil productivity and hydrologic function. Soil quality standards and guidelines have been established to help direct soil quality improvement, maintenance and/or enhancement within managed portions of the Forest. These standards and guidelines have been incorporated in the 1997 Revised Forest Plan.

Air Quality

Consequences Which Vary *by* Alternative - Alternative 1M allows the most open motorized routes, however this is not as much potential activity as described for Alternative 1 in the RFP-FEIS (page IV-15). Alternative 1M has the most potential for adverse effects to air quality from dust. The three 3M alternatives have somewhat less potential for air quality impacts from open roads.

Another consequence which would vary would be potential for severe wildfire as indicated in the RFP-FEIS (page IV-15). As more roads are decommissioned from Alternative 1M toward Alternative 3M(-), the potential for severe wildfire increases because access for fire crews becomes more restricted.

Caves

Consequences *Common to All Alternatives* - Impacts on cave resources would result from normal recreational use that would be similar for all alternatives (RFP-FEIS page IV-16).

Lands

Consequences *Common to all Alternatives* - There would be no impacts on lands from any alternative (RFP-FEIS page IV-16).

Minerals

Consequences Which Vary by Alternative - Since overall access will decrease from Alternative 1M through Alternative 3M(-), access for potential mineral exploration or development could likewise be limited somewhat

BIOLOGICAL ELEMENTS

Aquatic and Riparian Ecosystems

Analysis of consequences specific to these motorized travel alternatives is covered under the soils, water, and fisheries sections. The Revised Forest Plan FEIS addressed the major aquatic and riparian issues which dealt mostly with improving riparian vegetation conditions to meet Desired Vegetative Condition (DVC) and Properly Functioning Condition (PFC) objectives along the hydric greenline (HGL) - (RFP-FEE, pages IV-17-19). Overall, aquatic and riparian conditions (DVC and PFC) will improve as the alternative range moves from 1M toward 3M(-). The effects of Alternative 1M would result in slow improvement of vegetative composition and percent of riparian areas meeting DVC. The three 3M alternatives would all have a slightly improved rate of recovery of these ecosystems over the recovery rate of Alternative 1M.

Water

Indicators:

- 1 Miles of road and trail in AIZ
- 2 Acres of road and trail in AIZ
- 3 Number of Stream Crossings

Consequences Common to All Alternatives - Land disturbance and impacts to riparian resources will take place under all alternatives, however, the magnitude of the impacts will vary between alternatives as discussed below. Decommissioning of roads and trails in the AIZ will result in soil disturbance, with short-term creation of sediment sources which will have the potential to deliver sediment to streams for approximately 3 years, or until they are stabilized. Determination of exact amounts of sediment is very difficult due to the wide variety of soils, slopes, vegetation, etc that exist on the Forest. Decommissioning would, however, provide a long-term benefit to aquatic and riparian resources once it became effective (i.e., when the vegetation is established). Closing roads by installation of gates may slowly provide benefits over time, by not allowing continued rutting of road surfaces, but recovery is slower than if a road is decommissioned (i.e., ripped). Since road prisms will not be removed where they exist in floodplains (Appendix B - Road Decommissioning Protocol), floodplain and stream functions could be adversely affected by the confinement presented by these features, even with road decommissioning and/or closure. This is the reason for including closed roads as sources of impact in the assessment of effects.

Consequences Which Vary by Alternative - Direct impacts to streams and riparian areas are of three general types (p. IV-19, RFP-FEIS)

- 1 Changes in riparian soil, vegetation and streambank characteristics,
- 2 Direct in-channel alterations (e.g., putting a structure into a stream or altering its geometry),
- 3 Changes in the amount of sediment delivered to streams and therefore the load that the stream must transport (Note some of this may be a result of indirect effects)

Roads and trails in Aquatic Influence Zones (AIZs) have the potential to cause the impacts listed in numbers 1 and 3, above. The greatest overall potential for direct impacts would exist under Alternative 1M, with 863 miles (3020 acres) of roads and trails in AIZs (Table IV-2), followed by Alternatives 3M(+), 3M, and then 3M(-) - the latter having 641 miles (2244 acres) of AIZ roads and trails. Such a decrease in roads and trails within the AIZ means a proportional decrease in the potential for sediment delivery to streams, for delivery of other pollutants and for detrimental impacts to riparian areas (RFP-FEIS, page IV-20). A relative comparison of the four alternatives follows.

Alternative 1M vs 3M(+) - Alternative 1M would have more open, motorized roads and trails than 3M(+) and the other 3M alternatives along Fritz Cr , Henrys Fork, Brockman Cr , East and West Camas Cr , and Sheridan, North Moody, and Kelly Canyon These streams are either listed by the State as existing or proposed Water Quality Limited (WQL) streams or are streams recognized as being potentially impacted by adjacent roads Therefore, there is more potential for adverse effect to WQL streams in Alternative 1M than in the other alternatives However, improvement of the Skyline Road in Alternative 1M would reduce the risk of impacts to water quality in at least one location

Table IV-2 Indicators of Potential Effects to Water Quality

Alternatives	1M	3M(+)	3M	3M(-)
Miles of rd/tr in AIZ	863	702	677	641
Acres of rd/tr in AIZ	3,020	2,457	2,370	2,244
Number of stream crossings	4,248	3,263	3,153	2,988

Alternative 3M(+) vs Alternatives 3M and 3M(-) - Under Alternative 3M(+), there would be approximately 13 more miles of road and motorized trail along intermittent tributaries to perennial streams than under Alternative 3M, with the associated potential to deliver sediment to streams Most of these miles are on the Dubois Ranger District There are also approximately 12 more miles along probable perennial stream reaches than under 3M and again, most of the miles are proposed on the Dubois Ranger District The most noteworthy differences between Alternative 3M(+) and Alternative 3M would include the following conditions in 3M(+) which would not exist in Alternative 3M

- Proposed open roads and trails up Fritz Creek under 3M(+) are in the headwaters of a perennial stream that has its lower reaches (from the Forks to Medicine Lodge Creek) listed as Water Quality Limited (WQL)
- The four wheel drive road/trail up Grouse Canyon under 3M(+) would be along a perennial stream which flows into a listed WQL stream (Warm Springs Creek)
- Two roads/trails would exist under 3M(+) up intermittent tributaries to West Camas Creek, which flows into Camas Creek - a listed WQL stream
- A road/trail crosses the headwaters of tributaries to Horseshoe Creek under 3M(+), which is WQL listed

All roads or motorized trails being proposed for deletion under Alternative 3M(-) are on the Palisades and Teton Basin Ranger Districts Approximately 21 miles are proposed to be dropped along probable perennial reaches of stream, while an additional 10 miles are proposed for deletion along intermittent tributaries to perennial streams Noteworthy deletions include the following

- Patterson Creek the road is confining the creek and is frequently flooded at the lower end The district is considering graveling the flooded section of the road and installing a culvert to remedy the wet area problems Under Alternative 3M(-) the road would be closed and the impacts to riparian-dependent resources reduced
- Henderson Creek AIZ Road Inventory Forms cited this road as confining the stream channel Closing it would benefit riparian-dependent resources
- Murphy Creek, Pole Canyon, and Patterson are included in the WQL reach of the Teton River that includes the headwaters to Trail Creek confluence
- North and South Indian Creeks (from the Wyoming state line to Indian Creek) are newly proposed for listing as WQL on the 1998 list
- There is a gully in the bottom of Long Spring Canyon that developed in the existing road during spring runoff in 1997 Watershed specialists advised moving the trailhead further down the

canyon to avoid large-scale vehicle **use** where the gully occurred. An improved road/trail could exacerbate runoff-related problems, while in contrast, leaving the area undeveloped and rehabilitated under **3M(-)** would reduce the probability of similar impacts.

Stream crossings, including both fords and those that have crossing structures (mainly culverts), have the potential to cause the impacts listed in numbers 1, 2, and 3 (above) during construction, and numbers 2 and 3 in the long run. Unprotected ford crossings may cause accelerated sediment delivery to streams via five major processes (Brown, 1994)

- a undercutting of banks due to vehicle bow-wave attack on banks (waves created by the vehicle),
- b creation of wheel ruts (on approaches) and the concentration of surface runoff after a precipitation event ,
- c backwash created by water draining from a vehicle as it emerges after fording a stream,
- d the existence of tracks, and therefore areas of exposed surface, and
- e compaction and subsequent reduction in infiltration rates of soils, leading to increased surface runoff

Although culverts and bridges reduce or eliminate these effects, placement and maintenance of structures still creates sediment sources, and approaches to crossings may still be rutted during precipitation events or early in spring. For all these reasons, stream crossings are used as an indicator of potential impacts to water resources. Potential for adverse impacts associated with stream crossings is highest under Alternative 1M, with 4248 crossings. This potential then decreases from Alternative **3M(+)**, through **3M**, to a low under **3M(-)** which has a total of 2988 stream crossings.

Indirect effects include higher water quantities (flows) from Alternative 1M than from the 3M alternatives which would be approximately the same in terms of quantity. This is a result of higher delivery to streams due to greater amounts of collection surfaces and more efficient delivery systems (culverts, ditches, etc).

Cumulative Effects - Effects discussed above would be cumulative in the sense that all roads remaining under each of the alternatives, regardless of when they were constructed, would contribute to any resulting effects to streams and riparian areas. Potential for sediment delivery to streams, and changes in other channel and water quality parameters (e.g., water temperature) would all be reflected in the indicators chosen. Actual implementation of Best Management Practices and Revised Forest Plan (RFP) objectives, standards, and guidelines will largely determine the on-the-ground success of management in protecting aquatic and riparian-dependent resources. This will be independent of the alternative chosen. All alternatives would meet State water quality standards (RFP-FEIS, page IV-21) Forest-wide except for localized areas with possible sedimentation concerns.

Fisheries

Indicators

- 1 Miles of open and closed road and motorized trail within AIZs occupied by cutthroat trout
- 2 Number of stream crossings of open and closed road and motorized trail within cutthroat trout streams

Consequences Common to A// Alternatives

1 Miles of Open and Closed Road and Motorized Trail - Impacts to AIZ's along cutthroat trout streams from land management activities associated with livestock grazing, grazing by recreational stock, camping in designated and dispersed sites, fishing, firewood cutting, and vehicular travel on and off of designated routes will continue under all alternatives. These activities are secondary impacts associated with roads and motorized trails and tend to increase with increased access (Furniss, et al 1991). RFP standards and guidelines do not fully protect AIZs, they merely limit the amount and type of impacts which are permissible (refer to RFP pps III-106-112). Additional impacts may occur which are associated with inadvertent, unauthorized or planned events such as human caused fire, forest insect and disease due to fire exclusion, or violations of vehicular travel regulations. Also,

impacts associated with natural processes such as natural levels of wildfire, forest insects and disease, and erosion will continue regardless of alternative implemented

Under any of the alternatives, there are at least 545 stream crossings and 157 miles of road and motorized trail within AIZ's occupied by cutthroat trout. These roads, motorized trails, and stream crossings will continue to degrade cutthroat trout habitat as long as they exist (unless completely decommissioned, e.g. removed). Roads, motorized trails, and their associated stream crossings tend to modify stream structure and function (Furniss et al. 1991, King 1989). Roads located within stream floodplains effectively reduce the size and shape of the floodplain. When a stream no longer has access to its floodplain, stream energy is adjusted (equalized) by increasing stream velocity, resulting in downcutting or lateral scour of the stream channel. When roads impinge on stream floodplains, stream sinuosity is reduced. Pool quality and quantity are reduced when stream courses are straightened. Sediment is increased through road construction and maintenance and through stream erosion caused when roadbeds cause stream confinement. When sediment is increased beyond what the stream can transport, it can alter the productivity and character of the stream. As pool size is reduced due to sediment deposition, the number of large age class fish that the stream can support is also reduced (McIntyre 1991). Unnaturally high amounts of sediment deposited in streams can settle in spawning gravel and kill cutthroat eggs and embryos and reduce fry development (Thurrow 1991, Hausle and Coble 1976, and Furniss et al. 1991). Sediment also reduces the productivity of aquatic invertebrates used as forage by cutthroat trout (Cordone and Kelly 1960). When trees and shrubs are removed within road rights-of-way, woody debris is removed from the stream ecosystem. This reduces the amount of woody substrate in the stream and reduces many aquatic invertebrates. Woody debris also forms pools and creates areas of spawning gravel deposition. Pools provide necessary hiding and resting cover for cutthroat trout.

2 Number of Stream Crossings Within Cutthroat Trout Streams - Same as above

For further details of other potential consequences, refer to RFP-FEIS, page IV-19

Consequences Which Vary by Alternative

1 Miles of Open and Closed Road and Motorized Trail - Table IV-3 displays the number of stream crossings, miles of open/closed road and motorized trail, and miles of decommissioned road within AIZ's occupied by cutthroat trout that would be allowed under each alternative. Alternative 1M would allow the most total miles of road and motorized trail at 203. Alternative 3M+ would allow 179 total miles. Alternative 3M would allow 170 total miles. Alternative 3M- would allow the fewest at 157 total miles. Conversely, under Alternative 1M, no roads would be decommissioned, while under Alternative 3M+, 10 miles would be decommissioned, and under Alternatives 3M and 3M-, 13 miles would be decommissioned. Approximately one mile of road along Ching Creek would be open under Alternatives 1M and 3M+ but closed under Alternatives 3M and 3M-. Nearby Moose Creek would have 0.7 mile of open road in Alternative 3M+ that would be closed in all other alternatives.

There is a difference between alternatives in the amount of motorized trail access in cutthroat trout habitat. No motorized trail would be decommissioned under any alternative. Motorized trails in cutthroat trout habitat, which vary by alternative, affect primarily Calamity, Rainey, North Indian, and South Indian Creeks as described in Table IV-4. Rainey Creek is a very high priority stream for protection because it is one of four main spawning tributaries supporting the cutthroat trout fisheries on the South Fork Snake River. The specific type and amount of impact of increased motorized access to the streams listed above would depend upon the specific road or trail surface, road or trail location, type of stream crossing(s), amount and type of use, season of use, level of user compliance, watershed health and stability, and fish population health on each site.

Up to 13 miles of road would be decommissioned within cutthroat AIZ (Table IV-3). This would include culvert and culvert fill removal and seeding of bare soil adjacent to streams, but not road fill removal within the stream floodplain (Appendix B - Road Decommissioning Process Guidelines). Where road fill would remain in the stream floodplain, stream structure and function would continue to be impaired. Where this is extensive, the rate of recovery of stream structure and function would be very slow and total recovery of the area may not occur (would remain nearly the same). Where roads occur primarily at stream crossings, (as opposed to paralleling the stream), recovery of decommissioned road segments would be relatively rapid (3-5 years) and complete. It is expected that trees and

shrubs would become established within the abandoned rights-of way within approximately 7-10 years. These trees and shrubs would provide shade within 20-30 years and provide woody material to the stream environment within 100-400 years. Recruitment of large wood to the stream would improve stream structure and function.

Table IV-3 Number of Stream Crossings and Miles of Open/closed Road, and Motorized Trail Within AIZ's Occupied by Cutthroat Trout by Alternative

Alternative	1M	3M(+)	3M	3M(-)
Number of stream crossings	618	610	595	545
Open & closed road miles	122	109	104	106
Open motorized trail miles	81	70	66	51
Decommissioned road miles	0	10	13	13

Table IV-4 Miles of Motorized Trail Within AIZs Occupied by Cutthroat Trout Streams Showing the Greatest Differences Between Alternatives

Alternative	1M	3M(+)	3M	3M(-)
STREAM -				
Calamity	2	2	2	1
Rainey	16	16	12	9
North Indian	11	11	11	0
South Indian	9	9	9	0

2 Number of Stream Crossings Within Cutthroat Trout Streams - The number of stream crossings existing under each alternative is displayed in Table IV-3. The number of stream crossings increases as the miles of open and closed road increases. The general impacts of stream crossings are similar to that of roads and motorized trails within the AIZ and are described above. Specifically, stream crossings are of three general types: ford, culvert, and bridge.

Stream fords tend to generate sediment at the crossing site, and if not properly designed or constructed, can channel streamflow down the road or trail. Culverts may halt fish movements during low water conditions and during spawning migrations (Furniss et al 1991). Culverts may become clogged and cause the stream to scour out portions of roads which causes excessive sediment delivery to streams. Culvert crossings tend to impinge upon the stream floodplain and may alter the stream gradient. Culverts occasionally wash out due to inadequate size or inadequate maintenance. Culvert failures usually result in increased sediment input to the stream. The effects of excessive sediment input are described above. Properly designed and maintained bridges tend to produce the least impact to stream structure and function and fisheries.

For further details of potential consequences, refer to RFP-EIS IV, pages 19-21.

Cumulative Effects (for Indicators 1 and 2) - The difference in cumulative effects between alternatives is not great. However, cumulative adverse impacts to cutthroat trout habitat and populations would increase as the miles of road and stream crossings increase. Most of the healthy cutthroat trout populations occur within unroaded or slightly roaded drainages.

Cutthroat trout are also affected by roads outside the AIZ, livestock grazing, fishing, streambank trampling by fishermen, OHV use, logging, firewood cutting, past logging within AIZs, and so on.

Although it is unlikely that any of the proposed alternatives would threaten the population viability of native cutthroat trout over the next 10-15 years, differences in rate of recovery of degraded habitats and overall habitat quality would result from implementation of the various alternatives (see Appendix D of this DEIS). Fisheries habitat quality, including that for native cutthroat trout, would be the lowest

under Alternative 1M Alternative 1M would result in a slow rate of recovery of degraded habitats Alternatives 3M(+), 3M, and 3M(-) would result in a moderate rate of recovery of degraded habitats and slightly higher levels of fish habitat quality

Wildlife Associated with Aquatic and Riparian Ecosystems

Process Paper D and the FEIS for the Revised Forest Plan are incorporated by reference and present additional information about wildlife populations and habitat which will not be repeated in this EIS, because it is not pertinent to the issues of this analysis

Bald Eagle Habitat

Consequences Common to A//Alternatives - All of the bald eagle nesting territories on the Targhee National Forest, except for a couple of territories along Palisades Reservoir, contain roads and trails either within their primary use areas (Zones I and II) or their total foraging areas Most of these roads and trails were present prior to the time when the bald eagles established their territories (most of the bald eagle territories became established on the Forest from the mid-1970's to the present) For the four alternatives being considered in this EIS, there is no difference in the miles of roads and trails within bald eagle territories

Forest-wide standards and guidelines for bald eagles provide management direction for roads and trails in bald eagle habitat, and this management direction is the same in all Alternatives The following management prescriptions also provide suitable habitat for bald eagles 2 9 1, 2 9 2, 2 3, 2 4, 2 5, and 2 8 3 All existing bald eagle nesting territories will be maintained in all alternatives

Vehicular traffic (including watercraft) traveling along prescribed routes or within strict spatial limits and at relatively predictable frequencies is least disturbing to bald eagles (Greater Yellowstone Bald Eagle Working Group, 1996).

In a study along the Snake River in Wyoming (reported in Greater Yellowstone Bald Eagle Working Group, 1996), some bald eagle pairs' primary use areas were on the most heavily impacted section of the River Despite continuous and often highly intensive human use, eagles shifted their activity patterns in apparent response to periods when their presence would be least obvious to humans - very early morning and evening Eagles used perches on the shoreline of the Snake River with much greater frequency and duration than those on the opposite shore, where a heavily used state highway and associated boat ramps, campgrounds, and vehicle pullouts were situated

Some bald eagles are more tolerant of human activity in the Greater Yellowstone area than others. There are apparently "urban" and "rural" eagles Mean distance at which resident eagles flushed from human activity was greater when relative exposure to human activity was less Thus, eagles in the vicinity of continuously inhabited areas of high human density may become habituated to human presence and tolerant of certain human activities more than their rural counterparts Urban eagles may be exposed to more human activity at gradually increasing levels, usually within clearly defined limits (towns, villages, roads) while human activity to which rural eagles are exposed is distributed and moving randomly (campgrounds, hikers, boats) at varying intensities and often seasonal and abrupt Whether individual eagles become progressively more tolerant to human activity over time or if areas subjected to excessive human activity are occupied by more tolerant eagles is unknown (Greater Yellowstone Bald Eagle Working Group, 1996)

Cumulative Effects- The Forest-wide standards and guidelines for bald eagle nest zones and primary use areas apply to human activities which the Forest Service has authority to manage Bald eagle nest zones and primary use areas occur on adjacent National Forests, BLM lands, state and private lands Along the South Fork of the Snake River, a "Snake River Activity/Operations Plan" was approved by the BLM and the Forest Service in 1991 Bald eagle habitat management was a key component of that Plan

Management actions of other agencies, such as management of fishing and fish populations by the State Fish and Game agencies, and management of river flows by the Bureau of Reclamation and the SE Idaho irrigators, may have positive or negative effects on the bald eagle population In some places, such as where summer homes have been built or are being built on private lands, additional roads and trails have been or are being built in bald eagle habitat However, at this time, we have no

indication that this additional access has been or will be detrimental to maintaining a recovered bald eagle population in SE Idaho

According to records which we have been able to compile from 1972 to the present, the bald eagle population has increased in SE Idaho and currently exceeds recovery plan goals

Trumpeter Swan Habitat

Consequences Common to A// Alternatives - The response of trumpeter swans to roads and trails varies greatly. Some swans are more tolerant of human activity than others. Swans in the vicinity of continuously inhabited areas of high human density may become habituated to human presence and tolerant of certain human activities, such as the swans which have historically nested along U S Highway 20 in Island Park. Vehicular traffic along prescribed routes or within strict spatial limits and at relatively predictable frequencies is least disturbing to swans. Whether individual swans become progressively more tolerant to human activity over time or if areas subjected to excessive human activity are occupied by more tolerant swans is unknown.

For the four alternatives being considered in this EIS, there is no difference in the miles of open roads and motorized trails which would have an effect on trumpeter swan habitat. Forest-wide goals, standards and guidelines provide the same management direction and protection for trumpeter swans in all alternatives. All trumpeter swan habitat is also within the aquatic influence zone management prescription. This management prescription has eight guidelines specifically dealing with roads and trails. Suitable habitat will be maintained in all alternatives.

Cumulative Effects - Cumulative effects are the same as discussed in the FEIS (page IV-22) for the Revised Forest Plan which indicates many of the lakes and ponds historically used by trumpeter swans are naturally filling in with sediment and are becoming too shallow for swan use.

Spotted Frog Habitat

Consequences Common to A// Alternatives - The aquatic influence zone management prescription provides the same management direction for spotted frog habitat in all alternatives. This management prescription has eight guidelines specifically dealing with roads and trails. This management direction provides suitable habitat conditions for spotted frogs. With our existing knowledge of habitat and populations, we expect the existing known distribution and abundance of spotted frogs on National Forest lands will be maintained in all alternatives.

Cumulative Effects - In some places, such as on private lands, additional roads and trails have been or could be built in wetland and riparian habitats which could adversely affect spotted frog habitat and populations. Other cumulative effects are the same as discussed in the FEIS (page 1\1-2223) for the Revised Forest Plan.

Common Loon Habitat

Consequences Common to A// Alternatives - All alternatives are the same in respect to roads and trails in the proximity of potential common loon habitat on the Forest. The aquatic influence zone management prescription provides the same management direction for common loon habitat in all alternatives. This management prescription has eight guidelines specifically dealing with roads and trails. The Revised Forest Plan has an objective to evaluate the potential to provide and maintain suitable breeding habitat for common loons at specific sites on the Forest. If this evaluation proves that these sites are suitable breeding habitat for common loons, the Forest is to develop common loon management plans for these sites. Current habitat conditions will be perpetuated at these sites in all alternatives.

Cumulative Effects - Recreational fishing activity is encouraged by the State Fish and Game Departments at some of the lakes which have had documented common loon observations. Recreational activity during the loon nesting and brood rearing seasons can be detrimental, especially on small lakes and ponds where birds would not be able to find seclusion away from human activity.

Harlequin Duck Habitat

Consequences Common to All Alternatives - There are four creeks on the Forest which have had documented harlequin duck observations, including the rearing of broods. Portions of these four creeks have existing roads and trails adjacent to them. All of the alternatives maintain the presence of existing roads and trails along these four creeks. A Forest-wide guideline, which applies to all alternatives, establishes management direction to avoid establishing new trails, new roads, or new recreation facilities within 300 feet of any stream reach with documented harlequin duck breeding activity. Also, the aquatic influence zone management prescription provides the same management direction for harlequin duck habitat in all alternatives. This management prescription has eight guidelines specifically dealing with roads and trails. Existing habitat conditions for harlequin ducks will be maintained in all alternatives.

Cumulative Effects - Portions of the four creeks with harlequin duck activity have livestock grazing, existing recreational facilities, are open to fishing and other dispersed recreation activity. The effects of these activities is unknown. However, harlequin duck presence has existed with these existing activities.

TERRESTRIAL ECOSYSTEMS

Upland Forested Ecosystems

These ecosystems were addressed by the RFP-FEIS (page IV-24-25) and these alternatives will have little or no effects.

TES and Biodiversity

Consequences Common to All Alternatives - Site-specific activities such as culvert or fill material removal along roads to be decommissioned will be evaluated prior to disturbance to insure compliance with direction and policy of no loss to the threatened Ute ladies'-tresses (*Spiranthes diluvialis*) or sensitive species and protection of habitats of high plant biodiversity, e.g. peatlands. With our existing knowledge of Ute ladies'-tresses occurrence on the Forest (floodplain of the South Fork of the Snake River), we expect that the existing known distribution and abundance of the species will be maintained in all alternatives.

Cumulative Effects - Forest-wide, implementation of all alternatives is not likely to significantly or adversely affect the protection of TES or biodiversity indicator plant species. However, the potential of cumulative adverse impacts to these species and their habitat would increase as the miles of road increase. These species can also be affected by livestock grazing, natural forest or riparian habitat succession, OHV use, vegetation manipulation (e.g. logging, prescribed fires), exotic plant introduction not associated with roads, wildfires and so on.

Impacts to Ute ladies'-tresses known populations along the South Fork of the Snake River such as livestock grazing, management of river flows and recreation have been addressed in a joint Forest/BLM Biological Assessment, separate from the DEIS.

Upland Nonforested Ecosystems

Consequences Common to All Alternatives - Implementation of all four alternatives is not likely to significantly or adversely affect the management of the upland nonforested vegetation.

Consequences *Which Vary by* Alternative - None.

Cumulative Effects - Forest-wide, implementation of all alternatives is not likely to significantly or adversely affect the management of upland nonforested vegetation.

Noxious Weeds

Consequences Common to All Alternatives - The effects of noxious weed management are disclosed in the 1987 Targhee National Forest Noxious Weed EA and Decision Notice and are incorporated by reference into this analysis and the 1997 FEIS for the Revised Forest Plan (RFP-FEIS page IV-27). Regardless of which alternative is selected, management of noxious weeds does not change.

Consequences Which Vary by Alternative - Obviously, motorized vehicles on roads and trails that are open for travel contribute to the spread of noxious plants. On the Targhee National Forest, most of the infestations of noxious weeds are along roads open to motorized vehicles, rather than trails. Therefore, Alternative 1M would tend to have more potential for noxious weed infestations than the three 3M alternatives which have less open, motorized roads. Decommissioned roads will be monitored for new infestations and appropriate control measures will be taken.

Cumulative Effects - Forest-wide, implementation of any of the alternatives is not likely to significantly or adversely affect noxious weed management activities.

Wildlife Associated with Terrestrial Ecosystems

Process Paper D and the FEIS for the Revised Forest Plan are incorporated by reference and present additional information about wildlife populations and habitat which will not be repeated in this EIS, because it is not pertinent to the issues of this analysis.

Elk Vulnerability (EV)

Elk vulnerability (EV) is defined as a measure of elk susceptibility to being killed during the hunting season (Lyon and Christensen 1992, IDFG letter May 12, 1995). EV models (Unsworth et al. 1993) have been proposed as a predictive tool that managers can use to predict mortality rates and monitor elk vulnerability (IDFG letter May 12, 1995). There are two primary variables in this EV analysis: 1) the density of open motorized roads, open motorized trails, and motorized cross-country travel, 2) the density of hunters, expressed in terms of hunter-day densities.

For the Idaho portion of the Forest, this EV analysis is used to predict percent mortality of bull elk during the general antlered elk rifle hunting season. For the Wyoming portion of the Forest, this EV analysis is used to predict percent mortality of bull elk during the general license any elk rifle hunting season. State Fish and Game Departments have goals or thresholds for percent bull elk mortality. For the Idaho portion of the Forest, these goals or thresholds are 50 percent or 60 percent depending on the particular Game Management Unit. For the Wyoming portion of the Forest, these goals or thresholds are 50 percent. The State Fish and Game Departments also have goals pertaining to the number of branch antlered bulls in the harvest and the population (which is explained in Process Paper D).

The primary effect over which the Forest Service has control in this EV analysis is the density of open motorized roads, open motorized trails, and motorized cross-country travel. (Motorized cross-country travel was previously decided in the Revised Forest Plan, and is not under consideration in this EIS. The amount of motorized cross-country travel allowed in the Revised Forest Plan is included in this EV analysis.) The combined density of open motorized roads, open motorized trails, and motorized cross-country travel is referred to as 'motorized access density' (MAD). Process Paper D of the RFP-FEIS describes the details of EV analysis.

Consequences Which Vary by Alternative - Table IV-5 displays the hunter-day densities, the MAD, and the estimated percent bull elk mortality for each principal watershed (Figure IV-1) on the Forest for each alternative. In Alternative 1, five watersheds exceed the goals/thresholds of the State Fish and Game Departments for EV, this is about 15 percent of the Forest not meeting the State EV goals or thresholds. In Alternative 3M+, three watersheds exceed the goals/thresholds of the State Fish and Game Departments for EV, this is about 10 percent of the Forest not meeting the State EV goals or thresholds. In Alternatives 3M and 3M-, two watersheds exceed the goals/thresholds of the State Fish and Game Departments for EV, this is about 9 percent of the Forest not meeting the State EV goals or thresholds.

Cumulative Effects - This analysis does not include bull elk mortality associated with archery seasons, controlled hunt seasons, black powder hunt seasons, or other special seasons which the State Fish and Game Departments may authorize. Watersheds which are at or near the threshold level in this analysis may actually exceed the thresholds when mortality from other seasons is considered.

Hunter-day densities were provided by the State Fish and Game Departments. If hunter-day densities change in the future, due to changes in hunting seasons, motorized access restrictions, or human populations, then this analysis will need to be updated.

The degree of public compliance with, and/or enforcement of the Forest Travel Plan is also an important factor related to EV Noncompliance will result in higher EV

Elk Habitat Effectiveness (EHE)

EHE is defined as the percentage of available habitat that is usable by elk outside the hunting season (Lyon and Christensen 1992) For this EHE analysis, it is the spring, summer, and early fall habitat that is usable by elk outside the general elk rifle hunting seasons EHE is not a measure of elk populations and it is not a measure of habitat carrying capacity (Lyon and Christensen 1992)

There are two primary variables in this EHE analysis 1) the density of open motorized roads and open motorized trails, 2) elk hiding cover (measured as a percentage of an area in cover) (The amount of elk hiding cover was previously decided in the Revised Forest Plan, and is not under consideration in this EIS) Process Paper D describes the details of EHE analysis

Consequences Which *Vary by Alternative* - Table IV-6 displays cover values and motorized access values (based on the density of open roads and open motorized trails), and EHE for each principal watershed on the Forest for each alternative In Alternative 1, EHE ranges from 0.45 to 0.60 in the watersheds, with a Forest-wide average of 0.59 In Alternative 3M+, EHE ranges from 0.50 to 0.60 in the watersheds, with a Forest-wide average of 0.62 In Alternatives 3M and 3M-, EHE ranges from 0.50 to 0.60 in the watersheds, with a Forest-wide average of 0.63

Cumulative Effects - All roads and trails receiving motorized use are incorporated in this EHE analysis All previous timber harvesting, plus all future proposed timber harvesting are incorporated in this EHE analysis The effects of planned and unplanned fires is not incorporated into this EHE analysis, as it was not possible to predict where, when, and how many acres would potentially burn

The degree of public compliance with, and/or enforcement of the Forest Travel Plan is also an important factor related to EHE Noncompliance will result in lower EHE

Effects of Motorized Use on Trails

During the Revised Forest Plan, there was considerable debate about whether the effects of motorized use on trails was equal in magnitude to the effects of motorized use on roads We are not aware of any new research which would shed new light on this debate The discussion and analysis about this debate presented in the FEIS for the Revised Forest Plan, and in Process Paper D, is still valid in our opinion Therefore, this analysis also considers motorized roads and trails having equal effects on wildlife as indicated in the RFP-FEIS No additional discussion on this debate is presented in this EIS

40	0.32	0.58	0.50	0.64	0.54	0.64	0.54	0.64	0.54

1/ Refer to Figure IV-1 for locations of watersheds

2/ Cover Value is based on the amount of elk hiding cover provided by vegetation in each watershed. If 50 to 60 percent of the watershed vegetation provides elk hiding cover, the cover value is 1.0, the cover value declines from 1.0 when there is more than 60 percent or less than 50 percent of the watershed vegetation providing elk hiding cover. Details are presented in Process Paper D.

3/ MAV = motorized access value. MAV is based on the density of open roads and open motorized trails in the watershed. An MAV of 1.0 would mean no open roads and open motorized trails in a watershed. As the density of open roads and open motorized trails increases, the MAV value declines. Details are presented in Process Paper D.

Figure IV-1 Targhee National Forest Principal Watersheds

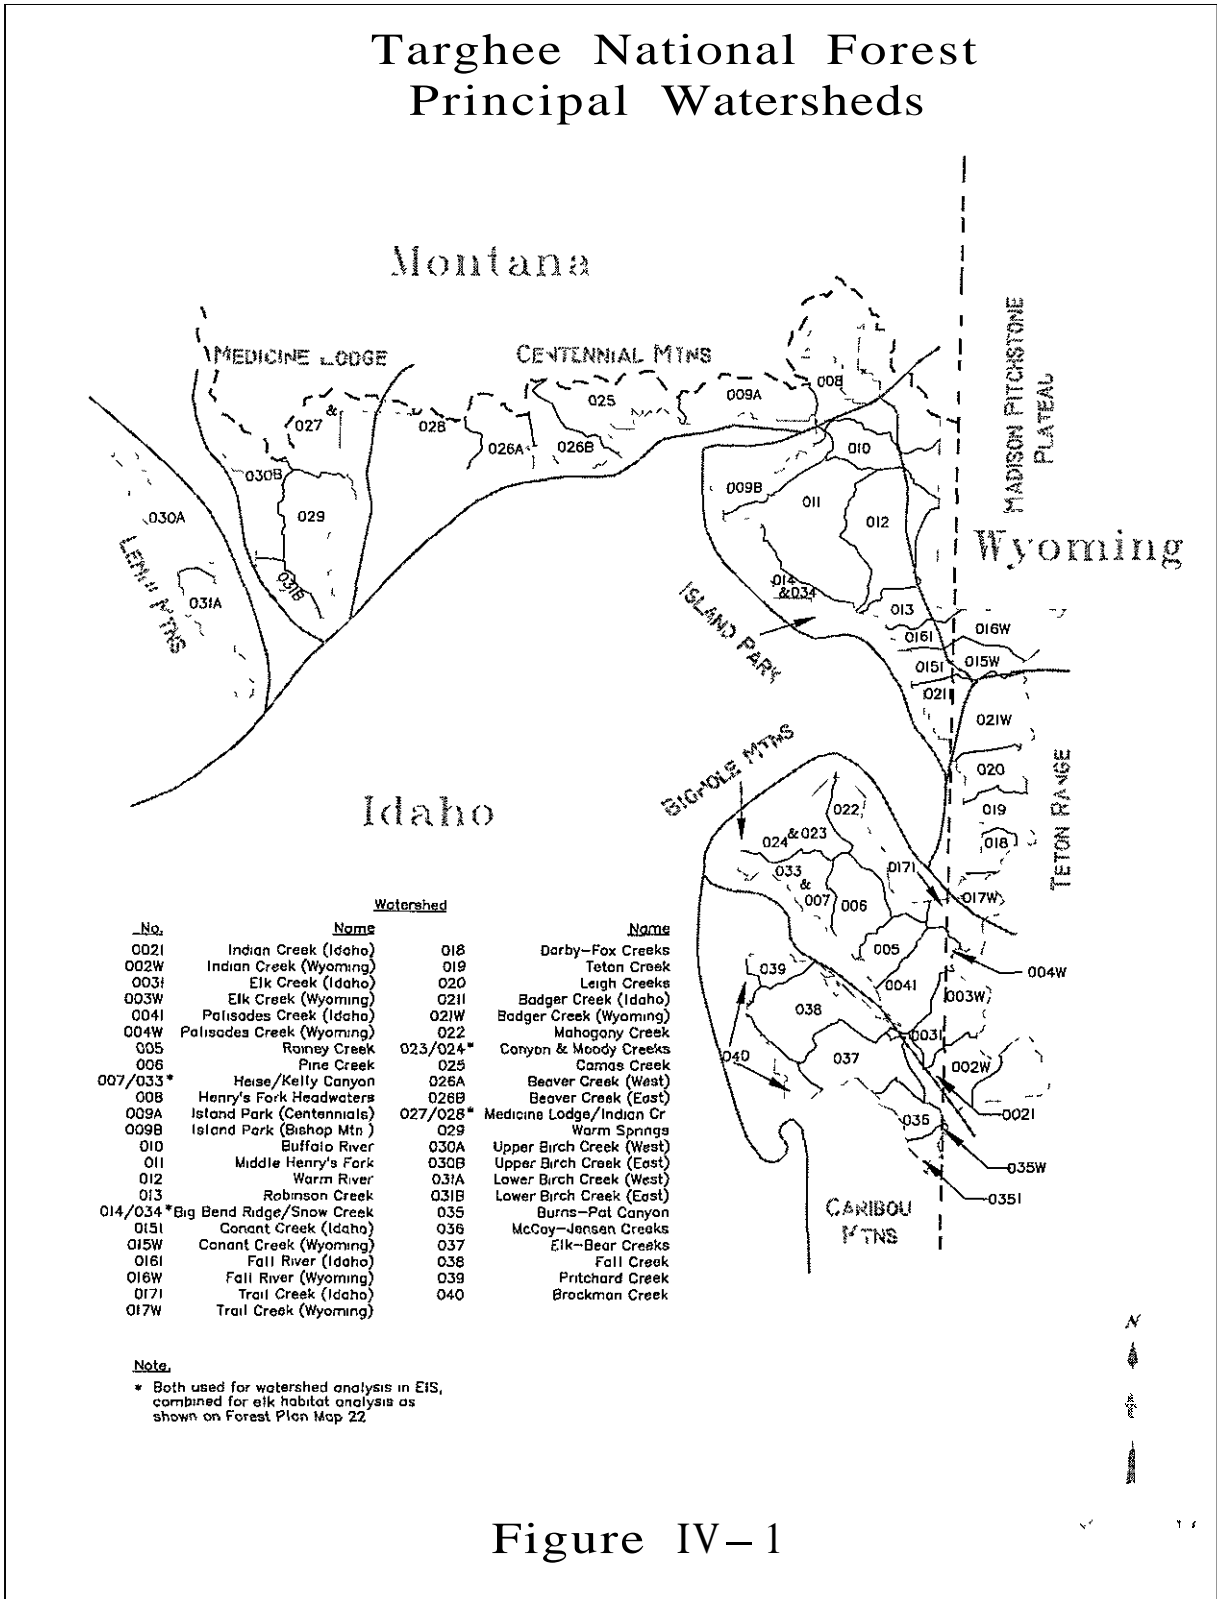

Figure IV-1

Elk and Deer Winter Ranges

Motorized access during the winter period on elk and deer winter ranges was decided in the Revised Forest Plan. Those decisions are not changed in any of these alternatives. The effects on elk and deer winter ranges are the same as described in the Revised Forest Plan (page IV-30). As stated in the Revised Forest Plan, improvements in the number of acres meeting DVC's and increased restrictions on cross-country snowmachine use will result in improved winter range conditions for deer and elk, but populations may not increase over existing levels.

Grizzly Bear Habitat

The following overview on the effects of motorized access is summarized from the Interagency Grizzly Bear Committee Task Force Report, 1994 and 1998.

"History has demonstrated that grizzly bear populations survived where frequencies of contact with humans were very low. Populations of grizzly bears and other large carnivores persisted in those areas where large expanses of relatively secure habitat were retained and where human induced mortality was low. In the lower 48 conterminous states, this is primarily associated with National Parks, Wilderness areas and large blocks of public lands.

By managing motorized access on the landscape, the following grizzly bear management objectives can be met:

- Minimize human interaction and potential grizzly bear mortality
- Minimize displacement from important habitats
- Minimize habituation to humans
- Provide relatively secure habitat where energetic requirements can be met

Historically, management of motorized use has been primarily accomplished through restriction of certain types of motorized use on established access routes. Restrictions on vehicle use through timing and type of vehicle have been commonplace. Evaluation of the effects of motorized access have been based primarily on the density of open roads.

Recent research has indicated that evaluation of open road density alone is not a complete measure of the effects of motorized access on use of habitat by grizzly bears. In addition to open road density, total motorized access route density along with the presence of core areas, are important elements in the management of human access within grizzly bear recovery zones. Core areas are free of motorized traffic and high levels of human use. (Designated core areas were established in the Revised Forest Plan by specific management prescriptions, and are not changed by any alternative in this EIS.)

The management of human use levels through access route management is one of the most powerful tools available to balance the needs of grizzly bears and many species of wildlife with the needs and activities of humans. It has been documented in several research projects, both completed and ongoing, that unregulated human access and development within grizzly bear habitat can contribute to increased bear mortality and affect bear use of existing habitat. It is also documented that human use of grizzly bear habitat within many recovery zones continues to increase.

Habitat security conditions cannot be defined entirely by motorized access route density. Other factors such as vegetation (food, cover), concentrated human use locations (e.g. town sites, campgrounds), heavily used non-motorized trails and areas of high levels of dispersed human use will also influence the effectiveness of area in regards to habitat security. However, motorized access routes and the human use associated with these routes are one of the most easily defined and measurable factors that we can evaluate. Motorized access is also one of the more influential parameters affecting habitat security."

In January 1996 a study was completed on the relationships among grizzly bears, roads, and habitat in the Swan Mountains, Montana (Mace et al 1996, in press) The following is quoted from the summary of that study

"Seasonal use by grizzly bears of areas within a 0.5 km buffer surrounding roads was evaluated. Most grizzly bears exhibited either neutral or positive selection for buffers surrounding closed roads and roads receiving <10 vehicles/day, but avoided buffers surrounding roads having >10 vehicles/day "

Consequences Common to All *Alternatives* - Motorized access in the grizzly bear management units was a key issue in the Revised Forest Plan. The Revised Forest Plan established motorized access standards for each bear management unit on the Forest. These motorized access standards were reviewed by the U.S. Fish and Wildlife Service during consultation, and were addressed in their Biological Opinion. All of the alternatives in this EIS meet these standards (**see** Biological Assessment Update - Appendix D). There are some small differences between the alternatives, which **are** displayed in Table IV-7(a-e), however, all alternatives would comply with grizzly bear recovery objectives.

Cumulative Effects- Cumulative effects is the same as presented and discussed in the Revised Forest Plan, Process Paper D, and the Biological Opinion from the U.S. Fish and Wildlife Service, and will not be repeated here.

1/ Only includes acres within the Targhee National Forest				

Gray Wolf Habitat

Consequences Common to All *Alternatives* - The Revised Forest Plan established Forest-wide standards and guidelines implementing the nonessential experimental population rules established by the U S Fish and Wildlife Service This management direction is not changed by any of these alternatives The U S Fish and Wildlife Service stated the following concerning roads (U S Fish and Wildlife Service 1994a and 1994b)

"Based upon (1) current open road information, (2) the success of wolf packs in highly roaded habitats in Montana, and (3) that these roaded areas of public land being proposed for wolf recovery are adjacent to large (about 4-5 million acres) roadless areas, it appears unlikely that road density guidelines must be employed as a wide-spread land management strategy to support wolf recovery

This gray wolf reintroduction does not conflict with existing or anticipated Federal agency actions or traditional public uses of park lands, wilderness areas, or surrounding lands (USDI Fish and Wildlife Service 1994b) The intent of the experimental rule is that land-use restrictions not be routinely used solely to enhance wolf recovery However, land-use restrictions may be temporarily used by land or resource managers to control intrusive human disturbance, primarily around active den sites between April 1 and June 30, when there are 5 or fewer breeding pairs of wolves in a recovery area After 6 or more breeding pairs become established in a recovery area, land-use restrictions would not be needed (USDI Fish and Wildlife Service 1994a) "

Cumulative Effects - Cumulative effects is the same as presented and discussed in the Revised Forest Plan, Process Paper D, and the Biological Opinion from the U S Fish and Wildlife Service, and will not be repeated here Application of the Forest-wide standards and guidelines is expected to allow wolf pairs to receive the protection of the nonessential experimental population rule (RFP-FEIS, page IV-34)

Primary Cavity Nesting Habitat

The management direction established in the Revised Forest Plan for primary cavity nesting species is not changed by any of the alternatives in this EIS The effects presented in the Revised Forest Plan FEIS (pages IV-39-40) and Process Paper D for Alternative 3M are the same effects for all of the alternatives in this EIS This management proposal is expected to have little effect on cavity nesting habitat

Forest Owl Habitat

The management direction established in the Revised Forest Plan for forest owl species is not changed by any of the alternatives in this EIS The effects presented in the Revised Forest Plan FEIS (page IV-40) and Process Paper D for Alternative 3M are the same effects for all of the alternatives in this EIS

Furbearer Habitat

Road access concerns were discussed for American marten, fisher, lynx and wolverine in the publication titled "The Scientific Basis for Conserving Forest Carnivores American Marten, Fisher, Lynx and Wolverine in the Western United States (USDA U S Forest Service 1994) However, no specific recommendations for road density standards or guidelines for these species were presented

At this time, the analysis of furbearer habitat presented in the Revised Forest Plan FEIS (page IV-40) and Process Paper D is not changed by any of the alternatives in this EIS The effects presented in the Revised Forest Plan and Process Paper D for Alternative 3M are the same effects for all of the alternatives in this EIS

Road access concerns relating to Canada lynx have recently been summarized by the U S Fish and Wildlife Service in their proposal to list the lynx as threatened in 16 States (U S Fish and Wildlife Service 1998) However, no specific recommendations for road density standards or guidelines for Canada lynx were presented

Goshawk Habitat

All known goshawk territories on the Forest have open motorized roads and trails within portions of their territories. At this time, we do not know of any studies which document the effects of roads and trails on goshawks (Process Paper D)

The management direction established in the Revised Forest Plan for goshawk habitat is not changed by any of the alternatives in this EIS. The effects presented in the Revised Forest Plan FEIS and Process Paper D for Alternative 3M are the same effects for all of the alternatives in this EIS. The proposed management activity would maintain effective habitat and viable populations are expected to be sustained (RFP-FEIS, page IV-41)

Red Squirrel Habitat

The effects presented in the Revised Forest Plan FEIS (page IV-41) and Process Paper D for Alternative 3M are the same effects for all of the alternatives in this EIS.

Peregrine Falcon Habitat

All of the peregrine falcon nesting territories on the Forest have roads and trails within them. The presence of these roads and trails has not adversely affected the growth of the peregrine falcon population. The U. S. Fish and Wildlife Service (1994) has provided the following overview:

Other known negative factors, such as illegal shooting and collisions with wires, fences, cars, and buildings, are much **less** significant to the western American peregrine falcon at the population level. On an individual nest-site basis, human-caused disturbance or habitat alterations close to an active peregrine falcon nest can be a problem. For example, in some areas, rock-climbing is a growing sport and has resulted in nest failure. Breeding-season closure of rock-climbing cliff areas also in close proximity to nesting American peregrine falcons has recently prevented adverse effects. Power lines, especially distribution lines, cause peregrine falcon mortality, but the rate must be low, because many peregrine falcons nest successfully each year near power lines, especially in urban areas. Land-use practices adjacent to American peregrine falcon eyries that do not result in extensive habitat changes or excessive disturbance sometimes appear to have little adverse effect on nesting success. Generally, the recent apparent increase in the number of pairs of American peregrine falcons in the West provides evidence that significant adverse factors affecting the western subspecies at the population level are being alleviated or have been reduced.

The management direction established in the Revised Forest Plan for peregrine falcon habitat is not changed by any of the alternatives in this EIS. The effects presented in the Revised Forest Plan FEIS and Process Paper D for Alternative 3M are the same effects for all of the alternatives in this EIS. Suitable habitat will be maintained for all existing nesting pairs plus any new nesting pairs which may become established.

Bighorn Sheep Habitat

The management direction established in the Revised Forest Plan for bighorn sheep habitat is not changed by any of the alternatives in this EIS. The effects presented in the Revised Forest Plan FEIS (page IV-41-42) and Process Paper D for Alternative 3M are the same effects for all of the alternatives in this EIS.

Neotropical Migratory Birds

The effects presented in the Revised Forest Plan FEIS (page IV-43) and Process Paper D for Alternative 3M are the same effects for all of the alternatives in this EIS.

Predator Control

Consequences Common to All Alternatives - Implementation of any of the four alternatives is not likely to significantly or adversely affect predator management activities. The effects of predator management activities on the Targhee National Forest are incorporated by reference in this analysis from the FEIS for the 1997 Revised Forest Plan (page IV-43). Predator control activities that will occur in travel restricted areas will be coordinated and approved by the District Ranger prior to the activity and

authorized by a "travel permit" This process was initiated in the spring of 1998 and is not expected to adversely affect the open road and trail densities for any management prescription area

Consequences Which Vary *by* Alternative - None

Cumulative Effects - Forest-wide, implementation of any of the alternatives is not likely to significantly or adversely affect predator control management activities

Unique Ecosystems - Research Natural Areas

Consequences Common *to all* Alternatives - Forest-wide standards and guidelines (RFP-FEIS page III-4) apply equally with all four alternatives Also, site-specific direction is identified in the Establishment Records for existing Research Natural Areas (RNAs) Proposed RNAs will have a site specific analysis conducted at a later date to determine their suitability for RNA status Regardless of which alternative is selected the number of proposed and existing **RNA's** and their management does not change by alternative

Consequences Which Vary *by* Alternative - None

Cumulative Effects - Forest-wide, implementation of any of the alternatives is not likely to significantly or adversely affect Research Natural Area management activities

FOREST USE AND OCCUPATION

Access Management

Road and Trail System and Motorized Access

Consequences are presented for summer motorized road and trail travel only The range of alternative consequences has been found to be very similar to the consequences found in the Revised Forest Plan for those alternatives The following indicator data, when compared to the data in the RFP-FEIS, shows that RFP Alternative 1 and 2 closely resemble Alternative 1M, Alternative 3 (RFP) is close to Alternative 3M(+), and Alternative 3M (RFP) closely resembles Alternative 3M and 3M(-) in this analysis

Indicators

- 1 Miles of open, motorized roads
- 2 Miles of seasonally restricted roads
- 3 Miles of yearlong restricted roads
- 4 Miles of road decommissioned inside and outside the BMU's
- 5 Miles of open, motorized trails
- 6 Miles of seasonally restricted trails
- 7 Miles of yearlong restricted trails

Consequences Common *to All* Alternatives -There will be some reduction from current levels in miles of open, motorized roads and trails in all alternatives This would result in increased needs and costs for law enforcement and signing to manage the system of restricted roads and trails (RFP-FEIS page IV-44) The decommissioning work necessary to close the roads in each alternative will also result in some reduction in hiking, horseback riding and winter snowmachine use on roads where large amounts of rock or tree placement and ripping or trenching occur These adverse impacts will occur mostly in the grizzly bear unit road closure areas which are currently used for snowmachining and hunting

Consequences Which Vary *by* Alternative -Table IV-8 shows the comparison of alternatives in terms of the indicators listed above Alternative 1M has the most open roads and trails and the least decommissioned roads The three 3M alternative variations show only minor differences between them in

open roads or trails and decommissioned roads, but have significantly fewer open roads and trails and significantly more decommissioned roads than Alternative 1

Table IV - 8 Road and Trail Access by Alternative (Miles)

Alternative	Alt 1(M)	Alt 3M(+)	Alt 3M	Alt 3M(-)
ROADS				
Open	2,077	1,672	1,617	1,613
Seasonal Restrict	51	70	62	62
Yearlong Restrict	399	289	303	303
Decom in BMU's	467	466	463	465
Decom outside BMU's	0	473	521	524
Total Miles	2,994	2,970	2,966	2,967
TRAILS				
Open	725	536	511	454
Seasonal Restrict	0	0	0	0
Yearlong Restrict	651	862	879	933
Total Miles	1,376	1,398	1,390	1,387
Total Rds/Trs.	4,370	4,368	4,356	4,354

Costs for signing designated routes; decommissioning of roads, and providing law enforcement will increase significantly from Alternative 1M through Alternative 3M(-). This effect and others mentioned in the RFP-FEE, page IV-45-46 will be similar for these four alternatives in the same order as the range of alternatives discussed in the Plan Revision

Appendix C(M) shows the specific resource or administrative reasons why each road is open, restricted, or closed for each alternative. This information was considered throughout the analysis for each resource in this EIS.

The RS 2477 assertions by the Counties were mapped and compared to the preferred alternative (3M+) as displayed in Map #1 in the map packet. The majority of the assertions would be open to motorized travel as shown on this map. Alternative 1M would have slightly more open routes that would match assertions and Alternatives 3M and 3M(-) would have slightly less. Many of the assertions not covered by open, motorized routes on Map #1 are trails rather than roads and many of these are not open in the current travel plan. Out of 910 miles of RS 2477 assertions, 72 miles are not shown as open in 3M+ (the preferred alternative). Twenty-seven miles of these are trails and 45 miles are roads. Madison County has the most assertions that are not covered by open roads or trails in Alternative 3M+. Many of these Madison County assertions are on logging roads that have been built and decommissioned in the last 40 years in accordance with the NEPA decision for timber sales in these areas. We do not propose to reopen these roads because alternate routes are available.

Cumulative Effects - As acres and roads/trails open to summer motorized access decrease from Alternative 1M through Alternative 3M(-), the density of motorized users on designated routes will generally increase on the remaining open routes (RFP-FEIS, page IV-46). The increased interaction may result in increased user or resource conflicts and additional resource impacts. This could result in an overall effect of **loss** of enjoyment of the recreation activity for some people in some of the areas. A secondary effect of decreasing motorized access and decommissioning roads would be reduction of motorized hunting and fishing opportunities and increase in non-motorized opportunities. This might not be too significant a difference in Alternative 1M, but could be more significant as reductions toward Alternative 3M(-) are implemented.

There would also be adverse effects from closing roads and trails in terms of maintenance (including funding) and possible reductions in recreation opportunities as indicated on page IV-46 of the RFP-

FEIS In addition, emergency access for fire or rescue would be reduced. However, no groomed snowmachine trails would be impacted by decommissioning roads.

The potential effects of RS 2477 assertions in addition to those already open roads and trails in the existing transportation system (red routes on Map #1) have not been included in resource consequence discussions. If these routes were opened to motorized travel, there would be increased adverse effects on motorized route density, elk habitat, soils, vegetation, water quality, and fisheries habitat.

A Forest Travel Plan would be implemented as a result of the decision reached in the FEIS for this proposal. As a result of the analysis to date, the preferred alternative would be the proposed travel plan. That plan would include the Transportation Plan Map #4, the proposed Forest Plan amendments, the 1998 Travel Plan Addendum and Access Tables. The entire package would be combined and prepared similar to the 1997 Travel Plan Map with a legend and other information to help Forest users understand travel opportunities. If another alternative were selected in the FEIS-Record of Decision then that alternative would be implemented as described here.

WILDERNESS AND RECREATION RESOURCES

The following topics present the effects and consequences of the alternatives on the various wilderness and recreation resources. Key alternative comparison indicators for these resources are displayed in Table 11-1. Overall, total recreation use would not change much between alternatives, but the types of use probably would change slightly. The trend from Alternative 1 to 3M(-) would be away from semi-primitive motorized and roaded natural appearing (Recreation Opportunity Spectrum - ROS) to an increase in ROS of primitive and semi-primitive non-motorized, although some semi-primitive motorized opportunities would remain. This overall trend would be due to the reduction in motorized access. Such a trend would also support a shift from currently evolving tourism and rural development to a slower developing, eco-tourism type pattern.

Wilderness, Wilderness Study Areas (WSA), and Recommended Wilderness

Consequences Common to All Alternatives - Quality and character of designated wilderness, WSA, and recommended wilderness would not be degraded by any alternative. This is the same as indicated in the RFP-FEIS on page IV-47.

Consequences Which Vary by Alternative - The number of acres of recommended wilderness would vary by alternative as it did in the Forest Plan analysis (RFP-FEIS, page 11-20 and IV-47), but it does not significantly affect the miles of road or trail open to motorized use between alternatives.

Cumulative Effects - Since the Jedediah Smith Wilderness Plan would be in effect for all alternatives, there should be little cumulative impact or secondary effects on wilderness values.

Roadless Areas

Indicator: Miles of motorized road and trail in Roadless

Consequences Common to All Alternatives - Although roads and trails remain open to motorized use in roadless areas in all alternatives, this is not expected to have adverse effects on resources or on potential for wilderness designation. The motorized roads and trails are stable, and are not causing impacts to soils or vegetation.

Consequences Which Vary by Alternative - Miles of motorized road and trail in roadless vary as follows:

Alternative 1	776
Alternative 3M(+)	548
Alternative 3M	520
Alternative 3M(-)	469

This slight difference only effects the opportunity for recreation or other access, and as noted above, would have little effect on resources

Cumulative Effects • **Inventoried** roadless areas have essentially remained unchanged (total acres), even during the last Forest Plan (1985 - 1995) Projected roading and timber harvest never occurred in areas planned, and these road and trail management alternatives are not expected to have any significant affect on inventoried acres during the next decade

Wild, Scenic and Recreational Rivers

Consequences Common to All Alternatives - The eligibility of these rivers will not be affected by any of the alternatives, and all of the outstanding resource values will be protected by management prescriptions of the Revised Forest Plan until such time as suitability studies are completed (RFP-FEE, page IV-50)

Visual Resources

Consequences Which Vary *by* Alternative - There would be only slight differences in effects on visual resources between alternatives Alternative 1 would have the most chance for ground-disturbing activity from motorized vehicles, but it would only be slightly higher than Alternative 3M(+) or 3M Alternative 3M(-) would have the least chance of adverse visual effects from motorized travel on roads and trails

Developed Recreation

Consequences *Common* to All Alternatives - Consequences *will* basically be the same for all *alternatives* because developed recreation facility construction and reconstruction will be about the same in all *alternatives* (RFP-FEIS, page IV-51)

Cumulative Effects - As the alternatives become more restrictive in terms of motorized access and opportunity (i.e., Alternatives 3M and 3M-), there would likely be some displacement of recreation from areas now being used (RFP-FEIS, page IV-51) This could place a heavier burden on existing developed facilities and create a need for new ones in a more concentrated geographic area

Dispersed Recreation

Consequences *Common to* All Alternatives - Approximately the same number of road-accessed, dispersed campsites (293) would continue to be used in all alternatives (RFP-FEIS, page IV-51). The number of sites would probably stay the same, because existing sites that would become unavailable due to new management allocations would simply be relocated to sites in other adjacent areas

Cumulative Effects - It is possible in Alternatives 1 and 3M(+) that some existing, dispersed camping sites and trails would need to be moved or closed to resolve conflicts with wildlife or aquatic management standards and guidelines (RFP-FEIS, page IV-52) In Alternatives 3M and 3M(-), displacement or closure of such areas would be due to less access and because aquatic buffer restrictions are greater This could have an adverse impact on recreation experiences, due to having to add more facilities elsewhere or due to crowding or congestion in smaller geographic areas This could result in a need for increased **monitoring**, law enforcement and management costs to prevent unacceptable impacts to soil, vegetation, aquatic or wildlife resources

Outfitters and Guides

Consequences Which Vary *by* Alternative - The number of new outfitter and guide permits issued would probably be slightly less in Alternatives 3M and 3M(-) than in Alternatives 1 and 3M(+), (RFP-FEIS, page IV-52) Overall activity and amount of outfitted use would also be less in Alternatives 3M and 3M(-) This is due to the closure of access **routes** that could be used for snowmachine or other motorized tours Also, there is very little opportunity remaining in non-motorized, backcountry areas

The type of activities outfitted in Alternatives 3M and 3M(-) would be more related to backcountry, nonmotorized uses than in Alternative 1 and 3M(+), due to increased restrictions on motorized and mechanized equipment in roadless, recommended wilderness and designated wilderness

Special Uses (Recreation)

Consequences Common to All Alternatives - Requests for special use permits for activities such as special events (e.g., races, group activities, etc.) and outfitting and guiding will likely increase gradually for all alternatives. At some point of saturation, the permitted activities would reach a plateau and level off (RFP-FEIS, page IV-52)

Consequences Which Vary by Alternative - The trend for special uses in response to alternatives would be similar to that for developed sites. In Alternatives 1 and 3M(+), there would be more increase in demand for special events and motorized access permits. However, in Alternatives 3M and 3M(-), the trend would be more towards undeveloped, backcountry experiences such as mountain biking, backpacking, horsepacking, hunting and similar opportunities. The number of new special use permits would probably be less in the alternatives with less motorized access, and overall recreation use under permitted activities would also be less.

Cumulative Effects - Cumulative impacts of actual recreation use would likely be higher in alternatives 1 and 3M(+), but those impacts would tend to be in the more easily accessed areas and closer to existing developed areas or special interest roads, trails or attractions. In Alternative 3M and 3M(-), the additional cumulative impacts of recreation use would tend to be in more undeveloped, backcountry areas with a more primitive experience level. These too, could have a slight, measurable effect on wildlife, etc.

ECONOMIC AND SOCIAL EFFECTS

Consequences Common to All Alternatives

Population - The area is experiencing significant population increases (REIS 1996). The rate of increase (itself a function of birth, death and net-migration) is not expected to be significantly affected by any of the alternatives under consideration.

As the population of the area continues to grow, the percentage of the population that looks to the Forest for recreational use is expected to increase. Correspondingly the percentage of the population that looks to the Forest as a source of timber and livestock forage is expected to decline.

Many people see the National Forest as a good neighbor - literally. Real estate which borders the Forest is frequently advertised as such. It is a selling point. The increased level of development of private property located within or along the Forest's boundaries, and the associated contributions to local tax bases and demands for government services, are expected to continue regardless of which alternative is selected. Increasing development may jeopardize traditional uses of private land like livestock grazing. It may simply not make good sense financially for an individual to run livestock on land ripe for real estate development.

In and of itself, the permanence of the Forest does provide a certain attraction for those considering relocating a family or business. Private property can be managed many different ways while the Forest will "always" be managed as a National Forest.

Land Use Patterns - Lands adjacent to and within the Forest are increasingly passing from traditional uses like ranching to new uses like subdivisions. Forest management has to consider these new neighbors when deciding how best to manage Forest resources - with particular attention being devoted to fire protection, visual quality and recreation opportunity. This challenge can be expected to continue to increase under all alternatives as the human population of the area increases.

Some newcomers to the area have deviated from long-held local custom by closing off access through their property to Forest lands. Their focus on having a Forest in a more natural condition has also been at odds with those who see the Forest as being a resource to be used. These sorts of conflicts can be expected to continue, if not worsen, under all the alternatives due to continuing immigration.

American Indians - Input from the Shoshone-Bannock tribes indicates their strong concern for continuing the viability and abundance of plants, fish and wildlife on the Forest for the use of their members consistent with their treaty rights (Shoshone-Bannock 1992 a-b). Some of that input has focused on providing designated routes for motorized access during the tribes' hunting season. The tribes

have also commented on their need to have the public and the Forest Service respect their rights to practice their native religion. All the alternatives are structured so as to afford tribal members the rights guaranteed them by treaty.

Economics and Lifestyles - Jobs, personal income, and payments to local governments are not expected to be significantly affected by the selection of any given alternative. The alternatives do not vary significantly in terms of timber harvest, livestock grazing, or water available to downstream users. However, crowding is expected to occur on those trails which remain open to motorized use.

The overall level of recreational use is expected to continue to increase along with its associated income and employment opportunities. Increased recreation use means more people from outside the immediate local area visiting, spending money and in some cases investing in local property. The overall increase in recreation is expected to occur regardless of which alternative is selected. A certain percentage of the people visiting Yellowstone National Park can be expected to visit Forest attractions like Mesa Falls, for instance.

It is likely that there will be an increased level of summer motorized use on those roads and trails which remain open in each alternative. The increased use would change directly and in proportion to the amount of roads and trails closed to motorized use in each alternative. Surplus capacity exists for motorized use on Forest roads, but that is not the case with motorized trails.

As Yellowstone and Grand Teton National Parks become more crowded the Forest can expect to accommodate more of the resulting spillover traffic. For instance, because snowmachining in Yellowstone National Park is reaching saturation levels, the Forest is expected to receive more of that traffic - regardless of which alternative is selected.

The area also provides opportunities for further development of recreational activities. The recently opened Grizzly Bear/Wild Animal Park near Rigby is an example of the kind of development which might occur regardless of which alternative is selected.

Civil Rights - No civil rights effects associated with age, race, creed, color, national origin or sex have been identified.

Consequences *Which Vary By* Alternative

American Indians - Tribal members use the Forest in many ways. Some of these uses are identical to those of the general population and are described elsewhere herein. Other interests may be unique to tribal members. For instance, gathering Forest products is an important part of the culture of some tribal members. Those who rely on open roads or motorized trails to access favorite spots may have to find alternative sites if motorized access is restricted in a given alternative. It is also possible that closing some motorized access routes may effectively deny access to some areas for some users.

Discussions with the tribes to-date have not revealed a preference for more or less roading per se. Concerns have been voiced about closing roads during the tribes' hunting season - something that needs to be addressed on a continuing, site-specific basis. In general though, as the alternatives reduce the amount of roads and trails available for motorized use, the time and effort involved in hunting is expected to increase. That also applies to other tribal activities which require access to the land. Reducing motorized use may improve the suitability of the land for vision quest and various other cultural activities.

Attitudes, Beliefs, Values - Many people believe that the Forest should remain open to motorized access at previous levels. They point out that considerable money has been spent building and maintaining Forest travel routes and want them to remain open for a variety of reasons associated with use and enjoyment of the Forest resource. Because Alternative 1 maintains the highest degree of motorized access, it would best address their values. The other alternatives are less responsive to their needs in direct proportion to the amount of motorized access eliminated.

Conversely, those who enjoy the Forest for nonmotorized uses are likely to benefit more from those alternatives which restrict motorized use. Thus, closing a motorized route may deny one family access to a traditional firewood-gathering site, but create an enjoyable mountain bike trail for another.

Conflicts associated with enforcement efforts needed to ensure that roads and trails closed to motorized use are not used by motorized vehicles are likely to vary directly and proportionally to the amount of roads and trails closed to motorized use

Big game hunting and in particular elk hunting, is a major event on the Forest. Participants eagerly await the season's arrival. Elk Vulnerability models indicate that the greater the degree of motorized access, and the higher the hunter densities, then a higher percentage of the elk population is harvested. On the Targhee, the major concern has been the high percentage of elk bulls harvested during the general rifle season. Land management agencies control the amount of motorized access, and State Fish and Game agencies control the hunter densities. In the past, high motorized access has resulted in the IDF&G using spike only hunting season regulations and shorter hunting seasons in some areas of the Forest to reduce the percentage of bulls being harvested. IDF&G goals include lengthening the general rifle season for bulls, and allowing any bull elk to be harvested. In order for these goals to be achieved, motorized access needs to be reduced.

Sense of Control, Sense of Self-sufficiency - To the extent that any individual's or group's sense of control or sense of self-sufficiency is associated with motorized access, that sense will be affected directly proportional to the extent of motorized access permitted in each alternative. Thus, those who find their motorized access to traditional hunting or recreation areas cut off, would likely feel their sense of control reduced. Those who enjoy a more physically demanding hunt or recreation opportunity, without the chance of a motorized unit disrupting the experience, might appreciate the reduction in motorized access.

Social Organization, Community Cohesion and Community Stability - Selecting any alternative as opposed to any other alternative would not likely affect community cohesion or community stability. Economic effects associated with these alternatives are minimal, if not unnoticeable. It's not a case of certain individual's or group's losing their jobs or a substantial portion of their personal income. It's more a case of whether the Forest is being managed along the lines of an individual's or group's preferences - which they hold to be very important.

Civil Rights - Those who require motorized access due to disability will find their access to the Forest affected directly and proportionally by the amount of roads and motorized trails restricted or decommissioned. This adverse effect would be the lowest with Alternative 1M and the highest with Alternative 3M(-). This may be mitigated to an extent by a special program administered by the Forest with the assistance of the Idaho Department of Fish and Game to provide increased access for the disabled. As indicated in the Revised Forest Plan (page III-24), "During the big game hunting season, persons with disabilities may be permitted to use motorized vehicles, if needed for mobility, on restricted roads and trails which are designated for such use, with an authorized motor vehicle hunting permit issued by the District Ranger. These persons must have a Disabled Hunting Permit issued from the State Fish and Game Departments."

PRODUCTION OF COMMODITY RESOURCES

Timber

Consequences Common to All *Alternatives* - Access for timber management would be approximately the same for all alternatives because the open road system is almost the same in the areas of marketable timber. In alternatives with less access, additional roads could be decommissioned so that alternate access could be established (within road density) to reach desired timber areas.

Livestock Grazing

Indicators-none

Consequences Common to All *Alternatives* - For all alternatives, livestock permittees will be required to obtain a "travel permit" to have motorized access in travel restricted areas. This direction is identified on page III-30 of the Revised Forest Plan (Process Paper M, RFP-FEIS). As per their grazing permit, livestock permittees are required to maintain their assigned improvements and to properly manage their allotment. Doing so requires motorized access off designated routes. Depending on specific management prescriptions, all permittees will be required to comply with the road density

standards on their allotments. Most grazing allotments have more than one management prescription area within their allotments.

Permitted livestock numbers, seasons of use, and AUM's as well as the number of permittees, allotments, and grazing permits will not be affected by any of the four alternatives. However, the RFP-FEIS (page IV-71) did show a reduction in number of permits, but this was due to grizzly bear and bighorn sheep concerns and not motorized access.

All maintenance and reconstruction of existing and proposed range improvements will be needed equally with all four alternatives as outlined in the Revised Forest Plan.

Consequences Which Vary by Alternative - None

Cumulative Effects - Forest-wide, implementation of any of the alternatives is not likely to significantly or adversely affect livestock grazing or permittee management of grazing allotments.

IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES

Adverse Environmental Effects that Cannot be Avoided - There would be some irretrievable losses to soil hydrologic function and site productivity in areas of roads or road or trail maintenance or reconstruction (RFP-FEIS page IV-74). There would also be irretrievable loss of motorized access and recreation opportunities on closed and non-motorized roads and trails due to road restrictions and decommissioning. Irreversible commitments include soil losses caused by erosion and sedimentation from roads and trails. Intermittent and localized decrease in air quality may result due to dust from road construction, road maintenance and use, and due to smoke from wildfires, and campfires (RFP-FEIS page IV-74). Potential for additional conflicts between recreation use and other land use activities would increase in some alternatives (RFP-FEIS page IV-75) where proposed management would restrict recreation use such as motorized travel. Also, temporary disturbance of wildlife and their habitat conditions in localized areas may result from increased human activity or changed vegetation conditions. Increased soil compaction may occur on activity sites such as recreation or OHV use areas.

Short-term Uses of the Human Environment and the Maintenance of Long-term Productivity - Short-term uses include providing access for motorized and non-motorized recreation or hunting and fishing opportunity, seasonally. Short term uses would also include access for permittee, contractor or administrative uses. Long term productivity would be recovered from decommissioned roads as vegetation becomes established and disturbed sites become stabilized over time.

Appendix

Appendix A. Addendums to 1997 Travel Plan
Maps, March 24, 1998

Appendix B. Road Decommissioning
Process Guidelines

Appendix C. Appendix C(M) Access Status
Tables and Appendix C (1998
Update) Access Status Tables

Appendix D. Biological Evaluation and
Biological Assessment Process

APPENDIX A

This Appendix contains the cross-country matrices which remain unchanged from the **1997** Travel Plan Map for the Dubois, Palisades, and Teton Basin District maps. The **1997** Travel Plan Map (summer and winter) displays the location of the Area Reference letters (A, B, C, etc.) for each area designation in the matrices. These **1997** Travel Plan Maps are available at the Targhee National Forest Supervisor's Office and District offices. This Appendix A also contains the following Addendum to the **1997** Travel Plan Maps.

ADDENDUM TO 1997 TRAVEL PLAN MAPS - March 24, 1998

For purposes of clarification, the following changes/corrections now apply to the Winter and Summer Travel Plans for the **PALISADES** and **TETON BASIN** Ranger Districts until further notice.

WINTER TRAVEL PLAN - (the new 1997 plan/map)

1 The following new introductory statement replaces the first and second paragraphs under "**TARGHEE NATIONAL FOREST WINTER TRAVEL PLAN**":

This map describes winter travel opportunities on the Targhee National Forest from THANKSGIVING DAY UNTIL SOMETIME IN THE SPRING as local conditions become suitable to support wheeled vehicle traffic on roads and trails without damage.

SEE THE ATTACHED NEW "**WINTER CROSS-COUNTRY USE AND WINTER DESIGNATED ROUTES**" MATRICES. THESE REPLACE THOSE AT THE BOTTOM OF THIS MAP AND GIVE DETAILED DIRECTIONS ABOUT OPPORTUNITIES AND RESTRICTIONS FOR WINTER TRAVEL.

Additional closures or restrictions may be made at any time for resource protection or public safety. To avoid inconvenience, Forest visitors are encouraged to contact local District Ranger Offices for current travel information.

For information regarding summer travel opportunities, see the reverse side of this map and the attached addendum information.

2 For the "**CROSS-COUNTRY USE**" Matrix, the following changes have been made:

- a DELETE the entire "**Wheeled Motorized Vehicles**" column and the associated footnote below the Matrix.
- b For "**Area Reference Letter B**" in the "**Non-motorized Uses**" column, the wording has been changed to read, "**Open April 15 to Dec 15 on the Palisades Ranger District and April 15 to Thanksgiving Day on the Teton Basin Ranger District**".
- c For "**Reference Area Letter C**" in the "**Over-snow Motorized Vehicles**" column, the wording has been changed to read "**Open Thanksgiving Day to June 1 on the Teton Basin Ranger District and Dec. 15 to June 1 on the Palisades Ranger District**".

3 For the "**WINTER DESIGNATED ROUTES**" Matrix, the following change has been made:

- a ADD the **ATV SYMBOL** to the "**Over-snow Motorized Vehicles**" column.

SUMMER TRAVEL PLAN - (the new 1997 plan/map)

1 The following new introductory statement replaces the first and second paragraphs under "**TARGHEE NATIONAL FOREST SUMMER TRAVEL PLAN**":

Welcome to the **Palisades** and **Teton Basin Districts** of the Targhee National Forest, yours to enjoy and use for a variety of purposes. In order to protect forest values, safeguard users, and minimize conflicts between users, it has become necessary to establish certain regulations for the use -- both non-motorized and motorized -- of areas off designated routes and the use of designated roads and trails. This map identifies these opportunities and restrictions. Please study the map carefully. Your understanding and observance of these travel opportunities and restrictions will minimize the need for enforcement action.

This map is intended to help the summer recreationist enjoy the Targhee National Forest safely while protecting the natural resources. Additional closures or restrictions may be made at any time for resource protection or public safety. To avoid inconvenience, Forest visitors are encouraged to contact local District Ranger Offices for current travel information.

For information regarding winter travel opportunities, see the reverse side of this map and the attached addendum information.

2 The "**CROSS-COUNTRY USE MATRIX**" shown on this map **is in force.** (This matrix is also shown on the old 5/1/94 Travel Plan maps - revised March 24, 1998)

PLEASE NOTE THE FOLLOWING:

1 Delete in their entirety the last paragraph under HOW TO USE THIS MAP and the paragraph under NOTICE -CLOSURE AREAS. Substitute the following paragraph:

UNLESS OTHERWISE POSTED, DIRECT MOTORIZED ACCESS IS ALLOWED FOR PARKING AND CAMPING WITHIN 300 FEET OF ROADS AND TRAILS WHICH ARE OPEN FOR MOTORIZED USE. PLEASE SELECT YOUR ACCESS ROUTES CAREFULLY SO AS TO AVOID DAMAGING VEGETATION AND OTHER FOREST RESOURCES. DO NOT CROSS MEADOWS AND AVOID CROSSING STREAMS.

REMEMBER. NO MOTORIZED USE IS PERMITTED WITHIN DESIGNATED WILDERNESS.

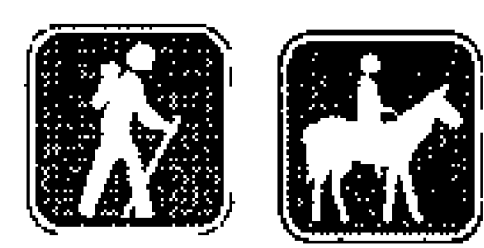

2 If you have any questions about any aspect of the Travel Maps and regulations, please contact any Ranger District Office.

PALISADES AND TETON BASIN RANGER DISTRICTS TRAVEL PLAN

WINTER (Opportunities and Restrictions) USE MATRIX Designated Routes			
	  		
AREA REFERENCE LETTER	NON-MOTORIZED USES	OVER-SNOW MOTORIZED VEHICLES	PURPOSE OF REGULATION
A	OPEN	CLOSED - except on designated routes	To protect wilderness or wildlife ranges and cross-country ski areas
B	Open April 15 to Dec 15 on the Palisades RD and April 15 to Thanksgiving Day on the Teton Basin RD	CLOSED - except on designated routes	To protect wildlife in winter range areas
C	OPEN	OPEN Thanksgiving Day to June 1 on the Teton Basin RD and Dec 15 to June 1 on the Palisades RD	To protect wildlife going to and from winter ranges
D	OPEN except in designated ski resorts during the ski season	CLOSED except for administrative purposes	For user safety

WINTER DESIGNATED ROUTES (Opportunities and Restrictions)			
	  	 	
DESIGNATED ROUTE	NON-MOTORIZED USES	OVER-SNOW MOTORIZED VEHICLES	PURPOSE OF REGULATION
	OPEN to cross-country skiing only	CLOSED	Cross-country ski routes
	OPEN	OPEN	Designated winter travel route (frequently groomed for snowmobiles)
	OPEN	OPEN	Designated winter travel route (may or may not be groomed for snowmobiles)

PALISADES AND TETON BASIN RANGER DISTRICTS TRAVEL PLAN

SUMMER CROSS-COUNTRY USE MATRIX (Opportunities and Restrictions off Designated Routes)							
							
AREA REFERENCE LETTER	NON-MOTORIZED USES	BICYCLES	TWO-WHEEL MOTORIZED VEHICLES	ALL TERRAIN VEHICLES (ATV's) <50" in width	HIGH CLEARANCE VEHICLES (4x4 & pickups) >50" in width	SEDANS <50" in width	PURPOSE OF REGULATION
A	OPEN	CLOSED	CLOSED	CLOSED	CLOSED	CLOSED	To protect wilderness and other special management area resource values
B	OPEN	OPEN	CLOSED	CLOSED	CLOSED	CLOSED	To protect grizzly bear and other wildlife habitat and provide a variety of recreation experiences
C	OPEN	OPEN	OPEN June 1 to Sept 30	OPEN June 1 to Sept 30	CLOSED	CLOSED	To provide a semi-primitive motorized recreation experience
E (see the footnote below)	Generally open HOWEVER , special use permits may restrict some of these uses	Forest sites are closed Areas under special use permits may restrict this type of use	CLOSED	CLOSED	CLOSED	CLOSED	To protect developed recreation site facilities and offer a variety of developed recreation uses

FOOTNOTE These areas are generally too small to show on this map They include all Developed Recreation Sites such as **campgrounds**, picnic areas, boating sites/ramps, trailheads, snowparks, scenic and wildlife viewing areas and fishing access points

It also applies to Special Use Permit Recreation Sites such as ski areas, resorts, **summer** home sites and organization camps

ADDENDUM TO 1997 TRAVEL PLAN MAPS - March 24, 1998

For purposes of clarification, the following changes/corrections now apply to the Winter and Summer Travel Plans for the **ISLAND PARK** and **ASHTON** Ranger Districts until further notice

WINTER TRAVEL PLAN- (the new 1997 plan/map)

1 The following new introductory statement replaces the first and second paragraphs under "**TARGHEE NATIONAL FOREST WINTER TRAVEL PLAN**":

This map describes winter travel opportunities on the Targhee National Forest from THANKSGIVING DAY UNTIL SOMETIME IN THE SPRING as local conditions become suitable to support wheeled vehicle traffic on roads and trails without damage

SEE THE ATTACHED NEW "**WINTER CROSS-COUNTRY USE AND WINTER DESIGNATED ROUTES**" MATRICES THESE REPLACE THOSE AT THE BOTTOM OF THIS MAP AND GIVE DETAILED DIRECTIONS ABOUT OPPORTUNITIES AND RESTRICTIONS FOR WINTER TRAVEL

Additional closures or restrictions may be made at any time for resource protection or public safety To avoid inconvenience, Forest visitors are encouraged to contact local District Ranger Offices for current travel information

For information regarding summer travel opportunities, see the reverse side of this map and the attached addendum information

2 For the "**CROSS-COUNTRY USE**" Matrix, the following changes have been made

- a DELETE the entire "**Wheeled Motorized Vehicles**" column and the associated footnote below the Matrix
- b For "**Reference Area Letter C**" in the "**Over-snow Motorized Vehicles**" column, the wording has been changed to read, "**OPEN Thanksgiving Day to June 1 on the Teton Basin, Ashton, and Island Park Ranger Districts.**"

3 For the "**WINTER DESIGNATED ROUTES**" Matrix, the following change has been made

- a ADD the **ATV SYMBOL** to the "**Over-snow Motorized Vehicles**" column

SUMMER TRAVEL PLAN (the new 1997 plan/map)

1. The following new introductory statement replaces the first and second paragraphs under "**TARGHEE NATIONAL FOREST SUMMER TRAVEL PLAN**":

Welcome to the **Island Park** and **Ashton** Districts of the Targhee National Forest, yours to enjoy and use for a variety of purposes In order to protect forest values, safeguard users, and minimize conflicts between users, it has become necessary to establish certain regulations for the use -- both non-motorized and motorized-- of areas off designated routes and the use of designated roads and trails This map identifies these opportunities and restrictions Please study the map carefully Your understanding and observance of these travel opportunities and restrictions will minimize the need for enforcement action

This map is intended to help the summer recreationist enjoy the Targhee National Forest safely while protecting the natural resources Additional closures or restrictions may be made at any time for resource protection or public safety To avoid inconvenience, Forest visitors are encouraged to contact local District Ranger Offices for current travel information

For information regarding winter travel opportunities, see the reverse side of this map and the attached addendum information

2 For the "**CROSS-COUNTRY USE MATRIX**" shown on this new 1997 map, the following changes have been made **This revised "Matrix" is in force.** (This revised matrix is also shown on the old 5/1/94 District Travel Plan map - revised March 24, 1998)

- a. For "Area Reference Letter F" in the "All Terrain Vehicles (ATV's) <50" in width" column, the wording has been changed to read "OPEN".
- b. For "Area Reference Letter G" in the "Two-Wheeled Motorized Vehicles" column, the wording has been changed to read "Open Jun 15 to Sept 30".
- c. For "Area Reference Letter G" in the "All Terrain Vehicles (ATV's) <50" width column, the wording has been changed to read "Open Jun 15 to Sept 30".

PLEASE NOTE THE FOLLOWING:

- 1 Delete in their entirety the last paragraph under HOW TO USE THIS MAP and the paragraph under NOTICE - CLOSURE AREAS. Substitute the following paragraph

UNLESS OTHERWISE POSTED, DIRECT MOTORIZED ACCESS IS ALLOWED FOR PARKING AND CAMPING WITHIN 300 FEET OF ROADS AND TRAILS WHICH ARE OPEN FOR MOTORIZED USE PLEASE SELECT YOUR ACCESS ROUTES CAREFULLY SO AS TO AVOID DAMAGING VEGETATION AND OTHER FOREST RESOURCES DO NOT CROSS MEADOWS AND AVOID CROSSING STREAMS REMEMBER. NO MOTORIZED USE IS PERMITTED WITHIN DESIGNATED WILDERNESS.

- 2 If you have any questions about any aspect of the Travel Maps and regulations, please contact any Ranger District Office

ISLAND PARK AND ASHTON RANGER DISTRICTS TRAVEL PLAN

WINTER CROSS-COUNTRY USE MATRIX (Opportunities and Restrictions off Designated Routes)			
AREA REFERENCE LETTER	 NON-MOTORIZED USES	 OVER-SNOW MOTORIZED VEHICLES	PURPOSE OF REGULATION
A	OPEN	CLOSED- except on designated routes	To protect wilderness or wildlife ranges and cross-country ski areas
C	OPEN	OPEN - Thanksgiving Day to June 1 on the Teton Basin, Ashton and Island Park RDs	To protect wildlife going to and from winter ranges
E	OPEN	OPEN January 1 to April 1	To protect wildlife going to and from winter ranges

WINTER DESIGNATED ROUTES (Opportunities and Restrictions)			
DESIGNATED ROUTE	 NON-MOTORIZED USES	 OVER-SNOW MOTORIZED VEHICLES	PURPOSE OF REGULATION
	OPEN to cross-country skiing only	CLOSED	Cross-country ski routes
	OPEN	OPEN	Designated winter travel route (frequently groomed for snowmobiles)
	OPEN	OPEN	Designated winter travel route (may or may not be groomed for snowmobiles)
	OPEN	OPEN	Designated winter travel route (occasional use routes snow depths may not allow snowmachine use some years)

SUMMER CROSS-COUNTRY USE MATRIX (Opportunities and Restrictions off Designated Routes)							
							
AREA REFERENCE LETTER	NON-MOTORIZED USES	BICYCLES	TWO-WHEEL MOTORIZED VEHICLES	ALL TERRAIN VEHICLES (ATV's) <50" in width	HIGH CLEARANCE VEHICLES (4x4 & pickups) >50" in width	SEDANS <50" in width	PURPOSE OF REGULATION

It also applies to Special Use Permit Recreation Sites such as ski areas, resorts, summer home sites and organization camps

APPENDIX B

ROAD DECOMMISSIONING PROCESS GUIDELINES

The following is a description of the procedures to be followed during road reclamation and decommissioning as directed by the Revised Forest Plan

Culverts - On perennial streams, culverts will be pulled and the edges of the fill slopes for bedding will be pulled back until the fill slopes are rounded off, but not all of the bedding, fill will be removed from the trench. On intermittent streams, the majority of the pipes will be pulled and treated as on perennial streams—especially where it is evident the culvert has carried water repeatedly. Dry culverts with no water flow evident will remain in place. These culverts generally have heavy vegetation growth of trees, grass, and bushes in the stream channel above the pipe. Where culverts are removed, dig to grade of natural stream channel and to a width that the stream will not undercut remaining fill.

Surface Ripping - This will be done on a case by case basis where needed to remove visual evidence of a road or access to it or adjacent areas. These are generally areas with long straight Right-of-Ways where there is little adjacent vegetation, or other barricade along wide open road surfaces. Ripping will also be done in areas where it would be important to expose additional soils to allow vegetation to reestablish.

Trenching/Surface Debris Placement - This will be done as needed, and mostly at the start of decommissioned segments to prevent travel behind closure gates.

Fill Slopes - These will not be reclaimed or pulled back into the road cut - even when in AIZ or adjacent to a stream, unless significant stream impacts are occurring or are anticipated.

Seeding - The seed mix developed by Rose Lehman and Duane Monte will be used on all disturbed soils in or near perennial stream channels or water bodies, on disturbed soils that occur within watersheds identified as WQL streams, and along road segments that have slopes that are over **10%** grade. The contract inspectors will mark these areas needing seeding on forest maps, so that crews can easily locate the areas and apply the seed as soon after disturbance as possible. In areas away from water, and where natural seed sources are available, we will depend on natural seeding.

Location Direction - Roads inside the BMUs that have been or will be decommissioned are shown on Map #4 - Alternative 3M(+). These roads will be decommissioned according to the guidelines in this Appendix. Roads to be decommissioned outside the BMUs in the next few years will be decommissioned in a similar way to those inside the BMUs with treatments varying from complete obliteration in some cases to less intensive treatments as necessary to deter summer motorized use. Those routes outside the BMUs do not need to meet the Interagency Grizzly Bear Committee access management guidelines, so there will be more flexibility to use less intensive closure methods on these roads.

APPENDIX C

APPENDIX C (1998 Update) AND C(M) ACCESS STATUS TABLES

This appendix contains the following, two, access status tables. Appendix C (1998 Update) is the same as Appendix C for the 1997 Travel Plan ROD, except that the 1997 tabular forms (Update of Appendix C - Summer and Winter Access - Final Environmental Impact Statement for the Revised Forest Plan - August, 1997) have been further updated by deleting the rows with "strikeovers" and by adding ratings in the blanks to show reasons why every road was left open, or closed. Appendix C (1998 Update) has been provided as a bridge between the 1997 Update version and the new Appendix C(M). Appendix C(M) was developed by using ratings from Alternative 3M from the 1998 Update and by adding ratings for the three new alternatives considered. Roads and trails have been rated in these forms according to the letters (segments open) or numbers (segments closed) on the status criteria cover sheets for each table.

This access analysis is based on the same process outlined in the RFP-FEIS, pages C-1 through C-5. Page C-5 of the RFP-FEIS states:

"Determinations for leaving a road open were made using a priority system. First priority was given to Federal Highway system roads, State and county roads, existing roads needed to access private property, Yellowstone National Park, State Parks and State lands, and existing roads that access administrative sites, electronic sites, communication sites (under permit) or high **use** recreation sites such as ski areas, boat ramps, etc. In some areas, the application of management prescriptions and the road density standard resulted in these "first priority" roads being the only roads designated "open" for the area. The Forest incorporated guidelines from the Eastside Ecosystem Management Project (EEMP) to establish a rule set to insure consistency as each District prepared their access maps. District personnel and Forest planning specialists met over several months to fine tune and coordinate motorized access between Districts. Roads and trails were selected for restriction or closure depending on the need to maintain wildlife habitat, prevent resource damage, and to balance the level of use to recreation opportunity. Cost of maintaining the road or trail was also a factor. A set of Road Decision Criteria Tables have been developed, showing the decision in keeping roads and trails open in each alternative."

It should be noted that roads which are not open in any alternative have been removed from table C(M) because they have been or will be decommissioned (due to road density limits needed to meet objectives for Forest Plan management prescriptions) and are not available for motorized travel. Roads inside the BMUs that have been or will be decommissioned are shown on Map #4 - Alternative 3M(+). These roads will be decommissioned according to the guidelines in Appendix B. Roads to be decommissioned outside the BMUs in the next few years will be decommissioned in a similar way to those inside the BMUs with treatments varying from complete obliteration in some cases to **less** intensive treatments as necessary to deter motorized use. Those routes outside the BMUs do not need to meet the Interagency Grizzly Bear Committee access management guidelines, so there will be more flexibility to **use** less intensive closure methods on these roads. These routes are also displayed on map #4 in the map packet. These decommissioned roads have been fully considered in the consequences analysis in this EIS (see the Soils and Access consequences sections for specific details).

APPENDIX C(M)

OPEN ROAD AND MOTORIZED TRAIL ROUTE (OROMTRD) DECISION CRITERIA TABLES

CRITERIA DEFINITIONS

Open to Motorized Use:

- A Core Access Needed to access private property, adjoining State and Federal Parks or State Lands and roads that access administrative sites, campgrounds and picnic areas, electronic sites, permitted communication sites, ski areas, boat ramps and special recreation sites such as Mesa Falls and Big Springs
 - B First Priority These roads were selected to remain open or be seasonally restricted because they are one of the only roads left on the system in the area
 - C Eastside Ecosystem Management Project (EEMP) Guidelines EEMP guidelines used to establish a rule set to insure consistency as each District prepared their access maps
 - D Coordinated Access Roads/trails that provide inter-District and intra-District access for administrative use
 - E Maintenance of Wildlife Habitat Road/trail selected causes less impact
 - F Resource Damage Road/trail selected caused less impact
 - G Cost Lower cost to maintain road/trail
 - H District-specific criteria (e.g. historical, etc.)
 - I District-specific criteria (e.g. berry picking, etc.)
 - J RS 2477 assertions by county
 - K Additions within the Open Road Open Motorized Trail and Route Density (OROMTRD) in response to a specific road and trail comment
- * Roads that are seasonally restricted

Closed to Motorized Use (year-round closure):

- 1 No longer needed for re-occurring resource activities
 - 2 For the protection of wildlife and reduced road maintenance costs
 - 3 To avoid soil erosion and protect water quality
 - 4 To meet Open Road Open Motorized Trail and Route Density (OROMTRD)
 - 5 To respond to specific road and trail comments
 - 6 No longer accessible
- Roads not on the ground

Note Roads and trails shown with letter(s)/number(s) are multiple segment routes, part of which are open and part closed Refer to the Transportation Map for details

APPENDIX C - (1998 UPDATE)

OPEN ROAD AND MOTORIZED TRAIL ROUTE (OROMTRD) DECISION CRITERIA TABLES

Note This table is similar to the 1997 Update version. However, "strikeovers" (deletions) on the 1997 table were deleted in the 1998 update. Also, rating for closed roads have been added to show reasons for closure.

DEFINITIONS

Following are the definitions of the criteria used on the OROMTR Decision Criteria Tables

Open to Motorized Use:

- A Core Access. Needed to access private property, adjoining State and Federal Parks or State Lands and roads that access administrative sites, campgrounds and picnic areas, electronic sites, permitted communication sites, ski areas, boat ramps and special recreation sites such as Mesa Falls and Big Springs
- B First Priority. These roads were selected to remain open or be seasonally restricted because they are one of the only roads left on the system in the area
- C Eastside Ecosystem Management Project (EEMP) Guidelines. EEMP guidelines used to establish a rule set to insure consistency as each District prepared their access maps
- D Coordinated Access. Roads/trails that provide inter-District and intra-District access for administrative use
- E Maintenance of Wildlife Habitat. Road/trail selected causes less impact
- F Resource Damage. Road/trail selected caused less impact
- G Cost. Lower cost to maintain road/trail
- H District-specific criteria (e.g. historical, etc.)
- I District-specific criteria (e.g. berry picking, etc.)

* Roads are seasonally restricted

Closed to Motorized Use (year-round closure):

- 1 No longer needed for re-occurring resource activities
 - 2 For the protection of wildlife and reduced road maintenance costs
 - 3 To avoid soil erosion and protect water quality
 - 4 To meet Open Road Open Motorized Trail and Route Density (OROMTRD)
 - 5 To respond to specific road and trail comments
 - 6 No longer accessible
- Roads not on the ground

Note Roads and trails shown with letter(s)/number(s) are multiple segment routes, part of which are open and part closed. Refer to the Transportation Map for details.

APPENDIX D

BIOLOGICAL EVALUATION AND BIOLOGICAL ASSESSMENT PROCESS

The Biological Evaluation (BE) and Biological Assessment (BA) for the 1997 Forest Plan Revision FEIS have been reviewed and considered in relation to the analysis of this DEIS. As indicated by the analysis in Chapter IV of this DEIS, there are no consequences which would indicate any different conclusions than those reached in the Biological Evaluation and Biological Assessment for the 1997 Forest Plan Revision. The summary of conclusion of effects for sensitive species is displayed in the following table.

SENSITIVE SPECIES BIOLOGICAL EVALUATION SUMMARY OF CONCLUSION OF EFFECTS for the AGENCY PREFERRED ALTERNATIVE

Species	No Impact	May Impact Individuals Or Habitat, But Will Not Likely Contribute To A Trend Towards Federal Listing Or Loss Of Viability To The Population Or Species	Will Impact Individuals Or Habitat With A Consequence That The Action May Contribute To A Trend Towards Federal Listing Or Cause A Loss of Viability To The Population Or Species	Beneficial Impact
WILDLIFE SPECIES				
Northern Goshawk		X		
Flammulated Owl		X		
Boreal Owl		X		
Great Gray Owl		X		
Trumpeter Swan		X		
Spotted Frog		X		
Common Loon		X		
Harlequin Duck	X			
Spotted Bat	X			
Townsend's Big-eared Bat	X			
Fisher		X		
Wolverine		X		
Three-toed Woodpecker	X			
Cutthroat Trout		X		
PLANT SPECIES				
Pink agoseris (<i>Agoseris lackschewitzii</i>)		X		
Sweet-flowered rock jasmine (<i>Adonisace chamaejasme</i> var. <i>carinata</i>)		X		
Lost River milkvetch (<i>Astragalus amnis-amissi</i>)	X			
Lemhi milkvetch (<i>Astragalus aquilonius</i>)		X		
Meadow milkvetch (<i>Astragalus diversifolius</i>)		X		
Park milkvetch (<i>Astragalus leptaleus</i>)		X		
Payson's milkvetch (<i>Astragalus paysonii</i>)		X		
White Cloud milkvetch (<i>Astragalus vexilliflexus</i> var. <i>nubilus</i>)	X			

Species	No Impact	May Impact Individuals Or Habitat, But Will Not Likely Contribute To A Trend Towards Federal Listing Or Loss Of Viability To The Population Or Species	Will Impact Individuals Or Habitat With A Consequence That The Action May Contribute To A Trend Towards Federal Listing Or Cause A Loss of Viability To The Population Or Species	Beneficial Impact
Centennial rabbitbrush (<i>Chrysothamnus parryi</i> <i>ssp montanus</i>)	X			
Douglass' wavewing (<i>Cymopterus douglassii</i>)		X		
Welsh rockcress draba (<i>Draba globosa</i> (D densifolia var <i>apiculata</i>)		X		
Payson's bladderpod (<i>Lesquerella paysonii</i>)		X		
Lemhi penstemon (<i>Penstemon lemhiensis</i>)		X		
Alkali primrose (<i>Primula alcalina</i>)	X			
Weber's saussurea (<i>Saussurea weberi</i>)	X			

X--represents **evaluated** level of effects

A BE and BA addressing all appropriate species are being prepared to reflect the analysis in this DEIS. The BA will be submitted for consideration by the US Fish and Wildlife Service during the final analysis for this proposal, and a Biological Opinion will be published along with the FEIS and Record of Decision.

**List of
Preparers**

LIST OF PREPARERS

The following is a list of the current Forest Leadership Team (FLT) and Forest Interdisciplinary Team (IDT) members and others who developed this Travel Plan EIS, and supporting documents

A Current Forest Leadership Team

Lynn Ballard
Public Affairs Officer

Patricia Bates
District Ranger, Teton Basin Ranger District

Terry Bowerman
Acting Branch Chief for Land Management Planning

Wally Bunnell
Acting Branch Chief for Engineering, Lands and Minerals

Ron Dickemore
District Ranger, Palisades Ranger District

Adrienne Keller
District Ranger, Ashton and Island Park Ranger Districts

Mac Murdock
District Ranger, Dubois Ranger District

Jerry Reese
Forest Supervisor

Ric Rine
Branch Chief for Ecosystems

Chuck Sorenson
Administrative Officer and Branch Chief for Fire Management

B. Interdisciplinary Team (IDT)

Leon Bleggi	
Transportation Planner	
Education	Associate Degree, Engineering, Utah Valley Community College Wildlife Management, University of Southern Utah
Experience	Bureau of Reclamation Engineering Design and Inspection\ Underwater Inspector (SCUBA diver)--7 years
Function	U S Forest Service Engineering Design and Inspecton--10 years Forest Transportaion Planner--14 years Engineering and access management analysis

Mark Orme
 Wildlife Biologist
 Education' B S , Forestry, University of Idaho
 M S , Wildlife Management, University of Idaho
 Experience U S Forest Service--20 years
 University of Idaho--2years
 Function Wildlife analysis

Alan Silker
 Recreation Staff Officer
 Education B S , Forest Management
 M S , Forest Recreation Management
 Experience U S Forest Service
 Recreation Management--28 years
 Winter Sports Planning--22years
 Function IDT Leader, Access, Roadless, Wilderness, and Wild,
 Scenic, and Recreational Rivers analysis

Kris Drewes
 GIS Coordinator
 Experience U S Department of Defense--5 years
 U S Forest Service--17 years
 Function GIS data management and analysis

Bart Andreasen
 Landscape Architect
 Education B S , Landscape Architecture and Environmental Planning
 Experience Bureau of Land Management
 Visual Resources, Recreation Management--1 year
 U S Forest Service
 Visual Resources, Recreation Management--22 years
 Function Visual Resources, ROS, and Travel Plan analysis

Dan Delany
 Forest Fisheries Biologist
 Education B S , Wildlife Management
 Experience Bureau of Land Management
 Range Management--2 years
 Fisheries and Wildlife Management--14 years
 U S Forest Service
 New Perspectives--1 year
 Fisheries and Wildlife Management--8years
 Function Fisheries management and aquatic ecology analysis

Walt Grows
 Range Management Specialist
 Education B S , Forest Recreation (major), range management (minor)
 Experience U S Forest Service
 Resource Management--23 years
 Forest Planner, Range sub-staff, District Ranger, Resource Officer
 and range conservationist
 Function Range management, noxious weeds, predator control, and
 unique ecosystems (RNAs) analysis\

Duane Monte
Soil Scientist

Education B S, Natural Resource Management/Biology
Post Graduate Work—Soil Science
Experience U S Soil Conservation Service—4 years
U S Forest Service—19 years
Function Soil, riparian, wetland, aquatic influence zone analysis

Ronna Simon
Hydrologist

Education B S , Geology
M S , Geography
M S , Water Resources Management
Experience U S Forest Service
Watershed Management--10 years
U S Geological Survey
Water Resource Monitoring, Quality Assurance--1 year
Function Water and wetlands analysis

Rose Lehman
Botanist

Education B A , Biology with Botanical Sciences emphasis
University of Montana
Experience U S Forest Service, Botanist--5 years
Function. TES plant species analysis

West Yellowstone
Montana

Content of Travel Plan

The new Forest Travel Plan to be published in 1999 will include: the details from this Transportation Plan Map (#4); the 1997 Travel Plan Addendum (Appendix A of this EIS); and the designated road, trail and cross-country matrices displayed in the Addendum. The Travel Plan Map and Restriction Order will be developed and implemented in the same format as the 1997 Travel Plan Map.

DISCLAIMER

Users of undeveloped forest areas assume the obvious and inherent risks associated with the activities in which they participate. Safety problems from use of undeveloped forest areas may arise due to the user's lack of familiarity concerning dangers of undeveloped areas, inexperienced vehicle operators, and from conflicts among user groups.

Beginning in 1998, the Forest began to decommission some additional roads on the forest - in particular in the Island Park and Ashton areas. These decommissioned roads are now considered undeveloped forest areas. The method of decommission includes constructing "Kelly" humps (earthen berms), falling trees across the road, and pulling slash and rocks into the road prism. During the summer months, these conditions will be readily noticeable. HOWEVER, during the winter months, they may not be as noticeable to the winter user and in particular to snowmobilers. THEREFORE, it is the responsibility of the forest user to negotiate undeveloped forest areas in a safe and prudent manner.

NOTE: It is possible that some decommissioned roads are not displayed on this map. Additional information may be obtained at the local Ranger District Office.

Cross-Country Travel

The motorized cross-country area designation letters have been added to this map for convenience only. The decision on cross-country use was made by the Forest Plan Revision and it is not part of this DEIS. See the cross-country matrices in Appendix A for interpretation of travel opportunities in these areas. Non-motorized travel designations (areas) are not shown on this map. Refer to the 1997 Travel Plan for non-motorized restrictions which apply.

Update of Appendix C Summer & Winter Access Final Environmental Impact Statement for the Forest Plan Revision

Update of Appendix C, Summer and Winter Access
August 1997

Final Environmental Impact Statement for the
Forest Plan Revision

Targhee National Forest

The District tables contained in Appendix C of the Final Environmental Impact Statement for the Forest Plan Revision have been updated as shown on the attached sheets.

Deletions are shown as strike-overs. Changes and additions are shown in bold. Most of the changes are the result of relabelling roads and trails to correspond with current designations. A large number of duplicate entries have been eliminated.

OPEN ROAD AND OPEN MOTORIZED TRAIL ROUTE (OROMTRD) DECISION CRITERIA TABLES

DEFINITIONS

Following are the definitions of the criteria used on the OROMTR Decision Criteria Tables:

- A. Core Access: Needed to access private property, adjoining State and Federal Parks or State Lands, and roads that access administrative sites, campgrounds and picnic areas, electronic sites, permitted communications sites, ski areas, boat ramps and special recreation sites such as Mesa Falls and Big Springs.
- B. First Priority: In some areas the application of management prescriptions and density standards resulted in this type of road/trail being the only facility designated "open" in the area.
- C. Eastside Ecosystem Management Project (EEMP) Guidelines: EEMP guidelines used to establish a rule set to insure consistency as each District prepared their access maps.
- D. Coordinated Access: Roads/trails that provide inter-District access.
- E. Maintenance of Wildlife Habitat: Road/trail selected causes less impact.
- F. Resource Damage: Road/trail selected caused less impact.
- G. Cost: Lower cost to maintain road/trail.
- H. District-specific criteria (if any).
- I. District-specific criteria (if any).

Record of Decision for the Open Road and Open Motorized Trail Travel Plan

TARGHEE NATIONAL FOREST

OPEN ROAD AND OPEN MOTORIZED TRAIL TRAVEL PLAN

RECORD OF DECISION

Bonneville, Butte, Clark, Fremont, Jefferson, Lemhi, Madison
and Teton Counties, Idaho

Lincoln and Teton Counties, Wyoming

THE DECISION - AN OVERVIEW

This document presents my decision for the open motorized road and trail network for the Targhee National Forest. It explains why I have selected the Travel Plan Portion of Alternative 3M, as modified between the draft EIS and final EIS [displayed as Alternative 3M in the Final Environmental Impact Statement (final **EIS**) for the 1997 Revised Forest Plan].

The purpose and need of this Travel Plan is to offer a balanced range of motorized road and trail related recreation opportunities in the Forest that is consistent with the management prescriptions adopted in the Revised Forest Plan. These prescriptions include standards for the miles of open roads and motorized trails allowed per square mile. This Travel Plan shows which roads and trails will remain open to meet these road and trail density standards.

The Travel Plan in Alternative 3M, as modified from the Revised Forest Plan draft **EIS**, in response to site specific public comments, responds to the need for a reasonable network of motorized roads and trails that meet the open road and open motorized trail route density (OROMTRD) standards in the Revised Forest Plan. This decision provides for 1,577 miles of open motorized roads, 25 miles of seasonally restricted roads and 540 miles of open motorized trails. Prior to this decision 1,985 miles of roads were open, 73 miles of road were seasonally restricted and 773 miles of trail were open for motorized use. Therefore, there will be a reduction of approximately 408 open miles of road, 48 miles of seasonally restricted road, and 233 miles of open motorized trail from existing condition to meet the OROMTRD standards specified in the Revised Forest Plan. For more specifics, see Table IV-13 on page IV-45 in the final **EIS**.

Some signing of open motorized routes will begin this fall consistent with the Travel Plan maps.

We will also implement a monitoring and evaluation strategy to assess the effectiveness of this motorized travel plan. This monitoring item is a priority one for the Forest (See Revised Forest Plan, Chapter V for further details), which means it is mandatory.

In the process of preparing this Record of Decision and its accompanying Travel Maps we identified numerous instances in which Appendix C of the Final EIS could be clarified and updated. This decision is based on that corrected Appendix C.

BACKGROUND

One of the most controversial aspects of the Revised Forest Plan is the key issue of access and what level of motorized access is appropriate for the Targhee National Forest. The Revised Plan has numerous management prescriptions and included in most of these prescriptions is an access table that indicates the type of access (motorized or nonmotorized), cross country travel and road and trail travel that is allowed year round and seasonally, including an open road and open motorized trail route density for most prescriptions. This Record of Decision designates the roads and trails that will be open for motorized use to begin implementation of the Revised Forest Plan.

The final **EIS** for the Revised Forest Plan portrays both the cumulative effects and site specific considerations for the motorized road and trail network (See Appendix C of the final **EIS** for further information).

During the Revision of the Forest Plan, each motorized road and trail was carefully scrutinized by the Interdisciplinary Team (IDT) and field going personnel from the Ranger Districts. Resource concerns included elk security and elk habitat effectiveness, Threatened, Endangered and Sensitive species habitat, riparian areas, sensitive soils and steep slopes. The public was also involved in this analysis and disclosure which is summarized below.

PUBLIC INVOLVEMENT

Public involvement has been extensive throughout the planning and analysis process leading to this decision. Key public comment and participation was obtained on numerous occasions. I feel confident that all interested publics have had ample opportunities to participate and share their concerns regarding this Travel Plan. The following outlines the major steps in the public involvement effort.

* In October of 1994, meetings were held in Idaho Falls and Driggs to give the public an opportunity to identify which individual areas, roads and trails should be permanently open, permanently closed, obliterated or seasonally restricted.

* Open houses were held in June 1995 in Idaho Falls, Ashton, and Rexburg at the Henry's Fork Watershed Council meeting to present the proposed action, (Alternative 3M in the draft **EIS** for the Revised Forest Plan) to interested people, gather information and exchange ideas.

The **DEIS** was available for a 90-day comment period from February 1996 to June 1996. The Travel Plan was displayed on maps 11 and 12. other alternatives in the Draft **EIS** displayed different Travel Plans to meet the road and trail density standards for those alternatives (various maps 2-20).

During the comment period, numerous public information meetings were held throughout the local area. Detailed travel maps were on display for Alternative **3M** and participants were asked at each meeting to provide input as to why individual roads and trails should be open or closed.

Substantive access comments and the responses are listed in Appendix A of the final **EIS** for the Revised Forest Plan (Pgs. **I-1** through **1-84**).

Public involvement and discussions continue. We listened to all points of view and incorporated many suggestions. I am confident the staff listened, and that public involvement in this process has strengthened this decision.

PLANNING RECORDS

With the above collaboration with the public, other agencies and expertise from many Forest Service employees, an IDT completed the environmental analyses as summarized in the Final **EIS** (Chapter IV) & the updated Appendix **C**. The Team has provided detailed explanations of the analysis and results of the planning process in planning records. Detailed planning records can be reviewed at:

Forest Supervisor's Office
Targhee National Forest
420 N. Bridge Street
St. Anthony, Idaho 83445

ALTERNATIVES CONSIDERED

Based on available data, public involvement, and Final **EIS** Appendix **C** (as updated), three reasonable alternatives that address varying Travel Plans were considered. The three Alternatives analyzed in detail are briefly described below. For a more complete discussion of alternative development see the final **EIS**, Appendix **C**.

Alternative 1 "NoAction" - This alternative would leave the 1996 Travel Plan in place. This alternative was displayed on travel maps for Alternative 1 in the draft EIS and final EIS (maps 2 and 3). Approximately 1,985 miles of road, 73 miles of seasonally restricted road, and 773 miles of motorized trail would remain open, as are currently available. No additional road closures would be implemented at this time.

Alternative 3M (draft EIS) - The alternative is the travel plan for Alternative 3M, as displayed in the draft EIS for the Revised Forest Plan (maps 2 and 3). It was also the proposed action. This alternative had 1,560 miles of open road, 120 miles of seasonally restricted road, and 438 miles of open motorized trail.

The selected alternative, Alternative 3M (final EIS), as modified between draft and final EIS - approximates the travel plan that was displayed in the final EIS for the Revised Forest Plan (maps 11 and 12). As displayed in the final EIS, this alternative had 1,577 miles of roads, 25 miles of seasonally restricted road, and 540 miles of motorized trails open for use.

OTHER ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED STUDY

The draft EIS and final EIS also displayed open motorized road and trail travel plans for five other alternatives considered (2,3,4-6). Neither of these alternatives were selected by the Regional Forester to be the Revised Forest Plan and therefore were eliminated from detailed study in this travel plan analysis because they did not meet the densities decided upon in the Revised Forest Plan.

THE DECISION

My decision is to adopt the road and trail network as shown in Alternative 3M which was modified after reviewing site specific public comments made on the draft EIS for the Revised Plan (see attached map).

The system, as mapped, will offer a variety of motorized and nonmotorized use across the Forest in an environmentally acceptable way. The map clearly describes where people may go to either enjoy or avoid motorized activities.

The following illustrates the miles of roads and trails which will be open for motorized use by Ranger District:

	Miles of Road Open For Motorized use	Miles of Seasonally Restricted Roads	Miles of open Trail
Dubois District	359	11	98
Island Park	423	4	24
Ashton	356	0	18
Palisades	287	7	258
Teton Basin	152	3	142
TOTAL	1,577	25	540

MONITORING COSTS AND IMPLEMENTATION OF ROAD AND TRAIL CLOSURES

This project includes the commitment of the Forest to implement all the road and trail closures and to monitor the effectiveness of the closures as described in the Monitoring Plan for the Revised Forest Plan.

RATIONALE FOR THE DECISION

Alternative 3M, as detailed in the accompanying Travel Maps and updated final EIS Appendix C, is the result of the alternative development and public involvement stages of the Forest Plan Revision process. Important considerations to protect the environment that have influenced my decision include:

Protection of the basic resources (air, soil, and water), as mandated by our agency's mission, vision and guiding principles, are provided for with the Travel Plan.

The local and national people who use the Targhee National Forest, the communities they live in, and the relationship of the Forest Service with people and local communities.

Compared to the other alternatives, Alternative 3M, as modified, will implement the open motorized road and trail density standards for the Forest. Reasonable access to the Forest is provided on a system of designated routes.

This decision is one that involved a balancing of compelling resource concerns and competing public interests with timely, responsible ecosystem recovery. I have reached my decision after careful consideration of the environmental analysis of the effects of the three alternatives, public comments received between draft and final EIS and associated planning records.

I selected the Travel Plan for Alternative 3M, as modified, because it best meets the most important objectives of the Regional Forester's decision in selecting Alternative 3M as the Revised Forest Plan: management of the Forest for sustainability of all components of the ecosystem, maintaining or improving habitat for all wildlife species, especially elk and grizzly bear, maintaining or improving riparian conditions, protecting long-term soil productivity and providing an array of recreational opportunities. Other important considerations were: roadless area resources, fish habitat, and elk and deer winter range.

FINDINGS REQUIRED BY OTHER LAWS

As the Forest Supervisor (Deciding Officer), I have considered the multitude of statutes governing management of the Targhee National Forest, and I believe that this decision represents the best possible approach relative to harmonizing and reconciling the current statutory duties of the Forest Service related to Travel Management.

This decision complies with the 1997 Revised Forest Plan for the Targhee National Forest. The open motorized road and trail network, as proposed in Alternative 3M, as modified, meets the open motorized road and trail route density standards for all prescription areas for the Forest.

This decision complies with the Clean Water Act, the National Historic Preservation Act, the Endangered Species Act, and the Clean Air Standards Act as shown by the conclusions presented in Chapter IV of the Final EIS for the Revised Forest Plan and Appendix C of the Final EIS.

This Travel Plan complies with the Endangered Species Act and the US Fish and Wildlife Service Biological Opinion as shown in the conclusions presented in Chapter IV, Wildlife section of the Final EIS.

THE ENVIRONMENTALLY PREFERRED ALTERNATIVE

I am identifying the selected Alternative 3M, as modified, as environmentally preferable based on the following interpretation of the law and agency policy.

Regulations implementing the National Environmental Policy Act (NEPA) require agencies to specify the alternative or alternatives which were considered to be environmentally preferable (40 CFR 1505.2(b)). Forest Service policy further defines environmentally preferable as an alternative

that best meets the goals of section 101 of NEPA. Ordinarily this is the alternative that causes the least damage to the biological and physical environment and best protects, preserves, and enhances historical, cultural, and natural resources. In some cases there may be more than one environmentally preferable alternative (FSH 1909.15-05).

Section 101 of NEPA declares national environmental policy, calling on federal, state, and local governments and the public to create and maintain conditions under which humans and nature can exist in productive harmony. This broad policy is further defined in six goals:

- (1) fulfill the responsibilities of each generation as trustee of the environment for succeeding generations;
- (2) assure for all Americans safe, healthful, productive, and aesthetically and culturally pleasing surroundings;
- (3) attain the widest range of beneficial uses of the environment without degradation, risk to health or safety, or other undesirable and unintended consequences;
- (4) preserve important historic, cultural, and natural aspects of our national heritage and maintain wherever possible an environment which supports diversity and variety of individual choice;
- (5) achieve a balance between population and resource use which will permit high standards of living and a wide sharing of life's amenities; and
- (6) enhance the quality of renewable resources and approach the maximum attainable recycling of depletable resources.

The goals of Section 101 are similar to the principles of ecosystem management and of the Revised Forest Plan, calling for sustainable and balanced use, and provision for future generations. Section 101 does not call for the exclusion of Americans from use of their natural resources, but does demand that such uses avoid degradation of the environment. Alternative 3M, as modified best meets the goals of Section 101 of NEPA. By this standard, the selected Alternative 3M, as modified is the environmentally preferable alternative for this Travel Plan.

MITIGATION AND MONITORING

All practicable means to avoid or minimize environmental harm from the proposed designation of open motorized roads and trails in Selected Alternative 3M, as modified, have been adopted. Monitoring the effectiveness of road closures in priority one (per Chapter V, Revised Forest Plan) and will check the effectiveness of the closures and achievement of Total Motorized Access Route Density and open Road and Open Motorized Trail Route Density (further information can be found on pages V-39 through V-41 of the Revised Forest Plan).

APPEAL AND IMPLEMENTATION

This decision is subject to administrative review pursuant to 36 CFR 215. Any appeal of this decision must be fully consistent with 36 CFR 215.14, Content of Notice of Appeal, including the reasons for appeal and must be filed with:

Appeal Reviewing Officer
USDA-Forest Service
324 25th Street
Ogden, Utah

Any appeal must be postmarked within **45** days from the date the legal notice of this decision is published in the Idaho Falls Post Register.

If no appeal is filed, implementation may occur on, but not before, **5** business days from the close of the appeal filing period. If an appeal is filed, implementation may not occur for 15 days following the date of appeal disposition.
