Definition

Minimum reporting level (MRL)—smallest measured concentration of a constituent that may be reliably reported by using a given analytical method (Timme, 1995).

Datum

Horizontal coordinate information is referenced to the North American Datum of 1983 (NAD 83).

Concentrations of Glyphosate, Its Degradation Product, Aminomethylphosphonic Acid, and Glufosinate in Ground- and Surface-Water, Rainfall, and Soil Samples Collected in the United States, 2001–06

By Elisabeth A. Scribner¹, William A. Battaglin², Robert J. Gilliom³, and Michael T. Meyer¹

Abstract

The U.S. Geological Survey conducted a number of studies from 2001 through 2006 to investigate and document the occurrence, fate, and transport of glyphosate, its degradation product, aminomethylphosphonic acid (AMPA), and glufosinate in 2,135 ground- and surface-water samples, 14 rainfall samples, and 193 soil samples. Analytical methods were developed to detect and measure glyphosate, AMPA, and glufosinate in water, rainfall, and soil. Results show that AMPA was detected more frequently and occurred at similar or higher concentrations than the parent compound, glyphosate, whereas glufosinate was seldom found in the environment. Glyphosate and AMPA were detected more frequently in surface water than in ground water. Trace levels of glyphosate and AMPA may persist in the soil from year to year. The methods and data described in this report are useful to researchers and regulators interested in the occurrence, fate, and transport of glyphosate and AMPA in the environment.

Introduction

Nonpoint-source contamination of water resources from herbicides became a major water-quality concern during the 1990s in the United States. To address this issue, numerous studies of ground and surface water, rainfall, and soil were completed by the U.S. Geological Survey (USGS) (Scribner and others, 2005). The Organic Geochemistry Research Laboratory (OGRL) was established by the USGS in Lawrence, Kansas, to identify new or seldom-studied contaminants that may have deleterious effects on water quality or may be useful indicators of geochemical transport processes and to conduct

research on the fate and transport of contaminants in the hydrogeologic system.

To accomplish this, analytical methods have been developed by OGRL using solid-phase extraction (SPE), gas chromatography/mass spectrometry (GC/MS), liquid chromatography/mass spectrometry (LC/MS), and liquid chromatography/tandem spectrometry (LC/MS/MS) to detect and measure pesticides, antibiotics, and their degradation products, including glyphosate, its degradation product, aminomethylphosphonic acid (AMPA), and glufosinate in ground and surface water, rainfall, and soil throughout the United States as identified in this report.

Glyphosate, often referred to as Roundup™, currently (2007) is the most commonly used agricultural herbicide in the United States and the world. Glyphosate herbicides have been popular since first marketed in 1974. In agriculture, glyphosate is used extensively with genetically modified herbicide-tolerant crops, but it also is commonly used around homes in yards, gardens, and other nonagricultural areas (Williams and others, 2000; Cox, 2004). In the past 10 years, it has become one of the most extensively used herbicides for weed control in corn and soybeans in the United States.

Glufosinate, a shortened name for glufosinate-ammonium salt, is a broad-spectrum, contact herbicide first introduced in the United States in 1997 and is used to control a wide range of weeds after the crop emerges or for total vegetation control. Glufosinate herbicides also are often used to desiccate crops before harvest (Friends of the Earth, 2001). Use of glufosinate is expected to increase substantially in the next few years due to the cultivation of crops, such as corn and soybeans, that have been genetically engineered to tolerate it (Cox, 1996).

Purpose and Scope

The purpose of this report is to present methods and data that document the occurrence and concentrations of glyphosate, its degradation product, AMPA, and glufosinate (chemical structures shown in fig. 1) in 873 ground- and 1,262 surface-water samples, 14 rainfall samples, and 193 soil

samples collected from 2001 through 2006. These samples were collected as part of several ongoing USGS studies being conducted throughout the United States, including studies conducted with Federal and State cooperative agencies and other USGS programs such as the National Stream Quality Accounting Network (NASQAN) Program, the National Water-Quality Assessment (NAWQA) Program, and the Toxic Substances Hydrology (Toxics) Program. The data in this report were collected from studies funded, in part or whole, by these programs. This report also includes a chemical description of glyphosate, AMPA, and glufosinate and documents the sample-collection and processing methods in addition to laboratory and analytical methods.

Description of Study Sites

Water samples were collected and analyzed as part of various USGS studies listed below.

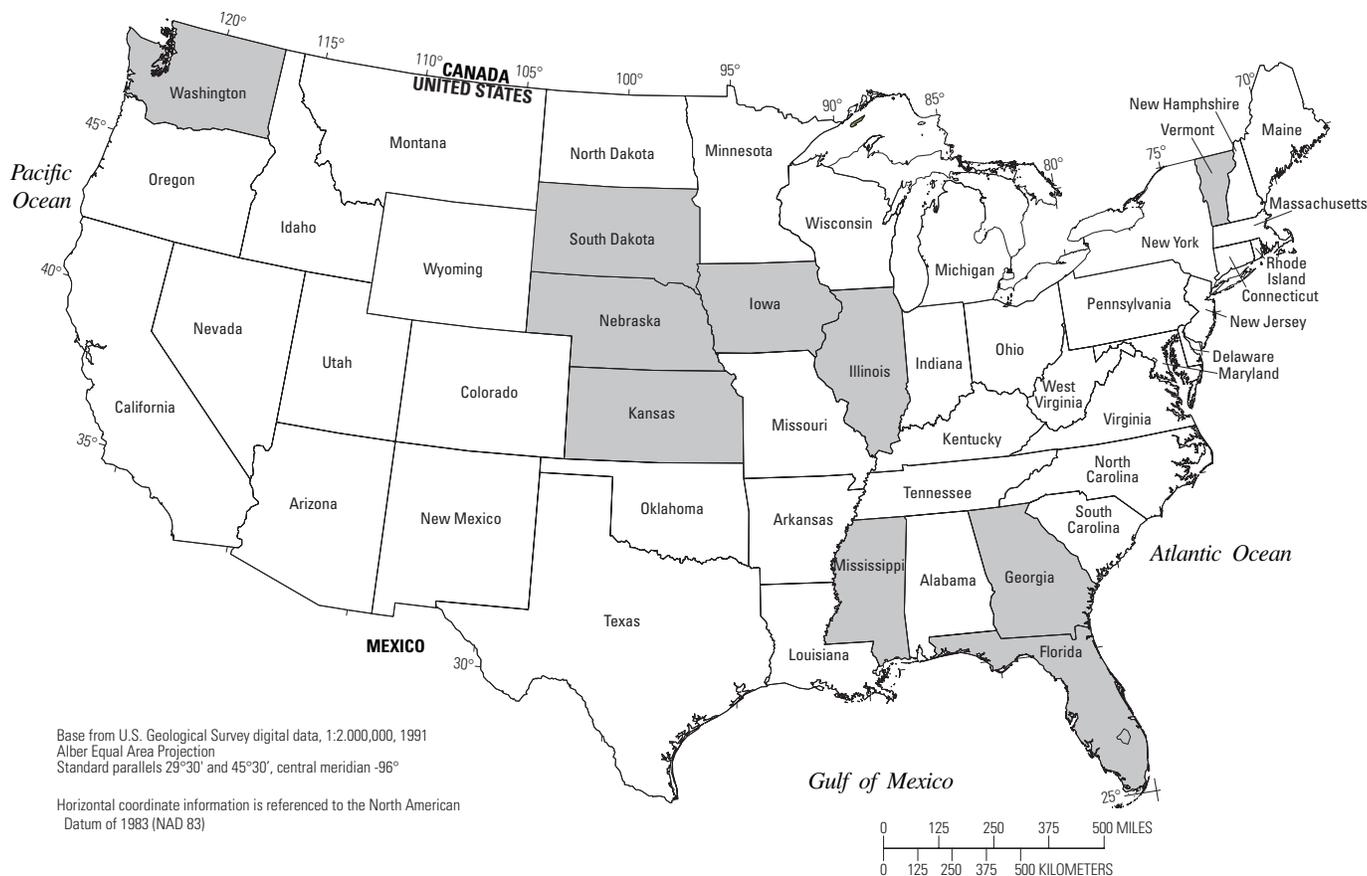

1. USGS cooperative studies with various Federal and State agencies investigated glyphosate, AMPA, and glufosinate

transport in aquatic ecosystems (fig. 2). In some cases, these cooperative studies evaluated agricultural contamination of ground and surface water from nonpoint and distributed point sources. For example, herbicide-related samples were collected in 2002 in cooperation with the U.S. Environmental Protection Agency to study urban contributions of glyphosate and AMPA to streams in the United States (Scribner and others, 2003).

2. The NASQAN program was established to develop a long-term water chemistry data set from five major river basins—the Colorado, Columbia, Mississippi, Rio Grande, and Yukon (fig. 3). In 2002, water samples from four streamflow-gaging stations in the Mississippi River Basin were collected for analysis (fig. 3) and results for glyphosate, AMPA, and glufosinate are reported herein. These data are important in characterizing baseline hydrology conditions and variations in chemical and sediment concentrations that occur throughout the year, during different seasons, during periods of high and low streamflow, and under different conditions of land use (Hooper and others, 1997; Coupe and Goolsby, 1999; Hooper and others, 2001; U.S. Geological Survey, 2006a).
3. NAWQA includes investigations of 51 major river basins and aquifer system study units (fig. 4) that provide the framework for national and regional status and trends in the quality of the Nation's ground- and surface-water resources (U.S. Geological Survey, 2003; Gilliom and Hamilton, 2006; Gilliom and others, 2006). Data for glyphosate, AMPA, and glufosinate from 23 of the 51 study units are included in this report.
4. The USGS Toxic Substances Hydrology (Toxics) Program, Pesticide Research Group, provides unbiased scientific information on the occurrence, movement, flux, fate, and effects of agricultural chemicals in the Nation's hydrologic environments. The program includes development and quantification of methods to measure contaminants and their degradation products at concentrations low enough to understand fate and transport in hydrologic systems (Buxton, 2000). An example of studies funded by Toxics includes herbicide and degradation product concentrations evidenced during a reconnaissance of 51 streams in nine Midwestern States in the Midwest Corn Belt during 2002 (fig. 5; Scribner and others, 2003; Battaglin and others, 2005; Kolpin and others, 2006).

Description and Use of Glyphosate, Aminomethylphosphonic Acid, and Glufosinate

Glyphosate [N-(phosphonomethyl)-glycine] is a non-selective, postemergence herbicide used for perennial weed control. Glyphosate was developed by J.E. Franz, Monsanto Corp., in 1971 and was released commercially in 1974 (Iowa State University, 1997). In the early 1980s, it became the first

EXPLANATION

 State where samples were collected—Results are shown in table 3

Figure 2. Ten States where samples were collected for analysis of glyphosate, its degradation product, aminomethylphosphonic acid, and glufosinate, 2001–06.

individual pesticide with worldwide sales of over 1 billion dollars (Iowa State University, 1997). Glyphosate use in the United States rapidly increased with the introduction of genetically modified glyphosate-resistant soybeans in 1997 and corn in 1998. Glyphosate also is used extensively in yards, gardens, parks, and other nonagricultural areas (Cox, 2004). Glyphosate was the world's most extensively used herbicide in 2000 (Baylis, 2000). In the United States, estimated usage is between 103 and 113 million lbs (Cox, 2004; Kiely and others, 2004). Herbicide use is an important factor affecting the concentrations of herbicides measured in Midwestern streams (Battaglin and Goolsby, 1999; Scribner and others, 2000; Battaglin and others, 2005). About 55 million lbs of glyphosate were applied to agricultural land in nine Midwestern States (fig. 6) during 2003 compared to atrazine, which decreased to about 40 million lbs during the same timeframe (Scribner and others, 2005; U.S. Department of Agriculture, 2006).

Glyphosate is absorbed directly through plant leaves and rapidly spreads throughout the plant. It blocks the activity of an enzyme used by plants to make amino acids. Without

these amino acids, the plant cannot make proteins required for various life processes, resulting in the death of the plant (Monsanto Company, 2002; Cox, 2004). Glyphosate is known to bind tightly to particles that are adsorbed to soils that may prevent excessive leaching or being taken up from the soil by nontarget plants (Carlisle and Trevors, 1988). Glyphosate is degraded primarily by microbial processes producing AMPA [alpha-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid] (Sprankle and others, 1975; Rueppel and others, 1977). Studies show that glyphosate has a water solubility of 12,000 to 900,000 mg/L at 20°C and that the half-life can vary from 2 to 174 days (Extension Toxicology Network, 1994).

Glufosinate [2-amino-4-(hydroxy-methylphosphinyl) butanoic acid], a broad-spectrum contact herbicide used to control a wide range of weeds after the crop emerges or for total vegetation control on land not used for cultivation, is produced by AgrEvo, a joint venture by the German chemical corporations, Hoechst and Schering. The herbicide was first introduced in Japan and the United Kingdom in 1984. Registration in the United States was in 1993. Glufosinate is

4 Concentrations of Glyphosate, Aminomethylphosphonic Acid, and Glufosinate in Water and Soil Samples

Figure 3. Location of streamflow-gaging stations where samples were collected for analysis of glyphosate, its degradation product, aminomethylphosphonic acid, and glufosinate as part of the U.S. Geological Survey National Stream Quality Accounting Network Program, 2002.

registered for use in more than 40 countries. AgrEvo introduced a glufosinate formulation for use on crops resistant to glufosinate in the late 1990s (Pesticide Action Network UK, 1998).

Studies show that 1,370 g of glufosinate can be dissolved in 1 L of water and the half-life will vary from 12 to 70 days, with an average of about 40 days (Cox, 1996). Usage of glufosinate in the United States was 847,000 lbs during 2003 (U.S. Department of Agriculture, 2006) and included nine

States (California, Iowa, Michigan, Minnesota, North Dakota, Oregon, South Dakota, Washington, and Wisconsin).

Acknowledgments

The authors wish to acknowledge the USGS scientists and hydrologic technicians who provided essential support to the studies just described by identifying candidate stream

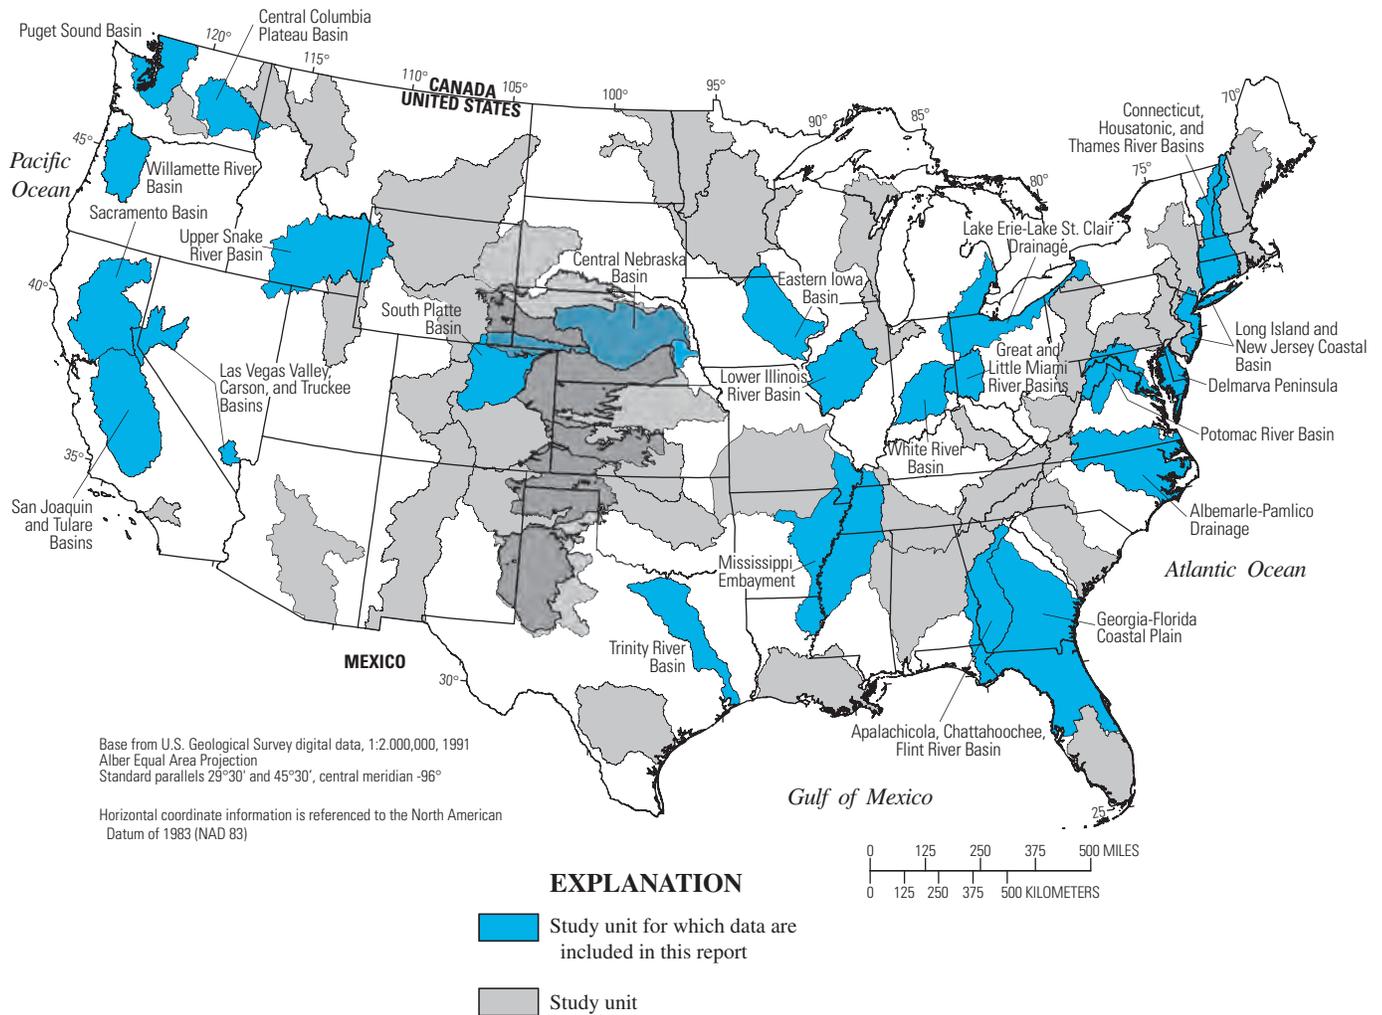

Figure 4. Location of National Water-Quality Assessment Program study units where samples were collected for analysis of glyphosate, its degradation product, aminomethylphosphonic acid, and glufosinate, 2001–06.

sites across the United States and in collecting and processing stream samples. In addition, thanks go to E. Michael Thurman (retired USGS research scientist) and Edward A. Lee (former OGRL staff member) for their important contributions in developing and interpreting the analytical methods used on samples described in this report.

Sampling Methods and Procedures

Sampling Sites

Drainage basins for surface-water sampling sites ranged in size from just a few acres to one of the largest river basins in the world (the Mississippi) and everywhere in-between. The data presented in this report are not meant to be a representative examination of the occurrence of glyphosate in the Nation’s water but rather are a compilation of individual studies conducted for various purposes and with different

objectives. The interpretation of these data as a whole should reflect this fact. However, these data do give an indication of the breadth and scope of the occurrence of glyphosate in the Nation’s water from 2001–06.

Sample Collection and Processing

Hydrologic technicians collected water samples that accurately represent the water-quality characteristics of the ground water, surface water, rainfall, or soil at a given time or location following instructions of the USGS National Field Manual for Collection of Water-Quality Data (U.S. Geological Survey, 2006b). Sample-collection equipment was made of Teflon or stainless-steel material and was free of materials that might leach interfering compounds into water samples or absorb the target analytical compounds from the water samples.

Ground-water samples were discharged directly into the filtering device through tubing connected to sample taps at water-supply wells or the discharge outlet on sampling pumps.

6 Concentrations of Glyphosate, Aminomethylphosphonic Acid, and Glufosinate in Water and Soil Samples

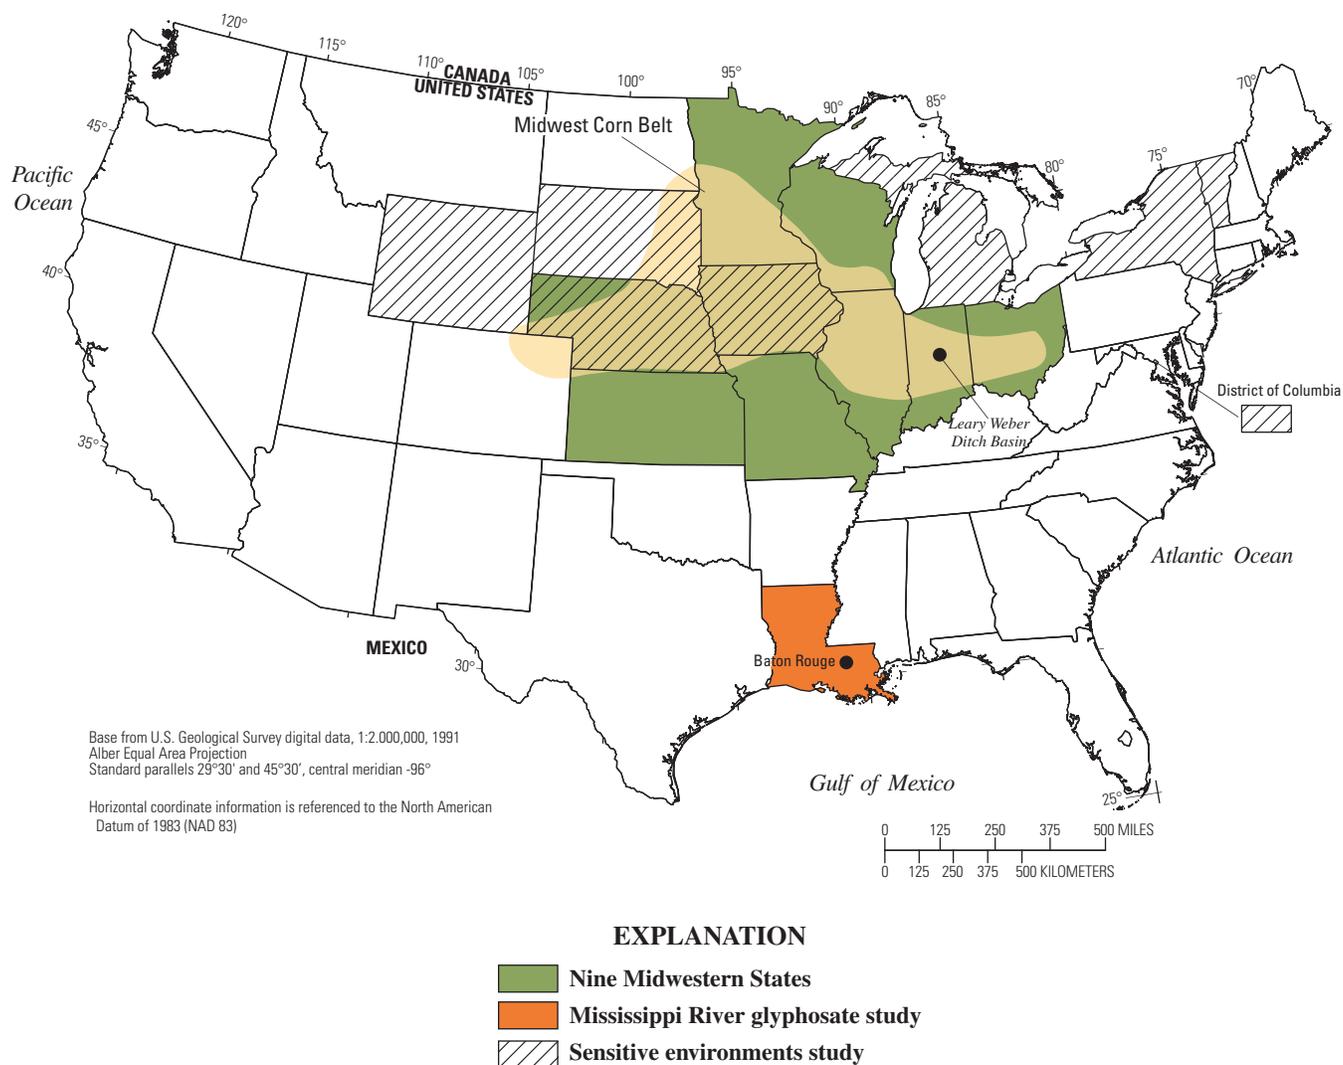

Figure 5. Location of Midwest Corn Belt and Toxic Substances Hydrology Program studies where samples were collected for analysis of glyphosate, its degradation product, aminomethylphosphonic acid, and glufosinate, 2001–06.

The water samples from each surface-water site were composited in a single container and filtered through a nominal 0.7- μm glass-fiber filter using a peristaltic pump. Filters were preconditioned with about 200 mL of sample water prior to collection of the sample. The filtrate for analysis was collected in baked 125-mL amber glass bottles with Teflon-lined lids. All samples were chilled immediately and shipped to OGRL and stored at approximately 4°C until analyzed.

Rainfall samples were collected by a refrigerated wet-deposition sampler as described in Baker and others (2006). Soil samples were collected at three depths at each site (for a total of nine samples per site for every sample-collection period). A soil core sampler was used to collect samples from 0–6 in., 6–12 in., and 12–18 in. at each of the three randomly chosen sample locations. Clean aluminum sampling tubes were inserted in the core sampler and the first 6-in. section (0–6 in.) of soil was extracted. The section was removed from the sampling tube (with nitrile gloves) and placed in a labeled

glass jar. Clean sampling tubes were inserted in the core sampler, and the second 6-in. section (6–12 in.) of soil was extracted from the same hole. The same procedure was used on the third 6-in. section (12–18 in.) of soil.

Analytical Methods and Procedures

Liquid Chromatography/Mass Spectrometry and Liquid Chromatography/Tandem Mass Spectrometry

The analytical method for glyphosate, AMPA, and glufosinate compounds in water is described in Lee and others (2002a,b) and is suitable for the determination of concentrations, using online SPE and LC/MS (from 2001 to 2004), and was modified to use an LC/MS/MS method in 2004.

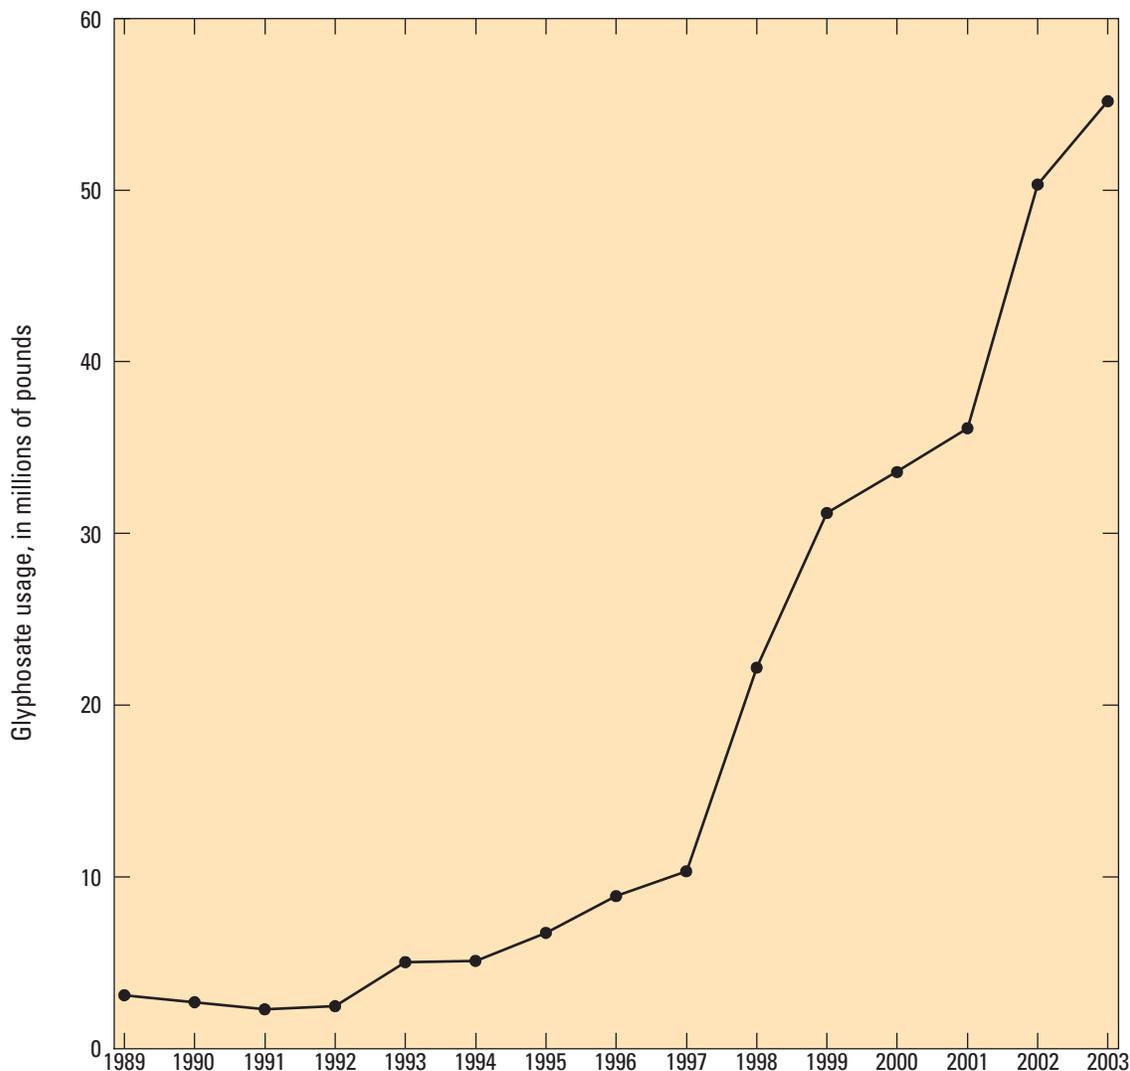

Figure 6. Glyphosate use in nine Midwestern States, 1989–2003 (data from U.S. Department of Agriculture, 2006).

Materials

Analytical grade standards of glyphosate, AMPA, and glufosinate were obtained from ChemService, Inc. (West Chester, Pennsylvania) for use as internal standards. Stable isotope-labeled glyphosate ($2\text{-}^{13}\text{C}$, ^{15}N) purchased from Cambridge Isotope Laboratories (Andover, Massachusetts) was used as an internal standard for LC/MS method as described in Lee and others (2002a). Stable isotope-labeled [$^{13}\text{C}_2$, ^{15}N – glyphosate (glyphosate +3)] and [^{13}C , ^{15}N , methylene- D_2 – AMPA (AMPA +4)] were purchased from GmbH Company (Germany). The second isotope-labeled AMPA [^{13}C , ^{15}N – AMPA (AMPA +2)] came from Cerfilliant Corporation (Round Rock, Texas). There was no stabilized isotope-labeled internal standard available for glufosinate. The internal standard cysteic acid was obtained from Sigma, St. Louis, Missouri. All solvents were high-performance liquid chromatography (HPLC) grade.

Derivatization of Samples

Water

As described in Lee and others (2002a), each water sample (ground water, surface water, rainfall) was derivatized by dispensing 10 mL into two labeled, 19-mL, screw-capped plastic tubes. The sample in the tube labeled “standard addition” was fortified with 1 $\mu\text{g/L}$ of each compound to be analyzed. Internal standard solutions were added to both tubes, the sample was buffered to pH 9.0 standard units by adding borate buffer, and after mixing, a solution of 9-fluorenylmethylchloroformate (FMOC) was added to all tubes. Derivatization was conducted in the dark in a water bath at 40°C. After 24 hours, the reaction was stopped and stabilized by adding 2-percent phosphoric acid, then tubes were stored in a refrigerator at 4°C until analyzed.

Soil

Soil samples were placed on an aluminum foil sheet, and a spatula was used to break up and mix the sample. Five grams (5 g) of soil sample were weighed into a labeled 50-mL plastic centrifuge tube using at least ten 0.5-g aliquots from different areas of the sample. Twenty-five milliliters (25 mL) of 0.5 M potassium hydroxide (KOH) were added to the sample tube, which was placed on a mechanical shaker for 45 min at medium speed, then centrifuged for 10 min to extract the compounds.

Five milliliters (5 mL) of the centrifuged KOH soil extracts were pipetted into a new labeled 50-mL centrifuged tube to which 5.1 mL of 0.5 M hydrochloric acid (HCl) were added. Five-tenths M HCl was added drop-wise until a pH of 3.0 to 4.0 standard units was obtained. Ten milliliters (10 mL) of borate buffer were added by drop until pH was adjusted to 9.0 standard units. The internal standard and FMOC solutions then were added to the sample eluate and placed in a 40°C water bath for 24 hours. The reaction was stopped and stabilized by adding 2-percent phosphoric acid, then tubes were stored in a refrigerator at 4°C until analyzed.

Online Solid-Phase Extraction

A Prospekt automated online SPE instrument with the Triathlon autosampler (Spark-Holland, The Netherlands) were used to extract the samples. Each sample and the matching standard-addition sample were loaded into the sample tray of the autosampler. The SPE instrument were loaded with cartridges. The Prospekt had one cartridge clamp to rinse the cartridge and load the sample and another cartridge clamp to elute the previously prepared cartridge. The sample lines were rinsed and deactivated with a sodium hydroxide (NaOH) and ethylenediaminetetraacetic acid (EDTA) solution between samples. The SPE cartridge was rinsed with methanol and conditioned with reagent water, and then 10 mL of soil sample were loaded onto the cartridge from the autosampler at a rate of 2 mL/min. The cartridge was washed with reagent water at the same rate for 15 sec. The SPE cartridge then was eluted with 750 µL of acetonitrile (ACN) and by diverting the liquid chromatography (LC) mobile-phase stream through the cartridge. The mobile-phase composition was set to elute the compounds of interest and leave the excess derivatization reagent on the cartridge (Lee and others, 2002a).

Liquid Chromatography/Mass Spectrometry

Samples were analyzed on a Hewlett Packard (Wilmington, Delaware) model 1100 high-performance liquid chromatograph (HPLC) with autoinjector and mass spectrometry detector. The concentration of each compound was calculated by determining the ratio of the compound to the internal standard to the ratio of the same compound in the standard-addition sample minus the ratio of the sample. The sample and

standard-addition sample were analyzed sequentially using the same method and instruments (Lee and others, 2002a). The reporting limit for the LC/MS method was 0.10 µg/L from 2001 through 2004.

Liquid Chromatography/Tandem Mass Spectrometry

Samples were analyzed on an Agilent 1100 series liquid chromatography (LC) system (Wilmington, Delaware) and a Waters Quattro Micro atmospheric pressure ionization (API) tandem mass spectrometer (MS/MS) system with electrospray ionization in negative-ion mode (Milford, Massachusetts). A Luna C-18 (2) analytical column (Phenomenex, Torrance, California) was used to separate glyphosate, AMPA, and glufosinate. The LC column was equilibrated with the mobile phase approximately 2 hours prior to analysis. A reporting level of 0.02 µg/L for the LC/MS/MS method has been used since 2004.

Quality Assurance

Sample Collection

All water samples for these studies were collected either by or under the direction of USGS personnel in accordance with a written work plan for the study. Field blank and equipment blank samples were collected to ensure cross contamination did not occur due to contaminated equipment. Field replicate samples were collected to document analytical variability. Quality-control samples included 28 field blanks and 184 field replicates. The blanks were free of glyphosate, AMPA, and glufosinate. Of the 184 field replicates, 135 samples contained analytes, whereas 49 samples were nondetections. All replicates matched the regular sample within 20 percent. The analytical results from these samples are listed along with the results from the regular samples in tables 3 through 6 at the end of this report.

Internal Standards

Internal standards were added to correct quantitative results for slight differences in extract volume as well as to compensate for differences in the injected sample volume. Internal standards also were used to monitor instrument conditions, such as extract injection errors, retention time shifts, or instrument abnormalities or malfunctions.

Laboratory Blank

The laboratory blank was reagent water prepared to monitor the entire sample preparation and analytical procedure for

possible laboratory contamination. The blank was considered acceptable when a compound was undetected or detected at less than the minimum reporting level (MRL; Timme, 1995). On the basis of data analysis, there were no interferences in the laboratory blanks.

Laboratory Spike

The percentage recovery from the laboratory reagent spike was calculated from the spiking procedure described. The recovery was used to monitor the method performance for the sample preparation without considering the effects of sample matrix. The laboratory spike results were compiled for long-term recovery performance used for creating control limits and charts. If the recovery of a compound was not within control limits, the source of the problem was identified and corrected before continuing the procedure.

Instrumental Analysis Quality Control

A sample analytical sequence used for this method is listed in table 1. Sample extracts were analyzed in an instrument sequence to provide additional information to facilitate corrective actions that might be required if performance criteria were not met.

Concentrations of Glyphosate, Aminomethylphosphonic Acid, and Glufosinate

A summary of ground-water, surface-water, rainfall, and soil samples collected for State cooperative studies, the National Stream Quality Accounting Network Program, the National Water-Quality Assessment Program, and the Toxic Substances Hydrology Program, and analyzed by OGRL for glyphosate, AMPA, and glufosinate is presented in table 2.

Analytical results for glyphosate, AMPA, and glufosinate in 2,135 ground- and surface-water samples, 14 rainfall samples, and 193 soil samples collected from various study areas throughout the United States are provided in tables 3 through 6 at the end of this report. Laboratory duplicates also are shown in tables 3 through 6 but not included in the sample count in table 2.

State Cooperative Studies

During the State cooperative studies, 271 ground- and 281 surface-water samples were analyzed (table 3 at end of report) from 10 States ranging from Washington to Vermont and south to Mississippi. In the ground-water samples analyzed, there was no glyphosate detection and only one AMPA detection of 0.33 $\mu\text{g/L}$ in water from a well in Kansas. There

also were no samples from the State cooperative studies with a reportable glufosinate concentration. The lack of ground-water detections may have been the result of a higher reporting level (0.1 $\mu\text{g/L}$) prior to 2004 compared to a reporting level (0.02 $\mu\text{g/L}$) that was later achieved with the LC/MS/MS system. Glyphosate was detected in about 50 percent of the surface-water samples. A maximum glyphosate concentration of 99 $\mu\text{g/L}$ was found in a sample collected in April 2002 from a site in Mississippi surrounded by cotton fields being treated with glyphosate to prepare for planting.

National Stream Quality Accounting Network (NASQAN) Program

Twenty-seven samples (table 4 at end of report) were collected from four NASQAN river sites in the Mississippi River Basin during 2002 (fig. 2). Overall, AMPA was detected at greater frequencies than glyphosate in these surface-water samples. There were two glyphosate detections with concentrations of 0.33 and 0.14 $\mu\text{g/L}$, and 17 AMPA detections with a maximum concentration of 0.38 $\mu\text{g/L}$ (tables 2 and 4).

National Water-Quality Assessment (NAWQA) Program

A total of 1,093 water samples were collected from 23 study units for the NAWQA Program during 2001–06 (fig. 3 and table 5 at end of report). In 485 ground-water samples, maximum concentrations were 0.67 $\mu\text{g/L}$ for glyphosate (28 detections) and 0.62 $\mu\text{g/L}$ for AMPA (47 detections). In 608 surface-water samples, maximum concentrations were 9.7 $\mu\text{g/L}$ for glyphosate (196 detections) and 8.7 $\mu\text{g/L}$ for AMPA (313 detections). There were two detections (0.11 and 0.56 $\mu\text{g/L}$) of glufosinate in surface water from the Mississippi Embayment and White River Basin NAWQA study units. These results concur with results from previous studies that found the glyphosate degradation product, AMPA, occurs more frequently or at similar or higher concentrations than glyphosate, whereas glufosinate was seldom found in the environment (Scribner and others, 2003; Battaglin and others, 2005).

Toxic Substances Hydrology (Toxics) Program

The USGS Toxic Substances Hydrology Program funded several studies focused on the fate and transport of glyphosate and AMPA in ground and surface water including overland flow, tile-drain flow, rainfall, and soil since 2001 (table 6 at end of report). Overall, these studies show that glyphosate and AMPA were detected more frequently in surface water than in ground water, and AMPA was detected at greater frequencies than glyphosate in surface water. The data also indicate that levels of glyphosate and AMPA may persist in the soil from year to year (Baker and others, 2006). Table 2 shows

the number of ground- and surface-water, rainfall, and soil samples collected, number of detections, and the minimum and maximum concentrations.

Reconnaissance Data From 51 Streams in Nine Midwestern States

During 2002, 171 samples were collected from 51 streams in nine Midwestern States during three periods of runoff (table 6 at end of report). Glyphosate was detected in 63 samples with a maximum concentration of 8.7 µg/L, AMPA was detected in 117 samples with a maximum concentration of 3.6 µg/L, and glufosinate was detected in two samples at concentrations of 0.26 and 0.14 µg/L (table 2; Scribner and others, 2003; Battaglin and others, 2005).

Lower Mississippi River Basin

Results from systematic water-quality sampling from sites in the lower Mississippi River were used to investigate the occurrence, fate, and transport of selected pesticides and their degradation products (U.S. Geological Survey, 2006a). Water samples were collected from the lower Mississippi River at Baton Rouge, Louisiana (site 07374000) (fig. 5) during April 1991 through December 2003 to help determine the occurrence and transport of selected herbicides, their degradation products, and nutrients in the lower Mississippi River Basin and the delivery to the Gulf of Mexico (Scribner and others, 2006).

During 2001–03, water samples were collected twice monthly to study the occurrence of glyphosate, AMPA, and glufosinate. There were no detections of either glyphosate or glufosinate in the 35 samples; however, there were 31 detections of AMPA, with a maximum concentration of 0.38 µg/L (tables 2 and 6).

Sensitive Environments Study

Vernal pools are sensitive environments of natural water that provide critical habitats for many species, including amphibians. These small water bodies are not always protected by pesticide label requirements for no-spray buffer zones, and the occurrence of pesticides detected is poorly documented. In the Sensitive Environments study (W.A. Battaglin, USGS written commun., June 19, 2007), glyphosate was detected in 31 of 76 samples with a maximum concentration of 328 µg/L, whereas AMPA was detected in 30 samples with a maximum concentration of 41 µg/L. Glufosinate was detected in one sample at 0.05 µg/L (table 2).

Leary Weber Ditch Basin, Indiana

A joint collaboration between Toxics and NAWQA was formed to study the agricultural chemicals source, transport,

and fate within the Leary Weber Ditch Basin, a part of the White River Basin, a NAWQA study unit in Indiana (figs. 4 and 5). In 2004–05, samples were collected from various hydrologic compartments in the Leary Weber Ditch Basin and analyzed for glyphosate, AMPA, and glufosinate.

Agricultural chemicals were found in Leary Weber Ditch and every other hydrologic compartment sampled during 2004–05 (Baker and others, 2006). Of the 117 ground-water samples analyzed, glyphosate was detected in 40 samples with a maximum of 4.7 µg/L, and AMPA was detected in 85 samples with a maximum of 2.6 µg/L (tables 2 and 6). There were no glufosinate detections. Glyphosate was detected in 54 of the 64 surface-water samples with a maximum concentration of 427 µg/L, and AMPA was detected in 52 of the 64 samples with a maximum concentration of 29 µg/L at Mohawk, Indiana (table 6). In the Leary Weber Ditch, 51 of 64 water samples analyzed contained both glyphosate and AMPA. Higher concentrations in the Leary Weber Ditch occurred soon after application to fields and coincided with rainfall. Glufosinate was found in two surface-water samples from the Leary Weber Ditch at concentrations of 1.5 and 0.24 µg/L (tables 2 and 6).

Both glyphosate and AMPA were detected in 12 of the 14 rainfall samples collected. Concentrations ranged from 0.02 to 1.1 µg/L. Glufosinate was not detected in any of the rainfall samples.

To examine the potential transport of glyphosate and AMPA through the unsaturated zone, soil cores were collected from April through October 2004 from both the north and south field sites in the Leary Weber Ditch Basin. Agricultural practices were the same for both fields. The maximum concentration for glyphosate was 476 µg/kg, whereas the maximum concentration for AMPA was 956 µg/kg (table 2). The data show that the maximum concentration of AMPA during preapplication (April) was 23 µg/kg. These data results may indicate that trace levels of glyphosate can persist in the soil from year to year (Baker and others, 2006). One north field soil sample (6–12 in. depth) contained glufosinate at a concentration of 1.0 µg/kg (table 6).

Summary

The Organic Geochemistry Research Laboratory (OGRL) was established by the USGS in Lawrence, Kansas, to identify contaminants that may have deleterious effects on water quality or be useful indicators of geochemical transport processes and to conduct research on the fate and transport of contaminants in the hydrogeologic system. Essential analytical methods have been developed using state-of-the-art liquid chromatography and mass spectrometry to accomplish this.

This report presents results of analyses by OGRL for glyphosate, its degradation product, aminomethylphosphonic acid (AMPA), and glufosinate in 2,135 ground- and surface-water samples, 14 rainfall samples, and 193 soil samples collected from 2001 through 2006. The data are used to document

the occurrence, distribution, and concentrations of glyphosate, its degradation product, aminophosphonic acid (AMPA), and glufosinate at locations across the United States. The data were collected as part of various ongoing USGS studies, such as those done for Federal and State cooperative agencies, the National Stream Quality Accounting Network (NASQAN) Program, the National Water-Quality Assessment (NAWQA) Program, and the Toxic Substances Hydrology (Toxics) Program.

Glyphosate is among the most commonly used herbicides in the world. Its use has substantially increased in the United States with the introduction of genetically modified glyphosate-resistant corn and soybeans; however, it also is used extensively in yards, gardens, parks, and other nonagricultural areas. Studies show glyphosate is degraded primarily by microbial processes producing aminomethylphosphonic acid (AMPA). Samples also were analyzed for glufosinate, a broad-spectrum contact herbicide, used to control a wide range of weeds after the crop emerges or for total vegetation control on land not used for cultivation.

Results show that AMPA was detected more frequently and occurred at similar or higher concentrations than the parent compound, glyphosate, whereas glufosinate was seldom found in the environment. Further study also shows that glyphosate and AMPA were detected more frequently in surface water than in ground water. Both glyphosate and AMPA were detected in rainfall samples in Indiana. The data also indicate that trace levels of glyphosate and AMPA may persist in the soil from year to year. These data were valuable for acquiring information about the occurrence, fate, and transport of these compounds and to show the importance of analyzing not only glyphosate but also AMPA in water-quality studies.

Analytical results show that the methods developed at OGRl were valuable for acquiring information about the fate and transport of glyphosate, AMPA, and glufosinate in ground and surface water, rainfall, and soil. The data also indicate the importance of including both parent compounds and their degradation products in herbicide studies.
