Temperature in degrees Celsius ($^{\circ}C$) may be converted to degrees Fahrenheit ($^{\circ}F$) as follows:

$$^{\circ}F = (1.8 \times ^{\circ}C) + 32$$

Temperature in degrees Fahrenheit ($^{\circ}F$) may be converted to degrees Celsius ($^{\circ}C$) as follows:

$$^{\circ}C = (^{\circ}F - 32) / 1.8$$

ABBREVIATED WATER-QUALITY UNITS

Chemical concentration and water temperature are given only in metric units. Chemical concentration in water is given in milligrams per liter (mg/L), micrograms per liter ($\mu g/L$), or nanograms per liter (ng/L). Milligrams per liter is a unit expressing the solute mass (milligrams) per unit volume (liter) of water. One thousand micrograms per liter is equivalent to 1 milligram per liter. One thousand nanograms per liter is equivalent to 1 microgram per liter. For all concentrations in this report, concentrations in milligrams per liter are about the same as for concentrations in parts per million. Specific conductance is given in microsiemens per centimeter at 25 degrees Celsius ($\mu S/cm$ at $25^{\circ}C$).

ABBREVIATED CHEMICAL NAMES

Throughout this report, chemical elements and compounds are abbreviated according to their chemical symbols. The table below describes these.

Symbol	Name	Symbol	Name	Symbol	Name
Al	Aluminum	Ho	Holmium	SO_4	Sulfate
As	Arsenic	K	Potassium	Sb	Antimony
B	Boron	La	Lanthanum	Se	Selenium
Ba	Barium	Li	Lithium	Si	Silicon

Water-quality Data from two Agricultural Drainage Basins in northwestern Indiana and northeastern Illinois: III. Biweekly Data, 2000-2002

By Ronald C. Antweiler, Richard L. Smith, Mary A. Voytek, John Karl Böhlke and David H. Dupré

Abstract

Methods of data collection and results of analyses are presented for biweekly water-quality data collected from two nearby agricultural drainage basins in northwestern Indiana and northeastern Illinois, the Iroquois River and Sugar Creek. Over the course of 28 months, from February 2000 to June 2002, 110 discrete samples were collected from a single sampling site on each drainage in northwestern Indiana. Data were collected for nutrients, including nitrate, nitrite, ammonium, total dissolved nitrogen and phosphorus; major inorganic constituents (excepting bicarbonate and carbonate); trace elements; suspended sediment; dissolved trace gases; and chlorophyll-*a* concentrations. In addition, field measurements of pH, specific conductance, air and water temperature, and dissolved oxygen concentrations were collected for all sampling events.

Introduction

Scientists first recorded hypoxic, or low-oxygen, zones on the continental shelf of the northern Gulf of Mexico in the 1970s (Turner and Allen, 1982), and began systematic assessments of these zones in 1985 (Rabalais and others, 1991). Studies have concluded that nutrient loads being carried by the Mississippi River are one of the dominant causes of this hypoxia (Bierman and others, 1994; Justic and others, 1993, 1995a, b; Rabalais, 1998; Rabalais and others, 1996, 1998; Turner and Rabalais, 1991, 1994). Other studies (e.g., Antweiler and others, 1996a; Goolsby and others, 1999; Carey and others, 1999; Battaglin and others, 2001) determined that one of the chief sources of these nutrients within the Mississippi River was agricultural practices in the Upper Mississippi River basin (that part of the Mississippi River basin upstream from the confluence with the Missouri River, herein called UMRB). At the same time, various modeling programs (for instance, SPARROW, Smith and others, 1997; and Howarth and others, 1996) based on our present understanding of nutrient processing in streams, indicated that large amounts of nitrate should have been removed by natural denitrification reactions within the surface waters of the UMRB, especially in the headwaters of small streams before reaching the Gulf of Mexico. These models indicated that nitrate concentrations in some parts of the UMRB should be lower than they are based on current understanding. The apparent inconsistencies between the model results and observations led the U.S. Geological Survey (USGS) to undertake a study, in cooperation with the U.S. Department of Agriculture, to determine the sources and fate of nitrogen in representative headwater streams of the UMRB. Accordingly, two small predominantly agricultural drainage basins of the Illinois River (one of the chief tributaries of the Mississippi River in the UMRB) in northwestern Indiana and northeastern Illinois were selected for in-depth, intense study. Two sites were selected on the Iroquois River and one of its tributaries, Sugar Creek, both in northwestern

Indiana (fig 1) . The chief purpose motivating the overall study was to collect data both spatially and temporally along each of the two selected drainages, with an ultimate aim to understanding in-stream processes, particularly involving nitrogen.

Purpose and Scope

This report describes water-quality data that were collected at two specific sites (one in each drainage basin) during a biweekly sampling effort spanning 28 months, from February 2000 through June 2002, and which resulted in 110 discrete samples – 55 from each drainage. In addition, field measurements were made coincident with each sample collection, comprised of air and water temperature, dissolved oxygen concentration, pH, specific conductance, and streamflow. Short-term temporal data, consisting of collecting samples every 2 to 4 hours for as many as 4 days, were obtained on each drainage during four discrete sampling trips between 1999 and 2001 (Antweiler and others, 2005). The spatial component was examined by collecting Lagrangian and synoptic data along a reach on each drainage that included the sampling sites in this report (Antweiler and others, 2004). Additional work, including tracer studies, ground-water analyses, and incubation studies also were performed at these sites. This report only describes the biweekly data, that is, the data that were collected every other week between February 2000 and June 2002 in each drainage.

Acknowledgments

This work was supported in part by U.S. Department of Agriculture Grant #2001-35102-09870. We wish to acknowledge the contributions of George Groschen, Mike Friedel, Elizabeth Murphy and Phillip Gaebler of the USGS Illinois Water Science Center; the personnel of the USGS Indiana Water Science Center who maintain the stream gages at the study site; Kevin Richards of the USGS Wisconsin Water Science Center; and Terry Plowman, Dave Roth, Dale Peart, Howard Taylor, Julie Kirshstein, Brendan Aiken, Deborah Repert, Charles Hart and Seanne Buckwalter of the USGS National Research Program.

Sampling Locations and Times

Figure 1 shows the location of the two sites. The Iroquois River site was at the USGS streamflow gaging station near Foresman, Ind. (USGS station number 05524500), where Indiana State Highway 55 crosses the river approximately 5 kilometers east of Brook, Ind. The Sugar Creek site was at the Indiana State Highway 71 bridge crossing, which was approximately 3 kilometers east of the Illinois-Indiana state line and about 12 kilometers southwest of Kentland, Ind.

The first biweekly samples were collected on February 24, 2000. Thereafter, samples were collected (on the average) every 2 weeks until June 17, 2002. There were two gaps in sample collection lasting more than 24 days: from September 20, 2000 to November 2, 2000 (43 days); and from September 13, 2001 to October 11, 2001 (29 days).

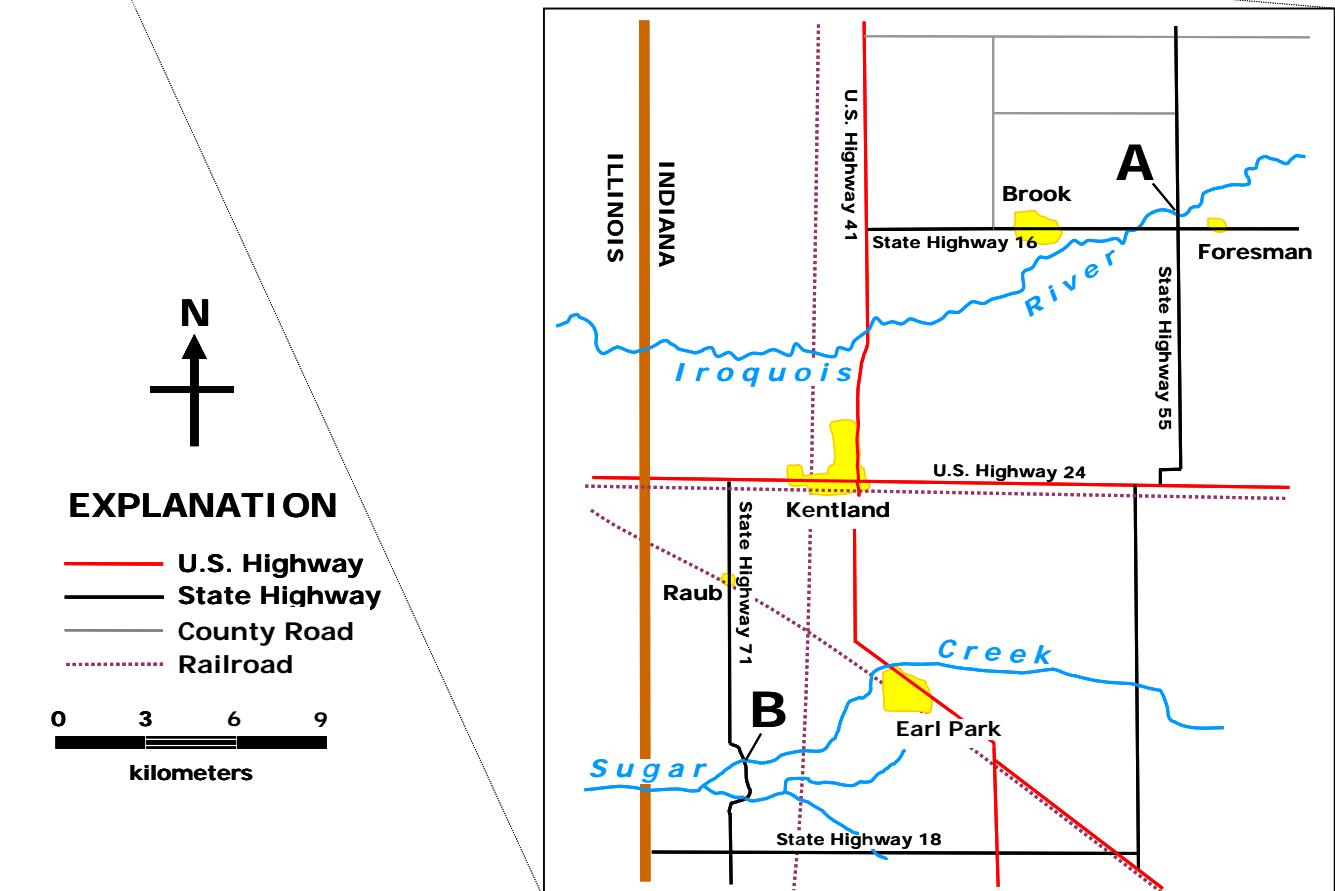

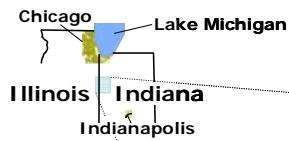

Figure 1. Location of the two sampling sites. A. Iroquois River at State Highway 55 bridge (USGS station number: 05524500); B. Sugar Creek at Indiana Highway 71 bridge.

Precipitation

Although no rainfall measurements were made at the two sampling sites, there were eight nearby National Weather Service weather stations which surrounded the study area (fig. 2) and which collected daily precipitation data during the entire period of sampling. The daily values for each station were summed on a monthly basis, and these totals were averaged for all eight stations. Figure 3 shows this monthly average precipitation over the course of the study. One of the interesting features of this graph is the overall consistency of the data: of the 33 months presented in figure 3, there were only three with less than 30 millimeters (mm) of precipitation (November 1999, and January and March 2001), and only one (October 2001) with greater than 140 mm. In addition, the graph shows seasonal variations with (on average) the greatest precipitation occurring during the summer (May-August) and the least during the winter (November-March).

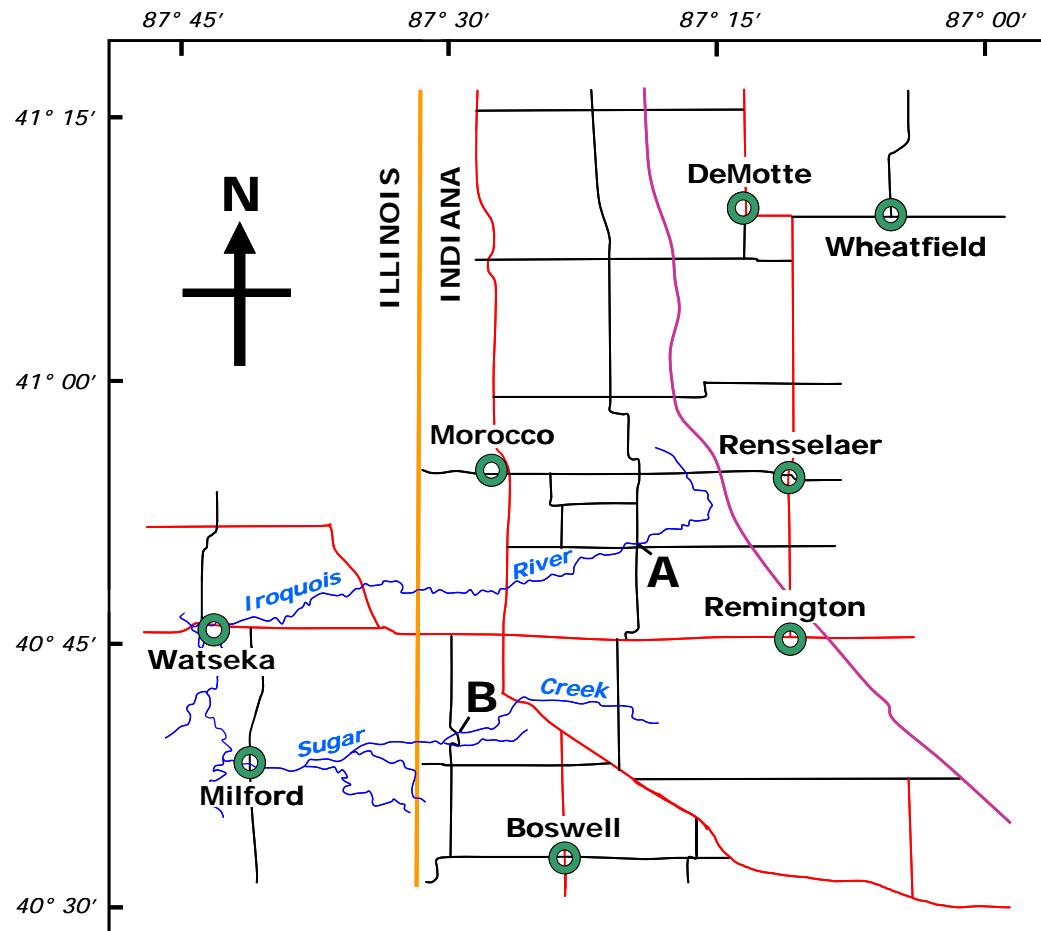

Field Methods

Collection of Field Data

Prior to the collection of samples, streamflow was determined at each site. At the Iroquois River site near Foresman, this was normally done by reading the gage height from the USGS gage (station number 05524500) located there. Occasionally, the stage/discharge rating was checked by measuring streamflow using standard USGS protocols (U.S. Geological Survey, variously dated). This involved selecting between 15 and 25 vertical measurement locations across the channel, measuring the water depth and average velocity at each vertical, and integrating over all verticals in a section to obtain the total streamflow. Because the Sugar Creek site had no USGS gage, streamflow measurements were always made (Rantz and others, 1982) when samples were collected.

Measurements made on-site included air and water temperature, pH, specific conductance, and dissolved oxygen concentration. Air temperature was determined using an alcohol thermometer. The other four parameters were measured using a YSI Model 600XL-4 parameter instrument which was calibrated daily against known standards according to standard USGS protocols (Wilde and Radtke, 1998). Measurements were obtained in-situ at the center of flow of the stream, as well as examining a cross-section to determine mixing in the vertical and horizontal stream column.

Beginning on November 19, 2001, photographs were taken looking both upstream and downstream at each of the two sites. These photographs were taken during every sample collection period thereafter, until the study ended on June 17, 2002. A representative portion of this record is shown in figure 4 for the Iroquois River and figure 5 for Sugar Creek. These photographs were all taken at the same location on each river at six different sampling periods, each spaced by about a month and a half.

Sample Collection

Samples were collected using isokinetic, depth-integrated methods outlined in the USGS National Field Manual (U.S. Geological Survey, variously dated). Equipment used to collect and process samples were cleaned following protocols outlined in the National Field Manual for the cleaning of equipment for inorganic sample collection. The cleaning protocols were used to help ensure that the sampling equipment was not a source of foreign substances that could affect the ambient concentrations of target analytes. In addition, care was taken to ensure that clean sample handling techniques were observed during the collection and processing of all samples, including the wearing of polyvinyl gloves. While the field parameters were determined, stream water was sampled using a weighted-bottle sampler. Samples were composited into a 3-L bottle which was shaken and immediately thereafter a 250-mL polyethylene bottle was filled using a peristaltic pump. This bottle, which was subsequently chilled, was used for the estimation of the suspended sediment concentration. The 3-L bottle was then completely remixed by shaking and, using a peristaltic pump, approximately 1-L of water was pumped through a 0.4- μm nominal pore-size 47-mm glass fiber filter (GFF) held in a Swinnex filter holder. The volume of water pumped through the filter was measured and recorded. Using forceps, the GFF was folded, placed in a sleeve holder, and frozen. This filter was used for the determination of chlorophyll-*a* concentration. Finally, samples for the determination of dissolved constituents were collected. The peristaltic pump was attached to a 0.45- μm nominal pore size in-line Gelman cartridge filter, and approximately 500-mL of water from the 3-L sampler was passed through the filter and discarded. Then, the following three samples were collected: (1) a 60-mL polyethylene bottle for the determination of ammonium and total dissolved nitrogen (TDN). This sample was kept chilled for immediate shipping (see below); (2) a 125-mL polyethylene bottle for the determination of anions (including chloride, sulfate, nitrate and nitrite, but excepting bicarbonate and carbonate). This sample was frozen as soon as possible after collection (typically 3-5 hours); and (3) a 125-mL polyethylene bottle for the determination of trace metals, major cations and silica. As with the ammonium sample, this bottle was kept chilled for immediate shipping. The remainder of the composite sample was discarded.

A second 3-L composite sample was collected for the dissolved trace gas samples. Approximately 25 mL of stream water was collected in a 30-mL plastic syringe, taking care to exclude air bubbles. After filling, a needle was placed on the syringe and 20 mL was injected into a 30-mL serum bottle that had been fitted with a thick butyl rubber stopper and aluminum crimps and which contained 0.2 mL 12.5 normal sodium hydroxide and a helium headspace. The filled serum bottle was stored at room temperature.

The chlorophyll-*a*, anions, and dissolved gases samples were stored at the USGS Illinois Water Science Center in Urbana until a sufficient number of them had been collected to effect a shipment to the analyzing laboratories. However, the cations/trace metals, ammonium/TDN, and suspended sediment samples were overnight shipped on ice to the USGS National Research Program (NRP) laboratories in Boulder, Colo. either on the day of collection or the next day. Upon receipt, suspended sediment samples were refrigerated. From the ammonium/TDN bottles, a 1.8-mL aliquot was pipetted into a baked (250°C) 2-mL glass autosampler vial fitted with a Teflon septa cap for the determination of TDN. These samples were preserved by adding 14 μL of 1 normal hydrochloric acid and subsequently refrigerated until analysis (Bronk and others, 2000). The remainder of the ammonium/TDN samples were then acidified with 1-mL of concentrated sulfuric acid for the determination of ammonium. Both of these aliquots were stored at room temperature until analysis. Upon receipt, the cations/trace metals samples were immediately

acidified with 1 mL of double-distilled trace-metal-grade nitric acid and stored at room temperature until analysis.

Methods of Analysis

The methods of analysis for most samples have been described in detail elsewhere (Antweiler and others, 2004) and will be summarized here. Major cations, total phosphorus, silica, and dissolved iron were determined by inductively coupled-atomic emission spectrophotometry (ICP-AES) (Mitko and Bebek, 1999, 2000); trace elements were analyzed by inductively coupled-mass spectrometry (ICP-MS) (Taylor, 2001); Suspended sediment concentrations were measured gravimetrically (Antweiler and others, 2004); Nitrite was analyzed colorimetrically (Antweiler and others, 1996b); Nitrous oxide and methane were measured by gas chromatography (Brooks and others, 1992; Weiss and Price, 1980; Yamamoto and others, 1976). All of these analyses were done at the USGS NRP laboratories in Boulder, Colo. Chlorophyll-*a* was determined at the USGS NRP laboratories in Reston, Vir., by fluorescence following the procedures of Arar and Collins (1997).

Dissolved chloride, nitrate and sulfate were analyzed by ion chromatography on a Dionex DX500 instrument which utilized an AS15A analytical column; details can be found in Savoie and others (2004). Ammonium was analyzed by ion chromatography on a Dionex DX300 instrument which utilized a CS12A analytical column; analytical details can be found in Savoie and others (2004). These analyses were done at the USGS NRP laboratories in Boulder, Colo.

Total dissolved nitrogen was determined with an Antek Model 9000N Total N Analyzer equipped with a Model 735-740 multi-matrix sample drive and Model 738 autosampler. Organic and fixed inorganic nitrogen were converted to nitric oxide (NO) by high temperature combustion (1050°C) and oxidation using ultra-pure oxygen (99.997%). The NO gas was then reacted with ozone to create metastable NO₂, producing a chemiluminescent emission which was measured. Analytical details can be found in Bronk and others (2000). These analyses were done at the USGS NRP laboratories in Boulder, Colo.

Detection limits for the constituents listed in this report are given in Antweiler and others (2004).

Quality Control/Quality Assurance

The quality of the analytical data for trace metals and major cations was assessed by a vigorous laboratory program involving a large number of quality-control (QC) standards, which were analyzed as unknowns during the analysis of all samples collected during the study. The frequency of analysis of these QC standards was variable depending upon the methodology used, but was always at least 20 percent of the total number of samples collected. All of the analyses for QC are presented in Antweiler and others (2004). Results of these analyses indicated good agreement between the published values and the observed concentrations for all trace elements and major cations.

The quality of the chloride, sulfate, nitrate and ammonium analyses by ion chromatography was assessed by analyzing a subset of the calibration standards and blanks every eight to ten samples and by standard reference samples analyzed at the beginning and end of the analysis runs. Table 1 contains the results of these analyses, given as the range and mean for each of the reference standard analytes, as compared with the published "Most Probable Values" for each. The quality of the gas samples was assessed by analyzing a subset of the calibration standards and blanks every eight to ten samples. There are no standard reference materials available that are appropriate for gas samples.

Table 1. Summary of laboratory quality-control data for samples analyzed by ion chromatography.

Results of Analyses

Tables A1-A8 within Appendix A contain the results of all field measurements and water-quality analyses for the biweekly sampling. The general structure of these tables is as follows: Field measurements are presented first, with Iroquois River results (table A1) presented before Sugar Creek results (table A2). Next, results are presented for nutrients, trace gases, chlorophyll-*a* and suspended sediment concentrations (tables A3-A4), followed by major anions (excepting bicarbonate and carbonate), cations and silica (tables A5-A6), and, finally, trace elements (tables A7-A8). Bicarbonate and carbonate were not determined. Within these tables, many analytes were determined from replicate measurements within the laboratory; for these analytes, the data in the tables are presented as “averages” and “standard deviations” of the replicate measurements. Those data which were determined from a single measurement are headed in the tables by the term “Value”.

Figure 6 is a graph showing streamflow measurements at the Iroquois River at the Foresman, Ind. gage over the course of the sampling. The graph shows the mean daily streamflow and also includes the instantaneous streamflow measurements at the sampling times; as can be seen, actual sampling times occurred during both high- and low-flow conditions, although (in general) tended to miss the peak flows. Figure 7 includes the streamflow measurements for Sugar Creek. In this case, there are no mean daily streamflow measurements, so the graph only shows the measured streamflows.

Representative graphs of the data are presented in figures 8-10, showing both the ranges of values and seasonal patterns of selected constituents. For example, figure 8 shows nitrate (fig. 8A) and phosphorus (fig. 8B) concentrations. Whereas nitrate concentrations are practically the same in both drainages, phosphorus concentrations are uniformly higher in the Iroquois River than in Sugar Creek. Also, nitrate concentrations show a seasonal pattern with highs in the spring/early summer and lows in the fall; phosphorus concentrations on the Iroquois River show a different cyclicity, with highs in the late summer/early fall and lows in the winter and spring. Total dissolved nitrogen – by virtue of the fact that nitrate was the largest component of this – also showed a seasonal pattern.

Representative graphs for the major elements are shown in figure 9, which shows the data for sodium and magnesium. Sodium concentrations (fig. 9A) tend to be higher in the Iroquois River, and have a seasonal cycle, although it is far less pronounced than for the nutrients. Magnesium concentrations (fig. 9B) are usually higher in Sugar Creek and do not display a seasonal pattern for the Iroquois River, although there appears to be a very rough pattern for Sugar Creek. For both of these cations (but especially for magnesium), the effects of sampling during storms can be seen clearly as low concentrations. Of the major elements, sodium and potassium appear to have a rough seasonal pattern on both drainages, whereas chloride and silica have a cyclicity on the Iroquois River but not on Sugar Creek, and sulfate and magnesium have a weak cyclicity on Sugar Creek but not on the Iroquois River.

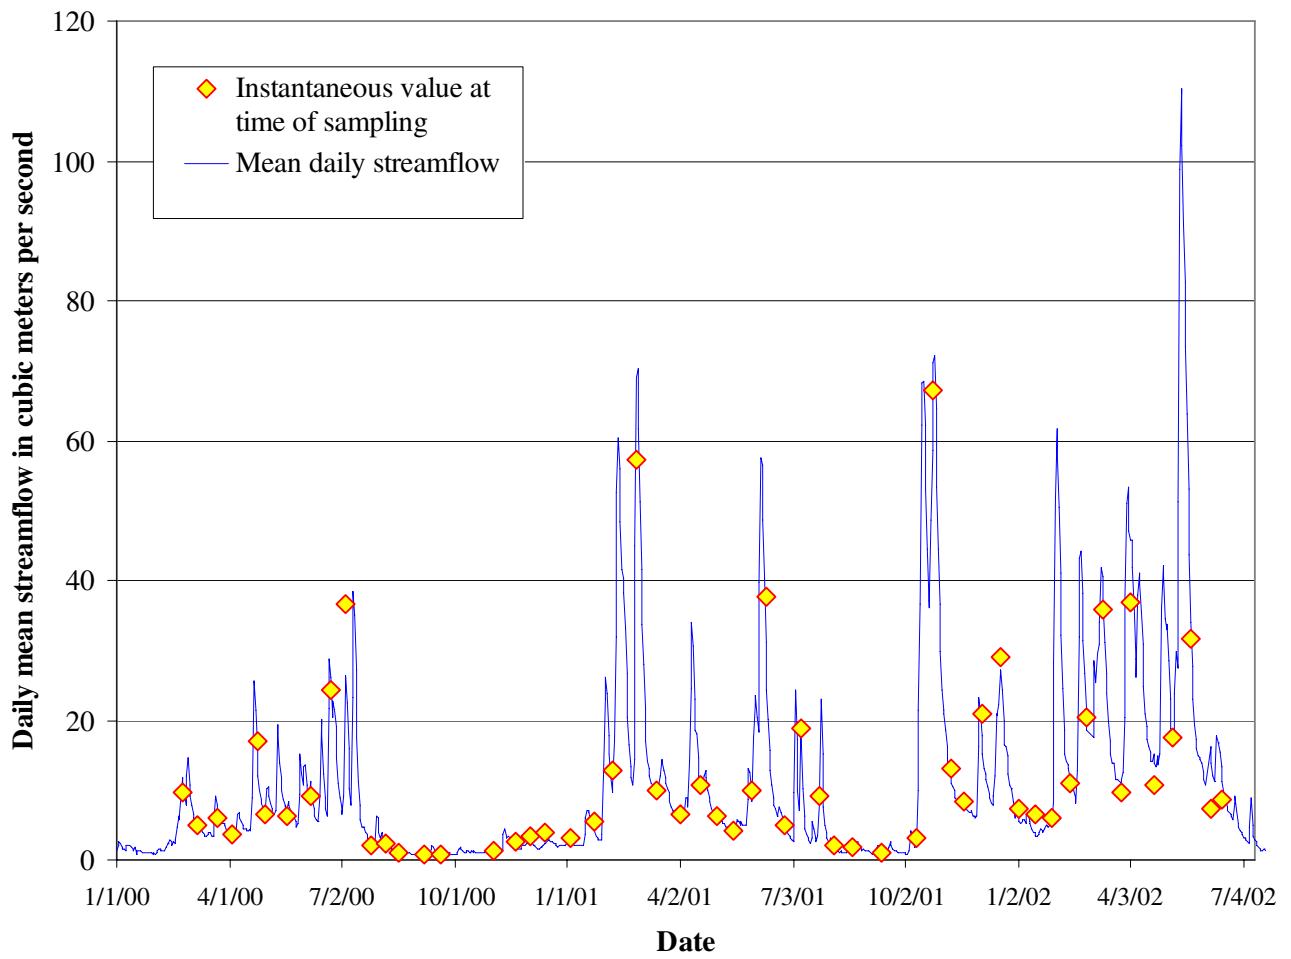

Figure 6. Mean daily streamflow and instantaneous discharge at the time of sampling for the Iroquois River at Foresman, Ind. (USGS station number 05524500)

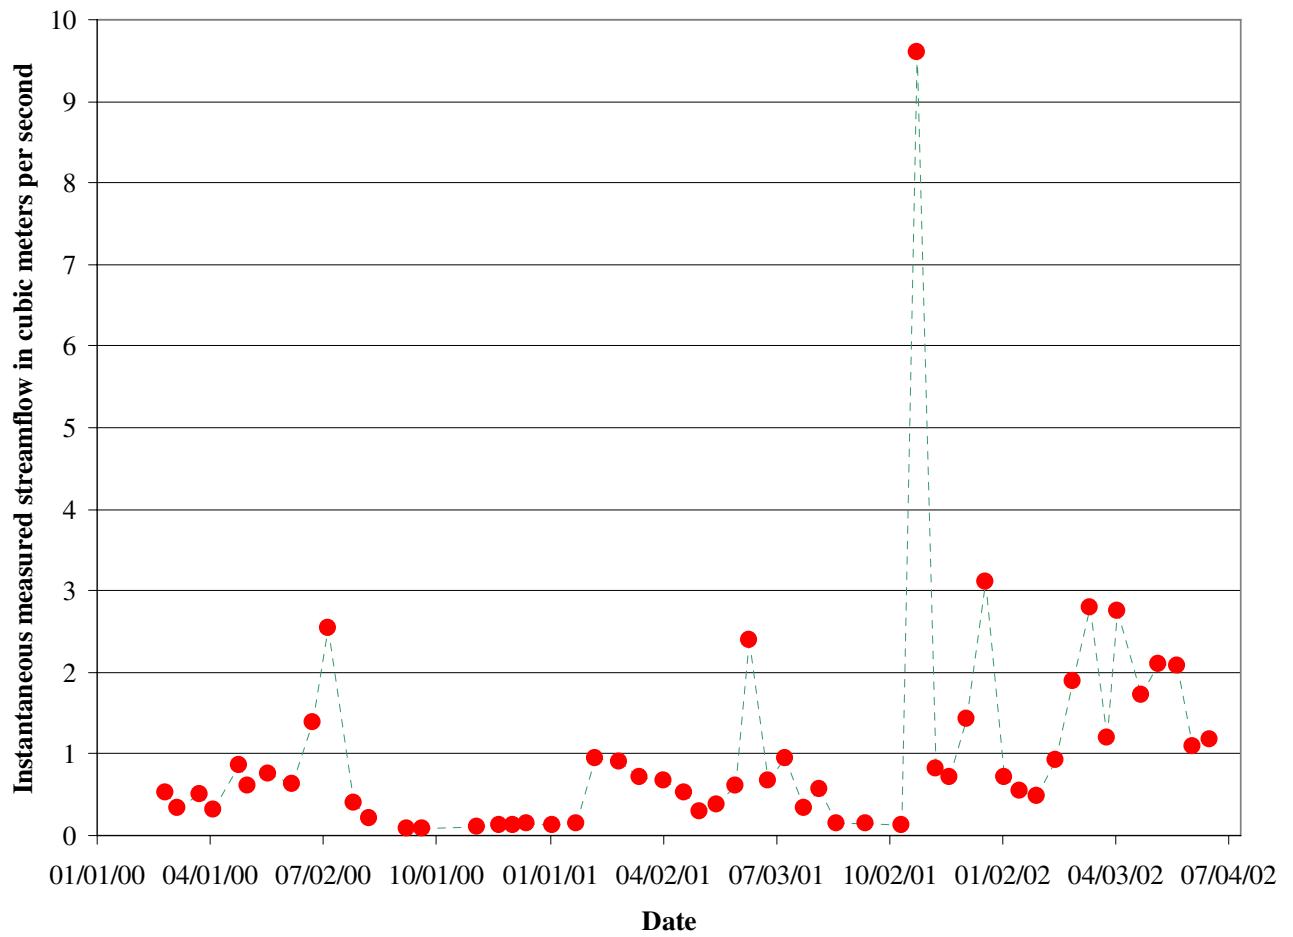

Figure 7. Instantaneous streamflow measurements at the time of sampling for Sugar Creek at the State Highway 71 bridge crossing, Indiana.

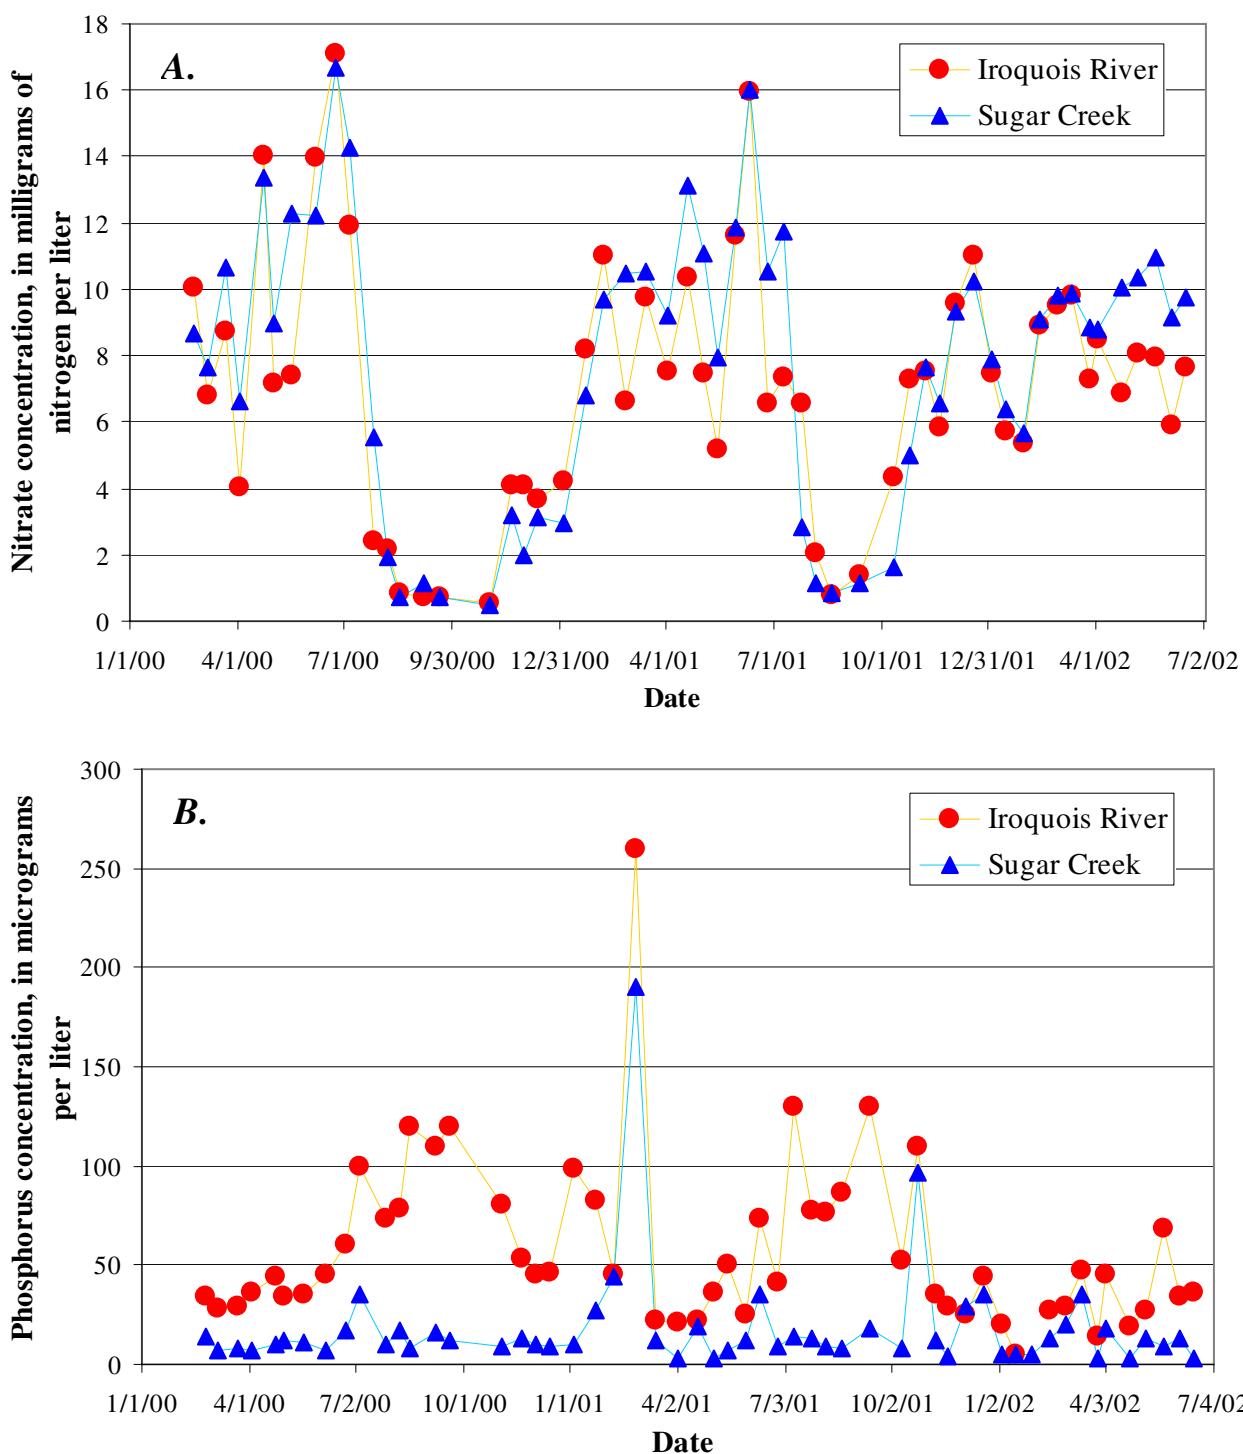

Figure 8. Representative nutrient concentrations for the Iroquois River at Foresman, Ind. (USGS station number 05524500) and Sugar Creek at the State highway 71 bridge. A) Nitrate; B) Phosphorus

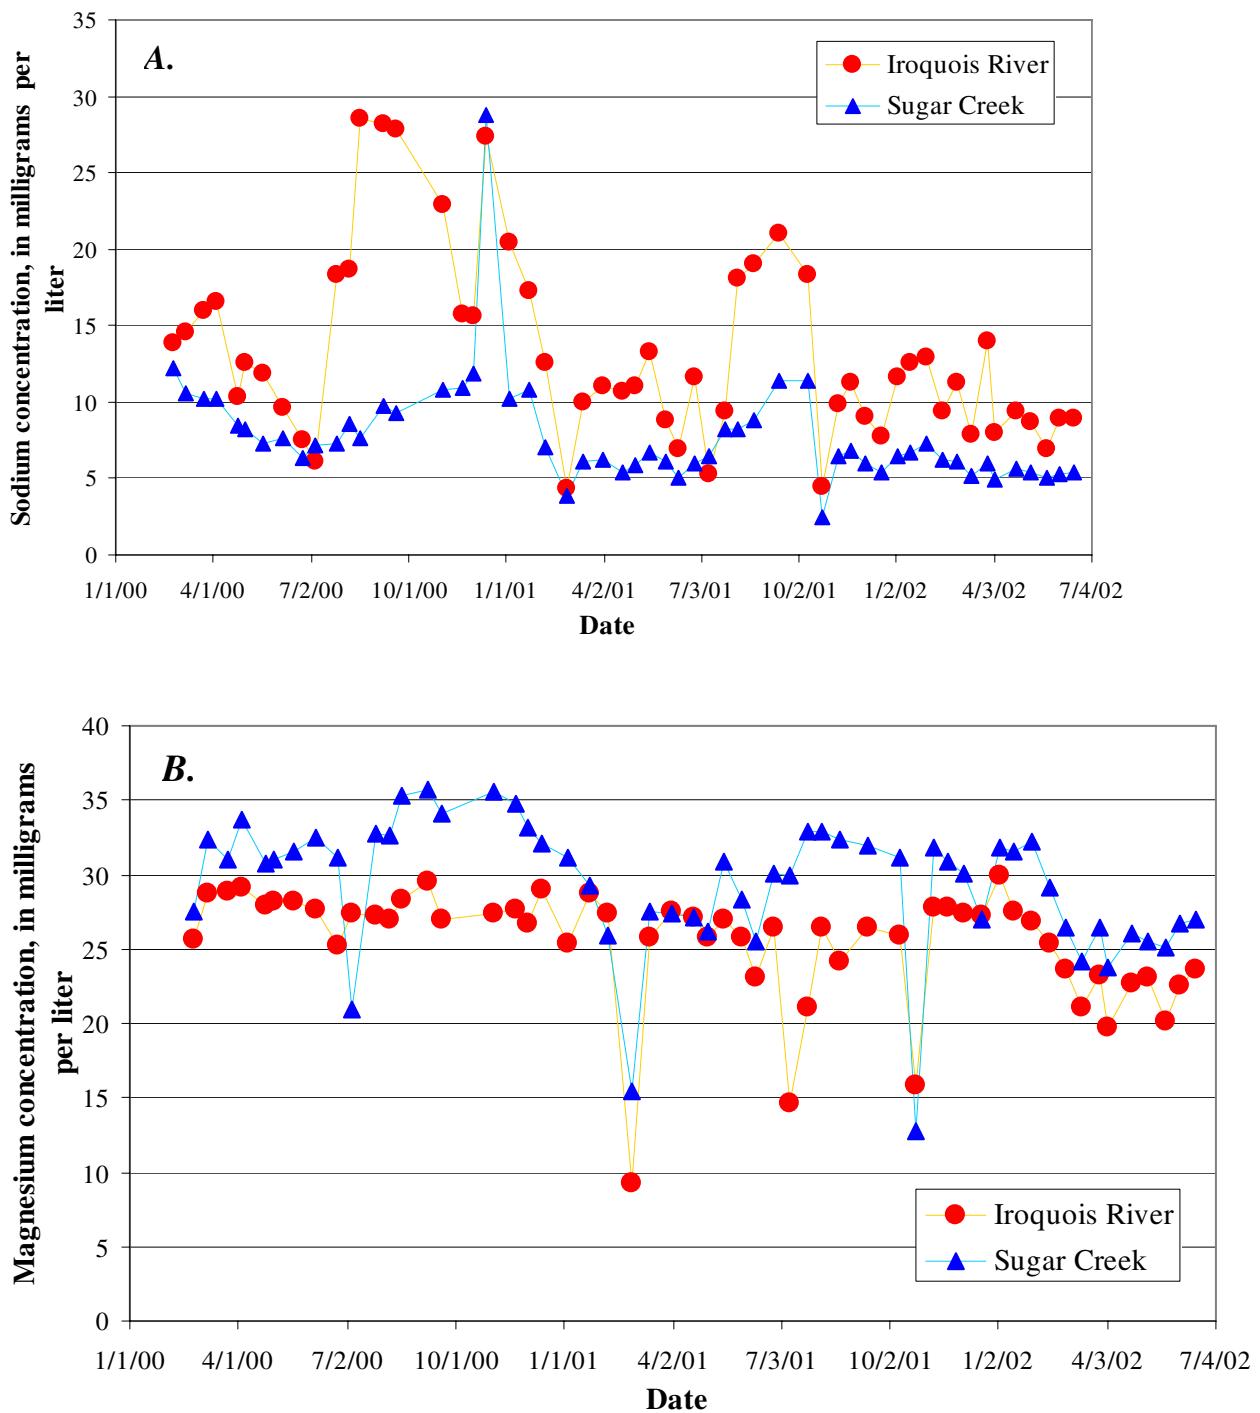

Figure 9. Representative major cation concentrations for the Iroquois River at Foresman, Ind. (USGS station number 05524500) and Sugar Creek at the State highway 71 bridge. A) Sodium; B) Magnesium.

Finally, figure 10 shows the concentrations of two trace elements, arsenic (fig. 10A) and lutetium, a rare-earth element (fig. 10B). For both of these elements, the Iroquois River had higher concentrations, and this, as a general rule, was the pattern for most elements: only magnesium and sulfate concentrations were normally higher in Sugar Creek than in the Iroquois River. Arsenic (figure 10A) shows a clear seasonal pattern in concentration, with highest values occurring in the fall. Other trace elements which showed a seasonal pattern on both drainages were antimony, boron, lithium, rubidium, selenium and vanadium, but the time of concentration maxima did not necessarily agree between constituents. Lutetium (fig. 10B) does not show any clear seasonality, and this was the case for most of the trace elements.

Summary

This report contains the results of analyses of water-quality data from a biweekly sampling program at one site each on the Iroquois River and Sugar Creek, two primarily agricultural drainages located in northwestern Indiana and northeastern Illinois. The sampling program spanned 28 months, beginning on February 24, 2000, and ending on June 17, 2002. During this time, 110 discrete samples were collected, 55 from each drainage. In addition, field parameters consisting of streamflow, air and water temperature, pH, specific conductance, and dissolved oxygen concentrations were made. In the later part of the study, photographs were taken at each sample site every time samples were collected. Samples were collected for nutrients, including nitrate, nitrite, ammonium, total dissolved nitrogen, and phosphorus, major inorganic constituents (excepting bicarbonate and carbonate), trace elements, suspended sediment, dissolved trace gases, and chlorophyll-*a* concentrations.

The data showed various patterns, but included the following features: 1) Streamflow was widely variable throughout the study, and although the sampling occurred during both high and low flows, peak flows were under-represented; 2) In general, concentrations tended to be higher on the Iroquois River than on Sugar Creek; 3) Several constituents, including nitrate, total dissolved nitrogen, sodium, potassium, antimony, arsenic, boron, lithium, rubidium, selenium and vanadium showed seasonal variations on both drainages, but the time of concentration maxima did not necessarily agree between constituents; and 4) The remainder of the constituents did not show seasonal patterns on both drainages, although a number showed (localized) increases or decreases caused by storm events.

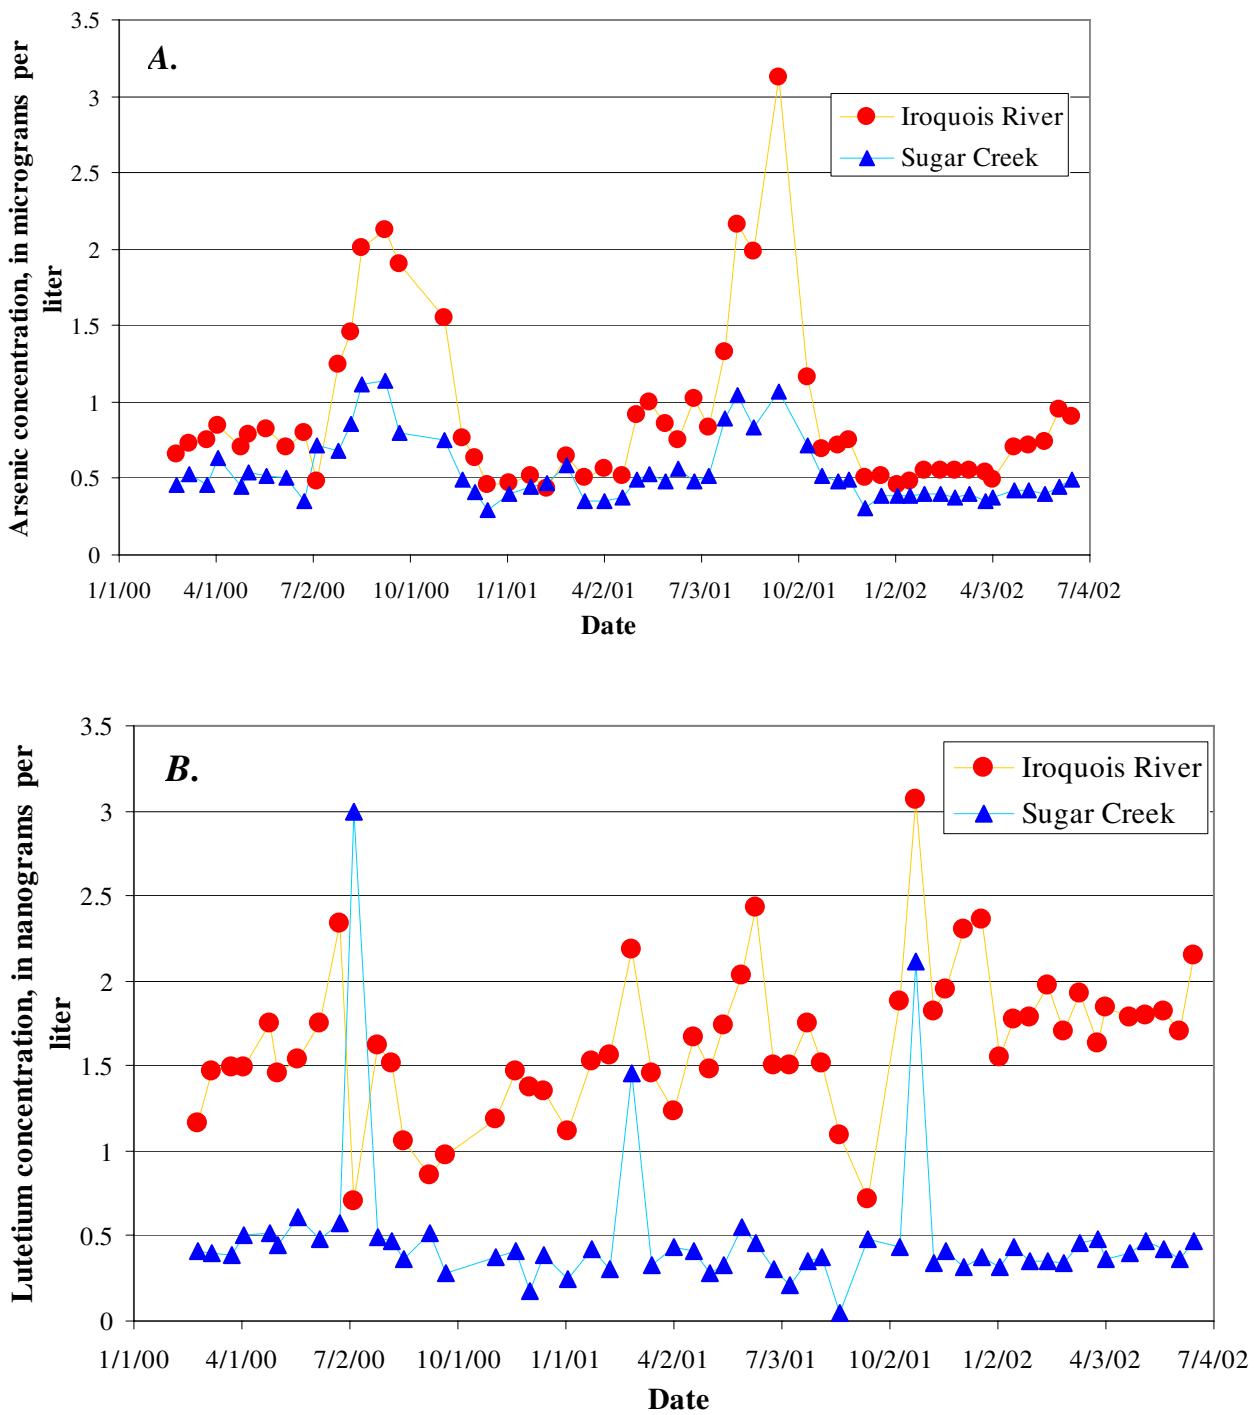

Figure 10. Representative trace element concentrations for the Iroquois River at Foresman, Ind. (USGS station number 05524500) and Sugar Creek at the State highway 71 bridge. A) Arsenic; B) Lutetium.
