Composition, Volume, and Prices for Major Softwood Lumber Types in Western Oregon and Washington, 1971-2020

James F. Weigand

Abstract

Weigand, James F. 1998. Grade composition, volume, and prices for major softwood lumber types in western Oregon and Washington, 1971-2020. Res. Pap. PNW-RP-509. Portland, OR: U.S. Department of Agriculture, Forest Service, Pacific Northwest Research Station. 61 p.

An analysis of lumber prices provided regressions for price trends during the period 1971-95 for composite lumber grades of major timber species found in the Pacific Northwest west of the crest of the Cascade Range. The analysis included data for coastal Douglas-fir and hem-fir lumber; coastal and inland Pacific Northwest ponderosa, sugar, and western white pines; and inland Pacific Northwest and Rocky Mountain lodgepole pine. Future prices of grades by species group are based on these price trends and the latest average regional lumber values established in the Timber Assessment Market Model (TAMM). Land managers can use the price projections in financial analyses of management practices that are designed to affect the quality of timber resources.

Keywords: Douglas-fir, hem-fir, lodgepole pine, lumber prices, ponderosa pine, price trends, sugar pine, Timber Analysis Market Model, western white pine, white woods.

Time series of lumber prices for major timber species in the Pinaceae in western Washington and Oregon were developed based on annual average prices for lumber recorded by the Western Wood Products Association, Portland, OR, for 1971 to 1995. In this paper, the numerous lumber grades are categorized for individual species or species groupings into composite lumber grades that follow the system used by the Pacific Northwest Research Station in its quarterly reports of *Production, Prices, Employment, and Trade in Northwest Forest Industries* for coast Douglas-fir, coast hem-fir, and ponderosa pine lumber. New composite categories were created for sugar pine, western white pine, and white wood species.

Calculated regressions correlated prices of individual composite grades to annual average real prices for Pacific Northwest lumber. Many prices for composite grades of pine species, in particular, correlated better with average prices for lumber produced east of the Cascade Range. To make forecasts of future prices of lumber by composite lumber grade, the grade price regressions may be applied to future projections of average regional lumber prices from projections of the Timber Assessment Market Model (TAMM) used by the USDA Forest Service for analysis conducted under the Forest and Rangeland Renewable Resources Planning Act of 1974. Land managers then can use lumber price projections by species and composite grade, together with results of mill utilization studies and information about manufacturing and stump-to-truck costs, to calculate future stumpage prices from trees in stands under their management.

Summary

Introduction

Land managers provide multiple outputs of goods from public forests. Suitable management satisfies criteria for both the quantity and quality of production. Increasingly, criteria for production also must satisfy societal goals for biological diversity, conservation of biological processes, recreation, and clean air and water. Interest in longer timber rotations and uneven-aged stand management is growing (Curtis 1995, Halpern and Spies 1995, Weigand and others 1994). The call for more complex forest management with multiple goals necessitates site-specific vegetation management. Management of timber resources in the Pacific Northwest now involves more tree species, more ecosystem types, and more products and services than ever before.

Commercial reforestation in the Pacific Northwest traditionally has been concentrated on Douglas-fir, western hemlock, and ponderosa pine. As forest landscape management broadens to consider concerns of biological diversity and economic diversification based on multiple species, timber species not previously intensively managed are receiving more attention. In the Pacific Northwest west of the crest of the Cascade Range, these species may be uncommon or local in distribution (for example, sugar pine and western white pine) or higher elevation species, such as mountain hemlock, noble fir, Pacific silver fir, and lodgepole pine. Reasons for their silvicultural neglect have been unfamiliarity with species and site conditions (Halverson and Emmingham 1982), problems with disease and pathogens (Snellgrove and Cahill 1980), and preferred use of timber resources with better quality or easier access. Timber production with lodgepole pine, for example, in the Rocky Mountains (Cole and Koch 1995, Koch 1996) and in Europe (Fitzsimmons 1989) demonstrates the economic prospects for lodgepole pine in the Pacific Northwest. In addition, attention to a greater array of tree species under management also supports, in part, the goals of increased biological diversity in managed forests.

A shift in the quality of lumber production and a shift toward stand compositions that replicate natural species diversity have coincided with the phaseout of old-growth timber harvests in the Pacific Northwest. In Federal public forests, the timber supply over the long term may be quite different from production in the recent past. One important objective of the Northwest Forest Plan (Jacobs 1994) is creation and maintenance of managed forest stands that conserve endangered species. Timber of small diameter or variable size and quality will be available from thinnings in stands managed for eventual re-creation of old-growth or late-seral features. Also, particularly for late thinnings in long rotations or for cyclic cuttings in uneven-aged stands, timber may be harvested that produces high-quality lumber products, of the sorts that have become rare over the last 25 years. The future timber supply for producing lumber from Federal lands in the Pacific Northwest may differ considerably from the timber supply from private industrial forest lands as well.

Forest managers need to know the likely product premiums for lumber from future timber produced in managed forests of the Pacific Northwest. Several tools exist to estimate the costs of management for improved timber and lumber quality; for example, models to predict premiums for pruned wood are available (Bolon and others 1992, Fight and others 1987). The present analysis provides information about lumber prices that is useful in decisions about stand management in the region. This study updates

¹ Appendix 3 contains the scientific names of all commercial timber species found west of the crest of the Cascade Range. Other scientific names are included in the text.

and expands work by Adams and others (1988) and Haynes and Fight (1992) for western Oregon and Washington. An overview summarizes general and species-specific trends in the amount, quality, and value of lumber production in the Pacific Northwest from 1971 to 1995. Regression equations based on existing data relate lumber prices for specific grade categories to average prices for regional lumber production. The regressions are extrapolated to 2020 to give a scenario of future prices of lumber grades for six major species or species groups in western Washington and Oregon. A discussion of the implications of future price trends on production and value of timber resources on Federal public land in the Pacific Northwest concludes the study.

Data Sources

The database for this study consisted of records for lumber quantities sold and average lumber prices, both in aggregate and by individual tree species and grade. Data were from year-end issues of the Coast F.O.B. Price Summary and the Inland F.O.B. Price Summary published by the Western Wood Products Association (WWPA 1971-95a, 1971-95b). Sample data published for lumber prices in WWPA reports account for 65 to 70 percent of annual regional lumber production. The WWPA summaries provide nominal prices (unadjusted for inflation) for actual transactions for lumber production.

Table 1 gives average annual prices, expressed in 1990 U.S. dollars, of lumber in aggregate produced in Pacific Northwest mills. The use of constant dollars removes effects of inflation to allow comparison of real prices over time. Average lumber prices for the region west of the Cascade crest (west side) come directly from WWPA reports. Estimates of prices for the Pacific Northwest east of the Cascade crest (east side) are derived by using the method of Adams and others (1988). The east-side figures are a lumber price index consisting of inland West production of ponderosa pine, Douglas-fir, western larch (*Larix occidentalis* Nutt.), and hem-fir lumber, weighted by volume.

For lumber grade categories of Douglas-fir, hem-fir, and ponderosa pine, definitions follow the system established in Haynes and Fight (1992). New lumber grade categories are established in this study for sugar pine, western white pine, and white wood (including lodgepole pine) lumber. Prices and product proportions for individual lumber grade categories used in this study were volume-weighted averages of prices for composite lumber grades. Appendix 2 provides details of grade composition of lumber grade categories combined into the composite grades for four species and two species groups.

Nominal prices and proportions for the lumber grade categories of Douglas-fir, hem-fir, and ponderosa pine, for 1971-90, are taken from Haynes and Fight (1992), and from Warren (1996) for 1991-95. These sources originally derived their data from the WWPA sources. Nominal prices and proportions for the new timber species groups also were synthesized from the WWPA publications. Nominal prices by species group and lumber grade category are listed in tables 2 through 7. Information about weighted proportions of lumber grade categories to total regional lumber production are found in tables 8 to 13. Real prices in 1990 U.S. dollars were calculated from nominal prices by using the producer price index for total industrial commodities (Office of the President 1996; see table 14). Real prices for 1971-95 for individual species or species groups by lumber grade categories appear in tables 15 through 20.

² Table 1 and all other tables are found in appendix 1.

Trends in Lumber Prices and Production, 1971-95 General Price Trends

Five additional years of data (1991-95) substantiate many of the trends in lumber prices observed by Haynes and Fight (1992). The annual average value of west-side lumber has remained below the computed value of lumber produced in east-side mills for all years, 1971-95 (table 1). Average real lumber prices in both the west-side and east-side Pacific Northwest for 1971-95 have fluctuated cyclically. A decline in real lumber prices that began in the late 1970s ended in the late 1980s as court injunctions and plans to conserve endangered species restricted timber sales. Lumber prices during the past eight decades have increased at an annual rate 0.9 percent (Sohngen and Haynes 1994). Rising average prices for lumber since 1985 may represent resumption of this long-term trend or an extended cycle of high prices induced by political events—a cycle possibly on the downside since 1994. During the extended period of overall higher lumber prices (1986-95), average annual real prices for the coastal region lumber never exceeded average annual real prices for the banner years 1973 and 1979.

Douglas-Fir

Production of high-quality Douglas-fir lumber in the Pacific Northwest is indicative of trends in Pacific Northwest lumber manufacturing (fig.1). High-quality grades, such as selects and shops, declined both in proportional and absolute amounts from 1971 through 1995 (table 8). In 1991-95, 1.1 percent of lumber production was in select and shop categories in contrast to more than 11 percent in the early 1970s. Production has become increasingly concentrated in the midvalue light and heavy framing grades. Commodity production and engineered products have replaced the high-value products. Framing grades comprised more than 75 percent of total production in 1991-95 in contrast to 56 percent in the early 1970s. At the same time, a move to middle grades is occurring from below. Production volume of lumber in lower valued utility grades has declined by half from 1971 to 1995, while economy grade volumes have remained roughly constant.

Highest quality lumber grades sustained a continual real price increase from 1985 to 1994 (table 15), but with one exception, 1990s real prices have yet to exceed 1979 real prices, the high for the period. The category for D select and shop lumber is the only category to have had an all-time price maximum during 1991-95. Select and shop grades, structural items, and heavy framing lumber offered price premiums above the average Douglas-fir lumber prices for the coastal Pacific Northwest. The average real value of Douglas-fir lumber spiked upward in 1993 with a 40-percent increase over the 1992 average real price (Sohngen and Haynes 1994). In 1994-95, real prices dropped to values still substantially higher than prespike values (fig. 2 and table 15).

Coast Hem-Fir

Trends in the composition of hem-fir lumber production (fig. 3 and table 16) largely reflect trends occurring with Douglas-fir. Select and shop grades have virtually disappeared in hem-fir lumber production. The long-term decline in the proportion of utility grade material also continues, and production volume of utility lumber declined by half in 1971-95. Economy grade lumber has remained relatively constant in proportion but is subject to substantial price swings. The most striking difference is the small amount of hem-fir in structural items. Here the difference in physical properties of hem-fir and Douglas-fir seems to favor Douglas-fir. Hem-fir has remained a less valuable resource overall with a greater proportion of the lumber resource produced in heavy framing and lower grade categories as compared to Douglas-fir. In 1983-95, prices for hem-fir lumber in all lumber grade categories except economy grade remained lower than prices for comparable grades of Douglas-fir lumber.

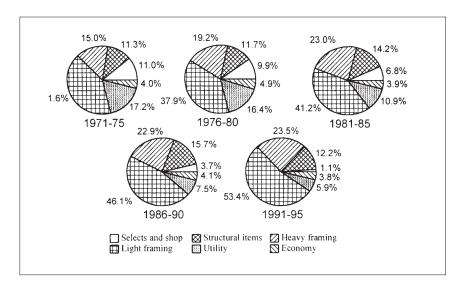

Figure 1—Douglas-fir lumber grade composition, Pacific Northwest coast mills, 1971-95

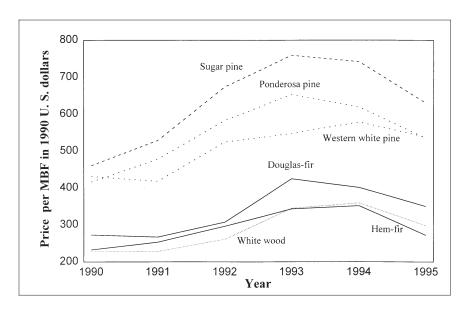

Figure 2—Lumber prices for commercial timber species in the Pacific Northwest, 1990-95

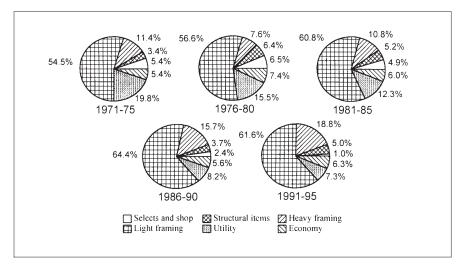

Figure 3—Hem-fir lumber grade composition, Pacific Northwest coast mills, 1971-95

Ponderosa Pine

Ponderosa pine lumber production exceeds lumber production from all other pine species together in the Western United States (WWPA 1995c). Division of ponderosa pine lumber into 16 grade categories reflects this large and diversified production. The production capacity for ponderosa pine lumber has not mirrored the growth seen for coast Douglas-fir since 1982. Between 1991 and 1995, total Western United States production of ponderosa pine has fallen by nearly one-third. In the coastal Pacific Northwest region, timber comes primarily from southwestern Oregon.

As with coast hem-fir and Douglas-fir, higher valued ponderosa pine select and no. 1 shop grade categories comprise an ever smaller part of total production (fig. 4 and table 17) between 1971 and 1995. Less than 4 percent of the total lumber production for these grades in 1995 contrasts with 11.4 percent in 1971. Loss of product quality also has changed the composition of ponderosa pine lumber supply. Moulding and better and no. 2 shop grades have had their alltime lowest share of ponderosa pine lumber production since 1990. Lower value no. 3 shop, shopout, and 2 common grades were the only categories with higher percentages in 1990-95 than in the previous 20 years. Among the grades with increasing volumes of lumber, no. 3 shop and 2 common grades had annual average prices higher than the average annual prices for total east-side lumber. Despite loss of quality, ponderosa prices in 1993-94 recorded the highest real prices for 1971-95 for 2 common, all shop, moulding, and select grade categories (table 17). Prices for grades of ponderosa pine lumber below the east-side average prices rose considerably during the 2-year period but did not exceed real price levels in the banner year 1973.

Sugar Pine

The supply of sugar pine lumber has historically amounted to about one-tenth of the board-foot lumber volume (table 11) of ponderosa pine (table 10) and has tracked with the production volume and composition of ponderosa pine lumber (figs. 4 and 5). Sugar pine lumber volumes have experienced relatively steeper cycles in production fluctuation than those for ponderosa pine. Since the alltime high production of sugar pine lumber in 1987-88, production has declined by two-thirds to the 1995 level. For 1971-95, lowest lumber production occurred in 1995.

Grade groupings of sugar pine lumber correspond for the most part with those used for ponderosa pine. Fourteen grades of sugar pine lumber, instead of 16 grades for ponderosa pine, are considered here. D select, 12-inch lumber has been merged into the C and better, 4-inch, and D select, 4-10-inch; utility items are incorporated into the category comprised of 4 common, 4-12-inch, and no. 3 lumber.

The value of the sugar pine production has been historically greater than any other species considered here (fig. 2 and table 18). Its physical properties and appearance make the species highly marketable. Since 1992, the value of sugar pine lumber has averaged \$100 more per thousand board feet than ponderosa lumber. In 1990-95, higher value grade categories of sugar pine lumber were consistently more valuable than comparable ponderosa pine grade categories. Low-value grades of sugar pine lumber have recently commanded prices equal to or lower than ponderosa pine lumber. This represents a change from 1971, when all grades of sugar pine were more valuable than ponderosa pine.

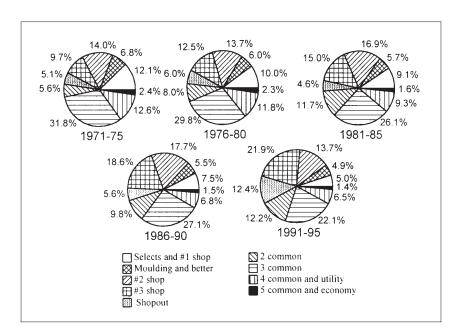

Figure 4—Ponderosa pine lumber grade composition, Western U.S. mills, 1971-95

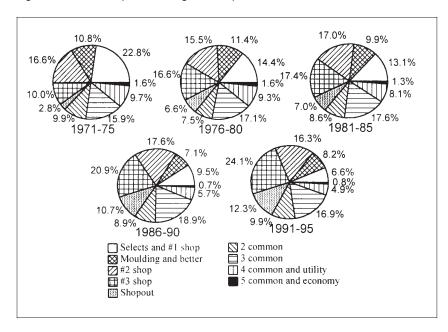

Figure 5—Sugar pine lumber composition, Western U.S. mills, 1971-95

Western White Pine

Western white pine lumber represents a nearly exhausted resource in the Western United States (table 12). Volume of timber production has declined steadily since 1971, when the highest volume for 1971-95 was recorded. Much lumber production came from salvaged logs harvested after mortality caused by white pine blister rust (Snellgrove and Cahill 1980). The proportional loss of select grade lumber is not as steep as for other species, but absolute volume of high-value select grades is very small. As with the previous two pine species, greatest increase in proportion of lumber in the last 25 years has occurred in 2 common grade (fig. 6). For 2 common grade, western white pine ranks with sugar pine in value, above ponderosa pine (tables 17 through 19).

White Woods (Including Lodgepole Pine)

This category is a catchall for lodgepole pine, Sitka spruce, and Englemann spruce. The greatest proportion of lumber manufactured has historically been in the 3 common grade category (fig. 7 and table 13). The share of 3 common grade in lumber production has been declining since the mid-1980s as the proportion of 2 common grade category has increased. White woods comprise the only lumber group that has seen a recent growth trend in the proportional importance of utility grades. During the early 1990s, small amounts of shops and better lumber were produced. Production of white wood lumber varies cyclically and reached peaks in 1977-79 and 1987-92.

White woods commonly are considered the least valuable of the commercial softwood species. Figure 2 and table 20 show that the average value of lumber produced from white woods is not substantially different from the hem-fir resource in the west side of the Pacific Northwest. White wood lumber has been irregularly tracked and deserves more study to understand its present and potential role in lumber supply from the Pacific Northwest.

Method of Analysis

The focus of this study was somewhat different from that of Haynes and Fight (1992). As in their study, regression equations were developed for aggregated lumber grades by species or species group. But here, the regressions for lumber types are related to average regional prices for lumber (table 1), as compiled by the WWPA, rather than to a dominant lumber class (for example, Douglas-fir light framing as the base price series for all other Douglas-fir and hem-fir lumber grade categories). The aim was to derive historical relations for use in forecasting lumber prices for the existing range of lumber grade groupings defined in this study.

The present analysis emphasized only the commercial timber species in the Pinaceae from the Pacific Northwest west of the Cascade crest. Timber species in the Cupressaceae (various cedars) will be treated elsewhere. Although five pine species, ponderosa, Jeffrey, western white, lodgepole, and sugar, are commercial timber species in the west-side Pacific Northwest, average annual real prices for lumber east of the Cascade crest and in California better characterize prices for many grades of the west-side pine species. East of the Cascade crest, ponderosa pine lumber dominates the supply; accordingly, average east-side prices are often better indicators of price behavior for pine lumber grades and end uses in contrast to Douglas-fir and hem-fir lumber grades.

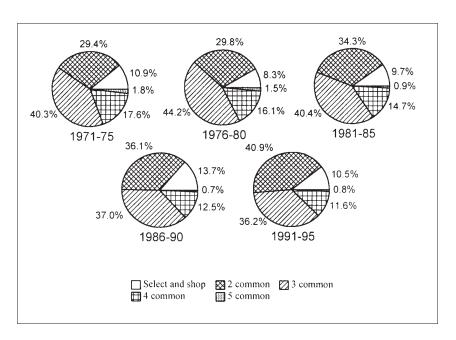

Figure 6—Western white pine lumber grade composition, Western U.S. mills, 1971-95

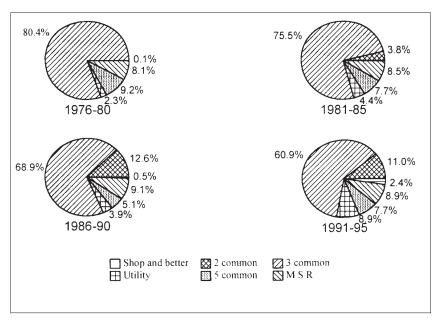

Figure 7—White wood lumber grade composition, Western U.S. mills, 1974-95

Lumber grade categories for the species treated in this study are based on similar end use. This approach to classification assumes that lumber prices of different grades and species have a fixed proportional relation. In general, price relations for one grade will not differ substantially from prices of similar grades within a species or comparable grades among species. Possibilities for substitution enable consumers to replace one grade for another grade or replace the same grade from a different species if prices begin to change. Substitution enables prices to equilibrate. Hem-fir lumber, for example, consists of grades derived from timber of multiple species of *Abies* and *Tsuga*, all having similar physical properties.

Each lumber grade category for each species was regressed against both east- and west-side lumber prices series to determine which series provided the better fit. Two simple equation forms were used to develop regressions that characterize the historic pattern of relation between a lumber grade category and average lumber price for a region. The first set of equations follows the form suggested for marketing margins (George and King 1971):

grade price_{it} =
$$b_{0j} + b_{1j} * price_{average lumber, t}$$
, (1)

where

grade $price_{jt}$ = Pacific Northwest coast lumber prices for the j^{th} species and grade in year t;

 b_{0j} = the estimated intercept value of the price relation for the j^{th} species and grade;

b_{1j} = the estimated coefficient representing the proportional response to change in grade price_{it} to change in a given price_{average lumber, t}; and

price $_{average\ lumber,\ t}$ = the average price for all lumber products (west or east of the Cascade crest) in year t.

The other equation form is the natural log transformation of the same relation,

In (grade price_{it}) =
$$b_{0i} = b_{1i} * In (price_{average lumber, t})$$
. (2)

In many instances, the natural log transformation produced intercept b_{0j} values that were statistically significant, in contrast to intercept values in untransformed equations.

Durbin-Watson test statistics showed that serial autocorrelation occurs in the majority of regressions between prices from a lumber grade category and average lumber prices. A grid-search algorithm provided corrections for autocorrelations in equations with serial autocorrelation (Hildreth and Lu 1960). Whenever the Durbin-Watson statistic fell between upper and lower bounds of statistical significance in detecting autocorrelation, an alternative test (Durbin 1970) ascertained statistical significance for autocorrelation at α =0.05. Best regressions for lumber grade categories are presented by species or species groups in tables 21 through 26. Best regressions are those equations having a high adjusted r^2 value, a Durbin-Watson statistic close to 2.0, and a coefficient value of b_1 significant at α =0.05.

presupposes that past relations between the average price of a lumber grade category and the regional average price will hold in the future. Under this assumption, regressions from tables 21 through 26 serve as price projections for lumber grades for 1996-2020. Future average annual prices for lumber in the east- and west-side regions of the Pacific Northwest (table 27) were taken from the baseline scenario of the 1993 version of the Timber Assessment Market Model (TAMM) (Adams and Haynes 1996). Price projections for each lumber category are arranged by species in tables 28 through 33.

One application of these regression equations is price forecasting. This application

Results and Conclusions

Projections of prices for specific lumber grades during the next 25 years have been developed. Regressions between historical relations of lumber grades to regional average prices have been extrapolated to the future by using the average annual future prices for lumber in the Pacific Northwest as projected by TAMM. A different pattern of price trends emerges from the model than from the pattern of actual lumber during the past 25 years.

Over the past 25 years, the composition of lumber production has changed substantially in the Pacific Northwest west of the Cascade crest. Greatest production increases have occurred in midvalue categories, as select and shop grades have declined in overall proportion and volume of the lumber production. Best regressions based on average regional prices are for these midvalue grade categories—an indication of the preponderant share of these grades in lumber production. Two and 3 common grades in pine species fit the average lumber price series from the west side as well. Prices for these pine grades correspond approximately to structural items and heavy framing grade prices for Douglas-fir and hem-fir in western Oregon and Washington.

The comparatively poor explanatory power for regressions with higher grade categories indicates that those grades respond to additional factors other than average regional prices for lumber. Overall, the rate of projected price increases has been less for high-quality select and shop lumber than for midgrade framing lumber from Douglas-fir and hem-fir species and for common grade lumber from pine species. Projections based on regressions of lumber prices indicated that Douglas-fir and sugar and ponderosa pine species will continue to have commanding premiums for high-quality wood. Real price increases on the order of 11 to 16 percent for highquality Douglas-fir are forecast at the end of the projection period, 2020, in comparison to real 1995 prices. Price increases for select grades of ponderosa and sugar pines are projected at lower rates of increase, between 5 and 9 percent. The historical ranking by value of select timber prices from each species or species group remains the same throughout the forecast period; from highest to lowest, the ranking is sugar pine, ponderosa pine, Douglas-fir, and hem-fir (tables 28 through 33). Ranking by rate of price increase in value from highest to lowest is different: Douglas-fir, hem-fir, ponderosa pine, and sugar pine.

Hem-fir grade lumber is interchangeable in quality and price with Douglas-fir in the framing grades. Efforts to develop high-grade hem-fir likely would occur only with pruning management, because of the high rate of decay and defect in older trees of hem-fir species (Harmon and others 1996). Price similarity for midpriced products on many sites could render yield and value from hemlock and true fir species equal to the value of Douglas-fir yield. This outcome is likely where Douglas-fir is at the margin of its range, for example at higher elevations or close to the Pacific coast.

At the same time, loss of higher-quality lumber supplies and steep reductions in available resources from several pine species has prompted new thinking about means to reestablish supplies from certain timber species, such as western white pine and sugar pine. Prices of common grade lumber from sugar, western white, and ponderosa pine show an 11-percent real price increase by 2020. This fact may prove to be an incentive for more intensive planting and management for pine species.

Investment in uncommon species, such as sugar and western white pines, will be rewarded as the price of commons grades for the soft pines remains consistently higher than the price for comparable grades of the hard pines (ponderosa and lodgepole pines) throughout 1996-2020. The one pine species that, until now, shows no great real price increase is lodgepole pine when used as "white wood." Such lower valued products maintain an 8- to 11-percent real price increase from 1996 to 2020. More intensive management of lodgepole pine to improve yield has not taken hold in the Pacific Northwest west of the Cascade crest, in contrast to the Rocky Mountain region.

Several means to develop higher value lumber sources through stand management are attracting interest among forest managers. Commercial thinnings of subdominant trees can extend rotations of thriftily growing retention trees. Infrequent, heavy intermediate thinnings may be able to carry the cost of developing a high-quality lumber source in forests with late-seral features designed to meet other social objectives, such as conservation of biological diversity. Curtis (1995) documents that lengthening rotations for Douglas-fir maintains good growth in large, old trees retained as canopy emergents.

Pruning young trees to reduce knot size and promote clear wood growth (Hanley and others 1995) in species not conventionally pruned can add more value to smaller diameter trees. Inclusion of high-value pine species, such as western white pine and sugar pine, as significant components of otherwise uniform stands of Douglas-fir or hem-fir species holds promise for augmenting overall stand value. Implementing advances in management (Cole and Koch 1995, Hungerford and others 1982) for pine species can forestall premature mortality through disease and infestation to realize gains in stand-level investments for lumber product quality.

Alternative sources of incomes from a stand also may come from nontimber products in the understory. These alternatives have the potential to finance young stand management for improved timber quality. As yet, options for harvesting understory vegetation or fungi with high market values are poorly known (von Hagen and others 1996). Although stand management may become more complex with multiple crops, more intensive management can make management of forest overstories for timber quality more feasible. Joint management of residual trees to develop higher-quality timber can conversely prolong understory conditions beneficial for economic yields of non-timber products. An example of the latter strategy is research ongoing in the Winema and Umpqua National Forests (southern Oregon) to develop a high-quality timber supply and more abundant pine mushroom (American matsutake) crops concurrently.

Acknowledgments

Funding for this study came from the U. S. Department of Agriculture, Forest Service, Demonstration of Ecosystem Options Program (DEMO), a multidisciplinary project for forest research and innovative stand management in the Gifford Pinchot and Umpqua National Forests. Susan Willits contributed her expertise for developing the lumber grade categories used here for western white pine and white wood species. James Yuhas and Barbara Leline from the Western Wood Products Association provided data sets. Judy Mikowski diligently checked the accuracy of figures.

Appendix 2

Following is a list of Western Wood Products Association (WWPA) lumber grades classified by the lumber grade categories used by the U.S. Department of Agriculture, Forest Service, Pacific Northwest Research Station.

The aggregate lumber grade categories used by the Pacific Northwest Research Station in reporting regional lumber prices are listed in **boldface** under the appropriate timber species or species group. Names of commercial lumber grades included in a given category for analysis are listed underneath the corresponding category along with the years in which the lumber grade is recorded by the WWPA.

A. Grade categories for Douglas-fir lumber

Note: Grades in use from 1977 to 1995 are included here.

Appendix 3

Scientific names of commercial timber species in the Pinaceae found in western Oregon and Washington.

Scientific name	Common name
Abies amabilis Dougl. ex Forbes	Pacific silver fir
Abies concolor (Gord. and Glend.) Lindl. ex Hildebr.	white fir
Abies grandis (Dougl. ex D. Don) Lindl.	grand fir
Abies magnifica A. Murr. var. shastensis Lemmon	Shasta red fir
Abies procera Rehd.	noble fir
Picea engelmannii Parry ex Engelm.	Englemann spruce
Picea sitchensis (Bong.) Carr.	Sitka spruce
Pinus contorta Dougl. ex Loud.	
var. murrayana (Grev. and Balf.) Engelm.	lodgepole pine
Pinus jeffreyi Grev. and Balf.	Jeffrey pine
Pinus lambertiana Dougl.	sugar pine
Pinus monticola Dougl. ex D. Don	western white pine
Pinus ponderosa Dougl. ex Laws.	ponderosa pine
Pseudotsuga menziesii (Mirb.) Franco	Douglas-fir
Tsuga mertensiana (Bong.) Carr.	mountain hemlock
Tsuga heterophylla (Raf.) Sarg.	western hemlock

Weigand, James F. 1998. Grade composition, volume, and prices for major soft-wood lumber types in western Oregon and Washington, 1971-2020. Res. Pap. PNW-RP-509. Portland, OR: U.S. Department of Agriculture, Forest Service, Pacific Northwest Research Station. 61 p.

An analysis of lumber prices provided regressions for price trends during the period 1971-95 for composite lumber grades of major timber species found in the Pacific Northwest west of the crest of the Cascade Range. The analysis included data for coastal Douglas-fir and hem-fir lumber; coastal and inland Pacific Northwest ponderosa, sugar, and western white pines; and inland Pacific Northwest and Rocky Mountain lodgepole pine. Future prices of grades by species group are based on these price trends and the latest average regional lumber values established in the Timber Assessment Market Model (TAMM). Land managers can use the price projections in financial analyses of management practices that are designed to affect the quality of timber resources.

Keywords: Douglas-fir, hem-fir, lodgepole pine, lumber prices, ponderosa pine, price trends, sugar pine, Timber Analysis Market Model, western white pine, white woods.

The **Forest Service** of the U.S. Department of Agriculture is dedicated to the principle of multiple use management of the Nation's forest resources for sustained yields of wood, water, forage, wildlife, and recreation. Through forestry research, cooperation with the States and private forest owners, and management of the National Forests and National Grasslands, it strives—as directed by Congress—to provide increasingly greater service to a growing Nation.

The United States Department of Agriculture (USDA) prohibits discrimination in its programs on the basis of race, color, national origin, sex, religion, age, disability, political beliefs, and marital or familial status. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means of communication of program information (Braille, large print, audiotape, etc.) should contact the USDA's TARGET Center at (202) 720-2600 (voice and TDD).

To file a complaint, write the Secretary of Agriculture, U.S. Department of Agriculture, Washington, DC 20250, or call (800) 245-6340 (voice), or (202) 720-1127 (TDD). USDA is an equal employment opportunity employer.
