

Before the  
 FEDERAL COMMUNICATIONS COMMISSION  
 Washington, D.C. 20554

In the Matter of: )  
 )  
 E-911 AUTOMATIC LOCATION )  
 IDENTIFICATION ROUND TABLE )

Commissioners Meeting Room  
 The Portals  
 445 12th Street, S.W.  
 Washington, D.C.

Monday,  
 June 28, 1999

The parties met, pursuant to notice, at 1:10 p.m.

APPEARANCES:

DALE HATFIELD, Chief  
 Office of Engineering and Technology (OET)

DR. MARK BIRCHLER, Manager  
 Wireless Access Technology Research  
 Motorola Labs

DR. OLIVER HILSENATH, President and CEO  
 U.S. Wireless Corporation

JOHN MALONEY, Vice President and Chief Scientist  
 KSI Inc.

DENNIS KAHAN, CEO  
 SigmaOne Communications

LOU STILP, Executive Vice President  
 TruePosition, Inc.

WALTER BELL, Vice President of Engineering  
 SnapTrack, Inc.

KANWAR CHADHA, Founder and VP Marketing  
 Sirf Technology, Inc.

BETH FRASCO, RF Planning Manager  
 Aerial Communications, Inc.

Heritage Reporting Corporation  
 (202) 628-4888

## APPEARANCES (CONT.):

DAN A. PRESTON, Chief Technology Officer  
Integrated Data Communications

TOM SUGRUE, Chief  
Wireless Telecommunications Bureau (WTB)

JIM SCHLICHTING, Deputy Chief  
Wireless Telecommunications Bureau

JULIUS KNAPP, Chief  
Policy and Rules Division, OET

ROBERT ECKERT, Chief  
Technical Analysis Branch  
Electromagnetic Compatibility Division, OET

RON NETRO, Senior Electronics Engineer  
Policy Division, WTB

MATS CEDERVALL, Location Technology Researcher  
Ericsson Inc.

ANNA SILLANPAA, Senior Standards Engineer for  
Location Technologies  
Nokia

TONY SMITH, Director, Strategic Marketing  
Wireless Solutions  
Nortel Networks

SAMIR SOLIMAN, Vice President for Technology  
QUALCOMM Inc.

ANTHONY CHADNEY, Principal Engineer  
Network Engineering & Planning  
AirTouch Communications, Inc.

BOB MONTGOMERY, Senior Manager  
Regulatory and Technology Department  
Nextel Communications, Inc.

## APPEARANCES (CONT.):

JIM NIXON, Manager, Public Safety Affairs  
Omnipoint Communications, Inc.

EAMON O'LEARY, Director - Intelligent Network  
Systems  
Technology Development Group  
AT&T Wireless Services, Inc.

RON RUDOKAS, Executive Director  
Performance Engineering and New Technologies  
Western Wireless Corp.

BHASKAR SRINIVASIAH, Manager  
Technology Support  
GTE Wireless

CAPT. JOE HANNA, President-Elect  
Association of Public-Safety Communications  
Officials International, Inc. (APCO)

S. ROBERT MILLER, Technical Issues Director  
National Emergency Number Association (NENA)

P R O C E E D I N G S

1  
2 MR. HATFIELD: Okay, if we can get started,  
3 please? Is that better? There we go. Good afternoon, I'm  
4 Dale Hatfield of the Office of Engineering and Technology  
5 and I want to start right out by thanking all of you for  
6 coming today.

7 The purpose of this round table -- well,  
8 rectangular table, I guess -- is to discuss together a  
9 better understanding of the technologies being proposed to  
10 provide wireless Phase II enhanced 911 service to the  
11 public.

12 Our rules require covered wireless carriers to no  
13 later than October 1, 2001, deploy automatic location  
14 identification technology capable of locating a caller  
15 dialing 911 to a given degree of accuracy, namely longitude  
16 and latitude within 125 meters, using the RMS methodology,  
17 and, to provide that information to public safety answering  
18 points or PSAPs.

19 Currently, our Phase I location rules require  
20 location only to the cell side, which, of course, could be  
21 from as small as a few blocks to as large as several square  
22 miles. We're not, however, going to address any of the  
23 issues for deployment concerns regarding Phase I today.  
24 Rather, our sole focus here will be on Phase II.

25 We recognize that our rules were adopted before we

1 understood that a GPS-based handset solution was an option.  
2 The record, unfortunately, is still extremely sparse in  
3 terms of technical data on the viability, reliability and  
4 accuracy of the various potential Phase II solutions and we  
5 hope, of course, to correct that deficiency today.

6 I also sincerely urge all of you here today and  
7 particularly those that we have not been able to accommodate  
8 and include on the panel to provide us with information on  
9 your proposed solutions, particularly information that  
10 answers the type of questions we're posing today. You can  
11 do this through our normal ex parte procedures or by filing  
12 in response to the June 1, 1999 public notice, copies of  
13 which, I believe, have been provided in the rear.

14 Today's presentations are being carried live on  
15 closed circuit TV within the FCC for the benefit of the  
16 staff who is not down here in the room. The audio feed is  
17 also being carried on the Internet via real audio running  
18 off our FCC web page. The audio feed will remain on the  
19 home page and a transcript of the hearing will become  
20 available on the FCC page in about two weeks.

21 The addenda that we set forth today starts with a  
22 high-level overview of the basic, underlying technologies,  
23 both for the network based and the handset based solutions.  
24 The overview will be presented by Dr. Mark Birchler, Manager  
25 of Wireless Access Technology Research at Motorola Labs.

1 The slides for the presentation are posted on the web page  
2 so that those listening via real audio can follow along.

3 After the overview, we'll have several proponents  
4 of network based solutions and handset based solutions  
5 follow-up with brief eight to ten minute presentations that  
6 highlight the unique features of their particular solution,  
7 provide information about the status of testing of their  
8 systems and how they perform in terms of achieving our  
9 standards of reliability and accuracy.

10 I'll let the panelists introduce themselves and  
11 identify their companies at the beginning of their  
12 respective presentations. One housekeeping matter is that  
13 our timekeeper will let you know when you have two minutes,  
14 one minute and then no time remaining. In order to keep to  
15 the agenda and make sure everybody has a fair shot, I'm  
16 going to be very rude and cut you off if you go over the  
17 allotted time.

18 After a short break, then we'll have the  
19 representatives of the manufacturers, carriers and public  
20 safety join us at the round table and at this point, we'll  
21 engage in a question and answer session, moderated by the  
22 FCC staff. In selecting the participants for the round  
23 table, we tried to provide a balanced group representing  
24 both advocates of network based solutions and handset based  
25 solutions, manufacturers and so forth. I'm looking forward

1 to an informative session at the end of today. I hope to  
2 have a much better understanding, we hope to have a much  
3 better understanding of how these new technical solutions  
4 will help address the important objective of insuring our  
5 nation's wireless telecommunications system is as safe and  
6 reliable for persons needing emergency systems as in our  
7 wire line system.

8 So with that, we'll start with Dr. Mark Birchler.

9 DR. BIRCHLER: Thank you, good afternoon. Okay,  
10 we can flip to the first slide. Okay, the goals of this  
11 presentation are fairly modest. I'd like to, at the end of  
12 it, have generated a common terminology that we can all  
13 refer to as we are moving through our various presentations  
14 throughout the afternoon.

15 I'd also like to describe the basic system types  
16 that are available for the E-911 Phase II location solutions  
17 and some of the key differentiating features of the various  
18 basic system types or technologies that are being developed.  
19 On this first slide, I have a short list of acronyms that  
20 covers very briefly some of the most important acronyms that  
21 we would be using throughout the afternoon. Covered, in  
22 alphabetical order, are the various systems, A-GPS for  
23 Assisted Global Positioning System, angle of arrival and so  
24 on and so forth. I'll let you just take that in yourselves.  
25 But you can refer back to this if you have a question about

1 an acronym throughout the presentation.

2           Okay, we can move to the next slide. Okay, this  
3 slide attempts to show a very high level overview of the  
4 basic technologies that are utilized to deliver location.  
5 As you can see, we have a handset that we're wondering where  
6 it is and we have two basic solution types that meet this  
7 desired end.

8           The first solution type is called network and the  
9 other is handset. The key differentiating feature that  
10 would make a solution network or handset assisted is where  
11 the fundamental information by which the handset is located  
12 is collected and generated. For a network solution, that  
13 fundamental information is obtained by listening to  
14 transmissions on the handset, using equipment at the sites  
15 themselves or at other sites.

16           In a handset solution, the core information  
17 required to locate the handset is measured at the handset  
18 itself. This doesn't mean that the network plays no part in  
19 a handset solution. It simply means that the core  
20 information is generated in the handset.

21           Now, as you can see, there are a number of  
22 different solutions in each of these basic solution spaces.  
23 I've only attempted to cover the fundamental types of  
24 information generation systems in this talk, knowing full  
25 well that there are many different permutations of the

1 various possibilities and some of them are shown on this  
2 slide.

3 But on the network side, you can see that we have  
4 three main areas or ways of developing the information  
5 required for location. There's a multi-path fingerprint,  
6 moving from left to right here, TDOA and AOA, or Time  
7 Difference of Arrival and AOA or Angle of Arrival. Then,  
8 there are various permutations, combinations of these  
9 systems.

10 On the handset side, there are two main types, the  
11 first shown, going, continuing from left to right is EOTD  
12 for Enhanced Observed Time Difference, which is a time  
13 difference of arrival solution in the handset, and Assisted  
14 GPS. So I think we can move onto the next slide.

15 Okay. Now what I'd like to do is discuss each one  
16 of these solution types in a little bit more detail,  
17 focusing in on the key differentiating attributes of each  
18 type. And I'll be happy, if there's any extra information  
19 in the panelists that I've missed in any of these slides,  
20 I'll be happy to take those suggestions as I go along.

21 Each slide is very similar, in that on the left  
22 hand side, I have a pictorial view of the system and a  
23 couple of comments on the general location solution method.  
24 And then, on the right hand side, there's been an attempt  
25 made to, at a very high level, explain the various impacts

1 and systems addressed for each solution.

2 Now, for the Time Difference of Arrival network  
3 based solution, one of the key things to remember is that a  
4 minimum of three sites are required to receive the signal,  
5 detect its presence and conduct time measurements on the  
6 signal in order to arrive at a location solution. And these  
7 solutions are based on the apparent differences and times of  
8 arrival between pairs of sites. And from there,  
9 triangulation technique to be used to estimate the location  
10 of the handset. And of course, there's a tremendous amount  
11 of intellectual property and good engineering that goes into  
12 doing the best job possible of finding the accurate time  
13 differences out in the harsh environment.

14 There are some obviously network impacts for this  
15 solution and these are going to be similar for most of the  
16 solutions that are network-based, which means that you have  
17 to have elements in the network that control the location  
18 receivers that are utilized to make the measurements, and  
19 you also need -- for digital systems, you may well need to  
20 have focused into the operator's network in order to get at  
21 the information required to fully obtain all the information  
22 you need to locate a specific handset.

23 At the sites, you're going to need extra location  
24 receivers for most of these solutions. The handset impact,  
25 there is none, and so therefore, this solution will work for

1 Legacy handsets and for TDOA, as far as I can tell, all the  
2 systems that are out there, first and second generation  
3 wireless communication systems are addressed by this  
4 technology. So I think we can move onto the next slide.

5 In an Angle of Arrival solution, you see that  
6 we've gone from three cells being shown to two, and the  
7 reason for that is that only two cells are needed to find  
8 the location of the handset as a minimum. With this type of  
9 solution, the apparent Angle of Arrival of the transmissions  
10 from the handset are utilized to generate the core  
11 information at the site and then, once again, triangulation  
12 methods are used to calculate the apparent position of the  
13 handset.

14 This solution has similar network impacts, as did  
15 the TDOA solution. On the site impact, in addition to the  
16 requirement for location receivers, there is also the  
17 additional requirement for antenna rays, which are capable  
18 of unambiguously determining the direction of arrival of a  
19 signal.

20 Once again with this solution, there is no handset  
21 impact and most of the systems appear to be addressed by  
22 this technology, as well. And of course, since there's no  
23 necessary changes to the handset, Legacy handsets would be  
24 covered by this solution.

25 The third and last core technology that, on the

1 network-based side that I'm going to talk about, is multi-  
2 path fingerprint technology. This solution is different  
3 from the two previous solutions in that it requires a  
4 database of tested locations to be available that you can  
5 match a fingerprint generated from an unknown location to  
6 this database to figure out where the apparent location of  
7 signal transmission originated from.

8           As you can see in this solution, only one site is  
9 shown and that's because this solution can locate a handset  
10 based on only a single, receiving information only at a  
11 single site. The network impacts are the same as the other  
12 two. You will need location receivers at the site. The  
13 impact on the handset is none. There are no known changes  
14 you'd have to make to a handset transmission to make the  
15 solution work, and this solution addresses amps, CDMA and, I  
16 believe, also, a TDMA system. And of course, Legacy  
17 handsets are covered.

18           Okay. Now, what we have here is the only  
19 composite solution that I have in my talk and it's simply to  
20 show that there are unique possibilities for creation of  
21 hybrid systems that may increase the reliability and  
22 accuracy of a location solution. This is by no means the  
23 only hybrid approach. QUALCOMM has another CDMA hybrid  
24 approach that uses various system elements.

25           But in this example, we have a situation where we

1 have enhanced forward link triangulation, where information  
2 is generated both at the network and by the handset. And  
3 therefore, this solution, if you go back to the original  
4 high-level view, spans the network and handset-based sides  
5 of the plane. This is a unique CDMA solution. It's network  
6 impact is the addition of location, calculation and control  
7 elements in the network. You may need to increase the  
8 calibration accuracy of the sites to make it work well, but  
9 it will work without any handset changes, and it's a CDMA  
10 unique solution. So only CDMA is addressed, and Legacy  
11 handsets are covered.

12           Okay, next slide. Now, I'm going to move into the  
13 handset assisted area, and there are two primary solutions  
14 for this. Although, once again, I should point out that  
15 this is not all encompassing. One of the primary handset  
16 assisted solution methods is called A-GPS or Assisted GPS.  
17 In this system, what's required for minimum requirements for  
18 a four-location solution are con activity, datacon activity  
19 to at least one site, which would most likely be the serving  
20 site, and also, the ability to receive transmissions from  
21 three GPS satellites. GPS is Global Positioning System and  
22 it's a system of satellites put up by the Department of  
23 Defense that is used for military positioning, for high  
24 precision use. But also, there's a part of the system  
25 that's available for general public use, and this is the

1 part of the system that's utilized for E-911 location.

2 In Assisted GPS, the network provides the GPS  
3 functionality in the handset, with additional information  
4 which allows it to lock on more quickly to the satellites  
5 and receive their signals with higher sensitivity. For this  
6 type of solution, you will need a GPS assist box in your  
7 network. There's a potential for enhancements to the  
8 synchronization of systems, in order to support the GPS  
9 assist functionality.

10 With this solution, as with all handset solutions,  
11 there are impacts on the handset now, which would include,  
12 perhaps, a second GPS antenna, partial or full GPS  
13 functionality in the handset. Minimally, a GPS front end  
14 and processing. There are memory needs and needs for new  
15 software.

16 I should also point out that you can view a stand  
17 alone GPS solution as simply Assisted GPS without the  
18 assistance. And I'm aware that there are suggestions that  
19 stand alone GPS is a solution to be considered, as well.

20 The Assisted GPS solution is being standardized  
21 for CDMA, for PCS 1900 and GSM. It's under investigation  
22 for IDEN and also TDMA, and of course, Legacy handsets are  
23 not covered in this solution.

24 Okay, next slide. The final solution type I'm  
25 going to talk about is EOTD or Enhanced Observed Time

1 Difference. This is a TDOA solution, but the measurements  
2 are conducted in the handset by measuring apparent time  
3 differences and received time of signals transmitted from  
4 the network equipment. Once, as with all TDOA solutions, at  
5 least three sites are required in order to come up with a  
6 location solution, so the handset must be able to detect and  
7 measure time of arrival information from three sites. And  
8 once again, the location solution is based on the apparent  
9 time differences in transmissions from these three sites.

10 The network impact, there may be need for location  
11 calculation and control. At the sites, we will need either  
12 some sort of accurate time synchronization enhancement,  
13 because this solution requires that the synchronization  
14 characteristics of the supporting infrastructure be either  
15 very well controlled or very well known in order for a  
16 successful solution, high accuracy solution, or the site air  
17 measurements must be calculated and sent to a centralized  
18 location that can correct for the synchronization errors at  
19 the sites.

20 For the handset impact, there will be new software  
21 required in the handset. In most handsets, no new memory  
22 will be required, but it's conceivable in some cases, rare  
23 cases, that new memory could be required, if they were  
24 operating right up to the edge of their existing memory.  
25 But we believe in most cases it would just be a software

1 upgrade.

2 The GSM PCS 1900 community are standardizing this  
3 solution, and this solution is also under investigation for  
4 IDEN. And then, finally, as with all handset-assisted  
5 solutions, Legacy handsets are not covered.

6 Okay, so this is our final slide here and the  
7 purpose of this slide is to just point out that there are  
8 various combinations of these fundamental location  
9 technologies that can be utilized to the advantage of the  
10 performance of the system. There are suggestions that Angle  
11 of Arrival be combined with receive signal strength to  
12 enhance coverage and performance. There are vendors who  
13 have a combination of Angle of Arrival plus time difference  
14 of arrival, network overlay solutions. There's discussion  
15 of combining the two primary handset-assisted solutions,  
16 EOTD and Assisted GPS, to improve the efficiency and  
17 accuracy of the overall solution.

18 And then, there is a suggestion of combining in  
19 the CDMA system, combining Assisted GPS with E-FLT. And  
20 then, in the other column, there's also a QUALCOMM proposal  
21 to combine Assisted GPS with round trip time of arrival  
22 estimates to improve the performance of that solution. So  
23 that concludes my discussion of the various solution types  
24 that are out there. I hope it will be helpful in moving  
25 this discussion forward and I thank you for your attention.

1 MR. HATFIELD: And thank you, Dr. Birchler, and  
2 thank you also for keeping us on time and on schedule.

3 We'll shift now to presentations by the proponents  
4 of the different ALI technologies and we'll start off to my  
5 right with the representative from U.S. Wireless  
6 Corporation.

7 DR. HILSENATH: Thank you very much, Dale. U.S.  
8 Wireless Corporation, I have three colleagues with me here.  
9 We're founded and started our activities in 1996. We are  
10 concerned by the mandate, with the objective of developing  
11 wireless location and with anticipation of the deadline of  
12 2001. Headquartered in the San Francisco Bay area. We're a  
13 provider of wireless location information for Emergency 911,  
14 and we're anticipating that be the first step in a much  
15 bigger industry.

16 We're a Nasdaq company and in our better days,  
17 we're a \$100 million market count. The market strategy for  
18 U.S. Wireless is to build and operate a nationwide location  
19 service bureau, so we're of the opinion that this market  
20 requires a leadership in operating these services, in  
21 gathering all the moving parts together, and we intend to  
22 offer that leadership and set this capability up as a shared  
23 platform.

24 We're very active in the last couple of years of  
25 setting off systems in a variety of environments. The main

1 places where radio camera product is operating is Oakland,  
2 which is our home; in Billings, Montana; and in Baltimore.  
3 We're expanding a little bit on the Baltimore activity,  
4 where Bell Atlantic is our sponsor. It is also a CDMA  
5 development group event of one of the network CDMA trials.

6 The significance of this investment to be made in  
7 fairly wide and distributed deployment is to gather a  
8 portfolio of a variety of performance environments. As you  
9 can see, you have the fairly steep downtown of Baltimore and  
10 quite complex downtown of Oakland, but also the very rural  
11 environment in Montana. I would expand a little bit on our  
12 Montana involvement, in which we're actually very active.  
13 Recently, we gathered an entire team of companies that you  
14 see on the slide from Western Wireless, who was the carrier,  
15 U.S. West, wire line carrier, Zypoint, Nortel, in offering  
16 an end-to-end 911 event from the caller all the way to the  
17 PSAP, which has operated for the last couple of months on a  
18 211 test basis, in order to avoid obvious liability issues.

19 So we are looking at this as a miniature of  
20 service bureau type scenario. A few words to add to Mark's  
21 description about technology. Radio Camera is a location  
22 fingerprint strategy. The video camera is located at base  
23 stations and extracts complex fingerprints through the  
24 existing antennas at the base station, which it then  
25 measures against a look up table, which is pretrained in

1 that environment. That matching results in a preferred  
2 location of impingement of that handset and the recognition  
3 of its location on the map.

4 The system is sent to end to end tracking  
5 environment, therefore, of course, the tracking of the  
6 motion is being taken into account to generate even better  
7 performance, as I'll show you in a second.

8 An important piece of this deployment is what  
9 exactly is being stored at the base station? This is a  
10 multi-mode radio camera. You can see from the size of it,  
11 this is practically the only installation at the base  
12 station that uses the existing antennas by the carrier.

13 To show you just a touch of the many months of  
14 field trials, you can see our display of the Oakland area,  
15 downtown, as well as suburban, and the Berkeley area, for  
16 whoever is familiar. The little circles you see are many  
17 times of station recalls that were put from those locations  
18 and to flip directly to the summary of the performance, you  
19 can see a 67 percent measure with 69 meters. And ours  
20 measures at 98 meters. And something that is important to  
21 us, also, 90 percent measure at which we're looking, because  
22 we're anticipating directions to be given to callers in the  
23 future, in which we're assuming that the accuracy  
24 requirement might be higher.

25 Going to a different scenario, which is a motion

1 mixed highway and the local roads, extensive trial in that  
2 same environment would result to 65 meters and 57 meters  
3 ours, and it's natural to see a slightly better performance  
4 due to the motion involved in the process.

5 A very interesting document that I just put here  
6 just for reference, we were offered a very concise and well-  
7 designed audit plan by one of the companies here in the  
8 audience, which I would like, with Ron's permission, to  
9 submit as a potential way of standardizing trials of  
10 location systems. Going through everything which is  
11 interesting -- light urban, suburban, in building, near  
12 grid, off grid, stationary, in a well organized fashion.  
13 You can see pretty much a summary of our performance. We're  
14 looking at performance between 40 and 100 meters in all  
15 these environments, and one of the interesting capabilities  
16 of radio camera is also to operated based on a single site  
17 in a remote area, in which, of course, the performance is  
18 likely degraded, but it is an interesting solution for the  
19 states of rural America.

20 A touch of CDMA. I'll put the slide up just to  
21 remind everybody that CDMA is more complex than anything  
22 else we've seen, but these are the famous fingers of CDMA.  
23 CDMA has built a reputation of being the toughest mountain  
24 to climb for location, and I think that people have  
25 forgotten the fact that CDMA is bringing some opportunities

1 that the other standards don't. So it's band wave and it's  
2 a delayed finger strategy by QUALCOMM.

3 Looking at CDMA radio camera performance, you see  
4 quite similar results to what we've seen in amps and, as a  
5 matter of fact, due to the multiple fingers arrangement, the  
6 67 percent measures out to much better than the range of 30  
7 meters. Although, RMS tends to be at the same level to what  
8 we've seen before.

9 We believe that CDMA is a major opportunity for  
10 network solutions through the richness of its signal, not  
11 necessarily a complexity hurdle.

12 The message with wireless is for anyone to work  
13 nationwide, 911 by 2001. The summary, we believe that we  
14 have currently a functioning location system all the way  
15 from urban, which line of sight is a big issue, to sparse  
16 settings. We're looking and required of ourselves a high  
17 performance system with anticipation that the public safety  
18 community will get even hungrier for performance in the  
19 future than the mandate is stipulating.

20 We're looking at trunking as an opportunity of  
21 building additional safety capabilities, as well as  
22 additional business. Again, we're applauding the wireless  
23 capabilities to a shared platform. We believe that this is  
24 going to simplify and going to also, at some extent, focus  
25 the deployment of this capability nationwide. And at this

1 point, in our portfolio, we have amps, TDMA, CDMA and the  
2 next system in our first phase, going to the next second  
3 phase was richer in standards.

4 We're planning we'll focus the entire effort of  
5 the team, as well as the financial backing of the company,  
6 is to make this nationwide capability available by 2001 and  
7 we're here to strengthen the FCC's hands in making sure that  
8 this capability will be out there for the American public.  
9 Thank you.

10 MR. HATFIELD: Thank you. You didn't identify  
11 yourself at the start.

12 DR. HILSENATH: Oh, I'm Oliver Hilsenrath,  
13 President and CEO, U.S. Wireless.

14 MR. HATFIELD: Thank you, and thank you again for  
15 keeping us on time. Next is our representative from KSI  
16 Inc.

17 MR. MALONEY: My name is John Maloney. I'm vice  
18 president and chief scientist at KSI. KSI, as an  
19 organization, is built on a core technical staff that's been  
20 designing and developing location tracking systems for 25  
21 years or more. We realize the value of doing this in the  
22 commercial cellular systems and in 1990, we had it  
23 demonstrated already on normal, everyday, unmodified  
24 cellular phones involved in normal cellular communications.  
25 We described those results to the FCC and were cited in the

1 NPRN initially published in the docket.

2 Those results were, of course, amps based and were  
3 supported with snapshot locations on control channels and  
4 then follow up voice channel continuously updated tracking.  
5 With the infusion of capital in '97, we then advanced the  
6 results and started demonstrating TDMA results last year,  
7 along with the amps results, and right now, we are  
8 evaluating a preliminary results from a rural trial. Top  
9 management and ownership is from the cellular ranks. The  
10 East Coast cellular companies we have had populate our CEO,  
11 COB and vice president and COO positions. Next slide.

12 There's been a lot of misstatements made about  
13 infrastructure approaches and hopefully, with a little bit  
14 of reality, I can dispel some of the myths. As I mentioned,  
15 for a decade now, or in this decade, we have demonstrably  
16 had amps availability and we are right now doing digital  
17 processing with TDMA signals. We have had early sale  
18 agreement with some of our trial equipment, but frankly,  
19 production, full scale production will follow on orders,  
20 which will be, hopefully, stimulated by disambiguation of  
21 the regulatory issues.

22 The requirements have been met with all the data  
23 that we have published throughout the record and in these  
24 years and will continue to be met with all future phones.  
25 We are currently right now implementing software. Our

Heritage Reporting Corporation  
(202) 628-4888

1 operational hardware is in the lab for all the other digital  
2 interfaces besides TDMA. Right now, our rural trials have  
3 gone through preliminary integration testing. The FCC's  
4 requirements have been met and we have, with that system,  
5 done end to end real time location based routing among PSAPs  
6 with cell spacings of 12 to 20 miles.

7           The Commission has asked for comments on  
8 comparative costs. There are lots of different models. A  
9 simple one might ascribe zero cost to the location  
10 enablement. The basic phone itself will cost \$200 and with  
11 1,000 of them per cell site, the \$200,000 would be of the  
12 order of ten-fold of what you might estimate for  
13 infrastructure equipment.

14           You could argue that it's \$150 a handset. You  
15 could argue that there's 1,500 handsets a cell site. You  
16 could amortize costs over time, but the basic conclusion is  
17 that the handset approach is many more time more costly than  
18 the infrastructure.

19           Locations, I repeat, are not required to be  
20 obtained only from three or more sites. We routinely  
21 demonstrate two sites and one site location capabilities,  
22 and, of course, our location calculations are implemented to  
23 optimally exploit whatever information is available. That  
24 includes measurements of angles, times, signal strength,  
25 from however many sites are available, includes the

1 collateral information such as road map data. And when area  
2 interfaces are modified to support transmission of handset  
3 derived location information, our calculations already  
4 include the capability to exploit that information in the  
5 location calculation. Next slide.

6 So the TeleSentinel, our system name development,  
7 has already demonstrated amps and TDMA. Our hardware in lab  
8 revel, is being augmented with the software to support the  
9 other interfaces and to be rebanded to the other  
10 frequencies. The SMR will be a super modification of the  
11 TDMA capability, since it's very similar in band width.

12 Others of my colleagues here at the table have  
13 already achieved the colleagues in other error interfaces  
14 that we have not yet. Next.

15 So the location infrastructure benefits certainly  
16 support all phones, all the time, all interfaces, all  
17 services, even enhanced communication services, which will  
18 benefit 911 also, and provide for security, both at the  
19 personal and public level. Next.

20 Basic issues we think the Commission should look  
21 into are how are amps handsets going to be located? We have  
22 heard that GPS processing and signals are very similar to  
23 those of CDMA signals and can be accommodated with your  
24 interface changes to allow for data transmissions. But even  
25 a CDMA signal operates as an amps phone in a rural
