Simply stated, soil quality can be defined as the capacity of a particular soil to perform a specific soil function. Soil quality is comprised of three interdependent components – the biological, the chemical, and the physical. Several indicators of soil quality have been identified within each component. Practical field tools and approaches have been developed to measure these indicators to assess the quality of a soil. Data and observations made will aid in making better decisions to sustain and improve the soil resource for future generations.

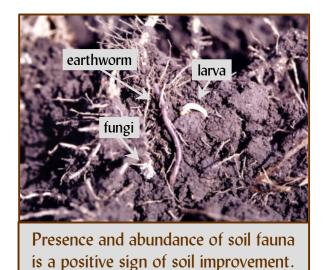

Acknowledgments: The USDA – Natural Resources Conservation Service Soil Quality Team would like to recognize the collaboration efforts of USDA – Agriculture Research Service for the development of the soil quality tool kit, and for providing science-based information and technology to help develop this poster.

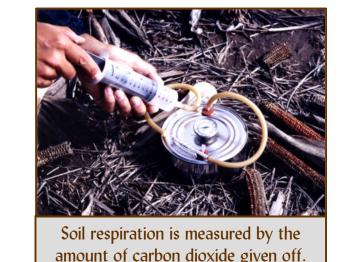

Biological Indicators

Biological soil indicators increase awareness of the soil as a dynamic and living system. The soil food web is a complex system consisting of earthworms, fungi, bacteria, mites, ants, beetles, and numerous other organisms. Measurements of organic matter, earthworm populations, soil respiration, decomposition rates, crop yields, and also the smell of the soil have been used as biological indicators.

with a healthy soil.

Cotton strips measure decomposition

Darker soil (right) indicates more organic matter and better nutrient cycling.

Chemical Indicators

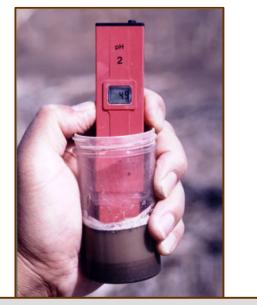

The chemical component of the soil has an effect on the available plant nutrients, soil and plant relationships, soil's buffering capacity, water quality, and mobility of soil nutrients and contaminants. Cation-exchange capacity, soil pH, electrical conductivity, and nitrate-nitrogen are among the chemical indicators that help determine the capacity of the soil to store and release nutrients, and can also be indicators of potential soil, plant, and ground water toxicity.

A pocket electrical conductivity meter is a quick method to measure salts in the soil solution.

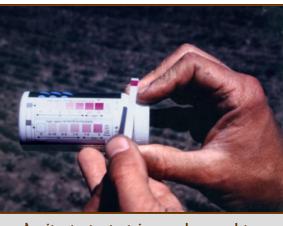

Soil salinity can influence biological, chemical, and physical properties and processes in soils.

Soil pH can be measured with a pocket pH meter.

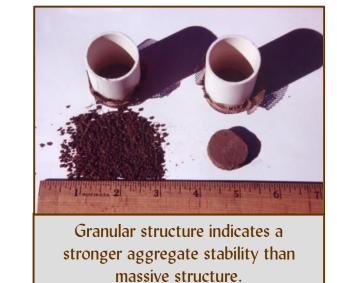

In arid regions, depth to calcium carbonate can be used as a soil quality indicator.

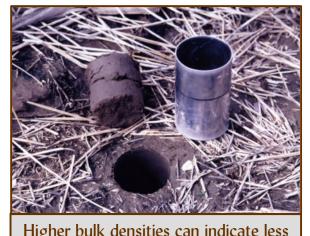

A nitrate test strip can be used to determine nitrate-nitrogen levels in the soil.

Physical Indicators

Physical characteristics of the soil refer to the arrangement of solid particles and pores. Physical indicators such as texture, infiltration rate, bulk density, soil compaction, aggregate stability, and soil crusting can help determine how well water and roots are able to move through the soil and how stable the soil resource is to the effects of climate. Top soil thickness, soil color, subsoil exposure, sediment fans, and soil structure are visual examples of physical indicators.

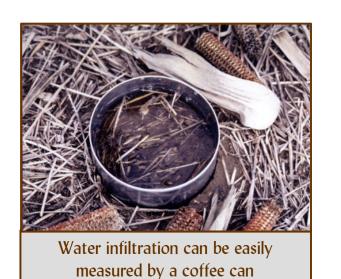

Higher bulk densities can indicate less pore space, less oxygen, and increased resistance to root penetration.

Soil compaction has restricted root development on the wheel track.

infiltrometer.

Wind and water erosion degrade soil

The U.S. Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, gender, religion, age, disability, political beliefs, sexual orientation, and marital or family status. (Not all prohibited bases apply to all programs.) tact USDA's TARGET Center at 202-720-2600 (voice and TDD). To file a complaint of discrimination, write USDA, Director, Office of Civil Rights, Room 326W, Whitten Building, 14th and Independence Avenue, SW, Washington, DC 20250-9410 or call 202-720-5964 (voice or TDD).

USDA is an equal opportunity provider and employer.

Enhanced soil quality can help to reduce the cost of soil erosion, improve nutrient efficiencies, and ensure that the soil resource is sustained for future use. The information that is gathered can be used in different ways: (1) as benchmarks to compare with future soil quality measurements; (2) to determine the present condition of the soil resource as compared to its inherent potential; and (3) to determine which management practices could be applied to enhance the soil resource.
