# World No Tobacco Day — May 31, 2008

The theme for World No Tobacco Day 2008 is Tobacco-Free Youth: Break the Tobacco Marketing Net. The tobacco industry spends billions of dollars worldwide on advertising, promotion, and sponsorship. Recent data from the Global Youth Tobacco Survey indicate an increase in tobacco use among adolescent girls in many countries (1). Much of this increase has been attributed to aggressive marketing by the tobacco industry (2), which encourages potential users, especially adolescents, to try tobacco and become long-term consumers.

Evidence-based tobacco-control strategies that are comprehensive, sustained, and support nonsmoking behaviors have been shown to prevent and reduce tobacco use (3). The World Health Organization Framework Convention on Tobacco Control calls on countries to implement scientifically proven measures to reduce tobacco use and its impact (4). Additional information on World No Tobacco Day 2008 activities is available at http://www.who.int/tobacco/wntd/2008/en/index.html

## Tobacco Use Among Students Aged 13–15 Years — Sri Lanka, 1999–2007

Tobacco use is one of the major preventable causes of premature death and disease in the world (1). The World Health Organization (WHO) attributes approximately 5 million deaths per year to tobacco use, a number expected to exceed 8 million per year by 2030 (2). In 1999, the Global Youth Tobacco Survey (GYTS) was initiated by WHO, CDC, and the Canadian Public Health Association to monitor tobacco use, attitudes about tobacco use, and exposure to secondhand smoke (SHS) among students aged 13-15 years. Since 1999, the survey has been completed by approximately 2 million students in 151 countries (3). A key goal of GYTS is for countries to repeat the survey every 4 years. This report summarizes results from GYTS conducted in Sri Lanka in 1999, 2003, and 2007. The findings indicated that during 1999-2007, the percentage of students aged 13-15 years who reported current cigarette smoking decreased, from 4.0% in 1999 to 1.2% in 2007. During this period, the percentage of never smokers in this age group likely to initiate smoking also decreased, from 5.1% in 1999 to 3.7% in 2007. Future declines in tobacco use in Sri Lanka will be enhanced through development and implementation of new tobacco-control measures and strengthening of existing measures that encourage smokers to quit, eliminate exposure to SHS, and encourage persons not to initiate tobacco use.

GYTS is a school-based survey that collects data on students aged 13-15 years using a standardized methodology for constructing the sample frame, selecting schools and classes, and processing data. The Sri Lanka GYTS uses a two-stage cluster sample design that produces representative samples of students in grades 8-10, which are associated with ages 13–15 years (3). At the first sampling stage, school selection was proportional to the number of students enrolled in grades 8-10. At the second stage, classes within the selected schools were randomly selected. All students attending school in the selected classes on the day the survey was administered were eligible to participate. A weighting factor was applied to each student record to adjust for nonresponse (by school, class, and student) and probability of selection at the school and class levels (3). A final adjustment sums the weights by grade and sex to the population of school children in the selected grades in each sample site (3). In 1999, a total of 2,896 students completed GYTS; 1,845 did so in 2003, and 1,764 did so in 2007. The school response rate was 85.7% in 1999, 100% in 2003, and 100% in 2007. The class response rate was 100% in all survey years. The student response rate was 89.0% in 1999, 79.1% in 2003, and 85.0% in 2007. The overall response rate was 76.3% in 1999, 79.1% in 2003, and 85.0% in 2007.\*

This report describes changes during 1999-2007 in several important tobacco-use indicators, including 1) lifetime cigarette smoking<sup>†</sup>; 2) current cigarette smoking<sup>§</sup>; 3) current use of other tobacco products<sup>9</sup>; 4) likely initiation of smoking in the next year among never smokers (i.e., susceptibility) (4)\*\*; 5) exposure to SHS in public places<sup>††</sup>; 6) exposure to pro-tobacco advertising and promotion, either direct (e.g., exposure to billboards, newspapers, and magazines) or indirect (having been offered a free cigarette by a cigarette company representative or having an object

<sup>\*</sup> The overall response rate is calculated as the school response rate × the class response rate × the student response rate.

<sup>†</sup> Based on a positive response to the question, "Have you ever tried or experimented with cigarette smoking, even one or two puffs?"

<sup>§</sup> Based on a response of "1 or more days" to the question, "During the past 30 days (1 month), on how many days did you smoke cigarettes?"

Based on positive responses to either of the following questions: "During the past 30 days (1 month), did you use any form of smoked tobacco products other than cigarettes (e.g., cigars, water pipe, cigarillos, little cigars, or pipes)?" and "During the past 30 days (1 month), did you use any form of smokeless tobacco products (e.g., chewing tobacco, snuff, or dip)?'

<sup>\*\*</sup> Based on a responses of anything but "definitely no" to the questions, "If your best friend offered you a cigarette, would you smoke it?" and "Do you think you will try smoking a cigarette in the next year?"

 $<sup>^{\</sup>dagger\dagger}$  Based on a response of "1 or more days" to the question, "During the past 7 days, on how many days have people smoked in your presence, in places other than your home?"

with a cigarette logo on it)<sup>§§</sup>; 7) cessation efforts (among current smokers)<sup>§§</sup>; and 8) tobacco education.\*\*\* Statistical differences were determined by comparing 95% confidence intervals; nonoverlapping confidence intervals were considered statistically significant. Data are based on at least 35 respondents for each denominator.

The percentage of students aged 13–15 years in Sri Lanka who reported lifetime cigarette smoking declined from 1999 (12.1%) to 2003 (6.3%); the percentage in 2007 (5.1%) was not significantly different from 2003 (Table 1). Boys were more likely than girls to have ever smoked cigarettes in 1999 and 2003, but no significant difference was observed in 2007. For boys, current cigarette smoking decreased from 1999 (6.2%) to 2007 (1.6%); for girls the percentage did not change significantly. Boys were more likely than girls to smoke cigarettes in 1999, but no significant difference was observed in 2003 and 2007. Current use of other tobacco products remained unchanged from 1999 and 2007, both overall and for both sexes. Boys were more likely than girls to use other tobacco products in 1999, but no significant difference was observed in 2003 and 2007. Current use of other tobacco products was higher than cigarette smoking overall in 1999, 2003, and 2007; for boys in 2003 and 2007; and for girls in 1999 and 2003. The percentage of never smokers who were susceptible to initiation of smoking did not change significantly from 1999 to 2007, both overall and for both sexes. Susceptibility was higher for boys than girls in 1999, but no significant difference was observed in 2003 and 2007.

The percentage of students who reported that their parents smoke decreased from 50.8% in 1999 to 41.2% in 2003 to 29.9% in 2007; however, exposure to SHS in public places remained unchanged over time (67.9% in 1999 and 65.9% in 2007) (Table 2). Support for a ban on smoking in public places did not change from 1999 (91.4%) to 2007 (87.9%).

Exposure to cigarette advertising and promotion decreased from 1999 to 2007. The percentage of students who saw pro-cigarette advertisements on billboards did not change from 1999 to 2003 but decreased from 2003 (79.3%) to 2007 (67.4%). The percentage of students who saw pro-cigarette advertisements in newspapers or magazines decreased from 1999 to 2007 (83.4% in 1999, 78.4% in 2003, and 68.4% in 2007). The percentage of students who owned an item with a cigarette brand logo on it did not change from 1999 to 2003 but decreased from 2003 (11.0%) to 2007 (5.7%). The percentage of students who reported receiving free cigarettes from a cigarette company representative decreased from 1999 (6.4%) to 2007 (3.0%).

In 2007, 76.5% of current smokers indicated that they would like to stop smoking; this percentage was not significantly different from 1999 to 2007. The percentage of students who reported having been taught in school during the past school year about the dangers of tobacco use increased from 1999 (62.7%) to 2003 (79.8%) but remained unchanged from 2003 to 2007 (72.8%).

**Reported by:** PW Gunasekara, Ministry of Education, Sri Lanka. K Rahman, PhD, DN Sinha, MD, South-East Asia Regional Office, World Health Organization, New Delhi, India. CW Warren, PhD, J Lee, MPH, V Lea, MPH, S Asma, DDS, CDC.

**Editorial Note:** The findings in this report indicate that, among students aged 13–15 years in Sri Lanka, cigarette smoking and the likely initiation of smoking by never smokers decreased from 1999 to 2007, whereas other tobacco use remained unchanged over time. During 1999–2007, other tobacco use was consistently higher than cigarette smoking.

Some of the changes in tobacco use reflected in this analysis can be attributed to various tobacco-control policies implemented by the government of Sri Lanka (2). In 2003, Sri Lanka ratified the WHO Framework Convention on Tobacco Control (WHO FCTC) (5). In 2006, the Parliament of Sri Lanka enacted the National Authority on Tobacco and Alcohol Act (NATAA) (6). NATAA includes 1) a ban on smoking in health-care, education, and government facilities and in universities, indoor offices, and other indoor workplaces; 2) prohibition of pro-tobacco advertisements on national television and radio, in local magazines and newspapers, on billboards, at point of sale, and on the Internet; and 3) a ban on tobacco-product promotions, such as free distribution, promotional discounts, and sponsored events. In concordance with NATAA, Sri Lanka has enacted strong enforcement policies (2).

Based on 1) a response of "a lot" or "a few" to the question, "During the past 30 days (1 month), how many advertisements for cigarettes have you seen on billboards?" 2) a response of "a lot" or "a few" to the question, "During the past 30 days (1 month), how many advertisements or promotions for cigarettes have you seen in newspapers or magazines?" 3) a positive response to the question, "Do you have something (t-shirt, pen, backpack, etc.) with a cigarette brand logo on it?" and 4) a positive response to the question, "Has a cigarette company representative ever offered you a free cigarette?

Based on a response of "1 or more days" to the question, "During the past 30 days (1 month), on how many days did you smoke cigarettes?" and a positive response to the question, "Do you want to stop smoking now?"

<sup>\*\*\*</sup> Based on a positive response to the question, "During this school year, were you taught in any of your classes about the dangers of smoking?"

TABLE 1. Percentage of students aged 13-15 years who reported using tobacco products and, among never smokers, percentage likely to initiate smoking in the next year, by sex and year — Global Youth Tobacco Survey, Sri Lanka, 1999, 2003, and 2007

Confidence interval.

Exposure to pro-cigarette advertising and promotion declined from 1999 to 2007, but exposure to SHS in public places did not decrease. One reason for this might be that the NATAA ban on SHS exposure does not include smoking in restaurants, pubs, or bars; thus, the overall impact of the ban might be limited. To protect the health of all persons from the harmful effects of SHS, WHO recommends that countries enact and enforce legislation

requiring all indoor workplaces and public places to be 100% smoke-free (7). GYTS has been shown to be useful for monitoring the impact of NATAA provisions (3), and it will be a useful data source for monitoring the impact of the WHO FCTC.

The findings in this report are subject to at least three limitations. First, because the sample surveyed was limited to youths attending school, it is not representative of all Sri

<sup>†</sup> Based on a positive response to the question, "Have you ever tried or experimented with cigarette smoking, even one or two puffs?"

<sup>§</sup> Based on a response of "1 or more days" to the question, "During the past 30 days (1 month), on how many days did you smoke cigarettes?"

¶ Based on positive responses to either of the following questions: "During the past 30 days (1 month), did you use any form of smoked tobacco products other than cigarettes (e.g., cigars, water pipe, cigarillos, little cigars, or pipes)?" and "During the past 30 days (1 month), did you use any form of smokeless tobacco products (e.g., chewing tobacco, snuff, or dip)?"

Based on a responses of anything but "definitely no" to the questions, "If your best friend offered you a cigarette, would you smoke it?" and "Do you think you will try smoking a cigarette in the next year?

Based on a response of "1 or more days" to the question, "During the past 30 days (1 month), on how many days did you smoke cigarettes?" and a positive response to the question, "Do you want to stop smoking now?"

Lanka youths aged 13–15 years. Second, the findings apply only to youths who were in school on the day the survey was administered and who completed the survey. However, student response was high (89% in 1999, 79% in 2003, and 85% in 2007), suggesting that bias attributed to absence or nonresponse was limited. Finally, data are based on self-reports of students, who might have underreported or overreported their tobacco use or that of their parents. The extent of this bias cannot be determined; however, responses to tobacco-related questions on surveys similar to GYTS have shown good test-retest reliability (8).

Comprehensive tobacco-control programs are the most effective means to reduce tobacco use (1). Such programs include demand-reduction measures (primarily those that increase the price of tobacco) and other interventions, such as restrictions on smoking in public places and work places, a complete ban on advertising and promotion by tobacco companies, dissemination of information on the health consequences of smoking through various media (e.g., prominent warning labels on cigarette packets and counter-marketing campaigns), and development and implementation of school-based educational programs in combination with community-based activities. Although current cigarette smoking is low among students aged 13-15 years in Sri Lanka (1.2% in 2007), future declines in the use of other tobacco products will depend on development of new measures aimed at those products.

# State Smoking Restrictions for Private-Sector Worksites, Restaurants, and Bars — United States, 2004 and 2007

Secondhand smoke (SHS) contains more than 50 carcinogens and causes heart disease and lung cancer in nonsmoking adults (1). Eliminating smoking in indoor spaces is the only way to fully protect nonsmokers from SHS exposure (1). Smoking restrictions limit smoking to certain areas within a venue; smoke-free policies prohibit smoking within the entire venue. A *Healthy People 2010* objective (27-13) calls for establishing laws in all 50 states and the District of Columbia (DC) that make indoor public places and worksites completely smoke-free (2). To assess progress toward meeting this objective, CDC reviewed the status of state laws restricting smoking in effect as of December 31, 2007, updating a 2005 study that reported on such laws as of December 31, 2004 (3). This report summarizes the changes in state smoking restrictions for private-sector worksites, restaurants, and bars that occurred from 2004 to 2007. The findings indicated a substantial increase in the number and restrictiveness of state laws regulating smoking in these three settings, providing nonsmokers with increased protection from the health risks posed by SHS. If current trends continue, achieving the national health objective by 2010 might be possible.

This report focuses on smoking restrictions in indoor areas in private-sector worksites, restaurants, and bars. These three settings were selected because worksites are a major source of SHS exposure for nonsmokers and because workers in restaurants and bars are especially likely to be exposed to SHS, often at high concentrations (1). The smoking restrictions in effect in each of the 50 states and DC\* as of December 31, 2004, and December 31, 2007, were categorized into one of four levels (Table). The four levels were 1) no restrictions, 2) designated smoking areas required or allowed (i.e., smoking is restricted to specific areas), 3) no smoking allowed or designated smoking areas allowed if separately ventilated, and 4) no smoking allowed (i.e., 100% smoke-free). These data were compiled from CDC's State Tobacco Activities Tracking and Evaluation (STATE) System database, which contains tobacco-related epidemiologic and economic data and information on state tobacco-related legislation (4). The data used for this

<sup>\*</sup> For this report, DC is included among results for states.

<sup>\*</sup>None = no restrictions; designated = designated smoking areas required or allowed; ventilated = no smoking allowed or designated smoking areas allowed if separately ventilated; smoke-free = no smoking allowed (i.e., 100% smoke-free).

Restriction exempts restaurants that are off-limits to minors.

Restriction bans smoking in most settings, but exempts separately ventilated employee break rooms or lounges.

Restriction bans smoking in most settings, but exempts separately verminated employee broak rooms of loanges.

Corrected from 2005 report. Idaho and Maryland were previously listed as making private-sector workplaces smoke-free. Vermont was previously listed as making restaurants smoke-free.

report were collected quarterly from an online database of state laws, analyzed using a coding scheme and decision rules, and transferred into the STATE System database. The STATE System tracks state smoking restrictions in government worksites, private-sector worksites, restaurants, bars, commercial and home-based child care centers, and other settings, including shopping malls, grocery stores, enclosed arenas, public transportation, hospitals, prisons, and hotels and motels. Tobacco-control personnel in state health departments reviewed and verified the coding of smoking restrictions in their states.

This study did not include laws that were enacted or became effective after December 31, 2007. For example, Illinois and Maryland enacted smoking restrictions in 2007 that went into effect in early 2008, and were therefore not included in this study.

During December 31, 2004-December 31, 2007, based on the effective date of state laws (i.e., the date that these laws actually took effect, not the date they were enacted) and the STATE System coding scheme, the level of smoking restrictions became more protective for private-sector worksites in 18 states, for restaurants in 18 states, and for bars in 12 states. No states relaxed their smoking restrictions in any of these three settings during the study period. In addition, the number of states requiring private-sector worksites to be smoke-free increased from five to 22. As of December 31, 2004, Delaware, Florida, Massachusetts, New York, and South Dakota had banned smoking in private-sector worksites. As of December 31, 2007, an additional 17 states (Arizona, Arkansas, Colorado, DC, Hawaii, Louisiana, Minnesota, Montana, Nevada, New Jersey, New Mexico, North Dakota, Ohio, Rhode Island, Tennessee, Utah, and Washington) had done so. During the study period, the number of states with no smoking restrictions in place for private-sector worksites decreased from 24 to 13.

During the 3 years ending December 31, 2007, the number of states requiring restaurants to be smoke-free increased from seven to 21. By the end of 2004, Delaware, Florida, Idaho, Maine, Massachusetts, New York, and Utah had banned smoking in restaurants. As of December 31, 2007, 14 additional states (Arizona, Colorado, DC, Hawaii, Louisiana, Minnesota, Montana, Nevada, New Hampshire, New Jersey, Ohio, Rhode Island, Tennessee, and Washington) had done so. During this same period, the number of states with no smoking restrictions for restaurants decreased from 19 to nine.

During the same 3-year period, the number of states requiring bars to be smoke-free increased from four to 13. By the end of 2004, Delaware, Maine, Massachusetts, and New York had banned smoking in bars. As of December 31, 2007, an additional nine states (Arizona, Colorado, DC, Hawaii, Minnesota, New Jersey, Ohio, Rhode Island, and Washington) had done so. During the 3 years of this study, the number of states with no smoking restrictions for bars decreased from 43 to 31.

From December 31, 2004 to December 31, 2007, the number of states requiring all three venues included in this study to be smoke-free increased from three to 12. By the end of 2004, Delaware, Massachusetts, and New York had banned smoking in all three settings. As of December 31, 2007, Arizona, Colorado, DC, Hawaii, Minnesota, New Jersey, Ohio, Rhode Island, and Washington also had implemented such comprehensive laws. During the study period, the number of states with smoke-free provisions in place in at least one of the three settings included in this study increased from eight to 25. During this same period, the number of states without any smoking restrictions in place for any of these settings decreased from 16 to eight. **Reported by:** M Tynan, Maya Tech Corporation, Silver Spring, Maryland. S Babb, MPH, A MacNeil, MPH, Office on Smoking and Health, National Center for Chronic Disease Prevention and Health Promotion, CDC.

**Editorial Note:** The findings of this analysis indicate that the number and restrictiveness of state laws regulating smoking in private-sector worksites, restaurants, and bars increased substantially from December 31, 2004, to December 31, 2007. This increase has provided U.S. non-smokers with increased protection from SHS exposure and its health effects (1).

As of 2003, the most recent data available, 77% of U.S. indoor workers aged ≥18 years reported that their workplace had an official policy that prohibited smoking in indoor work areas and public or common areas (5), compared with 47% during 1992–1993 (1). However, the proportion of workers covered by such policies varied by occupation. In 2003, for example, 83% of white collar workers reported working under a smoke-free workplace policy, compared with 75% of service workers, 63% of blue collar workers, and 72% of food-service workers (5). As a result of continuing gaps and disparities in policy coverage for many private-sector worksites, restaurants, and bars, millions of U.S. nonsmokers continue to be exposed to SHS and its health effects in these settings, either as employees or as patrons.

Smoke-free workplace policies are the only effective approach to ensure that SHS exposure does not occur in the workplace (1). Separating smokers from nonsmokers, cleaning the air, and ventilating buildings cannot eliminate SHS exposure (1). Smoke-free laws and policies reduce SHS exposure and improve health among nonsmoking restaurant and bar employees, and reduce SHS exposure among nonsmokers in general, as assessed by self-report and objective measures (1,6-8). Smoke-free workplace policies also help smokers quit (1). Smoke-free policies do not have an adverse economic effect on restaurants and bars (1). Studies also have reported high levels of public support for and compliance with smoke-free laws (1).

The findings in this report are subject to at least three limitations. First, the STATE System captures only certain types of state smoking restrictions (primarily statutory laws and executive orders) and does not capture state administrative laws, regulations, or implementation guidelines. As a result, the manner in which a state smoking restriction is implemented in practice might differ from how it is coded in the STATE System. Second, some state smoking restrictions apply only to private-sector worksites with more than a specified number of employees, to restaurants with more than a specified number of seats, or to bars of at least a certain size. In these cases, the state laws were coded according to the level of these restrictions, even though these restrictions do not apply to venues that are below the specified limits. Finally, because the STATE System only collects state-level data, it does not reflect local smoking restrictions in effect in many states.

The 2006 Surgeon General's Report on *The Health Consequences of Involuntary Exposure to Tobacco Smoke* concluded that SHS causes premature death and disease in children and nonsmoking adults (1). The report also concluded that no level of SHS exposure is risk free and that only completely smoke-free environments fully protect nonsmokers from SHS exposure (1). States, communities, employers, business proprietors, and the public are acting on this information to reduce SHS exposure. The American Nonsmokers' Rights Foundation estimates that, as of April 2008, 33% of U.S. residents have been living under state or local laws that make worksites, restaurants, and bars completely smoke-free, and 64% of U.S. residents have

been living under state or local laws making at least one of these three settings smoke-free (9). Largely because of the trend toward increased protection by state and local smoke-free laws and voluntary policies covering worksites and public places, SHS exposure among U.S. nonsmokers has decreased substantially since 1988 (10). The trends in the adoption of state smoking restrictions described in this report suggest that the national health objective of establishing laws making indoor public places and worksites smoke-free in all states by the year 2010 might be achievable.

## Increased Detections and Severe Neonatal Disease Associated with Coxsackievirus B1 Infection — United States, 2007

Enteroviruses generally cause mild disease; however, neonates are at higher risk for severe illness because of the immaturity of their immune systems. Neonatal systemic enterovirus disease, characterized by multiorgan involvement, is among the most serious, potentially fatal conditions associated with enterovirus infection. Typical clinical presentations include encephalomyocarditis (characteristic of group B coxsackieviruses) and hemorrhage-hepatitis syndrome (typical of echovirus 11) (1,2). To describe the severity of neonatal illness associated with coxsackievirus B1 (CVB1) infection, CDC analyzed case reports and preliminary data from the National Enterovirus Surveillance System (NESS) for 2007. This report describes the results of that analysis, which indicated that, in 2007, CVB1 for the first time was the predominant enterovirus in the United States, accounting for 113 (25%) of 444 enterovirus infections with known serotypes. In addition, phylogenetic analysis of the 2007 CVB1 strains suggested that the cases resulted from widespread circulation of a single genetic lineage. Health-care providers and public health departments should be vigilant to the possibility of neonatal disease caused by CVB1. Testing for enteroviruses in clinically compatible cases and reporting of identified enteroviruses to NESS should be encouraged.

NESS is a voluntary, passive surveillance system for monitoring enterovirus infections in the United States. Participating laboratories, which include public health and private laboratories and the CDC Picornavirus Laboratory, report enterovirus detections to NESS on a monthly basis. Each report includes age, sex, state, specimen type and collection date, and enterovirus serotype.

Beginning in August 2007, CDC received multiple reports of cases of severe neonatal illness and death associated with enterovirus infection. CVB1 was identified as the causative agent in many of these cases. Previously, no fatal infection of CVB1 had been reported to NESS (3). On the basis of these reports, CDC began a review of clinical, virologic, and surveillance data related to enterovirus for 2007, in collaboration with local and state public health departments and hospitals. A case of CVB1 infection was defined as detection of enterovirus by reverse transcription—polymerase chain reaction (RT-PCR) or viral culture, with the virus typed as CVB1 by molecular (i.e., RT-PCR sequencing) or antigenic (i.e., neutralization or immunof-luorescence) methods.

As of February 1, 2008, NESS had received 514 reports of enterovirus infections in 36 states for 2007. CVB1 was the most commonly detected enterovirus reported to NESS, accounting for 113 (25%) of 444 reports with known serotypes (Figure). Other most frequently reported serotypes included echovirus 18 (63 [14%]), echovirus 9 (49 [11%]), and echovirus 6 (37 [8%]). Children aged <1 year accounted for 65 (68%) of 95 CVB1 reports with known age, including 50 (53%) infants aged ≤1 month. CVB1 was detected in 19 states; 58% of all CVB1 detections were reported from California (n = 38) and Illinois (n = 28).

Phylogenetic analysis of current CVB1 strains based on partial sequence of the VP1 gene revealed that all were closely related to each other and to a 2006 strain from Colorado. Analysis also revealed that the strains were more distantly related to earlier strains.

A total of five CVB1-associated neonatal deaths were identified: two from California, one from Illinois, and one death each from Colorado and New Mexico. These came to CDC attention in connection with requests for laboratory assistance (Table). In all five cases, the neonates had multisystem disease with onset within the first 4 days of life. In four of the five fatal cases, the mothers had febrile illness or chorioamnionitis around the time of delivery, suggesting vertical mother-to-infant transmission.

The three distinct clusters of severe enterovirus illness, including illnesses caused by CVB1, detected in Los Angeles, California, Chicago, Illinois, and Kotzebue, Alaska, during 2007 are described below.

Los Angeles County, California. In September 2007, in response to reports of three cases (two of them fatal) of neonatal enterovirus myocarditis, including two in CVB1-positive neonates, the Los Angeles County Department of Public Health asked all hospitals in the county to report

FIGURE. Number of reports of coxsackievirus B1 (CVB1) infection and percentage of CVB1 reports among all enterovirus infections with known serotypes — National Enterovirus Surveillance System, United States, 1970–2007

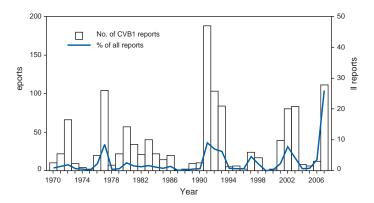

TABLE. Clinical summaries of five fatal cases of neonatal coxsackievirus B1 (CVB1) infection reported to CDC — United States, 2007

Case no.	State	Clinical summary	Virus detection
1	California	A full-term male was born via cesarean delivery. His mother had a peripartum fever. The infant went home with his mother on day 5 of life. He was admitted to the hospital on day 7 with thrombocytopenia, hepatitis, and myocarditis. The infant died the next day. Autopsy revealed severe hepatitis with extensive necrosis, severe myocarditis, and pneumonitis.	CVB1 isolated from blood
2	California	A full-term female was born via normal spontaneous vaginal delivery. Her mother was febrile during labor. The infant became febrile 36 hours after birth. She was diagnosed with myocarditis, meningitis, respiratory distress, and disseminated intravascular coagulation on day 4 of life; she died the same day.	CVB1 isolated from cerebrospinal fluid (CSF)
3	Illinois	A male was born via cesarean delivery at 37 weeks. His mother had chorioamnionitis. The infant developed fever on day 3 of life and was diagnosed with severe myocarditis and hepatitis on day 5; respiratory failure and cardio-vascular collapse ensued on day 7. The infant received intraveneous immuno-globulin on day 11 and was started on steroids on day 12. He died from severe myocardial dysfunction on day 12.	CVB1 detected by reverse transcription-polymerase chain reaction (RT-PCR) in CSF and isolated postmortem from heart tissue
4	Colorado	A full-term male was born via normal spontaneous vaginal delivery. He developed respiratory problems on day 5 of life and thrombocytopenia on day 7. He was diagnosed with enteroviral myocarditis on day 10 after acute cardiac decompensation. Subsequently, he had multiorgan failure with hepatic and renal dysfunction, persistent pulmonary hemorrhage, and bilateral intracranial hemorrhage. He was removed from life support on day 23 and died.	CVB1 detected by RT-PCR in CSF and in serum
5	New Mexico	A female was born via spontaneous vaginal delivery at 34.5 weeks. Before delivery, her mother had abdominal pain, fever, nausea, vomiting, and maternal/fetal tachycardia. The infant developed respiratory distress, requiring life support on day 5 of life, followed by thrombocytopenia and intracranial hemorrhage on day 6. She died on day 7. Autopsy revealed significant frontal lobe hemorrhagic infarcts, encephalitis, massive acute hepatic necrosis, interstitial edema, airspace hemorrhage, and patchy hyaline membranes in lungs.	CVB1 isolated premortem from nasopharyngeal and rectal swabs and isolated postmortem from lungs and nasopharyngeal swab

all enterovirus-positive cases of severe or fatal myocarditis, aseptic meningitis, or sepsis-like febrile illness that occurred among children during June–November 2007.

A total of 30 enterovirus-positive patients from seven hospitals were identified (all with illness diagnosed by RT-PCR). Median age was 15 days (range: <1 day–14 years); 22 (73%) were aged <1 month. Four (13%) patients aged <1–7 days died, and another 14 (47%) required intensive-care unit (ICU) treatment. Clinical presentations included meningitis (22 patients), myocarditis (12), sepsis-like illness (five), hepatitis (two), coagulopathy (six), and respiratory difficulties (three). Eleven patients, including all nine patients aged <7 days at admission, had illness with multiorgan involvement.

Enterovirus serotype was determined in 19 cases for which isolates obtained by viral culture were available. CVB1 accounted for 14 cases; CVB2 accounted for two cases, and CVB3, CVB4, and echoviruses 7 and 11 accounted for one case each. One patient was coinfected with CVB1 and CVB3. Two of the four patients who died were infected with CVB1 (Table). Specimens from the other two patients who died were not available for virus characterization.

**Chicago, Illinois.** In September 2007, the CDC Picornavirus Laboratory identified CVB1 as the source of

infection in two cases of severe neonatal disease at Children's Memorial Hospital in Chicago. Subsequently, a review of the hospital's laboratory and medical records was conducted to identify additional enterovirus-positive cases and obtain diagnoses and clinical syndrome information. Fifty enterovirus-positive children (all diagnosed by RT-PCR) were admitted during June 6–November 2, 2007, a two-fold increase compared with the entire years 2005 (25 patients) and 2006 (26 patients). Median age of patients was 33 days (range: <1 day−8 years); 40 (80%) patients were aged ≤1 month.

Serotype was determined for nine patients admitted to ICU; CVB1 was found in eight patients, and echovirus 18 in one patient. In two other patients, an enterovirus was identified by immunofluorescence staining as a group B coxsackievirus. Specimens from the remaining 39 RT-PCR-positive patients were not available for further virus characterization.

Twelve (24%) infants aged <1–12 days required ICU admission. Their clinical presentations included myocarditis (11 patients), respiratory distress (nine), hepatitis (eight), coagulopathy (six patients), aseptic meningitis (four), and meningoencephalitis (three). Eleven (92%) patients had multiorgan involvement, including five with myocarditis,

meningitis, or meningoencephalitis, and hepatitis (three also had coagulopathy). One CVB1-positive patient died (Table), and one required heart transplantation.

Kotzebue, Alaska. In early September 2007, Maniilaq Health Center notified the Alaska Department of Health and Social Services of an increase in severe febrile illness among hospitalized young infants (including three with myocarditis). Medical record review indicated that during August 15-September 11, 2007, seven infants aged ≤1 month (23% of 31 babies born in the Northwest Arctic Borough region since July 1, 2007) had been admitted to the health center with fever and respiratory distress, myocarditis, or meningitis (median age: 18 days; range: 5-48 days). Six patients, five with multiorgan involvement, required ICU treatment, referral to a higher-level hospital, or both. Of these, three patients had myocarditis with aseptic meningitis and respiratory failure (including one with elevated liver enzymes and coagulopathy), two had aseptic meningitis and respiratory distress, and one had aseptic meningitis. The patient with milder illness had a febrile syndrome. None of the patients died.

One patient with myocarditis tested enterovirus-positive by RT-PCR, but the specimen was not available for further virus characterization. CVB1 was isolated from a stool specimen of the patient with aseptic meningitis. The etiologic agent remained unknown in five cases. In addition, CVB1 was isolated from a respiratory specimen of an infant aged 12 months with pneumonia who was treated at the health center as an outpatient during the same period.

Editorial Note: In 2007, an increased level of CVB1 activity was associated with severe neonatal disease and multiple deaths in the United States. The actual extent of CVB1-associated morbidity and mortality likely was much greater because 1) nonpolio enterovirus infections are not nationally reportable, 2) diagnostic testing for enteroviruses

often is not pursued in clinical settings, and 3) serotype identification from enterovirus-positive specimens is not performed routinely. CVB1 has an epidemic pattern of circulation, with increases usually lasting 2-3 years (Figure). During 1970–2005, CVB1 accounted for a small (2.3%) but increasing proportion of all enteroviruses reported in the United States (3). In 2007, CVB1 was the most commonly reported serotype, accounting for 25% of all reported enterovirus infections with known serotypes. Until 2007, CVB1 had never been the most commonly reported serotype and, even in peak years, accounted for <10% of all enterovirus reports (Figure). The year 2007 also was unusual for the number of CVB1-associated fatalities reported to NESS: 5 fatal cases were reported for the year. CVB1associated deaths are reported rarely (4-6), and had not been reported previously to NESS (3,7).

Historically, two thirds of CVB1 detections have been among children aged <1 year (3). During 1983–2003, neonates accounted for 22% of CVB1 reports versus 11% for other enteroviruses (7), suggesting a propensity to infect newborns. Cases of neonatal CVB1-associated disease identified in 2007 were characterized not only by myocarditis and central nervous system involvement typical of group B coxsackieviruses but also, on multiple occasions, by hepatitis and coagulopathy, which usually are reported with echovirus 11 infections.

Enterovirus infections are common, particularly during summer-fall months and typically are spread person-to-person via the fecal-oral or oral-oral routes and through respiratory droplets and fomites. Perinatal transmission from mother to infant occurs transplacentally or from exposure to maternal blood or secretions during delivery. Maternal enterovirus illness around the time of delivery and lack of maternal antibodies to an infecting serotype increase the risk for transmission. Onset of enterovirus disease resulting from perinatal transmission occurs in the first 1–2 weeks of life and carries a higher risk for severe illness and death than enterovirus infection acquired during the postnatal period (1,2,8).

No treatments approved by the Food and Drug Administration for enterovirus are available. Intravenous immunoglobulin sometimes is used, but its effectiveness in neonatal enterovirus disease is uncertain (2). Use of the candidate antiviral drug pleconaril (Schering-Plough, Kenilworth, New Jersey) showed benefit in neonates with life-threatening enterovirus disease (9); a phase 2 clinical trial of pleconaril in neonates is under way (10).

In the absence of vaccines, nonpolio enterovirus transmission can be reduced by adherence to good hygienic practices, such as thorough hand-washing (especially after

diaper changes), disinfection of contaminated surfaces by chlorine-containing household cleaners, and avoidance of shared utensils and drinking containers. To prevent nosocomial transmission of enteroviruses, neonatal hospital units should strictly enforce routine infection-control measures.

Serotype identification is important for recognizing differences in clinical profiles and outcomes between enteroviruses during seasonal outbreaks (2). Enterovirus RT-PCR testing allows rapid and sensitive detection of enteroviruses in clinical samples but does not differentiate serotypes. Molecular typing of enteroviruses based on VP1 gene sequence, which permits rapid identification of any enterovirus and provides data for phylogenetic analysis, is increasingly available at public health laboratories (2). Because serotype-specific surveillance for enteroviruses is helpful for monitoring trends in enterovirus circulation and identification of the emergence of new predominant serotypes or strains, public health agencies and private laboratories should report enterovirus detections to NESS.

## **QuickStats**

## FROM THE NATIONAL CENTER FOR HEALTH STATISTICS

Age-Adjusted Percentage of Adults\* Aged ≥20 Years with Hypertension,<sup>†</sup> by Poverty Level<sup>§</sup> — National Health and Nutrition Examination Survey, United States, 2003–2006

- \* Age-adjusted to the 2000 standard population using five age groups: 20–34 years, 35–44 years, 45–54 years, 55–64 years, and ≥65 years.
- † Hypertension is defined as having measured elevated blood pressure (systolic pressure: ≥140 mmHg or diastolic pressure: ≥90 mmHg) and/or taking antihypertensive medication. Persons with elevated blood pressure also might be taking prescribed medicine for high blood pressure. Those taking antihypertensive medication might not have measured elevated blood pressure, but are still classified as having hypertension. Respondents were asked, "Are you now taking prescribed medicine for your high blood pressure?"
- § Poverty level is based on family income and family size.
- ¶ 95% confidence interval.

The percentage of U.S. adults with hypertension was associated with income, with those at the lowest income level more likely to have hypertension than those in the highest income group.

- —: No reported cases. N: Not notifiable. Cum: Cumulative year-to-date counts.
  - \* Incidence data for reporting years 2007 and 2008 are provisional, whereas data for 2003, 2004, 2005, and 2006 are finalized.
  - † Calculated by summing the incidence counts for the current week, the 2 weeks preceding the current week, and the 2 weeks following the current week, for a total of 5 preceding years. Additional information is available at http://www.cdc.gov/epo/dphsi/phs/files/5yearweeklyaverage.pdf.
  - Not notifiable in all states. Data from states where the condition is not notifiable are excluded from this table, except in 2007 and 2008 for the domestic arboviral diseases and influenza-associated pediatric mortality, and in 2003 for SARS-CoV. Reporting exceptions are available at http://www.cdc.gov/epo/dphsi/phs/infdis.htm.
  - Includes both neuroinvasive and nonneuroinvasive. Updated weekly from reports to the Division of Vector-Borne Infectious Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases (ArboNET Surveillance). Data for West Nile virus are available in Table II.
  - \*\* The names of the reporting categories changed in 2008 as a result of revisions to the case definitions. Cases reported prior to 2008 were reported in the categories: Ehrlichiosis, human monocytic (analogous to *E. chaffeensis*); Ehrlichiosis, human granulocytic (analogous to *Anaplasma phagocytophilum*), and Ehrlichiosis, unspecified, or other agent (which included cases unable to be clearly placed in other categories, as well as possible cases of *E. ewingii*).
- the Data for H. influenzae (all ages, all serotypes) are available in Table II.
- §§ Updated monthly from reports to the Division of HIV/AIDS Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention. Implementation of HIV reporting influences the number of cases reported. Updates of pediatric HIV data have been temporarily suspended until upgrading of the national HIV/AIDS surveillance data management system is completed. Data for HIV/AIDS, when available, are displayed in Table IV, which appears quarterly.
- 11 Updated weekly from reports to the Influenza Division, National Center for Immunization and Respiratory Diseases. Seventy-two cases occurring during the 2007–08 influenza season have been reported.
- \*\*\* The one measles case reported for the current week was indigenous.
- Data for meningococcal disease (all serogroups) are available in Table II.
- \$55 In 2008, Q fever acute and chronic reporting categories were recognized as a result of revisions to the Q fever case definition. Prior to that time, case counts were not differentiated with respect to acute and chronic Q fever cases.
- No rubella cases were reported for the current week.
- \*\*\*\* Updated weekly from reports to the Division of Viral and Rickettsial Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases.

C.N.M.I.: Commonwealth of Northern Mariana Islands.
U: Unavailable. —: No reported cases. N: Not notifiable. Cum: Cumulative year-to-date counts. Med: Median. Max: Maximum.

\* Incidence data for reporting years 2007 and 2008 are provisional.
Updated weekly from reports to the Division of Vector-Borne Infectious Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases (ArboNET Surveillance). Data for California serogroup, eastern equine, Powassan, St. Louis, and western equine diseases are available in Table I.

Not notifiable in all states. Data from states where the condition is not notifiable are excluded from this table, except in 2007 for the domestic arboviral diseases and influenza-associated pediatric mortality, and in 2003 for SARS-CoV. Reporting exceptions are available at http://www.cdc.gov/epo/dphsi/phs/infdis.htm.

Contains data reported through the National Electronic Disease Surveillance System (NEDSS).

U: Unavailable. —:No reported cases.

\* Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of ≥100,000. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.

† Pneumonia and influenza.

<sup>§</sup> Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks. 
¶ Because of Hurricane Katrina, weekly reporting of deaths has been temporarily disrupted.

\*\*Total includes unknown ages.

The Morbidity and Mortality Weekly Report (MMWR) Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format. To receive an electronic copy each week, send an e-mail message to listserv@listserv.edc.gov. The body content should read SUBscribe mmwrtoc. Electronic copy also is available from CDC's Internet server at http://www.cdc.gov/mmwr or from CDC's file transfer protocol server at ftp://ftp.cdc.gov/pub/publications/mmwr. Paper copy subscriptions are available through the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone 202-512-1800.

Data in the weekly *MMWR* are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Data are compiled in the National Center for Public Health Informatics, Division of Integrated Surveillance Systems and Services. Address all inquiries about the *MMWR* Series, including material to be considered for publication, to Editor, *MMWR* Series, Mailstop E-90, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333 or to *mmwrq@cdc.gov*.

All material in the MMWR Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.

Use of trade names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services.

References to non-CDC sites on the Internet are provided as a service to MMWR readers and do not constitute or imply endorsement of these organizations or their programs by CDC or the U.S. Department of Health and Human Services. CDC is not responsible for the content of these sites. URL addresses listed in MMWR were current as of the date of publication.
