health outcomes, possibly affecting cognitive performance. Benzo(a)pyrene [B(a)P], and 2, 3, 7, 8, tetrachlorodibenzo-p-dioxin (TCDD) are two prototypical polyaromatic hydrocarbon environmental contaminants. A systematic review of the literature indicates that there is a relationship between health disparities and, normal and dysfunctional cognitive development and functioning. Gestational exposure studies were conducted where timed-pregnant rats were exposed to: 100µmg/m3 B(a)P (GD14-17; nose-only inhalation) and/or 700 ng/kg TCDD (GD 14; gavage). The results reveal polyaromatic hydrocarbon/mixture induced decrements in: 1) birth index, 2) NMDAR mRNA expression, 3) long-term potentiation (LTP), 4) fixed-ratio performance learning behavior, and 5) activity related cytoskeletal associated protein (Arc) mRNA and protein expression. These data provide a point of reference for neurotoxicological studies of polyaromatic hydrocarbon/ mixture effects on development in general, and on specific indices of learning and memory in particular. The data support associations between gestational exposure to environmental levels of these contaminants and neurodevelopmental delay that has been previously reported in historical cohort studies. The data suggest that the effect of gestational exposure to polyaromatic hydrocarbon/mixtures is to dysregulate hippocampal-based synaptic plasticity mechanisms.

1849

PRENATAL EXPOSURE OF TCDD DECREASED HIPPOCAMPAL ARC AND NMDAR1 EXPRESSION IN F1 GENERATION RATS.

J. Wu, <u>T. Nayyar</u>, T. Tu, S. Johnson and <u>D. B. Hood</u>. pharmacology, meharry medical college, Nashville, TN.

Activity-regulated cytoskeleton-associated protein (Arc) is an effector immediateearly gene that is proposed to involve synaptic plasticity. Sensory stimulation and placement in a novel environment induce expression of this gene, which is associated with learning new behaviors. Newly synthesized Arc mRNA migrates to dendrites and, following induction of long-term potentiation (LTP), localizes to activated post-synaptic dendritic domains in an N-methyl-D-aspartate receptor (NMDAR) dependent manner. TCDD (2, 3, 7, 8-tetrachlorodibenzo-p-dioxin) is a prototypical polyaromatic hydrocarbon environmental contaminant that is widely distributed and persistent throughout the ecosystem. Our previous studies demonstrated that prenatal exposure to TCDD reduced LTP in the hippocampal dentate gyrus and caused the deficits in learning and memory behavior in F1 generation rats. To explore the molecular basis of these changes, timed-pregnant Long-Evans rats were exposed to TCDD (100 or 700ng/kg BW) by gavage on GD 14. The mRNA and protein expression of Arc and NMDAR1 were quantified by Realtime PCR and western blot analysis from the hippocampus of F1 generation rats that were specially trained for fix-ratio performance on PND70. The results showed that: (1) Arc mRNA and protein expression in trained rats were found to be significantly induced as compared to constitutive expression in untrained rats. (2) A dose-dependent decrease (20-30%) in Arc mRNA and protein expression was observed in TCDD exposed trained rats relative to unexposed trained rats. (3) The constitutive Arc mRNA and protein expression is also significantly decreased in TCDD exposed untrained rats relative to unexposed untrained rats. (4) A downregulation (15-20%) in NMDAR1 mRNA and protein expression was found in TCDD exposed rats as compared to unexposed control rats. These data correlate well with our previous findings from LTP testing and the fixed-ratio performance learning behavior studies and suggest that prenatal TCDD exposure decreases the capacity for synaptic plasticity and learning ability in offspring.

**1850** ASSESSING THE BIOLOGICAL AND ENVIRONMENTAL RISKS OF NANOPARTICULATES.

D. B. Warheit<sup>1</sup> and J. Everitt<sup>1</sup>. <sup>1</sup>DuPont Haskell Lab., Newark, DE and <sup>2</sup>GlaxoSmithKline, Reseach Triangle Park, NC.

This symposium is a basic primer on nanoparticles and health. After a brief introduction, Dr. Vicki Colvin, director of Rice University CBEN will discuss potential environmental risks related to nanomaterials. Few data exist on the environ. effects of engineered nanomaterials, yet some NGOs are calling for bans on these systems. Govt. policy issues will also be presented. Next, Dr. Sally Tinkle will discuss skin exposure to fine particulates: mechanism of entry and biological response. Previously, it was assumed that exposures to fine particles could not penetrate the stratum corneum of the skin; however, particle size may play a role in skin penetration potential. Dr. Gunter Oberdorster will discuss the pulmonary and extrapulmonary disposition of inhaled nanoparticles. Airborne particles <100 nm in diam. in urban air along with nanotechnol. particles (<10 nm) raise health concerns for humans. Toxicology. studies with different types of nano/ultrafine particles suggest a range of adverse effects. Translocation of 10 to 50 nm sized particles from the respiratory tract to other organs, including the CNS and heart, have also been demonstrated. Dr. Jeff Everitt will next discuss a recent interspecies study of lung responses to inhaled ultrafine TiO2 particles. Female rats, mice and hamsters were exposed to aerosols of ufTiO2 particles for 13 weeks and evaluated through 1 year. At higher doses the adverse lung responses in rats were significantly greater than the other 2 species. The final presentation will discuss lung bioassay studies of intratracheally instilled single wall carbon nanotubes (SWCNT). Individual SWCNT have dimensions of 1 nm (diameter) and lengths > 1 um, yet, SWCNT have a high electrostatic potential and thus agglomerate, forming bundles of 10 to 100 SWCNT, so-called nanoropes. There are very low respirable concentrations of SWCNT in the workplace (i.e., < 0.1 mg/m3). SWCNT instilled in the lungs of rats or mice have produced granulomas. Because of agglomeration, however, the relevance of these findings are questionable and should be confirmed *via* an inhalation study with SWCNT.

1851 ENVIRONMENTAL IMPACTS OF ENGINEERED NANOMATERIALS: RESEARCH FROM THE CENTER FOR BIOLOGICAL AND ENVIRONMENTAL NANOTECHNOLOGY.

V. Colvin. Rice University, Houston, TX. Sponsor: D. Warheit.

Traditionally, nanotechnology has been motivated by the growing importance of very small (diameter < 50 nm) computational and optical elements in diverse technologies. However, this length scale is also an important and powerful one for living systems. At Rice, we believe that the interface between the 'dry' side of inorganic nanostructures and the 'wet' side of biology offers enormous opportunities for medicine, environmental technologies, as well as entirely new types of nanomaterials. As part of our work on the potential biological applications, we also consider the unintended environmental implications of water soluble nanomaterials. Given the breadth of nanomaterial systems, we use a carefully selected group of model nanoparticles in our studies and focus on natural processes that occur in aqueous systems. We characterize the size and surface-dependent transport, fate and facilitated contaminant transport of these engineered nanomaterials. Models from larger colloidal particles can be extended into the nanometer size regime in some cases, while in others entirely new phenomena present themselves. We also consider biological interactions of nanoparticles and evaluate their biotransformation, bioremediation and accumulation under realistic environmental conditions. Finally, this exposure data is placed in the context of the known health effects of nanomaterials. In this regard, there is surprisingly little concrete data on the health or environmental effects of engineered nanomaterials, but that hasn't stopped a number of organizations from calling for bans on these systems. An overview of the latest policy and media coverage of this timely issue will be highlighted along with a summary of the current state of knowledge in the area.

**1852** SKIN EXPOSURE TO PARTICLES: PENETRATION IS DEPENDENT ON PARTICLE SIZE.

S. S. Tinkle. NIAID, NIH, Bethesda, MD. Sponsor: D. Warheit.

Previously, skin exposure to fine or nanoparticles was not considered hazardous. The external layer of the skin, the stratum corneum (SC), is considered a mechanically strong and resilient structure that protects internal organs from environmental exposures. We tested the ability of particles of varying size to traverse intact SC and initiate an immunological response in the epidermis. Fluorospheres, 0.5 to 4 micron diameter, were applied to recovered human skin for 0, 15, 30 or 60 minutes, in the presence and absence of a 45 degree flexing motion, as occurs at the wrist. Location of these fluorescent particles in the skin was examined by laser scanning confocal microscopy. Fluorospheres, 1 micron or smaller, penetrated the SC and reached the epidermis in 41% and 54% of the skin samples flexed for 30 and 60 minutes, respectively. In addition, no fluorospheres were observed in the epidermis in the absence of flexing motion. We tested the ability of skin particulate exposure to induce murine cutaneous hypersensitivity using beryllium oxide. Beryllium (Be) stimulates an MHC Class II-restricted, CD4+ T cell-mediated immune response in approximately 3 to 5% of Be-exposed workers. Topical application of BeO to C3H/HeOuJ mice stimulated Be-specific lymphocyte proliferation and changes in the T lymphocyte cell activation markers CD44 and CD69L. To examine the effects of particulate exposure on gene expression, we compared 24 hour exposure of MH-S cells to both 1 micron chemically-inert polystyrene spheres and to size-selected beryllium oxide particles using the Affymetrix gene array. Polystyrene beads induced significant changes in structural proteins and cellular metabolism genes, whereas BeO particles induced changes in adhesion molecules and the MHC Class III region genes. These data support our hypothesis that skin exposure to smaller particles, in the size range of 0.5 - 1.0 um, can penetrate intact SC and induce a CMI response. Particles in the nanoscale size range (i.e., < 100 nm) have not yet been tested. Furthermore, inert particle exposure alters gene expression and cellular metabolism differently than exposure to a sensitizing particle.

#### 1853 BIOLOGICAL EFFECTS AND FATE OF INHALED NANO/ULTRAFINE PARTICLES.

G. Oberdorster. Environmental Medicine, University of Rochester, Rochester, NY.

Airborne particulates <100 nm in diameter, occur at very high number concentrations in ambient air, specifically urban air, and at certain workplaces. More recently, nanotechnological developments have created new and even smaller sized spherical particles (<10 nm) concomitant with the development of nanotubes for applications ranging from electronics to biomedical fields. Their use in these areas raises concerns regarding potential exposures of humans and subsequent potential adverse health effects should they become airborne. Toxicology studies involving different types of nano- or ultrafine particles have revealed a wide range of adverse effects, ranging from mild to very potent acute pulmonary inflammatory responses, to effects on extrapulmonary organs such as the cardiovascular system. The large surface area per given mass of ultrafine particles is of toxicological importance because it correlates well with their potential to cause lung inflammation and oxidative stress. In addition, ultrafine particles at sizes below 50 nm have a high probability to be deposited throughout the respiratory tract upon inhalation. Following deposition, translocation of 10 to 50 nm sized particles from alveolar regions of the respiratory tract to interstitial sites as well as to other extrapulmonary organs, including the CNS, has also been demonstrated, yet many unanswered questions remain regarding their potency to cause health effects at these sites. Examples of anthropogenic ultrafine particles at the workplace and in the ambient air will illustrate human exposure scenarios. And results from toxicological investigations are presented to demonstrate their potential for causing adverse health effects.

#### 1854 COMPARISON OF INTERSPECIES LUNG RESPONSES TO ULTRAFINE (NANO) TITANIUM DIOXIDE PARTICLES.

J. Everitt and E. Bermudez. CIIT, Research Triangle Park, NC.

The pulmonary responses of 3 rodent species to inhaled nanoTiO2 particles, i.e., ultrafine TiO2 (uf-TiO2) particles (15 to 40 nm particle size) were compared. Female rats, mice, and hamsters were exposed to aerosol concs. of 0.5, 2.0, or 10 mg/m3 uf-TiO2 particles 6 h per day, 5 days per week for 13 weeks. Following the exposure period, animals were held for recovery periods of 4, 13, 26 or 52 weeks (49 weeks for the uf-TiO2-exposed hamsters) and at each time point uf-TiO2 burdens in the lung and lymph nodes and selected lung responses were examined. Retained lung burdens were maximal at the end of exposure in all three species and increased in a dose-dependent manner. Lung burdens in all three species decreased with time after exposure and at the end of the recovery period the percentage of the lung particle burden remaining in the 10 mg/m3 group was 57, 45, and 3 % for rat, mouse, and hamster, respectively. The retardation of particle clearance from the lungs in mice and rats of the 10 mg/m3 group indicated that pulmonary particle overload had been achieved in these animals. Pulmonary inflammation was evident in rats and mice exposed to 10 mg/m3 as evidenced by increased numbers of macrophages and neutrophils and increased concentrations of soluble markers in bronchoalveolar lavage fluid (BALF). There were no significant changes in cellular response or of markers indicating toxicity in hamsters, reflecting the capacity of these animals to rapidly clear particles from the lung. Progressive epithelial and fibroproliferative changes were observed in rats of the 10 mg/m3 group and were limited to this species. Clearance of particles from the lung was markedly impaired in mice and rats exposed to 10 mg/m3 uf-TiO2, whereas clearance in hamsters did not appear to be affected at any of the administered doses. These data are consistent with the results of a companion study using inhaled pigmentary (fine mode) TiO2 (Bermudez et al., 2002) and demonstrate that the pulmonary responses of rats exposed to ultrafine particulate concentrations likely to induce pulmonary overload are different from similarly exposed mice and hamsters.

#### 1855 PULMONARY BIOASSAY STUDIES WITH CARBON NANOTUBES IN RATS.

D. B. Warheit. Pulmonary Toxicology, DuPont Haskell Lab., Newark, DE.

The pulmonary toxicity of intratracheally instilled single wall carbon nanotubes (SWCNT) in rats was evaluated. The lungs of rats were instilled with either 1 or 5 mg/kg of 1) SWNT; 2) quartz particles, or 3) carbonyl iron particles (CI) Phosphate-buffered saline (PBS) + 1% Tween 80 instilled rats served as additional controls. For the lung tissue studies, graphite particles were added as an additional particle control. Following exposures, the lungs of PBS and particle-exposed rats were assessed both using bronchoalveolar lavage (BAL) fluid biomarkers, cell proliferation methods, and by histopathological evaluation of lung tissue at 24 hrs, 1 week, 1 month and 3 months post-instillation exposure. Exposures to high dose (5 mg/kg) SWCNT produced mortality in ~15% of the SWCNT-instilled rats within 24 hrs post-instillation due to mechanical blockage of the airways. The bronchoalveolar lavage and cell proliferation results demonstrated that lung exposures to quartz particles but not SWCNT or CI produced sustained increases vs. controls in pulmonary inflammation, cytotoxicity, and lung cell parenchymal cell proliferation indices. Histopathology indicated that pulmonary exposures to quartz particles (5 mg/kg) produced dose-dependent inflammatory responses, concomitant with foamy alveolar macrophage accumulation and lung tissue thickening at sites of normal particle deposition. Pulmonary exposures to SWCNT in rats produced a non dose-dependent series of multifocal granulomas in the airways, which was evidence of a foreign tissue body reaction. Due to the agglomerative nature of the SWCNT, the lack of lung toxicity by assessing lavage and cell proliferation parameters, the non-uniform distribution of lesions, and the low exposure potential measured in occupational exposure assessment studies, the physiological relevance of these results remains to be determined. Therefore, to reconcile the apparent results discrepancies in this pulmonary bioassay study, it is critical that the pulmonary effects of SWCNT soot in rats must by evaluated by conducting an inhalation toxicity study.

## **1856** MOLECULAR PROFILING AND COMPUTER

MODELING IN EARLY DETECTION AND TREATMENT OF CANCER.

R. Thomas. Canswers, McLean, VA.

Cancer diagnosis is traditionally an ad hoc activity where the quality of diagnosis and treatment is often limited by experience and available tools. There exists an opportunity to provide clinicians with important new tools to increase the potential for patients to receive superior diagnosis and treatment. At the core of this opportunity are enhanced research and bioinformatics tools which allow toxicologists and other researchers to identify and exploit gene and molecular profiles associated with many stages of cancer development. For example, such profiles are currently being explored as methods for early detection of ovarian and breast cancer. In addition, gene and molecular profiles have shown promise in identifying aggressive tumor subtypes and in predicting patient outcomes. The purpose of this symposium will be to explore some of the most recent advances in gene profiling and bioinformatics tools now available to toxicologists, clinicians and other researchers.

## 1857 THE MOLECULAR STAGING OF COLORECTAL

W. E. Grizzle<sup>1</sup>, University. Manne<sup>1</sup>, N. Jhala<sup>1</sup>, C. Suarez-Cuervo<sup>1</sup>, S. Meleth<sup>2</sup> and D. Alexander<sup>3</sup>. <sup>1</sup>Pathology, University of Alabama at Birmingham, Birmingham, AL, <sup>2</sup>Medicine/Biostatistics Unit, University of Alabama at Birmingham, Birmingham, AL and <sup>3</sup>Epidemiology, University of Alabama at Birmingham, Birmingham, AL. Sponsor: R. Thomas.

Outcomes of patients with adenocarcinomas of the colorectum (CRC) are best predicted by TNM staging and by race and age. The nodal component of stage  $(\hat{N)}$  is the "gold standard" for predicting the clinical outcome of CRCs. We identified molecular features which are useful in predicting clinical outcome of patients with CRC. CRCs are separated into tumors of the proximal colon (cecum, ascending colon, hepatic flexture and first two thirds of transverse colon), distal colon (last one third of the transverse colon, splenic flexture, descending colon, and sigmoid colon), and rectum based on the embryologic derivation and different therapies for rectal cancers. We reported that the nuclear accumulation of p53 (p53-nac) in Caucasians with all stages of proximal colonic tumors and very low expression of Bcl-2 in all locations of Stage II CRC are correlated with a poor outcome. In Caucasians but not African-Americans, increased expression of MUC-1 but not MUC-2 in all locations of CRCs is correlated with a poor clinical outcome. Also, decreased expression of p27-kip-1 is correlated with a poor clinical outcome in Stage III CRC in both Caucasians and in African-Americans. Combinations of these molecular features are at least additive. Thus, for Stage II proximal adenocarcinomas of the colon in Caucasians, a poor clinical outcome is predicted by p53nac, very low expression of Bcl-2 and high expression of MUC-1. For African-Americans, prognosis (hazard ratio) of CRCs is predicted primarily by nodal stage modified by low expression of p27-kip-1. We will demonstrate how hazard ratios for these molecular features of CRCs can be coupled with staging and demographic information for an overall hazard ratio for patients with CRCs.

#### 1858

PREDICTING CLINICAL PROGNOSIS IN COLORECTAL CANCER PATIENTS USING MOLECULAR PROFILE DATA AND BIOINFORMATICS TECHNOLOGIES.

R. D. Thomas<sup>1, 2</sup>, W. E. Grizzle<sup>3</sup> and University. Manne<sup>3</sup>. <sup>1</sup>Canswers, Inc., McLean, VA, <sup>2</sup>INTERCET, LTD., McLean, VA and <sup>3</sup>Department of Pathology, University of Alabama at Birmingham, Birmingham, AL.

Current cancer diagnostic and assessment benchmarks, such as tumor staging and grading are limited in their ability accurately assess the nature of disease and fail to provide oncologists with tools capable of predicting disease process and outcome.

Advances in molecular biology have provided insight into the mechanisms of cancer development and have led to the creation of gene and protein expression profile databases for various cancers. In addition, advances in bioinformatics have led to the creation of tools capable of identifying specific marker profiles capable of predicting such things as disease onset and clinical prognosis. The present study examines the use neural networks and data mining techniques to extract prognostic relationships within a molecular profile database containing immunohistochemical data on multiple cellular markers in 492 colorectal cancer patients. Multiple analysis approaches were used to identify which markers held the best prognostic potential and what cut-off values gave the most accurate prediction. Results of this study show that the certain markers, when analyzed in combination with particular diagnostic and demographic fields, are capable of predicting the likelihood of five year survival in a subset of the patient population. This presentation will focus on efforts to use bioinformatics tools to predict clinical prognosis using a combination of demographic, diagnostic and molecular profile data from historical cancer patients and will highlight the clinical potential of these technologies.

1859

THE EFFORTS TO UTILIZE SERUM PROTEIN PATTERNS AND ARTIFICIAL INTELLIGENCE BASED PATTERN RECOGNITION TOOLS FOR NCI-SPONSORED CLINICAL TRAILS OF OVARIAN AND PROSTATE CANCER DETECTION.

E. F. Petricoin. National Cancer Institute, Bethesda , MD. Sponsor:  $\underline{\mathbb{R}}$ . Thomas.

The FDA-NCI Clinical Proteomics Program has invented and is pioneering a new diagnostic paradigm: serum proteomic pattern diagnostics. The combined use of artificial intelligence-based pattern recognition tools and high throughput mass spec profiling of the low molecular weight (LMW) range of the blood proteome have allowed for the discovery of biomarkers that achieve much higher sensitivity and specificity for disease detection than any single biomarker alone. We have found that these LMW diagnostic fragments bind to specific carrier proteins that serve to enrich and amplify their signal. These discoveries are serving the basis for clinical trials which will begin at the end of 2003 for ovarian cancer detection. Ongoing work is also being extended to breast, prostate, colon, lung and pancreatic cancer early detection.

1860

THE INTEGRATION OF MOLECULAR PROFILING, TOXICOLOGY AND PATHOLOGY DATASETS FOR KNOWLEDGE DISCOVERY.

M. Waters<sup>1</sup>, P. Bushel<sup>1</sup>, G. Boorman<sup>2</sup>, W. Eastin<sup>2</sup>, S. Gustafson<sup>4</sup>, P. Hurban<sup>5</sup>, R. Irwin<sup>2</sup>, A. Merrick<sup>1</sup>, J. Nehls<sup>3</sup>, K. Olden<sup>3</sup>, R. Paules<sup>1</sup>, J. Selkirk<sup>1</sup>, S. Stasiewicz<sup>1</sup>, N. Stegman<sup>3</sup>, K. Tomer<sup>3</sup>, B. Weis<sup>3</sup>, J. Yost<sup>4</sup>, S. Xirasagar<sup>4</sup> and R. Tennant<sup>1</sup>. National Center for Toxicogenomics (NCT), Research Triangle Park, NC, <sup>2</sup>National Toxicology Program (NTP), Research Triangle Park, NC, <sup>3</sup>NIEHS, NIH, DHHS, Research Triangle Park, NC, <sup>4</sup>Science Applications International Corporation, Germantown, MD and <sup>5</sup>Paradigm Genetics, Research Triangle Park, NC.

The integration of multiple domain datasets for knowledge discovery is an important goal of the Chemical Effects in Biological Systems (CEBS) knowledge base (Waters, et al., 2003, Environ Health Perspect 111, 811-824). CEBS uses international database standards developed by the Microarray Gene Expression Data (MGED) Society, including those for data representation and exchange. By extending the microarray object model (MAGE-OM) to capture proteomics, metabonomics, toxicology and pathology data, CEBS SysTox-OM combines molecular expression and metabolite profiling with conventional toxicology and pathology to support hypothesis-driven and discovery research. To enable visualization of pharmacological and toxicological responses, molecular expression datasets (e.g., experimental outliers or determined proteins) are projected onto known biological pathways. Continuously updated gene and protein annotation is brought to CEBS datasets through the use of cancer bioinformatics infrastructure objects (caBIO) technology developed for the National Cancer Institute's Center for Bioinformatics. caBIO is a standards based set of genomic components including genes, chromosomes, sequences, libraries, clones, ontologies, etc. caBIO provides access to genomic data sources including GenBank, UniGene, LocusLink, HomoloGene, EnsEMBL, GoldenPath, BioCarta, dbSNP, among others. Improved gene annotation fidelity is achieved through maximal use of probe set sequence definition and alignment to respective genome scaffold sequences and vetted sets of synonym gene names for literature mining. CEBS is being designed to meet the information needs of systems toxicology.

1861 NOVEL APPROACHES TO ENGAGING TOXICOLOGISTS IN K-12 SCIENCE EDUCATION AND OUTREACH.

D. L. Eaton<sup>1</sup>, C. Marcus<sup>3</sup>, D. Dixon<sup>2</sup> and L. O'Fallon<sup>2</sup>. <sup>1</sup>Occupational and Environmental Health Sciences, University of Washington, Seattle, WA, <sup>2</sup>NIEHS, Research Triangle Park, NC and <sup>3</sup>College of Pharmacy, University of New Mexico, Albuquerque, NM.

Toxicologists are encouraged to become engaged in K-12 classroom activities with the goal of increasing student interest in and awareness of toxicology and environmental health. The SOT K-12 education subcommittee has been very supportive of providing toxicologists with tools and resources to help them prepare for K-12 classroom visits. This session will spotlight positive impacts of classroom visits by toxicologists, and will provide SOT members with novel approaches, tools and resources that can be used to facilitate toxicology education in the K-12 setting. During this workshop, there will be hands-on demonstrations of a variety of tools that toxicologists can use before and during classroom visits. Presenters will include toxicologists who have been actively engaged in K-12 outreach as well as K-12 teachers who have utilized toxicology in the classroom. The presenters will highlight successful models for taking students into the field to learn more about local issues that affect their life and health. The purpose of the session is to show how toxicologists are making a positive impact; provide them with, and direct them to, locations where they can obtain tools; and show them how specific tools can be used effectively in the classroom. In addition, SOT members will learn how to take the classroom learning experience into the field to study local environmental health issues.

1862 POSITIVE IMPACTS OF TOXICOLOGIST VISITS TO THE CLASSROOM: A TEACHER'S PERSPECTIVE.

D. Becker<sup>1</sup>, A. Renkwitz<sup>1</sup>, F. Ross<sup>2</sup> and B. Tharp<sup>3</sup>. <sup>1</sup>Cambridge-South Dorchester High School, Baltimore, MD, <sup>2</sup>Robert Poole Middle School #56, Baltimore, MD and <sup>3</sup>Baylor College of Medicine, Houston, TX. Sponsor: <u>D. Eaton</u>.

Panelists will present a summary of environmental health sciences (EHS)/toxicology projects with their students to demonstrate how toxicologists can become positively engaged in learning activities/projects to increase student awareness of and interest in EHS/toxicology and addressing: \* The interdisciplinary nature of EHS topics \* How students receive and engage in EHS/toxicology information and how they perceive it as an extension of their science, social studies, mathematics, and/or language arts. \* State Standards and assessments, with suggestions on how scientists can make impact/inroads on their local state curricula agenda. \* Positive impacts (for teachers and students) of classroom visits by/interactions with scientists/toxicologists, featuring examples of student work. \* The importance of "Community Connections" to local EHS issues: -taking students into the field to learn about/study-students sharing with others in schools, homes, and communities

1863 TOXICOLOGISTS IN THE CLASSROOM: SUCCESSFUL MODELS FOR K-12 OUTREACH.

D. L. Eaton<sup>1</sup>, N. I. Kerkvliet<sup>2</sup>, C. Marcus<sup>3</sup>, S. H. Safe<sup>4</sup> and M. A. Trush<sup>5</sup>.

<sup>1</sup>Environment Occup. Health Sciences., University Washington, Seattle, WA,

<sup>2</sup>Environment Molec. Toxicology., Oregon St. University, Corvallis, OR, <sup>3</sup>College of Pharmacy, University New Mexico, Albuquerque, NM, <sup>4</sup>Vet. Physiol. & Pharmacology, Texas A & M University, College Station, TX and <sup>3</sup>Environment Health Sciences., Johns Hopkins University, Baltimore, MD.

A panel of toxicologists with extensive K-12 classroom experience will share insights and provide examples of successful approaches and potential problems which can be employed by toxicologists for effectively conveying toxicology information to K-12 students and their teachers. Successful communication of toxicology to K-12 students is dependent on the specific grade, age and location of the students, cooperation of teachers and principals, and integration of toxicology with other disciplines in the curriculum. The KIS approach (keep it simple!) has been found to be important when communicating basic toxicology to K-12 audiences. Examples of simple experiments using dye indicators in weak buffer solutions can be used to engage students, while illustrating such concepts as dose-response, thresholds, cumulative toxicity, and individual susceptibility, in an engaging hands-on way. Students from urban and rural areas have a different appreciation of real-life toxicological issues such as air pollution and pesticide spraying. The Texas A&M PEER program has developed an extensive rural education program that includes a series of handson learning modules that illustrate relevant toxicology problems to student (grades 6 - 8) in rural schools. "Intuitive risk assessment" is used by middle and high school students as they form opinions about risk and make personal health-related decisions. However, most teachers lack sufficient knowledge of toxicology to be comfortable interjecting principles of toxicology, risk assessment and risk perception

into their everyday teaching in the classroom. Examples of "teacher-friendly" toxicology and risk assessment presentations to teachers will be presented as other types of successful outreach activities for professional toxicologists.

## **1864** HANDS-ON FUN: TOOLS FOR TOXICOLOGISTS ENTERING THE K-12 CLASSROOM.

L. O'Fallon. NIEHS, Research Triangle Park, NC. Sponsor: D. Eaton.

During this interactive session, toxicologists will be introduced to simple, inexpensive activities and tools that can be used when visiting classrooms. The 6 tables of hands-on activities will be organized by grade-level appropriateness. Bio Buildup and Separating Solutions, K-3 Bio Buildup is a math investigation that toxicologists can use with elementary students to simulate bioaccumulation in a simple aquatic ecosystem using stick-on dots. Separating Solutions is an engaging activity where elementary students use coffee filter "paper chromotography" to investigate a mysterious liquid. Toxicologists can use this activity to show students that many different substances can be in solution simultaneously. Peak Flow Lab., High School This activity provides toxicologists a creative way of using a peak flow meter to discuss the effects of toxic respiratory exposures (e.g., tobacco smoke and occupational exposures) on peak flow and lung function within and across individuals. Bioassay Basics, Middle & High School Bioassay activities using lettuce seeds and brine shrimp are demonstrated. These simple and inexpensive investigations can be used by toxicologists with middle and high school students. Enviromysteries, Middle School Toxicologists can use videos and video clips from 'Breaking the Mold' at the Enviromysteries website with grade 5-9 students when addressing sources of air pollution or health outcomes, e.g., asthma and water-born illnesses. Toxicology-ina-box and EH Fact Files, Middle School Toxicology-in-a-Box is a literal and virtual suitcase of materials that can be used by toxicologists for many presentations to a wide range of students. The kit includes activities, slides, demonstrations, and a script of explicit instructions and tips for the presenter. EH Fact Files is a resource that can be used by toxicologists to prepare for a classroom visit. This tool helps toxicologists distill complex scientific and historical information about specific health topics into age-appropriate language. Respiratory System, Middle School Toxicologists will learn about an engaging activity used in rural Texas middle

#### 1865 CLASSROOM TO FIELD: PUTTING TOXICOLOGY IN A LOCAL CONTEXT.

<u>I. Lewis</u><sup>1</sup> and B. Sattler<sup>2</sup>. <sup>1</sup>University of New Mexico Health Sciences Center, Albuquerque, NM and <sup>2</sup>University of Maryland School of Nursing, Baltimore, MD.

Teaching students about toxicology and environmental health can be very challenging. Sometimes methods used are fairly dry and the topics may appear remote to the students, especially when the focus is on the processes of toxicology and environmental contamination, rather than on public health impacts. Therefore, finding novel ways of highlighting, and/or involving students directly in, real issues in their community can serve to engage the students and thereby more effectively teach them about the science of toxicology and environmental health. In addition, it can also give students the added benefit of being seen as resources in their community and serve as a means of raising the awareness of parents, friends, and family members. The presenters in this session will highlight their efforts in taking students into the field to teach them about toxicology through local environmental health issues in New Mexico and Masachusetts. In New Mexico, environmental health concerns include extensive uranium and other mine-related pollutants, as well as air and water pollution in this primarily rural and poverty-stricken state. University of New Mexico has built lasting relationships with the diverse population to address the health disparity in chronic diseases such as asthma, diabetes and cancers of unknown etiology that provide an excellent opportunity to make toxicology relevent to k-12 sutdents and teachers. Urban environmental health issues such as asthma and children's health have been a primary focus at the University of Maryland. Programs that engage nursing students in the environmental health sciences have been particularly successful in building community and addressing local environmental health issues. The presenters will discuss 'nuts and bolts' of this approach and the benefits to students, teachers, toxicologists, and communities.

#### 1866

THE NATIONAL CHILDREN'S STUDY: PROGRESS DEVELOPING METHODS APPROPRIATE FOR ASSESSING CHILDREN'S EXPOSURE, BIOMARKERS AND GENETIC SUSCEPTIBILITY.

C. A. Kimmel<sup>2</sup> and B. D. Abbott<sup>1</sup>. <sup>1</sup>RTD, NHEERL, ORD, USEPA, Durham, NC and <sup>2</sup>NCEA, ORD, USEPA, Silver Spring, MD.

The National Children's Study is a long term prospective study of the effects of environmental influences on the development and health of children across the United States. This study is a collaborative effort authorized by the Children's

Health Act of 2000. The National Institute of Child Health and Human Development (NICHD), the National Institute of Environmental Health Sciences (NIEHS), the Center for Disease Control and Prevention (CDC), and the USEPA (EPA) are involved in planning and conduct of the study. This study will include approximately 100, 000 children, following them from before birth to adulthood. Social, behavioral, cultural, chemical, physical, and genetic factors need to be considered to assess the broad and complex influences of the environment on child health and development. In this symposium, individuals involved in various aspects of study planning and/or advisory groups will present recent progress in developing improved methods for identifying biomarkers, evaluating genetic susceptibility, and modeling children's exposure. A final presentation will discuss the issues and concerns related to childhood asthma, one of the major themes of the study, and progress in that research area. The NCS and the ongoing pilot studies to develop the final form of that study, represent a rich resource for the toxicological and epidemiological community. This symposium provides an introduction to this vast resource, an update on research in this arena and an indication of future research directions in studies of children's environmental health.

#### 1867

### AN OVERVIEW OF THE NATIONAL CHILDREN'S STUDY.

P. Mendola. *Human Studies Division, USEPA, Research Triangle Park, NC.* Sponsor: B. Abbott.

There is substantial public health concern that aspects of the environment adversely impact child health and development. Children may be more vulnerable to environmental threats but little comprehensive research exists to identify which factors are harmful, harmless or helpful. Research with a life-course approach is needed to explore the links between multiple exposures and multiple health outcomes over time. The National Children's Study will "investigate basic mechanisms of developmental disorders and environmental factors, both risk and protective, that influence health and developmental processes" (Children's Health Act, 2000). A large sample size of approximately 100, 000 is planned to allow the evaluation of links between low level environmental exposures, social and behavioral factors with less common outcomes, as well as the interaction between genetics and the environment. The study will focus on children's environmental health themes of major public health concern that are best suited to this type of longitudinal study, such as pregnancy outcomes, neurobehavioral development, asthma, obesity and altered physical development, and injury. Pregnant women from across the United States will be enrolled as early as possible in pregnancy (or before pregnancy) and their children will be evaluated during prenatal development, through birth, childhood, and into adulthood. Strong partnerships between federal and non-federal scientists and community, parent, advocacy, and industry groups are being emphasized throughout the planning process. Planning and organization of the study are underway with a chartered federal advisory committee and working groups considering issues such as hypotheses and study design, ethics, development and behavior, chemical and physical exposures, injuries, emerging technologies to measure exposures and outcomes, and community outreach/participation. This study, similar in importance to the Framingham study and the Women's Helath Initiative, will provide a legacy for future generations on the role of environmental factors on children's health and development, and well-being.

## VALIDATION OF NON-INVASIVE BIOLOGICAL SAMPLES: PILOT PROJECTS RELEVANT TO THE NATIONAL CHILDREN STUDY.

J. E. Gallagher<sup>1</sup>, T. Lehman<sup>2</sup>, R. Modali<sup>2</sup>, S. Rhoney<sup>1</sup>, J. Rockett<sup>1</sup>, M. Clas<sup>1</sup>, J. Inmon<sup>1</sup>, D. Dix<sup>1</sup>, C. Mamay<sup>1</sup>, <u>S. Fenton<sup>1</sup></u>, S. McMaster<sup>1</sup>, <u>S. Barone</u><sup>1</sup> and <u>R. Sams<sup>1</sup>. <sup>1</sup>NHEERL, USEPA, Research Triangle Park, NC and <sup>2</sup>Bioserve Biotechnologies LTD, Laurel, MD.</u>

Advances in genetic technology and the work of the human genome project to map and sequence the human genome are expediting our understanding of genetic determinants of common diseases. Determination of most genetic polymorphisms associated with disease susceptibility has been accomplished utilizing DNA from tissue such as whole blood or buffy coats. MALDI-TOF (matrix assisted laser desorption/ionization time of flight mass spectrometry)combines enzymatic amplification reactions, bioinformatics and a miniaturized chip based format which together provide high throughput genetic analyses. To date, we have successfully applied MALDI -TOF for genotyping DNA isolated from fingernails, buccal swabs, saliva, sputum, mouthwash lavages and urine. We have extended our studies to evaluate the degree to which specific metabolism, detoxification and repair polymorphisms account for variation in genetic expression and sensitivity/responsiveness. To accomplish our goals, we obtained whole blood samples from children, adult and elderly through ongoing EPA clinical and field studies. Ex-vivo treatment of cells was then conducted with environmental toxicants. Recognizing that cumu-

lative risk to an individual is the combined risk from aggregate (multi-pathway, multi-source and multi-route) exposures to multiple agents, we focused on measuring gene expression and immune and oxidative/antioxidant measurements since they likely reflect the effects of cumulative exposures/stressors. They may also be early exposure/effects biomarkers for chronic diseases such as cancer, cardiovascular disease, diabetes and inflammatory disease. Understanding the extent to which genetic differences account for individual variations in response, will assist in better understanding gene-environment interactions, a major focus of the National Children's Study. This abstract does not necessarily represent EPA policy.

#### 1869

DEVELOPMENT AND USE OF BIOMARKERS OF EXPOSURE FOR CDC'S NATIONAL EXPOSURE

L. L. Needham. Organic Analytical Toxicology, Centers for Disease Control and Prevention, Atlanta, GA. Sponsor: B. Abbot.

In environmental public health involving potential exposure to chemicals, it is essential to assess exposure and any effects in an accurate manner. Our laboratory has developed analytical methods for measuring chemicals or their metabolites in biological specimens. We have used these to support epidemiological investigations, emergency response investigations, and for exposure assessment studies. In each of these types of studies, it is very helpful to have a reference value for these chemicals in the general population. We recently reported reference range concentrations of several chemicals in segments of the US population. The National Health and Nutrition Examination Survey was used to collect these urine and blood samples. The results were examined based on age, sex, and race/ethnicity. These results, applications of these results, and future plans for collecting such data will be discussed.

**1870** STUDY DESIGN CONSIDERATIONS FOR THE EXPOSURE COMPONENT OF THE NATIONAL CHILDREN'S STUDY.

H. Ozkaynak<sup>1</sup>, L. Needham<sup>2</sup>, R. Whyatt<sup>3</sup> and J. Quackenboss<sup>4</sup>. <sup>1</sup>NERL, USEPA, Washington, DC, <sup>2</sup>CDC, Atlanta, GA, <sup>3</sup>Columbia University, New York, NY and <sup>4</sup>NERL, USEPA, Las Vegas, NV. Sponsor: <u>H. Ozkaynak</u>.

An ideal strategy for the exposure monitoring component of the planned National Children's Study (NCS) is to measure indoor and outdoor concentrations and personal exposures of children to a variety of pollutants, including ambient particulate and gaseous pollutants, biologicals, endocrine disrupting chemicals, metals, pesticides, among others. However, due to the large sample size of the study (about 100, 000 children), it is not feasible to measure every possible exposure of every child in the study. Thus, an important technical and logistical challenge is to develop an appropriate study design with adequate statistical power that will permit detection of exposure-related health effects, based on exposure and biomonitoring measurements on a smaller subset of the target population. Since the study will follow a longitudinal design, a related challenge will be deciding: a) which exposure-related measurements need to be assessed repeatedly over time; b) the timing of such repeated exposure assessments, and c) the appropriate type of direct and/or indirect (e.g., survey based) monitoring methodology to be employed, given various resource and participant burden considerations. The Chemical Exposure Work Group of the NCS project is currently undertaking an evaluation of these issues by utilizing the expertise represented within the group, as well as, those of outside contractors, in evaluating the available information on exposure monitoring in the context of an epidemiological study design. This presentation will summarize the recent findings from this NCS sponsored work group activity regarding potential alternatives for exposure and biological sampling, and inference of subject-specific exposures in the context of an epidemiologic study design. Disclaimer: This work has been partially funded by the United States Environmental Protection. It has been subjected to Agency review and approved for publication. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

**1871** ENVIRONMENTAL EXPOSURE AND ASTHMA: HYPOTHESES FOR THE NATIONAL CHILDREN'S

S. J. London. Epidemiology Branch, National Institute of Environmental Health Sciences, Research Triangle Park, NC. Sponsor: B. Abbott.

Asthma hypotheses for the National Children's Study were developed by the Interagency Coordinating committee with input from the Asthma Working Group which developed hypotheses and coordinated the work of many other working

groups that also submitted asthma hypotheses. The goal was to identify the most important hypotheses for asthma regarding the environment, both physical and social. We also focused on hypotheses which must be addressed in the context of a longitudinal study beginning as early in life as possible. Out of the two year process came the following asthma hypotheses: 1. Exposure to outdoor and indoor air pollution and bioaerosols (allergens, fungi) is associated with increased risk of developing asthma. 2. Respiratory viral infection in early life is associated with increased risk of developing asthma. 3. Maternal stress during pregnancy and in the early life of the child is associated with increased risk of developing asthma. 4. Dietary factors influence the risk of asthma. In particular, dietary antioxidants and other micronutrients decrease the risk of asthma, while obesity increases the risk of asthma. 5. Early exposure to certain bacteria and their products (ex: endotoxin) decreases the risk of asthma. This encompasses the "Hygiene Hypothesis" of asthma. 6. Access to health care and management of asthma are strongly related to asthma hospitalization and morbidity. The asthma working group has been organizing workshops aimed at developing methodologies needed to address these hypotheses in a cost-efficient manner in the National Children's Study.

#### 1872 DEVELOPING THE USE OF THRESHOLD CONCEPT FOR PROTEIN ALLERGENS.

<u>I. Vodela</u><sup>1</sup> and <u>T. D. Landry</u><sup>2</sup>. <sup>1</sup>Residue Branch, USDA/FSIS, Washington DC, DC and <sup>2</sup>Environment, Health and Safety, Dow Chemical Company, Midland, MI.

Public exposure guidelines are meant to protect all segments of the population, including the very young and the very old, pregnant women, and hypersensitive individuals. Each year the Food & Drug Administration receives reports of consumers who experienced adverse reactions following exposure to an allergenic substance in foods. Food allergies are abnormal responses of the immune system, especially involving the production of allergen specific IgE antibodies, to naturally occurring proteins in certain foods that most individuals can eat safely. Although the number of food proteins with allergenic potential is not clearly established, there are a limited number of proteins involved in commonly observed food allergy. When the immune system recognizes a food protein as foreign and harmful, cellular and biochemical cascades are initiated that may lead to sensitization and ultimately allergic reactions. There is a significant incidence of food allergy to naturally occurring allergens in children (5% to 6 % in US) and adults (2% US). Although protection may require exposure avoidance (e.g. to peanuts in peanut sensitive persons), it would be preferable to be able to apply the "dose makes the poison" concept to induction and / or elicitation. This round table will provide recent scientific information on the health effects of protein allergens and will consider how the "threshold" concept for sensitization to allergens may be applied to establishing non-zero exposure guidelines.

#### **1873** FOOD ALLERGENS-THE FDA PERSPECTIVE.

K. Falci. US Food and Drug Administration, Center for Food Safety and Applied Nutrition, College Park, MD. Sponsor: J. Vodela.

Food allergies affect an estimated 6% of young children and 2% of adults in the United States. A food allergy is an IgE-mediated immunologic reaction to an ingested food and may result in a variety of symptoms including the skin, gastrointestinal tract, and respiratory tract. Eight major foods account for 90% of all food allergies: milk, egg, peanut, tree nuts, fish, crustacea, soy, and wheat. As the Agency responsible for the safety of the nation s food supply, the United States Food and Drug Administration (FDA) is actively involved in efforts focused on food allergy for the eight most common allergenic foods. Currently regulations require the declaration of all ingredients on the food label, yet undeclared allergens remain an important issue. Failure to declare ingredients, collective naming of flavors, colors, and spices, advisory labeling statements, recalls, and test kits for allergen protein detection are just some of the issues of concern to both the FDA and allergic consumers. Through allergen inspections, outreach to industry and consumers, and enforcement of regulations, USFDA continues efforts to improve food allergen activities

FACTORS AFFECTING THE DETERMINATION OF 1874 THRESHOLD DOSES FOR ALLERGENIC FOODS: TOXICOLOGICAL ASPECTS.

S. Hefle. Food Allergy Research and Resource Program, University of Nebraska, Lincoln, NE. Sponsor: T. Landry.

While there are numerous anecdotal reports of activities such as opening packages of the offending food or kissing the lips of someone who has eaten an allergenic food being capable of eliciting allergic responses in food-allergic individuals, the majority of experiences indicate that non-zero thresholds exist and that severe allergic reactions have usually been associated with high levels of contamination. There are several factors that affect how studies for minimum eliciting doses of allergenic foods are designed and the resulting data interpreted. A description of the challenges that a group that sought to determine whether existing data on threshold doses for commonly allergenic foods were sufficient to allow consensus to be reached on the establishment of threshold doses for specific foods (Taylor et al. (2002); J. Allergy Clin. Immunol.) found and the development of a globally recognized consensus protocol for doing threshold studies will be covered. Problems of interpretation of results and assigning safety factors will be discussed, such as comparing subjective reactions to objective reactions, study design issues, the uncertainty in using LOAEL to establish threshold doses for allergenic foods, and the large variability of individual threshold doses. One mathematical model for thresholds that has been proposed (Bindslev-Jensen et al. (2002) Allergy) will be discussed. Additional issues will be covered such as the decision to use adults vs. children (and the challenges associated with outgrowth of childhood food allergies), issues with the nature of the challenge material or allergen content of the challenge materials and the fact there are no validated animal models for allergenic food thresholds to date. There is no widespread agreement on whether the current statistics used in threshold studies will be acceptable to regulatory agencies; evolving ideas on what the safety factors should be will also be presented.

### 988

#### 1875 FACTORS AFFECTING THE DETERMINATION OF THRESHOLD DOSES FOR ALLERGENIC FOODS-CLINICAL ASPECTS.

J. Hourihane. Infection Inflammation and Repair, University of Southampton, Southampton, United Kingdom. Sponsor: J. Hourihane.

There are many factors that contribute to a variation of eliciting doses in an individual exposed to a food allergy by accident in the community or deliberately during a formal food challenge. Some of these factors are intrinsic and unavoidable: age and gender, for example, or asthma. Other factors may be predictable but not easily controllable, such as the degree of asthma control (which appears critical), exposure to allergens during the pollen season (reactions may be more likely if the food allergen is associated with pollens) and predicting situations that may be associated with higher risk (eating the allergen after exercise or while consuming alcohol). Other factors may be out of the control of the individual. The most important one of these is the adequate training and awareness of manufacturers and caterers who aim to provide safe and nutritious meals to their allergic and non-allergic customers alike. Subjects can react in different ways to the same dose, if the allergen is presented in different food combinations or after different cooking processes: egg becomes less allergenic with cooking, peanut becomes more allergenic. Exploration of eliciting doses during food challenges is now a widely accepted clinical practice. People can volunteer for research motivated food challnges or may have clinicallymotivated (physician-directed) challenges modified to embrace exploration of lowest eliciting doses. Safety considerations mean that challenge subjects must be in optimal physical condition with stable asthma and atopic dermatitis. They are also self-selected to a degree in that subjects who consider themselves high risk do not volunteer for studies. This means they may not be representative of the group of patients at highest risk in the community. Threshold data generated in formal challenges represent the current state of the art but several confounding variables affect these data and a broader view needs to be taken before legislating about threshold amounts of allergens in foods.

### 1876 COMMUNICATING RISKS ASSOCIATED WITH FOOD ALLERGENS.

D. W. Achesson. Center for Food Safety and Applied Nutrition, Food and Drug Administraion, College Park, MD. Sponsor: J. Vodela.

Allergy to foods is a significant cause of morbidity and mortality in the United States. Current estimates of the burden on the health care system are difficult to determine due to an apparent underreporting of serious adverse events and death associated with exposure to food allergens. Part of a successful strategy to combat allergy from foods is to ensure both consumers and health care professionals are well educated regarding the risks and preventative strategies that could be adopted. Education campaigns are frequently more successful if focused on targeted populations. To that end gaining a better understanding of the at-risk populations as well as the true disease burden would facilitate a more directed consumer message. FDA continues to explore ways to improve communication to stakeholders regarding allergens as well as methods to improve understanding of the overall morbidity and mortality associated with food allergy

### 988

## EVIDENCE FOR THRESHOLDS FOR TYPE 1 ALLERGY TO ENZYMES USED IN THE DETERGENT INDUSTRY.

K. Sarlo. Central Product Safety, Procter & Gamble Company, Cincinnati, OH.

Occupational allergy to enzymes used in the detergent industry is well recognized. The industry has been able to control the development of IgE antibody to enzymes and the onset of disease via strict adherence to exposure guidelines. These guidelines help to minimize exposure via management of product formula, equipment, ventilation, clean-up procedures, air and medical monitoring and employee training and education. Decades of prospective monitoring of the workforce has shown that individuals with enzyme-specific IgE antibody can continue to work in the industry with a greatly reduced risk for developing symptoms of allergy caused by enzymes. During the late 1960s, approximately 50-60% of the workforce had IgÉ antibody and 15% of these individuals developed asthma within 1 year of use of enzyme in the detergent industry. Currently, only 10-20% of the workforce has IgE antibody to enzyme and there have been only 2-3 cases of enzyme-induced asthma over the past 12 years. These observations show that the intensity of exposure needed to induce the generation of IgE is less than the intensity needed to elicit symptoms. Studies in animal models of enzyme allergy support the observations made in man: low exposure to enzyme will induce antibody but is not sufficient to elicit respiratory reactions. Prospective and retrospective clinical evaluations of consumer populations exposed to different enzyme-containing products also show that thresholds exist for induction of IgE antibody. Exposure to enzyme via use of detergents for hand laundry or machine laundry does not lead to induction of IgE antibody yet exposure to enzyme via personal care cosmetic products can. The exposure from detergent use is very different from the exposure from personal care use, supporting the existence of thresholds for induction of IgE. The experience of managing type 1 allergy to enzymes tell us that there are different thresholds of exposure for inducing IgE and for eliciting allergy symptoms and that the development of IgE antibody does not equate to disease.

### 1878 AN *IN VITRO* SURROGATE FOR DRUG-INDUCED PHOSPHOLIPIDOSIS.

R. E. Morgan, A. Kriauciunas, B. Berridge, J. Sullivan and D. K. Monteith. Lead Optimization Toxicology, Eli Lilly Research Labs, Greenfield, IN.

Drug-induced Phospholipidosis (PL) is the lysosomal accumulation of phospholipids likely due to interference in phospholipase activity, though other mechanisms have been described. The disorder has not been causally linked to aberrant cell function, however its occurrence is of concern in drug development. This condition is characterized by the presence of intralysosomal lamellar inclusions, appearing as electron-dense whorls in electron micrographs, and can occur in concert with organ toxicity. Drug molecules that possess a polar motif comprised of a lipophilic region and a charged region are aptly named cationic amphiphilic drugs (CAD), and have been shown to induce PL in a variety of tissues. Current in vitro screening strategies for PL are qualitative and afford limited throughput. Therefore, a 96-well method of screening for PL was developed and validated utilizing primary rat hepatocytes, a phospholipid-conjugated dye (NBD-PE), a laser-scanning fluorescence detection system, and several CAD. Concentration-response curves were established for chloroquine, amiodarone, propranolol, imipramine, maprotiline, two proprietary molecules, and two negative controls (amikacin & isoniazid) to validate the assay. EM confirmed the ability of the in vitro hepatocyte assay to detect PL. This assay was then employed to screen candidate drugs from various platforms for PL; the results correlated well with *in vivo* findings. In screening one drug platform, several molecules induced the formation of vacuoles that were absent of NBD-PE fluorescence and appeared as intracellular dark-holes under fluorescence microscopy. EM of hepatocytes exposed to these drug candidates revealed the presence of clear cytoplasmic vacuoles, not consistent with PL. Subsequent in vivo studies confirmed the presence of clear cytoplasmic vacuoles in several tissues in the absence of typical PL. In summary, this assay quantified PL in vitro with accuracy, reproducibility and moderate throughput, and was shown to correlate well with in vivo histologic changes.

## 1879 MODELLING THE ESTROUS CYCLE *IN VITRO* USING 3-D RAT VAGINAL EPITHELIUM CELL CULTURES.

R. Caldelari<sup>1</sup>, B. D. Car<sup>2</sup>, L. D. Lehman-McKeeman<sup>2</sup>, E. J. Muller<sup>1</sup> and M. M. Suter<sup>1</sup>. <sup>1</sup>CELLnTEC advanced cell systems, Bern, Switzerland and <sup>2</sup>Bristol Myers Squibb, Princeton, NJ.

The vaginal epithelium undergoes significant, hormone induced morphological changes during the estrus cycle. To date, assessment of estrous cycle disruption has relied on animal-intensive procedures, including cytology of cells from vaginal lavage, direct histology of the vaginal epithelium, or the uterotrophic assay measuring uterine weight change. Here we describe a dynamic 3-D *in vitro* model that accurately mimics the cyclical structural changes exhibited by the multilayered strati-

fied squamous vaginal epithelium during the estrous cycle *in vivo*. This model was established from long-term (40 passage) cultures of rat vaginal keratinocytes using CELLnTEC's serum-free medium CnT-03. Following cyclical alteration of the progesterone and estradiol concentrations in the culture medium over a 4-day period, histological investigation revealed characteristic morphological alterations including transient production of mucous cells, followed by cornification. The cyclical morphology observed closely matched the stages of diestrous 1, diestrous 2, proestrous, and estrous as seen *in vivo*. Addition of progesterone alone was not sufficient to induce these cyclical changes. Overall, based on histological examination this model appears to accurately mimic the structural changes seen during the estrous cycle *in vivo*, and therefore represents the first *in vitro* alternative to the use of live animals for assessment of estrous cycle disruption.

## 1880 PREDICTION OF OVARIAN FUNCTION DEFECTS BY MOUSE FOLLICLE CULTURE.

J. E. SMITZ<sup>1</sup>, I. Hellinckx<sup>2</sup> and R. Cortvrindt<sup>1, 2</sup>, <sup>1</sup>Reprod Med., AZ-VUB, BRUSSELS, Belgium and <sup>2</sup>EggCentris NV, Zellik, Belgium. Sponsor: P. McAnulty.

Regulatory agencies demand for the development of in vitro systems to replace current in vivo testing protocols. Today most often in vitro assays use isolated cells / cell lines of the target organ. The ovary is composed of follicles, functional units to grow and mature the oocyte and produce steroid hormones. Folliculogenesis is a lengthy process consisting of oocyte growth and maturation along with theca cell recruitment, granulosa cell proliferation and differentiation. Follicle development is characterised by an intense paracrine signalling between the different cell types. Disruption of the unit results in dedifferentiation of the somatic cells and block growth and maturation of the oocyte. The only relevant assay to correctly assess ovarian function in vitro is follicle culture. Preantral mouse follicles were cultured singly for 12 days in  $\alpha$ MEM with 5 % FCS, ITS and gonadotrophins. The preantral follicles attach by outgrowh of the theca cells and undergo a remodelling process. By day 8 granulosa cells differentiate into mural and cumulus cells separated by antral-like cavities. By day 12, follicles reach the preovulatory stage and respond to an hCG/LH stimulus. Denuded oocytes were analysed for nuclear maturation. Results were expressed in % of follicles that reached the criterion within the set of follicles (10/15). 330 sets were collected over time and analysed for reproducibility. Defined end-parameters (Mean +/-SD): day 12:Follicle Survival (97 +/-6%), Antrum formation (80 +/- 17%); day 13: Mucification (97 +/- 5%); PB oocytes (85 +/- 11%). Steroidogenesis: estrogen on day 4(41 ng/l) (preantral stage), day 8 (3969 ng/L), day 12 (17256 ng/L). Progesterone levels on day 8 and 12 (0.37 and 3, 97  $\mu$ g/L) and increased steeply 16 h after the hCG stimulus to 247.2  $\mu$ g/L. Conclusion: Cultured preantral mouse follicles progress in vitro as in vivo within a strictly defined time frame. Under defined culture conditions the outcome is reproducible and can be used to study ovarian function in vitro. This multi-parametric assay is suitable for female fertility risk assessment.

## 1881 AN *IN VITRO* SURROGATE ASSAY FOR MITOCHONDRIAL TOXICITY.

B. Li, D. Watson, <u>R. Morgan</u> and <u>D. Monteith</u>. *Lilly Research Laboratories, Greenfield, IN*.

Nucleoside analogs are prominent agents in antiviral and anticancer therapies; however, these compounds have been implicated in a variety of organ toxicities in patients. These dose-limiting toxicities occur after prolonged treatment and have been linked to effects on the mitochondria (Mt). Therefore, it is considered important to evaluate nuceloside analogs for their effect on Mt in human cell systems. A mechanism for the Mt effects involves the inhibition of DNA polymerase gamma. In the present research, several endpoints were evaluated to determine cytotoxicity in proliferating and static cultures of human hepatocytes. In addition, specific Mt effects were assessed by determination of MtDNA content using a novel TaqMan® analysis of MtDNA and nuclear DNA. Confluent and low-density cultures of HepG2 cells were treated for 4 to 8 days with a range of nucleoside analog concentrations. AZT, dideoxycytidine (ddC), and ribavirin (Rbv) were selected as compounds with different mechanisms for inhibiting DNA synthesis. The test compounds did not induce cytotoxicity in static cell cultures at concentrations up to 300 microM by the assessment of cellular ATP or neutral red uptake. All three compounds induced effects on ATP and neutral red uptake in proliferating cells. Effects were concentration-dependent, evident at 4 days and progressed with increasing duration of treatment. Rank order potency of the compound-mediated cellular effects was Rbv>AZT>ddC. At 8 Days, cytotoxicity in the proliferating cultures was observed at 30 to 100 microM. Interestingly, cytotoxicity or potential growth inhibition was not associated with effects on MtDNA content. AZT or Rbv did not affect MtDNA content. In contrast, ddC did decrease MtDNA content in a concentration-dependent manner in both proliferating and static cultures and this effect was not associated with cytotoxicity. In summary, the in vitro assay quantified MtDNA content associated with cellular effects with accuracy, reproducibility and moderate throughput.

### 1882 INVESTIGATING APOPTOTIC MECHANISMS OF CELL DEATH USING POSITIONAL BIOSENSORS.

J. R. Haskins, A. M. Peters, M. Weiss, J. Strauss, R. DeBiasio and Y. Chen. *Assay Development, Cellomics, Inc., Pittsburgh, PA.* Sponsor: <u>E. McGuire</u>.

Apoptosis is integral to many normal developmental processes, but can lead to premature cell death when triggered by xenobiotics. There are several key criteria for determining whether a cell is undergoing apoptosis, including distinct changes in cellular morphology and alterations in specific biochemical and molecular markers. The general patterns of apoptotic signals are comparable, but mechanistic drivers can vary significantly depending on cell type and causative agent. Among key proteases that can trigger apoptosis are the caspases. We have developed two positional biosensors for in vitro monitoring intracellular caspase 3 and 8 activity in living or fixed cells. Both biosensor designs are based on measuring the intracellular redistribution of fluorescent reporters from an initial subcellular compartment to a targeted compartment upon activation. These biosensors are composed of recombinant polypeptides containing several key components, including reporting, sensing and targeting elements. Following proteolytic cleavage of the sensing element by the activated caspase, the targeting and reporting elements are driven by a nuclear localization signal to the nucleus where they are easily detected using quantitative image analysis. To demonstrate applicability of this approach, a 240 compound library of known toxins was screened against HeLa cells stably expressing either the caspase 3 or 8 biosensor at concentrations of 1, 10 or 50 µM for up to 4 hours. By adding additional fluorescent probes for detecting changes in nuclear morphology, mitochondrial transmembrane potential and membrane permeability, further details were elucidated that allowed differentiation of apoptotic mechanisms. Individual cellular responses were quantitated using automated fluorescence microcopy. Results indicated the value of positional biosensors as a new generation of fluorescent protein reagents that function as temporal and spatial reporters of cellular

## 1883 C. ELEGANS RESPONSE TO MAMALIAN ANTIOXIDANT RESPONSE ELEMENT INDUCER TRHO

M. Calkins<sup>1,3</sup> and <u>J. A. Johnson</u><sup>1,2,3</sup>. <sup>1</sup>Molecular and Environmental Toxicology Center, University of Wisconsin, Madison, WI, <sup>2</sup>Waisman Center, University of Wisconsin, Madison, WI and <sup>3</sup>School of Pharmacy, University of Wisconsin, Madison, WI

Caenorhabditis elegans has proved to be a useful model for many human dieases and conditions. The response of c. elegans to pharmacological agents is often very similar to the human response. As such c. elegans can provide a simple, easily manipulated whole organism model for pharmacological processes that are relevant to humans. In this regard we have begun to evaluate the response of c. elegans to known antioxidant response element (ARE) inducers, especially tert butyl hydroquinone (tBHQ). The ARE is a cis-acting enhancer sequence that mediates expression of phase II detoxification enzymes in response to oxidative stress. This response is centered on the cap n collar transcription factor Nrf2. tBHQ has been shown to induce Nrf2 activity and activate the ARE in mammalian systems by a mechanism that is independent of oxidative stress. Early microarry data has revealed a set of genes in c. elegans that are inducible by tBHQ treatment in mixed population cultures. Many of the identified genes are involved in antioxidant protection and phase II conjugation. Additionally, we have shown that tBHQ treatment extends lifespan and that pretreatment can protect against oxidative insults. These results suggest that there is a homologous ARE type response in c. elegans. Furthermore, it is possible that the mechanism by which tBHQ activates ARE gene expression in mammals is conserved as well. Since this mechanism is unknown in mammalian systems, c. elegans may prove to be a useful model for elucidating this response. In order to further characterize the response to tBHQ we conducted RT-PCR analysis of staged cultures at different time points, and found that tBHQ dependant induction occurs in larval and adult worms. In dauer worms however, we find a much different response. Specifically there is a downregulation of the transcription factor Skn-1, which is known to be homologous to Nrf2 in structure and function. We are currently investigating the mechanism by which tBHQ activates gene expression in the nematode c. elegans.

#### 1884

WOUND HEALING RESPONSE OF THE EPIDERM FULL THICKNESS (EPIDERM-FT) *IN VITRO* HUMAN SKIN EQUIVALENT AFTER SOLAR UV IRRADIATION: COMPARISON TO EXCISED HUMAN SKIN.

<u>P. J. Hayden</u>, B. Burnham, <u>M. Klausner</u>, J. Kubilus and J. E. Sheasgreen. *MatTek Corp., Ashland, MA*.

Normal human epidermal keratinocytes (KC) and dermal fibroblasts (FB) were cultured to produce full-thickness skin equivalents consisting of FB-containing dermal and stratified epidermal components with a fully developed basement membrane at

the dermal/epidermal junction (EpiDerm-FT 200, EFT). The wound healing response of EFT after solar UV-irradiation was compared to excised human skin. H&E stained paraffin sections of EFT displayed a dose-dependent increase in apoptotic sunburn cells at 24 h post-irradiation. After 48 h, high dose (61 J/cm2, metal halide lamp) samples showed extensive epidermal damage and some dermal damage. After 72 h, sunburn cells still persisted in mid dose samples (40 J/cm2), which were thinner than controls (indicating a major decrease in KC proliferation) but still without major epidermal damage. Epidermal destruction of high dose samples was nearly complete at 72 h with significant loss of dermal matrix also evident. However viable basal cells remained in some areas, with signs of proliferation and epidermal regeneration. MMP-1 activity in the culture media was also evaluated by ELISA. A 50% increase in activity was observed in irradiated samples at 24 h. By 48 h, mid dose samples showed a 100% increase in activity, while high dose samples showed a 150% increase. At 72 h, mid dose sample MMP-1 activity was comparable to controls, while high dose sample activity remained elevated by 125%. Similar experiments were conducted with excised human skin. The response was similar to EFT. The earliest response was increased sunburn cell formation, with tissue thinning at 40 J/cm2 and extensive damage at 61 J/cm2. Basal cell proliferation and epidermal regeneration was also observed in the excised human skin by 72 h in high dose samples. These results show that the EFT human skin equivalent behaves similarly to excised human skin in terms of solar UV induced damage and wound healing. The model may thus prove useful for additional applications in dermal/epidermal wound healing phenomena.

## 1885 MURINE EMBRYRONIC STEM CELLS AS A MODEL TO IDENTIFY BIOMARKER PROFILES OF PPAR AGONISTS.

M. Pang<sup>1</sup>, T. Downey<sup>2</sup>, S. Kim<sup>3</sup>, K. L. Rose<sup>1</sup>, R. Snodgrass<sup>3</sup> and <u>A. E. Vickers<sup>1</sup></u>. <sup>1</sup>BioMarker Development, Novartis Pharmaceuticals, East Hanover, NJ, <sup>2</sup>Partek, Inc., St. Charles, MO and <sup>3</sup>VistaGen Therapeutics, Inc., Burlingame, CA.

Murine embryonic stem (ES) cell differentiation represents a dynamic biological system for investigating compound induced effects on a wide range of cell types and tissue-tissue interactions in vitro. Our goal is to identify biomarker profiles that are characteristic of PPAR activators. The PPAR activators included in this study are PPAR $\gamma$ -agonists (troglitazone, pioglitazone and rosiglitazone), PPAR $\alpha$ -agonists (WY14643, fenofibrate, bezafibrate), and the mixed PPARα-γ agonists (KPR297 and AZ242). Previously, concentration profiles eliciting a 20-50% decrease in cell number at the end of a 6-day differentiation embryoid body (EB) assay using the murine embryonic stem cell line CCE-Lena (derived from 129Sv mouse strain) were determined. Here, we investigate the effect of each compound on ES cell differentiation and development by comparative analysis of the gene expression profile of cultures exposed for either 6-days, or for the last 3-days following an initial 3-day EB development period. Gene expression profiles were established using the Affymetrix murine genome array (Û74Av2) followed by statistical analysis of the data via hierarchical clustering, principal components analysis, and 3-way analysis of variance based on exposure time, type of PPAR agonist ( $\alpha$ -agonists,  $\gamma$ - agonists, or mixed), and individual compound. Preliminary findings indicate that it is possible to separate the PPAR-agonists from each other according to the type of PPAR activator and length of compound exposure. Global gene expression and quantitative RT-PCR analysis of marker genes suggest a PPAR activator related effect on murine stem cells, increasing immature mesoderm differentiation and suppression of liver and blood-related differentiation.

## 1886 EMBRYONIC STEM CELL-DERIVED HEPATOCYTE CULTURES AS A MODEL TO IDENTIFY BIOMARKER PROFILES OF PPAR AGONISTS.

H. R. Snodgrass<sup>1</sup>, Y. S. Kim<sup>1</sup>, O. A. Callan<sup>1</sup>, G. Keller<sup>2</sup>, A. Kubo<sup>3</sup> and <u>A. Vickers<sup>4</sup>. <sup>1</sup>VistaGen Therapeutics, Inc., Burlingame, CA, <sup>2</sup>Mount Sinai School of Medicine, New Youk, NY, <sup>3</sup>Nara Medical University, Nara, Japan and <sup>4</sup>Novartis Pharmaceuticals, East Hanover, NJ.</u>

The goals of these studies are to identify biomarker profiles that are characteristic of PPAR activators, and to evaluate the utility of *in vitro* cultures of hepatocytes differentiated from murine embryonic stem (ES) cells as a system for early toxicity assessment. ES cell differentiation systems represent a dynamic *in vitro* biological system for investigating compound induced effects on a wide range of cell types and tissue-tissue interactions. The PPAR activators included in this study are PPARγ-agonists (troglitazone, pioglitazone, rosiglitazone and KRP297), PPARα-agonists (WY-14643 and fenofibrate), and the mixed PPAR agonists (bezafibrate and AZ242). Here, we report on the effect of each compound on an ES cell culture system, designed to optimize hepatocyte differentiation, by adding the compound during the last 2 days of a 14 day culture. The effects of the compounds were evaluated by monitoring gene expression using microarrays. The data were analyzed by a variety of statistical tools including analysis of variance, hierarchical clustering, principal components analysis, and class prediction algorithms. Preliminary analy-rincipal components

ses indicate that, contrary to the results with the 6-day EB assay (presented in another abstract), troglitazone had a more pronounced effect, than pioglitazone and rosiglitazone, on the differentiation of these cultures. The expression of a significant number of the genes relating to liver development was modified by these compounds. Predictive gene biomarkers were identified which had an 89% success rate of distinguishing troglitazone from pioglitazone and rosiglitazone effects, and a 85% success rate of distinguishing PPAR $\alpha$  from PPAR $\gamma$  agonists. These data suggest that, in combination with the 6-day EB system, the ES differentiation system may be a very useful early screen for compound toxicity and pathway effects.

## 1887 CHEMICALLY INDUCED CELL DEATH IN HUMAN KERATINOCYTES.

O. E. Clark, E. W. Nealley, K. L. Finke, R. E. Roberts and W. J. Smith. *Biochem Pharmacology Br, US Army Med. Rsch Inst of Chem Defense, Aberdeen Proving Ground, MD.* Sponsor: <u>A. Brimfield</u>.

Our laboratory studies the mechanism of toxicity of the chemical blistering agent sulfur mustard (SM) for the purpose of developing medical countermeasures to this chemical threat agent. SM is a cytotoxic alkylating agent with mutagenic and vesicating properties. The exact mechanism of SM-induced skin vesication is not completely understood. The human epidermal keratinocyte (HEK) in culture is the in vitro equivalent of the basal epidermal cell of human skin, a principal target for the toxicity of SM in tissue. In this report, our laboratory evaluated several markers of cytotoxicity in HEK exposed to SM and a variety of chemical toxicants. The markers studied were protein content, cellular morphology, membrane integrity, annexin V labeling and DNA fragmentation. The chemical toxicants were calcimycin (A23187), staurosporine (STR), cycloheximide (CHX), actinomycin D (ActD) and camptothecin (CPT). All six compounds lowered cellular protein levels at 24 hours post-exposure, with A23187 and STR having significant effects as early as 4 hours after exposure. A23178 caused an early (1 hr) annexin V response, but these cells rapidly die as determined by an uptake of propidium iodide (PI). By 4 hours, only STR shows an increase of annexin positive cells. SM failed to generate annexin staining at either 4 or 24 hours post-exposure. As for morphological changes, only STR and A23187 led to changes at 4 hours. STR resulted in stellate-shaped cells, whereas A23187 yielded cells that rounded up and had contracted cytoplasm. At 24 hours, A23187 caused DNA-containing cytoplasmic blebs, whereas SM-exposed cells had blebbing without DNA content. Comet analysis of DNA fragmentation did not discriminate different types of death processes by the different toxicants. These results help elucidate the contributions of various death processes following toxicant exposure and hopefully will contribute to a better understanding of critical events in SM pathology.

## 1888 SULFUR MUSTARD ALTERS LAMININ 5 AND GELATINASE MNRA LEVELS AND INCREASES

GELATINASE MNRA LEVELS AND INCREASES
GELATINASE ACTIVITY IN A MOUSE EAR VESICANT
MODEL.

Bis(2-chloroethyl)sulfide (sulfur mustard, HD), is a chemical warfare agent that penetrates the skin rapidly, and, after several hours, causes extensive blistering. Epidermolysis bullosa (EB) is a genetic disease with a similar skin phenotype as that of HD blistered-skin. Some forms of EB are caused by mutations in the genes for any of the three polypeptides (laminin- $\alpha 3$ , laminin- $\beta 3$  and laminin- $\gamma 2$ ) that form the basement membrane protein, laminin 5. Matrix metalloproteinases (MMPs) may play a role in the chronic structural damage incurred in EB. We treated mouse ears with 80µg of liquid HD and examined whether the expression of the laminin 5 chains or MMPs are altered after HD exposure. Ear specimens were taken at 6, 12, 24, and 72 hours after mustard exposure for histology, real-time PCR and gelatinase activity assays. HD caused a time-dependent increase in skin weight and damage relative to vehicle controls. HD exposure increased mRNA levels for MMP-9 (gelatinase B), laminin- $\alpha$ 3, laminin- $\beta$ 3 and laminin- $\gamma$ 2, whereas MMP-2 (gelatinase A) mRNA levels decreased. There was a time-related increase in overall gelatinase activity observable 6 hours after HD exposure. The enzyme activity peaked at 24 hours, and persisted throughout the study. This increased MMP activity may contribute to the blister damage. An understanding of these in vivo MMP patterns following HD skin exposure may lead to defining the pathogenic mechanisms of HD injury and the development of pharmacological countermeasures. \*This work is supported by the US Army Medical Research and Materiel Command under Contract No. DAMD17-02-C-0091

Sulfur mustard (SM) is an alkylating agent that has been used as a chemical warfare agent in numerous conflicts around the world. The lung is a primary target of SM exposure. To understand the mechanism of SM-induced lung injury we analyzed global changes in gene expression in a rat lung SM exposure model. Male Sprague-Dawley rats were injected in the femoral vein with liquid SM, which circulates directly to the pulmonary vein and then to the lung. This results in a deep lung SM exposure. Rats were exposed to 1 mg, 3 mg or 6 mg of SM, and lung tissue was harvested at 0.5, 1, 3, 6 and 24 hours post-injection. RNA was extracted from the lung and used as starting material for the probing of oligonucleotide microarrays. The gene expression data were analyzed using principal component analysis and twoway analysis of variance to identify the genes most significantly changed as a result of variation over time and dose. These genes were rank ordered by p-value and categorized based on molecular function and biological process. Previously, inflammation has been shown to play a role in SM injury, and our data corroborate these findings. However, the most significant changes in gene expression reflect alterations in the cell cycle and vesicular trafficking. In particular, the changes in cell cycle reflect a potential cell cycle block at the G1/S transition due to activation of the p53 pathway. Although our data do not determine directly the activation of p53, many of the genes that are significantly upregulated in a dose dependent fashion have been shown by other investigators to be p53 responsive genes. Thus, SM exposure appears to induce a robust p53 response in the lung.

GENOMIC ANALYSIS OF THE MECHANISM OF ACTION OF POTENTIAL VESICANT COUNTERMEASURES.

J. F. Dillman<sup>1</sup>, L. M. Dorsch<sup>1</sup>, A. I. Hege<sup>1</sup>, C. S. Phillips<sup>1</sup>, Y. W. Choi<sup>2</sup>, R. C. Kiser<sup>2</sup> and <u>C. L. Sabourin<sup>2</sup></u>. <sup>1</sup>Applied Pharmacology, USAMRICD, Aberdeen Proving Ground, MD and <sup>2</sup>Medical Research and Evaluation Facility, Battelle Memorial Institute, Columbus, OH.

Sulfur mustard (SM) is a potent alkylating agent that induces cutaneous vesication. We are developing medical countermeasures to reduce the injury caused by SM exposure. Screening in the mouse ear vesicant model has identified three lead compounds: British anti-lewisite (BAL), indomethacin, and octyl homovanillamide. To understand the molecular mechanism of action of these compounds we used oligonucleotide microarrays to compare gene expression profiles in unexposed skin (vehicle control), SM-exposed skin, and skin pretreated with each compound before SM exposure. Male CD-1 mice were topically exposed on the inner surface of the right ear to SM alone or pretreated for 15 minutes with one of the lead compounds and then exposed to SM. Left ears were vehicle-exposed. Skin tissues were harvested 24 hours later for ear weight determination (an endpoint indicating compound efficacy). RNA was extracted from the tissues and used as starting material to probe oligonucleotide microarrays. The gene expression data were analyzed using principal component analysis (PCA) to identify sources of data variability. Our PCA results reveal partitioning of the samples based on drug treatment and SM exposure. Vehicle-exposed mouse ears cluster together away from the other treatment groups. Mouse ears pretreated with BAL or octyl homovanillamide cluster more closely with vehicle-exposed ears, while indomethacin-treated mouse ears cluster more closely with SM-exposed ears. This clustering of the samples is supported by the relative ear weights, in which the indomethacin group has ear weights closer to the SM-exposed group, whereas the BAL and octyl homovanillamide groups have ear weights closer to the vehicle-exposed group. These data provide the basis for understanding what gene expression changes are important in the development of efficacious SM exposure treatments.

## 1891 TIME- AND DOSE-DEPENDENT ANALYSIS OF GENE EXPRESSION IN SULFUR MUSTARD-EXPOSED MICE.

C. L. Sabourin<sup>1</sup>, J. V. Rogers<sup>1</sup>, Y. W. Choi<sup>1</sup>, R. C. Kiser<sup>1</sup>, <u>R. P. Casillas<sup>1</sup></u>, <u>M. C. Babin<sup>1</sup></u> and <u>J. J. Schlager<sup>2</sup></u>. <sup>1</sup>Medical Research & Evaluation Facility, Battelle Memorial Institute, Columbus, OH and <sup>2</sup>Pharmacology Division, US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.

The chemical warfare agent sulfur mustard (SM) produces blister formation with a severe inflammatory reaction in skin of exposed individuals. The development of efficacious countermeasures against SM vesication requires an understanding of the cellular and molecular mechanism of SM-induced tissue injury. This study examined SM-induced alterations in gene expression using microarrays (5002 genes) to identify transcriptional events associated with SM skin injury. Mice (n=3) were exposed topically to SM (0.04, 0.08, and 0.16 mg) on the inner surface of the right

ear and skin tissues were harvested at 1.5, 3, 6, and 12 h. Genes were selected based on the three mice in the same dose group demonstrating a ≥2 fold increase or decrease in gene expression for the SM-exposed tissue when compared to the methylene chloride vehicle control ear at all 3 doses and 4 time points. At the 0.04 mg SM dose, the genes observed were primarily involved in inflammation, apoptosis, and cell cycle regulation. Exposure to 0.08 mg SM increased the expression of genes related to inflammation and cell cycle regulation. Exposure to 0.16 mg SM led to a total of six genes that were changed at all observed time periods; however these genes do not appear to be directly influential in biological mechanisms such as inflammation, apoptosis, and cell cycle regulation as was observed at the lower SM doses of 0.04 and 0.08 mg. These functional categories have been observed in previous studies utilizing both *in vivo* and *in vitro* model systems of SM-induced dermal injury, suggesting that molecular mechanisms associated with inflammation, apoptosis, and cell cycle regulation may be appropriate targets for developing prophylactic/therapeutic treatments for SM skin injury. Supported by the ÛS Army Medical Research and Materiel Command under Contract No. DAMD17-99-D-0010, Task Order 0007.

LOW-LEVEL INHALATION EXPOSURE TO SARIN AND CYCLOSARIN LEADS TO ENHANCED EXPRESSION OF NEURONAL CELL DEATH AND REGENERATION RELATED GENES.

J. W. Sekowski<sup>1</sup>, J. Bucher<sup>1</sup>, M. Orehek<sup>1</sup>, M. Horsmon<sup>1</sup>, D. Menking<sup>1</sup>, C. E. Whalley<sup>2</sup>, B. Benton<sup>2</sup>, M. Vahey<sup>3</sup>, M. Nau<sup>3</sup>, D. Burnett<sup>2</sup>, J. Jarvis<sup>2</sup>, B. Gaviola<sup>2</sup>, R. Mioduszewski<sup>2</sup>, <u>S. Thomson<sup>2</sup></u> and J. J. Valdes<sup>1</sup>. \*Molecular Engineering Team, US Army RD&E Command, APG-EA, MD, <sup>2</sup>Toxicology Team, US Army RD&E Command, APG-EA, MD and <sup>3</sup>WRAIR, US Army MRMC, Rockville, MD.

The acute effects of chemical weapons have been widely studied since World War I and are well understood. Since the description of Gulf War and Balkans Syndromes, however, there has been increased concern for exposure of personnel to sub-acute and low-level doses of chemical warfare (CW) agents that may occur as a result of decontamination procedures or due to use of such agents by an adversary. There is a considerable body of literature suggesting that exposures to organophosphorus (OP) compounds used as pesticides result in significant cognitive and neurological decrements. However, there is a paucity of literature regarding the molecular effects of low-level exposures to OP nerve agents. In this study, male and female Sprague-Dawley rats were exposed to aerosolized sarin (GB) and cyclosarin (GF) via whole body inhalation for 240 minutes at several concentrations near the ECT50 for miosis. Controls were exposed to air under the same conditions for the same time period. Alteration of gene expression levels in the brain of the exposed animals was assessed using DNA microarray analysis, RT-PCR, and Western blot. To date, our results indicate that low-level inhalation exposure to GB and GF results in the persistent differential expression of a number of important genes at one week post-exposure. Many of the altered genes participate in cellular processes critical to neuronal injury, death, and regeneration. Furthermore, our analyses reveal several differently altered genes between the female and male animals. Additional studies with nerve agents such as soman and VX will reveal whether these differences translate into true sex-linked susceptibility to increased OP toxicity, and whether a genetic fingerprint can be defined for a class or a particular OP agent.

#### 1893

TOXIC EFFECTS OF A WHOLE-BODY INHALATION SARIN (GB) VAPOR EXPOSURE IN THE GOTTINGEN MINIPIG

Way<sup>1</sup>, J. L. Edwards<sup>2</sup>, J. M. McGuire<sup>2</sup>, J. A. Scotto<sup>1</sup>, D. C. Burnett<sup>1</sup>, B. I. Gaviola<sup>1</sup>, J. R. Jarvis<sup>2</sup>, R. A. Evans<sup>2</sup>, K. L. Matson<sup>2</sup>, C. L. Crouse<sup>2</sup>, J. H. Manthei<sup>1</sup>, R. J. Mioduszewski<sup>1</sup> and <u>S. A. Thomson<sup>1</sup></u>. <sup>1</sup>Toxicology, US Army Soldier and Biological Chemical Command, Aberdeen Proving Ground, MD and <sup>2</sup>Geo-Centers, Inc., Aberdeen Proving Ground, MD.

Due to a steep dose-response slope, there is a fine line between nerve agent doses that cause minimal signs of exposure and those that are potentially lethal. In order to assess chemical defense materiel requirements, it is essential to fill gaps in toxicological databases that define the physiological progression; from the first noticeable effect (miosis) to potentially fatal effects of inhalation exposure. In this study a sexually mature male Gottingen minipig was implanted with a jugular cannula. The pig was placed in a dynamic, whole-body inhalation chamber and exposed to a fixed, toxic dosage of sarin (GB) vapor. Pupil constriction was assessed using infrared pupillometry. Internal dose of GB (regenerated GB) was estimated in serial blood samples drawn through a jugular catheter. Changes in RBC cholinesterase activity were quantified along with other physiological parameters (glucose, Na, K, lactate, pH, etc.). The pig was also monitored for real-time changes in EEG spectra, respiratory rate and cardiac function. The first noticeable sign of GB exposure was

pupil constriction followed thereafter by muscle tremors and labored respiration. Following the exposure, a necropsy was performed and tissue analysis for regenerated GB (R-GB) yielded the highest levels in the lungs and RBCs, with other organs such as the liver containing lesser amounts. Sections of the brain with highlevels of cholinergic activity exhibited measurable levels of R-GB (caudate >frontal cortex>temporal cortex).

#### 1894

DEVELOPMENT OF A MICROFLUIDIC MICROARRAY FOR THE RAPID DETECTION OF TOXICOGENOMIC SIGNATURES

<u>I. West</u><sup>1</sup>, R. M. DeVay<sup>1</sup> and <u>S. Micheal</u><sup>2</sup>. <sup>1</sup>Microfluidics Research Group, Sandia National Laboratories, Livermore, CA and <sup>2</sup>VetMed: Molecular Biosciences, University of California, Davis, CA.

The development of toxicogenomic microarrays capable of detecting alterations in expression of thousands of genes resulting from a toxic chemical/drug exposure in single experiment has rapidly advanced and become a widespread application technology. Two significant drawbacks to this technology in its current format are the long and tedious processing time for RNA/DNA sample preparation, taking up to 2 days, and exquisite sensitivity to of the aforementioned samples to degradation from ambient DNA and RNA nucleases. In order to tackle these inherent weaknesses in microarray analysis we are developing a microfluidic microarray for detecting toxic chemical or biological exposures. This single Chip will concentrate, fluorescently label and hyribridize target genes on a single device. The potential advantages of such a device are the dramatically reduced sample throughput time, decrease sample degradation, and small size, which is amenable to portable devices. This device will combine the use of microfluidics and microarrays to facilitate the detection of unknown target genes. Here we present an optimized strategy for DNA microarray probe synthesis requires less than thirty minutes in bench top synthesis. We demonstrate comparable hybridization efficiencies with much reduced time of analysis. Moreover, the current method will be more amenable to integration with the fabricated microfluidic chip as the labeling reaction is enzyme free. We further report the fabrication of the first integrated microfluidic chip with both sample-processing channels for monolith polymerization and the fabrication of a high-density microarray on the same chip.

Arsenic (As) is a carcinogen whose most important target organs include the skin and lungs. Exposure can occur via water ingestion, or inhalation, as As is a by-product of fossil fuel combustion and other industrial activities. The carcinogenic mechanism of action for As remains unclear. One hypothesis proposes As induces cancer by creating oxidative stress. In previous studies we found modest evidence of increased peroxidation after exposure of cells to inorganic As as arsenite (iAs). To study the possible mechanistic link between As exposure and lung carcinogenesis, we examined iAs induction of DNA single strand breaks (SSBs) using a human bronchial epithelial cell line (BEAS-2B). SSBs were assessed *via* the comet assay, and a novel colorimetric assay that indirectly measures SSBs repair. This assay is based on the premise that DNA SSBs induce the activation of the repair enzyme poly(ADP-ribose)polymerase, which in turn depletes intracellular NAD+/NAD(P)H (Nucleic Acids Res. 31(17):e104, 2003). We did not find any statistically significant differences in DNA SSBs between the control and iAs (1nM-10µM) treated cells with the comet and NAD(P)H assays with up to 4h exposures at 37°C. In addition, no increase in SSBs was observed when the cells were exposed at 4°C, which inhibits DNA repair. In these studies, H2O2 and methyl methanesulfonate induced increased SSBs. These data suggest that iAs does not directly induce an increase in SSBs in this cell line, possibly because BEAS-2B cells may be more resistant to damage than other extrapulmonary cell types shown to have increased SSBs upon iAs exposure. Furthermore, iAs can be converted in vivo to methylated organic species that may be more potent inducers of oxidative stress and SSBs. Further analyses into the possible contributions of the aforementioned factors is underway. [This abstract may not necessarily reflect official EPA policy. Supported by EPA/UNC CT827206].

## 1896 CYTOGENETIC EVALUATION OF ARSENIC TRIOXIDE TOXICITY IN SPRAGUE-DAWLEY RATS.

A. K. Patlolla and P. B. Tchounwou. Center for Environmental Health, Jackson State University, Jackson, MS.

Arsenic is metalloid that exhibits a high degree of toxicity to human. It has been shown to induce cardiovascular diseases, developmental abnormalities, neurobehavioral disorders, diabetes, hearing loss, hematologic disorders, gastrointestinal

disorders, and various types of cancer including skin, liver, lung, bladder, and kidney neoplasms. However, studies of its carcinogenic potential in animals have not been conclusive. In this study, we investigated the genotoxic potential of arsenic trioxide in bone marrow cells obtained from Sprague-Dawley rats; using structural chromosomal aberrations and mitotic index as toxicological end-points. Four groups of six male rats each, weighing approximately 50 g per rat, were injected intraperitoneally, once a day for five days with doses of 5, 10, 15, 20 mg/kg body weight (b.wt) of arsenic trioxide dissolved in distilled water. A control group was also made of 6 animals injected with distilled water without chemical. All the animals were sacrificed on day 6, and chromosome preparation was obtained from bone marrow cells following standard protocols. Chromatid and chromosome aberrations were investigated in 300 metaphase cells per animal. Arsenic trioxide exposure resulted in a significant increase (p<0.05) of the number of structural chromosomal aberrations that included ring chromosomes, chromosome gaps, chromosome breaks, multilocus deletions and chromosome fragments. Mitotic indices of 11.76+/-0.88%, 6.93 +/- 0.66%, 6.86 +/- 0.57%, 5.59 +/- 0.156%, and 4.01 +/- 0.24% were recorded for the control group, 5, 10, 15, and 20 mg/kg b.wt., respectively; indicating a gradual decrease in mitotic index, with increasing dose of arsenic trioxide. These findings demonstrate that arsenic trioxide has a strong clastogenic/genotoxic potential as evidenced by the induction of structural chromosomal aberrations, and reduction of mitotic index in the bone marrow cells of Sprague-Dawley rats

## 1897 ARSENITE DEPRESSES POLY(ADP-RIBOSYL)ATION IN HUMAN SKIN KERATINOCYTES AND IN MOUSE SKIN.

T. G. Rossman, E. V. Komissarova, A. N. Uddin and <u>P. Li</u>. Environmental Medicine, New York University School of Medicine, Tuxedo, NY.

Drinking arsenic-contaminated water is associated with neoplasias of the skin, lung, bladder, and possibly other sites. Previously, we demonstrated that arsenite in drinking water enhances solar ultraviolet irradiation-induced skin carcinoma in the mouse. We suggest that alterations in DNA repair and genomic stability play a role in arsenite carcinogenesis. Although DNA repair enzymes are not inhibited by arsenite, evidence suggests that poly(ADP-ribose) (PAR) synthesis is inhibited in arsenite treated cells. Poly(ADP-ribosyl)ation of proteins contributes to DNA repair and maintenance of genomic stability. Human skin keratinocytes (HaCaT) were exposed to 0.1µM sodium arsenite for different times, lysed, and levels of PAR and poly(ADP-ribose)polymerase (PARP-1) were analyzed by Western blotting. PARP-1 protein levels increased up to 2.5 fold after 4 days exposure and remained high for at least 14 days. During this time, growth in arsenite caused decreases in total protein poly(ADP-ribosyl)ation, suggesting that arsenite inhibits PARP-1 enzyme activity. Because PARP-1 regulates its own transcription via PARP-1 auto-poly(ADPribosyl)ation, we suggest that the inhibition of PARP-1 activity by arsenite resulted in enhanced PARP-1 transcription. Arsenite's effects on protein poly(ADP-ribosyl)ation were also demonstrated in mice. Skh1 hairless mice were given 10 mg/l (non-toxic concentration) of sodium arsenite in drinking water for 29 weeks. Immunohistochemistry of normal skin obtained at the end of the experiment showed an increased epidermal thickness and decreased level of nuclear protein poly(ADP-ribosyl)ation, compared with control mice. Our results suggest that inhibition of poly(ADP-ribosyl)ation by arsenite may contribute to arsenite-associated carcinogenesis by its effects on DNA repair, DNA-damage-signaling, and transcription. We have constructed a vector for PARP-1 RNA interference to test the role of PARP-1 in arsenite-induced cell transformation.

# 1898 P-GLYCOPROTEIN EXPRESSION LEVEL HAS A SIGNIFICANT IMPACT ON CLASTOGENICITY *IN VITRO*.

A. M. Peters, J. Strauss, M. Weiss and J. Haskins. Assay Development, Cellomics, Inc., Pittsburgh, PA. Sponsor: E. McGuire.

The micronucleus assay is among a new set of genetic toxicology assays wherein cultured cells are treated with compounds and scored for evidence of clastogenicity through monitoring micronucleus formation. This *in vitro* clastogenicity assay helps enable evaluation of compounds earlier in the drug discovery process. Automated measurement of genotoxicity in intact cells represents a faster, more functional, and accurate assay as compared to the time-consuming, manual process of scoring slides. By using the cytokinesis-block method, a quantitative software module, and automated fluorescence imaging microscopy, we were able to implement an optimized assay to quickly evaluate genotoxicity in multiple cell lines. Through these investigations, it was discovered that the clastogenic activity of certain positive control compounds was cell-type dependent. For example, cells exposed to equimolar concentrations of vinblastine sulfate (13 nM) had micronucleus frequencies of 6%, 12% and 39% for CHO-K1, V79-4, and Balb/3T3 cells, respectively. Since vinblastine is a P-glycoprotein (P-gp) substrate, it was theorized that differences in P-gp expression between the various cell lines might be responsi-

ble for the differential induction of clastogenicity. To investigate this phenomenon, each cell line was evaluated for P-gp expression level through functional and biochemical methods. Using a fluorescent substrate for P-gp, a kinetic live-cell assay employing an automated imaging system was designed to assess functional P-gp expression. Each cell line was evaluated in the presence or absence of specific inhibitors of P-gp, including cyclosporin A and verapamil. Quantitative analysis of kinetic response profiles revealed that a strong relationship existed between P-gp expression level and micronucleus induction. These results eloquently demonstrate the potential need to evaluate compounds for clastogenicity in multiple cell types. Evaluations of this magnitude are only mad possible through utilization of automated imaging systems.

1899

*N*-ETHYL-*N*-NITROSOUREA (ENU) INCREASED BRAIN MUTATIONS IN PRENATAL AND INFANT MICE BUT NOT IN THE ADULTS.

W. Slikker III<sup>1</sup>, N. Mei<sup>2</sup> and T. Chen<sup>2</sup>. <sup>1</sup> College of Letters and Science, University of California, Los Angeles, CA and <sup>2</sup> Division of Genetic and Reproductive Toxicology, NCTR/FDA, Jefferson, AR.

There are rising trends in the incidence of childhood cancer. The reported incidence of gliomas, one of the most common cancers for children, in the under-15 age group rose by about 40% (Ries et al., 1997). The rising trend of childhood cancer in brain may be associated with environmental exposure to genotoxins and susceptibility to mutation induction in early development. To investigate age-dependent mutagenic sensitivity of brain to genotoxins, the Big Blue mouse model was utilized in this study. Groups of 5 Big Blue transgenic mice were treated with 120 mg/kg ENU, a known potent mutagen and carcinogen, at three days before birth (prenatal), and eight days (infant) and eighteen weeks (adult) after birth. The animals were sacrificed 6 weeks after the treatment. The mutant frequencies (MFs) and types of mutations in the brain cII gene from ENU-treated and concurrent control mice were determined. A significant increase in MF over control was found in the prenatal and infant groups (235 x 10<sup>-6</sup> in prenatal and 117 x 10<sup>-6</sup> in infant vs. 44 x  $10^6$  in control, p < 0.001 respectively), whereas there was no significant difference between the adult group and its control (62 x  $10^6$  in treatment vs. 35 x  $10^6$  in control). Molecular analysis of the mutants also indicated that the mutational spectra from the ENU-treated mice were age-dependent. A:T  $\rightarrow$  T:A transversion, the signature mutation induced by ENU, was the major type of mutation in mice from prenatal and infant ENU-treated groups, while G:C → A: T transition, a typical mutation type for spontaneous mutation, was the main type of mutation in the adult and control groups. These results demonstrate a differential mutagenic effect of ENU on mouse brain depending on the age and suggest a potential brain cancer hazard for perinatal exposure to genotoxins. It also indicates that future mutagenesis assays should take into account the age-related differential mutagenicity response of age to a test agent, especially in early development.

A MODEL OF SENSITIVITY: 1, 3-BUTADIENE INDUCES HPRT MUTANTS IN MICE LACKING MICROSOMAL EPOXIDE HYDROLASE ACTIVITY.

J. Wickliffe, M. M. Ammenheuser, L. Galbert, J. Salazar and <u>J. Ward</u>. *University of Texas Medical Branch, Galveston, TX*.

Increased sensitivity to the genotoxic effects of 1, 3-butadiene (BD) is associated with a human polymorphism in the xenobiotic metabolizing enzyme, microsomal epoxide hydrolase (mEH). There exists a lack of mechanistic research that sufficiently explains the variation in sensitivity attributable to this polymorphism. A targeted knockout mouse was developed in which the function of mEH has been abolished. To evaluate this model as a surrogate for increased human sensitivity to BD, we examined Hprt mutant frequencies (MFs) following exposure of wild-type and knockout mice to BD (inhalation) and to the principal mutagenic metabolite of BD, butadiene diepoxide (BDO<sub>2</sub>, IP). In both experiments, unexposed wild-type and knockout mice had MFs that were not significantly different from one another. Knockout mice (n = 6) exposed to 20 ppm BD (6 hours/day, 5 days/week for 4 weeks) exhibited a significant (p < 0.05) 12.4-fold increase in MF over unexposed controls (n = 10) and a significant 5.4-fold increase in MF over exposed wild-type mice (n = 6). Knockout mice (n = 3) exposed to 30 mg/kg BDO<sub>2</sub> (2 x 15 mg/kg IP) exhibited a significant 5.2-fold increase in MF over unexposed controls (n = 5) and a significant 1.7-fold increase in MF over exposed wild-type mice (n = 3). In the latter experiment, however, there was some evidence of acute toxicity, which may have led to a depressed response. Additional research examining the mutagenic effects of the initial reactive epoxide, butadiene monoepoxide (BDO), in this knockout mouse is currently underway. Our initial experiments demonstrate that mice lacking mEH function are substantially more sensitive to BD and BDO2 than their wild-type counterparts. This model should serve as an appropriate, initial surrogate for studies assessing variation in human susceptibility to BD.

1901

FORMATION OF DNA ADDUCTS IN F344 RAT NASAL TISSUE BY 2, 6-DIMETHYLANILINE AND 2, 6-DIETHYLANILINE, BUT NOT ALACHLOR.

J. D. Duan<sup>1</sup>, M. Genter<sup>2</sup>, A. M. Jeffrey<sup>1</sup> and G. M. Williams<sup>1. 1</sup>Department of Pathology, New York Medical College, Valhalla, NY and <sup>2</sup>Department of Environmental Health, University of Cincinnati, Cincinnati, OH.

Alachlor (AC), a chloracetanilide herbicide, is an N substituted 2, 6-diethylaniline (DEA) which has produced increases in tumors of the nasal mucosa (NM) in rats. Whole body autoradiograms of the distribution in rats with oral administration showed that radiolabeled AC was specifically associated with the NM. The oncogenicity of chloroacetanilides has been linked to the formation of 2, 6-dialkylbenzoquinoneimines. These metabolites bind extensively to glutathione and thiols in proteins, resulting in sustained proliferation of the tissue, which is postulated to be the basis of carcinogenicity, although weak genotoxicity of AC has been reported. Moreover AC is biotransformed to DEA which is closely structurally related to 2, 6dimethylaniline (DMA), which is also a rodent nasal carcinogen, and yields wellcharacterized DNA adducts in the NM (Drug Chem Toxicol, 25: 93, 2002; Chem Res. Toxicol, 14: 165, 2001). In the present experiments rats were administered DMA or DEA by gavage, and AC in the diet (310, 382, and 126 mg/kg/day for 7, 7 and 90 days, respectively) and the nasal epithelium DNA was extracted using Qiagen columns. For adduct analysis, the DNA was digested, adducts enriched using OASIS HLB columns (Waters Corp) and postlabeled. DNA isolated from both DMA- and DEA-treated rats gave clear spots by postlabeling while DNA from AC-treated rats did not. In these studies the amount of DEA administered was greater per day than AC, although the cumulative exposure to AC was greater. Additional studies are underway to measure the dose response for DNA adduct formation to determine if this was the cause for the apparent lack of DNA binding of AC. The finding of DEA adducts in the nasal mucosa suggests that it, like DMA, could be a nasal carcinogen. Supported in part by NIH grants ES-08799.

1902

THE ROLE OF O6 METHYLGUANINE DNA REPAIR METHYLTRANSFERASE AND MOUSE 3-METHYLADENINE DNA GLYCOSYLASE IN REPAIRING ANTHRACYCLINE-INDUCED DNA ADDUCTS IN SALMONELLA TYPHIMURIUM AND ESCHERICHIA COLL

W. J. Mackay, J. Armagost, R. Robinson and E. Scully. Biology & Health Services, Edinboro University of PA, Edinboro, PA.

For more than thirty years, the natural anthracycline antibiotics represent one of the most commonly used classes of anticancer drugs. However, the clinical usefulness of these drugs is limited due to acute cardiotoxic effects and a dose-related cardiomyopathy. It is known that anthracyclines interact with DNA in a very complex manner. Studies in our lab have shown that anthracyclines can induce mutations in Salmonella typhimurium. In future attempts to improve the clinical efficacies and reduce the pre-carcinogenic effects of these compounds, it will be important to better understand the role of DNA repair pathways, which are involved in correcting anthracycline-induced DNA damage. Current research involves the analysis of the protective functional role of O6methylguanine DNA repair methyltransferase (O6 MTase) and 3-methyladenine DNA glycosylase (Aag) in recognizing and repairing anthracycline-induced DNA adducts. E. coli strains (MB1900), which lack Aag (alkA tag), are extremely sensitive (107-fold) to adriamycin-induced cell killing relative to wild type (AB1157) strains. In addition, mutant Salmonella strains (YG7108), which lack MTase (ada ogt), exhibit an increase of daunomycin-induce mutations (8.2-fold) relative to parental strains (TA1535) that display normal levels of MTase activity.

1903

INVESTIGATION OF THE MUTAGENIC POTENTIAL OF EMISSIONS FROM ASPHALT FORMULATIONS WITH AND WITHOUT CRUMB-RUBBER MODIFICATION.

L. D. Olsen<sup>1</sup>, V. S. Houk<sup>2</sup>, S. H. Warren<sup>2</sup>, <u>L. D. Claxton</u><sup>2</sup>, K. W. Hanley<sup>1</sup>, A. K. Miller<sup>3</sup>, G. A. Burr<sup>1</sup>, D. Almaguer<sup>1</sup> and G. M. Kinnes<sup>1</sup>. <sup>1</sup>NIOSH, Cincinnati, OH, <sup>2</sup>USEPA, Research Triangle Park, NC and <sup>3</sup>USEPA, Denver, CO.

In 1991, Congress enacted legislation that required each state to use a minimum amount of crumb-rubber modified (CRM) hot-mix asphalt in road paving operations. However, because of concerns over the lack of information on the environmental and human health effects caused by CRM asphalts, Congress passed a temporary moratorium and directed that these effects be evaluated. In 1995, Congress eliminated the requirement to use CRM asphalts but continued the requirement to conduct research. Because asphalt emissions may contain mutagenic compounds (e.g., polycyclic aromatic hydrocarbons), their mutagenic potential was investigated using a spiral Salmonella mutagenicity assay. Asphalt emissions were collected above

open ports of heated asphalt storage tanks, at seven hot-mix plants in six states. At each site, asphalt emissions from the same asphalt formulation, with or without crumb-rubber, were collected on 37-mm polytetrafluoroethylene filters at 28.3 L/min over approximately 8 to 10 hrs. Asphalt samples were extracted with methylene chloride, evaporated to dryness for total mass determination, and dosing solutions were prepared in dimethyl sulfoxide. The spiral Salmonella mutagenicity assay was conducted using tester strains TA98 and TA100, with and without 10% S9 metabolic activation. Because of dispersion problems (sample formed beads on the plate) with samples from the first three sites, the remaining samples were extracted using hexane and half of the extract was fractionated into aliphatic compounds, polycyclic aromatic compounds, and polar compounds using NIOSH Method 5800. These fractions and the remaining extract were dried for total mass determination. As before, dosing solutions were prepared, and the spiral Salmonella assay was conducted. Test doses ranged from 13 to 900 μ/mL equivalents per plate. None of the asphalt emissions or fractions were found to be mutagenic at the doses tested. (This is an abstract and does not necessarily reflect EPA policy.)

PBDES IN US NURSING MOTHERS MILK, FOOD, AND ELECTRONIC APPLIANCES: LEVELS AND ESTIMATED INTAKE BY VARIOUS ROUTES.

A. J. Schecter<sup>1</sup>, O. Paepke<sup>2</sup>, J. J. Ryan<sup>3</sup>, J. Olson<sup>4</sup>, R. Malisch<sup>5</sup>, <u>L. Birnbaum<sup>6</sup></u> and M. Pavuk<sup>1</sup>. <sup>1</sup>Environmental Sciences, University of Texas School of Public Health, Dallas, TX, <sup>2</sup>ERGO Research Laboratory, Hamburg, Germany, <sup>3</sup>Health Canada, Ottawa, ON, Canada, <sup>4</sup>Pharmacology & Toxicology, University at Buffalo, Buffalo, NY, <sup>5</sup>State Laboratory for Chemical and Veterinary Analysis, Freiburg, Germany and <sup>6</sup>Experimental Toxicology Division, USEPA, Research Triangle Park, NC.

Polybrominated diphenylether (PBDE) flame retardants are currently used in the USA to a larger extent than in Europe. They have recently been measured in human tissues, fish, dust and other environmental samples. Although animal studies find toxicity including carcinogenicity, endocrine disruption, reproductive/developmental alterations, nervous system alterations, and immune system perturbation, no human health studies have yet been published. To determine dose and routes of intake in humans from the USA, milk from nursing Texas mothers, food from Texas supermarkets and wipe samples from Texas electrical products including computers and computer monitor cases, were analyzed for up to 13 polybrominated diphenyl ethers(17, 28, 47, 66, 77, 85, 99, 100, 138, 153, 154, 183, and 209). Milk was obtained from a Dallas clinic and an Austin, Texas, milk bank. All nursing mothers milk was contaminated with PBDEs. Combined congener levels for the first 47 samples varied from 6-419 ppb lipid. The mean was 74 and the median was 34 ppb. These human milk levels are higher than in other countries, up to 10-100 times those in Europe. No correlations with the mothers age, ethnicity, or length of time nursing were found. Findings were in the range previously reported in human tissue from elsewhere in the USA. Our working hypothesis based on dioxin, dibenzofuran and PCB data and the limited PBDE data, is that most intake into humans in the US is through a food route, particularly food containing animal fat. Preliminary analysis supports this conclusion. (This abstract does not reflect the policy of the USEPA.)

1905

DEVELOPMENTAL NEUROTOXICITY OF POLYBROMINATED DIPHENYLETHERS (PBDE): STEROID-DEPENDENT BEHAVIOR, SEXUAL DEVELOPMENT AND CIRCULATING STEROIDS.

H. Lilienthal, A. Hack, A. Roth-Haerer, L. Altmann, G. Winneke and <u>H. Wiegand</u>. Neurobehavioral Toxicology, Med. Institute of Environmental Hygiene, Duesseldorf, Germany.

Recent studies detected increasing levels of brominated flame retardants, including PBDEs in human breast milk. The purpose of the present investigation was to test if maternal PBDE exposure affects steroid-dependent behavior, markers of sexual development, and serum concentrations of steroids. Pregnant rats were exposed by daily SC injections with 0, 1, or 10 mg PBDE 99/kg body wt. from gestational day 10-18. An additional group received the technical PCB mixture Aroclor 1254 (30 mg/kg body wt.) for comparison. Exposure to PBDE 99 and PCBs caused reductions in circulating concentrations of estradiol and testosterone in male offspring at weaning which became even more pronounced in adult males. The higher dose of PBDE 99 decreased anogenital distance only in male rats. The higher dose also delayed puberty onset in females, while the lower dose caused an acceleration in males. Dose-dependent elevations in sweet preference were detected in PBDE-exposed adult male offspring, indicating a feminization of this sexually dimorphic behavior. Since several interactions between the nervous system and the active form of vitamin D3 (1, 25-dihydroxyvitamin D3 - 1, 25-D) have been recently described and since reductions in circulating concentrations of this steroid were found after exposure to a reconstituted PCB mixture in a previous study of our lab, we wanted to test if PBDE exposure alters 1, 25-D dependent behavior. First, it was shown

that 1, 25-D caused dose-related increases in conditioned taste aversion (CTA) in non-exposed rats, demonstrating affective properties of this steroid. Then, an intermediate dose of 1, 25-D was selected for induction of CTA in exposed rats. PBDE exposure resulted in dose-related increases in 1, 25-D induced CTA. Taken together, these results indicate endocrine-modulating effects of PBDE 99 which influence the development of the nervous system. DEVELOPMENTAL NEUROTOXICITY OF PBDES:IMPAIRMENT OF SYNAPTIC PLASTICITY IN RAT CORTEX AND HIPPOCAMPUS. WIEGAND, H., ALTMANN, L., AND LILIENTHAL, H. MED. INST. ENVIRONM. HYG. AT THE HEINRICH-HEINE-UNIVERSITY. DUESSELDORF. GERMANY.

H. Wiegand<sup>1</sup>, L. Altmann<sup>2</sup> and H. Lilienthal<sup>3</sup>. <sup>1</sup>Med.Inst.Environm.Hyg., Heinrich-Heine-University, Duesseldorf, Germany, <sup>2</sup>Med.Inst.Environm.Hyg., Heinrich-Heine-University, Duesseldorf, Germany and <sup>3</sup>Med.Inst.Environm.Hyg., Heinrich-Heine-University, Duesseldorf, Germany.

Epidemiological studies indicate a marked increase of PDBE levels in breast milk during the last decade in european and north-american populations. However, mechanisms of actions of PBDEs in the developing CNS are largely unknown. Therefore, we assessed synaptic plasticity in different rat brain regions of immature and aged offspring after prenatal PBDE99 treatment (1 or 10 mg/kg during gestational day 10-18). Recordings from brain slices were performed ex vivo. Samples of brain and fat tissues were analyzed for PBDE99 content. Results in immature rats:No effects were found for body weight (- gain) in dams or offspring as well as in the excitability of neurons in both brain regions tested (10mg/kg and control group, respectively). In cortical slices long-term potentiation (LTP) and pairedpulse facilitation (PPF) differed from controls. While LTP was reduced mainly in the deeper cortex layers III to IV, PPF was only affected in layers II to III In the hippocampal CA1 region only LTP of the EPSP slopes was significantly reduced in the 10 mg/kg animals while LTP of the somatic population spikes as well as the EPSP amplitudes were not affected by exposure. No effects of exposure were found on the amount of hippocampal PPF. Results in aged rats: The amount of LTP measured in cortical slices was reduced in the 10 mg/kg group in comparison to the control or 1 mg/kg group. PPF was reduced. In the hippocampal CA1 region the amount of LTP was found to be statistically significantly reduced in the 10 mg/kg group as compared to the controls. PPF was unaffected. Conclusion: There is clear cut evidence for developmental neurotoxicity of prenatal PBDE99 treatment producing fat tissue levels in an order of magnitude not far from PBDE levels of north-american population mother milk samples. 1907

COMPARATIVE DEVELOPMENTAL NEUROTOXICITY OF PBDE 99 IN TWO DIFFERENT MOUSE STRAINS AND RAT.

H. Viberg, A. Fredriksson and <u>P. Eriksson</u>. *Environmental Toxicology, Uppsala University, Uppsala, Sweden.* 

Flame-retardants are used to suppress or inhibit combustion processes in order to reduce the risk of fire. One class of flame-retardants, polybrominated diphenyl ethers (PBDEs), have been found to increase in the environment and in human mothers milk. In recent studies we have seen that neonatal exposure to some brominated flame-retardants, such as PBDE 47, PBDE 99, PBDE 153 and PBDE 209, can cause permanent aberrations in spontaneous behaviour in NMRI mice, an effect that worsen with age, and affect the cholinergic system. The present study compares the neurotoxic effect between different speices, mouse strains and genders. Male NMRI mice, male and female C57 Bl. mice and male Sprague-Dawley rats were exposed to PBDE 99 in the dose range 0.8 to 16.0 mg/kg b.wt., as one single oral dose, on postnatal day 10. Spontaneous behaviour was observed in adult NMRI and C57 Bl. mice and adult SD rats. Male NMRI mice exposed to 0.8 or 12.0 mg PBDE 99/kg b.wt. on postnatal day 10 showed significantly impaired spontaneous motor behaviour as adults. This effect was dose-response related. Male and female C57 Bl. mice exposed to 0.8 8.0 or 16.0 mg PBDE 99/kg b.wt. on postnatal day 10 showed significantly impaired spontaneous motor behaviour as adults. This effect was dose-response related. Male Sprague-Dawley rats, exposed to 0.8, 8.0 or 16.0 mg PBDE 99/kg b.wt. on postnatal day 10 showed significantly impaired spontaneous motor behaviour as adults. This effect was dose-response related. In conclusion, neonatal exposure to PBDE 99 induces behavioural derangements in adult mice and rats, an effect that is dose-response dependent. PBDE 99 causes similar developmental neurotoxic effects in rats, compared to male and female mice of different strains.

#### 1908

EXPOSURE TO AN ENVIRONMENTALLY RELEVANT DOSE OF PBDE 99 DISRUPTS THYROID HORMONE HOMEOSTASIS AND CAUSES NEUROBEHAVIOR DISTURBANCES IN RAT OFFSPRING.

S. N. Kuriyama, C. Talsness, W. Wittfoht and I. Chahoud. Department of Toxicology, Institute of Clinical Pharmacology and Toxicology, Charite University Medical School Berlin, Campus Benjamin Franklin, Berlin, Germany. Sponsor: <u>E. Silbergeld</u>.

Thyroid hormone levels and locomotor activity were evaluated in offspring rats exposed in utero to a low dose of PBDE 99. The two doses were selected to be 100and 500-fold higher than the average found in human adipose tissue in Europe. Wistar dams (n=10) were treated by gavage on gestation day 6 with a single dose of 60 or 300 µg PBDE 99/kg body weight or peanut oil (control). A reference control group composed of dams treated with 0.5% of PTU in drinking water from GD 7 to 21 was included. Serum samples obtained from dams (PND1 and PND 22) and offspring (PNDs 1, 14 and 22) were analyzed for circulating total and free T4, T3 and TSH. On PNDs 36 and 71, the locomotor activity of two males and two females per litter, were monitored during a 24 h period using the Mobiltron apparatus. A statistically significant reduction in T4 levels was observed in PBDE treated offspring at the end of lactation (PND 22). PTU-exposed offspring showed a decrease in T4 and TSH levels at the beginning of lactation (PND 1), which has restored to normal levels at weaning. The analyses of the locomotor activity show a statistically significant hyperactivity in PBDE-exposed offspring after weaning (median LBC / day: control - 434; PBDE300 - 570) and at puberty (median LBC / day: control - 903; PBDE60 - 1014; PBDE300 - 1005). Transient hyperactivity was noted in PTU-treated animals with normal activity being restored at puberty. Neonatal PTU-induced hypothyroidism has been shown to be associated with hippocampal dysfunction in hyperactive rats. Since we have observed decreases in thyroxin level during lactation in both PBDE and PTU groups, our data suggest that transient neonatal hypothyroidism in PBDE-treated rats leads to a persistent hyperactive state. In utero exposure to an environmentally relevant dose of PBDE 99 interferes with thyroid hormone homeostasis and neurobehavior development in rat offspring.

## **1909** 2, 2', 4, 4'-TETRABROMODIPHENYL ETHER (PBDE-47) ALTERS THYROID FUNCTION IN RATS.

J. M. Hedge<sup>1</sup>, <u>K. M. Crofton<sup>1</sup></u>, <u>S. C. Laws<sup>1</sup></u>, <u>M. J. DeVito<sup>1</sup></u>, D. G. Ross<sup>1</sup> and P. C. Das<sup>2</sup>. <sup>1</sup>NHEERL, ORD, USEPA, Research Triangle Park, NC and <sup>2</sup>Curriculum in Toxicology, UNC, Chapel Hill, NC.

Two commercial PBDE mixtures, DE-71 and DE-79, cause dose-dependent depletion of serum T4 *via* induction of UGTs and increased CYP1A1 activity. This work characterized the effect of a major congener, PBDE-47, in DE-71 for effects on hepatic enzymes and thyroid hormones. Female 27 day-old LE rats (n=8-14/group) were gavaged with 0, 0.3, 1, 3, 10, 30, 100 mg/kg bw PBDE-47 for 4 days. An additional group was treated with 30 mg/kg/day DE-71 (n=12) as a comparative control. Serum and liver tissues were collected on the 5th day. Serum total T4, T3, and TSH were assayed by RIA, and hepatic microsomal EROD, PROD, and UDPGT enzyme activities were determined. PBDE-47 dose-dependently decreased serum total T3 and T4 (~25%, and ~75% at the highest dose), and failed to alter TSH concentration. DE-71 was slightly more potent (10-15%) compared to the same dose of PBDE-47. These data clearly demonstrate the PBDE-47 is a thyroid hormone disrupter. *This is an abstract of a proposed presentation and does not necessarily reflect University. S.EPA policy.* 

## 1910 DISPOSITION OF 2, 2', 4, 4'-TETRABROMODIPHENYL EITHER (BDE 47) IN FEMALE MICE.

D. Staskal<sup>1</sup>, J. Diliberto<sup>2</sup>, M. DeVito<sup>2</sup> and L. Birnbaum<sup>2</sup>. <sup>1</sup>Curriculum in Toxicology, UNC, Chapel Hill, NC and <sup>2</sup>ETD, NHEERL, ORD, USEPA, Research Triangle Park, NC.

2, 2′, 4, 4′-tetrabromodiphenyl ether (BDE 47) is present in commercial mixtures of polybrominated diphenyl ethers (PBDEs), which are used as a flame retardant in a wide variety of consumer products. Levels of BDE 47, the major PBDE congener in wildlife and human tissues, are steadily increasing in North America. The continued production and use of PBDEs suggests that peak body burdens have not yet been reached and concern has risen because the effects and fate of these chemicals are unknown. Information on the toxicokinetics of BDE 47 is limited. In this study, the disposition of a single oral dose of [14C]BDE 47 (0.0, 0.1, 1.0, 10, or 100 mg/kg) was assessed in female C57BL/6N mice five days following exposure. Residual radioactivity was measured in excreta, liver, lung, kidney, adipose, blood, muscle, skin, and brain. Cumulative excretion in the urine after five days was 41, 40, 32, and 14% of the dose (0.1, 1.0, 10, or 100 mg/kg, respectively). In feces, 46% was excreted in the highest dose group (100 mg/kg), and approximately 35%

in all others. This data demonstrates a rapid elimination of BDE 47 in mice; at the low dose (0.1mg/kg), over half of the administered dose was eliminated in two days. Preliminary chromatographic data suggests that most of the [14C]BDE 47 in excreta is parent compound, which raises several mechanistic questions concerning its disposition. We estimate that at least 80% of the dose was absorbed at all dose levels; however, the overall elimination of BDE 47 is dose dependent. This toxicokinetic behavior has important implications for extrapolation of toxicological studies to the assessment of health risk in humans. (This abstract does not reflect EPA policy. This work was partially funded by EPA NHEERL-DESE CT826513).

# 1911 EFFECTS OF POLYBROMINATED DIPHENYL ETHERS (PBDES) ON BASAL AND TCDD-INDUCED CYTOCHROME P450 1A1 ACTIVITY IN MCF7, HEPG2 AND H4IIE CELLS.

L. Peters<sup>1</sup>, M. van den Berg<sup>1</sup>, A. Bergman<sup>2</sup> and <u>T. Sanderson<sup>1</sup></u>. <sup>1</sup> Institute for Risk Assessment Sciences, University of Utrecht, Utrecht, Netherlands and <sup>2</sup> Department of Environmental Chemistry, University of Sweden, Stockholm, Sweden.

Polybrominated diphenylethers (PBDEs) are used as additive flame-retardants in consumer products to reduce the chances of ignition and burning. Levels of some PBDE congeners have been increasing in fish, wildlife, and human tissues during the last decades. Some are highly lipophilic and persistent, resulting in bioaccumulation in the environment. The structural similarity of PBDEs to other polyhalogenated aromatic hydrocarbons such as certain PCBs, has raised concerns that PBDEs might act as agonists for the aryl hydrocarbon receptor (AhR). To study the possible dioxin-like effects of the environmentally relevant PBDEs (BDE47, 77, 99, 100, 153, 154, 183, 209), the Ah receptor-mediated induction of the cytochrome P450 enzyme CYP1A1 was studied in human breast carcinoma cells (MCF7), human hepatocellular carcinoma cells (HepG2), and rat hepatoma cells (H4IIE). 7-Ethoxyresorufin-O-deethylase (EROD) was used as a marker for CYP1A1 activity. The cells were exposed to several concentrations (0.01-10 µM) of these PBDEs. Positive controls were 2, 3, 7, 8-TCDD (0.001-2.5 nM) and PCB126 (1-10 µM). EROD activity was measured after 72 hours. None of these PBDEs was capable of inducing EROD activity; this was confirmed by real time RT-PCR for CYP1A1 mRNA. However, when the cells were exposed to PBDEs in combination with TCDD, there was a concentration dependent inhibition of TCDD-induced EROD activity. At maximum TCDD-induced CYP1A1 (EROD) activity, BDE153 reduced this AhR-mediated activity by as much as 40% at a concentration of 10 µM. All PBDEs tested showed the same effect in all three cell lines, though quantitative differences were observed. Catalytic inhibition and cytotoxicity by MTT assay was not observed and did not appear to explain the observed decrease in CYP1A1 activity. Whether this antagonism is due to direct interaction with the Ah receptor or some other unknown mechanism of downregulation will be further assessed.

#### 1912

EFFECTS OF BROMINATED FLAME RETARDANTS ON THE ACTIVITY OF THE STEROIDOGENIC ENZYME AROMATASE (CYP19) IN H295R HUMAN ADRENOCORTICAL CARCINOMA CELLS IN CULTURE.

R. Fernandez Canton<sup>1</sup>, <u>T. Sanderson</u><sup>1</sup>, <u>R. Letcher</u><sup>3</sup>, A. Bergman<sup>2</sup> and <u>M. Berg</u><sup>1</sup>. Institute for Risk Assessment Sciences, Utrecht, Netherlands, <sup>2</sup>Department of Environmental Chemistry and Analytical Chemistry, Stockholm University, Stockholm, Sweden and <sup>3</sup>Great Lakes Institute for environmental Research, Windsor, ON, Canada.

Flame retardants are substances used in plastics, textiles, electronic circuitry and other materials to prevent fire ignition processes. Brominated flame retardants (BFRS) are ubiquitous chemicals with large and global industrial use. Due to this fact, several BFRs are found in quantifiable levels in wildlife and humans. Several in vitro studies have shown that these chemicals have endocrinological effects. Our study focuses on the potential interactions of a wide range of these BFRs with aromatase (CYP19). We used the human H295R adrenocortical carcinoma cell line to assess the effects on aromatase activity after a 24h exposure to twenty different BFRs. These included polybrominated diphenyl ethers (PBDEs) and several of their hydroxylated metabolites (OH-BDEs, MeO-BDEs), tetrabromobisphenol-A (TBBPA), hexabromocyclodocedane (HBCD) and brominated phenols (BP). Effects were studied in the concentration range from 0.5 to 7.5 μM. Aromatase activity was measured using the tritiated water-release assay. MTT and LDH assays were used to measure cytotoxicity of these BFRs. Exposure of H295R cells to 6OH-BDE47 and 6OH-BDE99 showed an inhibitory effect on aromatase activity at concentrations > 2.5 µM and > 5 µM, respectively, although 6OH-BDE47 caused a decrease in cell viability at concentrations > 2.5 µM possibly explaining the aromatase inhibition. Replacement of the 6OH group by a methoxy group eliminated cytotoxicity, while significant aromatase inhibition remained. A concentration-dependent induction of aromatase activity was caused by 2, 4, 6-tribromophenol(TBP) between 0.5 and 7.5 µM. These inductive properties were lost

when the OH-group was replaced by a MeOH-group or adjacent bromines were removed. These results give a first indication of possible structure activity relationships for interaction of BFRs with aromatase.

## 1913 POLYBROMINATED DIPHENYLETHERS INHIBIT TCDD-INDUCED EROD-ACTIVITY IN CARP HEPATOCYTES.

R. V. Kuiper<sup>1, 2, 3</sup>, J. G. Vos<sup>3, 2</sup>, A. Bergman<sup>4</sup> and <u>M. van den Berg<sup>1, 1</sup> Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands, <sup>2</sup> Pathobiology, Utrecht University, Utrecht, Netherlands, <sup>3</sup> National Institute for Public Health and the Environment, Bilthoven, Netherlands and <sup>4</sup> Environmental Chemistry, Stockholm University, Stockholm, Sweden.</u>

Ethoxyresorufin-O-deethylase (EROD) activity is a popular biomarker for exposure to AhR agonists. In environmental studies, complex mixtures of xenobiotics are subject to investigation where a number of pollutants inhibiting EROD activity may hamper adequate exposure assessment. This study investigates the effect of the increasingly environmentally detected polybrominated diphenylethers (PBDEs) on EROD activity in carp hepatocytes. BDEs-47, -99, -100 and -153 were selected based on their environmental abundance. Commercial penta-BDE (DE-71, Great Lakes Chemical Corp.) untreated and after clean up to remove planar impurities, a BDE-47 metabolite, 6OH-BDE-47, and PCB-153, a known inhibitor of EROD activity, were included. Freshly isolated carp hepatocytes were co-exposed for 5 days to 2, 3, 7, 8-TCDD (0, 1, 3, 10, 30 and 100 pM), and one of the pure PBDE/PCB congeners (0, 0.25 and 2.5 $\mu$ M) or either DE-71 fraction (0, 0.1 and 10  $\mu$ M), and EROD activity was determined. Exposure to TCDD alone resulted in dose-dependent increase of EROD activity. This induction was significantly reduced in the presence of BDEs-47, -99, -153, and both DE-71 fractions, dependent on PBDE dose, and generally not paralleled by reduced catalytic conversion of MTT as viability parameter. Particularly strong inhibition was observed for the environmentally most abundant congener BDE-47 (down to 6% of the corresponding control at 2.5  $\mu M$  BDE), and cleaned-up DE-71 (to 4% of the control at 1.0  $\mu M$  DE-71). BDEs-47 and -153 added shortly prior to measurement did not reduce EROD activity, indicating that inhibition is not catalytic. PCB-153 did not affect EROD activity in this study. Thus, environmentally relevant PBDEs may interfere with EROD measurement in vitro, resulting in underestimation of toxic hazard in environmental samples. Supported by FIRE, EU contract number QLK4-CT-2002-00896.

## 1914 CHILDREN'S HEALTH RISK ASSESSMENT OF THE COMMERCIAL PENTABROMODIPHENYL ETHER PRODUCT.

T. L. Serex<sup>1</sup>, R. J. Wenning<sup>2</sup>, J. A. Biesemeier<sup>1</sup>, A. Von Burg<sup>2</sup>, S. Braithwaite<sup>2</sup>, A. M. Shipp<sup>3</sup> and G. Lawrence<sup>3</sup>. <sup>1</sup>Regulatory Affairs, Great Lakes Chemical Corp., West Lafayette, IN, <sup>2</sup>ENVIRON International Corp., Emeryville, CA and <sup>3</sup>ENVIRON International Corp., Ruston, LA.

A health risk assessment of the commercial pentabromodiphenyl ether (pentaBDE) product was conducted for the United States Environmental Protection Agency USEPA) Voluntary Children's Chemical Evaluation Program Pilot (VCCEPP). The commercial pentaBDE product is made in the United States and used almost exclusively as a flame retardant in flexible polyurethane foam (FPUF) in bed mattresses and cushioning in upholstered products. Hazard information was compared with screening-level exposure models to evaluate all plausible pathways by which children and prospective parents might be exposed in the workplace, home, school, office, and ambient environments. Three non-cancer health effect benchmark values were used for comparison to theoretical daily intakes. Changes observed in thyroid T4 levels and the incidence of thyroid hyperplasia in rats were used to develop screening toxicity values. The BMDL10 for thyroid hyperplasia ranged from 4 mg/kg/day in male rats to 9.6 mg/k/day in female rats. Applying a 100-fold uncertainty factor to the lowest BMDL10 (4 mg/kg/day for thyroid hyperplasia), resulted in a screening toxicity value of 0.04 mg/kg/day. The BMDL10 for changes in T4 levels was 4.5 mg/kg/day for data from PND 4 and 5.9 mg/kg/day for PND 14 in weanling rats. By applying a 30-fold uncertainty factor, the resulting toxicity value calculated for changes in T4 homeostasis was 0.2 mg/kg/day. Liver enzyme induction was identified as the basis for USEPA's oral reference dose (RfD; 0.002 mg/kg/day), this endpoint was used in the assessment to provide an upper-bound estimate of the potential health hazards. The results of the screening-level exposure assessment indicated that the highest hypothetical exposures occurred in children <1 year, 1-2 years and 3-5 years old. Total daily intakes ranged from 0.00004 to 0.0009 mg/kg/day. Calculated daily intakes for children and adults were well below the three screening toxicity benchmarks.

#### 1915

DEVELOPMENTAL EXPOSURE TO POLYBROMINATED DIPHENYL ETHERS IMPAIRS SYNAPTIC TRANSMISSION AND LTP IN HIPPOCAMPUS.

M. E. Gilbert<sup>1</sup>, L. Sui<sup>2, 1</sup> and K. M. Crofton<sup>1</sup>. <sup>1</sup>Neurotoxicology, USEPA, Research Triangle Pk, NC and <sup>2</sup>National Research Council, Washington, DC.

Polybrominated diphenyl ether (PBDE) flame retardants bioaccumulate in wildlife and in humans and reduce circulating levels of thyroxine (T4). The present work examined hippocampal function in adult offspring of LE rats treated daily by oral gavage with 0, 30 or 100 mg/kg of a commercial PBDE mixture, DE71 from gestational day 6 to weaning on postnatal day (PND) 21. This regimen produced moderate decreases in T4 (40-70%) during the early postnatal period with recovery to control levels by PND36. Spatial learning and hippocampal synaptic transmission were evaluated in adult male offspring. Learning was assessed in a Morris water maze (2 trials/day for 15 days). Several weeks later, electrodes were implanted in the perforant path and dentate gyrus under urethane anesthesia, to examine synaptic function. Input/output (I/O) and paired-pulse functions were collected to assess baseline synaptic transmission and short-term facilitation. Long-term potentiation (LTP) was induced by delivering theta burst stimulation at a modest (300µA)and a high (1500μA) stimulus intensity. No effect of DE71 was seen on spatial learning. In baseline I/O recordings, population spike amplitude was increased in the 100 mg/kg group relative to controls, with no effect on EPSP slope amplitude. Despite an increase in baseline synaptic transmission, LTP of the population spike was impaired in response to both stimulus strengths in the 100 mg/kg dose group. The data suggest that the reductions in T4 induced by a 100 mg/kg dose of DE71 were sufficient to alter synaptic transmission in the hippocampus. Effects of DE71 on hippocampal synaptic function are similar to those produced by developmental exposure to the polychlorinated biphenyl mixture, A1254, which also failed to affect learning in the Morris water maze. Collectively, these results suggest that identifying behavioral correlates of subtle changes in hippocampal synaptic function may require more sophisticated tests of learning and memory. ## 1916 PERFLUOROOCTANE SULFONATE (PFOS) ALTERS LUNG DEVELOPMENT IN THE NEONATAL RAT.

R. C. Grasty<sup>1, 2</sup>, N. Roberts<sup>1</sup>, B. E. Grey<sup>1</sup>, <u>C. Lau<sup>1</sup> and J. M. Rogers<sup>1, 2</sup>.</u>

\*Reproductive Toxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC and <sup>2</sup>Curriculum in Toxicology, UNC Chapel Hill, Chapel Hill, NC.

Perfluorooctane sulfonate is an environmentally stable compound used widely in industrial and household products; its presence has been detected in both humans and wildlife. Chronic prenatal exposure to PFOS in rodents leads to mortality in newborns within hours to days after birth. We have previously demonstrated that treatment on gestation days (GD) 19-20 is sufficient to induce neonatal death in the rat; while the underlying pathophysiological mechanism remains to be determined. Here, timed-pregnant Sprague-Dawley rats were treated by oral gavage with 0, 25, or 50 mg/kg/d PFOS/K+ on GD 19-20; and lungs from fetuses and newborns (within 1 h after birth) were harvested for evaluation. Histological examination of the fetal lungs taken on GD 19-21 did not reveal any difference between control and treated animals. Lungs from newborns indicated morphological abnormalities in some of the treated animals (A) in both dose groups, whereas no abnormalities were apparent in others (B), as compared to controls (C). Lungs from control newborns and 50 mg/kg group were then compared using morphometric analysis. In all measurements taken, no differences were found between samples from groups B and C. In contrast, the proportion of cross-sectional lung area occupied by solid tissue was 0.43 in group A samples and 0.26 in group C (p<0.05). The proportion of airway space was significantly decreased in group A as was the ratio of airway:tissue area (2.41 in A vs. 2.94 in C). Ultrastructural evaluation of the alveolar epithelial cells with electron microscopy confirmed the histological findings, and indicated subcellular disorganization in the newborn lungs exposed to PFOS. These results thus demonstrate that exposure to PFOS on GD 19-20 critically impacts normal lung development in the rat, potentially leading to pulmonary dysfunction in the newborns. This abstract does not reflect EPA policy.

## 1917 EFFECTS OF PERFLUOROOCTANE SULFONATE (PFOS) ON THYROID HORMONE STATUS IN ADULT AND NEONATAL RATS.

M. N. Logan<sup>1</sup>, J. R. Thibodeaux<sup>2</sup>, R. G. Hanson<sup>2</sup> and C. Lau<sup>2</sup>. <sup>1</sup>Biology, North Carolina Central University, Durham, NC and <sup>2</sup>USEPA NHEERL, Research Triangle Park, NC. Sponsor: J. Rogers.

Perfluorooctane sulfonate is an environmentally persistent compound ubiquitously found in humans and wildlife. Previous studies have suggested that PFOS alters thyroid hormone status in laboratory animals. The current study examines whether hormone metabolism is involved in PFOS-mediated thyroid deficiency. Adult

Sprague-Dawley rats were given (oral gavage) 3 or 5 mg/kg PFOS/K+ for 21 days, while controls received 0.5% Tween-20 vehicle. Serum thyroxine (T4) and triiodothyronine (T3), and liver uridine diphosphate-glucuronosyl transferase (UDP-GT), a microsomal enzyme that metabolizes (T4), were determined at days 3, 7, 14 and 21 after initiation of treatment. Significant reductions in serum total T4 (58%), free T4 (70%), and total T3 (23%) were noted in the PFOS-treated rats in as little as three days in both dose groups. Hormonal deficits were sustained throughout the study. However, no significant alterations in T4-UDP-GT activities were detected; at day 21, mean T4-UDP-GT activities were 0.614, 0.571, and 0.654 pmol/mg protein/min for control, 3, and 5 mg/kg PFOS groups, respectively. Previously, we have shown that prenatal exposure to PFOS led to hypothyroxinemia in rat pups during postnatal development, while serum T3 levels were not affected. The current study extended the chemical exposure to the postnatal period. PFOS (10 mg/kg, p.o.) was given to rat pups daily from PD1 to PD48. All pups survived the chemical treatment, but serum tT4, fT4 and tT3 were significantly reduced by 64%, 68% and 29% of controls, respectively. The hormonal deficits persisted into young adulthood. These results suggest that PFOS reduces circulating thyroid hormones effectively in both mature and developing rats, but enhancement of hepatic metabolism of the hormones is not likely involved in altering the hormone economy. (Funded by EPA/NCCU Toxicology research program, training agreement CT 829460 with the Department of Biology, NCCU. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

## 1918 PERFLUOROOCTANOIC ACID: RELATIONSHIP BETWEEN REPEATED INHALATION EXPOSURES AND PLASMA PFOA CONCENTRATION IN THE RAT.

P. M. Hinderliter, M. P. DeLorme and G. W. Jepson. Haskell Laboratory for Health and Environmental Sciences, Newark, DE.

A large pharmacokinetic database exists describing the behavior of perfluorooctanoic acid (PFOA) following oral exposure. The objective of this study was to quantify plasma PFOA concentrations in male and female rats, following single and repeated inhalation exposures, for the purpose of bridging the oral and inhalation exposure data sets. The study was comprised of two separate experiments: single (6 hour) and repeated nose only exposures (6 hours per day, 5 days per week for three weeks) to an aqueous aerosol of 0, 1, 10, or 25 mg/m<sup>3</sup> PFOA. Levels were selected to produce plasma concentrations similar to those observed in previous oral gavage studies. For the single exposure, blood was drawn pre-exposure, during exposure and post-exposure. For the repeated exposure, blood was collected immediately before and after the daily inhalation exposure period three days per week. Plasma derived from the whole blood samples was analyzed by liquid chromatography-mass spectrometry (LC-MS). PFOA appeared rapidly in the blood of both male and female rats exposed *via* the inhalation route. PFOA elimination was sex-dependent, with female rats eliminating PFOA from the plasma much more efficiently than male rats. PFOA plasma concentrations were proportional to atmospheric exposure concentrations from 1 to 25 mg/m<sup>3</sup>. Repeated daily inhalation exposures produced little plasma carryover in female rats, but significant carryover in male rats. Male rats reached a steady state plasma concentration by three weeks with plasma concentrations of 8, 21, and 36 µg/mL respectively when exposed to 1, 10, and 25 mg/m³ PFOA. Female rats reached post exposure plasma concentrations of 1, 2, and 4 µg/mL respectively but returned to baseline levels for the pre-exposure time points. This study provides the data necessary to relate external atmospheric concentrations of PFOA to PFOA levels in male and female rat plasma. This research was sponsored by the Association of Plastics Manufacturers in Europe (APME) Fluoropolymers Committee.

## 1919 CONSIDERATIONS RELEVANT TO CONSTRUCTING A HUMAN PBPK MODEL FOR PERFLUOROOCTANOIC ACID (PFOA).

D. J. Paustenbach<sup>1</sup> and G. W. Jepson<sup>2</sup>. <sup>1</sup>ChemRisk, San Francisco, CA and <sup>2</sup>Biochemical and Molecular Toxicology, Haskell Laboratory for Health and Environmental Sciences, Newark, DE.

Perfluorooctanoic acid (PFOA) is a surfactant, which has received significant interest in recent years due to its reported prevalence in blood samples from many US citizens. Consequently, there has been some activity associated with constructing a human PBPK model to relate inhalation and oral exposures to PFOA levels in plasma. While there have been many kinetic studies conducted on rodents, the rodent kinetic data have not been useful in extrapolation to PFOA kinetics in humans. There are several considerations relevant to the construction of a human PBPK model that will determine how, or even if, such a model is appropriate for PFOA. First, PFOA is a surface-active chemical, which will affect its behavior in biological systems and has thus far complicated any efforts to determine tissue to blood partition coefficients. Second, PFOA is reported to be unmetabolized in mammalian systems, thereby eliminating the need for explicit description of me-

tabolizing organs or tissues. Third, the elimination rate is dramatically different between humans and rodents. The reported half-life in humans is approximately 4 years as compared to 2 hours in the female rat. Further, rats have sex dependent elimination rates, which do not appear to be relevant to humans. Fourth, controlled human exposures to PFOA are lacking; therefore, any attempts to validate a PBPK model would be severely limited. This is further complicated by the fact that elimination mechanisms have not been completely elucidated in rats and humans. These considerations and gaps in the understanding of species-specific elimination of PFOA make it impractical to construct and apply a human PBPK or generic kinetic model to predict PFOA concentrations in plasma following ingestion or inhalation of PFOA. The basis for constructing and validating a human PBPK model for PFOA was described and evaluated.

## 1920 A LONG-TERM TREND OF SERUM LEVELS OF PERFLUOROOCTANE SULFONATE (PFOS) AND PERFLUOROOCTANOATE (PFOA) IN JAPANESE.

K. Harada, A. Koizumi, T. Yoshinaga, K. Inoue and N. Saito. *Health Environmental Sciences, Kyoto University Graduate School of Medicine, Kyoto, Japan.* Sponsor: R. Reitz.

PFOS and PFOA are chemicals of a new class of Pops. They have been used from 1950s as various purposes. The aim of this study is to assess a long-term trend of PFOS and PFOA exposures using serum samples collected from late 1970s to 2003 in Japan. Methods. Human serum. We used samples in the sample bank. We collected serum samples in Miyagi (Miyagi samples), Akita (Akita samples) and Kyoto (Kyoto samples). În Miyagi, Akita, Kyoto, we collected samples in 1970s and 2003, in the early 1990s and 2003, in 2002 and 2003 respectively. Analysis: the 0.5 ml of serum were used for determination of PFOA and PFOS by LC/MS (Saito et al., 2003). Results. The PFOS and PFOA levels in serums [GM(GSD)](PFOS and PFOA in order :microgram/L) were; in Miyagi samples in 1970s 1.1(1.8) and 0.2(2.0) for females (n=40); in 2003 5.7(1.8) and 3.3(2.0) for males (n=32) and 3.5(2.9) and 2.8(1.5) for females (n=23). In Akita samples they were; in 1991, 10.2(1.5) and 2.2(1.4) for males (n=16) and 8.0(1.4) and 1.7(1.5) for females (n=40) and in 2003 12.9(1.5) and 3.4(1.5) for males (n=66) and 5.0(3.2) and 2.4(1.7) for females (n=54). In Kyoto, they were in 2003; 21.8(1.7) and 9.4(1.5) for males (n=28) and 12.7(1.5) and 6.1(1.5) for females (n=26) . In Miyagi PFOS and PFOA concentrations have increased 3 times and 14 times, respectively. In Akita, there are no increase between 1990s and 2003 for PFOS but the level of PFOA was increasing. There are large gender differences in the concentrations of PFOS and PFOA at three locations. Furthermore, there are predominant regional differences for both PFOS and PFOA concentrations. Systematic collection of samples at different time periods, genders, and locality enabled us to analyze the exposure trends.Reference.Saito et al.; (2003) Arch. Environment Contam. Toxicol. 45: 149-58

## 1921 PERFLUOROOCTANOATE AND PERFLUOROOCTANE SULFONATE CONCENTRATIONS IN SURFACE WATERS IN JAPAN.

N. Saito<sup>2</sup>, A. Koizumi<sup>1</sup>, T. Yoshinaga<sup>1</sup>, K. Harada<sup>1</sup> and K. Inoue<sup>1</sup>. <sup>1</sup>Health Environmental Sciences, Kyoto University Graduate School of Medicine, Kyoto, Japan and <sup>2</sup>Health and Environmental Sciences, Iwate Environmental Institute, Morioka, Japan. Sponsor: R. Reitz.

Perfluorooctanoate (PFOA) and perfluorooctane sulfonate (PFOS) are Pops widely used in Japan. We analyzed their concentrations in surface water samples collected from all over Japan. Methods: Water samples were collected from rivers, coastal sea waters and tap waters. For all sampling, a two-L sample was collected. Samples were passed through the Presep-C Agri column at a flow rate of 10 mL /min using a Waters Concentrator System (Concentrator Plus, Waters, Tokyo, Japan). Presep-C cartridges were then eluted with 1.5 mL of methanol and concentrated at room temperature. The methanol extracts were chromatographed using HPLC and Mass spectra were taken on an LC/MS. The fragment ions for PFOA m/z 413 (C7F15CO2-) and for PFOS m/z 499 (C8F17SO3-) were monitored for quantification. Results and discussion: The lowest limits of detection (LOD) (ng/L) were 0.06 for PFOA and 0.04 for PFOS. The lowest limits of quantification (LOQ) (ng/L) were 0.1 for both analytes. The levels [geometric mean (GM); geometric standard deviation (GS)] (ng/L) of PFOA and PFOS in the surface waters were GM (GS): 0.97 (3.06) and 1.19 (2.44) for Hokkaido-Tohoku (n=16); 2.84(3.56) and 3.69 (3.93) for Kanto (n=14); 2.50 (2.23) and 1.07 (2.36) for Chubu (n=17); 21.5 (2.28) and 5.73 (3.61) for Kinki (n=8); 1.51 (2.28) and 1.00 (3.42) for Chugoku (n=9); 1.93 (2.40) and 0.89 (3.09) for Kyushu-Shikoku (n=15). The GM of PFOA in Kinki was significantly higher than in other areas (ANOVA p<0.01). Systematic searches of Yodo and Kanzaki Rivers revealed two potential sources, a public-water-disposal site for PFOA and an airport for PFOS. The former was estimated to release 18 kg of PFOA/day. PFOA in drinking water in Osaka city [40

(1.07) ng/L] was significantly higher than in other areas. The present study confirms that a large amount of PFOA is produced and released in Kink, and causes drinking water contamination.

## 1922 PAHS EXPOSURE AND BIOMARKERS: SIMULTANEOUS ANALYSIS OF 1-HYDROXYPYRENE AND ITS CONJUGATES IN URINE.

Y. Hu<sup>1</sup>, X. Xue<sup>1</sup>, Z. Zhou<sup>2</sup>, J. Fu<sup>2</sup>, B. S. Cohen<sup>1</sup>, A. A. Melikian<sup>3</sup>, M. Desai<sup>1</sup>, X. Li<sup>1</sup>, E. Tang<sup>1</sup>, X. Huang<sup>1</sup>, N. K. Roy<sup>1</sup> and Q. Qu<sup>1</sup>. <sup>1</sup>Institute of Environmental medicine, New York University School of Medicine, Tuxedo, NY, <sup>2</sup>Department of Toxicology, School of Public Health, Peking University, Beijing, China and <sup>3</sup>American Health Foundation, Valhalla, NY. Sponsor: L. Chen.

The present study is part of the biomarker validation project conducted in a Chinese occupational population. 57 subjects, including 28 exposed workers and 29 controls, were recruited and monitored for their personal exposures to PAHs and excretions of 1-hydroxypyrene (1-OHP) in urine. The average personal exposure levels of pyrene, benzo(a)anthracene (BaA) and BaP in exposed workers were  $15.2 \pm 9.1 \text{ ug/m3}$ ,  $4.4 \pm 1.6 \text{ ug/m3}$  and  $4.3 \pm 1.6 \text{ ug/m3}$ , respectively. The corresponding levels in control subjects were  $0.016 \pm 0.017$  ug/m<sup>3</sup>,  $0.022 \pm 0.011$ ug/m3, and  $0.011 \pm 0.011$  ug/m3. A variety forms of 1-OHP, including free 1-OHP and its conjugates of glucocorunide (1-OHP-G) and sulphate (1-OHP-S), were analyzed simultaneously in urine samples collected from participating subjects after work. The average levels of total urinary 1-OHP were  $7.15 \pm 5.35$  umol/mole creatinine in exposed workers and  $0.71 \pm 0.43$  umol/mole creatinine in the controls. Among the three forms, 1-OHP-G was found to be predominant, which represents 93.7% and 74.2% of total 1-OHP excretions in exposed and control subjects, respectively. A strong correlation was observed between urinary concentrations of 1-OHP-G and personal exposure levels of pyrene, BaA and BaP (r=0.896, 0.904 and 0.907 respectively). Multiple linear regression analyses indicated that after adjustment for potential confounding by the amount of smoking, there was still a strong association between PAHs exposure and levels of 1-OHP in urine (p<0.01). The estimated half-life of 1-OHP in urine is about 15.2 hours after cessation of exposure. Further validation of 1-OHP and other biomarkers for low level exposures is being investigated in humans exposed to PAHs at or above ambient levels.

## 1923 THE CARCINOGEN 7, 8-DIHYDRO-9, 10-EPOXY-7, 8, 9, 10-TETRAHDROBENZO[A]PYRENE AND BENZO(A)PYRENE REDUCED ANDROGEN RECEPTOR

EXPRESSION IN HUMAN LUNG CELLS.

P. Lin and J. Ko. Toxicology, Chung Shan Medical University, Taichung, Taiwan.

5-Alpha dihydrotestosterone significantly increased cell growth of lung adenocarcinoma cell lines H1355. Benzo[a]pyrene (BaP) is a pulmonary carcinogen found in cigarette smoke. Treatment with 1 mM BaP tremendously reduced androgen receptor (AR) expression in H1355 cells, as determined with Western immunoblot and the real-time RT-PCR assay. Similarly, 1 mM BaP significantly reduced AR mRNA levels in human bronchial epithelial cells BEAS-2B. Although BaP, 2, 3, 7, 8-tetrachlorodibenzo-p-dixin (TCDD) and polychlorinated biphenyl 126 (PCB126) activated aryl hydrocarbon receptor (AhR) which subsequently induced cytochrome P4501A1 (CYP1A1) and 1B1 (CYP1B1) expression in H1355 cells, neither TCDD nor PCB126 reduced AR expression. Antagonizing AhR activation with alpha-naphthoflavone, or inhibiting CYP1B1 activity with 2, 4, 3, 5-tetramethoxystilbene, however, prevented BaP-induced AR reduction. We also found that 7, 8-dihydro-9, 10-epoxy-7, 8, 9, 10-tetrahydrobenzo[a]pyrene (BPDE), a BaP carcinogenic metabolite catalyzed by CYP1A1 and CYP1B1, significantly reduced AR expression in H1355 cells and human lung fibroblasts WI-38. Furthermore, inhibiting tyrosine phosphorylation with genestein tremendously prevented BaP-induced AR reduction in H1355 cells. This is the first study reported that BaP and BPDE reduced endogenous AR expression. These data suggest that metabolically activated BaP may disrupt androgen function by reducing AR levels in androgenresponsive organs.

#### 1924

DEVELOPMENT OF A HIGH PERFORMANCE LIQUID CHROMATOGRAPHIC METHOD FOR THE SIMULTANEOUS DETERMINATION OF PYRENE-1, 6-AND -1, 8-DIONE IN ANIMAL AND HUMAN URINE.

A. Ruzgyte, M. Bouchard and C. Viau. Environmental & Occupational Health, University of Montreal, Montreal, QC, Canada.

Pyrene is a major and ubiquitous representative of most mixtures of polycyclic aromatic hydrocarbons (PAHs). A number of field studies indicated that 1-hydroxypyrene (1-OHP) in urine is a good biomarker of occupational exposure to pyrene,

while it lacks sensitivity as an indicator of low-dose environmental exposure. Recent mass-balance and kinetics studies in rats exposed to <sup>14</sup>C-labelled pyrene suggest that 1-OHP is not the major excreted metabolite of pyrene. The purpose of this study was thus to identify and quantify metabolites of pyrene other than 1-OHP, in animal and human urine. Using a liquid chromatography-electrospray-mass spectrometry method, it was first observed that dioxygenated pyrene metabolites (m/z = 233) were present in significant amounts in urine samples of rats treated with pyrene. A high-performance liquid chromatography method with fluorescence detection techniques was then developed to simultaneously determine pyrene-1, 6-dione (P16D) and pyrene-1, 8-dione (P18D) metabolites. Interestingly, results using both rat and human samples showed that P16D molar concentrations exceed that of 1-OHP by 30 to 90 times and P18D concentrations exceed 1-OHP by 4 to 9 times. These urinary metabolites thus appear as potentially useful biomarker of low-dose environmental exposure to pyrene.

## 1925 EFFECTS OF POLYAROMATIC HYDROCARBON CONTENT IN VEHICLE GASOLINE EMISSION EXHAUST ON GSH/GSSG RATIO *IN VITRO*.

R. P. Balan<sup>1</sup>, J. L. Garcia-Tavera<sup>1</sup>, A. Zambrano-Garcia<sup>2</sup>, J. L. Arriaga<sup>2</sup>, University. Gonzalez-Macias<sup>2</sup>, I. Zapata-Penazco<sup>2</sup>, <u>M. E. Cebrian<sup>1</sup></u>, E. S. Calderon-Aranda<sup>1</sup> and A. De Vizcaya-Ruiz<sup>1</sup>. <sup>1</sup> Toxicology, CINVESTAV-IPN, Mexico D.E., Mexico and <sup>2</sup> Ecotoxicology, IMP, Mexico D.E., Mexico.

Mobile sources contribute with an 84% of total emissions to the air in Mexico City, among their components are polyaromatic hydrocarbons (PAHs), which have been described as the responsible components of most of the toxic effects from diesel emissions. Limited information is available on the effects from PAHs mixtures from vehicle gasoline emissions exhaust on mammalian cells. The objective of this study is to provide information on the toxic effects on J774A.1 macrophages exposed to PAHs organic extracts (PAH-VEE) from gasoline emissions using oxidative stress as a potential biomarker of toxicity. Gaseous and particulated emissions were obtained from a 1.7 L gasoline engine vehicle operated under the FTP-75 method using two Mexican commercial gasolines and analyzed under US-EPA TO13. Average PAHs content in the organic extracts of the vehicle emissions were 42.43ng/µL in the gaseous and 1.97ng/µL in the particulated phase, two ring compounds being the most abundant. J774A.1 cells were exposed to the PAH-VEE from the gaseous and particulated phases at a dose equivalent to a 160m of urban operation conditions. No cytotoxicity assayed by MTT was observed. The GSH/GSSG ratio was determined using the recycling method with 2-VP as a scavenger in J774A.1 cells exposed to the PAH-VEE at 06, 12 and 24h. No evident alteration on GSH/GSSG ratio, in cells exposed to both phases of gasoline emissions was observed under these conditions. The lack of effect could be attributed to a low concentration of hydrophilic compounds, or to the triggering of other antioxidant elements involved in the antioxidant response in macrophages, such as  $\gamma$ -GCS, GSH synthetase, GST, SOD and catalase. Further research using higher concentrations of PAHs in the organic extracts and the use of GSH synthesis inhibitors could be performed to rule out a possible antioxidant compensation response. (Financed by FIES-IMP 98-119-VI).

### 1926

*IN VIVO* AND *IN VITRO* IMMUNOSUPPRESSIVE EFFECTS OF BENZO[K]FLUORANTHENE IN FEMALE BALB/C MICE.

T. Jeon, C. Jin, S. Lee, D. Lee, N. Kim, S. Hyun and <u>T. Jeong</u>. *Pharmacy, Yeungnam University, Kyungsan, Kyungbuk, South Korea.* 

Although polycyclic aromatic hydrocarbons (PAHs) have been known to suppress immune responses, few studies have addressed the immunotoxicity of benzo[k]fluoranthene (B[k]F). In this study, we investigated the immunosuppression of B[k]F, both in vivo and in vitro, in female BALB/c mice. To assess the effects of B[k]F on humoral immunity as splenic antibody response to sheep red blood cells (SRBCs), B[k]F was given a single dose or once daily for 7 consecutive days po with 30, 60 and 120 µmoles/kg. Acute oral administration of B[k]F induced a dose-related increase in liver weight. B[k]F also induced activities of hepatic ethoxyresorufin Odeethylase and pentoxyresorufin O-depentylase. Oral B[k]F reduced the number of antibody forming cells (AFCs) in a dose-dependent manner. Subacute treatment with B[k]F caused weight increases in liver and decreases in spleen and thymus. Interestingly, subacute B[k]F inhibited the hepatic activity of methoxyresorufin Odemethylase. The number of AFCs was dramatically decreased by B[k]F in a dosedependent manner. In a subsequent study, mice were subacutely exposed to same doses of B[k]F without an immunization with SRBCs, followed by splenic and thymic lymphocyte phenotypings using a flow cytometry and ex vivo mitogen-stimulated proliferation. B[k]F exposed mice exhibited reduced splenic and thymic cellularity, decreased numbers of total T cells, CD4<sup>+</sup> cells and CD8<sup>+</sup> cells in spleen and immature CD4<sup>+</sup>CD8<sup>+</sup> cells, CD4<sup>+</sup>CD8<sup>-</sup> cells and CD8<sup>+</sup>CD4<sup>-</sup> cells in thymus. In ex vivo lymphocyte proliferation assay, B[k]F inhibited splenocyte proliferation by

LPS and Con A. In *in vitro* mitogen-stimulated proliferation by untreated splenic suspensions, B[k]F only suppressed splenocyte proliferation to LPS. These results suggest that B[k]F might have immunotoxic potential by mechanisms associated with metabolic processes. (Supported by a grant from Korea Food and Drug Administration).

## 1927 DNA ADDUCT AS BIOLOGICAL EFFECT MARKER IN A CHINESE POPULATION WITH ENVIRONMENTAL EXPOSURES TO PAHS.

Q. Qu¹, Y. Hu¹, X. Xue¹, Z. Zhou², J. Fu², B. Cohen¹, D. Li³, X. Li¹, E. Tang¹ and N. Roy¹. ¹Environmental Medicine, NYU School of Medicine, Tuxedo, NY, ²Toxicology, Peking University School of Public Health, Beijing, Beijing, China and ³Gastrointestinal Medical Oncolog, University of Texas, M.D Anderson Cancer Center, Houston, TX. Sponsor: L. Chen.

A biomarker validation study has been being conducted in a Chinese population with occupational or environmental exposures to PAHs. So far, 142 subjects (99 male and 43 female) have been recruited from coke oven workers, residents in a metropolitan area and surrounding suburb. All participating subjects were monitored for their personal exposures to PAHs and DNA adduct levels in lymphocytes. The average personal exposure levels of pyrene, benzo(a)anthracene (BaA) and BaP were 3.28, 1.044, and 0.957 ug/m3 with corresponding median levels of 0.155, 0.137, and 0.072 ug/m3, respectively. The bulky PAH-DNA adducts were determined by 32p-postlabeling analysis (P1 enrichment procedure). A moderate significant correlations were observed between DNA adduct levels and personal exposure levels of BaP (r=0.355, P<0.0001) and total PAHs (r=0.335, P<0.0001). The multiple regression analyses of DNA adducts on PAHs exposure indicated that smoking status and cotinine levels had no significant effect on DNA adducts. Genotype assays are now being conducted to evaluate whether or not the polymorphisms of genes, including CYP1A1, mEH, GSTT1, GSTM1, etc., play roles in determining individual variations in susceptibility to PAHs-induced DNA adducts formation.

### 1928

BENZO(A)PYRENE INDUCES ATM-DEPENDENT P53 PHOSPHORYLATION AND CELL CYCLE ARREST IN HUMAN PLACENTAL AND ENDOMETRIAL CELL LINES.

J. M. Kitzman, T. A. Medrano and <u>K. T. Shiverick</u>. *Pharmacology & Therapeutics, University of Florida, Gainesville, FL.* 

Maternal cigarette smoking disrupts placental growth and function, and is linked to uterine disease and infertility. Benzo(a)pyrene (BaP), a major toxicant in cigarette smoke, has been previously shown to inhibit proliferation of human placental JEG-3 and uterine endometrial RL95-2 cells. ATM, a serine/threonine kinase, is known to function as a primary sensor of DNA damage that activates p53 through phosphorylation on serine-15 (p53 ser-15phos). This study investigated whether BaP inhibition of cell cycle progression involves ATM-dependent p53 serine-15 phososphorylation in JEG-3 and RL95-2 cells. In trophoblastic JEG-3 cells, flow cytometry analysis shows that 10 uM BaP produced G2/M phase accumulation by 24 hr that continued through 96 hr. Western immunoblot analysis showed that BaP significantly increased p53 ser-15phos at both 24 and 48 hr, followed by increased expression of p21Cip1 (p21), a key cyclin dependent kinase inhibitor, at 48 hr. The presence of 20 uM wortmannin, a specific inhibitor of ATM kinase, markedly inhibited BaP-induced p53 ser-15phos at 24 hr, as well as p21 expression at 48 hr. In endometrial RL95-2 cells, BaP (10 uM) treatment produced G2/M cell cycle accumulation at 48 and 72 hrs accompanied with a 600% increase in p53 ser-15phos at 48 hr. Again, the presence of 20 uM wortmannin markedly inhibited the BaP-mediated effect on p53 phosphorylation. In summary, data indicate that the anti-proliferative effects of BaP in JEG-3 and RL95-2 cells involve G2/M cell cycle arrest in association with ATM-dependent p53 serine-15 phosphorylation. (Supported by NIH ES07375)

## 1929 IN VIVO AND IN VITRO COMPARISONS OF POLYCYCLIC AROMATIC HYDROCARBONS-INDUCED IMMUNOTOXICITY IN MICE.

D. Lee, T. Jeon, C. Jin, S. Lee, N. Kim, S. Hyun and <u>T. Jeong</u>. *Pharmacy, Yeungnam University, Kyungsan, Kyungbuk, South Korea.* 

Effects of five PAHs, such as benz[e]acephenanthrylene (B[e]A), 1, 2-benzanthracene (1, 2-BA), pyrene, chrysene and benzo[a]pyrene (B[a]P), on immune functions were compared in female BALB/c mice. PAHs were given a single dose or once daily for 7 consecutive days po at either 30, 60 or 120 µmoles/kg. Activities of hepatic CYP-dependent enzymes were also determined following the administration of PAHs. Additionally, subacute effects of PAHs on splenic and thymic lym-

phocyte phenotypes and ex vivo mitogen-stimulated proliferation were determined. Finally, in vitro splenocyte proliferation, following a direct addition of PAHs, was measured. Acute oral administration of pyrene and B[e]A induced a dose-related decrease and increase in thymus and liver weights, respectively. Oral B[a]P and B[e]A suppressed the antibody response most potently. Subacute treatment with B[a]P, B[e]A and 1, 2-BA induced weight decreases in spleen. All PAHs significantly induced hepatic EROD activities. B[e]A, pyrene and chrysene induced PROD activities. Subacute oral treatment with most PAHs suppressed the antibody response dose-dependently. The subacute exposure to B[a]P, B[e]A and 1, 2-BA without an immunization showed decreases in thymus weights. In addition, B[a]P, B[e]A and 1, 2-BA exposed mice exhibited characteristic suppression profile of splenic and thymic cellularity, numbers of total T, T-subset and B cells in spleen and CD4+CD8+, CD4+CD8- and CD4-CD8+ cells in thymus. In ex vivo lymphocyte proliferation assays, B[a]P and 1, 2-BA suppressed splenocyte proliferation by LPS and Con A. No PAHs had effects on in vitro mitogen-stimulated proliferation directly. These findings suggest that the immunotoxic potential of PAHs studied would be ranked as B[e]A, B[a]P > 1, 2-BA > chrysene, pyrene, and that B[a]P and 1, 2-BA might require metabolic activation for their immunotoxicity. (Supported by a grant from Korea Food and Drug Administration).

### 1930 DIETARY FAT MODULATED METABOLISM OF FLUORANTHENE (FLA) IN F-344 RATS.

S. A. WALKER and <u>A. RAMESH</u>. *PHARMACOLOGY, MEHARRY MEDICAL COLLEGE, NASHVILLE, TN.* 

Chemically contaminated diets rich in fat leads to a greater intake and retaining of toxic chemicals in the body with an increased risk to human health. This study was conducted to measure the metabolism of fluoranthene (FLA), a polycyclic aromatic hydrocarbon compound, subsequent to acute oral exposure under different dietary regimens. F-344 male rats were given 50 µg/kg FLA via oral gavage using test meals comprising peanut, corn, and coconut oils as representatives of monounsaturated, polyunsaturated and saturated dietary fats respectively. Control animals were either exposed to vehicle only or unexposed. After exposure, rats were sacrificed at different time points; trunk blood, urine and feces were collected. Stomach, intestine, liver, lung, testis and brain tissues were removed. Samples were subjected to liquidliquid extraction using water, methanol and chloroform. The extracts were analyzed for FLA and metabolites by reverse-phase HPLC with fluorescence detection. The FLA metabolite concentrations varied with the type of dietary fat intake. For e.g. FLA dosed in test meal containing saturated fat produced the greatest quantity of metabolites followed by test meals containing polyunsaturated and monounsaturated fat. The FLA 2, 3-diol is the predominant metabolite followed by i) trans-2, 3-dihydroxy-1, 10b-epoxy-1, 2, 3, 10b tetrahydro FLA (2, 3 D FLA), ii) FLA-2, 3dione, iii) 3-hydroxy FLA and iv) 8-hydroxy FLA. The concentrations of FLA 2, 3diol and 2, 3 D FLA were high in plasma of rats that were administered saturated fat, followed by polyunsaturated and monounsaturated fat. On the other hand, the concentrations of 3 (OH) FLA (detoxification product of FLA) were low in plasma of rats that ingested saturated fat compared to those that ingested poly, and monounsaturated fat. Our findings indicate a) dietary fat type influences the overall concentration of FLA metabolites b) the qualitative distribution of FLA metabolites in plasma and target tissues also depend on lipid type (Supported by NIEHS grant #1R15ES12168-01, NIGMS-SCORE grant #2S06GM08037-32, RISE grant #2R25GM59994 and NCRR-RCMI grant #G12RR03032).

## 1931 DMBA BONE MARROW TOXICITY SELECTIVELY AFFECTS THE GRANULOCYTE POPULATION, MONOCYTE VS. NEUTROPHIL.

N. Galvan<sup>1, 2</sup>, C. J. Czuprynski<sup>1, 3</sup> and C. R. Jefcoate<sup>1, 2</sup>. <sup>1</sup>Molecular and Environmental Toxicology, UW-Madison, Madison, WI, <sup>2</sup>Pharmacology, UW-Madison, Madison, WI and <sup>3</sup>Pathological Sciences, UW-Madison, Madison, WI.

Treatment of mice with the prototypical polycyclic aromatic hydrocarbons (PAHs), 7, 12-dimethylbenz(a)anthrecene (DMBA) and benzo(a)pyrene (BP), leads to bone marrow toxicity, lymphoid tumors and immunosuppression. Resistance to the DMBA toxicity with the CYP1B1-/- and TNFR-/- mice has provided compelling evidence that implicate CYP1B1 and TNFR (and by implication TNFα) in this response. We have used in situ hybridization and RT-PCR to show the presence of CYP1B1 and induction by PAHs in the bone marrow. In addition, we demonstrated that CYP1A1 is not present in bone marrow, and that low levels of CYP1B1 are sufficient for DMBA bone marrow toxicity. Our previous *in vitro* studies show that bone marrow stromal fibroblasts activate PAHs *via* CYP1B1. Others have shown that leukocytes can bioactive PAHs *via* CYP1B1 metabolism, while mononuclear phagocytes secrete TNFα following PAH treatment. We have demonstrated that 48 hours after DMBA treatment of C57Bl/6 mice is then followed by a decrease in the granulocyte (Gr-1+) population. In this study, we aimed to identify the specific type of hematopoietic cells that express CYP1B1 within the

bone marrow and populations that are susceptible to DMBA toxicity. The use of 7/4 and Gr-1 monoclonal antibodies has allowed us to identify and separate by FACS the myeloid population into monocytes (Gr-1lo/7/4hi) and neutrophils (Gr-1hi/7/4hi). These data will allow us to determine the susceptibility of these bone marrow populations to DMBA. In addition, RT-PCR analysis will determine their relative CYP1B1 expression, and of inflammatory cytokines that further modulate DMBA bone marrow toxicity.

### 1932 SPECIES-SPECIFIC INTESTINAL MICROSOMAL METABOLISM OF FLUORANTHENE.

A. RAMESH, S. A. WALKER, L. WHITTEN and G. SEALS. PHARMACOLOGY, MEHARRY MEDICAL COLLEGE, NASHVILLE, TN.

Several species respond differently to toxic chemical exposure. The magnitude of susceptibility to toxicant exposure may depend on the ability of animals to metabolize the chemicals. The present study has been undertaken to see whether any differences exist among mammals in the metabolism of fluoranthene (FLA), a polycyclic aromatic hydrocarbon (PAH) compound. Since intestine is the functional interface between orally ingested FLA and the body, microsomes were isolated from the small intestine of rat, mouse, hamster, guinea pig, goat, sheep, pig, dog, and humans (commercially procured) and incubated for 15 min with 125 µl of FLA solution (0.807 mg/ml). The reaction was stopped by the addition of 8 ml ethyl acetate containing butylated hydroxytoluene. The post-incubation samples were extracted twice with ethyl acetate, concentrated, and analyzed for FLA/metabolites by reverse-phase HPLC with fluorescence detection. The concentrations of FLA metabolites produced by microsomes varied among the species. The invitro metabolism of FLA was in the order- human > dog > pig > goat > sheep > guinea pig > hamster > rat > mouse. The FLA metabolites identified were FLA 2, 3-diol, trans-2, 3-dihydroxy-1, 10b-epoxy-1, 2, 3, 10b tetrahydro FLA (2, 3 D FLA), FLA-2, 3dione, 3-hydroxy FLA, and 8-hydroxy FLA. The rodent microsomes produced considerably higher proportion of FLA 2, 3-diol, and 2, 3 D FLA than did pig, dog, and humans. On the other hand, the pig, dog, and human microsomes converted a greater proportion of FLA to 3-hydroxy FLA, the detoxification product of FLA. Our results revealed that the metabolism of widely distributed PAHs such as FLA is species-specific. Overall, our findings suggest that dog, pig, and humans are the species best equipped to process FLA. These findings will be of help in extrapolation of metabolic data from one species to another and identify the susceptible species from a risk assessment perspective (Supported by NIEHS grant #1R15ES12168-01, NIGMS-SCORE grant #2S06GM08037-32, RISE grant #2R25GM59994 and NCRR-RCMI grant # G12RR03032).

## 1933 IN VITRO AND IN VIVO GENOTOXICITY OF ISOLATED FRACTIONS FROM PAH AND CHLOROPHENOL MIXTURES.

T. D. Phillips, A. M. Gillespie, L. Cizmas, L. He, G. Zhou, T. J. McDonald, Y. Qian and K. C. Donnelly. Texas A&M University, College Station, TX.

Creosote and pentachlorophenol are chemicals found in wood preserving waste (WPW). Improper disposal of WPW has lead to contamination of soil and groundwater in many locations. This study compares the in vitro and in vivo genotoxicity of isolated fractions of WPW with chemical composition. The WPW was fractionated using liquid-liquid extraction to obtain acid, base, and neutral fractions following the EPA 3650B Method. The neutral fraction was then enriched for chlorinated dioxins (PCDDs) using a mixed bed silica column followed by a carbon column; and enriched for polycyclic aromatic hydrocarbons (PAHs) using sequentially an alumina-silica column and a carbon column. The fractions were then analyzed for their chemical content using GC/MS, and tested in the Salmonella/microsome assay, E.coli prophage induction assay, and <sup>32</sup>P postlabeling assay to characterize genotoxicity. The chemical analyses indicate that the chlorophenols were concentrated in the acid fraction, the base fraction contained PAHs and phenolic compounds; and the neutral fraction contained PAHs and PCDDs. The PCDD fraction contained primarily hepta and octa chlorinated PCDDs along with the low molecular weight PAHs. The PAH fraction contained a large amount of the higher molecular weight and carcinogenic PAHs. In the Salmonella/microsome assay, the base fraction induced 119 net revertants at a dose of 0.1 mg/plate, while crude extract induced 19 net revertants at the same dose. In the prophage induction assay, both the acid and base fractions induced positive genotoxic responses. In the <sup>32</sup>P postlabeling assay, the PAH fraction produced approximately 3 times the DNA adduct frequency observed in the other fractions. Although the base fraction contained the lowest amount of benzo(a)pyrene, it induced the maximum genotoxic response in vitro. The data indicate that isolation of the most genotoxic compounds from a complex mixture may be necessary to obtain a more accurate measurement of potential carcinogenicity.

## 1934 PAH *O*-QUINONES PRODUCE SIGNIFICANT AMOUNTS OF 8-OXO-7, 8-DIHYDRO-2'-DEOXYGUANOSINE (8-OXO-DG) IN SALMON TESTIS

J. Park, L. M. Szewczuk and T. M. Penning. pharmacology, school of medicine, university of pennsylvania, philadelphia, PA. Sponsor: S. burchiel.

Polycyclic aromatic hydrocarbons (PAHs) are procarcinogens that require activation by host metabolism. Aldo-Keto-Reductases (AKRs) activate PAHs to reactive and redox active o-quinones, which can cause oxidative DNA damage. Spectrophotometric analysis showed that NADPH promoted PAH o-quinones to enter futile redox-cycles, which result in the depletion of excess cofactor. Copper (II) amplified NADPH-dependent redox-cycling of the quinones, whereas rat liver S9 did not stimulate redox-cycling except for naphthalene-1, 2-dione. Concurrent with NADPH oxidation, molecular oxygen was consumed, indicating the production of reactive oxygen species (ROS). To measure 8-oxo-dG formation in salmon testis DNA by PAH o-quinones, three pre-requisite experimental conditions were satisfied. Quantitative complete enzymatic hydrolysis of DNA was achieved, adventitious oxidation of dG was eliminated by the use of Chelex and Desferal, and basal levels of 8-oxo-dG were lower than 2 adducts/10<sup>5</sup> dG. This method was validated by spiking the DNA with standard 8-oxo-dG and demonstrating quantitative recovery by EC-HPLC. EC-HPLC analysis revealed that in the presence of NADPH and Copper (II), submicromolar concentrations of PAH o-quinones generated > 60 8-oxo-dG adducts/10<sup>5</sup> dG. The dependency on Copper (II) suggests that Copper (I) fenton-chemistry may be responsible. The rank order of 8-oxo-dG generated *in vitro* was naphthalene-1, 2-dione benz[a]anthracene-3, 4-dione 7, 12-dimethylbenz[a]anthracene-3, 4-dione benzo[a]pyrene-7, 8-dione. Experiments are being performed to detect whether ROS or Cu(I)OOH is the DNA damaging species. (Supported by P01-CA-092537 & R01-CA-39504 awarded to Trevor M. Penning)

### 1935 PYRENE ALTERS GENE EXPRESSION AND FATTY ACIDS IN CD-1 MICE.

L. Y. Hernandez and L. J. Bain. Biological Sciences, University of Texas at El Paso, El Paso, TX.

Pyrene is a polycyclic aromatic hydrocarbon that is ubiquitous in the environment as a product of the incomplete combustion of fossil fuels. A large amount of literature exists for the toxicity and carcinogenicity of PAHs, but data for pyrene is very limited. In order to further understand the toxic effects of pyrene at nonlethal doses, CD-1 adult male mice were fed pyrene in honey for 7 days. Six mice were assigned to a control group, 5 mice were assigned to the 3 mg/kg pyrene group, and 5 mice were in the 30 mg/kg pyrene group. The differential expression of the CYP1A2, AhR and ARNT genes, which have been shown to be differentially expressed as a result of PAH exposure, was also determined by real-time PCR. There was no significant difference in levels of expression of CYP1A2. There was a significant 2.3-fold increase in expression of AhR in 3 mg/kg mice compared to controls. A significant 1.5-fold decrease in expression of ARNT in the 30 mg/kg group was observed. This decrease might be the organism's mechanism for compensating with the increased levels of pyrene in order to avoid overexpression of enzymes that could lead to inflammation. To determine whether liver damage or fatty acid class alteration occurred, total levels of serum triglyceride, cholesterol, and bilirubin were measured. Serum triglycerides decreased by 1.5-fold in the 30 mg/kg group, which may be due to alteration of fatty acid cycle. Serum bilirubin decreased by 1.9-fold in 3 mg/kg group and 2.2-fold in 30 mg/kg group. Lipids were then extracted from the livers of control and treated mice to determine if fatty acid class alteration occurred using thin layer chromatography. There was no significant change in concentration of monoglycerol, monooleic acid or triolein in control compared to treated mice. However, the diolein concentration was 2.1-fold lower in the 3 mg/kg group and 3.9-fold lower in the 30 mg/kg group. These results suggest that pyrene exposure causes differential expression of genes and alters the expression of fatty

### 1936 DEVELOPING A CARCINOGENIC BIOASSAY FOR COMPLEX MIXTURES.

D. Warshawsky, K. LaDow, R. Albert, M. Anderson, W. Xue, S. Spalding, G. Boivin, D. Ginsburg and P. Succop. *Environmental Health, University of Cincinnati, Cincinnati, OH.* 

Complex mixtures of combustion and related products contain many carcinogens such as polycyclic aromatic hydrocarbons as well as anti-carcinogens that interact in theoretically unpredictable ways. The conventional mouse skin tumor carcinogenesis assay is time-consuming and expensive, and skin tumor assays based on initiation models alone are of uncertain accuracy in the prediction of cancer outcomes and are also not rapid. We are evaluating a more rapid approach for assessing car-

cinogenic potency with carcinoma production as the endpoint. Using a dominantnegative p53 mutant transgenic mouse (VAL p53) skin model, we are studying the potency of complex mixtures in an initiation-progression assay, with concurrent exposure to a topical application of the test mixture and a strong promoter, 12-Otetra-decanoylphorbol-13-acetate (TPA). As a positive control comparison, the mixtures are also tested in a complete carcinogenesis assay. Three dose levels of Benzo(a)pyrene (BaP) were tested to confirm the sensitivity of the model. At 16 and 32 ug of BaP, tumors start appearing at 7 weeks following the start of exposure using the initiation-progression assay. However, tumors start appearing at 15 weeks at 32 ug using the complete carcinogenesis assay while no tumors have appeared following 22 weeks of exposure with 16 ug. The resulting tumors were determined to be carcinomas in situ and the number of mice with tumors indicates a dose related response. Three mixtures studies are underway using an NIST Coal Tar standard (CT), a 7H-Dibenzo[c, g]carbazole (DBC) and BaP mixture, or a DBC, BaP and CT mixture. Of the 9 mice that have completed the entire 26 week period of CT treatment, 4 have tumors; 6 of 14 additional mice now in the 19th week of treatment have tumors. Use of the transgene model using either CC or initiationpromotion shortens the latency period of the assay, thereby accelerating the appearance of tumors compared to conventional assays. (Funded by USEPA Star Grant)

1937

METABOLISM OF POLYCYCLIC AROMATIC HYDROCARBON *trans*-DIHYDRODIOLS BY CYTOCHROME P450 AND ALDO-KETO REDUCTASE FN7YMFS

A. M. Quinn, H. Jiang and T. M. Penning. *Pharmacology, University of Pennsylvania, Philadelphia, PA.* Sponsor: S. Burchiel.

Polycyclic aromatic hydrocarbons (PAH) are environmental pollutants and human carcinogens that require metabolic activation to exert their deleterious effects. Activation of PAH in humans has previously been assigned primarily to the cytochrome P450 (CYP) enzymes, including CYP1A1, CYP1A2, and CYP1B1. However, members of the aldo-keto reductase superfamily (AKR) can oxidize the trans-dihydrodiols of PAH to generate cytotoxic and mutagenic o-quinones. In vitro reconstituted systems and in vivo culture methods have been established to measure (±)-trans-7, 8-dihydroxy-7, 8-dihydrobenzo[a]pyrene (BP-7, 8-diol) metabolism by both the CYP and AKR pathways using quantitative RP-HPLC methods. Rates of BP-7, 8-diol metabolism were measured in in vitro systems containing CYP1A1 and CYP1B1 Supersomes or bis-cistronic constructs expressing NADPH cytochrome P450-reductase with either CYP1A1 or CYP1B1 in bacterial membranes. Purified recombinant AKR1C1-AKR1C3 enzymes were also used to determine rates of BP-7, 8-diol metabolism. In human cell lines, AKR1C expression was identified by isoform-specific RT-PCR, Western blot analysis, and by functional assay of 1-acenaphthenol oxidation. Treatment of cells with 10 nM 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin induced expression of CYP1A1 and CYP1B1, confirmed by RT-PCR, Northern analysis, Western blot, and ethoxyresorufin O-deethylation. These methods have been used to screen for human cell lines that possess both AKR and CYP activities, so that the relative contribution of each pathway to PAH trans-dihydrodiol metabolism may be established. (Supported by Grants R01 CA39504 and P01 CA92537 awarded to T.M.P.)

1938

QUANTITATIVE ANALYSIS OF PHOSPHOLIPID PEROXIDATION: APPEARANCE OF OXIDIZED PHOSPHATYDYLSERINE ON THE SURFACE OF HL-60 CELLS DURING INTRINSIC APOTOSIS.

V. B. Ritov<sup>2</sup>, V. A. Tyurin<sup>1</sup>, <u>Y. Y. Tyurina</u><sup>1</sup> and <u>V. E. Kagan</u><sup>1</sup>. <sup>1</sup>Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA and <sup>2</sup>Medicine, University of Pittsburgh, Pittsburgh, PA.

We have demonstrated that oxidation of phosphatidylserine (PS) is required for its externalization during apoptosis. Since PS and oxidized PS (PSox) act as ligands for macrophage cognant receptor(s) required for effective phagocytosis of apoptotic cells we hypothesized that PSox appears, along with PS, on the cell surface during apoptosis. To test the hypothesis, we developed a new protocol for assessment of aminophospholipid (APL) oxidation on cell surface. The protocol is based on covalent labeling of APLs with cell impermeable reagent fluorescamine, (FC), followed by separation of phospholipids (PLs) using 2D-HPTLC. PLs spots are subjected to hydrolysis using a phospholipase A<sub>2</sub> (PLA<sub>2</sub>)/melittin. The fatty acid hyroperoxides (FA-OOH) released are quantified by a fluorometric assay using Amplex Red reagent (10-acetyl-3, 7-dihydroxyphenoxazine) and horseradish peroxidase (HRP) or microperoxidase (MP). In this system, FA-OOH react with Amplex Red reagent at a stoichiometry of 1:1 to generate a fluorescent product, resorufin (ex=563 nm, em=587 nm) that was resolved by HPLC. Before exposure FA-OOH to HRP/Amplex Red all PLs were hydrolyzed by PLA<sub>2</sub>. MP was able to interact with PLs hydroperoxides without its pretreatment with PLA<sub>2</sub>. Using the protocol, we assessed PS oxidation in two models of apoptosis triggered in HL-60 cells by an oxi-

dant  $(H_2O_2)$  or non-oxidant (staurosporine). In both cases, apoptosis was effectively induced as evidenced by caspase-3 activation and PS externalization. Analysis of PSox on the cell surface demonstrated that all PSox underwent externalization and became available to FC during apoptosis. Our results demonstrate that Amplex Red/MP-based assay can be used as a reliable and specific tool for quantification of PL hydroperoxides. We conclude that PS oxidation during apoptosis results in externalization of PSox where it can act as an important "eat-me" signal for macrophages. Supported by NIH HL70755.

1939

ENHANCMENT OF TRANSBILYER DIFFUSION OF PHOSPHATIDYLSERINE BY ITS OXIDATION PRODUCTS: MECHANISM OF PHOSPHATIDYLSERINE EXTERNALIZATION DURING APOPTOSIS.

Y. Y. Tyurina<sup>1</sup>, Q. Zhao<sup>1</sup>, V. A. Tyurin<sup>1</sup>, M. Djukic<sup>1</sup> and <u>V. E. Kagan<sup>1, 2, 3</sup></u>.

<sup>1</sup> Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA,

<sup>2</sup> Pharmacology, University of Pittsburgh, Pittsburgh, PA and <sup>3</sup> Cancer Institute,
University of Pittsburgh, Pittsburgh, PA.

Our previous work established that intrinsic apoptosis is associated with selective PS oxidation preceding its externalization. We hypothesized that PS oxidation enhances its externalization by one of the following mechanisms: (i) aminophospholipid translocase (APT) fails to recognize oxidized PS (PSox), (ii) reactive PS oxidation product poisons the enzyme, and (iii) PSox facilitates transbilayer diffusion of PS and/or PSox. To experimentally address these hypotheses we utilized HL-60 cells and Raji cells. PS or PS PSox were integrated into plasma membrane by incubation of cells in the presence of PC liposomes containing different amounts of PS or PSox. This resulted in a significant enrichment of plasma membrane with PS or PSox as evidenced by HPTLC analysis of phospholipids. PSox was effectively recognized and internalized by APT. Neither PS nor PSox had any significant effect on APT activity in both cell lines as monitored with a fluorescently-labeled PS homolog, NBD-PS. We further utilized Raji cells with a very low endogenous scramblase activity, to study diffusion of internalized PS to the outer leaflet of the membrane. APT was inhibited by depletion of ATP. To quantify PS exposure we used two different assays: (i) flow cytometric analysis of fluorescently labeled annexin V to evaluate the number of cells with externalized PS, and (ii) derivatization of externalized aminophospholipids by a non-permeable reagent for primary amines, fluorescamine, to determine the amount of PS on the cell surface. We found that PSox increased both the number of cells with externalized PS as well as the content of externalized PS. These results suggest that oxidation of PS stimulates its externalization through increased rate of PS and/or PSox transmembrane diffusion thus contributing to regulation of recognition and phagocytosis of apoptotic cells. Supported by NIH HL70755.

1940

CYTOCHROME *C-I-* CELLS FAIL TO TRIGGER PHOSPHATIDYLSERINE SIGNALING DURING APOPTOSIS.

J. Jiang<sup>1</sup>, V. Kini<sup>1</sup>, Y. Y. Tyurina<sup>1</sup>, G. G. Borisenko<sup>1</sup>, A. J. Schroit<sup>2</sup> and V. E. Kagan<sup>1</sup>. <sup>1</sup> Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA and <sup>2</sup> Cancer Biology, The University of Texas M.D. Anderson Cancer Center, Huston, TX.

Cytochrome c (cyt c) has been demonstrated to participate in phosphatidylserine (PS) signaling through catalysis of PS oxidation. We hypothesized that cyt c catalysis of selective PS oxidation is central to its subsequent externalization and recognition of apoptotic cells by macrophages. To address the hypothesis, we examined the PS oxidation and externalization in cyt c deficient mouse embryonic Cyt c-/- cells. Upon cycloheximide (CHX)/TNF-α treatment, caspase-3 was activated in Cyt c-/cells as determined by cleavage of z-DEVD-AMC. Double staining with Annexin V-FITC and Hoechst 33342 showed that induction of apoptosis was not accompanied by PS externalization suggesting that caspase-3 activation was insufficient for PS externalization in Cyt c -/- cells. No lipid peroxidation was detectable in apoptotic cells by cis-parinaric acid assay. We next attempted to use N-ethylmaleimide (NEM), that was able to release cyt c in Raji cells and overcome its inability to express PS during apoptosis. However, exposure of Cyt c-/- cells to NEM failed to externalize PS. Further, we reintroduced cyt c into Cyt c -/- cells by mild sonication. Intracellular concentration of cyt c was dramatically increased as evaluated by Western blot. In the presence of  $H_2O_2$ , cyt c-enriched cells responded by a more than 2.5-fold greater PS oxidation than control. Importantly, integration of cyt c potentiated CHX/TNF-α triggered apoptosis and re-enacted PS externalization. Finally, we found that peroxidase activity of cyt c was enhanced in the presence of PS-containing (DOPC/DOPS (1:4)) liposomes as compared with cyt dDOPC liposomes or cyt c in the absence of liposomes as monitored by oxidation of dichlorofluoresceine (DCFH<sub>2</sub>). We suggest that once released into the cytosol, cyt c interacts with PS on inner leaflet of plasma membrane, catalyzes (in the presence of H<sub>2</sub>O<sub>2</sub>) PS oxidation, and facilitates its externalization during intrinsic apoptosis. METALLOTHIONEIN MEDIATES GLUCOCORTICOID HORMONE RESPONSIVENESS IN IMMORTALIZED MOUSE FIBROBLASTS AND PRIMARY THYMOCYTES.

F. Haq<sup>1</sup>, R. K. Zalups<sup>2</sup> and J. Koropatnick<sup>3</sup>. <sup>1</sup>Department of Microbiology & Immunology, University of Western Ontario & London Regional Cancer Center, Ontario, ON, Canada, <sup>2</sup>Basic Sciences, Mercer University, Macon, GA and <sup>3</sup>Departments of Physiology & Pharmacology, Oncology, & Pathology, University of Western Ontario, & London Regional Cancer Center, Ontario, ON, Canada.

We have previously reported that the amount of zinc-associated metallothionein (MT) in mammalian cells correlates with glucocorticoid receptor (GR) activity in vitro. To assess the role of MT on immune function in vivo, we measured the capacity of immortalized fibroblasts from MT-null and wild type mice to support GR-mediated gene transcription, and primary thymocytes to undergo apoptosis in response to a synthetic glucocorticoid (dexamethasone, DEX). We report that in MT-null fibroblasts, there is a reduction in the response to DEX (to mediate transcription from a GR-responsive luciferase reporter gene), indicating a role for MT in GR-induced gene transcription. MT-null and wild type mice were maintained on either a zinc-deficient or control diet for a period of 1 month. Thymocytes were isolated and treated ex vivo for 4 hours with concentrations of DEX ranging from 10<sup>-6</sup>-10<sup>-9</sup> M. DEX-induced apoptosis was measured flow cytometry. Čells from male and female mice showed a concentration-dependent increase in apoptosis in response to DEX, indicating that DEX was active and the cells responded to signaling. DEX-induced apoptosis was lower in thymocytes from male MT-null mice than in those from male wild type mice under both zinc-conditions. The opposite was observed in females: a higher fraction of thymocytes from MT-null mice underwent DEX-induced apoptosis under both zinc-conditions than thymocytes from MT-WT mice. These data indicate that the absence of MT in knockout mice affects responsiveness of primary thymocytes to glucocorticoid-induced apoptosis, mediated through the zinc-dependent GR. Furthermore, the effect of loss of MT on GR activity is sex-related. ACUTE ETHANOL PRE-EXPOSURE SENSITIZES LIVER AND KIDNEYS TO FUROSEMIDE-INDUCED APOPTOTIC AND NECROTIC CELL DEATHS BY SELECTIVELY INFLUENCING OXIDATIVE STRESS AND GENOMIC DNA FRAGMENTATION *IN VIVO*.

C. Patel, R. R. Raje and S. D. Ray. Mol. Toxicology. Program, Division of Pharmacology & Toxicol., Long Island University, Brooklyn, NY.

Ethanol (EtOH) and furosemide (FUR) both are well-known apoptogenic hepatoand nephrotoxins. FUR, a loop diuretic, is frequently used to treat left ventricular failure, high blood pressure, and associated edema. Although alcoholics are frequently associated with cardiovascular malfunctions, it is not known if FUR has any adverse effects in such patients. Since, it is also known that EtOH does not induce any form of FUR-metabolizing CYP-450, this study was designed to investigate whether acute EtOH pre-exposure:(i) potentiates FUR-induced hepato- and nephro toxicities, (ii) influences FUR-induced bcl-XL expression in the liver, (iii) alters oxidative stress in the liver and kidneys, and (iv) modulates FUR-induced apoptotic and necrotic cell deaths in the liver and kidneys. Adult male ICR mice (8-10 wks old) were divided into four groups: Control, EtOH, FUR and EtOH+FUR. EtOH was (7.6 ml/Kg, 10% solution) gavaged 48 hours prior to FUR exposure, and sub-toxic doses of FUR (300 mg/kg, i.p.) were administered to study this interaction. Mice were sacrificed 24h after FUR administration, and their blood, liver and kidneys were collected for histopathology and biochemical analysis. Analysis of serum chemistry revealed a substantial increase in hepatotoxicty (ALT University/L: FUR-1377, EtOH+FUR-2021) and nephrotoxicity (BUN mg/dl:FUR-34, EtOH+FUR-56). Organ toxicities were amplified at higher doses of FUR. Quantitations of various forms of cell deaths (VIDEO microscopy) disclosed a dramatic increase in apoptotic death in EtOH+FUR-exposed liver and kidney sections. Qualitative analysis of DNA damage showed a greater induction of Caspase activated DNAse in EtOH+FUR compared to FUR alone, and mirrored the pattern of oxidative stress. Analysis of bcl-XL expression in the liver closely reflected the changes observed in biochemical parameters. Collectively, these data suggest that EtOH may accelerate FUR-induced liver and kidney injuries in vivo. [Supp. By AMS Coll. of Pharmacology]

### 1943 HYPOXIA-MEDIATED NFKB ACTIVATION IS INHIBITED BY N-ACETYLCYSTEINE IN TUMOR CELLS.

S. Qanungo and A. Nieminen. Case Western Reserve University, Cleveland, OH.

Hypoxic cancer cells resist the oxygen-dependent toxicity of ionizing radiation and chemotherapy. The transcription factor NF $\kappa$ B is an important regulator in oncogenesis. The aim of this study was to examine the role of NF $\kappa$ B in hypoxia-mediated

apoptosis in cancer cells. p53+/+ and p53-/- mouse embryonic fibroblasts (MEFs) transformed with proto-oncogenes Ras and E1A were exposed to hypoxia (-0.2% O2) for 0-14 h. Hypoxia induced 12% apoptosis in p53+/+ MEFs compared to 2% during normoxia. N-acetylcysteine (NAC) enhanced hypoxia-mediated apoptosis in a dose-dependent manner, 20 mM NAC having a maximum effect and causing 46% apoptosis. p53-/- MEFs were completely resistant to hypoxia and NAC-mediated apoptosis. NAC also induced cytochrome c release into the cytosol during hypoxia. Hypoxia alone induced 67% increase in reactive oxygen species (ROS) formation measured by DCF fluorescence and this increase of ROS was inhibited by NAC as well as other potent antioxidants like epigallocatechin gallate and Trolox (vitamin E analog). Furthermore, hypoxia-mediated ROS generation induced NF B activation which was blocked by NAC as measured by p65 specific ELISA using nuclear extracts. Confocal microscopy also showed that hypoxia induced translocation of the active subunit of NFkB (p65) to the nucleus whereas this translocation was inhibited by NAC. To identify the downstream targets of NFKB signaling during hypoxia we determined the expression of the anti-apoptotic protein Bcl-xL but found no changes in Bcl-xL protein levels following hypoxia or NAC treatment. In conclusion, our results suggest that hypoxia-mediated ROS formation results in NFkB activation providing survival pathway. Inhibition of ROS formation by potent antioxidants results in inhibition of NFkB activation and enhancement of apoptosis. Utilizing the NF $\kappa$ B inhibition as a therapeutic strategy to sensitize cancer cells to hypoxic apoptosis may be useful. Supported by NS39469 and CA43703

PHAGOCYTOSIS OF APOPTOTIC JURKAT CELLS BLOCKS ZYMOSAN-INDUCED INTRACELLULAR PRODUCTION OF REACTIVE OXYGEN SPECIES AND NITRIC OXIDE IN RAW 264.7 MACROPHAGES.

B. F. Serinkan, H. N. Babu, A. I. Potapovich, F. Gambelli, L. A. Ortiz and <u>V. E. Kagan</u>. Environmental and Ocupational Health, University of Pittsburg, Pittsburgh, Physical Physics of Pittsburgh, Physics o

Apoptosis is an effective way for clearance of injured cells without damaging surrounding tissues and massive inflammatory response. Proper removal of apoptotic cells is achieved by different "eat-me" signals on the cell surface, such as phosphatidylserine (PS), recognizable by phagocytes. Interactions of macrophages with apoptotic cells trigger release of anti-inflammatory cytokines and block the production of pro-inflammatory cytokines. Because activated macrophages generate cytotoxic reactive oxygen species (ROS) and nitric oxide (NO·), we hypothesized that limitation of inflammatory damage by apoptotic cells should involve inhibition of ROS/NO· production. To test the hypothesis, we prepared anti-Fas-induced apoptotic Jurkat T cells and co-cultured them with murine macrophage RAW 264.7 cells stimulated by zymosan (0.25 mg/ml). We used dihydroethidium (DHE) and diaminofluorescein-2 diacetyl (DAF2-DA) as probes for intracellular production of superoxide and NO·, respectively. We found that phagocytosis of apoptotic cells blocked zymosan-induced intracellular ROS and NO· production in macrophages. Flow cytometric measurements revealed that 38±1% and 57±16% of macrophages were DHE- and DAF2-positive cells, respectively, after phagocytosis of apoptotic cells as compared with the maximal effect elicited by zymosan alone (100%). Notably, similar effect was observed when non-apoptotic target cells with integrated PS-containing liposomes were used in place of apoptotic cells. In this case, 60±9% of DHE-positive cells was observed as compared with the maximal effect produced by zymosan alone. We confirmed that PS-dependent apoptotic signaling was important for regulation of the release of pro- and anti-inflammatory cytokines by RAW 264.7 macrophages. We conclude that PS signaling may be a promising approach to control the magnitude of inflammatory response in vivo. Supported by NÎH HL 70755.

### 1945 NITRIC OXIDE INDUCES P53-DEPENDENT APOTOSIS IN RAT NEURAL CELL LINES.

C. Brynczka<sup>1</sup>, B. A. Wetmore<sup>1</sup>, C. McNeil-Blue<sup>1</sup>, W. A. Freed<sup>2</sup> and B. A. Merrick<sup>1</sup>. <sup>1</sup>NCT, NIEHS, NIH DHHS, Research Triangle Pk, NC and <sup>2</sup>Cell Neurobiol Rsch Branch, NIDA, NIH, DHHS, Baltimore, MD.

The involvement of nitric oxide in neural cell death was investigated in the well-characterized rat PC12 pheochromocytoma cell line and the AF5 undifferentiated rat mesencephalic cell line using sodium nitroprusside (SNP). We hypothesized that the nitric oxide donor, SNP, may produce p53 pathway-mediated apoptosis in exposed cultured cells. In PC12 cells, SNP causes accumulation of p53 and its transcriptional target gene, p21-waf1, in a dose and time-dependent manner. AF5 cells, however, accumulate p53 and p21-waf1 in only modest amounts compared with PC12 cells. Contrary to evidence in other cell types, NFkB does not appear to be involved in the accumulation of p53 in PC12 cells as evidenced by lack of IkB phosphorylation and protein degradation across a variety of SNP dose ranges. Evidence of p53 activation was shown by phosphorylation at serine 15 in a dose and time-dependent manner in both PC12 and AF5 cells. Increases in phospho-

p53 levels occurred over a range of 0.1 to 1.0 mM of SNP and attained a maximal level of phosphorylation at 12 hours after 1mM SNP. Treated PC12 cells display cytochrome c release into the cytosol and Bax translocation to the mitochondria at 24 hours post 0.5mM SNP treatment. These trademark signs of apoptosis are significantly diminished by the addition of the p38 MAPK inhibitor SB202190, implicating p38 MAPK as an upstream regulator of both p53 and the apoptotic response. AF5 cells do not show marked Bax translocation to the mitochondria or in cytochrome c release into the cytosol. Pretreatment of PC12 cells with 20mM SB202190 attenuates cell death in SNP-treated cells as determined by trypan blue exclusion, with a greater effect seen in 1mM versus 0.5mM or less doses of SNP. Pretreatment with 20mM SB202190 does not significantly decrease cell death in nitric oxide exposed AF5 cells as determined by trypan blue exclusion. These results support our hypothesis that nitric oxide induces a p53-mediated apoptotic response in PC12 cells, with p38 MAPK involvement in this apoptotic pathway.

1946

SIMILAR APOPTOTIC ULTRASTRUCTURAL DAMAGE BUT DIFFERENT BIOCHEMICAL PATHWAYS INDUCED BY ROTENONE AND CAMPTOTHECIN IN HUMAN NEUROSPHERES.

J. Li, M. L. Spletter and J. A. Johnson. School of Pharmacy, University of Wisconsin at Madison, Madison, WI.

We used rotenone (RO) and camptothecin (CA) to investigate ultrastructural damage and apoptotic pathways. Neurospheres treated with RO (0.1-16 µM), CA (0.1-20 μM), or vehicle for 2-24 hours were harvested and prepared for the subsequent experiments. TUNEL staining showed a dose-dependent increase in TUNEL positive cells after treatment with RO and CA. TEM observation showed that RO and CA treated cells have characteristic hallmarks of apoptotic morphology including nuclear condensation, chromatin margination, and intact cellular membrane. CA treatment results in the cleavage of PARP and caspase-3, depolarization of the mitochondrial membrane, release of cytochrome c, and increased caspase activity in both time-course and dose response studies, indicating that CA induced apoptosis is mediated by a caspase–dependent pathway. The cell death also was attenuated by pretreatment with a pan-caspase inhibitor, zVAD ( $50\mu M$ ). RO treated cells, in contrast, show low caspase activity and little PARP or caspase-3 cleavage. However, RO treatment results in depolarization of the mitochondrial membrane, release of AIF, and subsequent translocation of AIF to the nucleus. Combined with apoptotic-like morphological characteristics, this suggests that RO induced apoptosis is mediated by a caspase-independent pathway. Pretreatment with zVAD (50μM) does not prevent RO induced cytotoxicity. In contrast to CA, RO promptly decreased the ATP level, and fluorometry assay indicated the addition of ATP to the cell lysates obtained from RO-treated samples was sufficient to activate both caspase 9 and caspase 3. These results present a unique ultrastructural and molecular characterization of RO and CA induced cytotoxicity in human neurospheres. Mitochondria are integrated into both caspase dependent (CA) and independent (RO) apoptotic pathways. Intracellular ATP level may contribute an important role to determine whether neuronal progenitors undergo a caspase -dependent or -independent pathway after acute insults from neural toxicants.

1947

ANTI-APOPTOTIC MECHANISM OF MOUSE LEYDIG CELL LINE TM3 AFTER BENZO(A)PYRENE EXPOSURE IS ASSOCIATED WITH THE UP-REGULATION OF X-CHROMOSOME LINKED INHIBITOR OF APOPTOSIS PROTEIN.

J. Chung, J. Kim, J. Kim, J. Kim, K. Yoo, Y. Yoo and J. Kim. *Department Anatomy & Cell Biology, Dong-A University, Busan, South Korea.* Sponsor: K. Yang.

Benzo[a]pyrene (BaP) belongs to one of the polycyclic aromatic hydrocarbons affects cellular signal transduction mechanism and induces apoptosis. In the present study we investigated the anti-apoptotic cellular mechanism of testicular Leydig cell line TM3 after BaP treatment. Up to 100 uM concentration of BaP has been challenged to the cells for 72 hours, however, the apoptosis rate was not changed significantly compared to that of control. Meanwhile, cell cycle analysis showed that the treatment of BaP (10 uM) significantly results in increase of S phase. BaP treatment in TM3 increased both Ah receptor and Arnt protein contents. Both transcriptionally and translationally the CYP1A1 levels were elevated significantly by the BaP treatment, indicating that BaP metabolizing activity is present in the cells. Therefore, we next asked question how the TM3 cells can remain survived in the presence of a high CYP1A1 activity. Caspase-3, a central and effector protease in the apoptotic cellular pathway, was then first studied in this system. Procaspase-3 protein content obviously increased after BaP treatment, but its activation was not occurred as evident by absence of cleavage products of procaspase-3 in the Western blot analysis. This indicates that while procaspase-3 protein expression can be induced by BaP, its activation is somehow strongly suppressed by certain upstream molecules that involve anti-apoptotic mechanism. X-chromosome linked inhibitor of apoptosis protein (XIAP) has been identified as a potent cellular inhibitory protein against caspase-3 activation. Interestingly, XIAP protein content increased and maintained coincidental with those of procaspase-3 and CYP1A1 after BaP exposure. Finally the BaP treatment to TM3 cells did not evoke decrease of mitochondrial membrane potential as well as cytochrome c release. In conclusion, the anti-apoptotic cellular mechanism in TM3 cells after BaP might be strongly related to the role of XIAP and cellular specific mitochondrial integrity.

1948 CASPASE 2 AND THE MITOCHONDRION IN PAH-INDUCED PRO/PRE-B CELL APOPTOSIS.

H. Ryu<sup>1</sup>, J. K. Emberley<sup>2</sup>, J. J. Schlezinger<sup>1</sup>, L. L. Allan<sup>2</sup> and D. H. Sherr<sup>1, 2</sup>. Environmental Health, Boston University Sch. of Medicine, Boston, MA and <sup>2</sup>Microbiology, Boston University Sch. of Medicine, Boston, MA.

PAH are common environmental pollutants which suppresses the immune system in part by inducing pro/pre-B cell apoptosis. Previously, we demonstrated that DMBA, a prototypic PAH, induces apoptosis in pro/pre-B cells co-cultured with bone marrow stromal cells (BMS2) and that caspase 8 plays an important role in early apoptosis signaling. The purpose of this study was to define whether a second apoptosis pathway involving caspase 2, mitochondrial activation, and caspase 9 is also likely to be invoked. Western blotting indicated cleavage of pro-caspases 2, 3, and 9 within 8, 8, and 18 hrs of DMBA exposure respectively. Inhibitors specific for each of these three caspases protected pro/pre-B cells from DMBA-induced death. Primary pro-B cells from caspase 2<sup>-/-</sup> mice were relatively resistant to DMBA-induced apoptosis, confirming a role for that caspase in DMBA-induced apoptosis. Markers for mitochondrial activation such as cytochrome C release and membrane potential loss (MPL), were also observed in apoptotic BU-11 cells. Interestingly, cytochrome C was released into the cytosol within 4 hrs of DMBA exposure while MPL occurred concurrent with caspase 2 activation at 8 hrs. However, MPL loss was not blocked by caspase 2-, 3-, 8-, or 9-specific inhibitors, suggesting that membrane potential loss was not dependent on any of these caspases. That the mitochondrion was involved in apoptosis signaling was further supported by the appearance of the Bid cleavage product, tBid, after DMBA exposure and by the demonstration that Bax-f- pro-B cells were relatively resistant to PAH-induced apoptosis signals. These results support the hypothesis that PAH-induced bone marrow B cell death is mediated by two pathways. One pathway is initiated by caspase 8 while the other involves caspase 2, the mitochondria, and caspase 9.

1949

TESTICULAR SERTOLI CELLS SURVIVE DESPITE CISPLATIN-INDUCED INJURY DUE TO THE EXPRESSION OF INHIBITOR OF APOPTOSIS PROTEINS THAT DISRUPT MITOCHONDRIAL-MEDIATED APOPTOTIC SIGNALING.

P. Sawhney and J. H. Richburg. College of Pharmacy, The University of Texas at Austin, Austin, TX.

Functional spermatogenesis and male fertility are critically dependent on the longterm survival of testicular Sertoli cells. Systemic exposure to a variety of toxicants results in the initiation of apoptosis in testicular germ cells. However, very few reports exist regarding apoptosis of Sertoli cells, and those that do, describe its occurrence during embryonic and neonatal testicular development, a time period where Sertoli cells are still dividing. Differentiated Sertoli cells appear to be resistant to apoptosis but, little is known about the mechanisms by which these cells are sustained throughout adult life. Here, we evaluate effects of cisplatin exposure in testes of 11 wk old C57/Bl/6J mice that have been exposed to either one, two or four cycles (one injection daily for 5 days with a recovery phase of 21 days between cycles) of 2.5 mg/kg cisplatin. Our observations indicate that Sertoli cells (1) demonstrate cleavage of caspase-9 (2) express the prototypical IAP family member XIAP (3) activate the transcription factor NF-KB after exposure to cisplatin, which has been implicated in activation of IAPs and (4) activate kinase dependent survival pathways which have been implicated in both activation of NF-κB and regulation of pro-apoptotic members of the Bcl-2 family. These data indicate that Sertoli cells are resistant to toxicant-induced apoptosis, despite the cleavage if caspase-9, due to the expression of XIAP and its ability to disrupt mitochondrial mediated apoptotic signaling. We will also present data to demonstrate that multiple parallel pathways for cellular survival are activated in Sertoli cells in order to ensure survival of this nonrenewable cell population in the presence of toxicant exposure, in order to preserve fertility of the animal. Which of these multiple pathways plays the predominant role in ensuring survival of Sertoli cells remains to be tested (Supported, in part, by grants from NIH/NIEHS ES09145 & ES07784 and from the Lance Armstrong Foundation).

E. J. Martin and P. Forkert. Anatomy and Cell Biology, Queen's University, Kingston, ON. Canada

1, 1-Dichloroethylene (DCE) causes hepatotoxicity in mice. Our studies suggested that functional alterations in mitochondria initiated the toxic response. Mitochondria have been implicated in apoptotic cell death through transient opening of the permeability transition pore (PTP). This event may cause mitochondrial swelling and rupture of the outer membrane to release cytochrome c, which then activates the caspase cascade and sets apoptosis in motion. Here, we have undertaken studies to test the hypothesis that DCE induces apoptosis in murine liver. Female CD-1 mice were treated with DCE (125 mg/kg, i.p.). A decrease in hepatic mitochondrial membrane potential was detected at 2 h using the fluorescent dye JC-1. Western blotting of liver cytosolic proteins showed greater immunoreactivity for cytochrome c in fractions from mice treated with DCE for 4 h than in those from control animals. Furthermore, caspase-9 activity was significantly increased at 4 h after DCE exposure. These alterations were inhibited by pretreatment with cyclosporin A (CsA; 50 mg/kg), a specific inhibitor of the mitochondrial PTP. Immunohistochemical studies with an antibody to active caspase-3 and TUNEL staining were used to detect apoptotic cells. In both experiments, positive reactivity was observed at 12 and 24 h after DCE in centrilobular hepatocytes, although a few individual hepatocytes in other areas of the parenchyma were also stained. No reactivity was observed in liver sections from control animals. Additionally, centrilobular hepatocytes showing morphological criteria of apoptosis (chromatin condensation and margination, cell shrinkage, apoptotic bodies) were observed at 24 h. Liver toxicity, as assessed by serum alanine aminotransferase (ALT) activity, was also evaluated. ALT levels were significantly elevated at 2 to 24 h after DCE or DCE and CsA treatment. These data suggested that DCE produces apoptotic cell death by inducing a mitochondrial permeability transition that causes release of cytochrome c into the cytosol and caspase activation. Supported by Grant No. MOP 11706 from CIHR.

#### 1951

BCL- $X_L$  and cyclosporin a (CsA) inhibit leadinduced rod photoreceptor apoptosis and decreased mitochondrial respiration by blocking cytochrome c release.

<u>D. A. Fox</u><sup>1</sup>, <u>L. He</u><sup>2</sup>, A. T. Poblenz<sup>3</sup> and C. J. Medrano<sup>1</sup>. <sup>1</sup>University of Houston, Houston, TX, <sup>2</sup>UNC, Chapel Hill, NC and <sup>3</sup>UT MDACC, Houston, TX.

Photoreceptor apoptosis and visual deficits occur in man and animals with inherited and chemical-induced retinal degenerations, retinal diseases and injuries, and aging. Rod-selective apoptosis, mediated by cytochrome c-caspase, is produced by developmental lead exposure in mice and rats, and by  $Pb^{2+}$  and/or  $Ca^{2+}$  in isolated rat retinas (EER, 1988; JBC, 2000; PNAS, 2003). This study used isolated mice retinas and rat retinal mitochondria: 1) to compare in vivo and ex vivo lead studies in  $Bcl-x_L$  transgenic mice, 2) to examine species differences and 3) to investigate the mechanism of Pb2+-induced alterations in mitochondrial bioenergetics. Adult retinas from wild-type and transgenic mice overexpressing  $Bcl-x_L$  only in photoreceptors were briefly exposed to  $1~\mu M~Pb^{2+}$  and/or  $0.5~mM~Ca^{2+}$ . Isolated adult rat retinal mitochondria, in the presence of different site-specific substrates, were exposed to 10 pM-30 nM Pb<sup>2+</sup>. In adult mice, Pb<sup>2+</sup> and/or Ca<sup>2+</sup> induced rod-selective apoptosis characterized by genomic DNA fragmentation, decreases in rod mitochondrial respiration and membrane potential (depolarization), cytochrome c release and caspase activation. Bcl-x<sub>1</sub> overexpression or CsA completely blocked all the Pb<sup>2+</sup> and/or Ca<sup>2+</sup> effects. Pb<sup>2+</sup> produced concentration-dependent decreases in mitochondrial respiration at sites I, II and III: largest effects were with NAD-linked substrates (site I). Nevertheless, CsA completely blocked the Pb<sup>2+</sup>-induced inhibition of mitochondrial respiration. These results suggest that  $Bcl\text{-}x_L$  and CsA prevented Pb<sup>2+</sup>-induced mitochondrial depolarization, inhibition of the electron transport chain and rod apoptosis - in rats and mice as well as in vivo and in vitro - by blocking the release of cytochrome c through the permeability transition pore. These findings have relevance for therapies in human and animal retinal and neuronal degenerations where lead exposure, calcium overload and/or mitochondrial dysfunction occur. Supported by NIH Grants ES03183, ES012482, EY07024.

### 1952

CASPASE-2 DIRECTLY IMPAIRS MITOCHONDRIAL FUNCTION AND STIMULATES CYTOCHROME C RELEASE.

J. D. Robertson<sup>2, 1</sup>, V. Gogvadze<sup>1</sup>, A. Kropotov<sup>1</sup>, H. Vakifahmetoglu<sup>1</sup>, B. Zhivotovsky<sup>1</sup> and S. Orrenius<sup>1</sup>. Toxicology, Karolinska Institutet, Stockholm, Sweden and <sup>2</sup>Pharmacology, Toxicology, and Therapeutics, University of Kansas Medical Center, Kansas City, KS.

Although caspase-2 has been implicated in a variety of cell death paradigms, the mechanism by which this protease executes apoptosis remains obscure. Recent findings indicate that caspase-2 is activated early in response to DNA-damaging anti-

neoplastic agents and may be important for the engagement of the mitochondrial apoptotic pathway. We demonstrate here the ability of caspase-2 to stimulate cytochrome c release and cause mitochondrial dysfunction directly. In particular, purified recombinant human caspase-2, but not caspase-3, triggers a concentrationand time-dependent release of cytochrome c from mitochondria in permeabilized Jurkat T-lymphocytes. This effect depends on the catalytic activity of caspase-2 as evidenced by the fact that inactivating the protease with an irreversible caspase-2 inhibitor, benzyloxycarbonyl-Val-Asp-Val-Ala-Asp-fluoromethyl ketone (z-VDVADfmk), or by introducing an active site mutation results in a significant attenuation of cytochrome c release. Further, experiments performed with isolated mitochondria indicate that caspase-2-induced cytochrome c release does not depend on the presence or cleavage of a cytosolic substrate, such as Bid, suggesting that a caspase-2 death substrate likely resides at the level of mitochondria. Finally, functional studies of mitochondria revealed that caspase-2 markedly stimulates state 4 respiration and decreases the respiratory control ratio due, in large part, to an uncoupling effect. Taken together, our data indicate that caspase-2 retains a unique ability to stimulate cytochrome c release by damaging mitochondria directly and thus may act as the initiator caspase in response to certain death stimuli.

## 1953 THE MITOCHONDRIAL PERMEABILITY TRANSITION (MPT) IS A KEY FACTOR IN ACETAMINOPHEN KILLING OF HEPATOCYTES.

K. Kon<sup>1</sup>, J. Kim<sup>1</sup>, E. A. Doyal<sup>1</sup>, H. Jaeschke<sup>2</sup> and J. J. Lemasters<sup>1</sup>. <sup>1</sup>University of North Carolina, Chapel Hill, NC and <sup>2</sup>University of Arizona, Tucson, AZ.

BACKGROUND. Acetaminophen (AAP) overdose causes massive hepatic failure by mechanisms involving glutathione depletion, oxidative stress and sensitization to inflammatory cytokines. The ultimate target causing cell death remains uncertain. Our AIM was to characterize the MPT in AAP-induced hepatocyte killing. METHODS. Hepatocytes were isolated from fasted C3Heb/FeJ male mice and cultured in RPMI 1640 supplemented with insulin, transferrin, selenium and fatty acids. Necrotic cell killing was determined by propidium iodide fluorometry. Apoptosis was assessed by TUNEL. Mitochondrial polarization and permeabilization were visualized by confocal microsopy of TMRM and calcein. RESULTS. AAP (10 mM) caused 81±3% necrotic killing after 16 h. Fructose (20 mM) plus glycine (5 mM) (F+G) decreased this killing to 33±1%. Cyclosporin A (CsA) and NIM 811 (2 µM), MPT blockers, decreased killing after 6 h by 40%, but cytoprotection was lost after 16 h. 2-Aminoethoxydiphenyl borate (APB, 1-30 µM), a blocker of the CsA-insensitive MPT, protected cells dose-dependently: 30 µM APB decreased killing to 25±1% after 16 h. Ru360 (mitochondrial calcium uniporter blocker) did not prevent killing. After 16 h, 45±4% of hepatocytes exposed to AAP were TUNEL positive. F+G increased TUNEL labeling to 62±8%, and CsA decreased this apoptosis by half. Mitochondrial depolarization and inner membrane permeabilization preceded AAP killing and were blocked by CsA. CONCLUSIONS. CsA and NIM 811 protect early but not late against AAP toxicity, whereas APB protects both early and late. F+G protects against oncotic necrosis but paradoxically increases CsA-sensitive apoptosis. These findings suggest that AAP promotes a CsA-sensitive MPT early and a CsA-insensitive MPT late in toxicity, which induces either apoptosis or necrosis depending, in part, on ATP availability by glycolysis.

### 1954 LIVER CELL DEATH AFTER ACETAMINOPHEN (AP) OVERDOSE: APOPTOSIS OR ONCOTIC NECROSIS.

S. Phadke, C. Patel, R. Raje and S. D. Ray. Mol. Toxicology. Program/Pharmacology & Toxicol., Long Island University, Brooklyn, NY.

Although, criteria to distinguish NECROSIS from ONCOTIC NECROSIS are lacking, results from several laboratories have provided consistent biochemical, histopathological, ultrastructural and molecular evidence in favor of APs apoptogenic potential (Liu et al, Hepatology, 2003; Ishida, et al, FASEB J, 2002; Antonelli, Br.J.Pharmacology:2002; Ferret, et al, Hepatology:2001; Zhang, et al, Nature Biotech: 2000; Ray, et al, JPET:1996). However, at least one study has proposed that alternatively, AP might stimulate oncotic necrosis (Gujral, et al., Toxicology. Sciences. 67:322, 2001). To revisit the question of APs apoptogenic/necrogenic potentials, male ICR (fed) and B6C3F1 (fed), and female B6C3F1 (starved) mice were treated with AP (300-500 mg/kg, ip) and sacrificed 0, 6, 18 and 24 hr later. AP increased serum ALT and liver-DNA fragmentation over time in all strains. Although apoptotic cell quantitation in in vivo models is difficult (due to their rapid clearance), VIDEO-microscopic quantitations revealed that the highest dose of AP caused liver-injury maximally up to 60-70% in all the species and over 50% of cells showed characteristic features of apoptosis (12 to 24h). Lowest AP dose (300 mg/kg) at 6h showed maximum variability in all the parameters tested (ALT increased 5- to 10-fold; glycogen depletion was minimal; low injury with weak apoptogenicity). Apoptotic cells were not detectable at 0h, only a few were detected at 6h, and were maximal between 12-24h. Thus these results are consistent with apoptosis rather than oncotic necrosis as the mechanism for AP toxicity. Potential differences between this study and those proposing oncotic necrosis as a mechanism of AP toxicity might include: 1) differences in AP treatment doses;

2) different methods employed for apoptotic quantification; 3) lack of corrections for phagocytic dead cell clearance and caspase-independent pathways; and 4) different magnifications utilized for ultrastructural determinations of apoptotic markers.

1955 ALTERED GENE PROFILES IN RAT TESTES AFTER INHALATION EXPOSURE TO 1-BROMOPROPANE AND 2-BROMOPROPANE.

W. Li<sup>1</sup>, E. Kitagawa<sup>2</sup>, H. Iwahashi<sup>2</sup>, H. Wang<sup>1</sup>, S. Ichihara<sup>1</sup> and <u>G. Ichihara<sup>1</sup></u>.

<sup>1</sup>Occupational and Environmental Health, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan and <sup>2</sup>Human Stress Signal Research Center, National Institute of Advanced Industrial Science and Technology, Tsukuba, Ibaragi, Japan.

As alternatives for chlorofluorocarbons, 1-Bromopropane (1-BP) and 2-Bromopropane (2-BP) have been recently introduced to the workplace. Our previous studies have shown that 2-BP targets spermatogonia, while its isomer 1-BP causes spermiation failure in rats. The present study was performed to compare the mechanism of male reproductive toxicity between 1-BP and 2-BP at gene expression levels. Eighteen Male F344/NSlc rats were divided randomly into 3 groups of six each. The three groups were exposed to 1-BP at 1000 ppm, 2-BP at 1000 ppm, or fresh air for 8 hours in inhalation chambers. Sixteen hours after the end of exposure, rats were sacrificed by decapitation and testes were immediately removed. Global changes in gene expression were determined by cDNA microarray analysis using rat genital chips (DNA Chip Research Inc., Yokohama, Kanagawa, Japan). In each group, three chips were repeated using different testis samples. Results showed rather high repeatability of the altered gene profile. Among the 5082 genes in the genital chip, 351 genes were suppressed by both 1-BP and 2-BP, which includes S100, creatinine kinase and gluthatione S-transferase genes; 37 genes were suppressed by 1-BP only, which includes sex hormone synthesis genes; 119 genes were suppressed by 2-BP only, which includes proto-oncogenes or cell cycle checkpoint genes. This difference of altered gene profiles might reflect a difference in toxic mechanism between 1-BP and 2-BP, when taken together with previous studies suggesting that 1-BP disrupts the endocrine balance while 2-BP disrupts undifferentiated cells.

1956 GENE EXPRESSION IN MOUSE BRAIN FOLLOWING SUBCUTANEOUS INJECTIONS OF SARIN.

C. M. Garrett, S. J. Paton, D. R. Cool, R. D. Grubbs, W. R. Price and M. Morris. *Pharmacology/Toxicology, Wright State, Dayton, OH.* Sponsor: J. McDougal.

Sarin is an organophosphate chemical warfare agent, which acts non-competitively to inhibit acetylcholinesterase (AChE). It has been linked to Gulf War Syndrome because of its effects on central nervous system function. Understanding the transcriptional response of the brain to Sarin will increase our understanding of the mechanisms and symptoms of toxicity. Male C57Bl mice were injected subcutaneously on two consecutive days with Sarin (0.05 or 0.4 LD50). Control mice were injected with isotonic saline. Animals were sacrificed 4 hr after the second injection. Blood and brain were rapidly collected and assayed for ChE activity and mRNA expression. Total RNA was immediately isolated from pre-frontal cortex and hypothalamus. Biotin labeled cRNA targets were prepared according to Affymetrix standard protocols, hybridized to Affymetrix MGU74Av2 mouse arrays. Our results indicate that cholinesterase activity in the blood, hypothalamus and cortex were reduced at the higher sarin dose but not the lower one. Exposure to Sarin produced changes in gene expression in the cortex and hypothalamus. mRNA changes in the cortex were greatest with the lower dose and greatest in the hypothalamus at the higher dose In the cortex at the low dose, genes encoding protein kinases, structural proteins and prostaglandin synthesis were up regulated, while genes encoding receptor kinases, intracellular signaling proteins, GTPases, and synaptic vesicle membranes were all down regulated. At the high dose, calcium binding proteins and transcription factors were increased and tachykinins were decreased. In the hypothalamus, no genes were significantly increased in either dose but prostaglandin synthesis related genes were down regulated at both doses. These results document the effect of Sarin exposure on gene expression in mice brain. They suggest that the cortex is more sensitive to sarin's effects than the hypothalamus as seen by changes in gene expression without concomitant changes in AChE activity. (supported by the Department of Defense contract #DAMD 17-00-C-0020)

1957

GLOBAL GENE EXPRESSION CHANGES UNDERLYING TOXICOLOGICAL INTERACTIONS OF *STACHYBOTRYS CHARTARUM* TOXINS AND MURINE ALVEOLAR MACROPHAGES.

H. Wang and J. S. Yadav. Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH. Sponsor: D. Warshawsky.

Inhalation of toxin-containing spores of the toxic indoor mold *Stachybotrys chartarum* (SC) has been associated with severe respiratory problems, particularly acute pulmonary hemorrhage in infants. This SC toxicity has been ascribed mainly to its

trichothecene mycotoxins that are potent protein synthesis inhibitors. Alveolar macrophages play an important role in phagocytosis and clearance of inhaled fungal spores and toxins. Our recent studies using murine alveolar macrophages showed that SC toxins induced inhibited cell proliferation, DNA damage, and caused apoptosis and cytotoxicity, but the mechanism underlying this toxicity is not yet clear. To understand molecular interactions between SC toxins and host alveolar macrophages, we monitored the genome-wide gene expression changes using oligonucleotide microarray (13, 443 genes) and real-time quantitative RT-PCR analyses. Macrophages treated with SC toxins showed 546 genes upregulated (2- to 24-fold) and 538 genes downregulated (2- to 64-fold). Among the 80 most upregulated genes (> 4-fold), 27 genes code for proteins with unknown function. The toxin regulated genes with known function ranged from those involved in apoptosis, cell cycle regulation, cytoskeleton, and cell adhesion to DNA repair, signal transduction, immune response, transcription factors, and metabolism. Proapoptotic genes were upregulated and anti-apoptotic genes were down regulated, indicating the basis of the observed apoptosis induction in macrophages. Some genes for MAPK and NF-kB pathways were upregulated indicating toxin induction of stress signaling. Genes encoding members of tumor necrosis factor ligand/receptor superfamily and selected chemokine and growth factors were downregulated indicating a decreased inflammatory and immune response of the host alveolar macrophages. In conclusion, both de novo synthesis and synthesis inhibition reactions are associated with the observed toxicity during SC toxin-macrophage interactions.

1958

GENETIC TOXICITY AND GENE EXPRESSION PROFILES IN TK6 CELLS EXPOSED TO IONIZING RADIATION.

G. Akerman<sup>1</sup>, O. E. Domon<sup>1</sup>, B. Rosenzweig<sup>3</sup>, M. E. Bishop<sup>1</sup>, L. J. McGarrity<sup>1</sup>, C. A. Tsai<sup>1</sup>, P. S. Pine<sup>3</sup>, J. T. MacGregor<sup>2</sup>, F. D. Sistare<sup>3</sup>, J. J. Chen<sup>1</sup> and S. M. Morris<sup>1</sup>. <sup>1</sup>NCTR, Jefferson, AR, <sup>2</sup>NCTR, Washington, DC and <sup>3</sup>USFDA, Laurel, MD.

Human p53-proficient TK6 cells were treated with 0.5, 1, 5, 10 and 20 gray (Gy) ionizing radiation (IR). Following exposure, the cells were cultured for either 4 or 24 h and aliquots of the cells were then used to measure genetic toxicity endpoints and develop gene expression profiles. Significant decreases in cloning efficiency were detected at all doses, whereas decreases in cell viability were observed only at the 5, 10 and 20 Gy doses. The micronucleus frequency was increased at the low doses (0.5 and 1 Gy), but insufficient binucleated cells were available for scoring at the 5, 10 and 20 Gy doses. Microarray analysis was performed on RNA isolated from the 5, 10 and 20 Gy samples using a 350-gene human cDNA array. Fewer genes were up-regulated (>1.5- fold) or down-regulated (<0.67-fold) at 4 h than at 24 h. Genes differentially expressed at 4 h included those primarily associated with cell proliferation, DNA repair and the initiation of apoptosis. At 24 h, there was an up-regulation of glutathione-associated genes in addition to genes involved in apoptosis. Additional genes involved in cell cycle progression and mitosis were down-regulated at 24 h. When the gene expression profiles from IR-treated cells were compared to BPDE-treated TK6 cells at a dose with similar survival levels (<10%), genes unique to IR and to BPDE were identified. We also identified a number of "genes in common" that were differentially expressed with both genotoxic agents. Real-time quantitative RT-PCR (SYBR Green) was used to confirm the differential expression of selected genes and to evaluate expression changes at the lower IR exposures. Gene expression changes were observed at the lower doses which yielded significant alterations in micronucleus frequency.

1959 TRANSCPRIPTIONAL RESPONSES OF MOUSE EMBRYO CULTURES EXPOSED TO BROMOCHLOROACETIC

E. D. Karoly<sup>1, 2</sup>, J. E. Schmid<sup>2</sup> and S. Hunter<sup>2</sup>. <sup>1</sup>Curriculum in Toxicology, UNC Chapel Hill, Chapel Hill, NC and <sup>2</sup>Reproductive Toxicology Division, USEPA, NHEERL, ORD, Research Triangle Park, NC.

A major class of disinfection by-products (DBPs) found in municipal drinking water are the haloacetic acids. Bromochloroacetic acid (BCA), a common and abundantly found DBP included within the family of haloacetic acids, is a reproductive toxicant in animal models. The mechanism of haloacetic acid embryotoxicity has not been defined, but may be mediated in part through the inhibition of protein kinases. In order to examine altered gene expression in mouse embryos following exposure to BCA, CD-1 mouse embryos (3 to 6 somite stage) were cultured in 300µM BCA for 0, 1, 3 and 6h. Additionally, embryos were exposed to 30 and 3µM BCA for 6h. Following exposure, embryos were terminated and a total of 30 heads per treatment were pooled for RNA isolation. Total RNA was reverse transcribed with amino allyl-dUTP and indirectly labeled with Cy3 and Cy5. Fluorescently labeled cDNA from treated and untreated samples were labeled with

Cy5 and hybridized against a Cy3 labeled standard reference sample onto custom glass slide arrays. Arrays were spotted with 17, 388 70mer oligonucleotide probes from the Operon Array-Ready Oligo Set for the mouse genome version 2 (Qiagen Operon, Valencia, CA). The data were normalized by slide using an intensity dependent local regression (SAS Proc Loess). Two-way ANOVA identified 276 genes as being differentially expressed across dose and/or time. Cluster analysis and linear models were used to identify the transcriptional responses in mouse embryo culture exposed to BCA and their association with mouse embryotoxicity. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy. Funded by EPA/UNC Toxicology research program, training agreement CT 827206 with the Carrolina of Toxicology, University of North Carolina at Chapel Hill, North Carolina.

### 1960 IN VITRO GENE EXPRESSION PROFILING OF HEPATOTOXINS USING DNA MICROARRAYS.

C. M. Glatt<sup>1</sup>, K. A. Ewane<sup>2</sup>, D. L. Nabb<sup>1</sup> and <u>R. A. Kemper<sup>1</sup></u>. <sup>1</sup>Haskell Laboratory, DuPont, Newark, DE and <sup>2</sup>Biological Sciences, University of Delaware, Newark, DE.

A major effort has been made to identify potential hazards associated with new compounds as early as possible and on as many potential chemical leads as possible in order to guide discovery programs towards the development of safer products. Consequently, there is an increasing need to develop assays for toxicity that use small amounts of experimental compounds while providing an accurate prediction of toxicity. It has been proposed that toxicogenomic biomarkers be used in a discovery toxicology screening mode to reduce overall animal usage and time by enabling one to discover and eliminate toxic compounds from the pipeline earlier in the development process. The objective of this study was to determine if compounds with similar mechanisms of toxicity produce similar changes in gene expression in vitro. Freshly isolated primary rat hepatocytes were cultured on a hepatocyte Matrigel? matrix and treated for 72 hours with a set of known hepatotoxins including indomethacin, 2-thiouracil, carbon tetrachloride, vinyl acetate, and dicumarol. The compounds used are known to cause a variety of hepatocellular injuries including hepatic carcinoma, necrosis, and hypertrophy. Doses were based on published in vitro IC50 values as well as our own cytotoxicity (MTT) data. Microarray analysis was done on total RNA isolated from the hepatocytes and several gene expression changes were revealed for each treatment compared to control. Our results suggest that hepatotoxins may be characterized and classified based on gene expression. While the analysis of gene expression profiles may contribute to our capability to predict adverse toxicity, toxicogenomics also has great capacity to further our mechanistic understanding of toxicant action and increase the fidelity of comparing toxicity across species or extrapolating results to humans. The technological advances promise to improve our ability to characterize hazard and eventually to provide the data to apply to mechanistic-based risk assessment.

MICROARRAY ANALYSIS OF LUNG GENE EXPRESSION IN MOUSE PUPS AFTER FETAL DRINKING WATER EXPOSURE TO URANYL-NITRATE.

J. M. Orozco<sup>1</sup>, S. L. Marion<sup>3</sup>, C. Begay<sup>3</sup>, <u>P. Hoyer</u><sup>3</sup>, C. Dyer<sup>4</sup> and <u>R. C. Lantz</u><sup>2</sup>. 

<sup>1</sup> Pharmacology and Toxicology, University of Arizona, Tucson, AZ, <sup>2</sup> Cell Biology and Anatomy, University of Arizona, Tucson, AZ, <sup>3</sup> Physiology, University of Arizona, Tucson, AZ and <sup>4</sup> Biological Sciences, Northern Arizona University, Flagstaff, AZ.

In some areas of the US, including the southwestern states, ground water concentrations of uranium are at or above the EPA standard of 30 ppb. The effects of uranium in drinking water have not been well studied but some recent studies indicate an association with chemically mediated genotoxicity in addition to radiological effects. The present study replicates uranium concentrations that are representative of human exposures in some locations of the US. Female C57BL/6 mice were exposed to 0.5, 2.5, 12.5, and 60 ppb uranyl-nitrate in the drinking water throughout the entire pregnancy. Lungs from 1-day-old mouse pups were harvested and tissue from litters consisting of 9 to 12 pups was pooled for isolation of RNA. No changes in litter size or pup weight were observed. Three litters were analyzed from each condition. Total RNA was used for Affymetrix microarray analysis using Mouse 430A gene chips. Two-fold or greater changes in gene expression were seen at all exposures. At the highest dosage of uranyl-nitrate, 211 genes were upregulated greater than 2 fold and 124 were downregulated greater than 2 fold. Expression changes were seen involving regulation of stress response, apoptosis, cell differentiation and proliferation, and immune responsive genes. This study shows that environmentally relevant uranium exposures produce gene expression changes that may modulate lung physiology. (Supported by NIH grant #CA96281, CA96320 and ES06694)

### 1962

EFFECT OF VALPROIC ACID ON THE EXPRESSION OF GENES IN THE LIVERS OF PREGNANT MICE.

J. Fuscoe<sup>1, 2</sup>, C. D. Melvin<sup>1, 2</sup>, C. L. Moland<sup>1, 2</sup>, W. S. Branham<sup>1, 2</sup>, L. Shi<sup>3</sup> and D. K. Hansen<sup>2</sup>. <sup>1</sup>Center for Functional Genomics, NCTR, Jefferson, AR, <sup>2</sup>Division of Genetic and Reproductive Toxicology, NCTR, Jefferson, AR and <sup>3</sup>Division of Biometry and Risk Assessment, NCTR, Jefferson, AR.

Valproic acid (VPA) is used extensively in the therapy of epilepsy and neurological disorders. However, it produces developmental abnormalities in laboratory animals and humans, especially defects of the neural tube. In addition, VPA is a hepatotoxin. The mechanisms underlying VPA's teratogenic and hepatotoxic effects are unclear. It has been suggested that VPA may interact with folic acid metabolism, and it is known to be a histone deacetylase inhibitor in vitro. To better understand the mechanisms involved in hepatotoxicity, gene expression profiles were examined in liver of mice exposed to VPA. Pregnant CD-1 mice were injected with either the vehicle (saline) or VPA at 600 mg/kg on gestation day 8. This dose of VPA produces neural tube defects in over 70% of embryos. Six hours later, the mice were sacrificed. The RNAs from the livers of 5 control and 5 VPA-exposed mice were isolated, reverse transcribed, labeled with Cy5 and hybridized with Cy3 labeled reference RNA to microarrays consisting of 5000 mouse genes on glass slides. Reverse labeling was also performed to reduce dye-specific bias effects. After normalizing and combining the data, Statistical Analysis of Microarrays (SAM; PNAS 98: 5116, 2001) showed approximately 65 genes were differentially expressed with a false discovery rate of <5%. Genes involved in xenobiotic biodegradation, and amino acid and lipid metabolism were significantly altered.

### 1963

TOXICOGENOMIC STUDIES ON THE MECHANISMS OF SARIN-INDUCED NEURODEGENERATION IN RATS

T. V. Damodaran, S. T. Greenfield, A. G. Patel and M. B. Abou-Donia. Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.

Sarin induced global gene expression patterns for an early time point (2 hrs: 0.5 X LD50 ) and late time point (3-months:1 X LD50) were studied using affymetrix: Rat Neurobiology U34 chips in Dawley-Sprague rats. A total of 46 and 38 genes were identified, showing statistically significant alteration from control levels at 2 hrs and 3-months respectively. At 2 hrs, genes that are classified as ion channels (8), calcium channels and binding proteins (6) were more in number than any other groups. Other genes that showed changes included: ATPases and ATP-based transporters (4), growth factors (4), G-protein coupled receptor pathway related molecules (3), neurotransmission and neurotransmitter transporters (3), cytoskeletal and cell adhesion molecules (2), hormones (2), mitochondrial associated proteins (2), myelin proteins (2), stress activated molecules (2), cytokines (1), capsases (1), GABAnergic (1), glutamergic (1), immediate early gene (1), prostaglandins (1), transcription factors(1), and tyrosine phosphorylation molecules(1). At threemonth, genes that are classified as calcium channels and binding proteins, cytoskeletal and cell adhesion molecules, GABAnergic signaling molecules were more in number than any other group. The microarray data showed persistent altered expression in 8 genes at all time points. Selected genes from each of these time points were further validated using RT-PCR. Principal component analysis (PCA) of the expression data of the time points was used for comparative analysis of the gene expression, which indicated that the changes in gene expression is a function of dose, time of euthanasia after the treatment and age of the animal. Our model also predicts that both degenerative and regenerative pathways activated early, contribute to the level of neurodegeneration at later time, leading to neuropathological alterations. (Supported in part by DOD contract: DAMD 17-98-8027).

### 1964

INVESTIGATION OF A COMPOUND-INDUCED VASCULAR INFLAMMATORY SYNDROME IN DOGS USING GENE EXPRESSION ANALYSES.

Q. Huang, O. DiSorbo, Y. Yu, S. Jayadev and K. Blanchard. Toxicology and Safety Assessment, Boehringer Ingelheim, Ridgefield, CT.

Safety assessment of a proprietary compound, compound X, identified a compound-induced vascular inflammatory syndrome in dogs but not in rats or monkeys. The occurrence of vascular lesions in dogs was usually accompanied by an elevation in peripheral blood neutrophil counts suggesting that neutrophils may play a role in the vascular inflammatory response. In the current study, compound X-induced gene expression changes in human and canine polymorphnuclear cells (PMNs) were investigated. The goals of the study were two-fold: 1) to define the role of neutrophils in vascular inflammation, and, 2) to identify canine-specific gene changes which could delineate the dog-specific vascular inflammation. PMNs isolated from the periphery blood of a male human or a male dog were cultured in the presence of compound X or zymosan A at 37oC for 6 hrs. Zymosan A, a strong activator of neutrophils, was used as a positive control. Gene expression was ana

lyzed using Affymetrix U133A human chips (-22, 000 fragments) or gITOX-CF1a canine chips (-12, 000 fragments). Zymosan A affected 836 genes and 1, 784 genes by greater than or equal to two-fold in canine and human PMNs respectively. Compound X affected expression of 140 genes and 230 genes by greater than or equal to two-fold in canine and human PMNs, respectively. Inflammatory mediators such as ICAM-1 (13.5 fold), complement component 3 (9.9 fold), CD69 (4.8 fold) and TNFAIP3 (4.4 fold) were found to be induced exclusively in canine PMNs in response to compound X treatment. The current study begins to provide mechanistic understanding of compound X-induced vascular inflammation. Additionally, these studies are identifying differences in the response of dog and human PMNs to compound X treatment. On-going studies using larger sets of donor PMNs will serve to validate the findings from the current pilot study and should help us identify more subtle changes elicited by compound X.

### 1965

THE EFFECT OF ANTI-HEPATITIS B PRODRUG HEPAVIR B ON HEPATIC TOXICOLOGICAL GENE EXPRESSION IN RATS.

R. Yan, C. Fang, C. Lim, D. Vitarella, P. Srivastava, Y. Liu, L. Yeh and C. Lin. R&D Department, ICN Pharmaceuticals Inc., Costa Mesa, CA.

Background: PMEA is an acyclic nucleoside phosphonate analog with potent antihepatitis B virus activity. However it has low oral bioavailability and accumulated at high levels in kidney. Hepavir B is an orally bioavailable prodrug of PMEA and metabolized primarily by cytochrome P450 (CYP) 3A4 in liver, resulting in preferential distribution of PMEA in the liver over kidney. Aim: To detect if there are any hepatic damage and toxicological gene response to prolonged treatment of Hepavir B. Methods: Five male rats per group were dosed orally with Hepavir B (300 mg/kg/day) for 8 days and 28 days. RNA samples were isolated from the liver tissue and Affymetrix Rat Toxicology Arrays were employed. Results: A greater than 3fold up-regulation of detoxification enzymes (i.e. GSTA5, Mdr1b, carboxylesterase and dUTPase) and cell proliferation regulators (Cdc2 and cyclin G) could be detected by microarrays as early as on the 8th days of Hepavir B treatment, before the appearance of any significant pathology in the liver. Twenty-eight-day dosing of Hepavir B increased the mRNA level of p21 protein, UGTR-2, Aflatoxin B1 aldehyde reductase, NAD(P)H-menadione oxidoreductase, CYP2C12 and CYP51, in addition to the above mentioned genes. The expression of GSTA5, Mdr1b, Cyclin G and p21 was further confirmed by RT-competitive PCR. Histological examination demonstrated no effects after 8 days of Hepavir B dosing, only slight to moderate hepatocytic hypertrophy and diffuse hyperplasia of the bile duct were found after 28 days of Hepavir B treatment. LC/MS analysis showed that 8 or 28-day dosing of Hepavir B significantly increased liver PMEA up to 23.9  $\pm$  9.4 or 25.7  $\pm$ 13.5 µg/g tissue. Conclusions: (1) Microarrays can be a useful tool for early predictive toxicology. (2) Hepavir B (at 300 mg/kg/day up to 28 days) did not cause significant liver damage in rats. (3) Up-regulation of detoxification and proliferation genes may contribute to liver tolerance to the Hepavir B-converted high level of PMEA.

### 1966

IDENTIFICATION OF GENE EXPRESSION IN THE UROTHELIUM OF RATS FED DIMETHYLARSINIC ACID USING MICROARRAY ANALYSIS.

S. M. Cohen, M. Wei, L. L. Arnold and J. D. Eudy. Path/Micro, University of Nebraska Med. Ctr, Omaha, NE.

Dimethylarsinic acid (DMA), a major organic metabolite of arsenic in most mammals including humans, has been shown to be a bladder carcinogen in rats when administered in the diet or in the drinking water. However, the molecular mechanisms underlying DMA bladder carcinogenesis remain unclear. The purpose of the present study is to identify the DMA-responsive genes in the urinary bladder epithelial cells of rats. Female F344 rats were fed 100 ppm DMA or control diet. Five rats from each group were sacrificed 24 hours and 2 weeks after the start of treatment and RNA was isolated from urinary bladder epithelial cells using the Qiagen method. RNA of DMA-treated and control rats was labeled with Cy3 and Cy5 fluorescent tags respectively and simultaneously hybridized to a Rat 10K chip (MWG Biotech) containing 10, 000 genes. Genes in which the expression ratio of paired DMA-treated to control tissue showed a greater than 2-fold difference and was observed in at least 4 rats were considered to be DMA-responsive genes. Seventeen genes were down-regulated after 24 hours of DMA treatment and no up-regulated genes were observed. After 2 weeks of DMA treatment, an expected increase in the number of DMA-responsive genes was found (32 genes). Seven of these genes were up-regulated by DMA, while 25 genes were down-regulated by DMA. Furthermore, the expression of 12 genes was suppressed both after 24 hours and 2 weeks. These findings suggest that analysis of expression profiles may provide clues for elucidation of DMA-induced bladder carcinogenesis. Further investigation of gene expression after long-term DMA administration is underway.

#### 1967

XENOBIOTIC-INDUCED CHANGES IN RAT HEART GENE EXPRESSION

B. P. Hirakawa<sup>1</sup>, B. Jessen<sup>1</sup>, A. de Peyster<sup>2</sup> and G. Stevens<sup>1</sup>. <sup>1</sup>Drug Safety Evaluation, Pfizer Global Research and Development, San Diego, CA and <sup>2</sup>Graduate School of Public Health, San Diego State University, San Diego, CA.

Little is known about the changes in cardiac gene expression following xenobioticinduced toxicity. Understanding the changes at the molecular level will provide insights into the toxicological mechanisms of injury and identify possible relevant biomarkers for xenobiotic-induced cardiotoxicity. In an effort to initially examine these changes, four xenobiotics known to affect the heart (digoxin, doxorubicin, isoproterenol and lipopolysaccharide) were studied. The toxicants were chosen on the basis of their diverse mechanisms of action. Adult male Sprague-Dawley rats were treated with acute doses of digoxin (20 mg/kg), doxorubicin (30 mg/kg), isoproterenol (70 mg/kg), or lipopolysaccharide (10 mg/kg) and sacrificed either 6 or 24 hours later. Doses were selected based on the maximum tolerated dose in preliminary studies, or were determined after a thorough review of the literature. Total RNA was extracted from cardiac tissue and gene expression measured using Affymetrix U34A rat GeneChips. Initial results indicate that these four xenobiotics elicit significant changes in expression levels for a number of genes when compared to untreated samples. Common genes induced by all four xenobiotics have the potential to become sensitive biomarkers for cardiotoxicity. These genes are associated with the immune response (complement protein, interferon gamma receptor), stress response (metallothionein, heme oxygenase), or cellular growth and repair (neuropilin, integrin, cyclin D2, grb2). Similar experiments on samples treated with additional xenobiotics and/or heart tissue undergoing various disease states, can reveal unique biochemical mechanisms of xenobiotic-induced cardiotoxicity and more sensitive measures of toxicity.

#### 1968

HEPATIC GENE EXPRESSION PROFILES INDUCED BY PREGENOLONE 16α-CARBONITRILE.

V. Bhaskaran, D. M. Nelson, W. R. Foster, <u>B. Gemzik</u>, <u>B. D. Car</u> and <u>L. D. Lehman-Mckeeman</u>. *Discovery Toxicology, Bristol-Myers Squibb, Princeton, NJ.* 

The goal of the present work was to determine global hepatic gene expression changes after exposure to pregenolone 16α-carbonitrile (PCN), a prototypical PXR agonist. Male and female SD rats were dosed with PCN (100 mg/kg) and gene expression patterns were analyzed at 6 and 24 hr after a single dosage or after 5 daily dosages using Affymetrix U34A gene arrays. Expression of known PXR-regulated genes, including induction of CYP3A1/2 and oatp-2 and repression of CYP7A1 were readily detected. Induction of other xenobiotic metabolizing enzymes was observed, including CYP2B1/2, UGT1A1 and glutathione-S-transferases, whereas PCN treatment decreased expression of CYP4B1 and sulfotransferase 1a. However, although the increase in hepatic CYP2B mRNA levels was confirmed by RT-PCR, there was no corresponding increase in O-dealkylation of 7-pentoxyresorufin. PCN treatment did not alter serum thyroid hormone levels after 5 days of dosing, but TSH levels were increased in female rats nearly 2.5-fold. Hepatic expression of thyroxine binding globulin was also decreased at 5 days, particularly in female rats. Several other major changes observed in PCN-treated liver were increased Mdm2 expression and decreased expression of S-adenosylhomocysteine hydrolase (SAHH) and glycine-N-methyltransferase (GNMT). Mdm2 induction was observed at all times, with maximal induction in male and female rats representing a 5- and 11fold change, respectively. GNMT was decreased as early as the 6 hr time point, whereas SAHH expression was decreased at 24 hr and 5 days in female rats and at 5 days in male rats. For GNMT and SAHH, maximal repression determined by real time PCR was approximately 30 and 65% of control values, respectively. These results demonstrate altered hepatic expression of known PXR-dependent genes by PCN treatment and provide evidence to suggest additional genes regulated in a PXR-dependent manner. Furthermore PCN alters hepatic expression of genes that may contribute to alterations in thyroid hormone homeostasis, cell transformation and methyl group metabolism.

### 1969

THE SKELETAL MUSCLE INJURY INDUCED BY COMPOUND A WITH INHIBITORY EFFECTS ON HMG-COA REDUCTASE IS REVERSIBLE.

K. Tanaka<sup>1</sup>, N. Kiyosawa<sup>1</sup>, S. Sharyo<sup>1</sup>, <u>M. Teranishi<sup>1</sup></u>, <u>S. Manabe<sup>1</sup></u> and H. Ozaki<sup>2</sup>. <sup>1</sup>Medicinal Safety Res. Labs., Sankyo Co., Ltd., Fukuroi-shi, Shizuoka, Japan and <sup>2</sup>Department of Vet. Pharmacology, University of Tokyo, Bunkyo-ku, Tokyo, Japan.

When compound A (2-methyl-butyric acid 4-([1, 3]dioxan-5-ylmethoxyimino)-8-[2-(4-hydroxy-6-oxo-tetrahydro-pyran-2-yl)-ethyl]-7-methyl-6-oxo-1, 2, 3, 4, 6, 7, 8, 8a-octahydro-naphthalen-1-yl ester), which has inhibitory effects on HMG-CoA reductase, was given to rats, the rats showed clinical signs of skeletal muscle injury.

However, despite further treatment, the injury was no longer detected at the scheduled autopsy of animals. In this study, we investigated the mechanism by an exhaustive gene expression analysis. Male F344 rats (7-week-old; n=5) were fed a diet contained 0.13% compound A (100 mg/kg/day) for 28 days. Creatine kinase (CK) levels were measured periodically during the treatment. Microscopy of the skeletal muscle was conducted on Days 12 and 28. Gene expression using GeneChip microarrays was analyzed the skeletal muscle on Day 28. The plasma concentration of M1, a major active metabolite, was measured on Days 8 and 28. CK levels increased from Day 7 and showed an approximately 30-fold increase on Day 10. Microscopy demonstrated severe degeneration/necrosis of the muscle fiber on Day 12. CK values, however, declined after that, and returned to control levels from Day 18 onward. Regeneration in the muscle was just observed on Day 28. GeneChip analysis revealed that the expression levels of cardiac (9-fold) and vascular (2-fold) α-actins, IGF-II (5-fold) and kallikrein (18-fold) had increased. No considerable changes in exposure levels of M1 throughout the dosing period were observed. Markedly elevated CK levels and microscopic changes demonstrated that compound A had caused skeletal muscle injury. After repeated exposure, the injury by compound A was reversible and the muscle acquired tolerance to the toxicity. GeneChip analysis demonstrated that the expression of some genes related to muscle regeneration had specifically increased. Thus, regeneration leading to a unique gene expression profile may be attributed to the acquired tolerance of the muscle.

#### 1970

GENE EXPRESSION STUDY OF ADRIAMYCIN INDUCED TOXICITY IN HEART OF MALE SPRAGUE-DAWLEY RATS.

M. Derbel, M. Cooper, D. Hutto, D. Enke, M. Subramanyam and J. Green. Preclinical and Clinical Development Sciences Division, Biogen, Cambridge, MA.

In the present study we evaluated the acute toxicity of doxorubicin following a single I.P. injection to male rats. Rats were assigned to one of three groups (10 animals/group). Each group received dose preparations containing the control article (50% PEG 400 in sterile water) or doxorubicin. Doses for doxorubicin were 2 and 20 mg/kg. Assessment of acute toxicity was based on mortality, clinical observations, and clinical, anatomic pathology evaluations and gene expression at two sacrifice intervals for each dose group (6 and 24 hours). The most notable clinical pathology effects of doxorubicin were consistent with an inflammatory response, stress or direct lymphoid tissue injury, and marked renal dysfunction. Sections of heart from control and doxorubicin-treated animals were evaluated microscopically. High dose doxorubicin animals exhibited focal to diffuse interstitial myocardial hemorrhage, as well as cleft-like spaces in the myocardium that contained granular basophilic material. Transcriptional profiling of the hearts of control and doxorubicin-treated animals was also evaluated. Gene expression analysis revealed several genes significantly regulated at the 2 and 20mg/kg reflecting drug activity and toxicity.

### 1971

PERSISTENT ALTERATIONS IN GENE EXPRESSION FOLLOWING CHRONIC DOXORUBICIN ADMINISTRATION IN RATS.

J. M. Berthiaume, J. A. Bjork and K. B. Wallace. Biochem. & Mol. Biology, Toxicology Graduate Program, School of Medicine, University of Minnesota, Duluth, MN

Doxorubicin (DOX, Adriamycin®) is a potent antineoplastic agent shown to be effective in the treatment of a variety of cancers. Although efficacious, DOX has been associated with the development of a cumulative, irreversible cardiomyopathy which may appear years after therapy. Numerous studies have been conducted to elucidate the mechanism of cardiotoxicity. However, the mechanism responsible remains elusive despite evidence implicating oxidative stress as a major contributor. In addition, DOX has been shown to alter the transcription of several genes, particularly in heart. This investigation was designed to assess global gene expression in order to identify transcriptional targets of DOX toxicity. The experimental model used was chosen to define persistent alterations of gene expression following chronic treatment with DOX. RNA was isolated from heart tissue extracted from adult male rats treated s.c. with 6 weekly injections of 2mg/kg DOX dissolved in saline, after which 5 weeks of recovery was allowed (saline n=5, DOX n=4). cRNA was generated and hybridized to Affymetrix 230A chips. Raw intensity data from samples were adjusted for background and normalized using the robust multichip analysis (RMA) method. Normalized data was filtered to produce a list of probes detectable in at least one experimental sample. Cluster analysis of the data revealed distinct expression profiles between treatment groups. Analysis by t-test revealed 53 transcripts were significantly altered following chronic DOX treatment. Classification of genes revealed several pathways that were modulated to varying degrees by DOX including; glycolysis, fatty acid metabolism, immune response, and oxidative stress response, among others. This comprehensive transcript profile provides important insights into critical targets and molecular adaptations that are characteristic of the persistent cardiomyopathy associated with long-term exposure to doxorubicin. (Supported by HL-058016).

GENE EXPRESSION PROFILING IN TESTIS AND LIVER OF MICE TO IDENTIFY MODES OF ACTION OF CONAZOLE TOXICITIES.

A. K. Goetz<sup>2</sup>, W. Bao<sup>1</sup>, J. E. Schmid<sup>1</sup>, C. Wood<sup>1</sup>, H. Ren<sup>1</sup>, D. S. Best<sup>1</sup>, R. N. Murrell<sup>2</sup>, J. C. Rockett<sup>1</sup>, M. G. Narotsky<sup>1</sup>, D. C. Wolf<sup>1</sup>, D. B. Tully<sup>1</sup> and D. J. Dix<sup>1</sup>. <sup>1</sup>Reproductive Toxicology, USEPA, Research Triangle Park, NC and <sup>2</sup>Department of Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC.

Conazoles are a class of azole fungicides used in both pharmaceutical and agricultural applications. This study focused on 4 conazoles that exhibit a range of carcinogenic and reproductive effects, in order to identify common and unique modes of action. Conazoles target cytochrome P450s (CYPs), and the inhibition and induction of various CYP activities may be part of the toxic modes of action in liver and testis. We used gene expression profiling to characterize a broader range of conazole effects and to identify additional modes of action. Adult male CD-1 mice were dosed by gavage for 14 days with fluconazole, propiconazole, myclobutanil or triadimefon (three doses each). Relative liver weight increased following fluconazole and propiconazole exposure, and histological analysis revealed centrilobular hepatocyte hypertrophy in response to all 4 conazoles. No weight or histological changes were observed in testis, and serum testosterone and luteinizing hormone were also unchanged. Microarrays queried expression of 16, 475 genes, and identified 2, 081 and 1, 424 differentially expressed genes in liver and testis, respectively, following conazole exposure. Of these genes, 118 in the liver and 94 in the testis were common to two or more conazoles. The majority of differentially expressed genes related to stress response, oxidative stress, xenobiotic metabolizing enzymes, steroidogenesis or carcinogenesis. Expression profiles between conazoles and between tissues affected similar biological pathways, suggesting the potential for common modes of action. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy. Funded by EPA Cooperative Training Agreement CT826512010 with North Carolina State University.

### 1973

GENE EXPRESSION CHANGES ASSOCIATED WITH ALTERED GROWTH AND DIFFERENTIATION IN BENZO(A)PYRENE OR ARSENIC EXPOSED NORMAL HUMAN EPIDERMAL KERATINOCYTES.

D. S. Perez, <u>R. S. Yang</u> and J. A. Campain. *Quantitative & Computational Toxicology Group*, Center for Environmental Toxicology & Technology, Department of Environmental & Radiological Health Sciences, Colorado State University, Fort Collins, CO.

Normal human epidermal keratinocytes (NHEK) have been chosen as an in vitro model for mechanistic studies into how altered regulation of differentiation may play a role in the transformation process in human cells. Our initial work demonstrated that two high priority skin carcinogens, arsenic and benzo[a]pyrene (BaP), inhibit terminal differentiation in NHEK in vitro. Arsenic (>2 µm) also decreases proliferation in a manner suggestive of a G2 block. In contrast, BaP increases proliferation rates and induces rapid progression through the cell cycle, possibly by a shortened G2 phase. Differentiation is much more sensitive to chemically-mediated perturbations than is proliferation, indicating that the former process may be the initial target at environmentally prevalent concentrations. To identify molecular alterations that are responsible for the observed chemical-specific effects, microarray analysis was carried out on NHEK treated with BaP and arsenic. From this analysis, chemically altered genes were selected that are known to be involved in growth regulation (Ras, IL-1 α and β, TGF ), differentiation (RA/INF-inducible protein, YY1-associated factor 2), RNA synthesis (tRNA exportin, RNA cyclase homolog), cell structure/adhesion (Cadherin 5, α-integrin binding protein), apoptosis (CASP8, programmed cell death 10), and chromatin structure/function (RAD50, REV1). Alterations in expression of these genes induced by arsenic and/or BaP are currently being examined using highly quantitative Real-Time RT-PCR. Through extensive time-course and dose-response studies, we will aim to clarify whether similar, highly central, pathways are disrupted by these diverse skin carcinogens or whether only chemical-specific effects are evident. This research was supported by NIEHS Grant # RO1 ES09655 & Minority Supplement # RO1 ES09655-01S1.

### 1974

CHARACTERISTIC EXPRESSION PROFILES INDUCED BY GENOTOXIC AND NON-GENOTOXIC CARCINOGENS IN RAT LIVER ANALYZED ON AFFYMETRIX GENECHIPS.

<u>H. J. Ahr</u><sup>1</sup>, H. Ellinger-Ziegelbauer<sup>1</sup>, <u>B. P. Stuart</u><sup>2</sup> and <u>B. S. Wahle</u><sup>2</sup>. <sup>1</sup>Molecular and Genetic Toxicology, Bayer Health Care AG, Wuppertal, Germany and <sup>2</sup>Toxicology, Bayer Crop Science, Stilwell, KS.

Application of the recently developed gene expression profiling techniques using microarrays in toxicological studies (toxicogenomics) facilitate the interpretation of a toxic compound's mode of action. In this study we investigated whether geno-

toxic and non-genotoxic carcinogens at doses known to induce liver tumors in the two year rat bioassay deregulate characteristic sets of genes in a short term in vivo study. Male Wistar Hanover rats were treated for up to 14 days with the genotoxic carcinogens Dimethylnitrosamine (DMN, 4 mg/kg/d), 2-Nitrofluorene (2-NF, 44 mg/kg/d), 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK, 20 mg/kg/d), and Aflatoxin B1 (AB1, 0.24 mg/kg/d), and the nongenotoxic carcinogens Wy-14643 (Wy, 60 mg/kg/d), Methapyrilene HCl (MPy, 60 mg/kg/d), Diethylstilbestrol (DES, 10 mg/kg/d), and Piperonylbutoxid (PBO, 1200 mg/kg/d). After 1, 3, 7, and 14 days the livers were taken for histopathology and for analysis of the expression profiles. Using statistical and clustering tools, characteristically deregulated genes were extracted and then functionally annotated. For the genotoxic carcinogens commonly affected pathways were DNA damage response, a distinct detoxification response, and the activation of proliferative and survival signaling pathways. The nongenotoxic carcinogens showed more compound-specific effects with regard to the functional classes of deregulated genes, yet a common characteristic seemed to be the induction of an oxidative stress response as well as deregulation of genes reflecting DNA replication and cell cycle progression. Thus, with a short term in vivo study a common gene expression response could be identified for several genotoxic carcinogens. Although many of the gene deregulations by the nongenotoxic carcinogens implied more diverse mechanisms, there were also similarities in some pathways, which might then also allow to identify a nongenotoxic carcinogenic potential from short term studies.

1975

GENE EXPRESSION PROFILING OF MAMMARY TISSUE FOLLOWING NMU TREATED SENSITIVE FISHER 344 AND RESISTANT COPENHAGEN RAT STRAINS IN DIFFERENT TIME POINTS.

X. Ren<sup>2, 1</sup>, R. C. Sullivan<sup>1</sup>, A. S. Kim<sup>1</sup> and <u>H. Zarbl</u><sup>1, 2</sup>. <sup>1</sup>Human Biology, Fred Hutchinson Cancer Research Center, Seattle, WA and <sup>2</sup>Department of Environmental and Occupational Health, University of Washington, Seattle, WA.

While human genetic linkage analyses have identified tumor suppressors that are responsible for familial breast cancer, many susceptibility genes are likely to be partially penetrant, due to the modifying effects of diverse genetic backgrounds and gene-environmental interactions. The study of inherited cancer susceptibility genes in inbred animal models can facilitate the identification of cancer suppressor mutations that have low penetrance in the human population, as these may present as highly penetrant phenotypes in experimental tumor models. Genetic mapping study indicated in the Fischer 344 rat, genetic susceptibility to nitrosomethylurea-(NMU) induced mammary cacinogenesis is a recessive trait controlled by a locus on rat chromosome 12. To gain insight into the putative tumor suppressor locus, we compared normal mammary cells gene expression profiles from the susceptible Fisher 344 and the resistant Copenhagen rat strains. We identified ~1000 genes whose expression levels are significantly different (P < 0.001) between the two rat strains, which implicated several biochemical pathways to differential sensitivities mammary carcinogenesis. In the present study we used Agilent Rat Genome GeneChips to compare the patterns of gene expression induced in mammary cells in response to NMU in the Fisher 344 and Copenhagen rat strains as well as F1 (F344 X COP). Briefly, NMU was administered to female rats at onset of puberty (55 days of age) in dose of 50mg/kg. The time points examined included 6 hours and 1, 7, 30 days. To further enrich for a subset of genes whose altered expression directly contribute to differential susceptibility we are also comparing these results with expression profiles in control and NMU treated N2 backcross progeny. Analyses of these data will provide insights into the underlying mechanisms and biochemical pathways that are associated with the differential sensitivities to mammary carcinogenesis.

1976

SERUM CYTOKINE ANALYSIS AND TRANSCRIPTIONAL PROFILING OF PBMCS IN CHIMPANZEES TREATED WITH A LYMPHOTOXIN BETA RECEPTOR AGONIST.

<u>M. Cooper</u><sup>1</sup>, E. Stanford<sup>2</sup>, M. Wu<sup>1</sup>, M. Derbel<sup>1</sup>, J. Goyal<sup>2</sup>, <u>J. Green</u><sup>2</sup>, M. Subramanyam<sup>2</sup> and D. Enke<sup>1</sup>. <sup>1</sup>Biomarker Development and Validation, Biogen, Cambridge, MA and <sup>2</sup>Preclinical and Clinical Development Sciences, Biogen, Cambridge, MA.

Described herein are the results of serum cytokine profiling and transcription profiling of PBMCs isolated from chimpanzees treated with LTBR mAb. The goal of this study was to identify potential biomarkers for LTBR mAb drug response. LTBR mAb is a monoclonal antibody that acts as an agonist to LTBR. The LTBR is expressed on both neoplastic and normal tissues. Activation of the LTBR is expected to induce cell death or differentiation of neoplasms. LTBR mAb is biologically active in humans and chimpanzees, but not macaques or other common laboratory species. Previous investigations have shown evidence of MIG (Monokine Induced by Gamma interferon; a ligand for the CXCR3 receptor), IP-10, and

ITAC release in response to LTBR mAb treatment in in vitro and in vivo models. In this study, we observed a dose-dependent release of MIG into the serum of chimpanzees at 2-hours postdose in response to LTBR mAb treatment. This response was not observed with IP-10 or Th1 and Th2 cytokines. Additional studies with proper specificity controls are required to confirm and validate these findings in vivo. In addition, transcriptional profiling results suggested potential migration of certain lymphocyte cell types out of the free blood compartment, consistent with MIG-mediated PBMC activation via the CXCR3 receptor. Indeed, many transcripts associated with particular lymphocyte cell types were decreased in abundance in PBMC samples with high LTBR mAb and MIG levels. These transcripts included cathepsin W, killer cell immunoglobulin-like receptor, natural killer cell group 7, granulysin, granzyme B, and perforin. Additional studies including validation of the expressed transcripts using TaqMan PCR and additional in vitro or in vivo studies with appropriate controls will be required to confirm these findings. It was concluded that MIG and the MIG pathway should be further investigated as sources of potential biomarkers for LTBR mAb in vivo.

1977

BLOOD GENE EXPRESSION PROFILING: A BIOMARKER PILOT STUDY COMPARISON OF SMOKERS AND NONSMOKERS.

G. M. Hellmann<sup>1</sup>, W. T. Morgan<sup>2</sup> and C. N. Overman<sup>2</sup>. <sup>1</sup>Physiology and Pharmacology, Wake Forest University, Winston-Salem, NC and <sup>2</sup>R. J. Reynolds, Winston-Salem, NC. Sponsor: D. Pence.

Transcriptional profiling of peripheral blood has attracted considerable attention within the field of toxicogenomics as a minimally invasive technique utilizing an easily accessible tissue representative of systemic physiological state. We hypothesized that the effects of cigarette smoking would be manifest in transcription profiles obtained from the peripheral blood of smoking subjects, and that those profiles could be distinguished from those of non-smoking subjects. To investigate this hypothesis, peripheral blood samples were obtained from adult smokers (n=8) and control never-smokers, stabilized by collection in PAXgene<sup>TM</sup> blood collection tubes, and the RNA subject to array analysis on a 1200-gene nylon membrane cDNA array. An extensive set of blood count parameters including total white count, differential leukocyte counts, and red blood cell and platelet counts was also determined from a second blood draw taken at the same time. Absolute levels of monocytes exhibited a mean increase of 56% in the smoking group. No other statistically significant differences in any of these metrics were noted between the smoking and non-smoking groups. However, above physiological variation and intrinsic interindividual variation, array analysis revealed 23 genes showing both statistically significant differences (p<.05) in the levels of the corresponding transcripts and fold-change greater than 2. Ignoring fold-change restrictions, a total of 133 statistically significant differences were noted. Differential regulatory responses included changes in relative mRNA levels for the following: upregulation of c-myc, GM-CSF, TNFα and the proinflammatory cytokines IL-6 and IL-13, and downregulation of MMP-9. The data support the hypothesis that there is a peripheral blood genomic response to smoking, and this response is associated with altered regulation of a set of mRNAs that can serve as important biomarker indicators of smoking-associated physiological status.

### 1978 ROLE OF INTESTINAL PERMEABILITY IN NSAID- AND LPS-INDUCED ACUTE PHASE RESPONSE IN RATS.

S. Tugendreich, S. Baumhueter, G. Day, S. Dunlea, B. Eynon, M. Fielden, S. Fujimoto, B. Ganter, R. Idury, K. Jarnagin, K. Kolaja, M. Lee, R. Nair, G. Natsoulis, S. Nicholson, C. Pearson, A. Roter, S. Thode and A. Tolley. *Iconix Pharmaceuticals, Mountain View, CA*.

To improve compound selection during drug discovery we have developed a large library of biomarker sets for important toxicities and mechanisms of action. These signatures derive from a comprehensive database that connects results derived from treating rats with 580 drugs at up to two doses and four time points in triplicate with traditional measurements of toxicity, pathology and pharmacology. The database contains ~13, 000 micorarray gene expression measurements. We have profiled ~50 immune-modulating compounds, and have found that high doses of most non-steroidal anti-inflammatory drugs (NSAIDs) induce an acute phase response expression pattern like that elicited by endotoxin (LPS). We hypothesize that NŜAIDs increase intestinal permeability, allowing LPS to escape into the blood and stimulate an acute phase response in the hepatic macrophages. We conducted a study using indomethacin, ibuprofen, and several of the ĈOX-2 selective "coxibs". Animals were necropsied after 1 and 3 daily doses and evaluated for intestinal histology and gene expression changes. Several drug treatments induced an acute phase response as indicated by blood inflammatory proteins and hepatic gene expression markers. Acute phase genes such as stat3 and lipocalin2 were induced by 2.5 to 30-fold. The mechanism of intestinal damage and associated hepatic changes is examined and discussed relative to various hypotheses related to COX selectivity.

TOWARDS QUANTITATIVE PREDICTIONS OF HEPATOTOXICITY USING GENE EXPRESSION PROFILES.

Y. Yang, R. X. Ciurlionis and J. F. Waring. Department of Cellular and Molecular Toxicology, Abbott Laboratories, Abbott Park, IL.

Despite improved toxicology testing, hepatotoxicity associated with new drug candidates remains a major hurdle in drug discovery. Recent advances in microarray technology have provided a relatively high throughput tool to monitor toxicity responses on a genome scale. The purpose of this study was to develop a quantitative approach to predict hepatotoxicity based on gene expression profiles. To do so, a toxicogenomics database was constructed from three-day rat studies treated with a large number of hepatototoxins and non-hepatotoxins. A set of marker genes was identified that distinguished the hepatotoxins from the non-hepatotoxins using ANOVA analysis. Using neural networks coupled with principle component analysis for dimension reduction, a quantitative model was established to classify compounds according to a composite toxicity score. Our results showed that, using gene expression analysis, the neural network classified compounds based on their potential to cause hepatotoxicity with a high degree of sensitivity and specificity. Additional studies using compounds outside of the initial database were also correctly classified using the neural network. Our study demonstrates that a predictive gene expression based model has the potential to discriminate among different levels of toxicities. This type of assay would allow drug discovery teams to prioritize compounds for safety at the pre-investigational toxicology stage, resulting in a lower rate of attrition at later stages of drug development.

#### 1980

BIOMARKER DEVELOPMENT INFORMATION MANAGEMENT SYSTEM (BMD-IMS): ELECTRONIC FORMS IN A 21 CFR PART 11 COMPLIANT LIMS SYSTEM.

D. Enke<sup>1</sup>, <u>M. Cooper</u><sup>1</sup>, M. Derbel<sup>1</sup>, M. Wu<sup>1</sup>, Q. Duong<sup>1</sup>, M. Subramanyam<sup>1</sup>, S. Subramaniam<sup>2</sup>, M. Means<sup>2</sup>, M. Christow<sup>2</sup>, M. Wang<sup>2</sup>, Z. Xu<sup>2</sup>, A. Siva<sup>2</sup>, K. Natarajan<sup>2</sup>, J. Calabro<sup>2</sup> and M. Rosenberg<sup>2</sup>. <sup>1</sup>Biomarker Development, Biogen, Cambridge, MA and <sup>2</sup>Research Informatics, Biogen, Cambridge, MA.

The application of new and complex technologies to drug development, including transcriptional profiling, has generated a need for a LIMS system capable of supporting multi-step workflows in a 21 CFR part 11 and GLP compliant environment. In an effort to create a system that can seamlessly support complex laboratory procedures such as the Affymetrix workflow as used to support regulatory filings, we have designed and implemented the Biomarker Development Information Management System (BMD IMS). This system is fully compliant and utilizes electronic forms for all data capture and witnessing functions. A Documentum document manager controls the laboratory workflow and audit trail. Data is input by the user into electronic forms *via* a PDF interface with tablet or desktop PCs, and all information is captured in an Oracle database. When a user completes a procedure, the system automatically notifies members of the group via email that the electronic forms are ready for witnessing, and witnessing functions are performed electronically through the PDF interface. Finally, data can be queried and reports generated through use of Business Objects. This system has been piloted to support the Affymetrix workflow, however, the system is highly flexible and can be used to support electronic forms for any laboratory procedure.

### 1981

HEPATIC GENE EXPRESSION SIGNATURES IDENTIFY MULTIPLE PATHWAYS RELATED TO AH RECEPTOR ACTIVATION FOLLOWING SHORT- AND LONG-TERM COMPOUND ADMINISTRATION IN RAT.

S. Nicholson, S. Baumhueter, G. Day, S. Dunlea, B. Eynon, M. Fielden, S. Fujimoto, B. Ganter, R. Idury, K. Jarnagin, K. Kolaja, M. Lee, R. Nair, G. Natsoulis, C. Pearson, A. Roter, S. Thode, A. Tolley and S. Tugendreich. *Iconix Pharmaceuticals, Mountain View, CA.* 

To improve compound selection during drug discovery, we used several linear classification methods, SVM variants, to develop a large library of biomarkers, Drug Signatures™, highly interpretable short gene lists, for important toxicities and mechanisms of action. These signatures were derived from a comprehensive database that marries −13, 000 micorarray gene expression measurements, obtained by treating rats with 580 drugs at two doses and four time points in triplicate, with traditional measurements of toxicity, pathology and pharmacology. Chronic aryl hydrocarbon receptor (AhR) activation can lead to hepatocarcinogenicity, immunomodulation, and drug-drug interactions, all of which are undesirable. To show that DrugSignatures™ predict the effects of AhR activation, male SD rats were orally administered AhR agonists, 3MC (300, 30, 12.5 mpk), beta-naphthoflavone (1500, 150, 80 mpk), and TCDD (0.02, 0.001, and 0.0007 mpk), and the weak agonist alpha-naphthoflavone (80 mpk), for 5, 28, and 91 consecutive

days. Expression profiles of liver samples from control and treated rats were obtained and analyzed against our DrugSignature<sup>TM</sup> library. Examination of the AhR DrugSignature<sup>TM</sup> shows consistent induction of CYP1A1, CYP1A2, and glutathione-S-transferases, as well as genes associated with cell cycle regulation. A number of genes specific to TCDD-treatment were also affected. Long-term administration of AhR agonists modulates the expression of many additional genes, including those related to oxidative stress. These changes in gene expression occur in the absence of changes in classical endpoints (e.g. histopathology, clinical chemistry, and hematology) and highlight the powerful insight of toxicogenomic evaluation.

### 1982 A GENOMIC MODEL OF BENZO(A)PYRENE INDUCED ATHEROGENESIS.

C. D. Johnson<sup>1, 2</sup>, T. L. Thomas<sup>3</sup> and <u>K. S. Ramos<sup>1, 2</sup></u>. <sup>1</sup>Center for Genetics and Molecular Medicine, University of Louisville, Louisville, KY, <sup>2</sup>Biochemistry and Molecular Biology, University of Louisville, Louisville, KY and <sup>3</sup>Biology, Texas A&M University, College Station, TX.

Atherogenic stimuli trigger complex responses in vascular smooth muscle cells that culminate in activation/repression of overlapping signal transduction cascades involving oxidative stress. In the case of benzo(a)pyrene (BaP), a polycyclic aromatic hydrocarbon present in tobacco smoke, the atherogenic response involves interference with redox homeostasis by oxidative intermediates of BaP metabolism. In the present study, experiments were conducted to further define early global gene expression profiles in murine vascular smooth muscle cells challenged with BaP in the presence or absence of chemical antioxidants. Profiles of gene expression were defined using analysis of variance and clustering methodologies. Supervised and nonsupervised analyses identified a number of gene clusters that were uniquely regulated by BaP, antioxidant, or the combined chemical treatments after acute (8 hr) challenge. NAD(P)H dehydrogenase, quinone 1 (Nqo1), cyclooxygenase 2 (Cox2), and TRNA-specific eukaryotic elongation factor (TREEF), were identified as redox-regulated genes in response to BaP challenge. Elongation factor TREEF is of particular interest given its role in the synthesis of thioredoxin reductase 2 (Txnrd2), an antioxidant enzyme regulated by heat shock factor 2 and linked to cytochrome p450 1b1. A number of previously unreported redox responsive genes, such as nuclear factor I/B and 1/X (Nfib, Nfix), and SRY-box containing gene 4 (Sox4) were also identified as putative targets of BaP in vascular smooth muscle cells. The latter genes are of interest in light of their involvement in Hmg signaling in mammalian cells. Collectively, these results indicate that oxidative stress plays a prominent role in the regulation of gene expression during the early stages of chemical atherogenesis. (Supported by NIH grants ES04849, ES09106, ES07273 to KSR, and ES012117 to CDJ).

### 1983 COMPOUND CLASSIFICATION USING TRANSCRIPT PROFILING.

S. ruepp<sup>1</sup>, G. Steiner<sup>2</sup>, <u>F. Boess<sup>1</sup></u>, R. Gasser<sup>1</sup>, S. Evers<sup>3</sup>, M. De Vera<sup>1</sup>, S. Albertini<sup>1</sup> and L. Suter<sup>1</sup>. <sup>1</sup>PRBN-S, Roche, Basel, Switzerland, <sup>2</sup>PRBI-B, Roche, Basel, Switzerland and <sup>3</sup>PRG, Roche, Basel, Switzerland.

Toxicogenomics is expected to improve sensitivity, accuracy and speed of toxicological investigations. The main assumption of toxicogenomics is that toxicity is accompanied by changes in gene expression that are either causally linked to the toxicity or represent a response to toxic alterations. Toxicogenomics can be used for mechanistic investigations or for predictive tasks. The effect of various hepatotoxic compounds was studied in male Wistar and Sprague-Dawley rats. The compounds chosen for this study induced cholestasis, steatosis, peroxisomal proliferation or were "direct-acting". Histopathology and clinical chemistry were used as conventional methods to assess liver toxicity. Gene expression changes in the liver were evaluated using Affymetrix Gene-chip? microarrays (RG-U34Ă). Gene-chip analysis was performed on five individual animals within a treatment group. Different kinds of support vector machines (SVMs) were used for classification purposes. Compound profiles, not included in the training set for SVMs, could subsequently be assigned to the correct toxicity categories. Non-toxic pharmacologically active substances were correctly grouped with control gene expression profiles. The relationship of number of genes used for classification and accuracy of classification was studied by implementing recursive feature elimination (RFE). Results demonstrate that gene expression profiles can be used to discriminate toxicants with different modes of action from each other and from controls using only a small number of genes. Small sets of genes could potentially be used as sensitive surrogate markers for toxicity. Fingerprints derived from Wistar rats were successfully used to classify gene expression profiles derived from Sprague-Dawley rats. Furthermore, gene expression analysis successfully identified non-responding animals as defined by conventional endpoints. Toxicity of several substances could be detected at an earlier time than by conventional endpoints highlighting the potential of this apTHE COMPARATIVE TOXICOGENOMICS DATABASE (CTD).

C. J. Mattingly<sup>1</sup>, G. T. Colby<sup>1</sup>, M. Rosenstein<sup>1</sup>, J. N. Forrest<sup>2, 1</sup> and J. L. Boyer<sup>2, 1</sup>. Bioinformatics, MDI Biological Laboratory, Salisbury Cove, ME and <sup>2</sup>Medicine, Yale University, New Haven, CT. Sponsor: W. Toscano.

Sequencing of the human genome has stimulated a new way of thinking in biology; however, our understanding of the sequence is limited by our ability to retrieve meaning from it. The human and other vertebrate sequencing projects have underscored the significance of comparative studies to reveal conserved sequences that may be functionally significant. The Comparative Toxicogenomics Database (CTD) will be the first publicly available, curated database devoted to genes and proteins of human toxicological significance. The major goals of this resource include: 1) curating and integrating sequence, reference and toxicant data for toxicologically important genes and proteins; 2) promoting comparative studies of these genes and proteins across evolutionarily diverse organisms; and 3) integrating information from existing molecular and toxicology resources. The infrastructure of data in CTD includes nucleotide and amino acid sequences, references from the published literature and controlled vocabularies for taxonomy and substances/toxicants. The current focus of curation and integration efforts in CTD is to create explicit associations between nucleotide and amino acid sequences, references and toxicants, as well as between sequences and genes through the construction of Gene Sets. Gene Sets place sequences in a comparative context by grouping all sequences from diverse species for a gene or related genes with associated toxicants, references and gene synonyms. CTD will provide focused access to data that is of toxicological interest and will facilitate interspecies comparisons of toxicological genes to promote understanding about their role in modulating human health.

1985

DISCOVERING SYSTEM-LEVEL FEATURES OF THE EARLY MOUSE EMBRYO USING MITOCHONDRIAL BENZODIAZEPINE RECEPTOR LIGANDS, MICROARRAY AND COMPUTATIONAL METHODS.

K. R. Nemeth, A. V. Singh, R. C. Craig, K. B. Knudsen, N. H. Owens, B. Nibbio, M. Green and T. B. Knudsen. Pathology, Anatomy and Cell Biology, Thomas Jefferson University, Philadelphia, PA.

Exposure of early mouse embryos to some teratogens (MeHg, EtOH, 2CdA, hypoxia) can invoke a stress response involving the mitochondrial benzodiazepine receptor and downstream changes to at least two nuclear transcription factors: p53 tumor suppressor (Trp53) and nuclear respiratory factor (Nrf1). A working model proposes this receptor (Bzrp) is activated during mitochondrial dysfunction and generates a signal culminating in down-regulation of Nrf1 expression; furthermore, Bzrp signals induce p53 protein to accumulate in the nucleus. Since Nrf1 and Trp53 play key roles in respiratory and cellular differentiation, the mitochondrial localization of Bzrp may relay important information to the nucleus regarding oxygen metabolism states. In a microarray-based study we have begun to characterize the response signature linked with different receptor states. Study of 100 microarrays revealed 244 genes differentially affected by low-level teratogen exposure (10% average risk for malformation). Many changes correlated with p53 activating exposures and intervention with PK11195, a Bzrp antagonist. Preliminary analysis implies strong cross-regulation between p53-dependent and growth factor-mediated survival pathways (PTEN, v-akt/PKB), regulation of ribosomal protein expression, and chromatin remodeling (p300/CBP, HMG-A1, SMARC-A4) systems. An emergent property is inverse coupling between the Bzrp state and cellular plasticity; e.g., stimulating the receptor (as in respiratory distress) drives p53 to invoke checkpoints for cell growth, differentiation and death whereas antagonizing the receptor (pharmacologically) suppresses signals upstream to p53 induction and drives genes for chromatin remodeling and anaerobic (glycolytic) metabolism, pushing the system to a more primitive state. (Supported by grants AA13205 and ES09120 from the NIH, T32 ES07282 from the NIH/NIEHS, and grant R 827445 from the EPA but does not reflect agency policy).

1986

PROTEOMIC IDENTIFICATION OF INSULIN-LIKE GROWTH FACTOR BINDING PROTEIN-6 INDUCED BY SUBLETHAL  $\rm H_2O_2$  STRESS FROM HUMAN DIPLOID FIBROBLASTS.

L. Xie and Q. M. Chen. Pharmacology, University of Arizona, Tucson, AZ.

Fibroblasts are the most ubiquitous cell type within various organs of our body. They produce various factors such as proteases, cytokines, growth factors and extracellular proteins to maintain the structure and texture of a particular organ or tissue. To identify the secreted protein factors and the alteration of these protein factors upon oxidative stress, we exposed confluent human diploid fibroblasts (HDFs) in culture to sublethal oxidative stress induced by  $600~\mu\text{M}~\text{H}_2\text{O}_2$  for 2 hours. Such treatment caused the cells to develop a phenotype of senescence prematurely after 3

days. The control and premature senescent cells were kept in a medium deprived of serum for analyzing secreted proteins after collecting the conditioned medium. Concentrated conditioned media were used for Electrospray Ionization Liquid Chromatography Tandem Mass Spectrometry (ESI-LC-MS/MS) analyses and Sequest database search. Insulin-like growth factor binding protein-6 (IGFBP-6) was reproducibly detected in the  $\rm H_2O_2$  stressed group but not in the control group. Other proteins such as fibronectin, lumican, matrix metalloproteinase-2 (MMP-2) and collagen alpha1(VI) chain were consistently detected in both control and  $\rm H_2O_2$  stressed groups. Western blot analysis was used to verify the data obtained from ESI-LC-MS/MS approaches. The conditioned media from  $\rm H_2O_2$  treated HDFs showed a significant elevation of IGFBP-6, whereas no difference for fibronectin and MMP-2 was detected between the control and stressed groups. We conclude that  $\rm H_2O_2$  causes HDFs to secrete IGFBP-6, and that proteomics is a powerful technique for identifying proteins secreted by cells.

### 1987 NEW OPPORTUNITIES TO EXPLOIT THE HAZARDOUS SUBSTANCES DATA BANK USING TEXT MINING.

A. Porter<sup>2</sup>, M. Szczur<sup>1</sup>, H. F. Chang<sup>1</sup>, J. Goshorn<sup>1</sup> and D. Schoeneck<sup>3</sup>. <sup>1</sup>National Library of Medicine, National Institutes of Health, Bethesda, MD, <sup>2</sup>Technology Policy and Assessment Center, Georgia Institute of Technology, Atlanta, GA and <sup>3</sup>Search Technology Inc., Norcross, GA. Sponsor: V. Hudson.

Biomedical research findings and toxicological information are compiled in rich databases, including the Hazardous Substances Data Bank (HSDB), MEDLINE, and TOXLINE. This project explores ways that text mining can help extract embedded information to aid toxicology researchers. We imported 73 selected fields of 4586 HSDB records into VantagePoint software. The full record file and the citation record file were created to facilitate knowledge discovery. The capability to easily compile cross-record information generates "bird's eye" perspectives. It also facilitates "drilling down" to identify agent information salient to particular research questions. Five essential steps in exploiting the body of knowledge on a selected topic are search, retrieval, data cleaning, analysis, and representation of findings. We illustrate these for one agent (phenol) and one effect (asthma). Most exciting is the capability to deliver quick "research profiles" focused on particular user needs. Tailored scripts can automate the five steps to generate otherwise inaccessible topical profiles. We present a sample profile based on asthma-associated information from thousands of HSDB, MÊDLÎNE, and TOXLINE records. This "one-pager" targeted for a novice researcher spotlights: a) research activity trends b) leading sources c) "top, " "hot, " and "new" topics identification d) a topical cluster map We explore ways that this new method to access information can enrich toxicology. "Research profiles" can alert researchers to the advent of new approaches, tools, and issues. We see special promise in improving cross-disciplinary access to scientific findings. Desktop database mining can help researchers uncover agent-effect-organ interactions, including second-order linkages. Such research domain profiling, performed at the onset of new projects, could enhance research efficacy by increasing awareness of related findings.

1988

USING A CDNA MICROARRAY FOR GENE EXPRESSION PROFILING OF WHOLE BLOOD IN LIPOPOLYSACCHARIDE-TREATED RATS.

R. D. Fannin, J. T. Auman, M. E. Bruno, S. O. Sieber, S. M. Ward, C. J. Tucker, B. A. Merrick and R. S. Paules. *National Ctr Toxicogenomics, NIEHS, Research Triange Pk, NC.* 

cDNA microarrays have been used to evaluate the expression of thousands of genes in diseased tissues. However, very few studies have investigated the change in gene expression profiles in one of the most easily accessible tissues, whole blood. We utilized an acute inflammation model to investigate the possibility of using a cDNA microarray to measure the gene expression profile in whole blood. Whole blood was collected in male F344 rats at 2 and 6 hr after treatment with 5 mg/kg i.p. lipopolysaccharide (LPS). Hematology showed marked neutrophilia accompanied by lymphopenia at both time points. TNF $\alpha$  and IL6 levels were elevated at  $2\,\mathrm{hr}$  indicating acute inflammation, but by 6 hr the levels had declined. Total RNA was isolated from whole blood and hybridized to a rat 6, 700 cDNA microarray chip. Results showed that 216 and 180 genes were differentially expressed after 2 and 6 hr of LPS treatment, respectively. Many of the differentially expressed genes are known to play a role in the inflammation process, but differential expression was also noted in genes involved in cytoskeleton/cell adhesion, oxidative respiration, and transcription. Genes prominently upregulated at both time points include those involved in acute phase response, such as lipocalin 2 and IL1β. Genes commonly downregulated by LPS at both time points include those for antigen/processing, ribosomal proteins and protein kinase C related genes. In addition, a number of genes were differentially expressed at only one time point, such as TIMP2 that was upregulated at only 2 hr, while IL6 receptor was downregulated at only 6 hr after LPS treatment. Real-time PCR confirmed the differential regulation of 9

genes discovered by cDNA microarray. Principle component analysis could discriminate between acute inflammation at 2 hr and recovery at 6 hr. These studies indicate that inflammatory changes in gene expression profiles can be detected in whole blood despite the adaptive shifts in leukocyte populations that accompany inflammatory processes.

## 1989 APPLICATION OF CDNA MICROARRAYS FOR SCREENING CARCINOGENICITY OF CHEMICALS IN THE 28-DAY REPEAT-DOSE TOXICITY STUDY.

M. Otsuka<sup>1</sup>, H. Matsumoto<sup>1</sup>, Y. Yakabe<sup>1</sup>, M. Takeyoshi<sup>1</sup>, <u>K. Saito</u><sup>2</sup>, K. Sumida<sup>2</sup>, M. Sekijima<sup>3</sup>, K. Nakayama<sup>3</sup>, Y. Kawano<sup>3</sup>, M. Tsuchiya<sup>3</sup>, Y. Shinohara<sup>4</sup> and <u>T. Shirai</u><sup>5</sup>. <sup>1</sup>Chemical Evaluation and Research Institute, Japan, Tokyo, Japan, <sup>2</sup>Sumitomo Chemical Co., Ltd., Osaka, Japan, <sup>3</sup>Mitsubishi Chemical Safety Institute Ltd., Ibaraki, Japan, <sup>4</sup>Hokkaido University, Sapporo, Japan and <sup>5</sup>Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan.

In the present study, male Fischer 344 rats aged 5-week old were treated by daily oral gavages with known carcinogenic and non-carcinogenic compounds, such as peroxisome proliferators, enzyme inducers or hepatotoxicants, at two dose levels for 28 days. The livers were sampled at the following 5 timepoints: Day 1, 3, 7, 14 and 28. Physical signs, organ/body weight ratios, plasma enzyme activities of alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP) and total bilirubin, and histological changes were measured. For monitoring the gene expression levels, the in-house microarray containing approximately 8, 000 genes and ESTs from the liver, kidney, spleen and colon of rats was prepared and GeneChip (Affymetrix) was also applied for comparison. Clofibrate, for example, produced hepatocellular granular eosinophilic cytoplasm and swelling of hepatocytes without any changes in plasma enzymes. In the liver tissue, gene expression such as acyl-CoA oxidase, acyl-CoA dehydrogenase, mitochondrial acyl-CoA thioesterase, 3-hydroxy-3-methylglutaryl-CoA synthetase, cytosolic epoxide hydrolase, malic enzyme, CYP4A1, and aldehyde dehydrogenase were upregulated, whereas apolipoprotein AIV or cyclin D1 were downregulated. These gene expression profiles obtained were consistent with previous observations reported elsewhere. We are going to build database of gene- and protein-expression profiles and develop data processing algorithms using reference compounds being carcinogenic and non-carcinogenic to establish a test system for screening of the carcinogenicity of chemicals. ### 1990 QUANTITATIVE PROTEOMIC ANALYSIS OF HEPATIC RESPONSES TO 28-DAY REPEATED DOSE.

H. Yamanaka<sup>1</sup>, M. Otsuka<sup>1</sup>, Y. Yakabe<sup>1</sup>, M. Takeyoshi<sup>1</sup>, <u>K. Saito</u><sup>2</sup>, K. Sumida<sup>2</sup>, M. Sekijima<sup>3</sup>, K. Nakayama<sup>3</sup>, Y. Kawano<sup>3</sup>, M. Tsuchiya<sup>2</sup>, Y. Shinohara<sup>4</sup> and <u>T. Shirai<sup>3</sup></u>. <sup>1</sup>Chemical Assessment Center, Chemical Evaluation and Research Institute, Japan, Saitama, Japan, <sup>2</sup>Sumitomo Chemical Co., Ltd.,, Osaka, Japan, <sup>3</sup>Mitsubishi Chemical Safety Institute Ltd.,, Ibaraki, Japan, <sup>4</sup>Hokkaido University, Sapporo, Japan and <sup>3</sup>Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan.

We ran quantitative proteomic analysis on liver homogenates of rats by thirty chemicals with known carcinogenicity using the quantitative fluorescent 2D-DIGE (2D-Differential Gel Electrophoresis) method (Amersham Biosciences, UK Limited). Thirty chemicals tested includes 2 genotoxic carcinogen, 11 non-genotoxic carcinogen and 17 non-carcinogen. F344 rats were repeatedly dosed for 28 days with two levels of chemicals together with vehicle control. Individual liver sample of low and high dosed rats was labeled with Cy3 and Cy5, respectively. Each gel image of them was matched to one master gel, which generated with a pooled one of all samples (livers of low and high dosed and control rats) labeled with Cy2, with Decyder software to identify and quantify the spot of protein expressed in rat liver. These protein expression patterns potentially represent signatures of organ responses to specific chemicals or offer insights into tumorigenesis processes. Significant change in expression level compared to control was observed in response to administration of chemical depending on the test chemical and dose level. For example, 2D-DIGE of Clofibrate treated liver (250mg/kg/day, 28days) indicated significant (p<0.001) quantitative changes in 108 liver proteins compared to controls. The cluster analysis was applied with all protein expression data to find the protein expression profile specific to carcinogenicity of chemicals. Acknowledgement: This work was sponsored by NEDO (New Energy and Industrial Technology Development Organization).

#### **1991** BIOMARKERS OF ASPHALT FUME EXPOSURE.

C. Keshava<sup>1</sup>, N. Keshava<sup>1</sup>, B. Law<sup>2</sup>, D. Lewis<sup>2</sup> and <u>A. Weston<sup>1</sup>. <sup>1</sup>TMBB</u>, National Institute for Ocupational Safety and Health, Morgantown, WV and <sup>2</sup>Analytical Services Branch, NIOSH, Morgantown, WV.

It has been estimated that at least 24, 000 occupationally related cancers are diagnosed in the US each year. The introduction of occupational cancer biomarkers in cross-sectional epidemiologic research may be a useful approach in the develop-

ment of strategies for intervention. Here we have used "gene chip" technology (high density DNA-oligonucleotide arrays) to identify potential biomarkers of asphalt fume condensate (AFC) exposure. A rat lung epithelial cell line (RLE-6TN) was exposed to AFC (270µg/ml) in vitro for 12h and 24h. At the end of the treatment period, RNA was extracted from the cells, subjected to reverse transcription, in vitro transcription, fluorescence labeling and hybridization to Affymetrix TM rat genome microarrays (U34A). Transcription of 348 genes on the array was observed to be altered by a factor of at least 2 fold. A battery of genes induced (p<0.01) by this exposure included Phase I and II metabolism genes (CYP1A1, CYP1B1, GST-A1 and NQO1), oxidative stress and inflammatory genes (ALDH, CAT and COX-2), DNA damage response genes (GADD45, GADD153), and transcription factors and oncogenes (EIF-2 and FRA-1). These genes were selected for further investigation by reverse transcription and polymerase chain reaction (RT-PCR). The RT-PCR confirmed the induction of this battery of genes and RT-PCR was reasonably well correlated with the oligonucleotide array data ( $r^2 = 0.6$ , t = 3.3, p<0.01, df = 20). Genes that are turned-on in response to such exposures are potential candidate biomarkers that should be investigated further. This study identified several candidate biomarkers of asphalt fume exposure. Future studies will investigate the effects of chemopreventive agents on these candidate biomarkers and associated end-points like DNA damage in human epithelial cells.

### 1992

USING CORRELATION ANALYSIS AND HIERARCHICAL CLUSTERING TO DISCRIMINATE GENES ASSOCIATED WITH HEPATIC VASCULITIS FROM SUBSEQUENT HEPATIC INFLAMMATION.

B. lu¹, L. Nelms¹, <u>G. Floyd</u>² and <u>M. Lawton</u>¹. ¹Molecular and investigative toxicology, Pfizer, Groton, CT and ²Pathology, pfizer, Groton, CT.

During a pre-clinical study, compound X was found to induce hepatic vasculitis in rats. In an experiment designed to understand the molecular details of this lesion, groups of male Sprague-Dawley rats were given daily oral doses of vehicle, 10 mg/kg or 1000 mg/kg of compound X and animals were euthanized 24, 48, 144 and 240 hours after the first dose. Liver samples were harvested for gene expression profiling with RG\_U34A Genechip and serum from blood was used for proteomics analyses. Clinical chemistry, hematology and histopathology data were also collected from the study. At 24 hours, histological vascular changes induced by highdose compound X were consistent with endothelial activation, and frank vascular inflammation that sometimes extended secondarily into the hepatic parenchyma was evident at 48 hours. Clinical chemistry and hematology data both reflected the presence of inflammation at 48 hours. We then focused on genes that were differentially regulated at 24 or 48 hours to look for potential biomarkers for liver vasculitis. Changes in gene expression could be due to the endothelial proinflammatory response, vascular inflammation, inflammation of the perivascular hepatic parenchyma or activation of the hepatocellular acute phase response. To differentiate genes in these tandemly linked but different processes, we used statistical methods to calculate and identify genes that are highly correlated with severity of the vascular and perivascular inflammation. In addition, we have compared the hepatic gene expression profile induced by compound X to other compounds known to induce a hepatic acute phase response secondary to inflammation at sites other than the liver. Using data from Gene Logic's ToxExpress database, we also subtracted genes activated by hepatic inflammation from the compound X response and helped to in silico select candidate genes that are involved in the hepatic vascular inflammatory response rather than in the hepatic acute phase response that occurs secondary to inflammation.

## 1993 DBZACH: A COMPREHENSIVE TOXICOGENOMIC INFORMATION MANAGEMENT AND KNOWLEDGE DISCOVERY SYSTEM.

E. Dere, L. D. Burgoon, P. C. Boutros, S. Doran, S. S. Pai, R. Aiyar, J. Vakharia, R. Rotman, A. Adams, B. Lau and <u>T. R. Zacharewski</u>. Pharmacology & Toxicology, Biochemistry & Molecular Biology, National Food Safety & Toxicology Center, Institute for Environmental Toxicology, Michigan State University, East Lansing, MI.

dbZach (http://dbzach.fst.msu.edu), a Minimum Information About a Microarray Experiment -Toxicology (MIAME/Toxicology) supportive toxicogenomic relational database, uses Java-based data mining and visualization tools to facilitate knowledge discovery. The system consists of the dbZach database back-end, and the dbZach software suite of data mining and knowledge discovery tools. The architecture for the dbZach database is modular and flexible, consisting of core subsystems (i.e. Clones, Genes, Protocols, Sample Annotation) which are required, in silico subsystems (Gene Regulatory, Pathway) which facilitate data interpretation, and 3) experimental subsystems (Microarray, Affymetrix, Real-Time PCR, Toxicology) that store raw as well as processed data . The modular architecture allows portions of the database to be cordoned off to facilitate development, fixes, fu-

ture expansion of the project, and incorporation into other existing database systems. The software suite allows the system to go beyond information management by providing query and knowledge discovery tools that support 1) data mining, 2) quality control and inspection of microarray data, 3) up-to-date gene annotation, 4) orthologous gene identification, 5) protocol cataloguing and inspection, 6) integration of disparate biological and toxicological data, and 7) data analysis and interpretation. Future developments for dbZach include management of biological pathway information, the development of a pipeline from dbZach to the ArrayExpress genomic data repository, and other data visualization tools. The dbZach System will be made source-available for local implementation as an independently-operated laboratory information management and knowledge discovery system. Supported by NIH grants \*T32 ES07255 ES 04911-12, ES 011271 and ES 011777.

#### 1994

COMPARISON OF THE MODIFIED LOOP AND INDEPENDENT REFERENCE DESIGNS FOR MICROARRAY STUDIES.

L. D. Burgoon<sup>1</sup>, D. R. Boverhof<sup>1</sup>, J. E. Eckel<sup>2</sup>, C. Gennings<sup>2</sup> and <u>T. R. Zacharewski<sup>1</sup>. <sup>1</sup>Pharmacology & Toxicology, Biochemistry & Molecular Biology, National Food Safety & Toxicology Center, Institute for Environmental Toxicology, Michigan State University, East Lansing, MI and <sup>2</sup>Biostatistics, Virginia Commonwealth University, Richmond, VA.</u>

It remains unclear what impact the choice of experimental design may have on the identification of changes in gene expression following drug or chemical exposure. To examine this further, a hepatic time-course experiment combining the modified loop (MLD) and independent reference (IRD) designs was used to identify changes in genes expression following treatment by gavage with ethynyl estradiol (EE), an orally active estrogen. Immature, ovariectomized female mice were gavaged once or 3x24hr with 0.1mg/kg EE or vehicle (sesame oil) and hepatic tissue was harvested at 0, 2, 4, 8, 12, 24 or 72 hrs. Murine cDNA microarrays with 3, 068 clones, spotted in duplicate, representing 2, 259 distinct genes, were used to examine changes in gene expression elicited by EE. Each experimental design was replicated three times with independent biological samples. The data were normalized using a General Linear Mixed Model (GLMM), and gene effects were estimated using a gene-specific GLMM. The designs were compared using percentile range lists constructed using t-values from a model-based t-test. For comparison purposes, the 4hr time-point was chosen, as it was representative of the other time points. A 40% overlap exists between the designs at the highest 10th percentile, where the most active genes reside. 50% and 90% overlaps were evidenced at the 30th and 90th percentiles, respectively. The difference in gene lists is due to the number of measures taken per gene in the MLD, evidenced as a greater amount of variance per genetreatment-time unit compared to the IRD. Cost-comparisons between the designs illustrate a significant cost-savings in performing the IRD. These results suggest the use of the IRD with a greater number of biological replicates, bringing the cost inline with the MLD, to increase statistical power. Supported by NIH grants: \*T32 ES07255 and ES011271.

### 1995 ASSESSING TOXICOGENOMIC DATA: ANALYSIS OF MICROARRAY QUALITY CONTROL MEASURES.

M. Ramer, L. D. Burgoon, D. R. Boverhof, B. Jeremy, C. Fong and T. Zacharewski. Pharmacology & Toxicology, Biochemistry & Molecular Biology, National Food Safety & Toxicology Center, Institute for Environmental Toxicology, Michigan State University, East Lansing, MI.

Adoption of the microarray technology brings with it many benefits, such as the ability to measure the expression of thousands of genes simultaneously. However, in addition to substantial costs, it also harbors significant technical difficulties. Although the technology continues to mature, quality assurance and quality control measures for assay performance and data quality are lacking. Average signal intensity, background intensity and dynamic range were compared across five independent microarray data sets to assess their predictive value in determining data quality using spread vs. level (SVL), principal components biplots, shewhart, feature not detected (FND), boxplots, and saturated features (SF) plots. The anomalies identified included 1) high global background, 2) low feature signal intensity, and 3) compressed dynamic range which skewed or abbreviated normalized distributions, resulting in disrupted comparisons and confounding the results of statistical tests as well as pattern recognition algorithms (i.e., clustering). Average signal intensity, background intensity and dynamic range proved to be valuable measures to monitor assay and operator performance within and between studies. Moreover, these analyses suggest background intensity values should be sacrificed in favor of a higher PMT gain setting in order to maximize dynamic range. This work was supported by NIH grants: \*T32 ES07255 and ES011271.

#### 1996

PREDICTION OF TOXICITY FROM *LISTERIA MONOCYTOGENES* INFECTION IN MICE USING GENOMIC DATA.

H. H. Ng<sup>1</sup>, C. E. Frantz<sup>1</sup>, L. Rausch<sup>1</sup>, J. Shimon<sup>1</sup>, E. Riccio<sup>1</sup>, S. Phillips<sup>1</sup>, S. Smith<sup>1</sup>, C. Litterst<sup>2</sup> and J. C. Mirsalis<sup>1</sup>. <sup>1</sup>BioSciences, SRI International, Menlo Park, CA and <sup>2</sup>National Institute of Allergy and Infectious Diseases, NIH, Bethesda, MD

The infection of mice with Listeria monocytogenes (LM) is a widely used model to study host response to intracellular bacterial pathogens and to examine potential immunotoxic effects of therapeutics. We have previously demonstrated increases in the liver enzymes AST and ALT and hepatic necrosis in mice 24 hr after infection with 5.3 x 10<sup>4</sup> CFU of LM, confirming that the liver is a target organ for LM infection. The purpose of this study was to characterize the short term changes in gene expression in mice after infection with LM, and to evaluate the predictive value of gene expression in liver and blood. Female BALB/c mice (14/group) were iv administered medium broth (controls) or 2 x 10<sup>3</sup> CFU (non-lethal dose) or 7 x 10<sup>4</sup> CFU (lethal dose) of LM and sacrificed 6 hr later. Gene expression was determined using Affymetrix Murine U74Av2 GeneChips. Multiple genes were found to be differentially expressed including genes associated with immune function, and liver function or toxicity, such as T-cell specific GTPase, cytochrome P450 and serum amyloid A protein. In addition, gene expression profiles in selected samples (designated as Training Set) were used in a K-nearest neighbor algorithm to establish a prediction rule to classify samples designated as unknowns (Test Set). Small sets of genes were identified that could predict control, non-lethal, and lethal doses of LM 6 hr after infection. An 8-gene set in liver samples was  $\geq 90\%$  accurate at predicting survival, and a 10-gene set in blood was ~80% accurate; however, different genes were predictive in each tissue. Our results suggest that class predictor genes should be able to distinguish samples in treatment groups with varying severity of infection, and serve as an early biomarker for subsequent conventional toxic endpoints. This approach will also be useful for the assessment of gene expression changes following administration of therapeutics for treatment of infection. Supported by NIAID Contract N01-AI-05417.

### 1997

TISSUE SPECIFIC OXIDATIVE STRESS AND GLUTATHIONE METABOLISM IN STREPTOZOTOCININDUCED DIABETIC RATS.

H. Raza, A. John and L. A. Kumar. Biochemistry, Faculty of Medicine and Health Sciences, UAE University, Al Ain, United Arab Emirates.

Increased oxidative stress is an important factor in the etiology and complications of diabetes. In this study we have investigated hyperglycemia-associated changes in cellular oxidative stress and glutathione level in different tissues of rats treated with streptozotocin (STZ). In addition, we also studied the level of oxidative stress in neonates of diabetic rats. Our results showed that ROS production and oxidative stress differentialy affect GSH metabolism in different tissues of rats and neonates of diabetic mothers. The pancreas and kidney appeared to be the target organs and were affected more severely than the liver. Based on catalytic activities, immunohistochemistry and Western blot analysis, we demonstrated an increased expression of cytochrome P450 2E1, specific gluathione S-transferase (GST) isoenzyme and other stress related proteins in diabetes. Increased membrane lipid peroxidation and accumulation of 4-hydroxynonenal (HNE), accompanied by a decreased enzymatic regeneration of glutathione appeared to be the main factors for tissue specific degeneration in diabetes. HNE induced oxidative stress and alterations in GSH metabolism were also confirmed by using cell culture model under in vitro conditions. These results suggest the possible role of oxidative stress and GSH metabolism in the etiology and pathology of diabetes.

### 1998

ASSESSMENT OF S-NITROSOTHIOLS IN BIOLOGICAL FLUIDS: CONTENT OF S-NITROSOTHIOLS IN PLASMA.

Kagan</u><sup>1</sup>. <sup>1</sup>EOH, University of Pittsburgh, Pittsburgh, PA, <sup>2</sup>CCM, University of Pittsburgh, Pittsburgh, PA, <sup>3</sup>Surgery, University of Pittsburgh, Pittsburgh, Physiology, Pittsburgh, PA, <sup>5</sup>OBGJN&RS, UCSF, San Francisco, CA, <sup>6</sup>PPRB, NIOSH, Morgantown, WV and <sup>7</sup>Physiology, George Washington University, Washington, DC.

In plasma, nitrosylated thiols, mainly S-nitrosoalbumin, (Alb-S-NO), are the major reservoirs of releasable NO. Estimates of plasma concentrations of RSNO have been reported to range from 5 nM up to 15  $\mu$ M. Both underestimates and overestimates in the assessment of RSNO are implicated as potential sources of high variability. We utilized four independent protocols to assess Alb-S-NO in plasma. The samples were pretreated with NEM and separated by affinity-chromatography to

obtain an albumin-enriched fraction. Decomposition of RSNO results in the stoichiometric production of NO● and a reduced thiol as the two primary relatively stable products. We employed two assays to detect released NO● (an EPR-based trapping using an NO● chelator, MGD2-Fe, as well as a fluorogenic scavenger of NO●, DAF2) as well as two protocols to evaluate Alb-SH (biotin-switch assay using NitroGlo<sup>TM</sup> kit, and ThioGlo-1<sup>TM</sup>-based assay with a maleimide fluorogenic SH-reagent, and subsequent fluorescence assay of Alb-SH after reduction of Alb-SNO by high concentrations of ascorbate). Procedures utilizing sulfanilamide gave false negative results due to decomposition of RSNO by the reagent. This may explain very low concentrations of RSNO reported by workers who utilized sulfanilamide treatments. All the protocols used give reasonably concordant results: low micromolar concentrations (20-100 pmol/mg protein). These levels are physiologically justified as they provides for its physiologically-relevant vasodilatory functions as assessed in our experiments with isolated mouse mesenteric arteries. Supported by NIH HL64145.

1999

4-HYDROXYNONENAL AND MALONDIALDEHYDE SUPRESS CONSTITUTIVE ACTIVITY OF NFKB IN PRIMARY RAT HEPATOCYTE CULTURES BY MODULATING MAPKS UP-STREAM OF IKK.

B. P. Sampey, M. S. Taylor and D. R. Petersen. Pharmaceutical Sciences, University of Colorado HSC, Denver, CO.

Lipid peroxidation (LPO) and the accumulation of proteins covalently modified by the resulting lipid-aldehydes are early events that persists through the initiation and progression of alcoholic liver disease (ALD). Malondialdehyde (MDA) and 4-hydroxynonenal (4-HNE) are products of LPO involved in the pathogenesis of alcohol-induced liver injury, likely through their ability to form protein-adducts. 4-HNE has been implicated in the modulation of NFKB activity in vitro and in various cells of differing pathologic states. However, a complete understanding of the cell-specific effects 4-HNE and MDA impose on this pathway remains to be defined. The purpose of this study was to use control, primary rat hepatocytes to identify the kinases associated with constitutive NFKB activity that are affected by the lipid-aldehydes 4-hydroxynonenal and malondialdehyde. Primary hepatocytes were isolated from naive, shelf-fed male Sprague-Dawley rats using a collagenaseperfusion method. Isolated cells were seeded onto 100mm tissue culture plates coated with extracellular matrix (ECM) at a density of 3.5X10E6 in 5ml of RPMI-1640 with serum and Penicillin/Streptomycin. After a 12 hour incubation under normal culture conditions, the media was removed along with non-adherent cells and replaced with serum-free media containing 0-100µM 4-HNE or 0-100µM MDA. After a 4 hour treatment period, the cells were washed with PBS (3X), the ECM removed, and total cellular protein isolated from cells of each treatment group for SDS-PAGE gel seperation. Utilizinging antibodies raised toward the activated kinases of the NFKB pathway, immunoblot analysis of the gel-separated lysates demonstrates, when compared to control, both 4-HNE and MDA decrease the activated forms of SAPK & JNK over the physiologically relevant doses used here, and that these reductions correlate well with decreases observed in the activated form of p65/NFkB. (supported by NIH/AA09300: D R P)

### 2000

INAPPROPRIATE CELL CYCLE CHECK POINT CONTROL DURING ROS- INDUCED ONCOTIC CELL DEATH.

S. Ramachandiran, S. S. Lau and T. J. Monks. Pharmacology/Toxicology, University of Arizona Health Sciences Center, Tucson, AZ.

2, 3, 5-tris-(Glutathion-S-yl)hydroquinone (TGHQ) is a potent ROS generating metabolite of the nephrotoxicant, hydroquinone. TGHQ catalyzes the formation of single strand breaks in DNA, followed by growth arrest and oncotic/necrotic death in renal proximal tubule epithelial cells (LLC-PK1). Cyclin dependent kinase1 (p34 cdc2) is the key protein kinase regulating mitotic entry in eukaryotic cells. Treatment of LLC-PK1 cells with TGHQ (200 µM) causes an initial (0-2h) phosphorylation and activation of the DNA damage inducible protein kinases Chk1 and Chk2, followed by increases in inhibitory tyrosine15 phosphorylation of p34 cdc2, indicative of cell cycle arrest. However subsequent (> 2h) cell death is associated with a clear decrease in Chk1 and Chk2 phosphorylation, followed by decreases in cdc2 Y15 phosphorylation, indicating inappropriate activation of cdc2 during the growth arrest and DNA damage repair response. TGHQ induced ERK and p38 MAPK also contribute to LLC-PK1 cell death, probably *via* histone H3 phosphorylation, which occurs concurrently with premature chromatin condensation. The activation of cdc2 in growth arrested LLC-PK1 cells suggests that premature mitosis might induce mitotic catastrophe, which may be the mechanism of cell death in this model. A similar phenomenon also occurs during H2O2 induced oncotic/necrotic death of LLC-PK1 cells. In contrast, cisplatin, an alkylating agent that induces apoptotic LLC-PK1 cell death, does not activate cdc2. Indeed, cisplatin treatment results in prolonged inhibitory Y15 phosphorylation of cdc2, even

after 12h of treatment. The data suggests that inappropriate activation of cdc2 may contribute to oncotic /necrotic death of otherwise growth arrested LLC-PK1 cells. (Supported by NIH grant DK 59491)

### 2001

USING CRYOPRESERVED NEURONAL CELLS FOR ASSESSMENT OF CHEMICALLY INDUCED OXIDATIVE CELL STRESS IN PRIMARY CELL CULTURE.

A. Krantis<sup>1, 2</sup>, W. Staines<sup>1, 2</sup>, S. VandenHoek<sup>2, 1</sup> and T. Durst<sup>1, 2</sup>. <sup>1</sup>Cellular& Molecular Medicine, University Ottawa, Ottawa, ON, Canada and <sup>2</sup>CRBB, University Ottawa, Ottawa, ON, Canada. Sponsor: M. Aschner.

Cryopreserved primary neuronal cells from the rat brain represent an ideal and sensitive cell culture assay for screening drug neuroactivity. When thawed and grown in cell culture, these dissociated neuronal cells display normal morphology, neurochemistry and physiological responsiveness within 10 days. We have obtained similar results with neuronal cells dissociated from the mouse brain. However, the susceptibility of cryopreserved rodent brain neuronal cells to neurotoxic stress in primary culture is unknown. Such information would be useful in determining their suitability for employment in assay screens for chemically induced neurotoxicity. On this basis, we examined cryopreserved neuronal cells prepared from mouse and rat cortex for the effects of exposure to a classic oxidative stress, hydrogen peroxide (H2O2), and to a series of novel compounds for their putative oxidative vs protective properties. Neuronal cells dissociated from brain cortex and cryopreserved by QBM Cell Science, were thawed and cultured in 96 well plates (100, 000 cells/well) for 10days. At this stage they displayed typical neuronal neurite networks and morphology. Wells were then treated for 24hrs with H2O2 (50-100µM), or with novel compounds over a range of concentrations (0.1-50µg/ml). The wells were then assayed using the OxyDNA (Biotrin) fluorescence-based assay for detection of DNA damage. Typical cell damage and disruption of neurite networks were evident with H2O2 50µM as monitored by phase contrast microscopy. A concentration dependent increase in fluorescence associated with 8-oxoguanine fragments, typical of DNA damage due to free radical action was also evident. The novel compounds could be classified as either protective or deleterious. These results show the sensitivity of cryopreserved rodent brain neuronal cells for plate based cell culture assay of oxidation induced neurotoxicity.

### 2002 OXIDATIVE INACTIVATION OF THE THIOREDOXIN SYSTEM.

W. H. Watson<sup>1</sup> and D. P. Jones<sup>2</sup>. <sup>1</sup>Environmental Health Sciences, Johns Hopkins School of Public Health, Baltimore, MD and <sup>2</sup>Medicine, Emory University School of Medicine, Atlanta, GA.

The thioredoxin system, composed of thioredoxin 1 (Trx1), thioredoxin reductase, NADPH, and the peroxiredoxins, protects against the toxicity of peroxides and other oxidants by supporting both detoxification and repair mechanisms. The active site of Trx1 becomes oxidized to a disulfide as part of its catalytic mechanism and must be restored to the dithiol form by thioredoxin reductase and NADPH. We recently described the formation of a non-active site disulfide (Cys62-Cys69) in Trx1 under oxidizing conditions within the cell. In the present study, the effect of the non-active site disulfide of Trx1 on the reduction of the active site was examined in an in vitro assay system. Fully oxidized Trx1 (containing both disulfides) was initially reduced very slowly by thioredoxin reductase. After this initial lag phase, Trx1 was rapidly reduced to the two dithiol form. The early lag phase was dependent on the Cys62-Cys69 disulfide because a mutant of Trx1 bearing Ser at positions 62 and 69 exhibited no lag phase. An active site mutant of Trx1, bearing only the Cys62-Cys69 disulfide, was not a substrate for thioredoxin reductase. However, addition of a catalytic amount of wild type Trx1 resulted in the complete reduction of this non-active site disulfide. These findings suggest a mechanism by which Trx1 can be temporarily inactivated under oxidizing conditions, facilitating oxidant-mediated signal transduction and the induction of oxidative stress response machinery.

### 2003 THE ROLE OF CYSTEINE REGULATION IN ADIPOGENESIS.

M. Cimafranca<sup>2</sup>, <u>P. R. Hanlon</u><sup>2</sup> and <u>C. R. Jefcoate<sup>1,2</sup></u>. <sup>1</sup>Pharmacology, University of Wisconsin, Madison, WI and <sup>2</sup>Molecular & Environmental Toxicology Center, University of Wisconsin, Madison, WI.

2, 3, 7, 8 - tetrachlorodibenzo-p-dioxin (TCDD) inhibits adipogenesis in the mouse embryo fibroblast cell line C3H10T1/2 (10T1/2). cDNA microarray analysis of 10T1/2 after 24 hours of exposure to the adipocyte differentiation stimulus was performed in the presence and absence of TCDD. An 8-fold increase in both cysteine dioxygenase (CDO) and  $\gamma$ -glutamyl cysteine ligase (GCL), together with their partial suppression by TCDD under adipogenic conditions, suggest that cys-

teine is an important factor for early regulation in adipogenesis. In the presence of TCDD, our preliminary data shows the addition of N-acetylcysteine (NAC) or the GCL inhibitor buthionine sulfoximine (BSO) substantially inhibits adipogenesis in a dose-dependent manner; these agents each potentially increase intracellular levels of cysteine but have opposing effects on glutathione. This report further addresses the effects of these agents on PPAR $\gamma$ 1 expression, a key mediator of adipogenesis that is suppressed by TCDD. A more detailed analysis of the time course of CDO and GCL expression in relation to PPAR $\gamma$ 1 will be presented along with the effects of manipulating intracellular cysteine levels via NAC, BSO, and DL-propargylglycine (PPG), an inhibitor of cystathionine  $\gamma$ -lyase which blocks endogenous production of cysteine. We will also examine whether a putative AhR response element found in the CDO flanking region is indeed responsive to TCDD.

2004

FREE RADICAL DETERMINANTS OF AMPHETAMINE NEURODEGENERATION: PROSTAGLANDIN H SYNTHASE (PHS)-CATALYZED FREE RADICAL FORMATION AND REACTIVE OXYGEN SPECIES (ROS)-MEDIATED OXIDATIVE DNA DAMAGE IN NEURONAL DEGENERATION AND FUNCTIONAL DEFICITS.

W. Jeng<sup>1</sup> and P. G. Wells<sup>1, 2</sup>. <sup>1</sup>Pharmacy, University of Toronto, Toronto, ON, Canada and <sup>2</sup>Pharmacology, University of Toronto, Toronto, ON, Canada.

When incubated in vitro with purified PHS-1, the amphetamines 3, 4-methylenedioxymethamphetamine (MDMA, Ecstasy), 3, 4-methylenedioxyamphetamine (MDA) and methamphetamine (METH) were bioactivated to free radical intermediates, characterized by electron paramagnetic resonance spectrometry, which initiated the formation of ROS that caused oxidative DNA damage. These PHS-dependent processes were time- and amphetamine concentration-dependent, stereoselective, and blocked by the PHS inhibitor eicosatetraynoic acid. Similarly in vivo, these amphetamines stereoselectively caused oxidative DNA damage, dopaminergic neurodegeneration and permanent motor coordination deficits, which all were blocked by a single pretreatment with the PHS inhibitor aspirin (with MDA), or reduced in a gene dose-dependent manner in PHS-1 knockout mice (with MDMA). Regional amphetamine-enhanced DNA oxidation correlated positively with the level of PHS-1, which varied significantly among brain regions. These results implicate PHS-catalyzed bioactivation and ROS-mediated oxidative damage in amphetamine-initiated neurodegeneration, providing a novel hypothesis potentially relevant to the mechanisms and risk factors for xenobiotic-enhanced neurodegeneration. 2005

INCREASED MITOCHONDRIAL THIOREDOXIN INHIBITS OXIDANT-INDUCED APOPTOSIS BY A GSH-INDEPENDENT MECHANISM IN SH-SY5Y NEUROBLASTOMA CELLS.

J. Cai, Y. Chen and <u>D. P. Jones</u>. Department of Medicine, Emory University, Atlanta. GA.

Aging and age-related degenerative diseases often involve increased production of reactive oxygen species (ROS) and oxidative damage in neuronal tissues. A major proportion of ROS are produced from mitochondria which contain multiple defensive mechanisms to protect against oxidative injury. Mitochondrial thioredoxin (mtTrx; Trx2) is a newly identified thioredoxin family protein that is localized in mitochondria and functions as an antioxidant protein. In the present study, we have measured whether an overexpression of mtTrx in SH-SY5Y human neuroblastoma cells could protect against apoptosis induced by t-butylhydroperoxide (tBH). Results showed that treatment with 50 microM tBH caused over 75% of SH-SY5Y cells to undergo apoptosis that was inhibited by overexpressing mtTrx. The level of protection correlated with the level of mtTrx overexpression. MtTrx protected loss of mitochondrial membrane potential induced by tBH but not by calcium ionophore (Br-A23187) treatment. Although no significant changes were observed in total cellular GSH, mitochondrial glutathione pool was oxidized by tBH and that was not inhibited by increased mtTrx. Mutations of Cys90 and Cys93 to serine rendered mtTrx ineffective in protection against tBH toxicity. These data indicate that mtTrx controls mitochondrial redox status independently of GSH and is a major component of the protective mechanism against oxidative injury in neuronal cells. (Supported by NIH grant ES09047 and a pilot grant from Emory Parkinsons Disease Center).

### **2006** FETAL HEMATOPOIETIC STEM CELLS ARE SENSITIVE TARGETS OF 4-HYDROXYNONENAL.

C. G. Moneypenny, <u>C. M. Huisden</u> and <u>E. P. Gallagher</u>. Department of Physiological Sciences, University of Florida, Gainesville, FL.

During fetal development, the liver serves as the primary hematopoietic organ in which hematopoietic stem cells (HSC) comprise a large component of hepatic cell populations. Because, HSC are pluripotent and are capable of initiating long-term

hematopoiesis, injury to these cells may have toxicological ramifications with regards to the etiology of blood-borne diseases. In the current study, we examined the effects of 4-hydroxynonenal (4-HNE), a mutagenic  $\alpha, \beta$ -unsaturated aldehyde that can be produced in utero, on the extent of HSC proliferation, differentiation, viability and 4-HNE-protein adduct formation. Exposure of HSC to 5  $\mu M$  4-HNE resulted in a decrease in the rate of HSC proliferation and a loss of viability. These effects were not observed at 1  $\mu M$  4-HNE. HSC exposed to either 5  $\mu M$  or 50  $\mu M$  4-HNE resulted in the formation of multiple 4-HNE-protein adducts that were resolved by two-dimensional gel electrophoresis. MALDI-TOF and HPLC-mass spectral analysis revealed that several cell structure proteins and their precursors, as well as heat shock and tumor rejection antigen proteins were targets of 4-HNE. Collectively our data indicate that cellular levels of 4-HNE consistent with oxidative injury cause a loss of proliferation and viability in human fetal HSC. Furthermore, these data are supportive of 4-HNE-protein adduct formation as a mechanism of 4-HNE toxicity in HSC. Supported by NIH ES09427 and USEPA STAR R827441.

2007

MOUSE GLUTAMATE-CYSTEINE LIGASE CATALYTIC AND MODIFIER SUBUNITS COMPLEX IN-VITRO, TO FORM HOLOENZYME EXHIBITING OPTIMIZED CATALYTIC EFFICIENCY.

Y. Chen, S. N. Schneider, H. G. Shertzer, D. W. Nebert and T. P. Dalton. Environmental Health and Center for Environmental Genetics, University of Cincinnati, Cincinnati, OH.

Glutamate-cysteine ligase (GCL) is the rate-limiting enzyme in glutathione (GSH) biosynthesis. The holoenzyme is a heterodimer formed by the catalytic subunit (GCLC) and the modifier subunit (GCLM). GCLC alone can catalyze the formation of L-γ-glutamyl-L-cysteine (γ-GC); however, GCLM can increase its catalytic efficiency by lowering the Km for glutamate and decreasing sensitivity to GSH inhibition in experiments with rat and human purified proteins. To determine the subunit interaction and catalytic characteristics of mouse GCL, we expressed and purified mouse GCLC and GCLM. Interaction of GCLC with GCLM to form holoenzyme could be monitored because GCLC, GCLM and GCL have distinct mobilities in nondenaturing PAGE. Western immunoblot analysis demonstrated that all detectable GCLC and GCLM were interaction-competent. The apparent Km of glutamate for GCLC was 2.6-fold higher than that for GCL (1.8 mM vs 0.51 mM), and GCLC was more sensitive to inhibition by GSH. Titration of GCLC with GCLM gave a linear increase in GCL activity, and GCL was ~4-fold more active than mGCLC alone (185 vs 800 nmol/min/mg protein). A similar increase in GCL activity was observed when complementing tissue cytosol from Gclm(-l-) mice with recombinant GCLM. Thus, *in vivo* GCLC stands poised to accept GCLM. Interestingly, addition of GCLM to wild-type tissue cytosol resulted in increased GCL activity and the relative increase was reproducibly dependent on the tissue type. Thus, in many tissue cytosols, GCLC is more abundant than GCLM, and perhaps an increase in GCLM alone in the context of many cell types would lead to an increase in γ-GC production. ——-Supported, in part, by NÎH grants P30 ES06096 and R01 ES10416.

2008

GENERATION OF REACTIVE OXYGEN BY HALOGENATED AROMATIC HYDROCARBONS IN MOUSE LIVER MICROSOMES.

T. P. Dalton, M. Genter, C. D. Clay, M. C. Chames, S. N. Schneider, G. G. Oakley, D. W. Nebert and H. G. Shertzer. Department of Environmental Health and Center for Environmental Genetics, University of Cincinnati Medical Center, Cincinnati, OH.

Using liver microsomes from 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD)-induced or vehicle-treated (non-induced) mice, we evaluated the in vitro effects of added chemicals on the production of reactive oxygen due to substrate/P450-mediated uncoupling. Catalase-inhibited NADPH-dependent H2O2 production was lower in induced than non-induced microsomes. Various chemicals, added to microsomes at 2.5 µM, were evaluated for their effects on H2O2 production. There were three groups of compounds that elicited distinct effects. Group 1 were highlyhalogenated and coplanar compounds that increased H2O2 production, as well as the H2O2/O2 and H2O2/NADPH ratios in induced, but not in non-induced, microsomes. Group 2 were non-coplanar halogenated biphenyls that did not affect H2O2 production nor H2O2/O2 or H2O2/NADPH ratios. Group 3 were minimally-halogenated biphenyls and benzo[a]pyrene. Group 3 compounds decreased H2O2 production, and also H2O2/O2 and H2O2/NADPH ratios. Microsomal lipid peroxidation was proportional to H2O2 production. Although TCDD induction decreased microsomal production of H2O2, addition of Group 1 compounds to TCDD-induced microsomes in vitro stimulated the second-electron reduction of CYP1A1 and CYP2E1 and subsequent release of H2O2 production. This pathway is likely to contribute to the oxidative stress response, and associated toxicity, produced by many of these biologically-persistent environmental chemicals. (Supported by grants R01 ES10133, R01 ES06321, R01 ES08147, R01 ES08799, T32 ES07250, and P30 ES06096)

GLUTATHIONE DEFICIENCY IN PANCREATIC BETA CELLS PREDISPOSES MALE MICE TO THE DEVELOPMENT OF DIABETES.

S. N. Schneider, Y. Chen, Y. Yang, H. G. Shertzer, D. W. Nebert and T. P. Dalton. Environmental Health and Center for Environmental Genetics, University of Cincinnati, Cincinnati, OH.

Diabetes is a complex disease caused by the combination of genetic and environmental factors. Many studies implicate oxidative stress as an important factor in the development of diabetes; the results of such studies suggest that the insulin-producing pancreatic beta cells are sensitive to oxidative stress because they possess relatively low levels of antioxidant enzymes. To develop an animal model in which beta cells have increased susceptibility to oxidative stress, we have made a glutamate-cysteine ligase catalytic subunit (Gclc) conditional knockout mouse line in which Gclc gene disruption occurs specifically only in beta cells. GCLC is essential for production of the antioxidant glutathione (GSH). Beta cell-specific knockout of Gclc occurs when a floxed allele [Gclc(f)] allele is present in a mouse that carries the rat insulin2 gene promoter (RIP)-Cre transgene. Gclc(f) behaves like the wild-type Gclc allele but, in the presence of RIP-Cre, beta cell Gclc(f) becomes the  $Gclc(\beta)$  null allele. We monitored the development of diabetes in a colony of male and female  $Gclc(\beta/\beta)$  and littermate Gclc(f/f) controls by measuring fasting blood glucose (FBG) at 5, 20, 40 and 60 weeks of age. Male and female Gclc(fff) mice and female  $Gclc(\beta/\beta)$  had normal fasting blood glucose levels throughout the course of the study. In contrast, male  $Gclc(\beta/\beta)$  mice displayed a trend for elevated FBG as early as 5 weeks of age; FBG in this group by 20 weeks was significantly elevated to diabetic levels (greater than 126 mg/dL), compared with all other groups and continued to rise through 60 weeks. We conclude that male mice, lacking the capacity to synthesize GSH in pancreatic beta-cells, develop diabetes as characterized by significantly increased blood glucose levels associated with age. These mice will be useful in understanding the processes underlying oxidant stress-induced diabetes and in developing therapies for its prevention. — --Supported, in part, by NIH grants P30 ES06096 and R01 ES012463.

### 2010

BRAIN UPTAKE, METABOLITE DISTRIBUTION AND METABOLIC SHIFT FOLLOWING [14C]-1, 3-DINITROBENZENE ADMINISTRAION IN THE SPRAGUE-DAWLEY RAT.

J. Tobias, R. T. Miller and P. Venkatakrishnan. Toxicology, University of Kentucky, Lexington, KY.

1, 3-Dinitrobenzene (1, 3-DNB) is a CNS toxicant. Studies regarding 1, 3-DNB toxicity in multiple systems have been done and while some data is available regarding 1, 3-DNB toxicity in the brain, uptake studies and possible shifts in metabolism following multiple doses have not yet been conducted. This study attempts to address these questions. Male Sprague-Dawley rats were dosed ip with 20 mg/kg of [14C]-1, 3-DNB in corn oil every 12 hr x 3. Following the last dose, brain levels of 1, 3-DNB were measured as a function of time. Results showed 1, 3-DNB was rapidly taken up by brain with levels decreasing steadily over time. In separate experiments, rats were dosed ip with 20 mg/kg of [ $^{14}$ C]-1, 3-DNB in c. o. either singly or every 12 h x 3. At 45 and 90 min thereafter, brains were removed and dissected into forebrain, brainstem and cerebellar regions. In both groups, the major metabolites were 1, 3-DNB and 3-nitroaniline (3-NA). We identified a reactive intermediate, N-nitroso-3-nitrobenzene (NNB) in cerebellum and brainstem in each group. Major cerebellar metabolites at 45 min were 1, 3-DNB and 3-NA (58 and 24% of total radioactivity after single dose and 52 and 39% after 3 doses.) NNB accounted for 18% after a single dose and 9% after 3 doses. At 90 min, 1, 3-DNB and 3-NA represented 38 and 33% after a single dose, 56 and 31% after 3 doses. NNB accounted for 28% after a single dose and 13% after 3 doses at 90 min. In brainstem at 45 min, 1, 3-DNB and 3-NA accounted for 45% each after a single dose and 39 and 52% after 3 doses. NNB represented 10% after a single dose and 9% after 3 doses. At 90 min both 3-NA and NNB accounted for 27% after a single dose and 1, 3-DNB for 44%. In multiple dose animals, NNB was 71% and 1, 3-DNB and 3-NA 24 and 5%. Data are expressed as percent of total radioactivity in the brain at 45 or 90 minutes after single or third dose. Collectively, these data demonstrate both that 1, 3-DNB is taken up by the brain and that there are differences in its metabolic profile between regions in the brain.

### 2011 PROTECTIVE ROLE OF URIC ACID AGAINST NITRIC OXIDE-MEDIATED OXIDATIVE INJURY.

R. M. Uppu and B. Kandlakunta. *Environmental Toxicology, Southern University and A&M College, Baton Rouge, LA*. Sponsor: J. Ward.

Uric acid (UA) was viewed as a toxic metabolite till recently. Excessive production of UA can induce gout, a disease that affects joints and the kidneys. A landmark hypothesis by Ames that UA constitutes an important defense mechanism against ox-

idative damage, which occurs in aging and other degenerative diseases, has contributed to a change in the perception of UA as a toxic metabolite. Uric acid exists as urate monoanion at physiological pH, and demonstrates a potent antioxidant activity as seen in several in vitro assays. It exhibits strong therapeutic effects in animals suffering from experimental allergic encephalitis in which peroxynitrite (PN) is suspected to be the causative agent. The PN-mediated oxidation of UA was examined in the present work as PN is a potent oxidant formed during the down regulation of nitric oxide. Our results show that PN reacts with urate both directly and through a carbon dioxide-dependent pathway, producing identical product profiles. Interestingly, allantoin, which is often considered to be the major product, is formed in yields less than 25% of the overall oxidation of UA. The product profile in the PN/carbon dioxide/UA resembles that of the UA/hydrogen peroxide/peroxidase reaction, which proceeds via the formation of the urate radical. In view of this, we hypothesize that PN/carbon dioxide oxidizes urate to a metastable nitroderivative; this reaction occurs via a free radical mechanism involving nitrogen dioxide and the carbonate radical. The nitroderivative thus formed loses nitrite to become dehydrourate, which, in turn, hydrolyzes to allantoin, parabanic acid, and other products. The current efforts are directed towards examining pathways for the decay of dehydrourate (hydrolysis-driven) that can result in electrophilic intermediates with potential for binding DNA or cause depletion of cellular antioxidants. ## 2012 SYNTHESIS OF PEROXYNITRITE USING ISOAMYL NITRITE AND HYDROGEN PEROXIDE IN A HOMOGENOUS SOLVENT SYSTEM.

R. R. Kancharla, B. Kandlakunta and R. M. Uppu. *Environmental Toxicology, Southern University and A&M College, Baton Rouge, LA.* Sponsor: J. Ward.

The peroxy isomer of nitrate, peroxynitrite is a versatile oxidant that can be formed in biological systems from the reaction of nitric oxide with superoxide and oxygenated heme proteins, in particular, oxyhemoglobin. Several different methods of synthesis of peroxynitrite have been reported (for a review, see R.M. Uppu et al. (1996) Methods Enzymol. 269, 285-295). These include synthesis in a two phase system wherein alkaline-H2O2 in water (aqueous phase) was allowed to react with a water-insoluble alkyl nitrite, isoamyl nitrite (organic phase) (R.M. Uppu and W.A. Pryor (1996) Anal. Biochem. 236, 242-249). In the present studies, we modified the method of Uppu and Pryor by way of introducing solvents of intermediate polarity that abolish phase separation of the reactant pair hydroperoxide anion and isoamyl nitrite. This simple modification allows a rapid and efficient synthesis of peroxynitrite with much less nitrite, nitrate, and carbonate contamination. The modification does not necessitate any additional post-processing other than the one reported earlier for reactions performed in the two-phase system. In view of shortening of reaction times, the modification eliminates the need for metal ion chelators such as diethylenetriaminepentaacetic acid. The present method is amenable for large scale synthesis and, therefore, promotes industrial applications of peroxynitrite as an oxidizing agent. For example, we find that peroxynitrite and its secondary reaction products with CO<sub>2</sub> afford oxidation of indigo and indigo carmine, the two major organic pollutants in waste waters from textile industries. Studies are underway to examine other industrial applications of peroxynitrite; including its use as bleach additive (US Pat. 5, 914, 305). (Funding support from NIEHS grant ES10018 is acknowledged. Corresponding author: rao\_uppu@cxs.subr.edu. Fax: 225/771-5350.) Rao M. Uppu. E-mail:

# 2013 PROTECTIVE EFFECTS OF ENHANCED GLUTATHIONE SYNTHESIS ON TNFA-INDUCED HEPATOTOXICITY IN GLUTAMATE-CYSTEINE LIGASE TRANSGENIC MICE.

<u>S. Shi</u>, D. Botta, <u>C. C. White</u>, P. A. Vliet, S. Chatterton-Kirchmeier and <u>T. J. Kavanagh</u>. *Environmental & Occupational Health Sciences, University of Washington, Seattle, WA*.

Oxidative stress plays a critical role in tumor necrosis factor-a (TNFa) cytotoxicity, which involves both necrotic and apoptotic processes. Glutathione (GSH) is a major free radical scavenger and an important factor in detoxification of reactive oxygen species and xenobiotics. The rate-limiting enzyme in the synthesis of GSH is glutamate-cysteine ligase (GCL) which consists of two subunits: GCLC and GCLM. We have generated transgenic mice that conditionally express GCLC and GCLM in the liver using a mifepristone (RU486)-responsive transactivator. To test the hypothesis that enhanced GSH synthesis would prevent TNFa-induced hepatotoxicity, GCL transgenic mice and their non-transgenic littermate controls were treated with TNFa after sensitization by actinomycin D (ActD). GCLM protein levels and GCL activities were significantly increased in GCL transgenic mice with RU486 induction as revealed by Western Blotting and biochemical assay. TNFa /ActD treatment caused liver injury as indicated by serum alanine aminotransferase (ALT) activity. However, ALT levels in GCL transgenic mice induced with RU486

were lower than those in transgenic mice not induced and also lower than control mice receiving TNFa /ActD. Phospho-Erk levels were greatly increased 15 minutes after treatment with TNFa, but this response was attenuated in GCL transgenic mice induced with RU486. These results support the role of oxidative stress in TNFa induced liver injury, and the protective role of GSH synthesis in this process. Supported by NIH grants 1P42ES04696, P30ES07033 and 1R01ES10849-02.

### 2014 HYPEROXIA-INDUCED MAP KINASE ACTIVATION IN LUNG CELLS.

M. Wu<sup>1, 2</sup>, L. Volk<sup>2, 1</sup> and W. J. Martin<sup>2, 1</sup>. <sup>1</sup>Biochemistry & Mol Biol, University of North Dakota, Grand Forks, ND and <sup>2</sup>College of Medicine, University of Cincinnati, Cincinnati, OH. Sponsor: D. Sens.

Oxygen toxicity is a well established model for studying adult respiratory distress syndrome. Mitogen-activated protein (MAP) kinases are a group of enzymes that have been well identified to be activated by exposure to various stresses. However, the role of hyperoxia in regulating MAP kinase in lung cells is not clear. We have studied the signaling transduction of MAPK in lung epithelial cell line A549 under hyperoxia. The main method was the MAP kinase activity assay, using Western blotting with specific antibodies against p38 and p44/42 following immunoprecipitation of phosphorylated p38 and p44/42 molecules. The results demonstrate that phosphorylation of p44/42 in A549 cells was increased by exposure to 95% O2 compared with the control (in room air). It has also been shown that p38 activity in A549 cells was enhanced by exposure to 95% O2 compared with the control. Furthermore, we have transduced A549 cells with human enzyme 8-oxoguanine DNA glycosylase (hOgg1) using retroviral vector pSF91 and tested the regulatory function of hOgg1 on MAP kinase. Our results demonstrate that over-expression of hOgg1 did not alter the p38 activation in the presence of 95% O2 but decreased the expression of p44/42. This is consistent with that MAP kinases are related to the cell cycle arrest. When oxygen damages DNA, cells are halted at G1 or S phase. With the repair of damaged DNA, cells may resume their cycle and progress into M phase. Our results indicate that base excision repair proteins may be useful for repairing oxygen damage in lung cells.

### 2015

DEP-INDUCED *FRA-1* EXPRESSION CORRELATES WITH A DISTINCT ACTIVATION OF AP1-DEPENDENT GENE TRANSCRIPTION IN ALVEOLAR EPITHELIAL CELLS.

Q. Zhang<sup>1</sup>, <u>S. R. Kleeberger</u><sup>2</sup> and S. P. Reddy<sup>1</sup>. <sup>1</sup>Environmental Health Sciences, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD and <sup>2</sup>Laboratory of Pulmonary Pathobiology, NIEHS, Research Triangle Park, NC.

Recent studies indicate a potential role for Fra-1, a heterodimeric partner of AP1, in toxicant-induced epithelial injury, repair, and cellular transformation. Here, we have investigated the effects of diesel exhaust particles (DEP) on fra-1 expression in C10 cells, a nonmalignant murine alveolar type II-like epithelial cell line. DEP caused a marked up-regulation of fra-1, but not fra-2, expression. The increase in fra-1 mRNA expression correlated well with its protein and DNA binding activity. DNA binding assays with antibodies specific to each of the other AP1 family members revealed a predominant presence of Jun-B and Jun-D in the AP1 complex. Interestingly, DEP did not alter Jun-B and Jun-D protein levels. Transcriptional analysis revealed that fra-1 induction is regulated in part at the transcriptional level. The -379 to +32 bp 5'-flanking region mediated this induction. Furthermore, inhibitors of ERK1/2, JNK1 and p38 mitogen-activated protein kinases (MAPKs) significantly suppressed DEP-stimulated fra-1 promoter activity and expression, suggesting their involvement in the induction process. Consistent with this finding, DEP stimulated phosphorylation of ERK1/2, JNK1 and p38 MAPKs with a distinct activation pattern. Overexpression of Fra-1 down-regulated both basal and c-Jun-enhanced AP1 transcriptional activity. It had a similar effect on basal and Nrf2enhanced ARE-mediated reporter gene expression. In contrast, Fra-1 had the opposite effect on MMP-9 promoter activity. In particular, it bound to the functional TRE sequence of the MMP-9 promoter after DEP stimulation. Consistent with this result, DEP also markedly up-regulated MMP-9 promoter activity. Collectively, these findings suggest that fra-1 induction by DEP may play a role in selectively regulating gene expression involved in alveolar epithelial cell injury and repair. #### 2016

HUMAN MITOCHONDRIAL THIOREDOXIN (MTTRX) IS MORE SENSITIVE TO PEROXIDE-DEPENDENT OXIDATIVE STRESS THAN CYTOPLASMIC THIOREDOXIN (TRX1).

Y. Chen, J. Cai and <u>D. P. Jones</u>. Department of Medicine, Emory University, Atlanta, GA.

Thioredoxins (Trx) are a family of small proteins containing a conserved -Cys-X-X-Cys- motif at their redox active center. In the presence of thioredoxin reductase and NADPH, Trx undergoes reversible oxidation/reduction in the active center. Trx has

been implicated in the regulation of fundamental cellular functions such as proliferation, transcriptional regulation and apoptosis. The majority of these biological functions, if not all, rely on the reversible oxidation/reduction in the active center. A mitochondria-localized Trx family protein, mitochondrial Trx (mtTrx, also known as Trx2), has been described in different species including human. MtTrx has been shown essential to cell survival and has been linked to regulation in apoptosis. Trx system is a crucial antioxidant system which not only scavenges reactive oxygen species (ROS) but also functions to prevent protein damage, and furthermore, repair protein damage if happened. The existence of two complete and separate Trx system in different compartments, the cytosol and mitochondria, raises an interesting question, i.e, whether different Trx systems have different responses to oxidant insult. In this study, we used a Redox Western technique which detects endogenous redox status of proteins of interest following thiol alkylation and SDS-PAGE. We investigated the redox status change of both Trx1 and mtTrx in response to three different chemical oxidant treatments. Results showed that mtTrx was more sensitive than Trx 1 to t-butylhydroperoxide (tBH) and hydrogen peroxideinduced oxidation, while the responses to diamide treatment were similar. In cells treated with 300 µM of tBH, recovery of the reduced form or mtTrx was slower than Trx 1. At 60 min, when the majority of Trx 1 returned to reduced state, nearly 60% of mtTrx was still oxidized. These data shows that the redox change of mtTrx is different from that of the cytosolic Trx1 in response to oxidants. MtTrx may be a sensitive biomarker for measurement of mitochondrial oxidative stress. (Supported by NIH grant ES09047).

### 2017 INJURY DYNAMICS FOLLOWING SUBLETHAL BLAST OVERPRESSURE EXPOSURES.

N. M. Elsayed<sup>1, 2</sup>, N. V. Gorbunov<sup>3</sup>, S. J. McFaul<sup>3</sup> and J. L. Atkins<sup>3</sup>. <sup>1</sup>Hurley Consulting Associates, Chatham, NJ, <sup>2</sup>SUNY Downstate Medical Center, Brooklyn, NY and <sup>3</sup>Walter Reed Army Institute of Research, Silver Spring, MD.

Detonation of explosives produces blast overpressure (BOP) waves with magnitudes proportional to the exploding charges. Primary blast injury (PBI) from direct exposure to BOP includes primarily hearing loss and pulmonary contusion. Both military personnel during combat or training and civilians exposed to terrorist bombings sustain PBI. While physical protection has a greater military priority, treatment is more critical for injured civilians. We have shown previously that exposure to BOP waves induce lung injury characterized by rupture of capillaries and alveolar walls leading to hemorrhage, transient hypoxia, inflammation and oxidative stress. In a previous study, we found that rats exposed to multiple low-level BOP (-60 kPa) sustained lung injury after the first exposure, and that the effect of subsequent exposures was not additive. A progressive increase of red blood cells infiltration into the alveoli was observed microscopically, but no gross hemorrhage was visible. However, iron-transferrin [Fe3+]TRF complexes did not increase in lung tissue after BOP exposures. In the present study, we exposed rats to a moderate, sublethal level of BOP (~120 kPa) which produced greater lung contusion and assessed TRF and polymorphonuclear leuckocytes (PMNs) in lung and blood after 1, and 3 h. At 1 h, steady state TRF concentration remained unchanged. At 3 h, TRF was markedly decreased (38%, P<0.05). In contrast, PMNs increased in blood during the same period: 2.7-fold at 1 h and 5-fold at 3 h. Increased PMN count could reflect disruption of PMN adhesion to the vascular endothelium leading to their trans-endothelial migration. Resident macrophages in lung tissue were also increased suggesting activation of phagoctytosis. These observations combined with other findings suggest that a dynamic and complex process continues to develop after initial PBI and stresses the importance of initiating medical triage within the first hour, even in the absence of visible signs of injury.

## 2018 GENERATION AND CHARACTERIZATION OF A GLUTAMATE-CYSTEINE LIGASE MODIFIER SUBUNIT NULL MOUSE.

L. McConnachie<sup>1</sup>, F. N. Hudson<sup>2</sup>, C. B. Ware<sup>3</sup>, C. Fernandez<sup>1</sup>, P. A. Vliet<sup>1</sup>, C. C. White<sup>1</sup> and <u>T. J. Kavanagh</u><sup>1</sup>. <sup>1</sup>Environmental and Occupational Health Sciences, University of Washington., Seattle, WA, <sup>2</sup>Pathology, University of Washington, Seattle, WA and <sup>3</sup>Comparative Medicine, University of Washington, Seattle, WA.

The rate-limiting step in glutathione (GSH) biosynthesis is catalyzed by glutamate cysteine ligase (GCL). This enzyme is a heterodimer composed of a catalytic and a modifying subunit. The modifying subunit, GCLM, functions to modify the activity of GCL by increasing its affinity for glutamate and attenuating the feedback inhibition of GCL by GSH. To more thoroughly characterize the role of GCLM in GSH biosynthesis, we have created a GCLM-null mouse model. We replaced exon 1 of the GCLM gene with a beta-galactosidase/neomycin phosphotransferase fusion protein, allowing in situ detection of GCLM promoter activity. Western blots performed on tissues, including liver and kidney, indicate the -/- (null) mice do not express immunodetectable levels of GCLM, while the +/- mice express GCLM at 50% of wild-type (+/+) controls. Furthermore, hepatic GCL activities in -/- and +/-

mice are 23% and 71% of controls while GSH levels were 22% and 96% of controls, respectively. Conversely, beta-galactosidase activity was increased in the -/- and +/- mice when compared to the controls. DNA microarray analysis of hepatic gene expression confirmed that the -/- mice express no GCLM, whereas expression in the +/- mice is 50% of wild-type. Furthermore, this analysis revealed compensatory alterations in gene expression exclusively in the null mice, relative to the controls. Up-regulated genes include those involved in antioxidant defense and amino acid transport. Down-regulated genes include those involved in signal transduction and protein translation. In sum, these data indicate that the targeted disruption of GCLM results in mice with severely compromised GSH biosynthesis. These mice will be very useful in further characterizing the function of GCLM. (Supported by NIH Grants 1P42ES04696, 1R01ES10849, 1T32ES07032, 1P30ES07033, and 2T32AG000057).

## 2019 THE ROLE OF ANTIOXIDANTS IN URAEMIC PATIENTS. Z A FADHEL, UNIVERSITY OF PETRA, AMMAN IORDAN

Z. A. Fadhel. Division of Neurotoxicology, HFT-132, National Center for Toxicological Research/FDA, Jefferson, AR.

Many studies have implicated oxygen radicals and other oxygen-derived species as important causative agents of many human diseases. High levels of reactive oxygen species (ROS) can overwhelm the antioxidant defenses and cause pathological conditions. Dietary factors and nutrition are considered to be of major importance in the etiology of diseases. The present study was undertaken to evaluate the extent of serum and RBCs lipid peroxidation, as well as the role of various free radicals in uraemic patients. Methods: Twenty uraemic and 12 healthy males, aged  $50 \pm 10$ years were studied. Serum and RBC membranes were evaluated for their ability to form thiobarbituric acid reactive substances (TBARS) as an index of oxidative stress. Various free radical scavengers such as mannitol, ethanol, sodium benzoate, histidine, aminopyrine, β-carotene were added to the RBC incubation mixtures from control and uraemic patients. Results: The results indicate that patients with high levels of urea showed 20-30% increases in the serum and RBC content of TBARS. Furthermore, addition of free radical scavengers to the incubation mixtures decreased TBARS formation with RBC from uraemic patients to 5.2-7.1%, while they decreased TBARS formation with control to 22-43% of the values contained in the absence of free radical scavengers. Conclusions: The results suggest the existence of low levels of endogenous antioxidants and indicate that dietary factors could be used to provide some protection in uraemic patients.

### **2020** DETERMINATION OF PARTITION COEFFICIENTS FOR SELECTED N-ALKANES.

A. Q. Smith, J. L. Campbell and <u>J. Fisher</u>. Environmental Health Science, University of Georgia, Athens, GA.

JP-8 is the primary aviation fuel source used by US and NATO aviation assets. JP-8 is comprised of a complex mixture of hydrocarbons. Exposure occurs primarily via inhalation and dermal contact. A complex mixture PBPK model for JP-8 is in development to aid in understanding target tissue dosimetry. The n-alkanes, particularly n-octane through n-dodecane (C8-C12) comprise a large majority of neat JP-8 (by weight). As part of the model development efforts, partition coefficients for C8-C12 n-alkanes were determined using Sprague-Dawley rat tissues. Rat tissue:air partition coefficients for liver, muscle, brain, fat, and whole blood were determined using a modified version of the vial equilibration method used by Sato and Nakajima (1979), and later by Gargas et al. (1989). A tissue smear technique was used to place the solid tissue on the side of the vial. The mean blood:air and fat:air partition coefficients for C8, C9, C10, C11, and C12 were 3.13, 5.80, 8.13, 20.41, 24.57, and 771.91, 1588.16, 3037.59, 10797.14, 18777.12, respectively. Tissue:air partition coefficient values increase with carbon length for C8-C12 hydrocarbons, with few noted exceptions. Additional chemicals found in JP-8 with similar volatility are currently being studied. Funded by AFOSR [grant # F49620-03-1-0157].

### 2021 COMPARATIVE METABOLISM OF HYDROQUINONE IN RAT AND HUMAN HEPATOCYTES.

T. S. Poet<sup>1</sup>, H. Wu<sup>1</sup>, J. C. English<sup>2</sup> and R. A. Corley<sup>1</sup>. <sup>1</sup>Cntr for Biological Monitoring and Modeling, PNNL, Richland, WA and <sup>2</sup>Eastman Kodak Company, Rochester, NY.

Hydroquinone (HQ) is an important industrial chemical that also occurs naturally in several plant species and food products. Exposure of laboratory animals to HQ may result in a species, sex, and strain-specific nephrotoxicity. The sensitivity appears to have a pharmacokinetic component related to differences in the rates of

formation and further metabolism of key nephrotoxic metabolites formed via a minor glutathione conjugation pathway. To improve our understanding of the role of pharmacokinetics in renal sensitivity, an iterative, nested approach was used to determine metabolic rate constants for each step in the metabolism of HQ in hepatocytes isolated from male F344 rats and human donors. HQ and each subsequent metabolites along the mono-glutathione conjugation pathway were each used separately as substrates with analysis by reversed phase HPLC/UV detection. A pharmacokinetic model was used to analyze each experiment by simultaneously fitting the disappearance of each substrate along with the appearance of subsequent metabolites over a range of substrate concentrations using Michaelis-Menten equations to define metabolism. The pharmacokinetic model was constrained by the requirement that rate constants determined during analysis of individual steps in the metabolism of HQ must also satisfy the complete, integrated metabolism scheme including competitive metabolic pathways such as the formation of di-glutathione conjugates and the major pathways of glucuronide and sulphate conjugation. The results from this study indicated that the overall capacity for metabolism of HQ and its mono-glutathione conjugate is greater in hepatocytes from humans than those isolated from rats. Rats were found to have a greater capacity for forming diglutathione conjugates than humans, which could favor the production of more toxic metabolites. These data will form the basis for modifications of an existing physiologically based pharmacokinetic model to improve current estimates of target tissue doses.(Sponsored by the HQ Panel of the American Chemistry Council)

# 2022 A COMPREHENSIVE APPROACH FOR PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODELS USING THE EXPOSURE RELATED DOSE ESTIMATING MODEL (ERDEM) SYSTEM.

A. Ruiz<sup>1</sup>, A. M. Tsang<sup>1</sup>, J. Licitra<sup>1</sup>, F. Power<sup>2</sup>, <u>J. Blancato<sup>2</sup></u> and <u>C. Dary<sup>2</sup></u>. <sup>1</sup>Las Vegas Technical Center, Anteon Corporation, Las Vegas, NV and <sup>2</sup>Human Exposure & Atmospheric Sciences Division, USEPA, Las Vegas, NV.

The implementation of a comprehensive PBPK modeling approach resulted in ERDEM, a complex PBPK modeling system. ERDEM provides a scalable and user-friendly environment that enables researchers to focus on data input values rather than writing program code. ERDEM efficiently manages these inputs and provides reporting and model output assessment capabilities, for toxicologists, risk assessors, exposure scientists and managers. As PBPK models grow in complexity, the implementation of models, the preparation and maintenance of inputs, and the assessment of model output results has become more tedious and error prone. Combining this experience with intensive research produced a comprehensive modeling approach for designing ERDEM and other PBPK modeling projects. The goal of this modeling approach is to improve the modeling process from planning to application for multimedia exposure assessments. The core activities for this approach include identification and implementation of the model design and performance criteria, the model hardware/software specifications, and the model testing and evaluation. As a comprehensive modeling system, ERDEM contains a PBPK model engine component that can create scenario-based simulations and target dose estimates in multiple compartments for exposure of a species to multiple chemicals and metabolites. The input management component uses a Windows based graphical user interface and relational database, enabling the user to enter, edit, report, and export data sets of user assigned physiological information. The stochastic component evaluates the uncertainty associated with input parameters and output model results. ERDEM replaces the traditional program-oriented modeling approach, which is error prone, with a sophisticated and user-friendly model simulation and data management system. ## 2023 APPLICATION OF THE EXPOSURE DOSE ESTIMATING MODEL (ERDEM) TO ASSESSMENT OF DERMAL EXPOSURE IN THE RAT TO MALATHION.

M. V. Evans<sup>1</sup>, F. W. Power<sup>2</sup>, C. C. Dary<sup>2</sup>, R. Tornero-Velez<sup>2</sup> and J. N. Blancato<sup>2</sup>. <sup>1</sup>PKB, USEPA, Research Triangle Park, NC and <sup>2</sup>National Exposure Research Lab., USEPA, LV, NY.

Renewed interest in the study of dermal exposure to malathion has emerged as a consequence of the prescriptive use of this organophosphorus (OP) insecticide as a pediculicide. The present PBPK/PD model in ERDEM was expanded to include metabolic descriptions needed to link exposure scenarios involving use patterns of malathion with potential health effects. This model allows for the estimation of malathion and malaoxon concentrations in the following organs: skin, fat, kidneys, brain, liver, rapidly perfused, and slowly perfused organs. Physiological values were obtained from the literature. Partition coefficients for parent and metabolites were calculated using tissue-composition based equations. An oral gavage study combining time course metabolite data at different doses was used to calibrate the complex

metabolic scheme described in the model. An acceptable fit was obtained for all the metabolite data by adjusting the metabolic parameters in the model. Computer predicted values for malaoxon concentration were then related to acetylcholinesterase (AChE) levels. A preliminary estimate for the maximum velocity (Vmax) of malaoxon activation was 3x10-5 mg/hr-kg, with an affinity constant (Km) of 8x10-3 mg/liter. The AChE equations described aging, as well as regeneration of AChE. The rat PBPK model was used to extrapolate to humans to predict AChE inhibition in children of different ages exposed dermally to malathion when treating head lice. (This work has been funded by the United States Environmental Protection Agency. It has been subjected to Agency review and approved for publication).

## 2024 KINETIC MODELING OF ORAL UPTAKE AND ELIMINATION OF <sup>54</sup>MN FOLLOWING ORAL AND COMBINED ORAL/INHALATION EXPOSURE.

H. J. Clewell<sup>1</sup>, J. G. Teeguarden<sup>2</sup> and M. E. Andersen<sup>3</sup>. <sup>1</sup>ENVIRON Health Sciences Institute, Ruston, LA, <sup>2</sup>ENVIRON Health Sciences Institute, Collegeville, PA and <sup>3</sup>CIIT Centers For Health Research, Research Triangle Park, NC.

Simple two-compartment pharmacokinetic (PK) models have been the standard for describing the bulk kinetics of radiolabeled tracer studies with metals such as manganese (Mn). The resulting characterizations, especially the elimination rates, are of limited usefulness as predictive kinetic tools for describing exposure:tissue dose relationships; nonetheless, these descriptions can serve as building blocks of more comprehensive PK models. Here we have attempted to link two simple (two compartment) PK models developed by us previously to describe (1) the influence of oral and inhalation Mn exposure rates on tracer (54Mn) elimination kinetics and (2) uptake and elimination of ingested Mn. The unified model failed to describe both tracer kinetics and uptake and elimination for three tested oral Mn exposures and four combined inhalation/oral Mn exposures. Measured liver Mn concentrations could not be maintained while fitting elimination kinetics, and changes in the flux of Mn between a central (plasma) compartment and the deep tissue and liver compartments with dose did not follow an identifiable pattern. Failure of the simple combined PK model structure indicated the existence of kinetically distinguishable pools of Mn, one in the GI-tract derived portal blood and the other in the venous/arterial blood. This conclusion is consistent with our knowledge about the speciation of Mn in the body. Revised to account for route differences in availability, the model provided much improved descriptions of oral and inhalation route kinetics. Route dependent differences in handling of absorbed Mn are a necessary component of physiologically based PK models for Mn.

## 2025 DOSE METRIC SENSITIVITY TO CHANGES IN PBPK MODEL INPUT FUNCTIONS USED TO SIMULATE DAILY ORAL OR INHALATION EXPOSURE.

R. S. DeWoskin<sup>1</sup> and H. A. Barton<sup>2</sup>. <sup>1</sup>ORD/NCEA/HPAG, USEPA, Research Triangle Park, NC and <sup>2</sup>ORD/NHEERL/ETD, USEPA, Research Triangle Park, NC.

Some dose metrics are more sensitive than others to variations in how an oral or inhalation daily exposure is modeled. Continuous exposure via drinking water or inhalation can be simulated in a variety of ways in a physiologically based pharmaco-kinetic (PBPK) model. The total dose amount may be modeled to enter the lung or GI compartment: 1) as a uniform concentration that is continuously inhaled or ingested over 24 hours; 2) as a specified number of equal or unequal bolus doses (ingestion) or peak concentrations (inhalation) delivered at certain times and intervals throughout the day; or 3) as a single daily bolus or peak concentration. In a simulation of the kinetics of a parent compound using a perfusion-limited PBPK model without metabolism, peak concentration (PC) or time above some critical concentration (TCC) are more sensitive dose metrics to the amount of dose delivered per unit time than total area under the curve (AUC). When nonlinear metabolism terms are added, dose metric sensitivity for both parent and metabolite is further influenced by the parameter values for Vmax, and Km. Sample PBPK models for bromodichloromethane or 1, 1, 2-trichloroethane were used to evaluate the sensitivity of different dose metrics to variations in model input functions for a continuous daily ingestion or inhalation exposure. In the standard oral exposure animal bioassay, test chemical is administered either as a single bolus gavage dose or as a continuous exposure in drinking water or food. For inhalation studies, exposure to the test chemical in air is generally for 6 hours per day, 5 days per week. The PBPK models were parameterized to fit standard bioassay data, and the concentrationtime curves for various dose metrics were then compared based upon the use of different model input functions for a daily exposure. The simulation results demonstrate the importance of the choice of dose metric and model input function when extrapolating from bioassay data to a continuous daily exposure. [This abstract does not necessarily reflect EPA policy.]

#### 2026

PHYSIOLOGICAL PARAMETERS OF RATS FOR PHARMACOKINETIC MODELS OF PRENATAL EXPOSURE.

T. Leavens, B. Elswick and <u>D. Dorman</u>. Center for Developmental Dosimetry, CIIT Centers for Health Research, Research Triangle Park, NC.

Physiologically based pharmacokinetic (PBPK) models that predict the fate of environmental chemicals in developing animals during pregnancy provide a tool for reducing uncertainty in animal to human extrapolation. Currently there is a lack of information concerning representative values for physiological parameters in rats during pregnancy and how these values compare with simulations from physiological models. The objectives of our research were to compile values for physiological parameters during the entire period of gestation and to compare the literature values with simulations derived from a model that has been used extensively to simulate physiological changes in rodents during pregnancy (O'Flaherty, et al., 1992, Toxicol Appl Pharmacol 112: 245-56). Values for physiological parameters including maternal and fetal body weight, maternal and fetal organ volumes, maternal cardiac output, and maternal organ blood flows were obtained from peer-reviewed, published research and unpublished data generated from reproductive and developmental studies. In general the gestational blood flow data was not as robust as data on body weights and tissue volumes, partly because of the scarcity of measurements made in nonanesthetized rats. The majority of blood flow data was measured at gestation day (GD) 0 and 18-21 and reported as normalized tissue flow. Model simulations of blood flow fell within the range of data over the period of gestation for most tissues. The model-simulated change in cardiac output, which peaked at GD 11 before decreasing and then increasing in later pregnancy, could only be supported by the original dataset used to generate the equations. The model under-predicted weight gain in the dam, particularly during the period from GD 0 to 16. The compilation of data will serve as the basis for updating a physiological model for rat pregnancy. The ranges of data will be useful for conducting sensitivity analyses to determine the impact of uncertainty in model parameters on blood concentrations of environmental chemicals in rats exposed during pregnancy.

### 2027

PHARMACOKINETIC MODEL FOR TESTOSTERONE AND ITS METABOLITES, DIHYDROTESTOSTERONE AND ESTRADIOL, IN THE PERINATAL RAT.

R. Clewell and M. E. Andersen. CIIT Centers for Health Research, Research Triangle Park, NC.

Male sexual development is dependent upon both adequate testosterone (T) levels and specificity of timed surges in T production and release. In order to evaluate time-dependent changes in T levels, a physiologically-based pharmacokinetic model has been developed, which describes T production, distribution and conversion to its active metabolites, dihydrotestosterone (DHT) and estradiol (E2), in the perinatal male rat. Physiological and hormone-specific kinetic parameters, such as T production rates and affinity constants for metabolizing enzymes, were available from literature. The T, DHT and E2 models include diffusion-limited compartments for testes, brain and body. The three models are linked via conversion of T to DHT and E2 described with Michaelis-Menten metabolism in the blood. Thus, mass is transferred from the T model to the appropriate metabolite model. Fitted parameters included tissue permeability, first order metabolism of E2 and DHT and maximum capacity for DHT and E2 production. The current model successfully reproduces age-dependent changes in fetal and neonatal testes T and serum T, DHT, and E2 levels from gestation day (GD) 15 to post-natal day 3. Two peaks in serum T occur in development, the first on GD 18 and another at 1 to 3 hours after birth. Changing T production appears to be responsible for the prenatal T surge and the model adequately reproduces measured T using production rates from published in vitro data. The post-natal T surge, however, is much shorter-lived than that in the fetus, and the increase in serum levels is much greater (3-fold increase in serum T). The mechanism of this observed hormone surge is unknown, although T stored in the testes may be released at birth. This testes-release hypothesis is supported by the ability of the model to fit measured data based on this mode of action. This model will be used to develop a predictive tool in the assessment of perinatal risk resulting from decreased T production induced by perinatal exposure to endocrine active compounds, such as di-n-butylphthalate.

### 2028

PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODELING OF DI-N-BUTYL PHTHALATE (DBP) IN PREGNANT RATS.

J. Kremer, R. A. Clewell and <u>S. J. Borghoff</u>. *CIIT Centers for Health Research, Research Triangle Park, NC.* 

DBP is a phthalic acid ester widely used as a plasticizer and solvent and a known reproductive toxicant. PBPK models incorporate physiological and chemical specific parameters to make quantitative predictions of tissue concentrations over time. The objective of this study was to develop a PBPK model to predict fetal exposure to monobutylphthalate (MBP), the proposed toxic metabolite of DBP, during the critical window of reproductive development in rats (gestation days GD12-20). A flow-limited PBPK model for a pregnant rat was developed based on an existing model (O'Flaherty et al., 1992, Toxicol. Appl. Pharmacology 112: 245-256). Physiological parameters were obtained from peer-reviewed published literature reports. Chemical specific parameters were obtained from or calculated using data available from literature. Specifically, DBP to MBP metabolism in the gastrointestinal (GI) tract was modeled using Michaelis-Menten kinetics, and MBP uptake from GI fluid was calculated using a first-order rate constant. MBP metabolism was assumed to follow Michaelis-Menten kinetics in the liver. We evaluated the ability of this PBPK model to predict MBP concentration by comparing model output with data on maternal plasma, placenta, and fetal plasma following oral administration of DBP (0.5 and 1.5 g/kg) in pregnant rats on GD14 (Saillenfait et al., 1998, Toxicol. Sciences. 45: 212-224). Model simulations predicted the time course of MBP uptake, distribution, and elimination from maternal plasma, placenta, and fetal plasma. Experimental data were underpredicted but model outputs were consistent with the rapid clearance of DBP and MBP, greater than 90% excreted within 48 hours, seen experimentally. Sensitivity analysis indicated that model predictions depend strongly on the rate-function used for MBP absorption from the GI tract following oral administration of DBP. Targeted experimental data on pathways of oral absorption and metabolism parameters during pregnancy will be required to improve predictions of MBP concentrations in maternal and fetal tissues.

2029

PBPK MODELING OF PHARMACOKINETIC INTERACTIONS FOR THE LACTATIONAL TRANSFER OF METHYLMERCURY AND PCB CONGENERS: IMPLICATIONS OF TRANSPORT PROTEINS.

S. Lee, M. B. Reddy, M. Lohitnavy and R. Yang. Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO.

A PBPK model was developed to simulate pharmacokinetic interactions for the lactational transfer of methyl mercury (MeHg) and PCB congeners (PCB 153, PCB 126) in mice. Model structure and parameters were based on previously developed PBPK models describing the lactational transfer of MeHg or PCB congeners. However, mechanistic involvement of transport proteins were incorporated into the PBPK model. Earlier studies suggested: (1) MeHg and PCB congeners could affect the plasma levels of albumins and lipoproteins; and (2) MeHg binds to albumins in plasma, and a major portion (~60%) of PCBs could binds to lipoproteins in plasma. Thus, we investigate the effects of lipoproteins and albumins on the lactational transfer of MeHg and/or PCBs using PBPK modeling. The following hypotheses regarding the roles of lipoproteins and albumins were tested using PBPK modeling: (1) Only unbound MeHg or PCB congeners could be transferred to the pups; (2) Only bound MeHg or PCB congeners could be transferred to the pups; and (3) The rate of association with transfer proteins could determine the transfer levels of MeHg or PCBs to the pups. Simulation results showed that the levels of lipoproteins and albumins were important factors determining the amounts of lactational transfer of MeHg and PCB congeners. These model simulations are validated iteratively with perinatal pharmacokinetic studies using lactating mice and their pups. Our strategy in using PBPK modeling with incorporation of mechanistic information may improve risk assessment for the mixture of MeHg and PCBs in the developing organisms (Supported by NIEHS R03 ES 10116 and ATSDR Cooperative Agreement U61/ATU 881475).

### 2030

SIMULATING THE DOSE-DEPENDENT LAG IN BILIARY EXCRETION OF GENISTEIN USING A HEPATIC DISPERSION MODEL.

M. G. Zager<sup>1, 2</sup>, H. T. Tran<sup>2</sup> and <u>P. M. Schlosser</u><sup>1</sup>. <sup>1</sup>CIIT Centers for Health Research, Research Triangle Park, NC and <sup>2</sup>Center for Research in Scientific Computation, NCSU, Raleigh, NC.

Genistein is an endocrine-active compound found naturally in soy products and linked to both beneficial and adverse health effects. Data suggest that genistein is extensively conjugated in the liver and these conjugates undergo enterohepatic recirculation. Sfakianos, et al. (J Nutr, 127:1260-1268, 1997) infused four doses of genistein into the hepatic vein of rats and observed a dose-dependent delay in the biliary excretion of genistein conjugates. Typical physiologically based pharmacokinetic (PBPK) models fail to accurately describe these data. We developed a model to simulate the distribution, metabolism and biliary excretion of genistein and conjugates in the liver that accounts for spatial variations in compound concentrations (dispersion) and in physiological parameters. Our model treats the liver as two parallel tubes, representing the blood vessel space and bile duct space, respectively, with hepatocytes in between. Numerical code was developed for model simulations and to calibrate the unknown model parameters using the data of Sfakianos, et al. Parameters that determine the extent of dispersion within the tubes were adjusted

to obtain biologically relevant concentration distributions for genistein and conjugates. The model was first calibrated to each of the four doses separately, but this led to a distinct parameter set for each dose. Analysis of the parameter variation between doses suggests that several parameters in the model are concentration-dependent. When a single parameter set was fit to the data for all four doses the model over-predicted some data and under-predicted others in a manner that supports this conclusion. Possible explanations for this observed dose-dependence are that excretion into the bile duct is saturable or that genistein causes a dose-dependent change in the rate of biliary excretion. Ultimately, the dispersion model can serve as a template for other chemicals that undergo enterohepatic recirculation. (This research was supported by the American Chemistry Council.)

### 2031 MATHEMATICAL MODELING OF FAST AND SLOW GENISTEIN PHARMACOKINETICS (PK) IN RATS.

P. M. Schlosser<sup>1</sup>, S. J. Borghoff<sup>1</sup>, N. G. Coldham<sup>2</sup>, H. T. Tran<sup>3</sup> and <u>M. G. Zager<sup>1,3</sup>. <sup>1</sup>CIIT Centers for Health Research, Research Triangle Park, NC, <sup>2</sup>Department of Bacterial Diseases, eterinary Laboratories Agency, Surrey, United Kingdom and <sup>3</sup>Center for Research in Scientific Computation, NCSU, Raleigh, NC.</u>

Phytoestrogens such as genistein are endocrine-active compounds produced naturally by plants. High concentrations of genistein occur in soy products such as tofu and soy infant formula. Genistein is associated with a range of effects from chemoprevention of breast and prostate cancer and cardiovascular disease to observed reductions in weight and anogenital distances of rodents at birth. To estimate circulating levels of genistein during health-effects studies, physiologically based pharmacokinetic (PBPK) models for genistein in rats are being developed. Tissue concentration data were obtained in rats dosed with 4 mg/kg of  $^{14}$ C-genistein (IV or oral; 30-min to 48-hr time-points). These data show a terminal half-life of ~ 1 hr for elimination from the blood after IV dosing and rapid appearance in the blood after oral dosing (peak by 30 min). After oral dosing, total activity in gastro-intestinal (GI) tissue was 1-2 orders of magnitude greater than any other tissue and the elimination half-life from GI tissue was greater than 5 hr. An initial PBPK model with a single GI tissue compartment and perfusion- or diffusion-limited transport between the GI compartment and blood, could not describe these data. Because the oral doses were administered in corn oil, we considered uptake into GI-associate lymph tissues, which were assumed to be included in measures of total GI activity, and this allowed us to successfully describe the fast and slow PK after IV vs. oral dosing. We also observed biphasic elimination of genistein from serum after IV administration and found that it could be described if binding of genistein to serum proteins was included. Experimental evidence already exists for binding to serum proteins but the suggestion that transport is occurring via GI-associated lymph ducts should be confirmed experimentally. (This research was supported in part by the American Chemistry Council and the Food Standards Agency, UK.)

### 2032

A PRAGMATIC METHOD FOR SIMULATING THE PHARMACOKINETICS OF INTERACTING CHEMICALS IN MIXTURES: A CASE STUDY WITH TOLUENE IN MIXTURES.

K. Price and <u>K. Krishnan</u>. Occupational and Environmental Health, Universite de Montreal, Montreal, QC, Canada.

The change in tissue dose of components of mixtures is often a consequence of metabolic interactions. When metabolic interactions are well characterized, their impact on tissue dose can be simulated with PBPK models. It is not always possible to characterize all metabolic interactions, especially with increasing complexity of mixtures. The aim of this study was therefore to develop a pragmatic method that does not require interaction data for simulating change in kinetics of chemicals competing for hepatic metabolism during mixed exposures. A case study was undertaken to predict the inhalation pharmacokinetics of toluene in rats exposed to this chemical (50 or 100 ppm, 4 hr) in the presence of 50 or 100 ppm of increasing number of interacting chemicals (m-xylene, p-xylene, o-xylene, ethylbenzene, dichloromethane, benzene, perchloroethylene, trichloroethylene, styrene). The methodology involved the use of the individual chemical PBPK model for toluene along with the hepatic extraction ratio (E) specific for mixed exposures, calculated on the basis of total dose of mixture components expressed as toluene-equivalents. The results indicate that the E value for toluene changed from 0.71 for an individual exposure at 50 ppm to 0.08, 0.03 or 0.02 in mixtures of 4, 8 or 10 components, respectively. The E also decreased from 0.3 for a single exposure at 100 ppm to 0.07 or 0.03 during mixed exposures to 3 or 5 chemicals. With the use of the modified value of E in the toluene PBPK model, its blood concentrations during mixed exposures were simulated. The toluene blood concentrations at the end of 4-hr inhalation exposures, predicted by this method, for different mixture complexity (n = 2, 3, 4, 5, 8, 10), chemical combinations and exposure concentrations, varied by a factor of 0.9 to 1.2 of experimental values previously obtained in the rat. These results suggest that the kinetics of chemicals in mixtures can be predicted using individual chemical PBPK models, when competitive inhibition is the underlying interaction mechanism.

#### 2033

A GENERAL PHYSIOLOGICAL AND TOXICOKINETIC (GPAT) MODEL FOR SIMULATION OF COMPLEX TOLUENE EXPOSURE SCENARIOS IN HUMANS.

E. M. Kenyon<sup>1</sup>, T. Colemen<sup>2</sup>, C. Eklund<sup>1</sup> and V. Benignus<sup>3</sup>. <sup>1</sup>ORD/NHEERL, USEPA, Research Triangle Park, NC, <sup>2</sup>Biological Simulators, Inc., Jackson, MS and <sup>3</sup>HSD, USEPA, Chapel Hill, NC.

Many environmental exposure scenarios require dynamic methods in which exposures and human activities vary continuously as a function of time. Simulation of physiological scenarios with commonly available software packages and simulation languages is often highly programming intensive and complex. To simplify this process, a "whole-body" human physiological simulation model, Quantitative Circulatory Physiology, Research Version 4.0, (QCP4), was coupled with a physiologically-based toxicokinetic (PBTK) model for toluene. Chemical-specific parameters and initial organ volumes and blood flow rates were obtained from the literature. Compartments in the model included lung, slowly and rapidly perfused tissue groups, fat, liver, gut and brain. QCP4 updated changing physiological parameters required by the PBTK model appropriate to varying activity level of the human subject as the model was iteratively executed over time. The GPAT model adequately predicted toluene blood concentrations under varying exercise levels and exposure scenarios from 4 different studies reported in the peer reviewed literature. In comparison to a similar model executed in Advanced Continuous Simulation Language (ACSL), the GPAT model required less coding and had greater flexibility to vary activity levels. The coupled GPAT modeling framework can also simulate physiological alterations in response to changes in altitude, temperature, diet, and illness. When linked with a toxicokinetic model this provides a powerful tool for both risk assessment (e.g., effects on sensitive subpopulations) and experimental design applications. (This abstract does not necessarily reflect EPA policy.)

#### 2034

IMPACT OF PEAK EXPOSURE AND BIOLOGICAL VARIABILITY ON THE KINETICS OF TOLUENE IN MAN - A PBTK ANALYSIS.

J. Bessems, J. Lammers, G. Schaafsma, T. Bouwman, L. Ravensberg and A. Freidig. *Toxicological Risk Assessment, TNO Chemistry, Zeist, Netherlands.* Sponsor: V. Feron.

Occupational exposure limits generally reflect to time-weighted average exposures and an average healthy worker. However, peak exposures and interindividual variation in physiological and biochemical parameters may influence dosimetry. Using a PBTK (physiologically based toxicokinetic) modeling approach and toluene as model compound, we investigated the impact of these variables on internal exposure. Male volunteers were exposed by inhalation to a constant toluene concentration of 40 ppm for 4 h or to three peaks of 110 ppm for 0.5 h (within 4 h) such as to make total dose similar in both exposure scenarios. Blood toluene concentration (BTC) and urinary o-cresol excretion were measured. In the constant exposure scenario, BTCs increased constantly. For some individuals, it appeared that BTC was almost reaching equilibrium after 4 h. For this scenario, the largest interindividual differences in BTCs during exposure were about a factor of two. BTCs were very similar 2 h after the exposure had stopped. In the peak scenario, external peaks were reflected by fluctuating BTCs, with the highest BTC measured at the end of the third exposure peak. At this time-point, the lowest and highest BTC differed about a factor of two again. Our PBTK simulation provided a fairly good prediction of the means of the BTCs in both exposure scenarios. According to model calculations, BTC appeared not to be impacted by interindividual variation in body weight and body fat content nor to variation in the blood:air partition coefficient. In contrast, the model was sensitive to changes in the metabolic clearance parameters Vmax and Km as well as to changes in the blood flow to the fat compartment and the liver compartment. It is concluded that the impact of peak exposure and variability in biological parameters on BTC can be modeled reasonably well using the PBTK approach. PBTK modeling may provide an additional instrument in the setting of short-term exposure limits (STEL), thereby taking into account human variability in physiological and biochemical parameters.

### 2035

PRELIMINARY DEVELOPMENT OF PHYSIOLOGICALLY-BASED PHARMACOKINETIC/ PHARMACODYNAMIC(PBPK/PD) MODEL FOR LOW LEVEL EXPOSURE TO CHEMICAL WARFARE AGENT (CWA) IN MINIPIG.

K. O. Yu<sup>1</sup>, R. J. Mioduszewski<sup>2</sup>, E. M. Jakubowski<sup>2</sup>, S. Hulet<sup>2</sup>, <u>S. M. Thompson</u><sup>2</sup> and <u>J. M. Gearhart</u><sup>1</sup>. <sup>1</sup>Air Force Research Laboratory, US Air Force, Wright-Patterson AFB, OH and <sup>2</sup>Edgewood Chemical and Biological Center, US Army, Aberdeen Proving Ground, MD.

Chemical warfare organophosphorous agents inhibit acethylcholine esterase (AChE) that hydrolyzes a neurotransmitter, acethylcholine. A PBPK/PD model for the CWA sarin was developed in a miniature swine (Gottingen strains) to better es-

timate human exposure compared to rodent models. The vapor exposure data and model have different routes including inhalation and absorption through dermal and ocular contact. The majority of organ volumes and blood flows of the minipig were obtained from the literature, while some parameter values were scaled from other species using standard allometric relationships. Since one of the observed effects of low-level Sarin exposure is constriction of the ocular pupil (miosis), the ocular compartment for eyes was added to address this pharmacodynamic effect. In this model sarin is absorbed through the eyes where it internally binds with AChE. Pupil constriction from external, systemic or combined delivery of sarin could be predicted based on AChE inhibition in the ocular muscles. The PBPK/PD model was used to simulate AChE inhibition after different routes and different doses of exposure and to predict potential pharmacodynamic effects at the eye and other target tissues. Sensitivity analysis will be performed to find which model parameters have the greatest influence on AChE inhibition. This model will provide quantitative dose-response relationships to assess the physiologically significant consequences of low-level exposures of sarin in the minipig.

#### 2036

A QUANTITATIVE DESCRIPTION OF SUICIDE INHIBITION OF DICHLOROACETIC ACID IN RATS AND MICE.

D. A. Keys<sup>1</sup>, I. R. Schultz<sup>2</sup>, R. D. Stenner<sup>3</sup>, D. A. Mahle<sup>4</sup> and J. W. Fisher<sup>1</sup>.

<sup>1</sup>Environmental Health Science, University of Georgia, Athens, GA, <sup>2</sup>Pacific Northwest Division, Battelle, Sequim, WA, <sup>3</sup>Pacific Northwest Division, Battelle, Richland, WA and <sup>4</sup>Mantech Environmental Technology Inc., Dayton, OH.

Dichloroacetic acid (DCA) is a minor metabolite of trichloroethylene that remains an important risk assessment issue because of its carcinogenic potency and its distribution in water supplies as a production of chlorination. DCA has been shown to inhibit its own metabolism by irreversibly inactivating glutathione transferase zeta (GSTZ). To better predict internal dosimetry of DCA, a physiologically based pharmacokinetic model was developed which included a description of DCA suicide inhibition. Suicide inhibition was described dynamically by having the rate of maximal metabolism of DCA (Vmaxt) vary with time. Resynthesis (zero-order) and degradation (first-order) of metabolic activity were also described. Published iv pharmacokinetic studies in rats following exposure to 1, 5, or 20 mg/kg DCA were used to estimate initial VmaxC and Km values. Degradation and resynthesis rates were set at values estimated previously from rat immunoreactive GSTZ protein time courses. The first-order inhibition rate, kd, was estimated to these same GSTZ protein time courses. Residual linear metabolism (Kfc) was estimated from DCA time courses following exposure to DCA in drinking water. With all parameters set to estimated values, the PBPK model predictions were validated by comparing predicted DCA concentrations to measured DCA time courses in published studies of rats pre-treated with DCA following iv exposure to 0.05, 0.25, 1, 5 or 20 mg/kg DCA. The same model structure was used to simulate DCA time-courses following 5, 20 and 100 mg/kg iv exposures in naive and pre-treated mice and exposure of mice to DCA in drinking water. Comparisons of PBPK model predicted values to measured was favorable lending support for the further development of this model for application to DCA or TCE human health risk assessment. (Supported by DOE Coop. Agreement DE-FC09-02CH11109)

### 2037 PBTK-TD MODEL FOR ACUTE POISONING BY HYDROGEN CYANIDE.

G. Johanson. Work Environment Toxicology, IMM, Karolinska Institutet, Stockholm,

Several studies suggest that fire fatalities are primarily caused by fire smoke. Hydrogen cyanide (HCN), formed in the combustion of polyurethane and other N-containing materials, may contribute significantly. The low awareness of this risk is in part due to lack of knowledge on the absorption, distribution, metabolism, and excretion (ADME) of HCN. Further, it is dificult to estimate HCN exposure in fire victims since HCN is eliminated from blood also after death. Yet a number of studies show markedly elevated blood HCN levels in fire victims and even higher levels in deceased victims. The aim of this study was to develop a PBTK-TD model for HCN, as no such models have hitherto been published. The model has 5 compartments: lungs, plasma/liver, muscle tissues, other tissues, sulphur pool. Chemical independent model parameters were taken from the literature. Chemical dependent parameters (partition coefficients, sulphur-dependent saturable detoxification to thiocyanate, and saturable methemoglobin binding) were estimated from published studies on HCN. The effect of exercise on ADME was also incorporated. The TD model describes the degree of cytochrome oxidase inhibition as a sigmoid function of plasma HCN. The cut-off level for acute toxicity (lethality) was set to 70% inhibition. All simulations were performed with Berkeley Madonna. The model accurately reflected reported fatal HCN air and blood levels. Simulated human exposures agreed well with experimental animal data. Thus, the model predicted a value of 1.8 compared to 1.9 in monkeys for the exponent n in the equation  $C^n \times T = k$ , where C is the exposure concentration and T the time to lethality.

The strong non-linearity in kinetics and dynamics is further illustrated by T values of 13 h and 1 h for exposures to 50 ppm and 200 ppm HCN, respectively. The influence of work was also dramatic. At light exercise (50W) the corresponding T valued a dropped to 1.5 h and 0.15 h. The PBTK-TD model for HCN may be used to study different exposure scenarios, to improve the basis for diagnosis and treatment, and for Acute Exposure Guideline Levels (AEGLs).

### 2038

DEVELOPMENT OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL FOR DECANE, A CONSTITUENT OF JET PROPELLENT-8.

R. Perleberg<sup>1</sup>, <u>D. A. Keys</u><sup>1</sup>, J. L. Campbell<sup>1</sup>, W. Everett<sup>1</sup>, A. Q. Smith<sup>1</sup>, T. Almekinder<sup>1</sup>, K. Frank<sup>1</sup>, M. G. Bartlett<sup>2</sup> and <u>J. Fisher<sup>1</sup></u>. Environmental Health Science, University of Georgia, Athens, GA and Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA.

Decane, a 10 carbon alkane, is one of the highest vapor phase constituents of jet propellent-8 (JP-8). Decane was selected as a representative compound of the semi-volatile fraction of JP-8. Male Fisher 344 rats were exposed to decane vapors in a 31 L leach chamber for 4 hours to time weighted average (TWA) concentrations of either 1200, 781, or 273 ppm. Time course samples for the 1200 ppm decane exposure were collected from blood, brain, liver, fat, bone marrow, lung, skin, and spleen tissues, while end of exposure samples were collected with these tissues for 781 and 273 ppm vapor exposures. A physiologically based pharmacokinetic (PBPK) model for decane was developed using flow-limited (liver and lung) and diffusion-limited (brain, bone marrow, fat, skin, and spleen) equations to describe the uptake and the clearance of decane in the blood and tissues. *In vivo* partition coefficient values for blood/air and tissue/blood were estimated by fitting end of exposure blood and tissue concentrations. Decane pharmacokinetic behavior is unlike short chain halogenated hydrocarbons, which are described primarily by flow-limited conditions using in-vitro derived partition coefficients.

### 2039 DEVELOPMENT OF A PBPK-CHEMICAL LUMPING MODEL FOR GASOLINE VOLATILES.

J. E. Dennison<sup>1</sup>, M. E. Andersen<sup>2</sup>, H. J. Clewell<sup>3</sup>, M. M. Mumtaz<sup>4</sup> and R. S. Yang<sup>1</sup>. <sup>1</sup>ERHS, Colorado State, Fort Collins, CO, <sup>2</sup>CIIT Centers for Health Research, Research Triangle Park, NC, <sup>3</sup>Environ Corp, Ruston, LA and <sup>4</sup>ATSDR, Atlanta, GA.

A PBPK model was previously developed for several representative GASOLINES using a 6-component mixture model structure. We extended the model to volatile components of gasoline, reflecting common human exposures. The mixture PBPK model includes benzene, toluene, ethylbenzene, o-xylene, and n-hexane and a lumped component that represents all remaining components. Competitive inhibition of saturable metabolism between each component was included. We prepared samples of gasoline that were enriched in the more volatile components by heating the liquid and collecting the vapors. Samples represented (1) the first third of the neat liquid to evaporate and (2) the first two thirds to evaporate. Closed chamber experiments were performed with male F344 rats using an autosampling gas uptake system with GC/FID. At higher exposure concentrations, the data indicated that ventilation rates (QP) declined, possibly due to irritation and/or CNS depression. The best fits were obtained with QPs of 12.5, 13.5 and 14.9 L/hr/kg^0.74 for high, medium, and lower exposures. The different fractions required modification of the blood:air partition coefficient (PB) for the lumped chemical. The optimal PBs were 1.6, 2.3, and 3.0 for the 1/3 cut, 2/3 cut, and whole gasoline, respectively. Other parameters were similar to those used in the previous model. Except for o-xylene, which may be affected by absorption to the animals fur, an excellent correspondence between the model and the chamber uptake data was obtained for all chemicals, including the lumped chemical. We conclude that complex mixture PKs can be described using this lumping approach and that different fractions of a mixture can be incorporated into the general method with appropriate adjustments in physicochemical parameters.

### 2040

PHYSIOLOGICAL MODELING OF DECAMETHYLCYCLOPENTASILOXANE (D5) INHALATION KINETICS IN RATS AND HUMANS.

M. Reddy<sup>1</sup>, J. M. Tobin<sup>2</sup>, D. A. McNett<sup>2</sup>, M. L. Jovanovic<sup>2</sup>, M. J. Utell<sup>3</sup>, P. E. Morrow<sup>3</sup>, K. P. Plotzke<sup>2</sup> and M. E. Andersen<sup>4</sup>. <sup>1</sup>Quantitative Toxicology Group, Center for Environmental Toxicology and Technology, Colorado State University, Fort Collins, CO, <sup>2</sup>Toxicology, Health and Environmental Sciences, Dow Corning Corporation, Midland, MI, <sup>3</sup>Departments of Medicine and Environmental Medicine, University of Rochester Medical Center, Rochester, NY and <sup>4</sup>Division of Biomathematics and Physical Sciences, CIIT Centers for Health Research, Research Triangle Park, NC.

D5 is a silicone fluid used in a variety of consumer applications including personal care. An extensive dataset of D5 distribution in the rat following inhalation exposure was used to develop a physiologically based pharmacokinetic (PBPK) model.

The D5 model followed a similar model structure that successfully described the distributional characteristics of another cyclic siloxane, octamethylcyclotetrasiloxane (D4). The rat model structure for D5 incorporated deep compartments in the lung and liver and had two fat compartments as well as an unusual combination of low blood:air and high fat:blood partitioning. For the disposition of D5 in humans, a PBPK model structure was developed based on the rat model but was simplified due to the less extensive human dataset. However, a similar model structure successfully described D5 pharmacokinetics in both rats and humans. A key component of both the rat and human model was a sequestered pool of D5 that was presumed to be in lipoproteins. This bound D5 was released from the liver, distributed by the blood and cleared into the fat. Although D5 metabolism is essentially flow-limited, due to its low blood:air partition coefficient (0.2 in rats and 0.5 in humans in vivo), the primary mechanism of D5 elimination was exhalation. Despite high fatiblood partitioning, D5 is not expected to accumulate due to rapid clearance by exhalation and metabolism. Supported in part by the Silicones Environmental, Health and Safety Council of North America.

INCORPORATION OF THE GENETIC CONTROL OF ALCOHOL DEHYDROGENASE INTO A PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL FOR ETHANOL IN HUMANS.

G. M. Pastino<sup>2</sup>, L. G. Sultatos<sup>1</sup>, C. A. Rosenfeld<sup>1</sup> and E. J. Flynn<sup>1</sup>.

<sup>1</sup>Pharmacology and Physiology, UMD- New Jersey Medical School, Newark, NJ and

<sup>2</sup>Schering-Plough Research Institute, Lafayette, NJ.

The assessment of the variability of human responses to foreign chemicals is an important step in characterizing the public health risks posed by non-therapeutic hazardous chemicals, as well as the risk of encountering adverse reactions with drugs. Of the many sources of interindividual variability in chemical response so far identified, hereditary factors are some of the least understood. Physiologically based pharmacokinetic modeling linked with Monte Carlo sampling has been shown by various investigators to be a useful tool for quantification of interindividual variability in chemical disposition and/or response when applied to biological processes that displayed single genetic polymorphisms. The current project has extended this approach by modeling the complex hereditary control of alcohol dehydrogenase, which includes polygenic control, as well as polymorphisms at two allelic sites. The physiologically based pharmacokinetic model for ethanol indicated that peak blood ethanol levels and time to peak blood ethanol levels were marginally affected by alcohol dehydrogenase genotypes, with simulated subjects possessing the B2 subunit having slightly lower peak blood ethanol levels and shorter times to beak blood levels compared to subjects without the B2 subunit. In contrast, the area under the curve (AUC) of the ethanol blood decay curve was very sensitive to alcohol dehydrogenase genotype, with AUCs from any genotype including the ADH1B2 allele considerably smaller than AUCs from any genotype without the ADH1B2 allele. Furthermore, the AUCs in the ADH1C1/C1 genotype were moderately lower than the AUCs from the corresponding ADH1C2/C2 genotype. Moreover, these simulations demonstrated that interindividual variability of ethanol disposition is affected by alcohol dehydrogenase, and that the degree of this variability was a function of the ethanol dose. (Supported by a grant from the American Chemistry Council).

#### 2042

TOWARDS A GENERIC PBPK MODEL OF PYRETHROID PESTICIDES: MODELING DELTAMETHRIN AND PERMETHRIN IN THE RAT.

R. Tornero-Velez<sup>1</sup>, H. Nichols<sup>4</sup>, M. V. Evans<sup>2</sup>, M. J. DeVito<sup>2</sup>, C. C. Dary<sup>1</sup>, M. Dellarco<sup>3</sup> and J. N. Blancato<sup>4</sup>. <sup>1</sup>National Exposure Research Laboratory, USEPA, Las Vegas, NV, <sup>2</sup>National Health and Environmental Effects Research Laboratory, USEPA, Research Triangle Park, NC, <sup>3</sup>National Center for Environmental Assessment, USEPA, Washington DC, DC and <sup>4</sup>National Exposure Research Laboratory, USEPA, Research Triangle Park, NC.

Pyrethroids have emerged as a major class of insecticide due to their selective potency in insects and their relatively low potency in mammalian studies. Pyrethroids exert toxicity by binding to voltage-gated sodium channels, thereby eliciting excitatory neurotoxicity. The Food Quality Protection Act (FQPA) of 1996 requires the USEPA to consider the cumulative effects (multiple chemicals by aggregate routes of exposure) of pesticides having a common mechanism of toxicity. In such evaluations it is necessary to accurately estimate the dose available to critical tissues. Towards this end, studies examining the pharmacokinetics of permethrin and deltamethrin in rodents were used to derive a common PBPK model structure. The model included skin, fat, liver, brain, and lumped tissue compartments. Physiological values were obtained from the literature. Tissue-blood partition coefficients were based on Log P and tissue composition. Diffusion-limited tissue uptake in all tissues provided a better visual fit to the data than flow-limited kinetics. Apparent coefficients of permeability were held constant for both pyrethroids at 5% of tissue flow for fat and muscle tissues, 2% for brain tissue, and 0.2% for richly

perfused tissue. While the terminal half life of deltamethrin in blood was 2.5 times longer than permethrin, the kinetics of these two pyrethroids were adequately described by the same model structure. This initial modeling exercise suggests that the kinetics of other pyrethroids may be described by a common model structure. This may allow the development of a single unified PBPK model for use in the cumulative risk assessment of pyrethroid pesticides. (This work has been funded by the United States Environmental Protection Agency. It has been subjected to Agency review and approved for publication).

## 2043 PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODELING OF CHLOROETHANE DISPOSITION AND GLUTATHIONE DEPLETION.

L. M. Sweeney<sup>1</sup>, J. W. Holder<sup>2</sup> and M. L. Gargas<sup>1</sup>. <sup>1</sup>The Sapphire Group, Dayton, OH and <sup>2</sup>USEPA, Washington, DC.

A validated physiologically based pharmacokinetic (PBPK) model of chloroethane (CE) for rats, mice, and humans would useful for assessing internal dose-response relationships and performing high-to-low dose and interspecies extrapolations. Such extrapolation is useful because of species differences in incidence of uterine tumors in ĈE-exposed animals in a single, high-concentration bioassay. An existing PBPK model for chloroethane in rats (Gargas et al., 1990) was evaluated, expanded, and refined. Considerations in the expansion and refinement were the available pharmacokinetic data pertinent to evaluation of chloroethane disposition and potential mode(s) of action for uterine cancer observed in the bioassay. Physiologic compartments were included for complete mathematical description as related to potential mode(s) of action in target organs, storage depots, major site of oxidative metabolism and glutathione (GSH) conjugation, secondary sites of GSH metabolism with available GSH depletion data, and for tissue mass/blood flow balance. Rat model parameters were taken from the literature (physiology, partitioning, and oxidative metabolism by cytochrome P450) or determined through best fit methods for the most complete data set for CE-induced GSH depletion (parameters for GSH conjugation and synthesis). Limited validation was achieved by comparison to other GSH depletion data sets and studies in which 14C-CE exhalation was monitored in 14C-CE-exposed rats. Model predictions were used to elucidate the behavior, as inhaled concentration increases (1-15000 ppm), of the flux through two elimination pathways, and blood and tissue concentrations. Nonlinear behaviors were observed due to saturation of oxidative metabolism and GSH conjugation with increasing inhaled concentration. Similar high-dose nonlinear kinetic behaviors are anticipated for mice, a species susceptible to CE-induced uterine tumors; such behavior may have implications for identification of potential mode of action and risk assessment of chloroethane in humans.

## PARTITIONING OF BISPHENOL A (BPA) IN RAT TISSUE FOR PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODELING.

I. A. Ross<sup>1</sup>, <u>H. M. Luu</u><sup>2</sup>, P. P. Sapienza<sup>1</sup>, W. Johnson<sup>1</sup>, J. C. Hutter<sup>2</sup> and C. S. Kim<sup>1, 2</sup>. <sup>1</sup> Toxicology, US Food and Drug Administration, Laurel, MD and <sup>2</sup>Radiological Health, USFDA, Rockville, MD.

The rat tissue partitioning of BPA in artificial cerebrospinal fluid (CSF) for brain and Krebs phosphate buffer (Krebs) for other organs was measured in vitro by using the BPA concentration ratio of tissue to medium at steady state. Tissue slices were prepared and incubated in artificial CSF or Krebs, containing 14C-BPA (140, 000 dpm/ml medium, sp. act. 55 mCi/mmol) plus cold BPA 0.1 mg/ml medium. The tissues were incubated under 95% oxygen/5% carbon dioxide at 37oC with constant agitation until steady-state uptake was reached (90 min). At the end of the incubation period, tissue slices were processed for radioactivity measurement. The BPA tissue/blood or tissue/CSF partition coefficients were estimated by dividing tissue concentration (mg/g) by incubation medium concentration (mg/ml) in Krebs or CSF. The following results were obtained from the study: heart, 7.5; liver, 6.1; kidney, 6.4; fat, 3.6; muscle, 2.6; breast, 3.6; ovaries, 9.1; uterus, 5.9; stomach, 5.1; small intestine, 6.7; pituitary gland, 12.8; brain stem, 6.1; cerebellum, 6.4; hippocampus, 7.1; hypothalamus, 6.1; frontal cortex, 4.9 and caudate nucleus, 6.8. This information is a requisite for constructing the PBPK model of BPA for its quantitative risk assessment.

## 2045 HALOACETIC ACID PHARMACOKINETICS IN RHESUS MONKEYS AND HUMANS: CLASSICAL AND PBPK MODELING APPROACHES.

I. Schultz<sup>1</sup>, R. E. Shangraw<sup>2</sup>, R. D. Stenner<sup>3</sup>, D. A. Keys<sup>4</sup> and J. W. Fisher<sup>4</sup>.

<sup>1</sup>Battelle PND, Sequim, WA, <sup>2</sup>OHSU, Portland, OR, <sup>3</sup>Battelle PND, Richland, WA and <sup>4</sup>University of Georgia, Athens, GA.

Halogenated acetic acids (HAs) are a major class of drinking water disinfection byproduct. Several of the chlorine and bromine substituted forms are established rodent carcinogens and reproductive/developmental toxins. Epidemiological studies

have not ruled out a link between disinfection by-product exposure and adverse reproductive outcomes. Because of potential health risks, current EPA standards limit the combined total of five common HAs in drinking water to 60 ug/L with an eventual goal of eliminating certain HAs from drinking water. Thus, improving the understanding of HA pharmacokinetics and oral bioavailability is critical to accurately assessing public health. However, measurement of HA pharmacokinetics in humans at actual drinking water exposure rates is problematic because of analytical detection limitations and the influence of prior exposures. In our studies, we measured dichloroacetate (DCA; used as a model di-HA) bioavailability in human volunteers and tri-HA bioavailability in rhesus monkeys (used as a surrogate for humans) using a semi-simultaneous experimental design. Volunteers were given an oral dose of 12C-labeled DCA followed 10 min later by a iv dose of 13C-labeled DCA, which serves as a reference for elimination. Monkeys were given a mixture of four 12C / 13C labeled tri-HAs. To reduce the influence of prior exposure, volunteers or monkeys were provided purified drinking water for 2 weeks prior to studies. Estimation of bioavailability using classical PK modeling approaches indicated large inter-volunteer variation ranging from 5 - 65 %. A previous PBPK model for DCA based on rodent and human in vitro data proved inadequate for describing the observed data due to underestimation of peak plasma levels and observed elimination rates. A modified PBPK model was developed that more accurately describes oral absorption and incorporates key aspects of tri-HA disposition. (Supported by EPA STAR grants R825954, R825954).

#### 2046

A PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODEL FOR INTRAVENOUS AND INHALATION-ROUTE PHARMACOKINETICS OF BUTYL ACETATE (BA) AND METABOLITES N-BUTANOL (BOH) AND N-BUTYRIC ACID (BOOH).

J. G. Teeguarden<sup>1</sup>, P. J. Deisinger<sup>2</sup>, T. S. Poet<sup>3</sup>, C. English<sup>2</sup>, R. A. Corley<sup>3</sup>, H. A. Barton<sup>4</sup>, H. J. Clewell<sup>1</sup> and W. D. Faber<sup>5</sup>. <sup>1</sup>ENVIRON Health Sciences Institute, Collegeville, PA, <sup>2</sup>Eastman Kodak Co., Rochester, NY, <sup>3</sup>PNNL, Richland, WA, <sup>4</sup>NHEERL, USEPA, Research Triangle Park, NC and <sup>5</sup>WFTC, LLC, Victor, NY.

Risk assessment for n-butyl acetate and metabolites n-butanol and n-butyric acid (the butyl series) can be accomplished with limited toxicity data and pharmacokinetic data for each compound through application of the "family approach" (Barton et al., 2000). The necessary quantitative and interpretive tool is a PBPK model describing the inhalation-route blood kinetics of the series members. A series of revisions of the initial model were carried through to validation of the inhalation route (BA and BOOH) for male SD rats. Rats were implanted with dual indwelling cannulae and administered BA, BOH or BOOH by IV bolus dose, IV infusion or by inhalation in a recirculating closed chamber. Hepatic, vascular and extravascular metabolic constants for metabolism were estimated by fitting the model to the blood time course data. The respiratory bioavailability of BA (100%) and BOH (~50%) was estimated from a novel closed chamber inhalation study design (Poet, 2002) involving simultaneous measurement of ventilation rates, chamber loss (uptake) and blood kinetics. The resulting PBPK model successfully reproduces the blood time course of these compounds following inhalation exposure to BA and BOH, verifying the description of the blood kinetics based on i.v. studies. This effort highlights the value of new, cost effective dosimetry based approaches to risk assessment for metabolically related compounds. (This abstract does not represent EPA policy).

### 2047

DEVELOPMENT OF A PRIMATE PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODEL FOR DI-2ETHYLHEXYL PHTHALATE AND ITS METABOLITE MONO-2ETHYLHEXYL PHTHALATE.

E. D. McLanahan<sup>1</sup>, <u>R. Conolly<sup>2</sup></u> and D. Keys<sup>1</sup>. <sup>1</sup>Environmental Health Science, University of Georgia, Athens, GA and <sup>2</sup>Center for Computational Biology & Extrapolation Modeling, CIIT Centers for Health Research, Research Triangle Park, NC.

Di-2ethylhexyl phthalate (DEHP) is a commercially important plasticizer and environmental contaminant. Many studies have established that oral dosing of DEHP in rats and mice results in testicular toxicity and teratogenic effects at high doses. In contrast, non-human primates appear relatively insensitive to the testicular effects of DEHP. DEHP is rapidly metabolized in the gut to mono-2ethylhexyl phthalate (MEHP), which is the active metabolite for testicular toxicity. A physiologically based pharmacokinetic (PBPK) model for DEHP and MEHP has been developed in adult male rats previously. The objective of this work was to test the hypothesis that the same PBPK model structure developed for the rat could adequately predict primate pharmacokinetic data. Blood concentrations of DEHP and MEHP were available in marmosets following single and repeated oral exposures to 30 and 500 mg/kg DEHP. Physiological parameters were set to marmoset-specific values. Simple allometric scaling of metabolic parameters was inadequate for predicting

blood concentrations. Metabolic and absorption parameters were fit to the marmoset pharmacokinetic data. The maximum rate of marmoset metabolism of DEHP to MEHP in the gut, VmaxgC (mg/hr/kg<sup>0.75</sup>) was lower than previously estimated for the rat, indicating a species difference in DEHP gut metabolism. Alternatively, the fecal loss rate, loss (1/hr) was higher in the primate model than the rat model, suggesting less complete absorption. The MEHP concentration time courses following repeated exposure were well predicted with parameters estimated from acute exposure time courses. Once validated, a primate PBPK model for DEHP will be able to predict dose metrics for use in human health risk assessment. (Supported by a gift from the American Chemistry Council)

USING *IN VIVO* GAS UPTAKE STUDIES TO ESTIMATE METABOLIC RATE CONSTANTS FOR CCL CHEMICALS: 1, 1-DICHLOROPROPENE AND 2, 2-DICHLOROPROPANE.

C. T. Mitchell, M. V. Evans and E. M. Kenyon. ORD/NHEERL, USEPA, Research Triangle Park, NC.

The Safe Drinking Water Act Amendments of 1996 required the USEPA to develop Candidate Contaminant Lists (CCL), to aid in the setting of priorities for the Agency's drinking water research program. 1, 1-Dichloropropene (1, 1-DCPe) and 2, 2-dichloropane (2, 2-DCP) are two of the high priority chemicals identified from the first CCL. Since both are volatile organic compounds, the gas uptake technique was used to estimate rates of metabolism. The gas uptake system is a closed inhalation chamber system in which an initial bolus injection of chemical is made into the chamber, and allowed to decline to obtain a set of decay curves. Individual male F344 rats (200-250g) were exposed to initial chamber concentrations of 50 ppm, 200 ppm, 500 ppm, or 1200 ppm of either 2, 2-DCP or 1, 1-DCP for up to six hours (n=4 rats/exposure level/chemical). Each rat was exposed only once to a single concentration of each chemical. Partition coefficients were estimated using a published quantitative structure-property relationship methodology (Beliveau et al., 2003). These partition coefficients were used with the PBPK model to generate estimates of VmaxC (mg/hr/kg) and KM (mg/L). Optimized VmaxC and KM were 4.9 and 3.17, respectively, for 2, 2-DCP. Optimized VmaxC and KM were 5.76 and 0.31, respectively, for 1, 1-DCPe. The shape of the gas uptake curves for 2, 2-DCP compared to 1, 1-DCPe and the V/K ratios suggest that 2, 2-DCP is more slowly metabolized. These metabolic rate estimates are critical parameters for PBPK models that can ultimately be used for animal to human extrapolation. They are also a vital part of a developing data base comparing in vivo to in vitro methods for determination of metabolic rate parameters. (This abstract does not reflect EPA policy).

HUMAN MITOCHONDRIAL DNA AMPLIFICATION AND SEQUENCING STANDARD REFERENCE MATERIALS 2392 AND 2392-I.

B. C. Levin<sup>1</sup>, D. K. Hancock<sup>1</sup>, H. Cheng<sup>1</sup>, K. Holland Deckman<sup>2</sup> and K. L. Richie<sup>1</sup>. <sup>1</sup>Biotechnology Division, National Institute of Standards and Technology, Gaithersburg, MD and <sup>2</sup>Chemistry Department, Gettysburg College, Gettysburg, PA.

The National Institute of Standards and Technology (NIST) supplies industry, academia, and government with over 1300 Standard Reference Materials (SRMs) of the highest quality. These SRMs provide laboratories the quality control and assurance that their results with unknown samples are accurate and compatible with other measurements. NIST has revalidated the human mitochondrial DNA (mtDNA) SRM 2392 and developed the new SRM 2392-I to provide quality control when performing the polymerase chain reaction (PCR) and sequencing of mtDNA for forensic identification, medical diagnosis, or mutation detection. They may also serve as controls when performing PCR and sequencing any DNA. SRM 2392 is certified for the sequences of the entire human mtDNA (16, 569 base pairs) from two lymphoblastoid cell lines (CHR and 9947A) from apparently normal individuals and the cloned HV1 region of CHR containing a C-stretch, following which it is difficult to sequence. SRM 2392-I is certified for the entire mtDNA sequence from HL-60, a promyelocytic cell line from the blood leukocytes from an individual with acute promyelocytic leukemia. The mtDNA sequences (but not the DNA) from two other cell lines (GM03798 and GM10742A) that were amplified and sequenced in their entirety at NIST are provided for information and comparison purposes. The sequences of fifty-eight unique primer sets that allow any area or the entire mtDNA to be amplified and sequenced under the same conditions are also given. Many of the single nucleotide polymorphisms (SNPs) found in these five mtDNA templates did result in amino acid changes when compared with the Cambridge Reference Sequence. Two interlaboratory evaluations for the amplification, sequencing, and data analysis of SRM 2392 and SRM 2392-I were each conducted by three different laboratories and NIST. Corroboration of the results in these SRMs will provide quality assurance that any unknown mtDNA is also being amplified and sequenced correctly.

POLYMORPHISMS IN CYTOCHROME P4503A5 (CYP3A5) MAY BE ASSOCIATED WITH TUMOR SIZE IN BREAST CANCER PATIENTS.

A. N. Deigert, L. Lewis, K. Tkaczuk and J. Flaws. Epidemiology and Preventive Medicine, University of Maryland, Baltimore, MD.

CYP3A5 is one of the most important members of the cytochrome P450 superfamily. Although this enzyme has been shown to have two polymorphisms (CYP3A5\*3 and CYP3A5\*6), little is known about the prevalence of these polymorphisms, and whether they are associated with biologic outcomes. Since polymorphisms in other enzymes differ by race, and have been associated with tumor characteristics, the purpose of this work was to test the hypothesis that there are racial/ethnic differences in the odds of having a CYP3A5 polymorphism and that polymorphic status in CYP3A5 affects tumor status in women with breast cancer. To test this hypothesis, 107 women with breast cancer were recruited from a single clinic at the University of Maryland. Each patient completed a survey that obtained information on race and potential confounding factors (age, date at diagnosis, body mass index) and provided a blood sample. Information on tumor characteristics (size, receptor status, nodal involvement) was collected by abstraction of medical records. Blood samples from each patient were subjected to genomic DNA extraction followed by PCR for CYP3A5\*3 and CYP3A5\*6. The associations between race, polymorphic status, and tumor characteristics were assessed using t-tests and logistic regression models. The data indicate that 40.7% of the women had the CŸP3A5\*3 polymorphism, and 9.1% had the CYP3A5\*6 polymorphism. In addition, white women were 26 times more likely to carry the CYP3A5\*3 polymorphism than black women, whereas black women were 9 times more likely to carry the CYP3A5\*6 polymorphism than white women. Further, there was significant difference in mean tumor size in women with the CYP3A5\*6 polymorphism  $(3.6 \text{cm} \pm 0.98)$  compared to those without the polymorphism  $(2.0 \text{cm} \pm 0.18)$ (p<0.02). These findings suggest that there are racial/ethnic differences in the prevalence of CYP3A5 polymorphisms, and that polymorphic status may be associated with the size of breast tumors. GSTP1 A1578G (ILE105VAL) POLYMORPHISM IN BENZIDINE-EXPOSED WORKERS: AN ASSOCIATION WITH CYTOLOGICAL GRADING OF EXFOLIATED UROTHELIAL CELLS.

Q. Ma<sup>1</sup>, G. Lin<sup>1</sup>, Y. Qin<sup>2</sup>, D. Lu<sup>3</sup>, <u>K. Golka</u><sup>4</sup>, F. Geller<sup>5</sup>, C. Jigang<sup>2</sup> and J. Shen<sup>1</sup>. <sup>1</sup>Institute of Plant Physiology and Ecology, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences, Shanghai, China, <sup>2</sup>Disease Prevention and Control, Municipal Center, Shanghai, China, <sup>3</sup>State Key Laboratory of Genetics Engineering, Fudan University, Shanghai, China, <sup>4</sup>Institute for Occupational Physiology, University of Dortmund, Dortmund, Germany and <sup>3</sup>Institute of Medical Biometry and Epidemiology, Philipps-University Marburg, Marburg, Germany.

A polymorphism at codon 105 (Ile/Val) in the GSTP1 gene has been associated with a higher risk for different cancer types. To assess the role of GSTP1 polymorphisms in the development of benzidine-related bladder cancer, GSTP1 AA, AG and GG alleles were determined in occupationally benzidine-exposed Chinese workers without known disease and benzidine-exposed bladder cancer patients from the same cohort of the Shanghai area. An increased but not significant frequency of GSTP1 AG or GG carriers was observed in the occupationally exposed bladder cancer patient group (OR=1.95, 95% CI 0.70-5.46). The odds ratios for the most important non-genetically determined risk factors for bladder cancer in males were as follows: Age (increase per year): OR 1.05, 95% CI 0.99-1.11, ever smoker: OR 1.31, 95% ČI 0.47-3.69, duration of exposure (increase per year): OR 1.19, 95% CI 1.10-1.29, and high exposure: OR 4.50, 95% CI 0.70-5.46. Significant differences were found between all benzidine-exposed workers without known disease with modified exfoliated urothelial cells (grade II and higher) and all workers without known disease with at most minor changes (less than grade II) according to Papanicolaou (OR 1.90, 95% CI 1.13-3.20). These findings show for the first time an association between the GSTP1 AG or GG genotype and higher cytological gradings of exfoliated urothelial cells from formerly benzidine-exposed

2052

GENETIC VARRIATION IN TGF-BETA1 BUT NOT ANTIOXIDANT GENES IS ASSOCIATED WITH PROGRESSIVE MASSIVE FIBROSIS IN COAL WORKERS.

B. Yucesoy, V. J. Johnson, M. L. Kashon, K. Fluharty, P. Willard, V. Vallyathan and M. I. Luster. Health Effects Laboratory Division, NIOSH/CDC, Morgantown, WV.

Progressive massive fibrosis (PMF) is the severe form of coal worker's pneumoconiosis. Although the severity of PMF is mostly dependent on the total amount and duration of dust exposure, genetic factors also play an important role in the devel-

opment of disease and modify the individual susceptibility. Studies have implicated reactive oxygen species (ROS) in the pathogenesis of fibrosis and other lung diseases. Many chemicals and physical agents including mineral dusts are potent generators of ROS. Lung tissue is protected against ROS by a variety of antioxidant mechanisms such as superoxide dismutases (SOD) and glutathione s-transferases (GSTs). Transforming growth factor beta (TGF $\beta$ ) is a key profibrotic growth factor implicated in fibrosis, including the deposition of extracellular matrix proteins. Antioxidant enzyme and cytokine genes are subject to polymorphisms in their regulatory regions which affect their expression level and thus contribution to disease process. This study was undertaken to examine the association between the functional polymorphisms of TGFβ and antioxidant enzyme genes and progression of PMF as well as possible gene-gene and gene-environment interactions. We genotyped DNA collected from lung autopsy tissues from 270 miners diagnosed with PMF as well as in 270 control miners with no disease using a case-control study design. Polymorphisms in GSTP1, GSTM1, GSTT1, MnSOD and TGFβ were anylised by Taqman® assay to determine each genotype. Our results showed an association of PMF prevalence with TGF  $\beta 1$  (-509) TT genotype (OR 1.77; 95% CI 1.03-3.09), whereas no statistically significant differences in the allele frequencies of antioxidant genes were observed between the cases and controls. The results suggest that interactions of genetic background with environmental exposure may affect the pathogenesis of PMF.

2053

GENETIC INFLUENCES ON HUMAN ENDOTHELIAL CELL FUNCTION AND SURVIVAL: INFLUENCE OF THE NOS3 EXON7 (GLU298ASP) AND ACE (I/D) POLYMORPHISMS ON GLUCOSE AND FREE 3-NITROTYROSINE INDUCED CELL TOXICITY IN

M. S. Joshi<sup>2, 1</sup> and J. A. Bauer<sup>1, 2, 1</sup> Center for Cardiothoracic Medicine, Columbus Children's Research Institute, Columbus, OH and <sup>2</sup>Division of Pharmacology, The Ohio State University, Columbus, OH. Sponsor: C. Smith.

Genetic polymorphisms of NOS3 and ACE have been implicated in diabetes related cardiovascular disease risk in humans. The functional relevance of NOS3 and ACE genetic variations to endothelial cell function is largely unstudied. The objective of this study was to test the functional relevance of NOS3 (Glu298Asp) polymorphism and ACE (I/D) polymorphism to the endothelial cells in-vitro. The central hypothesis was that the presence of these genetic polymorphisms alters endothelial cell sensitivity to glucose and 3-nitrotyrosine, two known diabetes-related vascular toxicants. Primary cell preparations (HUVECs) were initially screened for NOS3 and ACE genotypes. Unstimulated growth characteristics were in initially investigated and cells were incubated with various concentrations of glucose (10, 20, and 30mM), free 3-nitrotyrosine (10nM-5mM), or a combination of these two toxicants. No significant differences in unstimulated growth rates were observed among genotype groups (n=3-6 per group), but significant differences in glucose induced cell death (at 20mM Glucose: 9.27%: 30.35%: 28.69%; Glu/Glu: Glu/Asp: Asp/Asp. p<0.05) and free 3-nitrotyrosine induced cell death (LC50 values: 12.94±1.38 μM: 1.55±1.48 μM: 10.78±1.20 μM; Glu/Glu: Glu/Asp: Asp/Asp. p<0.05) were observed among the NOS3 genotypes. Combined exposures of glucose/3NT caused increased toxicity among the NOS3 genotypes. In contrast, no differences were observed among the ACE genotypes in terms of their responses to these concentrations of the toxic agents. These data demonstrate that the exon 7 NOS3 genotype may an important predictor of or mechanistically involved in endothelial vulnerability to these two diabetes related toxicants, whereas the ACE I/D genotype is apparently less important. Thus the NOS3 (Glu298Asp) genetic variation may play a specific role in vulnerability to diabetes related vascular complications

2054

PARAOXONASE STATUS IN A MEXICAN POPULATION AND ITS RELATIONSHIP TO THE SUSCEPTIBILITY TO DNA DAMAGE ON CULTURED HUMAN LYMPHOCYTES TREATED WITH METHYL-PARATHION AND PARAOXON.

E. Rojas-Garcia, L. Vega L, M. J. Solis-Heredia and <u>B. Quintanilla-Vega</u>. *Toxicology Section, CINVESTAV-IPN, Mexico City, D.F., Mexico*.

Human paraoxonase (PON) is an enzyme that participates in the detoxification of organophosphorus pesticides (OP). PON polymorphisms responsible for different catalytic activities and expression levels have demonstrated the relevance of PON in OP toxicity (mainly acethylcholinesterase inhibition), and the importance of evaluating PON status (genotype/phenotype). No information is available about the role of PON in the susceptibility to DNA damage. The aim of this study was to evaluate the role of PON status in the susceptibility to cytogenetic effects on cultured human lymphocytes treated with methyl-parathion or paraoxon. Serum PON activities were assayed using phenylacetate and paraoxon as substrates. Three PON

variants (–108, 55 and 192) were evaluated by PCR-RFLP. Induction of sister-chromatid exchange and mitotic index were determined in cultured lymphocytes added with homologous serum from two individuals with the haplotypes PON C  $_{108}L_{55}R_{192}$  ("resistant") or two individuals with the haplotypes PON T  $_{108}M_{55}Q_{192}$  ("susceptible"). Participants (n=74, 28.6 years old) were individuals of both sexes. PON activity with paraoxon was 632.9 IU/L (range 123.4-1645.6), and with phenylacetate was 199.2 IU/ml (range 85.2-422). Genotype frequencies for PON  $_{108}$  were 0.14CC, 0.5CT and 0.36TT; for PON  $_{55}$  were 0.09MM, 0.27ML and 0.64LL, and for PON  $_{192}$  were 0.24RR, 0.33QR and 0.43QQ. Enzymatic activities were different (p<0.005) according to genotype. Paraoxon and methyl-parathion showed cytogenetic effects in cultured lymphocytes but a difference in response according to PON genotype was observed only with paraoxon: lymphocytes from "resistant" individuals had lower cytogenetic effect than the "susceptible" individuals. The difference between paraoxon and parathion effect could be explained by the fact that PON hydrolyzes oxons and not the parent compound. Our results suggest that PON could have an important role in the cytogenetic effects caused by OP exposure.

2055

THE ARYL HYDROCARBON RECEPTOR 1 (AHR1) LOCUS IS HIGHLY POLYMORPHIC IN ATLANTIC KILLIFISH (FUNDULUS HETEROCLITUS): RELATIONSHIP TO DIOXIN RESISTANCE.

M. E. Hahn<sup>1</sup>, B. R. Evans<sup>1, 2</sup>, S. I. Karchner<sup>1</sup> and D. G. Franks<sup>1</sup>. <sup>1</sup>Biology, Woods Hole Oceanographic Institution, Woods Hole, MA and <sup>2</sup>Biology, Boston University, Boston, MA.

AHR agonists such as 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) and polynuclear aromatic hydrocarbons (PAHs) are highly toxic to most vertebrate animals. To understand the role of the AHR pathway in differential sensitivity to TCDD and PAHs, we are studying populations of the Atlantic killifish (Fundulus heteroclitus) that differ in their sensitivity to the toxic and biochemical effects of these compounds. Killifish inhabiting New Bedford Harbor (MA, USA), a federal Superfund site, have developed heritable resistance to AHR agonists. To investigate the mechanism of resistance and the possible role of AHR genetic variability, we cloned killifish AHR1, AHR2, ARNT2, and AHR repressor. AHR1, but not AHR2, ARNT, or AHRR, is differentially expressed between dioxin-sensitive and -resistant fish. Sequencing of AHR1 cDNAs from multiple individuals from several sites in Massachusetts, New York, and New Jersey revealed extensive polymorphism at the AHR1 locus. We identified 39 single nucleotide polymorphisms, 14 of which were non-synonymous. Alleles were assigned to three groups: AHR1\*1, AHR1\*2, and AHR1\*3. AHR1\*1 alleles were under-represented in a New Bedford Harbor fish (dioxin resistant) as compared to fish from Scorton Creek, MA (dioxin-sensitive). Initial functional analysis of the two most divergent variants (AHR1\*1A and AHR1\*3A) expressed by in vitro transcription and translation indicated similar [3H]TCDD-binding affinities. In transient transfection assays using mammalian cells, AHR1\*1A and AHR1\*3A exhibited similar transactivation potentials in the presence of TCDD. Thus, the killifish AHR1 locus is highly polymorphic and allele distributions differ between some dioxin-sensitive and dioxin-resistant populations. The role of AHR1 polymorphisms in the resistant phenotype remains uncertain. (Superfund Basic Research Program (5P42 ES07381) and the Hudson River Foundation.)

EFFECT OF ALDH2 GENE POLYMORPHISMS ON THE METABOLISM AND TOXICITY OF 2-ETHOXYETHANOL IN THE EXPOSED WORKERS.

R. WANG<sup>1</sup>, M. Suda<sup>1</sup>, X. Gao<sup>2</sup>, B. Wang<sup>2</sup> and T. Honma<sup>1</sup>. <sup>1</sup>Department of Health Effects Research, National Institute of Industrial Health, Kawasaki, Kanagawa, Japan and <sup>2</sup>Beijing Institute of Industrial Hygiene and Occupational Diseases, Beijing, China. Sponsor: M. Chiba.

2-Ethoxyethanol (ethylene glycol monoethyl ether) has been known to be toxic to testes and blood system. It is metabolized by alcohol dehydrogenase and CYP P450 2E1 to ethoxyacetic aldehyde, and then transformed by aldehyde dehydrogenase (ALDH) to ethoxyacetic acid, which is excreted in urine. It is not clear which metabolite, the aldehyde or the organic acid, plays the role in the occurrence of the injuries induced by the solvent. ALDH2 is the major enzyme in the metabolism of many short chain alcohols. The single nucleotide polymorphisms at nucleotide 1510 (G/A) of the gene result in a substitution of Glu to Lys at amino acid position 487. Approximately 30% of the Orientals possess ALDH2\*2 allele encoding the enzyme without activity. In this study, we investigated the toxic effects of 2-ethoxyethanol exposure among workers, and analyzed whether ALDH2 polymorphisms exerts any effect on the toxicity of the compound. It was found that the quantity and quality of sperm were both decreased in the males exposed to high concentration of 2-ethoxyethanol; the organic solvent seemed not to affect the blood concentrations of the sex related hormones such as testosterone, LH, FSH at

the present exposure levels; the RBC count and Hg content were decreased by the exposure to the solvent; liver function was normal even in the exposed subjects; the genetic polymorphisms of ALDH2 affected the toxicity of 2-ethoxyethanol in both the spermatogenesis and the hematopoiesis, and the ALDH2  $^*1/^*2$  seemed to be a protective factor from the damage caused by the compound.

#### 2057

COMPARATIVE ASSESSMENT OF THE INHIBITION OF HUMAN RECOMBINANT CYP19 (AROMATASE) BY AZOLES USED AS FUNGICIDES IN AGRICULTURE, AS ANTIMYCOTIC DRUGS, AND FOR TUMOR THERAPY.

W. K. Lutz<sup>1</sup>, K. Scholz<sup>1</sup>, E. R. Troesken<sup>1</sup>, R. W. Lutz<sup>2</sup>, W. Voelkel<sup>1</sup> and J. A. Zarn<sup>3</sup>. <sup>1</sup>Toxicology, University of Wuerzburg, Wuerzburg, Germany, <sup>2</sup>Statistics, Swiss Federal Institute of Technology, Zuerich, Switzerland and <sup>3</sup>Food Science, Swiss Federal Office of Public Health, Zuerich, Switzerland.

Azole compounds (imidazoles, triazoles) are widely used as antifungal agents in agriculture and as antimycotic drugs in medicine. They are also used for the treatment of estrogen-dependent conditions, e.g. in tumor therapy. The antifungal/antimycotic activity is due to their inhibitory activity against CYP51 (lanosterol-14 alpha demethylase), the interference with the sex hormone balance is based on their inhibition of CYP19 (aromatase). For antifungal use, inhibition of CYP19 is a side effect that may affect the endocrine system. The inhibitory potency may therefore be a useful quantitative indicator of toxicity. Human recombinant CYP19 from Gentest was used in a fluorimetric assay for enzyme inhibition, with dibenzylfluorescein as substrate. Dose responses for 20 azoles were established in duplicate and the data were analyzed statistically with a nonlinear mixed-effects model using a probit curve with a logarithmic dose scale and attributing a random effect to the start value of the fluorescence. IC50 values of 13 fungicides ranged from 0.012 to 37  $\mu$ M, the range of five antimycotics was from 0.014 to >88  $\mu$  M. Imidazoles tended to be more potent than triazoles. The two tumor therapeutic agents fadrozol and letrozol showed IC50 values of 0.0055 and 0.011 µM, respectively. The data indicate that azoles used as antifungal agents or antimycotic drugs can be as potent inhibitors of aromatase as the drugs used in tumor therapy. For the development of new antifungal agents, this activity should be taken into consideration. It may also be of interest to investigate the steroid hormone balance in humans treated with azole antimycotics and to monitor azoles used for crop protection in farmers and exposed wildlife.

### 2058 HUMAN EXPOSURE TO IMIDACLOPRID FROM DOGS TREATED WITH ADVANTAGE®.

M. Craig<sup>2</sup>, R. C. Gupta<sup>1</sup>, T. D. Canerdy<sup>2</sup> and D. A. Britton<sup>1</sup>. <sup>1</sup>Toxicology, Murray State University, Hopkinsville, KY and <sup>2</sup>Agriculture, Murry State University, Murray, KY.

The objective of this investigation was two-fold: (1) to determine the transferable residue of imidacloprid in gloves worn while petting experimental household dogs after the application of Advantage®and (2) to determine the imidacloprid residue in the dog's blood. Advantage® contains 9.1% imidacloprid, which controls fleas on dogs for up to 30 days. Imidacloprid produces toxicity by interacting with nicotinic receptors. Advantage® (240 mg imidacloprid/dog) was applied topically to six household dogs. The glove and blood samples were collected at 24hr, 72hr, and then on a weekly basis for 5 weeks post-Advantage® application. The glove samples were collected by petting each dog for five minutes while wearing a different glove per dog. The blood samples (5 ml from each dog) were collected into EDTA tubes. The imidacloprid residue was determined in the blood extracts and glove samples using RP-HPLC. The highest levels of imidacloprid residues were detected at the 24 hr interval in both the glove (254.163.00 ppb) samples. The blood imidacloprid residue was reduced by 1/3 at the 72 hr interval (18.73±2.00 ppb) and was not detected after 1 week. Imidacloprid residue in the glove samples decreased approximately 1/3 between each collection interval. The residue of imidacloprid in the glove extract by the fourth week was very low (0.08±0.02 ppm) and not detected by the fifth week. The findings suggested that following topical application of Advantage®, imidacloprid residue can be detected in the dog's blood for up to 72 hrs, and transferable residue on the dog's coat can be detected for up to 4 weeks. Repeated exposure to imidacloprid may pose possible health risks to veterinarians, veterinary technologists, and dog handlers.

### 2059 HUMAN EXPOSURE TO SELAMECTIN FROM DOGS TREATED WITH REVOLUTION®.

T. M. Acosta, R. C. Gupta, M. B. Masthay, T. D. Canerdy, R. J. Provost, B. H. Atieh and R. J. Keller. *Toxicology, Murry State University, Hopkinsville, KY.* 

This study was undertaken to determine selamectin residue in dog's blood and in gloves worn while petting dogs after Revolution®application. Revolution®contains the active ingredient selamectin (a semi-synthetic avermectin), which controls

ecto-and endoparasites including adult fleas, flea eggs, ticks, heartworms, ear mites, and sarcoptic mange in dogs, for 30 days. Revolution® was applied topically on a group of six adult household dogs (240mg selamectin/dog). The glove worn for 5 minutes while petting the dog and a serial blood sample (5ml/dog) were collected via the jugular vein at 0 hr, 24 hr, and 1, 2, 3, 4, and 5 weeks post-Revolution® application for selamectin residue determination. At no time during the study did the dogs show any signs of toxicity, weight loss, or change in body temperature. Extracts of the blood and the gloves were analyzed for selamectin residue using RP-HPLC, coupled with a UV detector (246nm). Selamectin standard used for peak identification and quantitation was purified from Revolution®. Selamectin residue was detected in the blood (10.26±1.06 ng/ml) only at 72 hrs post-Revolution®application, probably due to its poor dermal absorption and rapid elimination from the circulation. In the glove extracts, the highest concentration of selamectin (518.90±66.80 ppm) was detected 24 hrs after Revolution®application. Transferable residue of selamectin in gloves from dog's coat was detected at a lesser magnitude one week after Revolution®application, and that followed by a further descending trend during the 2nd, 3rd, and 4th weeks. No selamectin residue was detected in the glove extracts after the 5th week. This appears to be due to rapid elimination of selamectin from the dog's coat. In spite of selamectin's binding to the sebaceous glands of the skin, gloves contained significant transferable residue. Thus, these findings suggest that repeated exposure to selamectin can pose potential health risks, especially to veterinarians, veterinary technologists, dog trainers/handlers, and pet owners.

### 2060 MODULATION OF HEPATIC CYTOCHROME P450S IN RATS AND MICE BY TRIAZOLE CONAZOLES.

G. Sun<sup>1</sup>, A. K. Goetz<sup>2</sup>, D. Tully<sup>1</sup>, G. R. Lambert<sup>1</sup>, <u>D. J. Dix</u><sup>1</sup> and S. Nesnow<sup>1</sup>.

<sup>1</sup>NHEERL, Research Triangle Park, NC and <sup>2</sup>North Carolina State University, Raleigh, NC.

Conazoles are azole antifungal agents used as both pesticides and drugs. Some of these compounds are hepatocarcinogenic in mice and some can induce thyroid tumors in rats. The modes of conazole-based toxicity and tumorigenicity are not known. Many N-substituted azoles can induce and/or inhibit mammalian hepatic cytochrome P450s that are responsible for the metabolism of endogenous as well as exogenous compounds including drugs and xenobiotic chemicals. In the present study, four triazole-containing conazoles: fluconazole, myclobutanil, propiconazole, and triadimefon, were studied for their effects on hepatic P450s in Sprague-Dawley rats and CD-1 mice. Alkoxyresorufin O-dealkylation (AROD) methods were used as measures of P450 enzyme activities. The selectivities of AROD were studied using recombinant rat liver P450s. Animals were administered the following compounds (mg/kg body weight) by gavage daily for 14 days: fluconazole (2, 25, or 50), myclobutanil (10, 75, or 150), propiconazole (10, 75, or 150), or triadimefon (5, 50, or 115). Animals were sacrificed 24 hrs after the last dosing and hepatic microsomes were prepared. Each conazole significantly induced pentoxyresorufin O-dealkylation (PROD) and benzyloxyresorufin O-dealkylation (BROD) at mid and high doses in liver microsomes of both rats and mice (high dose fold-inductions: rats/fluconazole: BROD-7.1, PROD-5.3; rats/myclobutanil: BROD-13, PROD-8.1; rats/propiconazole: BROD-5.7, PROD-7.3; rats/triadimefon: BROD-28, PROD-18; mice/fluconazole: BROD-7.2, PROD-8.6; mice/myclobutanil: BROD-2.7, PROD-2.3; mice/propiconazole: BROD-3.8, PROD-5.4; mice/triadimefon: BROD-2.4, PROD-2.6). The inductions of PROD and BROD were dose dependent. No induction or slight induction of methoxyresorufin O-dealkylation or ethoxyresorufin O-dealkylation was detected. Triadimefon and fluconazole were the most potent AROD inducers in rats and mice respectively. Our results indicate that these four conazoles induced cytochrome 2B and/or 3A families of isozymes. This abstract does not reflect EPA policy

### 2061

DEVELOPMENTAL EFFECTS OF CHLORPYRIFOS EXTEND BEYOND NEUROTOXICITY: CRITICAL PERIODS FOR IMMEDIATE AND DELAYED-ONSET EFFECTS ON CARDIAC AND HEPATIC CELL SIGNALING.

A. Meyer<sup>1, 2</sup>, F. J. Seidler<sup>1</sup> and T. A. Slotkin<sup>1</sup>. <sup>1</sup>Pharmacology & Cancer Biology, Duke University Med. Ctr, Durham, NC and <sup>2</sup>Escola Nacional de Saude Publica, Rio de Janeiro, Brazil.

The fetal and neonatal neurotoxicity of chlorpyrifos (CPF) and related insecticides is a major concern. Developmental effects of CPF involve mechanisms over and above cholinesterase inhibition, notably events in cell signaling that are shared by non-neural targets. In the current study, we evaluated the immediate and long-term effects of CPF exposure of rats during different developmental windows (gestational days 9-12 or 17-20, postnatal days 1-4 or 11-14), on the adenylyl cyclase (AC) signaling cascade in the heart and liver. In addition to basal AC activity, we assessed the responses to direct AC stimulants (forskolin, Mn2+), to isoproterenol

and glucagon, which activate signaling through specific membrane receptors, and to NaF, which activates the G-proteins that couple the receptors to AC. Few immediate effects on AC were apparent when CPF doses remained below the threshold for systemic toxicity. Nevertheless, CPF exposures on GD9-12, GD17-20 or PN1-4 elicited sex-selective effects that emerged by adulthood (PN60), whereas later exposure (PN11-14) elicited smaller, nonsignificant effects, indicative of closure of the window of vulnerability. Most of the effects were heterologous, involving signaling elements downstream from the receptors, and thus were shared by multiple inputs; superimposed on this basic pattern, there were also selective alterations in receptor-mediated responses. These results suggest that the developmental toxicity of CPF extends beyond the nervous system, to include cell signaling cascades that are vital to cardiac and hepatic homeostasis. Future work needs to address the potential implications of these effects for cardiovascular and metabolic disorders that may emerge long after the end of CPF exposure. Support: USPHS ES10387 and ES10356.

### 2062 INHIBITION OF DIAZINON METABOLISM BY CHLORPYRIFOS IN RAT LIVER MICROSOMES.

H. Wu, <u>C. Timchalk</u> and <u>T. Poet</u>. Cntr for Biological Monitoring and Modeling, Battelle, Pacific NW Division, Richland, WA.

Chlorpyrifos (CPF) and diazinon (DZN) are major organophosphorus pesticides that are structurally and mechanistically similar, but have very different rates of metabolism. Their toxicity is mediated via CYP450 metabolism to oxons. Detoxification of the oxons is mediated by CYP450 and A-esterases, resulting in the formation of trichloropyridinol from CPF and 2-isopropyl-4-methyl-6-hydroxypyrimidine (IMHP) from DZN. Since exposures often involve more than one pesticide, this study was conducted to assess the effect of co-incubation with both CPF and DZN on the metabolism of DZN. Substrate concentrations of DZN ranging from 20 to 575  $\mu$ M were incubated with 0, 100, 300, or 750  $\mu$ M CPF for 15 min and bioactivation to DZN-oxon and deactivation to IMHP quantified. Data was analyzed using Lineweaver-Burke (1/v; 1/s) plots, by fitting the Michaelis-Menten equation to the data with non-linear regression using SlideWrite Plus®, and by fitting the data to a mathematical model written in Simusolv®, which employed Michaelis-Menten equations including inhibition constants to describe metabolism. The 1/v; 1/s plots were used to estimate the types of inhibition. Metabolism to IMHP appeared to be competitively inhibited whereas metabolism to the oxon was uncompetitive (or suicide). Fitting the data with non-linear regression, apparent Km concentrations vary for the production of IMHP, but not the apparent Vmax; whereas, the apparent Vmax rates change for the production of oxon, confirming the types of inhibition. Inhibitory rate constants (Ki) for oxon and IMHP metabolism were ~250  $\mu$ M and ~50  $\mu$ M, respectively. Using the different methods to predict Vmax and Km, apparent Vmax and Km with inhibition, and Ki resulted in similar estimations. The mathematical model has the advantage of providing a methodology by which all parameters are considered at once. The relatively high Ki values indicate the importance of metabolic interactions on kinetics of in vivo coexposures to DZN and CPF may be limited to high acute dose exposures. (Sponsored by CDC/NIOSH Grant R01 OH03629-01A2 and EPA grant R828608).

COMPARISON OF CHLORPYRIFOS-OXON AND PARAOXON ACETYLCHOLINESTERASE INHIBITION DYNAMICS: POTENTIAL ROLE OF A PERIPHERAL BINDING SITE.

A. Kousba<sup>1</sup>, L. G. Sultatos<sup>2</sup>, T. Poet<sup>1</sup> and C. Timchalk<sup>1</sup>. <sup>1</sup>Center for Biological Monitoring and Modeling, Pacific NW Nat'l Lab., Richland, WA and <sup>2</sup>UMDNJ, Newark, NJ.

The primary mechanism of action for organophosphorus (OP) insecticides involves the inhibition of acetylcholinesterase (AChE) by active oxon metabolites. This inhibition has been attributed to the phosphorylation of the serine hydroxyl group in the active site of AChE. Inhibition is described by the bimolecular rate constant (Ki), which is used to assess OP inhibitory capacity. It has been reported that the Ki for inhibition of AChE by certain oxons changes as a function of oxon concentration, and that this phenomenon could be explained by the presence of a peripheral binding site. When such a putative site would be occupied, the capacity of additional oxon molecules to phosphorylate the active site is reduced. Therefore, the objective of the current study was to evaluate the in vitro inhibition of AChE by a wide range of chlorpyrifos oxon (CPO) and paraoxon (PO) concentrations (0.5 pM -100 nM) using the Ellman assay combined with a dynamic model. The results indicated that the Ki is inversely changed in proportion to the oxon concentrations. The Ki determined using high oxon concentrations, were 238 and 22 µM-1h-1 and the spontaneous reactivation rates were 0.087 and 0.078 h-1 for CPO and PO, respectively. While the estimated Ki using high oxon concentrations were similar to those reported previously, the Ki estimates following 1 pM oxon, which have not been reported previously, were >1000-fold higher. Surprisingly, the Ki estimated using 1 pM CPO was similar to the Ki estimate using an equivalent PO concentration (0.18 and 0.25 pM-1h-1, respectively). This implies that both oxons exhibit similar inhibitory potency at the lower concentration, in contrast to the marked difference following higher concentrations, which was explained by considered peripheral binding site. The potential of a peripheral site should be considered when modeling AChE kinetics particularly at low environmentally relevant concentrations. (Sponsored by CDC/NIOSH Grant R01 OH03629-01A2 and EPA grant R828608)

#### 2064

PHARMACOKINETIC & PHARMACODYNAMIC INTERACTIONS OF A BINARY MIXTURE OF CHLORPYRIFOS AND DIAZINON IN THE RAT.

C. Timchalk, T. S. Poet, M. N. Hinman, A. L. Busby and A. Kousba. Center for Biological Monitoring and Modeling, Pacific NW Division, Richland, WA.

Chlorpyrifos (CPF) and diazinon (DZN) are organophosphorus (OP) insecticides, with the potential for concurrent exposures. Their oxon metabolites are potent inhibitors of cholinesterases (ChE). This study evaluated the impact of an acute binary OP exposure on dosimetry and ChE inhibition in rats. Groups (3-4/time point) of male S-D rats were orally administered CPF, DZN or a CPF/DZN mixture (0, 15, or 60 mg/kg) and blood and brain were collected at 0, 3, 6, 12 and 24 hr post-dosing. CPF, DZN and their respective metabolites trichloropyridinol (TCP) and 2-isopropyl-4-methyl-6-hydroxypyrimidine (IMHP) were quantified in blood and/or urine using gas chromatography. A modified Ellman method was used to measure ChE inhibition in blood and brain. Co-exposure at 15 mg/kg, did not appreciably alter the pharmacokinetics of CPF, DZN or TCP. The total amount of urinary TCP was decreased ~50% for the co-exposed group, but the amount of urinary IMHP was not altered. Co-exposure to 60 mg/kg delayed and increased the Cmax for both CPF (1.6x) and DZN (7.2x), and resulted in the respective blood AUCs increasing 145 and 422%. The AUC for TCP decreased to \$2%, but was slightly increased (107%) for IMHP. For the co-exposed group the total amount of urinary TCP was decreased -60%, but did not appreciably alter the amount of IMHP excreted relative to the single exposure. These results suggest that both CPF and DZN are capable of inhibiting each other's metabolism, but the effect is observed at higher doses (>15 mg/kg). A dose-dependent inhibition of ChE activity was also noted in plasma, RBC and brain homogenates for both the single and coexposures to CPF and DZN. In all tissues, CPF exposure resulted in greater ChE inhibition than DZN, however the overall ChE response appeared to be additive for the co-exposures. These results characterize both the pharmacokinetic and pharmacodynamic interactions of CPF and DZN in the rat and will be used to further develop a binary kinetic/dynamic model for OPs. (Sponsored by CDC/NIOSH R01OH03629-01A2)

### 2065

CONTINUOUS SYSTEMS MODELING OF THE INTERACTIONS OF PARAOXON WITH HUMAN RECOMBINANT ACETYLCHOLINESTERASE.

C. A. Rosenfeld and L. G. Sultatos. Pharmacology and Physiology, UMD- New Jersey Medical School, Newark, NJ.

Previous studies from this laboratory have reported that the inhibitory constant  $k_i$ for the inhibition of acetylcholinesterase by the organophosphate paraoxon (O, Odiethyl p-nitrophenyl phosphate) changes as a function paraoxon concentration. The  $k_i$  values were calculated by the application of continuous systems modeling to experimentally determined residual acetylcholinesterase activity following the addition of various paraoxon concentrations. The current study used the fluorescent compound N-methylacridinium to ascertain an independent measure of active site concentration for human recombinant acetylcholinesterase, which was then used in the model for a precise determination of  $\vec{k_i}$  over a range of oxon concentrations at both 24°C and 37°C. Incubations at 24°C used oxon concentrations ranging from 78 pM-750 nM with active sites concentrations ranging from 3.01-4.87 pM. The  $k_i$  for 750 nM paraoxon was 0.111 nM<sup>-1</sup>h<sup>-1</sup> whereas the  $k_i$  for 78 pM paraoxon was 0.410 nM<sup>-1</sup>h<sup>-1</sup>. Incubations at 37°C used oxon concentrations ranging from 15 pM-100 nM with active sites concentrations ranging from 4.36-5.60 pM. The  $k_i$ for 100 nM paraoxon was  $0.146 \text{ nM}^{-1}\text{h}^{-1}$  whereas the  $k_i$  for 78 pM paraoxon was  $4.21 \text{ nM}^{-1}\text{h}^{-1}$ . These data suggest that individual paraoxon molecules at the lower concentration have a greater capacity to inhibit acetylcholinesterase than individual paraoxon molecules at the higher concentration (consistent with previous data from our lab). At  $37^{\circ}$ C the difference from the highest k, to the lowest was approximately 30 fold whereas at 24°C the difference from the highest  $k_i$  to the lowest was approximately 4 fold. These data indicate that the kinetic scheme utilized for the derivation of the inhibitory constant  $k_i$  is inadequate to explain the interaction of human recombinant acetylcholinesterase and paraoxon.

PERMETHRIN AND NICOSULFURON MIXTURES
ALTER TOXICITY AND GLUTATHIONE STRANSFERASE ACTIVITY IN CORN EARWORMS
(HELICOVERPA ZEA)

O. Jacobs, P. S. Burns, R. Massa and S. L. Chao. *Natural Sciences, Fayetteville State University, Fayetteville, NC.* Sponsor: J. Casida.

Recent studies of synergism or potentiation related to pesticide mixtures and neurotoxicity have affirmed the need to explore mechanisms underlying such interactions. This study explores synergism with mixtures of a widely used insecticide, herbicide, and ammonium nitrate found in fertilizers. Corn earworm larvae (Helicoverpa zea) were exposed to the following chemicals alone and in mixture: permethrin, nicosulfuron, and ammonium nitrate. Toxicity of larvae was measured using a dip bioassay. Increased mortality was observed consistently with mixtures of nicosulfuron and permethrin; however nitrate and mixtures of nitrate did not consistently increase toxicity. Acetylcholinesterase (AChE) and glutathione s-transferase activities were measured in larvae exposed to above pesticide mixtures. The increased toxicity observed with pesticide mixtures did not appear to be associated with changes in AChE activity; however, glutathione s-transferase activity was altered with exposure to mixtures of above pesticides.

### 2067 ROLE OF CYP3A METABOLISM IN HEPG2 CYTOTOXICITY OF ALACHLOR.

S. R. Miranda and S. A. Meyer. Toxicology, University of Louisiana at Monroe, Monroe, LA.

Alachlor [2-chloro-2', 6'-diethyl-N-(methoxymethyl)acetanilide] is a chloroacetanilide herbicide used in agriculture and is a drinking water contaminant (MCL = 2ppb). Previous studies in our laboratory have shown that alachlor is acutely hepatotoxic to rats at doses > 400mg/kg. N-dealkylation of alachlor is believed to be rate limiting to the formation of a reactive metabolite, diethylbenzoquinoneimine (DEBQI) and Coleman et al (1999, Chem.Biol.Interactions, 122:27-39) have shown that CYP3A4 catalyzes alachlor N-dealkylation. We propose that CYP3A mediated N-dealkylation leading to the ultimate toxicant DÊBQI is causal to the hepatotoxicity of alachlor. The objectives of this study were to determine the toxicity of 2, 6-diethylaniline (DEA), a precursor to DEBQI, and secondly to examine the role of CYP3A in alachlor hepatotoxicity. HepG2 human hepatoblastoma cells were chosen as a model system since these cells express constitutive and dexamethasone-inducible CYP3A7 and can be further induced by dexamethasone to express CYP3A4 (Krusekopf, et al. 2003. Eur. J. Pharmacology 466:7-12). Release of lactate dehydrogenase (LDH) into the culture medium was used as the endpoint for cytotoxicity. In the present studies, we observed that alachlor hepatotoxicity was time-dependent with an EC50 of 700µM and 400µM after treatment for 6 hr and 24 hr, respectively. DEA at concentrations up to 800μM was not toxic after 24 hr. Further, pretreatment with dexamethasone (25µM, 48 hr) resulted in a two-fold increase in alachlor toxicity. Collectively, these data suggest that CYP3A-mediated metabolic activation of alachlor to a reactive metabolite other than DEBQI may be causal to hepatotoxicity. Support: Johnston Science Foundation and Louisiana Board of Regents.

### 2068 DIAZINON ALTERS SPERM CHROMATIN STRUCTURE BY NUCLEAR PROTAMINE PHOSPHORYLATION.

B. Pina-Guzman<sup>1</sup>, B. E. Reyes-Marquez<sup>2</sup>, M. J. Solis-Heredia<sup>1</sup> and <u>B. Quintanilla-Vega</u><sup>1</sup>. <sup>1</sup>Toxicology Section, CINVESTAV-IPN, Mexico City, D.F., Mexico and <sup>2</sup>Department of Cell Biology, CINVESTAV-IPN, Mexico City, D.F., Mexico.

Diazinon (DZN) is an organophosphorous pesticide (OP) widely used in agriculture and pest control in Mexico, which has been associated with male reproductive effects. As an OP compound, DZN might phosphorylate nuclear protamines that pack sperm DNA during the latest steps of spermatogenesis, contributing to its reproductive toxicity. Shortly after their synthesis, protamines are phosphorylated followed by a dephosphorylation process required for the correct binding to DNA. Any alteration in protamine-DNA binding alters the sperm chromatin structure. The aim of this study was to evaluate the effect of DZN on the sperm chromatin structure and its ability to phosphorylate nuclear protamines as the mechanism of action, after a unique dose (8.12 mg/kg, i.p.) in adult male mice. Animals (NMRI, 9-weeks old) were sacrificed 8 and 15 days after treatment and sperm quality, chromatin condensation, phosphorous content in protamines and sperm heads, and phosphorylation sites in protamines were evaluated in spermatozoa from cauda epidydimis and vas deferens. Chromatin condensation was measured by the sperm chromatin structure assay (SCSA) parameters: DFI (αt) and DFI% (COMP-αt). At 8 days post-treatment, DFI and DFI% increased 50% and 4.5 fold, respectively, indicating an alteration on sperm chromatin condensation as well as DNA damage; significant alterations were also shown in sperm viability, motility, and morphology. Increases in the phosphorous content in protamines (50%) and sperm heads (140%) were also observed at this time, as well as in the immunodetected phosphoserine residues at 8 days (99%) and 15 days (33%) post-treatment. These data suggest that spermatozoa exposed during the latest steps of spermatic maturation (late spermatide) were the target cells of DZN exposure. Finally, DFI and DFI% strongly correlated (r=0.8413 and r=0.8431, respectively) with phosphorous content in protamines, suggesting that nuclear protein phosphorylation is involved in the DZN effects observed on sperm chromatin structure.

#### 2069

THE EFFECT OF THIOFLAVIN-T AND PARAOXON ON THE GROWTH PROMOTING FUNCTION OF ACETYLCHOLINESTERASE IN NG108-15 CELLS.

H. M. Campanha and E. J. flynn. UMD-New Jersey Medical School, Newark, NJ.

Acetylcholinesterase (AChE) is widely studied for its role in the hydrolysis of Acetylcholine (ACh). This enzymatic activity is inhibited by a number of organophosphate insecticides. Allowable human exposure to insecticide levels are set by their ability to inhibit AChE enzymatic activity, which leads to cholinergic crisis. However, recent evidence has accumulated indicating AChE may also have a non-cholinergic function. For example, studies have shown AChE expression in the cells of the chick neural tube, prior to synaptogenesis. It has also been shown that over expression of AChE leads to process extensions and increased cell adhesion. Concern has been raised that, in humans, this non-cholinergic function of AChE may be altered from the exposure to environmental pesticides and lead to effects on neuronal growth and development. In order to investigate the non-cholinergic function of AChE in the nervous system, we used a cultured hybrid mouse neuroblastoma-rat glioma cell line, NG108-15, which expresses AChE in its undifferentiated and differentiated state. These cells were grown on tissue culture plates on a substratum containing varying amounts of AChE. Following incubation times for up to 96 hours, the degree of cell adherence was assessed by staining attached cells with crystal violet. There was an increase in cell adherence dose related to the amount of AChE added to the substratum. The AChE induced adherence was decreased when cells were grown in the presence of Paraoxon (PO) at concentrations of 0.5 mM and 1 mM. Similarly, there was a decrease in adherence when NG108-15 cells were grown on AChE coated plates in the presence of Thioflavin-T at concentrations ranging from 1nM to 100 uM, in a dose dependent manner. In addition, cells grown in the presence of PO on uncoated plates, showed a decrease in cell adherence. These observations suggest that PO and Thioflavin-T can interfere with the growth promoting function of AChE by decreasing its effect on cellular adherence.

#### 2070

IN VIVO AND IN VITRO EFFECTS OF THE ORGANOPHOSPHATE INSECTICIDE TETRACHLORVINPHOS ON CHOLINESTERASE AND CARBOXYLESTERASE ACTIVITIES IN HORSES.

S. Karanth<sup>1</sup>, L. Mason<sup>1</sup>, T. Holbrook<sup>2</sup>, C. MacAllister<sup>2</sup> and C. Pope<sup>1</sup>. <sup>1</sup>Physiol Sciences, Oklahoma State University, Stillwater, OK and <sup>2</sup>Vet. Clin Sciences, Oklahoma State University, Stillwater, OK.

Tetrachlorvinphos (TCVP) is used in "feed-through" larvicides for fly control around horse stables. Relatively little is known, however, on the effects of TCVP on target (acetylcholinesterase, AChE) or non-target (butyrylcholinesterase, BChE; carboxylesterase, CE) enzymes in the horse. While erythrocytes exclusively express AChE, plasma ChE activity was primarily BChE and muscle contained predominantly AChE. Plasma ChE activity was substantially more sensitive (>10000 fold) in vitro than erythrocyte ChE activity to TCVP ( $IC_{50}$ : plasma, 97 nM; erythrocyte, >1mM). Muscle ChE and plasma CE were also markedly less sensitive than plasma ChE ( $IC_{50}$ : 116 uM and 27 uM respectively). Adult, male horses (n=3/group, 364-590 kg) were given either sweet feed alone or sweet feed supplemented with a TCVP-containing larvicide (Equitrol®) daily for 21 consecutive days to provide approximately 700 mg TCVP per animal/day (according to label instructions). Clinical signs (vital signs, abdominal auscultation, ophthalmic exam, body temperature) were recorded on a daily basis. Heparinized blood samples were taken at days -1, 1, 3, 7, 21, 28 and 42 while muscle (semimembranous) biopsies were taken under aseptic conditions on days -1 and 21. No signs of toxicity were noted at any timepoint. Plasma ChE activity was significantly inhibited (33%) in larvicidetreated horses after 1 day of treatment and apparent peak inhibition (68 and 71%) was noted at days 7 and 21. Following cessation of dosing, plasma ChE activity recovered (46 and 83% of control on days 28 and 42). Neither erythrocyte ChÉ activity nor plasma CE activity was affected by larvicide treatment in vivo. Muscle ChÉ activity was surprisingly variable among individual horses (pre-treatment range: 0.50-4.92 nmole.min'mg protein), but there was no evidence of treatmentrelated reduction in muscle ChE activity. The results suggest remarkable tissue- and enzyme-specific differential effects of TCVP on target and non-target enzymes in

#### 2071

IN VITRO METABOLISM OF PYRETHROIDS IN RAT LIVER MICROSOMES.

S. J. Godin<sup>1</sup>, R. A. Harrison<sup>2</sup>, <u>M. F. Hughes<sup>2</sup></u> and <u>M. J. DeVito<sup>2</sup></u>. <sup>1</sup> Toxicology, University of North Carolina, Research Triangle Park, NC and <sup>2</sup>NHEERL, USEPA, Research Triangle Park, NC.

Pyrethroids are neurotoxic pesticides that bind to sodium channels. These pesticides are used in a variety of agricultural and household applications. In order to determine in vitro kinetic parameters for pyrethroids, an LC/MS method was developed for the detection and quantification of deltamethrin, esfenvalerate and cyfluthrin. These chemicals were separated using a Zorbax Eclipse XDB - C18 column (4.6 x 50 mm, 3.5 micron) and an isocratic mobile phase of 90:10 methanol:water with 0.01% formic acid. Using a flow rate of 0.5 ml/minute all chemicals were separated and eluted within 5 minutes. In our LC/MS system (Agilent 1100 series ion trap LC/MS) all three chemicals formed sodium adducts. The adducted molecular ions used to quantify these chemicals were m/z 527.8, 442.1 and 456.0 for deltamethrin, esfenvalerate and cyfluthrin, respectively. Detection limits were as low as 10 ng/ml. Initial kinetic studies were performed with deltamethrin. Liver microsomes were prepared from 65 day old male Long Evans rats. The in vitro assay was performed in 1ml of 100 mM Tris (pH 7.5), 1 mg/ml NADPH and 1mg microsomal protein/ml. The reaction was carried out for 0, 5, 10, 20, and 30min, and was done in duplicate. The reaction was started with the addition of deltamethrin at concentrations ranging from 2 - 200nM. The reaction was stopped by the addition of 5 ml of cold n-pentane. Extraction efficiencies were greater than 80%. Nonlinear regression analysis was used to estimate Km and Vmax. Estimates of Km and Vmax for deltamethrin are 53.8 nM and 185 pmoles/min/mg protein, respectively. (This abstract does not represent USEPA policy. SJG supported by NHEERL-DESE, USEPA CT826513)

### TOXICITY OF SODIUM METAM IN THE RAINBOW TROUT.

T. Bunch<sup>1</sup>, M. A. Haendel<sup>2, 3</sup> and <u>G. S. Bailey<sup>1, 2, 3, 1</sup> Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR, <sup>2</sup>Linus Pauling Institute, Oregon State University, Corvallis, OR and <sup>3</sup>MFBSC, Oregon State University, Corvallis, OR.</u>

Sodium metam (sodium methyldithiocarbamate (NaM) CAS# 137-42-8) was the third most used pesticide by volume in 1999. Primarily used as a soil fungicide, it is also a nematocide, herbicide and wood preservative. Applied up to 300 pounds per acre, it has the potential to contaminate groundwater. Therefore, there exists the possibility for human or aquatic organism exposure and the long-term effects of NaM have not been intensely investigated. We have selected the rainbow trout model to initiate studies of NaM toxicity in an aquatic species. Rainbow trout fry (5-months post-spawn) were exposed to varying concentrations between 0 and 100ppm of pure (99%) NaM for 48-hours with solution replacement after 24-hrs in aerated containers. The  $LC_{50}$  was determined to be 0.8ppm. Subsequently, a long-term experiment was conducted to examine the consequences of a 24-hour NaM bath exposure to 5-month old fry at concentrations of 0, 0.7 and 0.8ppm. Upon sampling at 14 months, the NaM treated fish exhibited an elevated liver somatic index and a dose-dependent severe hepatic pre-ductular stem cell hyperplasia heretofore un-described in this animal model. In order to determine if NaM causes DNA damage, we performed Comet assays on a rainbow trout hepatoma (RTH) cell line. RTH cells were exposed to NaM concentrations from 1ppm to 130ppm. A significant increase in tail moment was seen at the highest concentration. Based on these observations, we believe NaM exerts significant toxic effects on rainbow trout at concentrations of potential environmental relevance, with liver a primary target organ. Supported by NIH grants ES03850, ESS00210, ES07060.

EVALUATION OF WHITE BLOOD CELL COUNT IN RAT SPLEEN AND THYMUS EXTRACTS USING THE ADVIA 120 HEMATOLOGY ANALYZER.

L. LeSauteur, J. McCartney, L. Huard and Y. Deschamps. *Immunology, CTBR, Senneville, QC, Canada.* 

The objective of this work was to verify the use of the ADVIA 120 Hematology analyzer for measuring the total white blood cell count and differential count of spleen and thymus extracts from the Sprague-Dawley rat. Linearity of dilution was determined for the white blood cell count of spleen and thymus extracts. Smears of the spleen and thymus extracts were evaluated microscopically to qualitatively confirm the automated differential counts. Spleen extract samples from 4 rats and thymus extract samples from 5 rats were analyzed on the ADVIA 120 Hematology analyzer; samples were diluted with 0.9% saline to obtain at least 3 different levels of cell counts. Linearity of dilution results provided correlation coefficient values greater than 0.990 for all spleen and thymus samples and were considered acceptable since the correlation was greater than 0.900 and the slope was within 0.7500 and 1.2500. A 1:10 dilution of the extract samples was judged to provide maximal

accuracy of the results and to avoid aspiration problems due to sample viscosity. Microscopic evaluation of the spleen and thymus extract smears qualitatively confirmed the automated differential results. In conclusion, the total white blood cell count and differential count obtained on the ADVIA 120 Hematology analyzer shows acceptable reactivity for testing rat spleen and thymus extracts.

### 2074 ESTABLISHING AN IMMUNOPHENOTYPING SPECIES SPECIFIC BIOLOGICAL CONTROL.

J. Van Ness, J. Sibley, J. Elliott and D. Walker. *Clinical Pathology, Wyeth, Chazy, NY.* Sponsor: M. Seme Nelson.

The FDA Immunotoxicology guidelines for preclinical drug safety testing suggest immune cell phenotyping be utilized as an indicator of immunosuppression. When conducting cell phenotyping in a GLP environment, one must consider the use of a preserved species specific biological control material to maintain interassay consistency and precision. However, currently there are no commercially available control material suitable for phenotyping non-human lymphocytes. For the purpose of generating rat-specific reference material for phenotyping blood and tissue lymphocytes, we excised rat spleens and homogenized the tissue to a single cell suspension. These spleenocytes were prepared for cryo-preservation (at a physiological equivalent density to whole blood) by mixing with culture media, fetal bovine serum, and dimethylsulfoxide. Aliquots of the suspension were placed at -80°C to freeze at a controlled rate. Fresh and thawed aliquots of the control material were stained and analyzed for lymphocyte subpopulation distribution of CD4+, CD45RA+, and CD8a+ cells. To determine stability of, and establish ranges of each subtype within the control material, analysis was performed upon initial isolation, day one, week one, and monthly there after. Our results yielded a consistent recovery of CD4+ (41.3  $\pm$  6.0%), CD45RA $^+$  (23.8  $\pm$  3.7%), and CD8a $^+$  (24.6  $\pm$  3.5%) cells. The total recovery percentage over a 22 week period was 88.9 ± 5.5%. These results compared favorably with the spleenocytes analyzed before preservation. Stability tests are ongoing and will continue until an appreciable degradation is detected. For testing purposes, we generated the control material with and without the use of paraformaldyhide to determine the amount of interference the endogenous fluorescence of paraformadyhide would have. With this method, one can successfully create a suitable control material for rat lymphocyte phenotyping to meet the rigors of a GLP environment.

### 2075 THE MEASUREMENT OF RABBIT ANTI IDIO-TYPE ANTIBODY USING BIOSENSOR ASSAY.

K. Harada, N. Ohtake, S. Hayashi and J. Kawahara. *Toxicology, Pharmaceutical laboratory in Kirin Brewery Co.Ltd., Maebashi-shi, Japan.* Sponsor: F. Sagami.

The measurement of antibody titer in serum is recquired in preclinical and clinical studies of biotechnology pharmaceutical drugs, and Radioimmunoassay (RIA) and Enzyme immunoassay (EIA) are generally used in these studies. Because these methods can be used only in the limited facilities and/or are not adequate to some pharmaceutical drugs, the development of new method to measure the antibody titer based on the different strategy is needed. We studied in the usefulness of the measurement of the anti idio-type antibody using biosensor assay as one of the basic studies for the development of new method. Rabbits were immunized with Rituxan, pharmaceutical antibody, in complete and incomplete Freund' adjuvant, and antiserum were collected. Rituxan, as full length or Fab fragment, were immobilized to biosensore chip and rabbit anti-rituxan antibody titer were measured with Biacore 3000. We studied the specificity, the intra-assay reproducitibity, the interassay reproducibility and the dose-dependency of antiserum to confirm the usefulness of the method using biosensor assay. As results, these items were confirmed to be well. These results suggest that the method of the measurement of anti idio-type antibody in serum using assay is useful.

### 2076 CELL CHIP TECHNOLOGY - AN ALTERNATIVE METHOD FOR IMMUNOTOXICITY SCREENING.

T. Ringerike<sup>1</sup>, E. Ulleras<sup>2</sup>, G. Nilsson<sup>2</sup>, R. J. Vandebriel<sup>3</sup>, J. Dastych<sup>4</sup> and M. Lovik<sup>1</sup>. <sup>1</sup>Department of Environmental Immunology, Norwegian Institute of Public Health, Oslo, Norway, <sup>2</sup>Department of Genetics and Pathology, Uppsala University, Uppsala, Sweden, <sup>3</sup>Laboratory for Pathology and Immunobiology, National Institute of Public Health and the Environment, Bilthoven, Netherlands and <sup>4</sup>Laboratory of Molecular Immunology, International Institute of Molecular and Cell Biology, Warsaw, Poland. Sponsor: E. Dybing.

It is important to find new technologies for high throughput immunotoxicity testing. Until recently, most tests for immunotoxicity have been developed and validated in experimental animals. The Cell Chip is an *in vitro* project that aims at using changes in cytokine expression upon exposure to chemicals as a measure of

immunotoxicity. The background for this approach is increasing evidence showing that at least certain types of immunotoxicity, like those leading to hypersensitivity and autoimmunity, are associated with modulation of cytokine production. Mouse T-cell lymphoma cells were transfected with the promoter region of different cytokines coupled to the sequence for green fluorescent protein (GFP). Hence, an increased expression of cytokine will result in an increased level of GFP fluorescence. To examine depression of cytokine expression, cells were incubated in the prescence of an induction mix of Ionomycin and PMA. Cells were incubated with different test compounds with already established immunotoxic potential, and GFP expression was measured by flow cytometry. Compounds were incubated with the cells for 24 hours and in 3 different concentrations. The highest dose tested was selected to result in 10% cytotoxicity, the two other doses were 10% and 1% of this dose. Our results indicate that the prototype immunotox Cell Chip is able to detect inhibition of cytokine expression following incubation with immunosuppressive chemicals such as Cyclosporin A, Rapamycin and Pentamidine. Use with other classes of chemicals (e.g. contact and respiratory allergens) will have to be explored further. (This project is A European Commission Shared-cost Research projet: QLK4-CT-2000-00787 and is patent pending).

### 2077 IN SEARCH OF A BIOMARKER FOR STRESS-INDUCED IMMUNOMODULATION.

P. Hebert, C. Schwab and S. B. Pruett. Cellular Biology & Anatomy, LSUHSC-Shreveport, Shreveport, LA.

Toxicological testing of compounds often is conducted at the maximum tolerated dose. These high doses can cause immunotoxicity. Gross changes indicating a generalized stress response have been used as evidence that immunosuppression is stress-mediated. Regulatory changes require objective evidence prior to claiming that these high doses are immunotoxic only due to the induction of a stress response. To separate immunomodulatory effects of stress (indirect) and chemical compounds (direct), a biomarker would be helpful. Serum corticosteroid (cort) levels in mice have been used to indicate stress levels, but often are obtained a single time during a study. Our lab has found that a good indication of stress that is predictive of immunosuppression in mice is the area under the curve (AUC) of cort vs. time as graphed from a time-course experiment. These experiments are time- and labor-intensive and require the use of many animals. We have found that the amount of MHC II expression on the surface of B cells correlates best with the AUC and can be used as a surrogate biomarker for stress-induced immunotoxicity. Our present objective is to find a similar biomarker for stress in rats. Female Sprague-Dawley rats, age 8 to 10 weeks, were subjected to various stressors (exogenous cort, restraint, EtOH). Serum cort data were collected for AUC analysis at 0, 1, 2, 4, 8, 12, and 24 h. Data were analyzed for body and organ (spleen and thymus) total and relative weights, organ cellularity, blood differential counts, cell surface expression of CD4/CD8 and MCH II, caspase activity (thymus), histology and immunohistochemistry. No definitive parameter has emerged as a reliable biomarker in acute (≦24 h) studies. However, 20 mg/kg cort given twice a day at 4 h intervals for 4 days resulted in a decrease of MHČ II expression from  $55.96 \pm 1.90$ percent (vehicle) to  $50.34 \pm 1.48$  percent (cort) (p<0.05). These studies emphasize that rats are not just big mice and the search for a stress-related biomarker will be quite different in these rodents.

### 2078 ROLE OF STRESS-INDUCED IMMUNOTOXICITY IN 28-DAY EXPOSURE STUDIES: CHEMICAL-SPECIFIC HABITUATION AND LACK OF HABITUATION.

S. B. Pruett, Q. Zheng, R. Fan, C. Schwab and P. Hebert. Cell. Biol. & Anatomy, LSU Health Sciences. Center, Shreveport, LA.

We have previously documented that the immunotoxicity caused by acute exposure to some chemicals is mediated in part by a neuroendocrine stress response. Following daily exposure for various periods of time, rodents can become habituated to some stressors, leading to a diminished stress response. A few studies suggest that this may also be true for some chemical stressors, but these studies have not been done in a manner consistent with standard pre-clinical or safety testing. In the present study this was done by exposing female B6C3F1 mice to 28 days of daily administration of three compounds previously shown to induce a strong stress response after a single dose: atrazine (37.5, 75, 112.5, and 150 mg/kg, in corn oil i.p.); ethanol (4, 5, 6, and 7 g/kg, at 32 percent v/v in water by gavage); propanil (50, 75, 100, and 150 mg/kg in corn oil, i.p.). Serum corticosterone concentrations were determined at various times after the last dose of each compound, and a separate set of mice was used to determine total and differential blood leukocyte counts, total nucleated cells in the spleen, B cells, T cells, and MHC class II positive cells in the blood and spleen, and splenic NK cell activity. The results demonstrate that mice become habituated to ethanol and propanil (as indicated by minimal corticosterone responses and loss of stress-induced immunosuppression), but not to atrazine (as indicated by corticosterone responses and immunological changes very

similar to those noted after a single dose). These results have implications for interpreting immunotoxicity data in pre-clinical and safety testing involving rodents. Supported by NIEHS grant R01 ES09158.

### 2079

EVALUATION OF ANTI-CD3 INDUCED T-CELL PROLIFERATION ASSAY FOR ASSESSING THE IMMUNOTOXICITY OF VERAPAMIL, NIFEDIPINE, CYCLOSPORIN A, AND FK506.

S. Mittelstadt, B. Hulette, G. Fadayel, M. Hare and <u>F. Gerberick</u>. *Procter & Gamble, Cincinnati, OH.* 

It is well known that compounds that adversely effect calcium flux can inhibit Tcell proliferation in vitro and immune responses in vivo. The purpose of these experiments was to determine if inhibition of anti-CD3-induced T-cell proliferation could be used to rank order the immunosuppressive potential of Verapamil, Nifedipine, Cyclosporin A, and FK506. Cyclosporin A (CsA) and FK506 were chosen because they are known to be immunosuppressive in the clinic whereas evidence for Verapamil is that it is not immunosuppressive in the clinic. To do this, we deployed a T-cell blastogenesis assay that utilized aCD3 as the stimulus for T-cell proliferation. First, we determined the optimal dose of aCD3 to stimulate a robust T-cell proliferation using peripheral blood mononuclear cells (PBMC). PBMC were cultured in 96-well culture plates for 72 hrs in the presence of 4 ng/ml aCD3 with and without chemical treatment. The cultures were pulsed with 3H-thymidine (1 mCi/well) for 18 hrs, harvested and counts per minute (CPM) determined using a microplate scintillation counter. Next, we determined the IC50 concentrations for the above-mentioned chemicals using dose responses covering ranges over several orders of magnitude: FK506 0.05 mM, CsA 0.8 mM, Verapamil 18 mM, and Nifedipine > 50 mM. Our results indicated that FK506 > CsA > Verapamil > Nifedipine as inhibitors of aCD3-induced T-cell proliferation and these data correlate well with what is known about the immunosuppressive activity of these compounds. The IC50 concentrations from FK506 to Nifedipine spanned several orders of magnitude making this assay useful to predict the immunosuppressive potential of chemicals of similar class working through similar mechanisms.

#### 2080

PERIPHERAL LEUKOCYTE PHENOTYPING AND SYSTEMIC ANTIBODY RESPONSE AS FIELD TESTS TO EVALUATE IMMUNOTOXICITY IN BEEF CATTLE.

D. Bechtel<sup>1</sup>, C. Waldner<sup>1</sup>, W. C. Davis<sup>2</sup> and M. Wickstrom<sup>1</sup>. <sup>1</sup>University of Saskatchewan, Saskatoon, SK, Canada and <sup>2</sup>Washington State University, Pullman, WA.

As part of an effort to develop tests for use in field studies of livestock immunotoxicology, a pilot study was conducted to evaluate the sensitivity of peripheral leukocyte phenotyping and systemic antibody response to vaccination in immunosuppressed cattle. Twenty four yearling heifers were divided randomly into two groups of 12 each. Cattle in the treatment group were given dexamethasone IM at 0.1 mg/kg on experiment days -3 through 3, and again on days 20 through 24, to suppress immune function. Cattle in the control group were given a representative dose of saline IM. Animals in both groups were inoculated with a commercial rabies vaccine (IMRAB Bovine Plus, Merial Canada Inc.) on days 0 and 21. Blood was collected from all animals prior to injection with dexamethasone or saline on day -3, and again on days 0, 21 and 42. Rabies antibody titre in day 0 (baseline), 21, and 42 samples was measured by the standardized Rapid Fluorescent Focus Inhibition Test (a rabies neutralizing antibody test). Sub-populations of peripheral blood leukocytes (CD4+, CD8+ and γδ+ T-cells, B cells, and subsets of activated T-cells) were determined in day 0, 21 and 42 samples by flow cytometry. Average daily weight gain and body condition scores for all animals were incorporated into the statistical model as covariates. Peripheral blood leukocyte counts were significantly increased (P<0.05) in the dexamethasone treated animals. The increase is rationalized by the large increase in the circulating polymorphonuclear cells. Alternatively, CD4+ and CD8+ T-cells were significantly depressed in the treated group. Results of this study will be used to optimise our approach to assessing immune function in cattle chronically exposed to airborne contaminants from oil and gas production and processing facilities in western Canada.

#### 2081

COMPARISON OF THE EFFECTS OF CYCLOPHOSPHAMIDE AND DEXAMETHASONE ON PFC ASSAY, ANTI-KLH AND ANTI-TETANUS TOXOID ELISA RESPONSES IN RATS.

F. Condevaux<sup>1</sup>, J. Guichard<sup>1</sup>, N. Eltschinger<sup>1</sup>, C. Cretinon<sup>1</sup> and <u>J. Descotes</u><sup>2</sup>.

\*\*IMDS Pharmacology Services, L'Arbresle, France and Poison Center, Lyon, France.

There is a consensus that a T-dependent antibody response assay is the best method for the early screening of the immunosuppressive potential of new molecular entities. However, the selection of the most appropriate antigen is a matter of debate. In

this study, groups of 10 SD rats treated with 5 mg/kg/day cyclophosphamide (CY) ip or 0.25 mg/kg/day dexamethasone (DEX) orally for 21 days were immunized either with SRBC on day 17, KLH on days 7 and 14 or tetanus toxoid (TTox) on days 7 and 14. Two groups treated with CY or DEX were not immunized. The PFC assay was performed on day 21. KLH and tetanus toxoid IgM and IgG levels were measured by ELISA on days 7, 14 and 21. Both CY and DEX induced a significant decrease in the PFC response. No changes whatsoever in anti-KLH IgM levels were seen, but IgG levels on days 7 and 14 were significantly decreased by CY and DEX. No anti-TTox antibodies were detected on day 14. There was a statistically significant decrease in both IgM and IgG levels on day 21 in animals treated with either CY or DEX. Although decreases in antibody responses were of a similar magnitude with either drug in the 3 assays, the suppressive effect of CY was moderately greater than that of DEX in the PFC and TTox assays, but not in the KLH assay. These results suggest that TTox is a valuable alternative to SRBC and KLH in a T-dependent antibody response assay. Importantly, unlike SRBC nor KLH, responses to TTox can be used as endpoints in clinical trials. Finally, there were no differences in the histology of the lymphoid organs or clinical pathology parameters following treatment with CY or DEX and/or immunization with SRBC, KLH or TTox. This lends support to the claim that immunization of animals is feasible in regulatory toxicity studies without compromising the evaluation of the toxicity profile of the tested compounds.

### 2082

VALIDATION OF A METHOD FOR THE DETECTION OF ANTI-KEYHOLE LIMPET HEMOCYANIN (KLH) IGM ANTIBODIES IN FISCHER-344 RAT SERUM BY ENZYME-LINKED IMMUNOSORBENT ASSAY (ELISA).

N. Rouleau, M. Boutet, P. Gauthier, V. Girard and L. LeSauteur. *CTBR, Senneville, QC, Canada.* Sponsor: <u>L. LeSauteur</u>.

Immunotoxicity testing guidance: (FDA) Final Guidance for Industry: "Immunotoxicology Evaluation of Investigational New Drugs", the European Agency for the Evaluation of Medicinal Products (EMEA): "Note for Guidance on Repeated Dose Toxicity" and the "Interim Draft Guidance for Immunotoxicity testing" (MHLW/JPMA) have recommended the T-cell dependent antibody response assay to monitor the immune response. In this study, the T-cell dependent primary antibody response in Fischer-344 rats was monitored using KLH as an antigen and a quantitative ELISA. Fischer-344 rats were immunized intra-peritoneally with 0.5 mL of KLH (0.2 mg/mL) and blood was collected pre- and post-KLH immunization (i.e. 5 to 7 days). The ELISA consisted of a plate coated with KLH, blocked with blocking buffer, loaded with control and study samples, then an antibody specific to rat IgM conjugated with peroxidase was added, followed by substrate, and the reaction was stopped and read at 450 nm. Validation of the ELISA, including specificity, linearity of dilution, intra- and inter-assay precision and accuracy, stability and prozone effect, met the acceptance criteria. Study samples can be diluted up to 1/12000, the validated range is 30.0 to 1000.0 ng/mL, the samples were shown to be stable at room temperature for up to 3 hours, at approximately 4°C for up to 7 hours, after 4 freeze-thaw cycles at approximately  $70^{\circ}\text{C}$  and after storage at approximately  $70^{\circ}\text{C}$  for up to 29 days. The anti-KLH IgM antibody response gave results ranging from below the lower limit of quantitation (LLOQ) to 198.0 µg/mL from 3 to 7 days post-KLH immunization. Assessment of the Tcell dependent antibody response using KLH as antigen, administered intra-peritoneally to Fischer-344 rats and the detection of anti-KLH IgM antibodies in serum using an ELISA was shown to be suitable for its intended use.

### 2083

PRIMARY ANTIBODY PRODUCTION TO A T CELL-DEPENDENT ANTIGEN: REPLACEMENT OF THE SRBC PLAQUE-FORMING CELL ASSAY BY A KLH-BASED PROTOCOL.

M. van Zijverden, E. I. Klein Koerkamp, P. T. van den Berg and A. H. Penninks. Experimental Immunology, TNO Nutrition and Food Research, Zeist, Netherlands. Sponsor: V. Feron.

To assess potential effects of pharmaceuticals on the immune system, a primary antibody response to a T cell-dependent antigen is suitable to complete the initial screening phase (EMEA guidance CPMP/SWP/1042/99, and FDA Guidance for Industry, Immunotoxicology Evaluation of Investigational New Drugs Oct 2002). The recommended standard protocol is based on immunization with sheep red blood cells (SRBC) as antigen during test compound treatment. The possible immunomodulation is determined four days later by means of the plaque-forming cell (PFC) assay, in which the number of SRBC-specific IgM-forming cells is assessed in spleen. However there are different disadvantages related to this protocol. First, the antigen (SRBC) is not standard and will differ between different labs. Second, the PFC assay is a terminal assay so it can only be performed at one time point, only IgM can be determined, and it is very laborious. The replacement of SRBC by a

standard antigen (for example keyhole limpet haemocyanin, KLH) and of the PFC assay by an ELISA would greatly improve the assessment of T cell-dependent immunity. Therefore we assessed the response to KLH after using different dosing regimes in mice. Those were respectively single subcutaneous (s.c.) and intraperitoneal (i.p., with and without adjuvant) dosing, and repeated i.p. (6x) dosing. At day 0 (n=6), 7 (n=3) and 14 (n=3) blood was taken. Results showed optimal IgM titers were determined at day 7, and the i.p. regimes induced higher titers than s.c. injection. Addition of adjuvant prolonged the presence of IgM, as did repeated dosing, optimal IgG1 titers were determined at day 14, which was very well induced by i.p. adjuvant or the repeated i.p. injections. Single s.c. or i.p. injections induced less clear titers. Also for rat we are now comparing different routes of KLH immunization, during 28-day oral treatment with known immunosuppressants (cyclosporine A, cyclophosphamide) to validate the assay for the rat.

#### 2084

T-CELL DEPENDENT ANTIBODY RESPONSES TO KEYHOLE LIMPET HEMOCYANIN (KLH) IN PRECLINICAL IMMUNOTOXICITY TESTING.

T. Bigwarfe, M. Abbott, D. DeVona, D. Gonchoroff, <u>H. Haggerty</u>, E. McAvoy, L. Phelps, K. Price and <u>T. Reilly</u>. *Immunotoxicology, Bristol-Myers Squibb, Syracuse, NY.* 

Assessing the effects of drug candidates on immune function during preclinical toxicology studies is an integral part of drug safety evaluation. Recent guidelines set by the Food and Drug Administration and European Agency for the Evaluation of Medicinal Products have recommended the assessment of a T-cell dependent antibody response as part of the Tier 1 immunotoxicity testing strategy to assess the immunotoxic potential of human therapeutics. Keyhole limpet hemocyanin (KLH), a protein purified from the mollusk, Megathura crenulata, is capable of stimulating a T-cell dependent antibody response, which depends upon B-cells, T-cells, and macrophages for its development. Accordingly, antibody responses to KLH should serve as a surrogate for monitoring the potential effects of drug candidates on the immune system. To verify its utility, T-cell dependent humoral responses were assessed following administration of KLH to mice, rats, dogs, and monkeys *via* various routes of administration and over a range of doses (0.25 - 5 mg). Serum samples were collected at least weekly and KLH-specific IgM and IgG responses were monitored using a specific enzyme-linked immunosorbent assay to determine endpoint-titers. Robust anti-KLH antibody responses were observed in all species and optimized accordingly (e.g., 0.5 mg, subcutaneously in rats; peak IgM on day 7; peak IgG on day 21). In each species, the optimized methods were sensitive, specific, and reproducible. KLH antibody responses were significantly repressed by dexamethasone and cyclophosphamide and have since been used to evaluate the induction and reversibility of immunologic tolerance caused by immunomodulatory drugs with diverse mechanisms of action as well as the potential effect of non-immune-based therapeutics on immune function. These studies support the utility of using an anti-KLH antibody response to assess the pharmacologic and toxicologic effects of new drugs on immune function in multiple preclinical species.

### 2085

VALIDATING THE T-DEPENDENT ANTIBODY RESPONSE IN DOGS WITH A KNOWN IMMUNOSUPPRESSIVE AGENT (NEORAL).

D. L. Finco-Kent, J. Dugas, A. Hudson, R. Barnes and <u>T. Kawabata</u>. WWSS, Pfizer, Groton, CT.

The dog is commonly used for safety assessment of drugs in development. If standard toxicology studies indicate immunotoxicity, additional in depth testing may be required. The in vivo primary T-dependent antibody response (TDAR) has been recommended to assess the acquired immune response in mice and rats. A validated TDAR in the dog has not been reported. Our lab previously conducted studies to determine the appropriate dose of antigen (KLH), route and kinetics of the antibody response in the dog. An ELISA was developed to measure KLH-specific IgM and IgG in serum samples. To validate the sensitivity of this method, we investigated the TDAR to KLH in the dog with a known immunosuppressive drug, Neoral. In one study, Neoral was administered once/day for 17 days at 5 and 25 mg/kg. Dogs were immunized on day 5 with KLH and blood was drawn on days 12 and 17. A slight decrease in the IgM antibody response to KLH was observed in some dogs receiving either dose of Neoral. In contrast, the IgG antibody response to KLH was decreased considerably in the dogs that received Neoral. A subsequent study evaluated the IgM and IgG response in dogs receiving Neoral twice/day for 17 days at doses of 20 and 40 mg/kg. The design of this study was the same as before, however, additional blood samples were collected to evaluate cyclosporine trough levels and for hematology and serum chemistry. All dogs had normal hematology and serum chemistry results at the time points checked during the study. The low dose Neoral group had cyclosporine trough levels slightly below levels recommended for immunosuppression while the high dose group had levels at or above recommended immunosuppressive levels. IgM titers to KLH were slightly lower in the Neoral group compared to the controls, whereas IgG titers to KLH

were significantly lower in the Neoral-treated dogs. In conclusion, the results of this study demonstrate that the primary IgM and IgG response to KLH can be used to monitor the immune response in dogs. The IgG response appeared to be more sensitive to Neoral treatment than the IgM response.

### 2086 VALIDATION OF CYNOMOLGUS MONKEY IMMUNOPHENOTYPING BY FLOW CYTOMETRY.

D. Baker, D. Finco-Kent, W. Reagan and <u>T. Kawabata</u>. WWSS, Pfizer, Groton, CT.

Reports on the optimization and validation of immunophenotyping of lymphocytes subsets from Cynomolgus monkey peripheral blood for toxicology studies have been limited. Thus, studies were conducted to determine the optimal conditions for staining and sample processing and stability of peripheral blood samples. Validation studies of intra-assay reproducibility and technician-to-technician and lab-to-lab variability were evaluated. In addition, the day-to-day variability of lymphocyte subsets and a reference range were determined. Pan T cells (CD3+), T-helper (CD3+CD4+), NK cells (CD3-CD16+), T cytotoxic/suppressor (CD3+CD8+) and B cells (CD3-CD20+) were analyzed by flow cytometry. As a positive control for staining, processing and analysis, stabilized human blood (Streck, Inc.) was included in each sample run. Our studies showed that performing 4 color staining using a lyse wash method had good intra-assay precision (less than 5 % CV for all subsets) for cynomolgus peripheral blood. Inter-assay precision was determined using the stabilized human blood tested 18 times over a 3 month period and found to be less than 5% CV for all subsets. Variability between technicians and labs was minimal and reference ranges for the subsets were similar to other reports in the literature. The validated method is extremely robust and can be performed under good laboratory practice conditions.

#### 2087

PRE- AND POSTNATAL THYMUS DEVELOPMENT IN THE CYNOMOLGUS MONKEY: RELEVANCE TO IMMUNOTOXICOLOGY.

E. Buse, G. Habermann, S. Friderichs-Gromoll, J. Kaspareit, F. Vogel and <u>P. Thomas</u>. *Pathology, Covance Laboratories GmbH, Muenster, Germany.* 

Imunosuppression/-modulation have become highy relevant in toxicological research. Special attention is being paid to the ontogenetic development of the immune organs, and in peculiar the thymus as the primary lymphoid organ responsible for T-cell differentiation. Due to the complex function of its multiple cell types, receptors and mediating factors, the thymus represents an important target for drugs and drug related side effects. In order to better characterize development of thymic immune cell phenotypes in this species, this organ was studied from gd 35 to the stage of advanced involution in a 21-year old monkey. Special emphasis was placed on early thymus cell generation and cellular pattern formation during development. Histological standard stains and immunocytochemical methods were used to distinguish between thymic subpopulations. At gd 35 the epithelial bud of the thymus was visible in a sagital position at the level of the appertura thoracica. At gd 50 first lymphocyte-like cells and HLA-DR immunoreactivity of a few cells became obvious. The cortico-medullary differentiation, Hassall's body precursors and faint immmunoreactivity for T-lymphocytes were detected from gd 60 onward. First macrophages were apparent at day 70, first CD 20 immunoreactive cells (B lymphocyte-like cells) at gd 85, and M1014 immunoreactive cells (natural killer cells) at gd 100. At gd 100 all evaluated cell populations present in the adult cynomolgus thymus were in place as demonstrated by at least minimal immunoexpression. By contrast, there was never any indication of CD 34 and CD 117 and CD 35 immunoreactivity at this time. The gd 100 - immunoreactivities persisted, partly with changing distribution patterns, until the advanced age of 21 years with the exception of M1014 immunoreactive cells, which were found only until adult ages. The observed pattern of thymic development was similar to that described for human thymus. The cynomolgus monkey thus represents a suitable model for the study of thymic function in developmental toxicity studies.

#### 2088

FLOW CYTOMETRY-BASED EVALUATION OF LYMPHOCYTE SUBSETS AND NATURAL KILLER CELL ACTIVITY IN DEVELOPING AND ADULT CYNOMOLGUS MONKEYS.

W. Frings and G. Weinbauer. *Covance Laboratories GmbH*, *Muenster, Germany*. Sponsor: P. Thomas.

Nonhuman primates are frequently the animal model of choice for immunotoxicologic evaluation of biologics functional peptides because of high protein-homology to humans, thus ob *via*ting the problems of non-responsiveness or induction of drug-clearance by neutralizing antibodies. The cynomolgus monkey (Macaca fasci-

cularis) is currently the predominating primate model in use. We established a 4colour immunophenotyping protocol using anti-human antibodies and investigated 75 adult animals of each sex in comparison to 10 human volunteers of each sex, and analysed the postnatal development of lymphocyte populations in infant animals. Natural killer cell activity was studied in adult animals and in infants up to 2 years of age. For the latter, K562 human myeloma cells were used as target cells (ORPEGEN Pharmacology Kit) and various E/T ratios were studied in the presence and absence of IL-2. Animals were also treated with 0.25 mg/kg iv dexamethasone. Our immunophenotoyping results indicate that identical staining protocols can be used for human and cynomolgus monkey blood, demonstrating good species comparability. Monkeys generally exhibited larger inter-species variations and had a slightly modified CD4/CD8 ratio. During early infant development in monkeys, a progressive decrease of CD4/CD8 ratio was seen which was similar to CD4/CD8 ratio change described for human postnatal development. Dexamethasone transiently suppressed natural killer cell activity. Overall, natural killer cell activity was comparable for adult and infant animals suggesting early activation of non-specific defense systems. In conclusion, adult and developing lymphocyte subset populations share similarities between cynomolgus monkey and

### 2089 EVALUATION OF T-DEPENDENT ANTIBODY RESPONSE IN CYNOMOLGUS MONKEYS.

J. D. Alvey and J. R. Piccotti. Safety Sciences, Pfizer Global Research & Development, Ann Arbor, MI. Sponsor: M. Bleavins.

The Committee for Proprietary Medicinal Products (CPMP) and the Food and Drug Administration (FDA) recommend evaluating a primary T-dependent antibody response when assessing the immunotoxicity potential of new drug candidates. We recently developed and validated an assay to measure a primary IgM response to keyhole limpet hemocyanin (KLH) in rats. The current study was designed to develop and test an IgM response to KLH in a non-rodent model. In the initial phase, 3 male cynomolgus monkeys were given a single intramuscular injection of KLH at 3, 10 or 30 mg per animal. Serum samples were collected prior to immunization, and on Days 3, 5, 7, 10, 14 and 21 post-immunization. IgM specific for KLH was measured by an ELISA developed in our lab, using a detection antibody with high reactivity to monkey IgM and no cross-reactivity with monkey IgG. In contrast to what was observed in the rat, low to moderate levels of anti-KLH IgM were detected in monkeys prior to KLH injection. The IgM in pretest sera was specific for KLH, since antibody was not detected in uncoated wells. Interestingly, anti-KLH IgM was detected in the majority of naive stock monkeys tested. Since cynomolgus monkeys eat crab and other shellfish, it is possible that animals are exposed to KLH in diet. Although IgM was detected in sera of monkeys predose, antibody concentrations were significantly elevated over pretest by Day 5 after KLH injection. The peak IgM responses occurred between Days 7 and 14, with antibody levels decreasing slightly by Day 21. The greatest antibody response was elicited by the monkey given 3 mg, which also was the animal with the highest pretest titer. Additional experiments are underway to increase the number of monkeys evaluated, and to better characterize the timing of the IgM response to KLH. Experiments evaluating alternate T-dependent antigens also are planned.

#### 2090

INHIBITION OF IL-6 BUT NOT TNF $\alpha$  INHIBITS THE ANTIBODY RESPONSE TO KLH IN CYNOMOLGUS MACAQUES.

P. L. Martin<sup>1</sup>, J. Cornacoff<sup>1</sup>, P. Bugelski<sup>1</sup>, S. Hersey<sup>3</sup>, E. C. Martin<sup>2</sup>, J. E. Sutherland<sup>2</sup> and G. Treacy<sup>1</sup>. <sup>1</sup> Toxicology, Centocor, Malvern, PA, <sup>2</sup> Charles River Laboratories, Worchester, MA and <sup>3</sup> Charles River Laboratories, Sparks, NV.

Tumor necrosis factor  $\alpha$  (TNF $\alpha$ ) and interleukin-6 (IL-6) are proinflammatory cytokines believed to play a role in a variety of autoimmune diseases. Inhibitors of TNF $\alpha$  and IL-6 have been shown to be effective therapeutically in a number of animal disease models. However, the role of these cytokines in immune surveillance is not well understood. In this study, the effects of TNFα and IL-6 monoclonal antibodies (mAbs) on the humoral immune response (IgG and IgM) to keyhole limpet hemocyanin (KLH), a T-dependent antigen were evaluated in cynomolgus macaques. Male and female macaques were administered 0.1 mg of KLH in 1 mL of Incomplete Freund's Adjuvant (IFA) intramuscularly. KLH/adjuvant was administered on two occasions separated by 14 to 18 days. Treatment with the cytokine inhibitors was initiated 9 - 11 days prior to the first KLH/adjuvant administration. Serum samples for measurement of anti-KLH antibodies were collected prior to and for up to six months during anti-cytokine treatment. Titers of anti-KLH antibodies (IgG and IgM) were measured using an ELISA method. Anti-KLH antibodies were detectable 12-13 days after the first KLH administration. KLH antibody titers continued to rise following the second KLH administration and peaked at 23

to 26-days post challenge. The TNF $\alpha$  inhibitor had no effect on anti-KLH antibody development. The IL-6 inhibitor produced a modest (~20%) reduction in anti-KLH antibody titers. This study shows that KLH can be used to evaluate the immune competence of cynomolgus macaques treated with cytokine inhibitors. The results suggest that IL-6 but not TNF $\alpha$  is involved in the development of the antibody response to KLH/IFA in cynomolgus macaques. These results in non-human primates are consistent with published data obtained in mice.

# 2091 DEVELOPMENT AND IMMUNOMODULATION OF DELAYED-TYPE HYPERSENSITIVITY (DTH) IN CYNOMOLGUS MONKEYS.

K. D. Price, L. Mezza, R. Diters, S. Wells, D. DeVona, Z. Tzogas and H. Haggerty. Bristol-Myers Squibb, Syracuse, NY.

DTH is a measure of cellular immunity useful in assessing multiple aspects of the immune response. Although others have described monkey DTH models, clinical reactions have not been robust or consistent in our hands. To address this issue, monkeys were given s.c. injections of an Ag cocktail containing diphtheria (Dp;15 Lf), trichophyton and C. albicans (6375 PNU) toxoids in IFA on days 1, 4, 7, 10, and/or 13. At 2-24 wk postsensitization, monkeys received i.d. injections of each Ag (4-10X lower amounts), Ag cocktail, or diluent. Dermal responses (reaction diameter, induration, erythema) were measured at 24-96h postchallenge and skin biopsies were obtained for histology and immunohistochemistry. Elicitation of DTH responses at 2 weeks post-sensitization was unsuccessful, complicated by a nonprogressive neutrophilic response that was only distinguishable microscopically. Classical DTH was observed at ≥4wk post-sensitization and sustained for >24wk. Erythema preceded induration, which peaked at 72h. DTH cellularity was observed microscopically even if a clinical reaction was not, and was preceded by an influx of neutrophils and some macrophages at 24h (subacute), followed by angiocentric distribution of lymphocytes and macrophages (chronic inflammation) at 48-96h. Immunohistochemistry revealed an influx of macrophages and T-cells (CD8>CD4) but not B-cells. Clinical reactions following oral (Î week during challenge) dexamethasone (Dex, 2 or 20 mg/kg) or cyclosporin A (120 mg/kg) were not diminished and humoral immunity to Dp was not suppressed. However, dose-related decreases in cellularity and subacute rather than chronic inflammation was observed in monkeys given Dex. Humoral immunity to Dp was augmented in monkeys receiving 1 mg of oligo CpG (during sensitization), but DTH was not enhanced. Thus, clinical reactions may not always predict classical DTH and microscopic confirmation is needed, particularly to monitor immunomodulation.

# 2092 IMMUNOLOGICAL, HEMATOLOGICAL AND CLINICAL PATHOLOGY PARAMETERS DURING POSTNATAL DEVELOPMENT IN THE CYNOMOLGUS MONKEY:

G. Weinbauer, G. Habermann, I. Osterburg, J. Kaspareit, S. Friderichs-Gromoll, S. Srivastav, W. Mueller and F. Vogel. *Covance Laboratories GmbH*, *Muenster, Germany.* Sponsor: <u>P. Thomas</u>.

PRELIMINARY FINDINGS.

Nonhuman primates are gaining increasing importance as preclinical animal model for the study of developmental and reproductive toxicology. A major reason for the increased need of nonhuman primates is the fact that many immunotherapeutics and biotechnology products do not interact with rodent tissues and receptors or are immunogenic in rodents and frequently only cross-react with primate tissue. This and the issuance of new guidelines mandating immunotoxicity screening of new drugs has led to increased demands of using the cynomolgus monkey (Macaca fascicularis) in pre-/postnatal development studies. This investigation compiles developmental control data from more than 80 infant cynomolgus monkeys over the age of one month to two years. Wherever possible a comparison to published human pediatric data was attempted. For the study of B cell- and T cell-mediated immune response, keyhole-limpet-hemocyanin (KLH) and delayed-type-hypersensitivity (DTH) testing were used. Antibody formation was seen by 6-7 months of age and lymphocyte subset development was similar for monkey and human. Hematological parameters such as red and white blood cell count, hematocrit and platelet count showed a comparable developmental pattern relative to human data. Although highly variable across animals, the average pattern of immunoglobulins A, G and M appeared comparable to that described for human. Data for selected clinical pathology parameters, e.g. glucose, potassium, cholesterol, triglycerides, total protein and liver enzymes, also revealed close similarity to human reference data. Our preliminary evaluation suggests that the postnatal development of various cynomolgus monkey organ systems shares similarities with that in humans. These observations support the use of the cynomolgus monkey for toxicity evaluation in pre-/postnatal development studies.

### 2093 EFFECT OF CHRONIC EXPOSURE TO ISOFLAVONE ON POSTNATAL DEVELOPMENT OF MICE.

K. Takashima<sup>1,2</sup>, H. Fukata<sup>2</sup>, H. Kato<sup>3</sup>, T. Iguchi<sup>4,5</sup>, M. Komiyama<sup>6</sup> and C. Mori<sup>1,5</sup>. <sup>1</sup>Department of Bioenvironmental Medicine, Graduate School of Medicine, Chiba University, Chiba, Japan, <sup>2</sup>Department of Environmental Medical Science (SRL), Graduate School of Medicine, Chiba University, Chiba, Japan, <sup>3</sup>Nihon Bioresearch Inc., Hashima, Japan, <sup>4</sup>Center for Integrative bioscience, Okazaki National Research Institutes, Okazaki, Japan, <sup>5</sup>CREST, JST, Kawaguchi, Japan and <sup>6</sup>Center for Environment, Health and Field Sciences, Health and Field Sciences, Chiba University, Chiba, Japan.

We have investigated the effect of chronic exposure to isoflavone (IF) on postnatal development of C57BL/Cr Slc mice. Mother mice were fed with an IF-free purified diet (IF-free group) or the purified diet supplemented with 0.05% IF (0.05%-IF group) from 1, 3 or 5 weeks before gestation to the end of lactation, and their pups were fed with the same diets after weaning until sacrifice at postnatal day (PND) 31. The IF-free diet was composed of 24.5% milk casein, 45.5% corn starch, 10% granulated sugar, 6% corn oil, 5% cellulose powder, 1% α-starch, 1% vitamine mix and 7% mineral mix. The dose of 0.05% IF is comparable to a daily intake of IF for some of Asian people and that for neonates who are fed on soy-based formula. Thus, the mice examined were chronically exposed to isoflavone in utero and during postnatal period. Body weight and other developmental landmarks of the neonatal mice were monitored at evry seven days till PND 31. Regarding the body weight and anogenital distance, there was no significant difference between IF-free group and 0.05%-IF group. However, viginal opening in 0.05%-IF group was several days earlier than that in IF-free group, significantly. This result suggests that chronic exposure to IF causes earlier puberty to female neonates.

### 2094 PRACTICAL ASPECTS OF JUVENILE SAFETY STUDIES IN MINIPIGS.

A. Makin and A. Christensen. *Toxicology and Pharmacology, Scantox A/S, Lille Skensved, Denmark.* Sponsor: R. Harling.

Toxicity testing of pharmaceuticals for regulatory purposes should be suited to the target population. Standard non-clinical testing requirements cover, usually, adult animals and also address the subject of reproductive function. The reproductive studies cover the full reproductive cycle from mating performance of the parents through to the same stage in the F1 generation. However, at no stage is there a requirement for direct dosing of the offspring. There is a recognition that this leaves a gap in the safety evaluation of a pharmaceutical whereby the period from birth to adulthood is incompletely studied. In 2003, a draft guidance on non-clinical safety evaluation of pediatric drug products was issued. However, studies in young animals present many practical challenges, particularly when using non-rodent species. Long gestation periods, small litter sizes and a general lack of background data for young animals present difficulties. Because of the relatively short period from birth to sexual maturity in laboratory species compared to humans, it is important that testing in the animal species should commence as soon after birth as is practicably possible. This is particularly important where drugs are intended for use in neonatal humans. Particularly for non-rodent species the arrangement of pre-weaned animals into experimental groups is a key consideration. A practical challenge is having the birth of the experimental animals synchronised in order to have a study design that is optimum. At Scantox we have performed studies to establish the minipig as a suitable non-rodent model for non-clinical testing of pharmaceuticals for use in pediatric human populations. We demonstrate the practical feasibility of randomised cross-fostering, and we have established the possibility of performing the standard techniques e.g. for parenteral administration of drugs, and repeated collection of blood samples for TK. We have a growing background database of clinical pathology, and pathology parameters in relation to animal age. This poster describes the practicalities of performing such studies and presents background data.

#### 2095 PRENATAL DOSE LEVEL OF 3, 3', 4, 4', 5-PENTACHLORBIPHENYL (PCB 126) TO INDUCE HYPOSPADIAS IN FEMALE RATS.

M. Shirota<sup>1, 2</sup>, Y. Sakurada<sup>2</sup>, K. Hayasaka<sup>2</sup>, K. Inoue<sup>2</sup> and K. Shirota<sup>2</sup>. <sup>1</sup>Hatano Research Institute, Food and Drug Safety Center, Hadano, Kanagawa, Japan and <sup>2</sup>Research Institute of Biosciences, Azabu University, Sagamihara, Kanagawa, Japan. Sponsor: H. Ono.

We have shown that prenatal but not postnatal exposure to PCB 126 induces genital dysmorphogenesis, such as hypospadias, in female rats. In the present study, we examined a relation between prenatal dosage of PCB 126 and incidence and severity of the malformation. Each six pregnant Sprague-Dawley rats were orally given

PCB 126 at a dose level of 0 (corn oil, control), 0.3, 1, 3, 10 or 30 µg/kg on gestational day 15, and were allowed to deliver spontaneously. One day after the delivery, their litter size was examined and then was standardized to 8. The female offspring (35-41 offspring/group) were examined for external appearance on postnatal day (PND) 1 and at necropsy (on PNDs 25-28), and were determined body weight on PND 1 and at weaning (PND 21) and the necropsy. External genital malformations were classified based on the grossly appearance as slight (partial cleft formation between urethral orifice and vaginal orifice), moderate (more severe cleft formation between urethral orifice and vaginal orifice) and severe (hypospadias). Levels of statistical significance were analyzed by ANOVA, followed by a Dunnetttest. No adverse effects of the treatment were observed in any dam. Whereas viabilities of the offspring were comparable among the groups, body weight of the offspring in the groups given PCB 126 at 3 µg/kg and more was significantly lower than that of age-matched control. Abnormal external appearance was not observed on PND 1, however, genital anomalies became evident at the necropsy in the groups given PCB 126 at 3 µg/kg and more. Severity of the anomalies increased in relation to the prenatal doses of PCB 126, and hypospadias was developed in 2.5, 2.8 and 27.3 percent of the offspring in the 3, 10 and 30 µg/kg-treated groups, respectively. From these results, the lowest oral dose of PCB 126 to induce genital dysmorphogenesis in rats is concluded to be 3  $\mu$ g/kg on gestational day 15.

2096

ECOLOGICAL INDICATORS, ENVIRONMENTAL CONTAMINANTS, AND AUTISM: PRELIMINARY FINDINGS FROM MINNESOTA.

M. G. Opler<sup>1</sup>, L. Moy<sup>2</sup>, K. Eng<sup>2</sup> and M. Bresnahan<sup>3</sup>. <sup>1</sup>Psychiatry, Columbia University, New York, NY, <sup>2</sup>Bronx High School of Science, Bronx, NY and <sup>3</sup>Epidemiology, Columbia University, New York, NY. Sponsor: W. Zheng.

Autism, a developmental disorder of unknown etiology is characterized by marked difficulties in social relations and communication during early childhood and throughout the lifecourse. Prevalence data collected by the Department of Education of the State of Minnesota suggests that rates are increasing rapidly. While no specific genetic or environmental risk factor has been conclusively linked to autism, several ecological and environmental indicators may help to guide investigations, including developmental malformations in free-living amphibian populations, timber damage, and various pollutant levels. Data was taken from studies conducted by the Minnesota Pollution Control Agency, the USEPA, and the US Biological Service. This data was dichotomized to high and low categories, using the median as a cutoff for each indicator. Annual increases in autism rates in children aged 6-11 in the public school system were calculated, and group differences were measured using different indicators. When county-level rates of amphibian malformations were examined, autism rates in children aged 6-11 were significantly higher in those counties with malformation rates ≈ 2% (p=0.016). Reported airborn releases of toxins, including heavy metals such as cadmium, mercury, and lead were also tested. Autism rates were higher in counties with total airborn pollutant levels above the median. These differences were not statistically significant. In counties with high aggregate timber loss per square mile due to fire, logging, drought, etc., autism rates increased more quickly and demonstrated a trend towards significance(p<0.1). When the results were stratified by population, the results were not measurably altered, excepting the case of total air pollutant levels, which demonstrates a statistical trend when the most populous counties (top 10%) are excluded. Further analyses are required to expand these findings, using more complete data, specific exposures, and rigorous analyses.

2097

A TERATOLOGY STUDY OF ZICONOTIDE UTILIZING DOUBLE-STAINING AND POST NATAL EXAMINATIONS TO ELUCIDATE DELAYED OSSIFICATION.

M. J. Skov<sup>1</sup>, <u>G. M. Shopp</u><sup>1</sup>, L. Pouliot<sup>2</sup>, K. J. Robinson<sup>2</sup> and J. C. Beck<sup>3</sup>. <sup>1</sup>Safety Evaluation, Elan Pharmaceuticals, Inc., South San Francisco, CA, <sup>2</sup>CTBR Bio-Research Inc., Senneville, QC, Canada and <sup>3</sup>Roche, Palo Alto, CA.

Ziconotide (PRIALT<sup>TM</sup>) is the synthetic equivalent of a 25-amino acid, polybasic peptide found in the venom of the marine snail, *Conus magus*. Ziconotide is a potent and selective N-type calcium channel blocker being developed as an intrathecal (IT) analgesic agent for severe, chronic pain. The effects of ziconotide on rat embryo-fetal development were evaluated by continuous intravenous (IV) infusion from gestation day (GD) 6 through 15, at doses of 1.5, 4.5 and 15 mg/kg/day. Fetal abnormalities were limited to a significant increase in the incidence of incompletely ossified or unossified pelvic bones in the fetuses and litters of the high-dose dams compared to vehicle. These effects were seen at a dose where maternal toxicity coexisted and consisted of significant weight loss and reduced food consumption

from GD 6 to 9. In an effort to show that the incomplete ossification was a transient effect, a repeat study was performed utilizing double-staining with Alizarin red S for bone and Alcian blue for cartilage. A littering phase was incorporated to assess the post-natal skeletal development of the pelvic girdle in Day 4 post-partum pups. Consistent with the first study, significant weight loss and reduced food consumption were noted from GD 6 to 9 in dams treated with 15 mg/kg/day zi-conotide and the incidence of incomplete ossification of the pubic bone(s) was increased for fetuses and litters examined at GD 20. Pelvic bones were normal for all Day 4 post-partum pups. These findings indicate that the reduced bone formation of the pelvic girdle in fetuses at GD 20 was due to a transitory delay in ossification, and not a permanent effect. In conclusion, ziconotide was not teratogenic in a study of rat prenatal development when administered by continuous IV infusion from GD 6 through 15 at systemic exposures producing maternal toxicity and greater than 2500-times the maximum measured human systemic exposure after IT administration.

2098

NEONATAL EXPOSURE TO GENISTEIN, A SOY PHYTOESTROGEN, ALTERS MAMMARY GLAND DIFFERENTIATION.

E. Padilla-Banks, <u>W. Jefferson</u> and R. Newbold. *NIEHS, Research Triangle Park, NC.* 

Some reports suggest developmental exposure to genistein (Gen) protects against mammary carcinogens later in life; however, in vitro studies suggest the opposite, i.e., that Gen stimulates breast cancer cells to proliferate. Further, exposure to estrogens, including the period of fetal development, is a well-known risk factor for the development of breast cancer. Numerous experimental studies involving the mammary gland and the reproductive tract attest to the proliferative and carcinogenic potency of estrogens. Since soy products including soy based infant formulas are increasingly being marketed to children, and to adults for potential health benefits and hormone replacement therapy, we investigated the effects of early exposure to genistein on the mammary gland. Neonatal CD-1 mice were treated on days 1-5 with Gen 0.5-50 mg/kg/day; these doses span the range for human exposures. At 5 and 6 wks, mammary glands (#4) were examined by whole mount analysis. Estrogen receptor (ER)α, ERβ and progesterone receptor (PR) were studied by immunohistochemistry and/or Western blots. Control mice exhibited an increase in terminal end buds (TEBs) from 5 to 6 wks of age indicating active ductal morphogenesis. Mice treated with Gen-0.5 showed similar increase in the number of TEBs from 5 to 6 wks but the numbers were higher than controls at both ages. Gen-5 showed a different pattern of mammary gland development with more TEBs present at 5 wks but less at 6 wks of age suggesting an advance in differentiation at this dose. The highest dose of Gen showed similar numbers of TEBs as controls, but mammary gland development was inhibited with smaller ducts and less ductal branching. As another indication of altered development, the length of the furthest elongated duct was measured; the expanding mammary ductal mass increased after exposure to Gen-0.5 at 5 weeks, and the 0.5 and 5 doses at 6 wks. In contrast, mammary glands from Gen-50 showed growth inhibition of the genistein exposed gland; this stunted development persisted throughout life.

2099

FEASIBILITY STUDY TO ASSESS SKELETAL DEVELOPMENT IN NON-CLINICAL PEDIATRIC STUDIES.

K. Robinson, A. Varela, N. Doyle, J. Jolette, C. Luc, M. Sabourin, C. Chevrier and S. Smith. *CTBR, Senneville, QC, Canada.* Sponsor: M. Vezina.

The increased emphasis placed upon non-clinical pediatric testing in recent years and the focus upon the development of several organ systems including the skeleton has lead to the adaptation of a variety of techniques for these evaluations. The pediatric use of drug classes such as the quinolones, glucocorticoids and bisphosphonates and their effects on the skeleton, highlights the need to evaluate new test agents on the immature skeleton during non-clinical testing. Morphological abnormalities, longitudinal bone growth and epiphyseal closure is effectively monitored using standard radiography (X-rays) while the more specialized technique of Dual Energy X-ray Absorptiometry (DXA) provides information on bone area, bone mineral content and bone mineral density for the whole body, axial and appendicular skeleton. Peripheral quantitative computed tomography (pQCT) provides information on the trabecular and cortical bone compartments and bone geometry at the proximal tibia and/or distal radius. These techniques can be performed repeatedly on the same animals at a range of ages, from neonatal pups to juvenile animals of several months of age. DXA scans have been performed successfully in our laboratory on dog pups from 1 day of age up to adulthood. Histopathological and histomorphometric techniques further evaluate treatment effects on bone and cartilage. Bone structural variables were accurately measured on 29-day old rat pups. Growth plate width was measured to assess the potential for effects on bone mineralization. The articular cartilage structural integrity was assessed using Safranin-O stained sections to target the proteoglycan content and chondrocyte population. We have shown that DXA provided reproducible and repeated non-invasive measurements of bone density in vivo in skeletally immature animals, and that radiography was a useful tool to assess bone growth. Post-mortem evaluations using morphometry and histology techniques were used to further characterize the structural changes of bone and/or cartilage.

### 2100 SAFETY ASSESSMENT OF CARGLUMIC ACID IN JUVENILE RATS.

R. Forster<sup>1</sup>, G. Chevalier<sup>1</sup>, M. Attia<sup>1</sup>, L. Martin<sup>2</sup> and M. Fortun<sup>2</sup>. <sup>1</sup>CIT, Evreux, France and <sup>2</sup>Orphan Europe, Paris, France.

Carglumic acid (N-carbamoyl-L-glutamic acid) is currently the only specific drug therapy for N-acetylglutamate (NAG) synthase deficiency, a very rare congenital disorder of the urea cycle. Sufferers from this condition are unable to eliminate nitrogen which accumulates as ammonia in the blood, with consequent harmful effects, in particular for the brain, and rapid lethal course in most cases. Carglumic acid can substitute for the lacking NAG in activating the first enzyme of the urea cycle (carbamoyl phosphate synthetase) and thus re-establishing nitrogen elimination. As part of a package of regulatory studies to support registration of the pharmaceutical grade carglumic acid supplied by Orphan Europe as an orphan drug, a chronic toxicity study was performed in rats. Since childhood therapy is often required, the study included an evaluation of growth and development during the juvenile period. Carglumic acid was administered daily to rats from age 4 weeks for a period of 6 months. In addition to standard parameters (body weight, clinical observations, ophthalmology, haematology, blood biochemistry, urinalysis and histopathology) the study included evaluation of the development of bone (by DXA in vivo and ex vivo), teeth and body length. Drug levels in plasma and urine samples were determined in order to investigate systemic exposure and elimination of the compound. On completion of 26 weeks treatment, potential effects on the immune system were assessed through histopathology of lymphoid organs and lymphocyte subset determinations. Cell proliferation in selected tissues was quantified by PCNA staining (kidneys, liver and testes). Potential effects on reproductive functions were evaluated in males (by mating trial with untreated females and seminology) and in females (estrus cycle). Treatment with carglumic acid was well tolerated at the selected dose-levels, which represents appropriate multiples of the clinical long-term treatment-levels, supporting the safety of the proposed clinical use in NAGS deficiency.

# 2101 COMPARATIVE TOXICITY STUDY OF PHENYTOIN IN JUVENILE AND ADULT CYNOMOLGUS MONKEYS.

R. M. Perez<sup>1</sup>, F. P. de Villa<sup>1</sup>, L. S. Antonio<sup>1</sup>, T. Hayashi<sup>1</sup>, N. Muto<sup>2</sup>, E. Suzuki<sup>2</sup> and M. Nomura<sup>2</sup>. <sup>1</sup>INA RESEARCH PHILIPPINES, INC., Laguna, Philippines and <sup>2</sup>Ina Research Inc., Nagano, Japan.

The decision to utilize particular animal species as test systems is based on similarities in the drug metabolic profile and the developmental status of the target organs between such species and humans. The 2C enzymes of the adult monkey are known to be comparable to their human counterpart. Juvenile monkeys exhibit developmental characteristics similar to pediatric patients making them potentially excellent test systems for assessing toxicity in the pediatric population. In this study, the comparative toxicity of oral phenytoin (PHT), a drug known to be largely metabolized by the CYP2C9 and CYP2C19 isoforms of the cytochrome P450 enzyme system, at dose levels of 15 and 30 mg/kg/day for 14 days was evaluated in juvenile and adult cynomolgus monkeys. Six- and 18-month old male and female juvenile monkeys were randomly divided into control and treatment groups. Adult (4.5year old) male and female monkeys were included in the treatment group. The treatment group initially received 15 mg/kg/day for 2 weeks. No remarkable changes in the neurobehavioral scores, body weights, food consumption, hematology and clinical chemistry parameters, ECG or EEG measurements were observed among the animals given 15 mg/kg/day. PHT plasma concentrations were comparable in all age groups of both sexes on Day 1 at 24 hours after administration. However, the PHT plasma concentration was apparently higher in the 6-month old animals compared to those in the 18-month old and adult monkeys. The findings were suggestive of the slower metabolic rate in the 6-month old monkeys compared to the relatively older animals. The results are explained in terms of the age-related differences in the development of toxicity and their relationship with CYP enzyme activities. Our results support the necessity of conducting nonclinical toxicological evaluation of drugs intended for the pediatric population.

# 2102 GLOBAL ANALYSIS OF ABERRANT DNA METHYLATION INDUCED BY NEONATAL EXPOSURE TO DIETHYLSTILBESTROL USING RESTRICTION

LANDMARK GENOMIC SCANNING (RLGS)

K. Sato<sup>1</sup>, H. Fukata<sup>2</sup>, Y. Kogo<sup>3</sup>, J. Ohgane<sup>3</sup>, K. Shiota<sup>3</sup> and <u>C. Mori</u><sup>1,4</sup>.

<sup>1</sup>Department of Bioenvironmental Medicine, Graduate School of Medicine, Chiba University, Chiba, Japan, <sup>2</sup>Department of Environmental Medical Science (SRL), Graduate School of Medicine, Chiba University, Chiba, Japan, <sup>3</sup>Laboratory of Cellular Biochemistry, Veterinary Medical Science/Animal Resource Science, The

Cellular Biochemistry, Veterinary Medical Science/Animal Resource Science, The University of Tokyo, Tokyo, Japan and <sup>4</sup>Core Research for Evolutional Science of Technology (CREST), Japan Science and Technology Corporation (JST), Kawaguchi, Japan.

Exposure to endocrine disruptors during the critical periods of development causes persistent induction or suppression of certain genes, and is supposed to result in abnormality of reproductive organs and cancer. In these processes, epigenetic changes such as DNA methylation and histone modification (acetylation, methylation, or phosphorylation) suggested to be involved. In the present study, we examined the effect of an endocrine disruptor on global DNA methylation. Synthetic estrogen, diethylstilbestrol (DES) was injected into C57BL/6 mice from neonatal day 1 to 5 (3 μg/day). At day 30, genomic DNA was collected from epididymis or uterus. Restriction landmark genomic scanning (RLGS) is a two-dimensional gel electrophoresis method that allows detection of DNA methylation if a methylationsensitive landmark enzyme such as NotI is used. Using RLGS method, DNA methylation profiles of collected samples were analyzed. In the epididymis of DEStreated group, 6 loci were demethylated and 1 locus was methylated in about 1,000 loci, as compared to untreated group, and in the uterus, 6 loci were demethylated and 5 loci were methylated. Furthermore, effects of lower dose of DES (from 0.00003 to 0.3 µg) in uterus were examined. The number of loci which status of methylation changed was increased dose-dependently. We suggest that global analysis of DNA methylation using RLGS is an effective approach to assess the toxicity of exogenous agents including endocrine disruptors.

2103 DETERMINING THE RESPIRATORY BIOAVAILABILITY OF WATER-SOLUBLE VAPORS USING PBPK MODELING AND A COMBINED GAS UPTAKE INHALATION, PLETHYSMOGRAPHY, AND BLOOD SAMPLING SYSTEM.

A. Woodstock<sup>1</sup>, T. S. Poet<sup>1</sup>, J. J. Soelberg<sup>1</sup>, H. Wu<sup>1</sup>, J. G. Teeguarden<sup>2</sup>, W. Faber<sup>3</sup>, B. Francis<sup>4</sup> and R. A. Corley<sup>1</sup>. <sup>1</sup>Pacific Northwest National Laboratory, Richland, WA, <sup>2</sup>Environ, Collegeville, PA, <sup>3</sup>WFTC, LLC, Victor, NY and <sup>4</sup>American Chemistry Council, Arlington, VA.

A novel approach involving PBPK modeling and a combined gas uptake inhalation, plethysmography and blood sampling system was developed to determine the respiratory bioavailability of a series of ethyl, propyl, isopropyl, butyl, isobutyl and amyl alcohols and acetate esters in rats. Six male SD rats, with jugular cannulas exteriorized through a gas uptake chamber, were individually exposed for 2 hr to initial chamber loading concentrations of 2000 ppm for each chemical. Chamber concentrations and respiratory rates were determined simultaneously while blood samples were collected for analysis of each parent chemical and its key metabolites. Respiratory rates rapidly decreased at the start of each exposure then increased linearly as chamber concentrations decreased. A generic gas uptake PBPK model using published partition coefficients and metabolism rates, was modified to incorporate measured, time-dependent respiration rates to analyze the data. For these highly water-soluble vapors, chamber concentration data were highly sensitive to respiratory rates and bioavailability; thus, incorporating plethysmography in the gas uptake system was critical to the determination of respiratory bioavailability. In contrast, chamber concentration data were not sensitive to either metabolic rates or blood:air partition coefficients >10. However, the concentrations of parent chemical in blood during each exposure were highly sensitive to metabolism as well as ventilation rates and fractional absorption. Thus, the blood data served as an internal validation of the bioavailability estimated from the chamber concentration data. The resulting respiratory bioavailabilities averaged ~40-50% of total ventilation for the alcohols and ~50-70% for the acetates. (Sponsored by the Oxo Process Panel of the American Chemistry Council).

#### 2104

ROLE OF TUMOR NECROSIS FACTOR ALPHA AND INTERLEUKIN-1 BETA IN THE DEVELOPMENT OF PULMONARY TOXICITY FROM EXPOSURE TO ADVANCED COMPOSITE MATERIAL COMBUSTION ATMOSPHERES.

P. G. Reinhart<sup>1</sup>, D. L. Courson<sup>2</sup>, J. E. Reboulet<sup>3</sup> and E. C. Kimmel<sup>3</sup>. <sup>1</sup>Naval Health Research Center (Toxicology Detachment), Wright-Patterson AFB, OH, <sup>2</sup>Man Tech Environmental Technology Inc., Wright-Patterson AFB, OH and <sup>3</sup>Geo-Centers Inc., Wright-Patterson AFB, OH.

Exposure to advanced composite material (ACM) combustion atmospheres results in a significant release of inflammatory cytokines tumor necrosis factor alpha (TNF- $\alpha$ ) and interleukin-1 beta (IL-1 $\beta$ ) as well as an influx of inflammatory cells entering the airways and an increase in pulmonary epithelial permeability. The purpose of this study was to evaluate the role of these cytokines in the development of ACM smoke-induced pulmonary toxicity. Genetically altered mice (TNF-α -/-, and IL-1 $\beta$ -/-) and their genetic controls were exposed to ACM combustion atmospheres for 1 hour. Twenty four hours later the lungs were lavaged and the lavage cells counted and identified. The lavage fluid was analyzed for inflammatory cytokines and albumin. To determine the effectiveness of pre-treatment, antibodies against TNF-α as well as IL-1β were administered immediately prior to smoke exposure. The results revealed significant reductions in total lavage cells, percentage of neutrophils, IL-1 $\beta$ , and IL-6 in the TNF- $\alpha$ -/- group when compared to controls. In the IL-1 $\beta$  study, significant reductions in total lavage cells and percentage of neutrophils were noted. The use of antibodies failed to protect against changes in epithelial permeability based on lavage fluid albumin levels. No changes were noted in the levels of TNF- $\alpha$  or IL-1 $\beta$  in antibody treated groups as compared to controls. Anti-TNF-α resulted in a significant reduction in the percentage of PMNs in the lavage fluid while anti-IL-1\beta resulted in a higher percentage. Both antibody treatments resulted in elevated levels of IL-6. In conclusion, silencing of either TNF-α or IL-1 $\beta$  gene results in a significant reduction in ACM smoke induced inflammatory response while pretreatment with the appropriate antibody failed to prevent the inflammatory responses.

#### 2105

TIME COURSE OF PULMONARY EFFECTS FROM EXPOSURE TO ADVANCED COMPOSITE MATERIAL COMBUSTION ATMOSPHERES.

D. L. Courson<sup>1</sup>, P. G. Reinhart<sup>2</sup>, J. E. Reboulet<sup>3</sup> and E. C. Kimmel<sup>3</sup>. <sup>1</sup>Man Tech Environmental Technology Inc., Wright-Patterson AFB, OH, <sup>2</sup>Naval Health Research Center (Toxicology Detachment), Wright-Patterson AFB, OH and <sup>3</sup>Geo-Centers Inc., Wright-Patterson AFB, OH.

While the use of advanced composite materials (ACM) provides a significant benefit as a lighter alternative to metallic components, their downside is their combustibility. The effects of exposure to such atmospheres are not completely known. To address this data gap, we exposed Fischer 344 rats to ACM combustion atmospheres. Rats were exposed for 1 hour in whole body chambers to smoke produced by the pyrollysis of 60 g of carbon/graphite/epoxy material. Controls were exposed in a similar fashion to filtered air. After 1, 3, 7, 21, and 156 days post-exposure, the animals were evaluated for pulmonary toxicity. Bronchoalveolar lavage was performed and the cellular components identified and quantified. The lavage fluid was analyzed for tumor necrosis factor alpha (TNF-α), înterleukin-1 beta (ÎL-1β), interleukin-6 (IL-6), and albumin. Significant increases in TNF-α were noted in all of the smoke-exposed groups. Significant increases in IL-1β were noted on days 1 and 21 while IL-6 was significantly elevated on day 1 only. Albumin levels in the lavage fluid were significantly greater in the smoke exposed groups for all time points examined, with the exception of day 156. Cell differentials in the smoke-exposed animals revealed significant increases in neutrophils on days 1 and 3 while total lavage cell counts were significantly higher for all time points with the exception of day 7. In conclusion, exposure to ACM combustion atmospheres results in a time dependent release of inflammatory cytokines with a sustained influx of inflammatory cells, and changes in epithelial permeability.

#### 2106

FUNCTIONAL ROLE OF TRANSFERRIN IN THE UPTAKE OF METALS TO THE BRAIN VIA THE OLFACTORY PATHWAY.

D. C. Dorman, B. A. Wong, M. Sar, B. E. McManus, A. M. McElveen, D. G. Wallace, E. E. Gross and D. B. Rao. CIIT Centers for Health REsearch, Research Triangle Park, NC.

Environmental and occupational exposures to metals *via* inhalation are associated with several neurodegenerative diseases. Although inhaled or instilled Mn can be directly transported from the nasal olfactory mucosa (OM) to the brain, the exact mechanism of uptake and transport to the brain remains undefined. Manganese and iron share structural, chemical and physiological similarities and studies with

both metals have alluded to a common transport protein such as transferrin (Tf). This study investigates the role of Tf with respect to inhaled metals in the rat nose. Initial experiments demonstrate for the first time, the presence of Tf and Tf receptor in the rat nasal mucosa (using immunohistochemistry and western blots). Subsequent experiments involving nasal instillations with 59FeSO4 show that iron is co-localized with Tf in the nasal mucosa (cellular autoradiography plus immunohistochemistry). Results from the above experiments suggest that inhaled iron deposited in the nose may not be available for transport to the brain. To test the latter hypothesis, rats were exposed to 59FeSO4 for 90 min via inhalation and then euthanized at various time-points postexposure. Tissues from the nose (olfactory mucosa and nonolfactory mucosa) and brain (olfactory bulb, olfactory tract plus tubercle, and striatum) were collected. Tissue 59Fe concentrations were determined by gamma spectrometry, and heads were collected for autoradiography to visualize the localization of 59Fe from the nasal mucosa across to the brain. Data obtained from both gamma spectrometry and autoradiography reveal that iron remained in the nasal regions of the olfactory system. Analysis of olfactory mucosa by combined HPLC and gamma spectroscopy revealed that iron was associated with Tf. In conclusion, unlike manganese, inhaled iron remains in the nose and is not transported to the brain. Differences in stability of different valence states of Mn (Mn2+) versus Fe (Fe3+) may permit diffusion of soluble Mn in nervous tissue while limiting Fe to the mucosa.

#### 2107

CORRELATION OF NASAL SURFACE-AREA-TO-VOLUME RATIO WITH PREDICTED INHALED GAS UPTAKE EFFICIENCY IN HUMANS.

R. Segal<sup>1</sup>, G. M. Kepler<sup>2</sup>, D. L. Kalisak<sup>1</sup>, R. B. Richardson<sup>1</sup> and <u>J. S. Kimbell</u><sup>1</sup>.

<sup>1</sup>CIIT Centers for Health Research, Research Triangle Park, NC and <sup>2</sup>Consultant, Chapel Hill, NC.

Variances in nasal anatomy, airflow, and patterns of inhaled gas uptake among human individuals may cause significant differences in the regional dose of inhaled gases or vapors in the nasal passages and subsequently to the lung. Computational fluid dynamics (CFD) models can quantify the contribution of anatomical variation to risk assessment uncertainty and reduce the reliance on default uncertainty values. For water-soluble, reactive gases, nasal surface area and volume may be predictors of nasal scrubbing efficiency. To test this hypothesis, nasal surface area and volume from the nostrils to the posterior end of the nasal septum were calculated from digitized MRI scans of the head for a number of adult individuals provided to us by Dr. Ray Guilmette and the Lovelace Respiratory Research Institute. Four subjects were selected whose ratio of nasal surface area to volume (SAVR) represented a range of values: 1.07, 1.03, 0.94, and 0.85 mm<sup>-1</sup> for Subjects A (male), 12 (female), 14 (male) and 18 (female), respectively. Anatomically-realistic CFD models for the nasal passages of these individuals were constructed by a semi-automated process that provided input to a commercial mesh generator (Gambit, Fluent, Inc., Lebanon, NH). Allometrically-scaled minute volume flow rates were calculated to be 16.1, 12.9, 16.2, and 13.9 L/min for Subjects A, 12, 14, and 18, respectively. Steady-state inspiratory airflow at individualized flow rates and inhaled gas uptake were simulated for a reactive, water-soluble, low-molecular-weight gas using commercial CFD software (FIDAP, Fluent, Inc., Lebanon, NH). Total nasal uptake was estimated to be 90, 89, 85, and 84% for Subjects A, 12, 14, and 18, respectively, suggesting a correlation with SAVR. These studies and their extension to additional individuals form a basis for developing an empirical means of characterizing populations that may be at a higher risk for developing respiratory tract effects than the general population.

#### 2108

EVALUATION OF THREE COMMERCIALLY AVAILABLE AEROSOL GENERATORS FOR ANIMAL BASED RESEARCH STUDIES.

M. Eifrid, M. J. Brooker and R. Moutvic. Toxicology, Battelle, Columbus, OH.

The purpose of this study was to compare the aerosol output and particle size distribution of three different aerosol generators and to evaluate their use for animal based research studies. The generators tested were the Aeroneb® Pro, Omron MicroAir®, and the Pari LC® Plus. The study was performed using a simple matrix approach. Three different concentrations of saline (9, 30, and 70 mg/ml) were used as the testing solutions. Airflow rates of 5, 10, and 15 L/min were used for the collection of aerosol filter samples. Particle size distributions were sampled using 5 L/min In-Toxicology cascade impactors. The generation system consisted of a 2-inch inner diameter (I.D.) acrylic tube, two conical delrin end caps, and an anesthetic wye piece(s). The total volume of the system was approximately 400 ml. The nebulizer being tested was connected to one limb of an anesthetic wye piece, and the common limb of the wye piece was connected to one of the end caps. The remaining limb of the wye piece was capped or used for the addition of positive pressure air. All sampling was performed downstream of the nebulizer. All nebulizer-testing systems were composed of the same components with exception of any

special fittings needed to attach the nebulizer to the anesthetic wye piece. All generators produced similar aerosol concentrations with each concentration of saline. Particle size distribution measurements for all nebulizers resulted in mass median aerodynamic diameters (MMAD) that were suitable for animal based research studies. However, differences in the MMAD were observed between the nebulizers were a deciding factor depending on species of animal being used. The Omron MicroAir® was the only device which needed special adaptations to be used in an animal exposure system. The overall results show that all 3-aerosol generators were suitable for animal based research studies.

## 2109 AIRFLOW DISTRIBUTION AND PARTICLE DEPOSITION IN DIFFERENT LOBES OF THE LUNG.

B. Asgharian and O. T. Price. Biomathematics and Physical Sciences, CIIT Centers for Health Research, Durham, NC. Sponsor: B. Wong.

Preferential, site-specific lung injury may be the result of nonuniform particle deposition on lung airway surfaces. Existing predictive models of particle deposition in the lung are based on simplified lung structures such as a typical path model and are unable to accurately predict dose inhomogeneity throughout the lung. A multiplepath dosimetry model was developed previously that allowed the prediction of particle losses due to the actual asymmetric nature of the lung (Anjilvel and Asgharian, 1995, Fundam. Appl. Toxicol., 28:41-50). Lung airways were assumed to expand and contract uniformly. As a result, airflow rate in an airway was proportional to the lung volume distal to that airway. Calculations of particle losses indicated that a major determinant of local particle deposition distribution was the volume of air going to that location of the lung. Thus, formulation of a realistic model of deposited dose variation requires accurate capture of airflow distribution in the lung. Based on physiological and physical considerations, three models of airflow distribution in the lungs of humans are presented and used in a dosimetry model of particles to calculate deposition in the lung. The airflow models examined were based on lung compliance and resistance, uniform expansion and contraction of lung airways, and conservation of the air mass and momentum transport in a lung with fixed airway dimensions during breathing. Under resting breathing conditions, the lung compliance and resistance model predicts up to 4% higher deposition fraction than the uniform expansion model. The difference in deposition diminished with increasing minute ventilation. While the total deposition between the two models remained relatively the same, the distribution of the deposited particles in different lobes of the lung varied. For example, the ratio of particles deposited in the upper to that in the lower lobes was 15% higher in the compliance and resistance model. The two models predict significantly different deposition values compared with the third model based on fixed lung geometry.

#### 2110

COMPARISON OF EXPERIMENTAL MEASUREMENTS WITH MODEL CALCULATIONS OF PARTICLE DEPOSITION EFFICIENCIES IN MONKEY AND RAT NASAL AIRWAYS.

B. A. Wong<sup>1</sup>, J. T. Kelly<sup>2</sup>, B. Asgharian<sup>1</sup> and <u>J. S. Kimbell</u><sup>1</sup>. <sup>1</sup>CIIT CHR, Research Triangle Park, NC and <sup>2</sup>UC Davis, Davis, CA.

One function of the nasal airways is to filter inspired air to prevent toxic particles from reaching the lungs. Particles in inspired air may deposit in the upper respiratory tract (URT) before reaching the lung. Experimental measurements of URT particle deposition efficiency involving hollow molds have been developed. In this study, acrylic molds of F344 rat and rhesus monkey nasal airways were produced using a lost-wax casting technique. The deposition of aerosols from 1 to  $10~\mu m$  was determined by measuring the concentration of a monodisperse aerosol at the inlet and the outlet of the molds. Air flow was maintained at constant inspiratory flow rates. Computational fluid dynamics (CFD) models of the nasal airways were also developed for the F344 rat and rhesus monkey. A numerical mesh describing the nasal airways was generated by digitizing images of tissue sections. Air flow patterns were calculated using CFD techniques to solve the Navier-Stokes equations governing the behavior of fluid flow. The deposition of particles as a function of size was determined from the air flow patterns using a computer model of particle dynamics developed in house. The experimental measurements of particle deposition efficiency resulted in a sigmoidally-shaped deposition curve in which larger particles deposited with approximately 100% efficiency, while smaller particles had a low deposition efficiency. The computer model calculations of particle deposition efficiency showed a similar trend. The predicted deposition of larger particles matched experimental data reasonably well. However, the computer model calculations overpredicted the deposition of smaller particles significantly. The reasons for the discrepancy at smaller particle sizes may be attributed in part to the density of the numerical mesh and to the initial conditions used in the CFD and particle computer model calculations. The comparison with experimental measurements helps evaluate model predictions to enable model refinements to reduce numerical error.

## 2111 NASAL TOXICITY OF CARBON TETRACHLORIDE IN RATS: DOSE RESPONSE AND TIME COURSE STUDIES.

C. Reed<sup>1</sup>, S. Simpson<sup>1</sup> and J. Foster<sup>2</sup>. <sup>1</sup>School of Biomolecular Sciences, Liverpool John Moores University, Liverpool, United Kingdom and <sup>2</sup>Pathology Department, AstraZeneca, Macclesfield, United Kingdom. Sponsor: <u>E. Lock</u>.

Carbon tetrachloride (CCl<sub>4</sub>) is known to be metabolised within the olfactory epithelium of rats, and its nasal toxicity has been alluded to. The aim of this work was to fully characterise the toxicity of CCl4 in the rat nasal cavity. Adult male Han Wistar rats (dose response, n = 4; time course, n = 6) were administered a single oral dose of CCl<sub>4</sub> in corn oil (10ml/kg; dose response, 0-2400mg/kg; time course, 1600 or 2400mg/kg). Animals were killed at 24hr (dose response) or at intervals between 4 and 96hr (time course). Heads and samples of liver were processed for morphological assessment. As expected, dose-dependent centrilobular degeneration was observed in the liver. Within the nasal cavity, only the olfactory epithelium was affected and the lesion was restricted to the septum and the medial aspects of endoturbinates 1-3. Both the extent and severity of the mucosal degeneration were dose-dependent. The severity of the mucosal degeneration increased from epithelial vacuolation (800mg/kg) to undulation and stripping (1600mg/kg). At higher doses CCl<sub>4</sub> appeared less toxic and at 2400mg/kg there was no evidence of epithelial stripping, only vacuolation and undulation. During the time course, hepatic degeneration was evident 4hr after dosing and was both dose- and time-dependent, with some evidence of recovery at 96hr. In the nasal cavity, degeneration of the olfactory mucosa was not apparent until 16hr after dosing, increased in severity up to 48hr and was less severe at 96hr. At all time points olfactory degeneration was more marked in the 1600mg/kg group compared to the 2400mg/kg group. Thus  $\mathrm{CCl_4}$ was found to be toxic to those regions of the nasal cavity that express high levels of cytochromes P450, suggesting in situ bioactivation. The reasons for the decrease in olfactory toxicity at high doses are unknown, but may include altered toxicokinetics due to damage to other organs such as the liver and gastrointestinal tract.

# 2112 APPLICATION OF MAGNETIC RESONANCE IMAGING IN THE DEVELOPMENT AND VALIDATION OF 3D COMPUTATIONAL MODELS OF THE RESPIRATORY SYSTEM.

R. A. Corley<sup>1</sup>, K. R. Minard<sup>1</sup>, B. Saam<sup>2</sup>, <u>C. Timchalk</u><sup>1</sup>, H. E. Trease<sup>1</sup>, L. L. Trease<sup>1</sup>, <u>C. G. Plopper</u><sup>3</sup>, J. Fowler<sup>4</sup>, E. M. Postlethwait<sup>5</sup> and <u>J. R. Harkema</u><sup>6</sup>. 

<sup>1</sup>PNNI, Richland, WA, <sup>2</sup>University of Utah, Salt Lake City, UT, <sup>3</sup>University of California, Davis, CA, <sup>4</sup>CGC, Los Alamos, NM, <sup>5</sup>UAB, Birmingham, AL and <sup>6</sup>MSU, Lansing, MI.

The development and validation of detailed 3D biologically based models of the respiratory system requires new techniques for measuring localized airflows, particle deposition, airway geometry and tissue mechanics. To obtain accurate 3D geometry datasets on nasal and pulmonary airways of rats and monkeys, several magnetic resonance imaging (MRI) techniques were developed including perfusion of airways with contrast agents to enhance imaging, intravenous infusion of contrast agents to enhance the imaging of tissues surrounding airways and the imaging of silicone casts of airways. Each technique provided important geometric information on the structures of the respiratory system with resolutions ranging from 50-200 µm. Geometry phantoms and correction algorithms were developed to correct for image distortions over the field of view. New, semi-automated digital data processing methods were refined to significantly reduce the time airway segmentation and generation of 3D computational meshes from imaging data. This will facilitate the processing of multiple data sets from a variety of species for use in computational fluid dynamics (CFD) airflow simulations. The data processing techniques were also applicable to spiral-CT scans of human and sheep lungs and confocal images of cellular structures lining airways of normal and asthmatic monkeys. In addition to reconstructing airway surface geometries, MRI techniques were developed to exploit the physical properties of hyperpolarized 3He. Hyperpolarized 3He imaging coupled with 1H imaging shows considerable promise for imaging the dynamic properties of respiratory system, localized airflows and particle deposition. Such data will be necessary for validating 3D, CFD models of the respiratory system. (Supported by DOE LDRD, DOE Contract DE-AC06-76RLO 1830 and NIEHS grant no. 1 P01 ES011617-01A1)

# 2113 INHALED SOLID ULTRAFINE PARTICLES (UFP) ARE EFFICIENTLY TRANSLOCATED VIA NEURONAL NASO-OLFACTORY PATHWAYS.

T. Feikert<sup>1</sup>, P. Mercer<sup>1</sup>, N. Corson<sup>1</sup>, R. Gelein<sup>1</sup>, <u>L. Opanashuk<sup>1</sup></u>, <u>A. Elder<sup>1</sup></u>, <u>V. Silva<sup>1</sup></u>, <u>J. Carter<sup>2</sup></u>, A. Maynard<sup>3</sup>, <u>J. Finkelstein<sup>4</sup></u> and <u>G. Oberdorster<sup>1</sup></u>.

<sup>1</sup>Environmental Medicine, University of Rochester, Rochester, NY, <sup>2</sup>Proter & Gamble Co., Cincinnati, OH, <sup>3</sup>NIOSH, Cincinnati, OH and <sup>4</sup>Pediatrics, University of Rochester, Rochester, NY.

Clearance pathways for inhaled solid UFP (<100 nm) depositing in the respiratory tract include their translocation to extrapulmonary sites. Our previous results in rats with inhaled ultrafine carbon particles suggested that nasally-deposited solid

UFP may be taken up by olfactory rods in the olfactory nasal mucosa and translocated along the olfactory dendrites and axons. Olfactory nerve translocation has been well demonstrated for inhaled soluble metal compounds. In order to test this hypothesis for solid UFP and determine the significance for causing health effects we exposed groups of rats to ultrafine MnO2 particles (31 nm) in whole-body exposure chambers for up to 11 days, with either both nostrils patent or the right nostril occluded. AAS analysis of Mn in lung, liver, kidney, olfactory bulb and several other brain regions as well as Atlas gene array and antibody protein array analyses of these brain regions were performed. After 11 days of exposure, Mn concentrations in the olfactory bulb were 3.6-fold higher whereas lung Mn concentrations only doubled, and there were also significant increases of Mn in striatum and frontal cortex and cerebellum. With the right nostril occluded, Mn accumulated only in the olfactory bulb of the side with the patent nostril. TNF  $\!\alpha$  mRNA and protein were significantly increased about 30-fold in the olfactory bulb and showed also increases in the other brain regions associated with increased Mn levels. MIP-2 and NCAM mRNA were also significantly increased. We conclude that the olfactory neuronal pathway is very efficient for translocating inhaled solid UFP to the CNS and that translocated UFP, depending on their chemistry, can cause serious adverse effects. We suggest further that despite differences between the human and rodent olfactory systems this pathway is likely to be operative in humans as well.

### 2114 CARBON BLACK-INDUCED NASAL LESIONS IN LABORATORY RODENTS: A SPECIES COMPARISON.

P. Santhanam<sup>1</sup>, <u>I. Wagner</u><sup>1</sup>, L. Bramble<sup>1</sup>, <u>A. Elder</u><sup>2</sup>, <u>G. Oberdorster</u><sup>2</sup> and <u>J. Harkema</u><sup>1</sup>. <sup>1</sup>Pathobiology & Diagnostic Investigation, Michigan State University, East Lansing, MI and <sup>2</sup>Environmental Medicine, University of Rochester, Rochester, NY.

Previously we demonstrated that rats repeatedly exposed to airborne carbon black particles (Cb) develop chronic rhinitis and persistent alterations in the nasal epithelium. The purpose of the present study was to determine if mice and hamsters subjected to similar long-term inhalation exposures to Cb would develop nasal lesions comparable to those in rats. Female F344 rats, B6C3F1 mice, and Syrian golden hamsters were exposed to filtered air alone or nominal concentrations of 1, 7 or 50 mg/m3 Cb (primary particle size 17 nm; airborne agglomerate 0.9 micron) for 6 h/day, 5 days/wk for 13 wk. Rodents were sacrificed 1 day, 13 wk, or 11 mo postexposure (PE). Nasal airways were processed for light microscopy. Volume densities of intraepithelial mucosubstances (IM) and numeric densities of airway epithelial cells were estimated using image analysis and morphometry. Rats exposed to 7 and 50 mg/m3 Cb had chronic rhinitis and mucous cell metaplasia (MCM) and hyperplasia (MCH) with increased mucous cells and IM. Mice exposed to these same concentrations of Cb showed similar but less severe rhinitis, MCM, and MCH. In contrast, Cb-exposed hamsters did not develop rhinitis or MCM, but rather only mild MCH in the nasopharynx. The magnitude of the lesions in all the rodents was dependent on dose and time PE. At 1 day PE, rats exposed to 50 mg/m3 Cb had 14, 22, and 11x more IM in the proximal, middle, and distal nasal airways, respectively, than did mice exposed to the same concentration of Cb. Hamsters exposed to 50 mg/m3 Cb had only minimal IM in these intranasal sites. Cb-induced lesions persisted in rats at 11 mo PE, but the lesions in mice and hamsters were resolved by 13 wk PE. These results indicate that Cb-induced nasal injury, like previously reported Cb-induced lung injury, is more severe in rats than in mice or hamsters. (Research sponsored in part by the International Carbon Black Association).

# 2115 THE BIOPERSISTENCE OF CANADIAN CHRYSOTILE ASBESTOS FOLLOWING INHALATION.

R. Rogers<sup>2</sup>, D. Bernstein<sup>1</sup> and P. Smith<sup>3</sup>. <sup>1</sup>Consultant in Toxicology, Geneva, Switzerland, <sup>2</sup>Rogers Imaging Corporation, Needham, MA and <sup>3</sup>Research & Consulting Company Ltd., Fullinsdorf, Switzerland.

Chrysotile asbestos is often included with other asbestos materials in evaluation and classification. However, chrysotile is a serpentine with markedly different physical and chemical characteristics in comparison to amphiboles (eg tremolite). To quantify the dynamics and rate of chrysotile removal from the lung the biopersistence of commercial "QS Grade 3-F" textile grade chrysotile (Eastern Townships - Quebec) was studied. As long fibers have been shown to have the greatest potential for pathogenicity, the chrysotile was chosen to have more than 200 fibers/cm3 L > 20 um in the exposure aerosol. Study Design: 1) Fiber clearance (lung digestions): At 1, 2, 7, 14 d, 1, 3, and 12m following a 5 d (6 h/d) inhalation exposure lungs were digested by low temperature plasma ashing and analysed by TEM for total chrysotile fiber number and size. 2) Fiber distribution (confocal microscopy): At 1, 2, 7, 14d, 1 & 3 m post exp. lungs of animals were analysed by confocal microscopy to determine the anatomic fate, orientation and distribution of the chrysotile fibrils deposited on airways and in the parenchymal region. Chrysotile was rapidly removed from the lung. Fibers L > 20 um were cleared with a T1/2 = 16 days, most likely by dissolution and disintegration into shorter fibers. The shorter fibers also rapidly cleared with fibers 5-20 um clearing even faster (T1/2 = 29.4 d) than those  $< \hat{5}$  um

in length (T1/2 = 107 d). This is within the range of clearance for insoluble nuisance dusts. The short fibers appeared as separate, fine fibrils occasionally unwound at one end. Short free fibers appeared in the corners of alveolar septa, and fibers or their fragments were found within alveolar macrophages. Neutrophil-mediated inflammatory response did not occur in the presence of chrysotile fibers at the time points examined. Taken in context with the scientific literature to date, this report provides new robust data which clearly supports the difference seen epidemiologically between chrysotile and amphibole asbestos.

# 2116 COMPARISON OF CALIDRIA CHRYSOTILE ASBESTOS TO PURE TREMOLITE: INHALATION BIOPERSISTENCE AND HISTOPATHOLOGY FOLLOWING SHORT TERM EXPOSURE.

<u>D. Bernstein</u><sup>1</sup>, J. Chevalier<sup>2</sup> and P. Smith<sup>3</sup>. <sup>1</sup>Consultant, Geneva, Switzerland, <sup>2</sup>EPS, Muttenz, Switzerland and <sup>3</sup>RCC Ltd., Fullinsdorf, Switzerland.

The differences between chrysotile, a serpentine mineral, and amphibole asbestos have been debated extensively. This study was designed to quantify the comparative clearance amd histopathological response of chrysotile and the amphibole asbestos tremolite. The inhalation biopersistence of of commercial grade Calidria RG144 chrysotile (Coalinga mine, New Idria, California) and of a long fiber tremolite were studied. For synthetic vitreous fibers, the biopersistence of the fibers longer than 20 µm has been shown to be directly related to their potential to cause disease. The chrysotile sample was specially prepared to have 200 fibers/cm3 L>20  $\mu$ m in the exposure aerosol. These longer fibers were found to be largely composed of multiple shorter fibrils. The tremolite sample was chosen to have 100 fibers/cm3 L>20 um in the exposure aerosol. Calidria chrysotile fibers clear from the lung more rapidly (T1/2 fibers L>20  $\mu$ m = 7 hours) than any other commercial fiber tested including synthetic vitreous fibers. The histopathological examination showed no sign of inflammation or pathology and was no different than the air control lungs. Following this 5-day exposure to tremolite, the tremolite fibers once deposited in the lung parenchyma do not clear and almost immediately result in inflammation and a pathological response in the lung. At 1d after cessation of exposure inflammation was observed and granulomas were already formed. By 14d these microgranulomas had turned fibrotic; and by 90d the severity of the collagen deposits had increased and interstitial fibrosis was observed in one rat. These findings provide an important basis for substantiating both kinetically and pathologically the differences between chrysotile and the amphibole tremolite. As Calidria chrysotile has been certified to have no tremolite fiber, the results of the current study together with the results from toxicological and epidemiological studies indicate that this fiber is not associated with lung disease.

## 2117 TOXICOLOGICAL AND MINERALOGICAL ANALYSIS OF RICHTERITE-WINCHITE ASBESTOS.

B. S. Van Gosen<sup>1</sup>, H. A. Lowers<sup>1</sup>, J. D. Hyde<sup>2</sup>, G. P. Meeker<sup>1</sup>, A. M. Bern<sup>1</sup>, S. J. Sutley<sup>1</sup>, <u>M. L. Witten<sup>2</sup></u> and <u>T. L. Ziegler<sup>1</sup></u>. <sup>1</sup>US Geological Survey, Denver, CO and <sup>2</sup>The University of Arizona, Tucson, AZ.

Inhalation of amphibole mineral fibers has been linked to respiratory disease, such as asbestosis and mesothelioma. As a result, the USEPA and OSHA chose to regulate occupational exposures to the asbestiform varieties of five amphiboles most commonly used in commercial asbestos applications, including grunerite (amosite), riebeckite (crocidolite), anthophyllite, tremolite, and actinolite. Fibrous varieties of other amphibole species have been increasingly recognized as toxic to the respiratory system. For example, high rates of respiratory disease in miners, mill workers, and residents of Libby, MT, are suspected to be due to fibrous sodic-calcic amphiboles that occur as accessories of the vermiculite ores mined and milled near Libby from 1923 to 1990. The Libby amphiboles may be classified compositionally as mainly winchite, with lesser amounts of richterite, tremolite, and magnesioriebeckite, and occur in a variety of particle shapes ranging from prismatic crystals to asbestiform fibers. For a comparative study, samples of amphibole asbestos were collected by the USGS from an abandoned mine site in CO. The samples display several properties typical of asbestos, such as bundles of separable, long, thin, hairlike fibers, which are <1  $\mu m$  in width, tens to thousands of  $\mu m$  in length, curved, and bendable. Our study of the samples included x-ray diffraction, x-ray fluorescence spectrometry, and scanning electron microscopy accompanied by energy dispersive x-ray spectrometry. These techniques determined that the fibers are sodiccalcic amphiboles, exhibiting chemical compositions consistent with the richterite-winchite solid-solution series. Toxicological analysis of this richteritewinchite asbestos material using an rat lung cell model is in progress. This study will compare the toxicity of the CO richterite-winchite asbestos to the toxicity of Libby amphiboles with similar composition but differing morphologies, supporting efforts to understand the roles of amphibole composition and morphology in toxic

### TOXICITY TESTING OF FIBROUS PARTICLES: THE APPROPRIATE USE OF SHORT-TERM ASSAYS.

S. Olin and . ILSI RSI Working Group. Risk Science Institute, International Life Sciences Institute, Washington, DC. Sponsor: P. Fenner-Crisp.

Natural and synthetic fibers are a diverse group of substances of potential toxicological and public health concern. While many of these fibers have wide industrial and commercial applications, information regarding their potential impact on human health is often limited. The ILSI Risk Science Institute convened an expert working group to review and evaluate the available short-term assay systems for assessing the toxic and carcinogenic potential of both inorganic and organic fibers. Short-term assay systems are important, at least in part, because the costs of carrying out chronic tests on all new and existing fibers are prohibitive. In addition, short-term assays may help to minimize the use of animals in toxicity testing. This poster presents the perspectives of the working group on the strengths and limitations of the various short-term assay systems and will lay out a strategy for the use of these assays in prioritizing fibers for long-term testing, distinguishing those that are unlikely to present a hazard from those that warrant further investigation. Assay systems include those that determine physical and chemical characteristics, those that measure biodurability in vitro or biopersistence in vivo, as well as in vitro and in vivo toxicity assays of varying duration with a wide range of endpoints. (Supported by EPA Cooperative Agreement X-82916701 and the ILSI Risk Science Institute.)

KINETICS OF ABSORPTION OF INHALED BENZO(A)PYRENE IN THE ISOLATED PERFUSED RAT LUNG

P. Ewing, A. Ryrfeldt and P. Gerde. Environmental medicine, Karolinska Institute, Stockholm, Sweden.

Recent data in the dog has shown that the inhalation and rapid absorption of polycyclic aromatic hydrocarbons (PAHs) through the alveolar epithelium is an important route of entry to the circulation of unmetabolized PAHs. In this study, the absorption of inhaled B(a)P through the alveolar epithelium was investigated in the in vitro isolated perfused lung (IPL) model. The IPL of the rat, perfused with Krebs-Ringer bicarbonate 2% BSA medium, was exposed to B(a)P as a dry powder aerosol. Silica particles, (3 µm in diameter), were coated with tritium-labelled B(a)P. This method allowed us to deliver a reproducible amount of soluble B(a)P to the deep lung. The bioavailability of the silica-bound B(a)P, simulated in vitro in a 1-Octanol assay, was ≥ 85 % within 10 min. Concentration of <sup>3</sup>HB(a)P in perfusate samples and lung tissue was measured by liquid scintillation counting. A minute-long inhalation exposure of the deep lung to a bolus of B(a)P-coated silica resulted in a deposited lung burden of  $\sim$  8 ng of B(a)P. Desorbing B(a)P appeared rapidly in the lung perfusate. One third of the deposited dose was absorbed through the alveolar epithelium within 30 minutes. The B(a)P concentration in the perfusate peaked after 2, 5 min at a concentration of 7, 5 pM and decreased subsequently to 2 pM after 20 min. Preliminary data indicates an absorption kinetics of inhaled B(a)P in the IPL similar to that observed in BaP-exposed dogs. However, in the IPL the concentration peaked within 150 s of exposure compared to 90 s in the dog, suggesting that canine blood is more effective in extracting PAHs than the perfusion medium. Presently we are investigating different medium compositions to better simulate absorption kinetics in vivo. This study demonstrates the usefulness of combining our novel dry aerosol generating system with the IPL model to expose rodent lungs by inhalation. The system could be used as a labor- and cost-efficient alternative to in vivo inhalation exposures in studying the absorption and metabolic interaction of substances with a route-of-entry in the respiratory tract.

#### 2120

TRACHEOBRONCHIAL AND NASAL CLEARANCE OF 1.0 MICRON PARTICLES IN THE RAT: COMPARISON WITH A TYPICAL PATH TRACHEOBRONCHIAL CLEARANCE MODEL.

E. C. Kimmel<sup>1,2</sup>, S. L. Prues<sup>1,2</sup>, J. E. Reboulet<sup>1,2</sup> and D. L. Courson<sup>1,3</sup>.

<sup>1</sup>Inhalation/Pulmonary Effects Laboratory, Naval Health Research Center (Toxicology), Wright-Patterson AFB, OH, <sup>2</sup>Geo-Centers, Inc., Wright-Patterson AFB, OH and

<sup>3</sup>ManTech Environmental, Wright-Patterson AFB, OH.

A typical path tracheobronchial (TPTB) model of particle clearance in rats based on application of flow continuity equations was recently developed (Kimmel et al., 2002, 2003). Based on a survey of the literature, TPTB predictions and reported particle retention at 24 hrs post exposure differed by -18 to +7% for a variety of aerosols (MMADs = 0.1 to 4.18  $\mu m$ ,  $\sigma gs = 1.0$  to 1.4) giving an average agreement of 95.1%. Experimental studies were undertaken to refine the TPTB by incorporation of non-uniform mucus coverage of the airways and to account for its effect on conservation of mucus mass and estimated transport velocity; and to characterize an extrathoracic clearance component of the model. Forty-eight F-244 rats received

a brief single, nose-only exposure to 1.0  $\mu m$  monodisperse, stable isotope labeled latex particles. Respiratory tract tissues were harvested (0, 6, 15, and 24 hrs post exposure), neutron activated, and tissue particle burden was determined by beta and gamma emissions counting. Initial TPTB predictions of particle clearance from the tracheobronchial and extrathoracic compartments were comparable to experimental observations, with differences between predicted and observed fractional clearance ranging from -8 to + 22%. Normalization of initial particle burden for differences in ventilation (measured continuously during exposure) significantly improved agreement between unmodified TPTB predictions and observed clearance/retention to an average 92% accross observed time points. Modifications of the TPTB that account for non-uniform mucus coverage as a function of airway generation are currently in progress and the impact on model performance will be reported.

COMPARATIVE ANALYSIS OF PULMONARY IRRITATION BY FUNCTIONAL MEASUREMENTS (PENH) AND PROTEIN IN BRONCHOALVEOLAR LAVAGE FLUID IN BROWN NORWAY RATS AND WISTAR RATS EXPOSED TO POLYISOCYANATE AFROSOI.

J. Pauluhn. Toxicology, Bayer HealthCare, Wuppertal, Germany.

Previous acute inhalation studies with polymeric methylenediphenyl-4, 4'-diisocyanate (MDI) aerosol provided experimental evidence that the effects related to lower respiratory tract irritation constitute the most sensitive changes and that they can be probed best by the measurement of protein in bronchoalveolar lavage (BAL). The objective of this study was to extend previous acute dose-response and timecourse studies in Wistar rats by determining both the concentration and temporal effects following a single 6-hour MDI aerosol exposure on the breathing dynamics with selected endpoints in BAL. Results show that total protein in BALF was amongst the most sensitive endpoints to probe early effects caused by exposure to irritant polyisocyanate aerosol. Baseline Penh increased in a concentration-dependent manner and paralleled closely the magnitude of increase in BAL-protein on postexposure day 1. The time-course of changes in Penh complemented those of BAL-protein observed in previous studies. The incremental change of Penh during a stepped MCh-challenge showed decreased responsiveness with increasing baseline Penh values. In summary, these data show that the exposure to irritant concentrations of aerosolized poly-isocyanate caused a transient perturbation of the blood/air-barrier which can suitably be probed by measurements of protein in BALF. Penh paralleled this change. This suggests that Penh mirrors changes occurring at the alveolar rather than airway level. Accordingly, Penh might be viewed to be a sensitive, although non-specific functional endpoint suitable to probe changes in breathing patterns indicative of effects occurring at the parenchymal level. In regard to Penh and selected BAL-endpoints both strains of rats were equally susceptible, although some endpoints displayed a higher variability in Brown Norway (BN) rats when compared to Wistar rats. This supports the conclusion that Wistar rats afford a higher diagnostic resolution than BN rats.

# 2122 EXHALED BREATH PROTEIN SAMPLING IN UNANESTHETIZED PIGS.

O. R. Moss<sup>1</sup>, N. Boggs<sup>2</sup> and J. Jackman<sup>2</sup>. <sup>1</sup>Biomathematics and Physical Sciences, CIIT Centers for Health Research, Research Triangle Park, NC and <sup>2</sup>Research & Technology Dev. Center, APL/JHU, Laurel, MD.

The early inflammatory response of the lung is useful for the identification of environmental, industrial, or biological warfare exposure agents and the evaluation of exposed individual response so as to expedite treatment. Exhaled breath has been used to assess the physiological state of humans by examining the levels of recoverable volatile compounds. More recently, non-volatile compounds, including proteins such as IL-4 and tumor necrosis factor, have been successfully recovered from human exhaled breath. In order to apply this method to rapid and specific identification of exposed individuals there is a need for enhanced analytical capability as well as the development of animal models. The work described here focuses on the development of a porcine model and evaluation of two techniques (a face mask and a "virtual" mask system) for obtaining exhaled breath from pigs. The face mask system is based on using a vacuum collection system and a modified anesthesia cone with one way valve. Each piglet (8 to 12 kg) is individually held during a half hour collection period. The "virtual" mask system is based on two funnels, one inside the other. In this system dry air is supplied in the annular passages between cones and is directed towards the head of the pig in such a way that the air surrounds the pigs snout, forming a virtual mask. This air flow turns back on itself into the inner funnel centered 5 to 8 cm from the nostrils of the animal. Exhaled breath is carried along in this sampling flow. Each pig is suspended in a standard restraint sling during sampling. Breath collections of approximately 45 piglets were initiated at a local farm in order to obtain real world samples of exhaled breath. In the field, the face

mask and virtual mask systems produced similar results of 3 to 5 ml of exhaled breath condensate collected per hour per pig for pigs weighing approximately 8 kg. (This work was performed under a subcontract to Applied Physics Laboratory, APL No 864736, as part of a DARPA funded project MDA972-01-D-005)

# 2123 EFFECTS OF 1, 3-BUTADIENE, ISOPRENE, AND THEIR PHOTOCHEMICAL DEGRADATION PRODUCTS ON HUMAN LUNG CELLS.

M. Doyle<sup>1</sup>, K. Sexton<sup>1</sup>, <u>I. Jaspers</u><sup>2, 1</sup>, K. Bridge<sup>1</sup> and H. Jeffries<sup>1</sup>. <sup>1</sup>ESE, University of North Carolina, Chapel Hill, NC and <sup>2</sup>CEMALB, University of North Carolina, Chapel Hill, NC.

Due to potential exposure in both workplace and ambient air, the known carcinogen 1, 3-Butadiene (BT) is considered to be a priority hazardous air pollutant (HAPS). Most of the studies investigating BT toxicity have examined carcinogenic endpoints. BT and its 2-methyl analog, Isoprene (ISO) are chemically similar but have very different toxicity, with ISO showing no significant carcinogenesis. The degradation chemistry of these compounds induced by sunlight is not fully understood, resulting in many unknown degradation products, which makes it difficult to identify their full toxic potential. In this study, we determined the relative toxicity and inflammatory gene expression induced by BT, ISO, and their photochemical, degradation products in A549 cells, a human alveolar type II-like cell line. A concentration of 200 ppb BT or ISO in the presence of 50 ppb NO were injected into separate photochemical smog chambers and allowed to photochemically react for approximately 4 hours. At sundown, A549 cells grown on membraneous support were exposed for 5 hours to either the gaseous precursor mixtures, i.e. BT+ NO or ISO + NO, or their gaseous photochemical reaction products. GC and GC/MS initial analysis indicates that the primary photochemical products produced during these experiments for BT are acrolein, acetaldehyde, and formaldehyde, while photochemical reactions of ISO generated methacrolein, methylvinylketone, and formaldehyde (both formed ozone  $\leq$  200ppb). Approximately 9 hours post-exposure, the cells were examined for cytotoxicity and IL-8 gene expression. BT induced a 2-3 fold greater cytotoxicity and IL-8 gene expression as compared to its photochemical reaction products. In contrast, ISO photochemical reaction products caused a significantly greater cytotoxicity and ÎL-8 gene expression as compared to the unreacted ISO precursor. Taken together, these data suggest that biogenic ISO becomes increasingly more toxic as it reacts within the natural atmosphere, unlike BT, which appears to become less toxic as it reacts with sunlight.

# 2124 ACUTE, FOUR-WEEK, AND MICRONUCLEUS INHALATION STUDIES IN RATS WITH HEXAFLUOROISOBUTENE EPOXIDE.

<u>D. P. Kelly</u><sup>1</sup>, M. Donner<sup>1</sup>, <u>L. A. Malley</u><sup>1</sup>, J. F. Hansen<sup>1</sup>, V. O. Wagner, III<sup>2</sup> and N. E. Everds<sup>1</sup>. <sup>1</sup> Haskell Laboratory, DuPont Company, Newark, DE and <sup>2</sup> BioReliance, Rockville, MD.

Hexafluoroisobutene epoxide (HFIBO) is an intermediate used in the preparation of perfluorinated compounds and it is considered to be moderately toxic following inhalation. A single 4-hr exposure to 820 ppm was lethal in 3 of 6 male (m) rats; ataxia was noted at 600 ppm, and weight loss at 600 and 200 ppm. After positive findings (strains TA 100 and WP2 uvrA) in an Ames Salmonella assay, HFIBO was found to be negative in an in-vivo bone marrow micronucleus study where m and f rats were exposed to 25, 125 or 350 ppm of HFIBO for 6 hr/day for 2 days. However, at 350 ppm, 3 of 12 f rats died on the 2nd exposure day. In a 4 wk study, groups of 20 m and 20 f rats were exposed for 6 hrs/day, 5 days/wk to 5, 25, or 125 ppm of HFIBO followed by a 4 wk recovery. No deleterious effects were observed in clinical observations or body weights during the exposure or recovery periods. Neurobehavioral tests (including grip strength, FOB, and motor activity tests) at the end of the 4-week exposure period showed no effects. Clinical pathology evaluation showed minimal changes in rats exposed to 125 ppm, including decreased platelets (m only), decreased mean cell hemoglobin concentration and red cell distribution width (f only), increased serum bilirubin and urea nitrogen (f only), and increased urine volume/decreased urine osmolality (m only). Urinary fluoride was increased only at 125 ppm, indicating metabolism of HFIBO. None of the clinical pathology findings were considered necessarily adverse; rather the changes were minimal, likely unrelated to the test substance, and within the range of normal values. A slight reversible increase in heart weights (but no corresponding histological observations) was seen in m and f rats in the 125 ppm groups. No other anatomic pathologic effects were observed in this study. Based on the increased heart weights at 125 ppm, the no-observed-adverse-effect-level (NOAEL) for repeated inhalation exposure was 25 ppm.

### 2125 SINGLE-PASS BUBBLE AEROSOL GENERATOR FOR INHALATION STUDIES.

R. Jaeger<sup>1</sup>, G. Mainelis<sup>3</sup>, K. DeVoe<sup>2</sup> and M. Yao<sup>3</sup>. <sup>1</sup>CH Technologies, Westwood, NJ, <sup>2</sup>BGI, Walham, MA and <sup>3</sup>Department Env Sciences, Rutgers University, New Brunswick, NI.

Inhalation exposure studies of pathogens require stable and reliable aerosol generators. As fragile organisms are aerosolized, their structural and biological integrity must be preserved. Air jet as well as ultrasonic nebulizers induce significant stress and reduced viability due to forceful agitation, high shear force and repeated "recycling" of the carrier media. Recently, an aerosol generator that produces particles from a bubbling liquid was reported. This technique promised low shear force but still recycled the fluid. We describe an improvement in particle generation from a bubbling liquid by eliminating fluid reuse. In this device, a thin film of liquid is pumped onto the upper surface of an encapsulated porous stainless steel disk. Porosity can be set from 0.2 to 100 microns. Air is forced through the disk from below and breaks the liquid film into bubbles that grow and subsequently burst, releasing aerosol particles to the air. The particles are gently stirred and entrained by eight or more streams of dry air parallel to the surface. These radial streams are above the disk. Particles not entrained collect in the glass vessel and play no further role. We aerosolized P. fluorescens bacteria and polystyrene latex particles (1 micron) and determined that the particle concentration increased as the airflow increased from 2 to 5 L/min. Drying airflow from 10 to 30 L/min increased aerosol output. Distance above the porous disk had little effect. Constant generation rate over one hour demonstrated stability. Since organisms go through the aerosolization process only once, no significant decrease in bacterial viability is expected during prolonged generation. As such, this instrument is useful in inhalation studies where extended delivery of stable and undamaged biological aerosols is required.

# 2126 COLLECTION, VALIDATION AND GENERATION OF BITUMEN FUMES FOR CHRONIC INHALATION STUDIES IN RATS

G. Pohlmann, A. Preiss and W. Koch. Aerosoltechnologie, Fraunhofer Institute of Toxicology and Experimental Medicine, Hannover, Germany. Sponsor: H. Muhle.

The objective of the study was to develop a laboratory generated exposure atmosphere to be used for chronic inhalation toxicity studies in rats that resembles, as closely as possible, personal exposures seen in workers during road paving operations. To achieve this, bitumen fume condensate (BFC) samples were collected from hot bitumen storage tanks and compared analytically with atmospheric workplace samples collected by different sampling devices and strategies. Two different laboratories analyzed personal and static samples taken at road paving worksites by different methods. Parameters determined were: Total Particulate Matter, Benzene Soluble Matter, Semi-Volatiles and Total Organic Matter, Boiling Point Distribution (BPD), Polycyclic Aromatic Hydrocarbons and UV Fluorescence (UVF). Different sampling methods were used to allow comparison of the standard German sampling method with the most commonly used industrial methods. A collecting procedure was developed that allowed sampling from hot bitumen storage tanks in an operational asphalt mixing plant. The sampling procedure has been optimized to collect material that matches the workplace samples as closely as possible. The validation procedure has been performed using a range of parameters that could be analyzed in both the workplace samples and the BFC collected from the tanks. BPD, UVF and content of individual PAHs were selected as parameters. For example the BPD of the collected sample did not differ more than 17 degree C from the average boiling point distribution of the work place samples, in the range from 5 to 95%. UVF of the BFC nearly exactly matched the average fluorescence of the workplace samples (105%). As a result, approximately 16 liters of BFC have been collected. A laboratory set-up for the re-generation of the airborne fume at three different exposure concentrations but with a similar composition was developed and has been running successfully for several months. The study was sponsored by the Bitumen industry assocaitions, ARBIT, Germany and Eurobitume,

# 2127 INHALATION TOXICITY OF THE FLAVORING AGENT, DIACETYL (2, 3-BUTANEDIONE), IN THE UPPER RESPIRATORY TRACT OF RATS.

A. F. Hubbs, L. A. Battelli, R. R. Mercer, M. Kashon, S. Friend, D. Schwegler-Berry and W. T. Goldsmith. *HELD, NIOSH, Morgantown, WV.* Sponsor: <u>D.</u> Porter.

Diacetyl (2, 3-butanedione) is a diketone found naturally in foods such as butter and "generally recognized as safe" for use in low concentrations as a food additive. Diacetyl imparts the odor and flavor of butter to foods and also has industrial applications. Recently, an increased prevalence of fixed airways obstruction was reported in workers at a microwave popcorn plant and the lung disease correlated

with diacetyl exposure. In a previous study, inhalation of diacetyl-containing artificial butter flavoring caused necrosis of the nasal, bronchial, and bronchiolar epithelium in rats. We have now investigated the hypothesis that inhalation of diacetyl produces epithelial injury. Therefore, male Sprague-Dawley rats were exposed in a whole-body inhalation chamber for 6 hours to 0, 99.3  $\pm$  0.07, 198.4  $\pm$  0.10, or  $294.6 \pm 0.20$  ppm diacetyl and euthanized the next day. Four levels of nose, three levels of trachea, and two lung sections were examined by light microscopy. In addition, the nose was examined by transmission electron microscopy (TEM) and the trachea was examined by TEM and scanning electron microscopy (SEM). At 198.4 ppm or higher, diacetyl inhalation resulted in significant necrosis of nasal epithelium with associated neutrophilic inflammation. At 294.6 ppm, diacetyl inhalation also caused significant necrosis of tracheal epithelium with associated neutrophilic inflammation. By SEM, diacetyl-induced tracheal changes included multifocal denuding of basement membrane with cell swelling, loss of microvilli, and loss of ciliated cells in the remaining epithelium. By TEM, tracheal changes included epithelial necrosis, denuded basement membrane, and elongation of epithelial cells near foci of exposed basement membrane. Diacetyl did not produce significant changes in the lung under these exposure conditions. These findings suggest that acute exposure to diacetyl alone is sufficient to cause upper respiratory tract epithelial necrosis in rats at concentrations of 198.4 ppm or higher.

## THE EVALUATION OF TWO ANESTHETICS FOR USE IN A BRONCHODILATOR SCREEN MODEL.

A. Sivillo, R. Moutvic, M. J. Brooker and I. M. Grossi. *Toxicology, Battelle, Columbus, OH.* 

The goal of this study was to develop a model for screening bronchodilator drugs using propofol and isoflurane as alternative anesthetics to morphine-chloralose. The first phase involved comparing 2 models: one using propofol and the other using isoflurane anesthesia, when performing methacholine (Mch) challenge experiments (using escalating graded-doses of Mch) in 3 canines. In establishing a bronchoconstrictive model, it was found that with both anesthetic models, the plateau dose-response (seen through dynamic lung resistance measurements) was not consistent even though the peak response was very stable. Shifting to the second phase of the study, the propofol-anesthetized model was chosen over the isoflurane-anesthetized model as it resulted in a lower hypotensive response to the Mch challenge. The second phase used 6 canines and implemented measuring the peak response only, performing a second challenge (directly following the first challenge) to evaluate short-term repeatability of the model, and repeating these experiments using morphine-chloralose anesthesia as a standard for comparison. Following the morphine-chloralose experiments, animals were euthanized due to the known longterm neurological side effects resulting after chloralose anesthesia. Results demonstrated that the propofol model did not produce consistent results to repeat Mch challenge whereas the morphine-chloralose model was repeatable. In conclusion, it is suggested that the morphine-chloralose anesthetized bronchoconstrictive dog model may have potential as a screen for bronchodilator drugs.

## VALIDATION OF AN ISO-KINETIC DILUTOR FOR USE WITH AN ANDERSON CASCADE IMPACTOR.

J. Frye, R. Moutvic, M. J. Brooker and I. M. Grossi. *Toxicology, Battelle, Columbus, OH.* 

The Anderson Cascade Impactor (ACI) is one of the most widely used and accepted devices employed by the Pharmaceutical industry for characterizing particle size distribution (PSD) of aerosols. For animal based pre-clinical toxicology studies, use of an ACI for PSD measurements is impractical due to the inlet flow rate required for operation (28.3 L/min). It is necessary to match impactor inlet flow rates to the aerosol available at the animal model-breathing zone. To accommodate the different inlet flows an iso-kinetic diluter was constructed for use with the ACI. The diluter allows the ACI to operate at its designed flow yet draw a low flow sample from the breathing zone in the exposure apparatus. The dilutor sample inlet tube cross-sectional face velocity was maintained equal to the ACI inlet cross-sectional face velocity, accommodating mixing sample aerosol with the dilution air in an iso-kinetic stream. Dilution air was added from a filtered compressed air source. Flow rates of the ACI and the dilution air were controlled and measured with calibrated mass flow meters. Two sample flow rates, representing small (0.5 L/min) and large (3.0 L/min) animal species were selected for validation. Jet nebulizers and solutions containing Certified Particle Size Standards (micro-spheres) were used to produce nearly mono-disperse aerosols in a holding plenum. The aerosol was dried in process before collection with the ACI. For each flow rate, three impactor collection samples were obtained at each of three particle sizes. Impactor stage masses were measured gravimetrically and the results analyzed for MMAD and GSD for each sample. Review and comparison of the results indicate good correlation between particle size samples collected at lower flow rates with the diluter and the nominal particle size used in aerosol generation. This diluter allows the use of the ACI to collect particle size samples from pre-clinical animal toxicology models at sample collection flow rates similar to production rates without significant alteration of PSD

### 2130 ACUTE RESPIRATORY RESPONSES OF THE MOUSE TO CHLORINE.

W. S. Wilkie<sup>1</sup>, D. J. Shusterman<sup>2</sup> and <u>J. B. Morris<sup>1</sup>. <sup>1</sup> Toxicology Program,</u> University of Connecticut, Storrs, CT and <sup>2</sup>Occupational and Environmental Medicine, University of California at San Francisco, San Francisco, CA.

In human subjects, fifteen minute exposure to 0.5 - 1.0 ppm chlorine gas causes a nasal obstructive response in the absence of a marked sensation of irritation. For comparative purposes, the current investigation was designed to assess the respiratory responses of the mouse to this irritant gas. Towards this end, respiratory physiological responses were measured in female C57Bl/6J mice exposed to 0.6 to 3.0 ppm chlorine. Chlorine was a potent sensory irritant, with an RD50 of 2.3 ppm. Chlorine exposure produced airway obstruction as indicated by a concentration dependent increase in specific airways resistance (sRaw) during exposure, which persisted for fifteen minutes post exposure. At 0.6 ppm, chlorine produced mild sensory irritation (<20% change in breathing frequency) and significant obstruction (65% increase in sRaw). Pretreatment with atropine was without effect on the obstructive response suggesting the lack of involvement of cholinergic pathways. Pretreatment with the sensory nerve toxin, capsaicin, dramatically reduced both the sensory irritation and obstructive responses, strongly suggesting the involvement of sensory nerves. Studies were also performed using the surgically isolated upper respiratory tract of the anesthetized mouse. Chlorine was efficiently scrubbed from the airstream (>95%) in that site and produced an obstructive response that was of sufficient magnitude to account for the entire response observed in the intact animal. In summary, chlorine gas produces an immediate nasal obstructive response in the mouse that appears to be similar to that in the human.

# 2131 COMPARISON OF DOSE AND TOXICITY AFTER ADMINSTRATION OF A FLUOROALKYLETHYL PHOSPHATE SURFACTANT BY DERMAL AND INHALATION ROUTES IN RATS.

C. Finlay, D. P. Kelly, N. E. Everds, J. F. Hansen and <u>J. C. Stadler</u>. *DuPont Haskell Laboratory, Newark, DE.* 

Fluorosurfactants are used as specialty wetting and leveling additives in cleaning and coatings formulations. Previously, this fluoroalkylethyl phosphate surfactant was evaluated for subchronic, developmental, and reproductive toxicity in gavage studies; the liver was the most sensitive target organ. Since the intended uses of this surfactant would predict that dermal or respiratory tract exposures are likely, studies were conducted to assess internal exposure and toxicity by these routes. In the 28-day study, the test substance was applied to the skin of male rats each day for 6 hours at doses of 0, 10, 100, and 1000 mg/kg/day (35% ai). There were no adverse effects on mortality, clinical signs, body weights, food parameters, anatomic pathology, or hematology. Aspartate- and alanine-aminotransferases and sorbitol dehydrogenase activities were increased at 1000 mg/kg/day. The NOEL for dermal exposure was 100 mg/kg/day. In the inhalation study, male rats were exposed nose-only to 0, 0.2, 2, or 20 mg/m3 of aerosol for 6 hrs/day, 5 days/wk for 2 wks. There were no effects on body weights, clinical signs, or clinical pathology parameters. The only histological effects were mild inflammation in the larynx and lung at 2 and 20 mg/m3. The NOEL for inhalation was 0.2 mg/m3. Internal exposures by the dermal, inhalation, and oral routes were compared by fluorine blood analysis (Wickbold Torch Combustion Method). Minimal levels of fluorine were detected at the two lowest doses administered dermally. Fluorine levels were apparent in all rats exposed by inhalation, however, the levels were equal to or less than levels in rats exposed orally. Based on the fluorine dosage results in the above studies and the findings in the respiratory tract after inhalation exposure, inhalation appears to be a more sensitive route of exposure than the dermal or oral routes for this fluorosurfactant.

# 2132 DEVELOPMENT OF A METHOD FOR THE SIMULTANEOUS ANALYSIS OF VINYL ACETATE AND ACETALDEHYDE CONCENTRATIONS IN THE NASOPHARYNGEAL CAVITY AND EXHALED BREATH OF HUMAN VOLUNTEERS.

R. E. Schwartz<sup>1</sup>, J. J. Soelberg<sup>2</sup>, <u>R. A. Corley</u><sup>2</sup>, K. K. Weitz<sup>2</sup>, L. Bloemen<sup>3</sup>, <u>M. S. Bogdanffy</u><sup>4</sup> and <u>K. D. Thrall</u><sup>2</sup>. <sup>1</sup>Otolaryngology, Richland, WA, <sup>2</sup>Battelle, Pacific Northwest Laboratories, Richland, WA, <sup>3</sup>Dow Benelux, Terneuzen, Netherlands and <sup>4</sup>DuPont, Newark, DE.

Vinyl acetate is a volatile monomer used in the plastics, coatings, and polymer industries. Inhaled vinyl acetate is absorbed by the nasal mucosa and rapidly hydrolyzed to acetaldehyde and acetic acid. A PBPK model has been developed to describe the uptake of vinyl acetate in the rat and human nasal cavity based on

parameters obtained from studies in rats. Thus, human nasal dosimetry data would be useful to verify the PBPK model predictions for humans. This study focused on the development of a real-time method to simultaneously measure vinyl acetate and acetaldehyde concentrations in the nasopharyngeal region of human volunteers on a breath-by-breath basis. A small-diameter air-sampling probe was inserted roughly 9 cm into one nostril such that the tip of the probe was in the nasopharyngeal cavity. The probe was threaded through a port on a facemask containing two one-way non-rebreathing valves and connected to a Teflon transfer line that fed directly into an ion-trap mass spectrometer to provide data sampling every 0.8 sec. A second transfer line attached to the exhale port on the facemask to permit the concentration of exhaled vinyl acetate to be measured using a second mass spectrometer. The 6 volunteers inhaled 13-C-labeled vinyl acetate at 1, 5, or 10 ppm for approximately 30 min under resting and exercise conditions while 13-C-vinyl acetate and 13-C-acetaldehyde were continually monitored in both the exhaled breath and in the nasopharyngeal cavity. A plethysmograph was used to match the airway concentrations to inhalation/exhalation oscillations. Preliminary results show little intra- or inter-variability in volunteers, thus indicating the feasibility of the method to differentiate the clearance process of vinyl acetate within a select region of the respiratory tract. (Supported by the Acetyls Sector Group, CEFIC).

THE USE OF FLUORESCENTLY LABELED
NANOPARTICLES TO DETERMINE THE EFFECT OF
PARTICLE SIZE ON TRANSLOCATION FROM THE
LUNG

J. M. Carter<sup>1</sup>, J. M. Kennedy<sup>1</sup>, G. Oberdorster<sup>3</sup> and E. D. Clark<sup>2</sup>. <sup>1</sup>Central Product Safety, Procter & Gamble, Cincinnati, OH, <sup>2</sup>The Health and Environmental Safety Alliance, Cincinnati, OH and <sup>3</sup>University of Rochester, Rochester, NY.

Nanoparticles or ultrafine particles, are particles generally considered to be less than 100nm in size. These particles have been implicated in morbidity and other adverse reactions associated with PM2.5. Due to their small size, these particles may translocate from the lung to remote sites such as the heart, liver, brain or other extrapulmonary organs after inhalation exposure. Additionally, it has been suggested that the translocation of these particles may be responsible for adverse effects from ultrafine particles. We have initiated studies to determine whether nanoparticles translocate to extrapulmonary organs after inhalation of particles in rats. Briefly, Fisher 344 female rats were exposed *via* an aspiration model to fluorescently labeled polystyrene ranging in size from 20 nm to 400 nm. Animals were sacrificed 1, 3, 7 and 14 days after exposure to nanoparticles. Lung, heart, brain, spleen, kidney and liver tissues were removed and preserved for histological examination. Blood was also collected for examination of nanoparticles. Tissue was examined via confocal microscopy for presence of fluorescent nanoparticles. In vitro experiments using EpiAirway tissue constructs were also performed to evaluate membrane/cell/particle interactions. Histological evaluations were performed on these tissues 2, 8, and 24 hours post exposure. In vivo experiments indicate a correlation between size and the ability of these particles to migrate from the lung after inhalation exposure. Additionally, in vitro data yielded similar findings indicating particle size is a factor in predicting translocation potential of nanosized particles.

#### 2134

THE EFFECT OF DOSAGE ERRORS AND STEP SELECTION METHOD ON THE PERFORMANCE OF THE UP-AND DOWN METHOD.

D. R. Sommerville. US Army Edgewood CB Center, Aberdeen Proving Ground, MD. Sponsor: S. Thomson.

The up-and-down method is a common approach for estimating the median effective dose/dosage (ED50) of a quantal response curve. It has been demonstrated in the literature that the method provides an accurate ED50 estimate while using a minimum number of individual trials. A major aspect of the method is the use of equally spaced log(dose) levels, typically chosen to be roughly equal to the standard deviation ( $\sigma$ r) of the response distribution of the test items. With some applications (e.g. inhalation toxicology), it is not possible to maintain equally spaced dosage levels. Irregular spacing will occur due to random errors from dosage administration  $(\sigma A)$  and measurement  $(\sigma M).$  The former is from the difficulty in precisely generated and the second s ating the target dosage, while the latter is the error in measuring what dosage was actually produced. A series of Monte-Carlo simulations of 6 to 10 items per trial series were performed to investigate the effect of  $\sigma A$  and  $\sigma M$  on the performance of the up-and-down method for small samples. Two separate sets of simulations were conducted: one where the dosage for the next step was based on the measured dosage from the previous trial (Method M) and the other from the previous target dosage (Method T). Two other factors were also investigated: the nominal step size and the location of the initial trial dosage relative to the true ED50. The method's efficacy was judged by how many individual trials were needed in a test series before a reliable/useable dataset was obtained. An example of a non-useable dataset is a series composed of either all responses or all non-responses. It was found that the method of step selection has a major effect on the efficacy and accuracy of the up-and-down method. Method T is superior to Method M with respect to both efficacy and accuracy. The negative influence of  $\sigma A$  and  $\sigma M$  on efficacy is greater for Method M than for Method T. In addition,  $\sigma M$  has 2.3 times the effect (compared to  $\sigma A$ ) on increasing the mean square error (MSE) of the difference between the estimated and actual ED50 for both methods (M and T) of step selection.

#### 2135

CHEMESTHESIS IN 15-MINUTE EXPOSURES TO OCCUPATIONALLY-PERTINENT CONCENTRATIONS OF GLUTARALDEHYDE VAPOR.

W. S. Cain, R. Schmidt and A. A. Jalowayski. *Otolaryngology, UCSD, La Jolla, CA*. Sponsor: J. Cometto-Muñiz.

In previous research, we found that human females could detect feel (chemesthesis) from brief exposures to concentrations of glutaraldehyde vapor in the range of hundreds of parts per billion (v/v). Threshold for feel in the eye (25-sec exposures) equaled 394 ppb and for feel in the nose (single-sniffs) equaled 472 ppb. Because chemesthesis shows the property of temporal integration for many materials, detection of glutaraldehyde might occur at lower concentrations in longer exposures. This study focused on levels pertinent to occupational exposure limits. Healthy females (n=50) between 18 and 35 years had four 15-min exposures to glutaraldehyde and five exposures to either blank air or VOC control in the course of a 7-hr day, as follows: once each to 35, 50, 75, and 100 ppb glutaraldehyde, three times to blank air, and twice to 10 ppm n-heptane. Exposures took place in a chamber, typically with two subjects present simultaneously. Analytical measurement (OSHA 64 method) confirmed the levels of glutaraldehyde. Subjects rated their confidence in the presence of stimulus-induced chemesthesis minute by minute. The outcome showed greater activity in the nose than in the throat or eyes. The activity increased progressively during exposure, but manifested itself as a reduction in the confidence of no chemesthesis rather than in the confidence of its presence. Even at the highest concentration, subjects failed to reach a 50% threshold for positive detection of chemesthesis by the end of exposure.

#### 2136

ASSESSMENT OF HUMAN SENSORY AND RESPIRATORY RESPONSES TO CONSUMER PRODUCTS.

University. Vedula<sup>5</sup>, L. Fell<sup>2</sup>, S. Selim<sup>4</sup>, R. Rogers<sup>3</sup>, P. Dalton<sup>6</sup> and <u>T. G. Osimitz</u><sup>1</sup>. Science Strategies, Charlottesville, VA, <sup>2</sup>ToxLink, LLC, Racine, WI, <sup>3</sup>Toxcon, Edmonton, AB, Canada, <sup>4</sup>selim and Associates Toxicology, Camelia, CA, <sup>5</sup>S. C. Johnson, Racine, WI and <sup>6</sup>Monell Institute for the Chemical Senses, Philidelphia, PA.

The prediction of human responses to consumer products is an important element of product stewardship. Conventional animal toxicology studies often provide little information on the subjective responses (shortness of breath, coughing, nasal congestion) that consumers sometimes report. To address this gap, a series of physiologic tests and survey instruments were used to assess such responses in 371 adults (including mild and mild to moderate persistent asthmatics) exposed to consumer product formulations in simulated residential exposure rooms (16 ft x 16 ft x8 ft ). An Institutional Review Board approved the protocol and informed consent package prior to conducting the study. Objective measures were chosen for pulmonary function, nasal congestion, and ocular irritation. Subjective Symptoms were evaluated by a self-administered survey for 20 different responses reflecting upper respiratory, lower respiratory, and non-specific symptoms. Experimental substances included a Test Substance (water-based air sanitizer - 6.1% triethylene glycol), a Reference Substance (water-based air freshener), and a Control Substance (distilled water). The products were sprayed in the exposure chamber according to label directions. The full set of assessments was performed immediately prior to exposure, after 5 min of exposure (mean TWA concentration of TEG =  $4.33 \pm 1.75$  mg/m3), and after 30 min of exposure during a period from 60-90 min (mean TWA concentration of TEG =  $0.098 \pm 0.023$  mg/m3). Sporadic changes in subjective and objective measures occurred throughout the study in across all groups. Overall, no clinically significant symptoms, or increase in symptoms from baseline, were observed regardless of exposure to Test, Reference, or Control Substances. In addition, the response of asthmatics was not clinically significantly different than that of nonasthmatics exposed to any of the substances tested.

COMBINED ARTERIAL BLOOD GAS ANALYSIS AND PLETHYSMOGRAPHY TO EVALUATE PULMONARY FUNCTION IN THE RAT.

K. D. Lake-Bruse, K. J. Smith and G. J. Schaefer. Safety Pharmacology, WIL Research Laboratories, Inc., Ashland, OH.

The purpose of this study was to evaluate the sensitivity and feasibility of combining plethysmography with arterial blood gas analysis to provide a more complete evaluation of pulmonary function without increasing the number of animals on

study. Restraint acclimated rats were implanted with arterial vascular access ports 7 days prior to pulmonary assessment. Ânimals (8 males/group) were dosed with saline or pentobarbital (PB; 10, 25, and 45 mg/kg, i.p.). Pulmonary function data consisting of pulmonary frequency (F), tidal volume (TV) and minute volume (MV) were collected at baseline, and at 0-6 hours and 24 hours post dosing. Pulmonary arterial O2 (PaO2) and CO2 (PaCO2) levels were determined in blood samples collected at pretest, and at 0.25, 1, 2 and 24 hours post-dosing. PB elicited a time and dose-dependent anesthetic effect with statistically significant changes in F, TV, MV, PaCO2 and PaO2 compared to saline control. Overall, peak decreases in F, TV, and MV occurred at 0.5 and 1 hr following the 25 and 45 mg/kg doses, respectively. F was decreased 15-37% for 1 hr and 22-44% for 2 hrs following the 25 and 45 mg/kg doses, respectively. TV was decreased 26-31% for up to 30 min and 30 38% for up to 2 hrs following the 25 and 45 mg/kg doses, respectively. MV was decreased 16% at 15 min, 21-56% for up to 1 hr, and 19-62% for up to 3 hrs following the 10, 25 and 45 mg/kg doses, respectively. From the blood gas analysis, the PaCO2 parameter was more statistically sensitive than PaO2. PaCO2 was increased 21% at 1 hour following the 25 mg/kg dose of PB, and increased 19%, 43% and 58% at 0.25, 1, and 2 hrs, respectively, following the 45 mg/kg dose of PB when compared to saline control. The 45 mg/kg dose of PB decreased overall (11 13%) the PaO2 for up to 24 hrs post dosing. In conclusion, combining plethysmography and arterial blood gas analysis within the same animal is a feasible approach that provides a more complete pulmonary function evaluation in rats.

## 2138 MECHANISMS OF ORGANOPHOSPHATE INSECTICIDE-INDUCED AIRWAY HYPERREACTIVITY.

P. Lein and A. D. Fryer<sup>2</sup>. <sup>1</sup>CROET, Oregon Health & Science University, Portland, OR and <sup>2</sup>Physiology and Pharmacology, Oregon Health & Science University, Portland, OR.

It has been suggested that insecticide exposure is a causal factor for the increased incidence of asthma in the United States and other industrialized nations. Mechanism(s) by which insecticides trigger asthma have yet to be established. Airway tone is controlled by the parasympathetic nerves in the lung. Dysfunction of autoinhibitory M2 muscarinic receptors on parasympathetic nerves is associated with airway hyperreactivity, a characteristic of asthma. One widely used class of insecticides, the organophosphates, has been shown to decrease M2 receptor expression and function in the central nervous system. Thus, exposure to the organophosphate insecticides may contribute to airway hyperreactivity *via* inhibition of neuronal M2 receptors in the lung. To test this hypothesis, airway hyperreactivity was measured in guinea pigs 24 hr after subcutaneous injection with varying concentrations of chlorpyrifos, diazinon, parathion and the non-organophosphate insecticide permethrin. Electrical stimulation of the vagus nerves caused frequency-dependent bronchoconstriction that was significantly potentiated in animals treated with the organophosphates, but not with permethrin. Neuronal M2 recep-

tor function was tested using the M2 agonist pilocarpine, which inhibits vagally-induced bronchoconstriction in control animals. In animals treated with organophosphate insecticide, pilocarpine dose-response curves were shifted significantly to the right, demonstrating decreased responsiveness of neuronal M2 receptors. In contrast, M3 muscarinic receptor function on airway smooth muscle was not altered by any of the organophosphates. Chlorpyrifos and diazinon caused airway hyperreactivity at doses that did not significantly inhibit acetylcholinesterase. These data demonstrate that organophosphate insecticides can inhibit neuronal M2 receptor function resulting in increased acetylcholine release from the parasympathetic nerves and airway hyperreactivity.

# 2139 CONTROLLED VENTILATION INHALATION EXPOSURE AND LUNG SCINTIGRAPHY APPLIED TO A PHARMACOKINETIC AND TISSUE DISTRIBUTION STUDY.

R. Moutvic<sup>1</sup>, D. B. Cearlock<sup>2</sup>, R. L. Beihn<sup>3</sup>, A. Zutshi<sup>4</sup> and <u>M. J. Brooker</u><sup>1</sup>.

<sup>1</sup> Toxicology, Battelle, Columbus, OH, <sup>2</sup> Zivena, Columbus, OH, <sup>3</sup> Scintiprox, Inc., Indianapolis, IN and <sup>4</sup> Pfizer, Inc., Kalamazoo, MI.

The study was designed to evaluate the pharmacokinetic profile and tissue distribution in the dog of a 14C labeled doxirubicin (C14D) administered intravenously and via inhalation. A combination of controlled-ventilation inhalation exposure and scintigraphic evaluation of lung deposition were utilized for the inhalation leg. The deep lung was the target for deposition of inhaled aerosols. Exposures to C14D via inhalation were performed at tidal volumes that were 75% of vital capacity and included a 4 second breath hold. Inhalation exposures were controlled by a computer program that manipulated pressure within a Spangler box (iron lung). The test subjects were anesthetized and entubated. The C14D solution was co-labeled with 99mTc for scintigraphic imaging and C14D aerosols were administered to 12 dogs at a deposited dose of 1.65 mg. Scintigraphic images were collected immediately post exposure and C14D deposition in the lung was determined quantitatively. A second set of 12 dogs was exposed to 1.90 mg of C14D via bolus intravenous infusion. Serial blood samples were collected for pharmacokinetic analysis. Animals were serially necropsied and tissues were harvested to evaluate time dependent tissue distribution of C14D through out the body. Results indicated inhalation and intravenous PK profiles with similar kinetic distributions and elimination half lives. Systemic bioavailability via inhalation was 65%. Tissue distribution analysis indicated that the inhalation exposure group had substantially lower systemic exposure indicated by lower C14D levels in all tissues except the lung at all time points evaluated.
