# Society of Toxicology 43<sup>rd</sup> Annual Meeting Baltimore, Maryland

# THE TOXICOLOGIST

# a supplement to TOXICOLOGICAL SCIENCES

An Official Journal of the Society of Toxicology

Volume 78, Number S-1, March 2004

### Preface

This issue of *The Toxicologist* is devoted to the abstracts of the presentations for the symposium, workshop, roundtable, platform and poster sessions of the 43<sup>rd</sup> Annual Meeting of the Society of Toxicology, held at the Baltimore Convention Center, Baltimore, Maryland, March 21-25, 2004.

An alphabetical Author Index, cross referencing the corresponding abstract number(s), begins on page 443.

The document also contains a Keyword Index (by subject or chemical) of all the presentations, beginning on page 473.

The abstracts are reproduced as accepted by the Program Committee of the Society of Toxicology and appear in numerical sequence.

Copies of *Program* and CD-ROM with the Itinerary Planner are available at \$45 each plus \$5 postage and handling (U.S. Funds) from:

Society of Toxicology 1821 Michael Faraday Drive, Suite 300 Reston, VA 20190

All text and graphics © by the Society of Toxicology unless noted.

This abstract document has been produced electronically by ScholarOne, Inc. Every effort has been made to faithfully reproduce the abstracts as submitted. The author(s) of each article appearing in this publication is/are solely responsible for the content thereof; the publication of an article shall not constitute to be deemed to constitute any representation by the Society of Toxicology or its Boards that the data presented therein are correct or are sufficient to support the conclusions reached or that the experiment design or methodology is adequate. Because of the rapid advances in the medical sciences, we recommend that independent verification of diagnoses and drug dosage be made.

## HERBALS AND DIETARY SUPPLEMENTS IN ATHLETIC PERFORMANCE ENHANCEMENT: FACT VS. FICTION.

T. S. Tracy. University of Minnesota, Minneapolis, MN. Sponsor: A. Fuciarelli.

Herbal products and dietary supplements have been used for years in an attempt to enhance athletic performances. However, this usage has not always been based on scientific data. Recent tragic cases, such as those involving ephedra supplements, have highlighted the need for an unbiased assessment of available data and additional research into their actions and effects. This presentation will discuss the various products used for athletic performance enhancement such as ephedra, androstenedione and androgens, creatine, gamma hydroxybutyrate, dimethylglycine, and others. Their promoted uses, purported mechanism of action, adverse effects/toxicities, and available clinical data will be presented to provide a perspective of what is known and areas in need of additional research. Additionally, the current regulatory status will be discussed and what factors may impact upon changes in this status.

#### **2** BASIC NEUROTOXICOLOGY.

W. Slikker, Jr¹, S. L. Schantz², M. G. Paule¹, E. C. Tiffany-Castiglioni³ and J. P. O'Callaghan⁴.¹ National Center for Toxicological Research, Jefferson, AR, ² University of Illinois Urbana, Urbana, IL, ³ Texas A&M University, College Station, TX and ⁴ CDC-NIOSH, Morgantown, WV.

Neurotoxicity may be defined as any adverse effect on the structure or function of the central and/or peripheral nervous system by a biological, chemical, or physical agent. Adverse effects can include both unwanted effects and any alteration from baseline that diminishes the ability of an organism to survive, reproduce or adapt to its environment. Neurotoxic effects may be permanent or reversible, and may result from direct or indirect actions on the nervous system. A multidisciplinary approach is necessary to assess neurotoxicity due to the complex and diverse functions of the nervous system. Many of the relevant effects can be measured by neurobiological, neurophysiological, neuropathological or behavioral techniques, as well as epidemiological approaches. After a general overview of neurotoxicity assessment from genes to human response, this basic course will present in greater depth the methods used to study populations, individual animals, cells, and genomes. Each speaker will review the basic concepts underlying the methodological approach presented. Selected neurotoxicants, including heavy metals, polyaromatic hydrocarbons, and drugs of abuse, will be used to illustrate principles. The first two lectures will address neurotoxic effects as studied by epidemiology in human populations and behavioral assessment in animal models, respectively. The next lecture will address the cellular responses of neurons, astrocytes, and oligodendrocytes to neurotoxicants. The course will be concluded with a description of a molecular approach to neurotoxicology including genomics. This course will be of interest to a broad range of scientists including drug developers, pharmacologists, neuroscientists, psychologists, regulators, and toxicologists.

### TOOLS FOR FUNCTIONAL GENOMICS (PM10 REPEATED).

H. I. Swanson<sup>1</sup>, E. D. Thompson<sup>1</sup>, Y. Tian<sup>2</sup> and K. Kim<sup>1</sup>. <sup>1</sup>University of Kentucky, Lexington, KY and <sup>2</sup>Texas A&M University, College Station, TX.

The goal of this course is to discuss cutting-edge tools and techniques that may be used in ascribing hierarchical, functional analyses of gene products following DNA microarray experiments. First, we will discuss the advantages and disadvantages of a variety of pharmacological and molecular tools (i.e., antagonists, dominant negative approaches, siRNA). We will also discuss the means by which the molecular tools may be introduced into the cell or animal model, including the use of retroand adenoviruses. Our second presentation will use data obtained in the laboratory to demonstrate the approaches that are typically used for determining whether the observed changes in mRNA of the gene product of interest occurs at the transcriptional or post-transcriptional levels. The third presentation will focus on use of the chromatin immunoprecipitation (CHIP) assay to demonstrate whether candidate transcription factors are involved in the regulation of the gene product of interest. Finally, our last presentation will introduce a novel approach, chemical genetics, that may be used to either activate or inactivate target gene products in able to discern their functional role(s) either the toxic or disease-related events.

## OF MICE AND MAGNETS: METABONOMICS TECHNOLOGY IN SAFETY ASSESSMENT.

D. G. Robertson<sup>1</sup>, L. D. Lehman-McKeeman<sup>2</sup>, J. D. Baker<sup>3</sup> and <u>D. A.</u>
<u>Casciano</u><sup>4</sup>. <sup>1</sup>Pfizer Global Research & Development, Ann Arbor, MI, <sup>2</sup>Bristol Myers
Squibb Company, Princeton, NJ, <sup>3</sup>Pfizer, Inc., Ann Arbor, MI and <sup>4</sup>National Center
for Toxicological Research, Jefferson, AR.

Although metabonomics as a technology has been in the literature for over a decade, it is only in the past 3 to 4 years that the technology has gained widespread attention within the industrial sector. Metabonomics as a topic was introduced to the Society in a well-received sunrise mini-course in 2000. This was followed by a highly attended IAT symposium and poster session on metabonomics at the 2002 meeting. The technology has reached the level of maturity such that a full CE course is called for. The objectives of this basic level course will be to introduce the technology to SOT members unfamiliar with it, emphasizing the strengths and weaknesses of the technology in a practical way. The presentations will be from a toxicologist's perspective - communicating essential principles, but will avoid NMR and statistical jargon. The course will be primarily from a pharmaceutical development point of view, but will be broad enough to provide useful information for anyone interested in the technology.

5

### FUNCTIONAL FLOW CYTOMETRY: APPLICATIONS IN TOXICOLOGY (PM12 REPEATED).

C. D. Bortner<sup>1</sup>, <u>D. Laskin</u><sup>2</sup>, <u>N. I. Kerkvliet</u><sup>3</sup> and <u>S. W. Burchiel</u><sup>4</sup>. <sup>1</sup>NIEHS, Research Triangle Park, NC, <sup>2</sup>Rutgers University, Piscataway, NJ, <sup>3</sup>Oregon State University, Corvallis, OR and <sup>4</sup>University of New Mexico, Albuquerque, NM.

Flow cytometry provides a powerful tool for analyzing multiple characteristics of individual cells in a complex mixture of cell types without having to physically separate the cells. Yet, even though each cell is examined individually, the flow cytometer can process thousands of cells within a few seconds, allowing superior sampling of the population as compared to microscopic counting. The myriad of phenotypic and functional characteristics of cells that can be measured by flow cytometry continues to expand with the development of novel fluorescent probes to a variety of cellular components. The field of immunotoxicology has been greatly influenced by the use of flow cytometry with applications ranging from screening for toxic effects on immune cells to elucidating the mechanisms of toxic action on specific subpopulations of cells. However, other areas of toxicology are beginning to recognize the value of flow cytometry for mechanistic investigations as well. To address this growing interest, the intent of this course is to introduce the audience to novel applications of flow cytometry that have been used to assess tissue injury and mechanisms of toxicity at the whole animal, cellular, and biochemical levels. Although the context of many of the examples will emanate from immunotoxicology studies, each speaker will focus less on the immunology and more on the methods used in their studies that are broadly applicable to other areas of toxicology. Examples of methods to be covered include: apoptosis, oxidative stress, membrane integrity and fluidity, cell cycling using carboxyfluorescein (CFSE), and cell signaling.

### 6

# UNDERSTANDING LIFESPAN CHANGES IN FORM AND FUNCTION OF THE FEMALE REPRODUCTIVE SYSTEM TO ASSESS AND INTERPRET TOXICITY.

P. M. Iannaccone<sup>1</sup>, P. E. Blackshear<sup>2</sup>, J. M. Cline<sup>3</sup> and <u>P. J. Wier<sup>4</sup>. <sup>1</sup>Northwestern University, Chicago, IL, <sup>2</sup>Integrated Laboratory Systems, Inc., Research Triangle Park, NC, <sup>3</sup>Wake Forest University School of Medicine, Winston-Salem, NC and <sup>4</sup>GlaxoSmithKline, King of Prussia, PA.</u>

This course reviews the basic morphology and endocrinology of the female reproductive system in rodents and primates as a basis for interpreting toxicity. Each of the 4 lectures will emphasize fundamental changes and vulnerabilities of the reproductive tract over the lifespan of the female. Both rodent and non-human primates will be discussed with respect to relevance to humans. The first lecture covers embryological development of the female reproductive system and will include key developmental and molecular events with an emphasis on timing of events in rodents and primates and potential periods of susceptibility to toxicity. The second lecture details the morphology and endocrinology of the female reproductive tract in rodents and will relate hormones and histology of the adult rodent reproductive tract from the onset of puberty to reproductive senescence and important sites of toxicity. The third lecture details the morphology and endocrinology of the female reproductive tract in nonhuman primates with emphasis on similarities and differences to rodents. The final lecture will combine the information of the first lectures and analyze issues of study design, endpoints to examine and interpretation of results in assessing female reproductive toxicity data.

# THE SAFETY ASSESSMENT OF PROTEINS: APPLICATIONS TO AGRICULTURAL BIOTECHNOLOGY.

B. Petersen<sup>1</sup>, J. Kough<sup>2</sup>, M. Pariza<sup>3</sup> and J. D. Astwood<sup>4</sup>. <sup>1</sup>Exponent, Inc., Washington, DC, <sup>2</sup>USEPA, Washington, DC, <sup>3</sup>University of Wisconsin-Madison, Madison, WI and <sup>4</sup>Monsanto Company, St. Louis, MN. Sponsor: B. Hammond.

Biotechnology has made it possible to introduce proteins into food crops to achieve desired biological effects. Întroduced proteins can impart important agronomic properties such as tolerance to topically applied herbicides to control weeds or protection of food crops against insect pest damage. Enzymes can be introduced into food crops that enhance the existing production of essential nutrients, or introduce nutrients into food crops that have potential health benefits. Proteins are also produced by microorganisms via fermentation such as enzymes used in food processing or pharmaceuticals (i.e. somatotropins) used to enhance the efficiency of milk production in dairy cows. A group of experts in the field of protein safety assessment will share their experience and learnings. The subject of protein allergy assessment will not be covered in this course as it has been thoroughly addressed in other courses and workshops held at SOT meetings. Toxicologists who attend this course will have a better understanding of the safety assessment strategies that have been developed for proteins in relationship to food safety. These strategies will differ in some respect from traditional safety testing approaches used for chemical xenobiotics that come in contact with food.

#### **8** SAFETY PHARMACOLOGY AFTER ICH S7A & S7B.

A. Bass<sup>1</sup>, P. Siegl<sup>2</sup>, D. J. Murphy<sup>3</sup>, S. Lindgren<sup>4</sup> and L. B. Kinter<sup>5</sup>. <sup>1</sup>Schering Plough Research Institute, Kenilworth, NJ, <sup>2</sup>Merck Research Labs, West Point, PA, <sup>3</sup>GlaxoSmithKline, King of Prussia, PA, <sup>4</sup>AstraZeneca Pharmaceuticals, Sodertalje, Sweden and <sup>5</sup>AstraZeneca Pharmaceuticals, Wilmington, DE.

Safety Pharmacology evaluations for human pharmaceuticals are dramatically redefined following implementation of International Conference on Harmonization Guidances S7A (2000), and finalization of S7B (anticipate in 2003). Those guidelines mandate evaluations for new drugs for unintended effects on cardiovascular, respiratory, and central nervous system functions (S7A core battery), renal and electrophysiological aspects of the cardiac repolarization (S7B) in support of phase I (first in man) programs. This introductory course will familiarize participants with rationale and tactics for modern safety pharmacology evaluations for expeditious development of human pharmaceuticals. An international faculty will present strategies for successful implementation of the core battery evaluations, including critical experimental endpoint, criteria for species selection, study design alternatives, dose selection, data analysis and interpretation, Animal Welfare and Good Laboratory Practice (GLP) issues. The Course will be of broad interest to both academic and industrial SOT Members engaged in pharmaceutical safety assessment and risk management.

### 9 SKIN SENSITIZATION AND ALLERGIC CONTACT DERMATITIS.

I. Kimber<sup>1</sup>, D. A. Basketter<sup>2</sup>, G. F. Gerberick<sup>3</sup> and D. M. Sailstad<sup>4</sup>. <sup>1</sup>Syngenta, Macclesfield Cheshire, United Kingdom, <sup>2</sup>Unilever Research US Inc., Bedfordshire, United Kingdom, <sup>3</sup>Procter & Gamble Company, Cincinnati, OH and <sup>4</sup>USEPA, Research Triangle Park, NC.

Skin sensitization resulting in allergic contact dermatitis is a very common occupational and environmental health problem and is without doubt the most common manifestation of an immunotoxic response. As a consequence there is a need to identify and characterize skin sensitization hazards and for accurate risk assessment paradigms. The last decade has witnessed very significant advances in our understanding of the cellular and molecular mechanisms that are associated with, and required for, the induction of skin sensitization and the elicitation of allergic contact dermatitis. In parallel there has been a growing appreciation of the characteristics that confer on chemicals the ability to cause allergic sensitization and the nature of apparent inter-individual differences in susceptibility. Such advances have translated into new opportunities for hazard identification, for assessment of relative skin sensitizing potency and for the development of new approaches to risk assessment. This basic continuing education course will describe for a general audience the immunobiology and chemistry of skin sensitization and clinical aspects of allergic contact dermatitis. This will be followed by a description of the methods available for hazard identification and for the determination of potency, approaches to risk assessment and the current global regulatory environment. This course will be of interest to immunotoxicologists, dermatotoxicologists, those involved in the safety assessment of chemicals and regulatory toxicologists. The course is sponsored jointly by the Dermal Toxicity and Immunotoxicology.

10

### TOOLS FOR FUNCTIONAL GENOMICS (AM03 REPEATED).

H. I. Swanson<sup>1</sup>, E. D. Thompson<sup>1</sup>, Y. Tian<sup>2</sup> and K. Kim<sup>1</sup>. <sup>1</sup>University of Kentucky, Lexington, KY and <sup>2</sup>Texas A&M University, College Station, TX.

The goal of this course is to discuss cutting-edge tools and techniques that may be used in ascribing hierarchical, functional analyses of gene products following DNA microarray experiments. First, we will discuss the advantages and disadvantages of a variety of pharmacological and molecular tools (i.e., antagonists, dominant negative approaches, siRNA). We will also discuss the means by which the molecular tools may be introduced into the cell or animal model, including the use of retroand adenoviruses. Our second presentation will use data obtained in the laboratory to demonstrate the approaches that are typically used for determining whether the observed changes in mRNA of the gene product of interest occurs at the transcriptional or post-transcriptional levels. The third presentation will focus on use of the chromatin immunoprecipitation (CHIP) assay to demonstrate whether candidate transcription factors are involved in the regulation of the gene product of interest. Finally, our last presentation will introduce a novel approach, chemical genetics, that may be used to either activate or inactivate target gene products in able to discern their functional role(s) either the toxic or disease-related events.

### Ø

#### 11 COMPUTATIONAL BIOLOGY, DOSE & RESPONSE.

J. W. Fisher<sup>1</sup>, M. Craven<sup>2</sup>, D. McMillen<sup>3</sup> and M. E. Andersen<sup>4</sup>. <sup>1</sup>University of Georgia, Athens, GA, <sup>2</sup>University of Wisconsin, Madison, WI, <sup>3</sup>University of Toronto at Mississauga, Mississauga, ON, Canada and <sup>4</sup>CIIT Centers for Health Research, Research Triangle Park, NC.

The past 40 years witnessed increasing emphasis on development of computational simulation models, including physiologically based pharmacokinetic (PBPK) and, on a more limited scale, physiologically based pharmacodynamic (PBPD) models for biological responses. The fidelity of model parameters with actual biological processes has steadily increased in concert with the explosion of basic biological information. Today computational biology and computational toxicology are undergoing rapid evolution to keep pace with the enormous expansion of our biological knowledge base. A variety of new computational tools and new software are available for computation and the breadth of problems accessible to computational analysis in biology has also increased. The insights derived from computational approaches in biology will influence research strategies to develop biologically based dose-response (BBDR) models in toxicology/pharmacology and undoubtedly form the basis of the next generation of mechanistic approaches for risk and safety assessments. This session consists of 4 talks covering (1) recent progress in PBPK modeling of xenobiotic and endogenous compounds, (2) development of new computational tools to examine cellular signaling networks, (3) modeling approaches for examining relationships between cellular circuitry and cellular function and (4) the possibility that cellular circuits may be regarded as targets for toxic responses. The session is designed to capture the status, current directions and future opportunities of computational biology that are likely to influence toxicological research strategies and risk and safety assessment.

### 12

## FUNCTIONAL FLOW CYTOMETRY: APPLICATIONS IN TOXICOLOGY (AM05 REPEATED).

C. D. Bortner<sup>1</sup>, <u>D. Laskin</u><sup>2</sup>, <u>N. I. Kerkvliet</u><sup>3</sup> and <u>S. W. Burchiel</u><sup>4</sup>. <sup>1</sup>NIEHS, Research Triangle Park, NC, <sup>2</sup>Rutgers University, Piscataway, NJ, <sup>3</sup>Oregon State University, Corvallis, OR and <sup>4</sup>University of New Mexico, Albuquerque, NM.

Flow cytometry provides a powerful tool for analyzing multiple characteristics of individual cells in a complex mixture of cell types without having to physically separate the cells. Yet, even though each cell is examined individually, the flow cytometer can process thousands of cells within a few seconds, allowing superior sampling of the population as compared to microscopic counting. The myriad of phenotypic and functional characteristics of cells that can be measured by flow cytometry continues to expand with the development of novel fluorescent probes to a variety of cellular components. The field of immunotoxicology has been greatly influenced by the use of flow cytometry with applications ranging from screening for toxic effects on immune cells to elucidating the mechanisms of toxic action on specific subpopulations of cells. However, other areas of toxicology are beginning to recognize the value of flow cytometry for mechanistic investigations as well. To address this growing interest, the intent of this course is to introduce the audience to novel applications of flow cytometry that have been used to assess tissue injury and mechanisms of toxicity at the whole animal, cellular, and biochemical levels. Although the context of many of the examples will emanate from immunotoxicology studies, each speaker will focus less on the immunology and more on the methods used in their

studies that are broadly applicable to other areas of toxicology. Examples of methods to be covered include: apoptosis, oxidative stress, membrane integrity and fluidity, cell cycling using carboxyfluorescein (CFSE), and cell signaling.

### 13 ADRENAL GLAND: MECHANISMS OF TOXICITY AND CARCINOGENESIS.

G. L. Foley<sup>1</sup>, C. C. Capen<sup>2</sup>, A. S. Tischler<sup>3</sup> and J. D. Obourn<sup>4</sup>. <sup>1</sup>Pfizer Global Research & Development, Ann Arbor, MI, <sup>2</sup>Ohio State University, Columbus, OH, <sup>3</sup>Tufts New England Medical Center, Boston, MA and <sup>4</sup>Pfizer Global Research & Development, Groton, CT.

The adrenal gland is a common target organ in safety assessment studies. Many times adrenal changes are attributed to "stress," because this organ produces glucocorticoid hormones and catecholamines. However, that simplistic interpretation ignores the complexity of this organ, of which a fuller understanding will facilitate the ability of toxicologists to investigate potential alternative mechanisms of action. For instance, the adrenal gland has a cortex with three defined zones (zona glomerulosa which produces mineralcorticoids; zona fasciculate which produces glucocorticoids; and, zona reticularis which produces sex steroids) and a medulla which contains chromaffin cells which synthesize catecholamines (predominantly epinephrine and norepinephrine). The goal of this continuing education course is to illustrate the various physiological roles of the adrenal gland, to provide several examples of toxicity including carcinogenicity, and to illustrate the tools necessary to investigate mechanisms of adrenal toxicity. The first speaker will review the physiology of the adrenal gland, focusing on the hypothalamic-pituitary-adrenal axis that regulates adrenal cortical function and the sympathetic control of adrenal medullary function. In addition, the comparative anatomy of the adrenal gland will be discussed, focusing on the common species used in toxicology studies (mouse, rat, dog, primate). The second and third speakers will build upon the physiology of the adrenal by describing mechanisms for adrenal cortical and medullary toxicity and carcinogenesis. These speakers will highlight mechanisms of toxicity, illustrate methods to assess adrenal toxicity, and discuss human relevance. The last speaker will provide a case study where the mechanism of adrenal cortical tumors induced by a selective estrogen receptor modulator (SERM) was elucidated and how this information was applied in assessing risk to patients.

### 14

# LIFE AS A TOXICOLOGIST - A GRADUATE STUDENT AND POSTDOC PRIMER TO CAREERS IN TOXICOLOGY.

D. Robinson<sup>2</sup> and R. J. Gerson<sup>1</sup>. <sup>1</sup>Endo Pharmaceuticals, Chadds Ford, PA and <sup>2</sup>Worldwide Safety Sciences, Pfizer Global R&D, New London, CT.

The proposed course will familiarize graduate students and post-docs with the day-to-day responsibilities, scientific challenges and activities of practicing Toxicologists in various professional fields of employment. The symposium will include presentations by Toxicologists from the Chemical/Agro Chemical, Pharmaceutical, Contract & Consulting arenas as well as Toxicologists from the EPA and FDA. The purpose of these presentations will be to familiarize aspiring Toxicologists with the specific activities and scientific challenges associated with these careers in Toxicology and provide perspective on career choices in Toxicology. Each presentation will include specific case studies of how Toxicology data are used and integrated within the specific career discipline. This course offering is designed to provide insight to Toxicology graduate students and post-docs as they begin to ponder their careers following their graduate/post-graduate education.

#### 15

## THE ROLES OF A TOXICOLOGIST IN A PHARMACEUTICAL COMPANY.

M. V. Kindt. Safety Assessment, Merck & Co., West Point, PA.

Toxicologists serve in a variety of roles in the preclinical development of pharmaceutical products. They conduct laboratory research in specialty areas such as acute, genetic, developmental and reproductive toxicology, as well as, general/chronic toxicity, safety pharmacology, and toxicokinetics. This research can range in focus from methodology development to drug candidate safety evaluation to mechanism-based research. For example, the toxicologist on general/chronic toxicity studies would likely be involved in study design, data interpretation (eg. body weight, food consumption, physical sign, clinical pathology, and electrocardiogram data), and report preparation. When adverse effects are identified with the drug development candidate, efforts may shift to mechanistic studies designed to determine the effects's importance for clinical development of the compound. Toxicologists may also serve as study directors for nonclinical safety studies, i.e., as the central point of overall control and responsibility for the study. The study director integrates the antemortem,

postmortem, and toxicokinetic data from the study. Finally, toxicologists also often represent their non-clinical safety department on interdepartmental teams that oversee the development of drug development candidates from basic chemistry through clinical trials. As the compound or product manager, the toxicologist works closely with the synthetic chemists to address impurity issues, with formulation chemists to approve vehicles for nonclinical and clinical use, and with clinicians to design a nonclinical program that will support the clinical development of the drug candidate. Often the toxicologist as compound/product manager is responsible for preparing regulatory documents and for representing in the company in discussions with regulatory agencies. General examples will be provided for illustration.

### 16

## THE ROLE OF TOXICOLOGY IN THE DEVELOPMENT OF HUMAN THERAPEUTICS - AN FDA PERSPECTIVE.

A. Weir. FDA/Center for Drug Evaluation and Research/ODE VI, Rockville, MD.

The Food and Drug Administration (FDA) has five centers regulating food and medical products intended for use in humans and animals. Each center has career opportunities for toxicologists, with the Center for Drug Evaluation and Research (ĈDER) providing opportunities to those interested in regulating human therapeutics such as small molecular-sized drugs and biotechnology-derived products (e.g. monoclonal antibodies and therapeutic proteins) intended for the treatment of various medical conditions, and more recently as defense against bioterrorism. Before starting clinical trials in humans, pharmaceutical companies must submit an investigational new drug application (ÎND) to CDER for a scientific team comprised of a toxicologist, a physician, and a chemist to review. A typical IND has data from a variety of toxicology/related studies, a protocol for the clinical trial, and data defining the product's chemistry and manufacturing. The toxicologists evaluate the design of the toxicology/related studies, identify toxicities, recommend safe doses for the clinical trial, and communicate issues to their review team and to their counterparts in pharmaceutical companies. After clinical trials are initiated, the toxicologists review additional studies needed to support the continued safety of clinical trials and, ultimately, the approval of the product after a biological licensing application (BLA) or new drug application (NDA) is filed with CDER. The wide variety of studies submitted with an IND and BLA/NDA, which will be illustrated by a sample data set, gives toxicologists the opportunity to develop specialized skills in areas such as toxicokinetics, reproductive toxicology, and immunotoxicity. CDER gives toxicologists the opportunity to actively participate in the development of therapeutic products, to keep pace with the cutting edge technology behind new therapies and their safety evaluation, and to actively engage in regulatory/scientific decision-making at the national and international level.

#### 17

## ENVIRONMENTAL PROTECTION AGENCY: SCIENTIFIC CHALLENGES.

V. Dellarco. Office of Pesticide Programs, USEPA, Washington DC, DC.

The USEPA (EPA) is responsible for remediating the damage done to the natural environment, establishing standards to ensure a cleaner environment, and the protection of ecosystems and human health. EPA employs approximately 18, 000 people in the program offices, regional offices, and laboratories. More than half are scientists, engineers or environmental protection specialists from a wide range of disciplines such as biology, chemistry, ecology, epidemiology, hydrology, oceanography, statistics/computer science, and toxicology. Implementation of environmental laws requires many different kinds of skills. Some programs have staff scientists who conduct health risk assessments on pollutants (e.g., Office of Air, ozone; Office of Water, arsenic; Office of Pesticide Programs, carbaryl). Other program office scientists may be involved in the development of standard test protocols or policy and guidance documents, or develop databases and risk tools that are used to identify and analyze human health or environmental effects. Some EPA scientists are responsible for managing major environmental programs such as drinking water disinfection by-products. Some have chosen to go into management and supervision of other scientists. Additionally, there are EPA scientists who conduct fundamental research. For example, scientists in the National Health and Environmental Effects Laboratory (located in Research Triangle Park, NC) are investigating the potential human health effects of exposure to environmental agents. Some of the things that attract scientists to EPA are the challenge of solving complex problems, contributing to environmental decision-making and working to protect the environmental and human health (frequently interacting with scientists from different disciplines inside and outside of EPA), and the constant learning of new science. A case study will be provided to illustrate how EPA uses toxicity and mode of action information to determine the potential human risks associated with exposure to environmental

## LIFE AS A TOXICOLOGIST IN THE CHEMICAL AND AGROCHEMICAL INDUSTRY.

#### M. S. Bogdanffy. DuPont Haskell Laboratory, Newark, DE.

Toxicology is a broad interdisciplinary field made even more diverse by its intent to understand chemical-induced harm in all sectors of society. In the chemical and agrochemical industries, the products are also quite diverse but there are two issues that are constant. First, many of the products and process intermediates are hazardous dictating a high level of concern for product safety. Second is the high degree of regulatory oversight expected by society and imposed on the industry by various governments. Consequently, life as a toxicologist in the chemical and agrochemical industry is very much driven by issues of workplace safety and environmental regulatory approvals necessary for freedom to operate. With the globalization of economies these hurdles become a maze of international regulatory complexities that the toxicologist must navigate. Toxicology testing, research and consulting are all part of the job although for all but the largest of chemical and agrochemical companies, much of the testing and research are farmed out to contract research organizations or universities. Therefore, in addition to good problem solving skills that make use of broad toxicology expertise, project management is an important component of the corporate toxicologist's life. Hands-on study director responsibilities and laboratory research opportunities exist for toxicologists of the larger chemical and agrochemical companies. Toxicologists of agrochemical companies frequently migrate to international product registration positions. The diversity of products and issues that a toxicologist in the chemical and agrochemical industry must attend to leave ample opportunity for very interesting and often long-term involvement in programs of product stewardship. This presentation will illustrate many of the day-to-day and year-to-year challenges facing a toxicologist in this industry by following the story of a high production volume carcinogenic chemical, the development of research to understand its mode of action and how this information impacts regulatory decision-making.

## 19 ON THE SERVICES SIDE: LIFE AS CRO SCIENTIST AND CONSULTANT.

#### D. J. Kornbrust. Consultant, Reno, NV.

The contract research organization (CRO) industry presents a wide range of career opportunities. Many of these institutions cater to the needs of the pharmaceutical industry, in terms of providing support for drug development programs, although some are more oriented towards assisting chemical companies. Services provided can range across the entire spectrum of nonclnical activities that comprise a therapeutic development program, from manufacturing operations to formulations to the performance of pharmacology, toxicology and pharmacokinetic studies that enable clinical testing of prospective pharmaceuticals. In general, the scientists within CROs are commonly referred to as "study directors" (SD). The role of the SD is to develop protocols and oversee the implementation, conduct and reporting of nonclinical studies that are "placed" with the CRO by the "Sponsor". This experience can differ substantially from that of a similar scientist role within a pharma or chemical company mainly with respect to the diversity of projects. The tradeoff is that opportunities to become deeply immersed in a project and obtain continuity of experience with individual programs are limited. Another distinguishing aspect of this line of work is that, as the SD develops skills and experience, he/she may become increasingly drawn into business development activities, possibly to an extent that dictates diminishing involvement with the basic science. Consequently, good business acumen and communication skills are highly valued in this industry. A background in the pharmaceutical industry combined with CRO experience can be an excellent springboard to move to independent consulting. Of course, one must develop a wide array of skills and be sufficiently "seasoned" to be successful in this endeavor, and there is considerable competition. To illustrate how projects can evolve from a basic service contract to a consulting role, an example of a program involving preclinical development of a biologic agent (human clotting factor) will be discussed.

### **20** TAKING COMMAND OF YOUR CAREER.

L. M. Kamendulis<sup>1</sup> and W. A. Toscano<sup>2</sup>. <sup>1</sup>Division of Toxicology, Indiana University School of Medicine, Indianapolis, IN and <sup>2</sup>Division of Environmental and Occupational Health, University of Minnesota School of Public Health, Minneapolis, MN.

An important mission of the Placement committee is to expand the traditional service role to that of a resource for career development issues for all career stages. This career development workshop, targeted at entry- to mid-career SOT members, addresses issues related to setting and achieving career goals in a dynamic and technical field. Many mechanisms exist for career advancement, however, the tools and

skills needed to advance are not always realized. The technical tools and prowess to keep on the cutting edge may often times get lost as increased managerial demands and other responsibilities are placed on individuals. The presentations in this workshop will focus on: How to take charge of your career to assure success, how to challenge oneself intellectually and scientifically in a subject matter for which one has both expertise and interest, how to garner and maintain the tools and skills necessary skills to make career advancements, and anticipating future trends in Toxicology. An interactive panel discussion, directed by questions from the audience will follow the presentations.

### 21 KEEPING SKILLS UP TO DATE.

#### J. E. Manautou. School of Pharmacy, University of Connecticut, Storrs, CT.

Staying competitive early in your professional career is essential in order to maximize your career growth opportunities. Since many avenues exist to maintain this competitive edge, it is key to develop a strategy to take advantage of all available resources while maintaining your current work responsibilities. Several widely available resources exist to develop your strategy and include attending continuing education classes, developing a scientific network with external colleagues, gathering information from recruiters seeking to place individuals with your expertise, and establishing career mentors. While solidifying your early and mid-career goals, it is important to expand your scientific and technological expertise as well. Staying current with the scientific literature is fundamental to keeping abreast of scientific knowledge and emerging technologies, however, other approaches such as engaging in scientific collaborations and sabbaticals provide excellent avenues to expand your scientific skills.

### 22

### SEEKING MID AND LONG TERM CAREER GOALS: PERSPECTIVES OF AN INDUSTRY TOXICOLOGIST.

#### J. Bus. TERC, Dow Chemical Co., Midland, MI.

One of the most exciting, but also most challenging aspects of a career in toxicology is that it potentially can touch all disciplines of biology. In an industry environment, toxicologists often are directed into two broad career options. These are: 1) being an expertise leader in one of the primary subdisciplines of toxicology, e.g., neurotoxicity, developmental toxicity, etc.; and 2) providing generalized toxicology expertise in support of business units, i.e., using your expert knowledge to guide business decisions on safety of products or processes. Several considerations can greatly facilitate choices that ultimately lead to satisfying and rewarding careers. Successful careers are always accompanied by technical excellence; lifelong learning and curiosity is essential and expected. Attention to development of communication and interpersonal skills, however, are equally important to expanding the breadth of available career options. Since the science of toxicology is very multidisciplinary, taking full advantage of professional networks is also essential to defining future career options. Seeking early opportunities to build relationships with trusted mentor(s) are critical. Mentors may be found through activities pursued within professional societies, within trade associations, or colleagues within your institution. Finally, toxicologists seeking careers within industry must develop a passion for applying the highest quality science to protecting the health of workers, customers and the public.

### 23

LEADERSHIP - STEERING YOUR CAREER TO ACHIEVE SOCIETAL AND PERSONAL GOALS AND THE WONDERFUL THINGS YOU LEARN ABOUT YOURSELF ALONG THE WAY.

### V. P. Wilson. Brown University, Providence, RI. Sponsor: W. Toscano.

Inspiring others to follow your vision to a better future is leadership. Some people are born with the qualities of leadership, but many others must learn to cultivate their abilities to become leaders. The rapidly changing scientific environment of toxicology provides novel challenges to emerging leaders. An effective leader must have a vision of the scientific and societal implications of modern toxicological sciences. This presentation will focus on how to develop and demonstrate effective leadership skills. Topics will include qualities of leadership in academic, government and industrial positions; how to motivate colleagues; and the use of leadership skills in career advancement.

24

## MAINTAINING TECHNICAL SKILLS WHILE RISING THROUGH MANAGEMENT.

L. D. Lehman-McKeeman. Discovery Toxicology, Bristol-Myers Squibb, Princeton, NJ.

As practicing toxicologists gain knowledge and experience, evolving career opportunities increasingly make demands on time or take scientists completely away from direct involvement in research or technical issues. As such, it is difficult to sustain a technical focus while assuming greater management or other leadership responsibilities within an organization. In order to find a balance between these often-competing priorities, it is first essential to recognize that no one person can do everything, and decisions on what is personally and professionally fulfilling and rewarding must be a deliberate choice. This is also a decision that all scientists need to re-examine and re-evaluate periodically. When a scientist decides that maintaining a technical focus is important, it is imperative to focus on sustaining a learning environment. In particular, this means that it is necessary to challenge oneself to continue to learn and to expand expertise into new technical areas. Whereas this is personally beneficial, it also helps to foster a learning environment within the larger organization. It is also essential to hire good researchers to work with you and to help and courage them to learn, grow and assume more responsibility as well. Coaching and mentoring good scientists provides them with the opportunity to expand their skills and is usually a long-term investment in the overall capacity of the laboratory or organization. Finally, it is important to learn from others, by asking questions, engaging in dialogue and discussion and being challenged to think about issues from different points of view. In the end, personal and organizational development is enhanced and job satisfaction is high.

### 25 TRANSDISCIPLINARY RESEARCH: RIDE THE WAVE.

J. Barrett, J. S. Wiest and L. Bennett. Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD.

The exponential rate at which discoveries are being made has resulted in science becoming more and more complex. In order to meet the challenges presented by this complexity, the new generation of independent investigators needs to work collaboratively; the time of the independent investigator working in isolation is vanishing. Today scientists will benefit from developing a solid understanding of the translational research process; moving discoveries made in the laboratory through a developmental process and into the clinical setting. No individual can be an expert in all areas of science, but by employing team science and exploiting scientific advances an individual can contribute to major scientific discoveries. Current training strategies should include plans for participating in transdisciplinary science. Having this expertise will provide the insights necessary to assemble a multidisciplinary team to tackle a problem and will empower the individual to establish himself or herself as a leader on a project and to assume the responsibility to make sure progress is made. Similarly, the necessity of contributing to a project for which one may not have a lead role will be appreciated. These strategies will be critical for recognizing contributions toward project success and for receiving the rewards that enable the science to move forward.

## 26 STEROID INACTIVATION: ALTERNATIVE MECHANISMS OF ENDOCRINE TOXICITY.

L. You. CIIT Centers for Health Research, Research Triangle Park, NC.

Normal reproductive development depends on the action of steroid hormones at specific tissue sites. Agents interfering with this process can elicit malformation or malfunction in the reproductive tract or other organs that rely on steroids to maintain normal physiology. While effects mediated by the steroid receptors have thus far been most extensively studied as targets for xenobiotic endocrine modulation, the consequences of increased or decreased inactivation of hormone ligands in relation to overall endocrine functions are less known. Many of the enzymes that control steroid biotransformation are responsive to xenobiotic induction. These enzymes include steroid hydroxylases that are members of the cytochrome P450 (CYP) family and the conjugation enzymes of sulfotransferases (ST) and uridine diphosphate-glucuronosyltransferases (UGT). Cloning and characterization of the nuclear receptor CAR and PXR in recent years have greatly improved the understanding of how some key members in the CYP enzyme family are transcriptionally regulated. Exposure to CAR and PXR receptor activators leads to up-regulation of CYP2B and 3A, which utilize steroid hormones as substrates. Similarly, xenobiotics can cause changes in the transcriptional control of ST, leading to alteration of its regulation on the bioavailability of free steroids. While these enzymatic changes may account for enhanced steroid metabolism, the physiological and toxicological consequences of such enzyme effects will require more assessment.

27

## XENOBIOTIC INTERFERENCE WITH HORMONE TRANSPORT PROCESSES.

G. A. LeBlanc. Environmental & Molecular Toxicology, North Carolina State University, Raleigh, NC.

The clearance of steroid and other hormones from critical target organs is regulated by enzymes that modify the mobility of the hormone. These enzymatic biotransformations also can target the hormone to active transporters that facilitate elimination of the hormone. Many of these enzymes and transporters also are involved in xenobiotic processing and are induced by chemical exposure through the regulatory action of xenobiotic sensors such as CAR and PXR. Such xenobiotic-mediated increases in these activities can result in enhanced elimination of some homones. For example, thyroid hormone (T4) is cleared from the body through its conjugation to flucuronic acid. This process is mediated by the glucuronosyl transferase enzyme UGT1 and is induced in response to CAR and PXR activators. Exposure of rats to some PCBs causes a significant increase in T4 glucuronidation and a commensurate decrease in serum T4 levels. Such effects of PCBs have been associated with cognitive deficits in exposed human populations. Xenobiotics also may suppress steroid modulating proteins resulting in increased levels of hormone. For example, acyl CoA-testosterone acyltransferase is responsible for conjugating fatty acids to testosterone. These conjugates have a prolonged half-life and are sequestered within lipid stores in the body for subsequent use. This enzyme is sensitive to inhibition by the biocide tributyltin. In the mud snail, Ilyanassa obsoleta, the inhibition of testosterone-fatty conjugation by tributyltin results in elevated testosterone levels. The increased testosterone is causally associated with an intersex condition whereby females express male sex characteristics. This endocrine toxicity has been demonstrated in over 150 snail species worldwide and is causally associated with environmental levels of tributyltin. Understanding the coordinated regulation of steroid biotransformation and transport proteins and their susceptibility to modulation by xenobotics may facilitate identification of modes of endocrine toxicity of many

#### 28 THE NUCLEAR RECEPTOR CAR IN REGULATION OF ESTROGEN METABOLISM.

M. Negishi. LRDT, NIEHS, Research Triangle Park, NC. Sponsor: L. You.

CAR and other xenosensors, such as PXR, may form a regulatory network that governs endocrine homeostasis by altering the levels of steroid-metabolizing enzymes such as CYP2B, CYP3A, SULT and UGT1A1. In response to steroid hormones, in addition to xenobiotics, CAR activates genes that encode those enzymes. Estradiol and estrone at pharmacological doses activated both mouse and rat CAR but not human CAR in cell-based transfection assays, while non-estrogenic metabolites estriol, estetrol and the synthetic diethylstilbestrol could not activate CAR. On the other hand, testosterone repressed CAR activity. Estrogen also elicits nuclear accumulation of CAR in mouse liver and primary hepatocytes. As estrogens and androgens have opposing actions on CAR, their endogenous role in CAR regulation was examined by ovariectomization and castration of female and male mice, respectively. Ovariectomy did not alter the level of CAR in the nucleus indicating that endogenous estrogen does not regulate CAR, whereas castration increased both basal and E2-induced CAR levels suggesting that endogenous androgen may repress CAR in male mice. These results suggested that CAR may play a role in regulating the levels of active estrogens.

29

## MOLECULAR REGULATION OF HEPATIC SULFOTRANSFERASES.

M. Runge-Morris. Inst. Environment Health Sciences., Wayne State University,

Sulfonated metabolites of thyroid hormone and estradiol are receptor inactive. Therefore, hormone metabolism by sulfotransferase enzymes represents a critical check-point for the control of bio-active intra-tissue hormone levels. Several of the cytosolic sulfotransferases function as key components of intra-hepatic steroid metabolism. For example, hepatic aryl sulfotransferase (SULT1A1) is responsible for sulfonating xenobiotic phenols, and thyroid hormone, as well as a variety of therapeutic agents such as acetaminophen, minoxidil, and estradiol at pharmaceutical concentrations. Hydroxysteroid sulfotransferase (SULT2A) catalyzes the sulfonation of xenobiotics, bile acids and the most abundant adrenal androgen in humans, dehdyroepiandrosterone (DHEA). The consequences of DHEA sulfonation are multifaceted. In mice, DHEA-3-beta-sulfate was reported to induce peroxisome proliferator gene expression, an effect that was ablated in PPAR-alpha knock-out mice. More recently, DHEA and DHEA-sulfate were shown to activate the expression of target genes through the constitutive androstane receptor transcription factor. Because of their important roles in xenobiotic detoxication and in the regulation of intra-tissue hormone homeostasis, it is critical to achieve a clearer understanding of the transcription factor machinery that regulates sulfotransferase gene expression. Our laboratory has demonstrated that glucocorticoid-inducible rat hepatic SULT2A gene transcription occurs as a result of glucocorticoid receptor, pregnane-X-receptor, and liver-enriched CCAAT binding enhancer protein-mediated mechanisms. We have also implicated a role for steroid-sensitive nuclear receptors in the transcriptional control of SULT2A gene expression in primary cultured human hepatocytes. In parallel studies, we demonstrated that glucocorticoid-inducible hepatic SULT1A1 gene transcription occurs as a result of a classical glucocorticoid receptor-mediated mechanism. These investigations provide a foundation for future work on the integrated role of nuclear receptors and liver-enriched transcription factors in the molecular regulation of hepatic sulfotransferases.

**30** 

NUCLEAR RECEPTOR PXR- AND CAR-MEDIATED INDUCTION OF STEROID BIOTRANSFORMATION ENZYMES AND RELATIONSHIP WITH REPRODUCTIVE DEVELOPMENT.

L. You, H. B. Hoffman, A. R. Laughter, E. J. Bartolucci-Page, S. Kirwan and M. E. Wyde. CIIT Centers for Health Research, Research Triangle Park, NC.

The actions of steroid hormones are maintained in part through a dynamic regulation of ligand bioavailability. Steroid hormone inactivation occurs at the liver as well as at target tissues. In the liver, steroid hydroxylation is mainly mediated by cytochrome P450 (CYP) family enzymes and conjugation by the sulfotransferases (ST) and uridine diphosphate-glucuronosyltransferases (UGT). These enzymes have wide spectra of endogenous and exogenous substrates including steroid hormones. Hepatic enzyme inducers can enhance the inactivation of pharmacological steroids, leading to diminished bioavailability and therapeutic efficacy. Whether such enzyme inducers can affect steroid-dependent physiology though altering the availability of endogenous steroid hormones is less clear. We conducted studies to evaluate the potential of xenobiotics to impact reproductive development through induction of liver enzymes. Several compounds, including DDE, phenobarbital (PB), and pregnenolone 16a-carbonitrile (PCN) were demonstrated to induce multiple hepatic biotransformation enzymes, partly due to their ability to activate the nuclear receptor constitutive androstane receptor (CAR) and pregane X receptor (PXR). These nuclear receptors are transcriptional regulators for several hepatic enzymes catalyzing steroid hydroxylation and conjugation. We observed altered biotransformation of injected testosterone in castrated rats treated with these enzymeinducing compounds. However, administration of PB, PCN, and other liver enzyme inducers during the pubertal stage did not result in discernible interference with pubertal sexual development in male rats. Our data suggest that, while induction of hepatic enzymes would result in altered biotransformation for steroid hormones, regulatory mechanisms for steroid homeostasis in intact animals may be able to adapt to such enzyme induction. (Supported by the Long-Range Research Initiative of the American Chemistry Council.

31

ASSURANCE OF ANIMAL WELFARE IN RESEARCH: COEXISTENCE OF TOXICOLOGY STUDIES WITH HUMANE ENDPOINTS.

S. M. Lasley¹ and J. I. Everitt². ¹Department of Biomedical & Therapeutic Sciences, University of Illinois College of Medicine, Peoria, IL and ²Comparative Medicine & Investigator Support, GlaxoSmithKline, Research Triangle Park, NC.

In the performance of toxicology studies, whether for purposes of product safety testing or identifying mechanisms of toxicant action, it is necessary to incorporate multiple regulatory, scientific, humane, and ethical factors into the use and care of laboratory animals. This Workshop will provide a forum for discussion of these various factors from different vantage points to better inform the audience, particularly with respect to utilization of humane endpoints. These issues are of timely importance because of continually increasing regulatory oversight of animal care and use, and thus this forum will be of broad interest to toxicologists. Consideration of these factors will be addressed from the standpoint of regulatory requirements and the types of data that must be submitted (Schechtman). A veterinary medicine perspective will be presented, highlighting the development of humane endpoints and their use to determine when study interventions are necessary (Stokes). The role of the IACUC will be defined, particularly in the refinement of the project experimental design and optimization of the proposed numbers of animals (Brown). The conduct of toxicology studies will also be presented from the viewpoint of the investigator, who must balance these factors to produce sound and reliable data (Mattsson). The final presentation will provide a European Union perspective, highlighting the manner in which approaches to these animal care issues are addressed differently in those countries, and indicating trends in regulatory oversight that may soon reach North America (Donovan).

**32** 

ASSURANCE OF ANIMAL WELFARE IN RESEARCH: COEXISTENCE OF TOXICOLOGY STUDIES AND HUMANE ENDPOINTS - ISSUES IN TOXICITY TESTING FOR REGULATORY PURPOSES.

L. M. Schechtman. NCTR/WO/HFT-10, US Food and Drug Administration, Rockville, MD.

Historically, toxicology studies for safety/hazard assessment have been primarily animal-based but with little regard for animal welfare. The emergence of alternative toxicological methods that employ fewer animals, refine procedures (cause less pain and distress), and rely on non-animal endpoints, is altering that paradigm. From a regulatory perspective, validation of an alternative method (determination of its reliability and accuracy for a specific purpose) lends itself to acceptance and implementation of methods for regulatory purposes. To address such validation issues, 15 US federal research and regulatory agencies have assembled to form the Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM), supported by its operational/scientific support center, the NTP Interagency Center for the Evaluation of Alternative Toxicological Methods (NICEATM). Different federal agencies and different regulatory units within a given agency often accept/solicit data from different test methods or batteries of tests, often dictated by the products within their purview and the regulatory mandates to which they respond. Data requirements for safety/hazard evaluations differ from one regulatory agency to another and those data may be generated using validated, unvalidated, traditional, and/or non-traditional test methods. Although regulatory agencies do have the option of considering data derived from non-conventional tests, often such data are used in a supplementary manner (e.g. to provide mechanistic information) to support the regulatory decision-making process. Some agencies (e.g. FDA) and its respective regulatory entities, provide direction to sponsors in the form of test guidances that help determine acceptable testing strategies/procedures for evaluating a regulated product. A number of these guidances have either directly or indirectly benefited animal welfare and have incorporated validated, animalfriendly methods that supplement or replace some of the routinely employed classical toxicological tests.

33

ASSURANCE OF ANIMAL WELFARE IN RESEARCH: COEXISTENCE OF TOXICOLOGY STUDIES WITH HUMANE ENDPOINTS - VETERINARY MEDICINE AND ANIMAL WELFARE ISSUES.

<u>W. S. Stokes</u>. DHHS/NIH/NIEHS, National Toxicology Program, Research Triangle Park, NC.

Toxicology studies using laboratory animals are conducted to determine the safety or potential adverse health effects of new chemicals and products. Local or systemic toxicity to animals in these studies may result in injury or disease involving significant pain and distress. Standard veterinary care would normally involve treatment with drugs to minimize or alleviate pain and distress, or removal of the involved animal(s) from the study. However, such veterinary care interventions can become problematic if they interfere with attainment of the study objectives. Decisions on appropriate interventions can be assisted by anticipating possible toxic effects and establishing, prior to the initiation of a study, appropriate criteria that can serve as the basis for ending a procedure when pain and distress become apparent. Such criteria are considered humane endpoints if they reduce the severity and/or duration of pain and distress experienced by an animal. Humane endpoints can also be established by systematic identification of early clinical signs or other physiological parameters that are predictive of specific toxicity outcomes of interest. Mechanismbased biomarkers of toxicity that serve as earlier more sensitive indicators of toxicity that can also be used to end experiments before the onset of significant morbidity or mortality. These biomarkers and endpoints should undergo appropriate validation to determine that they provide equivalent or better prediction than previously used endpoints. International guidance for the use of humane endpoints in toxicology studies has been established and should be considered when designing studies. The incorporation of humane endpoints in toxicology studies can be expected to facilitate decisions on appropriate interventions by veterinary care staff and study directors and provide for improved animal welfare.

34

THE IACUC AS A VALUE-ADDED COMPONENT OF TOXICOLOGY RESEARCH.

M. J. Brown. Animal Welfare and Training, Charles River Laboratories, Wilmington, MA. Sponsor: J. Everitt.

Toxicologists involved in animal research and testing must answer to many regulatory masters: FDA, USEPA, OECD, ICH, CCAC, USDA and AAALAC. The beneficiary of this research and testing, the public, has ever increasing demands for quality health care and a safe environment but is also highly sensitive about the use

of research animals. Added to these demands of the public and the regulatory community are the interests of study sponsors and those of contract research organizations. The Institutional Animal Care and Use Committee or Ethics Committee (IACUC/EC) and Study Director (SD) must work within these various demands and constraints to assure humane care of research animals and high quality science. Various regulatory agencies outline the roles and responsibilities of both the IACUC/EC, and the SD. These roles are often contradictory so it is not surprising that conflicts arise. This presentation will briefly discuss the roles and responsibilities of the IACUC/EC and SD and present strategies to minimize conflict and enhance both animal welfare and the quality of the science. Emphasis will be placed on protocol review activities that increase collaboration and communication. Mechanisms will be suggested to streamline the process, making it both more efficient and less time consuming while maintaining the quality of the review. Using examples of potential issues (such as the ordering of animals prior to IACUC approval, determining criteria for veterinary intervention, establishing humane endpoints, etc.), suggested mechanisms will be discussed.

### 35

# ANIMAL TESTING: THE DICHOTOMY BETWEEN NATURAL TOXICANTS IN FOOD AND SYNTHETIC PESTICIDES POINTS TO A PROBLEM.

#### J. L. Mattsson. Dow AgroSciences LLC, Indianapolis, IN.

The most highly regulated area of toxicology is the registration of pesticides, which will be the focus of this presentation. At this time, a theoretical minimum of some 7000 mammals and 3000 birds are required to register one pesticide for food use. The actual numbers of animals used per pesticide are actually much higher and are likely to increase still further unless there is a radical change in regulatory policy. In practice, pesticide residues in food are below the level of detection about 40% of the time, and other residue levels are typically very low (USDA Pesticide Data Program, 2000). On the other hand, natural toxicants such as glycoalkaloids and furocoumarins are present in food at much higher levels, and often, are more potent than synthetic chemicals found in food (Beier and Nigg. Ch. 2, Foodborne Disease Handbook, Vol. 3, Marcel Dekker, 2001; Carcinogens and Anticarcinogens in the Human Diet. National Research Council, 1996). In spite of these stark differences in dietary exposure, there is no systematic approach to safety evaluation of natural toxicants in food. This dramatic dichotomy in the regulation and testing of natural and synthetic toxicants in food cannot be justified scientifically. Under current paradigms, there is either an unreasonable excess in animal-based testing of synthetic chemicals, or a dramatic under testing of natural chemicals in foods. If animal testing of synthetic chemicals is excessive, then there exists a clear ethical problem on the use of animals. If animal testing of natural chemicals in foods is deficient, then there exists a clear ethical problem on the protection of public health. My opinion is in the middle ground, that there is both an excessive animal-based testing of food-use synthetic pesticides, and a deficient testing of natural toxicants of food. In the interests of food safety and ethics of animal experimentation, a more animal-efficient testing strategy is needed to allow proper resource allocation to all chemicals in food.

### 36

# EUROPEAN PERSPECTIVES ON ANIMAL WELFARE AND SCIENTIFIC ENDPOINTS IN ANIMAL STUDIES.

### J. C. Donovan. BioResources, Wyeth Research, Collegeville, PA. Sponsor: J. Everitt.

The growing internationalization of science has brought greater focus on differing approaches to animal welfare in biomedical research. Cultural attitudes and the evolution of animal welfare standards in various countries have resulted in practices which vary significantly. Not only do animal care, housing, and animal health standards influence research results, but there are other areas that have a more direct scientific impact. For example, decisions on study design, dosing/sampling volumes, environmental enrichment and scientific endpoints have important effects on the outcomes of studies using animals. Clearly, the comparability of results among academic, industrial and governmental institutions is challenged when differing practices governing animal research are applied. Animal welfare regulations and guidelines continue to evolve in Europe and the United States. Understanding the trends in regions having the most influence on scientific development can help steer the community towards common practices which are both scientifically sound and sensitive to animal welfare. European perspectives are already having a significant impact in the US in areas such as genetically-modified organisms, agricultural practices and animal welfare. A general lack of acceptance of genetically-modified food and the use of hormone growth promoters in the animal industry is effecting trade and politics with the US A growing number of Americans now feel concern is warranted. In the realm of research animal welfare it is generally accepted that, due largely to public demands for more protections for animals, European approaches have been more "progressive". Many of these attitudes are migrating to the US in the form of animal rights activism, changing perspectives in school-aged children towards animals and escalating animal welfare regulations. This presentation will look at animal welfare trends, guidelines and regulations in Europe, including scientific endpoints in animal studies and dosing/sampling guidelines, and how they may influence research practices in the US

### 37

## THE IMPORTANCE OF ELECTROPHYSIOLOGY IN NEUROTOXICOLOGY EVALUATION.

### C. G. Markgraf and A. Bass. Safety Pharmacology, Schering-Plough, Lafayette, NJ.

Neurons differ in their vulnerabilities to toxic agents, thus techniques that can selectively evaluate functional neuronal systems fill an important role in neurotoxicology. Electrophysiologic recording has long played such a role. Neuroelectrophysiology techniques add important information to studies that have pathology and/or behavior as outcome measures. Electrophysiologic recordings are able to detect toxic effects on the nervous system that may occur without morphologic correlates. In addition, techniques can be applied specifically to a functional neuronal system, allowing study of just that system. Data are quantifiable, reproducible and can be obtained repeatedly from an individual animal. The same techniques can be used in clinical studies, forming a stable bridge in determination of human risk. Furthermore, the extensive history of electrophysiology creates a strong database which can be used to provide perspective for data on new drugs. While these similarities are shared among the various techniques, there are important differences in evaluation of neuronal systems that can influence the interpretation of data, and there are different sensitivities to detection of abnormal results. The speakers in this workshop will discuss the strengths of electrophysiologic recording and factors critical to data interpretation in various functional systems, including the peripheral nervous system, sensory systems, hippocampal function and cortical dysfunction. This integrated examination of neuronal system functions using electrophysiology will provide insight into these data in the evaluation of new chemical entities, and their place in human risk assessment.

### 38

### NEUROPHYSIOLOGICAL EVALUATION OF SENSORY SYSTEM FUNCTION.

#### D. W. Herr. Neurotoxicology, USEPA, ORD/NHEERL, Research Triangle Park, NC.

Exposure to many neurotoxic compounds has been shown to produce a sensory system dysfunction. Neurophysiological assessment of sensory function in humans and animal models often uses techniques known as sensory evoked potentials. Because both humans and animals show analogous responses to sensory stimuli, extrapolation of effects from the laboratory to a clinical situation is simplified. Additionally, the methods are amendable to repeated testing, allowing the timecourse of changes in sensory system function to be monitored. Furthermore, examination of multiple sensory modalities allows the determination of the specificity of a sensory dysfunction. A change in a sensory evoked potential can often be associated with pathological damage. Auditory system function at the level of the periphery and the brainstem can be assessed using Brainstem Auditory Evoked Responses (BAERs). Decreased amplitudes of the early BAER peaks have been associated with a frequency-dependent loss of cochlear hair cells. In contrast, decreased amplitudes of later BAER peaks have been associated with brainstem lesions. Evoked potentials can also be used to investigate changes in the visual system from the level of the retina to the cortex. Alterations in the early portions of cortical visual evoked potentials have been associated with pathological changes in the retina, thalamus, or cells involved in the early cortical processing of the stimulus. Besides quantifying changes in sensory function produced by neuroanatomical lesions, knowledge of the neuropharmacology of evoked potentials can be used to interpret changes after exposure to substances known to alter specific neurotransmitter systems. This allows the use of evoked potential technology to assess not only undesirable effects, but also to monitor for intended pharmacological actions. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

### 39

## NEUROELECTROPHYSIOLOGICAL ENDPOINTS IN SAFETY STUDIES AND SAFETY PROGRAMS.

#### J. F. Ross. Ross Toxicology Services, LLC, Cincinnati, OH.

A subset of neuroelectrophysiological endpoints includes relatively noninvasive tests (e.g., peripheral nerve conduction velocity, auditory evoked potentials) that enjoy widespread use in both human and veterinary neurology practice. These tests are becoming popular additions to neurotoxicology safety programs, partly because they can provide detailed information about neurological disease without requiring the sacrifice of the subjects. Since neuroelectrophysiological tests are most often used in 2nd- or 3rd-rier safety studies, a primary set of data is generally available to help choose among the wide variety of available tests. The most important parts of

this data set include the neurological examination (e.g., observational battery) and neuropathology. The ultimate utility of the neuroelectrophysiological endpoints depends on a good fit with the neurological and neurohistopathological results.

### 40

### USE OF ELECTROENCEPHALOGRAPHY (EEG) IN DETECTING NEUROTOXIC EFFECTS.

J. C. Arezzo and M. S. Litwak. Neuroscience, Albert Einstein College of Medicine, Bronx, NY. Sponsor: A. Bass.

EEG is arguably the oldest direct physiologic measure of CNS function. When recorded from the intact scalp, it provides a non-invasive index of the overlapping activity pattern of large ensembles of neurons. Thus it can provide a highly sensitive, but non-specific measure of neurotoxic insult. Standard measures of EEG activity, such as power in specific frequency bands (eg., alpha, theta), voltage suppression or the presence of paroxysmal activity, are applicable to both human and experimental animal studies. EEG is sensitive to a wide range of neurotoxic effects including: hyper- or hypo-excitability, inflammation, anoxia, cortical neural degeneration, alterations of sleep-wake patterns, metabolic disorders and toxic encephalopathies. The identification of compound-induced epileptiform activity has always been a principal strength of EEG procedures. Studies have documented dose thresholds for seizure activity, the time course and duration of seizures, as well as frequency changes and subtle paroxysmal patterns that antecede and may predict seizure onset. Recent advances in computer modeling and in the analysis of nonlinear dynamic systems have greatly expanded the sensitivity of EEG to other deficits; while computer-aided spatiotemporal analysis allows exploration of neurotoxic effects distributed over both cortical and sub-cortical regions. An emerging strength of EEG is its ability to explore the effects of putative neurotoxins on inherent rhythms of the brain, such as the cortical beta/gamma waves (33-45 Hz). Finally, intracranial studies using two-dimensional spatial grids (eg., 12x12) or linear multicontact arrays, allow exploration of neurotoxic effects isolated within specific cortical laminae, or effects on the synchrony of EEG activity measured simultaneously across distinct cortical areas.

## 41 ASSESSING HIPPOCAMPAL CHANGES INDICATIVE OF NEUROTOXIC EFFECTS.

M. E. Gilbert. Neurotoxicology, USEPA, Research Triangle Park, NC.

Subtle changes in cognitive function are often the earliest indication of neurotoxic effects in humans. The hippocampus is a large forebrain structure subserving specific kinds of information encoding and consolidation in humans and other animals. Because of its laminar structure, it is ideally suited for neurophysiological assessment and it is readily accessible for both in vitro and in vivo examination. The homogeneity of the neural populations within each cell body layer results in large field potential recordings that faithfully reflect intracellular current flow. As such, these field potentials can be directly translated to activity at the cellular level. Hippocampal field potentials also display a high degree of synaptic plasticity and a well accepted synaptic model of memory, long-term potentiation, has been characterized in this structure. However, toxicological assessments of hippocampal function using this approach are relatively sparse, and in vitro assessments using slices or cultures are more prevalent than in vivo investigations. The bulk of neurotoxicological investigations in vivo have examined the long-term consequences of developmental exposure, although acute effects of chemical exposures have also been reported for pyrethroid, formamadine, and organochlorine pesticides. Developmental insults include pre and/or postnatal exposure to ethanol, carbon monoxide, lead, antimitotic agents, and thyroid disrupting compounds. The majority of these studies have demonstrated altered hippocampal synaptic function that in all likelihood represents permanent alterations in cell communication following early developmental insult. These perturbations are often present in the absence of overt pathological changes in structure and in the absence of behavioral impairments based on standard learning and memory assessments. Abstract does not necessarily reflect USEPA policy.

### 42

## LOW-DOSE EXTRAPOLATION: TIME FOR A FRESH LOOK AT AN OLD PROBLEM, OVERVIEW.

J. Bus<sup>1</sup> and R. Henderson<sup>2</sup>. <sup>1</sup>TERC, Dow Chemical Co., Midland, MI and <sup>2</sup>Inhalation Toxicology Research Institute, Albuquerque, NM.

The basic tenet of toxicology is the dose makes the poison. Thus, characterization of the dose-response remains a foundational element in the translation of animal toxicity information to estimation of potential human health hazard and risk. However, due the significant impact of regulatory and product stewardship interventions over the last 30 years, animal toxicity observed over the range of conven-

tionally-determined dose-response evaluations is becoming increasingly disparate from real-world exposures to many environmental chemicals. Given these growing disparities, toxicologists are increasingly challenged to provide rational methods and mechanisms to understand true adverse human health outcomes associated with these low-level chemical exposures. In order for these approaches to be scientifically credible, toxicologists must direct attention to how such mechanisms can differentiate health effects associated with low-dose environmental exposures to synthetic chemicals from those that might be due to the many thousands of toxicologically similar, but likely health beneficial natural compounds present in everyday diets. Future low-dose extrapolation paradigms failing to address this important issue will result in scientifically indefensible decisions regarding strategies designed to protect public health from adverse consequences of low-dose chemical exposures, be they synthetic or natural.

### 43

# HISTORICAL DEVIATIONS FORM THE LNT MODEL: HARMONIZATION OF CANCER AND NONCANCER ENDPOINTS.

M. L. Dourson. Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH.

Cancer and noncancer dose response assessment has historically been done differently due in part to differences in underlying assumptions, for example, whether the low dose response is due to a stochastic process or not. Recent understanding of underlying modes of action of cancer and noncancer endpoints, however, has created the basis for replacing such assumptions with data. Efforts to harmonize cancer and noncancer dose response assessment by SOT, USEPA and others have lead to new approaches to low dose understanding and response. Examples are given for perchlorate and chloroform, where the integration of cancer and noncancer toxicity has resulted in harmonized dose response assessment in the low dose range.

### 44

#### USE OF MECHANISTIC DATA TO HELP DEFINE DOSE-RESPONSE CURVES.

J. Preston. Environmental Carcinogenesis Division, University. S. Environmental Protection Agency, Research Triangle Park, NC. Sponsor: R. Henderson.

The cancer risk assessment process described by the USEPA necessitates a description of the dose-response curve for tumors in humans at low (environmental) exposures. This description can either be a default linear one when appropriate data are lacking, or a linear or nonlinear one when specific informative data are available. The challenge is to define the nature and extent of these specific informative data. Ideally, to use nontumor data for predicting tumor outcomes, the most informative endpoint is one that most accurately predicts the tumor outcome, namely an outcome that is part of the tumor response itself or is proximate to this response and along the tumor pathway. The current rapid development of whole genome response methods, such as RNA or protein array approaches, promises to aid substantially in the selection of informative biomarkers of response. Until progress has been made, it remains a common practice for genotoxic carcinogens to use overall genetic alterations (e.g. mutations and chromosome aberrations) as a tumor surrogate marker. The problem with this selection is that rarely are the appropriate data collected for defining shape of dose-response curve. In addition, since cancer is a multistep, multimechanism process, it is necessary to develop dose-response curves based on interactive processes for predicting tumor outcomes. For example, doseresponse curves for mutations need to consider the impact of cell proliferation on the mutation frequency. Other genotypic and phenotypic factors can equally influence the shape of a dose-response curve for mutations. The shape of a dose-response is definable for different scenarios when the mechanistic data to be used are developed on the basis of the need for which they are to be used, thereby helping to avoid their inappropriate use. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

## NEW DATA SUPPORT REVISED LOW DOSE EXTRAPOLATION MODELS.

B. R. Scott. Lovelace Respiratory Research Institute, Albuquerque, NM. Sponsor:  $\underline{R}$ . Henderson.

Low-dose extrapolation of carcinogenic risk for radiation and genotoxic chemicals is based on a relative risk (RR) paradigm for which RR is always greater than or equal to 1. Stated differently, no consideration is given to the possibility that RR for cancer induction can be less than 1 after low-dose exposure of humans. However, new in-vitro (mutation, neoplastic transformation), in-vivo (animal carcinogenesis), and epidemiological (cancer-induction) data are emerging that support the view that low-dose photon radiation (x and gamma rays) and certain chemicals (e.g. ethylene, propylene) can turn on protective processes (possibly mediated *via* apop-

tosis) that lead to a reduction in the frequency of stochastic effects below the spontaneous rate. These data strongly support a low-dose cancer risk assessment paradigm that includes RR < 1. Implications of the data for low-dose risk assessment for single-agents (radiation, genotoxic chemical) and combined exposures (different radiations, different chemicals, radiation and chemicals) will be briefly discussed including the need for revised low-dose, risk-extrapolation models. (Research supported by the US Department of Energy Offices of Science and Environmental Management).

## BIOLOGICAL BASIS FOR AND CONCEPTUAL APPROACHES TO LOW-DOSE NONLINEARITY.

R. Conolly. CIIT Centers for Health Research, Research Triangle Park, NC.

The initial interaction of a xenobiotic ligand with its biological receptor is low-dose linear. The initial interaction is usually the first step in a mechanism leading to a frankly adverse effect. For many, if not all environmental toxicants, adaptive and homeostatic mechanisms compensate for toxicant-induced changes to maintain a relatively constant internal environment. While the initial interaction may be lowdose linear, the ability of biological systems to compensate means that shapes of dose-response curves can change as we move downstream from the initial interaction. The shapes of dose-responses for frankly adverse effects are thus expected to differ from the dose-response shape of the initial interaction. Thresholds and nonmonotonic curves are possible. Numerous experimental studies are consistent with nonlinear and nonmonotonic dose-response behaviors. Theoretical modeling studies of mechanisms involving adaptive processes readily demonstrate threshold and nonmonotonic dose-responses. The assumption of low-dose linearity makes sense as a health protective measure in the absence of mechanistic data. Toxicologists and risk assessors need to think broadly, however, about the determinants of the shape of the dose-adverse effect curve. We should continue to characterize initial interactions and pharmacokinetic nonlinearities but we also need to evaluate how the organism responds to the toxicant. Characterization of compensatory processes is particularly important at low, environmentally relevant doses, where the risk of toxic effects is typically only inferred from effects observed at much higher doses. Biological compensation is most likely to be operative in this low-dose range, which is not studied in experiments that focus on demonstration and analysis of frankly adverse effects. A redefinition of the concept of toxicological mechanism to include elicited homeostatic and adaptive responses is needed. This redefinition is no more than a natural extension of the progression away from default-based towards mechanism-based human health risk assessment.

## HORMESIS: ITS IMPLICATIONS FOR HAZARD AND RISK ASSESSMENT.

E. J. Calabrese. Environmental Health Sciences, University of Massachusetts, Amherst, MA.

An ongoing comprehensive evaluation of the toxicology and pharmacology literature suggests that the biphasic dose response that characterizes hormesis is much more wide spread than is commonly recognized and may come to rival currently favored concepts/models (e.g., linear and threshold) describing toxicological dose responses used in risk assessment. The data indicate that hormetic responses occur in a high percentage of appropriately designed toxicological studies, are reproducible and that these responses are highly generalizable being independent of biological model, endpoint measured and chemical class. Numerous mechanistic studies have also been published which account for the hormetic biphasic dose response relationships in multiple biological dose response systems. The implications of these findings are significant since they have the capacity to affect not only our concept of the dose response in toxicology but also the selection of animal model, study design features, endpoints measured, and risk assessment applications.

LIPOMICS, AN IMPORTANT COMPONENT OF METABOLOMICS, AND POSSIBLE USE IN TOXICOLOGY STUDIES.

M. C. Madden. NHEERL\Human Studies Division, USEPA, Chapel Hill, NC.

Metabolites of endogenous biochemical substances can be considered to represent the ultimate organ and cellular responses to toxicants or other changes in an organism's environment. An important fraction of these endogenously produced metabolites are lipids; the comprehensive study of the production of these lipids is termed lipomics or liponomics. Lipids of various chemical classes have been implicated in mediating human diseases in the lung, cardiovascular, brain, and other organ systems. The emphasis of this session will be to provide an overview of strategies for quantifying lipids and key lipid metabolic steps, and subsequently organizing the resulting data into more usable and understandable formats. A brief overview of the biological relevance of lipids will initiate the session. A presentation on lipid chemistry and analytical chemistry strategies (along with the associated strengths and shortcomings) will follow in order to provide the audience with insights on some of the technologies needed to perform the first step involved in lipomics. Additional presentations will show: comprehensive lipid analyses (>400 lipids) of mice treated with the anti-hyperlipidemic agent rosiglitazone and subsequent data manipulation into a informative database; alterations of lung lipids collected in breath condensate from humans and animals models (mice, pigs) of lung disease; and using lipomics to monitor microbial biomass and composition for use in environmental remediation strategies, microbial ecology studies, and minimizing microbial populations in occupational settings. Use of lipomics, in combination with proteomics and genomics, can provide a more complete view of cellular responses. Monitoring of these responses can be used to assist in optimizing drug therapies, examining effects from toxicant exposures, determining the influence of nutrition on responses, and screening of the environment for microbial populations. [This abstract may not represent official EPA policy.]

### LIPIDS: A PRIMER ON MEASUREMENT, CLASSIFICATION AND FUNCTION.

J. Jackman<sup>1</sup> and <u>D. C. White<sup>2</sup></u>. <sup>1</sup>Applied Physics Laboratory, Johns Hopkins University, Laurel, MD and <sup>2</sup>Center for Biomarker Analysis, University of Knoxville, Knoxville, TN

Lipids are a structurally diverse class and functionally critical components of all biological organisms. Due the central role of lipid and lipid containing molecules in cell responses, there has been an enhanced interest in lipomics or the total lipid profile of cells. The revolutions in chromatographic resolution, high-resolution mass spectral detection, improvements in extraction, ionization methods and computing have increased the scope of lipomics. While most lipids can be extracted with organic solvents by classical extraction methodology, lipids covalently bound to carbohydrates (lipopolysaccharide, lipoproteins) are generally non-extractable due to poor solubility. Hence new techniques for extraction such as solid phase extraction methods and analysis such as mass spectrometry (MS) are being developed to overcome some of these issues. A convenient functional classification of lipids is based on the normal-phase bulk elution of components using gradients of polar phases. Neutral lipids (e.g., waxes, sterols, tri- and diglycerides) elute first; glycolipids elute next; followed by polar lipids (e.g., phospholipids). Each lipid class can be fractionated by normal or reverse phase chromatography. Lipid classes, fragments or total extracts can be hydrolyzed and derivatized to make them volatile for high-resolution capillary GC/quadrupole MS. Additional insight into the structural details can be greatly increased by utilizing ion traps capable of multiple fragmentations or tandem quadrupole MS for precursor and product ion scans. Replacement standard GC/MS systems with atmospheric pressure ionization (API) have expanded the mass range of analysis to include intact lipids. Increasing the mass resolution with coupled time-of flight, advanced quadrupole, or Fourier transform ion-cyclotron resonance MS with generation of multiply charged analytes allows the technologies developed for proteomics to be applied to complex glycolipids like gangliosides. Together these technologies have revolutionized the detection and functional analysis of lipids.

### 50

#### LIPOMIC PROFILING APPLICATIONS IN TOXICOLOGY.

S. M. Watkins. *Lipomics Technologies, Inc., West Sacramento, CA.* Sponsor: <u>M.</u> Madden.

Diet, environmental exposure, and genetic background exert profound influences on human metabolism that results in changes in lipid metabolites. Lipomics employs a quantitative and comprehensive assay that measures lipid metabolites from biological tissues and fluids. This technology is used to improve the understanding of the role of lipid metabolism in disease and to develop diagnostic profiles of drug safety and efficacy. A critical benefit of producing quantitative data on known metabolites is that the results of each analysis can be mapped against the known biochemical pathways. This presentation will demonstrate the application of quantitative metabolite profiling in determining the metabolic response to several chemical compounds including insulin-sensitizing agents and 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin. In the first example, a PPARs- $\gamma$  agonist and a  $\beta 3$ -adrenergic receptor agonist are shown to elicit dramatically different metabolic

responses in obese, diabetic mice, despite producing similar clinical chemistry profiles. In the second example, 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin is shown to selectively dysregulate cholesterol and phospholipid metabolism in pregnant rhesus monkeys. Lipomic profiling is uniquely suited for illuminating the metabolic basis of phenotype and advancing our understanding of adverse events. This technology should vastly improve therapeutic and diagnostic capabilities in the near future.

51

#### LIPIDS FROM BREATH CONDENSATE AS NON-INVASIVE BIOMARKERS FOR RESPIRATORY PATHOPHYSIOLOGY.

D. C. White<sup>1</sup>, R. Geyer<sup>1</sup>, J. Cantu<sup>1</sup>, S. Mani<sup>2</sup>, M. Jett<sup>2</sup>, J. Jackman<sup>3</sup> and M. Karlstad<sup>4</sup>. <sup>1</sup>Center for Biomarker Analysis, University of Tennessee, Knoxville, TN, <sup>2</sup>Walter Reed Army Institute of Research, Silver Spring, MD, <sup>3</sup>Applied Physics Laboratory, Johns Hopkins University, Laurel, MD and <sup>4</sup>Medical Center, University of Tennessee, Knoxville, TN.

Regulatory lipids readily form aerosols that can be recovered non-invasively by cooling expired breath to form breath condensate (BC). BC includes eicosanoids as well as the phosphatidylcholine (PC) based lipid surfactants, lysoPC and platelet activation factors (PAF) that modulate inflammatory and immune processes, and are reflective of oxidative stress and toxicity. Detection by mass spectrometry (MS) provides insights into presumptive harbingers of respiratory pathobiology. BC lipids recovered by solid phase extraction contain PC lipids (detected by HPLC/MS) and eicosanoids (derivatized prior to GC/MS). Responses of BC lipids and eicosanoids from piglets and rats exposed to aerosolized lipopolysaccharide (LPS) or Staphylococcal enterotoxin (SEB) showed similar responses as observed in exposed cultured cell supernatants and rat lung lavage. Molecular species of PC derived lipids and eicosanoids showed differential responses to the toxins and bacterial infections. Initial targets include prostaglandins, (PGE2, PGF2α), thromboxane (TXB2), and prostacyclin (as 6-Keto PGF1α) that show differential responses to inflammation; leukotriene B4 and PGD2 for allergic responses; and isoprostanes for free radical oxidative stress. PAFs and lysoPAFs have been shown to increase with inflammation. Pulmonary responses of piglets to intratracheal exposure of toxicants (LPS & SEB) show differential patterns of lipids and eicosanoids. Human BC is readily collected within 10-20 min with a disposable, commercially available apparatus, and its clinical human use has been approved in Germany. Preliminary data indicate numerous other BC eicosanoids are available for assay, and different infectious agents induce different patterns of eicosanoid responses suggesting an important application of lipomics in the non-invasive early assessment of lung pathobiology.

52

LIPID ANALYSES OF MICROBIAL COMMUNITIES-APPLICATIONS FOR ENVIRONMENTAL REMEDIATION, MICROBIAL ECOLOGY, AND MEDICINE.

E. Sobek and A. D. Peacock. *Microbial Insights, Rockford, TN.* Sponsor: <u>M.</u> Madden.

Lipid analysis of microbial communities provides quantitative details of microbial biomass and community composition. The nutritional and physiological status of the microbiota can be determined through lipid analysis. The vast majority of microbes in the environment are unculturable; lipomics circumvents this problem by direct examination of microbes in their natural environments. Lipids are readily concentrated and purified from complex environmental matrices and are amenable to structural analysis by GC/MS. Viable bacteria have intact polar phospholipid membranes and are assessed quantitatively with analysis of phospholipids esterlinked fatty acids (PLFA). PLFA generally do not exist as molecular fossils and may be considered as quantitative measures of viable microbial biomass. The community composition of microbial communities can be quantitatively discerned from the lipid composition which correlates with analyses from isolated rDNA and functional gene sequences. Specific patterns of lipids can indicate physiological and toxin induced stress. Lipid composition reflects both the genotypes and phenotypic responses at the specific microniches of the bacteria as well as providing specific biomass quantitation. Lipomics provides the unique capability of defining the in situ redox conditions which can be critical in subsurface bioremediation. Exposure to toxic environments converts monoenoic to cyclopropane PLFA, and a relative reversible increase in specific trans/cis monoenoic PLFA ratio. Prolonged exposure to low moisture conditions induce cyclopropane PLFA indicating stationary growth phase and increasing proportions of trans PLFA. The formation of poly  $\beta$ -hydroxyalkanoic acid (PHA) provides measures of unbalanced growth and accumulation of intercellular reductants. Specific lack of bioavailable phosphate induces ornithine-lipids in some environmental communities. The usefulness of microbial lipomics is evident in environmental remediation, community microbial ecology of biofouling, and in the persistence and nurture of pathogens in biofilms in the workplace and hospital settings.

### 53

DEVELOPMENTAL IMMUNOTOXIC EFFECTS OF PRENATAL ATRAZINE EXPOSURE.

A. M. Rowe<sup>1</sup>, <u>K. M. Brundage</u><sup>1, 2</sup>, <u>R. Schafer</u><sup>1</sup> and <u>J. B. Barnett</u><sup>1, 2</sup>. <sup>1</sup>Microbiology, Immunology and Cell Biology, West Virginia University, Morgantown, WV and <sup>2</sup>Mary Babb Randolph Cancer Center, West Virginia University, Morgantown, WV.

Atrazine, 2-chloro-4-ethylamino-6-isopropylamino-s-triazine, (ATR) is the most heavily used herbicide in the United States with over 70 million pounds of atrazine applied annually and it is the most common herbicidal contaminant of ground water in agricultural areas. It is our goal to characterize the effects of prenatal atrazine exposure on the developing mammalian immune system. We hypothesie that in *utero* exposure to ATR will result in a persistent and potentially debilitating effect on the organism's immune system. Using the Balb/c mouse as a model we exposed pregnant female mice to ATR for 21 days starting at day 10 of gestation. ATR or placebo was administered via a time-release pellet implanted subcutaneously. The matrix of the pellet allowed for the daily release of  $\hat{0}.7 mg$  of atrazine for 21 days. The pellets were inserted into the mothers at day 10 post coitus. The resulting offspring were immunized with heat killed S. pneumoniae (HKSP) between 9 and 10 weeks of age. Two weeks following immunization the spleens were harvested, and the splenocytes were phenotypically characterized by flow cytometry. The number of B-cells secreting HKSP-specific antibodies was enumerated *via* ELIspot analysis. Male offspring had a statistically significant increase in the number anti-HKSP secreting B-cells compared to the controls. There was not a statistically significant change in the number of total splenocytes or the number of CD4+, CD8+ or B220+ splenocytes. However, atrazine treated mice possessed an increased percentage of CD4+ splenocytes and a decrease in CD8+ splenocytes. Female offspring did not possess a statistically significant change in IgM production compared to controls. And unlike the males, the female offspring had a statistically significant increase in the percent of B220<sup>+</sup> splenocytes compared to the controls. These results demonstrate a gender-dependant immunotoxic effect of prenatal exposure to ATR on the offspring. Supported by NIOSH grant OH07686 and NIEHS grant ES010953

### 54

EFFECTS OF PRENATAL EXPOSURE TO CIGARETTE SMOKE ON TUMOR SURVEILLANCE IN THE OFFSPRING.

S. P. Ng, S. P. Doherty and <u>J. T. Zelikoff</u>. Environ Med., New York University School of Medicine, Tuxedo, NY.

More than 1 million infants in America are born each year after either exposure in utero from active or passive maternal smoke exposure. Since accumulating epidemiologic evidence suggests that prenatal exposure to intact cigarette smoke (CS) increases the incidence of cancer in the offspring, it is hypothesized that inhalation exposure of pregnant mice to mainstream cigarette smoke (MCS) decreases offspring resistance to tumor challenge due to alterations in surveillance mechanisms critical for the recognition and destruction of cancers. Thus, this study seeks to: (1) ascertain by means of an in vivo tumor challenge whether exposure of pregnant dams to MCS alters tumor induction/development in the offspring; and, (2) assess the degree to which exposure of dams to MCS during gestation modulates tumor surveillance mechanisms. Pregnant B<sub>6</sub>C<sub>3</sub>F<sub>1</sub> mice were exposed to MCS for 5 d/wk (4 hr/d from gestational d5 to parturition). Exposure levels of particulate matter and carbon monoxide, measured within the exposure chamber, were 16.2 and 21.5 ppm respectively; carboxyhemoglobin and cotinine levels, assessed as exposure dosimeters, were 3.6% and 28 ng/ml. In addition to this relatively low inhaled dose of MCS reducing litter size by 13% and shifting gender ratios (compared to air-exposed controls), prenatally-exposed male and female pups challenged at 5-wk of age with neoplastic cells demonstrated a 2- and 4- fold increase in tumor incidence, respectively, (relative to age-/gender-matched air-exposed offspring); control males developed significantly more tumors than exposure-matched females. In addition, MCS-exposed offspring had a shorter time to tumor formation. Finally, in utero-exposed male pups demonstrated significantly lower T-lymphocyte proliferative responses than age-/gender-matched controls. Results demonstrate that inhalation exposure of pregnant mice to a low dose of MCS alters gestational parameters, reduces immune function and decreases offspring resistance against nascent tumors 5-wk after exposures have ceased. Supported by Philip Morris Foundation

### 55

THE EFFECTS OF CANNABINOID EXPOSURE ON TUMOR GROWTH AND THE ANTI-TUMOR IMMUNE RESPONSE.

R. McKallip<sup>1</sup>, M. Nagarkatti<sup>1</sup> and P. S. Nagarkatti<sup>2</sup>. <sup>1</sup>Department of Microbiology and Immunology, VCU, Richmond, VA and <sup>2</sup>Department of Pharmacology and Toxicology, VCU, Richmond, VA.

Previous studies have shown that Delta 9-tetrahydrocannabinol (THC) has both immunosuppressive as well as antitumor activity. However, little is known about the effect of THC on the immune response to and growth of tumors that are resist-

ant to THC-induced apoptosis. In the current study, we tested the central hypothesis that exposure to TĤC can lead to enhanced growth of tumors that are relatively resistant to THC-induced apoptosis by specifically suppressing the anti-tumor immune response. Exposure of 4T1 breast cancer cells to  $20~\mu M$  THC led to induction of apoptosis, whereas lower concentrations were relatively ineffective, suggesting that 4T1 tumor cells are relatively resistant to THC-induced apoptosis when compared to the level of sensitivity of normal lymphocytes. Next, we examined the effect of THC exposure on the growth of 4T1 tumor cells *in vivo*. The results showed that exposure to 25 mg/kg body weight of THC led to significantly elevated tumor growth when compared to vehicle-treated mice. Examination of the effect of THC exposure on 4T1 metastasis revealed that exposure to 25-50 mg/kg THC led to a significant increase in the number and size of tumors metastasizing to the lungs. Evaluation of the effect of THC exposure on the immune response showed that exposure to THC significantly inhibited the proliferative response of splenocytes to various mitogens due to induction of apoptosis. Finally, we noted that exposure to THC significantly inhibited the specific anti-tumor immune response to 4T1 tumor cells in vivo. Together, the results from this study suggest that exposure to THC can induce apoptosis in immune cells in vivo and thereby downregulate the anti-tumor immune functions. Such findings suggest that marijuana abuse may increase the susceptibility to breast cancer as well as other cancers that are resistant to THC-induced apoptosis (Supported in part by NIH grants R01DA016545, R21DA014885, R01ES09098, R01AI053703, R01HL058641, DA14041 and American Cancer Society IRG-100035)

# 56 MOLECULAR MECHANISM OF ACTION OF THE FUNGICIDE MANCOZEB ON THE INHIBITION OF CYTOKINE PRODUCTION

E. Corsini<sup>1</sup>, S. Birindelli<sup>2</sup>, M. Marinovich<sup>1</sup>, C. Colosio<sup>2</sup> and <u>C. L. Galli<sup>1</sup></u>.

<sup>1</sup>Department Pharmacological Sciences, University of Milan, Milan, Italy and <sup>2</sup>ICPS, International Centre for Pesticide Safety, Busto Garolfo, Italy.

We previously observed in agricultural workers exposed to mancozeb a statistically significant decrease in lipopolysaccharide (LPS)-induced tumor necrosis factoralpha (TNF) production (p<0.01). The purpose of this work was to establish an in vitro model reflecting in vivo data on mancozeb and to characterize its molecular mechanism of action. The human promyelocytic cell line THP-1 was used to develop the in vitro model to study the effects of mancozeb and its main metabolite ethylenthiourea (ETU) on LPS-induced TNF release. Cells were treated with increasing concentrations of mancozeb or ETU for different times. TNF release was evaluated following LPS stimulation by specific ELISA. Mancozeb, but not ETU, at non cytotoxic concentrations, induced a dose and time related inhibition of LPSinduced TNF release. The results obtained indicated that THP-1 cells were indeed a suitable model to study the molecular mechanism of action of mancozeb. For the characterisation of the molecular mechanism of action the effect of mancozeb on TNF mRNA expression was first evaluated by semi-quantitavive RT-PCR. We observed that decreased TNF release following mancozeb and LPS treatment was due to a pre-transcriptional event. Successively, in order to better define the molecular target of mancozeb its effect on LPS-induced NF-kB activation and reactive oxygen species (ROS) generation was characterised. Transcription factor activation was evaluated measuring by ELISA the DNA binding by specific transcription factor present in nuclear extract obtained from cells treated in the presence or absence of mancozeb following LPS stimulation. ROS generation was evaluated using a flow cytometric method using the dye dichlorofluorescein diacetate. We demonstrated that mancozeb functioning as an antioxidant causes a direct inhibition of NF-kB activation, which in turn resulted in decreased TNF production in monocytes.

# 57 IMMUNOTOXICITY OF SILICA: T CELL ACTIVATION AND BAL CELL ANTI-APOPTOTIC PHENOTYPE PRECEDE GRANULOMA FORMATION IN CHRONIC SILICOSIS.

R. J. Langley, N. Mishra and M. Sopori. Immunology, LRRI, Albuquerque, NM.

Occupational exposures of low to moderate levels of silica (SL) may lead to silicosis many years after SL exposure. Current experimental animal models indicate that acute silicosis is associated with apoptosis. However, the role of apoptosis during granuloma formation in chronic silicosis is not known. To induce chronic silicosis in an animal model, Lewis rats were exposed via inhalation to filtered air or silica (1.75 mm mass median aerodynamic diameter) at an exposure concentration of 6.2 mg/m3, 6 h/d, 5 d/wk for 6 wk; and observed for up to 18 months after the exposure. Immunological changes, silica burden, histopathology and apoptotic phenotypes were monitored at various intervals during this time. In the early phase (0-28 days after exposure) SL is detected in the lung, spleen and brains of the SL-treated animals. SL is mostly cleared from all tissues within 10 wks after the exposure; however polarized microscopy revealed that a few, but significant number of SL particles are retained in the lung and tracheal-bronchus lymph nodes. In the early phase of silicosis, spleen cells from SL-exposed animals show increased antibody-forming cell response and T cell hyper-responsiveness (i.e. increased Con A-induced proliferation and increased intracellular Ca2+ levels in response to TCR-ligation.) These immune changes returned to normal within approximately 10 wks. Around this time, granulomatous changes in the lung were initiated with the accumulation of epitheliod macrophages; SL particles could be found inside the developing granulomas. This was accompanied by the presence of various anti-apoptotic molecules in bronchoalveolar lavage (BAL) cells (i.e. high levels of pro-caspase 3 and Bcl-2, and decreased levels of JNK1 and JNK2). In addition, BAL fluid contained increased levels of MMP2 and MMP9. Thus, silicosis starts with immune activation that is followed by granulomatous changes in the lung around SL particles and a strong anti-apoptotic phenotype of BAL cells.

## 58 GENE EXPRESSION PROFILES IN HEXACHLOROBENZENE-INDUCED TOXICITY.

J. Ezendam<sup>1, 2</sup>, F. Staedtler<sup>3</sup>, J. Pennings<sup>2</sup>, R. Vandebriel<sup>2</sup>, <u>R. Pieters<sup>1</sup></u>, J. Harleman<sup>3</sup> and <u>J. Vos<sup>2</sup></u>. <sup>1</sup>Immunotoxicology, IRAS, Utrecht, Netherlands, <sup>2</sup>National Institute for Public Health and the Environment, Bilthoven, Netherlands and <sup>3</sup>Novartis Pharmacology AG, Basel, Switzerland.

Hexachlorobenzene (HCB) is a persistent environmental pollutant with toxic effects in man and rat. Reported adverse effects are hepatic porphyria, toxic effects on reproductive and immune system, and neurotoxicity. The Brown Norway (BN) rat is very susceptible to HCB-induced immunopathology and oral exposure causes enlargement of liver, spleen and lymph nodes, increased serum levels of IgM, IgG and IgE and inflammatory skin and lung lesions. The mechanisms of HCB-induced immunopathology are not clear, but both T cells and macrophages seem to be involved. To gain more insight in the mechanisms of HCB-induced toxicity, gene expression levels were studied using microarrays. BN rats were exposed for 4 weeks to a diet supplemented with 0, 150 or 450 mg/kg HCB. Blood, thymus, kidney, liver, spleen and mesenteric lymph nodes (MLN) were collected and analysed using the Affymetrix rat RGU-34A GeneChip microarray. Most significant (p<0.001) changes occurred in spleen, followed by liver, kidney, blood and MLN, but only a few genes were affected in thymus. This was to be expected since the thymus is not a target organ of HCB. Known effects of HCB such as immunotoxicity and induction of enzymes involved in drug metabolism, porphyria and reproductive system were confirmed, and in line with histopathology were the increased transcript levels of markers for granulocytes and macrophages. New findings include upregulation of genes encoding mast cell markers, complement, cell adhesion molecules, chemokines, proinflammatory cytokines, acute phase proteins and antioxidants. In general, gene expression data provide evidence that HCB induced a systemic inflammatory response, accompanied by oxidative stress and an acute phase response. In conclusion, this study confirms previously observed toxicological effects of HCB but also reveals several new and mechanistically relevant genes. Thus, genomics can be considered to be an important tool for hazard identification of this compound.

### 59 DENDRITIC CELLS ARE A SENSITIVE TARGET OF THIMEROSAL AND ETHYLMERCURY.

S. R. Goth, R. A. Chu and <u>I. N. Pessah</u>. Department of Molecular Biosciences and the Center for Children's Environmental Health and Disease Prevention, UC Davis, Davis, CA.

Thimerosal is an organic mercurial compound widely used as a preservative in consumer products and vaccines. Dendritic cells (DC) are potent antigen presenting cells capable of initiating primary T cell responses to vaccines and infectious agents. Under normoxic (5% oxygen v/v) and reductant-free conditions, we tested whether thimerosal (THI) exposure modified effector functions of immature and mature DC subsets in vitro. After a 20h exposure to THI, DC viability, expression of class II MHC and CD86, and caspase activation were measured by fluorescence cytometry. Thiosalicylic acid (TSA) and ethylmercuric chloride (ÉtHgCl) were also assayed to determine if products of THI ionization contributed to its effects. The IC50 value for TSA was greater than or equal to 10uM for all parameters measured. The IC50 values for THI and EtHgCl induced cell death in immature DCs were 534nM and 690nM; in mature DCs they were 628nM and 477nM. In propidium iodide negative (viable) cells, the IC50 values for THI and EtHgCl induced downregulation of cell surface class II MHC in immature DCs was 1.2uM and 1.4uM; in mature DCs it was 2.5uM and 2.1uM. IC50 values for THI or EtHgCl induced downregulation of cell surface CD86 in immature DCs was 1.3uM and 1.7uM; in mature DCs it was 329nM and 358nM. Annexin V binding was upregulated in viable immature and mature DC after a 20h exposure to THI. Two hour exposure to 1uM THI and EtHgCl activated caspases in mature but not immature DC. DC pretreated with THI stimulated allogeneic CD4+ or peptide antigen specific CD8+ T cells less strongly than control cells. In summary DC are sensitive targets of THI, exhibiting cytotoxicity in the nanomolar range. Moreover enhanced apoptosis, downregulated expression of class II MHC and CD86, and reduced ability to stimulate allo- and antigen-specific T cells were observed in DC exposed to organic mercury. We conclude that THI and EtHgCl downregulate the viability and function of DCs by a mechanism consistent with apoptosis. Sponsored by NIEHS Grant P01ES11269

INORGANIC MERCURY INCREASES SEVERITY AND FREQUENCY OF AUTOIMMUNE MYOCARDITIS IN MICE

J. F. Nyland<sup>1, 2</sup>, D. Fairweather<sup>3</sup>, N. R. Rose<sup>1, 2, 3</sup> and <u>E. K. Silbergeld<sup>1</sup>. <sup>1</sup>EHS</u>, JHU Bloomberg School of Public Health, Baltimore, MD, <sup>2</sup>MMI, JHU BSPH, Baltimore, MD and <sup>3</sup>Pathology, JHU School of Medicine, Baltimore, MD.

Inorganic mercury (iHg, HgCl2) has a range of immunotoxic effects, including induction of autoimmunity in specific inbred strains of rats and mice. Epidemiological studies have demonstrated an association between Hg exposures and cardiac disease in human populations. We hypothesize that the expression of frank disease may require interactions between Hg and other susceptibility factors, genetic or acquired. To test this hypothesis, we have treated mice with low doses of iHg and then induced autoimmune cardiac disease using Coxsackievirus B3 (CB3) in BALB/c male mice. CB3 induces a biphasic cardiac disease in susceptible mice which is characterized by a primary acute viral phase, peaking at about day 12 after infection, and a chronic autoimmune phase, peaking at about day 35 post-infection. The animals were either pre-treated with iHg (200ug/kg, every other day for 15 days) before infection with CB3 or interim-treated (200ug/kg, every other day for 7 days) between the acute and chronic phases, approximately day 15 post-infection. We found that pre-treatment significantly increased the percent of inflammation in the heart during the chronic, but not the acute, stage. Further, the percentage of mice with dilated cardiomyopathy was significantly increased at the chronic stage with iHg pre-treatment. However, these increased pathological symptoms of myocarditis were not accompanied by changes in cytokine profile in the heart. In contrast, iHg interim-treatment did not significantly change the prevalance of dilated cardiomyopathy, but it did increase the levels of IL-12 and IL-4 in the heart at day 35. Neither iHg treatment reactivated virus in the heart at day 35. These preliminary results suggest that mercury lowers the threshold of activation for autoreactive cells before they have seen their autoantigen (before viral infection damages the cardiac tissue and releases cardiac antigens), and there is evidence for enhanced activity of autoreactive cells with later iHg exposure.

# 61 EFFECTS OF MERCURY (HG) EXPOSURE ON BIOMARKERS OF AUTOIMMUNITY IN HUMANS POPULATIONS

E. K. Silbergeld<sup>1</sup>, L. Burek<sup>2</sup>, N. Rose<sup>2</sup>, J. M. Souza<sup>3</sup>, E. C. Santos<sup>3</sup>, J. Graber<sup>1</sup> and I. Silva<sup>4, 1</sup>. Environmental Health Science, Johns Hopkins University Bloomberg School Public Health, Baltimore, MD, <sup>2</sup>JH Medical School, Baltimore, MD, <sup>3</sup>Evandro Chagas Institute, Para Belem, Brazil and <sup>4</sup>Institute Molecular Cell Biology, Porto, Portugal.

Mercury (Hg) compounds have long been associated with autoimmunity in rodents, especially in inbread mouse strains carrying the H-2s locus. However, to date there has been little evidence to associate risks of autoimmunity in humans with occupational or environmental exposures to Hg. To further examine potential immunotoxic effects of Hg in humans, we have studied populations in Amazonian Brazil exposed to both inorganic Hg and methyl Hg via direct and indirect contamination resulting from the use of Hg in gold extraction. Using serum samples from cross sectional surveys carried out in three Amazon communities, we analyzed for antinuclear autoantibodies (ANA) and antinucleolar autoantibodies (ANoA) using the indirect immunofluorescence microscopy method (INOVA Diagnostics). Overall, there was an association between Hg exposures (inorganic and methyl) and increased prevalence of elevated serum ANA and ANoA. Stratifying by Hg in hair < or = 8 ppm, and by time in gold mine, we found a significant positive association with odds of serum ANoA detectable at dilutions of 1:10 or greater, and 1:40 or greater, respectively. There was an apparent interaction between Hg exposure and frequency of malaria infection in increasing the prevalence of autoantibody elevations. These are the first indications that Hg exposures may induce autoimmunity in human populations, similar to those demonstrated in murine models. Research support by CNPq (Brazil), NIEHS-Fogarty, PAHO, and Heinz Family Foundation

### METABONOMIC EVALUATION OF IDIOSYNCRASY-LIKE LIVER INJURY IN RATS COTREATED WITH RANITIDINE AND LIPOPOLYSACCHARIDE.

J. F. Maddox<sup>1</sup>, J. P. Luyendyk<sup>1</sup>, G. N. Cosma<sup>2</sup>, A. P. Breau<sup>3</sup>, G. G. Harrigan<sup>4</sup>, R. H. Bible<sup>3</sup>, R. Goodacre<sup>5</sup>, P. E. Ganey<sup>1</sup>, G. H. Cantor<sup>2</sup>, G. L. Cockerell<sup>2</sup> and R. A. Roth<sup>1</sup>. <sup>1</sup>Pharmacology and Toxicology, Michigan State University, East Lansing, MI, <sup>2</sup>Investigative Toxicology, Pharmacia Corporation, Kalamazoo, MI, <sup>3</sup>Global Drug Metabolism, Pharmacia Corporation, Skokie, IL, <sup>4</sup>HTS Metabolic Profile Pharmacia Corporation, Chesterfield, MO and <sup>5</sup>Department of Chemistry, University of Manchester Institute of Science and Technology, Manchester, United Kingdom.

Idiosyncratic liver injury occurs in a small fraction of people undergoing therapy with certain drugs, including the histamine-2 receptor antagonist, ranitidine (RAN). The cause of idiosyncratic hepatotoxicity is not known; however, it has

been proposed that environmental factors such as concurrent inflammation initiated by bacterial lipopolysaccharide (LPS) or other inflammagens could increase an individual's susceptibility to drug toxicity. Recently, liver injury resembling human RAN idiosyncrasy was created in RAN-treated rats by cotreating them with a nonhepatotoxic dose of LPS. Biofluid metabonomics is showing promise in monitoring toxic liver injury. It has not, however, been used to segregate animals treated with a single drug from those coexposed to other agents. Rats were treated with RAN (30 mg/kg, iv) and/or LPS (44 x 10<sup>6</sup> EU/kg, iv, 2 h earlier) or the vehicles; and urine was collected for nuclear magnetic resonance (NMR)- and electrospray ionization mass spectrometry (ESI-MS)-based metabonomic analyses. Clinical chemistry and histopathologic analyses showed that rats cotreated with RAN and LPS developed hepatocellular necrosis, whereas those treated with either agent alone or with vehicles did not. Cluster analyses of the urine spectra by either NMR or ESI-MS revealed a clear separation of the rats treated with LPS/RAN from the other three groups. These findings support the potential use of a noninvasive metabonomic approach to identify individuals with toxic reactions to drug-inflammagen coexpo-

# CALPASTATIN EXPRESSION: A NEW LINE OF DEFENSE AGAINST PROGRESSION OF TOXICANT-INDUCED INJURY.

P. Limaye<sup>1</sup>, P. S. Palkar<sup>1</sup>, University, M. Apte<sup>1</sup>, J. C. Latendresse<sup>2</sup>, S. Yu<sup>3</sup>, P. Kashireddy<sup>3</sup>, J. K. Reddy<sup>3</sup> and H. M. Mehendale<sup>1</sup>. Department of Toxicology, University of Louisiana at Monroe, Monroe, LA, <sup>2</sup>Pathology Associates Intl., NCTR, Jefferson, AR and <sup>3</sup>Department of Pathology, Feinberg School of Medicine, Northwestern University, Chicago, IL.

We have previously demonstrated the role of calpain in the progression of acute liver injury initiated by a toxicant taking place even after the offending toxicant is long gone. It is known that stimulated tissue repair stops the progression of injury due to the resistance of the newly divided/dividing cells against the action of the death proteins such as calpain. However, the mechanism of such resistance is not known. We hypothesized that higher expression of calpastatin (CSTN), an endogenous inhibitor of calpain, in the newly divided/dividing cells provides resistance against calpain action. To test this hypothesis, hepatic expression of CSTN was studied over a time course after CCl<sub>4</sub> treatment of male S-D rats. Livers of the CCl<sub>4</sub>-treated rats exhibited high expression of CSTN from 24 to 72 h after CCl<sub>4</sub> injection, coincident with extensive cell division. Immunohistochemical analysis of PCNA and CSTN on serial liver sections indicated that newly divided/dividing cells stained positive for CSTN. CSTN expression was further studied in two additional models of cell division: 70 percent partial hepatectomy (PH) and liver cell division in the newborn rats. The 20-day-old newborn rat pup livers extensively expressed CSTN coincident with marked cell division. In PH, hepatic expression of CSTN was intense up to 4 days, declining thereafter to normal by 7 days after PH. To test further whether overexpression of CSTN will provide protection from toxicant mediated injury, an adenoviral vector expressing CSTN has been generated which will be used to induce CSTN overexpression in the livers of male SW mice and in primary hepatocytes. These models will be used to study toxicant induced injury to confirm the role of CSTN expression in the resistance exhibited by newly divided/dividing cells. (Supported by Kitty DeGree Endowed Chair and LBRSF)

# 64 MECHANISMS OF DIFFERENTIAL HEPATIC TOXICITY BETWEEN TROGLITAZONE AND ROSIGLITAZONE.

H. M. Rhee<sup>1</sup>, B. J. Song<sup>2</sup> and M. Bae<sup>2</sup>. <sup>1</sup>Metabolic Endocrine Drug Products, Food and Drug Administration, Rockville, MD and <sup>2</sup>Lab. Membrane Biochemistry and Biophysics, NIH, NIAAA, Rockville, MD. Sponsor: J. Colerangle.

Structurally troglitazone is a thiazolidinedione common to rosiglitazone and pioglitazone, which are classified as PPAR agonists. They have hepatic, renal, cardiac and bone marrow toxicities in animals, although they have strong antidiabetic activity. We hypothesize the various toxicities are due to formation of apoptotic cell cycle regulators. Methods: HepG2 and Chang liver human hepatoma cells were used. Cell viability, cell cycle analysis, and apoptosis-related proteins were determined (Toxicology Letter 139: 67-75, 2003). HepG2 cells (2x106 cells/dish) were treated with control vehicle, troglitazone, or rosiglitazone at doses of 12.5, 25, 50 and 100 uM for 48 hours. Approximately 10, 000 cells from each group were analyzed for DNA histograms and cell cycle phase distribution using a FACS Calibur cytometer. The percentage of cells undergoing apoptosis were determined by CellQuest software program. Results: Troglitazone damaged HepG2 cell drug dose dependently while rosiglitazone did not, even at 100 uM concentration. The percentage of HepG2 cells in the sub-G1(apoptotic cells) phase significantly increased as the concentration of troglitazone increased. Sub-G1 cell populations after troglitazone exposure are remarkably different from that of control while 50 uM rosiglitazone did not change the G1 cell population from the DMSO-treated control. We also determined the levels of p53 and its downstream proteins such as Gadd45, p21, and p27

in HepG2 cells. Indeed, troglitazone specifically increased the levels of mRNA for various transcription factors or apoptosis-related genes such as c-Jun, Bax, and Bad including the cell cycle regulator proteins. In addition, troglitazone decreased the activities of cdk2, cdc2, and cyclin A kinases at 24 h post-treatment. All these facts indicate that the hepatotoxic mechanisms of troglitazone may be due to its detrimental effects on cell cycle intermediates, which will eventually lead to cell death.

# GENOMIC AND PROTEOMIC INVESTIGATIONS INTO THE IDENTIFICATION OF SUSCEPTIBILITY FACTORS IN DRUG-INDUCED LIVER DISEASE (DILD).

K. Welch¹, T. Reilly², B. Wen³, T. Hays¹, J. Brady⁴, C. Masison⁴, M. Radonovich⁴, D. Goodlett⁵, E. Yi⁵, H. Lee⁵, <u>S. Nelson³</u> and <u>L. Pohl¹.¹LMI, NHLBI/NIH/HHS, Bethesda, MD, ²Bristol-Myers Squibb, Syracuse, NY, ³University of Washington, Seattle, WA, ⁴NCI/NIH/HHS, Bethesda, MD and ⁵Institute for Systems Biology, Seattle, WA.</u>

DILD causes significant morbidity and mortality and impairs new drug development. Recent evidence suggests that DILD is a complex polygenetic disease. Previously, we reported on differences in susceptibility to acetaminophen (APAP)induced liver disease using various strains of mice. Of the strains studied we found C57Bl/6 (B6) and SJL mice to be the most susceptible and resistant, respectively. Global hepatic gene expression profiling following APAP administration revealed an elevated mRNA expression of heat shock proteins (HSPs) 40 & 70 in SJL mice as compared to B6 mice. We have now further characterized susceptibility differences between SJL and B6 mice. SJLxB6-F1 hybrid mice developed an intermediate toxicity phenotype and intermediate expression profiles of HSPs 40 & 70 as compared with its parental strains. Further expression profile analyses revealed that several other potential hepatoprotective genes including HSPs 10, 86, and 105 and transcription factors involved in regenerative processes, such as c-jun, LRG-21, and Egr1, were more highly expressed in SJL and SJLxB6-F1 mice than B6 mice. Quantitative proteome analysis of livers from SJL and B6 mice before and after treatment with APAP, using isotope-coded affinity tag (ICAT) mass spectrometry, revealed that SJL mice have higher levels of several potentially important protective factors including glutathione peroxidase, GST Mu 1 & 2 and thioredoxin 2. There also appears to be a loss of many mitochondrial proteins from the livers of B6 mice, suggesting that the loss of functional mitochondria may indeed play a role in APAP-induced liver injury. These findings support the use of genomic and proteomic analyses of susceptible and resistant mouse strains in identifying susceptibility factors for DILD. (Support to SN from the UW NIEHS sponsored Center for Ecogenetics and Environmental Health: NIEHS P30ES07033).

# IN SILICO PREDICTION OF HEPATOTOXICITY OF DRUGS IN HUMANS USING POST-MARKET DATA AND MCASE SOFTWARE.

E. J. Matthews, N. L. Kruhlak, R. D. Benz and J. F. Contrera. USFDA, Rockville, MD.

FDA/CDER is conducting a pilot study to determine whether in silico methods can predict the potential adverse effects of drugs in humans. The study is using several structure activity relationship (SAR) software programs and adverse drug reaction (ADR) reports in CDER's post-market Spontaneous Reporting System and Adverse Event reporting System databases, Agency archives, and drug labeling. This presentation describes results of an investigation to estimate hepatotoxicity adverse effects (AEs) of drugs in humans using MCASE software (MultiCASE, Inc.) and our ICSAS Adverse Effect database (see related abstract). MCASE reduces the molecular structures of organic chemicals to 2-10 atom fragments, compares fragments of active and inactive molecules, and identifies fragments only present in active molecules. The investigation used our database to construct 14 FDA hepatotoxicity database modules and employed 46, 497 hepatotoxicity ADR reports for 47 liver adverse effect (AE) endpoints. A significant hepatotoxicity AE required: ≥4 ADR reports/generic drug and >20, 000 cases shipped/first 5-year of marketing; an AE Index (AEI) ≥4.0; and ≥1 biologically significant hepatotoxicity decision alert present in ≥2 concordant hepatotoxicity endpoints. The AEI estimates drug usage and human exposure and is calculated as: (# ADR report)/(# 5year units shipped) x (1, 000, 000). Results demonstrated that significant hepatotoxicity was restricted to a small subset of the drugs in our database (-20%) and only 6.7% of the drugs had concurrent liver enzyme, obstruction, and pathology AEs. Internal validation studies and an external validation study using 47 drugs being considered by the FDA/PhRMA Hepatotoxicity Workgroup showed that the MCASE program and FDA expert rules could be used to accurately predict hepatotoxicity of drugs. The experiments exhibited high positive predictivity (75–98%) and specificity (88–99%). This presentation also discusses the issues of low sensitivity of the current model (27-45%) and possible applications of the model.

## GENOMIC ANALYSIS OF THE HEPATOPROTECTIVE ROLE OF N-ACETYL-L-CYSTEINE.

M. L. Adams<sup>1</sup>, M. F. Radonovich<sup>2</sup>, J. N. Brady<sup>2</sup> and L. R. Pohl<sup>1</sup>. <sup>1</sup>Molecular and Cellular Toxicology Section, Laboratory of Molecular Immunology, National Heart Lung & Blood Institute, National Institutes of Health, Department of Health & Human Services, Bethesda, MD and <sup>2</sup>Virus Tumor Biology Section, National Cancer Institute, National Institutes of Health, Department of Health & Human Services, Bethesda, MD

N-acetyl-L-cysteine (NAC) is a well established therapeutic agent commonly used as a mucolytic as well as an antidote for acetaminophen-induced hepatotoxicity. More recently, NAC has been investigated as treatment for other forms of hepatic failure or prophylaxis for ischemia-reperfusion injury and radiocontrast media-induced nephropathy. Although the protective effects of NAC are believed to be mediated in part by its conversion into glutathione, the molecular basis of the pharmacological activity of NAC remains unclear. In an effort to help resolve this problem, the genome-wide changes in hepatic mRNA expression of wild type C57Bl/oJ mice 3h after treatment with NAC (450 mg/kg, i.p.) was investigated with the use of Affymetrix Murine Genome U74v2 Set GeneChip® Array (36, 767 probe sets on three sub-arrays). The results were compared to the expression data obtained following PBS vehicle treatment. Using the microarray analysis program GeneSpring, a gene list of 1, 594 genes with either at least two fold increase (1, 103 genes) or decrease (491 genes) in expression level was generated. Several gene categories of interest, including cell cycle regulation, acute phase response, calcium binding proteins, cell adhesion molecules, chaperone proteins, and growth factors were effected by NAC treatment. Additionally, changes were observed in glutamate-cysteine ligase modifier subunit, caspase-İ, glutathione peroxidase-3, hepatocyte growth factor, as well as metallothioneins 1, and 2. These findings suggest that the protective effects of NAC are likely due to its modulation of multiple networks involved in cellular homeostasis.

# PATHWAYS OF FIBROSIS CHARACTERIZED *IN VITRO*WITH ORGAN SLICES FROM RAT AND HUMAN TISSUE.

A. E. Vickers<sup>1</sup>, M. J. Saulnier<sup>1</sup>, R. Fisher<sup>2</sup>, E. Cruz<sup>1</sup>, K. Rose<sup>1</sup> and P. Olinga<sup>3</sup>.

<sup>1</sup>Biomarker Development, Novartis Pharmaceuticals Corp, E Hanover, NJ, <sup>2</sup>Vitron Inc., Tucson, AZ and <sup>3</sup>Department of Pharmacokinetics & Drug Delivery, University of Groningen, Groningen, Netherlands.

The extension of organ slice viability and morphology for 4-10 days with rat and human tissue expands this in vitro model for studying pathways of fibrosis. The contributing factors to increase organ slice survival include the use of a preservation solution, like UW, to perfuse the organ and prepare the slices, use of a cellulose insert atop the titanium mesh roller-insert to support the slice, and an optimized culture medium which is replaced daily to mimic multiple dosing. The slices are metabolically active as indicated by the maintenance of ATP and glutathione, and the synthesis of glycogen. This in vitro methodology triggers fibrogenic pathways as shown by the activation of stellate cells, portal and random proliferation of myofibroblast-like cells, and collagen deposition after 48 hr. An activation of stellate cells was characterized by the increased expression of the known stellate cell marker genes,  $\alpha$ -smooth muscle actin, collagen 1a1, desmin, and HSP47 using RT-PCR. Global gene expression profiling studies using Affymetrix gene chip arrays revealed an increased expression of many cytoskeleton genes including collagens and actins, as well as protein synthesis genes, while metabolic genes were repressed. The proliferation of myofibroblast-like cells was indicated by increased PCNA staining and immunohistochemical α-smooth muscle actin staining around the vessels initially and in the tissue by 72-96 hr. Increased collagen deposition was also demonstrated. The recent improvements in organ slice culturing methods, and the 3-dimensional cellular complexity of this system, allows its use as an in vitro model system to study pathways of fibrosis, and can potentially be extended to relate changes to the mechanisms of fibrotic liver diseases.

# 69 COMPLEMENTARY ROLES OF FARNESOID X RECEPTOR, PREGNANE X RECEPTOR, AND CONSTITUTIVE ANDROSTANE RECEPTOR IN PROTECTION AGAINST BILE ACID TOXICITY.

G. L. Guo<sup>1</sup>, G. lambert<sup>2</sup>, M. Negishi<sup>3</sup>, I. M. Ward<sup>4</sup>, H. Brewer<sup>5</sup>, S. A. Kliewer<sup>6</sup>, C. J. Sinal<sup>1,7</sup> and F. J. Gonzalez<sup>1</sup>. <sup>1</sup>Laboratory of Metabolism, NC\NIH, Bethesda, MD, <sup>2</sup>INSERM U539, Nantes, France, <sup>3</sup>Pharmacogenetics Section, Laboratory of Reproductive and Developmental Toxicology, NIEHS/NIH, Research Triangle Park, MD, <sup>4</sup>Veterinary and Tumor Pathology Section, NC\NIH, Frederick, MD, <sup>5</sup>Molecular Disease Branch, NHLB\NIH, Bethesda, MD, <sup>6</sup>University of Texas Southwestern Medical Center, Dallas, TX and <sup>7</sup>Dalhousie University, Halifax, NS, Canada.

The nuclear receptors, farnesoid X receptor (FXR) and pregnane X receptor (PXR), are important in maintaining bile acid homeostasis. Deletion of both FXR and PXR *in vivo* by crossbreeding B6;129-Fxrtm1Gonz (FXR-null) and B6;129-

Pxrtm1Glaxo-Wellcome (PXR-null) mice revealed a more severe disruption of bile acid, cholesterol and lipid homeostasis in B6;129- Fxrtm1Gonz Pxrtm1Glaxo-Wellcome (FXR-PXR double null or FPXR-null) mice fed a 1% cholic acid (CA) diet. Hepatic expression of the constitutive androstane receptor (CAR) and its target genes were induced in FXR- and FPXR-null mice fed the CA diet. To test whether up-regulation of CAR represents a means of protection against bile acid toxicity to compensate for the loss of FXR and PXR, animals were pretreated with CAR activators, phenobarbital (PB) or 1, 4-bis[2-(3, 5-dichlorpyridyloxy)]benzene (TCPOBOP), followed by the CA diet. A role for CAR in protection against bile acid toxicity was confirmed by a marked reduction of serum bile acid and bilirubin concentrations, with an elevation of the expression of the hepatic genes involved in bile acid and/or bilirubin metabolism and excretion (CYP2B, CYP3A, MRP2, MRP3, UGT1A, and GSTalpha), following pretreatment with PB or TCPOBOP. In summary, the current study demonstrates a critical and combined role of FXR and PXR in maintaining not only bile acid, but also cholesterol, and lipid homeostasis in vivo. Furthermore, FXR, PXR and CAR protect against hepatic bile acid toxicity in a complementary manner, suggesting that they serve as redundant but distinct layers of defense to prevent overt hepatic damage by bile acids during cholestasis.

## 70 UROPORPHYRIA CAUSED BY ETHANOL IN HFE(-/-) MICE OF DIFFERENT GENETIC BACKGROUNDS.

P. Sinclair<sup>1, 2</sup>, N. Gorman<sup>1, 2</sup>, H. Trask<sup>1, 2</sup>, W. Bement<sup>1</sup>, A. Zaharia<sup>1, 2</sup>, J. Szakacs<sup>3</sup>, G. Elder<sup>4</sup>, D. Balestra<sup>2</sup>, J. <u>Sinclair<sup>1, 2</sup></u> and G. Gerhard<sup>5, 1</sup>VA Medical Center, White River Junction, VT, <sup>2</sup>Dartmouth Medical School, Hanover, NH, <sup>3</sup>Pathology, University of Utah Medical School, Salt Lake City, UT, <sup>4</sup>Medical Biochemistry, University of Wales Medical Schl, Heath Park, Wales, United Kingdom and <sup>5</sup>Weis Ctr Research, Danville, PA.

Two major risk factors for the development of porphyria cutanea tarda (PCT) are alcohol consumption and homozygosity for the C282Y mutation in the hereditary hemochromatosis gene (HFE). We previously demonstrated that Hfe(-/-) mice of 129S6/SvEvTac background accumulate hepatic uroporphyrin (URO) when fed 10 per cent ethanol in their drinking water for 6.5 months. Here we show that increasing the ethanol concentration from 10 to 15 per cent decreased the time to onset of the uroporphyria, and further increased hepatic 5-aminolevulinate synthase activity as well as CYP1A2-catalyzed activities. There were no increases in non-heme iron. Treatment of C57BL/6 Hfe(-/-) mice with 15 per cent ethanol for 6.5 months failed to produce uroporphyria. In these latter mice, hepatic non-heme Fe was increased by the ethanol, but the total amount was much less than in 129S6 mice. Ethanol treatment of Hfe(-/-) mice of both strains caused increases in diffuse iron staining of parenchymal cells with more staining in 129 than C57BL/6 mice. Iron staining of either strain was no greater with 15 than with 10 per cent ethanol. The increase in ALAS activity caused by 15 per cent ethanol was similar in Hfe knockout mice of either background. Administration of Fe dextran, but not of Fe carbonyl, to wild-type 12986 mice treated with 10 or 15 per cent ethanol for 6-7 months, resulted in hepatic URO accumulation. Fe dextran only increased ALAS in wild-type S6 and Hfe(-/-) mice also treated with ethanol. In conclusion, the results of this study further support the hypothesis that the uroporphyrinogenic effect of ethanol is mediated by its effects on hepatic iron metabolism and localization. Other genetic factors than Hfe appear to modify host susceptibility to ethanol-mediated uroporphyria. This work was supported by the Department of Veterans Affairs.

# 71 PREDICTING THE CARCINOGENIC POTENTIAL OF PHARMACEUTICALS AND CHEMICALS USING MOLECULAR SIMILARITY, E-STATE INDICES AND MDL-QSAR SOFTWARE.

J. F. Contrera<sup>1</sup>. <sup>1</sup>Office of Pharmaceutical Science, USFDA Center for Drugs, Rockville, MD, <sup>2</sup>Office of Pharmaceutical Science, USFDA Center for Drugs, Rockville, MD and <sup>3</sup>Office of Pharmaceutical Science, USFDA Center for Drugs, Rockville, MD.

MDL QSAR software is one of several software systems under evaluation by the Informatics and Computational Safety Analysis Staff (ICSAS) of the FDA Center for Drug Evaluation and Research for regulatory and scientific decision support applications. MDL QSAR software contains an integrated set of tools for similarity searching, compound clustering and modeling of molecular structure related parameters that include 240 electrotopological E-state, connectivity and other descriptors. These molecular descriptors can be used to develop structure activity relationship (SAR) models that are statistically correlated with toxicological or biological endpoints. The goal of this research was to evaluate the feasibility of using MDL QSAR software and descriptors to develop SAR models to predict the carcinogenic potential of pharmaceuticals and organic chemicals. A validation study of 108 compounds that include 86 pharmaceuticals and 22 chemicals that were not present in a control rodent carcinogenicity learning data set of 1275 compounds demonstrated that MDL QSAR models had excellent coverage (92%) and

good sensitivity (74%) and specificity (72%) for rodent carcinogenicity. The software correctly predicted 73 % of non-carcinogenic compounds and compounds with carcinogenic findings. E-state descriptors contributed to more than half of the SAR models used to predict carcinogenic activity. The recent addition of non-parametric discriminant analysis functions to MDL QSAR software has further improved predictive performance to the 90% range. We believe that electrotopological E-state descriptors and MDL QSAR software are promising new in silico approaches for modeling and predicting rodent carcinogenicity that has wider application for other toxicological endpoints. Preliminary results suggest that this approach can also be used to estimate the maximum therapeutic dose and no effect dose level.

# 72 A MODEL TO ASSESS THE TUMORIGENIC POTENTIAL OF NATALIZUMAB (NAT), A RECOMBINANT HUMANIZED ANTI-α4 INTEGRIN ANTIBODY.

J. V. Rutkowski<sup>1</sup>, D. Lepage<sup>1</sup>, D. Hutto<sup>1</sup>, N. Wehner<sup>2</sup>, Y. Maxuitenko<sup>3</sup>, J. Heath<sup>3</sup>, M. Koratich<sup>3</sup>, C. Tenhoor<sup>1</sup> and J. Green<sup>1</sup>. <sup>1</sup>Biogen, Cambridge, MA, <sup>2</sup>Elan Pharmaceuticals, San Diego, CA and <sup>3</sup>Southern Research Institute, Birmingham, AL.

NAT binds to the  $\alpha 4$  subunit of  $\alpha 4\beta 1$  and  $\alpha 4\beta 7$  integrins and blocks interaction with their receptors, fibronectin, VCAM-1 and MadCAM-1. α4 expression is present on a variety of human tumors including melanomas and lymphomas. An alternative approach to the assessment of potential carcinogenicity of this antibody was undertaken since NAT lacks cross-reactivity to rodent \alpha4. Thus, the potential for NAT to either inhibit or potentiate human tumor cell growth and/or metastases was evaluated. A number of human tumor cell lines were screened for expression of α4 by IHC and flow cytometry and functionality was confirmed by an in vitro binding assay. Any cytotoxicity or induction of cell proliferation of the human tumor cells was evaluated by <sup>3</sup>H-thymidine incorporation. Cell lines for *in vivo* evaluation were selected based on the composite in vitro data. Either MOLT-4 or UACC-257 human tumor cells were implanted s.c. in the athymic nude or SCID mouse, respectively. Treatment with NAT or control material was initiated prior to or following establishment of a preformed tumor. In each instance, NAT was administered with a loading dose of 10 mg/kg and subsequent doses at 5 mg/kg, twice per week. To assess the effects of NAT on the growth of metastasis, one arm of the study design included a surgical excision of the tumors at an estimated size of 1 g from selected animals. All animals were sacrificed and evaluated for tumor regrowth and metastases by macroscopic and microscopic evaluation. Administration of NAT was well tolerated without deaths or body weight loss and did not affect tumor incidence or latency. Enhancement of xenograft growth rate was not evident. Extension of xenograft regrowth following excision was noted in the ventral abdominal skin. Metastasis or extension of the xenograft was not observed in any other tissue or organ. In summary, there was no evidence of exacerbation of regrowth or metastasis as a result of treatment with NAT.

# 73 ORAL TOXICITY AND ANGIOSTATIC POTENCY OF ANTI-VEGF DRUGS ZD-6474, ZK 222584, AND SU11248 IN MICE.

D. A. Badger<sup>1</sup>, J. M. Holland<sup>1</sup>, T. C. Malone<sup>3</sup>, S. R. Vanapalli<sup>1</sup>, J. L. Edelman<sup>2</sup> and G. W. DeVries<sup>2</sup>. <sup>1</sup>Safety Evaluation, Allergan, Irvine, CA, <sup>2</sup>Biological Sciences, Allergan, Irvine, CA and <sup>3</sup>Medicinal Chemistry, Allergan, Irvine, CA.

Based on their anti-VEGF receptor activity, ZD-6474 (ZD), ZK 222584 (ZK), and SU11248 (SU) are currently being developed for the treatment of cancer. This study determined if these structurally diverse drugs share common preclinical toxicity profiles. CD-1 mice (3 males/group) were given 50, 150, or 500 mg/kg/day ZD, ZK, or SU once daily by oral gavage (10 mL/kg/day in 2% carboxymethylcellulose) for 10 consecutive days. Viability, clinical observations, body weight, drug plasma concentrations, and histopathology were evaluated. Mortality associated with lethargy and dehydration was observed in mice given 500 mg/kg/day ZD, ZK, or SU. Mean drug plasma concentrations in mice given 150 mg/kg/day determined 1 hr post dose on day 11 were 4510 ng/mL ZD, 7680 ng/mL ZK, and 1260 ng/mL SU. Renal histopathology included tubular degeneration (ZD; ZK; SU) and glomerulonephropathy (ŽK; SU). Heart lesions included coronary vasculitis (ZD; SU), myocardial necrosis (SU) and myocardial hemorrhage (ZK; SU). Other lesions included hepatic hypertrophy (ZK; SU), hepatic vacuolation (ZD; ZK), lymphatic atrophy (ZD; ZK; SU), thymic atrophy (ZD; ZK; SU) and myeloid atrophy (ZD; SU). In general, drug toxicology profiles correlated with pharmacologic potency. Anti-angiogenic activity, determined by epiphyseal thickness at day 10, showed rank order efficacy of SU>ZD>ZK. In contrast, rank order pharmacologic potency using in vitro (kinase inhibition) and in vivo (Miles assay, 2 hrs post-dose) assays was ZK>SU>ZD. The reduced toxicity and lack of anti-angiogenic activity observed with ZK in the current study may be explained by pharmacokinetic/pharmacodynamic differences among models (a similar lack of activity was observed in a chronic rat model of choroidal neovascularization). Overall, these results suggest that the effects observed are likely related to pharmacological activities, although some chemical specific toxicity might be occurring.

#### SUBCHRONIC ORAL TOXICITY/ENZYME MODULATION STUDY OF FARNESOL IN RATS.

T. Horn<sup>1</sup>, L. Long<sup>1</sup>, M. Cwik<sup>1</sup>, W. Johnson<sup>1</sup>, R. Morrissey<sup>2</sup>, I. Kapetanovic<sup>3</sup> and D. McCormick<sup>1</sup>. <sup>1</sup>IIT Research Institute, Chicago, IL, <sup>2</sup>Pathology Associates, Chicago, IL and <sup>3</sup>National Cancer Institute, Bethesda, MD.

Farnesol is a naturally occurring phytochemical that inhibits cholesterol synthesis by suppressing 3-hydroxy-3-methylglutaryl CoA reductase. Farnesol has anticarcinogenic activity in animal models for human cancer, and is in preclinical development for cancer chemoprevention. The present study was performed to evaluate the toxicity of subchronic oral administration of farnesol in rats, and to determine the influence of farnesol on the activity of hepatic and renal drug metabolizing enzymes. CD rats (40/sex/group) received daily gavage exposure to farnesol (in corn oil) at doses of 0, 500 or 1000 mg/kg/day for 28 days; parallel groups of rats were necropsied on day 29 and on day 57 (after a 28-day recovery period). No deaths occurred during the study, and farnesol had no effects on body weight, food consumption, or hematology or coagulation parameters. Farnesol exposure was associated with statistically significant alterations in several clinical chemistry parameters; all clinical chemistry effects were reversible. At day 29, statistically significant increases in the absolute and relative weights of the liver and kidney were seen in farnesol-treated rats. These organ weight effects were not associated with any histopathologic alterations, and were not seen at day 57. Organ weight effects may be secondary to enzyme induction, as the activities of several drug metabolizing enzymes were elevated at day 29 in the liver (CYP2E1, glutathione reductase, NADPH quinone reductase) and kidney (glutathione-S-transferase). The influences of farnesol on the activity of drug metabolizing enzymes were reversible; enzyme activities did not differ from control after the 28-day recovery period. No evidence of limiting toxicity was observed at either farnesol dose used in the study. Subchronic administration of farnesol induced dose-related alterations in liver and kidney weights and increased drug metabolizing enzyme activities. These effects were reversible. (NCI-N01-25012)

#### 75 A TOXICITY EVALUATION OF HUMANIZED ANTI-CD20 ANTIBODY PRO70769.

K. P. McKeever<sup>1</sup>, T. Watson<sup>1</sup>, J. Beyer<sup>1</sup>, L. Nguyen<sup>1</sup>, B. Wu<sup>1</sup>, P. Fielder<sup>1</sup>, K. Howell<sup>1</sup>, F. Qureshi<sup>1</sup>, D. Auyeung<sup>2</sup>, H. Lowman<sup>1</sup> and Y. Vugmeyster<sup>1</sup>. <sup>1</sup>Genentech, Inc., South San Francisco, CA and <sup>2</sup>CRL DDS Sierra Division, Sparks,

PRO70769 is a humanized monoclonal antibody against CD20 present on normal and malignant B cells. PRO70769 is being evaluated for treatment of B cell-mediated diseases. To assess the safety and pharmacology of PRO70769, cynomolgus monkeys were administered drug (iv) on Days 1 and 15 with 10, 50 and 100mg/kg of PRO70769 (total dose of 20, 100, and 200mg/kg) and euthanized 2 weeks after the 2nd dose. Animals from control and high dose groups were also assessed for reversibility, persistence, or delayed occurrence of toxicity after 12 weeks of recovery. Flow cytometric analysis of peripheral blood showed a dose dependent decrease in B cells by Day 2. Decreased absolute lymphocyte counts also reflected this change, as compared to baseline values. Due to maximal depletion of B cells prior to the second dose, there was no evidence of additional drug-related decreases in absolute lymphocyte counts on Day 15. On Day 29, B cells remained depleted at 6.2%, 2.2% and 1.5% of baseline. By Day 113, B cells from the high dose animals had recovered to an average of 19.8% of baseline. Flow cytometric analysis of lymphoid tissues on Day 29 revealed that B cell numbers were also reduced, as compared to the control group: 39-52% in the bone marrow; 2-14% in the spleen; 13-34% in the inguinal lymph nodes; and 5-21% in the mandibular lymph node. Histologically, lymphoid atrophy was apparent in the spleen and lymph nodes. Depletion of B cells in these organs was confirmed by immunohistochemistry. There were no apparent PRO70769-related changes in clinical signs, physiological indices, physical examinations, or clinical chemistry parameters. Furthermore, there were no changes in gross pathology or non-lymphoid organ weights related to the administration of PRO70769. The results of this study demonstrate the ability of PRO70769 to decrease CD20+ B cells in the blood and lymphoid tissues, with pharmacologic depletion of CD20-expressing cells being the only treatment-related effect.

#### 76 EFFECTS OF CHRONIC PERTUZUMAB-MEDIATED HER2 PATHWAY INHIBITION.

K. M. Towndrow<sup>1</sup>, N. Dybdal<sup>1</sup>, L. Nguyen<sup>1</sup>, D. Allison<sup>1</sup>, F. Qureshi<sup>1</sup>, L. Bernier<sup>2</sup> and K. P. McKeever<sup>1</sup>. <sup>1</sup>Genentech, Inc., S. San Francisco, CA and <sup>2</sup>Covance, Inc., Vienna, VA.

Human epidermal growth factor receptors (HER) are important mediators of cell growth, survival, and differentiation. Pertuzumab, a monoclonal antibody, blocks dimerization of HER2 and other HER family members, including epidermal

growth factor receptor (EGFR), HER3, and HER4. Since pertuzumab is being developed as a cancer therapeutic, the effects of chronic exposure of monkeys to 15, 50, or 150 mg/kg (weekly i.v.) pertuzumab for 26 weeks, followed by an 8-week recovery period, were assessed. No drug-related changes in body weight, organ weight, body temperature, blood pressure, respiration rate, electrocardiograms, serum testosterone or serum troponin values were observed after pertuzumab administration. In addition, no drug-related histomorphologic findings occurred after either the 26-week treatment or following an 8-week recovery period and no positive antibody titers to pertuzumab were detected. An increased incidence of diarrhea occurred in all treatment groups, including control animals. Diarrhea was more frequent, but not dose-dependent, in pertuzumab-treated monkeys. All monkeys survived until scheduled necropsy except for one 50 mg/kg group female that was euthanized on Day 126 due to morbidity that was likely the result of dehydration caused by persistent diarrhea, unresolved with basic supportive care. Furthermore, no drug-related findings were observed during necropsy and histopathology examinations of this animal. One 15 mg/kg group male exhibited poor health during Week 12 and had recurring, transient episodes of diarrhea throughout the study; both of which required supportive care. Similar clinical observations were noted for one 150 mg/kg group female during Week 26. While there was a trend towards pertuzumab-related increases in diarrhea and dehydration, a direct relationship could not be determined or excluded. Aside from incidences of diarrhea and dehydration, chronic pertuzumab-mediated inhibition of the HER2 pathway was generally well tolerated in monkeys.

PRECLINICAL SAFETY ASSESSMENT OF A HUMAN LYMPHOTOXIN BETA RECEPTOR IMMUNOGLOBULIN FUSION PROTEIN IN CYNOMOLGUS MONKEYS

FOLLOWING REPEATED INTRAVENOUS AND SUBCUTANEOUS DOSING.

<u>C. Sachs</u><sup>1</sup>, <u>G. Beattie</u><sup>2</sup>, J. Gommerman<sup>1</sup>, <u>C. Chan</u><sup>2</sup>, J. Browning<sup>1</sup>, W. Meier<sup>1</sup>, P. L. Martin<sup>1</sup> and <u>J. D. Green</u><sup>2</sup>. <sup>1</sup>Biogen, Cambridge, MA and <sup>2</sup>Charles River DDS Sierra Division, Sparks, NV.

Lymphotoxin  $\alpha\beta$ , a TNF family member, plays a crucial role in the maintenance of the lymphoid microenvironment. Antagonism of this pathway has been efficacious in several animal models of immune disease. Cynomolgus monkeys (3-7/sex/group) were administered human lymphotoxinß immunoglobulin fusion protein (hLTBR-IgG) weekly at doses of 0, 0.8, 8 and 40 mg/kg by slow bolus intravenous (IV) injection or at 8 mg/kg by subcutaneous injection for 4 consecutive weeks. Necropsies were performed after 4 weeks of dosing, and 8 and 12 weeks after cessation of dosing. To evaluate functional follicular dendritic cell (FDC) activity (trapping of immune complexes) a subset of animals was administered an IV injection of goat peroxidase-anti-peroxidase immune complexes (PAP) 24 h prior to necropsy. There were no LTBR-IgG-related changes in clinical signs, body weight, clinical chemistry, coagulation, electrocardiographic, or occular evaluations. No target organs of toxicity were identified in routine histopathology. Immunohistopathology revealed LTBR-IgG-related decreases in FDC marker staining and PAP staining in the spleen after 4 weeks of treatment consistent with down regulation of FDC networks and function (immune complex trapping). Despite these changes in the FDC network, the primary immune response to keyhole limpet hemocyanin was not impaired. Recovery of staining for CD35 and PAP was observed during the 12-week treatment-free period. All doses were well tolerated and produced no evidence of toxicity. The results of this study supported the initiation of clinical trials.

**78** SAFETY AND BIODISTRIBUTION OF A MULTIPLE STRAIN EBOLA GENE DNA PLASMID VACCINE (VRC-EBODNA012-00-VP) IN THE NEW ZEALAND WHITE

T. S. Manetz<sup>1</sup>, J. Stein<sup>3</sup>, R. Sheets<sup>2</sup>, G. Wolfe<sup>1</sup>, C. Duffy<sup>4</sup> and P. Gomez<sup>2</sup>. <sup>1</sup>Gene Logic, Gaitherburg, MD, <sup>2</sup>Vaccine Research Center of NIH/NIAID, Bethesda, MD, <sup>3</sup>Consultant to the Vaccine Research Center, Ann Arbor, MI and <sup>4</sup>Althea Technologies, Inc., San Diego, CA.

These studies outline the pre-clinical safety studies for a candidate Ebola vaccine that is a recombinant multi-DNA plasmid vaccine (VRC-EBODNA012-00-VP). Previously published studies by Nabel and colleagues of the VRC showed protection in non-human primates to a prime/boost regimen of DNA prime and adenoviral vector boost. These studies evaluated the intramuscular safety and biodistribution of VRC-EBODNA012-00-VP in New Zealand White Rabbits. For the biodistribution study, rabbits received control or VRC-EBODNA012-00-VP by single Biojector 2000® (Biojector) injection on Study Day (SD) 1 and were necropsied for biodistribution analysis on SD 8, 30, and 60. For the safety study, rabbits received PBS or VRC-EBODNA012-00-VP by Biojector injection on SD 1, 22, 43, and 64, with necropsy on SD 66 and 78. Parameters evaluated include

mortality, clinical and Draize observations, body weights, food consumption, ophthalmology, immunogenicity, clinical pathology, organ weights, bone marrow, gross pathology, and histopathology. Biodistribution analysis determined the test article was present in injection site muscle and subcutis. Frequency and/or copy number progressively decreased over time, suggesting plasmid clearance. All animals treated with VRC-EBODNA012-00-VP had increased antibody titers to the Ebola vaccine epitopes, demonstrating vaccine immunogenicity. Increased recoverable Draize findings at the injection site were found in VRC-EBODNA012-00-VP-treated animals following the third and fourth injections. These likely resulted from the injection procedure and expected immune response against the transgene. Therefore, under these study conditions, repeat intramuscular administration of VRC-EBODNA012-00-VP to New Zealand White Rabbits did not exhibit any specific signs of systemic toxicity but resulted in increased levels of reversible Draize observations following the third and fourth injections.

79 A LONG-TERM IMMUNOGENICITY AND SAFETY STUDY OF AN IMMUNONEUTRALIZING VACCINE TARGETED TO INHIBIT CHOLESTERYL ESTER TRANSFER PROTEIN (CETP) IN RABBITS.

L. J. Thomas, M. D. Picard, E. G. Linnetz, K. M. Borrelli, R. A. Hammond and C. W. Rittershaus. AVANT Immunotherapeutics, Needham, MA.

CETP is a plasma glycoprotein that facilitates the transfer of neutral lipids and phospholipids between lipoproteins and contributes to the regulation of the plasma concentration of HDL. An immunoneutralizing vaccine targeted against CETP (designated CETi-1) was developed to reduce the lipid transfer function of CETP by eliciting antibodies to bind to CETP. CETi-1 is a synthetic chimeric peptide, including residues 461-476 of human CETP and residues 830-843 of tetanus toxoid, formulated with an alum adjuvant. CETi-1 has been shown to raise HDL, decrease LDL and reduce atherosclerotic lesions in a cholesterol-fed rabbit model. This vaccine could be administered to patients periodically over extended periods of time as a preventive measure or as a therapy for atherosclerosis. Consequent to its intended use, a study was conducted to determine the levels and duration of the immunogenicity of this vaccine when administered repeatedly to rabbits over more than four years. Male NZW rabbits were primed with a single injection of either 0.1ug, 1.0ug, 10ug, 100ug, or 1000ug of CETi-1 vaccine on week 1. The animals were boosted with the same dose of vaccine on weeks 67, 109, 135, 164, and 195. Blood samples were taken periodically up to the end of the study on week 223. Blood samples were evaluated by ELISA for antibodies to CETP and endpoint titers were determined. As expected, anti-CETP antibody titers in all rabbits were low following the first immunization, with none exceeding 1/200. For animals in each dose group, antibody titers increased with successive boosts. Upon repeated boosting the vaccine did not lose its ability to induce an immune response. Antibody titers were generally dose-dependent and returned to baseline levels over time. This data would support the concept that this vaccine would maintain, or improve, its immunogenicity when repeatedly administered. Furthermore, there were no observations of toxicity attributable to prolonged autoreactive anti-CETP antibody titers in these animals.

80 EFFECT OF OIL COMBUSTION PARTICLE
BIOAVAILABLE CONSTITUENTS ON EX VIVO
VASCULAR FUNCTION OF AORTAE RECOVERED
FROM HEALTHY AND EARLY TYPE 2 DIABETIC RATS.

K. Dreher<sup>1</sup>, S. E. Kelly<sup>2</sup>, S. D. Proctor<sup>2</sup> and J. C. Russell<sup>2</sup>. <sup>1</sup>USEPA, Research Triangle Park, NC and <sup>2</sup>University of Alberta, Edmonton, AB, Canada.

Epidemiological studies have reported statistical associations between air particulate pollution exposure and alterations in cardiovascular function particularly in individuals with recent myocardial infarctions or Type 2 diabetes. However, the physicochemical properties of particles and biological mechanisms responsible for these observations are not known. This study examines the ability of soluble constituents of air pollution particles to alter vascular function in arteries recovered from healthy and Type 2 diabetic JCR:LA-cp rats. Aortic rings recovered from healthy and diabetic rats were maintained in oxygenated Krebs Henseleit buffer at 37°C. Contractile force was measured for each aortic ring following exposure to various doses of a particle-free leachate of residual oil fly ash (ROFA-L) (1.5 to 12.5 μg/ml) and phenylepherine (PE) (10° to 10° M). ROFA-L exposure produced a dose dependent increase in PE-mediated vascular contractility in the aortae from both healthy and diabetic rats. However, at the lowest concentration of ROFA-L (1.5 μg/ml) diabetic aortae displayed a greater PE-induced contractile response when compared to aortae recovered from healthy rats. Interestingly, a very strong ROFA-L induced vascular contractile response was observed only in diabetic aortae follow

ing the initial ROFA-L exposure with PE stimulation. Finally, acetylcholine-mediated vascular relaxation was inhibited to a greater extent in diabetic aortae when compared to healthy aortae following exposure to higher ROFA-L doses (6.25 and 12.5  $\mu$ g/ml). Our results demonstrate that: 1) bioavailable constituents of oil combustion particles can directly impair vascular function; 2) exposure history and disease status maybe critical to this response; and 3) aortae from Type 2 diabetic rats were found to be more sensitive to alterations in vascular responsiveness following exposure to bioavailable constituents associated with oil combustion particles. (This abstract does not reflect EPA Policy)

81 VANADIUM EXPOSURE ALTERS SPONTANEOUS BEAT RATE AND GENE EXPRESSION OF CULTURED CARDIAC MYOCYTES.

D. W. Graff<sup>1</sup>, R. B. Devlin<sup>1</sup>, L. A. Dailey<sup>1</sup> and W. E. Cascio<sup>2</sup>. <sup>1</sup>NHEERL, USEPA, Research Triangle Park, NC and <sup>2</sup>Cardiology, University of North Carolina, Chapel Hill, NC.

Ambient air pollution particulate matter (PM) exposure is associated with increased morbidity and mortality. Recent toxicological studies report PM-induced changes in a number of cardiac parameters, including heart rate variability, arrhythmias, repolarization, and internal defibrillator discharges. In this study we identify cellular processes that might contribute to cardiac dysfunction after PM exposure. Isolated neonatal rat ventricular myocytes were cultured for 11 days and then exposed to different concentrations of vanadium (V), a common soluble PM component. A 30 min exposure to V decreased spontaneous myocyte beat rate by 10% compared to baseline, an effect that persisted at 1, 2, 4, and 24 hrs. To account for this decrease in beat rate, we used real-time PCR to test for changes in gene expression of several ion channels that contribute to repolarization, gap junction proteins (mediators of intercellular communication), and markers of inflammation following 6 and 24 hrs of V exposure. A 6 hr exposure did not affect connexin or ion channel gene expression but increased expression of IL-6, IL-1a, and HSP70 1.5-2-fold. A 24 hr exposure produced 1.5-2-fold increases in gene expression of the gap junction protein connexin 43, IL-6, and IL-1a, and a 50% decrease in the K+ channel coded for by the gene KvLQt1. These data suggest that soluble metals found in air pollution particles could contribute to PM-associated cardiac morbidity and mortality by affecting the function of cardiac myocytes. These effects may be triggered by an inflammatory response or by the remodeling of proteins associated with cellular communication and/or repolarization. This abstract does not necessarily reflect EPA policy.

# 82 SUBCHRONIC HEALTH EFFECTS OF CONCENTRATED AMBIENT PARTICULATE MATTER (CAP).

<u>L. Chen</u><sup>1</sup>, J. Hwang<sup>1, 2</sup>, <u>C. Nadziejko</u><sup>1</sup> and M. Lippmann<sup>1</sup>. <sup>1</sup>Environ Med., NYUSOM, Tuxedo, NY and <sup>2</sup>Statistical Science, Academia Sinica, Taipei, Taiwan.

Several epidemiologic cohort studies indicate that people who live in areas with elevated PM2.5 experience significantly reduced longevity in addition to acute effects. In this study, we hypothesized that subchronic exposure of normal and compromised mice to CAPs causes cumulative adverse effects on the respiratory and cardiovascular systems. A particle concentrator was used to expose mice to filtered air (FA) or CAPs for 6h/d, 5d/w, for up to 6 months to the regional background aerosol in Tuxedo NY. A cohort of C57 mice (n=17/group) was used to investigate respiratory effects. In addition, C57 (n=6/group) and ApoE knockout (n=9/group) mice, implanted with ECG transmitters, were used to investigate cardiovascular effects. A separate cohort of double knockout mice (DK, ApoE and LDLr knockout, n=6/gender/group) were also included to investigate histopathological changes and gene expression patterns of the cardiopulmonary systems. Preliminary results showed that CAPs (mean: 110±79 ug/m3, median: 89 ug/m3) had no effect on the lung lavage parameters in any of the mouse strains. In contrast, there were long term cumulative changes in heart rates (HR) in both C57 and ApoE after a 5 month exposure to CAPs. The pattern of alterations in HR was dependent on the strain of mice, and on the time of day when HR was measured. For example, by the end of the 5 months of exposure, for midnight to 4 am, there was a 28 beats/min reduction in HR in the ApoE, whereas the HR was increased by 22 beats/min in C57. There were also daily concentration-dependent changes in HR both during and post the CAPs exposure period in both strains of mice. In addition, several deaths occurred in both the CAPs and FA exposed DK mice. However, a log-rank test showed that CAPs did not affect the end of study survival in these mice. Taken together, our data showed that subchronic exposure to CAPs produced significant daily changes in the cardiovascular system in both healthy and health compromised animals and the effects appeared to be cumulative. Supported by: EPA (R827351) and NIEHS (ES00260).

EFFECTS OF INSTILLED EMISSION PARTICULATE MATTER (EPM) ON ELECTROCARDIOGRAPHIC INDICES AND HEART RATE VARIABILITY (HRV) IN SPONTANEOUSLY HYPERTENSIVE (SH) RATS.

L. Wichers<sup>1</sup>, J. P. Nolan<sup>2</sup>, W. H. Rowan<sup>2</sup>, M. J. Campen<sup>3</sup>, T. P. Jenkins<sup>4</sup>, <u>D. L. Costa<sup>2</sup></u> and W. P. Watkinson<sup>2</sup>. <sup>1</sup>SPH, UNC, Chapel Hill, NC, <sup>2</sup>ORD/NHEERL/ETD/PTB, USEPA, Research Triangle Park, NC, <sup>3</sup>LRRI, Albuquerque, NM and <sup>4</sup>Brody SOM, ECU, Greenville, NC.

Epidemiological studies have linked increased levels of ambient particulate matter (PM) with increased morbidity and mortality, noting higher correlations in persons with cardiovascular disease. To further investigate this phenomenon, we examined the effects of EPM (an "ambient-like" emission particle) in SH rats (a susceptible disease model). Rats were implanted with radiotelemeters capable of monitoring electrocardiogram (ECG), heart rate (HR), blood pressure (BP), and core temperature (T<sub>co</sub>). Animals (n=109) were divided into four groups and exposed via intratracheal instillation (IT) to suspensions of EPM (0.0, 0.83, 3.33, 8.33 mg/kg) in acidified saline vehicle. Telemetered rats were monitored continuously for 96h post-IT and ECG waveforms were acquired at 10-min intervals throughout the study. Ventilatory function was examined (Buxco Electronics) concurrently for 6h/day on postexposure Days 1-4 while subsets of rats underwent bronchoalveolar lavage (BAL) at 24h, 96h, and 192h post-IT. ECG abnormalities (rhythm disturbances, premature ventricular contractions) were observed primarily in the high dose group. Detailed analyses of ECG intervals and indices of HRV showed evidence of immediate (<2 hours) increases in HRV followed by a delayed (>2 days) return to control levels. Additionally, exposure to EPM induced dose-related decreases in HR, BP, and T<sub>co</sub>, that persisted for up to 72h. Significant increases in BAL indices of pulmonary injury were also noted. These studies demonstrate substantial deficits in cardiopulmonary function in SH rats after IT exposure to EPM. The observed changes in cardiopulmonary function in moderately compromised rodents support the results of previous epidemiological studies and may implicate similar biologically-plausible mechanisms in humans. (Abstract does not represent USEPA policy. This research was supported in part by EPA CT826513.)

# 84 ASSESSMENT OF TOXICITY OF OIL COMBUSTION EMISSION EXPOSURE IN NORMAL AND HYPERTENSIVE RATS.

M. I. Gilmour<sup>1</sup>, University, Kodavanti<sup>1</sup>, K. Dreher<sup>1</sup>, M. Daniels<sup>1</sup>, M. Schladweiller<sup>1</sup>, Q. krantz<sup>1</sup>, W. P. Linak<sup>2</sup>, C. Miller<sup>2</sup> and D. L. Costa<sup>1</sup>.

<sup>1</sup>NHEERL, USEPA, Research Triangle Park, NC and <sup>2</sup>NRMRL, USEPA, Research Triangle Park. NC.

It has been suggested that the increased morbidity and mortality associated with exposure to airborne particulates (PM) is related to materials derived from combustion sources such as gasoline, diesel, oil, wood and coal. In these studies hickory oil # 6 was burned in a residual oil combustor previously shown to produce approximately 150 mg/m3 of PM. The particles were then passed through a 2.2 mm cyclone and diluted with clean ambient air. The resulting PM was directed to a Hinners animal exposure chamber equipped for continuous monitoring of O2, CO, CO2, NOx, SO2, as well as total particle concentrations. Mean PM 2.5 concentrations ranged between 2 and 3 mg/m-3 with SO2 denuded to 2-3 ppm and 20-30 ppm NOx. Sprague-Dawley and spontaneously hypertensive (SHR) rats were exposed to the combustion atmosphere for 4 hrs for one or three days and immediately and 20 hr later assessed for changes in systemic and pulmonary markers of injury and inflammation. Exposure to the emission atmosphere caused an increase in neutrophils and BAL lysozyme in both rat strains, but no significant changes in other markers of lung injury such as protein and LDH. Increased vanadium levels detected in the plasma of CEAS-exposed Sprague-Dawley rats were associated with an elevated platelet count and decreased white blood cell numbers. Analysis of systemic biomarkers in SHR rats is in process. We conclude that these acute exposures resulted in modest levels of pulmonary inflammation in the two rat strains, and that the biological effects may be more prominent in the systemic circulation. Future studies will determine the relative contribution of gases versus particles on these responses, and will test whether animals with cardiopulmonary disease are further compromised by such exposures. (This abstract does not necessarily reflect EPA policy.)

## 85 MYOCARDIAL AND CARDIOVASCULAR EFFECTS FOLLOWING PULMONARY EXPOSURE TO ZINC.

P. S. Gilmour<sup>1, 2</sup>, A. Nyska<sup>2</sup>, M. C. Schladweiler<sup>3</sup>, A. D. Ledbetter<sup>3</sup> and <u>University. P. Kodavanti<sup>3, 1</sup>CEMALB, UNC, Durham, NC, <sup>2</sup>NIEHS, Research Triangle Park, NC and <sup>3</sup>PTB, USEPA, Durham, NC.</u>

Exposure to environmental particulate matter (PM) is associated with cardiovascular (CV) health effects. Although the mechanisms have yet to be determined, particle-associated metals are thought to play a role. Recent interest has focused on zinc,

a major constituent of ambient and combustion particles, however the roles of pulmonary zinc exposure on coagulation factors and inflammation in the heart are unknown. We have previously shown that pulmonary exposure to zinc-containing PM causes myocardial lesions in rats. Therefore, we hypothesized that pulmonary exposure to zinc causes lung and heart thrombosis, and cardiac inflammation and injury. Adult male Sprague-Dawley and Wistar-Kyoto (WKY) rats were intratracheally (IT) instilled with 0, 1 or 2 µmol/kg of zinc sulfate (ZnSO4). Inflammation, blood parameter changes, tissue plasminogen activator (tPA), thrombomodulin (TM), and tissue factor (TF) mRNA (PCR) in heart and lung tissue were analyzed post-ZnSO4 IT. Lung and cardiac injuries were evaluated 1-96 hr post-IT. Myocardial lesions were characterized by immunohistochemical staining for troponin and apoptosis in cardiac sections. Significant increases in bronchoalveolar lavage fluid neutrophils, protein, and LDH occurred in the zinc-exposed SD rats and not in controls. TF mRNA was significantly increased in the lung of zinc-exposed SD rats. The expression of tPA and TM was significantly decreased in heart tissue of zinc-exposed SD rats. Instilled zinc took 24 hr to clear during which time the liver Zn increased while there was only a modest increase in cardiac zinc. WKY rats exposed to Zn demonstrated cardiac lesions which consisted of multi-focal myocardial degeneration, acute-active inflammation, and myocardial necrosis. WKY rats exposed to air only contained no cardiac lesions. These data suggest that zinc has significant inflammatory and procoagulative effects in the lung and heart, and may play a critical role in PM-induced CV effects. # 86 ULTRAFINE PARTICLE (UFP) EFFECTS ON EXPERIMENTAL THROMBOSIS: THE EAR VEIN MODEL.

V. M. Silva, N. Corson, A. Elder, R. Gelein and G. Oberdorster. Environmental Medicine, University of Rochester, Rochester, NY.

Photodynamic excitation of rose bengal (RB) is commonly used to study thrombosis in the femoral vein. It generates singlet oxygen leading to endothelial damage and thrombus formation. Factors affecting this response include plasma RB concentration, time post RB administration and total excitation time. Also, manipulation of the vessel itself can affect RB-induced endothelial responses. We avoided this by adapting the RB-thrombosis model to the rat ear vein. Furthermore, initial experiments were aimed at optimizing RB plasma levels and keep them stable for an extended period of time. The animal was placed on an inverted microscope stage such that ear blood vessels and flow could by visualized. After RB was given, an ear vein was illuminated (532nm, 20mW) for 5 to 120 sec and thrombosis was captured with a digital camera. Animals received either intraperitoneal (ip, 200mg/kg), intravenous (iv, 10mg/kg) or iv infused (24mg/kg/hr) doses of RB in separate experiments. Blood was collected at different times to determine the kinetics of RB concentration up to 2 hrs. Our data indicate that the iv bolus resulted in a plasma RB concentration that decreased rapidly 5 min after injection, while the ip dose caused a continuous increase in plasma even 60 min after RB administration. This change in blood concentration produced by both routes of administration affected RB-induced endothelial damage irreproducibly. In contrast, a steady state RB level of 45ug/ml plasma was reached after 30 min of continuing infusion and a consistent reaction was observed after 10 sec illumination of the ear vein. Administration of iv ultrafine polystyrene particles 30 min after start of the RB infusion shortened the laser exposure time to  $\bar{5}$  sec. This data suggest that continuous iv infusion leads to more consistent plasma RB levels and that UFP can affect endothelial function directly. Furthermore, the advantages of using the ear model include: no manipulation of the vessel; and the availability of several veins on each ear make possible to perform several studies in the same animal.

# TCDD FROM AGENT ORANGE IS CURRENTLY AS ELEVATED IN VIETNAM AS DURING SPRAYING 30-40 YEARS AGO: A CASE STUDY ILLUSTRATING THE PERSISTENCE OF POPS.

A. Schecter<sup>2</sup>, H. T. Quynh<sup>1</sup>, O. Paepke<sup>3</sup>, R. Malisch<sup>4</sup>, J. D. Constable<sup>5</sup>, M. Pavuk<sup>2</sup> and K. Tung<sup>2</sup>. <sup>1</sup>Cancer Research Center, Hanoi, Viet Nam, <sup>2</sup>Environmental Sciences, University of Texas School of Public Health, Dallas, TX, <sup>3</sup>ERGO Research Laboratory, Hamburg, Germany, <sup>4</sup>State Laboratory for Chemical & Veterinary Analysis, Freiburg, Germany and <sup>5</sup>Massachusetts General Hospital, Harvard Medical School, Boston, MA.

The persistence of POPs, persistent organic pollutants, is among their least desirable characteristics. Over 400 pounds of one of the POPs, TCDD, a contaminant of the herbicide Agent Orange, was sprayed in Vietnam between 1962-1971. Between 1970 and 2003, we collected over 3, 200 Vietnam human, food, and environmental samples. In approximately a dozen locations elevated TCDD was

found in southern Vietnamese. In several of these dioxin hot spots, we did extensive sampling of humans, food, and the environment. In 1970 samples, human milk lipid from an Agent Orange sprayed area contained up to 1, 850 ppt of TCDD. The 1970 sampling also found fish TCDD levels as high as 810 ppt, wet weight. Recently, in one hot spot, Bien Hoa city, we found ducks, chickens, one (of 5) fish and one toad to have high TCDD levels, 7-331 ppt wet weight, similar to the 1970 findings. In 1988, we found elevated TCDD in pork, beef, snake and a turtle from a village near Bien Hoa. Typical values in the USA and in Vietnam for fish are currently less than 0.1 ppt wet weight TCDD. Levels in soil from this area, usually less than 1 ppt, were as high as 1, 100, 000 ppt, dry weight. In 2003 we obtained samples of blood and food from two potential dioxin hot spots and compare these data with the earlier findings. The findings of substantially elevated TCDD in humans, food, and the environment for up to 4 decades after initial contamination provides a striking example of the persistence of these compounds.

PBPK MODELED CHANGES IN TCDD BASED ON ESTIMATED COMMUNITY EXPOSURES THROUGH SEAFOOD CONSUMPTION: A CASE STUDY IN PUBLIC HEALTH ASSESSMENT.

D. B. Moffett<sup>1, 2</sup> and H. A. El-Masri<sup>1</sup>, <sup>1</sup>Computational Toxicology Laboratory/Division of Toxicology, CDC/ATSDR, Atlanta, GA and <sup>2</sup>United States Public Health Service, Atlanta, GA. Sponsor: <u>B. Fowler</u>.

Physiologically based pharmacokinetic modeling of data from a hazardous waste site was used to estimate long-term body burden of 2, 3, 7, 8-tetrachlorodibenzo-pdioxin (TCDD) in people who may be eating dioxin contaminated fish/shellfish as part of their diet. PBPK modeled levels of TCDD were estimated after 5-70 years of regular consumption of fish/shellfish from a contaminated estuary. The estimated daily intakes of TCDD from contaminated fish/shellfish consumption were compared to expected daily intake in the average US diet. The impact of replacing fish/shellfish consumption for protein sources containing less TCDD was also examined. For the exposed population, PBPK model simulations were run for a 5 year exposure period and a lifetime 70 year exposure using a consumption rate of 8 fish/shellfish meals per month. The results were 4 parts per trillion (ppt) dioxin in adipose tissue after a simulated 5 year exposure and 19 ppt dioxin in adipose tissue after a simulated 70 year chronic lifetime exposure. The predicted levels for the chronic exposure to dioxin from fish contribution only are higher than the reported average US population fat tissue value from all dioxin sources which ranges between 0.98-15.1 ppt with a mean value of 6.5 ppt. In addition, using the ATSDR Minimal Risk Level (MRL) of 1 pg/kg/day for an oral chronic exposure to dioxin, we obtained a predicted adipose tissue value of 17.5 ppt. A comparison of the modeled case study adipose tissue values and the modeled dioxin MRL adipose tissue value shows the case study results exceed the health based guidance value for chronic exposure but are below the known effect levels. This approach goes beyond traditional health assessment by examining the effects of increased dietary intake of TCDD on body burden to better understand the potential for adverse health effects due to a chronic exposure scenario.

89

THE INFLUENCE OF VARIABLE ELIMINATION RATE AND BODY FAT MASS IN A PBPK MODEL FOR TCDD IN PREDICTING THE SERUM TCDD CONCENTRATIONS FROM VETERANS OF OPERATION RANCH HAND.

C. Emond<sup>2</sup>, M. J. DeVito<sup>1</sup>, L. S. Birnbaum<sup>1</sup> and J. E. Michalek<sup>3</sup>.

<sup>1</sup>ORD/NHEERL/ETD, USEPA, Research Triangle Park, NC, <sup>2</sup>NRC, NAS, Washington, DC and <sup>3</sup>HEDB, AFRL, Brooks City-Base, TX.

Epidemiological and experimental studies suggest that the elimination rate of TCDD is influenced by the body burden and adipose tissue mass. Previous PBPK models for rodent and humans assumed a constant elimination rate. The aims of this study were 1) to compare PBPK models for TCDD that had used either a constant or variable elimination of TCDD and 2) study the influence of adipose tissue mass on the T½ in humans. A PBPK model was developed for TCDD in rats and then extrapolated to humans. This model was described with three diffusion-limited compartments (liver, fat and rest of the body). Ah receptor-mediated induction of CYP1A2 was also described. Parameters used in this model came from the literature. The variable elimination rate was described based on the dose response for induction of CYP1A2. TCDD serum concentrations were determined in over 300 Veterans of Operation Ranch Hand. This cohort was divided in two groups. One was used for the optimization of the model and the other was used for model validation. In an initial analysis, body fat mass was set at 26%. The results suggest that T½ could vary from <6 months in those with high initial body burdens (89 ng/kg)

to over 20 years for those with background body burdens. However, adipose tissue mass also plays a role in the elimination of TCDD. Using the example above, changing the adipose mass to 50%, the  $T^{1/2}$  varies from <1 to 30 years, depending on the body burden. This analysis indicates that the  $T^{1/2}$  of TCDD is dependent upon the body burden and the adipose tissue mass and that a variable elimination rate is critical for accurate model prediction of human exposures. This work aids in understanding the biological mechanisms of the variability for the  $T^{1/2}$  of TCDD in humans. (This abstract does not represent USEPA policy. Funded by in part by a cooperative agreement with NRC and EPA (CR 828790) and an interagency agreement between the US Air Force and EPA (FQ7624-00-YA085)).

SERUM 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) LEVELS AND SLEEP DISORDERS IN US AIR FORCE VETERANS OF THE VIETNAM WAR.

Y. Liu<sup>2, 1</sup>, J. E. Michalek<sup>3</sup> and <u>L. T. Frame</u><sup>1</sup>. <sup>1</sup>Pharmacology and Neuroscience, Texas Tech Health Sciences Center, Lubbock, TX, <sup>2</sup>The Institute of Environmental and Human Health, Texas Tech University, Lubbock, TX and <sup>3</sup>Air Force Research Laboratory, US Air Force, Brooks City-Base, TX.

TCDD is the contaminant of concern in the defoliant, Agent Orange. Recently, TCDD was shown to cause circadian disturbances in rodents, suggesting a mechanistic framework for understanding sleep disorders in TCDD-exposed humans. In this study, data were re-analyzed from an existing cohort study of 953 USAF Vietnam veterans involved in Operation Ranch Hand, exposed to Agent Orange between 1962-1971, and 1278 comparison veterans who were not involved with spraying herbicides. Participants were asked questions regarding sleep problems during an in-person interview in 1992. Exposure was assessed by serum TCDD levels measured in 1987 or 1992 and extrapolated initial serum TCDD levels. A firstorder elimination model assumed a 7.6 year biological half-life. Each veteran was assigned to 1 of 4 exposure categories, which included Comparison and Ranch Hands with background, low, or high exposure to TCDD. Risk ratios of sleep disorders in Ranch Hands relative to Comparisons were estimated by logistic regression. Overall sleep problems were increased among all Ranch Hands (RR = 1.26, 95% CI 1.11, 1.42). Risk of insomnia, as identified by reports of trouble falling asleep, waking up during the night, or waking up early and being unable to go back to sleep, was significantly increased in the High TCDD subgroup (RR=1.30, 95% CI 1.12, 1.51). Adjustment for other covariates did not reduce this estimate (RR = 1.78, 95% CI 1.27, 2.51). A greater proportion of Ranch Hand veterans in the High TCDD subgroup (RR=1.43, 95%CI 1.09, 1.90) complained of waking up unrefreshed as compared with the comparison group. In the adjusted analysis, this estimate was not reduced (RR=1.58, 95%CI 1.13, 2.22) and showed significant TCDD-dose dependence (RR for Ranch Hand Background=1.35, Ranch Hand Low=1.38, Ranch Hand High=1.60). These findings support a link between TCDD exposure and circadian dysregulation.

91

LOW DOSE *IN VIVO* EXPOSURE TO 2, 3, 7, 8
TETRACHLORODIBENZO-P-DIOXIN (TCDD OR
DIOXIN) ALTERS EXPRESSION OF THE CLOCKASSOCIATED PROTEIN, PERIOD, IN THE
SUPRACHIASMATIC NUCLEUS (SCN) AND LIVER OF
C57B6 MICE.

W. Li, R. L. Dickerson and L. T. Frame. Pharmacology and Neuroscience, Texas Tech Health Sciences Center, Lubbock, TX.

Halogenated arylhydrocarbons are present in the environment, bioaccumulate in the food chain, and have biological half-lives that can be measured in years. The most potent member of this class of compounds is TCDD. Low-dose TCDD exposure is associated with a spectrum of adverse health effects in humans, including disorders of sleep, lipid and glucose metabolism, behavior, and endocrine function. This suggests a TCDD-associated global circadian disorder. The master circadian clock is located in the suprachiasmatic nucleus (SCN) of the hypothalamus and drives a network of peripheral circadian clocks in other tissues. Circadian expression of the clock-associated protein, mPER, correlates well with locomotor activity and core body temperature, reaching a peak in the SCN during early subjective night. In this series of experiments, C57B6 mice were used to test the hypothesis that adverse health effects associated with TCDD exposure are linked through a common toxicological mechanism targeting the circadian system. Immunohistochemistry was used to quantify the time-course of expression for the clock-associated protein, mPer1, in SCN slices of corn oil- and TCDD-dosed animals. Western blot analyses were used to monitor the corresponding mPer1 expression in liver. In parallel experiments, surgically-implanted radiotelemetry probes (Mini-Mitter) were used to continuously monitor circadian rhythms of locomotor

activity and core body temperature. Low-dose exposure to TCDD (100ng/kg, i.p.) was associated with rapid and transient phase-shifts in the circadian expression of mPer1 in both the SCN and liver, which was followed within 5-7 days by stable resetting of circadian rhythms. Higher TCDD doses (>100 ng/kg i.p.) were associated with prolonged inhibition and pronounced disturbances in circadian rhythms. These results support the idea that diverse toxicities associated with TCDD exposure are mediated *via* effects on the central biological clock.

92 EFFECT OF 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) ON POSITIVE AND NEGATIVE SELECTION OF T CELLS IN THE THYMUS.

M. Fisher, M. Nagarkatti and P. S. Nagarkatti. Virginia Commonwealth University, Medical College of Virginia Campus, Richmond, VA.

The thymus is highly sensitive to the toxic effects of 2, 3, 7, 8-tetrachlorodibenzop-dioxin (TCDD). The purpose of the thymus is to generate a diverse T cell repertoire capable of MHC-restricted antigen recognition, while eliminating autoreactive T cells (positive and negative selection). In the current study, we investigated whether TCDD alters positive and/or negative selection using the HY-TCR mouse model. These mice bear a transgenic TCR that recognizes the male HY-antigen in the context of MHC class I H-2Db. Thymocytes from male HY-TCR mice (which have the HY-Ag) undergo negative selection, while those from female HY-TCR mice (lacking the HY-Ag) are positively selected. Adult male and female HY-TCR mice were exposed to 10-50  $\mu g/kg$  body weight TCDD. After 48-72 hrs, we measured thymic cellularity, T cell subsets and apoptosis. We found that male HY-TCR mice had greater thymic atrophy following TCDD exposure relative to HY-TCR females. In addition, HY-TCR males exhibit significant changes in T-cell subsets, while HY-TCR females did not. This was due to increased induction of apoptosis in the HY-TCR male thymus following TCDD exposure when compared to HY-TCR females. The difference in apoptosis was specific to immature T cell subsets, suggesting that TCDD induces apoptosis in the thymus in part by increasing the numbers of thymocytes that are negatively selected. Exposure to TCDD also induced the expression of the HY-TCR and MHC class I molecules, suggesting that TCDD might alter the dynamics of thymic selection by increasing the expression of molecules integral to the selection process. Finally, TCDD-induced alterations in Tcell subsets in the HY-TCR males were mirrored in the periphery, so that the effects of TCDD on the thymus may have functional consequences. Together, the current study suggests that TCDD alters the T cell selection process by inducing apoptosis and interfering with the signaling molecules (Supported by NIH grants RO1ES09098, F32ES011732).

IN VIVO MOLECULAR MECHANISMS OF TCDDINDUCED CELL DEATH IN THE THYMUS: EVIDENCE
FOR AHR-DEPENDENT APOPTOSIS VIA ACTIVATION
OF MITOCHONDRIAL AND DEATH-RECEPTOR
PATHWAYS.

I. A. Camacho<sup>1</sup>, M. Nagarkatti<sup>1</sup> and P. S. Nagarkatti<sup>2</sup>. <sup>1</sup>Department of Microbiology and Immunology, Virginia Commonwealth University, Richmond, VA and <sup>2</sup>Department of Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA.

The current study investigated the mechanisms of apoptosis induced by 2, 3, 7, 8tetrachlorodibenzo-p-dioxin (TCDD) in murine thymocytes, particularly addressing the role of AhR. AhR knock-out (KO) mice showed resistance to TCDD-induced thymic atrophy and apoptosis when compared to the wild-type AhR +/+ mice following exposure to 50 µg/kg TCDD. Microarray analysis revealed that TCDD induced the expression of several apoptotic genes including FasL in wildtype but not AhRKO mice. To further address the mechanisms of apoptosis, all experiments were performed in wild-type mice. TCDD treatment increased the expression of FasL on thymic stromal cells at the mRNA and protein level. Upregulated FasL induced by TCDD on Thy 1.2+ thymic stromal cells was able to kill untreated Fas+ Thy 1.1+ thymocytes. However, this effect was absent when TCDD-treated thymic stroma from FasL-defective mice was mixed with wild-type thymocytes or when TCDD-exposed wild-type stromal cells were mixed with Fasdeficient thymocytes. Also, the thymic stromal cell-induced apoptosis was significantly inhibited following addition of anti-FasL Abs to cultures. TCDD treatment in vivo caused cleavage of caspase-8, caspase-9, caspase-10, caspase-3 and Bid in thymocytes. However, Bid KO mice treated with TCDD showed thymic atrophy and susceptibility to TCDD-induced apoptosis, suggesting that Bid was not crucial for TCDD-induced apoptosis. Furthermore, TCDD treatment caused loss of mitochondrial membrane potential, release of cytochrome C and increased Bax protein. Taken together, these studies demonstrate that TCDD-induced apoptosis in thymocytes is regulated through the AhR involving death receptor and mitochondrial pathways, and that thymic stroma plays a critical role in this process. (This work was funded in part by grants from NIH: R01ES09098, R01 AI053703, R01 DA016545, F31ES11562, R21DA014885 and R01HL058641).

94 CHRONIC TOXICITY AND CARCINOGENICITY OF DIOXIN-LIKE COMPOUNDS IN FEMALE HARLAN SPRAGUE-DAWLEY RATS.

N. J. Walker<sup>1</sup>, A. Nyska<sup>1</sup>, C. Alden<sup>1</sup>, A. E. Brix<sup>2</sup>, L. T. Burka<sup>1</sup>, J. R. Hailey<sup>1</sup>, J. K. Haseman<sup>1</sup>, M. R. Hejtmancik<sup>4</sup>, M. P. Jokinen<sup>3</sup>, D. P. Orzech<sup>1</sup>, D. Sells<sup>4</sup>, C. S. Smith<sup>1</sup>, M. E. Wyde<sup>1</sup> and J. R. Bucher<sup>1</sup>. <sup>1</sup>NIEHS, Research Triangle Park, NC, <sup>2</sup>Experimental Pathology Laboratories, Research Triangle Park, NC, <sup>3</sup>Pathology Associates -A Charles River Company, Durham, NC and <sup>4</sup>Battelle Columbus, Columbus, OH.

The dioxin Toxic Equivalency Factor (TEF) methodology has been developed as a mathematical tool to assess the health risk posed by mixtures of structurally related dioxin-like compounds that bind to the aryl hydrocarbon receptor and exhibit biological actions similar to 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD). To address the adequacy of the TEF methodology for predicting the potency of different compounds to induce a variety of chronic responses, we conducted a series of kinetic and 2-year rat toxicity and carcinogenicity studies of dioxin-like compounds. Female Harlan Sprague-Dawley rats were treated by oral gavage five times per week with either TCDD, PCB126, 2, 3, 4, 7, 8-pentachlorodibenzofuran, or a mixture of these for up to 2 years with doses ranging up to 100 ng TCDD equivalents/kg. Interim necropsies were carried out at 14, 31, and 53 weeks. Dose-dependent increases in hepatic CYP1A1 and CYP1A2 activity were observed at all interim time points in all studies. In addition alterations in thyroid hormone homeostasis were observed in all studies. There were significant dose and time dependent increases in the incidence and severity of hepatotoxicity and increased incidences of non-neoplastic effects in multiple organs notably in the lung, adrenal gland, oral mucosa, pancreas, kidney, heart, thymus and thyroid gland. In addition increased incidences of neoplasms in several sites were seen in all studies notably in the liver, lung and oral mucosa. This pattern of neoplastic activity is consistent with a prior 2-year dosed-feed study of TCDD conducted in Spartan Sprague-Dawley rats. Qualitatively these data support one of the key assumptions in the use of the TEF methodology; that individual, and mixtures of dioxin-like compounds have similar site-specificity in terms of potential adverse responses following chronic exposure.

95 HEPATIC GENE EXPRESSION PROFILING OF HAHS AND THE IDENTIFICATION OF NOVEL DIOXIN-RESPONSIVE GENES.

B. J. Ovando<sup>1</sup>, R. J. Foxenberg<sup>1</sup>, <u>C. M. Vezina<sup>2</sup></u> and <u>J. R. Olson<sup>1</sup></u>. <sup>1</sup>Pharmacology and Toxicology, University at Buffalo, Buffalo, NY and <sup>2</sup>Pharmacy, University of Wisconsin, Madison, WI.

Comparative hepatic gene expression profiling was conducted in female Sprague-Dawley rats exposed to dioxin and structurally related halogenated aromatic hydrocarbons (HAHs) in order to better understand mechanisms for the toxicity of this class of agents. Rats were treated for 14 weeks with toxicologically equivalent doses (based on the respective toxic equivalency factors, TEFs) of TCDD (100 ng/kg/day), 2, 3, 4, 7, 8-Pentachlorodibenzofuran (PeCDF; 200 ng/kg/day), 3, 3, 4, 4, 5-Pentachlorobiphenyl (PCB126; 200 ng/kg/day), and the non-AhR ligand 2, 2, 4, 4, 5, 5-hexachlorobiphenyl (PCB153; 1000 ug/kg/day). Hepatic RNA from each animal was subjected to DNA microarray analysis on Affymetrix RGU34A GeneChips. The hepatic gene expression for toxicant-treated animals was compared to control animals and principal components analysis (PCA) was employed to compare the global expression profiles of each toxicant and filtered to identify genes that were differentially regulated by TCDD, PeCDF, and PCB126, but not PCB153. The gene expression profile for the non-AhR ligand PCB153 was substantially different from that of the AhR ligands TCDD, PeCDF, and PCB126, supporting their common receptor-based mechanism of action. Several genes were co-regulated by treatment with the AhR ligands TCDD, PeCDF, and PCB126, including classical AhR target genes and some novel genes such as cell-cell adhesion molecule 4 (CCAM-4) and adenylyl cyclase associated protein 2 (CAP2). Real Time RT-PCR analysis confirmed the dramatic up regulation of CCAM-4 (4-18 fold) and CAP2 (49-169 fold), not only following subchronic exposure to TCDD, but at 24 and 72 hr following a single po dose of 5 ug TCDD/kg. Thus, these novel dioxin-responsive genes are up regulated as initial events and are not secondary to hepatic injury. Together, these finding may help to expand current knowledge of the AhR signaling cascade and its role in the toxicity of these agents. (Supported in part by NIEHS ES09440, SOT, and University at Buffalo).

MOLECULAR STRUCTURE-BASED PREDICTION OF THE STEADY-STATE BLOOD CONCENTRATIONS OF INHALED ORGANICS IN RATS.

M. Beliveau and K. Krishnan. Occupational and Environmental Health, Universite de Montreal, Montreal, QC, Canada.

Environmental exposures to volatile organic chemicals (VOCs) often lead to steady-state condition. The establishment of quantitative relationships between steady-state blood concentrations (SS-BC) and molecular structures of such chemicals can be potentially useful. The objective of this study was therefore to investigate the relationship between the SS-BC in rat and the molecular structures of a series of VOCs that belong to multiple chemical families (alkanes, haloalkanes, haloalkenes and aromatics). The overall approach consisted of developing quantitative relationships between molecular fragments (CH3, CH2, CH, C, C=C, H, Cl, AC, H\_AC) in various alkanes, haloalkanes, haloethylenes, and aromatic hydrocarbons, as well as their SS-BC (per micromolar inhalation exposure) according to an additive model of Gao. This modeling approach implies that each fragment in the structure of a chemical has an additive and constant contribution to its SS-BC. A multilinear regression was performed using a commercially-available statistical software package (SPSS for Windows v10.0.7, SPSS Inc., Chicago, IL), and the results obtained were essentially the contributions associated with each of the nine structural fragments. This molecular structure vs SS-BC relationship was then validated using an external dataset on SS-BC for a series of aliphatic hydrocarbons obtained from the literature (hexane, heptane, octane, nonane, decane, 2-methyl heptane, 2methyl octane, 2-methyl nonane, 1-octene, 1-nonene, and 1-decene; 100 ppm). The ratio of experimental to predicted SS-BC for these chemicals ranged from 0.6 to 1.5. The results of this study suggest that steady-state blood concentrations of inhaled VOCs can be predicted using structure-activity type models.

97 TISSUE DISTRIBUTION OF NUCLEOSIDE TRANSPORTERS IN MALE AND FEMALE RATS AND MICE.

H. Lu, <u>C. Chen</u> and <u>C. Klaassen</u>. *University of Kansas Medical Center, Kansas City, KS* 

Concentrative nucleoside transporters (CNT) and equilibrative nucleoside transporters (ENT) have essential physiological functions and are important in disposition of many anticancer and antiviral nucleoside analogs. Various CNTs and ENTs have different but overlapping substrate specificity; however, knowledge of their tissue distribution in rodents is incomplete. Thus, the purpose of this study was to determine distribution of CNT1, CNT2, CNT3, ENT1, ENT2, and ENT3 mRNA transcripts in 19 tissues (heart, thymus, spleen, brain, pituitary, muscle, kidney, liver, blood vessel, duodenum, jejunum, ileum, large intestine, stomach, lung, testis, prostate, ovary, and uterus) of male and female Sprague-Dawley rats and C57BL/6 mice. The 6 CNT and ENT transcripts were determined using branched DNA signal amplification assay. Expression of CNT1 was highest in small intestine, intermediate in kidney, and lower in testis of both species. CNT2 was also highest in small intestine of rats and mice, intermediate in liver of rats but not mice, and somewhat lower in thymus and spleen of both species. The expression of CNT3 was markedly different in rats and mice; expression was highest in lung of rats, but highest in uterus of mice. ENT1 was highly expressed in testis and lung of both species, as well as liver and pituitary of mice. ENT2 was expressed at high levels in testis and brain of both species. Skeletal muscle expression of ENT2 was moderate in mice and rats, in contrast to the very abundant expression previously reported in humans. ENT3 expression was highest in kidney, followed by testis, in both rats and mice. These studies demonstrate that in general, tissue distribution of CNT and ENT is similar in rats and mice. However, a few differences do exist, such as with CNT2 in liver (high in rats; low in mice), CNT3 in lung (high in rats; low in mice), and ENT1 in pituitary (low in rats; high in mice). Such species differences could be responsible for some species differences in disposition and toxicity of xenobiotics that are substrates for these transporters. (Supported by NIH grants ES-09649 and ES-09716).

98 METABOLISM AND DISPOSITION OF [2-14C]-2-METHYL-1, 3-PROPANEDIOL (MPDIOL® GLYCOL) IN SPRAGUE-DAWLEY RATS FOLLOWING ORAL GAVAGE ADMINISTRATION.

R. J. Boatman<sup>1</sup>, H. B. Lantum<sup>1</sup>, <u>I. C. English</u><sup>1</sup>, M. Thomas<sup>2</sup>, W. D. Faber<sup>4</sup> and <u>M. I. Banton<sup>3</sup></u>. <sup>1</sup>Health and Environment Laboratories, Eastman Kodak Company, Rochester, NY, <sup>2</sup>Lyondell Chemical Company, Maidenhead, United Kingdom, <sup>3</sup>Lyondell Chemical Company, Houston, TX and <sup>4</sup>WFTC, LLC, Victor, NY.

The absorption, distribution, elimination, and metabolic fate of 2-methyl-1, 3-propanediol (MPDiol® Glycol) were determined in female Sprague-Dawley (SD) rats following oral gavage administration of [2-<sup>14</sup>C]-MPDiol® Glycol at either

1000 or 100 mg MPDiol® Glycol/kg. Absorbed radioactivity was eliminated rapidly, with the majority recovered by 12 h as either expired CO2 or in urine (combined urine and cage wash). Total amounts recovered for these two routes of excretion were similar at the high and low dose levels, but the relative proportions for the routes differed. At 1000 mg/kg, radioactivity in urine and expired CO2 accounted for 45.4% and 42.0%, respectively, of the administered dose; whereas at 100 mg/kg, the respective values were 31.3% and 57.5%. Only about 1% of the administered radioactivity was recovered in feces and 5% was present in combined tissues and carcasses. A total of 93.1% and 95.3% of the administered radioactivity was recovered from the 1000 and 100 mg/kg exposure groups, respectively, by 7 d. Based on residual radioactivity remaining in the body at each sampling point, the half-lives for the elimination of [2-<sup>14</sup>C]-MPDiol® Glycol from rats were calculated to be 3.57 h and 3.88 h, respectively, at the 1000 and 100 mg/kg dose levels. HPLC analysis of urine metabolites indicated the majority of the radioactivity was associated with two components. After conversion to the trimethylsilyl derivatives and GC/MS analysis, these were identified as 3-hydroxyisobutyric acid (3-HIBA) and unchanged MPDiol® Glycol. Stereospecific analysis by GC/MS of the 3-HIBA metabolite indicated the predominant urinary stereoisomer to be the (R)-(-)-enantiomer. It is proposed that MPDiol® Glycol may undergo metabolism in the rat predominantly by the pathway responsible for valine metabolism.

PAT MULTIDRUG RESISTANCE PROTEIN 4:
MOLECULAR CLONING AND CHARACTERIZATION
OF REGULATION.

C. Chen, A. L. Slitt, M. Z. Dieter and C. D. Klaassen. University of Kansas Medical Center, Kansas City, KS.

Multidrug resistance protein 4 (MRP4/ABCC4) belongs to a group of primary active transporters for organic anions. Human MRP4 has been cloned and shown to transport many chemicals, such as dehydroepiandrosterone-3-sulfate, cAMP/cGMP, methotrexate and antiviral nucleoside analogs. However, information on MRP4 regulation is limited. The aim of this study was to clone rat Mrp4 and characterize its expression under various conditions at mRNA and/or protein levels by branched DNA and immunoblot analyses, respectively. The deduced amino acid sequence of cloned rat Mrp4 cDNA had 1325 amino acids and was 83% identical to human MRP4. In Sprague-Dawley (SD) rats, Mrp4 mRNA was detected in a number of tissues examined: kidney and gonads had the highest levels, whereas the expression in liver was the lowest. Mrp4 expression in kidney was higher in males than females, and was low at birth but steadily increased between 20 to 30 days of age. Mrp4 expression in liver and kidney was not consistently inducible by prototypical Ah receptor ligands, CAR activators, PXR ligands, PPAR? ligands, EpRE activators, or CYP2E1 inducers. Mrp4 mRNA levels in kidney of transport-deficient (TR-) rats that lack Mrp2, were 100% higher than those in normal Wistar rats. Similarly, a 2-fold increase in Mrp4 protein was also seen in kidney of the mutant rats as compared to the normal rats. Furthermore, in kidney, the levels of Mrp4 transcript, but not protein, were increased up to 100% 1 and 3 days after bile-duct ligation in SD rats. In conclusion, the cloned rat Mrp4 encodes a protein that is orthologous to human MRP4. Mrp4 renal expression exhibits gender-specific and developmental patterns. Although Mrp4 is not readily induced by xenobiotics, its relative abundance in kidney, together with its up-regulation in kidney of TR- rats, suggests that Mrp4 is an important transporter for the urinary excretion of organic anions, and may be regulated by endogenous substrates for Mrp2. (Supported by NIH grants ES-09716 and ES-07079)

### 100 DISPOSITION AND METABOLISM OF 1-BROMOPROPANE IN RATS.

<u>C. Garner</u>, J. Davis, J. Burgess, Y. Yeuh, A. Jeffcoat, <u>T. Fennel</u> and J. Mathews. Drug Metabolism/Pharmacokinetics, RTI, Research Triangle Park, NC.

Experiments were conducted to determine the effect of dose on the disposition and metabolism of 1 [14C]bromopropane (1-BrP) in F-344 rats. Male rats were administered iv doses of 1-BrP at 5, 20, and 100 mg/kg and radiochemical content of expired breath volatiles (VOC), expired CO2, urine, feces, and selected tissues was measured. By 48 hours post dose, radioactivity in VOC accounted for ca. 25, 31, and 60% of administered dose at 5, 20, and 100 mg/kg, respectively. Radioactivity expired as 14CO2 was 28, 31, and 8% of those same doses. Urinary radioactivity was 17, 19, and 11% of recovered radioactivity. Excretion in feces was negligible. Radioactivity recovered in tissues accounted for 11, 11, and 2% of administered dose for the respective levels. The molar ratio of 14CO2 to bromide released decreased as dose increased, suggesting that the proportion of 1-BrP metabolized *via* oxidation relative to conjugative pathways is dose dependent. This was supported by a similar pattern in the ratios of CO2 to total metabolized dose. At 20 mg/kg

ca.17% of the administered radioactivity was excreted in urine, distributed between 10 metabolites. Two separate groups of 4 rats were pretreated with either buthionine sulfoximine (BSO), an inhibitor of GSH synthesis or with 1-aminobenzotriazole (ABT), a potent general P450 suicide inhibitor, prior to receiving an iv dose of 1-BrP (20 mg/kg). Relative to controls, ABT pretreatment resulted in profound changes in the proportion of radioactivity appearing in urine (-40%), VOCs (+45%), and CO2 (-80%). BSO pretreatment had no effect. Following inhibitor of oxidative metabolism with ABT, urine metabolites were reduced to a single metabolite, N-acetyl-(propyl)-S-cysteine which accounted for >90% of total radioactivity. Overall, the data suggest that oxidation by P450 plays a dominant role in 1-BrP metabolism and disposition, but diminishes as dose decreases.

### 101 COMPARATIVE DISPOSITION OF 2-METHYL-TETRAHYDROFURAN (MTHF) IN MALE F344 RATS AND B6C3F1 MICE.

R. F. Henderson, M. W. Gurule, J. D. McDonald, D. A. Kracko, B. M. Hedtke, K. Ghanbari and K. J. Dix. Lovelace Respiratory Research Institute, Albuquerque, NM.

MTHF is a component of P-series fuels and is used as a specialty solvent and reactant. Little information on MTHF metabolism and disposition is available in the literature. We report in vivo studies of MTHF disposition in rodents. Rates and routes of excretion, tissue distribution, and metabolism of MTHF were assessed after oral exposure of rats and mice to  $[^{14}C]MTHF$  (1, 10, and 100 mg/kg). In rats, pulmonary excretion in the form of  $^{14}CO_2$  was the major route of elimination (40) to 56%) and was inversely related to dose. This was followed by urinary excretion (ca. 24%), which was independent of dose. Recovery of radioactivity as exhaled volatile organics increased 28-fold with dose. The major compound in the exhaled breath at the high dose was identified by LC/MS/MS as the parent compound. This suggests a possible saturation of one or more metabolic pathways. Clearance of the administered dose was rapid, with approximately 80% of the dose excreted within 12 hours at all doses. In mice, urinary excretion was the major route of elimination (ca. 65-70%) followed by  $^{14}CO_2$  (ca. 35%) and volatile organics. As with the rats, there was a large (at least a 17-fold) increase in the amount of radiolabel recovered as volatile organics at the high dose compared to the low dose. Excretion was rapid, with over 90% of all doses excreted within 12 hr. Fecal excretion was greater for the high relative to lower doses in both species, and terminal tissue burdens were 7% to 21%. All data collected to date are consistent with saturation of one or more processes at the high dose. (Supported by the National Institute of Environmental Health Sciences, Contract No. N01-ES-25483.)

# 102 EFFECT OF NASAL ADMINISTRATION OF NICOTINE ON THE BRAIN DELIVERY THROUGH THE OLFACTORY BULBS IN RATS.

<u>H. J. Kim</u><sup>1</sup>, S. H. Chang<sup>2</sup> and H. S. Kim<sup>2</sup>. <sup>1</sup>Preventive Medicine, Daegu Haany University, Daegu, South Korea and <sup>2</sup>Preventive Medicine, Keunkook University, Chungju, South Korea.

Previously we have demonstrated that nasal administration of ganciclovir, a nucleoside analogue with antiviral activity, enhances brain delivery through the olfactory bulbs. In this study we explored the possibility of intranasal (in) administration of nicotine to provide an enhanced access to the brain through the olfactory pathway by determining the extent of systemic absorption and uptake of [3H]- nicotine in the brain after intravenous (iv) or in administration. Male CD rats were given 20  $\mu$ Ci/kg [<sup>3</sup>H]- nicotine by *iv* or *in* administration into the right nostril. Serial plasma samples were collected over 60 min and total radioactivities were analyzed. Olfactory bulbs, cerebrum, midbrain and cerebellum were also collected at 15 and 60 min post-dosing and analyzed. Nicotine was absorbed rapidly from the nasal cavity; peak radioactivity was reached within 2 min after in dosing. The absolute bioavailability of intranasally administered nicotine was close up to 1. The uptake of nicotine total radioactivity into the cerebrum, midbrain, and cerebellum did not show any significant difference after iv or in dosing and between left and right sides. The uptake into the right olfactory bulb reveals a statistically significant difference at 60 min post-dosing; 784 cpm (iv, mean) and 1364 cpm (in, mean), whereas the uptake into the left olfactory bulb was 1039 cpm (iv) and 1082 cpm (in), respectively. Also, 37% increase of nicotine uptake into the right olfactory bulb was observed 15 min after in dosing. In summary, we have demonstrated that the brain delivery of nicotine through the olfactory pathway was not dramatic in the same manner as ganciclovir. However, 34-37% increase of uptake into the right olfactory bulb by in administration implys that small quantity of nicotine may transport into the brain through the olfactory bulbs. Furthermore, nicotine was well absorbed through the nasal epithelium and transported into systemic circulation.

# 103 PRELIMINARY TOXICOKINETIC STUDY AND BIOLOGICAL SAMPLE ANALYSIS METHOD DEVELOPMENT/VALIDATION FOR DICHLOROACETIC ACID.

J. D. Johnson<sup>1</sup>, S. W. Graves<sup>1</sup>, D. Emmerling<sup>1</sup>, B. Burback<sup>1</sup>, J. Merrill<sup>1</sup> and <u>C. Smith<sup>2</sup>. <sup>1</sup>Toxicology, Battelle, Columbus, OH and <sup>2</sup>NIEHS, NIH, Research Triangle Park, NC.</u>

Dichloroacetic acid (DCA) has been detected in drinking water as a result of chlorine disinfection and is a hepatocarcinogen in rodents. A method utilizing derivatization of DCA followed by gas chromatography with electron capture detection was developed and validated for use in rodent plasma. Male F344 rats and female B6C3F1 mice were given a single intravenous (IV) administration at doses of 40 (R) and 100 (M) mg/kg or a single gavage administration at doses of 10 or 100 (R) and 20 or 200 (M) mg/kg. Dosing volumes were 2 (R) and 4 (M) mL/kg for IV and 5 (R) and 10 (M) mL/kg for gavage. Serial blood samples were collected after dosing and analyzed by the validated method. Analytical standards were prepared (range 0.1 to 20 ug/mL in plasma). A quadratic regression equation weighted 1/y2 was calculated, thereby relating the response (y) to the concentration (x) of the standards. The concentration of each sample was calculated using its individual response and the regression equation. IV plasma concentration time profiles were monophasic. For the rats, the Cmax, ke, and AUCinf were 91 ug/mL, 0.05 min-1, and 2650 min.ug/mL and, for the mice, were 122 ug/mL, 0.12 min-1, and 1900 min.ug/mL, respectively. Following gavage administration, the Cmax, Tmax, ke, and AUCinf values were 0.4 ug/mL, 20 min, 0.03 min-1, and 21 min.ug/mL at 10 mg/kg (R); 53 ug/mL, 90 min, 0.004 min-1, and 15, 600 min.ug/mL at 100 mg/kg (R); 2.5 ug/mL, 5 min, 0.20 min-1, and 18 min.ug/mL at 20 mg/kg (M); and 67 ug/mL, 10 min, 0.10 min-1, and 1, 030 min.ug/mL at 200 mg/kg (M). The results from this preliminary study provided the information necessary to design a definitive toxicokinetic study for DCA.

# 104 EFFECT OF DIFFERENT DOSING PARADIGMS ON THE BODY BURDEN OF CHLORPYRIFOS (CPF) IN NEONATAL SPRAGUE-DAWLEY RATS.

J. Y. Domoradzki<sup>1</sup>, M. S. Marty<sup>1</sup>, S. C. Hansen<sup>1</sup>, C. Timchalk<sup>2</sup> and J. L. Mattsson<sup>3</sup>. <sup>1</sup>The Dow Chemical Co., Midland, MI, <sup>2</sup>Battelle, Richland, WA and <sup>3</sup>Dow AgroSciences, LLC, Indianapolis, IN.

In some circumstances direct neonatal dosing has been recommended in EPA developmental neurotoxicity studies; however, there is a paucity of data on neonatal systemic exposure using different dosing paradigms. Male rats at postnatal day 5 were dosed with CPF (1 mg/kg) using different routes of exposure, or vehicles, and by single vs. divided dose. Blood concentrations of CPF and trichloropyridinol (TCP) were measured at multiple times through 24 h. Groups included: bolus vs. divided gavage doses in corn oil (3 times in 24 h), bolus vs. divided gavage doses in rat milk, and single sc injection in DMSO. Data were compared with lactational exposure of pups from dams exposed to CPF in the diet (5 mg/kg/day). In dams, blood CPF was 2-4 ng/g (limit of detection, 1 ng/g). In a published study, 5 mg/kg by gavage in corn oil resulted in maternal blood CPF levels of ~14 ng/g. CPF was not detected in blood of nursing pups from dietary maternal exposure while TCP blood concentrations ranged from 49-71 ng/g. In dams, TCP ranged from 281-1263 ng/g. In pup direct-dosing paradigms, the concentration of CPF in blood was non-quantifiable or usually <10 ng/g. Peak blood concentrations of TCP were 320, 112, 195, 100 and 171 ng/g for the bolus and divided corn oil, bolus and divided milk, and the sc DMSO groups, respectively. With all direct-dosing paradigms, higher blood levels of CPF and TCP were reached than blood levels in neonates exposed to CPF via nursing. With respect to vehicle, corn oil yielded higher peak TCP levels than milk, particularly with bolus dosing, and resulted in higher systemic exposure to CPF. Divided doses yielded lower peak TCP blood levels than a single dose. Contrary to expectations, sc injection of CPF in DMSO did not result in rapid and complete absorption. To be meaningful for risk assessment, neonatal studies require attention to the exposure scenario, since route, vehicle and frequency of administration result in different systemic exposure to a chemical and its metabolites.

# MORE RENAL AND LESS INTESTINAL ADDUCTION BY THE NSAID DICLOFENAC IN MRP2-DEFICIENT RATS.

M. Treinen-Moslen<sup>1</sup>, L. Kaphalia<sup>1</sup>, L. Lemley<sup>1</sup>, B. A. Rampy<sup>1</sup>, <u>C. R. Atchison<sup>2</sup></u> and <u>M. F. Kanz<sup>1</sup></u>. <sup>1</sup>Pathology, University of Texas Medical Branch, Galveston, TX and <sup>2</sup>HQ's USAMRMC, Fort Detrick, MD.

**Background:** Diclofenac and many of its structurally related carboxylic acid NSAIDs are converted to acyl glucuronide with sufficient electrophilic reactivity to form adducts with proteins in multiple tissues. When compared to the responses of

wild-type animals to diclofenac treatment, rats with a genetic deficiency in the hepatic canalicular MRP2 exporter have been found to show several pronounced differences in response, notably a marked decreases in biliary secreting of the acyl glucuronide metabolite with faster urinary clearance, less enteropathy, and less adduction of liver proteins. Goal and Approach: Experiments addressed unknowns about the influence of MRP2-deficiency on the fate of diclofenac using a well characterized antibody that recognizes drug-protein adducts as a biomarker of tissue exposure to reactive diclofenae entities. Specifically, we hypothesized less adduction of intestine and more adduction of kidney. MRP2- deficient TR -rats and wild type Sprague-Dawley were treated with diclofenac, 50 mg/kg orally. Blood and urine were collected for biochemical indices of renal dysfunction. Tissues were collected for histopathology and adduct characterization chiefly the semi-stable acyl glucuronide metabolite. Results: Consistent with their known impairment in biliary secretion of diclofenac acyl glucuronides, MRP2- deficient animals showed more intense adduction of the kidney with meager adduction in the biliary tract and intestine as well as greatly reduced enteropathy. However after drug treatment, wild type but not MRP2-deficient rats had mild kidney-dysfunction associated changes in serum Na, K, BUN and in urine K, glucose and uric acid. Conclusion: This is the first observation of more prominent adduction by an NSAID known to form reactive acyl glucuronides in the kidney of MRP2-deficient rats. # COMPARISON OF PARTITION COEFFICIENTS FOR A MIXTURE OF VOLATILE ORGANIC COMPOUNDS IN RATS AND HUMANS AT DIFFERENT LIFE STAGES.

D. A. Mahle<sup>1</sup>, C. C. Grigsby<sup>2</sup>, R. J. Godfrey<sup>1</sup>, J. M. Gearhart<sup>1</sup>, H. A. Barton<sup>3</sup>, J. C. Lipscomb<sup>4</sup> and R. S. Cook<sup>2</sup>. <sup>1</sup>ManTech Environmental Technology, Inc., Wright-Patterson AFB, OH, <sup>2</sup>AFRL/HEST, Wright-Patterson AFB, OH, <sup>3</sup>USEPA/ORD/NHEERL, Research Triangle Park, NC and <sup>4</sup>USEPA/ORD/NCEA, Cincinnati. OH.

Pharmacokinetic differences in child, adult and elderly populations remain ill-defined. Partition coefficients (PC) are an integral component of pharmacokinetic models, and determining differences in tissue partitioning of volatile organic chemicals across life stages can help reduce the uncertainty in risk assessment. Control male adult and aged (18 month) Sprague-Dawley (S-D) rats (n = 10) and control male and female S-D pups (n = 10 litters) at postnatal day 10 were sacrificed, and blood, liver, kidney, fat, muscle and brain were taken. Unused blood from male and female human pediatric and adult patients was collected for determination of agespecific PC. PC for methylene chloride, methyl ethyl ketone, chloroform, benzene, trichloroethylene and perchloroethylene were determined using a vial headspace equilibration method and analysis by gas chromatography. Human adult and pediatric blood:air PC were similar regardless of sex. Values for the solvents ranged from  $7.6 \pm 2.3$  (adult female, benzene) to  $192.7 \pm 6.0$  (pediatric male, methyl ethyl ketone). Liver:air methylene chloride PC for adult male rats averaged 20.4 ± 4.8 compared to 12.7 ± 1.0 for male rat pups. By quantifying the pharmacokinetic variances in PC for young, adult and elderly populations, biologically based models can be improved to reduce uncertainties in risk assessment.

## 107 ETHANOL PHARMACOKINETICS ARE ALTERED BY PREGNANCY AND CALORIC INTAKE IN FEMALE RATS.

M. HIdestrand<sup>1</sup>, <u>K. Shankar</u><sup>1</sup>, L. Humphrey<sup>2</sup>, R. Haley<sup>2</sup>, M. Zipperman<sup>2</sup>, <u>T. M. Badger<sup>3, 2</sup></u> and <u>W. D. McGuinn<sup>4</sup></u>. <sup>1</sup>Pharmacology & Toxicology, University of Arkansas for Med. Sciences, Little Rock, AR, <sup>2</sup>Arkansas Children's Nutrition Center, Arkansas Children's Hospital, Little Rock, AR, <sup>3</sup>Physiology, University of Arkansas for Med. Sciences, Little Rock, AR and <sup>4</sup>NA, Columbia, MD.

We have previously shown that the when ethanol is infused into rats intragastrically as part of a system of total enteral nutrition (TEN), blood and urine ethanol concentrations (BECs and UECs) do not achieve steady state but instead pulse from almost 0 to over 500 mg/dl every 6-7 d. During pregnancy the amplitude of the UEC pulses is significantly reduced in rats fed optimal levels of calories and the pregnancy effect is abolished by under nutrition. In the current study, we examined the pharmacokinetics of ethanol clearance in these animals. BECs were followed in chow fed 300 g pregnant and virgin rats following a single oral gavage of 3 g/kg ethanol at gestational day (GD) 8, 13 and 20. In each case, the area under the BEC time curve was reduced by the same amount in the pregnant animals (p<0.05). In a second experiment, pharmacokinetics of ethanol clearance was followed in chow fed pregnant rats at GD 13 and weight matched cycling rats following a single oral gavage of 3 g/kg or an IV bolus of 0.75 g/kg. Initial non-compartmental estimates of clearance and t1/2 were 0.014 vs 0.011 L/kg/min and 58 and 68 minutes for pregnant vs cycling rats respectively after an IV dose. For gavaged rats, these values were 0.023 vs 0.010 L/kg/min and 46 vs 100 min for pregnant vs cycling rats. Area under the BEC time curves was lower for pregnant rats administered ethanol by either route (p<0.05) but the pregnancy effect was significantly greater when ethanol was administered orally suggesting the involvement of a first pass component in addition to increased hepatic clearance. Caloric restriction in pregnant rats fed TEN diets at 220 or 154 kcal/kg3/4/d resulted in reduced ethanol clearance at GD13 when ethanol was administered either orally or IV (p<0.05). Thus pregnancy accelerates ethanol clearance and this effect is impaired by under nutrition. Supported in part by AA12819 (M.R.)

### 108 DOSE-DEPENDENCY OF ASPIRIN-TRICHLOROETHYLENE INTERACTION.

K. Kim, S. Muralidhara, S. Lee and J. Bruckner. Department of Pharmaceutical and Biomedical Sciences, The University of Georgia, Athens, GA.

1, 1, 2-Tricholoethylene (TCE), a rodent carcinogen and potential human cancer risk, is metabolically activated by cytochrome P450 2E1 (CYP2E1) to chloral hydrate (CH), trichloroacetic acid (TCA), dichloroacetic acid (DCA) and trichloroethanol (TOH). Acetylsalicylic acid (ASA) has been previously reported to enhance hepatic CYP2E1 activity. The therapeutic dose for analgesic and antipyretic effects of ASA is 325 mg ~ 1.0 g orally every 3 or 4 h for adults. The current study was conducted to: 1) characterize the dose- and time-dependency of CYP2E1 induction in rats by ASA, and 2) learn whether the significant induction of CYP2E1 would affect the metabolism of high and low doses of TCE differently. Groups of control and ASA (450 mg/kg bw)-treated male Sprague-Dawley rats of about 150 g were gavaged with one of a graded series of oral TCE doses 12 h after ASA treatment, the time of peak CYP2E1 induction by the drug. CH, TCA, DCA and TOH blood levels were monitored over time by headspace gas chromatography. The time-course profiles revealed that ASA markedly enhanced the metabolism of high doses of TCE, but had relatively little influence on lower, more environmentally-relevant doses. (Supported by DOE: DE-FC02-02CH11109)

## 109 BIO-DISTRIBUTION OF BISPHENOL A IN THE NEUROENDOCRINE ORGANS OF FEMALE RATS.

H. M. Luu<sup>2</sup>, W. Johnson<sup>1</sup>, J. C. Hutter<sup>2</sup>, C. S. Kim<sup>1</sup>, I. A. Ross<sup>1</sup> and P. P. Sapienza<sup>1</sup>. <sup>1</sup> Toxicology, US Food and Drug Administration, Laurel, MD and <sup>2</sup>Radiological Health, USFDA, Rockville, MD.

The bio-distribution of 14C Bisphenol A (BPA) in plasma and neuroendocrine organs was determined in the Fischer 344 female rats following three oral doses (0.1, 10, or 100 mg/kg). The distribution and pharmacokinetics between the plasma and neuroendocrine organs were compared. Within 25 minutes of dosing, the maximum concentrations of 14C- BPA were found to be 16.99 ?g/ml in plasma, 14.73 ?g/g in pituitary, 8.73 ?g/g in uterus/gonads, 6.96 ?g/g in hypothalamus and 7.12 2g/g in the rest of the brain at 48 h after 100 mg/kg dose, respectively. Plasma areasunder-the-curve (AUC) were found to increase with dose levels (0.06, 5.37, and 53.83 ?g-hr/ml at 48 h after 0.1, 10 or 100 mg/kg dose, respectively). However the AUCs of the pituitary gland and uterus/gonads were 16-21 % higher than that of plasma at 48 h after 100 mg/kg dose. The AUCs of hypothalamus and the rest of the brain were 43.7 % and 77% of the plasma AUCs, respectively. In the brain tissue, the exposure increased linearly with the oral dose, as the dose was increased from  $0.1\ \text{to}\ 10$  and  $100\ \text{mg/kg}$ ; the exposure in the brain relative to the plasma increased by factors of 1, 1.19 and 1.24. The increases of the uterus/gonads relative to the plasma were 1, 1.07 and 1.04. This indicates that the brain barrier systems do not limit the access of lipophillic BPA to the brain.

# 110 PRELIMINARY TOXICOKINETIC STUDY AND BIOLOGICAL SAMPLE ANALYSIS METHOD DEVELOPMENT/VALIDATION FOR 2-METHYLTETRAHYDROFURAN.

B. L. Burback<sup>1</sup>, <u>L. Fomby</u><sup>1</sup>, B. Harritos<sup>1</sup>, G. W. Steven<sup>1</sup> and <u>S. S. Cynthia<sup>2,3</sup></u>.

<sup>1</sup> Battelle Memorial Institute, Columbus, OH, <sup>2</sup>NIH, Research Triangle Park, NC and <sup>3</sup>NIEHS, Research Triangle Park, NC.

2-Methyltetrahydrofuran (MTHF) is a component of novel P-series alternative fuels and is being evaluated in toxicological studies. Methods utilizing a heated headspace gas chromatography with selected ion monitoring (SIM) mass spectroscopy for low concentration range and flame ionization detection for high concentration range were developed and validated for use in rodent plasma and brain tissue. Biological samples for validating the method were obtained by conducting a preliminary toxicokinetic study with male and female F344 rats and B6C3F1 mice given a single intravenous or gavage administration of MTHF and collecting samples at specified time points (one animal/species/sex/dosage level). Untreated animals were used to obtain samples for preparing matrix matched plasma or brain samples. Analytical standards were prepared (range 4.3 to 860 ng/mL in plasma for

the low concentration range and 0.645 ug/mL in plasma or for the high concentration range). A quadratic regression equation weighted 1/x was calculated relating the response (y) to the concentration (x) of the standards. The concentration of each sample was calculated using its individual response and the regression equation. Following a single intravenous dosage of 40 mg/kg, the maximum plasma and brain concentrations were similar between species and were approximately 29, 000 ng/mL and 24, 000 ng/g, respectively. After a single gavage dosage (400 mg/kg), the maximum plasma and brain concentrations in rats were approximately 269, 000 ng/mL and 334, 000 ng/g, respectively. Maximum plasma and brain concentrations in mice after gavage administration of 400 mg/kg were approximately 207, 000 ng/mL and 222, 000 ng/g, respectively. The validation of an analytical method for MTHF together with the preliminary toxicokinetic study results will be used to design a definitive toxicokinetic study in order to determine toxicokinetic parameters after MTHF administration.

DISPOSITION OF
DODECAMETHYLCYCLOHEXASILOXANE (D6) IN
FISCHER 344 RATS FOLLOWING A SINGLE ORAL

K. P. Plotzke, J. Durham, M. L. Jovanovic and J. M. Regan. Dow Corning Corporation, Midland, MI.

The disposition of  $^{14}\text{C-D6}$  was evaluated in male and female F344 rats following a single oral administration of 1000 mg of  $^{14}\text{C-D6}$  in corn oil/kg of body weight. Animals (N=4/sex) were housed in glass metabolism cages for collection of excreta and expired volatiles. At 168 hr post-dose, animals were sacrificed and selected tissues and remaining carcasses were collected. All samples were analyzed for radioactivity content. Feces and expired volatiles were also analyzed for parent D6 concentration. A separate group of animals, cannulated via the jugular vein, (N=6/sex) was used to determine radioactivity and parent D6 concentration in blood at predetermined time points. Whole-body autoradiography (WBA) was used for qualitative in vivo assessment of tissue distribution of radioactivity. The majority of administered radioactivity (>80%), regardless of sex, was eliminated in the feces. Total absorption (radioactivity recovered in urine, expired volatiles, expired CO2, tissues and carcass) in males and females was 11.88% and 11.83%, respectively. Both sexes showed similar patterns of disposition (Urine: 0.38% and 0.32%; Expired volatiles: 11.20% and 11.21%; Expired CO2: 0.13% and 0.09%; Tissues: 0.03% and 0.04%; Carcass: 0.14% and 0.17% for males and females, respectively). The entire radioactivity in the expired volatiles was attributed to parent D6. Metabolic profile evaluation showed that the entire radioactivity in the urine consisted of polar metabolites, whereas in the feces the majority was parent D6 with a trace of nonpolar metabolite. The WBA data also showed that the majority of D6 remained in the GI tract and was excreted in feces within 48 hr. Low levels of radioactivity were systemically available and distributed to organs and tissues such as liver, brown fat and bone marrow. Statistical analysis of the blood curves indicated the presence of small levels of metabolites in the blood (approximately 117  $_{\mu}g$  equivalent D6\*hr/g of blood). In summary, approximately 12% of  $^{14}C$ -D6 delivered in corn oil approximately 12% of  $^{14}C$ -D6 delivered in corn oil approximately 12% of  $^{14}C$ -D6 delivered in corn oil approximately 12% of  $^{14}C$ -D6 delivered in corn oil approximately 12% of  $^{14}C$ -D6 delivered in corn oil approximately 12% of  $^{14}C$ -D6 delivered in corn oil approximately 12% of  $^{14}C$ -D6 delivered in corn oil approximately 12% of  $^{14}C$ -D6 delivered in corn oil approximately 12% of  $^{14}C$ -D6 delivered in corn oil approximately 12% of  $^{14}C$ -D6 delivered in corn oil approximately 12% of  $^{14}C$ -D6 delivered in corn oil approximately 12% of  $^{14}C$ -D6 delivered in corn oil approximately 12% of  $^{14}C$ -D6 delivered in corn oil approximately 12% of  $^{14}C$ -D6 delivered in corn oil approximately 12% of  $^{14}C$ -D6 delivered in corn oil approximately 12% of  $^{14}C$ -D7 delivered in corn oil approximately 12% of  $^{14}C$ -D7 delivered in corn oil approximately 12% of  $^{14}C$ -D7 delivered in corn oil approximately 12% of  $^{14}C$ -D7 delivered in corn oil approximately 12% of  $^{14}C$ -D7 delivered in corn oil approximately 12% of  $^{14}C$ -D7 delivered in corn oil approximately 12% of  $^{14}C$ -D7 delivered in corn oil approximately 12% of  $^{14}C$ -D7 delivered in corn oil approximately 12% of  $^{14}C$ -D7 delivered in corn oil approximately 12% of  $^{14}C$ -D7 delivered in corn oil approximately 12% of  $^{14}C$ -D7 delivered in corn oil approximately 12% of  $^{14}C$ -D7 delivered in corn oil approximately 12% of  $^{14}C$ -D7 delivered in corn oil approximately 12% of  $^{14}C$ -D7 delivered in corn oil approximately 12% oil approximat peared to be absorbed after a single oral administration to F344 rats.

# PHARMACOKINETIC INTERACTION BETWEEN BUPRENORPHINE AND DESMETHYLFLUNITRAZEPAM IN RATS.

S. Pirnay<sup>1, 2</sup>, B. Megarbane<sup>2</sup>, S. Bouchonnet<sup>3</sup>, C. Monier<sup>2</sup>, P. Risede<sup>2</sup>, I. Ricordel<sup>1</sup> and <u>F. J. Baud</u><sup>2</sup>. <sup>1</sup>Laboratoire de Toxicologie de la Prefecture de Police, Paris, France, <sup>2</sup>INSERM U26, Hopital Fernand Widal, Paris, France and <sup>3</sup>DCMR, Ecole Polytechnique, Palaiseau, France.

Recently, a retrospective study reported fatalities linked to buprenorphine (BUP), in France from June 1997 to June 2002 (1). It showed evidence that buprenorphine is misused and administered by the intravenous route. Our in vivo experimental studies using a high dose of BUP and flunitrazepam (FNZ) confirmed significant respiratory depression, only when co-administered (2). The objective is to determine if the reported toxicity of FNZ with BUP is caused by a pharmacokinetic interaction. The study was realized on Sprague-Dawley male rats (Iffa-Credo, France). The day before the study, animals were intraperitoneally anesthetized with ketamine (70 mg/kg) and xylazine (10 mg/kg) and catheterized in the femoral vein (for administration of drugs) and artery (for collecting blood). Drugs plasma kinetics were performed in two groups (control group receiving the BUP solvent then FNZ 40mg/kg, study group receiving BUP 30 mg/kg then FNZ 40 mg/kg). FNZ and metabolites (desmethylflunitrazepam (DMFNZ) and 7-aminoflunitrazepam (7AMF)) dosages were performed by GC-MS (Agilent 5973). There was no statistically significant effect of BUP pretreatment on FNZ and 7AMF kinetic parameters. However, this study shows clearly, that concentrations, and AUC of  $\dot{D}MFNZ$  are significantly doubled (p=0.05), when BUP is associated. There is no pharmacokinetic interaction of BUP (30 mg/kg) on plasma kinetics of FNZ, but a significant

interaction of BUP (30 mg/kg) on DMFNZ concentrations. The pharmacokinetic interaction process is unknown yet, but may be related either to the distribution or the elimination of DMFNZ. 1. Pirnay S, Tourneau J, Ricordel I. Death associated to treatments of substitution. Retrospective study of 1600 postmortem toxicological cases. Le courrier des addictions. 2002;4:156-158. 2. ### 113 DETERMINATION AND QUANTITATION OF ANTHRAQUINONE URINARY METABOLITES.

S. Graves<sup>1</sup>, S. Runyon<sup>1</sup> and C. S. Smith<sup>2</sup>. <sup>1</sup>Toxicology Columbus, Battelle, Columbus, OH and <sup>2</sup>NIEHS, NIH, Research Triangle Park, NC. Sponsor: M. Hejtmancik.

A metabolism study was conducted using male Fischer 344 rats in which they were fed formulations of 4 lots of anthraquinone, produced by three different synthetic routes, with concentrations of 938, 3750 and 7500 ppm and a control diet containing no anthraquinone in irradiated NTP 2000 feed for seven consecutive days. One of the lots had been previously used to conduct subchronic and chronic rodent toxicity studies in feed. Ten animals were used per group. The formulations were prepared using anthraquinone with particle sizes smaller than 80 mesh and consistent in distribution for each lot. All animals were placed in individual metabolism cages following dosing and urine was collected for 24 hours. The urine of all animals from each group was pooled. The purpose of this study was to evaluate any difference in absorption and metabolism of the anthraquinone. A high performance liquid chromatographic method with ultraviolet absorbance detection (HPLC/UV) was developed to analyze the urine samples for 1- and 2-hydroxyanthraquinone, metabolites of anthraquinone. The method consisted of extracting 2 mL of urine with three 2-mL aliquots of ethyl acetate, combining them, evaporating, and reconstituting in 25% water:75% acetonitrile. The reconstituted extracts were analyzed using a C18 reverse-phase column, a mobile phase starting at 75% water:25% acetonitrile, remaining there for 5 minutes and then going to 25%water:75% acetonitrile over 20 minutes with a linear gradient, and a detection wavelength of 260 nm. This method was validated and found to have acceptable linearity, specificity, sensitivity, accuracy, precision, recovery, and ruggedness. Analysis of the samples found that the metabolic profiles and concentrations were consistent for each source of anthraquinone at a given dose level. 1- and 2-hydroxyanthraquinone and anthraquinone were found in all samples from the dosed animals. Within a given sample the concentrations of 2-hydroanthraquinone and anthraquinone were similar and the concentration of 1-hydroxyanthraquinone was approximately 2% of the other two.

# 114 IN VIVO PERCUTANEOUS ABSORPTION OF DECAMETHYLCYCLOPENTASILOXANE (D5) IN FISCHER 344 RATS.

M. L. Jovanovic, J. McMahon and K. P. Plotzke. Dow Corning Corporation, Midland. MI.

The percutaneous absorption of <sup>14</sup>C-D5 was evaluated in female F344 rats (N=4) when applied topically at 10 mg/cm<sup>2</sup> of skin for 24 hr. Animals were housed in glass metabolism cages for collection of excreta and expired or escaped volatiles associated with the test article. A 24 hr exposure group was used to evaluate disposition of the residual D5 six days after a soap and water wash. Additionally, four animals previously euthanized were dosed in order to differentiate expired volatiles from <sup>14</sup>C-D5 that escaped from the skin depot. All animals were exposed in a semioccluded manner using an aluminum skin depot with a charcoal basket for collection of volatilized test article. At the end of exposure, rats were sacrificed, skin was washed, tape stripped, excised, and remaining carcasses were collected. All samples were analyzed for radioactivity content. Total radioactivity in the expired volatile traps was compared to the amount of unchanged D5 determined by GC-MS analysis. Most (>80%) of the test article evaporated from the skin surface and was trapped in a charcoal basket placed above the exposure site. Data from the euthanized animal group suggested that the amount of radioactivity found in the expired volatile and CO2 traps could be attributed to leakage from the skin depot or background, and could be excluded from the total absorption. Overall, more than 99% of the recovered dose was found in the charcoal baskets and charcoal tubes combined for the animals exposed for 24 hr. The percent dose absorbed was determined as the amount of radioactivity in carcasses, feces, urine, skin dosing sites and cage rinses. Six days after the skin was washed, absorption of  $^{14}\text{C-D5}$  (0.089  $\pm$  0.0302% of applied dose) was significantly lower (p< 0.05) than that seen immediately after 24 hr of exposure (0.243 ±0.0259% of applied dose). These results demonstrated that the portion of D5 that remained in the skin after 24 hr of exposure, and was considered part of the absorbed dose, migrated to the skin surface and continued to evaporate, significantly decreasing apparent absorption of the D5.

K. J. Dix and B. M. Hedtke-Weber. Lovelace Respiratory Research Institute, Albuquerque, NM.

AOC is used almost exclusively as a coupler in oxidative (permanent) hair dyes. Hence, there is potential human exposure to AOC via dermal absorption, particularly in women. In vitro studies with pig skin and in vivo studies in rats, hairless guinea pigs, and humans have shown that AOC permeates the skin. Although AOC is an aromatic amine, a class of compounds with a structural alert for mutagenicity, evidence for AOC-induced mutagenicity is equivocal. AOC is relatively nontoxic; the dermal LD50 in rabbits is >5000 mg/kg (Loyd et al., 1977, Food Cosmet Toxicol, 15:607-610) and the oral LD50 is 2928 and 4355 in female and male rats (CIR Expert Panel, 1989, J Am College Toxicol, 8:569-587). Given the aromatic amine structural alert, the NTP is considering chronic carcinogenicity testing of AOC by the dermal route. In those studies, rodents would be exposed daily to AOC by skin-painting and the dose site accessible for grooming, which could result in oral and dermal doses of AOC. We have conducted dermal disposition studies of [14C]AOC (2 and 20 mg/kg) in female F344 rats in which the dermal dose site was protected or unprotected from oral grooming. Doses were prepared in ethanol the day prior to dosing and AOC in the formulation was ca. 90% radiochemically pure on dose day. When the dose site was accessible to grooming, much more radioactivity was absorbed as evidenced by urinary excretion; 33-55% of the applied dose was excreted in urine when the dose site was not protected from grooming compared with 5-7% when the dose site was protected. Less than 1% of the dose was excreted by all other routes. The remainder of the absorbed radioactivity was found in tissues. When the dose site was protected, the majority of the applied dose was recovered in dose-site washes and the protective appliance. We continue to evaluate AOC metabolism and disposition in female rats and B6C3F1 mice after oral administration to evaluate possible species-specific disposition of AOC to aid the NTP in designing toxicity and carcinogenicity studies to assess potential human health risk(s) from AOC exposure.

# 116 MOGCHOAECK REDUCES ETHANOL CONCENTRATION ELEVATED BY ALCOHOL INGESTION IN RATS.

T. W. Jeon<sup>2</sup> and <u>H. J. Kim</u><sup>1</sup>. <sup>1</sup>Preventive Medicine, Daegu Haany University, Daegu, South Korea and <sup>2</sup>Toxicology, Youngnam University, Daegu, South Korea.

This study was designed to investigate the effect of mogchoaeck on the ethanol concentration elevated by alcohol ingestion. Male Sprague-Dawley rats weighing 200 g were given mogchoaeck (10, 5 and 2.5 ml/kg, p.o.) and administered ethanol at a dose of 3 g/kg bw (25% in distilled water) by gavage 30 min after. To evaluate the effect of mogchoaeck on ethanol pharmacokinetics, blood was collected from caudal artery at 0.25, 0.5, 1, 2, 4, 8 and 12 hr after ethanol gavage. A dose of 10 ml/kg mogchoaeck significantly decreased the ethanol levels in blood; maximum concentration of 24.3±5.1 mg/dl (mean±S.E.) vs. 72.6±3.6 mg/dl in control rats. The administration of mogchoaeck significantly decreased the area under the serum alcohol concentrations-vs.-time curves; 502±50 (control) vs. 148±33 and 329±51 mg·hr/dl (10 and 5 ml/kg). With increasing doses of mogchoaeck, AUC decreased in a dose-dependent manner, -12, 35 and 71% reduction of control, respectively. These results clearly demonstrated that the intake of mogchoaeck reduces the ethanol concentration after alcohol ingestion.

# 117 STUDIES OF THE UPTAKE, DISTRIBUTION, AND ELIMINATION OF <sup>14</sup>C IN SPRAGUE-DAWLEY RATS GIVEN <sup>14</sup>C-LABELED N-ACETYL-L-CYSTEINE BY ORAL GAVAGE.

A. E. Jung, A. J. Bobb, A. R. Thitoff, E. W. Johnson, S. L. Lohrke and <u>D. P. Arfsten</u>. Naval Health Research Center Toxicology Detachment, Wright-Patterson AFR OH

N-acetyl-L-cysteine (NAC) is being studied as a possible chemoprotectant agent against chemicals of military significance. NAC is thought to provide protection against chemical toxicity by several mechanisms including free radical quenching, enhancement of tissue glutathione (GSH) synthesis, and possibly by modulating tissue glutathione-S-transferase (GST) concentration/activity. The uptake, distribution, and elimination of <sup>14</sup>C-NAC following oral intake has not been completely studied. SD rats, 8 weeks of age, were dosed once by oral gavage at a dose rate of 600 or 1, 200 mg NAC/kg containing 6 microCi/gram of <sup>14</sup>C-NAC. Animals were sacrificed at 0.5, 1, 2, 4, 6, and 12 hours post dosing. All major tissues were separated, homogenized, and tissue <sup>14</sup>C counts were collected with a Packard Tricarb Scintillation Counter. Radioactivity levels for urine and feces were both significantly elevated at all time points as compared with controls. Radioactivity levels were also significantly elevated for heart, lungs, thymus, spleen, liver, brown fat,

muscle, and skin. As expected, radioactivity counts were elevated for organs in the GI tract (stomach, large and small intestine, the liver) and for the kidneys. The amount of radioactivity present in each of the tissues at each time point was dependent on dose for most of the tissues; radioactivity levels remained elevated in many tissues for up to 12 hours post-administration. Brain tissue counts were not elevated at any time point which is consistent with the findings from previous studies involving intravenous administration of NAC. The finding that radioactivity levels were elevated for some tissues at up to 12 hours post-administration supports the hypothesis that oral NAC is probably utilized by certain tissues as a source of cysteine. These preliminary findings suggest that NAC oral supplementation may provide some benefit to tissues that are often a site of chemical exposure (e.g., skin, lungs) and possibly may benefit immune function.

# 118 A PHARMACOKINETIC STUDY OF CJC-1131, A NOVEL GLP-1 ANALOGUE, IN RATS USING DUAL ISOTOPE LABELING DEMONSTRATES A LONG ELIMINATION HALF-LIFE.

B. Lawrence<sup>1</sup>, S. Wen<sup>1</sup>, <u>S. Wilson</u><sup>2</sup>, V. Iordanova<sup>1</sup> and J. Castaigne<sup>1</sup>.

<sup>1</sup> ConjuChem, Montreal, QC, Canada and <sup>2</sup> Milestone Biomedical Associates, Frederick MD

CJC-1131 is an anti-diabetic compound designed by applying the Drug Affinity Complex (DAC) technology to the short acting glucagon-like peptide-1 (GLP-1). This chemical modification with maleimidoproprionic acid (MPA) allows CJC-1131 to covalently bond to circulating albumin, after parenteral administration, thus prolonging its half-life. In order to study the pharmacokinetic (PK) and tissue distribution profile of CJC-1131, the compound was either labeled with [14C] on the MPA or with [3H] on histidine at position 1 (His1) of the GLP-1 moiety. Rats were dosed subcutaneously (SC) with the formulated  $[^{14}C]^3H]$ -CJC-1131 at a target dose of 2.25 mg/kg. Quantifiable levels of  $[^{14}C]$  and  $[^3H]$  were observed in both plasma and blood up to 336 h post dose. Two blood and plasma peaks were observed between 40-50 minutes post dose and between 18-24 h post-dose. The elimination half-life  $(t_{1/2el})$  in blood and plasma was found to be long for both isotopes, ranging between 41-49 h for [ $^{14}$ C] and 121 h for [ $^{3}$ H]. The radioactivity of both isotopes was distributed in all tissues with the concentrations of [3H] being slightly greater than [14C] except in the kidneys. The highest concentration of radioactivity was in the kidneys, injection site, underlying muscle, and the skin surrounding the injection site, and the lowest levels in the brain and adipose tissue. Less than 1% of the injected dose remained at injection sites by 96 hours. Excretion was predominantly in the urine with <10% excreted in the feces. The mean mass balance of radioactivity for both isotopes at 336 h post dose was > 100%. In conclusion, the dual isotope labeling has provided a method to analyze the PK and distribution of the protein-conjugated CJC-1131, showing distribution within all examined tissues and a long plasma  $t_{1/2el}$  of 49-121 h.

# 119 EFFECT OF DOSE AND ROUTE OF EXPOSURE ON THE TOXICOKINETICS OF 1, 1-DICHLOROETHYLENE (DCE) IN RATS.

C. Hines, C. White, S. Muralidhara, C. Dallas and J. Bruckner. University of Georgia, Athens, GA.

The purpose of these experiments was to characterize the effects of route of exposure and dose on the bioavailability and toxicity of DCE in rats. Sprague-Dawley, fasted male rats received either 10 or 30 mg/kg of DCE by IV bolus, oral bolus (gavage) or gastric infusion (GI) over 2 hours. Other rats inhaling 100 or 300 ppm DCE for 2 hr retained 10 and 30 mg/kg DCE, respectively. DCE was quantitated by gas chromatography. Toxicity was contrasted in the 30 mg/kg (gavage and GI) and 300 ppm inhalation groups by measuring plasma sorbitol dehydrogenase (SDH) and urinary N-acetyl-B-glucosaminidase (NAG) and gamma-glutamyltranspeptidase (GGT) activitites. The half-life (113 vs. 120 min), clearance (0.06 vs. 0.06 L/min-kg) and volume of distribution (9 vs. 10 L/kg) of DCE were not significantly different between the 10 and 30 mg/kg IV dose groups, indicating linear kinetics in this dosage range. Clearance was not significantly different among routes of administration. However, the bioavailability of DCE was increased approximately 2-fold when the oral dose increased from 10 to 30 mg/kg (oral bolus and GI), indicating saturation of first-pass metabolism. Additionally, bioavailability of DCE was consistently higher with oral bolus administration than with GI. Rats inhaling 100 or 300 ppm DCE had significantly greater bioavailability than their respective oral groups. SDH levels, an index of liver damage, were significantly higher than controls in all 3 dosage groups at 4 and 24 hr and were most pronounced in the gavaged rats. The pattern of kidney injury was quite different. GGT and NAG excretion in the urine were markedly elevated in rats that inhaled 300 ppm DCE. No significant differences in GGT and NAG from controls were observed in the rats dosed orally (bolus and GI) with 30 mg/kg DCE. These findings reveal that route and rate of administration substantially influence the toxicokinetics and systemic toxicity of DCE. Support: DOE #DE-FC01-01CH11109

### BIOAVAILABILITY OF PHENANTHRENE FROM SOIL: CORRELATION BETWEEN A RAT MODEL AND A PHYSIOLOGICALLY BASED EXTRACTION TEST.

X. Pu<sup>1</sup>, G. P. Carlson<sup>1</sup>, R. Galinsky<sup>3</sup> and L. Lee<sup>2</sup>. <sup>1</sup>School of Health Sciences, Purdue University, West Lafayette, IN, <sup>2</sup>Department of Agronomy, Purdue University, West Lafayette, IN and <sup>3</sup>Department of Industrial and Physical Pharmacy, Purdue University, West Lafayette, IN.

Recently, a physiologically based extraction test (PBET) was developed to predict the bioavailability of soil-bound organic chemicals. There are limited data relating it to in vivo animal models. The bioavailabilities of phenanthrene (PA) from soils with varying characteristics were determined using a rat model and a PBET test to examine this relationship. Four soils varying in organic carbon, clay content and pH were spiked with 200 and 400 mg/kg PA. In the in vivo assay, soil suspensions containing 0.25 g soil/ml were administered by gavage. Equivalent doses were given by iv. PA blood concentrations at time points after administration were analyzed by HPLC-FD. Area under the blood concentration versus time curves for each soil was compared to the iv injection to calculate the absolute bioavailability of PA from soil. În the PBET tests, 1 g samples of soils were extracted by artificial saliva, gastric juice, duodenum juice and bile. The fraction of PA mobilized from each soil was calculated. The AUCs of all soils were significantly lower than those of iv injection, indicating that soil matrix could reduce the bioavailability of PA from soil. There was a trend that the higher the OC content, the lower the bioavailability of PA. A good correlation was observed between the fraction of PA mobilized from soil and its bioavailability at 400 mg/kg soil. At 200 mg/kg soil, there was a weaker, but suggestive correlation. These results suggest that PBET assay is a useful alternative to predict bioavailability of soil-bound organic chemicals. (Supported by a Purdue Research Foundation grant.)

# TISSUE DISTRIBUTION OF 2, 2', 4, 4'TETRABROMODIPHENYL ETHER FOLLOWING SINGLE AND MULTIPLE DOSES TO MALE F344 RATS.

J. M. Sanders<sup>1, 2</sup>, M. L. Cunningham and L. T. Burka LPC, NIEHS, Research Triangle Park, NC and Toxicology, N.C. State University, Raleigh, NC.

Polybrominated diphenyl ethers (PBDE's), widely used as flame retardants, are subsequently found as environmental contaminants and are present in mammalian tissues. 2, 2', 4, 4'-Tetrabromodiphenyl ether (BDE-47) makes up 24-38% of a commercial PBDE mixture used mainly in polyurethane foam and is a major PBDE congener found in the environment. BDE-47 is highly lipophilic and has some structural similarity to dioxins, PCB's, and thyroxine. In preparation for future toxicity studies of PBDE's by the National Toxicology Program, the present work has investigated distribution of BDE-47 in tissues of male F344 rats following single and repeated exposure to the compound. Dose concentrations closer to human exposure levels than those of published studies were used. Rats received either 1, 5, or 10 consecutive daily doses of 0.1  $\mu$ mol  $^{14}$ C BDE-47/kg by gavage in corn oil. Tissue distribution of  $^{14}$ C was determined 24 hr following the last daily dose to all rats (n=5/treatment group). Adipose tissue was the major depot of <sup>14</sup>C, containing up to 50% of each daily dose. BDE-47-derived <sup>14</sup>C accumulated extensively in skin, thymus, adrenal, and thyroid and to a lesser extent in liver, brain, blood, and muscle. The disposition of BDE-47 was further investigated following oral administration of single doses from 1-100 µmol/kg in corn oil. Analysis of major tissues and excreta indicated that both absorption of BDE-47 and tissue distribution of <sup>14</sup>C were dose-proportional in this range. Cumulative 24 hr excretion was ca. 0.5 and 35% total dose in urine and feces, respectively. A comparison of oral and iv excretion data indicated that ca. 70% of an orally administered BDE-47 dose was absorbed from the gut. However, absorption of BDE-47 apparently increased when delivered by gavage in an aqueous-based vehicle. In summary, these studies confirm bioaccumulation of BDE-47 in mammalian tissues at low exposure concentrations and provide tissue dosimetry data for design of future toxicity studies.

### DISPOSITION OF 2, 2', 4, 4', 5-PENTABROMODIPHENYL ETHER IN MALE F344 RATS.

E. H. Lebetkin, J. M. Sanders and <u>L. T. Burka</u>. *LPC, NIEHS, Research Triangle Park, NC*.

2, 2', 4, 4', 5-Pentabromodiphenyl ether (BDE-99) is the most abundant of the three major polybrominated diphenyl ethers (PBDE) in the flame-retardant DE-71. DE-71 is used as an additive in plastics, electronic equipment, textiles, and building materials. It is subsequently found in the environment, accumulates in mammalian tissues, and is present in human milk. PBDE's are of interest because of their structural similarity to PCB's and dioxins. Some of the intermediate molecular weight PBDE's are structurally similar to thyroxin. A disposition study of BDE-99 at a single 14.5 µmoles/kg dose has been reported. Toxicity studies being proposed by the National Toxicology Program are at lower doses. Therefore the dis-

position of <sup>14</sup>C-BDE-99 was studied in male F344 rats in single doses at 0.1 to 10 μmoles/kg. Based on the radioactivity excreted in feces (and present in the large intestine at termination) after oral and IV administration, 80-90% of the oral dose is absorbed. After an oral dose, BDE-99 concentrates in fat (17-23% of the total dose after 24 hours) and is excreted in the feces (35-38%), with less than 2% in urine. There is no dose effect on tissue distribution between 0.1 and 10 µmoles/kg. The liver/fat ratio is about 0.2 indicating that sequestration in liver, typical of dioxinlike chemicals is not occurring (for example, 3, 3', 4, 4', 5-PCB, has a liver/fat ratio of about 20 after 24 hr). BDE-99 concentration after an oral dose was higher in all tissues than in blood, with tissue/blood ratios over 10 in liver, kidney, skin, fat, thymus, and adrenal glands. The amount of BDE-99-derived radioactivity in thyroid is not significantly different from other tissues, such as muscle and lung, and is about an order magnitude less than the amount of PBE-47-derived radioactivity found in thyroid following the same molar dose of PBE-47. Over 70% of the BDE-99 in the blood was in the plasma. In summary, the tissue distribution of BDE-99 is typical of a lipophilic, polyhalogenated, aromatic chemical, but does not have high liver to fat ratio typical of dioxin-like chemicals.

## 123 INFLUENCE OF DIET RESTRICTION ON THE TOXICOKINETICS OF THIOACETAMIDE.

J. Chilakapati<sup>1</sup>, K. Shankar<sup>2</sup>, M. korrapati<sup>1</sup> and H. M. Mehendale<sup>1</sup>. <sup>1</sup> Toxicology, University of Louisiana at Monroe, Monroe, LA and <sup>2</sup>UAMS, Little Rock, AR.

Thioacetamide (TA) is bioactivated by CYP2E1 to TA sulfoxide (TASO), and further to sulfone, a reactive metabolite that initiates hepatic necrosis by covalent binding. Studies have shown that despite higher injury of TA by enhanced bioactivation, moderate diet restriction (DR) protects rats from a lethal dose (600 mg/kg, ip). It is known that DR induces CYP2E1. Low dose of TA (50 mg/kg) produces a 6-fold higher injury, whereas a lethal dose produces only 2.5-fold higher and delayed injury in DR rats compared to ad libitum (AL) fed rats. The objective of present work was to determine if lack of dose response for injury in AL rats and higher injury in DR rats could be explained by altered toxicokinetics. Male SD rats were 35% diet restricted and on day 22, AL and DR rats received 50 or 600 mg TA/kg. TA and TASO were quantified in plasma, liver and urine. In the AL rats, with increasing doses, half-lives of both TA and TASO were increased, revealing that TA bioactivation exhibits zero order kinetics. Greater elimination of TA and TASO was seen in urine with increasing doses. These results explain the lack of appreciable increase in bioactivation-based liver injury with the high dose in AL rats. Covalent binding of 14C-TA to macromolecules was higher for the low dose compared to the lethal dose further strengthening this notion. DR rats exhibited significantly lower plasma levels of TA at the 600 mg/kg dose compared to the AL rats. Hepatic TA levels were higher in the DR rats at that dose. Also there was an increase in TASO levels in the DR group, consistent with augmented liver injury. With regard to the low dose, there was a rapid and steep increase in TASO in the DR group at 60 min., which promptly declined thereafter, further explaining the six-fold increase in liver injury. Higher hepatic levels of TA in DR in combination with induced CYP2E1 explain higher injury. The lack of dose response may be attributed to saturation of bioactivation at the higher dose. (Supported by ES09870)

PRELIMINARY DISTRIBUTION, EXCRETION AND PHARMACOKINETICS OF POLYACRYLAMIDE NANOPARTICLES IN MALE RATS AFTER A SINGLE I.V. INJECTION.

R. J. Schneider<sup>1</sup>, R. Reddy<sup>2</sup>, T. Kropp<sup>1</sup>, B. Martin<sup>1</sup>, M. Sherman<sup>3</sup> and M. Philbert<sup>1</sup>. <sup>1</sup>Environmental Health Sciences, University of Michigan, Ann Arbor, MI, <sup>2</sup>Molecular Therapeutics, Inc., Ann Arbor, MI and <sup>3</sup>MPI Research, Inc., Mattawan, MI.

Polymer based nanoparticles are currently being developed for biomedical applications including drug delivery and magnetic resonance imaging (MRI). Despite the composition of the different nanoparticle matrices, pharmacokinetic data has shown consistent clearance from the blood via the mononuclear phagocytic cells that comprise the reticular endothelial system. This study was designed to determine the distribution, excretion and pharmacokinetics of PEGylated (surface-modified) and non-PEGylated polyacrylamide nanoparticle (PAA-PEG & PAA, respectively) suspensions. Preparations of nanoparticles with mean diameters of 60nm were administered as a single I.V. dose in the tail vein of healthy male rats. Plasma, tissue and excreta were collected between 0.083-120 hours. Preliminary data from these studies suggest PAApeg nanoparticles remain in plasma up to 48hr after administration while the non-PEGylated nanoparticles are removed as early as 8hr. Furthermore, preliminary tissue distribution and excretion analyses show accumulation of PAA and PAApeg nanoparticles in the liver, while urine analyses suggest renal clearance was not a major route of excretion. The difference in kinetics of the two suspensions was further investigated by analyzing the composition and quantity of proteins adsorbed onto the surface of the nanoparticles using SDS-PAGE and mass spectroscopy. Preliminary protein binding experiments show nanoparticle interactions with albumin, Apo Á-1, Alpha 1-Antitrypsin and various light and heavy immunoglobulin chains. Supported by NIH grants CA85878 and F003747.

J. D. Field<sup>1,2</sup>, <u>R. Tardif</u> and J. Nash<sup>2</sup>. <sup>1</sup>Environmental and Occupational Health, University of Montreal, Montreal, QC, Canada and <sup>2</sup>DMPK, CTBR BioResearch, Senneville, QC, Canada.

In much of the industrialized world, ethanol is added to gasoline in an attempt to reduce carbon monoxide emissions from automobile exhaust. This has led to speculation that the increased use of ethanol and inhalation of ethanol vapour during automobile refuelling may cause toxicity in some individuals. While the adverse health effects of ingested ethanol are well documented, toxicity via the inhalation route is unclear, especially in individuals deficient in alcohol dehydrogenase (ADH) and/or acetaldeyhyde dehydrogenase (ALDH). This preliminary study was conducted to investigate the toxicokinetics of ethanol and acetaldehyde in blood, and to assess the pulmonary inflammatory response of Long-Evans rats challenged with ADH and ALDH inhibitors prior to inhalation exposure of ethanol. Differences in ethanol metabolism between Long Evans (LE) and Sprague-Dawley (SD) rats were also evaluated. Following up to 4 hours of inhalation exposure to approximately 1300 ppm ethanol, (current exposure limit = 1000 ppm), blood ethanol (BETOH) and acetaldehyde (BACET) levels in rats treated with either metabolic inhibitors (4-MP or DDTC) or controls showed evidence that LE rats are rapid metabolizers of ethanol, compared to SD rats. Cmax and AUC parameters for both BETOH and BACET were consistent with the inhibition of ADH by 4-MP, but also inhibition of ALDH, which was stronger than by DDTC alone. In addition, results showed that the expression of ADH and/or ALDH may be different between genders and suggested that catalase may play a larger role in ethanol metabolism than previously believed. No evidence of a pulmonary inflammatory response could be established, although white blood cell counts appeared to decrease for animals with higher BETOH and BACET levels. While this appeared to have no immediate toxicological significance, it remains unclear if this decrease would limit an immune response over the long term for subjects with compromised ethanol metabolism, especially since acetaldehyde has been shown to be highly reactive.

126

DETERMINATION OF DICHLOROACETIC ACID (DCA) BY LIQUID CHROMATOGRAPHY AND MASS SPECTROMETRY (LC/MS) IN RATS DOSED WITH TRICHLOROETHYLENE (TCE).

A. M. Dixon<sup>1</sup>, D. C. Delinsky<sup>1</sup>, S. Muralidhara<sup>1</sup>, J. W. Fisher<sup>2</sup>, J. V. Bruckner<sup>1</sup> and M. G. Bartlett<sup>1</sup>. <sup>1</sup>Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA and <sup>2</sup>Environmental Health Sciences, University of Georgia, Athens. GA.

DCA is a compound commonly found in drinking water as a chlorination disinfection by-product. In addition, DCA is a metabolite of TCE, a VOC also found in many drinking water sources as a result of its widespread use as a metal degreaser and dry cleaning agent. As DCA has been shown to cause liver cancer in rats and mice, there is concern that DCA and TCE in drinking water may present a cancer risk to humans. Interestingly, no one has definitively shown that TCE is metabolized to DCA in vivo. The current study was designed to determine whether DCA could be detected in tissues and blood of rats dosed with TCE. Rats (n=3) were dosed with 2 g/kg of TCE. Liver, lung, kidney, and blood samples were then collected in a scintillation vial at the following post dosing times: 0, 0.5, 1, 2, 4, and 8 hours. Liquid nitrogen was added to each scintillation vial in order to stop metabolism. Each tissue sample was homogenized and protein precipitated by adding 100  $\mu L$  of acetonitrile (ACN) to each sample. After centrifugation at 16060 x g for 5 minutes, the supernatant was removed from each sample and diluted to a volume of 1 mL. Solid phase extraction was then performed on all samples. The sample eluate was dried under liquid nitrogen and reconstituted in 60:40 ACN:water prior to LC/MS analysis. Preliminary results show 2-20 times higher levels of DCA compared to blanks in all tissue and blood samples 0.5 - 8 hours after administration of TCE. These data indicate that TCE is metabolized to DCA by rats. Further studies using the LC/MS method described here will better characterize the extent of DCA formation in rats and mice. (Funded by DOE DE-FC02-02CH11109)

127

*IN VIVO* PHARMACODYNAMICS AND SUB-CELLULAR DISTRIBUTION OF A 2'-MOE MODIFIED ANTISENSE OLIGONUCLEOTIDE (ASO), ISIS 116847, TARGETING PUTATIVE PROTEIN TYROSINE PHOSPHATASE (PTEN) MNRA IN MICE AND RATS.

R. Yu, E. J. McArdle, R. Gina, K. Hoc, <u>K. C. Nishihara</u>, T. A. Watanabe, <u>S. Bhanot</u> and R. S. Geary. *ISIS Pharmaceuticals, Carlsbad, CA.* 

Purpose: To study and compare *in vivo* pharmacodynamics for a 2'-MOE ASO targeting to PTEN and to explore the differences in suborgan and subcellular distributions of ASO in the liver of these two species. Methods: Subcutaneous injections

of anti-PTEN ASO were given to mice and rats, respectively, at doses of 0 (control saline), 5, 10, 25 or 50 mg/kg twice a week for two weeks. Animals were sacrificed for sample collection 2 days after the last dose following two weeks of treatments. Liver samples from all groups were collected for the measurement of ASO concentrations, PTEN mRNA, and PTEN protein. Suborgan sample collection was performed for the 0 mg/kg and 25 mg/kg dose group for both species. For suborgan sample collection, liver was perfused in situ with collagenase buffer to isolate hepatocytes. PTEN ASO concentrations in whole liver, hepatocyte and subcellular fractions were quantitated by CGE or ELISA method. PTEN mRNA and protein were measured using RT-PCR and Western blot, respectively. Results: Body weight increased 5% and 30 % for mouse and rat, respectively, over the two week treatment period. ISIS 116847 concentrations in liver increased from 43 to 293µg/g and 57 to 388 µg/g in mouse and rat, respectively, as dose increased from 5 to 50 mg/kg. In vivo EC50 in whole liver, estimated by an inhibitory Emax model, was 157 µg/g and 105 µg/g in mouse and rat, respectively. Suborgan and sub-cellular distribution study showed that uptake by hepatocytes as well as subcellular fractions was nearly doubled in mouse compared to rat, yet equivalent message knock down was achieved. Conclusion: This study showed similar pharmacology for the ASO targeting to PTEN in mouse and rat at the level of whole organ, which correlates with whole organ pharmacokinetics. At suborgan level, we confirmed hepatocyte and nuclei had less ASO accumulation in rats, but achieved similar pharmacology compared to mice.

128

STRUCTURAL FACTORS THAT INFLUENCE THE PERFORMANCE OF MULTICASE IN THE ASSESSMENT OF MUTAGENICITY.

B. J. Braunstein, G. Mandakas, F. M. Goodsaid, R. D. Snyder and <u>I. Y.</u> Rosenblum. Molecular Toxicology, Schering-Plough Research Institute, Lafayette, NJ.

MCASE is a SAR package for the prediction of mutagenicity based on a statistical analysis of biophores and deactivating fragments derived from a learning set of chemical structures. We have characterized the output of MCASE versions defined by learning sets assembled from different combinations of reference structure databases and have challenged these MCASE versions in a matrix with structure sets not included in the specific learning set for each version. Structures for these learning sets were compiled from the original MCASE A2I database with the addition of compounds from databases populated with either environmental (UPSAL) and/or pharmaceutical (SCH (Schering-Plough) and PDR (Physicians Desk Reference)) compounds. The sensitivity and specificity of the different MCASE versions were only weakly dependent on the composition of their learning sets when challenged by any specific structure set. The specificity for all structure sets ranged between 89 and 94%. The sensitivity for the pharmaceutical structure sets ranged from 45-63% for SCH and PDR but up to 78-80% for UPSAL. Deactivating fragments were found in less than 20% of the true negative UPSAL set but in over 50% of true negative SCH and PDR sets and were also more frequent in true negative molecules than in false negative molecules within a set. Differences in molecular size between environmental and pharmaceutical molecules may account for the latter observations. An alternative explanation is that such differences are artifactual, based on the fragment size constraint (as short as 2 carbons) defined by the MCASE software. Finally, the sets of biophores identified for true and false positive molecules showed little overlap with each other, inferring that discreet subsets of biophores correlated with incorrect positive calls by MCASE. The results of this analysis suggest that changes in how MCASE identifies biophores and deactivating fragments from its learning sets may be required for improved sensitivity with pharmaceutical molecules.

129

UTILIZATION OF SAR FILTERS, CHEMICAL SIMILARITY AND HT SAFETY SCREENS TO ENHANCE COMPOUND SELECTION FROM COMBINATORIAL LIBRARIES.

N. Greene<sup>1</sup>, J. Aubrecht<sup>1</sup>, J. J. Osowski<sup>1</sup> and D. L. Grossman<sup>2</sup>. <sup>1</sup>Safety Sciences - Groton, Pfizer Global Research and Development, Groton, CT and <sup>2</sup>Department of Biology, Cedar Crest College, Allentown, PA.

While technology in combinatorial chemistry, molecular biology, and automation are flourishing, there is an increased demand for the development of high throughput screening to evaluate the safety of drugs in the early stages of drug development. In principle, Structure-Activity Relationships (SAR or structural alerts), and measures of chemical similarity could be used to predict the mutagenic behavior of a compound. Here we describe the use an SAR filter, DEREK, in combination with Selector, part of the SYBYL molecular modeling suite of programs; to aid in compound selection from a commercially-available library. A total of 274 compounds were selected, 150 compounds that did not contain a structural alert according to DEREK, and 124 compounds that did contain an alert on the basis of its structural similarity to a compound predicted negative. The Bioluminescent Ames assay was

used to assess the mutagenic activity of selected compounds and thus explore the utility of the selection process. The results of the study showed that DEREK was effective at reducing the number of mutagenic compounds in a compound selection thus potentially minimizing the potential safety concerns at a much earlier stage in the drug discovery process.

# 130 CONTROLLED VOCABULARY DEVELOPMENT FOR GENETIC TOXICITY TO MAXIMIZE INFORMATION INTEGRATION OF DATABASES.

D. Benz<sup>1</sup>, C. Yang<sup>3</sup>, G. Hollingshaus<sup>2</sup>, W. Johnson<sup>3</sup>, G. Myatt<sup>3</sup> and E. Zeiger<sup>4</sup>.

<sup>1</sup>Center for Drug Evaluation and Research, USFDA, Rockville, MD, <sup>2</sup>E.I. DuPont de Nemours & Co., Newark, DE, <sup>3</sup>Leadscope, Inc., Columbus, OH and <sup>4</sup>Errol Zeiger Consulting, Chapel Hill, NC. Sponsor: D. Johnson.

As the prediction of toxicity becomes more important for understanding chemically induced toxicity, the quality and availability of chemical structures and data become critically important. The synergistic relationship between the quality of data and accuracy of prediction models demands integration of data among disparate formats and in physically different locations. Translation and transformation of data such that multiple sources of information and structures can be pooled is in fact a pre-requisite for data mining and building prediction models. An XML standard based on a controlled vocabulary optimized for genetic toxicity has been developed and is presented here. Using this schema, a sample database for genetic toxicity was prepared for data mining and building predictive models. This sample database was used to demonstrate the effectiveness of the controlled XML vocabulary and the advantages of enriching chemical space by integration of databases.

# 131 DETECTION OF *N*-METHYL-*N*-NITRO-*N*-NITROSOGUANIDINE-INDUCED MUTATIONS IN GILL AND HEPATOPANCREAS OF *rpsL* TRANSGENIC ZEBRAFISH.

K. Amanuma, T. Nakamura and <u>Y. Aoki</u>. National Institute for Environmental Studies, Tsukuba, Japan.

We established a transgenic zebrafish line carrying a shuttle vector plasmid (pML4) for detecting mutagens in aquatic environments (Amanuma et al. Nat Biotech 2000). The plasmid contains a target gene (the wild-type allele of rpsL of E. coli) for detection of mutations and the kanamycin-resistance gene for rescue of the plasmid from the zebrafish chromosomal DNÁ. Using fish embryos, we detected mutations induced by several compounds. However, adult fish may be more useful for longterm exposure and detecting mutations in target organs. Therefore, to evaluate the mutation assay system in adult fish, we exposed female adult transgenic fish to Nmethyl-N'-nitro-N-nitrosoguanidine (MNNG), and examined the effect of concentration of MNNG and the effect of rearing time after exposure on mutations induced in rpsL. Fish were exposed to 0, 15, or 30 mg/L MNNG (dissolved in water) for 2 hours and killed after 2 weeks. The shuttle vector was successfully recovered from genomic DNA prepared from the gill and hepatopancreas. In the gill, MNNG induced a concentration-dependent increase in mutant frequency of the  $\it rpsL$  transgene (9, 18, 51 x 10  $^{-5}$ , respectively). In the hepatopancreas, only the group treated at 30 mg/L showed an increase in the mutant frequency. DNA sequencing revealed that the most predominant type of mutation was G:C to A:T transition, which is a typical effect of MNNG. Next, we examined the effect of rearing time after exposure. Fish treated at 15 mg/L were kept in MNNG-free water for 2 or 3 weeks. In both the gill and the hepatopancreas, a higher mutant frequency of rpsL was observed at 3 weeks than at 2 weeks, suggesting that a period of at least 3 weeks is preferable for showing effects. These results indicate that the gill and hepatopancreas in the fish are target organs of MNNG, and that *rpsL* transgenic fish may provide a useful *in vivo* assay for detecting waterborne mutagens.

## FINDING THE OPTIMUM APPROACH FOR GENETIC TOXICOLOGY SCREENING.

J. Kitching<sup>1</sup> and G. Barker<sup>2</sup>. <sup>1</sup>Experimental Biology, Huntingdon Life Sciences, Huntingdon, United Kingdom and <sup>2</sup>Gentronix, Manchester, United Kingdom. Sponsor: C. Atterwill.

20-25% of compounds test positive in *in vitro* regulatory genetic toxicology testing, leading to delays and compound attrition. To reach quality decisions on candidate compound selection reliable data needs to be made available from, in some cases, sub-mg quantities of substance. Meaningful genetic toxicology data is required as early as possible in this process. Huntingdon and Gentronix have compared the data obtained from the SOS/umu and GreenScreen? assays on over 100 compounds with the corresponding regulatory genetox results, where available. The umu assay uses two S.typhimurium strains in which lac-Z is under the control of

the SOS repair genes. TA1535/pSK1002 is the standard strain and NM2009 has high o-acetyl transferase activity to make it more sensitive to aromatic amines. The assay detects a wide range of mutagens, having a particularly good correlation with the regulatory Ames test (92% in this comparison). GreenScreen? is a yeast DNA repair reporter assay and is also sensitive to a wide range of mutagens, and clastogens. Compounds were tested up to approximately 2 mM in the umu and 1 mM in the GreenScreen? Although lower than the recommended regulatory upper concentration the assays are sensitive enough for this not to affect the prediction rate. Overall both assays had a similar prediction rate for positives (about 60%). The yeast assay, as expected, was able to predict more clastogens and the bacterial more of the Ames positives. The GreenScreen? assay, at present, cannot be used with S9 activation and although the yeast does have some p450 enzymes of its own the umu assay detected more of the in vitro with S9 only positives. As a result, when both assays were combined it led to a positive prediction rate of about 75%. It is concluded that a screen using both assays will provide a very sensitive prediction tool, leading to accurate ranking of candidate compounds and better designed regulatory testing strategies.

# THE UTILITY OF THE DEL ASSAY IN SACCHAROMYCES CEREVISIAE FOR DETECTION OF CHROMOSOME ABERRATIONS *IN VITRO*.

Z. Kirpnick<sup>1, 2, 3</sup>, N. Howlett<sup>4</sup>, M. Repnevskaya<sup>1, 2, 3</sup>, M. Homiski<sup>5</sup>, E. Rubitski<sup>5</sup>, J. Aubrecht<sup>5</sup> and R. H. Schiestl<sup>1, 2, 3</sup>. <sup>1</sup>Pathology, David Geffen School of Medicine at UCLA, Los Angeles, CA, <sup>2</sup>Radiation Oncology, David Geffen School of Medicine at UCLA, Los Angeles, CA, <sup>3</sup>Environmental Health Sciences, UCLA School of Public Health, Los Angeles, CA, <sup>4</sup>Pediatric Oncology, Dana-Farber Cancer Institute, Boston, MA and <sup>5</sup>Pfizer Inc., Groton, CT.

The DEL Assay for chromosomal rearrangement in the yeast S. cerevisiae is able to detect a wide range of carcinogens. In a study with approximately 60 compounds of known carcinogenic activity, the DEL assays detected 86% correctly whereas the Ames Salmonella assay detected only 30% correctly. Since the DEL assay is highly inducible by DNA double strand breaks, we examined the utility of the DEL assay for detecting chromosome aberrations. We have selected 10 model compounds with known genotoxic effects for testing using the DEL assay . The in vitro micronucleus assay in CHO cells, a commonly used tool for assessment of chromosomal aberrations, was performed on the same compounds and the results of the two assays were compared. The compounds tested were: Actinomycin D, Camptothecin, Methotrexate and 5-Fluorodeoxyuridine, which are anticancer agents, Noscopine and Furosemide are theraputics, Acradine and Methyl Acrylate are industrial chemicals, Diazinon is an insecticide and Resoricnol is a dye. Our data indicate that the DEL assay provides highly concordant data with the standard in vitro MN assay. The DEL assay might have a potential application as a robust, fast, and economical screen for detecting chromosome aberrations in vitro.

# THREE-COLOR LABELING SCHEME FOR FLOW CYTOMETRY-BASED SCORING OF RODENT AND HUMAN PERIPHERAL BLOOD MICRONUCLEATED RETICULOCYTES.

S. D. Dertinger<sup>1</sup>, D. Torous<sup>1</sup>, M. Bishop<sup>2</sup>, Y. Chen<sup>3</sup>, R. K. Miller<sup>4</sup>, C. Tometsko<sup>1</sup> and J. T. MacGregor<sup>5</sup>. <sup>1</sup>Litron Laboratories, Rochester, NY, <sup>2</sup>FDA-NCTR, Jefferson, AR, <sup>3</sup>Radiation Oncology, University of Rochester Medical Center, Rochester, NY, <sup>4</sup>Obstetrics and Gynecology, University of Rochester Medical Center, Rochester, NY and <sup>5</sup>FDA-NCTR, Rockville, MD.

Micronucleated reticulocyte (MN-RET) frequencies represent an index of recent cytogenetic damage. This report describes a modification to a well characterized flow cytometric scoring procedure for measuring the incidence of MN-RET in rodent and human blood samples. In the "standard" system, differential staining of young and mature erythrocytes, with and without micronuclei, is accomplished by combining the immunochemical reagent anti-CD71-FITC with a nucleic acid dye (propidium iodide plus RNase). The modification described here incorporates a fluorescent anti-platelet antibody into the labeling procedure (anti-CD61-PE and anti-CD42b-PE for rodent and human samples, respectively). This 3-color scheme was directly compared to the standard (2-color) procedure with serial blood samples that were obtained from rats before and over the course of daily vinblastine treatment (0 or 0.125 mg/kg/day). While the 3-color system did not add significant value to analyses of terminal day blood samples (obtained via heart puncture), it did improve the reliability of measurements for preceding day blood samples that were obtained via tail vein nick. The resulting dataset suggests that accuracy of flow cytometric MN-RET measurements can be maintained with the 3-color procedure, even when platelet-platelet and platelet-cell aggregates are present. In addition to these rodent blood analyses, human MN-RET measurements, for samples collected before and over the course of fractionated radiotherapy, are presented. Results of these analyses suggest that human samples benefit from the inclusion of a fluorescent anti-platelet immunochemical reagent.

OXYFLOW: DETECTION OF OXIDATIVE DNA DAMAGE TO HEMATOPOIETIC CELLS RESULTING FROM *IN VITRO* AGENT ADMINISTRATION USING FLOW CYTOMETRY.

I. N. Rich<sup>1</sup>, M. Shaw<sup>2</sup> and C. G. Kilty<sup>2</sup>. <sup>1</sup>HemoGenix LLC, Colorado Springs, CO and <sup>2</sup>Biotrin International, Ltd., Dublin, Ireland. Sponsor: M. McKenna.

Oxidative injury is indicated in a wide range of diseases. Damage occurs by the release of free radicals caused by agents, injury or normal metabolism. Free radicals can react with DNA and lead to mutation, carcinogenesis, teratogenesis or cell death. Oxidative damage can occur at any time during hematopoesis. The most susceptible cells are the stem and progenitor cells, since these are responsible for maintaining hematopoietic steady-state conditions. Damage to stem or lineage-specific progenitor cells can result in drastic perturbation of the system and even blood malignancy. The effect of agents that result in free radical formation and oxidative DNA damage can be detected by the presence of 8-oxoguanine, an oxidized nucleotide of 8-oxyguanosine and is the commonest DNA adduct produced as a result of exposure of DNA to oxygen free radicals. DNA mispairing and misreading can also occur. A fluorescein isothiocyanate (FITC)-conjugated binding protein with high avidity and specificity to 8-oxoguanine was used to detect oxidative DNA damage in cells from human peripheral blood, bone marrow or umbilical cord blood and hematopoietic cells from other mammalian species. Target cells were first permeabilized and fixed and then incubated with the FITC-conjugated binding protein. The target cells were resuspended and analyzed by flow cytometry using an Epics XL/MCL. Using different fluorochromes conjugated to antibody membrane markers, oxidative damage could be detected in specific hematopoietic subpopulations using multiparameter gating analysis. To standardize and validate the procedure, control cells were treated with methylene blue and light in a dose-dependent manner. At concentrations of methylene blue above 10 µM, there was a displacement to the right indicating increased fluorescence intensity due to binding of the FITC-conjugated binding protein to oxidised DNA. This new technique can be applied to toxicity testing, pharmacological and chemical high-throughput screening and occupational and environmental biomonitoring.

136 INCREASED FREQUENCIES OF MICRONUCLEATED RETICULOCYTES AND 8-OHDG LEVELS IN ALDH2 KNOCKOUT MICE.

N. Kunugita<sup>1</sup>, T. Isse<sup>2</sup>, T. Oyama<sup>2</sup>, K. Kitagawa<sup>3</sup>, M. Ogawa<sup>2</sup>, T. Yamaguchi<sup>2</sup>, R. Suzuki<sup>2</sup>, T. Kinaga<sup>2</sup>, A. Yoshida<sup>4</sup>, I. Uchiyama<sup>5</sup> and <u>T. Kawamoto<sup>2</sup></u>. <sup>1</sup>School of Health Sciences, University of Occupational and Environmental Health, Kitakyushu, Japan, <sup>2</sup>Department of Environm Health, University of Occupational and Environmental Health, Kitakyushu, Japan, <sup>3</sup>First Department of Biochemistry, Hamamatsu Medical University, Hamamatsu, Japan, <sup>4</sup>Beckman Research Institute of the City of Hope, Duarte, CA and <sup>5</sup>Graduate School of Engineering, Kyoto University, Kyoto, Japan.

Aldehyde dehydrogenase-2 (Aldh2) metabolizes acetaldehyde produced from ethanol into acetate and plays a major role in the oxidation of acetaldehyde *in vivo*. In order to investigate whether the induction on micronuclei by ethanol is associated with genetic polymorphisms of Aldh2 gene, the flow cytometric micronucleus (MN) assay were performed in Aldh2 knockout (Aldh2 KO) mice and wild type (Aldh2 WT) mice. The mice were given 24h free access to a 1% ethanol for alcohol group or water for control group for 20 weeks. We also estimated the 8-hydroxy-2′-deoxyguanosine (8OHdG) levels in mice urine by ELISA. In results, frequencies of MN in reticulocytes and erythrocytes significantly increased by ethanol drinking in Aldh2 KO mice, but not in Aldh2 WT mice. In addition, frequencies of MN and 8OHdG levels were significantly high in Aldh2 KO mice than in Aldh2 WT mice even in control groups. These results indicate that Aldh2 plays a major role not only in acetaldehyde detoxification but also in oxidative stress in mice.

137 QUANTITATIVE LONG PCR ANALYSIS OF DNA DAMAGE INDUCED BY PROSTAGLANDIN H2 SYNTHASE FORM-2: NORMALIZATION OF REPLICATION BY AN INTERNAL CONTROL.

H. Kim<sup>1,2</sup>, D. J. Kaplan<sup>1</sup>, Y. Yuan<sup>1</sup>, D. A. Putt<sup>1</sup> and B. Zhang<sup>1</sup>. <sup>1</sup>Detroit R&D, Inc., Detroit, MI and <sup>2</sup>Institute of Environmental Health Sciences, Wayne State University, Detroit, MI.

Human PGHS-2 was expressed in DNA damage repair-deficient XPA human fibroblasts. Genotoxicity mediated by prostaglandin H2 synthase form-2 (PGHS-2, COX-2) was quantitated by measurement of a lack of PCR replication with damaged DNA. The cells were treated with tert-butyl hydroperoxide (t-BOOH, a substrate of PGHS-2) and/or benzo(a)pyrene-7, 8-dihydrodiol (BPD, a known PGHS-activated DNA damaging agent). The 8.9 kb mitochondrial DNA fragments were replicated by 14 cycles of quantitative long PCR (QLPCR) with bits of the probability of the property of the probability of the prob

otinylated and non-biotinylated primers and quantitated by chemiluminescent and real-time PCR analyses, respectively. Levels of the 8.9 kb QLPCR products were normalized using levels of 6.9 kb internal controls added to each PCR reaction mixture. The 6.9 kb PCR controls containing intact primer binding sites were produced by deleting a 2 kb fragment from the 8.9 kb fragment. For chemiluminescent analysis, replicated DNA fragments were electroblotted to membrane and visualized by incubation of the blot with chemiluminescent substrates of horseradish peroxidase conjugated with streptavidin. For real-time PCR analysis, QLPCR products were quantitated using purified 8.9 kb standards ranging from 0.01 to 1, 200 pg. The detection limit of the method is lower than 0.01 pg. Both chemiluminescent and real-time PCR quantitation revealed that, whereas levels of the QLPCR-replicated mictochondrial DNA fragments failed to decrease after treatment of cells with 5  $\mu$ M BPD, the PCR products dramatically decreased after treatment of the cells with 0 to 15  $\mu$ M BPD in the presence of 0.5 mM t-BOOH. These results suggest that 0.5 mM t-BOOH treatment damaged DNA in PGHS-2-expressing cells and BPD treatment damaged DNA in the cell only in combination with t-BOOH. Sponsored by the NIEHS SBIR grant R44 ES11251 & the EHS Center grant P30 ES06639.

TIME COURSE OF *CII* GENE MUTANT FREQUENCIES AND MUTATION SPECTRA IN THE BONE MARROW OF *N*-ETHYL-*N*-NITROSOUREA-TREATED TRANSGENIC MICE.

J. Wang<sup>1, 2</sup>, N. Mei<sup>1</sup>, X. Liu<sup>1</sup>, M. M. Moore<sup>1, 2</sup> and T. Chen<sup>1</sup>. <sup>1</sup>DGRT, NCTR, Jefferson, AR and <sup>2</sup>Pharmacology and Toxicology, University of Arkansas for Medical Sciences. Little Rock. AR.

The in vivo transgenic mutation assays allow the mutation detection in multiple tissues. But the time required to reach the maximum mutant frequency (MF) is tissue specific. To identify the optimal sampling time, a time course study of cII gene mutant manifestation in the bone marrow of N-ethyl-N-nitrosourea (ENU) treated Big Blue mice was conducted. Six-month old female mice were treated i.p. with a single dose (125 mg/kg) ENU, then the bone marrow was sampled and assayed for cII gene MFs 1, 3, 7, 15, 30 and 120 days later. Compared with the MFs for concurrent controls  $[(34\pm14)\times10^{-6}]$ , all the MFs of ENU-treated mice (253, 374, 277, 235, 238 and 189×10<sup>-6</sup>) were elevated greatly. The maximum MF (day 3) was also significantly different from other MFs. To explain the differences, mutation spectra for day 1, 3 and 120 were analyzed. At day 1, the predominant mutation type is G:C to A:T transitions (32%), which can both result from unrepaired o<sup>6</sup>ethylGuanine and spontaneous mutation. A:T to T:A and A:T to G:C, the typical ENU-induced mutations, were 25% and 8%. At day 3, G:C to A:T were reduced to 26%, while A:T to T:A and A:T to G:C were elevated to 32% and 23%. At day 120, the three types were 26%, 34% and 26%, respectively. The spectrum of day 1 is significantly different from that of day 3 and 120, while the latter two are similar. The results suggest that the optimal sampling time is day 3 and transit cells in bone marrow are more sensitive to ENU than stem cells. While the replacement of immutable differented cells with mutated transit cells explains the MF elevation from day 1 to 3, DNA repair and spontaneous mutation contribute to their spectra difference. The similarity of the mutation spectra of day 3 and 120 suggests that their MF difference resulted from the lower sensitivity of stem cells to ENU, compared with the transit cells. The MF decline after day 3 is consistent with the loss of mutated transit cells, while mutated stem cells are responsible for the MF plateau.

139 AGE-DEPENDENT SENSITIVITY OF BIG BLUE TRANSGENIC MICE TO THE MUTAGENICITY OF ETHYLNITROSOUREA (ENU) IN LIVER.

N. Mei, J. Wang, R. H. Heflich, M. M. Moore and T. Chen. Division of Genetic and Reproductive Toxicology, NCTR/FDA, Jefferson, AR.

There are rising trends in the reported incidence of childhood cancer and recent evidence suggests an association between childhood cancer and environmental exposure to genotoxins. In addition, the liver of infant mice is extremely sensitive to tumor induction by carcinogens. In the present study, the Big Blue transgenic mouse model was used to determine whether specific periods in early life represent special windows of vulnerability to genotoxins. Groups of mice were treated with single doses of 120 mg ENU/kg body weight or vehicle control transplacentally at 3 days before birth or at postnatal days (PNDs) 1, 8, 15, 42 or 126, and the animals were sacrificed 6 weeks after the treatment. The cII mutation assay was performed to determine the mutant frequencies (MFs) in the livers of the mice. Liver cII MFs for both sexes were dependent on the age at which the animals were treated. Perinatal treatment with ENU (either transplacental treatment 3 days before birth or i.p. injection at PND 1) induced relatively high MFs. ENU treatment at PNDs 8 and 15, however, resulted in the highest mutation induction. The lowest mutation induction occurred in those animals treated as adults (PNDs 42 and 126). There was a significant difference (P<0.05) between the MFs in the infant animals

and those in the other treatment groups. For instance, the MF for the PND 8 female group was 646 x  $10^{-6}$  while the MF for female adults was only  $145 \times 10^{-6}$ , a more than 3-fold difference. Our mutagenicity results correlate well with the age-dependent sensitivity to carcinogenicity in mice and indicate that infancy is the period at which mouse liver is the most sensitive to mutation and tumor induction by genotoxins.

140

EFFECT OF OVARIECTOMY ON MUTATIONS INDUCED BY 7, 12-DIMETHYLBENZ(A)ANTHRACENE (DMBA) IN THE LIVER *CII* GENE OF BIG BLUE TRANSGENIC RATS.

T. Chen<sup>1</sup>, R. C. Hutts<sup>2</sup>, N. Mei<sup>1</sup>, M. E. Bishop<sup>1</sup>, S. Shelton<sup>1</sup>, M. G. Manjanatha<sup>1</sup> and A. Aidoo<sup>1</sup>. <sup>1</sup>Division of Genetic and Reproductive Toxicology, NCTR/FDA, Jefferson, AR and <sup>2</sup>Center for Toxicology and Environmental Health, Little Rock, AR.

Hepatocellular carcinoma (HCC) is one of the most common cancers. Women develop HCC with much less frequency and better prognosis for the disease than men. In rodent models, carcinogen-induced and spontaneous HCC also occurs at a lower incidence in females than in males. Although sex hormones have been implicated as an important factor associated with the development of HCC, the effects of estrogens on chemical mutagenesis in liver are presently unknown. To evaluate the role of endogenous estrogens in chemical hepatomutagenesis, 2 groups of 10 Big Blue female rats were treated with 80 mg DMBA (a multi-organ carcinogen)/kg body weight or vehicle, and 5 animals from each group were ovariectomized two weeks later. At 16 weeks after DMBA treatment, mutant frequencies (MFs) and types of mutations were determined in the liver cII gene of the overiectomized (ÔVX) and intact (INT) rats. The MFs were 203 x 10<sup>-6</sup> for the DMBA-treated OVX rats and 135 x 10<sup>-6</sup> for the DMBA-treated INT animals, compared to the untreated control MFs: 67 x 10<sup>-6</sup> for the OVX group and 44 x 10<sup>-6</sup> for the intact animals. DMBA significantly increased the MFs in both the OVX and INT rats. The MF in the DMBA-treated OVX rats was significantly higher than that in the DMBA-treated INT animals although there was no significant difference between the MFs in the untreated OVX and INT rats. Molecular analysis of the mutants showed that ovariectomy did not significantly alter the types of mutations in the DMBA-treated or untreated animals. However, a significant difference was found between spectra in the treated animals and the untreated controls. G:C  $\rightarrow$  T:A transversion was the most common type of mutation in both the treated OVX and INT groups, whereas G:C → A:T transition was the predominant mutation in both control groups. These results suggest that ovarian hormones inhibit mutation induction in the liver by carcinogens.

# 141 IDENTIFICATION OF IN VIVO MUTATION FOR THE $\Phi$ X174 TRANSGENIC MUTATION ASSAY USING THE FORWARD MUTATION ASSAY OF GENE A.

C. R. Valentine<sup>1</sup>, J. L. Raney<sup>1</sup> and R. R. Delongchamp<sup>2</sup>. <sup>1</sup>Division of Genetic and Reproductive Toxicology, NCTR, USFDA, Jefferson, AR and <sup>2</sup>Division of Biometry, NCTR, USFDA, Jefferson, AR. Sponsor: J. Valentine.

In vivo transgenic rodent mutation assays have high spontaneous mutant frequencies relative to induced mutant frequencies. The  $\Phi$ X174 transgenic mutation assay has a unique method for distinguishing in vivo from in vitro mutations: single burst analysis requires that a burst of phage from a single bacterium exceed a minimum size, indicating that the mutation was fixed before entering the bacterial cell. Bursts are identified by separating electroporated bacterial suspensions into many aliquots before plating on selective bacteria. We have conducted DNA sequencing of multiple mutants from aliquots of different plaque count to characterize the distribution of mutations from each. As expected, aliquots with larger plaque counts (>100) had multiple plaques with the same mutation, indicating progeny from a single, in vivo mutation. Aliquots with small plaque count had a greater variety of mutation, indicating their independent origin. Large bursts, from ENU-treated animals, fit the spectrum of ENU-induced mutation. The optimal plating density (µg DNA / aliquot) was reduced relative to the reversion assay in gene E in order to separate in vitro bursts because of the larger number of target sites for the forward assay. We have also determined the mutant spectrum in E. coli of the ΦX174 gene A forward assay. The mutant spectrum from control animals of mutations contributing <60 PFUs per aliquot was not different from that of ΦX174 grown in E. coli, which included two hotspot sites that dominate the spectrum, 4225A -> G, C, or T and 4218G→A or C. Therefore, the majority of mutant plaques from control animals was fixed in E. coli, not the animal. Single burst analysis allows the measurement of in vivo mutant frequencies below the spontaneous E. coli frequency. We are currently evaluating the frequency of in vivo bursts from control and ENU-treated animals treated with 40 mg/kg of ENU by the same protocol used to evaluate the lacI transgene in order to compare the relative sensitivity of the two assays.

142 POTENTIAL FOR PHENOL TO DISRUPT THE SPINDLE APPARATUS AS EVALUATED IN THE MOUSE BONE MARROW MICRONUCLEUS TEST (MNT).

P. J. Spencer<sup>1</sup>, V. A. Linscombe<sup>1</sup>, J. G. Grundy<sup>1</sup>, B. B. Gollapudi<sup>1</sup>, J. M. Waechter<sup>1</sup> and S. S. Dimond<sup>2</sup>. <sup>1</sup>Toxicology & Environmental Research & Consulting, The Dow Chemical Company, Midland, MI and <sup>2</sup>Health and Environmental Safety, GE Plastics, Huntersville, NC.

High doses of phenol cause significant hypothermia in treated mice. In the mouse, micronuclei (MN) were induced in the bone marrow polychromatic erythrocytes concomitant with phenol-induced hypothermia. Earlier attempts to distinguish direct vs. secondary mechanisms of phenol-induced MN by maintaining normal body temperature in phenol-treated mice were unsuccessful because of inadequate restoration of thermoregulatory homeostasis. In order to gain further insight into the mode of action responsible for phenol-induced micronuclei, the etiology of MN in phenol treated mice was investigated by staining the MN with antikinetochore antibody. Six male mice/group were administered phenol (300 mg/kg), the vehicle (saline) or the positive control for inducing kinetochores (vinblastine (VB), 4 mg/kg) as a single i.p. dose. Body temperature was monitored at 2 and 5 hrs postdosing and the formation of MN and kinetochore-positive (K+) MN were evaluated at 24 hr. Phenol at 300 mg/kg induced a marked and prolonged hypothermia as well as a significant increase in MN formation. VB induced a significant increase in K+MN (78% of MN cells were K+). Phenol also induced a significant but smaller increase in K+MN (16%) over the negative controls (0%). The presence of kinetochores in the MN from phenol-treated mice provides evidence for a mode of action that involves, at least in part, disruption of the spindle apparatus which could be linked to hypothermia. (Sponsored by the Phenol Panel of the American Chemistry Council, Arlington, VA).

### 143 INHIBITION OF DNA REPAIR AS A MECHANISM OF ARSENIC CARCINOGENESIS.

S. Liu, E. Kopras, M. Medvedovic, G. G. Oakley and K. Dixon. Environmental Health, University of Cincinnati, Cincinnati, OH.

Arsenic is a metalloid that is widely distributed in the environment. Exposure to arsenic has been associated with an increased risk of a variety of cancers, including skin, liver, bladder, kidney and lung cancer. However attempts to prove arsenic carcinogenesis in animals have been unsuccessful. A hypothesis has been proposed that arsenic might act as a co-carcinogen instead of a carcinogen itself. Recently Rossman's group demonstrated that arsenic enhanced the induction of skin tumors by UV irradiation in hairless Skh1 mice (Rossman, 2001). Consistent with its cocarcinogenic activity, arsenic by itself does not seem to induce point mutations in most of the bacteria and mammalian systems tesed. Instead, it can potentiate the mutagenicity of other mutagens, such as UV (Hartmann, 1996), Benzo(a)Pyrene (Maier, 2002) and N-methyl-N-nitrosourea (NMU)(Li, 1989). The mechanism of this co-mutagenicity remains unknown. The most tempting hypothesis is that arsenic can inhibit DNA repair. We have used arsenite at low concentrations in cultured human cells to test this hypothesis, in the hope of shedding light on the mechanism of arsenic mutagenesis and co-mutagenesis. Our study shows that (1) Arsenic at 1 uM is not mutagenic, but induces deletion/insertion mutations at 2.5 uM. Arsenic synergistically enhances UV mutagenicity at 2.5uM, but not at 1uM. (2) Arsenic treatment does not alter the UV mutation spectra. (3) Arsenic at 1-5 uM enhances and prolongs RPAp34 phosphorylation induced by UV irradiation, suggesting the persistence of the DNA damage signal that induces the phosphorylation response. This effect is less prominent in NER-deficient XPA cells. (4) Arsenic does not increase the generation of thymine dimers induced by UV assayed by FACS with thymine dimer-specific antibody, but it inhibits the removal of thymine dimers. All of these results suggest that arsenic inhibits DNA repair, probably nucleotide excision repair. Further work will be required to identify the mechanism of this inhibition. This work is supported by NIESH Superfund Basic Research grant ES04908.

## DISCOVERY AND FUNCTIONAL ANALYSIS OF XPA POLYMORPHISMS.

P. C. Porter<sup>1</sup>, I. Mellon<sup>2</sup> and J. States<sup>1</sup>. <sup>1</sup>Pharmacology & Toxicology, University of Louisville, Louisville, KY and <sup>2</sup>Pathology, University of Kentucky, Lexington, KY.

Inter-individual differences in nucleotide excision repair (NER) alter cancer risk. NER gene polymorphisms provide a readily detectable source of genetic variation in NER, but little is known about their functional impact. XPA is essential for NER. We detected missense polymorphisms in XPA and investigated their effects by complementation of XPA cells. XP12RO-SV, an SV40-immortalized XPA mutant cell line, was complemented with wild type, R228Q or V234L XPA. Both polymorphisms provided wild type survival in response to both ultraviolet light (UV)(Mellon et al. DNA Repair (2002) 1:531-46) and benzo[a]pyrene-diol-epoxide (BPDE) induced DNA damage despite low expression compared to wild type

XPA complemented cells . SV40-immortalization inactivates p53-dependent induction of global genomic repair, an NER sub-pathway. To provide a p53- and NER-proficient cell culture model, we investigated the use of telomerase-immortalized cells. Repair normal primary diploid human skin fibroblasts (GM00024) were immortalized with telomerase and named tGM24. tGM24 cells retain normal p53 induction and cell survival in response to UV and BPDE exposure. Primary XPA cells (GM02991) also were telomerase immortalized for complementation and named tGM2991. tGM2991 cells are hypersensitive to DNA damage compared to tGM24 cells. Similar survival decreases and p53 inductions were obtained in tGM2991 with 10-fold lower UV doses than in tGM24. Likewise, similar survival decreases were obtained with 5-fold lower BPDE doses. Our results support the hypothesis that telomerase immortalization does not alter the p53 DNA damage response. tGM2991 cells were stably transfected with wild type or one of three missense polymorphic XPA mini-genes (R228Q, V234L, L252V). Three cell lines expressing XPA protein at wild type levels are made: two contain the L252V XPA and one contains the R228Q XPA. (Support: University of Louisville Center for Envir. and Occup. Health Sciences and Center for Genetics and Mole. Med., KY EPSCoR, Markey Cancer Center, KY Research Challenge Trust Fund, and USPHS grant ES06460)

#### 145

DIFFERENCES IN DNA REPAIR ACTIVITY AND INHIBITION OF REPAIR BY ALFLATOXIN B<sub>1</sub> CORRELATES WITH SUSCEPTIBILITY TO CARCINOGENESIS IN MOUSE.

L. Bedard<sup>1</sup>, M. Alessi<sup>2</sup>, S. K. Davey<sup>3</sup> and <u>T. E. Massey<sup>1</sup>. <sup>1</sup>Pharmacology and Toxicology, Queen's University, Kingston, ON, Canada, <sup>2</sup>Chemistry, Queen's University, Kingston, ON, Canada and <sup>3</sup>Cancer Research Laboratories, Queen's University, Kingston, ON, Canada.</u>

Aflatoxin B<sub>1</sub> (AFB<sub>1</sub>) is a mutagenic and carcinogenic metabolite produced by the fungus Aspergillus. To exert carcinogenicity, AFB<sub>1</sub> requires bioactivation to AFB<sub>1</sub>exo-epoxide, which binds to guanine (Gua) residues in DNA, forming AFB<sub>1</sub>-N<sup>7</sup>-Gua that can be hydrolyzed to AFB<sub>1</sub>-formamidopyrimidine (AFB<sub>1</sub>-FaPyr). Removal of AFB, DNA damage occurs primarily by nucleotide excision repair (NER). The objective of this study was to compare DNA repair synthesis activities of whole mouse lung and liver and rat liver protein extracts, and to determine whether in vivo treatment of mice with AFB, inhibits their ability to repair AFB, DNA damage. DNA repair synthesis activity of cell-free whole tissue protein extracts was assessed using an in vitro assay that reproduces the entire NER reaction against substrate plasmid DNA with AFB<sub>1</sub> damage. Mouse liver extracts repaired  ${\rm AFB_1-N^7}$ -Gua and  ${\rm AFB_1-FaPyr}$  ~ 5 fold and 30 fold more efficiently than did whole lung extracts respectively (N=4, P<0.05). Furthermore, mouse liver repair activities were ~ 6 fold and 4 fold higher than those of rat liver against AFB<sub>1</sub>-N<sup>7</sup>-Gua and AFB<sub>1</sub>-FaPyr damage respectively. Lung extracts prepared from mice treated with a single tumourigenic dose of 50 mg/kg AFB<sub>1</sub> ip and sacrificed 2 h post-dosing demonstrated minimal repair synthesis activity against AFB<sub>1</sub>-N<sup>7</sup>-Gua damage (N=3, P<0.05). In contrast, liver extracts retained the ability to repair AFB<sub>1</sub>-N Gua (N=3, P>0.05). These results suggest that the lower DNA repair activity and sensitivity to inhibition by AFB<sub>1</sub> of mouse lung contributes to the susceptibility of mice to AFB<sub>1</sub>-induced lung tumourigenesis relative to hepatocarcinogenesis. Furthermore, lower ability of rat liver to repair AFB<sub>1</sub>-DNA damage may contribute to its relative susceptibility to hepatocarcinogenesis. In addition to AFB, DNA adducts being mutagenic, their genotoxicity may be enhanced by the ability of AFB, to inhibit their repair.

CHARACTERIZATION OF DNA REPAIR MECHANISMS FOLLOWING AFLATOXIN B $_1$  TREATMENT IN YEAST EXPRESSING HUMAN CYTOCHROME P450 1A2.

Y. Guo<sup>1</sup>, H. Zarbl<sup>3, 1</sup>, L. L. Breeden<sup>3</sup>, B. D. Preston<sup>2</sup> and D. L. Eaton<sup>1, 3</sup>.

<sup>1</sup>Environ Occup Hlth Sciences, University Washington, Seattle, WA, <sup>2</sup>Pathology, University Washington, Seattle, WA and <sup>3</sup>Fred Hutchinson Cancer Research Cntr, Seattle, WA.

Aflatoxin B<sub>1</sub> (AFB) is a human hepatotoxin and hepatocarcinogen produced by the mold *Aspergillus flavus*. In humans, AFB is bioactivated by hepatic CYP1A2 and 3A4 to a genotoxic epoxide that forms N<sup>7</sup>-guanine DNA adducts. Little is known about how these bulky DNA adducts are repaired. A series of yeast haploid mutants defective in checkpoints and DNA repair were transformed with human CYP1A2. The stability of CYP1A2 expression in these mutants was characterized by western blots and Methoxyresorufin O-demethylase (MROD) enzymatic activity. Mutant clones were screened, and those with comparable CYP1A2 activity to wild-type strain were treated with various doses of AFB. Colony-forming ability and the *L*-Canavanine resistance forward mutation assay were employed to observe cell survival and mutation, respectively. Strains defective in nucleotide excision repair (NER) (*rad14*), postreplication repair (PRR) (*rad6* and *rad18*) and checkpoints (*mec1-1* and *rad9*) exhibited significantly decreased cell survival after AFB treatment, relative to their wild type, while strains defective in recombinational repair (RR) (*rad51* and *rad54*) had moderate sensitivity. *rad6*, *rad18*, *mec1-1*, *rad9*, *rad51* 

and rad54 had significantly reduced AFB-induced mutation frequency. These results indicated the involvement of NER, PRR and RR in repair of AFB-induced DNA damage, and the requirement of PRR error-prone pathway in AFB-induced mutagenicity. Interestingly, while double mutant rad51 rad14 showed greatly enhanced sensitivity and mutation frequency towards AFB treatment in comparison with either single mutant, rad18 rad14 demonstrated neither lowered cell survival nor increased frequency of AFB-induced mutations comparing to either single mutant. These results demonstrate complex relationships among various DNA repair pathways and cell cycle control in AFB-induced cell cytotoxicity and mutagenesis in a yeast model. ## 147 MUCOCHLORIC ACID INDUCES SINGLE STRAND BREAKS IN XRCC1 DEFICIENT CELLS.

E. Bodes, J. Nakamura, A. Molinelli, Y. Li, B. Pachkowski and J. A. Swenberg. University of North Carolina, Chapel Hill, NC.

Epidemiologic studies indicate that long-term consumption of chlorinated disinfected water is associated with increases in cancer. Mucochloric acid (MCA) is a byproduct produced by the action of chlorine on humic acid in drinking water. While there is no direct link between MCA and cancer, we have shown that MCA is capable of damaging cells in culture. Our goal was to clarify whether the formation of single strand breaks (SSBs) was a mechanism by which MCA induces genotoxicity. We used the comet assay to detect SSB formation and a novel colorimetric assay that indirectly monitors PARP activation for SSB repair. While using NAD+ as substrate PARP binds to DNA nicks and recruits essential repair proteins to the damaged site. To understand the role of PARP activation in depleting intracellular NAD(P)H we applied several PARP inhibitors to our test systems. We used genetically matched CHO cells with and without functional XRCC1. XRCC1 is critical for genomic stability and it coordinates SSB repair. In both assays we detected a significant increase in SSBs across all doses after exposure to MCA. Transfecting deficient cells with hXRCC1 showed responses similar to proficient cells, supporting the role of XRCC1 in SSB repair after MCA exposure. In the colorimetric assay, pre-exposure with PARP inhibitors produced different results. 3-Aminobenzamide (AB) protected against a reduction in NAD(P)H at all doses whereas dihydroxyisoquinoline (DQ) was less effective at higher doses of MCA. Surprisingly, in the comet assay we detected dramatic differences in MCA-induced DNA damage upon pre-exposure to either AB or DQ, with AB forming significantly less SSBs. We hypothesized that opening of the lactone ring of MCA to an aldehyde allowed for the formation of a Schiff base conjugate with AB, but not DQ. We preincubated equal molar concentrations of MCA with the inhibitors and detected an MCA-AB conjugate by LC-MS/MS. These data explain the results obtained in both the comet and colorimetric assays. We concluded that covalent binding of AB with MCA prevents MCA from damaging DNA.

METHYL NITROSOUREA INDUCES
LEUKEMOGENESIS WITH PRACTICAL THRESHOLD
IN WILD TYPE MICE WHEREAS NONTHRESHOLD IN
P53 DEFICIENT MICE.

Y. Hirabayashi<sup>1</sup>, K. Yoshida<sup>2</sup>, Y. Kodama<sup>1</sup>, J. Kanno<sup>1</sup>, Y. Kurokawa<sup>3</sup>, I. Yoshimura<sup>4</sup> and <u>T. Inoue<sup>5</sup></u>. \*Cellular & Molecular Toxicology, Division, NIHS, Tokyo, Japan, <sup>2</sup>Division of Biology and Oncology, NIRS, Chiba, Japan, <sup>3</sup>Sasaki Research Institute, Tokyo, Japan, <sup>3</sup>Faculty of Engineering, Tokyo University of Science, Tokyo, Japan and <sup>5</sup>Center for Biological Safety & Research, NIHS, Tokyo, Japan.

A question, whether an absolute nonthreshold or a relative nonthreshold, i.e., a "practical" threshold, specifically at the low-dose level is present, may not be answered even with the use of a prohibitively large number of wild-type mice. Could the excessive incidence of tumorigenesis in p53-deficient mice contribute to our understanding of the threshold vs. nonthreshold issue in genotoxic carcinogenesis? This is considered because an exaggeration of tumorigenesis in p53-deficient mice is hypothesized to reduce or eliminate the range of threshold due to the p53-deficiency-mediated reduction of DNA repair and apoptosis. The present study of chemical leukemogenesis in p53-deficient mice by transplantation assay was designed to answer this question. Briefly, 218 C3H/He mice were lethally irradiated and repopulated with bone marrow cells from wild-type, heterozygous p53-deficient, and homozygous p53-deficient C3H/He mice. This was followed by treatment with a single and graded dose of methyl nitrosourea at 6.6, 14.8, 33.3, 50.0, and 75.0 mg/kg BW, with the vehicle-treated control groups treated with zero dose for each genotype. Whereas mice repopulated with p53-deficient bone marrow cells showed a marked reduction of the threshold for leukemogenicity, mice repopulated with wild-type bone marrow cells did not exhibit leukemia at a dose of 33.3 mg/kg body weight, and showed a curve with a high probability for the linear regression model with a positive dose intercept, predicting a threshold by the likelihood ratio test. Thus, the failure of wild-type mice to show an increase in incidence of leukemogenesis at low doses of genotoxic carcinogens may be due not to a statistical rarity, but to various p53-related functions possibly including DNA repair and apoptosis that may account for a threshold.

<u>I. L. Matta</u><sup>1</sup>, A. Ruiz<sup>1</sup>, R. A. Armstrong<sup>2</sup>, Y. Detres<sup>2</sup> and J. M. Ramos<sup>1</sup>.

Non-melanoma skin cancer (NMSC) is the most common cancer worldwide. UV radiation is an important risk factor for NMSC. UVA (320-400 nm) and UVB (280-320 nm) can cause DNA damage and mutations. Cancer risk is partly determined by the capacity of the body to repair DNA damage. DNA repair capacity (DRC) has been reported as an independent risk factor for the development of NMSC. A 3-year clinical study was performed in Puerto Rico to develop a model of how environmental factors (e.g. UV exposure and sunblock) and genetics (e.g. DRC and skin type) influence the risk of NMSC. UVA and UVB measurements were obtained over a 5-year continuous period using a Biospherical Instruments GUV-511 radiometer. All participants (n=550) completed an Informed Consent and a questionnaire that elicited information on risk factors. DRC was measured in peripheral blood lymphocytes using a host cell reactivation assay with luciferase reporter gene. NMSC risk factors were determined by logistic regression analysis. Monthly means of daily UV radiation fluxes ranged from 569 to 1504 kJ m-2 d-1. UV fluxes were 24% higher from March-September when compared with the October-February period. Persons with NMSC had a statistical significant lower DRC (42%) compared with controls. Significant risk factors (p<0.005) included a minimal of 3-hour weekly cumulative UV dose (OR=2.0, 95% CI=1.2-3.3), skin type I and II (OR=8.5, 95% CI=5.2-13.9), and the use of sunblock (OR=0.16, 95% CI=0.10-0.26). A high DRC (highest 10%) reduced NMSC risk 7-fold and a low DRC (lowest 33%) increased risk by 3.4-fold. Overall, for every 1% decrease in DRC, the risk of developing NMSC increased 20%. The model presented illustrates how genes-environment-disease interact to influence NMSC risk. Genetic factors are more important than environmental factors for the development of NMSC in the population studied. These findings may be useful for NMSC prevention programs. Supported by NIH-NCRR grant 2G12RR03050-19.

# 150 ALTERATION OF CHEMOTHERAPEUTIC-INDUCED DNA DAMAGE BY A COMMON HEALTH FOOD SUPPLEMENT.

W. Trinachartvanit<sup>1</sup>, <u>B. M. Francis<sup>2</sup></u> and A. Rayburn<sup>3</sup>. <sup>1</sup>Animal Biology, University of Illinois, Urbana, IL, <sup>2</sup>Entomology, University of Illinois, Urbana, IL and <sup>3</sup>Crop Sciences, University of Illinois, Urbana, IL.

In the US, use of health food supplements has increased rapidly in the last decade, especially in cancer patients. However, recent concerns have been raised as to whether specific health food supplements taken during chemotherapy interact with chemotherapeutic agents. If interactions occur, they could enhance the action of chemotherapy or interfere with it by decreasing the conventional medication effica-cies. Our aim was to investigate any potential interactions between an over-thecounter health food supplement, Fruit of LifeTM (which is advertised to consist of highly active antioxidants) and a chemotherapeutic agent, cytosine arabinoside (ara-C). Outbred CD1 mice were fed a semi-synthetic diet, supplemented with 0% (control), 0.2% (low dose) or 1.0% (high dose) of Fruit of LifeTM, for 4 weeks. Ara-C at 8 mg/kg was administered ip to half of the control and treated mice, 72 hours prior to the end of the feeding period. Prior studies had demonstrated that this dose of ara-C damages DNA in bone marrow without causing acute illness in the mice. Bone marrow was collected from all treatment groups and flow cytometry was used to determine DNA damage to the bone marrow cells. There were no significant differences in DNA damage between negative control mice and mice fed with 0.2% and 1.0% Fruit of LifeTM. Combined treatments of ara-C with either 0.2% or 1.0% Fruit of LifeTM significantly decreased the DNA damage level compared to ara-C treated mice on the unsupplemented diet. These results suggest that the health food supplement of interest (Fruit of LifeTM) interacts with the chemotherapeutic agent (ara-C) to decrease DNA damage caused by ara-C to normal bone marrow cells. Future studies are needed to determine how Fruit of LifeTM may alter the effectiveness of ara-C during chemotherapy. This work was supported by a grant from the Office of the Attorney General of the State of Illinois.

# 151 MODE OF ACTION FOR THE *IN VITRO*MUTAGENICITY OF BIOBAN CS-1246 AND IMPLICATIONS FOR ITS *IN VIVO* MUTAGENIC POTENTIAL.

B. B. Gollapudi<sup>1</sup>, G. Charles<sup>1</sup>, M. R. Schisler<sup>1</sup>, M. Cifone<sup>2</sup>, R. A. Budinsky<sup>1</sup> and P. J. Spencer<sup>1</sup>. The Dow Chemical Company, Midland, MI and <sup>2</sup>Covance Labs, Vienna, VA.

The biocidal agent, 7-ethyl bicyclooxazolidine (Bioban CS-1246, CAS# 7747-35-5) was concluded to be non-mutagenic in a bacterial reverse mutation assay using Salmonella typhimurium strains TA98, TA100, TA1535, TA1537 and TA1538,

and in an in vitro cytogenetics assay in Chinese hamster ovary cells both in the presence and absence of Aroclor-induced rat liver S-9. However, Bioban CS-1246 induced a mutagenic response in the mouse lymphoma (L5178Y TK+/-) forward mutation assay (MLA) both with and without S-9. Significantly, the mutagenicity was completely abrogated when the cultures were supplemented with formaldehyde (FA) dehydrogenase/NAD+ suggesting that the positive MLA response was attributable to the generation of FA in situ. The MLA findings are unlikely to be of relevance to an intact animal because of the efficient detoxification of low doses of FA in vivo. Evidence of this was obtained by the non-genotoxicity of Bioban CS-1246 in 2 in vivo assays. Firstly, in a mouse (male CD-1) bone marrow micronucleus test (MNT), in which there were no significant increases in micronucleated polychromatic erythrocytes following treatment with 0.5, 1 and 2 g/kg/day for 2 days and sacrificed 24 h later. Also, in an *in vivol in vitro* unscheduled DNA synthesis (UDS) study, male F344 rats were given a single oral gavage at 0, 1 and 2 g/kg of CS-1246. Livers were perfused at 2 time points (2-4 and 14-16 h) and the extent of UDS was quantified in hepatocyte cultures after exposure to 3H-thymidine and autoradiography. CS-1246 did not elicit an UDS response indicating the lack of DNA reactivity in vivo. Based upon the weight of evidence from an extensive array of genotoxicity tests and the mode of action data, it is concluded that CS-1246 is not an in vivo mutagen. These results clearly demonstrate that in vitro genotoxicity of CS-1246 is associated with FA and unlikely to have relevance in animals or humans because of the occurrence of efficient detoxification mechanisms.

#### 152 GENOTOXICITY EVALUATION OF THIODIGLYCOLND.

G. Reddy, M. A. Major and G. J. Leach. Directorate of Toxicology, US Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD.

Sulfur mustard (HD) undergoes hydrolysis to form thiodiglycol (TG) and small amounts of compounds in biological and environmental systems. The US Army has proposed to neutralize HD through a hydrolysis process with subsequent biodegradation of reaction products. TG has been detected in soil and water at certain Army installations. The toxicity data on TG are limited to only a few reports. Genotoxicity data on TG are not available to complete health and environmental risk assessments. Therefore, we developed genotoxicity data under extramural contract. These tests were conducted in accordance with Environmental Protection Agency Health Effects Testing Guide Lines in compliance with Good Laboratory Practice. The summary of test results of completed work will be reported here. Thiodiglycol did not produce mutagenic effects at any dose up to 5000 mg/plate in Salmonella typhimurium (TA98, TA100, TA1535 and TA1537) and Escherichia coli (WP2uvrA) tester strains with and without a metabolic activation system. TG did not increase mutantion frequency at levels up to 5000 mg/ml in mouse lymphoma L5178ytk+/- cells with and without metabolic activation. The effects of TG on in vitro chromosomal aberrations in Chinese Hamster Ovary (CHO) cells showed chromosomal aberrations at 5 mg/ml (without metabolic activation) and 4 mg/ml with metabolic activation. Thiodiglycol (up to 2000 mg/kg) when tested in vivo in the mouse micronucleus assay was not mutagenic in mouse bone marrow. These studies revealed that TG is not mutagenic in three assays (Ames test, mouse lymphoma and mouse micronucleus assay) but it positive in vitro in CHO cells chromosomes. On the basis of these studies we believe that TG does not appear to pose a genetic hazard to humans (Abstract does not reflect US Army Policy)

## DNA DAMAGE IN HUMAN LEUKOCYTES INDUCED *IN VITRO* BY 1- OR 2- BROMOPROPANE.

 $\underline{M.\ Toraason}^1,\ \underline{N.\ P.\ Singh}^2$  and  $\underline{D.\ W.\ Lynch}^1.\ ^INIOSH,\ Cincinnati,\ OH\ and\ ^2University\ of\ Washington,\ Seattle,\ WA.$ 

1-Bromopropane (1-BP; n-propyl bromide) (CAS No. 106-94-5) is an alternative to ozone-depleting chlorofluorocarbons that has a variety of potential applications as a cleaning agent for metals and electronics, and as a solvent vehicle for spray adhesives. Its analogue, 2-brompropane (2-BP; isopropyl bromide) (CAS No. 75-26-3) impairs antioxidant cellular defenses, enhances lipid peroxidation, and causes DNA damage in vitro. In the present study, DNA damage was assessed in human leukocytes exposed in vitro to 1-BP or 2-BP at 0, 0.01, 0.1, or 1 mM for 8 hr; or at 1 mM for 1, 2, 4 or 8 hr. Exposures to 1-BP or 2-BP were performed in triplicate samples of fresh heparinized venous blood from an adult male volunteer. For estimation of DNA damage, comets were produced by alkaline microgel-electrophoresis. In each sample, DNA damage was estimated in a minimum of 100 leukocytes using VisComet image analysis software. Apoptosis was assessed in leukocytes exposed to 1-BP or 2-BP using the DNA diffusion assay. 1-BP or 2-BP induced a significant increase in comet tail moment at 1 mM but not at 0.01 or 0.1 mM. DNA strand break number was significantly increased at 0.1 and 1 mM of 1-BP or 2-BP. In temporal studies, a significant increase in DNA damage was evident 1, 2, 4, or 8 hrs after exposure to 2-BP, whereas increased DNA damage was observed only after 4 or 8 hrs of exposure to 1-BP. Significant increases in apoptosis were evident after

exposure to 0.1 or 1 mM 2-BP, but only after exposure to 1 mM 1-BP. Results demonstrate the potential for 1-BP and 2-BP to induce DNA damage  $in\ vitro$  in human leukocytes.

# 154 GENOTOXICITY EVALUATION OF THE CHLOROHYDRIN HYDROLYSIS PRODUCT OF BISPHENOL A DIGLYCIDYL ETHER (BADGE-2HCL).

J. M. Waechter, V. A. Linscombe, M. R. Schisler, K. M. Jackson and <u>P. J. Spencer</u>. Toxicology & Environmental Research and Consulting, The Dow Chemical Co., Midland, MI.

Bisphenol A diglycidyl ether is the monomer for epoxy resins used for the production of lacquer coatings for food and beverage cans. Therefore, human exposure to BADGE and/or its hydrolysis products via the migration of the residual monomer from cured can coatings into foodstuffs may occur. Previous work has shown that one of the hydrolysis products of BADGE in the presence of aqueous gastric fluid its *bis*-chlorohydrin (2,2-bis[4-(3-chloro-2hydroxypropoxy)phenyl]propane) (BADGE-2HCl) reported to increase micronuclei in cultured human lymphocytes treated in vitro (Suarez et al., Mutation Res. 470: 221-228, 2000). The genotoxicity potential of BADGE-2HCl was studied in three in vitro assays with or without the presence of S9 activation. In a Salmonella-Escherichia coli reverse mutation assay, six concentrations of the test article were tested ranging from 1 to 1000 micrograms/plate and 10 to 5000 micrograms/plate, respectively. In a chromosomal aberration assay, rat lymphocytes were treated with concentrations ranging from 6.25 to 37.5 micrograms BADGE-2HCl/ml of media for determining the incidence of chromosomal abberations. In a mouse lymphoma forward mutation assay, concentrations of BADGE-2HCl ranged from 1.25 to 80 micrograms/ml without S9 and from 1.25 to 100 micrograms/ml with S9. BADGE-2HCl did not induce a mutagenic or clastogenic response in these assays. The in vivo genotoxic potential of BADGE-2HCl was studied using the mouse bone marrow micronucleus (MN) test using oral doses of 0, 250, 500, or 1000 mg/kg/day administered on two consecutive days. Groups of six CD1 mice per dose were sacrificed at 24 hours after the second treatment for the evaluation of polychromatic erythrocytes for MN (2000 cell/animal) which were not significantly increased at any dose relative to the negative controls. In summary, these data indicate that BADGE-2HCl does not represent a genotoxic hazard. (Sponsored by the Epoxy Resins Committee of the Association of Plastics Manufacturers in Europe)

# 155 INDUCTION OF DNA DAMAGE (COMET ASSAY) BY BISPHENOL A IN CHINESE HAMSTER OVARY (CHO) CELLS.

K. Rao. Toxicology, MicaGenix, Greenfield, IN.

Induction of DNA Damage (Comet Assay) by Bisphenol A in Chinese Hamster Ovay (CHO) Cells. Yong Xu, Ellen Shaw, K.S. Rao, and J.W. Parton, MicaGenix Inc., Greenfield, IN Bisphenol A (4, 4-isopropylidene-2-diphenol, BPA) is a key industrial monomer used for the synthesis of polycarbonate plastics and epoxy resins. BPA produces a weak response in uterotropic assays and there has recently been renewed attention to estrogenic potential of BPA due to widespread contamination of laboratory experiments by BPA through leaching from autoclaved polycarbonate cages (Koehler et. Al. Lab. Animal 32:24, 2002). Epoxy resin-based sealers were reported to induce DNA damage with Comet assay (Huang et al. J Endodontics 27:744, 2001), which might be related to recent findings of genotoxic activity of BPA. This study investigated the potential activity of BPA on DNA damage using the Comet assay in CHO cells in the presence or absence of S9 activation. A trypan blue exclusion assay was performed to determine the cytotoxic activity of BPA. A 30-50% cytotoxicity was observed at concentration levels of 39.1 ug/ml with S9 and 78.1 ug/ml without S9. It was concluded that the microsomal fraction S9 enhanced cytotoxicity of BPA. A Comet assay was performed by treating CHO cells with BPA for 2 hours with and without S9. A dose-related increase of DNA damage, represented by Comet moment, Tail length and % tail DNA, was observed. The effects were again higher in the cells with S9 activation than without S9. The results indicate a DNA damage effect of BPA and suggest this effect may be related to the metabolism of BPA.

# 156 PHOTOMUTAGENICITY OF BERGAMOTTIN AND ISOPIMPINELLIN.

J. Cocchiara and <u>A. Api</u>. Research Institute for Fragrance Materials, Inc., Woodcliff Lake, NJ.

The European Commission's Scientific Committee on Cosmetics and Non-Food Products (SCCNFP) recently released an opinion to limit all "furocoumarin-like" substances in cosmetic products to 1 ppm based on potential photocarcinogenic

and photomutagenic effects. Since it is not proven that all furocoumarins are photocarcinogens, the photomutagenicity of two furocoumarins found in citrus oils used in perfumery, bergamottin and isopimpinellin, was investigated in Salmonella typhimurium tester strains TA98, TA100, TA1535 and TA1537 and Escherichia coli strain WP2. Treatments were performed in all strains at concentrations up to precipitating dose levels. Specifically the bacteria were plated with bergamottin at doses of 15.8-5000 µg/plate, and isopimpinellin at doses of 3.16-1000 µg/plate in both the presence and absence of UV light. Irradiations of each strain used appropriate UVA light exposures, the higher exposure being the mutagenicity limit for each strain, having previously been demonstrated to induce approximately a doubling of revertant numbers or a 50% decrease in cell survival, and the lower exposure being a non-mutagenic and non-toxic dose. For bergamottin, none of the treatments resulted in any increases in revertant numbers indicative of any photomutagenic activity, and this material was considered negative under the conditions of this study. For isopimpinellin, there were no notable increases in revertant numbers in Salmonella typhimurium strains TA98, TA100, TA1535 or TA1537. However, statistically significant increases in revertant numbers in strain TA102 were observed following irradiation (both with the low and high UV irradiation levels), and were dose-related up to the precipitating dose levels. A confirmatory test in this strain was conducted. The increases were reproducible and these data are therefore considered indicative of photomutagenic activity of isopimpinellin in strain TA102 in this assay system. Additional photomutagenicity testing on other furocoumarins identified in essential oils is planned.

## 157 BACTERIAL MUTAGENICITY OF CIGARETTE SMOKE GAS/VAPOR PHASE.

F. J. Tewes and T. J. Meisgen. *PHILIP MORRIS Research Laboratories GmbH*, *Cologne, Germany.* Sponsor: <u>H. Haussmann</u>.

The in vitro mutagenicity of cigarette smoke is generally determined from the particle phase. In this study the mutagenicity of the gas/vapor phase of cigarette smoke was investigated. Mainstream smoke from University of Kentucky standard reference cigarettes and a research cigarette, generated according to ISO standards, was passed through a glass fiber filter to trap the total particulate matter (TPM) and then bubbled through ice-cold phosphate-buffered saline to trap the 'watersoluble fraction of the gas/vapor phase' (GVP). Mutagenicity was determined in the microsuspension modification of the Ames Salmonella mutation assay according to Kado (1983). Results revealed that GVP is mutagenic; however, in contrast to TPM, GVP contains significant amounts of direct-acting mutagens, as indicated by the response in the absence of a metabolic activation system, and causes mainly basepair substitutions, as indicated by the higher response in strain TA100 than in strain TA98. Validation of the microsuspension assay using the solvent as negative control and methyl methanesulfonate as positive control showed that the intra-day and inter-day variability of the assay, with a coffecient of variation of less than 20%, was well within the usual range of other in vitro genotoxicity assays. Comparison of the reference cigarettes with the research cigarette showed that these cigarettes could be discriminated on the basis of GVP mutagenicity (e.g., response at equivalent TPM doses was approximately four-fold higher for the research cigarette compared to the Reference Cigarette 2R4F). Screening for mutagenic constituents in GVP showed that acrolein and formaldehyde were active in the microsuspension assay and that acrolein was responsible for up to 40% of the GVP activity. The results of the study demonstrate that the gas/vapor phase of cigarette smoke is mutagenic and that the microsuspension assay may be a useful tool for further investiga-

# 158 GENOTOXICITIES OF SAMPLES FROM NICKEL REFINERIES: PREDICTIONS OF CARCINOGENIC POTENTIALS.

R. Verma and J. Landolph. Cancer Research Laboratory, Depts. of Mol. Microbiol. and Immunol., Path., and Mol. Pharmacology/Toxicol., USC/Norris Cancer Center, Keck School of Medicine/School of Pharmacy, University of Southern California, Los Angeles, CA.

Epidemiological studies and animal carcinogenicity data indicate that different nickel compounds have different carcinogenic potentials. This poses the problem of how to predict carcinogenic potentials of those nickel samples for which there are no valid animal inhalation studies and no, or inconclusive, epidemiological data. We have used short-term *in vitro* assays to determine the relative genotoxicities of several nickel samples, finding good agreement between *in vitro* and *in vivo* results. We have now extended this work to include four samples of nickel refinery dust: two samples from a sulfidic nickel ore refinery (MD, RD) and two samples from a lateritic nickel ore refinery (NiCOM, GNiO [<15 $\mu$ m]). The sample of refinery matte dust (MD), was significantly cytotoxic to cultured C3H/10T1/2 (10T1/2) mouse embryo fibroblastic cells, with an LC50 concentration of (1.5  $\pm$  1.2)  $\mu$ g/ml. This sample induced morphological transformation in 10T1/2 cells although it was

taken up by phagocytosis to approximately one fourth the extent that nickel subsulfide was. The roasting dust (RD) sample from the same refinery, was 20-fold less cytotoxic to 10T1/2 cells than the MD sample. The Nickel compact (NiCOM) sample from a lateritic ore refinery was phagocytosed and induced cytotoxicity, chromosomal aberrations (breaks and gaps), and morphological transformation in, 10T1/2 cells. The LC $_{50}$  of the NiCOM sample was  $18.5\,\mu g/ml$ . The fourth sample corresponds to the less than  $15\,\mu m$  subfraction of green nickel oxide (GNiO [<15 $\mu m$ ]). This sample was weakly cytotoxic compared to nickel subsulfide and other green (HT) nickel oxide samples previously tested. Our preliminary data suggest that the MD sample may have a carcinogenic potential similar to that of pure nickel subsulfide, in agreement with results from epidemiologic studies.

AMINO TERMINUS-DELETED CONSTITUTIVE
ANDROSTANE RECEPTOR VARIANTS ARE EXPRESSED
FROM DOWNSTREAM AUG AND CUG START

M. A. Stoner<sup>1</sup>, S. S. Auerbach<sup>2</sup> and C. J. Omiecinski<sup>1</sup>. <sup>1</sup>Department of Veterinary Science, The Pennsylvania State University, University Park, PA and <sup>2</sup>Department of Pharmacology, University of Washington, Seattle, WA.

The constitutive androstane receptor (CAR) (NR1I3) is a member of the nuclear receptor superfamily and regulates gene expression in response to xenobiotic signals, most notably phenobarbital-like compounds. CAR expression is highest in liver, where multiple mRNA splice variants have been characterized. Through use of a protein translation start site prediction program, we have identified at least six AUG and CUG putative start codons in the mRNA downstream of the usual start of CAR protein translation. Western blot analysis of human liver proteins reveals a complex banding pattern of CAR and CAR-like proteins, and in vitro translation of CAR using a wild-type DNA template yields the full-length product and a number of smaller proteins. One lower molecular weight band aligns with an amino terminus-deleted CAR variant that is missing the first 75 amino acids, apparently initiating translation at methionine 76. Truncated CAR variants were tested and did not efficiently drive transcription of a transiently transfected luciferase gene under control of a CAR/RXR binding site. However, co-expressed variant CAR proteins did appear to modulate the transcriptional activity of full-length CAR. Mutation of the full-length CAR translation start site results in increased expression of truncated CAR proteins, suggesting a cap-dependent model of protein translation, whereby the ribosome loads at one end of the transcript and scans for the next best putative Kozak sequence. Studies are ongoing to explain the involvement of amino terminus-deleted CAR variants in normal CAR signaling. (Supported by a Grant from the NIGMS, GM66411).

160 FUNCTIONAL ASSESSMENT OF A PUTATIVE PHOSPHORYLATION SITE IN A VARIANT ISOFORM OF HUMAN CAR.

S. S. Auerbach<sup>2</sup>, M. A. Stoner<sup>1</sup> and C. J. Omiecinski<sup>1</sup>. <sup>1</sup>The Pennsylvania State University, University Park, PA and <sup>2</sup>Department of Pharmacology, University of Washington, Seattle, WA.

The constitutive androstane receptor (CAR, NR1I3) is one of 48 nuclear receptors encoded in the human genome. CAR mediates transcriptional activation of genes involved in phase1, 2 and 3 xenobiotic and steroid metabolism in response to inducing agents such as the barbiturate, phenobarbital. Multiple isoforms of the receptor have been identified recently that are derived from alternatively spliced transcripts. CAR2 contains an insertion of 4 amino acids (SPTV) that generates a putative phosphorylation site in the ligand-binding domain. Mutation of the serine in this motif to an alanine blocks phosphorylation and enhances the ability of the receptor to transactivate an (NR1)5-driven luciferase reporter. However, mutation of the serine residue to an aspartate, generates a mock phosphorylated form of the receptor that completely disrupts transactivation. Studies using specific protein kinase inhibitors together with phospho-specific immunoblot analyses are in progress to determine the potential functional role of protein phosphorylation on the interaction of CAR2 with DNA targets and with transcriptional coregulators. The existence of structurally variant CAR receptors may be important in expanding the repertoire of functional activities governed by this receptor in human tissues. (Supported by a grant from the NIGMS, GM66411)

161 ROLE OF CONSTITUTIVE ANDROSTANE RECEPTOR IN THE INDUCTION OF CYP2B AND XENOBIOTIC TRANSPORTERS BY OLTIPRAZ.

L. Bird<sup>1</sup>, A. L. Slitt<sup>2</sup>, W. Huang<sup>3</sup>, D. D. Moore<sup>3</sup>, <u>C. D. Klaassen<sup>2</sup> and N. J. Cherrington<sup>1</sup>. <sup>1</sup>University of Arizona, Tucson, AZ, <sup>2</sup>University of Kansas Medical Center, Kansas City, KS and <sup>3</sup>Baylor College of Medicine, Houston, TX.</u>

Oltipraz (OPZ) induces Phase I & II drug metabolizing enzymes such as Cyp2B and glutathione S-transferases. Coordinate regulation of Phase I & II enzymes with xenobiotic transporters has been shown after treatment with microsomal enzyme

inducers. The purpose of this study was to determine whether OPZ also regulates xenobiotic transporter expression, and to determine the role of constitutive androstane receptor (CAR) in OPZ-mediated induction. To determine whether OPZ activates transporter gene expression via CAR, male and female Wistar-Kyoto rats were treated with OPZ and mRNA levels quantified by bDNA signal amplification. Wistar-Kyoto females express lower levels of CAR protein, such that they exhibit significantly lower induction of Cyp2B1 by phenobarbital as compared to Wistar-Kyoto males. OPZ induced UGT2B1 in males significantly higher than in females, suggesting activation through CAR. However, OPZ induced Mdr1b, Mrp3 and 4, mEH, NQO1, Cyp1A1, Cyp3A, and Cyp2B1/2 equally in both genders, indicating a CAR-independent mechanism of induction. Other transporters were unaffected by OPZ. To determine whether OPZ is capable of activating CARmediated transcription, CAR-1- mice were used to demonstrate the CAR-dependent induction of Cyp2B10 by OPZ. OPZ caused a robust induction of Cyp2B10 in wild type mice that was absent in CAR-<sup>1-</sup> mice. Finally, CAR-mediated induction of human CYP2B6 by OPZ was demonstrated using an *in vivo* transcription assay. Luciferase reporter constructs containing either a CYP2B6 promoter fragment containing the NR1 site or a multimeric NR1 site (NR1x5) alone were hydrodynamically transfected into mice. OPZ administration increased in vivo reporter activity of both the human CYP2B6 promoter and CAR specific response element constructs. In summary, OPZ coordinately increases hepatic xenobiotic transporter mRNA levels, along with Phase I & II enzymes via both CAR-dependent and CAR-independent mechanisms.

162 CONSTITUTIVE ANDROSTANE RECEPTOR (CAR)
INVOLVEMENT IN THE INDUCTION OF UDPGLUCURONOSYLTRANSFERASE (UGT) IN RAT LIVER
BY PHENOBARBITAL AND OTHER CYP2B INDUCERS.

M. K. Shelby<sup>1</sup>, A. L. Slitt<sup>1</sup>, N. J. Cherrington<sup>2</sup> and C. D. Klaassen<sup>1</sup>. <sup>1</sup>University of Kansas Medical Center, Kansas City, KS and <sup>2</sup>University of Arizona, Tucson, AZ.

UGTs are phase II metabolizing enzymes that catalyze the glucuronidation of numerous endobiotic and xenobiotic compounds. Phenobarbital (PB), a known Cyp2B inducer, increases UGT activity. Induction of Cyp2B by PB and other microsomal enzyme inducers is mediated by the nuclear receptor CAR. The purpose of this study was to determine the UGT isoforms in liver that are induced by the Cyp2B inducers PB, diallylsulfide (DAS), polychlorinated biphenyl 99 (PCB99), and trans-stilbene oxide (TSO), and whether CAR is involved in induction of those UGTs. In order to determine which UGTs are induced, UGT mRNA levels were determined in male Sprague-Dawley rats treated with the aforementioned Cyp2B inducers. UGT2B1 mRNA levels were increased by all four inducers, whereas UGT1A1 and 1A6 mRNA levels were induced by DAS, PCB99, and TSO. UGT1A5 mRNA levels were induced by DAS and TSO, and UGT2B12 mRNA levels were induced by PCB99 and TSO. The role of CAR in UGT induction was determined using Wistar Kyoto (WK) rats which posses a gender difference in liver expression of CAR where females express lower CAR levels than males. UGT mRNA levels were determined in male and female WK rats treated with PB, DAS, PCB99 and TSO. UGT1A1, 1A5, and 2B1 mRNA levels were induced in male WK rats by all four Cyp2B inducers. However, in female WK rats induction of UGT1A1, 1A5, and 2B1 mRNA levels was either abolished or diminished. UGT1A6 mRNA levels in WK rats were induced only by TSO. Additionally, there was no apparent difference in induction of UGT1A6 mRNA levels between male and female WK rats, suggesting induction of UGT1A6 by TSO is not CAR dependent. However, CAR appears to mediate, at least in part, induction of UGT1A1, 1A5, and 2B1 by PB, DAS, PCB99, and TSO. (Supported by NIH Grants ES-08156, ES-07079)

RESPONSE OF MAJOR HISTOCOMPATIBILITY
COMPLEX (MHC) CLASS II PROMOTER REGION TO
DEX AND RIFAMPICIN IN TRANSFECTED G3A CELLS
AND PRIMARY RAT HEPATOCYTES WITH HUMAN
PREGNANE X RECEPTOR (SXR).

E. Fuentes<sup>1</sup>, B. D. Jimenez<sup>1</sup>, L. C. Quattrichi<sup>2</sup>, B. Joyce<sup>2</sup> and P. S. Guzelian<sup>2</sup>.

<sup>1</sup>Biochemistry, University of Puerto Rico, Medical Sciences Campus, San Juan, Puerto Rico, <sup>2</sup>Medical Toxicology, University of Colorado Health Sciences Center, Denver, CO and <sup>3</sup>Center for Environmental & Toxicological Research, University of Puerto Rico, Medical Sciences Campus, San Juan, Puerto Rico.

Regulation of MHC class II gene expression is of considerable interest, the research presented here may provide new insight into novel pathways of immune regulation. Some evidence suggest that the expression of MHC class II proteins in non-APCs such as tumor cells could make the immune system respond better to tumors. Glucocorticoids such as Dexamethasone (DEX) and the antibacterial rifampicin (RIF) regulate gene expression by binding to the respective nuclear receptor and then interacting with specific promoter regions on the host cell DNA. To assess the

regulation of MHC II expression at the transcriptional level by DEX or rifampicin, we used the promoter region of HLA-DRa coupled to a luciferace reporter gene and transfected in G3A human fibrosarcoma cells line. Our results with transfected human fibrosarcoma cell line shows that the presence of SXR enhance MHCII gene expression significantly in these cells. This was confirmed with titration experiments using the SXR expression vector (pCDG-SXR). Our results also suggest that RIF treatment may mediate a non significant transcriptional activation of MHC II while DEX treatment inhibits it. Preliminary data in primary rat hepatocytes suggest that both Dexamethasone (DEX) and pregnenolone 16a-carbonitrile (PCN) induces the activity in these cells transfected with the human promoter of MHC II (HLA-DRa). These results are in agreement with those previously obtained in in vivo experiments conducted in our laboratory, which demonstrated induction of MHC II by these compound in non-APCs.

MECHANISTIC EXAMINATION OF GSK3 REGULATION BY PEROXISOME PROLIFERATORS AND ITS ROLE IN HEPATOCARCINOGENESIS.

K. A. Burns and J. P. Vanden Heuvel. Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA.

Peroxisome proliferators-activated receptors (PPARs) are ligand-activated transcription factors belonging to the nuclear receptor family. PPARs can be activated by a large group of chemicals called peroxisome proliferators (PPs) that include industrial pollutants and hypolipidemic drugs. It has been shown in murine models that administration of PPs results in hepatomegaly, mitogenesis, and eventually hepatocellular carcinoma. PPs are thought to cause cancer by altering gene expression and ultimately cell cycle regulation. While it is known that PPARa mediates these effects, the mechanisms responsible for the responses observed are not known. To discern these responses, previous studies in our laboratory were done to comprehensively analyze gene expression in rat and human hepatoma cells exposed to PPs. These studies showed that glycogen synthase kinase 3 (GSK3) was being regulated in response to PP treatment. GSK3 is a serine/theronine-specific kinase with a number of important targets. Western blot analysis shows that both GSK3 isoforms  $(\alpha \text{ and } \beta)$  protein levels are decreased in the PPAR $\alpha$  wild type hepatocyte model upon PP stimulation, but not in its PPARα -/- counter-part. Quantative RT-PCR analysis reveals no regulation at the transcriptional level; therefore, it is hypothesized that this regulation is occurring at the post-translational level. Experiments will be utilized to determine whether this regulation is the result of altered ubiquination and protein turnover. Since GSK3 is an important signaling molecule involved in diverse biological processes, regulation of this kinase may play a key role in PP induced cell cycle aberrant regulation.

PEROXISOME PROLIFERATOR-ACTIVATED RECEPTORβ (PPARβ) ATTENUATES COLON CARCINOGENESIS.

H. E. Marin<sup>1, 2</sup>, C. J. Nicol<sup>3</sup>, F. S. Harman<sup>2</sup>, F. J. Gonzales<sup>3</sup> and J. M. Peters<sup>2</sup>.

Recent data has shown that PPARB may be involved in colon cancer. PPARB expression is reported to be upregulated in human colon tumors containing an inactivated APC gene, as well as in human and azoxymethane-induced rodent tumors. In these studies, the functional role of PPAR $\beta$  in colon carcinogenesis was investigated using azoxymethane (AOM)-treated PPARβ(-/-) mice as well APC(+/-) x PPARβ(-/-) mutant mice. In the first study, PPARβ(-/-) mice were treated with AOM and colon polyp formation was examined. AOM treatment caused a dosedependent increase in colon polyp formation in wild-type mice, and this effect was exacerbated in PPARβ(-/-) mice. In the second study, APC(+/-) mutant mice were crossed with PPARβ(-/-) mice, generating double mutants, APC (+/-) x PPARβ (-/-). Similar to AOM-treated PPARB(-/-) mice, double mutant mice also exhibited increased polyp formation compared to control APC(+/-) mice. In addition, the double mutant mice showed increased mortality rate as compared with APC(+/-) controls. Interestingly, PPARy mRNA expression was decreased in colons of AOMtreated wild-type and PPARβ(-/-) mice, and more so in colon polyps. Decreased expression of PPARy mRNA was also found in colon polyps of both APC(+/-) and double mutant mice. Given the difference in phenotype observed between genotypes, this demonstrates that the increased incidence of polyp formation is not due to differences in PPARy expression. Further, in contrast to recent reports, results from these studies provide evidence that PPAR $\!\beta$  attenuates colon carcinogenesis in both a chemically-induced and genetic model. 166

Phthalate diesters are industrial plasticizers with ubiquitous human exposures due to their ability to readily leach from commercial products. Phthalate diesters are hydrolyzed into phthalate monoesters by esterases in the gut, liver and blood. Phthalates are known to activate peroxisome proliferator-activated receptors (PPARs), and the monoesters appear to be the active metabolite that binds PPARs. In this study the activation of both human and mouse PPAR $\alpha$ , PPAR $\beta$ , and PPAR $\gamma$ by phthalate monoesters were investigated by trans-activation assays using stably-transfected 3T3-L1 cell lines. MI7P, MINP, MEHP, MIDP, MnOP, MBenP and MI6P activated both mouse and human PPARa. The mouse PPARa was generally more sensitive than the human PPAR $\alpha$  to activation by phthalate monoesters. MIDP, MBenP, MEHA, MButP and MI6P activated mouse PPARβ, but human PPARβ was not significantly activated by any of the phthalate monoesters. MI7P, MINP, MEHP, MIDP, MnOP, MBenP, MEHA and MI6P activated both mouse and human PPARy. Further, both mouse and human PPARy had similar sensitivity to activation by phthalate monoesters. The hierarchy of potency for the activation of PPARα among the phthalate monoesters was determined to be MnOP> (MIDP≈MINP≈MI7P)> (MEHP≈MI6P)> MBenP>MEHA> (MButP≈MEP). The hierarchy of potency for the activation of PPARy among the phthalate monoesters was determined to be MnOP>MINP> (MIDP≈MI7P)> (MEHP≈MBenP)> (MI6P≈MEHA)> (MButP≈MEP). These results indicate that the potency of phthalate monoesters for the activation of PPAR $\alpha$  and PPAR $\gamma$  increases with increasing alkyl side chain length. This research was supported by The Phthalate Esters Panel of The American Chemistry Council and The Huck Institute for Life Sciences, The Pennsylvania State University.

167 CITED2 IS A COACTIVATOR OF PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR-α AND -γ TRANSCRIPTIONAL ACTIVITY.

E. Tien and J. P. Vanden Heuvel. Center for Molecular Toxicology and Carcinogenesis, Pennsylvania State University, University Park, PA.

The peroxisome proliferator-activated receptors (PPARs) are a class of nuclear receptors which respond to chemicals known as peroxisome proliferators (PPs). The PPARs can be further classified into three types ( $\alpha$ ,  $\beta$  or  $\delta$  and  $\gamma$ ). These three subtypes of PPAR have been implicated in many biological functions ranging from adipocyte differentiation to hepatocarcinogenesis. The ultimate physiological response of the PPARs to their respective ligands is dependent in large part to the recruitment and function of other proteins known as coregulators. The coregulator class of proteins can be divided into two main categories: coactivators and corepressors. It is becoming apparent that the composition of the transcriptional complex formed around the nuclear receptor hetero- or homo- dimer can vary depending on the ligand which activated the nuclear receptor. These recruitment differences can greatly alter the ability of a transcriptional complex to regulate aspects of cellular function in response to a chemical insult. In these studies, a novel PPAR coactivator (CITED2) was characterized and has been shown to be a basal and ligand induced coactivator for PPAR  $\!\alpha$  and PPAR  $\!\gamma$  but not PPAR  $\!\beta$  . Also, CITED 2 acts as a coactivator for PPARa in the presence of a wide range of agonists including fibrate hypolipidemic drugs and fatty acids. Expression of CITED2 is ubiquitous throughout the mouse which suggests that CITED2 may act as a general coactivator for PPARα-dependent effects. In addition, CITED2 is involved in the regulation of several PPARα-dependent target genes as well as PP-induced cell proliferation, suggesting a larger role for CITED2 in the overall maintenance of cellular homeostasis.

168 modulation of PKC $\alpha$ /mapk signaling pathway by Peroxisome Proliferator-activated receptor $\beta$  (PPAR $\beta$ ).

<u>D. J. Kim</u><sup>1, 2</sup> and <u>J. M. Peters</u><sup>1, 2</sup>. <sup>1</sup>Department of Veterinary Science and The Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA and <sup>2</sup>Graduate Program in Molecular Toxicology, The Huck Institute for Life Sciences, The Pennsylvania State University, University Park, PA.

Previous work has shown an enhanced epidermal hyperplastic response induced by the tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA), and increased incidence of skin tumor formation in a two stage bioassay in PPAR $\beta$ -null mice, suggesting a critical role of PPAR $\beta$  in attenuating epidermal cell proliferation. Protein kinase C (PKC) is the major cellular receptor that is activated by TPA. In

these studies, the role of PPAR $\beta$  in the regulation of PKC $\alpha$  was examined. Intracellular phosphorylation analysis showed phosphorylated PKCα and mitogenactivated protein kinase kinase (MEK) were increased in PPARβ-null mouse skin treated with TPA as compared to wild-type control. Similarly, western blot analysis showed that the level of phosphorylated PKC $\alpha$  was higher in TPA-treated PPAR $\beta$ null skin and keratinocytes compared to wild-type controls. Additionally, phosphorylated Raf, MEK and p42 MAPK (ERK2) were higher in TPA-treated PPARBnull skin compared to wild-type control. Two downstream effector molecules of the MAPK pathway, RSK1 and COX-2, were also higher in TPA-treated PPARβ-null skin compared to wild-type control indicating enhanced PKCα/MAPK signaling pathway in the absence of PPARβ expression. Inhibition of PKCα by selective inhibitors in cultured keratinocytes revealed that inhibition of PKCα effectively retarded cell proliferation in PPARβ-null keratinocytes in a dose-dependent manner, whereas it only slightly influenced cell proliferation in wild-type keratinocytes. Combined, these studies provide evidence that PPARB attenuates cell proliferation by modulating PKC $\alpha$ /MÅPK signaling pathway. (Supported by NIH, CA89607)

FORKHEAD BOX O1A (FOXO1A) AND PEROXISOME PROLIFERATOR ACTIVATED RECEPTOR ALPHA (PPARα) EXPRESSION LEADS TO MUTUAL REPRESSION OF THEIR TRANSCRIPTIONAL ACTIVITY.

T. Murosky and G. Perdew. Pennsylvania State University, State College, PA.

The FOXO Subclass of the Forkhead Box (FOX) proteins has been implicated in cell cycle regulation, metabolism, and apoptosis. The FOXO proteins are modulated by direct AKT (PKB) phosphorylation. AKT phosphorylation of FOXO1a blocks nuclear transport causing a repression in its transcriptional activity. Evidence exists showing FOXO proteins complexing with certain members of the Nuclear Hormone Receptor superfamily (e.g. Androgen Receptor, Estrogen Receptor) when the receptors are activated. Peroxisome Proliferator Activating Receptors (PPARs) are also implicated in cell cycle regulation, metabolism, and apoptosis. A continued high level activation of PPARα can lead to hepatocarcinogenesis and its tumor promotional properties in murine models. Activated PPARα can suppress apoptosis in many different model systems. To contrast, FOXO1a has been shown to induce apoptosis. The hypothesis that PPARα can antagonize FOXO1a activity was tested. In transient transfections in HepG2 cells, PPARα was co-transfected with wtFOXO1a or FOXO1a-AAA (constitutively active) and the PPRE Aco-Luc reporter vector. The wtFOXO1a was not able to repress PPARα, but the constitutively active form mediated a 2-fold repression of PPARα activity. In a reverse experiment, the presence of PPARα repressed the wtFOXO1a and FOXO1a-AAA activity on a FÔXO-driven reporter about 3-fold and 2-fold respectively. The conclusions of these experiments point to a functionally significant interaction between PPARα and FOXO1a, which may at least in part mechanistically explain the antiapoptotic activity of PPARa. Interestingly, the repressive activity of FOXO1a was also observed with PPARβ and PPARγ in transient cell transfection assays. Additional studies will be required to determine the actual mechanism of the mutual repression observed. (Supported by NIEHS grants ES04869 and ES07799)

## 170 CONJUGATED LINOLEIC ACID BINDS TO PPAR AND CAUSES DIFFERENTIATION OF 3T3-L1 CELLS.

B. J. Belda, J. T. Thompson and <u>J. P. Vanden Heuvel</u>. Penn State University, University Park, PA.

Conjugated linoleic acid (CLA) is a class of long chain, polyunsaturated fatty acids that are positional and geometrical isomers of linoleic acid (LA). CLA has many beneficial effects in laboratory animals including reduction of cancer and amelioration of symptoms of type 2 diabetes. To understand these effects we looked at the role CLA plays in differentiation of 3T3-L1 preadipocytes. CLA treatment increased Oil Red-O staining 1.5 to 2 fold over control treated cells, indicating that the CLA causes these cells to undergo differentiation. To elucidate the mechanisms involved in differentiation we conducted microarray analysis of CLA treated cells. In total 537 genes were significantly regulated in at least one of seven time points. Expression of genes indicative of adipocyte differentiation (ADFP, CD36 and the PPAR responsive UCP2) are increased with CLA treatment. However, expression of pro-apoptotic genes (BCL2, Bak, Trp53, and TNF) is reduced while anti-apoptotic gene (Birc4 and DAD1) expression is reduced. Because PPAR has been reported to play a key role in 3T3-L1 cell differentiation into adipocytes we also investigated the ability of CLA to activate a PPAR luciferase reporter construct. CLA along with two known PPAR activators, rosiglitazone and PGJ2 are all able to activate this reporter construct. These data support the claim that CLA may prevent diabetes by activating PPAR and causing 3T3-L1 cells to differentiate. This may also suggest a mechanism by which CLA inhibits cancer as PPAR ligands inhibit breast and prostate tumor cell growth. Research into the expression of PPAR regulated genes in this system is ongoing.

### 171 VAN/NAF1 IS A PPAR COREGULATOR.

A. M. Flores, R. Wilson, L. E. Vasina and B. J. Aneskievich. *Pharmaceutical Sciences, University of Connecticut, Storrs, CT.* 

Peroxisome proliferators increase differentiation and cell-specific gene expression in keratinocytes, the major cell type in the epidermis or upper layer of skin. This effect is mediated through peroxisome proliferator activated receptors (PPARs), members of the nuclear receptor (NR) superfamily of ligand activated transcription factors. In addition to ligand, NR function is governed by coregulator proteins, which contribute to either activation or repression of PPAR target gene transcription. To better understand PPAR function in keratinocytes, we sought to identify NR coregulator proteins present in these cells, define the basis for NR-coregulator interaction, and examine their activating or repressing effect on NR function. We screened a human keratinocyte cDNA library using the carboxyl portion of human PPAR $\alpha$  as bait in a yeast two-hybrid assay. In addition to previously identified PPAR-interacting proteins such as TRAP220/PBP and RXR, one candidate coregulator was represented nine times as the same two overlapping cDNA fragments of a previously identified protein known as Naf1 (Nef-associated factor 1) or VAN (Virion-associated nuclear shuttling protein). Interaction of the Naf1/VAN clones varied with the different PPARs. Each of the two overlapping clones contained the same LXXLL domain (NR box) which was demonstrated by site directed mutagenesis to be responsible for interaction with the receptors. In a similar manner, the PPAR AF-2 was also found to be required for interaction with the Naf1/VAN clones. Studies with the full-length Naf1/VAN protein have also detected strong interaction with PPAR, again in an isoform-specific fashion. Both full-length and the more-carboxyl clone regulate PPAR transcriptional activity at defined PP response elements. Immunostaining for Naf1/VAN protein in intact skin revealed a differentiation-associated expression pattern. Given this and its interaction with PPARs, we expect Naf1/VAN may play a significant role in regulating epidermal keratinocyte response to peroxisome proliferators.

# 172 CELL CONTEXT-DEPENDENT DIFFERENCES IN HORMONAL REGULATION OF E2F-1 IN HUMAN BREAST CANCER CELLS.

S. Ngwenya<sup>1</sup> and <u>S. Safe<sup>2</sup></u>. <sup>1</sup>Biochemistry & Biophysics, Texas A&M University, College Station, TX and <sup>2</sup>Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.

E2F-1 is a member of the E2F transcription factor family that plays an important role in cell cycle progression and cell proliferation. 17β-Estradiol (E2) induced E2F-1 gene expression in MCF-7 human breast cancer cells, and deletion analysis of the E2F-1 gene promoter showed that the -146 to -54 region was the minimal estrogen-responsive sequence. Subsequent analysis of this promoter in MCF-7 cells indicated that E2-induced transactivation was dependent on both upstream GCrich and downstream CCAAT motifs that bound estrogen receptor  $\hat{\alpha}$  (ERa)/Sp1 and NF-YA, respectively. The cooperative interaction of the resulting ERα/Sp1/NF-YA complex was required for enhanced gene expression. E2 also induced E2F-1 gene expression in ZR-75 human breast cancer cells, and deletion analysis showed that the -146 to -54 region was the minimal E2-responsive sequence. Mutation and deletion analysis of the E2F-1 promoter showed that both the upstream GC-rich and downstream CCAAT sites were independently E2-responsive, and this was in direct contrast to results obtained in MCF-7 cells where cooperative interaction of the ERa, Sp1 and NF-YA was required for transactivation. Analysis of the promoter constructs showed that the GC-rich sites, which bind Sp1, were activated by genomic ERα/Sp1, whereas the activation of the CCAAT sites, where NF-YA binds, was associated with activation of cAMP/PKA which in turn activated NF-YA in ZR-75 cells. Both indirect and direct antiestrogens ICI 182, 780 and TCDD inhibited E2-induced activity in cells transfected with pE2F-1h (-169/-111) and pE2F-1j (-146/-54). In ZR-75 cells, TCDD was more effective than ICI 182, 780 as an inhibitor of E2 induced activity in constructs containing GC- rich or CCAAT sites. These results demonstrate the importance of cell context importance in molecular mechanisms of E2F-1 activation and inhibition. (Supported by NIEHS E209106 and ES04176)

## 173 GENISTEIN REGULATES THE STEROID COACTIVATOR GRIP-1 IN THE RAT MAMMARY GLAND.

T. G. Whitsett and C. A. Lamartiniere. University of Alabama at Birmingham, Birmingham, AL.

Genistein is the predominant isoflavone found in soy and has been shown to suppress the development of chemically-induced mammary cancer in rats. One mechanism through which genistein may exert this chemoprotective effect is *via* the estrogen receptors alpha and/or beta. Nuclear receptors are known to interact with nuclear receptor coactivators, especially the SRC family (SRC-1, GRIP-1, and AIB1), to increase the efficiency of transcriptional regulation. The current study investigates the relationship between dietary genistein consumption and GRIP-1.

Female Sprague-Dawley CD rats were fed 250 mg genistein/kg AIN-76A diet or AIN-76A alone from conception until either day 21 or day 50 postpartum. Western blot analysis was performed on the mammary glands of these female rats. There was a 2 fold increase in the level of GRIP-1 protein in the 21 day old mammary glands of animals that were treated with dietary genistein compared to the 21 day old females consuming only AIN 76A. Conversely, the animals treated with dietary genistein until 50 days showed a 2.8 fold decrease in the levels of GRIP-1, when compared to the animals on the AIN-76A diet. We hypothesize that prepubertal exposure to genistein increases cell differentiation and maturation of the mammary gland resulting in protection against mammary cancer. An up-regulation of GRIP-1 due to genistein early in life could interact with nuclear receptors, especially ER, enhancing activation and increasing transcriptional rate at target genes, thus furthering an ER-based mechanism of action for genistein's protective effect against breast cancer. Subsequently, the adult rat which is characterized as having a more differentiated mammary gland has lower GRIP-1 levels and reduced susceptibility for carcinogenesis. Understanding the mechanism of action of genistein during critical periods of life should allow us to development novel approaches to cancer prevention.

## 174 EFFECTS OF DOPAMINE D1 FULL AGONISTS ON RECEPTOR CYCLING.

J. P. Ryman-Rasmussen<sup>1</sup> and R. B. Mailman<sup>1, 2, 3</sup>. <sup>1</sup>Curriculum in Toxicology, UNC Chapel Hill, Chapel Hill, NC, <sup>2</sup>Psychiatry, UNC Chapel Hill, Chapel Hill, NC and <sup>3</sup>DarPharma, Inc., Chapel Hill, NC.

Dopamine D1 receptor full agonists show promise in treating a number of neurological and psychiatric disorders including Parkinson's disease. Occupation of GPCRs by agonists is known to cause a variety of compensatory events (e.g., desensitization, internalization, etc.) that can affect drug response, yet there is minimal information on how different D1 full agonists compare to dopamine in affecting the processes of receptor internalization and intracellular trafficking that are important in the regulation of receptor function. We have used an HEK cell line stably transfected with an epitope-tagged, human D1 receptor to address this issue. We have found that internalization of cell surface receptors following agonist exposure in this model system occurs at a similar rate for dopamine and the novel agonists A77636 and dinapsoline, and reaches as steady-state by 30 min. Only with dopamine itself, however, is there a rapid up-regulation (within 1 h) following the removal of agonist, although a slower (over 24 h) up-regulation occurs with receptors exposed to dinapsoline. This up-regulation does not occur for receptors treated with A77636. These data raise the hypothesis that occupancy by dopamine targets the D1 receptor to a rapid recycling pathway, whereas A77636 targets D1 receptors for degradation. This hypothesis was supported by preliminary confocal microscopic studies of cells that had been treated with these three drugs. The regulation of the receptor by dinapsoline appears to involve both novel recycling and biosynthetic pathways that remain uncharacterized. [This work was supported by NIH grants NS39036 and MH 40537, and a gift from DarPharma, Inc. RBM has a COI related to equity in DarPharma, Inc.]

## 175 EVALUATION OF HEPATIC RECEPTOR CONCENTRATION BY QUANTITATIVE OPTICAL IMAGING.

L. M. McIntosh<sup>3</sup>, D. R. Vera<sup>1</sup>, R. F. Mattrey<sup>1</sup>, <u>S. Fournier</u><sup>2</sup>, S. Authier<sup>2</sup>, P. Gallant<sup>3</sup> and F. Lesage<sup>3</sup>. <sup>1</sup>University of California, San Diego, San Diego, CA, <sup>2</sup>LAB Pre-Clinical Research International, Inc., Laval, QC, Canada and <sup>3</sup>ART Advanced Research Technologies Inc., Saint-Laurent, QC, Canada.

Kinetic modeling is critical to isolate variables, such as blood flow, binding, dissociation constants and non-specific uptake, involved in targeting of receptors. Optical imaging has high sensitivity to fluorophores and can be utilized to non-invasively measure uptake. However, the method has not yet been used as a quantitative tool. In this study, a novel time-domain small animal optical imaging system was used to quantify receptor concentration of an optically labeled receptor binding diagnostic agent. The optical fluorophore Cy5.5 was covalently coupled to DPTA-galactosyldextran or DPTA-dextran. The Cy5.5 density for both agents was approximately 8 moles of Cy5.5 per mole of dextran T70. Male BALB-c mice were anesthetized and the Cy5.5 labeled agents were administered (24 nmole/kg dextran) intervenously. Immediately post-injection the animal was placed supine in the ART SAMI system for optical imaging. Regions of interest over the heart and liver were imaged over 30 minutes. Time-intensity curves were generated over these regions which represented fluorescent intensity in the heart and liver as a function of time. Images of the area were also produced to recover object shape, location and concentration. The time-activity curve and volumetric images for Cy5.5-DTPA-dextran did not show hepatic uptake. The agent resembled a blood pool tracer without any tissue specificity. However, the receptor-binding agent, Cy5.5-DPTA-galactosyl-dextran, displayed hepatic accumulation, peaking within 20 minutes. The study demonstrates the role for time-domain optical imaging in the evaluation of receptor diagnostic agents. Optical imaging has higher sensitivity (75-fold increase) than nuclear imaging, which allows quantification of receptor density, improved kinetic modeling and tomographic representations.

# 176 DURING CHOLESTASIS LOSS OF RXR $\alpha$ IS HEPATOPROTECTIVE AND INCREASES EXPRESSION OF GENES FOR METABOLISM AND TRANSPORT IN

A. L. Slitt<sup>1</sup>, N. J. Cherrington<sup>2</sup>, C. Chen<sup>1</sup>, J. M. Maher<sup>1</sup>, Y. Wan<sup>1</sup> and C. D. Klaassen<sup>1</sup>. <sup>1</sup>University of Kansas Medical Center, Kansas City, KS and <sup>2</sup>University of Arizona, Tucson, AZ.

Retinoid-X-receptor alpha (RXRa) is an important heterodimeric partner for nuclear hormone receptors (NHRs) such as Pregnane-X-receptor (PXR) and Farnesoid-X-receptor (FXR). PXR and FXR are activated by bile acids, and are responsible for the regulation of genes involved in bile acid metabolism and transport. Because RXR $\alpha$  functions as a dimeric partner, it was hypothesized that ablation of RXRα in liver would decrease the expression of a variety of genes that are induced via NHRs during cholestasis. Therefore, liver-specific RXRα-null mice (KO) and corresponding wild-type mice (WT) underwent either sham or common bile-duct ligation (BDL) surgery. Three days after BDL, serum bile acid concentrations were elevated 5.7-fold and 6.2-fold above control concentrations in WT and KO mice, respectively. Unexpectedly, the amount and severity of BDL-induced focal necrosis was greater in WT mice than that in KO mice. BDL decreased the mRNA levels of the bile acid uptake transporters Ntcp, Oatp1, Oatp3, and Oatp4 by at least 40% in both WT and KO mice. Oatp2 and Oatp5 mRNA was increased after BDL, with a larger induction occurring in KO mice. The mRNA levels of the phase I enzymes Cyp3a11, Cyp7a, NQO1, and the liver excretory transporters Mrp1, Mrp3, Mrp4, Mrp5, and Bsep were increased in livers from WT and KO mice, with the magnitude of induction being higher in livers from KO mice. The decreased hepatotoxicity in KO mice is likely due to increased liver gene expression of transporters that export BA from hepatocytes and not due to decreased expression of BA uptake transporters, because there was no difference in Oatp1 or 4 mRNA expression after BDL between WT and KO mice. The absence of RXRα may allow other NHRs to activate gene transcription. Alternatively, other RXR isoforms, such as RXR $\beta$  and RXR $\gamma$  may heterodimerize with PXR and FXR to activate gene transcription. ### 177 HUMAN DIETARY ALKALOIDS INHIBIT SONIC HEDGEHOG SIGNALING.

R. Lipinski and W. Bushman. Molecular and Environmental Toxicology Center, University of Wisconsin-Madison, Madison, WI. Sponsor: R. Peterson.

The Sonic hedgehog (Shh) signaling pathway plays an integral role in the patterning and development of diverse structures in the vertebrate embryo. Genetic abrogation of Shh signaling induces a spectrum of developmental field defects such as cyclopia, cleft lip, and cleft palate (collectively termed holoprosencephaly). Shh is a secreted peptide which binds to the transmembrane receptor Patched (Ptc), releasing its inhibition of Smoothened and inducing a signaling cascade that results in the upregulation of target genes including Gli1 and Ptc1. The plant steroidal alkaloid cyclopamine, which is an inhibitor of the Shh signaling pathway, induces holoprosencephaly when administered to a variety of vertebrate species. Although cyclopamine is not present in the human diet, there are several other dietary alkaloids of similar chemical structure, including tomatidine (derived from  $\alpha$ -tomatine in tomatoes), solanidine (derived from  $\alpha$ -chaconine and  $\alpha$ -solanine in potatoes), solasodine (derived from solasonine in eggplants), and diosgenin (from wild yams). To investigate the possible effects of these compounds on Shh signaling, we used NIH3T3 cells transfected with a Shh-responsive Gli1 luciferase construct. Addition of Shh peptide (ShhNp) increased luciferase activity six-fold. This ShhNp-mediated increase in luciferase activity was reduced to control levels by addition of cyclopamine (10 µM) or tomatidine (10 µM), reduced by 25% with solanidine (10  $\mu \dot{M}$ ), and reduced by 50% with solasodine (10  $\mu \dot{M}$ ). Diosgenin had no effect. Control experiments confirmed the specificity of inhibition and the lack of cytotoxicity. In a Ptc1-null primary fibroblast cell line with constitutive Shh pathway activation, cyclopamine, tomatidine, solanidine and solasodine all inhibited Shh signaling — suggesting that they act through a common mechanism downstream of Ptc1. Shh signaling is important in a variety of developmental processes. Its inhibition by dietary alkaloids may have important implications on human health, particularly during fetal development.

EVALUATION OF THE DEVELOPMENTAL TOXICITY OF 1-(1, 2, 3, 4, 5, 6, 7, 8-OCTAHYDRO-2, 3, 8, 8-TETRAMETHYL-2-NAPHTHALENYL)ETHANONE.

C. Letizia, J. Cocchiara, D. A. Isola and <u>A. Api</u>. Research Institute for Fragrance Materials, Inc., Woodcliff Lake, NJ.

The developmental toxicity of 1-(1, 2, 3, 4, 5, 6, 7, 8-Octahydro-2, 3, 8, 8-tetramethyl-2-naphthalenyl)ethanone (OTNE), a widely used fragrance ingredient, was evaluated in rats. OTNE, or the control article, were administered orally (gavage) to one-hundred pregnant female rats (25 rats/group) on days 7 through 17 of gestation at doses of 0.0 (control), 96, 240 and 480 mg/kg/day. Control animals were treated with reverse osmosis membrane processed deionized water. The rats were observed for viability twice daily. Clinical observations and observations for abortions, premature deliveries and deaths were conducted daily. On day 21, all rats were sacrificed and a gross necropsy of the thoracic, abdominal and pelvic viscera was performed, the uteri were removed and examined for pregnancy, number and distribution of implantations, fetal mortality and resorptions. Each fetus was examined macroscopically for the presence, shape and size of all organs. Approximately one half of each litter was examined for soft tissue alterations. No deaths or premature deliveries were caused by OTNE. The 480 mg/kg/day dose group produced persistent clinical observations and reductions in body weights and feed consumption. This dose also produced a minimal, but not statistically significant reduction in fetal body weights, but no other effects on development. No fetal gross external, soft tissue or skeletal malformations or variations were produced by OTNE. The number of ossification sites per fetus per litter was unaffected at dosages as high as 480 mg/kg/day. Dosages of 96 and 240 mg/kg/day caused excess salivation and transient reductions in body weight gains and feed consumption generally only during the first days of the dosage period. On the basis of this data, both the maternal and the developmental no-observable-adverse-effect-levels (NOAELs) of OTNE are 240 mg/kg/day.

179

CLONING OF RAT 5α-REDUCTASE TYPE2 GENE PROMOTER REGION AND AN EVIDENCE OF NO RELATIONSHIP BETWEEN ITS TRANSACTIVATION REGULATION AND ARYLHYDROCARBON RECEPTOR.

S. Ohsako, K. Kubota and <u>C. Tohyama</u>. Environmental Health Sciences Division, National Institute of Environmental Studies, Tsukuba, Ibaraki, Japan.

It has been established that development of ventral prostate of male laboratory animals was suppressed when exposed to a relatively low dose of 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) during pregnancy. This typical endocrine disrupting phenomenon was demonstrated to be completely dependent on arylhydrocarbon receptor (AhR) gene. Several studies showed that 5α-reductase type 2 (5RD) expression was increased during postnatal period in the rat ventral prostate exposed to TCDD in utero. We here cloned 5'-franking region of 5RD gene and examined if its transcriptional activity was affected by AhR. Rat 5RDpromoter region (5RDp, 1713 bp) cloned by genome walking had an androgen responsive element at -659 to -679 and the same transcription start site as mouse 5RDp. Despite the absence of TATA-box, the cloned 5RDp-luciferase reporter construct showed clear transcription activation in COS-1 cells and suppression in TM4 cells in an androgen receptor (AR) dependent manner. However, co-transfection of rat AhR and ARNT expression plasmid could not change the luciferase expression level regardless of in the presence or absence of testosterone. This level was also not changed by an increased amount of 3-methyl-cholanthrene. Therefore, it could be concluded that at least the 1713-bp rat 5RDp region was not affected by liganded-AhR complex, suggesting that the increase of 5RD expression during postnatal days is not caused by direct interaction TCDD-AhR with 5RD promoter, but that an indirect effect occurred in the ventral prostate of offspring exposed to dioxin in utero.

### 180

MATERNAL UNDERNUTRITION DURING PREGNANCY POTENTIATES INTRAUTERINE GROWTH EFFECTS OF ETHANOL.

K. Shankar<sup>1</sup>, M. Hidestrand<sup>1</sup>, L. D. Humphrey<sup>3</sup>, M. J. Ronis<sup>1,3,2</sup> and T. M. Badger<sup>3,2,1</sup>. <sup>1</sup>Pharmacology/Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR, <sup>2</sup>Physiology and Biophysics, University of Arkansas for Medical Sciences, Little Rock, AR and <sup>3</sup>Arkansas Childrens Nutrition Center, Little Rock, AR.

The incidence of fetal alcohol syndrome surprisingly represents a small proportion of all the children exposed to alcohol *in utero*. Since ethanol (EtOH) metabolism is significantly increased in pregnant rats infused EtOH *via* total enteral nutrition (TEN), this may serve as a protective mechanism. However, undernutrition during pregnancy abolished the increased metabolism of ethanol. To dissect the role of maternal undernutrition in alcohol-induced fetal toxicity, time-impregnated rats were fed either optimal (220 kcal/ kg<sup>3/4</sup>/d) or undernourished (154 kcal/ kg<sup>3/4</sup>/d) diets

containing either 12 g/kg/d EtOH or isocaloric amount of carbohydrates from gestation d 6-15. Undernourished dams had 1.6 fold higher urine EtOH concentrations (UECs) compared to optimally fed rats (p = 0.007) given the same dose of EtOH. Undernourished EtOH fed rats also showed marked increase in fetal toxicity parameters including decreased fetal weight and litter size (p < 0.05). 55% litter resorptions were seen in the undernourished EtOH-fed rats compared to only 2% in the optimally fed EtOH treated animals. Undernutrition alone in the absence of EtOH did not increase any parameters of fetal toxicity, indicating that EtOH toxicity is potentiated by undernutrition. To further investigate the mechanisms of intrauterine growth retardation we assessed maternal IGF1 status, thought to be an important regulator of fetal growth. Serum levels of IGF1 were measured by radioimmunoassay and hepatic IGF1 mRNA levels were quantitated using real-time PCR. Consistent with the fetal growth data, optimally fed EtOH treated animals did not show a decrease in IGF1. In contrast undernourished EtOH fed animals showed 2-fold lower levels of IGF1 mRNA (p = 0.0002). The present data suggest that undernutrition potentiates the fetal toxicity of EtOH in part by disrupting IGF1 signaling. Supported in part by R01 AA12819 (MJJR).

### 181 DEVELOPMENTAL TOXICITY OF ACETYL CEDRENE IN RATS.

A. Lapczynski, J. Cocchiara, D. Isola and A. Api. RIFM, Woodcliff Lake, NJ.

Acetyl cedrene, a widely used fragrance material was studied for its potential to produce developmental toxicity in rats. The test article was administered orally to 100 (25 rats/group) female rats on days 7 through 17 of presumed gestation at dosages of 0 (control), 25, 50 and 100 mg/kg/day. Control group was treated with corn oil. All rats were observed for viability at least twice each day. They were also examined daily for clinical observations of effects of the test article, abortions, premature deliveries and death before and after dosage administration. Body weights were recorded on day 0, daily during the dosage and postdosage periods and at sacrifice. Feed consumption values were recorded on day 0, 7, 10, 12, 15, 18 and 21. All rats were sacrificed on day 21 and gross necropsy of the thoracic, abdominal and pelvic viscera was performed. The number and distribution of implantation sites was recorded. Tissues with gross lesions were retained. Each fetus was weighed and examined for sex and gross external alteration. Approximately 50% of the fetuses in each litter were examined for soft tissue alteration. The remaining fetuses in each litter were eviscerated, cleared, stained with alizarin red S and examined for skeletal alterations. The results showed that the 100 mg/kg/day dosages caused significant reduction in body weight gain and reduced the absolute and relative feed consumption values. Rats in both 50 and 100 mg/kg/day dosage group exhibited a dose dependent incidence of salvation, but the clinical observation was attributed more to the gavage dosing and was not considered to be a direct toxic effect of the test article. Litter parameters were not affected by dosages of the test article. No gross external, soft tissue or skeletal fetal alterations (malformations or variations) were caused by dosages of Acetyl Cedrene as high as 100 mg/kg/day. On the basis of these data, the maternal no observable adverse effect level (NOAEL) of Acetyl Cedrene is 50 mg/kg/day and the developmental NOAEL is greater than 100 mg/kg/day.

### 182 FOLIC ACID PROTECTS AGAINST VALPROIC ACID-INDUCED NEURAL TUBE DEFECTS IN CD-1 MICE.

J. E. Dawson<sup>1</sup> and L. M. Winn<sup>1,2</sup>, <sup>1</sup>Pharmacology and Toxicology, Queen's University, Kingston, ON, Canada and <sup>2</sup>School of Environmental Studies, Queen's University, Kingston, ON, Canada.

Neural tube defects (NTDs) are the most common type of human congenital malformations, with an incidence frequency of 1-2 per 1000 live births. The use of antiepileptic drugs, such as valproic acid (VPA), during pregnancy has been associated with a 5-20 fold increase in the rates of NTDs. Rodent in utero exposure to VPA has been shown to induce NTDs in a dose and strain dependent manner. The mechanism of how VPA induces NTDs, and why certain strains are more susceptible than others, remains unclear. Folic acid (FA) supplementation during pregnancy has been shown to protect human and some rodent embryo's from teratogenic insult, however FA's ability to protect embryos from VPA induced NTDs is controversial. Human epidemiological studies provide evidence leaning toward a protective effect, in the mouse model this protection appears to be strain dependent. Recently, it has been demonstrated that FA prevents VPA induced NTDs in the TO mouse model. The objective of our study was to determine if FA prevents NTDs in a different mouse strain, the CD-1 mouse, after administration of a previously demonstrated teratogenic dose of VPA (400 mg/kg) during the period of neural tube closure (Gestational Day (GD) 9). Briefly, pregnant (plug = GD 1) CD-1 mice were administered 4 mg/kg FA three times daily on gestational days 5 to 10. These animals were also exposed to a teratogenic dose of VPA (400 mg/kg) on GD 9 prior to neural tube closure. VPA treatment alone caused a 24 percent incidence of NTDs in CD-1 mice which was reduced to 3 percent by the prolonged

folic acid treatment. These results suggest that the CD-1 mouse model can be used to investigate the molecular mechanism mediating folic acid protection against valproic acid induced neural tube defects. We are currently investigating the role of the p53 tumor suppressor gene in neural tube closure and VPA induced teratogenesis. Support: JP Bickell Foundation

EXPRESSION AND TERATOLOGICAL RELEVANCE OF INDUCIBLE NITRIC OXIDE SYNTHASE (INOS) AND CYCLOOXYGENASE-2 (COX-2) IN EMBRYONIC AND PLACENTAL TISSUES OF WILD-TYPE AND INOS KNOCKOUT MICE.

G. McCallum<sup>1</sup> and <u>P. G. Wells</u><sup>1, 2</sup>. <sup>1</sup>Pharmacy, University of Toronto, Toronto, ON, Canada and <sup>2</sup>Pharmacology, University of Toronto, Toronto, ON, Canada.

Previous studies from this laboratory have shown that wild-type embryos in culture from B6129PF2/J mice were more susceptible to the reactive oxygen species (ROS)-initiating teratogens phenytoin and benzo[a]pyrene (B[a]P) than embryos from iNOS (B6;129P-Nos2<sup>ml1au</sup>) knockout animals (Toxicologist 54: 71 [No. 335], 2000). This suggested that iNOS is constitutively expressed during organogenesis, and can contribute to ROS-initiated embryopathies. In the current studies however, immunoprecipitation experiments with gestational day (GD) 13 wildtype B6129PF2/J mice detected iNOS-specific immunoreactivity in placenta but not in embryonic tissue. Since COX-2 can catalyze the bioactivation of both phenytoin and B[a]P to ROS-initiating free radical intermediates, and nitric oxide has been implicated in the modulation of COX expression, the embryonic expression of COX-2 was also examined. Although embryonic COX-2 was constitutively expressed, protein levels in iNOS knockout and wild-type mice were identical. These results suggest that placental transfer of nitric oxide and related reactive nitrogen species can influence embryonic susceptibility to ROS-initiating teratogens via a mechanism unrelated to constitutive embryonic expression of iNOS or alterations in the level of embryonic COX-2 protein. (Support: Canadian Institutes of Health Research)

184 A COMPARISON OF EFFECTS ON REPRODUCTION AND NEONATAL DEVELOPMENT IN CYNOMOLGUS MONKEYS GIVEN HUMAN SOLUBLE IL-4R AND MICE GIVEN MURINE SOLUBLE IL-4R.

L. L. Carlock<sup>1</sup>, L. A. Cowan<sup>1</sup>, S. Oneda<sup>2</sup>, A. M. Hoberman<sup>3</sup> and J. L. Bussiere<sup>1</sup>.

<sup>1</sup>Toxicology, Amgen Inc., Thousand Oaks, CA, <sup>2</sup>SNBL USA Ltd.,, Everett, WA and <sup>3</sup>Argus Research Laboratories, Horsham, PA.

Inhibition of interleukin-4 (IL-4) is being evaluated to treat asthma. Amgen Inc. (formerly Immunex) evaluated effects of human soluble IL-4 receptor (sIL-4R) on monkey reproduction and murine sIL-4R on mouse reproduction. When pregnant cynomolgus monkeys received human sIL4R intravenously (IV) 2/week during organogenesis [gestation days (GD) 20-50] at 0, 0.2 or 2.0 mg/kg, there were no effects in clinical signs, body weight, food consumption, clinical pathology, or immunological evaluations. There was an increase in abortion/embryo-fetal death in the 0.2 (9/21 or 42.9%) and 2.0 (5/19 or 26.3%) mg/kg groups (controls: 3/17 or 17.6%). At cesarean, all fetuses were alive, no treatment effects noted. Three neonates were stillborn (2.0 mg/kg group). No neonates died after birth, no test article-related abnormalities noted. When pregnant Crl:CD-1®(ICR)BR mice (10 mice/group) received murine sIL-4R IV 1/day during organogenesis (GD 6-15) at 0, 25, 75, 250, or 625  $\mu g/mouse$ , there were no effects in clinical signs, body weight, number of pregnancies (9-10/group), gestation, litter size, liveborn, sex ratio or pup weights. Mean trough serum concentrations after first doses were slightly higher in high dose monkeys than in high dose mice (cyno: 11.175+/-2.9  $\mu$ g/mL; mouse: 3.47 +/-0.8  $\mu$ g/mL). Mean serum conc. after last dose (within 1 h) had similar ranges for both species (cyno: 5.38-54.51 µg/mL; mouse: 5.3-237 μg/mL). Antibody development did not influence toxicity in monkeys. However at last dose, 2/6 (25  $\mu$ g), 5/6 (75  $\mu$ g), or 6/6 (250 & 625  $\mu$ g) mice had antibodies to drug (mean serum conc. lower after last dose than after first dose; decrease more pronounced at 250 & 625 µg doses). It is unclear whether the lack of effects noted in mice and the increase in abortions and stillbirths observed in cynomolgus monkeys are due to species-specific responses to IL-4 inhibition, or whether the antibody response in the mice altered the activity of the drug.

## 185 DEVELOPMENTAL TOXICITY OF BETA-THUJAPLICIN (TP) IN RATS.

M. EMA, A. HARAZONO, S. FUJII and K. KAWASHIMA. Risk Assessment, National Institute of Health Sciences, Tokyo, Japan.

beta-Thujaplicin (TP) is a phenolic component of essential oils extracted from cypress trees. TP has been found to act as an antibacterial agent and an antitumor agent. In addition, it possesses phytogrowth-inhibitory effects. TP is used as a nat-

ural food preservative in Japan. In this study, the developmental toxicity of TP was determined. Pregnant rats were given TP by gavage at 15, 45, or 135 mg/kg on days 6-15 of pregnancy. The maternal body weight gain during administration at 45 and 135 mg/kg and after administration at 136 mg/kg and adjusted weight gain at 45 and 135 mg/kg were significantly reduced. A significant decrease in food consumption during and after administration was found at 45 and 135 mg/kg. A significantly lower weight was found in female fetuses at 135 mg/kg. A significantly lower weight was found in female fetuses at 45 and 135 mg/kg and in male fetuses at 135 mg/kg. Although a significantly increased incidence of fetuses with skeletal variations and decreased ossification were found at 135 mg/kg, no significant increase in external, skeletal and internal malformations was detected after administration of TP. The data demonstrated that TP had adverse effects on embryonic/fetal survival and growth only at maternal toxic doses. No adverse effects on morphological development were found in rats fetuses. Based on the significant decreases in maternal body weight gain and weight of female fetuses at 45 mg/kg and higher, it is concluded that the NOAELs of TP for both dams and fetuses are considered to be 15 mg/kg in rats.

## 186 INHALATION DEVELOPMENTAL TOXICITY STUDIES IN RATS WITH ANTIMONY TRIOXIDE (SB2O3).

P. E. Newton<sup>1</sup>, R. E. Schroeder<sup>1</sup>, L. Zwick<sup>1</sup> and T. Serex<sup>2</sup>. <sup>1</sup>MPI Research, Inc., Mattawan, MI and <sup>2</sup>Great Lakes Chemical Company, West Lafayette, IN.

In a range-find (RF) study, 5 groups of CD rats (5/group) were exposed to Sb2O3 via nose-only inhalation, 6 hrs/day, on Gestation Days (GD) 0 through 19. The mean exposure levels were 0, 0.39, 0.73, 1.48, and 6.07 mg/M3. The mass median aerodynamic diameters (MMAD) and geometric standard deviations (GSD) ranged from 1.59 to 1.96µM and 1.60 to 1.68, respectively. The NOEL for maternal toxicity in the RF was 6.07 mg/M3, the highest exposure level evaluated. The NOEL for developmental toxicity in the RF was 1.48 mg/M3 based on the suggestion of lower (8%) fetal body weights and smaller (4%) fetal size (crown-rump distance [CRD]) at 6.07 mg/M3. In the definitive Sb2O3 study, 4 groups of CD rats (26/group) were exposed to 0, 2.6, 4.4, and 6.3 mg/M3, respectively, from GD 0-19. The MMAD and GSD ranged from 1.59 to 1.82  $\mu$ M and 1.713 to 1.744, respectively. Animals were observed daily for mortality/clinical findings and gestation body weight and food consumption were measured at regular intervals. Females were euthanized on GD 20 and uterine implantation data recorded and fetuses taken for evaluation. Packed RBC components were collected from 10 females/group at GD 20 to determine bound Sb2O3 levels. A statistically significant dose-related increase in lung weights was seen in the treated groups. Absolute lung weights were 24.4, 31.1, and 38.6% heavier than control in the 2.6, 4.4, and 6.3 mg/M3 groups, respectively. Microscopically this was characterized by pigmented alveolar macrophages and inflammation. RBC levels of Sb2O3 were also statistically increased in the treated groups with values ranging from 3.1 to 5.6  $\mu g/g$ compared to 0.1 µg/g in controls. The NOEL for developmental toxicity was 6.3 mg/M3, as no effects were seen in uterine implantation data, fetal body weights, CRD, sex ratios or from external, visceral, or skeletal examinations. In summary, under the conditions of this study, Sb2O3 was not developmentally toxic. (Supported by the International Antimony Oxide Industry Association)

# 187 EFFECTS ON RAT EMBRYONIC DEVELOPMENT *IN VITRO* OF DI-(2-ETHYLHEXYL) PHTHALATE (DEHP) AND ITS METABOLITES.

<u>I. REGNIER</u><sup>1</sup>, C. Bowden<sup>2</sup> and J. Lhuguenot<sup>3</sup>. <sup>1</sup>Toxicology and Environment, ATOFINA, Paris-la-defense, France, <sup>2</sup>Huntingdon Life Science, Eye, United Kingdom and <sup>3</sup>ENSBANA, Dijon, France.

The embryotoxicity of DEHP and its main metabolites (mono-2-ethylhexyl phthalate (MEHP), 2-ethylhexanol (2-EH), 2-ethylhexanoic acid (2-EHA) and MEHPoxidized metabolites I, V, VI, and IX was evaluated on CD rat embryos in vitro. First, day 9 embryos were cultured in serum from pregnant CD rats collected approximately 1.5 hours after the final administration of 1000 mg/kg DEHP on GD 6-11. Afterwards, DEHP and its metabolites were evaluated individually. Embryos were cultured in roller bottles for approximately 48 hours at 38.0 +/- 1.0degC. Embryotoxic potential was assessed from effects on the survival, overall growth and development, and teratogenic potential from effects on the morphology of embryos. Serum from the DEHP-treated rats and culture media were analyzed by liquid scintillation and/or GC-MS to determine the achieved concentrations of DEHP and DEHP-metabolites. Embryos cultured in the serum from DEHPtreated rats exhibited reductions in crown-rump and head lengths, somite number and morphological score, when compare to controls. An increase in the number of malformations was also observed, which principally included malformations of the yolk sac circulation, flexion, forebrain, otic system, branchial bars and fore limb buds and unfused caudal neural tubes. The type of malformation observed with

DEHP-metabolites was similar to those observed with serum from DEHP-treated rats. A comparison of the lowest effect concentration at which statistically significant effects were observed on morphology parameters suggests the following order of developmental toxicity potency of the DEHP-metabolites: Metabolite IX > I >> VI = V > DEHP = MEHP = 2-EH >> 2-EHA. In comparison with the concentrations detected in the serum from the DEHP-treated rats, MEHP-oxidized metabolites, especially no. IX and I seem to be the ultimate developmental toxicants.

188

TERATOGENIC RESPONSES ARE MODULATED IN MICE LACKING EXPRESSION OF EPIDERMAL GROWTH FACTOR (EGF) AND TRANSFORMING GROWTH FACTOR-ALPHA (TGF).

B. D. Abbott, D. S. Best and M. G. Narotsky. Repro Toxicology Division, USEPA, Research Triangle Park, NC.

EGF and TGF regulate proliferation and differentiation in the embryo. EGF appears to mediate teratogenic responses, as the incidence of cleft palate (CP) is reduced and the severity and incidence of hydronephrosis are increased in EGF knockout (KO) mice after exposure to TCDD on gestation day (GD)12. Similarly, EGF KO mice have a lower incidence of CP after GD-12 exposure to retinioc acid (RA), whereas TGF KO mice show an increased incidence of CP after GD10 exposure. In the present study, pregnant C57BL/6J and TGF KO mice were exposed to a single oral dose of RA (100 mg/kg, 10 ml/kg) or vehicle on GD10, and wild type (WT) and EGF KO mice were exposed on GD12. GD18 fetuses were examined for external and visceral alterations. TGF KO mice and EGF KO mice had increased incidences of dilated renal pelvis compared to mice of background genotype; however, treatment of KO mice with RA significantly reduced the incidences compared to vehicle-treated KO mice. RA exposure produced effects on limb and heart development, however the incidence of specific limb defects was influenced by the developmental stage as well as the expression of EGF or TGF. After GD10 RA exposure, the incidence of forelimb digital and long-bone defects was significantly higher in TGF KO compared to C57BL/6J fetuses. Also, micrognathia, hindlimb digital deficits, and oligodactyly (fore and hind limbs) were only observed in the RA-treated TGF KO. RA exposure on GD12 of WT and EGF KO produced forelimb brachy-/oligodactyly and long-bone reduction of fore and hind limbs. However, the EGF KO was significantly more susceptible to digital deficits of the hind limb. In summary, in the developing limbs, the teratogenic effects of RA were influenced by developmental stage and responses were exacerbated in the absence of EGF and TGF expression. This study provides further evidence that the EGF pathway mediates responses to teratogens and that the influence depends on developmental stage and the target tissue. This abstract does not necessarily reflect EPA policy.

## 189 COMPARATIVE STUDY OF ALCOHOL TERATOGENIC EFFECT IN C57BL/6 AND DBA/2 MOUSE EMBRYOS USING EMBRYO CULTURE.

M. Kuwagata<sup>1</sup>, <u>T. Ogawa<sup>2, 1</sup></u> and F. C. Zhou<sup>1</sup>. <sup>1</sup>Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN and <sup>2</sup>Anatomy, Showa University School of Medicine, Tokyo, Japan.

Children born to chronic alcoholic women have a high incidence of fetal alcohol related spectrum disorder featuring psychosocial disorder, and craniaofacial malformations. Animal models also demonstrated that fetal alcohol exposure impaired development. In the rodent studies, inbred strains of different genetic background were often applied to investigate the role of genotype in their susceptibility to alcohol-induced teratogenecity. However, studies reported so far have generated inconsistent results which may, in part, be due to differential progressing in the stage of embryos. In the present study, we used two inbred strain mice, C57BL/6 (B6) and DBA/2 (D2), which were often used in alcohol studies. First, we investigated the embryonic stage with 2-hour breeding paradigm in the two strains of mice. When they were sacrificed on gestation day 8.25 at the same time, D2 embryos were all at presomite stage, while almost all B6 were at 3-6 somites stage. This result suggests D2 embryos are usually younger than B6 when treatments are applied in the study in vivo. Therefore, we applied whole embryo culture technique to compare sensitivity to alcohol between the two strains. Embryos with 3-6 somites were collected in both strains and cultured for 44 hours in the medium containing 400 mg/dL of ethanol and scored for morphological features. The alcohol treatment affected the growth of embryos in both strains and induced abnormalities including hypoplasia of optic vesicle in both strains with a different severity between B6 and D2 embryos. In conclusion, we found that in the current paradigm, differential progress of development exists between B6 and D2, which may contribute to inconsistent results in the literature. # 190 COMPARATIVE ASSESSMENT OF TWO EMBRYO CULTURE METHODS IN EVALUATING EMBRYOTOXICITY.

H. Huuskonen and H. Komulainen. Department of Environmental Health, National Public Health Institute, Kuopio, Finland. Sponsor: M. Viluksela.

Rat whole embryo culture (WEC) has been widely used in evaluating developmental toxicity of chemicals in vitro. In the ECVAM validation study, its predictivity and precision for strongly embryotoxic compounds was 100%. However, the precision for non-embryotoxic and weakly embryotoxic compounds was lower. In the present study, the embryotoxicities of five model compounds in mouse preimplantation embryo culture and rat whole embryo culture assays were compared. Preimplantation mouse embryos were collected from the superovulated and mated females at morula stage and cultured in microspots of medium at 37 OC in 5% CO<sub>2</sub> atmosphere for two days up to the blastocyst stage. The morphology and developmental rate were assessed at 24 and 48 hours using an inverted microscope with relief optics. In WEC, rat embryos were collected from pregnant females at 1-5 somite stage. They were dissected from the desidua and Reichert's membrane and cultured in bottles containing medium and a gas phase. The gas phase was changed twice a day for two days. The growth and morphology were assessed after the culture period of 46 hours under a stereomicroscope. The model chemicals, 5-fluorouracil (5-FU), methotrexate (MET), salicylic acid (SAL), dimethadione (DMD) and saccharin (SAC) were dissolved in the medium in both culture system. In both assays, 5-FU and MET were strongly embryotoxic, SAL and DMD weakly embryotoxic and SAC non-embryotoxic. The no-effect concentrations (NOECs) were 0.01 µg/ml for 5-FU and MET, 100 µg/ml for SAL, 500 µg/ml for DMD and 1000  $\mu g/ml$  for SAC in preimplantation embryo culture method. In WEC, the NOEC-values were 0.1  $\mu g/ml$  for 5-FU, 0.05  $\mu g/ml$  for MET, 100  $\mu g/ml$  for SAL, 500 µg/ml for DMD and 1000 µg/ml for SAC. The results showed a good correlation of the embryotoxic potential of these chemicals in both assays. The preimplantation embryo culture method may provide a simpler mammalian model to study embryotoxic potential of chemicals. # 191 TWO ZEBRAFISH ALCOHOL DEHYDROGENASES SHARING COMMON ANCESTRY AND FUNCTIONAL CHARACTERISTICS WITH MAMMALIAN CLASS I AND III GENES.

M. Reimers<sup>1,3</sup>, M. E. Hahn<sup>2</sup> and R. L. Tanguay<sup>3</sup>. <sup>1</sup>Department of Pharmaceutical Sciences, University of Colorado Health Sciences Center, Denver, CO, <sup>2</sup>Biology Department, Woods Hole Oceanographic Institute, Woods Hole, MA and <sup>3</sup>Department of Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR.

Ethanol is teratogenic to many vertebrates and we are using zebrafish as a model system to determine if there is an association between alcohol dehydrogenase (ADH) activity and developmental toxicity. To test this hypothesis, it is necessary to determine if zebrafish express ADH enzymes capable of ethanol metabolism during development. With the duplication of many genes in zebrafish, it is critical to ascertain the functional characterization of all identified enzymes. Here we report the isolation and characterization of two cDNAs encoding zebrafish ADH. Phylogenetic analysis of these zebrafish ADHs reveals that they are most closely related to the mammalian class 1 ADH enzymes and we have named them adh8a and adh8b. Both adh8a and adh8b were genetically mapped to chromosome 13 approximately 3.6 megabases from each other. At the predicted amino acid level, adh8a and adh8b are 77% identical to each other, and are 73% and 68% identical to the human class 1 ADH, respectively. To characterize the functional properties of ADH8A and ADH8B, the enzymes were recombinantly expressed and purified from SF-9 insect cells. Kinetic studies with a variety of substrates revealed differential substrate preferences. Consistent with mammalian class I enzymes, ADH8A metabolizes ethanol, with a 0.679 mM Km. Conversely, ADH8B does not oxidize ethanol, but does efficiently metabolize longer chain primary alcohols greater than 5 carbons and S-hydroxymethlyglutathione similar to class III enzymes. ADH8A does not efficiently metabolize these substrates. Finally, mRNA expression studies indicate that both ADH8A and ADH8B mRNA are expressed during early development. Together these results indicate that class I ADH enzymes are conserved in zebrafish, albeit with mixed functional properties. Supported by NIH grants AA12783, ES03850, and ES00210.

### 192 DEVELOPMENTAL TOXICITY OF METAM SODIUM IN ZEBRAFISH.

M. A. Haendel<sup>1,3</sup>, F. Tilton<sup>2,3</sup>, R. L. Tanguay<sup>2,3</sup> and G. S. Bailey<sup>1,2,3</sup>. <sup>1</sup>Linus Pauling Institute, Oregon State University, Corvallis, OR, <sup>2</sup>Environmental and Molecular Toxicology, OSU, Cor., OR and <sup>3</sup>EHSC and MFBSC, OSU, Cor., OR.

Sodium metam (NaM), a dithiocarbamate, is a potent agricultural biocide applied prior to planting for the elimination of nematodes, soil pathogens and weeds. There is a remarkable paucity of information about the risk that this class of chemicals

may pose to developing vertebrates and their mechanism of action. Zebrafish have been utilized as a model system because early developmental events and gene function are conserved with humans. We have characterized the toxicity during early life stage exposure to NaM in zebrafish. Zebrafish embryos were exposed to varying concentrations of NaM between 0 and 4.05  $\mu\text{M}$  for a 20-hour period beginning at 4 hours post fertilization (hpf). The LC50 curves are steep, and are estimated to be 2.3 µM (300 ppb) at 24 hpf and 0.4 µM (50 ppb) at 13 days. The most notable malformation, observed in 100% of the exposed animals at 0.8  $\mu M$ , was an enlarged and severely twisted notochord; the NOAEL was 0.05 µM. Surprisingly, this notochord defect is not immediately lethal and the animals continue to grow; however, they exhibit delays in hatching, apparent paralysis, and are unable to feed. To evaluate the effects on the notochord and nervous system, we have characterized changes in gene expression. Expression of  $\alpha$ -collagen II mRNA is localized to the notochord sheath cells in controls, whereas in NaM-exposed embryos, it is misexpressed in the notochord cells. MyoD and histological staining indicate muscle abnormalities; the myotomes of the NaM-exposed embryos are less defined, compacted and block-shaped compared to controls. There are more peripheral axonal branches in NaM-exposed embryos than in controls, as shown by ZN-12 antibody staining. Our preliminary results indicate that developing zebrafish are exquisitely sensitive to NaM sodium and we believe that this model is ideal to elucidate the molecular mechanism(s) and etiology of NaM toxicity in vertebrates. Supported by NINDS #NS11170, NIEHS #ES00210, and #ES03850.

### 193 THE TERATOGENIC EFFECTS OF ETHANOL EXPOSURE IN ZEBRAFISH.

E. J. Loucks<sup>1, 2</sup>, B. A. Wimpee<sup>1, 2</sup> and <u>M. J. Carvan<sup>1, 2</sup>. <sup>1</sup>University of Wisconsin-Milwaukee, Milwaukee, WI and <sup>2</sup>Great Lakes WATER Institute, Milwaukee, WI.</u>

Developmental ethanol exposure from maternal consumption of alcoholic beverages and many consumer products has been linked to developmental abnormalities in humans and laboratory animals. The long-range goal of this project is to elucidate the molecular mechanism by which ethanol perturbs embryonic and fetal development, and to identify genes that plays a role in the sensitivity to ethanol-induced teratogenesis. Fetal exposure to ethanol is primarily dictated by voluntary maternal behavior and societal influences. Consequences of fetal exposure can range from embryotoxicity, gross malformations and a large variety of more subtle morphological, biochemical and functional abnormalities depending on the duration and time of exposure. This can have a tremendous toll on the affected individuals, their families, and society as a whole. The sensitivity of an indivdual to ethanol-induced perturbation of developmental processes can also involve genetic factors. Twin studies in humans demonstrated that identical twins are equally susceptible to FAS, whereas fraternal twins have shown a marked discordance in the severity of FAS. Genetically distinct strains of zebrafish (Danio rerio) are differentially sensitive to alcohol and provide the best model system for genetic analysis of the developmental effects of ethanol to embryos. We have determined that zebrafish are very sensitive to the effects of ethanol on embryo/larval mortality, neurocranial and craniofacial skeletal development, and CNS apoptosis. We have also determined that the magnitude of these effects is strain-dependent, and that no single strain is the most sensitive in each assay. This data will be discussed in relation to our molecular characterization of genes that influence sensitivity to ethanol-induced teratogenesis.

## 194 DEVELOPMENTAL TOXICITY OF CARBARYL IN ZEBRAFISH.

H. Cheng, A. Lin and E. Chan. Biology and Chemsitry, City University of Hong Kong, Hong Kong, N/A, Hong Kong.

Carbaryl (1-naphthyl-N-methycarbamate; commercial name, Sevin) is one of the most commonly used broad-spectrum pesticides in urban and agricultural settings. It was used widely in turf management of golf courses, in controlling burrowing shrimp in oyster fields, in exterminating animal pests in forests, and even in treating head lice in school children. In the environment, field concentrations of carbaryl up to 4.8 mg/L have been found immediately following application. In streams draining agricultural and urban areas, carbaryl up to 1.5 and 2.5 ug/L have been reported respectively. Fertilsed zebrafish eggs were exposed to nominal concentrations of carbaryl from 1 to 100ug/ml from 4 hours post fertilisation (hpf) to 28 hpf. Percentages of mortality and abnormality were scored. All embryos died at carbaryl concentrations of 50 ug/ml or higher. Growth arrest was observed at 30 ug/ml while pericardial edema was observed at 10 ug/ml. No gross abnormality experimental model for pesticide induced developmental toxicity. We will establish the chains of events following the anticholinestarase activity of carbaryl to the resulting target

organ toxicity. developing vasculature. This project will contribute to the development of bioindicators for developmental toxicity and provide mechanism basis of pesticide risk assessment. $\mu\mu\mu$ 

## 195 ETHANOL PERTURBS CARDIOVASCULAR DEVELOPMENT IN JAPANESE MEDAKA, ORYZIAS LATIDES

A. K. Dasmahapatra<sup>1</sup> and M. L. Haasch<sup>1, 2</sup>. <sup>1</sup>Environmental Toxicology Research Program, Research Institute of Pharmaceutical Sciences, University of Mississippi, University, MS and <sup>2</sup>Department of Pharmacology, University of Mississippi, University, MS.

Although the cardiovascular defects in developmental ethanol exposure have been identified in both human and animal models, the molecular mechanism(s) for these abnormalities has not yet been fully characterized. We used the Japanese medaka(Oryzias latipes) developmental model to evaluate cardiovascular defects produced by acute ethanol exposure. Viable medaka eggs within 1h of fertilization were exposed to ethanol (0-400mM)in hatching solution. After 48h, ethanol was omitted from the embryo culture medium. Cardiovascular development was observed from 1-7 dpf. The embryos exposed to low ethanol concentrations (0-100mM) started circulation at 2 dpf but active circulation was significantly delayed at higher concentrations (200-400mM). Moreover, these higher concentrations (200-400mM) developed tube heart with blood clots in blood island and in circulating vessels. We hypothesized that the cardiovascular abnormalities seen in the developing Japanese medaka was due to one or more metabolites of ethanol metabolism. To examine this possibility, we have begun to characterize the genes for alcohol metabolizing enzymes in medaka. By applying-PCR based technologies, we have partially cloned two subtypes of alcohol dehydrogenase mRNA (ADHa and ADHb)in adult medaka liver. ADHa mRNA was expressed in liver, gill, eye, muscle, heart and GI of adult fish but not in brain and gonad. ADHb was expressed in all tissues examined. The expression patterns of ADHa and b mRNA were also different from each other during embryonic development. ADHa was expressed from the 2-cell stage to neurula (1dpf) but ADHb was first expressed 2dpf. Our results indicate that ADHa is the major enzyme expressed during the early part of the embryonic development and likely plays a significant role in the generation of ethanol metabolities and the subsequent development of cardiovascular defects. [Supported by ETRP and ORSP of the University of Mississippi]

# 196 EXENATIDE (SYNTHETIC EXENDIN-4) DEVELOPMENTAL TOXICOLOGY IN RABBITS: COMPARISON TO PAIR-FED CONTROLS.

R. Hiles<sup>1</sup>, T. Carpenter<sup>1</sup>, A. Hoberman<sup>2</sup> and R. Byrd<sup>3</sup>. <sup>1</sup>Amylin Pharmaceuticals, Inc., San Diego, CA, <sup>2</sup>Argus Research, Horsham, PA and <sup>3</sup>Eli Lilly & Co., Greenfield, IN.

SC administration of exenatide (EX) to pregnant rabbits on gestation days (GD) 6-18 caused a dose-related reduction in food consumption (FC) and reduced body weight compared to pre-dose value (ΔBW) (1). Fetal anomalies included umbilical hernias (UH) in 1.6, 5.6, 11.8% of fetuses at 11, 78, 130  $\mu$ g/kg EX, respectively. The current study's purpose was to evaluate the effect of reduced FC on UH. Groups of 20 pregnant dams were dosed SC with EX-diluent (ED), 1, 11, or 130 μg/kg EX BID on GD 6-18, while pair-fed (PF) control groups were dosed with ED and fed to match EX groups. EX caused a dose-related reduction in both FC (GD 6-9: 62, 32, 12% of ED group for 1, 11, 130  $\mu$ g/kg EX, respectively) and WC (GD 6-9: 82, 52, 19% of ED group for 1, 11, 130 μg/kg EX, respectively). ΔBW was +1.2, -1.7, -5.9, -10% for ED group, 1, 11, 130 μg/kg EX, respectively. Reduced WC was not observed among the PF groups. PF groups to match EX groups for 1, 11, 130 μg/kg EX exhibited ΔBW of -1.6, -3.5, -5.4%, respectively. Dose-related increases in serum beta-hydroxybutyric acid (BHBA), a starvation biomarker, were more elevated compared to ED group in EX groups than in PF groups (0.91, 1.14, 2.67, 2.82 mg/dL for ED group, 1, 11, 130 μg/kg EX, respectively and 0.77, 0.85, 2.33 mg/dL for PF groups for 1, 11, 130 µg/kg EX, respectively). UH (GD 29 Caesarean sections) were observed in 11 and 130  $\mu g/kg$  EX doses [5.9% (1 fetus in 1 litter) and 29% (8 fetuses in 5 litters of litters, respectively] (historical = 0 - 6.2%); no litters from 1  $\mu$ g/kg EX or PF controls had UH. Based on  $\Delta$ BW and BHBA, the PF group intended to match the 130  $\mu$ g/kg EX groups was more similar to 1 and 11  $\mu g/kg$  EX group and not the 130  $\mu g/kg$  EX group. Mean UH fetal BW was less than non-UH fetal BW (p<0.05). UH occurred concomitantly with fetal growth retardation related to severe maternal weight loss. EX does not appear to be a selective developmental toxicant. (1) Hiles, R.A., Hoberman A.M., & Christian, M.S. (2001). Toxicological Sciences 60 (Ab 1182),

COMPARISON OF GESTATIONAL DOSE (MG/DAY) IN GAVAGE VS. CONTINUOUS EXPOSURE STUDIES IN PATS

S. P. Parker<sup>1</sup>, C. B. Myers<sup>1</sup>, R. W. Tyl<sup>1</sup>, J. P. Van Miller<sup>2</sup> and R. L. Joiner<sup>3</sup>. <sup>1</sup>Life Sciences and Toxicology, RTI International, Research Triangle Pk, NC, <sup>2</sup>TRS, Charlottesville, VA and <sup>3</sup>GE, Pittsfield, MA.

In developmental toxicity studies, maternal animals are dosed during much or all of gestation. If administration is by gavage, the dose in mg/kg/day is held constant by adjusting the volume (ml/kg), based on the most recent body weight (BW) to correct for maternal BW gain during pregnancy. This convention has continued for other reproductive screening and definitive studies (e.g., 2-generation and OECD 421/422). The maternal rat may gain >150 g during gestation, but with the BW gain in the last trimester (>100 g) almost entirely from uterine contents. Test chemical (TC) intake (mg/day) in dosed feed/water studies is not increased from gestational day (gd) 14 to 20. In gavage studies, TC intake (mg/day) during the same time period is increased as much as 30% because of the adjustment for maternal BW. Thus, the dose (mg/kg/day), based on the actual maternal BW (i.e., minus uterine contents), is similarly increased (30%). This can result in overdosing the dam and conceptuses and is the likely cause of excessive maternal and perinatal toxicity observed in some studies. The risk of increased toxicity from bolus gavage dosing is also increased by the following: 1) the maternal liver is enlarged in late pregnancy, presumably in response to pregnancy and increased TC load, but it is not enlarged commensurate with increased TC dose; 2) TC may not be evenly distributed into the fetal compartment, and the relative maternal burden may, therefore, be even higher; 3) GI tract motility is reduced with potentially increased absorption of TC during late pregnancy. Such effects confound the interpretation of reproductive toxicity. Therefore, we recommend adjusting the dose from gd 0 to 14 of pregnancy and maintaining the dose (in mg/day by maintaining the gd 14 dosing volume) from gd 14 to pnd 0. This approach provides a dose appropriate to maternal BW (minus the uterine contents) in the latter part of gestation. This work is supported by the General Electric Company, Pittsfield, MA.

## 198 MATERNAL FUMONISIN EXPOSURE AND NEURAL TUBE DEFECTS: MECHANISMS IN AN *IN VIVO* MOUSE MODEL.

J. B. Gelineau-van Waes, L. Starr, J. Wilberding, F. Aleman and J. Maddox. Department of Genetics, Cell Biology & Anatomy, University of Nebraska Medical Center, Omaha, NE. Sponsor: R. Riley.

Fumonisin B1 (FB1) is a mycotoxin produced by F. verticillioides, a common contaminant of corn worldwide. An association between maternal FB1 exposure and increased risk for neural tube defects (NTDs) has recently been observed in human populations relying on corn as a dietary staple. FB1 disrupts sphingolipid biosynthesis by inhibiting ceramide synthase, resulting in elevated sphinganine levels, and depletion of downstream glycosphingolipids. We have previously demonstrated that early gestational exposure to FB1 results in NTDs in 80% of exposed inbred LMBc mouse fetuses. FB1 depletion of ganglioside GM1 altered plasma membrane microdomains, compromising folate uptake via the GPI-anchored folate receptor. Daily maternal folate supplementation reduced the incidence of NTDs, while replacement therapy with ganglioside GM1 restored folate uptake and rescued the phenotype. Since previous reports indicate that FB1 toxicity may be mediated by TNFa, the role of TNFa is evaluated in our model. Atypical expression of TNFa is seen in the developing neural tube following FB1 exposure. TNFa expression corresponds to positive TUNEL staining in the ventricular zone, but co-localizes with NF-κB in the marginal zone. TEM sections show a loss of adherens junctions following FB1 exposure, and phalloidin staining indicates disruption of the apical actin belt. Further studies show altered expression and/or post-translational modification of cytoskeletal proteins. FB1 exposure resulted initially in an increase in apoptosis, loss of cell adhesion and cell polarity, disruption of cytoskeletal integrity, disorganized cell migration, and failure of the neural folds to elevate. This was followed by eversion of the neural folds, and increased proliferation, as demonstrated by increased PCNA staining. Preliminary microarray data also indicate an alteration in cell cycle checkpoint genes, and an increase in tumor antigens/proto-oncogenes, growth factors, and cell survival (bcl-2) pathways.

### 199 ZEBRAFISH ASSAYS FOR ASSESSING DEVELOPMENTAL TOXICITY

C. Zhang, C. Parng, C. Willett, C. Ma and P. McGrath. *Phylonix Pharmaceuticals, Inc., Cambridge, MA.* Sponsor: P. Mayeux.

Developmental toxicity is a major problem with numerous pharmaceutical agents and screening for potential adverse effects is critical for assessing drug safety. Transparent zebrafish embryos offer unique advantages for assessing the effects of drugs on various developmental events. The processes involved in embryogenesis as well as the function of numerous genes have been well studied in zebrafish and are highly conserved compared to mammals. In this study, we developed a repro-

ducible, multi-endpoint scoring system to determine developmental toxicity using zebrafish embryos. We have established 26 parameters to visually assess drug induced effects on morphology and organogenesis. After drug treatment, we also established dose-response curves for mortality (LC50) and malformation (ED50), and the teratogenic index (TI ratio= LC50/ED50). As strong support for use of zebrafish as a model for assessing drug toxicity, we recently examined the effects of 100 known compounds and noted that LC50 and teratogenicity were remarkably similar to results in mammals, suggesting that zebrafish has a high predictive value for toxicity testing in humans.

### 200 CELL CYCLE INHIBITION AND CLEFT PALATE INDUCTION BY SECALONIC ACID D.

V. C. Dhulipala, W. Welshons and <u>C. S. Reddy</u>. Vet. Biomedical Sciences, University of Missouri, Columbia, MO.

Cleft palate (CP) is one of the most common birth defects affecting one in seven hundred newborns annually. Exposure in mice to secalonic acid -D (ŠAD), a mycotoxin produced by Pencillium oxalicum, is known to induce CP in association with smaller embryonic palatal shelves. Since the reduction in shelf size can result from a reduction in either palatal cell number or in the amount of extracellular matrix (ECM), the objective of this study was to delineate which of these mechanisms contribute to the teratogenic effect of SAD using the human embryonic palatal mesenchymal (HEPM) cells. The effect of increasing concentrations of SAD on HEPM cell numbers, survival, proliferation and ECM synthesis was assessed using cell counting, uptake of trypan blue, 3H-thymidine uptake and a combination of 3Hglucosamine incorporation and western analysis for the various ECM components (hyaluronic acid, sulfated glucosaminoglycans, fibronectin and tenascin), respectively. Exposure to SAD resulted in a dose-dependent reduction in HEPM cell number, levels of proliferating cell nuclear antigen (PCNA) in the nucleus and 3Hthymidine uptake with a no-effect concentration of 0.025 micro gm SAD/ml and an IC50 of 12.3 micro gm SAD/ml. Significant cytotoxicity and reduction in the ECM transport, but not synthesis, occurred only at the highest concentrations tested. Further studies using flow-cytometry and cyclin-dependent kinase (CDK) assay suggested that SAD blocked HEPM cell-cycle at the transition of G1/S phases, a conclusion supported by inhibition of CDK2 (active in G1/S phase) but not CDK1 (active in G2/M phase)by SAD. The results of this study strongly suggest that SAD-induced reduction in palatal shelf size and CP may be a result of its inhibition of cell-cycle and warrant further studies on the mechanism of its cellcycle block.(Supported by Alternatives Research and Development Foundation).

### 201 IMMUNE PROTECTION AGAINST MNU-INDUCED DIGITAL DEFECTS.

M. R. Prater<sup>2, 1</sup>, <u>S. D. Holladay</u><sup>1</sup> and E. D. Strahl<sup>1</sup>. <sup>1</sup>Veterinary Medicine, Virginia Tech, Blacksburg, VA and <sup>2</sup>Biomedical Sciences, Edward Via Virginia College of Osteopathic Medicine, Blacksburg, VA.

The present study investigated the role of the maternal immune system in protection against methylnitrosourea (MNU)-induced limb and digital birth defects in CD-1 mice. MNU's teratogenic effects are dose-specific and dependent upon the time of exposure in relation to gestational age. Maternal exposure to MNÛ at gestation day (GD) 9 resulted in reductions in limb length, formation of digital defects including syndactyly, oligodactyly and polydactyly, and distal limb hypovascularization in fetuses at GD 12 and 14. Limb lengths of GD 12 and 14 mice in the MNU group were 71% and 68% of control, respectively. Maternal intraperitoneal injection with interferon-gamma (IFN-gamma) two days prior to the GD 9 MNU treatment resulted in significantly increased limb lengths that were 88% and 84% of controls, respectively. These data suggest that nonspecific maternal immune stimulation with IFN-gamma, prior to MNU exposure, partially normalizes teratogeninduced fetal limb developmental lesions. This normalization may in turn relate to reduced limb defects seen in these animals at end-gestation. Further, histologic examination of placenta in MNU treated animals revealed intracellular and extracellular alterations in the spongiotrophoblast layer. This placental pathology was again lessened in pregnant mice that received IFN-gamma two days prior to MNU. It is not yet known if reduced day 12 and 14 distal limb dysmorphogenesis in MNU-exposed fetuses may be the result, in part, of improved placental integrity caused by IFN-gamma in MNU-exposed dams.

### 202

ORGANIC ANION TRANSPORTING POLYPEPTIDES (OATP) 9 AND 12 MNRA EXPRESSION: TISSUE DISTRIBUTION DURING PREGNANCY COMPARED WITH MALE AND NON-PREGNANT FEMALE SPRAGUE DAWLEY RATS.

T. M. Leazer and C. D. Klaassen. University of Kansas Medical Center, Kansas City, KS.

Pregnancy can influence the disposition and handling of chemicals as the maternal system changes to accommodate fetal and placental development. Knowledge of transporters is vital for the prediction of placental/fetal chemical accumulation and

susceptibility to toxicity. Hence, the purpose of this research was to characterize the tissue distribution of Oatp9 (Slc21a9) and 12 (Slc21a12) mRNA expression in male, non-pregnant female and pregnant rats. Oatp9 and 12 mRNA expression was determined with branched DNA signal amplification technology. Oatp9 mRNA was expressed highest in large intestine, stomach and term placenta; moderately expressed in liver, kidney, cerebellum, cerebral cortex and ileum; and was lowest in lung, duodenum and jejunum. Interestingly, for all sections of intestine, Oatp9 mRNA levels were higher in pregnant rats than in male and female rats. Oatp9 mRNA levels in placenta increased with the progression of pregnancy. Oatp12 mRNA levels were by far the highest in term placenta. In fact, Oatp 12 mRNA in placenta was 30-fold higher at term than any other tissue. Moreover, Oatp12 mRNA increased in placenta from gestation day 15 to 21. The next highest concentration of Oatp12 was in small intestine and stomach; expression was moderate in kidney, lung and large intestine; and lowest in brain. In ileum, Oatp12 mRNA transcripts were higher in pregnant female than non-pregnant or male rats. In summary, Oatp9 mRNA was most highly expressed in intestine, whereas Oatp12 was exceptionally highly expressed in placenta. The expression of both Oatp9 and 12 increased in the intestine during pregnancy, suggesting that these transporters are important in the absorption of chemicals needed during pregnancy. In addition, the extremely high level of Oatp12 in placenta and the increase in expression of Oatp9 and 12 in placenta during pregnancy suggest that they may be important in the transport of nutrients to the fetus. (Supported by NIH grants ES-09649 and ES-07079)

## 203 DEVELOPMENTAL EFFECTS IN RABBITS ASSOCIATED WITH ELEVATED PLASMA TYROSINE.

G. J. Moffat, M. E. Moxon, J. W. Botham and R. W. Lewis. *Syngenta CTL, Alderley Park, Cheshire, United Kingdom.* Sponsor: <u>I. Kimber</u>.

Selective inhibition of the enzyme 4-hydroxyphenylpyruvate dioxygenase (HPPD) by the herbicide mesotrione leads to perturbation of the tyrosine catabolism pathway. Subsequent tyrosinemia has been associated with a range of biological changes in rats, but to a much lesser extent in mice, where the plasma tyrosine elevation is less pronounced. Indeed, the incidence and severity of these changes in rodents correlated directly with plasma tyrosine concentration but not with concentrations of mesotrione. Importantly, the magnitude of tyrosinemia in humans following HPPD inhibition resembles that seen in mice. In a rabbit developmental toxicity study with mesotrione, the only treatment-related findings were minor changes in foetal ossification. To assess the human relevance of this finding, it was important to examine whether this skeletal effect was also attributable to elevated plasma tyrosine. Groups of 20 time-mated New Zealand White rabbits received 1% tyrosine in the diet (1%T) or 500 mg/kg/day mesotrione (MST) or a combination of 1% dietary tyrosine plus 500 mg/kg /day mesotrione (1%T+MST) during gestation. Assessment of maternal plasma tyrosine, revealed the expected range of tyrosinemia: 1%T<MST<1%T+MST. Similar to the previous study, there was no effect on foetal number, growth or survival and no evidence of teratogenicity or any effect on the incidence of external or visceral defects or variants. Indeed, even at plasma tyrosine levels exceeding those achieved with mesotrione alone, the only observed changes were in the patterns of foetal ossification. Furthermore, a clear relationship between the incidence of specific skeletal findings and plasma tyrosine was established ie the highest plasma tyrosine levels (1%T+MST) produced the largest difference from controls while the lowest increase in plasma tyrosine (1%T) had little effect on the pattern of ossification. This strong relationship between incidence of specific changes in foetal ossification and plasma tyrosine indicates a causal relationship with tyrosine rather than a direct effect of mesotrione.

### 204

THE SENSITIZING POTENTIAL OF NATIVE AND REDUCED/ALKYLATED BRAZIL NUT 2S ALBUMIN (BER E 1) IN AN ORAL BROWN NORWAY RAT FOOD ALLERGY MODEL.

S. J. Koppelman, L. M. Knippels, P. F. Nieuwenhuizen, E. I. Klein Koerkamp, H. H. de Jongh and A. H. Penninks. *Experimental Immunology, TNO Nutrition and Food Research, Zeist, Netherlands.* Sponsor: <u>V. Feron</u>.

2S albumin, a storage protein from Brazil nut, is an important allergen and classified as Ber e1. In this study the disulphide bounds of 2S albumin were reduced and alkylated (RA-2S albumin) resulting in loss of protein structure and an increased digestibility *in vitro*. The purpose of this study is to relate specific structural aspects of Brazil nut 2S albumin to the sensitizing capacity *in vivo* using an oral Brown Norway rat food allergy model. In addition, we wanted to demonstrate that the oral Brown Norway rat food allergy model is able to distinguish between the different potential allergenicities of native and RA-2 S albumin. Young Brown Norway rats (n=10) were orally exposed to 0.1 or 1 mg native- or RA-2S albumin by daily gavage dosing for 42 days without adjuvants. Serum samples were obtained at days 0, 28 and 42. As positive controls several animals (n=5) were injected i.p. with native

or RA-2S albumin at days 0, 2, 4, 7, 9 and 11. At day 0, alum was added as an adjuvant. These animals were bled at day 28. Serum samples were tested for antigen specific IgE, IgG1 and IgG2a using a passive cutaneous anaphylaxis assay and enzyme-linked immunosorbent assay (ELISA). Oral exposure to 0.1 or 1 mg native 2S albumin resulted in both native-2S albumin-specific IgG1 and IgG2a responses in 50-70% of the animals. In 50% of the animals of both groups native 2S albumin-specific IgE (day 42)was developed. In contrast, oral exposure to 1 mg RA-2S albumin only resulted in the development of RA-specific IgG1 and IgG2a in 60% of the animals whereas no specific IgE could be detected. Exposure to 0.1 mg RA-2S albumin did not result at all in a detectable immune response in any of the tested animals. The results of this study demonstrate the importance of the stability of protein structure in inducing food allergy. In addition, we show that the oral Brown Norway rat food allergy model is able to distinguish the different potential allergenicity of both proteins.

### 205 INCREASED ANTIBODY RESPONSE BY BDF1 MICE CO-ADMINISTERED OVALBUMIN AND LIPOPOLYSACCRIDE (LPS).

M. R. Woolhiser, J. M. Rase and T. D. Landry. Toxicology & Environmental Research and Consulting, The Dow Chemical Company, Midland, MI.

There is an urgent need for an animal model that predicts the allergenicity potential of novel proteins associated with biotechnology. Many protein test materials will be purified from bacterial sources and thus have the potential to contain appreciable amounts of LPS, a potential confounder in the interpretation of antibody responses. A recent study suggested that concurrent allergen and LPS administration would reduce an IgE response towards specific, allergenic protein(s). This study evaluated the antibody response in mice following concurrent, i.p. administration of ovalbumin (OVA) and LPS. Mice were injected on days 1 and 8 with OVA prepared in PBS at 0.1mg/ml [0.08 endotoxin units (EU)] or in combination with LPS (1-400 EU). Serum samples were prepared on day 14 for ELISA (OVA-specific IgG) and to measure OVA-specific IgE via passive cutaneous anaphylaxis (PCA). IgG sera titers from naive mice were undetectable at dilutions of 1:10, while mice treated with OVA alone had elevations in specific IgG (titer = 286) and specific IgG1 (titer = 149). Co-exposure to OVA and LPS (≥ 1.6 EU) more than doubled these IgG and IgG1 titers. LPS had no impact on the incidence of positive PCA responses as all mice injected with OVA (+/- LPS) developed specific IgE; undiluted sera from naive mice lacked OVA specific IgE. LPS and OVA administration enhanced the magnitude of IgE responses as determined via maximum PCA titer and PCA reaction area using undiluted sera. Maximal PCA titers using pooled sera samples indicated a two-fold increase in specific IgE titers when OVA was co-injected with 40-80 EU. IgE titer increased to greater than 100 in mice treated with OVA and 400 EU. These results confirm that LPS can alter a murine antibody response when co-administered with an allergenic protein. The nature of the antibody response (i.e., enhanced or diminished) may depend upon factors such as exposure route, interval or duration. This suggests LPS might serve as a confounder when predicting a novel protein's allergenic potential via IgE and IgG production.

MIXED ANTIBODY AND T-CELL RESPONSES TO PEANUT AND THE PEANUT ALLERGENS ARA H1, ARA H2, ARA H3 AND ARA H6 IN A MURINE ORAL SENSITIZATION MODEL.

F. van Wijk<sup>1, 2</sup>, S. Koppelman<sup>3</sup>, <u>R. Pieters</u><sup>1</sup> and L. Knippels<sup>2</sup>. <sup>1</sup>Immunotoxicology, IRAS, Utrecht, Utrecht, Netherlands, <sup>2</sup>Experimental Immunology, TNO Nutrition and Food Research, Zeist, Netherlands and <sup>3</sup>Protein Technology, TNO Nutrition and Food Research, Zeist, Netherlands.

Peanut allergy is known for its severity and persistence through life. Several peanut proteins have been identified as allergenic and are indicated as Ara h1-7. Very little is known about the mechanisms that underlie sensitization to peanut proteins. The purpose of the present study was to reveal the immune responses that are induced against peanut and the peanut allergens Ara h1, Ara h2, Ara h3 and Ara h6 during sensitization. Humoral and T-cell responses against peanut and the peanut allergens were examined in an early and later stage of sensitization in an established murine model of peanut anaphylaxis. Oral sensitization to peanut was characterized by a mixed cytokine response (IL-4, IL-5, IL-10 and IFÑ-γ) and polyisotypic humoral responses (IgE, IgG1 and IgG2a). Furthermore we demonstrated that these TH1/TH2 cytokine and antibody responses are also directed specifically against the major peanut allergens Ara h1, Ara h2, Ara h3, and Ara h6. The major peanut allergen Ara h1 induced the highest antibody responses followed by Ara h3, Ara h6 and Ara h2. This study implicates that both TH1 and TH2 phenomena are involved in the development of peanut allergy. Furthermore, we show that the present oral model is suitable to examine immune responses to food allergens during sensiD. A. Basketter<sup>1</sup>, R. J. Dearman<sup>2</sup>, C. A. The local lymph node assay (LLNA) is an alternative to guinea pig tests for identification of skin sensitising chemicals. In the LLNA protocol, CBA strain mice receive 3 consecutive daily topical applications of test substance (at 3 dose levels). Five days after the initiation of exposure, proliferative responses in lymph nodes draining the application site are measured by incorporation of radiolabelled thymidine. Chemicals that induce proliferative responses >3x those observed in concurrent vehicle treated control are considered to be skin sensitisers. The assay has been approved as a standalone method for the determination of skin sensitisation hazard by the FDA, the EPA, CPSC and others following approval by the Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM). The LLNA has also received formal approval from the European Centre for the Validation of Alternative Methods (ECVAM). The LLNA became OECD Guideline 429 in 2002, and in the EU awaits endorsement as Test Method B42 in the 29th Adaptation to Technical Progress. The UK Health and Safety Executive led the way as a European Competent Authority by announcing that for both scientific and animal welfare reasons the LLNA was the preferred method. Currently, regulatory authorities in the Far East increasingly are considering the method. However, challenges remain insofar as validation does not mean automatic acceptance, nor is the LLNA necessarily the most appropriate method in all circumstances. Experience with the assay for the assessment of complex mixtures is no better validated than are such evaluations using guinea pig methods, although at least for the LLNA considerable data are available on the impact of vehicles on the expressed potency of allergens.

208

VALIDATION OF A MINIMAL TRANSCRIPT BIOMARKER SET TO DIFFERENTIATE BETWEEN SENSITIZERS AND IRRITANTS IN THE LOCAL LYMPH NODE ASSAY.

W. R. Foster<sup>2</sup>, <u>G. S. Ladics</u><sup>1</sup> and C. M. Glatt<sup>1</sup>. <sup>1</sup> Haskell Laboratory, DuPont, Newark, DE and <sup>2</sup> Bristol-Myers Squibb, Wilmington, DE.

Previous studies utilized the LLNA in conjunction with DNA microarrays to evaluate expression profiling as a method to distinguish between sensitizers and irritants and to identify potential transcript biomarkers. Using a defined training set and analysis criteria, a set of potential biomarker genes that included proteases and protease inhibitors, and lymphocyte, cell cycle, and inflammatory related response transcripts were defined and had expression patterns in the array experiments suggesting they may discriminate between sensitizers and irritants. The objective was to validate the biomarker candidates using real-time PCR. Analyses were performed on auricular lymph node total RNA isolated from 8-week-old female CBA/JHsd mice (n=7-15/group) dosed with either 4:1 acetone/olive oil (vehicle), one of several different sensitizers, or one of several different irritants according to the standard LLNA protocol. Real-time PCR experiments were performed using the TaqMan® technology and primer/probe sets of each specific biomarker. Expression patterns for transcripts such as mLag3 (lymphocyte activation gene), TYMS (thymidylate synthase gene), and mBub1A (a mitotic checkpoint protein kinase) were consistent with the array results. These transcripts were generally upregulated in sensitizer-treated groups and unchanged in irritant-treated groups. The validated clusters of potential biomarkers effectively confirm proliferation-based scoring of sensitizers in the LLNA. Expression profiling performed on higher doses of the irritant, benzalkonium chloride, that typically score positive in the LLNA, revealed a similar induction of many cell cycle and inflammatory-response transcripts, providing a molecular basis for high-dose irritant scoring in the LLNA. These results illustrate the utility of expression profile databases that can be queried against for compound classification, and reveal several candidate biomarkers that may serve as sensitive endpoints for discriminating irritants from sensitizers using the LLNA.

## 209 EXPERIENCE IN THE ROUTINE USE OF THE LOCAL LYMPH NODE ASSAY (LLNA).

J. Le Bigot, B. Griffon, X. Manciaux, S. de Jouffrey and R. Forster. CIT, Evreux, France

The Local Lymph Node Assay (LLNA) is an *in vivo* alternative to traditional Guinea pig testing methods for assessment of the potential of chemicals to cause skin sensitization. In this assay, sensitizing activity is measured using parameters of the induction phase, rather than of the elicitation phase, by quantification of the proliferative responses in draining lymph nodes after topical application of the test item. Testing procedures have been formalized in a recently approved OECD

guideline (No. 429). In this guideline, skin sensitizers are defined as test items which, at one or more tested concentrations, elicit a 3-fold or greater increase in the incorporation of radioactivity (a measure of cellular proliferation) compared with vehicle controls, together with consideration of a dose-response relationship. As the method is described in the OECD guideline, the LLNA and its interpretation seem easy. However, based on our experience of over 150 individual studies performed in the last 12 months, it appears that interpretation may sometimes be problematic. We have previously shown that definitive classification of a test item as a skin sensitizer cannot be based only on the criterion of a stimulation index (SI). Integration of a quantitative measure of skin irritation (for example, by measurement of ear thickness) in the study protocol is necessary to permit unequivocal interpretation of the results since it is well established that an irritant action can give rise to "false positive" increases in cellular proliferation. More recently, in routine studies, we have been confronted by various data sets for which interpretation was problematic. For example, an SI greater than 4 at the highest tested concentration but accompanied by slight irritation? An SI exceeding 2 at the highest feasible dose-level, without evidence of dose-relationship? In our experience the LLNA is an informative and robust test but routine use requires careful attention to the interpretation of re-

### 210 COMPARISON OF TWO PROTOCOLS OF A MODIFIED LYMPH NODE ASSAY

K. Riecke and P. Kurth. Experimental Toxicology, Schering AG, Berlin, Germany. Sponsor: R. Stahlmann.

The Local Lymph Node Assay (LLNA) is a method to study sensitization using tritiated thymidine for assessment of cell proliferation. We tested the usefulness of auricular lymph node weight, lymph node cellularity and weight of an ear punch as alternative end points using two different study protocols. Female BALB/c mice (4 or 6 per group) were treated on three consecutive days on the back of both ears with the sensitizing reference compounds dinitrochlorbenzene (DNCB) or hexylcinnamic aldehyde (HCA) or mercaptobenzothiazole (MBT). Three concentrations of DNCB, HCA or MBT were selected which included the respective threshold concentrations (EC3) in the LLNA. The end points were assessed one ("short protocol", DNCB and HCA) or three days ("LLNA protocol", DNCB, MBT and HCA) after the last treatment. Lymph node cells from DNCB-treated animals were also studied by three color flow-cytometry analyzing CD4 or CD8 and CD44 and CD62L to differentiate between naive T-cells and cells having had antigen contact. Using the short protocol, HCA was positive at all concentrations exceeding the EC3 but DNCB was positive only at the 4-fold EC3. Using the LLNA protocol, all three reference substances were positive from their respective EC3 upwards. At the EC3, lymph node weights were approximately 1.5-times higher than in controls using the LLNA protocol. Flow cytometric analysis did not show clear cut effects in DNCB-treated mice up to a concentration of 0.25 mg/ml. Compared to the short protocol, the LLNA-protocol led to more pronounced increases of lymph node weight and lymph node cellularity. The LLNA protocol was able to classify all concentrations at or beyond the EC3 as positive with three reference substances which are considered as weak to moderate or strong sensitizers. The increase of lymph node weight (increase approx. 1.5 fold at EC3) seemed to be more sensitive than the increase of lymph node cellularity (increase 1.1 to 1.7 fold at EC3). Inclusion of flow-cytometric end points did not improve sensitivity of this assay.

## 211 ROUND II OF AN INTER-LABORATORY VALIDATION OF ALTERNATIVE ENDPOINTS OF THE MURINE LINA

J. Huesler<sup>9</sup>, <u>P. Ulrich</u><sup>1</sup>, H. Vohr<sup>2</sup>, G. Ehling<sup>3</sup>, M. Hecht<sup>4</sup>, A. Heusener<sup>10</sup>, A. Gamer<sup>5</sup>, <u>H. van Loveren</u><sup>6</sup>, <u>L. Ullmann</u><sup>8</sup>, T. Maurer<sup>9</sup> and K. Riecke<sup>11</sup>. <sup>1</sup>Preclinical Safety, Novartis Pharmacology AG, Muttenz, Switzerland, <sup>2</sup>Bayer AG, Wuppertal, Germany, <sup>3</sup>Aventis Pharmacology AG, Frankfurt, Germany, <sup>4</sup>ITA Fraunhofer Institute, Hannover, Germany, <sup>5</sup>BASF AG, Ludwigshafen, Germany, <sup>6</sup>RIVM, Bilthoven, Netherlands, <sup>7</sup>University of Bern, Bern, Switzerland, <sup>8</sup>RCC, Itingen, Switzerland, <sup>9</sup>Swiss Agency for Therapeutic Products, Bern, Switzerland, <sup>10</sup>Merck, Darmstadt, Germany and <sup>11</sup>Schering AG, Berlin, Germany.

The original Local Lymph Node Assay (LLNA) is based on the use of radioactive labelling to measure cell proliferation. However, other endpoints for assessment of proliferation are also authorized by the OECD guideline 429 provided there is appropriate scientific support, including full citations and description of the methodology. Here we describe the outcome of the 2nd round of an inter-laboratory validation of alternative endpoints in the LLNA conducted in nine laboratories in Europe. The validation study was managed and supervised by the Swiss drug agency. Statistical analysis was performed at the university of Bern, Department of Statistics. Ear-draining lymph node (LN) weight and cell counts were used to assess proliferation instead of radioactive labelling of lymph node cells. In addition, the acute inflammatory skin reaction was measured by ear swelling and weight of circular biopsies of the ears to identify skin irritating properties of the test items. Eleven

blinded test items were applied to female NMRI and/or BALB/c mice. The assessment of skin irritation potential supported the differentiation of pure irritative from contact allergenic potential. In contrast to the radioactive method irritants have been picked up by all the labs. An assessment scheme developed by the group turned out to be of extreme value in evaluation of the data from the different parameter. Similar to the EC3 values defined for the radioactive method, threshold values were calculated for the endpoints measured in this modification of the LLNA. It was concluded that all parameters measured have to be taken into consideration for the categorisation of compounds due to their relative sensitising potencies.

## 212 USE OF LOCAL LYMPH NODE ASSAY POTENCY DETERMINATIONS IN EXPOSURE-BASED RISK ASSESSMENT FOR SKIN SENSITIZATION.

C. Ryan<sup>1</sup>, P. McNamee<sup>2</sup> and <u>F. Gerberick<sup>1</sup></u>. <sup>1</sup>Procter & Gamble Company, Cincinnati, OH and <sup>2</sup>Procter & Gamble Company, Egham, Surry, United Kingdom.

The fact that a chemical is determined to be a contact allergen does not mean it cannot be formulated into a consumer product at safe levels, provided that one has a thorough understanding of ingredient exposure, allergenic potency and dose response. The local lymph node assay (LLNA), a validated method for the prediction of skin sensitization hazard, has been shown to be useful for the determination of relative sensitization potency. Relative potency is based upon calculation, from the LLNA dose response curve, of an EC3 value - the estimated concentration of chemical required to induce a threshold positive response (stimulation index = 3). To demonstrate both the application and value of LLNA-derived potencies to the risk assessment process, the example of two theoretical preservatives is used. For illustration purposes, we assume that in calculations from the resulting LLNA dose response curves Preservative A has an EC3 value of 12.9%, with a relative sensitization potency of weak and Preservative B has an EC3 value of 0.3%, giving it a relative potency of strong. Using an exposure-based risk assessment approach in which a default No Observed Effect Level (NOEL) is assigned based on the potency classification; the anticipated consumer exposure to the ingredient is compared to a sensitization reference dose calculated from the default NOEL and appropriate uncertainty factors to determine a margin of safety (MOS). An acceptable exposure is generally represented by an MOS≥1. Based on this risk assessment methodology, both preservatives were found to be acceptable for use in a 'rinse-off' product (e.g. shampoo) at a level of 50 ppm, while only Preservative A, the weak allergen, was appropriate for use in a 'leave-on' product (e.g. moisturizer) with the same level of preservative. These examples demonstrate the utility and importance of LLNA-derived potency classifications in the conduct of scientifically sound risk assessments for skin sensitizing chemicals.

## 213 CATEGORISATION OF HUMAN SENSITISATION POTENCY USING LOCAL LYMPH NODE ASSAY EC3 VALUES.

N. J. Gilmour<sup>1</sup>, D. A. Basketter<sup>1</sup>, G. Y. Patlewicz<sup>1</sup>, P. S. Kern<sup>2</sup>, <u>C. A. Ryan<sup>2</sup></u>, <u>F. G. Gerberick<sup>2</sup></u>, <u>R. J. Dearman<sup>3</sup> and I. Kimber<sup>3</sup>. <sup>1</sup>SEAC, Unilever, Sharnbrook, United Kingdom, <sup>2</sup>Procter & Gamble, Cincinnati, OH and <sup>3</sup>Syngenta CTL, Macclesfield, United Kingdom.</u>

Effective evaluation of skin sensitisation demands that potential contact allergens are identified and the risk of sensitisation amongst exposed populations assessed. Sensitisation hazard is not an all or nothing phenomenon; dose response relationships can be discerned and thresholds identified for induction and elicitation of contact allergy. These parameters, under the heading of potency, are vital for the risk assessment process. The murine local lymph node assay (LLNA) is a validated and accepted method for the identification of sensitisation hazards (a sensitiser is a chemical that induces a stimulation index 3 or more times that of the concurrent vehicle control). The LLNA has also been used to determine the potency of sensitisers, by derivation of an EC3 value, the estimated concentration of chemical required to induce a stimulation index of 3. At present, various agencies, including in EU and OECD, together with industry bodies, are considering whether and how to adapt these data into regulations which would place sensitisers into one of several potency categories. It is our view, based on an evaluation of over 250 chemicals, that five categories, extreme, strong, moderate, weak and negative, represent the optimal approach and is consistent with what is understood regarding the potency of skin sensitisers in humans. To illustrate this approach, an example dataset of 100 selected organic chemicals is shown, where we judge the accuracy of prediction of human potency to be in the region of 90%. This categorisation has utility as a simple guide for risk management strategies as well as representing an important first step in risk assessment.

## OBSERVATIONS ON THE UTILITY OF THE LLNA FOR DERMATOLOGIC DRUG PRODUCTS.

A. Jacobs, D. Allen, P. C. Brown, B. A. Hill, N. See and J. Wilkin. USFDA, Rockville, MD.

The local lymph node assay (LLNA) may be useful in the evaluation of contact hypersensitivity for some chemical substances. In Feb 1999, the Interagency Coordinating Committee on the Validation of Alternative methods (ICCVAM) published a validation study for the use of the LLNA as an alternative to traditional hypersensitivity methods. The LLNA was validated for neat liquids and for 50%, 25% and 10% solutions in acetone olive/oil. However, the LLNA was not validated for mixtures, clinical formulations, or with many substances with pharmacologic activity. Topical drug formulations usually have concentrations of active components at <1%. Because results using these formulations may be vehicle dependent, inclusion of a positive control in the clinical vehicle is desirable. Several issues related to drug substance and or drug products tested with the LLNA have arisen that have confounded interpretation of the LLNA These issues include: irritant vehicle, failure of DNCB in the clinical vehicle, vehicles that appear positive, pharmacologic activity (e.g., cytokine induction), false positives relative to both guine pigs and humans, and potency relative to DNCB not correlating with the guinea pig assay. Furthermore, intra-laboratory reproducibility of LLNA results has been inconsistent. It is not clear for which human population the LLNA was validated. Persons with or without atopic dermatitis may respond differently, as would persons in a challenge test or persons exposed without occlusion. Therefore, the LLNA should be used with caution; it may not be useful for many dermal drug products. In some cases, absence of effects in repeat-dose studies in animals, followed by repeat-dose studies in humans, may ob viate the need for nonclinical evaluation of dermal hypersensitivity.

# 215 APPLICATION OF A MODIFIED LLNA TO PETROLEUM-BASED PRODUCTS: DERMAL SENSITIZATION POTENTIAL OF CALCIUM LONGCHAIN ALKYLBENZENE SULFONATES.

S. A. Signs<sup>1</sup> and <u>G. L. DeGeorge</u><sup>2</sup>. <sup>1</sup>The Lubrizol Corporation, Wickliffe, OH and <sup>2</sup>MB Research Laboratories, Spinnerstown, PA.

Calcium long-chain (C15-30) alkylbenzene sulfonates are oil-based detergents used in a variety of mechanical lubrication applications. Low overbased calcium sulfonates (LOB) are generally regarded as dermal irritants whereas high overbased calcium sulfonates (HOB) are non-irritants. Existing data reveals a strong correlation between dermal irritant properties of calcium sulfonates and dermal sensitization potential observed in guinea pigs and humans. A flow cytometry-based murine local lymph node assay (LLNA) was used to further elucidate the influence of dermal irritancy on assessments of dermal sensitization potential. Female CBA/J mice (five per group) were treated with 3 concentrations of either LOB, HOB, 50% HCA (positive control) or ultra-pure petrolatum (vehicle control) by daily topical application to the dorsum of each ear for three consecutive days. Five days following the initial dose, the mice were injected with 5-bromo-2-deoxy-uridine (BrdU). This thymidine analog is incorporated into the DNA of proliferating cells. Five hours later, the auricular lymph nodes were isolated and single-cell suspensions of lymph node cells (LNC) were generated for each individual animal. An aliquot of each LNC suspension was analyzed by flow cytometry for immunotype expression (B220+, CD3+) and the total number of proliferating (BrdU+) cells was determined. Treatment with HOB resulted in no significant dermal irritation as measured by ear swelling and yielded a cellular SI <3 (not classified a dermal sensitizer). LOB treatment induced a dose-dependent increase in cellular proliferation (30% LOB; SI=4.54) which was accompanied by significant increases in ear thickness indicating a dermal irritation response. Additionally, the lack of increases in B220+ lymph node cells or in the B:T cell ratio following LOB treatment further confirms that changes in LNC proliferation are due to irritation rather than induction of dermal sensitization

# 216 EFFECTS OF LIPOPHILICITY AND VISCOSITY OF SOLVENTS ON DPM/LN BACKGROUND LEVEL IN MURINE LOCAL LYMPH NODE ASSAY (LLNA).

L. G. Ullmann, W. Wang-Fan, G. Arcelin, <u>S. Corney</u> and K. Blumbach. *Toxicology, RCC Ltd., Itingen, Switzerland.* 

In 253 LLNA studies with 1012 CBA/CaOlaHsd mice performed at RCC, 11 different solvent systems, most of them are recommended by OECD Guideline 429, have been used. As a standard level in the calculation of the stimulation index (S.I.), disintegrations per minute per lymph node (DPM/LN) of the control group plays a key roll in getting reliable and correct test results. However, the level of DPM/LN can be varied or influenced by many factors. The variety of vehicles used in LLNA is one of the most important factors which can directly effect the background level

of DPM/LN. Although some systematic deviations in a LLNA study can be eliminated by using a vehicle control group, further investigations on the background level of DPM/LN are still necessary in different solvent systems. This poster presents the results of our investigations into the following aspects of the LLNA: - The effect of different solvents on DPM/LN control level; - The possible range of variation of DPM/LN control level with different solvent systems; - How to interpret the solvents effects on DPM/LN background level. The results have helped to optimize the experimental methods and to increase the accuracy of the tests.

# 217 BISPHENOL A IS NOT SKIN SENSITIZING OR PHOTOALLERGENIC AS MEASURED BY A MODIFIED LOCAL LYMPH NODE ASSAY IN MICE.

H. Vohr, H. Ahr and G. D. Stropp. *Toxicology, Bayer AG, Wuppertal, NRW, Germany.* Sponsor: R. Shiotsuka.

A major chemical intermediate for the production of polycarbonates and epoxy resins is Bisphenol A (BPA). Experimental studies for dermal sensitisation potential of BPA have led to generally negative or equivocal results. Photosensitization studies were based on non-validated test systems or the results were not definitive. Casereports of dermal sensitisation are rare and generally involve presumed exposure to compounds produced from BPA and not the BPA monomer. Thus, the purpose of this study was to assess BPA for a skin sensitising or photoallergenic potential using a validated test system. A modified Local Lymph Node Assay (LLNA), the Integrated Model for the Differentiation of Skin reactions (IMDS; Homey, B, et.al, Toxicol. Appl. Pharmacology 153, 83-94, 1998; Vohr, H.-W., et al, Arch. Toxicol., 73, 501-509, 2000) was used to distinguish skin sensitization from acute irritation. The UV-IMDS assay was used to test for photo-reactivity. Female outbred NMRI mice (6/group) received dermal applications of either vehicle (DAE433), 3%, 10% or 30% (solubility limit) BPA on three consecutive days. For the investigation of photo-reactivity, mice were irradiated with 20J UV-A/cm2 directly after each application. Results showed no skin reaction in the BPA groups. In contrast to positive controls (HCA, Chlorpromazine, 8-MOP), neither a skin sensitizing or photoallergenic nor an irritating or photoirritating potential was observed. Therefore, BPA is not considered to be a skin sensitizer or photosensitizer in this validated test system.

## **218** EVALUATION OF THE SENSITIZATION POTENTIAL OF *PFIESTERIA* TOXIN IN BALB/C MICE.

R. M. Patterson<sup>1</sup>, E. Noga<sup>2</sup> and <u>D. Germolec</u><sup>1</sup>. <sup>1</sup>NIEHS, Research Triangle Park, NC and <sup>2</sup>N.C. State University, Raleigh, NC.

Members of the estuarine dinoflagellate genus, Pfiesteria, are reported to have been responsible for massive fish kills in the southeastern United States. The classic signs of Pfiesteria poisoning in fish are skin ulceration and swimming disruption. Some studies suggest that people exposed to waters having Pfiesteria blooms might exhibit toxin-induced skin and respiratory irritation and inflammation. High levels of exposure related to occupational setting have suggested disruptions in cognitive function. Although the putative toxin has not been isolated, available data suggest both hydrophilic and hydrophobic toxic components. The dermonecrotic properties have been proposed to be associated with the hydrophobic fraction. The C-18 bound fraction of the crude toxin extract from dinoflagellate cultures, confirmed to be ichthyotoxic, was examined in the current studies to evaluate its potential to produce inflammation and dermal sensitization. This fraction was cytotoxic to mouse Neuro 2A cells at  $1 \times 10^3 \,\mu g/ml$ , validating potency as described previously (McClellan-Green, 1997). In primary human epidermal keratinocytes, proliferation and *via*bility were also inhibited at  $1 \times 10^3 \, \mu \text{g/ml}$  of the C-18 fraction, as determined using the 3-(4, 5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium salt (MTS) and Neutral Red cytotoxicity assays. Exposure of Balb/C mice to 0.25-30 x 10<sup>3</sup> µg/ml of the C-18 bound fraction induced mild, localized inflammation, as evidenced by a 5-10% increase in ear swelling relative to control mice. There was no increase in lymph node cell proliferation as measured using the ICCVAM-validated (Dean, et al. 2001) local lymph node assay. These studies suggest that the C-18 bound fraction of the toxin is cytotoxic to keratinocytes in culture at high concentrations; that it induces mild, localized irritation, but not sensitization in mouse skin; and that the degree of dermal irritation and inflammation reported in human exposure studies may result from the combination of *Pfiesteria* contact and other confounding factors.

# 219 EVALUATION OF THE CONTACT HYPERSENSITIVITY-INDUCING POTENTIAL OF A COMMERCIAL WEAPON CLEANING AND MAINTENANCE COMPOUND.

S. Azadi<sup>1</sup>, <u>D. P. Arfsten<sup>2</sup></u> and <u>B. J. Meade<sup>1</sup></u>. <sup>1</sup>NIOSH, Morgantown, WV and <sup>2</sup>Naval Health Research Center Toxicology Detachment, Wright-Patterson AFB, OH.

Commercial cleaning, lubricating, and preserving compounds are used in both the military and civilian sectors for maintenance of small and large caliber weapons. The cleaning of weapons is a very labor intensive, hands-on operation and frequent,

repeated dermal contact with materials used in weapons maintenance is highly probable. Cleaning compounds are usually complex mixtures containing many constituents including polyalphaolefin oil, synthetic oils, esters, isoparaffinic hydrocarbons, and dibasic ester, some of which have the potential for being dermal sensitizers. These studies assessed the irritant and sensitizing potential of a weapon cleaning compound using a modified local lymph node assay (LLNA) and phenotypic analysis (PA) of draining lymph node cells. Female BALB/c mice (n=5) were topically exposed on the dorsal ear pinna for 3 (LLNA) or 4 (PA) consecutive days. In the LLNA, mice were injected i.v. with 3H-thymidine on day 6 and draining lymph nodes were radioassayed. Ear thickness was measured using a micrometer prior to sacrifice to evaluate irritancy. For PA, on day 10 post initial exposure, draining lymph node cells were stained with FITC labeled rat anti-mouse IgE or PE labeled rat anti-mouse CD45 B220. Blood was collected at the time of sacrifice for analysis of total serum IgE. The compound induced a dose-responsive increase in lymph node cell proliferation with the neat material resulting in a stimulation index of 13.4. PA demonstrated an elevation in B220+ cells. No increase in total serum IgE was detected. Animals exhibited thickened skin and hair loss at the site of exposure and a 42.5% increase in ear swelling was observed in animals exposed to the neat material as compared to controls 3 days following the final exposure. These studies indicate the potential for the compound tested to induce contact sensitization with no evidence of an IgE inducing potential. These studies were supported in part by NIEHS intra-agency agreement # Y1-ES-0001-03.

## 220 EFFECT OF CHLORINATED ORGANIC SOLVENTS IN DRINKING WATER ON TYPE I ALLERGIC REACTION.

M. Seo, T. Yamagiwa, T. Ikemoto, <u>M. Satoh</u> and H. Nagase. *Department Of Hygienics, Gifu Pharmaceutical University, Gifu, Japan.* 

The incidence of allergic diseases has been increasing. Some epidemiological studies suggest that this is due to exposure to environmental toxic substances. Chlorinated organic solvents are incombustible and low molecular chemicals, and have been used widely in a variety of industrial processes as solvents, softeners, paint thinners, dry-cleaning fluids at present. But chlorinated organic solvents have become major environmental pollutants. Previously we observed that some chlorinated organic solvents, such as tetrachloroethylene (PCE), trichloroethylene (TCE), and 1, 1, 1trichloroethane, increased histamine release from mast cells in vitro. In the present study, we investigated the enhancing effect of low concentration of PCE, TČE and 1, 1, 1-trichloroethane dissolved in drinking water on Wistar rat (male, 8weeks old). Each chlorinated organic solvent was dissolved in distilled water at a concentration of Japanese guideline for drinking-water quality, or its 100-fold concentration. After 2 or 4 weeks, we executed PCA reaction. The chlorinated organic solvents enhanced PCA reaction in a dose-dependent and time-dependent manner. In pathological studies, the skin lesions elicited in rat drinking PCE and TCE for 2 weeks showed a cellular infiltrate in the dermis that contained lymphocytes and mast cells. To further investigate the effects of chlorinated organic solvents, we measured IL-4 production from mast cells, rat basophilic leukemia cells (RBL-2H3), treated with chlorinated organic solvents for 6 hours. IL-4 production from the cells treated with 1mg/L PCE markedly enhanced. The mechanism of enhancing PCA reaction is assumed that chlorinated organic solvents increase IL-4 production, and it causes a Th1-Th2 imbalance and increases histamine release from mast cells accumulated excessively. The results suggest that the intake of chlorinated organic solvents as drinking water, even in a low concentration, would lead to the initiation of allergic diseases.

# 221 INVOLVEMENT OF PERTUSSIS TOXIN SENSITIVE G PROTEIN ACTIVATION IN HISTAMINE RELEASE INDUCED BY FLUOROQUINOLONE ANTIBACTERIAL AGENTS (FLUOROQUINOLONES) AND THEIR STRUCTURE-HISTAMINE RELEASE RELATIONSHIP.

M. Kazuhiko, M. Chikako and K. Furuhama. Drug Safety Reseach Laboratory, Daiichi Pharmaceutical Co., Ltd.,, Tokyo, Japan.

The present study was designed to clarify the involvement of pertussis toxin sensitive G protein activation in histamine release induced by fluoroquinolones and then to elucidate the relationship between their structures and histamine release using rat peritoneal mast cells. Levofloxacin (LVFX) at 1000 µM or more dose-dependently induced a non-cytotoxic histamine secretion. This action was rapidly completed within 30 s and was dependent on temperature, energy, pH and intracellular Ca2+. Histamine secretion due to LVFX was prevented by pretreatment with pertussis toxin or benzalkonium chloride which was a selective inhibitor of G proteins of Gi subtypes, or neuraminidase which induced hydrolysis of sialic acid residues on the cell surface. Moreover, LVFX increased GTPase activity in the supernatant of mast cell membrane homogenate. Next, histamine releasing activity of the 10 fluoroquinolones such as LVFX, ciprofloxacin (CPFX), lomefloxacin (LMFX), sparfloxacin (SPFX), gatifloxacin (GTFX), grepafloxacin (GPFX),

sitafloxacin (STFX), HSR-903, moxifloxacin (MXFX) and T-3762 was compared under the same experimental conditions. All of the fluoroquinolones tested except for T-3762 induced a non-cytotoxic histamine secretion in a concentration-dependent fashion. The order of its potency (10% histamine releasing concentration, µM) was GPFX (70) = HSR-903 (70)≥GTFX (110)≥TFX (120)≥CPFX (130)≥SPFX (140)≥MXFX (200)≥LMFX (250)>LVFX (1870)>T-3762 (>3000). The activation caused by these fluoroquinolones was evidently blocked by pretreatment with pertussis toxin. These results demonstrate that fluoroquinolones interact with sialic acid residues, followed by the activation of pertussis toxin sensitive G proteins leading to histamine release. Furthermore, the order of the potency of histamine release would be, at least in part, related to the positive charge of substituents at the 7 position of fluoroquinolone core structure.

DEVELOPMENT OF AN ORAL EXPOSURE ANIMAL MODEL WITH REPORTER ANTIGENS TO ASSESS IMMUNE-MEDIATED DRUG-HYPERSENSITIVITY

S. Nierkens, M. Aalbers, M. Bol and <u>R. Pieters</u>. *IRAS-Immunotoxicology, Utrecht University, Utrecht, Netherlands.* 

Adverse immune responses to drugs are of major concern to pharmaceutical companies, physicians and susceptible patients. Due to its idiosyncratic nature and complex etiology adverse immune effects are usually missed in routine toxicity studies. Previous reports suggest that the murine or rat popliteal lymph node assay (PLNA) may be a possible screen for hypersensitivity reactions. However, the PLNA involves administering the test compound via footpad injections rather than the relevant route of exposure. In addition, drug-induced immune responses may vary from chemical- to neo-antigen-specific, thus hampering straightforward detection of immunosensitizing potential in animal models. By using well-defined reporter antigens (RA) this problem has been successfully circumvented in the PLNA. The aim of this study was to investigate whether the RA-approach can be used in combination with oral exposures to assess the immunogenicity of drugs. Accordingly, female C3H/HeJ mice were injected i.p. with the RA TNP-OVA on day 0 and received 50 or 150 mg/kg D-penicillamine (D-Pen) by gavage or i.p. on day 0-7. On day 10, all experimental groups showed increased TNP-specific serum antibody responses and only the 150 mg/kg-dosed groups had increased DTH responses on day 15 and TNP-specific antibodies on day 20. In a separate study we found that a single oral dose of D-Pen (50 mg/kg) sensitized the immune system so that a paw-challenge with a sub-sensitizing dose of D-Pen in combination with the RA TNP-Ficoll (T cell independent antigen susceptible for neo-antigen-specific help) induced TNP-specific DTH and antibody secreting B cells in the draining lymph node. The response was drug-specific, as diclofenac did not induce TNPspecific responses in D-Pen-sensitized animals. In conclusion, we present two promising variations of an oral exposure model using RA to assess the immunosensitizing capacity of drugs. Other drugs are currently investigated using these models. This project is financially supported by ILI-HESI Immunotoxicology Technical Committee (ITC)

TEST STRATEGIES FOR IMMUNE SENSITIZATION BY PHARMACEUTICALS: A COMPARISON OF THE SUBCUTANEOUS LOCAL LYMPH NODE ASSAY AND POPLITEAL LYMPH NODE ASSAY USING REPORTER ANTIGENS.

R. Pieters, S. Nierkens, L. Nieuwenhuijsen and M. Thomas. IRAS-Immunotoxicology, Utrecht University, Utrecht, Netherlands.

Immune-mediated idiosyncratic drug reactions are a major problem for susceptible patients, physicians and pharmaceutical industries. Currently, validated screening tools to assess the immunosensitizing capacity of pharmaceuticals are not available. Recently, the Immunotoxicology Technical Committee of ILSI-HESI initiated a collaborative effort to evaluate the popliteal lymph node assay (PLNA) in comparison with a modified version of the local (auricular) lymph node assay (LLNA). Both assays are evaluated with regard to their potency to recognize drug-induced sensitization. We modified the LLNA to enable s.c. exposure, i.e. similar to the PLNA, and injected the compounds of interest between the layers of the ear. Compounds were injected together with the T cell independent antigen TNP-Ficoll, which only elicits switched isotypes when antibody producing B cells receive additional neo-antigen specific help. Using this approach, we positively identified D-penicillamine, streptozotocin (STZ), ofloxacin, and diphenylhydantoin as drugs with immunosensitizing capacity. Sulphamethoxazole and procainamide (known to require metabolism) and phenobarbital and metformin were tested negative. Thus, the number of TNP-specific IgG antibody secreting cells is a very useful and sensitive parameter to identify drug-induced hypersensitivity in both PLNA and modified LLNA. However, the type-1 associated parameters (CD8 cells, macrophages, IFN- $\gamma$ , TNF- $\alpha$  and IL-1 $\beta$ ) that are induced in the PLN by STZ were less pronounced in the auricular lymph node. Together, the PLNA and modified LLNA can both be used to distinguish sensitizing compounds from non-sensitizers with the use of reporter antigens. However, the modified LLNA is practically less convenient than the PLNA and the PLNA seems to provide more relevant immune information on the mechanisms of chemical-induced hypersensitivity reactions.

224 CYTOKINE RELEASE AS AN ENDPOINT TO IMPROVE THE SENSITIVITY AND SPECIFICITY OF THE POPLITEAL LYMPH NODE ASSAY (PLNA).

J. Descotes<sup>2</sup>, G. Ravel<sup>1, 2</sup>, M. Christ<sup>1</sup>, N. Eltschinger<sup>1</sup> and J. Guichard<sup>1</sup>. <sup>1</sup>MDS Pharmacology Services, L'Arbresle, France and <sup>2</sup>Poison Center & INSERM U503, Ivon. France.

The PLNA has been proposed for the preclinical prediction of the autoimmunogenic and sensitizing potential of drugs. The evaluation of over 130 compounds in this assay has resulted in several false positive (e.g. ethanol, imipramine) or false negative (e.g. ofloxacin, sulfamethoxazole) responses placing in question the sensitivity and specificity of the test. In this study, cytokine production in the popliteal lymph nodes of female Balb/c mice was evaluated as a possible endpoint to improve the sensitivity and specificity of the assay. Diclofenac, imipramine, hydralazine, glafenin and minocycline were tested in groups of 6 Balb/c mice using the classical primary PLNA procedure. Cellularity measurements were made 7 days after injection of the drug. In addition, Th1 (IL-4 and IL-5), Th2 (IL-2, IL-12 and IFN-7 and pro-inflammatory (IL-6, TNF-α and Monocyte Chemoattractant Protein-1) cytokines were measured in suspensions of popliteal lymph node cells by flow cytometry. Cellularity indexes above 5 (defined as positive responses) were obtained only in mice treated with diclofenac and imipramine. Diclofenac induced a significant increase in the Th1 and pro-inflammatory cytokines. All other drugs had no effects on the production of any cytokine. The measured cytokine levels did not help rule out the false positive and false negative responses obtained with imipramine and glafenin, respectively. These findings suggest that measuring cytokine release is unlikely to improve the sensitivity and specificity of the PLNA. In addition, minocycline, a tetracycline antibiotic not previously tested in the PLNA, but recognized as a cause of many autoimmune and hypersensitivity reactions in human patients, produced a negative PLNA response.

225 INTER-ANIMAL VARIATION IN CYTOKINE FINGERPRINTING OF CHEMICAL ALLERGENS.

H. Caddick, R. J. Dearman and I. Kimber. Syngenta CTL, Macclesfield, United Kingdom.

Repeated topical exposure of BALB/c strain mice to chemical contact and respiratory allergens stimulates cytokine secretion phenotypes consistent with the selective activation of type 1 and type 2 T cell subpopulations, respectively. Lymph node cells (LNC) isolated after treatment with the contact allergen 2, 4-dinitrochlorobenzene (DNCB) display a type 1 cytokine secretion pattern with relatively high levels of interferon  $\gamma$  (IFN- $\gamma$ ) and interleukin (IL) 12, but little of the type 2 cell products IL-4, IL-5, IL-10 and IL-13. Exposure to the respiratory allergen trimellitic anhydride (TMA) results in the converse type 2 cytokine expression profile. In previous experiments, in order to provide for sufficient supernatant to analyze the complete panel of cytokines by enzyme-linked immunosorbant assay, lymph nodes have been pooled on an experimental group basis. In these studies, DNCB-stimulated LNC invariably expressed higher levels of type 1 cytokines whereas TMA-activated LNC produced higher levels of type 2 cytokines. It is now possible to measure multiple cytokines in small volumes, using cytokine arrays with a fluorescent end point, allowing cytokine secretion patterns to be measured for individual animals. Very marked type 1 and type 2 cytokine secretion profiles, respectively, were observed for LNC isolated from DNCB- and TMA-exposed mice (n=5). LNC derived from DNCB-treated animals produced significantly more IFN- $\gamma$  (p<0.05) and IL-12 (p<0.01) than did those isolated from TMA-treated mice, whereas exposure to TMA stimulated significantly higher levels of IL-4, IL-5 and IL-10 (p<0.01). These data suggest that there is little inter-animal variation in the ability of DNCB and TMA to elicit distinct type 1 and type 2 cytokine secretion profiles and demonstrate that similar cytokine phenotypes are detected whether lymph nodes are pooled on a group basis or individual animals are as-

226 SENSITIZATION WITH
DINITROTHIOCYANOBENZENE (DNTB):
COMPARISONS WITH DINITROCHLOROBENZENE
(DNCB)

P. S. Friedmann<sup>1</sup>, <u>C. Pickard</u><sup>1</sup>, M. Cumberbatch<sup>2</sup>, <u>R. J. Dearman</u><sup>2</sup> and <u>I. Kimber</u><sup>2</sup>. <sup>1</sup>Southampton University, Southampton, United Kingdom and <sup>2</sup>Syngenta CTL, Macclesfield, United Kingdom.

DNCB is a potent contact sensitizer in man and rodents whereas it has been reported that prior exposure to the chemically related hapten DNTB can tolerize mice to subsequent sensitization with DNCB. We have therefore examined the

ability of DNTB to modify responses to DNCB and to induce de novo contact sensitization in humans. Ten volunteers were sensitized by application of 4 doses of DNCB (6.25, 8.8, 12.5, 18.8µg) to the forearm. Four weeks later, the other arm was challenged with the same doses of DNCB and elicitation reactions quantified at 48h as skinfold thickness using calipers. Marked responses were induced in all subjects (AUC sum of responses at each challenge dose, mean+/-SE; 5.9+/-1.02). Using the same treatment and challenge regimen, responses to DNTB were uniformly negative (n=7). Prior exposure (4 weeks earlier) to the same concentrations of DNTB was without significant effect on the subsequent response to sensitization and elicitation with DNCB (AUC mean+/-SE; 4.3+/-1.6). However, using the same exposure schedule, initial priming with high dose (35µg) DNTB did augment the elicitation reactions to DNCB (AUC mean+/-SE; 13.4+/-6.02, n=7). The differential activity of DNTB was not a result of poor penetration as volunteers that had been sensitized and challenged with DNCB exhibited equivalent skin reactions when challenged with the same doses of DNTB. Furthermore, priming with a very high dose DNTB (75µg) followed by challenges with DNTB 4 and 8 weeks later resulted in sensitization of 2 out of 10 volunteers. These data demonstrate that DNTB is not a tolerogen in man, but is a relatively weak sensitizer compared with DNCB. DNTB is equally effective as DNCB at eliciting challenge reactions, suggesting that it is less efficient at stimulating dendritic cells (DC) to activate naive T cells, but can drive DC to activate memory T cells.

# 227 MOLECULAR SCREENING FOR SKIN SENSITISATION HAZARD *IN VITRO* USING PROTEOMICS TECHNIQUES.

M. Divkovic<sup>2</sup>, <u>D. A. Basketter<sup>1</sup></u>, C. K. Pease<sup>1</sup>, A. Dell<sup>2</sup> and H. R. Morris<sup>2</sup>. <sup>1</sup>SEAC, Unilever, Sharnbrook, United Kingdom and <sup>2</sup>Biological Sciences, Imperial College, London, United Kingdom.

Covalent binding of hapten to a skin protein is a key process required for sensitisation. It has long been postulated that only sensitising chemicals will modify skin protein(s), whereas non-sensitising compounds and irritants do not. To pinpoint the amino acid residues involved in such modifications, we have employed mass spectrometry (MS) based proteomics techniques. Known sensitisers, non-sensitisers and irritants were incubated with human serum albumin (HSA). Modified HSA samples were digested by trypsin and matrix assisted laser desorption/ionisation (MALDI-MS) analyses were conducted on tryptic digests. Nano-electrospray tandem mass spectrometry (ES-MS/MS) analyses were conducted on modified peptides purified by high performance liquid chromatography (HPLC). The HSA sequence was mapped and modified peptides were identified. In HSA samples incubated with non-sensitisers and irritants there was no change compared to HSA incubated without chemical. Modified peptides were purified by HPLC and sequenced using ES-MS/MS. Lysine, histidine and cysteine were found to be involved in covalent modifications by the sensitising chemicals used. A complex adduct of one sensitiser (methylchloroisothiazolinone, courtesy of Prof. J.P.Lepoittevin, University Louis Pasteur, Strasbourg, France) on His 338 of the HSA molecule was also identified. Many more sensitisers need to be investigated in this way to establish similarities between covalent protein modifications of chemically related compounds. These results can be further employed to develop a simple, medium- throughput assay for covalent protein binding ability of chemicals. This could form part of a battery of tests needed to completely replace animal testing of new chemical entities for skin sensitisation potential.

# 228 AN INTER-LABORATORY STUDY FOR THE DEVELOPMENT OF AN *IN VITRO* SKIN SENSITIZATION TEST USING HUMAN CELL LINES.

Y. Yoshida<sup>1</sup>, T. Ashikaga<sup>2</sup>, H. Sakaguchi<sup>1</sup>, M. Miyazawa<sup>1</sup>, M. Hirota<sup>2</sup>, M. Ogo<sup>2</sup>, H. Itagaki<sup>2</sup> and H. Suzuki<sup>1</sup>. <sup>1</sup>Kao Corporation, Haga, Tochigi, Japan and <sup>2</sup>Shiseido Corporation, Yokohama, Kanagawa, Japan. Sponsor: J. Avalos.

In regard to *in vitro* skin sensitization tests, dendritic cells (DCs) derived from human peripheral blood have been considered in the development of new tests. Meanwhile, some methods using human cell lines have been reported recently. In our previous study, we suggested that measuring CD86 and/or CD54 expression on THP-1 cells (monocytic leukemia cell line) could be used as an *in vitro* skin sensitization method. An inter-laboratory study among Kao and Shiseido was undertaken in Japan in order to further develop our *in vitro* skin sensitization model. In the present study, we used two human cell lines: THP-1 and University-937 (histiocytic lymphoma cell line). We measured the expression of CD86 and CD54 on the above cells using flow cytometry after a 24-hour and 48-hour exposure to known allergens (e.g., DNCB, PPD, NiSO<sub>4</sub>) and non-allergens (e.g., SLS, Triton X-100). Both facilities used same test protocol, treatment concentration and clone of anti-CD86 and CD54 mAb for the study. For the sample test concentration, 4 doses (2x, 1x, 0.5x and 0.1x of the 50% inhibitory concentration (IC50)) were evaluated. IC50 was calculated using MTT assay. We found that allergens/non-al-

lergens were better predicted using THP-1 cells compared to University-937 cells following a 24-hour exposure, but for a 48-hour exposure, there was no significant difference. We also found that the 48-hour treatment time had a better accuracy than the 24-hour treatment time for both cell lines. Expression of CD86 and CD54 were good predictive markers for THP-1 cells, but for University-937 cells, expression of CD86 was a better predictor than CD54, especially at the 48-hour treatment time. The accuracy also improved when both markers (CD86 and CD54) were used as compared with a single marker, especially with THP-1 cells. These results suggest that our method, using human cell lines THP-1 and University-937, but especially THP-1 cells, may be a useful *in vitro* skin sensitization model to predict various contact sensitizers.

## 229 DEVELOPMENT OF AN *IN VITRO* SKIN SENSITIZATION TEST USING HUMAN CELL LINES.

T. Ashikaga<sup>1</sup>, Y. Yoshida<sup>2</sup>, M. Hirota<sup>1</sup>, M. Ogo<sup>1</sup>, H. Sakaguchi<sup>2</sup>, M. Miyazawa<sup>2</sup>, H. Suzuki<sup>2</sup> and H. Itagaki<sup>1</sup>. <sup>1</sup>Shiseido Corporation, Yokohama, Kanagawa, Japan and <sup>2</sup>Kao Corporation, Haga, Tochigi, Japan. Sponsor: J. Avalos.

Several studies have shown that allergens enhance CD86 expression on surface of dendritic cells (DCs) and it has been thought that this phenotypic change could be applied to the development of an in vitro skin sensitization test. In our previous study, we found that CD86 and/or CD54 expression on THP-1 cells (monocytic leukemia cell line) was enhanced after a 24-h exposure to allergens but not non-allergens. We suggest that THP-1 cells could be used for an in vitro skin sensitization test as a replacement of DCs. However, much work remains to be done in order to make the cell substitution suitable for practical use. In this report, we examined various test conditions to optimize a protocol to be used in an inter-laboratory study between Kao and Shiseido. At first, effect of subculturing time on the CD86 expression was studied. THP-1 cells were incubated for 24, 48 and 72 hours, respectively. After the incubation, the cells were transferred to fresh medium, and then the cells were exposed to DNCB for 24 hours. The expression of CD86 on DNCBtreated THP-1 cells tended to be high in the 48-hour and 72-hour subculturing time. The augmentation of CD86 expression has been often observed when cells were treated with a subtoxic dose of allergen. To determine dose setting, the cytotoxicity of the test sample was performed (MTT assay) using THP-1 cells and University-937 cells (histiocytic lymphoma cell line) and 50% inhibitory concentration (IC50) of each test samples was calculated. Furthermore, antibodies were diluted to several concentrations and cells treated with allergens/non-allergens (e.g., DNCB, NiSO4 / SLS) were stained in order to identify the appropriate level of antibody to use. The staining studies confirmed that the working dilutions of both CD86 and CD54 antibodies were appropriate for use in our method. Based on our findings, the experimental conditions to be used in a Kao-Shiseido inter-laboratory study were identified and the protocol for that study was optimized.

### 230 MECHANISMS OF CCR7 UP-REGULATION BY NISO4 ON HUMAN DENDRITIC CELLS.

F. Boisleve and M. Pallardy. Faculty of Pharmacy, INSERM U461, Chatenay-Malabry, France.

Despite progress in elucidating mechanisms of contact hypersensitivity induced by chemical haptens, the first stages including activation of the dendritic cells (DC) are still unknown. Haptens, like Nickel, penetrate into the organism and are taken up by immature DC and then presented to naive T-lymphocytes (LT) thus eliciting hypersensitivity reactions. Activation of DC by haptens induces the maturation of DC. During this process, DC migrates to lymph nodes to activate LT. Migration of DC involves many factors including the expression of the chemokine receptor CCR7. In this study, we tested the effects of nickel sulfate (NiSO4) on CCR7 expression on immature DC and investigated the signalling pathways involved in its expression. Immature DC were differentiated from cord blood CD34+ cells. Treatment of DC by NiSO4 (500 µM) during 24 hrs induced the maturation of these cells as assessed by the expression of CD83 and CD86. NiSO4 also elicited the migration of these cells in response to CCL19 through induction of CCR7 on their surface. To establish the mechanisms involved in the expression of CCR7, we examined the activation of the Mitogen-activated protein kinases (MAPKs), p38MAPK and c-jun N-terminal Kinase (JNK), and the activation of the Nuclear Factor (NF)-κB in NiSO4 stimulated-DC. In our model, stimulation of immature DC with NiSO4 induced phosphorylation of p38MAPK and JNK and also the activation of NF-kB. To evaluate the role of these transduction pathways in the expression of CCR7, we used specific inhibitors for each pathways. Cells pretreated with SB203580, a specific inhibitor of p38MAPK or parthenolide, an inhibitor of NF-KB activation, showed a down-regulation of CD83 and CCR7 expression induced by NiSO4. For the first time, the role of JNK in the maturation of DC was also demonstrated since CD83 and CCR7 expression were inhibited by SP600125, a specific inhibitor of JNK. These results suggested the predominant roles of p38MAPK, JNK and NF-κB pathways in the expression of CCR7 induced by the contact sensitizers.

STUDIES ON THE RESPIRATORY IMMUNE RESPONSE TO A PROTEASE AND IMPLICATIONS FOR THE SAFETY ASSESSMENT OF ENZYME-CONTAINING PERSONAL CARE PRODUCTS.

E. S. Finn<sup>1</sup>, S. P. Chapoval<sup>3</sup>, A. Xue<sup>2</sup>, V. Chowdhary<sup>2</sup>, L. C. Limardi<sup>1</sup>, A. C. Pursifull<sup>1</sup>, E. V. Marietta<sup>2</sup>, T. A. Gaffey<sup>2</sup>, B. Kirchner<sup>1</sup>, <u>K. Sarlo<sup>1</sup></u>, C. S. David<sup>2</sup> and D. N. Rubingh<sup>1</sup>. <sup>1</sup>Procter & Gamble Co., Cincinnati, OH, <sup>2</sup>Mayo Clinic, Rochester, MN and <sup>3</sup>Yale University, New Haven, CT.

Microbial enzymes have been safely used in detergents for over 30 years. Their use is expanding in new applications such as personal care products resulting in the potential for development of IgE-mediated allergy. Understanding the immune response to enzymes is a key step in the safety assessment of new enzyme-containing applications. Changing the enzyme so that it is less likely to induce an allergic response is one approach to address safety of these new applications. Humans and HLA Class II transgenic (tg) mice were evaluated for Ab and T cell responses and genetic susceptibility to the protease Y217L BPN. MHC Class II alleles were evaluated in occupationally exposed workers using SSP-PCR. A number of alleles were found among workers with Ag-specific IgE: DQ8 was statistically associated with development of IgE (susceptible) and DQ6/DR15 was associated with absence of IgE (protection). T cell epitope mapping studies in humans identified several epitopes with patterns of epitopes varying among individuals. Immunization of HLA-DQ6, DQ8, DR3 and DR4 tg mice showed that DQ8 mice were susceptible to development of Y217L BPN hypersensitivity based on development of Ag-specific IgG1/IgE and lung eosinophilia. DQ6 and DR3 mice developed an Ab response but required additional immunizations over a longer period of time. T cell epitope mapping studies in DQ8 and DQ6 mice identified several T cell epitopes many of which were similar between the two strains. Some of these epitopes were similar to epitopes recognized by humans. In summary, studies in humans and tg mice show the allergic response to the protease Y217L BPN is complex and diverse. This increases the complexity of safety programs needed to assure that native and modified enzymes are safe for use in personal care products. These safety programs must include exposure assessment and robust clinical testing.

### 232 ASSESSMENT OF IMMUNE RESPONSES TO PENICILLIUM CHRYSOGENUM AND CHARACTERIZATION OF ITS ALLERGENS.

Y. Chung<sup>1</sup>, M. E. Viana<sup>2</sup>, L. B. Copeland<sup>3</sup>, <u>M. K. Selgrade<sup>3</sup> and M. D. Ward<sup>3</sup></u>. <sup>1</sup>ESE, UNC/USEPA, Chapel Hill, NC, <sup>2</sup>CVM, NCSU, Raleigh, NC and <sup>3</sup>USEPA, Research Triangle Park, NC.

Molds have been associated with allergic disease but have not been studied extensively despite their widespread presence in the indoor environment. P. chrysogenum has been associated with both water damaged buildings and sick building syndrome. Our objectives in this study were to assess immune responses to P. chrysogenum and to identify allergenic (IgE inducing) proteins of the fungus. BALB/c mice were exposed four times over a four-week period by involuntary aspiration (IA) to 1, 10 or 100 μg of *P. chrysogenum* extract (PCE) or Hank's balanced salt solution as vehicle control. Positive control mice were exposed to 10 µg of Metarhizium anisopliae extract (MACA). Serum and bronchoalveolar lavage fluid (BALF) were collected before (D0), at 1 (D1) and 3 (D3) days following the final IA exposure. Only mice exposed to 100 µg of PCE showed responses different from vehicle control, but some of these mice were moribund. The mice exposed to PCE (100 µg) demonstrated significant increases in BALF levels of total protein, lactate dehydrogenase (LDH), total cell, macrophages, neutrophils, lymphocytes, and eosinophils at D0, D1 and D3, compared to vehicle control. Mice exposed once to  $100\,\mu g$  of PCE (inflammatory control) showed significantly increased levels of total protein, LDH and neutrophils in BALF at D1 and D3. Four exposures to PCE (100 µg) also resulted in significantly increased IgE in both serum and BALF compared to vehicle and inflammatory control. Eosinophils in BALF of mice exposed to 100  $\mu g$  of PCE was lower than that of mice exposed to 10  $\mu g$  of MACA but higher than the vehicle or inflammatory control. Western blot analysis showed 8 IgE inducing proteins in PCE, ranging from approximately 28 to 65.5 kD. Current data indicate that although PCE may induce allergic responses with less potency than MACA, it does contain IgE-inducing proteins. (Supported by UNC/EPA Cooperative Training Agreement CT826513 and this abstract does not reflect EPA policy.)

# 233 THE IDENTIFICATION AND CHARACTERIZATION OF AN IGE-INDUCING PROTEIN IN METARHIZIUM ANISOPLIAE EXTRACT.

M. Ward<sup>1</sup>, L. B. Copeland<sup>1</sup>, M. J. Donohue<sup>3</sup> and J. A. Shoemaker<sup>2</sup>. <sup>1</sup>NHEERL, USEPA, Research Triangle Park, NC, <sup>2</sup>NERL, USEPA, Cincinnati, OH and <sup>3</sup>Oakridge Institute for Science and Education, Cincinnati, OH.

BALB/c mice exposed by involuntary aspiration to Metarhizium anisopliae extract (MACA), a microbial pesticide, have shown responses characteristic of human allergic lung disease. The current study was undertaken to identify and characterize

fungal allergens from MACA. We have identified 4 protein bands on SDS-PAGE Western blots that bind IgE in hyperimmune serum. These proteins have an apparent molecular weight of 127.6 kDa, 114.7 kDa, 89.7 kDa, and 52.6 kDa, respectively. Immunoblots of 2-dimensional (2-D) gels shows 8 protein spots with acidic pIs ranging between pH 4.8 and pH 5.5. These protein spots were collected following alignment of 2-D gel Western blot autoradiographs with Coomassie blue stained 2-D gels. Subsequently, matrix assisted laser desorption ionization time-offlight mass spectrometry (MALDI-TOF-MS) and electrospray ionization mass spectrometry (ESI-MS/MS) were used to analyze these isolated fungal peptides and proteins. The MS data on molecular weight, peptide profiles, and amino acid sequence is currently being used to mine databases for potential sequence or domain homology to known allergens using the MASCOT database-mining algorithm. Identification, characterization, and purification of the IgE-inducing proteins in this fungal extract will provide a tool for assessing relative potency by comparison to better characterized allergens such as house dust mite. These newly characterized fungal proteins will be added to the database of allergens, which collectively can be used to identify other structures as potential allergens. (This abstract does not reflect EPA policy.)

# 234 TOPICAL SENSITIZATION AND INTRANASAL CHALLENGE TO TRIMELLITIC ANHYDRIDE INDUCES AN ALLERGIC RHINITIS SIMILAR TO THAT INDUCED BY INTRANASAL SENSITIZATION AND CHALLENGE

A. K. Farraj<sup>1, 2</sup>, J. R. Harkema<sup>2</sup> and N. E. Kaminski<sup>1</sup>. <sup>1</sup>Pharmacology and Toxicology, Michigan State University, East Lansing, MI and <sup>2</sup>Pathology and Diagnostic Investigation, Michigan State University, East Lansing, MI.

IN A/J MICE.

Allergic airway diseases induced by low molecular weight (LMW) chemicals, including trimellitic anhydride (TMA), are mediated principally by Th2 cytokines and characterized by airway mucus hypersecretion and an influx of eosinophils and lymphocytes. The most common route of human exposure to LMW chemical respiratory allergens is inhalation. In a previous study, we demonstrated that intranasal sensitization and challenge of A/J mice with TMA induced the characteristic immunologic and pathologic responses of LMW chemical-induced allergic rhinitis. However, in many murine models of human LMW chemical-induced airway allergy, the mouse is sensitized to the chemical by topical exposure. In the present study, we hypothesized that mice topically or intranasally sensitized to TMA would develop similar immunologic and pathologic responses in their nasal airways after intranasal challenge to this LMW chemical. A/J mice were topically or intranasally sensitized and then intranasally challenged with TMA in an ethyl acetate/olive oil vehicle. Nasal and pulmonary airways were processed for light microscopic examination. Total serum IgE was measured using an ELISA. Intranasal challenge with TMA in mice that were either topically or intranasally sensitized with TMA caused a marked allergic rhinitis characterized by an influx of eosinophils, lymphocytes and plasma cells. Both topical and intranasal sensitization also induced increases in total serum IgE compared to their corresponding vehicle controls after intranasal challenge. The data suggest that topical application is effective in sensitizing mice to TMA and induces a nasal airway lesion after intranasal challenge that is qualitatively similar to intranasal sensitization and challenge. Skin exposure may be a potential route of sensitization of the respiratory tract to LMW chemicals (funded in part by American Chemistry Council #0051).

# 235 PERSISTENT SPECIFIC AIRWAY RESPONSIVENESS IN RATS SENSITIZED TO AND CHALLENGED WITH TRIMELLITIC ANHYDRIDE (TMA).

P. D. Siegel, X. Zhang and D. M. Lewis. HELD/ASB, NIOSH/CDC, Morgantown, WV.

TMA is an organic acid anhydride that is widely used in industry. It can induce specific IgE and cause occupational asthma in sensitized individuals. Persistent occupational asthma, even with antigen/hapten avoidance can be seen is approximately 20% of the cases. Duration of both circulating TMA-specific IgE and specific airway responsiveness was studied in a TMA sensitized Brown Norway rat asthma model as possible contributory factors to persistent asthma. TMA powder (4 mg) was applied to 4 anesthetized rats' backs (clipped with scissors) on days 0, 7, 14 and 21 and washed off after 4 hrs. Specific IgE analyses and airway challenge with TMA (40 mg/m³ for 10 min) were performed on day 35 and day 386. The ELISA OD values for TMA-specific IgE were 0.46±0.07 and 0.12±0.02 on day 35 and day 386, respectively (non-specific binding from control sera OD=0.08±0.002). Dual, early- (EAR) and late-phase (LAR) airway responses (indicated by enhanced pause, an index of airway resistance) were observed on day 35. A dual response was noted upon rechallenge on day 386 in 3 rats and LAR-only in the 4th rat. These results demonstrate the persistence of specific airway responsiveness to TMA, even though circulating specific-IgE had drastically declined.

CROSS-REACTIVITY OF ACID ANHYDRIDES ASSESSED BY AIRWAY CHALLENGE IN RATS SENSITIZED WITH TRIMELLITIC ANHYDRIDE (TMA).

X. Zhang, J. S. Fedan, D. M. Lewis and P. D. Siegel. HELD, NIOSH/CDC, Morgantown, WV.

Previous studies using inhaled organic acid anhydride (OAA)-protein conjugates in studies of airway hyperreactivity have revealed immunologic cross-reactivity among OAAs. The present investigation evaluated cross reactivity between phthalic anhydride, (PA), tetrachlorophthalic anhydride (TCPA) and TMA with respect to their ability to induce asthma-like airway responses in TMA-hapten-sensitized Brown Norway rats. Four to 40 mg of dry TMA powder was applied to anesthetized rats' backs (hair removed with scissors) on days 0, 7, 14 and 21 and washed off with water 4 hours after each application. Inhalation challenge with TMA aerosol (40 mg/m<sup>3</sup>;10 min) was performed on day 35 and Penh, an index of airway resistance, was measured. The sensitized rats developed early(EAR)- and late(LAR)-phase obstructive responses. One week after TMA inhalation exposure, rats were challenged with TMA, PA or TCPA aerosol (40mg/m<sup>3</sup>, 10 min; n = 8 in each group). EAR developed in all rats challenged with TMA, 3 rats challenged with PA, and 7 rats challenged with TCPA. The LAR developed in all TMA-challenged, sensitized rats, but none of the TMA sensitized rats challenged with PA or TCPA developed the LAR. We have previously reported that low dose TMA airway challenge results in EARonly similar to the airway responses observed in the present cross-reactivity studies. It is concluded that cross-reactivity exists between TMA and both PA and TCPA. These airway responses are most likely immune mediated and the reason why this cross-reactivity was manifested only by EAR may be related to lower relative antigenic potency of PA and TCPA to that of TMA in TMA-sensitized rats.

237 INHALATION EXPOSURE OF TRIMELLITIC
ANHYDRIDE (TMA) AEROSOL IN A BROWN NORWAY
RAT MODEL.

D. M. Lewis, X. Zhang and P. D. Siegel. HELD, NIOSH/CDC, Morgantown, WV.

Inhalation is one of the TMA exposure routes for sensitization and subsequent asthma. The present work reported some characteristics after inhalation exposure of TMA aerosol. Brown Norway rats (n=8/group) were exposed, once a week from day 0 to day 63 with 40 mg/m<sup>3</sup> TMA or to day 70 with 4 mg/m<sup>3</sup> TMA in a noseonly system for 10 min. Enhanced pause (Penh, an index of airway resistance) was recorded in Buxco chambers overnight (>12 hours). Sera were collected weekly for antibody analyses. For the group with 40mg/m<sup>3</sup> of TMA, specific IgE level was significantly increased after day 7 and reached the peak by day 49. By day 14 these rats developed early- (EAR) and late-phase airway responses (LAR) following exposure. For the group exposed to 4mg/m<sup>3</sup> of TMA, specific IgE level was significantly increased by day 21 and reached the peak by day 56; however, no obviously airway responses were noted. Two weeks after the final exposure the 4 mg/m<sup>3</sup> TMA exposed rats were challenged with 40 mg/m<sup>3</sup> TMA resulting in both an EAR and LAR response. The specific IgE levels for rats with high dose of TMA were greater than that with low dose of TMA. We conclude that high dose and short term inhalation exposure may induce specific IgE and airway responses; low dose and short term exposure can induce specific IgE production to establish sensitization, while the development of airway responses needs high dose of TMA for challenge.

238 INTERSPECIES VARIATION AND LINEAGE SPECIFICITY IN HEMATOPOIETIC TOXICITY TESTING.

C. Pereira, J. Damen and E. Clarke. Contract Assay, StemCell Technologies Inc., Vancouver, BC, Canada. Sponsor: M. Ehrich.

In the search for efficient and cost effective ways to screen lead compounds for hematotoxicity, the use of Colony Forming Cell (CFC) assays has received a great deal of attention. These standardized assays allow the detection of toxicity on hematopoietic progenitor subsets (erythroid, myeloid, megakaryocytic) to evaluate potential cytopenic conditions, as well as mesenchymal progenitors to evaluate potential damage to the bone and connective tissue. As these assays require the growth of primary cells in culture for up to 14 days, they offer a high level of sensitivity and allow the quantitative and qualitative evaluation of colony growth and morphology, providing high functional content. Using CFC assays, the toxic effects of three antineoplastic compounds were tested on erythroid (CFU-E, BFU-E), myeloid (CFU-GM) and mesenchymal (CFU-F) progenitor growth. 5-Fluorouracil (5-FU), Hydroxyurea (HU) and Paclitaxel were incubated in culture with both human and

murine bone marrow progenitor cells for 10-14 days, after which colonies were scored and assessed. Results indicate that each compound displays a unique spectrum of toxicity on each progenitor lineage; erythroid, myeloid and mesenchymal lineages showing different relative susceptibility to toxicity depending on the compound tested. In addition, up to 10-fold differences were seen between human and murine progenitor sensitivity to each compound. Our data highlights the multifaceted nature of bone marrow and unique specificity of action of individual compounds. The results also illustrate the importance of using the most appropriate species model in preclinical studies to improve predictivity and clinical success.

239 A HIGH THROUGHPUT CELL-BASED ASSAY FOR ASSESSMENT OF HEPATOTOXICITY USING CRYOPRESERVED HUMAN HEPATOCYTES.

M. Chen, M. Hann and K. Zhang. *Pharmacology, Novartis Institute for Functional Genomics, San Diego, CA*.

Screening for hepatotoxicity during early stage of drug discovery may add another important tool, among others, to improve the quality of drug candidates advancing into lead optimization. We report here a high throughput cell-based assay (384-well plate) capable of detecting acute hepatotoxicity. Test compounds were exposed to cryopresevered primary human hepatocytes for 18 hours and cytotoxicity was measured using a luciferin/luciferase assay that quantifies cellular ATP levels. In a proof of concept study, we evaluated 30 reference compounds with known hepatotoxicity along with 8 non-hepatotoxicants using human hepatocytes obtained from three donors. Dose-dependent cytotoxicity was observed for 23 of the potential hepatotoxicants, such as aflatoxin B, tamoxifen, troglitazone, ketoconazole and flutamide, with measurable TC50 values (<115 uM) within the test concentration range. No apparent cytotoxicity was observed for the other 6 compounds (TC50 >500 uM) including phenytoin, Carbamazapine and crotaline. However, all of these six except carbon tetrachloride were reported hepatotoxic as a result of combination therapy with other drugs. For the 8 non-hepatotoxicants tested (Buspirone, Theophyline and Ibuprofen etc), none of them showed cytotoxicity (TC50 >500 uM). This data indicates that our assay is reasonably predictive in detecting acute hepatotoxicity of drug candidates and can be employed in the high throughput mode during lead optimization process. It should also be of interest for retrospective mechanistic studies of heptotoxicity observed in vivo.

PHASE I AND II RESULTS OF A VALIDATION STUDY TO EVALUATE *IN VITRO* CYTOTOXICITY ASSAYS FOR ESTIMATING RODENT AND HUMAN ACUTE SYSTEMIC TOXICITY.

M. Paris<sup>1, 2</sup>, J. Strickland<sup>1, 2</sup>, <u>W. Stokes</u><sup>1</sup>, S. Casati<sup>3</sup>, <u>R. Tice</u><sup>1, 2</sup>, H. Raabe<sup>4</sup>, C. Cao<sup>5</sup>, R. Clothier<sup>6</sup>, J. Harbell<sup>4</sup>, G. Mun<sup>4</sup>, A. Sizemore<sup>4</sup>, G. Moyer<sup>4</sup>, J. Madren-Whalley<sup>5</sup>, C. Krishna<sup>5</sup>, M. Owen<sup>6</sup>, N. Bourne<sup>6</sup>, J. Haseman<sup>7</sup>, P. Crockett<sup>8</sup>, M. Wenk<sup>9</sup>, M. Vallant<sup>7</sup> and A. Worthj<sup>3</sup>. <sup>1</sup>NICEATM, NIEHS, Research Triangle Park, NC, <sup>2</sup>ILS, Inc., Research Triangle Park, NC, <sup>3</sup>ECVAM, Ispra, Italy, <sup>4</sup>IIVS, Gaithersburg, MD, <sup>5</sup>US Army, Aberdeen Proving Ground, MD, <sup>6</sup>University of Nottingham, Nottingham, United Kingdom, <sup>7</sup>NIEHS, Research Triangle Park, NC, <sup>8</sup>ASI, Research Triangle Park, NC and <sup>9</sup>BioReliance, Rockville, MD.

Studies have identified a correlation between in vitro cytotoxicity and acute oral toxicity. NICEATM and ECVAM initiated a three-phase multi-laboratory validation study to evaluate the usefulness of two standardized in vitro basal cytotoxicity assays for estimating rodent and human acute toxicity and the extent that they may reduce animal use. Seventy-two coded chemicals (12 from each of five acute oral hazard categories; 12 unclassified/nontoxic chemicals) will be tested in mouse 3T3 fibroblasts and in normal human epidermal keratinocytes (NHK) using neutral red (NR) uptake assays. Protocols were optimized after each of the first two phases to minimize intra- and inter-laboratory variation prior to testing 60 chemicals in Phase III. Phase Ia established the historical databases for the positive control chemical, sodium laurel sulfate (SLS), for each of three laboratories. Three chemicals were tested in Phase Ib and nine in Phase II. Technical challenges arose in Phases Ia/Ib (i.e., formation of NR dye crystals; uneven growth of NHKs; slow growth of 3T3 cells) that were resolved with Phase II protocols. Significant variation in NHK growth occurred in Phase II with various lots of media and supplements. The optimized final protocols are being tested in Phase III. Rodent oral LD50 values were estimated using prediction models based on the Registry of Cytotoxicity data and Phase I/II results. Human toxicity will be estimated using a prediction model based on data from human poisoning reports and the Multicentre Evaluation of *In Vitro* Cytotoxicity (MEIC). Supported by: N01-ES-35504, N01-ES-75408; EPA IAG DW-75-93893601-0; European Commission 19416-2002-04 F2ED ISP GB.

J. Strickland<sup>1, 2</sup>, M. Paris<sup>1, 2</sup>, H. Raabe<sup>3</sup>, J. Haseman<sup>4</sup>, S. Casati<sup>5</sup>, R. Clothier<sup>6</sup>, C. Cao<sup>7</sup>, P. Crockett<sup>8</sup>, <u>R. Tice<sup>1, 2</sup></u> and <u>R. Stokes<sup>2</sup></u>. <sup>1</sup>ILS, Inc., Research Triangle Park, NC, <sup>2</sup>NICEATM, NIEHS, Research Triangle Park, NC, <sup>3</sup>IIVS, Gaithersburg, MD, <sup>4</sup>NIEHS, Research Triangle Park, NC, <sup>5</sup>ECVAM, Ispra, Italy, <sup>6</sup>University of Nottingham, Nottingham, United Kingdom, <sup>7</sup>US Army, Aberdeen Proving Ground, MD and <sup>8</sup>ACI, Research Triangle Park, NC.

NICEATM and ECVAM designed a multi-laboratory validation study to evaluate two in vitro basal cytotoxicity test methods using 72 coded chemicals with a wide range of acute oral toxicity. The study was designed in three phases to allow adjustments in the cytotoxicity protocols and data collection and evaluation procedures before the majority of the chemicals are tested in Phase III. An Excel template was distributed to the participating labs for collection of raw data, analysis for outliers among dose replicates, documentation of materials and procedures, simple graphical analysis of dose-response, and transformation of data to the proper format for further analysis. Rather than applying a linear interpolation technique to the dose response to calculate the IC50, GraphPad Prism software was used to perform a Hill function analysis. IC20, IC50, and IC80 values and associated 95 percent confidence limits were calculated, and the data and fitted model were graphed. Initial criteria for an acceptable dose-response for individual tests included one data point between 10 & 50 percent viability, one data point between 50 & 90 percent viability, and r2>0.8. A Prism template was distributed to the laboratories to automate and provide uniformity of analysis. To increase the speed of data collection and evaluation of the analyses by the Study Management Team (SMT) and consulting biostatisticians, the laboratories submitted Excel and Prism data files by e-mail. Results compiled by the SMT were returned to the originating laboratories for audit to ensure accurate transmission of data. Implementation of these procedures shows that automated data collection in relatively common, easy-to-use electronic formats can facilitate uniformity of data collection and analysis. Supported by: N01-ES 35504; EPA IAG DW-75-93893601-0; European Commission 19416-2002-04 F2ED ISP GB.

### 242 MANAGING TOXIC SYNERGISM IN HYPOCHLORITE-CONTAINING CLEANERS USING THE BOVINE CORNEAL AND PERMEABILITY (BCOP) ASSAY, PART II.

J. E. Swanson<sup>1</sup>, W. M. Rees<sup>1</sup>, D. S. Hilgers<sup>1</sup>, <u>J. C. Merrill</u><sup>2</sup> and J. W. Harbell<sup>2</sup>. <sup>1</sup>SC Johnson & Son, Inc., Racine, WI and <sup>2</sup>Institute for In Vitro Sciences, Inc., Gaithersburg, MD.

Consumers continue to seek products that will both clean and combat mold and mildew stains on various surfaces in the home. Such products are commonly formulated as alkaline hypochlorite and surfactant-containing aqueous solutions and usually have significant ocular irritation potential. Previous studies have shown the applicability of the BCOP Assay to evaluate this class of cleaners (Rees et al., 2001). In this study, a standard cleaner containing 0.25% sodium hypochlorite, anionic surfactant and alkali (pH 13, 0.24% active chlorine content) was compared to a 2.5% stabilized hypochlorite cleaner containing the same surfactant (sodium Nchlorosulfamate salts, pH 5, 2.4% active chlorine content). A worst possible case human exposure time of 5 minutes was utilized in the assay. Treatment and scoring followed the standard BCOP protocol (Sina et al., 1995). However, longer post-exposure incubation times of 4 and 20 hours were found to be necessary for detecting the irritation potential of oxidizing/reactive chemistries in earlier work. Results show that the pH 5, 2.5% stabilized hypochlorite cleaner is much less irritating than the standard alkaline 0.25% sodium hypochlorite cleaner. The BCOP In Vitro Scores were 5.2 and 4.3 for the stabilized hypochlorite cleaner compared to 55.6 and 59.7 for the sodium hypochlorite cleaner with 4 and 20 hour exposure times, respectively. Histology confirmed these results. These data suggest that ocular irritation and tissue damage potential for active chlorine-containing cleaners may be markedly reduced when alternative chemical forms of hypochlorite are employed, relative to conventional sodium hypochlorite-based compositions.

### 243 IN VITRO CYTOTOXICITY TESTING WITH CULTURED IMMORTAL HUMAN COLON CELLS.

R. Konsoula and <u>F. A. Barile</u>. Department of Pharmaceutical Sciences, St. John's University College of Pharmacy, Jamaica, NY.

An *in vitro* study was conducted to test the toxicity of 20 representative chemicals on immortal human colon cells (Caco-2). The study aims to develop a cell culture model that compares gastrointestinal absorption (GIA) with cytotoxicity. The chemicals were selected from the guidance document prepared by the Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM). Cultured Caco-2 cells have been traditionally used as an *in vitro* model of intestinal epithelium. Caco-2 cells were seeded in 96-well plates and cytotoxicity was deter-

mined using cell viability assays (MTT and NRU). Confluent monolayers were exposed to increasing concentrations of chemicals for 24- and 72-hrs. In addition, cells were seeded on polycarbonate filter membranes (Millicell® culture plate inserts). After 12 to 14 days, the differentiated monolayers were exposed to increasing concentrations of the chemicals from the apical side for 24- and 72-hrs. Transepithelial electrical resistance (TEER) was used to monitor paracellular permeability in the inserts. Inhibitory concentrations 50% (IC50s) were extrapolated from concentration-effect curves after linear regression analysis. The data suggest that the viability assays were more sensitive indicators of chemical exposure than TEER measurements. Comparison of the IC50s for the cytotoxicity data indicates that there was no significant difference between 24- and 72-hr exposures. In addition, the results from the MTT and NRU assays were statistically similar (paired students' t-test, P=0.05). Comparison of the IC50s in this model allows for the differentiation between the concentrations necessary for cytotoxicity and those needed to interfere with paracellular permeability. Development of an in vitro test system for GIA, in combination with acute toxicity, improves the predictive ability of in vitro acute cytotoxicity assays for in vivo lethality. (Supported by NIH/NIEHS/AREA R15 ES012170-01).

## 244 INDUCTION OF FIBROSIS BY BLEOMYCIN AND CARMUSTINE IN RAT LUNG SLICES.

H. P. Behrsing, K. Amin, C. Ip and <u>C. A. Tyson</u>. *Toxicology Laboratory, SRI International, Menlo Park, CA*.

At present, there are no generally accepted in vitro models for identifying and studying chronic effects of lung toxicants. Due to recent advances in slice culture techniques, precision-cut slices were evaluated as a potentially feasible option for this purpose. The slices were prepared from Fischer 344 rat lungs and placed on HATF-covered titanium inserts in a dynamic roller system. The incubations were conducted in supplemented M-199 medium for up to 28 days under a 5% CO<sub>2</sub>/air atmosphere in the presence or absence of bleomycin and carmustine, agents known to produce pulmonary toxicity. Tissue *via*bility and functionality was assessed weekly by measuring LDH and alkaline phosphatase content and histological examination with H&E and Masson trichrome stains. Control slices showed intact, adequately preserved parenchymal architecture with high viability and minimal or no fibrosis over the 28-day period. Exposure to bleomycin resulted in damage to tissue and loss of viability reflected in decreased enzyme levels and histological changes. Fibrosis was evident at the highest concentration at Day 8 and additionally at lower concentrations at Days 16 and 28. The fibrosis was characterized by a predominantly focal pattern present at the slice margin and around the bronchioles. These lesions mimicked the subpleural and peribronchiolar pattern of fibrosis observed by other investigators in intact lungs after systemic administration of bleomycin. The toxicity was less dramatic with carmustine. Mild-to-moderate damage was seen in bronchiolar and alveolar epithelium. An interesting finding was the development of fibrosis at Day 28 which is consistent with the fact that carmustine causes delayed fibrosis clinically. These results show that precision-cut lung slices can be successfully cultured in the dynamic roller system for at least 28 days and serve as a candidate model in vitro system for studying lung toxicants. This work was supported by NCI grant CA09748.

### 245 INDUCTION OF A ZONE OF CELL DEATH IN MULTI-WELL PLATES BY REFEEDING.

H. A. Raabe, G. O. Moyer, G. C. Mun, A. M. Sizemore, J. W. Harbell and J. C. Merrill. Institute for In Vitro Sciences, Inc., Gaithersburg, MD.

Multi-well plates provide an efficient format for cell-based bioassays. As the number of wells increases per plate, the surface area and number of cells per well decreases. Consequently, the use of the small-well format can present some problems. We have observed cell cultures in 96-well plates where significant populations of cells begin to die shortly after refeeding the cell cultures (dumping the spent medium by inverting the plate and adding fresh medium). The zones or areas of cell death appear to occur within a predictable ring just inside of the periphery of the multi-well plate wells, coinciding with the formation of a meniscus formed by the residual medium in the well following removal of the spent culture medium. This effect appears in larger well formats (e.g., 24-well plates) but has more impact in smaller well formats where the ratio of wall circumference to cell area is greater. The impact of these effects tends to be more pronounced when cultures are refed at relatively low confluence, resulting in areas devoid of cells. The zone is also more evident with cell types where cell migration is limited, presumably since those cell types are less apt to migrate to establish new colonies in the deserted areas. Cells cultured in the presence or absence of serum show qualitatively similar results. When uniform, 30% confluent lawns of human keratinocytes in 96-well plates were refed, the cells within the zone rapidly lost the ability to take up neutral red and showed nuclear condensation. After 48 hours, the neutral red uptake  $(\mathrm{OD}_{550})$ was significantly reduced in the refed wells  $(0.830 \pm 0.058$ , mean  $\pm$  standard de viation, n=6 assays) compared to wells that were not refed (1.066  $\pm$  0.034 where p  $\leq$  0.0001). These results were confirmed in 3T3 cells cultured in serum-containing medium. These observations show the impact of the medium change in the 96-well plate format, and suggest that protocols should be designed to minimize this cell loss.

## 246 ARE PRIMARY RAT HEPATOCYTE CULTURES APPROPRIATE FOR PREDICTIVE HEPATOTOXICITY TESTING OF PHARMACEUTICALS.

H. Powell, A. Quigley, J. Hopwood, J. Eakins and G. Kenna. Safety Assessment, AstraZeneca, Macclesfield, Cheshire, United Kingdom. Sponsor: T. Orton.

Liver toxicity is a significant cause of project attrition within the pharmaceutical industry and an important class of adverse drug reactions. This reflects an unmet need for approaches that aid selection of non-hepatotoxic compounds during drug discovery. Although cultured hepatocytes have been used extensively to explore mechanisms of toxicity, their predictive value is unclear. The aim of the present study was to investigate this issue. Hepatocytes from male Han Wistar rats (192-372g) were isolated by collagenase perfusion and cultured in collagen-coated 24well plates in monolayer or sandwich (i.e.  $Matrigel^{TM}$  overlay) configuration. The monolayers exhibited variable basal ATP levels and LDH leakage, and a progressive decrease in viability in culture that were not observed for sandwich cultures. Treatment of monolayer cultures with 5 non-hepatotoxic compounds (streptomycin, physostigmine, metformin, acyclovir, N-acetyl-m-aminophenol [AMAP]) resulted in IC<sub>50</sub> values for LDH leakage at 24 hr that exceeded 1.7 mM. More potent toxicity was observed with 9 hepatotoxic compounds (α-naphthylisocyanate, diclofenac, ibuprofen, chlorpromazine, amiodarone, tetracycline, methapyrilene, tacrine, gentamicin) but not with a further 8 hepatotoxins (acetaminophen [APAP], thioacetamide, valproate, methotrexate, phenobarbital, zidovudine, acetylsalicylate, vancomycin, ). Similar, albeit more reproducible, results were obtained when sandwich cultures were exposed to 3 of the non-hepatotoxins (streptomycin, metformin, AMAP) and 7 of the hepatotoxins (diclofenac, chlorpromazine, methapyrilene, tacrine, APAP, valproate, methotrexate). The most striking feature of these results is the absence of false positives amongst the non-hepatotoxic compounds. The sensitivity for detection of hepatotoxins (9 of 17; 53%) was modest, although this could be related to our choice of compounds. Use of additional endpoints of toxicity may improve predictivity, as may further assay refinement (e.g. repeat dose studies in sandwich cultures).

### 247 HIGH-THROUGHPUT ASSAY FOR ASSESSING LIVER TOXICITY

P. McGrath, C. Parng, C. Ton and C. Zhang. *Phylonix Pharmaceuticals, Inc., Cambridge, MA.* Sponsor: P. Mayeux.

The goal of this study was to develop a high-throughput whole animal bioassay to evaluate liver/gastrointestinal (GI) toxicity of potential therapeutics. We used the level of biotin as an in vivo toxicity marker. The sole known function of biotin in human cells is to act as cofactor of five biotin-conjugated carboxylases. These biotin-dependent carboxylases catalyze key reactions in gluconeogenesis, fatty acid metabolism, and amino acid catabolism. Decreased levels of these biotin-conjugated enzymes have been reported in infants with severe liver dysfunction and increased enzyme levels were observed in transgenic mice with massive liver enlargement. Using the well-characterized mechanism of the strong interaction of biotin with avidin conjugated with reporter enzymes, we measured enzyme levels indirectly based on the stochiometric relationship between the enzyme and biotin molecules throughout early liver/gut development. Since the zebrafish develops rapidly, and the liver is functional at 48 hpf (hours post-fertilization), a relative short experimental time is required to assess toxicity. This study demonstrated the utility of using zebrafish embryos to evaluate drug induced toxicity in a quantitative 96-well microplate format. Using soluble substrate and end product, we measured changes in total biotin content, which reflected carboxylase activity and other biotin-related functions. Next, we showed a clear dose response for several test drugs, and we correlated drug-induced changes in biotin content in zebrafish with liver damage in humans. We also demonstrated the pathology of liver disease such as fatty liver and the pharmacological response of CYP in zebrafish are comparable to those in human. Assessment of drug effects in a convenient vertebrate model, prior to proceeding to evaluation in a complex system, such as mouse, can potentially streamline drug development and dramatically reduce costs.

### 248

CHANGES IN ARGININE UPTAKE, GLUTATHIONE LEVELS, UREA AND NITRIC OXIDE SYNTHESES IN RAT LIVER SPHEROIDS AFTER EXPOSURE TO PROPRANOLOL.

M. Ma, J. Xu and W. Purcell. Faculty of Applied Sciences, University of the West of England, Bristol, United Kingdom. Sponsor: C. Atterwill.

Propranolol is an adrenergic  $\beta$ -blocker, used clinically in the treatment of cardio-vascular disorders and hypertension. It can cause liver injury in patients and hepatic cytotoxicity *in vitro*. The mechanism of its hepatotoxicity is however unclear. This

study examined the changes in arginine uptake, glutathione (GSH and GSSG) levels and urea and nitric oxide (NO) syntheses in rat liver spheroids after exposure to propranolol. Rat liver spheroids were prepared by a gyrotatory-mediated method in a 6-well plate format and exposed to propranolol at 62.5, 125, 250 and 500 μM respectively. The results showed that propranolol caused a concentration-dependent increase in arginine uptake (p < 0.01) and significantly increased NO synthesis (p < 0.01) and GSH levels (p < 0.05) at 250  $\mu$ M but decreased both endpoints at 500  $\mu M$  (p < 0.01). GSSG levels were similar across all concentrations of propranolol tested. Urea secretion was increased significantly (p < 0.05) at 125  $\mu \dot{M}$  of propranolol and decreased at 500 µM (p < 0.01) but no significant change was observed at the other concentrations tested. It is concluded that propranolol can cause extensive functional and biochemical changes in hepatocytes. The increase in urea secretion relates to the increase in arginine uptake. The increases in NO synthesis and GSH levels after exposure to 250 µM propranolol represent cells actively responding to the stressful challenge. Beyond a certain point cells may be seriously injured or die as indicated by urea, NO synthesis and GSH levels, which significantly decreased after exposure to higher concentrations of propranolol. It suggests that the changes in NO synthesis and GSH levels after exposure to propranolol may reflect the severity of cell injury.

### 249 A TWO-STEP PROTOCOL TO DETERMINE LIVER SPHEROID CELL SPREADING INHIBITION

SPHEROID CELL SPREADING INHIBITION CONCENTRATION (SCSIC) OF TOXICANTS.

J. Xu and W. M. Purcell. Faculty of Applied Sciences, University of the West of England, Bristol, United Kingdom. Sponsor: C. Atterwill.

Liver spheroid culture has been shown to be a valuable in vitro model in toxicology studies. An hepatocyte is a complex unit responding to challenges induced by chemicals and functional changes are dependent upon the nature of the toxicity induced. To elucidate the concentration dependent relationship between a challenge and a particular functional change, a suitable range is essential. Therefore, a reference concentration for deciding the 'dosing regimen' for in vitro studies is needed. We previously developed a new method, the Spheroid Cell Spreading Inhibition Test (SCSIT), to determine the minimum concentration causing Spheroid Cell Spreading Inhibition (SCSIC). SCSIC can be used as a reference concentration for subsequent experiments. This study further refined the protocol for SCSIT to determine the SCSIC of a toxicant more precisely by a two-step protocol. Rat liver spheroids were prepared from a Sprague rat liver by a gyrotatory spheroid culture method. Three hepatotoxicants, chlorpromazine, (2-chloro-10-[3-dimethylaminopropyl]phenothiazine), 2-propylpentanoic acid (valproic acid) and ethanol, which represent different levels of relative toxicity were selected. SCSIT was performed in a 24-well plate format. Five spheroids were used for each concentration. The first step covered a wide concentration range from 1  $\mu M$  to 1 M (1, 25, 50, 100, 500 and  $1000 \,\mu\text{M}$ , and 10, 50, 100, 500 and  $1000 \,\text{mM}$ ). The second step was based on the results of the SCSIC from the first step. The minimum SCSIC of each test compound from the first step was further diluted down to the highest SCSIT negative concentration. The results from the first step showed that the SCSIC for chlorpromazine was at 50 µM, for 2-Propylpentanoic acid at 50 mM and for ethanol at 1000 mM. The more precise results were obtained from the second step in that the SCSIC for chlorpromazine was at 30 µM, for 2-Propylpentanoic acid at 8 mM and ethanol at 600 mM. It is concluded that the two step protocol for SCSIT greatly improved the precision in determining the SCSIC of a test compound.

# 250 EVALUATION OF LIVER SPECIFIC FUNCTIONS AS HEPATOCYTOTOXIC ENDPOINTS USING A LIVER SPHEROID MODEL.

W. M. Purcell and J. Xu. Faculty of Applied Sciences, University of the West of England, Bristol, United Kingdom. Sponsor: C. Atterwill.

Liver specific functions such as albumin and urea syntheses, glucose secretion and galactose uptake are important in normal physiology. These functions reflect the status of hepatocytes in terms of protein synthesis, amino acid and energy metabolism and their changes can be easily detected in the blood. Therefore, they are ideal parameters to measure to assess liver functionality. How these functions respond to acute exposure to toxicants has not been evaluated in detail before. Previous studies have shown that mature spheroids (6 days) perform these specific functions much better and are more stable than immature ones (1-5 days). This study using the rat liver spheroid model investigated the changes of liver specific functions in the acute phase after exposure to model hepatotoxicants, diclofenac (100, 500 and 1000  $\mu$ M), galactosamine (5, 10 and 20 mM), isoniazid (5, 10 and 20 mM) and paracetamol (1, 5 and 25 mM). The results show that diclofenac, isoniazid and paracetamol significantly (p < 0.01) decreased albumin secretion, whereas galactosamine significantly (p < 0.05) increased albumin release at 5 mM and caused no significant change at other concentrations tested. The test toxicants significantly (p <

0.01) reduced galactose uptake except for isoniazid, which did not cause any significant detectable effect on galactose uptake. The changes in urea secretion after exposure to the four test toxicants were unpredictable. Diclofenac (1000  $\mu M)$  and paracetamol (25 mM) significantly (p < 0.01) increased urea secretion, galactosamine (10 mM) significantly (p < 0.05) decreased secretion and isoniazid had no apparent effect on urea secretion. Glucose secretion was significantly (p < 0.01) decreased in a concentration-dependent manner after exposure to each of the four toxicants. It is concluded that the test toxicants variously affected the different functional endpoints in liver spheroids with glucose secretion being the most sensitive indicator.

## 251 *IN VITRO* ANALYSIS OF MULTIPARAMETRIC CYTOTOXICITY AT THE INDIVIDUAL CELL LEVEL.

V. Abraham, B. Samson, O. Lapets and J. Haskins. *Cellomics, Inc., Pittsburgh, PA.* Sponsor: E. McGuire.

We have developed an automated image analysis algorithm for automated classification of individual cells in vitro according to their responses across multiple indicators of cytotoxicity. Measurements of each indicator are automatically computed in individual cells via analysis of high-resolution digital images captured using automated fluorescence imaging microscopy. Classification is achieved through defining 'Events' by combining individual indicator measurements with standard Boolean operators in a manner that is biologically meaningful. This functionality may be used to rank toxic effects and determine mechanism of toxicity (e.g. differentiating apoptosis from necrosis). Two sets of experiments were performed to validate this approach. In the first, the dose-dependent effects of valinomycin (K+ ionophore) and CCCP (protonophore) on HepG2 cells were evaluated. Cellular targets evaluated were mitochondrial transmembrane potential, membrane permeability and nuclear morphology. Events were defined to classify cellular responses according to acuteness of toxicity. This approach allowed analysis of dose-dependent effects across multiple relevant parameters and rapid comparison of multiparametric toxicity of valinomycin and CCCP on a molar basis. Secondly, we implemented an assay for phosphatidylserine (PS) translocation to detect apoptosis in Jurkat cells treated with camptothecin. Changes in nuclear morphology (indicative of late stage apoptosis) and onset of membrane permeability (indicating necrosis) were also monitored and incorporated in Event definitions. Events were defined to detect the frequency of occurrence of apoptosis in the absence of necrosis at the individual cell level. These results demonstrate the applicability this approach for rapid, automated analysis of individual cellular cytotoxicity profiles. În addition, this approach is particularly valuable in providing a method of data reduction for high-content cellular investigations that typically generate greater than 10<sup>5</sup> individual relevant cellular measurements per 96-well microplate.

# 252 ALLERGEN-INDUCED CHANGES IN CYTOKINE EXPRESSION BY CULTURED DENDRITIC CELLS: RELATIONSHIP WITH CYTOTOXICITY.

C. J. Betts<sup>1</sup>, M. Cumberbatch<sup>1</sup>, <u>B. Hulette<sup>2</sup></u>, <u>G. Gerberick<sup>2</sup></u>, <u>C. A. Ryan<sup>2</sup></u>, <u>R. J. Dearman<sup>1</sup> and <u>I. Kimber<sup>1</sup></u>. <sup>1</sup>Syngenta CTL, Macclesfield, Cheshire, United Kingdom and <sup>2</sup>Procter & Gamble, Cincinnati, OH.</u>

Epidermal Langerhans cells (LC) play pivotal roles in cutaneous immune responses, including skin sensitization. Analyses of these cells have been facilitated by the development of methods for the generation in culture of dendritic cells (DC) with an LC-like phenotype from murine bone marrow-derived precursors. Such cells may provide a basis for identifying alternative approaches for skin sensitization hazard identification. Bone marrow cells were isolated from the femurs and tibiae of female BALB/c strain mice and cultured in the presence of murine granulocyte/macrophage-colony stimulating factor over a period of 8 days. These cells acquired an immature DC-like phenotype with expression of low levels of MHC class II determinants and high levels of intracellular adhesion molecule 1 and CD11c, but were negative for CD80 and CD86. We have analyzed the cytokine secretion profiles during 24 hr culture with the water-soluble allergen dinitrobenzene sulfonic acid (DNBS). Control cells were cultured with medium alone, or with  $1\mu g/ml$  bacterial lipopolysaccharide (LPS). DC cultured in the presence of medium alone secreted measurable levels of interleukin (IL)-1α, IL-1β, IL-6 and IL-12 (p40 subunit). IL-12 (p70) was not detectable. Culture in the presence of 0.5mM DNBS, a dose that did not impact on cell viability, had relatively little impact on cytokine secretion, with modest increases only in IL-12 (p40 and p70). However, treatment with 1mM DNBS, a concentration that routinely caused a marked loss in cell *via*bility (0-20% *via*ble), resulted in increased production of IL-1α, IL-1β, IL-6 and both forms of IL-12. Culture of mouse DC with LPS (*via*bility greater than 90%) resulted in marked up-regulation of tumor necrosis factor  $\alpha$ , IL-10 and IL-17 in addition to those cytokines mentioned above. It may prove that optimal allergen-induced cytokine secretion by cultured DC requires a second signal in the form of cellular trauma

## 253 HEAT SHOCK PROTEIN RESPONSES IN TETRAFLUOROETHYLCYSTEINE-INDUCED CYTOTOXICITY.

H. Ho<sup>1</sup>, Y. Jia<sup>1</sup>, Z. Hu<sup>3</sup>, D. M. Hockenbery<sup>4</sup>, N. Fausto<sup>2</sup>, <u>S. D. Nelson</u><sup>1</sup> and <u>S. A. Bruschi<sup>1</sup></u>. <sup>1</sup>Medicinal Chemistry, University of Washington, Seattle, WA, <sup>2</sup>Pathology, University of Washington, Seattle, WA, <sup>3</sup>Amgen Inc., Seattle, WA and <sup>4</sup>Fred Hutchinson Cancer Research Center, Seattle, WA.

Tetrafluoroethylecysteine (TFEC), a metabolite of the industrial gas tetrafluoroethylene, initiates nephrotoxicity by the covalent modification of a relatively few mitochondrial proteins. The use of murine TAMH cell line faithfully reproduces TFEC bioactivation and renal cell injury with dose- and time-dependent inhibitions of both mitochondrial aconitase and α-ketoglutarate dehydrogenase. A cytotoxic dose of TFEC (e.g. 250  $\mu\text{M};~8~\text{h})$  significantly elevated the levels of inducible HSP70 (HSP70i). Alterations to stress protein HSP60, mtHSP70 and HSP25-related levels were also observed following TFEC treatment. Prior heat shock treatment induced levels of HSP70i, HSP40 and HSP25 and displayed a cytoprotective effect on TFEC toxicity. However, heat shock cross-tolerance and cytoprotection was more effective with diquat or rotenone treatment in comparison to TFEC. Supporting earlier evidence of BAX translocation and cytochrome c release, we also observed that constitutive overexpression of BCL-xL suppressed HSP70i induction but failed to inhibit the induction of stress-responsive transcription factor, ATF3. This suggests that participation of BCL-xL in cytoprotection precedes proteotoxicity and some cellular stress responses like HSP70i upregulation, but not others like ATF3. Overall, the results implicate a role for heat shock proteins in the modulation of TFEC-induced cytotoxicity. (Supported by NIEHS Center Grant P30ES07033 and Pfizer Inc.)

# 254 APPLICATION OF QSARs TO EVALUATE THE CYTOTOXICITY OF p-BENZOQUINONES TO RAT PRIMARY HEPATOCYTES AND PC12 CELLS.

A. G. Siraki, T. S. Chan and P. J. O'Brien. *Pharmaceutical Sciences, University of Toronto, Toronto, ON, Canada.* Sponsor: J. Uetrecht.

Quinones are found ubiquitously, and are involved in homeostasis, anti-cancer treatment, but are environmental contaminants or reactive metabolites that can cause cytotoxicity and induce carcinogenesis. Consequently, a better understanding of the molecular characteristics of quinones that induce cytotoxicity is desirable. We have performed a comparative study, where we apply quantitative structure-activity relationships (QSARs) to evaluate the cytotoxic effects of p-benzoquinone (BQ) congeners in rat PC12 cells and primary rat hepatocytes. Hepatocytes and PC12 cells were cultured and maintained at 37 °C, 5% CO<sub>2</sub>/Air. Cytotoxicity was determined by the MTT assay, and reactive oxygen species (ROS) formation was determined by 2', 7'-dichlorofluorescein after treatment with BQ derivatives. We derived robust QSARs for cytotoxicity which were dependent on the solvent accessible surface area (SA) and the Hammett substituent constant ( $\sigma$ , correlates to electron affinity) of the BQ: log LD50(hepatocytes) = 0.0146(±0.00154)SAS - $0.562(\pm 0.0461)\sigma + 0.694(\pm 0.149)$ . The PC12 equation was similar. The most cytotoxic compounds were the halogenated BQs and the least toxic were fully substituted alkyl BQs such as duroquinone and Coenzyme Q1. The relative order of BQ cytotoxicity in both cell types was similar, suggesting a similar mechanism of cytotoxic action. Since BQs are readily reduced by the two electron NADPH:Quinone Oxidoreductase (NQO), we evaluated cytotoxicity in NQO-inhibited (dicumarol treated) cells and derived a robust QSAR with only SA as a parameter. Finally, ROS formation was found to correlate with cytotoxicity, but BQ treatment in PC12 cells produced more ROS per dose than in hepatocytes. In conclusion, BQ cytotoxicity was dependent on SA and electrophilicity (σ). Second, BQ cytotoxicity with NQO-inhibition was dependent on SA suggesting that one-electron reductases have a structural requirement for reduction. Lastly, the greater amounts of ROS produced in PC12 cells than hepatocytes is likely a result of lower catalase levels compared to hepatocytes.

# 255 RELATIONSHIP BETWEEN CD86 EXPRESSION, CYTOTOXICITY AND EXPOSURE OF DENDRITIC CELLS TO CHEMICAL ALLERGEN.

B. Hulette<sup>1</sup>, <u>C. Ryan</u><sup>1</sup>, L. Gildea<sup>1</sup>, <u>I. Kimber</u><sup>2</sup>, <u>R. Dearman</u><sup>2</sup> and <u>F. Gerberick</u><sup>1</sup>.

Human peripheral blood derived dendritic cells (DC) respond to a variety of chemical allergens by up-regulating expression of the co-stimulatory molecule CD86. It has been postulated that this measure might provide the basis for an *in vitro* alternative approach for the identification of skin sensitizing chemicals. We recently reported that DC, exposed in culture to the highest non-cytotoxic concentrations of various chemical allergens, displayed marginal up-regulation of membrane CD86

expression; the interpretation being that such changes were insufficiently sensitive for the purposes of hazard identification. For the work presented here, immature DC were derived from human monocytes and treated with the chemical allergens 2, 4-dinitrobenzenesulfonic acid, nickel sulfate, p-phenylenediamine, oxazalone, Bandrowski's base, hydroquinone and propyl gallate for 48 hrs at concentrations which induced both non-cytotoxic and slight to moderate cytotoxicity. For comparison, DC were treated with the irritants sodium dodecyl sulfate (SDS), benzoic acid (BA), and benzalkonium chloride (BZC) at concentrations resulting in comparable levels of cytotoxicity. CD86 expression, as measured by flow cytometry, was consistently up-regulated (ranging from 190-386 % control) on DC treated with concentrations of chemical allergens that induced 10-15% cytotoxicity. The irritants SDS, BA, and BZC did not induce up-regulation of CD86 expression (ranging from 87-100 % control) when tested at concentrations that induced similar levels of cytotoxicity. Our results confirm that chemical allergens up-regulate CD86 expression on blood-derived DC and illustrate further that up-regulation of CD86 surface marker expression is more robust when DC are treated with concentrations of chemical allergen that induce slight to moderate cytotoxicity. We conclude that an association between CD86 expression and cytotoxicity appears evident, but the mechanism underlying this phenomenon have yet to be determined but is under investigation.

# 256 COMPARATIVE TOXICITY OF DIFFERENT EMISSION PARTICLES IN MURINE PULMONARY EPITHELIAL CELLS AND MACROPHAGES.

T. Stevens<sup>1</sup>, P. Singh<sup>2</sup>, M. Daniels<sup>2</sup> and M. Gilmour<sup>2</sup>. <sup>1</sup>Toxicology, UNC, Chapel Hill, NC and <sup>2</sup>NHEERL, USEPA, Research Triangle Park, NC.

Epidemiological studies have shown a correlation between levels of particular matter (PM) and hospital admissions and mortality due to respiratory illness. The chemical components of PM responsible for these effects are not known. This study investigated the ability of diesel exhaust particles (DEP) and fine coal fly ash (CFA) from different sources to cause injury and activation of lung cells. Murine pulmonary macrophages and epithelial cell lines were exposed for 1, 4, or 24 hours with varying doses of NIST 2975, Japanese DEP, German DEP, W Kentucky fine CFA, or Montana fine CFA (10 µg/ml, 50 µg/ml, or 150 µg/ml) as well as vehicle control and endotoxin (0.2 µg/ml, 1 µg/ml, or 5 µg/ml). After exposure, biochemical markers of cytotoxicity, lactate dehydrogenase (LDH) and ATP production, and pro-inflammatory cytokines (TNF-α, MIP-2, IL-6, and IL-1β) were analyzed. Overall, the DEPs caused more cytotoxicity than the CFA samples, and macrophages were more sensitive than epithelial cells. ATP effects were stronger and seen at earlier time points demonstrating this assay to be more sensitive than LDH. No differences in cytokine levels were observed in the epithelial cells of any treatment group. Each cytokine was greatly increased in LPS-exposed macrophages but showed variable patterns with the PM exposure treatments across time and concentration. While some increases were noted, there was a general decrease in cytokine output as exposure concentrations increased which may be related to either the decrease in ATP levels, or binding of cytokines by the particulates. We conclude that measurement of ATP levels in the murine macrophage cell line was the most sensitive endpoint of PM effects and that DEP samples are more potent than CFAs. Measurement of cell products such as cytokines may be confounded by changes in metabolic activity or physical interaction with the materials under study. ## 257 PRESENCE OF TIGHT AND ADHERENS JUNCTION PROTEINS IN AN IMMORTALIZED Z310 CHOROID PLEXUS CELL LINE.

W. Zheng¹, L. Shi¹, J. Li¹, J. Szmydynger-Chodobska² and A. Chodobski². ¹School of Health Sciences, Purdue University, West Lafayette, IN and ²Clinical Neurosciences, Brown University, Providence, RI.

The blood-CSF barrier (BCB), located mainly in the epithelium of the choroid plexus, has been demonstrated to play an important role in brain development, maturation, aging, endocrine regulation, and pathogenesis of certain neurodegenerative diseases. To facilitate the *in vitro* investigation of material transport on the BCB, we have recently developed an immortalized Z310 murine choroidal epithelial cell line (Zheng and Zhao, Brain Res, 958:371, 2002). This study further characterized the tight junction properties of this BCB cell model. The presence of tight and adherens junction proterins was investigated by Western blotting, immunocytochemistry, and RT-PCR. The expression of occludin, E-cadherin, and claudin-1, but not claudin-2, was confirmed by Western blot analyses. While ZO1 was detectable on immunoblots, the intensity of bands was low even with the high protein loading (40 ug per lane). The cellular localization of occludin and E-cadherin was investigated by immunocytochemistry; the presence of transcripts for these proteins was confirmed by RT-PCR. Transmission electron microscopy (TEM) was used to examine the intercellular tight junctions in Z310 cells grown on a semipermeable

membrane in a Transwell device. TEM showed a tight junction-type of structures located immediately below the apical surface between two adjacent cells. TEM also revealed the presence of microvilli on the apical domain of Z310 cells, suggesting a secretory function of these cells. The initial permeability rate constants, obtained with a paracellular permeability marker [\$^{14}C]sucrose, were 862, 432, and 538 fmol/min for devices without cells (control), with primary choroidal epithelial cells, and with Z310 cells, respectively. These data indicate that the Z310 cells possess the tight junction properties and may be suitable for the barrier transport studies. [Supported by: NIH/NIEHS R01 ES-08146 (WZ) and NIH/NINDS R01 NS-39921 (AC)]

# 258 DETERMINATION OF ENERGY AND REDOX STATES IN CELL CULTURE FOLLOWING CADMIUM EXPOSURE.

L. Yu<sup>1</sup>, R. C. Gupta<sup>2</sup> and M. S. Yang<sup>1</sup>. <sup>1</sup>Biology, Hong Kong Baptist University, Hong Kong, China and <sup>2</sup>Toxicology Department, Murray Sate University, Breathitt Veterinary Center, Hopkinsville, KY.

The present investigation was undertaken to determine energy and redox states by measuring the levels of ATP, ADP, AMP, GSH, and GSSG in HepG2 hepatoma and C6 glioma cell lines. Perchloric acid extracts of these cells were analyzed for ATP, ADP, and AMP using an isocratic RP-HPLC method and for GSH and GSSG using a fluorescence method. The values of these metabolites were used to calculate the energy charge potential (ECP=[ATP+0.5ADP]/TAN), total adenine nucleotides (TAN=ATP+ADP+ AMP), total glutathione (TG=[GSH+GSSG]/TAN) and the redox state (GSH/GSSG ratio). Findings revealed that ATP:ADP:AMP was 0.76:0.11:0.13 for the HepG2 cells and 0.80:0.11:0.09 for the C6 glioma cells. ECP was 0.81±0.01 and 0.85±0.01 for the HepG2 and the C6 glioma cells, respectively. TG was 3.2±0.54 and 2.03±0.05 for HepG2 and C6 glioma cells, respectively, indicating that the level of TG is 2-3 fold higher than the levels of energy metabolites in the two cell lines. GSH/GSSG was 2.66±0.16 for the HepG2 cells and 2.03±0.23 for the C6 glioma cells. Following a 3 hr incubation, CdCl2 at a low level (0.2 mM) caused some increases in TG in both cell lines. GSH/GSSG in the C6 glioma cells rapidly decreased at a dose of  $0.1\,$ mM CdCl2. The HepG2 cells on the other hand, showed no significant change in GSH/GSSG ratio until CdCl2 concentration reached 0.6mM. These results indicate that energy and redox states differ in these two cell lines and that the cell lines respond differently to cadmium exposure.

# 259 BASAL GENE EXPRESSION PROFILES AND EFFECTS OF HEPATOCARCINOGENS ON GENE EXPRESSION IN PRIMARY HUMAN HEPATOCYTES AND HEPG2 CELLS.

A. J. Harris<sup>1</sup>, S. L. Dial<sup>1</sup> and <u>D. A. Casciano<sup>2</sup></u>. <sup>1</sup>Center for Hepatotoxicity, NCTR, Jefferson, AR and <sup>2</sup>Office of the Director, NCTR, Jefferson, AR.

Toxicogenomics is a relatively new discipline of toxicology. Microarrays and bioinformatics tools are being used successfully to understand the effects of toxicants on in vivo and in vitro model systems, and to gain a better understanding of the relevance of in vitro models commonly used in toxicological studies. In this study, cDNA filter arrays were used to determine the basal expression patterns of cultured primary human hepatocytes from 3 male donors; compare the gene expression profile of HepG2 to that of primary human hepatocytes; and analyze the effects of 3 genotoxic hepatocarcinogens; aflatoxin B1 (AFB<sub>1</sub>), 2-acetylaminofluorene (2AAF), and dimethylnitrosamine (DMN), as well as acetaminophen (APAP) a non-genotoxic hepatotoxicant, on gene expression in both in vitro systems. Real-time PCR was used to verify differential gene expression for selected genes. Of the approximately 31, 000 genes screened, 3-6 % were expressed in primary hepatocytes cultured on matrigel for 16 hr. Of these genes, 870 were expressed in cultured hepatocytes from all donors. HepG2 cells expressed about 98% of the genes detectable in human hepatocytes, however, 31% of the HepG2 transcriptome was unique to the cell line. There was considerable variability in the response to chemical carcinogen exposure in primary hepatocytes from different donors. The expression of transcription factor genes, E2F1 and ID1, were increased 3-fold and 6-fold (P< 0.05, P< 0.01), respectively in AFB<sub>1</sub> treated primary human hepatocytes but were not altered in HepG2. ID1 expression was also increased by DMN, 2AAF and APAP in both primary hepatocytes and HepG2. This study suggests that identification of biomarkers of exposure to some chemicals may be possible in the human through microarray analysis, despite the variability in responses.

### **260** GENE EXPRESSION MICROARRAY-BASED HYPOTHESIS FOR CADMIUM-INDUCED BONE LOSS.

M. H. Bhattacharyya<sup>1</sup>, A. Regunathan<sup>1</sup>, D. A. Glesne<sup>1</sup> and A. K. Wilson<sup>2</sup>.

<sup>1</sup>Argonne National Laboratory, Argonne, IL and <sup>2</sup>Benedictine University, Lisle, IL.

To identify a mechanism of Cd-induced bone loss that did not rely on guessing the pathways involved, a whole-mouse genome gene-expression microarray was used to determine bone cell changes after a single Cd gavage to mice. To identify early pathways, time points were 2h and 4h after gavage, for a dose (200 ug Cd/mouse) at

which calcium release from bone starts at 8h. Three mouse strains [CF1, metallothionein-normal (MTN), and MT1, 2-deficient (MT1, 2KO)] were studied to identify a robust mechanism that applied across mouse strains. Results showed that ~18 genes increased significantly in mRNA concentration in bone cells in all 4 or in 3 of the 4 microarrays. High to low in Cd responsiveness, these were: cysteine-rich protein 61 (Cyr61), metallothionein 2 (MT2), transferrin receptor (TfR), glutamine synthetase pseudogene 1, MT1, acidic chitinase, RIKEN cDNA 3930, src-like adaptor protein, vacuolar proton pump ATPase, integrin alpha v, aquaporin 1, and p38 MAP Kinase. No genes showed analogous decreases. Concentration increases were small but validated by Northern analyses. Gene changes fit into the following hypothesis: Cadmium could, by currently unknown mechanisms, increase expression of cysteine-rich protein 61 (Cyr61) in osteoblasts and of p38 MAP kinase in osteoclast precursor cells. Cyr61, high in osteoblasts, is a secreted extracellular matrix-associated protein that could attract osteoclasts and bind to their surface integrin receptor, stimulating osteoclast migration, adhesion and activation. Activation would stimulate expression of other osteoclast genes, including integrin alpha-v, vacuolar proton pump ATPase (provides acid to dissolve bone calcium and activate acid proteases that degrade bone matrix), and transferrin receptor (provides needed iron). Osteoclast precursor cells contain high concentrations of p38 MAP kinase compared to other bone cells, and this kinase is required for osteoclast formation. The latter pathways could explain existing evidence that cadmium stimulates bone loss by increasing both osteoclast formation and activation.

BISMUTH-INDUCED RESISTANCE AGAINST CISPLATIN NEPHROTOXICITY AND GENE EXPRESSION PROFILE IN CULTURED TUBULAR EPITHELIUM.

<u>F. A. de Wolff</u><sup>1</sup>, B. T. Leussink<sup>1</sup>, J. J. Baelde<sup>2</sup>, T. M. Broekhuizen-van den Berg<sup>2</sup>, E. de Heer<sup>2</sup>, <u>A. Slikkerveer</u><sup>3</sup>, G. B. van der Voet and J. A. Bruijn<sup>2</sup>. <sup>1</sup> Toxicology Laboratory, Leiden University Med. Ctr, Leiden, Netherlands, <sup>2</sup> Department of Pathology, Leiden University Med. Ctr, Leiden, Netherlands and <sup>3</sup> Research Laboratories, Yamanouchi Europe BV, Leiderdorp, Netherlands.

Introduction Nephrotoxicity is the most important dose-limiting factor in cisplatinbased anti-neoplastic treatment. Pretreatment with bismuth salts, used as pharmaceuticals to treat gastric disorders, has been demonstrated to reduce cisplatin-induced renal cell death in clinical settings and during in vivo and in vitro animal experiments. Aim To investigate the genetic basis of the renoprotective effect of bismuth against cisplatin nephrotoxicity. *Methods* We exposed NRK-52E cells, a cell line of proximal tubular epithelial origin, to 33 μM Bi<sup>3+</sup> for 12 h, which made them resistant against cisplatin-induced apoptosis. Genes differentially expressed in treated and untreated NRK-52E cells were detected with subtraction PCR and microarray technology. Results Genes found to be down-regulated (0.17 to 0.31 times) were cytochrome-c oxidase subunit I, BAR (an apoptosis regulator), heat-shock protein 70-like protein, and 3 proteins belonging to the translation machinery (ribosomal proteins S7 and L17, and S1, a member of the elongation factor 1-α family). The only gene found to be up-regulated was glutathione S-transferase subunit 3A (1.89 times). Conclusions Glutathione has been demonstrated earlier to play a key role in protecting proximal tubular epithelial cells from cisplatin induced cell death. Local upregulation may therefore explain the renoprotective effect of bismuth. Guided by the expression levels of these genes, it may be possible to improve renoprotective treatments in the context of anti-neoplastic therapies.

TOXICOGENOMIC ANALYSIS OF ABERRANT GENE EXPRESSION IN NEWBORN MOUSE LIVER INDUCED BY TRANSPLACENTAL EXPOSURE TO CARCINOGENIC DOSES OF INORGANIC ARSENIC.

Y. Xie<sup>1</sup>, J. Liu<sup>1</sup>, B. A. Diwan<sup>2</sup>, J. M. Ward<sup>3</sup>, D. L. Logsdon<sup>3</sup> and M. P. Waalkes<sup>1</sup>.

Inorganic Carcinogenesis Section, LCC, NCI at NIEHS, Research Triangle Park, NC,

<sup>2</sup>SAIC, NCI at Frederick, Frederick, MD and <sup>3</sup>Office of Laboratory Animal Science,

NCI at Frederick, Frederick, MD.

We previously found that brief exposure of pregnant mice to arsenite in the drinking water induced hepatocellular carcinoma (HCC) in the offspring when they reached adulthood. Furthermore, adult mice exposed to carcinogenic doses of arsenite *in utero* show remarkable gene expression changes that could be related to oncogenesis. To help determine the onset of these changes, this study focused on aberrant gene expression in newborn mice induced by *in utero* arsenic (As) exposure at a dose shown in our prior work to induce HCC. Thus, groups of pregnant mice were exposed to drinking water containing 85 ppm As (as sodium arsenite) or unaltered water (control) from gestation day 8 to 18. The dams were allowed to give birth, and liver samples were taken from the newborn pups for analysis of As content, global DNA methylation status and altered gene expression. This dose was well tolerated and there was no evidence of maternal or fetal toxicity. In the neonatal liver As was detectable after *in utero* exposure (57.2 ng/g on average) but not

present in the controls, suggesting that As had crossed the placenta and accumulated in the fetal liver. Global hepatic DNA methylation status was not altered by As exposure. In As-treated neonates, 70 out of the 600 genes analyzed by microarray showed aberrant expression, which was confirmed for selected genes by PCR analysis. IGF (insulin-like growth factor)-related genes as well as genes encoding cytochrome P450 and GST showed particularly noticeable alterations. This included the reduced expression of IGF-1, IGF-2, IGFBP-1, IGFBP-2 and CYP1A2, 2B9, 2D9, 2E1, 2F2, 3A11, 3A13, 3A25, 4A10 and 4A14, and the enhanced expression of GST 5, GST P1 and GST theta 1. This study revealed that *in utero* exposure to As at non-toxic doses induces remarkable aberrant gene expression changes in the newborn liver, a target of As carcinogenesis.

263

FURTHER STUDIES ON GENE EXPRESSION CHANGES ASSOCIATED WITH TRANSPLACENTAL ARSENIC CARCINOGENESIS.

<u>I. Liu<sup>1</sup></u>, <u>Y. Xie<sup>1</sup></u>, <u>B. A. Diwan<sup>2</sup></u>, J. M. Ward<sup>3</sup>, D. L. Logsdon<sup>2</sup> and <u>M. P. Waalkes<sup>1</sup></u>. <sup>1</sup>Inorganic Carcinogenesis, LCC, NCI at NIEHS, Raleigh, NC, <sup>2</sup>SAIC, NCI-Frederick, Frederick, Frederick, MD and <sup>3</sup>Office of Laboratory Animal Sciences, NCI-Frederick, Frederick MD.

Our prior work shows arsenic alone is a transplacental carcinogen in male mice. In a follow-up study, pregnant C3H mice were given drinking water containing 85 ppm arsenic as sodium arsenite or unaltered water from day 8 to 18 of gestation. In order to promote arsenic-initiated tumors, mice received arsenic in utero and then 12-O-teradecanoyl phorbol-13-acetate (TPA), a tumor promoter, was applied to the skin of offspring (2 mg/0.1 ml acetone, 2 times/week) from 4-25 weeks. The administration of TPA did not promote skin tumors but significantly increased liver tumors in females. Thus, arsenic exposure in utero plus TPA at weaning produced liver tumors in both male and female mice. Liver tumors and non-tumorous tissues were taken at necropsy. Total RNA was isolated and purified to perform microarray analysis using a 600-gene custom array. Arsenic plus TPA treatment resulted in increased expression of a-fetoprotein, c-myc, cyclin D1, CYP2A4, cytokeratin-8, cytokeratin-18, glutathione S-transferases and insulin-like growth factor binding proteins, as well as decreased expression of betaine-homocysteine methyltransferase, CYP7B1, CYP2F2 and insulin-like growth factor-1 in liver tumor samples and arsenic-exposed non-tumorous surrounding tissue samples, as compared to controls. Regardless of sex, the expression of several of these genes, such as a-fetoprotein, c-myc, and cyclin D1, is associated with liver tumor formation. Microarray data were confirmed by real-time RT-PCR analysis on selected genes. The gene expression changes agree well with our prior genomic analysis on mice exposed to arsenic only in utero. Thus, inorganic arsenic exposure in utero plus inclusion of TPA after weaning caused liver tumor formation and remarkable alterations in gene expression in adult mice despite ending arsenic exposure during gestation. These aberrant expression changes may be associated with the formation of arsenic-induced tumors in the liver.

MODULATION OF AHR-REGULATED GENE EXPRESSION BY ARSENITE, CADMIUM, AND CHROMIUM.

R. H. Elbekai and A. O. El-Kadi. *University of Alberta, Edmonton, AB, Canada.* Sponsor: J. Koropatnick.

AHR ligands and heavy metals are environmental co-contaminants and their molecular interaction may disrupt the coordinated regulation of AHR-dependent gene expression. The aim of this study was to determine the effect of arsenite (As<sup>3+</sup>), cadmium (Cd<sup>2+</sup>) and chromium (Cr<sup>6+</sup>), on the constitutive and inducible expression of the AHR-regulated genes: cyp1a1, NAD(P)H: quinone oxidoreductase (QOR) and glutathione S-transferase Ya (GST Ya). For this purpose, murine hepatoma Hepa 1c1c7 cells were treated with increasing concentrations of As $^{3+}$  (1, 5, and 10  $\mu$ M), Cd $^{2+}$  (1, 5, and 25  $\mu$ M) and Cr $^{6+}$  (1, 5, and 25  $\mu$ M) with or without one of the AHR ligands: 2, 3, 7, 8-tetrachlorodibenzo -p-dioxin (0.1 nM), 3-methylcholanthrene (0.25  $\mu$ M),  $\beta$ -naphthoflavone (10  $\mu$ M), or Benzo[a]pyrene (1  $\mu$ M). Our results show that metals or AHR ligands alone increased the catalytic activities and the mRNA levels of all AHR-regulated genes. When metals were co-administered with AHR ligands, all three metals inhibited the induction of cyp1a1 activity by the AHR ligands but potentiated inducible mRNA expression of cyp1a1 in a dose dependent manner. În addition, all metals enhanced QOR constitutive activity and mRNA transcript levels in a dose-dependent manner but modulated its induction by AHR ligands in a dose, metal, and AHR ligand-dependent manner. Generally,  $\operatorname{Cr}^{6+}$  inhibited while  $\operatorname{As}^{3+}$  and  $\operatorname{Cd}^{2+}$  potentiated the induction of QOR activity and mRNA levels. Maximal elevations in GST Ya catalytic activity by As<sup>3+</sup> or Cd<sup>2+</sup> alone and with an AHR ligand co-treatment, occurred at the highest doses tested and were accompanied by increased mRNA transcript levels. Cr6+, however, depressed GST Ya catalyzed detoxification capacity of the cells at the mRNA and activity levels. The three metals enhanced the expression of heme oxygenase-1 (HO-1) in a dose-dependent manner suggesting that HO-1 is involved in the modulation of AHR-regulated gene expression by heavy metals. The ability of metals to alter the capacity of AHR ligands to induce the bioactivating phase I and the detoxifying phase II enzymes will influence the carcinogenicity and mutagenicity of the AHR ligands.

### 265 DIFFERENTIAL EFFECTS OF HEAVY METALS ON ARYL HYDROCARON RECEPTOR-REGULATED GENES.

H. M. Korashy and <u>A. O. El-Kadi</u>. Faculty of Pharmacy & Pharmaceutical Sciences, University of Alberta, Edmonton, AB, Canada.

Both simultaneous and sequential exposure to heavy metals and aryl hydrocarbon receptor (AHR) ligands potentially occur in human populations, yet there have been relatively few studies of combined effects of heavy metals and AHR ligands on AHR-regulated genes. The aim of this work was to investigate the potential effects of heavy metals, particularly mercury (Hg<sup>2+</sup>), lead (Pb<sup>2+</sup>), and copper (Cu<sup>2+</sup>), on the constitutive and the inducible expression of AHR-regulated genes; cytochrome P450 1a1 (cyp1a1), NAD(P)H:quinone oxidoreductase (QOR) and glutathione Stransferase Ya; (GST Ya) at the activity and mRNA levels. For this purpose, murine hepatoma hepa 1c1c7 wild-type cells were incubated with increasing concentrations of  $Hg^{2^+}$  (2.5, 5 and 10  $\mu$ M),  $Pb^{2^+}$  (10, 25 and 100  $\mu$ M), and  $Cu^{2^+}$  (1, 10 and 100 μM) alone or with the AHR-ligand, 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (0.1 nM), 3-methylcholanthrene (0.25  $\mu$ M),  $\beta$ -naphthoflavone (10  $\hat{\mu}$ M), or Benzo[a]pyrene (1 µM). Our results clearly showed that metals alone did not significantly alter the cyp1a1 activity, whereas a significant reduction in AHR ligandmediated induction of cyp1a1 activity was observed by all metals in a concentration-dependent manner. Interestingly, the decrease in cyp1a1 activity was associated with an increase in cyp1a1 mRNA level. With respect to QOR, the activity was strongly increased dose-dependently by all metals in the absence or presence of an AHR-ligand, with the exception of Cu<sup>2+</sup> which significantly decreased the activity. Changes in QOR at the mRNA levels were in accordance with the activity results. Differently, GST Ya activity was significantly increased by Cu<sup>2+</sup> and Pb<sup>2+</sup> and inhibited by Hg<sup>2+</sup>. All metals significantly increased the expression of stress protein, heme oxygenase-1 (HO-1). We conclude that heavy metals differentially modulate the constitutive and the inducible expression of AHR-regulated genes. Chronic exposure of heavy metals/AHR-ligands mixture would be less effective in inducing ÂHR-mediated toxicity than exposure to metals or AHR-ligand alone.

## 266 ARSENITE INITIATES AH RECEPTOR-INDEPENDENT REPRESSION OF CYP1A1 INDUCTION BY TCDD.

J. A. Bonzo<sup>1</sup>, A. Galijatovic<sup>1</sup>, S. Chen<sup>1</sup> and <u>R. H. Tukey<sup>1, 2</sup>. <sup>1</sup>Pharmacology,</u> University of California San Diego, La Jolla, CA and <sup>2</sup>Chemistry & Biochemistry, University of California San Diego, La Jolla, CA.

Arsenite (As3+) alters the expression and function of several drug-metabolizing enzymes, including cytochrome P450 1A1 (CYP1A1). In addition, it has been shown that CYP1A1 expression can be regulated in a cell cycle dependent manner. Interestingly, As<sup>3+</sup> interrupts cell cycle control by initiating G2/M arrest. To examine the impact of As<sup>3+</sup> on TCDD initiated induction of CYP1A1, HepG2 cells were treated with sub-cytotoxic (0.5  $\mu$ M to 50  $\mu$ M) doses of As<sup>3+</sup>. Exposure of HepG2 cells to TCDD and As<sup>3+</sup> revealed an As<sup>3+</sup> dose-dependent increase in G2/M phase arrest. Vinblastine causes G2/M arrest and was shown to decrease TCDD-induced CYP1A1 gene expression. Examination of the catalytic activity of CYP1A1 as measured by EROD assay in HepG2 cells demonstrated that As3+ led to a dose-dependent decrease in TCDD-induced EROD activity. This reduction correlated with a comparable reduction in CYP1A1 as determined by Western blot analysis. The addition of As3+ to microsomal preparations generated from TCDD treated cells did not influence EROD activity, suggesting that inhibition occurs upstream of translation. This was verified by quantitative analysis of CYP1A1 mRNA by real-time RT-PCR. The lowest concentration of  $As^{3+}$  (0.5  $\mu$ M) resulted in a 61% reduction in TCDD-induced CYP1A1 mRNA. Using HepG2 cells that express the human *CYP1A1*-luciferase reporter gene, it was demonstrated that As<sup>3+</sup> did not alter TCDD induction of *CYP1A1*-luciferase. Gel shift analysis confirmed activation of the AhR and subsequent binding to the XRE following co-treatment with TCDD and As<sup>3+</sup>. Combined, CYPIAI initiated transcription does not appear to be a target for the inhibitory properties of As<sup>3+</sup>. These results indicate that G2/M phase arrest may be a factor in As3+ inhibition of TCDD initiated induction of CYP1A1. Moreover, the mechanism of inhibition does not impact on activation of the AhR. (Supported by USPHS grant ES10337).

267 ARSENIC-TRANSFORMED HUMAN PROSTATE
EPITHELIAL CELLS SHOW CHANGES IN ANDROGEN
METABOLISM AND ESTROGEN RECEPTOR

EXPRESSION.

<u>L. Benbrahim-Tallaa</u><sup>1</sup>, M. M. Webber<sup>2</sup> and <u>M. P. Waalkes</u><sup>1</sup>. <sup>1</sup>Inorganic Carcinogenesis Section, NCI at NIEHS, Research Triangle Park, NC and <sup>2</sup>Michigan State University, East Lansing, MI.

Inorganic arsenic (As) is an important environmental toxicant, with natural and industrial sources. Human As exposure is linked to cancers in various tissues including the prostate. However, the molecular mechanisms of As carcinogenesis are still poorly defined. Steroid hormones play a critical role in stimulating the growth and differentiation of normal prostate epithelial cells, as well as in the initial growth of prostate cancer cells. Furthermore, genes involved in the prostatic steroid signaling pathways have been implicated in cancer development. Variation in the androgen or estrogen receptor genes, as well as in the steroid metabolizing enzymes, such as, the steroid 5lpha-reductase, have been linked to prostate cancer causation and progression. We have developed an in vitro model of As-induced prostate cancer by inducing malignant transformation of the immortalized, non-tumorigenic human prostate epithelial cell line RWPE-1 by chronic As exposure. To help understand the molecular mechanisms underlying As-induced malignant transformation, we performed gene expression comparisons between these chronic As transformed prostate epithelial cells (designated CAsE-PE) and control RWPE-1 cells. RT-PCR and western blot were used to examine expression of ER-α and ER-β. Our studies revealed an increase in ER- $\beta$  (1.6-fold) and a decrease in ER- $\alpha$  (45%) transcript in As transformed cells compared to control. However, the correlate receptor protein levels were significantly elevated from 20 and 100% in CAsE-PE cells. 5α-reductase transcript, which encodes for the enzyme that converts testosterone to its active metabolite, DHT, was markedly increased in CAsE-PE cells. These data suggest altered expression of steroid receptors and altered steroid metabolism occurs in CAsE-PE cells. These changes in steroid metabolism and sex steroid signaling pathways may be associated with As-induced malignant transformation and prostate cancer.

268 EXPOSURE TO SOLUBLE NICKEL ALTERS IRON-MEDIATED GENE TRANSCRIPTION AND ENZYME ACTIVITY IN A549 CELLS.

T. L. Davidson, H. Chen, T. Kluz and M. Costa. Department of Env. Med., New York University, Tuxedo, NY.

Nickel compounds have been identified as human carcinogens/cocarcinogens using both in vivo studies and epidemiological evaluations. Nickel is known to stabilize the hypoxia inducible factor- $1\alpha$  (HIF- $1\alpha$ ) protein, which is thought to be important in tumor progression. Since nickel affects HIF- $1\alpha$ , which is controlled by an iron dependent enzyme, we designed in vitro experiments to look at the effect of nickel on iron dependent processes in A549 cells. Using the Affymetrix Gene Chip, we identified several iron-regulated genes that were altered in reponse to nickel treatment. The mRNA levels of transferrin receptor and GADD45, both of which are increased in response to low iron levels, were substantially increased in response to nickel. In addition, the transcription of many HIF-1α-dependent genes was also increased. Nickel chloride was also able to block the induction of ferritin by ferrous iron. Atomic absorption was then performed to see if nickel had an effect on total iron levels in A549 cells. The levels of total iron were significantly lowered in response to 1mM nickel chloride. Furthermore, the enzyme activity of several iron dependent enzymes, including prolyl hydroxylase and aconitase, was significantly lowered when cells were exposed to 1mM nickel chloride. Surprisingly, when we treated a cell extract with concentrations of nickel chloride as low as 10 uM, prolyl hydroxylase activity was decreased. In sharp contrast, when we treated purified aconitase enzyme with concentrations of nickel chloride as high as 2mM, we observed no decline in enzyme activity. The prolyl hydroxylase enzymes that control the stability of HIF-1 appear to be very sensitive to very low concentrations of nickel. Iron dependent processes are a requirement for life and interference with these processes may be involved in nickel-induced carcinogenesis. These data may give new insight into the mechanisms of nickel induced carcinogenesis, as well as, contribute important information for the treatment and prevention of occupational diseases.

269 EUKARYOTIC TRANSLATION INITIATION FACTOR 4E (EIF4E) IS A CELLULAR TARGET FOR CADMIUM

S. Othumpangat and <u>P. Joseph</u>. Health Effects Laboratory Division, NIOSH, Morgantown, WV.

Cadmium, to which large numbers of people are occupationally and otherwise exposed, has been categorized as a human carcinogen by the International Agency for Research on Cancer (IARC). Several theories have been proposed to account for the mechanisms potentially responsible for cadmium toxicity and carcinogenesis. Recently, our laboratory has demonstrated a novel mechanism for cadmium carcinogenesis that involves the upregulation of translation initiation factor 3 and translation elongation factor-1 delta. Presently, we have investigated whether the translational proto-oncogene, eukaryotic initiation factor 4E (eIF4E) is a cellular target for cadmium toxicity and carcinogenesis. Four different human cell lines: HCT-15 (colorectal adenocarcinoma), PLC/PRF/5 (hepatocellular carcinoma), HeLa (adenocarcinoma) and Chang (likely derived from ĤeLa cells) cells, were exposed to 30  $\mu M$  cadmium chloride for time intervals up to 24-hours and the expression level of eIF4E was determined by Western blot analysis using an antibody against human eIF4E. Exposure to 30 µM cadmium chloride resulted in significant cytotoxicity and cell death in all four cell lines tested. Furthermore, exposure to cadmium chloride resulted in significant inhibition of eIF4E in all cell lines, and the highest inhibition was noticed following the 24-hours exposure to cadmium chloride. The significance of cadmium chloride-mediated inhibition of eIF4E was further investigated by silencing the expression of eIF4E by employing small interfering RNA (SiRNA) specifically targeting eIF4E. The SiRNA mediated silencing of eIF4E resulted in significant cell death. Our results thus suggest that eIF4E is a cellular target for cadmium toxicity and that the cadmium-induced cytotoxicity and cell death may be due to the inhibition of eIF4E.

## 270 LEAD IS MITOGENIC TO WTHBF-6 CELLS, BUT LEAD CHROMATE (LC) INDUCES CELL CYCLE ARREST.

J. Moreland<sup>1</sup>, S. Teufack<sup>1, 3</sup>, S. Sandwick<sup>1</sup>, J. Dufour<sup>1</sup>, <u>S. S. Wise<sup>1</sup></u>, A. Holmes<sup>1</sup>, M. Ketterer<sup>2</sup>, W. Wise<sup>1</sup></u>. <sup>1</sup>Wise Laboratory of Environmental and Genetic Toxicology, Center for Integrated and Applied Environmental Toxicology, University of Southern Maine, Portland, ME, <sup>2</sup>Department of Chemistry, Northern Arizona University, Flagstaff, AZ and <sup>3</sup>Department of Biology, University of Bridgeport, Bridgeport, CT.

Hexavalent chromium (Cr(VI)) is a human lung carcinogen of significant public health concern. The particulate Cr(VI) compounds are more potent carcinogens than soluble ones. Preliminary reports suggest that LC, a prototypical particulate Cr(VI) compound, partially dissolves to produce ionic lead (Pb) and Cr and that while the Cr ions are damaging DNA, the lead ions are stimulating cell growth. We found that Pb induced cell growth in WTHBF-6 cells: 250, 500, 1000, 2000 uM lead glutamate (LG) induced 40, 54, 85, and 142% increases in the mitotic index. However, LC did not stimulate cell growth: 0.5, 1.0, and 5.0 ug/cm<sup>2</sup> reduced the mitotic index by 52.9, 52.9, and 92.35% respectively and metaphases were absent at 10.0 and 50.0 ug/cm<sup>2</sup>. These same LC concentrations induced prolonged growth arrest. Furthermore, LC-induced arrest occurred at intracellular lead concentrations much lower than those found for growth stimulatory levels of ionic lead. We found that soluble sodium chromate (SC) also inhibited growth and the concentrations of Cr inside the cell after both LC and SC were equivalent. Further analysis of the cell cycle showed that 0.5, 1.0, 5.0 and 10.0 ug/cm<sup>2</sup> LC increased the percentage of cells in S-phase by 9.7, 24.3, 83.5, and 104% respectively. These increases coincided with a drop in the percentage of cells in G1 phase. SC also induced accumulation of cells in S-phase at moderate concentrations. Yet only 2000 uM LG, resulted in S and/or G2/M arrest. These results indicate that Cr, not Pb, is responsible for cell growth effects associated with LC. This work was supported by NIEHS grant 1R01 ES 10838-01 (J.P.W.).

# 271 MERCURY MODULATES CELL CYCLE PROGRESSION IN HUMAN LIVER CARCINOMA CELLS THOUGH INDUCTION OF C-FOS, CYCLIN-A, AND CYCLIN-D EXPRESSION, AND REPRESSION OF GADD153.

<u>P. B. Tchounwou</u> and D. J. Sutton. *Center for Environmental Health, Jackson State University, Jackson, MS.* 

Exposure to mercury has been associated with a significant number of adverse health effects on various organ systems, and cancer in some cases. Its toxicity has been attributed to its high affinity to sulfhydryl groups of proteins. However, little is known regarding the molecular mechanisms by which mercury exerts its toxicity, mitogenesis, and/or carcinogenesis. Recent studies in our laboratory have shown that mercury is cytotoxic and transcriptionally activates stress genes in human liver carcinoma (HepG2)cells. We hypothesized that mercury-induced expression of stress proteins and cyclins may play a role in the molecular events leading to toxicity and tumorigenesis. To test this hypothesis, we performed the MTT-assay for cell viability, and the Western Blot and densitometric analyses to assess the expression of specific cellular proteins including c-fos, GADD153, cyclin-A, and cyclin-D. Data obtained from the MTT-assay indicated a strong dose-response relationship with respect to mercury toxicity. The LD50 was computed to be 3.5 +/- 0.6 μg/mL upon 48 hrs of exposure. Western blot and densitometric analyses showed c-fos, cyclin-A, and cyclin-D expressions to increase in a dose-dependent manner within the dose-range of 0-3 µg/mL; showing a peak induction at 3 µg/mL and a sharp drop at 4 µg/mL, probably due to cell death at higher levels of mercury exposure. No statistically significant differences (p > 0.05) were found in GADD153 expression between control and mercury-treated cells. Taken together, these findings indicate that mercury is cytotoxic, and has the potential to modulate cell cycle control proteins in HepG2 cells. Induction of c-fos/cyclin-D and cyclin-A expression indicates its stimulation of cell cycle progression, respectively through the G1/S and G2/M transitions. The ramifications of these findings to our understanding of merucy-induced toxicity and tumorigenesis are important. [Research supported by NIH-RCMI Grant No. 1G12RR13459, and DoA-MACERAC Grant No. DACA-42-02-C-0057].

### 272 URANIUM IS CYTOTOXIC AND GENOTOXIC TO HUMAN LUNG CELLS.

W. Diaz, <u>S. Wise</u> and <u>J. P. Wise</u>. Wise Laboratory of Environmental and Genetic Toxicology, Center for Integrated and Applied Environmental Toxicology, University of Southern Maine, Portland, ME.

Maine has some of the highest rates in the nation for bladder and lung cancer. It is also a state that relies heavily on well water, and many of these wells are contaminated with uranium. In addition, uranium has also recently become a specific concern for the health of our soldiers, as well as for those exposed through fragments left behind in the environment, because of the heavy use of depleted uranium in military armor and munitions. Uranium potentially has both chemotoxic and radiotoxic effects. Previous investigations have largely focused on the radiotoxic effects of uranium and its decay products; much less is known about uraniums potential chemical toxicity. One major chemotoxic effect that has been characterized is nephrotoxicity, and there is reason to consider uranium a potential bladder carcinogen because chronic exposures have been shown to be carcinogenic. Uranium has also been associated with human lung cancer. As a first step to understanding the potential carcinogenic mechanisms of uranium, we treated WTHBF-6 cells, a human lung fibroblast cell line with concentrations ranging from 1- 200 uM uranium acetate for 24 h and determined its cytotoxic and genotoxic effects. We found that uranium was moderately cytotoxic over this range with 89.9%, 57.2%, and 40.6% relative survival at 25, 50 and 100 uM. We also found that uranium was clastogenic inducing multiple observable lesions in chromatid structure. At concentrations of 50, 100 and 200uM, 3%, 4% and 19% damage of mitophases was noted in preliminary data. The spectrum of chromosome damage included chromosome breaks, which are consistent with the types of karyotypic alterations seen in many neoplasms. Future research is aimed at understanding the genotoxic mechanisms involved in uranium-induced neoplastic transformation

# 273 INTERFERON- $\alpha$ INDUCTION OF METALLOTHIONEIN IN RAT LIVER IS NOT LINKED TO INTERLEUKIN-1, -6 OR TUMOR NECROSIS FACTOR- $\alpha$ .

E. Brambila<sup>1</sup>, A. Leon<sup>1</sup>, J. Guevara<sup>1</sup>, O. Castellanos<sup>1</sup>, <u>M. P. Waalkes<sup>2</sup></u> and <u>W. E. Achanzar<sup>2</sup></u>. <sup>1</sup>University of Puebla, Puebla, Mexico and <sup>2</sup>Inorganic Carcinogenesis Section, NCI at NIEHS, Research Triangle Park, NC.

Synthesis of metallothionein (MT) is induced by interferon- $\alpha$  (IFN- $\alpha$ ) in vitro and in vivo. In addition, IFN-α promotes redistribution of zinc (Zn) from the plasma to the liver in mice. However, it is not clear if IFN- $\alpha$  induces hepatic MT synthesis directly or indirectly via liberation of other cytokines. In order to address this issue, we determined hepatic MT levels, Zn concentration in plasma, liver and urine, and plasma levels interleukin-1 (IL-1), interleukin-6 (IL-6) and tumor necrosis factor-α (TNF-α) in rats following intramuscular injection of human IFN-α (1.5 X 106 UI/m2). Animals were housed in metabolic cages and sacrificed at various times after IFN-α administration. Zn concentrations in serum, urine and hepatic tissue were determined by atomic absorption spectrophotometry. MT protein was measured using the MT silver saturation method and Western-blot analysis. Plasma levels of IL-1, IL-6, and TNF-α were determined using an ELISA method. Hepatic MT levels began to increase at 2 h following IFN-α administration and reached maximum levels at 12 h post-treatment. IFN-α also produced biphasic increases in hepatic Zn, with levels peaking at 2 h, the time-point when MT levels are first increased, and again at 18 h. Concurrently, there were decreases in plasma Zn levels at these time points, suggesting IFN-α-induced movement of Zn from the blood to hepatic tissue. The decrease in plasma zinc was not due to increased excretion since urinary Zn levels were unaffected following IFN- $\alpha$  treatment. IFN- $\alpha$  administration had no effect on plasma IL-1, IL-6 and TNF- $\alpha$  levels. These results show that IFN-α promotes the increase of hepatic MT levels and plasma/liver redistribution directly, without IL-1, IL-6 or TNF-α participation

## 274 PROLYL HYDROXYLASES AS TARGETS FOR CARCINOGENIC NICKEL.

K. Salnikow<sup>1</sup>, A. Zhitkovich<sup>2</sup>, S. P. Donald<sup>1</sup>, J. Phang<sup>1</sup> and K. Kasprzak<sup>1</sup>.

<sup>1</sup>National Cancer Institute, Frederick, MD and <sup>2</sup>Brown University, Providence, RI.

Nickel is a well established human carcinogen, however mechanisms of its carcinogenicity are not understood. Recently, we performed a microarray analysis of cells exposed to soluble nickel and observed strong induction of hypoxia-inducible

genes. These data suggested that nickel activated HIF-1 transcription factor. It was shown previously that under normal conditions, hydroxylation of proline-564 in HIF-1 alpha leads to its interaction with von Hippel Lindau (VHL) tumor suppressor protein and rapid proteosomal degradation. In our experiments we found that nickel exposure resulted in increased stabilization of HIF-1 alpha protein suggesting that hydroxylation of this protein was diminished. Here we tested the hypothesis that inactivation of prolyl hydroxylase activity by nickel causes stabilization of HIF-1 alpha transcription factor. Using a reporter plasmid containing the oxygen-dependent degradation domain (ODD) of HIF-1 alpha with proline-564, fused with luciferase protein (ODD-Luc), we showed that exposure to nickel significantly stabilized this reporter when transfected into human airway epithelial (HAE) cells. Cobalt, deferoxamine and dimethyloxoglycine, known inducers of HIF-1 transcription factor, also stabilized the reporter in HAE cells. Additionally, we have shown that stabilization of ODD-Luc reporter by nickel takes place only in cells with normal, but not with mutated VHL. The induction of endogenous HIF-1 alpha protein by nickel was also confirmed by both induction of HRE-Luc plasmid and by induction of hypoxia-inducible protein NDRG-1/Cap43. Using cell extracts from nickel-exposed and control cells, we demonstrated that ODD-dependent conversion of 2-oxoglutarate into succinate was suppressed by nickel exposure. In conclusion, these data strongly indicate that nickel blocks hydroxylation of proline-564, which leads to the stabilization of HIF-1 alpha protein

### 275 LEAD INHIBITS OSTEOBLAST DIFFERENTIATION BY BLOCKING SMAD SIGNALING.

K. O. Hochberg, T. J. Sheu, E. M. Schwarz, M. J. zuscik, R. J. O'Keefe, R. N. Rosier and J. E. Puzas. Orthopedics, University of Rochester, Rochester, NY.

Rationale: For many years lead has been recognized as an environmental toxicant that adversely affects bone metabolism, especially osteoblast function. Prior studies have shown that lead interferes with the ionic milieu of cells; however, no studies have linked its effect to a direct control of gene expression. Our results indicate that lead inhibits osteoblast differentiation by affecting TGFb activation of the transcription factor(s), Smad2/3. Methods: In these experiments we used primary calvarial osteoblasts. Alkaline phosphatase (AlkPhos) activity, as measured by the hydrolysis of pNPP, was used as an indicator of cell differentiation. Transfection of the cells by electroporation with two reporters for the TGFb pathway (i.e. p3TP-luc and 4xSBE-luc) was used to measure TGFb pathway activity. Overexpression of a constitutively active Smad3 was accomplished with transfection of Smad3D-His-SV40. Cells were exposed to lead ranging from 0.08uM to 50uM for 24-72 hours. Results: Lead exposure resulted in a dose dependent decrease in osteoblast differentiation as demonstrated by a 50% decrease in AlkPhos activity after 24 hours. Transfection of cells with either Smad reporter occurred at an efficiency of 100% of surviving cells. Lead caused a decrease in activity for both reporters of between 25 and 80% at concentrations of lead ranging from 0.08 to 0.4uM after 24 hours. In order to determine if the effect of lead was upstream or downstream of Smad3 activation, we co-transfected the cells with a constitutively active Smad3 construct and the 4xSBE-luc reporter. Under these conditions, lead was unable to affect the Smad signaling pathway. Discussion: Our data support the hypothesis that lead interferes with osteoblast differentiation by inhibiting components of the TGFb/Smad signaling pathway. Since expression of a constitutively active Smad3 was able to rescue Smad signaling in lead exposed osteoblasts, we conclude that lead's effect is upstream of Smad3 activation. Our work will continue to elucidate the effects of lead on TGF-beta signaling.

## 276 IN VIVO ACTIVATION OF METALLOTHIONEIN ISOFORM 3 EXPRESSION IN HUMAN CANCER CELLS.

D. A. Sens<sup>1</sup>, V. Gurel<sup>2</sup>, S. H. Garrett<sup>2</sup>, S. Somji<sup>2</sup> and M. Sens<sup>2</sup>. <sup>1</sup>Surgery, University of North Dakota, Grand Forks, ND and <sup>2</sup>Pathology, University of North Dakota, Grand Forks, ND.

This laboratory has shown that the third isoform of metallothionein is overexpressed in human breast, bladder and prostate cancer. In breast cancer, MT-3 overexpression was confined to a subset of cancers and expression was associated with ductal carcinoma in situ lesions having a poor prognosis. In prostate cancer, MT-3 was also overexpressed in a subset of prostate cancers and expression correlated with Gleason score. In bladder cancer, MT-3 was shown to be overexpressed in all cancers with the degree of overexpression correlating to tumor grade. Despite the widespread occurrence of MT-3 overexpression in these cancers, most cell lines derived from these cancers have no or very low expression of MT-3 mRNA and protein. The goal of the present study was to determine if a feature of the in vivo environment could activate MT-3 expression in tumor cell lines having no in vitro expression of MT-3. This was tested by assessing the MT-3 expression of human tumor cell lines before heterotransplantation into immunocompromised nude mice and in the tumors produced by these heterotransplanted cell lines. The results demonstrated that tumorigenic cultures resulting from the treatment of the UROtsa bladder cell line with cadmium or arsenite had no in vitro expression of MT-3 mRNA or protein, but had high levels of expression in the tumors formed in the nude mouse. Likewise, it was shown that the commonly utilized PC-3 prostate cancer cell line had no *in vitro* expression of MT-3 mRNA or protein, but that the tumors produced in nude mouse heterotransplants had high levels of MT-3 mRNA and protein. This finding was further extended by an analysis of MT-3 mRNA and protein expression of the MCF-7, T-47D, Hs578t and MDA-MB-231 breast cancer cell lines under *in vitro* and *in vivo* conditions of growth. These results demonstrate that a factor associated with *in vivo* tumor growth can activate the expression of MT-3 mRNA and protein.

# 277 EXPRESSION OF METALLOTHIONEIN 3 PROTEIN IS RESTRICTED IN THE NORMAL BREAST EPITHELIAL CELL LINE, MCF-10A.

M. Sens<sup>1</sup>, V. Gurel<sup>1</sup>, <u>S. H. Garrett<sup>1</sup></u>, <u>S. Somji</u><sup>1</sup> and <u>D. A. Sens<sup>2</sup></u>. <sup>1</sup>Pathology, University of North Dakota, Grand Forks, ND and <sup>2</sup>Surgery, University of North Dakota, Grand Forks, ND.

The third isoform of metallothionein (MT-3) is not expressed in normal breast epithelial cells, but is overexpressed in some breast cancers and its expression is associated with a poor disease outcome. The goal of the present study was to determine the effect that overexpression of MT-3 would have on the immortal, but non-tumorigenic, MCF-10Â human breast epithelial cell line. The MCF-10A cells were stably transfected with the MT-3 coding sequence and MT-3 mRNA was determined by RT-PCR and MT-3 protein by immunoblot. It was demonstrated that the wild type MCF-10A cell had no basal expression of MT-3 mRNA or protein. Transfection of the MCF-10A cells with the MT-3 coding sequence resulted in a high level of expression of MT-3 mRNA but no MT-3 protein. Exposure of the MT-3 transfected MCF-10A cells to lethal and sub-lethal levels of Cd+2 did not cause expression of the MT-3 protein, but did result in enhanced expression of the MT-1 and MT-2 isoform proteins. As a control, the MT-3 gene was also transfected in the normal bladder epithelial cell line UROtsa, and in the human proximal tubule cell line, HK-2. Treatment of these cell lines with cadmium resulted in an increase in MT-3 protein in the HK-2 cells but not in the UROtsa cell line. These studies demonstrate that the normal human breast epithelial cell and the bladder epithelial cell can restrict the expression of the MT-3 protein and that MT-3 protein expression can be controlled at the post-transcriptional level.

# 278 EFFECT OF CADMIUM ON THE EXPRESSION OF METALLOTHIONEIN 1 AND 2 PROTEIN IN THE NORMAL BREAST TISSUE AND THE CELL LINE MCF-

V. Gurel<sup>1</sup>, D. A. Sens<sup>2</sup>, S. Somji<sup>1</sup>, S. H. Garrett<sup>1</sup> and M. Sens<sup>1</sup>. <sup>1</sup>Pathology, University of North Dakota, Grand Forks, ND and <sup>2</sup>Surgery, University of North Dakota, Grand Forks, ND.

The protein representing the first and second isoforms of metallothionein (MT-1/2) has been shown to be overexpressed in a sub-set of human breast cancers and that overexpression correlates to poor prognosis, type of tumor histology, estrogen receptor status and lymph node involvement. The goals of the present study were to determine the expression of MT-1 and MT-2 mRNA and MT-1/2 protein in normal human breast tissue and in the MCF-10A cell line, and to determine the effect cadmium exposure would have on MT mRNA and protein expression in the MCF-10A cells. It was shown that normal breast tissue expressed very high levels of MT-1X and MT-2A mRNA, but only low amounts of the MT-1/2 protein. Microdissection of normal breast tissue demonstrated that these mRNAs were present in high abundance in ductal breast epithelial cells. The MCF-10A cells were shown to have a very similar pattern of expression of the MT mRNAs and MT-1/2 protein to that found in normal breast tissue. Treatment of the MCF-10A cells with cadmium at both lethal and sub-lethal levels for up to 16 days was shown to result in negligible increases in MT mRNA, but in a large increase in the accumulation of MT-1/2 protein. Treatment of confluent MCF-10A cells with 7 micromolar cadmium increased MT-1/2 protein from 3.2 nanogram/microgram total cell protein at the time of addition to 52.8 nanogram/microgram total cell protein following 10 days of exposure. These studies provide evidence that cadmium can increase the accumulation of MT-1/2 protein in the human breast epithelium through a mechanism involving post-transcriptional control.

# 279 METALLOTHIONEIN AND GLUTAMYL-CYSTEINE LIGASE GENE EXPRESSION IN METAL-EXPOSED DEER MICE

H. LaVire<sup>1</sup>, S. Srinouanprachanh<sup>1</sup>, M. Hooper<sup>2</sup>, S. McMurry<sup>2</sup>, G. Cobb<sup>2</sup> and T. Kavanagh<sup>1</sup>. <sup>1</sup> University of Washington, Seattle, WA and <sup>2</sup> Texas Tech University, Lubbock, TX.

Site studies conducted at the Anaconda Smelter Site (Montana) show varying tissue concentrations of As, Pb, Cd, Cu, and Zn in small mammal tissues. This provides a unique opportunity to study heavy metal mixture dose-responses for gene expression in tissues from wild rodent populations. Glutamyl-cysteine ligase (GCL, the

initiating enzyme in glutathione synthesis) and metallothionein (MT) levels are known to increase with heavy metal exposures in mammalian tissues; this increase in GCL expression after semi-chronic heavy metal exposures suggests oxidative stress, however few field-based studies have been conducted. Here, GCL and MT expression levels in livers of Peromyscus maniculatus collected from Anaconda Smelter were measured with real-time quantitative PCR (RT-PCR) and Western blot analysis. Analyses of RT-PCR data indicate a significant correlation between gene expression of the normalizing gene  $\it Gapdh$  and  $\it Cd$  exposure (p<0.001), several endpoint correlations remain significant when normalized by other factors (i.e. RNA loaded,  $\beta$ -actin). These include correlations between Gclc and Cd and between Gclm and Cd, Cu, and Pb in females (p<0.05). No correlation was found for MT and any of the metals. A correlation was found between Gclc and Gclm expression for males and females (p<0.05), suggesting possible co-regulation. Also, Western blot analyses reveal several significant post-transcriptional trends. Most notable are an overall increase in GCLm protein level with Pb exposure (p<0.01), and increases in both GCL subunits in males with Pb exposure (p<0.05). The lack of correlations between MT and heavy metals could be due to post-transcriptional regulation or due to adaptation. In conclusion, under chronic exposure of small mammals to heavy metal mixtures, correlations between heavy metals (particularly Cd and Pb) and GCL subunits suggest that it may be a better biomarker of chronic heavy metal exposure under these conditions. Sponsored by NIEHS grants P42ES04696 and P30ES007033.

# 280 ACUTE CADMIUM EXPOSURE ENHANCES AP-1 DNA BINDING AND INDUCES CYTOKINES EXPRESSION AND HEAT SHOCK PROTEIN 70 IN HEPG2 CELLS.

V. Souza<sup>1</sup>, C. Escobar<sup>1</sup>, L. Gomez-Quiroz<sup>1</sup>, L. Bucio<sup>1</sup>, E. Hernandez<sup>1</sup>, E. Chavez Cossio<sup>2</sup> and <u>C. Gutierrez-Ruiz<sup>1</sup></u>. <sup>1</sup>Cs de la Salud, UAM-I, Mexico, DF, Mexico and <sup>2</sup>Bioquimica, Instituto Nacional Cardiologia Ignacio Chavez, Mexico, DF, Mexico.

Cadmium has been regarded as one of the inflammation-related xenobiotics. This study was undertaken to examine the effects of low cadmium concentrations in HepG2 cells in the IL-1β, TNF-α, IL-6 and IL-8 expression, production of Hsp70 and the activation of nuclear factors AP-1 and NF-KB. Also, the participation of TNF-α and oxidative stress in AP-1 activation was evaluated. RNA was isolated from HepG2 cells after 0.5, 1, 3 or 6 h incubation with 1, 5 or 10  $\mu$ M CdCl2. TNF-α and IL-1β presented a maximum response after 1 h treatment, while IL-6 and IL-8 maximum response was after 3 h treatment. The Hsp70, determined by Western blot, was constitutively produced, and it increased after 3 h Cd treatment. NF-KB activation, determined by EMSA, was not increased as a result of Cd treatment. DNA binding of AP-1 was detected and increased, with time up to 4 h with an increment of 24 times control value with 5µM CdCl2. The HepG2 cells were pretreated with anti-TNF- $\alpha$  antibody or 1 mM N-acetyl cysteine (NAC) one hour before Cd treatment. Anti-TNF-α treatment reduced 67% AP-1 activation, while NAC 47.5%. These data indicate that, Cd induced TNF- $\alpha$  and IL-1 $\beta$ , that probably, activate AP-1 transcription factor and IL-6 and IL-8 were induced. Anti-TNFα and NAC partially inhibited AP-1 activation. All imply that, a number of factors participate in AP-1 cadmium-induced activation. The Hsp70 is produced by the HepG2 cells after cadmium treatment, and probably has a role in the non-participation of NF-κB in the cellular response.

# 281 PARTICULATE HEXAVALENT CHROMIUM-INDUCED CLASTOGENESIS IS MEDIATED BY EXTRACELLULAR DISSOLUTION THAT DOES NOT REQUIRE PARTICLE-CELL CONTACT.

H. Xie<sup>1</sup>, A. Holmes<sup>1</sup>, <u>S. Wise</u><sup>1</sup>, N. Gordon<sup>2</sup> and <u>J. P. Wise</u><sup>1</sup>. <sup>1</sup>Wise Laboratory of Environmental and Genetic Toxicology, Center for Integrated and Applied Environmental Toxicology, University of Southern Maine, Portland, ME and <sup>2</sup>Department of Chemistry, University of Southern Maine, Portland, ME.

Hexavalent chromium (Cr(VI)) is a well-established human lung carcinogen commonly encountered in occupational settings and in the environment. Water solubility is a key factor in the carcinogenicity of Cr (VI), with the particulate compounds more potent carcinogens. We investigated the role of particle dissolution in WTHBF-6 cells, a human lung cell line, after exposure to particulate lead chromate (LC). We found that LC was clastogenic in a concentration-dependent manner with 0.1, 0.5, and 1 ug/cm² LC damaging 10, 27 and 37% of metaphases respectively, while 5, and 10 ug/cm² caused complete cell cycle arrest. We further found concentration-dependent increases of intracellular Cr levels of 1.3, 5.3, 8.4 and 16.7 uM/cell and extracellular Cr levels of 0.3, 1.2, 1.9 and 4.7 uM at these concentration. We investigated particle internalization using electron microscopy and found that in as little as 1 h, LC particles were internalized in tight vacuoles after cells were exposed to the four highest concentrations. In addition, there was an apparent relative increase with concentration; however, there was no particle internal

ization at the lowest dose (0.1 ug/cm²) even after 24 h. Further, we found no lysosomal association with the vacuoles containing particles suggesting that intracellular dissolution may not have occurred. Co-treating the cells with LC and vitamin C decreased extracellular dissolution of the particles and eliminated both uptake of ionic chromium and the clastogenic activity of the particles, but had no effect on internalization of the particles. Thus these data indicate that LC clastogenesis is mediated by the extracellular dissolution of particles and not intracellular dissolution or internalization. This work was supported by NIEHS grant 1R01 ES10838-01 (I.P.W.)

### 282 CHARACTERIZATION OF DNA DAMAGE INDUCED BY DEPLETED URANIUM.

M. Yazzie<sup>1</sup>, C. Salanga<sup>1</sup>, A. M. Hays<sup>2</sup>, R. Ahmad<sup>2</sup>, E. R. Civitello<sup>1</sup>, <u>R. C. Lantz</u><sup>2</sup> and <u>D. M. Stearns</u><sup>1</sup>. <sup>1</sup>Chemistry and Biochemistry, Northern Arizona University, Flagstaff, AZ and <sup>2</sup>Cell Biology and Anatomy, University of Arizona, Tucson, AZ.

The overall goal of this research is to measure the chemical genotoxicity of uranium. Previous work has shown that depleted uranium as uranyl acetate produced single strand breaks in plasmid DNA in the presence of vitamin C (ascorbate) in vitro. The purpose of the current study was two-fold: (1) to characterize the molecular mechanism of UA-induced strand breaks in vitro; and (2) to measure the production of DNA strand breaks in cultured cells. Incubation of depleted uranium as uranyl acetate with ascorbate in the presence of thymidylyl (3'-5')-2'-deoxyadenosine (dTpdA) produced hydrolysis of the dinucleotide by HPLC; however, the reaction was not as efficient as that of cerium(IV) with dTpdA. These data are consistent with the interpretation that uranyl ascorbate-induced strand breaks are not completely radical-mediated in vitro. Because either metal-catalyzed DNA hydrolysis or radical-induced DNA fragmentation may be readily repaired in cultured cells, the presence of DNA damage was sought in the Chinese hamster ovary (CHO) EM9 line, which is sensitive to DNA strand breaks. The presence of DNA strand breaks was detected by alkaline single cell gel electrophoresis (the comet assay). Greater tail moments were observed in the CHO EM9 line relative to the CHO AA8 line for all doses of H2O2 (40 - 80 uM) and uranyl acetate (50 - 300 uM) tested. Understanding the molecular mechanisms through which depleted uranium reacts with DNA will help to elucidate mechanisms of lung and other cancers in populations exposed to uranium. Supported by NIH grants CA096320 and CA096281.

# 283 HPRT MUTATIONS INDUCED BY URANYL ACETATE IN CHINESE HAMSTER OVARY AA8 AND EM9 CELLS: EFFECT OF DNA REPAIR INHIBITION.

D. M. Stearns<sup>1</sup>, V. H. Coryell<sup>1</sup>, A. Bradley<sup>1</sup>, A. M. Hays<sup>2</sup>, N. Denipah<sup>2</sup> and R. C. Lantz<sup>2</sup>. <sup>1</sup>Chemistry and Biochemistry, Northern Arizona University, Flagstaff, AZ and <sup>2</sup>Cell Biology and Anatomy, University of Arizona, Tucson, AZ.

Questions about possible adverse health effects from environmental and occupational exposures to uranium have arisen as a result of uranium mining, residual mine tailings, and the use of depleted uranium in the military. Previous work has shown that depleted uranium as uranyl acetate (UA) produced DNA strand breaks in the presence of vitamin C. The purpose of the current study was to measure the toxicity of depleted uranium as UA in mammalian cells. The cytotoxicity and genotoxicity of UA was compared in the parental CHO AA8 line, as well as the CHO EM9 line, in which the repair of DNA strand breaks is impaired. Cytotoxicity was measured by clonogenic survival. A dose of 200 uM UA over 24 hr produced 1.8fold greater cell death in the CHO EM9 than the CHO AA8 line, and a dose of 300 uM was 3-fold more cytotoxic. By comparison the CHO EM9 line was 2-fold more sensitive to 100 uM H2O2 than the CHO AA8 line. Mutagenicity at the hypoxanthine (guanine) phosphoribosyltransferase (hprt) locus was measured by selection with 6-thioguanine. A dose of 200 uM UA produced 10-fold higher induced mutation frequency in the CHO EM9 line relative to the CHO AA8 line. The hypothesis that UA was more cytotoxic and genotoxic under conditions of DNA repair inhibition was also supported by the observation that CHO AA8 cells exposed to UA in the presence of sodium arsenite were more sensitive to University(VI) than cells exposed to uranium in the absence of arsenic. These data may have implications for humans exposed to drinking water containing both uranium and arsenic. Supported by NIH grants CA096320 and CA096281.

## 284 MOLECULAR ANALYSIS OF HPRT MUTATIONS INDUCED BY CHROMIUM PICOLINATE IN CHO AA8

V. H. Coryell and <u>D. M. Stearns</u>. Chemistry and Biochemistry, Northern Arizona University, Flagstaff, AZ.

The dietary supplement chromium picolinate (CrPic) has previously been shown to induce mutations at the hypoxanthine guanine phosphoribosyl transferase (hprt) locus in Chinese hamster ovary (CHO) cells; however, the molecular mechanism

underlying this genotoxicity is unknown. The purpose of the current work was to characterize the nature of the mutations caused by this dietary supplement. Cells were exposed to 80 ug/cm2 chromium picolinate for 48 hr, and clones resistant to 6-thioguanine were expanded. The hprt mRNA from 42 mutants was amplified, using reverse-transcriptase polymerase chain reaction (RT-PCR) with a nested PCR, and this amplified cDNA was sequenced. Genomic DNAs of the cDNA deletion mutants were also amplified, using hprt exon-specific primers, and visualized on agarose gels. Thirteen of the mutants had point mutations evident in their cDNA; specifically, 11 had an A-to-T substitution at nucleotide 217 changing amino acid 73 from lysine to a termination signal, and 2 had a T-to-A mutation at nucleotide 220 resulting in a change at amino acid number 74 from phenylalanine to isoleucine. Four mutants were missing exon 6 (one of these was also missing exons 2-3 in its cDNA). Analysis of the genomic DNA of these mutants indicated that the deletion of exon 6 from the cDNA was due to a true genomic deletion of exon 6. Twenty seven other mutations were inferred to be splice site mutations due to the lack of evidence of genomic deletions; specifically one lacked exon 8, one was missing exon 2 (as well as having a point mutation); five mutants were missing exons 2 and 3, seventeen mutants lacked exons 2, 3, and 4; and three mutants lacked exons 2, 3, 4, 5, and 6 in their cDNA but not in their genomic DNA. At this time, the independence of identical mutants is not assumed; however, of the eight different types of mutations observed, 7/8 were putative point mutations. Elucidating the molecular pathways of chromium picolinate mutagenesis will aid in the evaluation of the safety of this human dietary supplement. Supported by NIH grant # CA75298.

## 285 CARCINOGENIC HEAVY METALS, AS<sup>3+</sup> AND CR<sup>6+</sup>, INCREASE THE AFFINITY OF NUCLEAR LIPOCORTIN I HETEROTETRAMER FOR DAMAGED DNAS.

A. Hirata, Y. Hou, <u>G. B. Corcoran</u> and <u>F. Hirata</u>. Pharmaceutical Sciences, Wayne State University, Detroit, MI.

Heavy metals such as  $\mathrm{As}^{3+}$  and  $\mathrm{Cr}^{6+}$  induce gene mutations. Accumulated evidence suggests that while they alone may not be mutagenic, they promote the mutagenic effects of DNA damaging agents. Therefore, these heavy metals apparently modify the DNA replication machinery to promote the translesion DNA synthesis bypassing damaged DNA sites, thereby causing mutations. We have recently demonstrated that purified nuclear lipocortin/annexin I heterotetramer can exhibit both ssDNA binding and helicase activities, essential for the translesion DNA synthesis. In this communication, we investigated its DNA binding and helicase activities with damaed DNA oligonucleotides as templates. Selected individual G\*s in the GTCCACTATTAAAG\*AACGTGGACTCCAACG\*TCAAAGG\*GC-GAAAAACG\*TCTATC-AGGGCGATGGCCCACTACGTGAACCA<sup>-3'</sup>, was replaced in each template by 8-oxo-G. Over various concentrations of the 8-oxo-G DNAs (14G, 30G, 37G and 48G), lipocortin I was found to have higher affinities for these damaged polynucleotides. To examine if heavy metals alter the specificity of lipocortin I for nucleotide sequence at the damage sites or if they alter the affinity of lipocortin I for damaged DNAs, we investigated effects of heavy metals on the DNA binding and DNA annealing activities of lipocortin I with 14G, 30G, 37G and 48G in the presence of various concentrations of As3+ and Cr6+. Concentrations of these heavy metals required for half maximal activities were essentially same with those (3 and 2.5 "M, respectively) for the naive oligonucleotide template, P1. When concentrations of 14G were varied, they apparently increased the affinity for the template rather than stimulated the maximal activity. From these results, we concluded that the carcinogenic heavy metals, As3+ and Cr6+, increased the translesion helicase activity of lipocortin I by replacing Ca<sup>2+</sup>, thus facilitating translesion DNA synthesis. (Supported in parts by ES10814 from NIEHS, NIH.)

## 286 CHROMOSOMAL INSTABILITY AS CONSEQUENCES OF MICROTUBULE INJURY BY CADMIUM.

<u>I. Chou</u><sup>1</sup>, Y. Zhao<sup>1</sup> and W. Li<sup>2</sup>. <sup>1</sup>Microbiology, Boston University School of Medicine, Boston, MA and <sup>2</sup>Biochemistry, Boston university School of Medicine, Boston, MA.

Cadmium[Cd(II)], a known human carcinogen, induces depolymerization of microtubules (MT), a major element of the cytoskeleton. MT are fundamental in regulation of cell division. Spindle MT organize chromosomes and are critical in pulling chromatids toward the spindle poles in mitosis. Thus, MT structural damage by Cd(II) could translate into functional deficiencies resulting in chromosomal abnormality. We tested this possibility by examining Cd(II) effects on cell cycle progression, cell division aberrations and chromosomal damage in cultured rat lung fibroblasts (RFL6). FACS analysis showed that serum-stimulated cell cycle progression was inhibited by Cd(II) in a dose (0, 2, 4 and 8  $\mu$ M)-dependent manner. Fluorescent double staining of spindle MT and chromosome showed that Cd(II)-exposed cells exhibited various cell division aberrations manifested by a defect in or the absence of spindle MT accompanied by chromosomal lagging, scattering, clus-

tering, etc. (in 60% of 300 cells counted), as compared to control cells (in only 2% of 300 cells counted). Furthermore, chromatid structural damage revealed by Giemsa-staining in hypotonically prepared chromosomes, e.g., gaps, breaks, deletions, etc., occurred at metaphase in 25% of 8  $\mu M$  Cd-treated cells compared to 3% in the control. In addition, Cd(II) treatment markedly increased the number of cells with anuploidy and polyploidy, reaching 25% and 18% in 8  $\mu M$ -Cd(II) exposed cells in comparison to 12% and 11% in controls, respectively. These results suggest that chromosomal instability manifested as disorientations and structural/numerical aberrations are closely linked to Cd-induced spindle MT damage with relevance to mechanisms of Cd carcinogenesity. (supported in part by NIH grants R01-ES 11164 and R01-ES 11340 and Philip Morris external research program).

### 287 ARSENITE MEDIATES GENE EXPRESSION IN HUMAN BLADDER EPITHELIUM.

X. Zheng<sup>1</sup>, T. G. Bredfeldt<sup>1</sup>, G. S. Watts<sup>2</sup>, S. E. Vaught<sup>2</sup>, A. G. May<sup>2</sup> and <u>A. Gandolfi</u>. <sup>1</sup>Pharmacology/Toxicology, University of Arizona, Tucson, AZ and <sup>2</sup>Arizona Cancer Center, University of Arizona, Tucson, AZ.

Epidemiological studies have demonstrated an association between elevated arsenic levels in drinking water and the incidence of urinary bladder transitional cell carcinomas. The mechanism(s) of this toxicity are not defined, but should involve genetic alteration. We therefore profiled the genes regulated by arsenite in uroepithelia cells using microarray. UROtsa (human urothelium) cells were exposed to 30  $\mu M$  sodium arsenite (AsIII) for 6 hr. The total RNA was isolated from treated and untreated cells followed by labeling with Cy3 or Cy5. The labeled probes were hybridized to a human oligonucleotide microarray (18, 861 genes) fabricated on site by the microarray core service. Hybridizations were performed three times using independent total RNA preparations to ensure reproducibility. The differential expressed genes were identified based on 2-fold cut off up or down and statistical (ttest analysis, p<0.05, after multiple testing correction) significance. A total of 109 altered genes were reported, among them 63 genes were up-regulated and 46 genes were down-regulated. About 20 percent of the up-regulated genes are stress response genes (HMOX1, MT and HSP gene families, etc). Together the altered genes were involved in regulation of cell cycles (CDC10, CCND1), transcription (KRML, SFRS1), translation (ERF4G2), signal transduction (ASIP, MCP), and DNA damage (DDIT3), oncogene (DEK, RPN1). These results are consistent with our previous array study on As(III) on HEK293 cells. Clearly, our array study suggests that arsenite induces complex cellular injury and the cellular adaptation to As(III) is associated with gene expression changes (NIEHS 04940, 06694 and NCI 023074).

# 288 CADMIUM AND HYDRAZINE TOXICITY IN BRL 3A CELLS AND PRIMARY RAT HEPATOCYTES BASED ON BIOCHEMICAL AND GENE EXPRESSION ANALYSIS.

S. Hussain<sup>1</sup>, K. Geiss<sup>2</sup>, J. Schlager<sup>2</sup>, V. Chan<sup>1</sup> and J. Frazier<sup>2</sup>. <sup>1</sup>Air Force Research Laboratory, Mantech Environment, Dayton, OH and <sup>2</sup>AFB, Dayton, OH.

The present study was conducted to compare the toxicity of cadmium and hydrazine in primary hepatocytes and the rat liver cell line (BRL 3A) in order to select the best model cell line for initial toxicity screening of chemical compounds. A comparison of the gene expression pattern of primary rat hepatocytes and BRL 3A cell line was also investigated to further define cell similarities. To obtain similar growth states of primary cells and cell lines, the BRL cell line was cultured until confluent in 6-well plates. DNA synthesis was evaluated by thymidine (3H) incorporation assay and showed a minimum rate of DNA synthesis at confluency suggesting contact inhibited cell stasis. After obtaining similar culture density, the primary hepatocytes and BRL 3A cells were exposed separately to cadmium (Cd) or hydrazine (HzN) for 2 h and further incubated in normal media for 24 h in the absence of test chemical. Biochemical end points for toxicity evaluation were LDH leakage, MTT reduction, GSH, and total ATP content. The BRL cells were found to be more resistant to Cd using all biochemical analysis whereas no difference was found with HzN compared to primary cells. The fluorescence probes YO-PRO-1 and propidium iodide were used to detect apoptotic, necrotic and viable cells in Cd exposed cells. Cd induced apoptosis in BRL 3A cells at 50 µM while a much lower concentration (1 µM) was required in primary rat hepatocytes. The results of DNA fragmentation indicated that BRL cells are more resistant to Cd-induced apoptosis than HzN. Baseline gene expression analysis (Affymetrix Rat Genome U34A) indicated significant differences in gene expression profiles between confluent BRL cells and rat primary hepatocytes. The differences in basal gene expression observed between primary and immortalized BRL 3A cells appear to support the increased sensitivity of primary cells to Cd exposure.

CHROMIUM INHIBITS TRANSCRIPTION FROM PAH-INDUCIBLE PROMOTERS BY BLOCKING THE RELEASE OF HDAC AND PREVENTING THE BINDING OF P300 TO CHROMATIN

Y. Wei<sup>1,3</sup>, M. Huang<sup>1</sup>, M. Sartor<sup>1</sup>, K. Tepperman<sup>2</sup> and <u>A. Puga<sup>1</sup>. <sup>1</sup>Center for Environmental Genetics and Department of Environmental Health, University of Cincinnati, Cincinnati, OH, <sup>2</sup>Department of Biological Sciences, University of Cincinnati, Cincinnati, OH and <sup>3</sup>MPH Program, Fort Valley State University, Fort Valley, GA.</u>

Chromium exposure has been shown to alter inducible gene expression, possibly due to the formation of chromium-DNA adducts, chromium-DNA cross-links, or to the disruption of transcriptional activator/coactivator complexes. Earlier studies from this laboratory have demonstrated that exposure of mouse hepatoma Hepa-1 cells to chromate inhibits the induction of the Cyp1a1 and Nqo1 genes by dioxin. To test the hypothesis that chromium blocks gene expression by interfering with the assembly of productive transcriptional complexes in the promoters of inducible genes, we have studied the effects of Cr on the expression of genes induced by B[a]P, another AHR agonist, and used chromatin immunoprecipitation assays to characterize the disruption of Cyp1a1 gene expression by chromium at the promoter level. Real-time RT-PCR and luciferase reporter gene assays showed that exposure of Hepa-1 cells to chromium caused a dose-dependent inhibition of both B[a]P-induced Cyp1a1 mRNA and luciferase activity. High density microarray analysis revealed that the inhibitory effect of chromium on B[a]P-dependent gene induction was generalized, affecting the inducibility of over 50 different genes involved in a variety of signaling transduction pathways. Immunoprecipitation of chromatin with anti-histone deacetylase-1 (HDAC-1) and anti-p300 antibodies showed that chromium prevented the B[a]P-dependent release of HDAC from Cyp1a1 chromatin, blocking the binding of p300 to the Cyp1a1 transcriptional complex and inhibiting gene transcription. These results provide a mechanistic explanation to the well-known observation that chromium inhibits inducible, but not constitutive gene expression. (Supported by NIH grants ES010807, P42 ES04908, P30 ES06096 and by a grant from Phillip Morris USA).

## 290 C-TERMINAL DELETION MUTANT OF MRE-BINDING TRANSCRIPTION FACTOR-1 INHIBITS MRE-DRIVEN GENE EXPRESSION.

T. Kimura<sup>1</sup>, N. Itoh<sup>2</sup>, T. Sone<sup>1</sup>, K. Tanaka<sup>2</sup> and M. Isobe<sup>1</sup>. <sup>1</sup>Department of Toxicoligy, Faculty of Pharmaceutical Sciences, Setsunan University, Hirakata, Japan and <sup>2</sup>Department of Toxicoligy, Graduate School of Pharmaceutical Sciences, Osaka University, Suita, Japan. Sponsor: M. Cherian.

MRE-binding transcription factor (MTF)-1 activates transcription in response to oxidative stress and regulates the expression of some cytoprotective factor genes, such as metallothionein, γ-glutamyl systeine synthetase and Cu/Zn-SOD. Therefore, it is thought that MTF-1 plays a role in cellular stress response. However, the physiological role of MTF-1 remains unclear because of lacking MTF-1 specific activator and/or inhibitor. To obtain MTF-1 specific inhibitor, we construct C-terminal deletion mutant of MTF-1 (MTF $\Delta$ C). The MTF $\Delta$ C could bound MRE, and compete MTF/MRE complex formation. Transient expression of MTFΔC could inhibit MRE-driven gene expression in HepG2 cells. Thus, MTFΔC was dominant-negative mutant of MTF-1. HepG2 cells stably expressing MTFΔC showed increased susceptibility to the cytotoxic effects of tert-butyl hydroperoxide (tBH). Furthermore, we constructed the recombinant adenovirus Ad5MTFΔC, contains an MTFΔC construct. Infection of the virus inhibited endogeneous MTF-1 and increased susceptibility to the cytotoxic effects of tBH. These results indicated that MTF-1 might help to control cellular redox state. Two other regultors of cellular stress response, namely c-Jun and NF-kB, could inhibit by the regulator specific inhibitors, such as a deletion mutant of c-Jun which acts as dominant-negative mutant, a mutated form of IκBα which acts as a superrepressor of NF-KB activity. The specific inhibitors were of utility value for clarify the role of c-Jun and NF-κB. The MTF-1 specific inhibitor, MTFΔC, might be useful tool to investigate the role of MTF-1.

## 291 THE TWO ISOFORMS OF RAT METALLOTHIONEIN ARE COORDINATELY REGULATED *IN VIVO*.

D. M. Todd<sup>1, 2</sup>, N. DelRaso<sup>2</sup>, J. Gearhart<sup>3, 2</sup>, V. Chan<sup>3, 2</sup>, D. Mahle<sup>3, 2</sup> and J. M. Frazier<sup>2</sup>. <sup>1</sup>Wright State University, Dayton, OH, <sup>2</sup>AFRL/HEST, Wright-Patterson AFB, OH and <sup>3</sup>ManTech Environmental Technology, Inc., Dayton, OH.

Metallothionein (MT) is an inducible protein whose unique structure contributes to its ability to detoxify heavy metals. Cadmium (Cd), which is an environmental pollutant and a hazard to both humans and animals, is detoxified by binding to MT. This study focuses on only MT I and MT II and limited information has been reported about their pattern of mRNA expression. This study investigated the hy-

pothesis that the two isoforms of rat metallothionein are coordinately regulated in vivo. Untreated rats were compared with treated rats that were exposed to 0.5, 1.0 or 2.0 mg/kg Cd acetate and the MT levels were determined by Real-Time PCR at various time points (0, 0.5, 1, 3, 6, 9, 12, 18 and 24 hours). The fold increase in MT expression was determined using the comparative C<sub>T</sub> method and plotted versus time. MT I exhibits a similar induction pattern at the 0.5, 1.0 and 2.0 mg/kg doses up to the 6 hour time point. By 12 hours both the 0.5 mg/kg and 1.0 mg/kg doses decline to baseline levels whereas the 2.0 mg/kg dose remains elevated until 24 hours. MT II's pattern of induction is similar for all three doses up to 9 hours. At 12 hours, the 2.0 mg/kg dose increases slightly and then decreases at 24 hours. The 0.5 mg/kg and 1.0 mg/kg doses of MT II both decline at the 12 hour time point and increase up to 24 hours. In comparing MT I and MT II expression, the results demonstrate that in all doses MT II peaks first followed by a decline at 3-6 hours at which time MT I peaks. As MT I decreases at 9 hours, MT II peaks at 9 hours. At the 0.5 mg/kg and 1.0 mg/kg doses both MT I and MT II decrease at 12 hours followed by an increase through to 24 hours. Even though MT I and MT II show similar induction patterns after 9 hours across all doses, the initial time points (<6 hours) exhibit a much different response. After comparing MT I and MT II mRNA patterns of induction, it is evident that the two isoforms are not coordinately regulated in vivo.

## 292 TOXICOGENOMICS OF DRINKING WATER ARSENIC IN VIVO: EFFECTS OF REPLICATES ON MICROARRAY ANALYSIS.

J. C. Davey<sup>1</sup>, <u>A. S. Andrew<sup>1</sup></u>, <u>A. Barchowsky<sup>2</sup></u>, <u>N. V. Soucy<sup>1</sup></u>, D. D. Mayka<sup>1</sup>, <u>R. Lantz<sup>3</sup></u>, A. Hays<sup>3</sup> and <u>J. W. Hamilton<sup>1</sup></u>. <sup>1</sup>Pharmacology & Toxicology, Dartmouth Medical School, Hanover, NH, <sup>2</sup>Environmental & Occupational Health, University of Pittsburgh, Pittsburgh, PA and <sup>3</sup>Cell Biology & Anatomy, University of Arizona, Tucson AZ.

Chronic exposure to low levels of arsenic in drinking water is associated with increased risk of lung cancer, cardiovascular disease and other diseases. The mechanisms underlying these various adverse effects are not known. As one approach, we have examined the effects of arsenic on gene expression in various target tissues using a mouse model. Affymetrix arrays of differential gene expression in lung tissue were used to examine the statistical impact of biological replication in deciphering functional genomics data. Three adult male C57BL/6 mice each were treated with or without 50 ppb arsenic(III) trioxide in drinking water for 5 weeks. Lung RNA from individuals was hybridized separately to Affymetrix mouse 430(A) 22, 000 gene probe arrays. With an n=1, comparison of individual control v. treated arrays for differential expression gave a range of 61 to 759 genes differing by 1.5 fold or greater, depending on the data pairs analyzed. Increasing the replication from n=1 to n=2 for control and treated and using coefficient of variance analysis narrowed the scope and range to 22-37 differentially expressed genes but with only partial overlap of resulting gene lists. Increasing replication to n=3 using the same analysis resulted in 25 differentially expressed genes with partial overlap to n=2 lists. A similar statistical trend was seen with analysis of heart array data. Differential gene expression was further statistically analyzed with the n=3 data sets using normalization with dCHIP/MBEI and Robust Multichip Analysis (Iobion) followed by statistical analysis using Bayesian statistics, SAM (Significance Analysis of Microarrays), ANOVA and simple fold change variation with similar results. These results indicate the importance of biological replication and multiple statistical comparisons in functional genomics studies. Supported by NIEHS SBRP grants ES07373 and ES04940.

# 293 DOSE-DEPENDENT ALTERATION OF OXIDATIVE STRESS AND DNA REPAIR GENE EXPRESSION BY DIMETHYLARSINIC ACID [DMA(V)] IN TRANSITIONAL EPITHELIUM OF URINARY BLADDER FROM FEMALE F344 RATS.

B. Sen<sup>1, 2</sup>, <u>A. Wang</u><sup>3</sup>, S. D. Hester<sup>1</sup>, J. L. Robertson<sup>3</sup> and <u>D. C. Wolf</u><sup>1</sup>.

<sup>1</sup>Environmental Carcinogenesis Divison, USEPA, Research Triangle Park, NC,

<sup>2</sup>NRC, Research Triangle Park, NC and <sup>3</sup>VA-MD College of Veterinary Medicine,

Blackshurg, VA.

Millions of people are at risk from drinking arsenic (As) contaminated water and exposure is associated with an increased incidence of urinary bladder cancer. DMA(V) is a major methylated metabolite of inorganic As and results in dose-dependent increase in urinary bladder tumors in F344 rats. The tumors arise from the transitional epithelium. Study of this target cell population is critical in understanding molecular events that develop following exposure. Enhanced cell proliferation, oxidative damage, and loss of DNA repair fidelity are implicated in As mediated toxicity and carcinogenicity. Simultaneous interactions of these effects may be important in As mediated neoplasia in the transitional epithelium of the urinary bladder. Female F344 rats were treated with DMA(V) (1, 4, 40 or 100 ppm) in the drinking water continuously for 28 days. After treatment, rats were euthanized, the bladder removed, flushed with saline, infused with Trizol TM and the contents were removed and frozen. Total RNA from the transitional epithelium was ex-

tracted and gene expression analysis using a custom spotted array with 4, 362 rat genes was performed. Analysis (GeneSpringTM) showed that 6.5% of all genes passed the statistical filter (1 way ANOVA, p<0.05). Genes involved in DNA repair and cellular response to oxidative stress were significantly altered. DMA(V) was also modulated expression of genes associated with protein degradation and several oncogenes. There was a dose-dependent response to the pattern of gene expression. As compared with controls, expression levels of most genes were up to 3-fold increased after 4ppm and decreased after 40ppm. Detection of genome wide dose-dependent effects in the target cell population may result in the development of reliable and sensitive markers of As toxicity and carcinogenicity. This abstract does not reflect EPA policy.

### 294 AGE-RELATED SUSCEPTIBILITY: A GENOMICS APPROACH

J. E. Royland. Neurotoxicology Division, USEPA, Durham, NC. Sponsor: S. Padilla. By the year 2030 more than 70 million Americans will be over the age of 65. These older adults are a subpopulation that may have special susceptibility to toxic insult due to critical characteristics of their life-stage. Current EPA testing guidelines do not identify the elderly as a special at risk group, however new initiatives have been implemented that focus research on this segment of the population. Monitoring global patterns of gene expression by microarray analysis allows one to examine multiple physiological mechanisms simultaneously. Our efforts are focused on pathways important in toxicological assessment. That is, pathways involved in ROS generation and elimination, enzymes involved in DNA maintenance and repair and genes that have wide ranging function in regulation of cell processes such as cell adhesion molecules, transcription factors and proteins in key signal transduction pathways. We used a commercial rat toxicology array (Atlas Rat Toxicology 1.2 from Clontech) to examine steady state expression levels of genes that have the potential to contribute to susceptibility. Hippocampus and striatum, brain areas associated with deficits in the aged, from the brains of non-dosed young (3 mos) and aged (23 mos) male Fisher rats were compared. Over 150 genes were found to be differentially expressed between the two age groups. Our data analysis concentrates on identifying and interpreting expression profiles in the different brain areas to determine potential region specific, age-related sensitivities. This abstract does not

295 THE ROLE OF HEME-OXYGENASE (HO-1) AND THIOREDOXIN IN RAT HIPPOCAMPAL ASTROCYTES PRETREATED WITH EBSELEN.

necessarily reflect USEPA policy.

D. Hardej and L. D. Trombetta. Pharmaceutical Sciences, St. John's University, New York NY

Ebselen is a synthetic seleno-organic compound shown to act as a potent antioxidant and anti-inflammatory agent. It has been suggested that increases in thioredoxin(Trx) may play a role in cytoprotection by ebselen. Thioredoxins are a class of small 12KDa redox proteins involved in protection against oxidative stress and scavenging of free radicals. Heme-oxygenase 1 (HO-1) is a 32KDa protein that is induced by toxic insults such as exposure to metals, and UV radiation. Induction of HO-1 has been demonstrated to decrease cytotoxicity and deficiencies to exacerbate toxicity. Previous work in this laboratory has shown that ebselen induces HO-1 in rat hippocampal astrocytes in a dose dependent manner. Transcriptional sites NF-KB and AP-1 have been demonstrated to be involved in regulation of both HO-1 and Trx. The purpose of this study was first, to determine if ebselen induces Trx in a dose dependent manner as was seen with HO-1. Secondly, to determine the role HO-1 induction might play in cytoprotection by ebselen. Previously, 24h pretreatment with 30umµM ebselen was demonstrated to significantly protect against 250 and 500µM cisplatin toxicity in such cells. Since HO-1 and Trx have similar transcriptional regulation, this study examines the relationship of ebselen on HO-1 and Trx induction. Cells were pretreated with ebselen and HO-1 antisense oligonucleotides to block transcription of HO-1 to determine if inhibition would affect ebselen's ability to protect against cisplatin toxicity. Results indicate that treatment of rat astrocytes with 60 and 120µM ebselen results in a significant dose dependent increase in Trx. Blocking of HO-1 with antisense oligonucleotides does not decrease ebselen's cytoprotection against cisplatin toxicity. We conclude that ebselen induces both Trx and HO-1 and such induction may be related to cytoprotection by ebselen.

296

ACUTE AND REPEATED INHALATION OF TOLUENE BY RATS PERFORMING A SIGNAL DETECTION TASK LEADS TO BEHAVIORAL TOLERANCE ON SOME PERFORMANCE MEASURES.

W. M. Oshiro and <u>P. J. Bushnell</u>. Neurotoxicology Division, USEPA, Research Triangle Park, NC.

Previous work showed that trichloroethylene (TCE) impairs accuracy and latency in a signal detection task (SDT) in rats, and that these effects abate during repeated exposures if rats inhale TCE during SDT testing. The present experiment compared the effects of acute and repeated exposure to toluene, another commonlyused solvent. Sixteen male, Long-Evans rats were trained to perform the SDT. Upon completion of training, rats were divided into 2 groups (n=8) with equivalent accuracies and response latencies. In Phase 1, concentration-effect functions were determined for toluene (0, 1200, 1600, 2000, 2400 ppm) in both groups. In this phase, toluene reduced the proportion of hits, P(hit); did not affect the proportion of false alarms, P(fa); and increased response times (RT). In Phase 2, Group 1 was exposed to 1600 ppm toluene during 11 daily SDT sessions, while Group 2 performed the SDT in air. The effect of toluene on P(hit) abated in Group 1 during this phase, indicating the development of tolerance to toluene. In Phase 3, concentration-effect functions for P(hit) were re-determined and showed a shift to the right in both groups, indicating that both groups had developed tolerance to toluene. Although there was a trend for Group 1 to show more tolerance on P(hit) measures than Group 2, it was not significant. However, subsequent analysis of corrected P(hit), a measure of overall accuracy, indicated that Group 1 was less sensitive to toluene in Phase 3 than was Group 2. Thus, repeated inhalation of toluene can lead to behavioral tolerance, which can develop after as few as 4 exposures (as occurred in Group 2 during Phase 1). Unlike TCE, however, toluene did not increase P(fa), nor did tolerance develop on the RT measure, indicating a possible difference in the mode of action of these two solvents. (This abstract does not necessarily reflect EPA policy.)

CARBONYL SULFIDE INHALATION PRODUCES BRAIN LESIONS IN F344 RATS. DL MORGAN, PB LITTLE, VC MOSER, DW HERR, AND RC SILLS. NIEHS, Research Triangle Park, NC; PATHOLOGY ASSOCIATES, INC., Research Triangle Park, NC; ORD/NHEERL, USEPA, Research Triangle Park, NC.

D. Morgan<sup>1</sup>, P. B. Little<sup>2</sup>, <u>V. C. Moser<sup>3</sup></u>, D. W. Herr<sup>3</sup> and R. C. Sills<sup>1</sup>. <sup>1</sup>NIEHS, Research Triangle Park, NC, <sup>2</sup>Pathology Associates, Inc., Research Triangle Park, NC and <sup>3</sup>ORD/NHEERL, USEPA, Research Triangle Park, NC.

Carbonyl sulfide (COS) is an intermediate in the production of pesticides and herbicides, and is a metabolite of the neurotoxicant carbon disulfide. The potential neurotoxicity of inhaled COS was investigated in F344 rats. Male rats were exposed to 0, 75, 150, 300, or 600 ppm COS for 6h/d. After 2 exposures to 600 ppm rats exhibited signs of neurotoxicity. Primary lesions included necrosis in the parietal cortex, thalamus, posterior colliculus and anterior olivary nucleus. Male and female rats were exposed to 0, 300, 400, or 500 ppm COS for 12 exposures (6h/d, 5d/w). All 10 males and 4/10 females exposed to 500 ppm were moribund. Rats exposed to 400 ppm had slight gait abnormalities, hypotonia, decreased motor activity and grip strength. Lesions at 400 and 500 ppm included necrosis in the parietal cortex and putamen, and at 500 ppm included bilateral necrosis in the retrospenial cortex, thalamus, posterior colliculus, and olivary nucleus. In a 12-week (6h/d, 5d/wk) study, male and female rats were exposed to 0, 200, 300, or 400 ppm COS. Microscopic lesions were present primarily in the parietal cortex and posterior colliculus of rats exposed to 400 ppm. Occasional areas of necrosis were present in the putamen, thalamus and anterior olivary nucleus. Decreases in brain stem auditoryevoked responses were detected in the posterior colliculus, lateral meniscus and auditory olivary nucleus in rats exposed to 400 ppm COS for 12 weeks. A concentration related decrease in cytochrome oxidase activity was detected in the parietal cortex and posterior colliculus. Cytochrome oxidase activity was decreased at COS concentrations that did not cause detectable lesions, suggesting that brain lesions may be preceded by disruption of the mitochondrial respiratory chain by COS with a subsequent decrease in cellular ATP. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

298

INDUCTION OF C-FOS GENE EXPRESSION IN DIFFERENT RAT BRAIN LOCATIONS, AS AN EARLY RESPONSE OF NEURONAL ACTIVATION, AFTER TREATMENT WITH NMDA ANTAGONISTS.

B. P. de Wergifosse<sup>1</sup>, B. Vanrossomme<sup>1</sup>, W. Dewe<sup>1</sup>, T. Murray<sup>2</sup>, M. J. O'Neill<sup>2</sup> and K. Kramer<sup>1</sup>, <sup>1</sup>Toxicology / Drug Disposition, Eli Lilly and Company, Mont-Saint-Guibert, Belgium and <sup>2</sup>Neurosciences Division, Lilly Research Centre, Windelsham, United Kingdom. Sponsor: C. Thomas.

Introduction N-methyl-D-aspartate (NMDA) antagonists such as ketamine and MK-801 produce behavioural activation syndrome in experimental animals and can precipitate psychotic syndromes in stabilized schizophrenic patients. Immunohistochemical data in cingulate/frontal cortex showed a MK-801-dependent increase of glucose utilisation that coincided with the induction of the immediate early c-fos gene expression. The aim of this study was to use real-time quantitative RT-PCR to study baseline c-fos expression levels and its major sites of induction in different regions of the rat brain following a subcutaneous injection of ketamine or MK-801. Methodology Male Sprague-Dawley rats (n=8) received one

subcutaneous injection of MK-801 (1 mg/kg), ketamine (25 mg/kg) or vehicle (5% glucose). Two hours after treatment, anterior and posterior cingulate cortex, striatum, and hippocampus were dissected from each brain. After total RNA extraction and reverse transcription, cDNA templates were amplified with an in-house optimised ABI Taqman assay (PDAR 4327115). Results Baseline c-fos mRNA levels were found to be brain location specific (frontal cingulate cortex > anterior cingulate cortex > striatum > hippocampus), which may reflect the presence of various cell populations and specific neurotransmitter receptors. MK-801 (1 mg/kg) produced a significant 2.0 to 2.5-fold increase of c-fos gene expression levels in anterior cingulate cortex (p<0.0001). A trend of induction was also observed in frontal cortex and hippocampus (p=0.07 and p=0.08, respectively). Ketamine produced a trend in c-fos induction in hippocampus (p=0.08). No effect was observed in striatum. Conclusions These RT-PCR-based results are in agreement with c-fos immunohistochemistry data in similar brain locations and set baseline data for studies to measure neuro-toxicity or efficacy of similar class of compounds.

## 299 DEVELOPMENT OF A RELIABLE MOUSE MODEL OF VINCRISTINE-INDUCE NEUROPATHY.

F. A. Wininger, S. A. Steinberg and <u>C. Massicotte</u>. Small Animal Clinical Sciences, University of Pennsylvania, Philadelphia, PA.

Vincristine, one of the most frequently used chemotherapeutic agents in humans, predictably produces peripheral neuropathy. In mice, the degree of neuropathy varies significantly with dosing regimen, treatment interval and mouse strain. Moreover, the dose necessary to produce neuropathy can be debilitating, even fatal. Till now, a reliable mouse model of vincristine-induced neuropathy has been lacking. Therefore we chose to develop such a model, both for its own value, and to study its mechanism of neurotoxicity. Vincristine was administered at 1.8mg/kg twice weekly to 25 FVB-1 mice over 8 weeks. To assess the degree of neuropathy induced, a battery of motor function tests including footprint analysis, videotaped gait scoring, and tail nerve conduction velocity (TNCV) were performed at the sixth, seventh and eighth week. Test mice were sacrificed and their sciatic nerves harvested for histopathology. Of 25 mice dosed, 19 displayed the neuropathy, 3 showed no signs of the neuropathy within 8 weeks, and 3 died presumably of other toxic side effects. Videotape gait scoring was an accurate method of detecting the neuropathy with 95 % sensitivity and 100 % specificity. Footprint analysis was also an effective means of detection. Control mouse average stri width  $(3.45 \pm .30 \text{cm})$ and stride length (10.03 ± 1.5 cm) differed greatly from experimental mouse average stride width (3.98  $\pm$  .42 cm) and stride length (7.97  $\pm$  .19 cm). TNCV of affected mice were significantly decreased in comparison to control mice. The average TNCV of control mice was 31.64 m/s (SD 6.55), while the average TNCV of experimental mice was 16.68 m/s (SD 3.70). Mild axonopathy with intact myelin sheaths was detected with light microscopy in the sciatic nerves of affected mice. Vincristine peripheral neuropathy is inducible in the mouse in a short dosing period and is easily detectable, thus making it an ideal model for examining underlying toxic mechanisms. Alteration of Na+, K+-ATPase activity is being studied in our laboratory as a possible cause of vincristine toxicity.

300 ACRYLAMIDE-INDUCED REDUCTIONS OF AXONAL SODIUM AND POTASSIUM CHANNELS IN PROXIMAL AND DISTAL CNS AXONS: COMPARISON WITH PNS

AXONS.

D. W. Sickles, J. Porter, T. Angela and D. Kumiski. Cellular Biology and Anatomy, Medical College of Georgia, Augusta, GA.

Inhibition of the motor protein kinesin and reductions in fast anterograde axonal transport are proposed critical actions of acrylamide (ACR) induced neurotoxicity (Sickles, Neurotoxicology 23:223-251, 2002). To determine whether these effects produce distal protein content deficits, we have used semiquantitative immunofluorescence of Na and K channels in proximal and distal CNS as well as PNS axons of male, Sprague-Dawley rats following high (50 mg/kg/d ip x 10d n=4;80-100 axons each) and low (20 mg/kg/d in drinking water x 48-50d; n=4;80-100 axons each) dosing rates of ACR. Behavioral analysis demonstrated ataxia with bothe high and low dosing rates; hindlimb paralysis was seen at the end of the chronic (49d)treatment. Both high and low dosing rates produced panoramic reductions (-20 to -60%)in K channel fluorescence in the nodes of Ranvier of sciatic and tibial nerve as well as the cuneate (proximal axons) and gracile (distal axons) fasciuli. Na channels were primarily reduced by low chronic dosing, especially in the distal axons of the tibial nerve and gracile fasciculus. Sodium channels were more affected by the low doses (-43% in tibial nerve, -40% in gracile fascicle) while higher doses generally reduced K channels more than Na channels. The results demonstrate reductions in both CNS and PNS axonal proteins following two different dosing rates of ACR known to produce different spectrum of pathologies. For both dosing rates, for both CNS and PNS axons, and for Na and K channels, distal axons were consistently reduced more than proximal ones. The greater effect on ion channels

of distal axons is consistent with inhibition of fast transport as the cause of the reduction. The reductions in K channels were correlated with ataxia of animals in both high and low dosing rates. The reduction in Na channels was correlated with hindlimb paralysis. The differential response on Na and K channels indicates selectivity in the effect of ACR on the dynamics of delivery and/or turnover of ion channels. (Supported by NIEHS # ES 11223)

301 DEXTROMETHORPHAN DOES NOT CAUSE NEURONAL VACUOLATION OR DEGENERATION IN THE POSTERIOR CINGULATE/RETROSPLENIAL

CORTEX OF RATS.

D. L. Shuey<sup>1</sup>, T. P. O'Neill<sup>2</sup>, R. Carliss<sup>1</sup> and R. J. Gerson<sup>1</sup>. <sup>1</sup>Endo Pharmaceuticals Inc., Chadds Ford, PA and <sup>2</sup>WIL Research Laboratories, Ashland, OH.

Dextromethorphan (DX) is a noncompetitive NMDA receptor antagonist. Potent NMDA antagonists (e.g., MK-801) produce specific neuropathologic changes in rodents, characterized by vacuolation and degeneration of neurons in the posterior cingulate/retrosplenial cortex after short-term dosing, and neurodegeneration in other limbic structures after chronic administration. In cultured cerebrocortical neurons, the neurotoxicity of NMDA antagonists is highly correlated with binding to the high affinity PCP receptor site. The affinity of DX and its metabolite dextrorphan for this site, based on Ki, are ~0.007x and 0.06x that of MK-801, respectively. This study was conducted to determine whether DX causes neuropathologic changes characteristic of potent NMDA antagonists. DX was administered orally for 30 days to Crl:CD®(SD)IGS BR rats at doses of 150, 275, or 400 mg/kg (males) and 120 mg/kg (females). The high doses were selected as maximum nonlethal doses, based on a range-finding study, although mortality occurred at the high doses in this study. MK-801, given as a single dose of 9 mg/kg (sc), was the positive control. Animals were killed 4-6, 24-28, or 48-52 h after the final dose. The brains were preserved by in situ perfusion fixation at necropsy, with subsequent immersion fixation. The brains were serial sectioned and evaluated using either amino cupric silver staining of thick frozen sections (right half) or hematoxylin and eosin (left half). Brains of animals given MK-801 showed expected histologic changes, including cytoplasmic vacuolation in neurons of the posterior cingulate/retrosplenial cortex 4-6 h after dosing, and argyrophilia and degeneration 24-48 h after dosing. Neuronal argyrophilia and degeneration in the piriform cortex, indisium griseum, and dentate gyrus were also observed in some animals. There were no findings in any animals given DX. Thus, DX does not produce histologic changes characteristic of potent NMDA antagonists in the brain, even after repeated administration of toxic doses.

THROMBIN PRECONDITIONING PROTECTS AGAINST 6-HYDROXYDOPAMINE, WHILE LARGE DOSES RESULT IN BEHAVIORAL DEFICITS.

J. Cannon, G. Xi, Y. Hua, T. Schallert and R. Keep. Neurosurgery, University of Michigan, Ann Arbor, MI.

Recent research suggests large doses of thrombin lesion dopaminergic neurons of the rat substantia nigra. However, low doses are protective against stroke models when administered prior to lesioning, termed thrombin preconditioning (TPC). Here, the ability of low (1U) and high dose (5U) thrombin to induce behavioral deficits and the ability of TPC to protect against behavioral deficits caused by 6-hydroxydopamine (6-OHDA) were evaluated. Male Sprague-Dawley rats (250-300g) were used. Thrombin groups received 1 (n=7) or 5 (n=7) University of thrombin in 50µL saline onto the medial forebrain bundle (MFB). 6-OHDA animals received stereotaxic injection of either saline (50 µL; n=10) or thrombin (TPC; 1U in 50  $\mu$ L; n=12) onto the MFB 3 days before administration of 6-OHDA (10  $\mu$ g/4  $\mu$ L saline+0.01% ascorbic acid). Behavioral deficits were assessed prior to injection and for 3 weeks after. Vibrissae-elicited placing was measured for both sides and the percentage of unsuccessful placings determined. A forelimb asymmetry score was calculated by observing the use of the left, right or both forelimbs, during rearing. Thrombin (5 University) resulted in significant placing deficits on days 3 (93±7; mean±%SE), 7 (69±18), 14 (69±18) and 21 (14±14), while 1U did not (0±0% at all days). Similarly, significant asymmetry differences were observed on days 3  $(87\pm8 \text{ vs. } 14\pm13)$ , 7  $(65\pm13 \text{ vs. } 5\pm9)$ , 14  $(73\pm7 \text{ vs. } 6\pm7)$ , and 21  $(75\pm6 \text{ vs. } 17\pm10)$ . Neither TPC or saline induced deficits prior to 6-OHDA. The TPC group exhibited a significantly (p<0.05) lower placing deficit on days 7 (22±11 vs. 62±13; mean±%SE) and 21 (4±4 vs. 53±15%) than the saline pretreated group. The asymmetry score for TPC was also significantly (p<0.05) lower than the 6-OHDA group on days 3 (32 $\pm$ 7 vs. 67 $\pm$ 7), 7 (24 $\pm$ 9 vs. 71 $\pm$ 12), 14 (28 $\pm$ 10 vs. 73 $\pm$ 9), and 21 (24 $\pm$ 10 vs. 67 $\pm$ 11). The results indicate that 5U thrombin causes behavioral deficits and TPC provides protection against 6-OHDA. Investigation of the role of thrombin as both a neuroprotective and neurodegenerative agent in Parkinson's disease is warranted.

LONG-TERM SURVIVAL, MIGRATION AND PHENOTYPIC EXPRESSION OF MARROW STROMAL CELLS TRANSPLANTED INTO THE ADULT RAT BRAIN.

T. M. Coyne<sup>1, 2</sup>, D. Woodbury<sup>2</sup> and I. Black<sup>2</sup>. <sup>1</sup>Joint Graduate Program in Toxicology, Rutgers University, Piscataway, NJ and <sup>2</sup>Department Neuorsi. & Cell Bio, UMDNJ Robert Wood Johnson Med. Sch., Piscataway, NJ. Sponsor: K. Reuhl.

Neurotoxic injury in the adult is generally considered irreversible. However, recent findings provide hope that restoration of neuronal function can be fostered through adult stem cell transplantation. We recently differentiated adult bone marrow stromal cells (MSC) differentiate into neurons in vitro. We have now transplanted MSCs in vivo to define their behavior in the intact, adult brain. BrdU-labeled MSCs were grafted into the hippocampus, a region critical for working memory, and the striatum, a region which regulates motor programs. At 2, 6 and 12 weeks post-operatively, MSČ survival, migration, and expression of neural genes were evaluated. At 12 weeks MSC survival was robust in both the hippocampus and striatum. At 2 weeks, the majority of cells transplanted into the hippocampus remained within the dentate hilus injection site with an apparent migratory subpopulation detected more than 1 mm from the graft core. Migration in the hippocampus appeared directed: at 6 and 12 weeks, BrdU-labeled cells were present predominantly along the dorsal leaf of the dentate gyrus. In the striatum, the majority of BrdU-labeled cells were present within the graft core, with apparent migration evident at 2 weeks. Migration within the striatum appeared non-directional, and continued with time: at 6 and 12 weeks, the number of BrdU-labeled cells distal to the graft core increased. Furthermore, small percentage of BrdU labeled cells in both graft regions expressed phenotypic markers of neurons, β-III tubulin and NeuN, and glia, GFAP. Our results suggest that adult MSCs exhibit neuronal ontogenetic processes, surviving, migrating, and expressing neuroglialspecific genes, after transplantation into the adult brain. Moreover, these characteristics encourage the development of neural transplantation strategies utilizing MSCs in the treatment of neurotoxic and neurodegenerative conditions. Support Contributed By: NIEHS (ES67148), NIH (HD23315), NJCSCR, & Zofchak

304 NEUROBEHAVIORAL EVALUATION AND KINETICS OF PEAK AND CONSTANT INHALATORY EXPOSURE TO TOLUENE IN HUMAN VOLUNTEERS.

J. H. Lammers, W. Meuling, L. van der Horst-Groeneveld, R. Pels Rijcken, D. de Groot and <u>V. Feron</u>. *TNO Nutrition and Food Research, Zeist, Netherlands.* 

The health risks of inhalatory exposure to volatile organic solvents may not only depend on the total external dose, but also on the pattern of exposure. It has been suggested that exposure to regularly occurring peak concentrations (peak exposure) may have a stronger impact on the brain than constant exposure. Recent animal experimental studies conducted in our laboratory using relatively high concentrations of toluene have shown different effects on discrimination performance and motor activity during and after exposure, depending on the exposure scenario. Relevance of these findings for humans was evaluated in a double-blind, single dose crossover volunteer study. In two sessions with a one week interval in between, twelve healthy men (age 20-50) were exposed by inhalation for 4 hours to a constant concentration of 40 ppm toluene or to three 30-minutes exposure peaks at 110 ppm during a 4 hours period. Neurobehavioral testing using selected tests from the Neurobehavioral Evaluation System (NES) was performed repeatedly during and after exposure. Blood concentrations of toluene were measured at relevant time points. Toluene concentration in blood increased during constant exposure. Peak concentrations in the test atmosphere were reflected by fluctuating concentrations in blood, with the highest concentration measured at the end of the third exposure peak. No clear changes were observed on neurobehavioral measures of motor performance, attention, perceptual coding and memory, or on measures on mood and affect. Although peak concentrations relevant to occupational settings induce fluctuating concentrations in the blood (and presumably in the brain), these exposure conditions do not seem to induce significant changes in central nervous system function similar to those observed at high concentrations in animals.

305 NEUROPROTECTION AGAINST ENDOGENOUS OXIDATIVE STRESS IN AGING PROSTAGLANDIN H SYNTHASE-1 (PHS-1) KNOCKOUT MICE.

P. G. Wells<sup>1, 2</sup>, A. Ramkissoon<sup>1</sup> and W. Jeng<sup>1</sup>. <sup>1</sup>Pharmacy, University of Toronto, Toronto, ON, Canada and <sup>2</sup>Pharmacology, University of Toronto, Toronto, ON, Canada.

PHS is implicated in neurodegeneration in aging, but the mechanism is unclear. To determine if PHS-1 expression is associated with increased oxidative DNA damage, we examined various brain regions of aging wild-type (+/+) PHS-1- normal, and heterozygous (+/-) and homozygous (-/-) PHS-1-deficient knockout mice for en-

dogenous DNA oxidation evidenced by 8-oxo-2-deoxyguanosine formation, characterized both by high-performance liquid chromatography coupled with electrochemical detection, and by immunohistochemistry. Compared to congenic +/+ PHS-1-normal mice, PHS-1 -/- mice had lower DNA oxidation in the cortex (p<0.002), hippocampus (p<0.02), cerebellum (p<0.002) and brainstem (p<0.04). DNA oxidation was similarly lower in the cortex, (p<0.02) hippocampus (p<0.01) and cerebellum (p<0.001) of PHS-1 -/- than +/- mice (p<0.02, p<0.001), the latter of which had consistently less oxidative damage than +/+ mice. This PHS-1 gene dose-dependent effect was corroborated immunohistochemically, with PHS-1 -/mice exhibiting less localized DNA oxidation than +/+ mice. To determine the potential mechanism for PHS-dependent reactive oxygen species (ROS) formation, purified PHS-1 was incubated in vitro with 2-deoxyguanosine and various endogenous neurotransmitters. Dopamine (p<0.03), L-DOPA (p<0.04) and epinephrine (p<0.04) but not glutamate or norepinephrine were excellent PHS substrates, resulting in PHS-dependent ROS formation that initiated DNA oxidation. These results provide the first evidence that endogenous ROS generated by PHS-catalyzed bioactivation of endogenous neurotransmitters may produce oxidative DNA damage in the CNS. This is consistent with the enhanced neurodegeneration observed in aging mutant mice deficient in the antioxidative enzyme glucose-6-phosphate dehydrogenase (Toxicologist 54: 178, 2000), and provides a novel hypothesis potentially relevant to the mechanisms and risk factors for age-related neurodegeneration. EVIDENCE FOR POSSIBLE STRAIN DIFFERENCES IN RESPONSE TO CLONIDINE IN THE ACCELERATING ROTAROD TEST OF MOTOR CO-ORDINATION IN SPRAGUE-DAWLEY AND HAN WISTAR RATS.

I. Strang<sup>1</sup>, S. Palethorpe<sup>1</sup>, K. Pitts<sup>2</sup>, W. S. Redfern<sup>1</sup>, J. Valentin<sup>1</sup> and <u>T. G. Hammond</u><sup>1</sup>. <sup>1</sup>Safety Pharmacology SAUK, AstraZeneca, Alderley Park, Cheshire, United Kingdom and <sup>2</sup>Drug Discovery DMPK, AstraZeneca, Alderley Park, Cheshire, United Kingdom.

Introduction: The accelerating rotarod is an established test of motor co-ordination in rodents, frequently used in safety pharmacology studies. Objective: To validate this model for use in the evaluation of effects of compounds on motor co-ordination in the rat. Clonidine was used for the pharmacological validation - an alpha-2 adrenoceptor agonist which impairs motor skills in humans [1]. Method: Male Han Wistar (207-256 g) and Sprague-Dawley rats (233-268 g) were given 2 fixed-speed training sessions, followed by 1 accelerating session prior to dosing. Animals were then dosed with one of the following (n = 8 per group): vehicle, clonidine 0.1, 0.3 or 1.0 mg/kg po, and tested 45 minutes later. Blood samples were taken after rotarod testing (1 h 15 min post-dose), and clonidine concentrations in plasma analysed by LCMS-MS. Results: % Impairment of rotarod performance (normalised for vehicle) were as follows: (clonidine 0.1, 0.3 and 1.0mg/kg respectively for each strain) Han Wistar: -30±13% (NS), -11±13% (NS), 24±13% (NS); Sprague-Dawley:  $48\pm13\%$  (p < 0.05),  $79\pm10\%$  (p < 0.01),  $99\pm9\%$  (p < 0.01). Plasma analysis values were: (clonidine 0.1, 0.3, 1.0mg/kg respectively for each strain) Han Wistar: 24±2 ng/ml, 36±1 ng/ml, 50±7 ng/ml; Sprague-Dawley: 17±2 ng/ml, 12±1 ng/ml, 21±3 ng/ml. Conclusion: Despite higher plasma exposure to clonidine in Han Wistar rats, less impairment of motor co-ordination was demonstrated compared to Sprague-Dawley rats. This suggests a potential strain difference in sensitivity to clonidine in this test. Further work is required to assess whether this apparent difference is specific to this pharmacological class. 307 REAL-TIME RT-PCR MONITORED SELECTIVE ALTERATIONS OF GENE EXPRESSION IN MICE INDUCED BY MPTP.

Z. A. Xu, K. McCastlasin, D. Cawthon, W. Slikker and S. F. Ali. Neurochemistry Lab., Division of Neurotoxicology, NCTR, Jefferson, AR.

1-methyl-4-phenyl-1, 2, 4, 6, -tetrahydropyridine (MPTP) is a selective neurotoxin which produces dopamine depletion and causes parkinsonism like symptoms in humans and is used to generate animal models for Parkinson's disease (PD). In this study, C57BL/6N mice were treated with MPTP acutely (3×20mg/kg, 2-h interval) and subacutely (30mg/kg, 5 consecutive days). Mice were then sacrificed at 24 hours (acute study) and 72 hours (subacute study), and brain tissue was collected. Specific genes of dopaminergic system and parkinsonism-related were examined using real time RT-PCR in substantia nigra. Dopamine (DA) concentration and its metabolites were examined using HPLC analysis in striatum. In both dose models, MPTP significantly suppressed expression of tyrosine hydroxylase (TH), dopamine transporter (DAT), and vesicle monoamine transporter (VMAT), coinciding with the pattern of dopamine concentration changes with MPTP treatment. The decrease of DAT was much higher in the acute model (5 folds) than that in the subacute (1.6 fold), which may suggest a recovery of DAT 72 hours after MPTP treatment. Although significant decrease of DA metabolites were found in striatum, there were no change in the expression of monoamine oxidases (MAOa, MAOb) nor catechol O-methyltransferase (COMT) in either model, indicating that the

changes of these enzymes were at the protein level as previously reported. The decrease of a-synuclein expression was only observed in the acute dose model, suggesting different mechanisms between the acute and subacute MPTP treatment. In addition, b-synuclein and parkin were not altered in either animal model. Our study using real-time PCR indicate that MPTP selectively alters gene expression and provide information for clinical studies in PD.

## 308 PROTEIN/DNA ARRAYS INDICATE SELECTIVE ALTERATIONS OF TRANSCRIPTION FACTORS IN MPP'-INDUCED NEUROTOXICITY IN PC12 CELLS.

S. F. Ali, Z. A. Xu, K. McCastlain and W. Slikker. Neurochemistry Lab., Division of Neurotoxicology, NCTR, Jefferson, AR.

MPP+ is the active metabolite of 1-methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP), a compound causing parkinsonism in human and animal models. MPP+treated PC12 cultured cells are frequently used to study dopaminergic neurotoxicity and are a possible model for Parkinson's disease. MPP+ depletes dopamine content and elicits cell death in these cells. Recently, differentiated PC12 cells have been widely used because they represent a more sensitive model than undifferentiated cells. However, the underlying mechanism of MPP+-induced neurotoxicity in PC12 cells is still unclear. In this study, the dose response and time course of MPP+induced DA depletion as well as decreased cell viability were determined at various time points. Protein/DNA-binding arrays were used subsequently to evaluate alterations of the PC12 cellular transcription factors (TF). Thirty-three TFs were identified in untreated cells with Panomics protein/DNA array I; many of them are related to neurotransmission, apoptosis, and oxidative stress. The data were analyzed with the bioinformatic software, Spotfire 7.1. K-means clustering identified five different patterns of protein/DNA-binding alterations, and modified Spotfire line charts were used to show the fold (%) changes from control with MPP+ treatment. 6 of the 33 TFs increased and 5 decreased above 50% of control with MPP+ treatment. In addition, 3 TFs decreased within the range of 25-50%. The alterations of these TFs were correlated to the changes of DA concentration and cell viability, indicating a complex mechanism of MPP\*-induced neurotoxicity in PC12 cells. These data indicated that MPP+ induced selectively altered TFs in PC12 cells, and may provide mechanistic information as a basis for animal studies with MPTP and clinical studies for Parkinson's disease.

## THE INJURED NEURON / PHAGOCYTIC MICROGLIA RATIO "R" REVEALS THE PROGRESSION AND SEQUENCE OF NEURODEGENERATION.

R. L. Jakab and J. F. Bowyer. Neurotoxicology, NCTR/FDA, Jefferson, AR.

Is an observed neurodegenerative process in its initial, peak or declining phase? Which region did it start in, and where did secondary degeneration occur? Here we present an experimental approach that can reveal the temporal progression and regional sequence of neurodegeneration. The method is based (n> 100 rats) on the finding that degenerated neurons and phagocytic microglia form pairs and are detected at a 1:1 ratio at the peak of neurodegeneration induced by amphetamine or ephedrine, if the drug treatment does not disrupt the blood brain barrier. One (Fluoro-Jade labeled; FJ+) injured neuron activates one (isolectin B4-labeled; IL+) microglia, and the activated microglia will then phagocytose the neuron. As the phagocytic clearance progresses, the value of the injured neuron/phagocytic microglia (FJ+/IL+) ratio "R" moves from R>1 (<2 days after start of neurodegeneration) to R-1 (2-3 days after start) to R<1 (= 4 days after start), because the degenerating neuron appears and disappears earlier than its phagocytic counterpart. Using histological sections from animals sacrificed at 5 days after an amphetamineinduced neurotoxic insult as an example, it can be ascertained that neurodegeneration starts first in the piriform cortex, later in the parietal cortex and last in specific thalamic nuclei. This was determined by the fact that the Rthalamus > Rparietal cortex > Rpiriform. Furthermore, the R values for the regions indicate that, neurodegeneration occurred at 1-2, 1-3 and 2-4 days, respectively in the 3 regions. This was verified by assessing the first appearance of FJ+ neurons from histological sections obtained 1, 2, 3, 4 and 5 days after insult. Because FJ+ counts drop to near zero within 7 to 10 days and IL+ phagocytes within 10 to 14 days, and the fact that severe neurotoxic insults often disrupt the blood brain barrier, our approach is most applicable to mild to moderate neurotoxic insults and is most suitable for acute or subchronic neurotoxic exposures. Supported by the USFDA/NCTR.

# 310 DERMAL EXPOSURE TO JP8 JET FUEL: DISRUPTION OF AUDITORY FUNCTION, AND INDUCTION OF DERMATITIS IN RATS.

L. D. fechter<sup>1</sup> and R. Gallucci<sup>2</sup>. <sup>1</sup>Research (151), Loma Linda VA Medical Center, Loma Linda, CA and <sup>2</sup>Pharmaceutical Sciences, University Oklahoma Hlth Sciences Ctr, Oklahoma City, OK.

Impairment of auditory function can result both from exposure to specific chemical contaminants and, more commonly, from contaminants in the presence of noise. Among agents that produce such hearing loss are several aromatic hydrocar-

bons that are present in JP-8 fuel. This project was designed to determine whether JP-8 given by dermal exposure could produce impaired auditory function by itself or potentiate noise-induced hearing loss. The rationale for this work stems from the frequent association of exposure to both jet fuel and to noise. Rats were exposed to JP-8 alone by dermal exposure, an octave band of noise designed to produce a very limited degree of permanent hearing loss in a specific frequency region of the rats audiogram, both agents in combination, and no experimental treatment. Pure-tone auditory thresholds were assessed 4 weeks later in order to measure permanent impairments in hearing. Additionally, analysis of JP-8 treated skin indicated that the expression of a number of cytokines/chemokines were significantly induced by JP-8 exposure including; IL-6, Eotaxin, Mip 1a, Mip-2, MCP-1, RANTES, and IP-10. Histology of skin biopsies showed mild to moderate inflammatory infiltrate, characterized primarily by neutrophils, and macrophages. The results indicate that JP-8 exposure alone and noise exposure alone both were able to produce hearing loss. The effect of combined exposure to these agents was an additive impairment in hearing. Dermatitis associated with JP-8 exposure is characterized by the induction of multiple cytokines, and primarily involved neutrophilic infiltrate. (supported in part by a grant from AFOSR through the DEPSCoR program F49620-02-1-0274)

## 311 TETRALIN AND METABOLITES: PROTEIN REACTIVITY, CHROMOGENICITY AND NEUROTOXICITY.

V. S. Palmer<sup>2</sup>, D. Tshala-Katumbay<sup>1</sup>, S. B. Hashemi<sup>1</sup>, <u>M. I. Sabri</u><sup>1, 2</sup> and <u>P. Spencer</u><sup>1, 2</sup>. <sup>1</sup>Center for Research on Occupational and Environmental Toxicology, Oregon Health & Science University, Portland, OR and <sup>2</sup>Department of Neurology, School of Medicine, Oregon Health & Science University, Portland, OR.

We have reported the protein-reactive, chromogenic, and neurotoxic properties of the aromatic and aliphatic solvent metabolites, 1, 2-diacetylbenzene (1, 2-DAB) and 2, 5-hexanedione (2, 5-HD) (Kim et al., Toxicol. Appl. Pharmacology 183:55, 2002). These agents react with lysine-rich cytoskeletal proteins and induce neurofilamentous axonal swellings with secondary demyelination distally (2, 5-HD) or proximally (1, 2-DAB), respectively. Proximal demyelination also characterized rats treated with acetylmethyltetramethyltetralin (AETT) (Spencer et al., Science 204, 633, 1979), which causes excretion of green urine comparable to that seen in 1, 2-DAB-treated rodents. Tetralin, a component of paints and varnishes that induces neurological disturbances (headache, restlessness, seizures, lethargy, and coma) in children and adults, is also reported to cause excretion of green urine in humans and rodents (Spencer et al., Int. J. Environment Hlth. 205:131, 2002). Neither tetralin nor its alpha-tetralol metabolite formed a chromogen when reacted in vitro at high concentrations (100-500 mM) with bovine serum albumin, but alphatetralol formed a non-chromogenic protein adduct. The spinal cord, spinal ganglia, and sciatic nerves of 12-week-old C57Bl/6 male mice (~25 g) treated i.p. daily 5 days/week with saline containing 10 percent acetone were indistinguishable at 14 and 35 days from tissue removed from animals comparably treated with 3 mmol/kg/d tetralin or 0.34 or 0.67 mmol/kg/d alpha-tetralol, the doses of the latter two increasing 50 percent every two weeks up to 35 days. Animals showed doserelated drowsiness, acute respiratory distress, lethargy, and body weight changes, with greater acute toxicity in alpha-tetralol-treated animals. In sum, neither tetralin nor alpha-tetralol formed colored pigments with proteins nor did they trigger axonal neuropathy under the conditions studied. Supported by NIEHS grants ES10338 & ES11384 & the Oregon Workers Benefit Fund.

# 312 COMPARATIVE ANALYSIS OF NEUROPSYCHOLOGICAL TOXICITY OF BIOLOGICAL, CHEMICAL, AND PHARMACEUTICAL AGENTS.

M. Peterson and R. C. Pleus. Intertox, Inc., Seattle, WA.

Neuropsychological tests are often used in a clinical setting to assess potential damage from exposure to various agents including diseases, therapeutic and environmental agents. Toxicologists are often tasked with determining the cause and effect relationships for exposure to chemical and biological agents. When evaluating specific cases where an exposure to an alleged agent has occurred, it is necessary to evaluate all possible agents when determining the most probable cause of neuropsychological effects. A comprehensive review of the literature was conducted in relation to three different types of agents that can influence neuropsychological test interpretation: biological, chemical, and pharmaceutical agents. Our initial review focused on three representative agents: hepatitis C (biological), tetrachloroethylene (chemical), and cocaine (pharmaceutical). We present the results of this work with an emphasis on the comparative effects of these agents considering exposure and dose (e.g., chemical and pharmaceutical) and pathogenicity (e.g., biological). Our research indicates that it is critical to consider medical histories, temporal relationships, sign and symptom progression, normative values, and consistency of test results with the neuropsychological literature when assessing cause and effect from

DECREASED NEUROLOGICAL SIDE EFFECTS WITH ARIPIPRAZOLE: A RESULT OF FUNCTIONALLY SELECTIVE ACTIVATION OF DOPAMINE  $\mathrm{D}_2$  RECEPTORS

J. D. Urban<sup>1</sup>, E. A. Gay<sup>2</sup> and R. B. Mailman<sup>2, 1</sup>. <sup>1</sup>Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC and <sup>2</sup>Department of Psychiatry, University of North Carolina, Chapel Hill, NC.

High affinity D2 dopamine receptor antagonism has long been implicated in the development of neurological side effects associated with the chronic administration of a number of antipsychotics. The recently marketed atypical antipsychotic aripiprazole demonstrates a very low incidence of these extrapyramidal side effects (EPS) despite the unusually high affinity the drug has for the D2 receptor. We hypothesize that the low incidence of EPS caused by aripiprazole is due, in part, to its ability to activate certain functions linked to the D<sub>2</sub> receptor differentially, a mechanism known as functional selectivity or agonist trafficking. Our previous studies using two D2-mediated functional endpoints (GIRK channel activation and GTP\gammaS binding) showed aripiprazole to be an antagonist (Shapiro et al., 2003), although the compound was a partial agonist against adenylate cyclase (Lawler et al., 1999; Burris et al., 2002; Shapiro et al., 2003). The current study investigated the actions of aripiprazole at the D<sub>21</sub>-mediated activation of MAP kinase. Using CHO cells stably transfected with the  $hD_{2L}$  receptor, we measured MAP kinase activation by means of an ELISA. Relative to the intrinsic activity of the  $D_2$  full agonist quinpirole, aripiprazole was determined to be a partial agonist. The data from effects on D<sub>21</sub>-mediated effects on adenylate cyclase and MAPK are being compared to D<sub>2</sub>mediated effects on phospholipase A<sub>2</sub> activation (i.e., [³H]arachidonic acid release) in the same stably transfected CHO cell line. Together, these studies will offer insight into the D<sub>21</sub>-mediated molecular mechanisms of G protein functional selectivity, and their role in decreasing neurotoxic side effects of the atypical aripiprazole.

## 314 IS THERE A LINK BETWEEN FREE RADICAL FORMATION AND CELL DEATH.

<u>F. Fonnum</u><sup>1</sup>, T. Reistad<sup>1</sup>, A. Dreiem<sup>1</sup> and E. Mariussen<sup>2</sup>. <sup>1</sup>Protection, Forsvarets Forskningsinstitutt, Kjeller, Norway and <sup>2</sup>Norwegian Institute of Air Research, Kjeller, Norway.

The purpose of this study is to discuss whether there is a correlation between free radical formation and cell death in cultured rat cerebellar granule cells. Free radical formation is assayed by the use of the fluorescent probe DCFH, and cell death is either monitored by trypan blue exclusion or by release of lactate dehydrogenase. Toxic compounds that are investigated are polychlorinated biphenyls, brominated flame retardants, perfluorinated compounds and hydrocarbon solvent. The results show that there is a correlation between free radical formation and cell death for PCB, although the higher PCB seems to be more toxic than expected from their DCFH-fluorescence. For brominated flame retardants tetrabromobisphenyl yields a high degree of DCFH-fluorescence and substantial cell death. The brominated diphenylethers are less active in DCFH-fluorescence, but active in killing cells. For the perfluorated compounds there is not a good correlation between cell death and DCFH-fluorescence. Aromatic and naphtenic hydrocarbons yield DCFH-fluorescence and cell death, whereas aliphatic hydrocarbons only produce free radicals.

### 315

COMPARISON OF RAT HIPPOCAMPAL GENE EXPRESSION UTILIZING LASER CAPTURE MICRODISSECTION (LCM), RNA AMPLIFICATION AND OLIGONUCLEOTIDE MICROARRAYS.

A. C. Kant<sup>1</sup>, <u>S. A. Ferguson</u><sup>1</sup>, P. M. Douglass<sup>2</sup> and <u>T. A. Patterson</u><sup>1</sup>.

<sup>1</sup>Neurotoxicology, NCTR/FDA, Jefferson, AR and <sup>2</sup>Agilent Technologies, Germantown, MD.

The hippocampus has a crucial role in transferring short-term memory to long-term memory, with diminished function associated with aging. Previously, spatial learning and memory in water-reinforced complex maze and escape-reinforced Morris water maze tasks for three rat strains were assessed in our laboratory. Distinctive learning differences were observed across strains and within strain. To determine if memory and learning performance are correlated to differential gene expression, hippocampi from fast-learning (FL) and slow-learning (SL) Sprague-Dawley, Spontaneously Hypertensive and Wistar-Kyoto aged rats (15 months) were examined. Frozen brain sections were mounted on glass slides, and then stained and dehydrated. Cells from the CA regions of the hippocampus were collected using a PixCell IIe LCM system and total RNA was extracted. First round RNA amplification was performed using a RiboAmp OA RNA amplification kit. Briefly, from total RNA, double-stranded (ds) cDNA was synthesized prior to *in vitro* transcription to generate aRNA, which was used in second round amplification to generate additional ds cDNA. The ds cDNA was introduced into an Agilent low RNA input

fluorescent linear amplification kit to generate labeled antisense cRNA. The FL and SL RNA samples within strain were labeled using Cy3 and Cy5 dyes, and were hybridized to Agilent rat oligo microarrays. Microarray slides were scanned and the data analyzed using the Rosetta Resolver data analysis system. Data analysis suggests minimal gene expression differences within strain between FL and SL rats, with approximately one dozen genes of interest. These expression differences will be verified using real-time PCR and the hippocampal gene expression between these aged rats and younger counterparts are currently being examined. By further exploring these changes, the molecular mechanisms of age-related memory disorders, such as Alzheimer's disease, may be elucidated.

### 316 STUDENT ROUNDTABLE ON EFFECTIVE PRESENTATIONS.

A. Wang. Biomedical Sciences and Pathobiology, Virginia Tech, Blacksburg, VA.

The ability to present information to an audience in a clear, concise manner is a critical academic and career skill. An effective presentation conveys important knowledge, generally as a summarization of a larger body of data or ideas, often within a specified format or time frame, and provides a forum for a productive exchange of ideas. Typical formats include posters and oral presentations. These can be used in academic settings (e.g., an oral classroom presentation, a proposal defense, or a thesis/dissertation defense), at professional/scientific conferences (e.g., a poster presentation or a platform talk), or even in job interviews. This symposium will address some of the skills needed to deliver an effective presentation. Students will find the topics to be particularly useful and informative. The speakers will cover general concepts of communication, provide practical hints for organizing and conveying information in posters and oral presentations, and discuss the skills needed to effectively answer questions and comments from the audience.

### 98

### 317 PRESENTING AN EFFECTIVE POSTER.

S. C. Fitzpatrick. Office of the Commissioner, USFDA, Rockville, MD.

Presenting a poster is an exciting opportunity to showcase your research efforts to your scientific colleagues. However presenting an effective poster requires planning and thought. First, make sure your research is at a point where you have something valuable to present. Have you been able to draw scientifically valid conclusions from the work? Second, decide whether you really wish to present a poster or if you should be giving a platform presentation. Presenting a poster gives you the unique opportunity for one on one interaction with other scientists in your field. It enables you to get feedback and suggestions on your research. It may lead to collaborations with other scientists doing similar work. Third, decide who your audience will be and determine their level of understanding of the general field in which you work. Is this a specialty meeting where everyone is conversant in your field or is it more of a general science meeting? This will determine the level of background you must add to your poster to make it meaningful to those who read it. Think carefully about how you organize your poster. It must be attractive enough to draw readers to it in a room of many posters. The care and detail you put into putting together your poster is indicative of the overall care you put in doing your research. Make sure your print is big enough to read easily from about two feet away. Remember us senior scientists who may give you valuable feedback do not necessarily have the best eyesight anymore. Graphics that illustrate your research and are easily understood are one very positive and important element of good posters. Colors are more appealing than black and white. Think about what attracts you to a poster and incorporate some of these suggestions into your work. Finally relax and enjoy yourself. Speak up and show your excitement for your work. If your research is not interesting to you, it will not be to anyone else either. Ask questions of those who come to talk to you. This is an opportunity for you to get feedback to enhance your research- not simply a time to present your data.

#### **318** PLATFORM PRESENTATIONS.

G. L. Kimmel. Office of Research and Development, USEPA, Washington, DC. Sponsor: A. Wang.

A platform presentation provides the speaker with an opportunity to present information in an uninterrupted manner. It is important that the speaker prepare in a way that the audience will be able to understand to flow of thought, the conclusions drawn and the take home message. The current talk will focus on three considerations that are important to an effective platform presentation: the audience, the speaker, and the preparation. The audience is the group of people on the other side of the platform. Who are they? Academics, bureaucrats, lawyers, "the public?" They are there for a reason. What is it? Do they want to hear your latest research results? Do they expect an introduction to a series of talks that will follow? Or do they

expect a defense of a position that you or your organization has taken? They are there; but where is "there?" Are they physically in the same room or on video- or tele-conferencing? Each audience requires some consideration in preparing and giving a talk. The speaker is you. What type of speaker are you? Confident, nervous, loud, quiet, a reader, an ad liber? Regardless of what descriptor best fits, the important thing is to recognize it and use it to your advantage. Leaving your script can give the appearance that you are confident with your material. But, if this style of presentation is not you, it can be disastrous. With the audience and your speaking style in mind, the preparation can begin. What are the things that are most important? Give the audience a clear idea of what you are going to tell them. Generally, an outline at the beginning is very helpful for this. At the end, summarize for the audience what you've told them and reiterate the important points. Once the talk is drafted, practice! This will not only indicate whether you can get everything in within the allotted time period, but if the projector blows, you may be able to give the talk without missing a beat. And finally, when you have the talk within the assigned time period, cut it down. You will never have as much time as you think.

### 988

#### **319** THINKING ON YOUR FEET.

<u>B. A. Schwetz</u>. Office for Human Research Protections, Department of Health & Human Services, Rockville, MD.

Answering questions from the audience after a presentation requires skills different from giving the talk itself. You can rehearse the talk until you are comfortable with its content; you can prepare visituals that help you present your message. Once the questions start, you share control with the audience. How well you answer questions reflects how well you think under presssure and sometimes under unfriendly conditions. This presentation will offer advice on how to remain in control, how to buy time to think of a good answer, how to admit that you don't know an answer, and how to handle an unfriendly or hostile person in the audience. Answering questions well can enhance your credibility with peers and with the public.

### 320 GENE EXPRESSION INFLUENCES ON METAL IMMUNOMODULATION.

D. A. Lawrence<sup>1</sup>. <sup>1</sup>Wadsworth Center, Albany, NY and <sup>2</sup>Wadsworth Center, Albany, NV

Metals can stimulate or modify immune responses by multiple modulatory mechanisms. The five topics in this symposium cover a wide range of different molecular means by which metals may directly or indirectly alter immunity, but all topics address differences that exist or can be better evaluated as a consequence of genetic differences or manipulations. The first presentation demonstrates how changes in the expression of metallothionein, whose exposure is modulated by certain metals, can alter immune responses at various cellular levels. The second talk discusses how genetic differences in one of the major histocompatibility complex antigens can affect T cell stimulation by beryllium. The third talk demonstrates how altered gene expression of select immune products such as cytokines can influence how lead modulates immunity. The fourth presentation will delve into the intracellular signaling networks to discuss genetic expressions associated with mercury-induced apoptosis of lymphocytes. The final talk will focus on the involvement of select genes in mercury exacerbation of autoimmune disease with emphasis on the various stages or check-points at which the development of autoimmune reactivities can be modified. In all, the presentations indicate that the metals can affect immune reactivities based on the genetics of the exposed cells as well as the influences of other environmental agents on altered gene expression.

## 321 INFLUENCE OF METALLOTHIONEIN GENE EXPRESSION ON STRESS-MEDIATED IMMUNOMODULATION.

M. A. Lynes<sup>1</sup>, X. Yin<sup>1</sup>, E. Canpolat<sup>1</sup>, K. C. Crowthers<sup>2</sup>, J. Youn<sup>3</sup> and N. Hadjout<sup>1</sup>. <sup>1</sup>Molecular and Cell Biology, University of Connecticut, Storrs, CT, <sup>2</sup>Pathology, University of Massachusetts Medical Center, Worcester, MA and <sup>3</sup>Anatomy and Cell Biology, Hanyang University, Seoul, South Korea.

Metallothionein is an unusual representative of the set of stress-response proteins that are produced by cells in response to changes in their environment. This small thiol-rich protein is usually associated with zinc and copper, and serves as an important reservoir of these essential metals. Metallothionein also acts as an important anti-oxidant, as a scavenger of toxic heavy metal cations, and as a regulator of specific transcription factor activity. In addition to these essential homeostatic roles, or perhaps because of them, metallothionein may serve as a critical regulator of immune functions in the context of toxicant exposures or oxidative stress. We have shown that metallothionein can be immunosuppressive, and that this suppression

can be blocked with a monoclonal anti-metallothionein antibody. Moreover, we have shown that metallothionein-null animals display an enhanced response to antigen challenge. Our lab and others have shown that manipulation of metallothionein *in vivo* can result in changes to the progression of autoimmune disease. Targeted disruption of metallothionein in congenitally autoimmune animals accelerates the progression of disease, and injection of metallothionein can diminish the progression of induced models of autoimmune disease. The principal target appears to be the T cell: T dependent, but not T-independent, humoral responses are suppressed by metallothionein, and cytotoxic T cell function is also diminished in the presence of metallothionein. This suppression may reflect metallothionein interactions at the plasma membrane. Metallothionein binds to T cells in proximity to the T cell receptor, and can initiate T cell chemotactic responses. In view of the potential population diversity in the synthesis and release of metallothionein to the extracellular environment, this protein may represent an important susceptibility factor for toxicant-induced immunomodulation.

#### 322 MHC GENETICS AND SENSITIVITY TO BERYLLIUM.

A. P. Fontenot. *University of Colorado Health Sciences Center, Denver, CO.* Sponsor: D. Lawrence.

Chronic beryllium disease (CBD) is a granulomatous disorder primarily affecting the lung that is caused by beryllium exposure in the workplace. Depending on the nature of the exposure and the genetic susceptibility of the individual, 2 to 16% of exposed workers eventually develop disease. CBD is characterized by a CD4+ T cell alveolitis, and evidence suggests that those T cells are critically involved in the immunopathogenesis of the disorder. Susceptibility to CBD is associated with the class II major histocompatibility complex (MHC) molecule HLA-DP, in particular, those HLA-DP molecules with a glutamate at the 69th position of the  $\beta$ -chain. The ability of certain HLA-DP molecules to bind and present beryllium to berylliumspecific CD4+ T cells provides a mechanism underlying this genetic susceptibility. For example, mAbs directed against HLA-DP abrogate beryllium-induced T cell proliferation and Th1-type cytokine production. These studies also pinpoint residues of the HLA-DP  $\beta$ -chain required for beryllium presentation. In addition, the presence of a defined antigen and an accessible target organ allow the performance of studies to further define the development of immunological memory. To date, it remains unknown how T cells recognize the beryllium-peptide-HLA-DP complex.

#### 323 CYTOKINE GENE EXPRESSION MODIFIED BY LEAD.

D. A. Lawrence, Y. Heo, J. Kasten-Jolly and T. Mondal. Wadsworth Center, Albany, NY.

The environmental toxicant lead (Pb) has multiple effects on different components of the immune and nervous systems. Some of the immunomodulatory effects of Pb on both CNS and immune activities are posited to be partially due to alterations of cytokine expression in the brain and secondary immune organs. In general, Pb causes a preferential activation of type-2 immune responses by enhancing the expression of the type-2 cytokines, such as interleukin (IL)-4 and IL-10 and inhibiting the expression of the type-1 cytokine interferon-γ (IFNγ). However, these effects are dependent on the genetics of the exposed animal and the influences of other environmental exposures. For example, with wild-type BALB/c mice, Pb lowers the production of the type-1 antibodies (IgG2a) to the immunogen KLH, but with IFNγ-deficient BALB/c mice, Pb enhances production of these antibodies. STAT4 and STAT6 deficient mice also respond in an unexpected manner to immune modulation. Thus, knockout of some of the genes involved in signaling certain immune responses can alter the immunomodulatory effects of Pb. In addition, some of the peripheral immune modulations by Pb may relate to differential CNS effects, in that Pb alters cytokine expression in the brain and modulates the expression induced by a peripheral infection. Thus, there appear to be multiple mechanisms responsible for Pb effects on neuroimmune circuits and immune defenses.

#### 324

MODULATION OF PROTEIN INTERACTIONS BY MERCURY: MOLECULAR ANALYSIS OF SIGNALLING PATHWAYS TO UNCOVER MECHANISMS OF Hg IMMUNOTOXICITY.

A. J. Rosenspire. Biological Sciences, Wayne State University, Detroit, MI.

While autoimmune disease can be understood as representing a breakdown in either central, or peripheral tolerance, or perhaps both, the specific etiology of most autoimmune diseases are unknown. The difficulties in elucidating these etiologies have generally been ascribed to the probability that in most instances the initiation

of autoimmune disease is likely multi factorial. In this regard a useful theoretical concept has been that autoimmune diseases can potentially be understood as arising as the result of a set of interactions between specific environmental inputs operating on susceptible genotypes. However while much progress has been made in recent years in elucidating the molecular biology and genetics of the normal mechanisms of peripheral and central tolerance, comparatively little is understood as to how environmental agents may interact with these mechanisms so as to initiate and/or perpetuate autoimmune disease. In fact, in most instances it has proven impossible even to conclusively link specific environmental agents with the onset of autoimmunity. One of the few exceptions is mercury (Hg), where animal studies have clearly established a connection between administration of the metal and systemic autoimmune disease in susceptible rodent strains. Recent work conducted in our laboratories has now established how non-cytotoxic concentrations of Hg interfere with the signal transduction pathways mediated by antigen receptors and CD95 in T and B lymphocytes. As antigen receptor mediated signal transduction has been shown to be crucial in the establishment of central tolerance, while CD95 mediated signaling is integral to the maintenance of peripheral tolerance, these findings suggest ways in which non-cytotoxic concentrations of Hg might deregulate immune system homeostasis so as to give rise to autoimmune disease. Supported by NIEHS grants ES011000, ES012403, and ES010351.

### 325 GENETIC CHECK POINTS IN HEAVY METAL INDUCED SYSTEMIC AUTOIMMUNITY.

K. M. Pollard. Molecular & Experimental Medicine, Scripps Research Institute, La Iolla, CA.

To investigate the role that specific genes play in systemic autoimmunity induced by heavy metals we have examined the disease profiles in mice with single gene deletions. In total 17 individual genes have been studied. Systemic autoimmunity was induced by subcutaneous injection of 40 ugs of mercuric chloride twice weekly for four weeks. Severity of disease was determined by measurement of hypergammaglobulinemia, autoantibodies, and tissue deposits of immune-complexes. Deletion of certain genes, such as CD40L, CD28, or Igh6 abrogated induction of autoimmunity. Other genes, including Igh5, IL-4, ICAM-1 or TNFRI and II, had little effect on the development of disease. Intermediate effects were observed in IL-6 deficient mice, while absence of β2microglobulin resulted in loss of hypergammaglobulinemia and IgG1 anti-fibrillarin autoantibodies but little change in antichromatin Abs levels or glomerular deposits. The most interesting observations were obtained with genes related to the expression or function of interferon- $\gamma$ . Genes involved in upregulation of IFN-γ expression, such as IL-12, STAT-4, or ICE, did not significantly influence autoimmunity whereas absence of IFN-γ or IFN-γ receptor led to greatly reduced autoantibody responses and immunopathology. Absence of IRF-1, a gene expressed in response to IFN-γ, resulted in selective retention of anti-chromatin Abs but little glomerular pathology. As the results with the IRF-1 knockout demonstrate, specific defects in signaling pathways and gene expression subsequent to IFN-γ/IFN-γ receptor interaction may influence expression of specific parameters of autoimmunity elicited by mercury. In addition, IFNγ influences the expression and function of other immunologically relevant genes such as IL-4, IL-6, and β2microglobulin. Thus the effects of these gene deletions on autoimmunity may result from the influence of downstream events following IFN- $\gamma$ /IFN- $\gamma$  receptor interaction.

### 326 OVERVIEW.

T. B. Knudsen<sup>1</sup> and W. Slikker<sup>2</sup>. <sup>1</sup>Pathology, Anatomy and Cell Biology, Thomas Jefferson University, Philadelphia, PA and <sup>2</sup>Neurotoxicology, NCTR/FDA, Jefferson, AR

Genomics and proteomics enable investigators to move from studies focused on single molecules, pathways and cells toward integrative function of the intact tissue and organism; however, new advances in bioinformatics and computational biology are needed to integrate these data and explain how processes work from a whole system perspective. This symposium will explore basic and applied concepts in systems biology as an emerging tool for computational methodologies, functional genomics, and molecular embryology to predict when, and understand how, molecular perturbations induced by drugs and chemicals might culminate in developmental toxicity. Basic concepts include the formal representation of cell signaling and gene regulatory networks in complex systems, how the flow of information within and between cells suggests a parody with similar phenomena in engineered systems, what efforts are needed to incorporate this kind of information into quantitative dose response models, and how to weave theoretical and empirical data into robust computational models that project to higher order functions in developmental processes and pathologies.

### 327 SYSTEMS BIOLOGY TOP DOWN.

E. Werner. Cellnomica, Inc., Munich, Germany. Sponsor: T. Knudsen.

Systems biology uses experimental, computational, theoretical methods to describe biological phenomena. In this talk, we give an introduction to the goals of systems biology as well as the methods used in systems biology to formalize what seem to be intractable and complex biological systems. In particular we focus on cell signaling and regulatory networks in multicellular genomes. Both cell signaling and genomic regulatory networks have become focal points for computational modeling and simulation efforts by engineers, computer scientists, mathematicians, and systems biologists. Computational biology methodologies require a precise description of the system under study, including key input and output variables and feedback control mechanisms, and use this description to simulate or model the described system. The formal representation of complex living systems is essential to the understanding of such systems as well as their pathologies. The use of in silico models to predict the dynamic behavior of a system in response to chemical agents may help in the processes of drug design, drug discovery and the development of therapeutic strategies. We will also discuss minimal multicellular organisms and their role in the future of systems biology and the health sciences. Minimal genomes for artificially constructed single cells and multicellular organisms will lead the way to integrating in silico simulations with in vitro and in vivo bioengineering methods. This will lead to the design of simple in vitro and in vivo multicellular systems making the science of systems biology realizable.

### 328 A GENE REGULATORY NETWORK FOR DEVELOPMENT.

G. Amore and E. H. Davidson. *Biology, Caltech, Pasedena, CA.* Sponsor: <u>W.</u> Slikker

Large networks of regulatory genes control every aspect of the development and evolution of the body plan in animals. We have carried out an experimental exploration of the gene regulatory network that underlies the specification of the endoderm and the mesoderm of the sea urchin embryo. Genetic interactions between more than 40 genes have been reconstructed using data obtained from large-scale perturbation analyses, in combination with computational methodologies, genomic data, cis-regulatory analysis, and molecular embryology. Several differential screenings were performed to discover new regulators involved in the whole process. Whole mount in situ hybridization was extensively utilized to confirm these initial data. Perturbation of gene expression was attained by means of injection of morpholino antisense oligonucleotides or engrailed fusion mRNAs, using multiplex quantitative PCR analyses to reveal the regulatory interactions between each gene encoding a transcription factor and any other genes in the network responding to that factor. Many of the cis-regulatory regions that control the expression pattern of these genes are being studied actively. Recognizing these regions is now an efficient procedure, thanks to original computational approaches developed in our lab. Functional analysis of these regions is already illuminating many of the upstream relationships between these regulators. The translation of maternal inputs into a specific zygotic regulatory state, the segregation of different fates inside an initially homogeneous field, the transition from signal-dependent to self-sustained gene expression and the locking in of particular regulatory states, are now described at a gene circuitry level. Elements conveying robustness to the architecture of the system can be recognized at every level such as the extensive employment of feedforward and feedback loops or redundancy. Interesting similarities as well as differences between evolution- and engineer-designed systems can be derived.

### 329

CHALLENGES AND OPPORTUNITIES IN UTILIZING SYSTEMS BIOLOGY APPROACHES FOR INFORMING DEVELOPMENTAL TOXICOLOGY.

E. M. Faustman. Center for Child Environmental Health Risks, University of Washington, Seattle, WA.

The "omic" revolution has provided us with not only unprecedented opportunities but also unforeseen challenges in unlocking it's riches for informing toxicology. In particular, for developmental toxicology, expected challenges of dose-response are complicated by the need for understanding dose and time responses across lifestages and within a three-dimensional context. Additional considerations for human development include the need for considering responses within the uterus where both genetic variations in response between the mother and conceptus can be significant. The purpose of this talk will be to provide some approaches for framing and modeling systems biology data for informing our understanding of mechanisms of developmental toxicology. The challenges and opportunities in utilizing systems biology information for understanding mechanisms of toxic action include understanding the importance of genomic conservation of cell signaling pathways,

the downstream diversification of cell systems, the three-dimensional characteristics of organ/system development, the concepts of dose and time response across multiple levels of biological organization and differences in environmental impacts on redundant versus unique cellular processes. Case examples using biologically based modeling approaches that build from physiologically based toxicokinetic and dynamic models will be presented. The use of both in vitro and in vivo data as well as model organism data will be discussed. Lessons learned as well as critical data needs will be highlighted. (Supported by the Center for Child Environmental Health Risks research through an EPA grant R826886 and NIEHS grants 1PO1ES09601, 32ESO7032, and ESO7033)

330

COMPUTATIONAL MODELING OF CELL SIGNALING PATHWAYS: A STEP ON THE ROAD TO IMPROVED CHARACTERIZATION OF DOSE- AND TIME-RESPONSE FOR THE ADVERSE EFFECTS OF TOXICANTS.

R. Conolly, Q. Zhang and M. Andersen. Center for Computational Biology & Extrapolation Modeling, CIIT, Research Triangle Park, NC.

Adverse reproductive and developmental outcomes arise when normal biological processes are disrupted by environmental stressors. Physiologically-based pharmacokinetic (PBPK) modeling is useful for characterizing the PK mechanisms that determine, in part, the dose-response and time to response relationships for these adverse effects. The greater challenge, however, is to understand the sequence of events that link the initial interactions of stressors at key sites in the target tissues with the final adverse outcomes. The relevant biology is so complex that intuition is not, by itself, an efficient tool. Computational models of biological processes, such as signal transduction, are just as capable of being wrong as is intuition. The models have the advantage, however, of a formal structure that can be iteratively refined through a process involving rigorous comparison of model behavior with data and revision of model structure. The model becomes increasingly accurate over time when linked with targeted laboratory studies. We are adapting computational models of signal transduction pathways (e.g., Science 297:1018-1023, 2002) with the longer-range goal of better understanding toxicological dose-response and time to response relationships. In this presentation we (1) exercise a computational model of the MAPK pathway to illustrate how this pathway can generate complex doseand time-to response relationships and (2) consider how a better understanding of these relationships will impact human health risk assessment.

331 CURRENT STATUS AND FUTURE CONSIDERATIONS FOR THE DEVELOPMENT OF SKIN TOXICOLOGY ALTERNATIVE METHODS.

G. Gerberick<sup>1</sup> and <u>I. Kimber</u><sup>2</sup>. <sup>1</sup>Procter & Gamble Co., Cincinnati, OH and Syngenta, Macclesfield, United Kingdom.

The need for alternative approaches and in vitro test methods has never been greater than it is today. The continued development of such approaches and use of validated alternatives test methods is an integral part of toxicology in the 21st century. Collaboration of researchers and external scientific validation organizations such as ICVAAM and ECVAM that were established to provide a mechanism for alternatives test methods validation test methods spearheaded the way forward. Such efforts have led to significant progress in the replacement of animals, reduction in the number used and refinement of in vivo studies. In addition to scientific considerations, significant regulatory challenges lie ahead with the implementation of the 7th Amendment to the European Union Cosmetics Directive, The European Union Chemicals Policy and the United States program on High Production Volume Chemicals. This workshop will focus on the development of alternative approaches and in vitro methods for the evaluation of cutaneous toxicology. It will include detailed discussion on the use of in vitro/in silico and other alternatives methods/approaches used today for the evaluation of skin irritation skin sensitization and skin penetration. The workshop will be introduced by an overview on the use of alternatives in toxicology today and challenges for the future and will close with placing into context the scientific and regulatory challenges relative to societal expectations.

OVERVIEW OF ALTERNATIVES IN TOXICOLOGY: 332 RECENT PROGRESS AND FUTURE OPPORTUNITIES.

W. S. Stokes. DHHS/NIH, NIEHS, Research Triangle Park, NC.

There has been significant progress in recent years in the use of alternative test methods and approaches for toxicological assessments. National and international authorities have adopted testing strategies that integrate the use of scientifically valid animal and non-animal alternatives, resulting in reduced animal use and reduced pain and distress. In some specific testing situations, hazard decisions can now be made without animals, whereas in others only a single animal or a small number of animals may be necessary. This progress has been aided by the establishment of processes and centers to facilitate the validation, scientific review, and regulatory acceptance of alternative methods. These include the Interagency Coordinating Committee on the Validation of Alternative Methods and the NTP Interagency Center for the Evaluation of Alternative Toxicological Methods in the US, and the European Center for the Validation of Alternative Methods in Europe. Despite current progress, recent events such as EU legislation imposing immediate and phased prohibitions on the use of animals for safety testing of cosmetic products and ingredients have created significant new scientific, regulatory, and ethical challenges. Focused research and application of new technologies will be essential to develop innovative alternative non-animal safety assessment methods that effectively address these new mandates and that continue to protect human, animal, and environmental health. This presentation will discuss the current status of alternative test methods, and challenges, opportunities, and strategies for future progress.

333

APPLICATION OF ALTERNATIVES IN THE EVALUATION OF SKIN IRRITATION.

D. A. Basketter. SEAC, Unilever, Sharnbrook, United Kingdom.

Considerable progress has been made over the past 10 years in the development of alternative methods for evaluation of potential skin irritants. Reliance on animal testing (e.g. the Draize rabbit skin irritation test) has been reduced significantly with the development of in vitro methods such as the use of skin equivalent models being used for assessing skin corrosion, as well as the deployment of these and other models for "in house" safety assessment. However, to date, there has been no success in the formal replacement of rabbit skin testing for regulatory assessment of skin irritation hazard. As a consequence, more basic work has been directed towards enhancing our fundamental understanding of the mechanism(s) of skin irritation. The aim ultimately is that new in vitro approaches can be developed which will be soundly based on this scientific knowledge. This presentation will consider in detail existing in vitro and in silico tools and ethical human testing strategies available as well as addressing the future opportunities for research in the area of skin irritation.

334

CHALLENGES IN DEVELOPMENT OF ALTERNATIVE METHODS TO EVALUATE SKIN SENSITIZATION.

G. Gerberick. Procter & Gamble Co., Cincinnati, OH.

There is considerable activity being directed at the development of alternatives test methods for evaluating skin allergens. Based on our increased understanding of the chemistry and biology of skin sensitization, effort is being directed at developing models which address the key hurdles of skin sensitization: penetration, protein reactivity and immune recognition. Techniques to address these areas such as QSAR modeling, peptide reactivity and molecular gene profiling will be discussed. This presentation will review scientific and regulatory progress made to date as well as focus on the challenges that lie ahead for the development of robust *in vitrol* in silico methods for reducing the need for animals for skin sensitization evaluations.

335

SKIN PENETRATION: CURRENT AND FUTURE DIRECTIONS IN THE USE OF ALTERNATIVE METHODS.

R. Bronaugh. Office of Cosmetics and Colors, USFDA, Laurel, MD.

A number of protocols have been developed in recent years for measuring skin penetration. A comparison of these protocols raises questions in the following major areas: (1) Should skin levels of absorbed chemical be included in measurements of systemic absorption? (2) What is the preferred diffusion cell receptor fluid? (3) Should human or animal skin be used? (4) Do you need viable or non viable skin? (5) What thickness of skin should be assembled in the diffusion cells? The OECD guideline on percutaneous absorption which was issued in 2003 attempted to reconcile some of these differences. The guideline states that skin absorption values at the end of a study must include skin levels as being systemically absorbed unless studies are conducted to demonstrate that these skin levels will not be systemically absorbed. It is also stated that the impact of metabolism of a test compound during skin absorption needs to be considered. The lack of a standard protocol has probably limited regulatory acceptance of this method. In vitro skin absorption studies are deemed appropriate for the evaluation of safety of cosmetics by the European Union. They have developed guidelines for conducting these studies. In the United States, in vitro measurements of skin penetration are routinely made by cosmetic companies. FDA expects the cosmetic industry to do appropriate safety testing and does not require specific tests for safety evaluations. For topical drug approval,

USFDA requires *in vivo* skin absorption data, in part, because of the need for a pharmacokinetic evaluation. *In vitro* studies may be useful in preclinical studies for a comparison of absorption from different formulations. Future efforts in developing this alternative method need to focus on the interlaboratory reproducibility of results from studies using a standard protocol. Also, the utility of pig skin as a suitable substitute for human skin needs to be more thoroughly addressed. The barrier properties of cultured human skin need to be improved. If not, its use in skin absorption evaluations may be limited to generating skin metabolism information.

336

SOCIETAL EXPECTATIONS ON THE USE OF ALTERNATIVES FOR THE PROTECTION OF ANIMALS AND HUMANS.

A. M. Goldberg. CAAT, Johns Hopkins University, Baltimore, MD.

Public concern over the use of animals in laboratory experiments has risen steadily over the last several decades. Questions about the morality, necessity and scientific validity of animal experiments have been raised. The publication in 1959 of "The Principles of Humane Experimental Technique," by W. Russell and R. Burch, set the scene for the modern animal welfare movement dedicated to the 3Rs of alternatives: replacing animal procedures, reducing the numbers of animals, and refining procedures to decrease or eliminate pain in animal experiments. Russell and Burch indicated that humane science (incorporating the 3Rs of alternatives) was also the best science. Over the last four decades, the search for alternatives has become a movement of global proportions, and the philosophy of the Three Rs - replacement, reduction and refinement - has enabled researchers and animal protection advocates to find common ground, to meet societal expectations on the use of animals in research, and to demonstrate that humane science is the best science.

337

DIESEL EMISSIONS: NEW HORIZONS IN THE CHEMISTRY, HEALTH EFFECTS AND REGULATIONS.

<u>I. Gilmour</u><sup>1</sup> and <u>J. L. Mauderly</u><sup>2</sup>. <sup>1</sup>NHEERL, USEPA, Research Triangle Park, NC and <sup>2</sup>Lovelace Respiratory Research Institute, Albuquerque, NM.

Diesel exhaust is a complex aerosol comprised of carbonaceous particles and a mix of hydrocarbons, aldehydes and gases. The physical and chemical composition of the emission can vary dramatically depending upon the age and type of engine, fuel composition, load characteristics, presence and efficiency of control devices and climatic conditions. In 2002 the USEPA completed a health assessment of diesel exhaust, which concluded, that "long-term (i.e., chronic) inhalation exposure is likely to pose a lung cancer hazard to humans, as well as damage the lung in other ways depending on exposure." The assessment also indicated, that "evidence from numerous studies have shown that exposure to diesel exhaust increases lung cancer risk, and there is recent evidence to show that diesel may also promote the incidence and severity of allergic asthma." As these health data have emerged, regulations have also evolved to limit exposure through the promotion of new "cleaner" engines, and the development of control technologies which limit diesel emissions in terms of particle mass, CO and NO(x) output. While these changes in diesel exhaust have led to a general decrease of PM mass output per engine, the number of units has increased in the US and Europe. In addition, newer engines have significantly different emission profiles compared to older engines and there is virtually no comparative health data between diesel exhaust from light and heavy-duty engines of different ages. This symposium will contrast the historical understanding of diesel exposures with current knowledge of diesel exhaust chemistry and health effects; describe new and planned regulations; and identify future research needs. This abstract does not reflect EPA policy.

338

HEALTH EFFECTS OF DIESEL EMISSIONS: EVOLVING QUESTIONS FOR AN EVOLVING ISSUE.

J. L. Mauderly, J. D. McDonald and J. Seagrave. National Environmental Respiratory Center, Lovelace Respiratory Research Institute, Albuquerque, NM.

Historic concerns for heath hazards from diesel emissions centered on cancer risk from the mutagens and carcinogens in solvent extracts of elemental carbon-based soot particles. Long-term inhalation studies during the 1980s showed that extreme exposures increased lung tumors in rats, but not in Syrian hamsters or mice, and that the rat response had a threshold above human exposures. Although the rat results were not useful for human risk assessment, numerous epidemiological studies showed associations between diesel-associated occupations and increased lung cancer. Human cancer risk may be better resolved through studies better documenting actual exposures. Both the amount and nature of diesel emissions are changing in response to progressive emission standards, almost certainly reducing health hazards. Research issues are also evolving. There has recently been greater recognition

of: 1) the scope of potential non-cancer hazards; 2) the importance of not only soot, but also other fractions of emissions; and 3) differences in toxicity between emissions from normal and high-emitting engines. Both particulate and non-particulate emissions have been shown to cause inflammatory responses and enhance allergic immune responses. Vapor-phase semi-volatile organics can be strongly inflammogenic. Environmental hot spot-level exposures may reduce resistance to viral infection. *In utero* (maternal) exposures may influence post-natal immune responses. Ultrafine particles, although historically present, may become relatively more important as soot emissions are reduced. Almost nothing is known about toxicity of the fraction of ultrafine particles consisting mostly of condensed organics. High-emitters may not only contribute more to exposure, but the toxicity may be greater per unit of mass. Overall, there has been little study of changes in health hazards as engines, fuels, and after-treatment technologies have evolved. As diesel emissions are strikingly reduced, comparisons of the residual hazards to those from alternate technologies are needed.

339 EPIDEMIOLOGY OF DIESEL: EXPOSURE ASSESSMENT AND HEALTH OUTCOMES.

E. Garshick<sup>1,2</sup>, F. Laden<sup>2,3</sup> and T. J. Smith<sup>3</sup>. <sup>1</sup>VA Boston Healthcare System, West Roxbury, MA, <sup>2</sup>Channing Laboratory, Brigham and Women's Hospital and Harvard Medical School, Boston, MA and <sup>3</sup>Department of Environmental Health, Harvard School of Public Health, Boston, MA. Sponsor: <u>I. Gilmour</u>.

Exposure assessment in epidemiological studies has been based on surrogate exposure markers for diesel exhaust. These markers have been suitable for identifying diesel exhaust as a health hazard, but have not provided insight into a dose-response relationship. Relating specific exposure levels to health outcomes has been complicated because diesel exhaust is a complex mixture of particles and gases, the agents responsible for each health effect are not known, different agents may be important in causing different health effects, and these agents may not be unique to diesel. Despite these limitations, a 20% to 50% excess lung cancer risk has been observed in occupations where diesel exhaust exposure was likely. Ambient fine particulate matter (PM2.5) has been associated with increases in daily cardiovascular and respiratory mortality, hospital admissions, and lung cancer. Since diesel exhaust contributes to ambient PM2.5, particularly in settings related to traffic, there is concern that diesel contributes to these health effects. Studies mainly in children have noted an association between residence near a roadway with respiratory symptoms, asthma, and pulmonary function changes. Experimental studies suggest that diesel can act to enhance the response to allergens, and therefore there is the possibility of an association with allergic disease. An exposure database is being developed for a study of lung cancer and other health outcomes in the US trucking industry. Exposure scenarios include traveling on local roads in a truck, in long haul tractortrailers on intercity highways, and upwind at urban and rural large and small truck terminals. Markers of exposure include elemental carbon (EC), organic carbon, and PM2.5, supplemented by molecular markers in particle-associated organics to estimate the source of EC. These data will provide exposure estimates in scenarios typical of general population exposures that have been previously unavailable.

340

CONTROLLED DIESEL EXPOSURES: INTER-PHASING HUMAN AND ANIMAL STUDIES AND THEIR USE IN THE RISK ASSESSMENT PROCESS.

M. C. Madden. NHEERL\Human Studies Division, USEPA, Chapel Hill, NC.

Particulate matter (PM) has been reported to be associated with health effects (e.g., premature deaths, hospitalizations, lung cancer), and gaseous components may influence the PM-induced effects. Diesel exhaust (DE) contributes to ambient PM and gaseous compounds, but the role that DE plays in PM-induced effects is not well established. Controlled exposure studies using human volunteers and animal models can confirm the role DÊ may play in PM toxicity; also the removal of a DE component (e.g., particles) may reveal whether the removed component is involved in the observed response(s). A limited number of acute, controlled exposure studies of human volunteers administered either whole DE or individual components by inhalation or instillation have been used to examine nasal and lung responses including indices of inflammation and allergy. More numerous acute exposures of nonhuman animal models have revealed similar pulmonary alterations, and have better linked lung responses to the composition of particles. Further acute exposure investigations with animal models have revealed DE-induced cardiovascular changes (hypertension, arrhythmias). Chronic exposure regimens have also been utilized with rodents to examine the carcinogenicity of DE. Exposures in vitro have been also utilized with cells from target organ systems in order to assess relative potencies of DE and DE constituents (e.g., organic solvent-extractable), potential mechanisms that operate in vivo (e.g., signal transduction), and other possible responses not widely examined in vivo. In combination with key human studies, animal and cell in vitro models have begun to elucidate the possible biological responses induced by DE exposure, determined bioactive component(s), better

established dose-response relationships, and identified possible susceptible populations. Findings from these studies assist in the assessment of risk from DE in different exposure scenarios, and ultimately in the management of health risks from DE exposure. [This abstract may not represent official EPA policy.]

### **341** FUTURE RESEARCH NEEDS FOR DIESEL EMISSIONS.

T. W. Hesterberg<sup>1</sup>, W. B. Bunn<sup>1</sup>, W. J. Slodowske<sup>1</sup> and <u>C. A. Lapin</u><sup>2</sup>.

<sup>1</sup>International Truck and Engine Corporation, Warrenville, IL and <sup>2</sup>Lapin and Associates, Glendale, CA.

Exposure of animals to diesel exhaust can produce lung and cardiovascular effects. However, most studies used exposure routes and dose levels that may not be useful for assessing the potential risks of diesel exhaust. Furthermore, many of these studies examined only the particulate matter fraction of the exhaust. Typically the diesel particulate matter (DPM) was collected on a filter and stored before being suspended in air or liquid for use in toxicity studies. The chemistry of DPM can change when concentrated and stored. When DPM is suspended in saline and instilled into animal lungs, the burdens can be very high and result in non-uniform distribution with local areas of even higher concentrations. In vitro studies have similar issues. Although a few animal studies have used concentrated airborne particles (CAPs) to increase the inhalation dose of DPM, there are also drawbacks to these studies. High exposure levels are often used and much of the gaseous components of the exhaust are removed. Removing the gaseous components not only could impact the overall toxicity of the exhaust, but may also alter the physico/chemistry of the concentrated DPM. Future studies should focus on exposing animals by inhalation to fresh whole diesel exhaust at multiple concentrations that are relevant to ambient and occupational levels. There are a number of animal inhalation models of lung and cardiovascular disease where whole diesel exhaust can be tested. In the last several years, to meet new EPA emission standards, the diesel industry has made significant improvements to engine technology that will result in near-zero emissions of particulate matter, hydrocarbons and other regulated chemicals. By 2010, USEPA regulations mandate that NOx emissions also be at near-zero levels. Toxicology data generated from past emissions profiles have limited relevance in evaluating health effects from exposure to current and future generation diesel engines. For assessing the newer technologies, emphasis should be on inhalation exposure to whole fresh engine exhaust tested at relevant exposure levels.

### 342 OVERVIEW- NUTRACEUTICALS AS A TOXICOLOGICAL DILEMMA.

### J. J. Pestka. Michigan State University, East Lansing, MI.

Ehrlich introduced the concept of therapeutic index (TI) almost a century ago which is identified as the ratio of dose of a chemical required to produce a toxic effect and the dose needed for desired therapeutic effect. Bioactive dietary chemicals that are used as nutraceuticals are extraordinarily diverse with respect to chemical structures and biological activities. When used as foods or in supplements, these chemicals have the potential for prevention or retardation of chronic diseases. Paradoxically, some of these chemicals can also induce subtle toxic effects that exacerbate disease. Given the current regulatory environment created by the Dietary Health and Education Act of 1994 (DSHEA), providers of nutraceuticals are not subject to the degree of safety evaluation required for drugs and food additives. Thus, clear definitions of potential negative effects of nutraceuticals are not readily accessible. This is further complicated by factors such as disease, predisposing factors, age and genetic background of humans. This workshop focuses on the challenge of this double-edged sword by examining, from a mechanism-based perspective, examples of dietary chemicals that are being used or considered for disease prophylaxis relative to potential safety concerns and disease exacerbation.

### 343 PLEIOTROPIC EFFECTS OF CANCER PROTECTIVE DIETARY INDOLES.

L. Bjeldanes. Department of Nutrition, University of California at Berkeley, Berkeley,

Indole-3-carbinol (I3C) is a product of Brassica plants that shows both cancer preventive and cancer promoting activities in different assays. I3C is converted to a series of self-condensation products that are responsible for the *in vivo* biological activities of this indole. One of the minor products, ICZ, is a potent ligand for the Ah receptor, and thus, behaves in some respects like the environmental toxin, TCDD. A major I3C product, CTI, is a potent ligand for the estrogen receptor and can induce the growth of estrogen responsive breast tumor cells. Studies of an additional

major in vivo I3C product, DIM, show that this product can activate the estrogen receptor in a manner that does not require ligand binding. These activities may contribute to the cancer promoting effects of I3C. In addition, however, DIM exhibits several novel activities that may contribute to the cancer preventive effects of DIM and I3C. The antiproliferative effects of DIM in cultured endometrial cancer cells are mediated in part by DIM-induced expression of TGF-alpha. DIM treatment of endometrial cancer cells stimulated levels of secreted TGF-alpha protein by over 10 fold. The ectopic addition of TGF-alpha inhibited the growth of these cells, whereas incubation with an anti-TGF-alpha antibody partially reversed the growth inhibitory effects of DIM. In other studies with prostate tumor cells, we found that DIM is a potent antagonist for the androgen receptor that blocks androgen induced signaling and strongly inhibits the proliferation of androgen sensitive prostate tumor cells. These activities were not produced in androgen independent prostate tumor cells. Moreover, DIM inhibited transcription of the endogenous prostate tumor marker, PSA, and reduced intracellular and secreted PSA protein levels induced by androgen in androgen-dependent prostate tumor cells. These studies provide a mechanistic rationale for the desirable and the adverse effects of I3C, and suggest that the two types of effects might be separable.

### 344

### BREAST CANCER THERAPIES AND DIETARY ESTROGEN (GENSITEIN) CONSUMPTION.

B. Helferich. Food Science and Human Nutrition, University of Illinois, Urbana, IL. Sponsor: J. Pestka.

Genistein, found in soy products, is a phytochemical with estrogenic activity. Our research has focused on the effects dietary genistein on growth of both estrogen (E)dependent in vivo. Genistein enhances the proliferation of E-dependent human breast cancer tumor growth. Genistin, the glycoside form of genistein simulates growth similar to that of genistein and withdrawal of either genistin results in tumor regression. We have also demonstrated that soy protein isolates processed to contain low, medium and high amounts of isoflavones simulate tumor growth in a dose dependent manner. Expression of the estrogen-responsive gene, pS2 was also induced in response to treatment with dietary genistein. To evaluate whether dietary genistein interacts with current anti-estrogen breast cancer therapy such as tamoxifen (TAM). We implanted E-dependent tumors into ovariectomized athymic mice and administered estradiol, estradiol plus TAM, or estradiol, TAM + dietary genistein. In these studies dietary genistein was able to negate the inhibitory effect of TAM on E-stimulated tumor growth. In summary, genistein can act as an estrogen agonist resulting in proliferation of E-dependent human breast cancer cells in vivo and can negate the inhibitory effects of TAM on E-stimulated growth of MCF-7 cell tumors (in vivo) implanted into ovariectomized athymic mice.

# ATTENUATION VERSUS POTENTIATION OF THE IMMUNE RESPONSE BY DIETARY OMEGA-3 POLYUNSATURATED FATTY ACIDS.

K. L. Fritsche. Animal Sciences, University of Missouri, Columbia, MO. Sponsor: J. Pestka.

Numerous studies have documented health benefits associated with increasing our intake of omega-3 polyunsaturated fatty acids (n-3 PUFA) found in fatty fish (e.g., tuna, herring, salmon, sardines). For example, consumption of 1-2 servings per week of such fatty fish has been shown to dramatically reduce the risk of dying from a heart attack. Greater amounts of n-3 PUFA can benefit people suffering from various inflammatory/auto-immune diseases. Concern arose, however, over the potential adverse effects of consuming large amounts of n-3 PUFA because these nutrients tend to have a suppressive effect on in vivo and in vitro immune responses. Evidence that n-3 PUFA affect, both positively and negatively, infectious disease resistance will be presented. The impact that n-3 PUFA have on host response to infectious agents is most likely a consequence their ability to reduce the biosynthesis of pro-inflammatory cytokines and eicosanoids. Novel findings by the authors suggest that n-3 PUFA may adversely affect host infectious disease resistance by reducing interferon-gamma receptor expression and signaling in macrophages. Direct examination of the effect of n-3 PUFA on human infectious disease resistance remains largely untested. We believe that the body of evidence suggests that such testing would be prudent.

### PROMOTION VERSUS SUPPRESSION OF CHEMICAL CARCINOGENESIS BY CHLOROPHYLLS.

G. S. Bailey and R. Dashwood. Linus Pauling Institute, Oregon State University, Corvallis, OR.

Although ample epidemiology data indicate a protective role for green and leafy vegetables in human cancer risk, there is relatively little evidence for natural chlorophylls in cancer chemoprevention. However, a simple non-toxic water soluble de-

rivative of chlorophyll, chlorophyllin (CHL), has displayed potent anti-mutagenic and anti-carcinogenic activity in many model systems. Anti-carcinogenic activity was first demonstrated in the rainbow trout, where dietary CHL co-treatment provided dose-responsive inhibition of aflatoxin-DNA damage to an extent that precisely predicted inhibition of eventual tumor outcome. Subsequent experiments showed that CHL co-treatment could inhibit cancer initiation in several rodent models as well. With this background, a clinical intervention trial was undertaken in the Peoples Republic of China in 1997, in a population at high risk due to unavoidable aflatoxin exposure in the diet. The results of the trial showed that daily CHL supplementation was as effective in humans as it was in trout at reducing biomarkers of aflatoxin uptake and liver DNA damage. Recent experiments in the trout model show that CHL has comparable biomarker and cancer preventive efficacy against highly carcinogenic polyaromatic hydrocarbons. Although CHL thus shows great promise to diminish the effects of carcinogen exposure in certain highrisk populations, CHL may not be entirely risk-free. While there is no evidence for CHL toxicity in humans, post-carcinogen CHL treatment protocols in the rat have yielded mixed results. These include dose-dependent suppression of tumor progression in some organs but an inverse dose-dependency for elevated progression in others, principally the colon. Mechanism studies indicate that CHL can have differing effects on gene pathways regulating tissue homeostasis in the colon, and that this may be mediated through the selective progression of initiated cells containing a sub-set of beta-catenin mutations. Initial studies indicate that this enhancement is not seen with natural chlorophylls.

## 347 EFFECTS OF NATURAL AND SYNTHETIC FLAVONOIDS ON AROMATASE (CYP19) IN H295R HUMAN ADRENOCORTICAL CARCINOMA CELLS.

T. Sanderson<sup>1</sup>, M. S. Denison<sup>2</sup>, M. Springsteel<sup>3</sup>, J. Hordijk<sup>1</sup>, M. H. Nantz<sup>3</sup> and M. van den Berg<sup>1</sup>. <sup>1</sup>Institute for Risk Assessment Sciences, University of Utrecht, Utrecht, Netherlands, <sup>2</sup>Department of Environmental Toxicology, University of California, Davis, CA and <sup>3</sup>Department of Chemistry, University of California, Davis, CA.

Flavonoid structures have various (anti-)estrogenic effects. We investigated the effects of various naturally occurring and synthetically derived flavonoids on the catalytic activity and promoter-specific expression of aromatase (CYP19; which converts androgens to estrogens) in H295R cells. All exposures were for 24 h. The steroidal aromatase inhibitor 4-hydroxyandrostenedione (positive control) had an IC50 of about 20 nM. The flavones 7-OH-flavone, chrysin, and apigenin had IC50 values of about 6, 7, and 30 µM, respectively. The flavanones 7-OH flavanone and naringenin had IC50s of about 80-90 µM close to the highest tested concentration of 100  $\mu$ M. In the case of apigenin and naringenin inhibition coincided with signs of cytotoxicity. The 7-methoxylated flavone and flavanone showed no aromatase inhibition, as was true for catechin and (-)-epicatechin. Several synthetic flavonoid and structurally related quinolin-4-one analogs were found to inhibit aromatase activity. The most potent inhibitor was 4'-tert-butyl-quinolin-4one (IC50=2  $\mu$ M) followed by several 2-pyridinyl-substituted  $\alpha$ -naphthoflavones (IC50s between 5 and 30 μM). The 2-pyridinyl-substituted γ-naphthoflavones consistently produced biphasic concentration-response curves, causing about 1.5fold aromatase induction below 1  $\mu M$  and inhibition above 1  $\mu M$  (IC50s between 10 and 100 µM). Various flavonoid structures with a bromine, fluorine or nitrogroup at the 4'-position of the B-ring were inactive. The natural flavone quercetin and isoflavone genistein induced aromatase activity 4- and 2.5-fold induction, respectively at 10 µM. This coincided with increased levels of intracellular cAMP, and pII and to a lesser extent 1.3 promoter-specific aromatase transcript. These results shed light on the structure-activity relationships for aromatase inhibition and mechanism of induction in human H295R cells.

### 348 EXPRESSION, CHARACTERIZATION AND MUTATION OF RAT CYTOCHROME P450C24A1 (CYP24A1).

A. J. Annalora<sup>1, 2</sup>, K. Bobrovnikova-Marjon<sup>2</sup>, A. Pastuszyn<sup>2</sup>, M. Chiu<sup>3</sup>, <u>C. Marcus</u><sup>1</sup> and J. L. Omdahl<sup>2</sup>. <sup>1</sup>College of Pharmacy, University of New Mexico, Albuquerque, NM, <sup>2</sup>Department of Biochemistry and Molecular Biology, University of New Mexico, Albuquerque, NM and <sup>3</sup>Department of Structural Biology, Abbott Laboratories, Abbott Park, IL.

The discovery of potent antiproliferative effects of 1, 25-dihydroxyvitamin-D3 on cancer cell lines has initiated a new era of pharmacological investigation focused on vitamin D. Cytochrome P450c24 (CYP24A1) is a multifunctional enzyme that mediates the side-chain cleavage and excretion of circulating vitamin D. Because CYP24A1 plays a central role in regulating vitamin D metabolism, identification of this enzyme's key residues and structural domains will be necessary to establish a biorational basis for future vitamin D-based drug development. A high level of functional recombinant rat CYP24A1 (40-50 mg/L) was obtained using an E. coli expression system. However, characterization of membrane-bound proteins, like

CYP24A1, is problematic as these proteins aggregate in solution rather than forming the ordered crystals required for x-ray analysis. Therefore, we constructed a homology-based computer model of rat CYP24A1, using InsightII<sup>TM</sup>, to help identify amino acid residues involved in substrate recognition and binding. Site-directed mutagenesis experiments were conducted to assess the role of these residues with respect to Km and Kd. It was determined that the 1a- and 25-hydroxyl groups on vitamin D3 metabolites were the major determinants for high-affinity binding to CYP24A1. Mutagenesis within the putative F-helix of CYP24A1 drastically altered substrate binding and metabolism. Most significant was the hydrophobic to polar mutant F249T that had a strong impact on lowering substrate-binding-affinity and catalysis of the final oxidation sequence from 24, 25, 26, 27-tetranor-1, 23-dihydroxyvitamin D3 to calcitroic acid. Two other hydrophobic 249 mutants (F249A and F249Y) also lowered substrate binding, but the associated metabolic defect occurred earlier in the pathway. Therefore, F249 was demonstrated to have a key role in properly aligning substrate in the CYP24A1 active site.

### 349 DEVELOPMENTAL EXPRESSION IN THE RAT PLACENTA OF ENZYMES INVOLVED IN FATTY ACID METABOLISM

T. J. Cook, Y. Xu and G. T. Knipp. Department of Pharmaceutics, Rutgers, The State University of New Jersey, Piscataway, NJ. Sponsor: K. Reuhl.

The placenta regulates the delivery of nutrients and xenobiotics to the fetus, thus nourishing and protecting the fetus during development. Fatty acids (FA) are critical for normal fetal development. The two primary processes that govern FA supply from mother to fetus are metabolism and transport. Metabolism of FAs in the placenta may occur via several pathways. While these pathways are described in many other tissues, there is a dearth of information on the expression of FA metabolizing enzymes in the placenta. In our initial efforts to describe the functional FA metabolic pathways in the placenta, we have determined the gene expression of several enzymes involved in FA metabolism in the developing rat placenta: cytochrome P450 isoforms CYP4A1, 4A2, 4A3, and 4A8; lipoxygenases 12/15-and 5-LOX; cyclooxygenases COX-1 and -2; and uncoupling proteins UCP1, 2, 3, and 4. Placentas from rats on days 11, 13, 16, 19, and 21 of the gestation period were harvested. The junctional (JXN) and labyrinth (LAB) zones were separated under dissecting microscope. Gene expression was determined by RT-PCR using gene specific primers for each enzyme isoform. The relative expression of the CYP4A isoforms were: 4A1>4A2>4A3, 4A8, with greater expression in the JXN zone. For the UCPs, the relative expression were: UCP2>UCP4>UCP1>>UCP3. There was no clear preference for JXN vs LAB for UCP2 and UCP4. UCP1 expression shifted from LAB to JXN between day 13 and 16. 12/15-LOX was expressed throughout the gestation period with 5-LOX undetected. COX-2 exhibited a greater expression than COX-1 after day 11 of gestation with a shift in spatial expression from LAB to JXN as gestation progressed. The results demonstrate that the rat placenta expresses several enzymes involved in FA metabolism. The differential expression suggests that there may be changes in placental FA metabolism as a function of gestational age that can alter FA supply to the fetus. In addition, these results establish a template for studying the influence of xenobiotics on placental FA metabolism. Financial support from NAAR.

### 350 CYP1A2 PROTECTS AGAINST REACTIVE OXYGEN PRODUCTION IN MOUSE LIVER MICROSOMES.

H. G. Shertzer, C. D. Clay, M. Genter, S. N. Schneider, D. W. Nebert and T. P. Dalton. Department of Environmental Health and Center for Environmental Genetics, University of Cincinnati Medical Center, Cincinnati, OH.

H2O2 production was evaluated in liver microsomes prepared from Cyp1a1/1a2(+/+) wild-type and Cyp1a1(-/-) and Cyp1a2(-/-) knockout mice, pretreated with 5 µg TCDD/kg body weight or vehicle alone. NADPH-dependent H2O2 production in TCDD-induced microsomes from wild-type mice was approximately one-third of that in non-induced microsomes. In Cyp1a2(-/-) mice, H2O2 production was the same for induced and non-induced microsomes, with levels significantly higher than that in wild-type mice. Cyp1a1(-/-) microsomes displayed markedly lower levels of H2O2 production in both induced and non-induced microsomes, compared with that observed in wild-type and Cyp1a2(-/-) microsomes. The CYP1A2 inhibitor furafylline exacerbated in vitro microsomal H2O2 production proportional to the degree of CYP1A2 inhibition. In contrast, the CYP2E1 inhibitor diethyldithiocarbamate decreased H2O2 production proportional to the degree of CYP2E1 inhibition. Microsomal H2O2 production was strongly correlated to the NADPH-stimulated production of thiobarbituric acidreactive substances, as well as to decreases in microsomal membrane polarization anisotropy, indicative of peroxidation of unsaturated membrane lipids. Our results suggest that, possibly acting as an electron sink, CYP1A2 might decrease CYP2E1and CYP1A1-mediated H2O2 production and oxidative stress. In this regard,

CYP1A2 may be considered an antioxidant enzyme. (Supported by NIH grants R01 ES10133, R01 ES06321, R01 ES08147, R01 ES08799, T32 ES07250, and P30 ES06096)

351 QUANTIFICATION AND LOCALIZATION OF ROS PRODUCTION BY POLYCHLORINATED BIPHENYLS AND BY 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN.

J. Goldstone and J. J. Stegeman. Biology, Woods Hole Oceanographic Institution, Woods Hole, MA.

The mechanisms by which planar polyhalogenated aromatic hydrocarbons (PHAH), such as non-ortho-substituted polychlorinated biphenyls (PCBs) and polychlorinated dibenzo-p-dioxins, exert toxicity are not well known but may involve oxidative stress. Our prior work has shown that cytochrome P450 1A (both fish CYP1A and human CŶP1A1) catalytic cycles can be uncoupled by non-ortho PCBs resulting in the release of reactive oxygen species (ROS) and in the irreversibly inactivation of the enzyme. TCDD causes a similar uncoupling, resulting in a burst of ROS release (initially 24 nmole O<sub>2</sub>/min/nmole CYP1A but rapidly declining to 8 nmol  $\mathrm{O}_2$  /min/nmol CYP1A), and rapid inactivation of CYP1A. An increase in TCDD-induced mitochondrial production of ROS has been demonstrated in mice. To evaluate the relative contributions of CYP1A uncoupling and mitochondrial production of reactive oxygen in response to TCDD, we have examined the cellular localization of ROS production in cultured mouse and zebrafish hepatic cell lines (Hepa-1c1c and ZF-L) using multilaser confocal microscopy. The fluorometric ROS probe dihydroethidium was used to determine the production of superoxide  $(O_2)$ . Localization of CYP1A (or CYP1A1) within individual cells was performed by examining the production of fluorescent resorufin following the CYP1A-mediated O-deethylation of ethoxyresorufin (EROD). The release of ROS resulting from the uncoupling of CYP 1As by pHAHs represents a possible mechanism of toxicity of these aryl hydrocarbon receptor agonists. (EPA R 827102-01-0, NIH P42-ES07381, NIH 1 F32 ES012794-01).

COAL DUST INCREASES BAX EXPRESSION, INCREASES 352 APOPTOSIS, AND SUPPRESSES CYP1A1 INDUCTION IN A RAT MODEL OF MIXED EXPOSURE TO POLYCYCLIC AROMATIC HYDROCARBONS AND RESPIRABLE PARTICLES.

M. Ghanem<sup>1, 2</sup>, L. Battelli<sup>1, 2</sup>, R. R. Mercer<sup>1, 2</sup>, M. L. Kashon<sup>1</sup>, J. F. Scabilloni<sup>1, 2</sup>, <u>V. Castranova<sup>1, 2</sup></u>, J. Nath<sup>2</sup>, V. Vallyathan<sup>1, 2</sup> and A. F. Hubbs<sup>1, 2</sup>. 'NIOSH, CDC, Morgantown, WV and <sup>2</sup>West Virginia University, Morgantown, WV.

Apoptosis has been described in lung following exposure to inflammatory agents, such as silica. The bax gene contains 2 Ah receptor response elements, suggesting a relationship between bax-mediated apoptosis and xenobiotic metabolism. Suppression of pulmonary CYP1A1 induction by coal dust (CD) exposure occurred in the rat lung. Therefore, we hypothesized that CD exposure in rat lung causes bax-mediated apoptosis and bax expression suppresses CYP1A1 induction. To explore this relationship, male Sprague-Dawley rats were intratracheally instilled with 2.5, 10, 20, and 40 mg CD/rat or vehicle (saline). On day 11, CYP1A1 was induced by intraperitoneal (IP) injection of 50 mg/kg beta-naphthoflavone (BNF). Rats were sacrificed on day 14, and lung sections were stained by immunofluorescence and morphometrically analyzed for CYP1A1, bax and an alveolar type II (AT-II) cell marker (cytokeratins 8/18). Bax expression was increased by CD in a dosedependent manner, and CYP1A1 expression was inversely related to bax expression in AT-II cells. Since bax is a pre-apoptotic protein, we investigated the association of apoptosis with CYP1A1 suppression. Therefore, rats were injected IP with the caspase inhibitor, Q-VD-OPH or vehicle (DMSO) on days 0, 5, 9, 10, 11, 12, and 13 post CD-exposure. CYP1A1 was induced by BNF injection on day 11. Rats were sacrificed on day 14. CD exposure significantly suppressed CYP1A1 activity, increased bax expression and increased apoptosis in pulmonary cells. The injection of Q-VD-OPH significantly suppressed bax expression and apoptosis. However, the CD-mediated suppression of CYP1A1 induction was not significantly affected. These findings suggest that CD exposure suppresses CYP1A1 induction, but this suppression is not caused by bax expression or pulmonary cell apoptosis.

353 COMPARISON OF ACUTE AND CHRONIC EXPOSURE TO NONYLPHENOL REVEALS THAT CHRONIC EXPOSURE ATTENUATES P450 INDUCTION AND

W. Baldwin, R. Acevedo, L. M. Chapman and H. Villanueva. Biological Sciences, University of Texas at El Paso, El Paso, TX.

Nonylphenol (NP) is an environmental estrogen that also binds the pregnane X-receptor (PXR). Different laboratory feeding studies have shown both up-regulation and down-regulation of P450s by nonylphenol. The inconsistencies between laboratories for the differential effects of nonylphenol may be due to length of treatment. FVB/NJ mice were treated for 7 days with 0, 25, 50 and 75 mg/kg/day NP, and FVB/N-TgN(MMTVneu)Mul202 mice were treated for 32 weeks with 0, 30 and 45 mg/kg/day NP. The transgenic mice treated for 32 weeks at 45mg/kg/day demonstrated higher incidence of mammary cancer, indicating that the dose of NP provided was sufficient to cause estrogenic effects. After exposure, mice were euthanized, livers excised, and steroid hydroxylase assays and Western blots were performed for CYP 3A, CYP2B6 and CYP 2B10. Western blots revealed that CYP3A was not significantly induced by nonylphenol, but CYP 2B6 and CYP2B10 were induced 1.6X and 5X, respectively after the 7 day exposure. Estradiol and testosterone hydroxylation assays demonstrated an increase in the production of estriol and 16β-hydroxytestosterone, respectively, further demonstrating the induction of CYP2B enzymes. However, 32-week treatment showed no significant increase in testosterone or estradiol hydroxylation, nor significant induction of P450s. Clontech cDNA Atlas® arrays were performed to determine a potential mechanism for the lack of induction in mice treated for 32 weeks. Interestingly, RXRa, PXR's heterodimerization partner was reduced 1.9X. Q-PCR was performed to confirm down-regulation and indicated a 2.5X decrease in transcript levels in mice treated for 32 weeks with NP. Mice treated for 7 days showed no change in RXR $\alpha$  levels. Furthermore, Q-PCR of PXR, CAR and ER were not altered in the livers of mice from either NP treatment group. This data suggests that long-term exposure to nonylphenol can reduce RXRα levels, and attenuate P450 induction. This may ultimately reduce an organism's ability to adapt to toxicant exposure.

354 A NOVEL CLASS OF CYTOCHROME  $\mathrm{P}_{450}$  REDUCTASE REDOX CYCLERS: CATIONIC MANGANOPORPHYRINS.

C. T. Kariya<sup>1</sup> and <u>B. J. Day</u><sup>1, 2</sup>. <sup>1</sup>Pharmaceutical Sciences, UCHSC, denver, CO and <sup>2</sup>Medicine, National Jewish Medical Research Center, Denver, CO.

Manganoporphyrins are potent antioxidants and are currently being developed as novel therapeutic agents. The objective of this study was to investigate whether manganoporphyrins inhibit drug metabolism. In vitro studies were done to examine this issue. Microsomal cytochrome  $P_{450}$  activity was assessed using two different substrates, benzyloxyresorufin (BR) and methoxyresurofin (MR). The cationic manganoporphyrins AEOL 10113 and 10123 were found to be potent inhibitors of cytochrome  $\acute{P}_{450}$  metabolism in both rat and human liver microsomes with IC  $_{50s}$  of 0.665  $\mu$ M and 0.607  $\mu$ M respectively. Since manganoporphyrins are redox active, we test the hypothesis that the mechanism of cytochrome  $P_{450}$  inhibition was due to redox cycling with cytochrome  $P_{450}$  reductase. We tested this hypothesis by examining their ability to stimulate NADPH and oxygen consumption in presence of purified human cytochrome  $P_{450}$  reductase. AEOL 10113 had  $Km = 4.3 \,\mu\text{M}$ , indicating that it was a potent redox cylcer. The manganoporphyrins AEOL 10113 and 10123 were nearly 2 orders of magnitude more potent than corresponding AEOL 10150 and 10201 in inhibiting cytochrome  $P_{450}^{\prime}$  metabolism and as redox cyclers with cytochrome P450 reductase. Structure activity relationships suggested that substitution of longer alkyl chains on the meso porphyrin position and decreased charged lessened the manganoporphyrin's ability to redox cycle with cytochrome  $P_{450}$  reductase and inhibit cytochrome  $P_{450}$  metabolism. To further examine the possible mechanism of cytochrome  $P_{450}$  inhibition, oxygen consumption studies were performed in the presence of a flavin domain inhibitor, diphenyleneiodinium (DPI). DPI blocked the consumption of oxygen in a concentration-dependent manner. These data are consistent with the hypothesis that manganoporphyrins redox cycle with the flavin domain of cytochrome P<sub>450</sub> reductase and compete for electrons with cytochrome P<sub>450s</sub>.

355 SF-1 FUNCTIONS SYNERGISTICALLY WITH CREB TO MEDIATE CAMP STIMULATION OF CYP1B1 VIA A FAR UPSTREAM ENHANCER (FUER).

W. Zheng and C. R. Jefcoate. Pharmacology, University of Wisconsin-Madison,

Cyp1B1 plays a key role in the activation of polycyclic aromatic hydrocarbons in tissues like the adrenal ovary and testis that are hormonally regulated via cAMP. In primary adrenal cells Cyp1B1 is substantially induced by cAMP. Previously we used Cyp1B1-luciferase reporters to characterize a cAMP stimulation mechanism in Y-1 adrenal cell line, which depends on a far upstream enhancer region (FUER, -5298 to -5110). SF-1 and CREB commonly mediate cAMP responses. Here we show that SF-1 and CREB are equally essential for the cAMP activation of FUER. Four SF-1-binding sites in FUER can participate relatively equally and additively in support of an essential CREB interaction at the 3' end of the FUER. DAX-1, a suppressor of SF-1, also blocked FUER activity. An AP-1 binding site in proximal promoter region regulates basal activity of Cyp1B1 which is enhanced by FUER in Y-1 cells. The role of FUER has been tested by chromatin immunoprecipitation assay with anti-acetyl histone H3 anti-body in primary rat adrenal cells. Stimulation by

cAMP was associated with greatly increased histone H3 acetylation in FUER (6.6 fold) and proximal promoter region (3 fold) but not in AhR binding region, suggesting that FUER chromatin remodeling mediates cAMP induction.

#### 356 METHOXYCHLOR-INDUCED ATRESIA WORKS THROUGH THE BCL-2 PATHWAY.

C. Borgeest<sup>1</sup>, K. P. Miller<sup>1</sup>, C. Greenfeld<sup>2</sup> and J. A. Flaws<sup>1</sup>. <sup>1</sup>Program in Toxicology, University of Maryland, Baltimore, MD and <sup>2</sup>Department of Physiology, University of Maryland, Baltimore, MD.

The organochlorine pesticide methoxychlor (MXC) has been shown to cause ovarian atresia (apoptosis of antral follicles). Bcl-2 (an anti-apoptotic protein) and Bax (a pro-apoptotic protein) are both important apoptotic factors in the ovary, and it is thought that the ratio of pro- to anti-apoptotic proteins is a determining step in whether follicles undergo atresia. Previous studies conducted in our laboratory have shown that MXC induces antral follicle atresia without changing serum levels of estradiol, follicle-stimulating hormone and luteinizing hormone. Since MXC induces antral follicle atresia without altering pituitary-gonadal hormones, our hypothesis is that MXC targets antral follicles directly through either Bcl-2 or Bax in the ovary. In order to test this hypothesis, CD-1 mice (39 days old) were treated with 64mg/kg MXC or sesame oil (vehicle), ovaries were collected during estrus and processed for immunohistochemical analysis of Bcl-2 or Bax proteins. Further, transgenic mice that overexpress Bcl-2 and mice deficient in Bax and their wildtype littermates were treated with either 64mg/kg MXC or vehicle, and their ovaries were collected during estrus and processed for morphological analysis of antral follicle atresia. Our results show that immunohistochemical staining for Bax was stronger in the MXC-treated mice, but Bcl-2 levels remain unchanged as compared to vehicle-treated mice. In addition, our results show that Bcl-2 overexpressing mice and Bax deficient mice were protected from MXC induced-atresia. There were significantly more healthy antral follicles in the MXC-treated Bcl-2 overexpressing mice than in the MXC-treated wild-type mice (Bcl-2 overexpressers = 903  $\pm$  123, wild-type = 540  $\pm$  72; n=7-9, p=0.03). MXC-treated Bax deficient mice had similar levels of atresia as the vehicle-treated Bax deficient mice (31% vs. 27%, respectively). Collectively, these data suggest that MXC induces antral follicle atresia via a mechanism that involves Bcl-2 and Bax. (Supported by NIH HD38955 and T32 ES07263-13).

#### 357 *IN VITRO* FOLLICLE ASSAY ALLOWS GONADAL RISK ASSESSMENT FOR BENZODIAZEPINE.

R. Cortvrindt<sup>1, 2</sup>, K. Van Wemmel<sup>2</sup>, University. Eichenlaub-ritter<sup>3</sup> and J. Smitz<sup>2</sup>. 
<sup>1</sup>EggCentris nv, Zellik, Belgium, <sup>2</sup>Follicle Biology Laboratory, Free University of Brussels, Brussels, Belgium and <sup>3</sup>Microbiology and Genetechnology, University of Bielefeld, Bielefeld, Germany. Sponsor: M. Martens.

It is currently not clear whether chronic use of benzodiazepines can affect female fertility. In vitro studies suggest that acute high doses of diazepam (DZ) interfere with the meiotic process. Follicles exposed in vitro to chronic low doses of DZ had a reduced survival rate and poor oocyte quality. To investigate efficacy & specificity of the follicle culture system, 3 benzodiazepins with different receptor specificity were tested. Flumazenil (FL) binds to receptors in the CNS while 3-chlorodiazepam (CD)to peripheral receptors, diazepam (DZ) to both. Mouse preantral follicles were cultured singly for 12 days to the preovulatory stage, in α-MEM with FBS, FSH, LH. At day 12 an ovulatory stimulus (hCG) was added. Follicles were continuously exposed to FL, CD or DZ to 5, 10 or 15 µg/ml. Follicle growth, steroid secretion, oocyte quality were concurrently analysed. At all doses tested FLexposure had no impact on folliculogenesis, steroid production or on oocyte maturation. CD acted similarly as DZ. Both drugs decreased follicle survival and altered steroid production dose dependently. At  $15~\mu g/ml$  only 25~% of the follicles survived the 12-day culture period. CD blocked meiosis reinitiation while oocytes exposed to DZ started meiosis but progression was disturbed. Analysis of spindle formation revealed an increased aberration rate in the MII-oocytes exposed to CD and DZ but not to FL. At a dose of 5 µg/ml, cytogenetic analysis revealed a diploidyrate of 15% and 29% for DZ and CD respectively. Five µg/ml FL had no effect on chromosome constitution. In accordance to their receptor binding specificity, benzodiazepines differ in their effects on ovarian function. FL was not cytotoxic during folliculogenesis while CD and DZ induced cytotoxicity and had an aneugenic effect on oocytes. The follicle culture system is a relevant in vitro model to study effects of NCE on the ovarian function and will be helpful to assess female fertility in

### 358 METABOLIC MECHANISMS OF METHOXYCHLOR TOXICITY IN MOUSE ANTRAL OVARIAN FOLLICLES.

K. P. Miller, C. Borgeest and J. A. Flaws. Program in Toxicology, University of Maryland, Baltimore, MD.

The organochlorine pesticide methoxychlor (MXC) is a reproductive toxicant that targets the mammalian ovary, causing reduced fertility and persistent estrus. Antral follicles are the primary targets of MXC toxicity, while less mature follicles are not

affected by MXC exposure. Previous studies indicate that antral follicles from in vivo-exposed mice show increased atresia and altered expression of apoptotic proteins. Although MXC toxicity in non-ovarian tissues has been attributed to cytochrome P450 (CYP) metabolism to polar compounds including bis-hydroxy MXC (HPTE), little is known about ovarian mechanisms of MXC toxicity. Our hypothesis is that MXC metabolites are responsible for antral follicle-specific toxicity, and that CYP enzymes expressed in the ovary mediate MXC metabolism to cause antral follicle toxicity. Antral follicles were isolated from immature mouse ovaries and exposed in vitro to MXC (0.01-100µg/mL) or HPTE (0.01-1µg/mL) for 96hrs. Follicle diameters were measured to assess growth in response to MXC or HPTE. Cultured follicles were also processed for morphological analysis of atresia, as determined by numbers of pyknotic bodies in granulosa cells. Immunohistochemistry was performed on ovaries from in vivo MXC-exposed mice (sesame oil, 32mg/kg MXC, 20 days) to evaluate expression of MXC metabolizing enzymes CYP3A4 and CYP2C19. MXC significantly inhibited growth of antral follicles in vitro compared to controls at  $10^\circ$  and  $100\mu\text{g/mL}$  (n=25 follicles/treatment; p<0.01), and increased atresia over controls at 100µg/mL. HPTE did not alter follicle growth, nor did it significantly induce atresia. Yet, both CYP3A4 and CYP2C19 were present in the ovary, and induced by MXC in corpora lutea, surface epithelium and antral/preovulatory follicles. These data suggest that metabolites other than HPTE may be responsible for suppression of antral follicle growth by MXC. Also, since CYPs are expressed in the ovary, metabolism of MXC by other ovarian components may subsequently cause antral follicle toxicity. (Supported by NIH HD38955, T32 ES07263-13 and a Colgate-Palmolive Fellowship).

# 359 ESSENTIAL ROLE OF NRF2 IN PROTECTION AGAINST OVARIAN FOLLICLE LOSS INDUCED BY 4-VINYCYCLOHEXENE AND 4-VINYLCYCLOHEXENE DIEPOXIDE IN MICE.

X. Hu<sup>1</sup>, Y. Kan<sup>2</sup> and Q. <u>Ma</u><sup>1</sup>. <sup>1</sup>HELD/CDC, TMBB/NIOSH, Morgantown, WV and <sup>2</sup>Laboratory Medicine, Howard Hughes Medical Institute, University of California, San Francisco, CA.

4-Vinylcyclohexene (VCH), an industrial chemical, and its metabolite 4-vinylcyclohexene diepoxide (VCD), represent a potential health hazard, because they selectively destroy oocytes in small pre-antral follicles leading to premature ovarian failure in animals. Previous studies suggest that metabolism of VCH and VCD by phase I and phase II drug-metabolism enzymes plays an important role in the ovotoxicity of these chemicals. Nrf2 is a member of the Cap "N" Colar bZip family of transcription factors that mediates the basal expression and induction of phase II enzymes such as NQO1. In this study, we examined the role of Nrf2-regulated gene expression in the ovotoxicity of VCH and VCD by using Nrf2 knockout mice. Immature (age, day 28) female wild-type and Nrf2-/- mice (both in B6 background) were treated with VCH or VCD using established protocols; 4 h following the final dose, ovaries were collected. Complete serial sections of ovaries were evaluated histologically for the presence of follicles. As expected, the primordial and primary follicle numbers in ovaries from wild type mice decreased significantly (p<0.05) following treatment with either VCH or VCD. However, the primordial and primary follicles in ovaries from Nrf2-/- mice exhibit much higher sensitive to the toxicity of VCH and VCD than those of wild type mice. Both VCH and VCD have no significant effects on growing or pre-antral follicles in either genotypes. Taken together, these results demonstrate that loss of Nrf2 function is associated with increased sensitivity to toxicity of VCH and VCD on ovary follicle development. The findings suggest that Nrf2-mediated expression of phase II genes plays an important role in detoxification of VCH and VCD, thereby protecting ovarian follicles from the ovotoxicity of the chemicals.

## 360 NEONATAL EXPOSURE TO GENISTEIN ALTERS OVARIAN DIFFERENTIATION RESULTING IN THE FORMATION OF MULTI-OOCYTE FOLLICLES.

W. Jefferson<sup>1, 2</sup>, M. Pepling<sup>3</sup>, E. Padilla-Banks<sup>1</sup> and R. Newbold<sup>1, 1</sup>Labortatory of Molecular Toxicology, NIEHS, Research Triangle Park, NC, <sup>2</sup>Department of Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC and <sup>3</sup>Syracuse University, Syracuse, NY.

Genistein (Gen), the primary phytoestrogen in soy products, including soy-based infant formulas, was investigated for potential adverse effects on the developing ovary. We have previously shown that mice treated with Gen during the first week of life develop a dose dependent increase in the number of multi-oocyte follicles (MOF) at 19 days of age. During ovarian differentiation murine ovaries are composed of oocyte nests on day 1 which dissociate leaving predominantly single oocyte follicles by 5 days of age. To determine if Gen inhibits the breakdown of oocyte nests leading to MOF, we treated outbred CD-1 mice by subcutaneous injection on neonatal days 1-5 with Gen at 50 mg/kg/day and compared ovarian differentiation to age-matched untreated controls. Ovaries were collected on days 1-6

and fixed in 5.3% paraformadehyde. Ovaries were labeled with an oocyte marker, STAT3 and analyzed by confocal microscopy to observe oocyte nest breakdown. At 2 days of age, there was no apparent difference in the percent of single oocyte follicles (control 8%; Gen-treated 5 %). However, by 4 days of age, there was an apparent decrease in the % of single oocyte follicles in the Gen-treated ovaries compared to controls (Control 44%; Gen 21%). This difference was still apparent by 6 days of age (Control 57%; Gen 36%). To further determine the mechanism by which MOF are formed and since mice lacking GDF-9 and/or BMP-15 demonstrate the presence of MOF, we are currently investigating the role of these oocyte-secreted proteins in the Gen-treated ovaries compared to controls. Neonatal exposure to Gen alters the differentiating ovary by inhibiting oocyte nest breakdown leading to the development of MOF. This altered phenotype may play a role in the infertility seen in mice exposed developmentally to genistein. Whether other environmental estrogens cause similar effects is being investigated.

# 361 QUANTIFICATION OF TOXICANTS IN COMMERCIAL BRAND CIGARETTES AND CHARACTERIZATION OF THEIR EFFECTS ON OVIDUCTAL FUNCTIONING.

K. Riveles<sup>1</sup>, R. Roza<sup>1</sup>, D. Kwan<sup>1</sup>, V. Tran<sup>1</sup>, J. Arey<sup>2</sup> and P. Talbot<sup>1</sup>. <sup>1</sup>Department Cell Biology & Neuroscience, UC Riverside, Riverside, CA and <sup>2</sup>Environmental Sciences, UC Riverside, Riverside, CA.

Previously, mainstream (MS) and sidestream (SS) smoke solutions and individual components (pyridines, pyrazines, phenols, quinolines, and indoles) in University of KY 2R1 research cigarettes were shown to be toxic to mammalian oviducts in ciliary beat frequency, oocyte pickup rate, and smooth muscle contraction assays. The purpose of this project was to compare the concentrations of toxicants in MS and SS smoke solutions from a variety of commercial and research brand cigarettes: Omni, Advance, Marlboro, Camel, Kool, 2R1 & 1R4F, and to test these solutions in the oviductal assays. Although exact concentrations have not yet been calculated, preliminary analysis of peak size has shown that the above toxicants are more concentrated in SS than in MS smoke solutions. MS and SS smoke solutions made from several of the commercial brand cigarettes have been tested in the oviductal assays. For MS smoke solutions, the percentages of inhibition for ciliary beat frequency, oocyte pickup rate, and smooth muscle contraction for Camel brand cigarettes were: (27.12%±5.12), (36.20%±3.16), and (89.72%±0.39) respectively; for Kool were (17.44%±3.02), (49.14%±2.68), and (89.52%±1.31) respectively; and for Omni Light were (32.3%±9.77), (43.29%±3.16), and (5%±0.56) respectively. For SS smoke solutions, the percentages of inhibition for ciliary beat frequency, oocyte pickup rate, and smooth muscle contraction for Camel were (37.75%±3.97), (93.84%±0.23), and (99.59%±0.50) respectively; for Kool (99.5%±0.34), (94.64%±0.25), and (99.5%±0.55) respectively; and for Omni Light were (41.4%±4.67), (46.4%±0.38), and (78.23%±1.65) respectively. The results of this study show that sidestream smoke solutions were more inhibitory in the oviductal assays than mainstream solutions when puff equivalents were made equal. In addition, oocyte pickup rate and smooth muscle contraction were more affected than ciliary beat frequency.

# 362 GESTATION-AGE RELATED INCREASES AND ACTIVATION OF PHOSPHOLIPASE A<sub>2</sub> ENZYMES MEDIATE PCB 50 INDUCED STIMULATION OF RAT UTERINE FUNCTION.

K. A. Brant and <u>R. Loch Caruso</u>. Environmental Health Sciences, University of Michigan, Ann Arbor, MI.

We previously reported a gestation day sensitivity of rat uterine muscle to stimulation by the ortho substituted polychlorinated biphenyl (PCB) congener 2, 2', 4, 6tetrachlorobiphenyl (PCB 50). PCBs have been reported to activate phospholipase A, to release arachidonic acid (AA) from membrane phospholipids. We hypothesized that PCB 50 stimulates uterine function through activation of PLA2 enzymes, with late gestation tissue being more sensitive to stimulation due to gestational increases in uterine PLA, expression. Western blot analysis on uterine tissue homogenates revealed a significant increase in calcium-independent and secretory  $PL\tilde{A}_2$  expression from mid (gd10) compared with late (gd20) gestation (p < 0.05), with no changes in cytosolic PLA2 expression. To examine the effects of PCB 50 on PLA<sub>2</sub> activity, primary cultures of gd20 rat uterine myocytes (rmc) were loaded with 0.5 μCi <sup>3</sup>[H]-AA prior to a 10, 20 or 30 min exposure to 1, 10, 15, 25, or 50 μM PCB 50, or 0.1% DMSO (control). PCB 50 stimulated the release of <sup>3</sup>[H]-AA from gd20 rmc in concentration- and time- dependent manners (p < 0.05). A significant release of <sup>3</sup>[H]-AA was first observed after 20 min in the 50 μM treatment group compared to control (p < 0.05). After 30 min, PCB 50 stimulated a concentration-dependent increase in  $^{3}[H]$ -AA release at 15, 25, and 50  $\mu$ M compared to control (p < 0.05), with values significantly greater than those observed at 10 and 20 min (p < 0.05). In the presence of 1 mM EGTA  $^3$ [H]-AA release following stimulation was reduced, suggesting the release is, in part, calcium-dependent. PCB 50stimulated  $^3$ [H]-AA release was also reduced in the presence of secretory, cytosolic and calcium independent PLA2 inhibitors (p < 0.05). These results indicate that PCB 50 stimulates  $^3$ [H]-AA release via activation of multiple PLA2s. Furthermore, the gestation age-related increases in secretory and calcium independent PLA2 expression provide a potential mechanism for the gestation day sensitivity to rat uterine stimulation by PCB 50.

# 363 STIMULATORY EFFECTS OF A MICROBIALLY DECHLORINATED POLYCHLORINATED BIPHENYL (PCB) MIXTURE ON RAT UTERINE CONTRACTION IN VITRO.

R. Loch-Caruso<sup>1</sup>, T. Tsuneta<sup>1</sup>, M. Hanna<sup>1</sup>, C. Grindatti<sup>1</sup>, J. F. Quensen<sup>2,3</sup> and S. A. Boyd<sup>2,3</sup>. <sup>1</sup>Environmental Health Sciences, University of Michigan, Ann Arbor, MI, <sup>2</sup>Crop and Soil Sciences, Michigan State University, East Lansing, MI and <sup>3</sup>Institute for Environmental Toxicology, Michigan State University, East Lansing, MI.

Previously, we reported that microbial dechlorination increases the ability of commercial PCB mixtures (Aroclor 1242, 1248 and 1254) to stimulate uterine contraction. In the present study, we analyzed the most abundant chlorobiphenyl (CB) congeners produced by microbial dechlorination of Aroclor 1260 in an attempt to identify stimulatory congeners. Aroclor 1260 was incubated under anaerobic conditions with bacteria isolated from Hudson River sediment to generate the partially dechlorinated mixture HR1260. A control mixture, Auto1260, was generated by incubating Aroclor 1260 with autoclaved Hudson River sediment microorganisms, and the congener composition of Auto1260 was identical to that of Aroclor 1260. To evaluate uterine contraction, uterine strips from midgestation rats were suspended in muscle baths and exposed in vitro to PCBs. HR1260 significantly increased contraction frequency to 718±134% at 70 µM, whereas Auto1260 and Aroclor 1260 had no significant effects on uterine contraction frequency. Compared with Auto1260, microbial dechlorination increased 2, 2', 4, 4-CB in  $HR1260\ to\ 24\ mol\ \%.\ Also,\ 2,\ 3',\ 3,\ 5-CB,\ 2,\ 3',\ 4,\ 5-CB,\ 2,\ 2',\ 4,\ 4',\ 6-CB\ and\ 2,$ 2', 4, 5', 6-CB co-eluted in a chromatography peak that increased 7.6 mol %. Of these congeners, only 2, 2', 4, 5', 6-CB and a mixture of 2, 2', 4, 4 -CB and 2, 2', 4, 5', 6-CB significantly increased contraction frequency to 129±5.1% and  $124{\pm}15\%$  at 100 and 60  $\mu\text{M},$  respectively, but the magnitude of the increases were modest compared to the stimulatory effects of HR1260. These results show that anaerobic microbes isolated from river sediments dechlorinated the commercial PCB mixture Arochlor 1260 and, in doing so, generated a highly uterotonic PCB mixture. The most abundant PCB congeners in the dechlorinated mixture did not account for the uterotonic activity of HR1260, however.

# 364 DEVELOPMENTAL EFFECTS OF *IN UTERO* EXPOSURE TO BISPHENOL A ON THE UTERUS OF RAT OFFSPRING.

G. Schoenfelder<sup>1</sup>, K. Friedrich<sup>1</sup>, X. Wu<sup>2,1</sup>, M. Paul<sup>1</sup> and I. Chahoud<sup>1</sup>.

<sup>2</sup>Department of Medicine, Thomas Jefferson University, Division of Endocrinology,

Diabetes and Metabolic Diseases, Philadelphia, PA. Sponsor: R. Stahlmann.

The origins of the endocrine disrupter hypothesis may be traced to reports on adolescent daughters born to women who had taken the synthetic oestrogen, diethylstilbestrol (DES), during pregnancy. Exposure to estrogenic compounds during critical periods of fetal development could result in adverse effects on the development of reproductive organs later in life. Bisphenol A (BPA) is widely discussed as a prime candidate for endocrine disruption. We examined the influence of BPA to address the question whether in utero exposure affects the uterus of the offspring. Gravid Sprague-Dawley dams were administered either 0.1 (low dose) or 50 mg/kg/d BPA or 0.2 mg/kg/d 17alpha-ethinyl estradiol (E2) by gavage on gestation days 6 through 21. Striking morphological changes, which are similar to DES-specific disruption patterns, were observed in the uterine epithelium of post-pubertal offspring during estrus of the *in utero* BPA-treated animals. Therefore, we examined uterine estrogen receptor (ERalpha) expression because BPA binds to the ERalpha which is important for growth of the uterine epithelium. It seems that within the 50 mg BPA dose-group the close epithelial-stromal tissue interaction is disturbed, because of the disorganization of ERalpha-immunostained stromal cells. Furthermore, in the E2- and 50 mg BPA-treated group the expression of ERalpha and intensity of the ERalpha-immunostaining increased at protein level when compared to the control and 0.1 mg BPA-treated uteri. Newly synthesized ERalpha could be demonstrated by significantly increased ERalpha-mRNA expression. In all, these results clearly indicate that in utero exposure (not neonatal) of rats to lowdoses of BPA induces a permament developmental change and promotes uterine

# METABONOMIC PROFILING OF URINE IN ANTIBIOTIC-INDUCED NEPHROTOXICITY IN FEMALE CYNOMOLGUS MONKEYS.

<u>I. W. Davis</u><sup>1</sup>, A. Buevich<sup>2</sup>, F. M. Goodsaid<sup>1</sup>, R. J. Smith<sup>1</sup>, L. A. Obert<sup>3</sup>, T. Chan<sup>2</sup> and <u>I. Y. Rosenblum</u><sup>1</sup>. <sup>1</sup>Molecular Toxicology, Schering-Plough, Lafayette, NJ, <sup>2</sup>Structural Chemistry, Schering-Plough, Kenilworth, NJ and <sup>3</sup>Pathology, Schering-Plough, Lafayette, NJ.

Metabonomics is defined as the use of nuclear magnetic resonance spectroscopy to analyze urine for small molecule biomarkers of toxicity. Rodent models have been used to identify urinary markers of target organ toxicity. We developed a nonhuman primate model of nephrotoxicity in an effort to evaluate metabonomic results reported from rodent studies. Female cynomolgus monkeys were dosed with the aminoglycoside antibiotic gentamicin (10 mg/kg) and/or everninomicin (30 or 60 mg/kg), an experimental oligosaccharide antibiotic, for seven days. Urine was collected for 24 hr by cage run-off into beakers packed in ice prior to the start of dosing and on Days 1, 3, and 7 from all monkeys. Monkeys receiving both drugs showed proximal tubular injury as early as Day 1, consistent with a potentiation of toxicity resulting from co-administration of both test articles. By Day 7 monkeys dosed with 60 mg/kg everninomicin alone developed similar lesions, while the group exposed to both compounds had more extensive tubular damage. Principal components analysis (PCA) of the spectra obtained from all urine samples revealed a substantial shift in the first component as early as Day 1 in all groups receiving everninomicin, which became more pronounced on Days 3 and 7. The PCA from animals treated with gentamicin alone also shifted in the same direction, although only on Days 3 and 7. Further analysis indicated that decreased urinary hippurate was primarily responsible for the observed clusters. Decreased urinary hippurate had previously been identified in rodent models of nephrotoxicity using metabonomics. Gene expression analysis of kidneys from these animals revealed a decrease in abundance of organic anion transporter, kidney-1 (OATK-1) mRNA, the primary transport protein responsible for hippurate clearance. These results provide the first non-human primate data characterizing urinary hippurate as a potential biomarker of antibiotic-induced nephrotoxicity.

#### 366 NMR-BASED METABONOMICS STUDY OF ETHANOL-FED RATS.

R. D. Beger<sup>1</sup>, L. K. Schoenbachler<sup>1</sup>, <u>Y. P. Dragan<sup>2</sup></u>, <u>M. J. Ronis<sup>3</sup> and T. M. Badger<sup>3</sup></u>. <sup>1</sup> Chemistry, National Center for Toxicological Research, Jefferson, AR, <sup>2</sup> Center for Hepatotoxcity, NCTR, Jefferson, AR and <sup>3</sup> Arkansas Children's Hospital and University of Arkansas for Medical Sciences, Little Rock, AR.

Adult male Sprague-Dawley rats were fed by continuous intragastric infusion of a diet containing ethanol sufficient to provide 13 g/kg/day. This paradigm has previously been reported to result in urine ethanol concentrations (UECs) that cycle between 0 and 500 mg/dl over a 6 - 7 day period in rats infused with ethanol diets. Further, Class I alcohol dehydrogenase (ADH) expression is elevated at these high UECs and this results in greater ethanol metabolism that drives the UEC down. After 3 days, the mean UEC levels are reduced to near zero and the ADH expression was decreased. Here, the UECs were monitored by 1D 1H NMR and principal component (PC) analysis of the NMR spectra with the bins corresponding to the ethanol peaks removed revealed that the high and low UEC were in well-separated clusters. Further inspection of the PC loading map showed samples with a low UEC had a corresponding increase in the spectral bins at 3.26 ppm and 3.42 ppm matching to taurine, the bin at 5.38 ppm increased which corresponds to a fatty acid peak and the spectral bin at 3.02 ppm which correspond to a creatine peak. Spectral bins at 3.30 ppm, 3.50 ppm, and 3.70 ppm decreased with a decrease in UEC which correspond to carbohydrate sugar compounds. The taurine levels were increased by 110% in the samples with the lowest UEC when compared to samples with the highest UEC. Taurine and creatine has been previously reported as markers of hepatic dysfunction. Supported by 6251-51000-003-06S.

### 367 URINARY METABOLITE PROFILING OF RENAL INJURY USING NMR OR GC-MS.

C. E. Thomas<sup>1</sup>, J. Colet<sup>2</sup>, J. Eckstein<sup>1</sup>, R. Julian<sup>1</sup>, J. Sefton<sup>1</sup>, J. Koers<sup>1</sup>, M. Bollard<sup>3</sup> and B. Ackermann<sup>1</sup>. <sup>1</sup>Toxicology & Drug Disp., Eli Lilly & Co., Indianapolis, IN, <sup>2</sup>Toxicology, Eli Lilly & Co., Mont-Saint-Guibert, Belgium and <sup>3</sup>Biol. Chem., Imperial College, London, United Kingdom.

The study of metabolite fluxes in biological systems may be useful in assessing the efficacy and/or toxicity of drug candidates. Metabo<u>nomics</u> has been used to describe the study of metabolites in living systems by NMR. Metabo<u>lomics</u> generally refers to a more detailed elucidation of the metabolome, often in less complex systems, using mass spectrometry (MS). We compared urinary metabolite profiling by 1H-NMR and GC-MS in rats treated with the renal toxicant mercuric chloride (HgCl<sub>2</sub>). Male, SD rats were treated with a single dose of HgCl<sub>2</sub> at 0.5 or 2 mg/kg

and urine collected serially to 168 hrs post-dose. At 2 mg/kg, HgCl, induced marked tubular necrosis by 48 hr; the low dose resulted in more modest injury. Urinary metabolite changes, as determined by NMR, were analyzed using principle component analysis. At both doses, maximal effects were observed at 48 hr postdose. Recovery of low dose animals was evident histologically and by the return of metabolites to near pre-dose values; the high dose group was still abnormal at 168 hrs. Separation of dose groups was attributable to a reduction in Krebs cycle intermediates including citrate, 2-oxoglutarate and succinate; and an increase in glutamate, leucine/valine and alanine. Urine from the 48 hr timepoint was derivatized, analyzed by GC-MS and peaks identified by comparison to authentic standards. Consistent with the NMR data, there was a dose-dependent decrease in 2-oxoglutarate, citrate, creatinine and hippurate. Conversely, a large increase in the excretion of urinary amino acids including glutamate, alanine and threonine was detected. A 'feature vector' method was developed to automatically identify significantly altered chromatographic peaks. Fifty two distinct peaks were identified; 23 were altered. Further metabolite identification and inclusion of more timepoints is ongoing. The results indicate that NMR and GC-MS data are largely in agreement and that MS can be used to identify key metabolites associated with target organ toxicity.

EVALUATION OF URINE METABONOMIC CHANGES IN ZDF RAT DURING THE DEVELOPMENT OF DIABETES AND TREATMENT WITH VANADYL ACETYLACETONATE.

J. A. Colet, A. Cauvin, K. Kramer and I. Smyej. *Toxicology, Eli Lilly and company, Mont-Saint-Guibert, Brabant, Belgium.* Sponsor: <u>C. Thomas</u>.

Introduction: New biomarkers of efficacy in animal models are needed for the development of anti-obesity drugs. Metabonomics is a new technology based on the analysis of metabolic changes in biofluids by proton Magnetic Resonance Spectroscopy (1H-NMR). Zucker diabetic fatty (ZDF) rat is a widely used model of Type 2 diabetes. The insulin-like potential of vanadium has been demonstrated in vitro and in vivo in rodents. Purpose: This study aimed at evaluating by 1H-NMR spectroscopy the urine metabolic changes occurring in ZDF rats during the development of the diabetic status, and during the subsequent treatment with vanadyl acetylacetonate (Vac). Methods: 5 ZDF (Gmi-fa/fa) rats and 5 lean rats (Gmi-lean +/+) were placed in metabolic cages at 6 week-old. Urine samples were collected daily for a period of 6 weeks for 1H-NMR analysis. Blood was collected once a week from tail vein for plasma glucose, fatty acids, triglycerides, cholesterol, and insulin measurements. At stabilized hyperglycemia, all animals received VAc in drinking water. The 1H-NMR spectra were acquired on a Bruker Avance 600 MHz spectrometer. Results: At 6 week-old, obese rats had higher plasma levels of insulin, glucose, and triglycerides than lean rats. At 9 week-old, the obese rats reached a stabilized hyperglycemia, and their metabonomic profile was clearly separated from the lean animals. This separation was mostly caused by higher urine levels of glucose, lactate, acetate, creatinine, TMAO/betaine, and methylamines. The treatment with Vac caused a progressive reduction in plasma levels of glucose in obese rats and an increase in cholesterol. Finally, a progression move from the obese metabonomic profile towards the lean profile was noticed in obese rats treated with Vac. Conclusion: This study has demonstrated the potential of metabonomics to follow the progressive metabolic changes in an animal disease model, as well as to evaluate the effect of a drug.

# 369 FOOTPRINT OF INFLAMMAGEN EXPOSURE IN THE RAT LIVER NUCLEAR PROTEOME AFTER LIPOPOLYSACHARIDE TREATMENT.

M. E. Bruno<sup>1</sup>, J. E. Madenspacher<sup>1</sup>, J. R. Dubin<sup>2</sup>, J. F. Foley<sup>1</sup>, K. B. Tomer<sup>2</sup> and <u>B. A. Merrick</u><sup>1</sup>. <sup>1</sup>Ntl Ctr Toxicogenomics, NIEHS, Research Triange Pk, NC and <sup>2</sup>LSB, NIEHS, Research Triange Pk, NC.

Lipopolysacharide (LPS), induces acute systemic endotoxemia and a widespread in-flammatory response after i.p. exposure with extensive release of cytokines, chemokines and bioactive peptides. Activation of Toll-like receptors and translocation of NF-кB from cytosol to nucleus precedes transcriptional activation for many target inflammatory genes. In liver, inflammatory effects and NF-кB activation usually subside after 24 hr with little residual histopathology. In this recovery state, we examined the hypothesis that LPS would leave a footprint upon the liver nuclear proteome reflected by continued changes in protein expression. Male, Sprague-Dawley rats were exposed a to 5 mg/kg i.p. dose of saline or LPS for 24 hrs. Rat nuclei were isolated, nuclear protein extraction performed and protein was separated by two dimensional (2D) gel electrophoresis followed by protein identification with mass spectrometry (MS). Image analysis revealed over 800 nuclear proteins, of which 41 proteins were altered at p(.05 significance level and an additional 17 proteins that were selected at a )2 fold change. Twenty six proteins were identified by MS using MALDI-MS and tandem MS. The proteins that underwent the greatest upregulation following LPS exposure were involved in inflammatory responses,

DNA binding and transcription-related pathways. LPS down-regulated proteins included splicing factor 3A, (SF3A) and formiminotransferase cyclodeaminase. Proteins not previously associated with LPS effects include coronin, nucleolin, ETI4A and SF3A. Additional western blot analysis validated the increased expression of HMG-1 and members of the ERM complex that were identified in LPS treated samples after separation by 2D gels electrophoresis. We conclude that a subset of nuclear protein changes persists, even after serum cytokines levels and liver NF-kB levels return to normal. Studies with additional inflammagens will solidify members of this nuclear protein footprint and further our understanding of inflammatory processes.

370 BIOMARKERS OF INFLAMMATION FROM RETENTATE CHROMATOGRAPHY MASS SPECTROMETRY ANALYSIS OF RAT SERUM AFTER ACUTE LIPOPOLYSACCHARIDE

TREATMENT.

J. H. Madenspacher<sup>1</sup>, L. Li<sup>1</sup>, J. A. Taylor<sup>1</sup>, M. E. Bruno<sup>1</sup>, <u>B. A. Wetmore<sup>1</sup></u>, A. Xu<sup>2</sup> and <u>B. A. Merrick<sup>1</sup></u>. <sup>1</sup>National Ctr Toxicogenomics, NIEHS, Research Triange Pk, NC and <sup>2</sup>Ciphergen Biosystems Inc., Fremont, CA.

Bacterial lipopolysaccharide (LPS) can induce septic shock by release of cytokines and vasoactive peptides. Serum from rats exposed to the model inflammagen, LPS, was analyzed by retentate chromatography mass spectrometry (RC-MS) to distinguish acute inflammatory response proteins over time. RC-MS is a type of proteomic analysis for biomarker discovery whereby serum proteins are selectively adsorbed to chromatographic surfaces and then read by a mass spectrometer (MS). Male Sprague-Dawley rats at 12 per group were treated with either saline or 5 mg/kg i.p. of LPS for 2 and 6 hr with biochemical characterization by TNF-alpha and IL6 serum ELISA. RC-MS analysis involved whole serum and multidimensional fractionation (MDF) of serum by strong anion exchange and step-wise pH elution. A map of differentially expressed proteins with peak changes at p(0.01 significance level showed 26 proteins were induced and 15 proteins were repressed overall with LPS exposure using MDF serum compared to only 6 protein changes detected from unfractionated serum. Most serum protein changes were detected after 2 hr LPS exposure compared to 6 hr. Additional bioinformatic analysis using the Genetic Algorithm/k-Nearest Neighbor technique (GA/KNN) for classification was used to screen combined data from entire mass spectrum scans for each animal for all analyzed multidimensional fractionated serums. GA/KNN analysis created a list of ten m/z peaks that were the most discriminative proteins in characterizing acute LPS exposure and these proteins are currently being identified. We concluded that RC-MS analysis of MDF serum is a more sensitive means of detecting LPS responsive biopeptides than whole serum alone and offers the opportunity for biomarker discovery. The differential expression profile in LPS treated animals at 2 and 6 hr also suggests RC-MS can accurately detect acute inflammatory responses in a temporal manner.

#### 371 NOVEL *IN VITRO* SKIN IRRITATION MARKERS IDENTIFIED USING MICROARRAY TECHNOLOGY.

S. Fletcher, C. Duggan and <u>D. Basketter</u>. SEAC - Safety and Environmental Assurance Center, Unilever, Sharnbrook, Bedfordshire, United Kingdom.

To develop a relevant and sensitive in vitro testing strategy for the identification of mild to more substantially irritant compounds, mechanistic information on the skin irritation response is required. This study investigated the mechanisms of mild skin irritation for a number of compounds, identifying specific and general markers. EpiDerm<sup>TM</sup> (MatTek, USA), a reconstructed human skin model, was treated in triplicate with 0.1mg/ml benzalkonium chloride (BKC), 2.5mg/ml phenol, 0.1mg/ml sodium lauryl sulphate (SLS) or media control for 15min, 2, 4 or 24 hours. The doses used were non-cytotoxic, as determined by MTT assay and histology. Microarray analysis of 5 biological replicates was performed using Cy3 and Cy5 labelled samples hybridised to an in-house skin chip comprising of 2100 skin relevant genes in triplicate. For each irritant chemical around 400 genes were upregulated. Known irritation markers found to be up-regulated, included IL-1α, IL-8, TNFα and EGF. 20% of genes were up-regulated with all three compounds and therefore could be classed as associated with general irritation, these included hsp27, integrin  $\beta 3$  and VCAM1 among others. In addition genes were found which were compound specific. IL-16, early growth response 1, caspase 8, caveolin 1, adenylate cyclase 8 are examples of genes up-regulated upon treatment with SLS. Treatment with BKC up-regulated, phospholipase A2, midkine, IL-12 receptor, retinoic acid receptor responder, transglutaminase 1, IL-6. Genes up-regulated in response to phenol included, fibronectin, integrin α6, calcitonin, serine protease inhibitor, transglutaminase 4 and thioredoxin. These results demonstrate that although compounds initially may use different mechanisms of action, there are nevertheless similarities and a number of genes could be investigated further as potential general markers of irritation.

372 THE ETAG MULTIPLEX ASSAY SYSTEM, A NOVEL
ASSAY PLATFORM FOR ANALYZING GENOMIC AND
PROTEOMIC ENDPOINTS DURING COMPOUND
SAFETY AND TOXICITY ASSESSMENTS

<u>K. Steinmetz</u><sup>2</sup>, T. Tian<sup>1</sup>, L. Chen<sup>1</sup>, Y. Badal<sup>1</sup>, D. Ackley<sup>3</sup>, K. Wehmeyer<sup>3</sup>, J. Troutman<sup>3</sup>, C. Virgo<sup>1</sup>, S. Moore<sup>1</sup>, V. Xiao<sup>1</sup>, X. Jin<sup>1</sup> and S. Singh<sup>1</sup>. <sup>1</sup>Aclara, Mt View, CA, <sup>2</sup>SRI Int., Menlo Park, CA and <sup>3</sup>P&G, Mason, OH.

Routine evaluation of OMIC endpoints during safety assessments is limited by the sample quantity, cost, and time requirements. The eTag Multiplex Assay System (eTag Assay) permits rapid analysis of biomolecular targets from cultures and tissues using minimal sample processing. The eTag Assay utilizes electrophoretically distinct fluorescent molecules coupled to a broad range of biomolecular binding moieties, such as oligonucleotides, peptides, or proteins. The eTag molecules' unique physical properties allow simultaneous reactions and detection (multiplexing) within the same sample. eTag Assays have been developed for identifying a variety of biomolecular targets. Primary rat hepatocyte cultures were treated with compounds representing different nuclear receptor signaling pathways. Hepatocytes treated with Lovastatin (L) and Clofibrate (C) resulted in increased expression of mRNAs for CYP4A (L:3.5, C:10.3), CYP3A (L:6.2, C:21.3) and CYP2B (L:2.3, C:25.5) whereas 3-methylcholanthrene induced mRNA for CYP1A (25.8) exclusively. Differential induction of phase II enzymes such as Gsta2 and Ugt1a was also observed. A strong correlation was observed between mRNA expression and protein levels in the experiments. To demonstrate eTag Assay versatility, samples of rat tissues were evaluated for both mRNA levels and protein expression. Hepatic CYP1A1 (19.7) and 1A2 (17.5) were induced following in vivo treatment with a CYP1A inducer whereas there was no induction of other CYP isoforms. eTag Assay results were confirmed using TaqMan and Western blot analyses. The results from these experiments demonstrate the sensitivity, accuracy, and versatility of the eTag Multiplex Assay System. eTag Assays are an ideal technology to gather mechanistic information during routine toxicology and safety studies thereby allowing better selection of compounds early in the drug-development process.

## 373 PROTEOMIC CHARACTERIZATION OF THE EFFECTS OF CLOFIBRATE ON PROTEIN EXPRESSION IN RAT LIVER

J. Leonard<sup>1</sup>, C. Saulnier<sup>1</sup>, M. Courcol<sup>1</sup>, A. Charbonnier<sup>1</sup>, E. Boitier<sup>1</sup>, <u>R. A. Roberts</u><sup>1</sup>, M. Duchesne<sup>2</sup>, F. Parker<sup>2</sup> and J. Gautier<sup>1</sup>. <sup>1</sup> Drug Safety Evaluation, Aventis Pharmacology, Vitry-sur-Seine, France and <sup>2</sup>Functional Genomics, Aventis Pharmacology, Vitry-sur-Seine, France.

Clofibrate is a peroxisome proliferator known to induce liver tumours in rats. A proteomics study was conducted in order to provide new insights into the molecular mechanisms of clofibrate-induced nongenotoxic hepatocarcinogenesis. Rats were treated with 250 mg/kg/day clofibrate orally and were sacrificed after 7 days. Proteins were extracted from liver and analyzed by 2D gel electrophoresis using differential gel electrophoresis technology. Protein identification of the up- and downregulated spots was performed by mass spectrometry. Data showed that clofibrate induced up-regulation of 77 proteins and down-regulation of 27 proteins. The highest expression ratios corresponded to proteins involved in a series of biochemical pathways such as lipid metabolism, fatty acid metabolism, amino acid metabolism, protein metabolism, citric acid cycle, xenobiotic detoxification and oxidative stress. Proteins implicated in cell proliferation and apoptosis such as prohibitin, 10formyl tetrahydrofolate dehydrogenase, senescence marker protein, pyridoxine 5'phosphate oxidase and vimentin were also identified as being regulated. These latter results provide leads for ongoing investigation into the molecular mechanisms of liver tumors induced by clofibrate. In addition, mass spectrometry results showed that several proteins such as 10-formyl tetrahydrofolate dehydrogenase, carnitine-O-palmitoyl transferase II, ATP synthase beta chain subunit, long chain fatty acyl CoA ligase, aspartyl tRNA synthetase were detected as several spots corresponding to different isoelectric points. Differential effects on those pI variants could result from specific post-translational modifications and could be a specific molecular signature of the clofibrate-induced protein expression modulation in rat liver.

### 374 LEAD BINDING TO HUMAN SEMINAL PROTEINS AND ZINC EQUILIBRIUM.

C. Sarmiento-Mariscal, I. Hernandez-Ochoa and B. Quintanilla-Vega. Toxicology Section, CINVESTAV-IPN, Mexico City, D.F., Mexico.

Seminal liquid has a high content of zinc (Zn) from prostatic origin which plays important roles on spermatozoa function, such as chromatin condensation. Zinc redistribution from molecules of low molecular weight (LMWP) towards high affinity seminal proteins of high (HMWP) and intermediate (IMWP) molecular weight occurs at ejaculation. Lead (Pb) exposure has been associated with male reproductive effects, particularly on sperm chromatin condensation, probably by al-

tering Zn equilibrium in seminal liquid (Zn-bound/free Zn) favoring Zn entering the cell. Lead has affinity for thiol groups in Zn-depending proteins; thus in this study we evaluated Pb binding to seminal liquid proteins and displacement of Zn from its binding sites. Human seminal liquid (3.6mM endogenous Zn) from healthy donors were applied to a Sephadex G-75 column, and eluted with Tris 0.05M/NaCl 0.15M, pH 7.4 (0.3 mL/min flow rate). Proteins were monitored at 280 nm in 4.5 mL-fractions. Later, seminal liquid was incubated with 0.48µM of Pb (maximum concentration in occupationally-exposed men) at 37°C/1 h, applied to the Sephadex G-75 column and eluted as mentioned. Fractions were subjected to Zn and Pb determination performed by atomic absorption spectrophotometry (using flame and graphite furnace, respectively). Endogenous Zn profile (Znbound to proteins) showed a major peak corresponding to molecules of <3 kDa (LMWP), a second one to proteins >80 kDa (ĤMWP) and two minor peaks to proteins from 27-38 kDa and from 2-6 kDa. After Pb incubation, Pb was bound to proteins in factions where Zn content was decreased, corresponding to proteins of approximately 270, 110, 31, 6 and 5 kDa, suggesting a displacement of Zn. Also, a Zn re-distribution was observed mainly among HMWP. *In vitro* experiments are in progress to evaluate the effect of Pb-binding to seminal proteins on human sperm chromatin condensation as well as to complete the characterization of Pb binding to Zn-seminal proteins.

#### 375 METALS IN INNER CITY AND SUBURBAN COMMUNITIES OF DETROIT AND NEW ORLEANS.

H. W. Mielke, C. Gonzales, A. Shah and E. Powell. College of Pharmacy, Xavier University, New Orleans, LA.

Nine metals (Pb, Zn, Cd, Mn, Ni, Cu, Cr, Co., and V) were analyzed in inner city and suburban census tracts of Detroit, Michigan and New Orleans, Louisiana. Detroit is located where glacial processes deposited tills during the Ice Ages. New Orleans is on alluvial soils deposited by fluvial processes of the Mississippi River Delta. Alluvial samples were taken from the Bonnet Carré Spillway after the flood of 1997. Soil samples from Detroit and New Orleans were collected from census tracts in the inner-city and suburbs of each city. Surface (2.5 cm) samples were collected according to a standard protocol (n=19). All samples were air-dried and sieved (2 mm screen). Soil metal extraction was done using a 5:1 ratio of 1 mol L-1 nitric acid (room temperature) to soil, shaken 2 hours, centrifuged (1000 x g - 15 min.) and filtered. Extraction pH and the temperature match the range of the human digestive tract. Metals were determined using inductively coupled plasmaatomic emission spectrometry. There are consistently smaller quantities of metals in the Bonnet Carré fresh alluvium compared to inner-city or suburban Census Tracts of New Orleans and Detroit. In both cities, the inner city soils always have larger metal quantities than the soils in suburban census tracts. Pb and Zn are exceptionally elevated in New Orleans compared with Detroit. The compactness of New Orleans compared to Detroit may explain this difference. Cd, Ni, Cr, Co and especially Mn are elevated in Detroit compared with New Orleans. Cu and V are about the same for both cities. In suburban census tracts Cd, Mn, Cr and Co are more elevated in Detroit and Zn is more elevated for New Orleans. Soil Mn and Zn probably reflect the geochemistry of glacial till compared to alluvium of the Mississippi River Basin. The Pb, Cu and V are similar in the suburban census tracts of these cities. Anthropogenic processes account for metals in each city, especially for Pb, Zn, Mn and Cu, and to a lesser extent Cd, Ni, Cr, Co., and V. Metal exposure probably influences human health in the inner cities.

# 376 MERCURY CONTAMINATION IN THE RED MEAT OF WHALES AND DOLPHINS MARKETED FOR HUMAN CONSUMPTION IN JAPAN.

T. Endo<sup>1</sup>, K. Haraguchi<sup>2</sup>, H. Yohei<sup>1</sup> and M. Sakata<sup>1</sup>. <sup>1</sup> Clinical Toxicology and Metabolism, Health Sciences University of Hokkaido, Ishikari-Tobetsu, Hokkaido, Japan and <sup>2</sup> Health Science and Chemistry, Daiichi College of Pharmaceutical Sciences, Fukuoka, Fukuoka, Japan.

We surveyed the total mercury (T-Hg) and methyl mercury (M-Hg) levels in odontocete red meat, the most popular cetacean products in Japan. We also analyzed the DNA of these to obtain information regarding species. According to the genetic analysis, the red meats originating from nine species of odontocete such as Dall's porpoise, pantropical spotted dolphin, Risso's dolphin, rough-toothed dolphin, bottlenose dolphin, false killer whale, pilot whale and Baird's beaked whale were sold in Japanese markets. T-Hg and M-Hg concentrations in all odontocete red meats (n=214) exceeded the provisional permitted levels of T-Hg (0.4  $_{\mu}$ g/wet g) and M-Hg (0.3  $_{\mu}$ g/wet g) in marine foods set by the Japanese government, respectively. The highest concentration of T-Hg was found in a false killer whale meat which contained 81.0  $_{\mu}$ g/wet g T-Hg and 13.4  $_{\mu}$ g/wet g M-Hg, exceeding the permitted levels by 200 and 45 times, respectively. The second highest concentration of T-Hg was found in a striped dolphin meat which contained 63.4  $_{\mu}$ g/wet g T-Hg and 26.2  $_{\mu}$ g/wet g M-Hg, exceeding the levels by 160 and 87 times, respectively. Chronic in-

toxication by Hg due to frequent consumption of odontocete red meats should occur. T-Hg versus the percentage of M-Hg/T-Hg in the red meat was well fitted by a logarithmic equation, suggesting the demethylation of M-Hg in the odontocetes. A high correlation was observed between T-Hg and selenium (Se) concentrations in the red meats, supporting the formation of Hg-Se complex. The formation of Hg-Se complex after the demethylation may contribute to the detoxification of M-Hg in odontocetes. The T-Hg concentration levels were slightly higher in Baird's beaked whales, pilot whales, bottlenose dolphins and striped dolphins caught off southern areas than those caught off northern areas, probably reflecting a higher Hg concentration in the seawater and/or their diet (squid and fish) in the southern area.

# 377 RENAL DYSFUNCTION IN CADMIUM EXPOSED HUMANS - RELATIONSHIP TO CHANGES IN BONE DENSITY AND METALLOTHIONEIN GENE EXPRESSION

G. F. Nordberg¹ and M. Nordberg². ¹Environmental Medicine, Umea University, Umea, Sweden, ²Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, ³Department of Occupational Health, School of Public Health, Fudan University, Shanghai, China, ⁴Unit of Industrial Toxicology, Catholic University of Louvain, Brussels, Belgium and ⁵Department of Bone Metabolism, Institute of Radiation Medicine, Fudan University, Shanghai, China.

Nordberg G(1), Nordberg M(2), Jin T(3), Lu J(3), Bernard A(4), Ye T(3), Wang H(5). Long term exposure to cadmium (Cd) can give rise to both renal dysfunction and bone effects. Only few studies have reported both bone effects and renal dysfunction in the same persons and it is unclear whether bone effects occur at lower or higher internal doses of Cd than renal dysfunction. 734 persons living in a cadmium polluted area in China were studied by measurements of Bone Mineral Density (BMD) and urinary levels of retinol binding protein (RBP) and beta-2-microglobulin (B2M).Internal doses of Cd were indicated by levels of Cd in blood (CdB) in microgram/l or Cd in urine (CdU)in micrograms /g creatinine. An increased prevalence (p<0.05) of low BMD was found aomng persons with CdB>20 or CdU>20, but not among those with lower CdB or CdU. Increased prevalence of renal dysfunction (increased levels of RBP and B2M) was found (p<0.05)among persons with CdB>10 and CdU >5-10. These observations thus show that renal dysfunction occurs at lower internal doses of Cd than bone effects. With more sensitive renal dysfunction indicators, e g urinary N-acetyl-beta-D-glucosaminidase (UNAG), renal effects can be observed at even lower internal doses of Cd. In parallell studies on 59 Chinese Cd-workers, metallothionein gene expression (MT-GE) in peripheral lymphocytes (PL) was determined by RT-PCR and renal dysfunction was assessed by measuring UNAG. The level of MT-GE in PL was found to be inversely related to the level of UNAG. This finding indicates that MT-GE in PL may be a useful biomarker of suceptibility to renal Cd toxicity in humans. Supported by European Commission INCO-DC and Swedish Agency for Cooperation with developing countries (SIDA).

# ANALYSIS OF THE FACTORS THAT INFLUENCE THE CHRONIC HEALTH EFFECTS IN RESIDENTS EXPOSED TO ARSENIC VIA THE DRINKING WATER IN INNER MONGOLIA, CHINA.

T. Yoshida<sup>1</sup>, T. Ito<sup>1</sup>, Y. Nakagi<sup>1</sup>, H. Yamauchi<sup>2</sup>, H. Aikawa<sup>3</sup>, J. Pi<sup>4</sup> and G. Sun<sup>4</sup>.

<sup>1</sup>Health Science, Asahikawa Medical College, Asahikawa, Hokkaido, Japan, <sup>2</sup>St.

Marianna Medical College, Kawasaki, Japan, <sup>3</sup>Tokai University Sch. of Med.,
Isehara, Japan and <sup>4</sup>China Medical College, Shengyang, China.

The relationship between chronic arsenic (As) exposure and adverse health effects such as skin lesions were studied among the residents who drunk naturally As contaminated well water in Inner Mongolia, China. For the villagers with the informed consent, interview on subjective symptoms and life style, physical examinations especially on skin lesions, collecting biological material (blood, urine and hair) for evaluation of arsenic exposure and use for another analysis, were done. Individual As exposure was evaluated based on an interview of past history of drinking water source and to measure all of various water samples that subjects used. The odds ratio of either skin lesions, hyperkeratosis or dyspigmentation verses average As concentration of the drinking water for past 5 years showed a moderate, but significant, dose-response relationship. Previous 5 years As exposure, however, didn't show any significant results. Detailed analysis on the recent As exposure revealed that significant relationship was found in the As exposure during past 3-5 years. Male showed higher odds ratio than female did. The dose-response relationships of skin lesions, especially dyspigmentation, were confirmed. The significant increase in the prevalence of skin lesions even at 0.005-0.01 mg As/L in the drinking water, a level lower than the drinking water quality standard of WHO, was observed. Relationship between the prevalence ratio of skin lesions and the concentration of As in blood was also analyzed to confirm the influence of individual methylation

activity against As, by comparison of serum concentration of mono-methyl arsenic, di-methyl arsenic and inorganic As on the subjects who were exposed to As at stable level for recent 5 years in Inner Mongolia. Only MMA concentration showed significant relationship with the prevalence ratio.

### 379 EFFECT OF SEAFOOD CONSUMPTION ON URINARY ARSENIC SPECIATION.

J. D. Park<sup>1</sup>, B. S. Choi<sup>1</sup>, E. S. Park<sup>2</sup>, K. S. Park<sup>3</sup>, S. T. Kim<sup>3</sup> and Y. P. Hong<sup>1</sup>.

Arsenic(As) is widely distributed in environment and has been known as a human carcinogen. The main route of As in general population is an oral exposure through food and drinking water. Seafood is containing high level of As, which is much less harmful organoarsenic, such as arsenobetaine, arsenocholine and arsenosugar. However, it is important to understand whether seafood consumption affects the urinary level of inorganic As metabolites, arsenite, arsenate, monomethylarsonic acid(MMA) and dimethylarsinic acid(DMA), in Korean, who eat seafood much. In this study, we investigated effects on the urinary total arsenic and inorganic metabolites (inorganic As, MMA, DMA) after consumption of seafood by volunteers(7 males and 9 females). Urinary total As was analyzed by hydride generation method after microwave digestion, and arsenic speciation was performed by using HPLC with ICP-mass spectrometry. The study subjects ingested seafood daily for 6 days consecutively, and the first voided urine in the morning was collected before ingestion and at day 1, 2, 3, 4, 5, 6, 7, 10, and 14 after ingestion, respectively. They were refrained from eating seafood for 3 days prior to the urine collection and during urine collection. We purchased seafood from the market. The daily mean intake of total As was 6.97 mg, which was 4.69 mg of seaweed(67 %), 1.75 mg of flat fish(25 %) and 0.53 mg of conch(8 %). We observed substantial increases of urinary total As and DMA from day 1 and recovered to control level at day 10 after the consumption of seafood in volunteers. DMA is more harmful metabolite than organoarsenic. This result suggests that it is necessary to consider As metabolism in assessing the health effect of seafood consumption in Korean.

#### 380 FLUORIDE EXPOSURE ALTERS THE METABOLISM AND EXCRETION OF ARSENITE IN MICE.

M. Espinosa, E. A. Garcia-Montalvo, O. L. Valenzuela and <u>L. M. Del Razo</u>. *Toxicology Section, Cinvestav-IPN, Mexico D.F, Mexico*.

Fluoride (F-) and arsenic (As) are ubiquitous compounds. Their co-exposure is frequent in several endemic areas due to the natural contamination of well waters supplies by F- and As-rich geological strata and/or domestic coal combustion, so many human populations are simultaneously exposed to high concentration to inorganic arsenic (iAs) and F-. The purpose of this study was to evaluate the excretion of Fand As species in three groups of female C57BL/6 mice dosed daily via gavage during 30 days with a) 3mgAs3+/kg of sodium arsenite, b) 10mg F-/kg of sodium fluoride, and c) both As and F-, 3mg/kg and 10mg/kg, respectively. Urine was recollected each week and the samples were analyzed for F- and As species including iAs monomethyl As (MMA) and dimethyl As (DMA). The putative more toxic trivalent arsenic species (iAsIII, MMAIII and DMAIII) were also speciated. The results indicated that subchronic arsenite exposure decreased (35-65%) the urinary concentration of F-, comparing with F- alone group. Similarly, the F- treatment altered the urinary concentration of As causing an increased of total As at first week with posterior decreased at 2nd, 3th and 4th weeks, comparing with As alone group. The main As specie that contributed to alteration of As excretion was DMAv. The present results clearly show that arsenite and fluoride may interact with each other. Studies to evaluate the potential toxicological consequences of simultaneous exposure to high levels to iAs and F-are warranted.

### 381 EFFECT OF DOSE ON THE EXCRETION AND METABOLISM OF MONOMETHYLARSONIC ACID IN THE MOUSE

M. F. Hughes<sup>1</sup>, V. Devesa<sup>2</sup>, B. C. Edwards<sup>1</sup>, C. T. Mitchell<sup>1</sup>, E. M. Kenyon<sup>1</sup> and D. J. Thomas<sup>1</sup>. <sup>1</sup>ORD/NHEERL, USEPA, Research Triangle Park, NC and <sup>2</sup>CEMALB, UNC-CH, Chapel Hill, NC.

Monomethylarsonic acid (MMA(V)) is found in urine and tissues of mice exposed to inorganic arsenic. In addition, the sodium salts of MMA(V) are registered herbicides in the United States. The objective of this study was to determine whether administered dose affects the excretion and metabolism of this methylated arsenical. Adult female B6C3F1 mice were gavaged with MMA(V) (disodium salt) at a dose level of either 0.4 or 40 mg As/kg. Mice received either  $^{14}\text{C-MMA}(V)$  (n=4/dose) or unlabeled MMA(V) (n=3/dose) and were housed in metabolism cages for collection of excreta. The 24-hr cumulative urinary excretion of chemical-derived  $^{14}\text{C}$  was significantly lower (p < 0.05, t-test) in the low dose group (65.4  $\pm$  9.5%) than in the high dose group (45.4  $\pm$  11.5%). The 24-hr cumulative fecal excretion of

chemical-derived  $^{14}\mathrm{C}$  was significantly lower (p < 0.01, t-test) in the low dose group (38.8  $\pm$  8.8%) than in the high dose group (61.8  $\pm$  8.6%). Analysis of urine of mice administered unlabeled MMA(V) by hydride generation atomic absorption spectrometry revealed the presence of monomethylarsonous acid (MMA(III)), dimethylarsinous acid (DMA(III)), trimethylarsine oxide (TMAO), MMA(V) and dimethylarsinic acid (DMA(V)). Administered dose did not affect the level of the arsenicals excreted. The rank order of excreted arsenicals was MMA(V) (88%), DMA(V) (7%), TMAO (2%), DMA(III) (2%), MMA(III) (1%). Dose affects the route of excretion of MMA(V) and metabolites but not its metabolism. (This abstract does not necessarily reflect EPA policy.)

# 382 COMPREHENSIVE ANALYSIS OF BIOLOGICALLY RELEVANT ARSENICALS BY PH-SELECTIVE HYDRIDE GENERATION-ATOMIC ABSORPTION SPECTROMETRY.

V. Devesa<sup>1</sup>, L. Del Razo<sup>4</sup>, S. Waters<sup>2</sup>, Z. Drobna<sup>3</sup>, M. Hughes<sup>5</sup>, M. Styblo<sup>1,3</sup> and D. Thomas<sup>3</sup>. <sup>1</sup>CEMALB, University of North Carolina at Chapel Hill, Chapel Hill, NC, <sup>2</sup>Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC, <sup>3</sup>Department of Pediatrics, University of North Carolina, Chapel Hill, NC, <sup>4</sup>CINEVSTAV, IPN, Mexico City, Mexico and <sup>5</sup>NHEERL, USEPA, Research Triangle Park, NC.

A method based on pH-selective generation and separation of arsines is commonly used for analysis of inorganic, methylated, and dimethylated trivalent and pentavalent arsenicals by hydride generation-atomic absorption spectrometry (HG-AAS). We have optimized this method to permit quantification of trimethylated arsenicals. Increasing adsorbent density in the cold trap and optimizing the temperature gradient during release of arsines from the cold trap, improved the separatory power of this method. This optimized technique permits analysis of most common biologically relevant arsenic species, including arsenite (iAsIII), arsenate (iAsV), monomethylarsonic acid (MAsV), monomethylarsonous acid (MAsIII), dimethylarsinic acid (DMAsV), dimethylarsinous acid (DMAsIII), and trimethylarsine oxide (TMAO). Selective generation of arsines of trivalent species and TMAO at pH 6, and of all arsenicals (trivalents and pentavalents) at pH 1 permits quantification of each species. Calibration curves are linear for analyte concentrations of 0.5 to 100 ng and recoveries range from 85 and 124%. The variation of the method does not exceed 15%. The method is equally effective for analyses in aqueous solutions and in simple biological matrices. The optimized technique has been used to analyze arsenical metabolites in cultured human hepatocytes exposed to iAsIII and in urine of mice treated with MAsV or DMAsV. Methyl- and dimethylated arsenicals, but not TMAO, were detected in hepatocytes or culture medium. Considerable amounts of TMAO were found in urine of mice treated with MAsV or DMAsV. Hence, this optimized HG-AAS technique can be used for comprehensive analysis of arsenicals in biological matrices that do not require extraction before assay. (This abstract does not reflect USEPA policy).

#### 383 INTERINDIVIDUAL VARIATION IN THE METABOLISM OF ARSENIC IN HUMAN HEPATOCYTES.

M. Sryblo<sup>1</sup>, F. F. Walton<sup>1</sup>, Z. Drobna<sup>1</sup>, S. B. Waters<sup>3</sup>, E. L. LeCluyse<sup>6</sup> and D. J. Thomas<sup>5</sup>. <sup>1</sup>Department of Pediatrics, UNC, Chapel Hill, NC, <sup>2</sup>Department of Pediatrics, UNC, Chapel Hill, NC, <sup>3</sup>Curriculum in Toxicology, UNC, Chapel Hill, NC, <sup>4</sup>Department Pediatrics, UNC, Chapel Hill, NC, <sup>5</sup>NHEERL, ORD, USEPA, Research Triangle Park, NC and <sup>6</sup>Division of Drug Delivery and Dispos., UNC, Chapel Hill, NC.

The liver is the major site for the enzymatic methylation of inorganic arsenic (iAs) in humans. Primary cultures of normal human hepatocytes isolated from tissue obtained at surgery or from donor livers have been used to study interindividual variation in the capacity of liver to metabolize iAs. To minimize variability related to donor's health status and medication, hepatocytes were cultured under standard conditions for 5 or 6 days before use. This interval allowed cellular functions (redox status and activities of drug metabolizing enzymes) to stabilize and assured the subsequent studies of methylation capacity reflected genotypic and phenotypic variability. Using standardized culture conditions, we compared methylation patterns for iAs in hepatocytes prepared from 8 donors. Methylation rates and yields and distribution of metabolites were determined in cells exposed to arsenite (iAsIII) (0.3, 0.9, 3, 9 or 30 nmol/mg protein) for 24 hours. For most donors, high iAsIII concentrations inhibited methylation (especially DMAs production) and decreased the DMAs/MAs ratio. However, for some donors, methylation was not inhibited even at the highest iAsIII concentrations. Maximal methylation rates (usually in cells at 3 or 9 nmol iAsIII/mg protein) varied from 2.6 to 20 pmol CH3 transferred/mg protein/hour. iAs and MAs were major metabolites retained in cells; iAs and DMAs were the major metabolites in culture media at low iAsIII levels. Statistically significant positive correlations were found between the amounts of iAs and MAs retained in cells and the methylation rate. These data suggest that significant interindividual differences exist in capacities of human liver to methylate iAs. These differences may underlie interindividual variation in susceptibility to toxic and carcinogenic effects of iAs exposure. (This abstract does not reflect EPA policy.)

ARSENIC TRANSPORT BY THE HUMAN MULTIDRUG RESISTANCE PROTEIN 1 (MRP1/ABCC1): EVIDENCE THAT A TRI-GLUTATHIONE CONJUGATE IS REQUIRED.

E. M. Leslie<sup>1</sup>, S. P. Cole<sup>2</sup> and <u>M. P. Waalkes<sup>1</sup></u>. <sup>1</sup>Inorganic Carcinogenesis Section, LCC, NCI at NIEHS, Research Triangle Park, NC and <sup>2</sup>Cancer Research Laboratories, Queen's University, Kingston, ON, Canada.

Tolerance to arsenic (As) is frequently associated with a glutathione (GSH) dependent reduction in cellular accumulation of this metalloid. Cell lines chronically exposed to As often over-express glutathione S-transferase P1-1 (GSTP1-1) and certain ATP-binding cassette transporters including the multidrug resistance protein 1 (MRP1) which mediates active transport of GSH, sulfate and glucuronide conjugated organic anions. MRP1 also co-transports certain unmodified compounds with GSH. Although MRP1 confers resistance to As in association with GSH, the chemical nature of the transported As species has been difficult to elucidate. As-GSH conjugates have never been isolated in culture media, possibly due to their chemical instability at physiological pH. Alternatively, MRP1 could efflux As with free GSH through a co-transport mechanism. In the present study we investigated the form of As transported by MRP1 using <sup>73</sup>As³+ and inside-out membrane vesicles prepared from the small cell lung cancer cell line H69AR, which over-expresses MRP1. We found that MRP1 transports As but only in the presence of GSH. Transport of As did not occur in the presence of the GSH analogs γ-glutamyl-αaminobutyryl-glycine and γ-glutamyl-methyl-Cys-Gly suggesting that the free thiol group of GSH is required. Transport of As in the presence of GSH was higher at pH 6.5 than at pH >7, consistent with the formation and transport of AsGS<sub>3</sub> which is more stable at acidic pH. The transport reaction was monitored by thin layer chromatography and AsGS<sub>3</sub> formation was observed. Interestingly, under the transport assay conditions used, AsGS<sub>3</sub> was not formed in the absence of membrane vesicles. Immunoblot analysis revealed the unexpected presence of GSTP1-1 in association with the membrane vesicle fraction, an enzyme normally found in the cytosol. Our findings suggest that the formation of AsGS3 is necessary for arsenic efflux by MRP1 and that GSTP1-1 could be important in this complex formation.

#### 385 KINETICS OF ARSENIC METHYLATION BY FRESHLY ISOLATED MOUSE HEPATOCYTES.

G. L. Kedderis<sup>1</sup>, K. A. Milne<sup>2</sup>, A. R. Elmore<sup>2</sup>, E. A. Crecelius<sup>3</sup>, <u>I. W. Yager</u><sup>4</sup> and <u>T. L. Goldsworthy</u><sup>2</sup>. <sup>1</sup> Independent Consultant, Chapel Hill, NC, <sup>2</sup> Integrated Laboratory Systems Inc., Research Triangle Park, NC, <sup>3</sup> Battelle, Sequim, WA and <sup>4</sup> FPRI, Palo Alto, CA.

The toxic and carcinogenic effects of arsenic may be mediated by both inorganic and methylated arsenic species, but the kinetics of arsenic methylation have not been studied in detail. Therefore the kinetics of arsenic methylation were determined in freshly isolated hepatocytes from male B6C3F1 mice. Hepatocytes (>90% viability) were isolated by collagenase perfusion and suspended in Williams Medium E with various concentrations of arsenic III (sodium m-arsenite). Aliquots of the cell suspension were lysed with 0.5% Triton X-100 and analyzed for arsenic species by ion pair chromatography-hydride generation-atomic absorption spectrometry. The formation of monomethylarsenic (MMA) from sodium arsenite (1 uM) was linear for >90 min. Dimethylarsenic formation did not become significant until 60 min. Metabolism of arsenic V was not observed, consistent with inhibition of arsenic V active uptake by phosphate in the medium. The formation of MMA III increased with increasing arsenic III concentrations up to approximately 2 uM and declined thereafter. The concentration dependence is consistent with a saturable methylation reaction accompanied by substrate inhibition of the reaction by arsenic III. Kinetic analysis of the data suggested an apparent KM of approximately 0.5 uM arsenic III and an apparent Vmax of approximately 3.2 mg MMA formed/L/hr/million cells. The kinetics of arsenic III methylation by isolated human hepatocytes will also be determined. These data will be compared with the mouse kinetic parameters and used as the basis for estimation of tissue exposure to MMA III following human exposure to arsenic. (Research supported by EPRI contract P10089/C5135).

386

RECOMBINANT RAT CYT19, AN ARSENIC METHYLTRANSFERASE, EFFICIENTLY GENERATES TRIMETHYLARSINE OXIDE IN THE ABSENCE OF GLUTATHIONE.

S. B. Waters<sup>1</sup>, V. Devesa<sup>2</sup>, Z. Drobna<sup>3</sup>, <u>M. Styblo<sup>2,3</sup></u> and <u>D. Thomas<sup>4</sup></u>.

<sup>1</sup>Curriculum in Toxicology, UNC-Chapel Hill, Chapel Hill, NC, <sup>2</sup>CEMALB, UNC-Chapel Hill, Chapel Hill, NC, <sup>3</sup>Department of Pediatrics, UNC-Chapel Hill, Chapel Hill, NC and <sup>4</sup>NHEERL, USEPA, Research Triangle PArk, NC.

Chronic exposure to inorganic arsenic (iAs), a toxic metalloid sometimes present in drinking water, is associated with increased prevalences of various cancers and other disorders. Humans and many other species enzymatically convert iAs into methy-

lated metabolites. The major metabolites are mono- and dimethylated arsenicals; however, trimethylated arsenicals have been detected in urine and expired breath following exposure to iAs. The As methyltransferase of rat liver is encoded by the cyt19 gene that produces cyt19, a 42kDa cytosolic protein. Recombinant rat cyt19 (rrcyt19) has been used to study the enzymology of As methylation. Mono- and dimethylated arsenicals generated in assays with rrcyt19 are usually resolved by thin layer chromatography using an acetone:water:acetate (3:1:1) solvent system. However, chromatography with an isopropanol:water:acetate (10:2.5:1) solvent system revealed an unidentified metabolite. This species comigrated with authentic trimethylarsine oxide (TMAO). This metabolite had identical properties with authentic TMAO when analyzed by hydride generation-atomic absorption spectrometry and was identified as TMAO by ICP-mass spectrometric analysis. Addition of glutathione (GSH) to reactions containing iAs and rrcyt19 increased the rate of formation of methylated and dimethylated arsenicals but suppressed formation of TMAO. Addition of GSH to reactions containing iAs and rrcyt19 also reduced the loss of a volatile arsenical that may be trimethly arsine (TMA). Although TMAO is a not a toxic methylated arsenical, TMA has recently been shown as a potent DNAdamaging compound. Thus, generation of TMA in cyt19-catalyzed reactions may be a pathway for metabolic activation of iAs. (This abstract does not necessarily reflect USEPA policy.)

CHARACTERIZATION OF UROTSA/RCYT19, A CLONAL HUMAN URINARY BLADDER CELL LINE EXPRESSING RAT  ${\rm AS^{III}}$ -METHYLTRANSFERASE.

Z. Drobna<sup>1</sup>, S. B. Waters<sup>2</sup>, F. S. Walton<sup>1</sup>, V. Devesa<sup>3</sup>, <u>D. J. Thomas</u><sup>4</sup> and <u>M. Styblo<sup>1,3</sup>, <sup>1</sup>Pediatrics, UNC, Chapel Hill, NC, <sup>2</sup>Curriculum in Toxicology, UNC, Chapel Hill, NC, <sup>3</sup>CEMALB, UNC, Chapel Hill, NC and <sup>4</sup>NHEERL, USEPA, Research Triangle Park, NC.</u>

In humans and rat, the methylation of arsenic (As) is catalyzed by an As<sup>III</sup>-methyltransferase (Cyt19) and yields methylated pentavalent and trivalent arsenicals. Cyt19 activity and expression levels vary among tissues. For example, Cyt19 is expressed in human hepatocytes that are efficient methylators of As, but not in UROtsa cells, a human urothelial cell line that does not methylate As. Thus, UROtsa cells are an ideal null background to assess the role of As methylation in modulation of toxic and cancer promoting effects of this metalloid. A retroviral gene delivery system (pLEGFP-N1) was used to transduce UROtsa cells with a rat Cyt19 (rCyt19). The expression of rCyt19 in neomycin-selected UROtsa/rCyt19 clones was confirmed by RT-PCR analysis of Cyt19 mRNA and by immunoblot analysis, using rabbit anti-rCyt19 antiserum. The metabolism of As was then examined in the parent cell line and in the clonal cells using radiolabeled carrier-free arsenite as a substrate. During a 65-hour incubation, UROtsa/rCyt19 cells methylated between 20 to 25% of arsenite. Both methylated arsenic (MAs) and dimethylated arsenic (DMAs) were found in the culture. DMAs was the predominant metabolite in both cells and medium. After the incubation, the parent UROtsa cells, that did not methylate arsenite, retained more As than methylating UROtsa/rCyt19 cells. The results of preliminary experiments show the parental cells are more susceptible to the cytotoxicity of arsenite and of methylarsine oxide than are UROtsa/rCyt19 cells. In contrast, iododimethylarsine is more cytotoxic in the clonal cells. These data suggest that the capacity to methylate As modifies the response of cells to acute cytotoxic effects of this metalloid. Future studies will provide information about the role of methylation in modulation of effects associated with chronic exposures to As. (This abstract does not reflect USEPA policy.)

EFFECTS OF ARSENITE AND MONOMETHYL ARSONOUS ACID ON UROTSA CELLS: LOW-LEVEL EXPOSURE CAUSES ACCUMULATION OF UBIQUITINATED PROTEINS WHICH IS ENHANCED BY REDUCTION IN CELLULAR GLUTATHIONE LEVELS

T. G. Bredfeldt<sup>1</sup>, M. J. Kopplin<sup>1</sup>, E. A. Mash<sup>2</sup> and <u>A. Gandolfi<sup>1</sup></u>. <sup>1</sup>Pharmacology and Toxicology, University of Arizona, Tucson, AZ and <sup>2</sup>Chemistry, University of Arizona, Tucson, AZ.

Arsenic is a ubiquitous environmental toxicant. Chronic arsenic exposure increases risk for the development of diabetes, vascular disease, and cancers of the skin, lung, kidney, and bladder. This study investigates the effects of arsenite [As(III)] and monomethyl arsonous acid [MMA(III)], a product of As(III) biotransformation, on human urothelial cells (UROtsa). As(III) toxicity was determined by exposing confluent UROtsa cells to As(III) (0.5-200 uM). Depleting cellular glutathione levels with BSO (butathionine sulfoximine) potentiated the toxicity of As(III). Cell viability was assessed with the MTT [(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide] assay. The ability of UROtsa cells to biotransform As(III) was determined by exposure to environmentally-relevant concentrations of As(III) followed by HPLC/ICP-MS analysis of cell media and lysate. UROtsa cells were found to oxidize and methylate As(III). Both pentavalent and trivalent monomethylated products were detected. Although cytotoxicity was observed at high

concentrations of As(III) (-100 uM), perturbations of a variety of molecular processes occurred at much lower concentrations. Exposure to low-level As(III) (0.5-25 uM) causes an accumulation of ubiquitin (Ub)-conjugated proteins. This effect is greatly enhanced when cellular glutathione levels have been reduced with BSO treatment. Ongoing studies investigating the effects of MMA(III) on UROtsa cells, suggest that this metabolite is more toxic than As(III) to UROtsa cells. Since As(III) and MMA(III) have many effects on UROtsa cells, a greater understanding of how these arsenicals affect cellular proteins in a target tissue will lead to a better understanding of the mechanism of toxicity and pathogenesis for low-level exposure to arsenic (NIEHS 04940, 07091, 06694).

INHIBITION OF LUMINAL CYSTINE TRANSPORT BY THE MERCURIC CONJUGATE CYS-S-HG-S-CYS IN ISOLATED-PERFUSED S2 SEGMENTS OF THE RABBIT RENAL PROXIMAL TUBULE.

D. W. Barfuss¹ and R. K. Zalups². ¹Biology, Georgia State University, Atlanta, GA and² Mercer University School of Medicine, Macon, GA.

Lumen-to-cell transport and cellular uptake of S35-L-cystine across the luminal membrane was studied in isolated perfused S2 (cortical pars recta) segments of the rabbit proximal tubule in the absence and presence of various concentrations of the mercuric conjugate Cys-S-Hg-S-Cys. In the absence of luminal Cys-S-Hg-S-Cys, isolated tubules perfused with a range of  $S^{35}$ -L-cystine concentrations (20 to 500  $\mu$ M) transported the  $S^{35}$ -L-cystine from the luminal fluid in a concentration dependent manor (curvilinear pattern), which was consistent with a single transport system having Michaelis-Menten kinetics. The calculated transport maximum for L-cystine was 800 fmol min<sup>-1</sup> (mm tubular length)<sup>-1</sup>, while the affinity (Km) of the L-cystine was approximately 50 µM. The presence of mercuric conjugate Cys-S-Hg-S-Cys in the luminal fluid inhibited the lumen-to-cell transport of S<sup>35</sup>-L-cystine in a concentration-dependent manor. Specifically, 100  $\mu$ M Cys-S-Hg-S-Cys inhibited the lumen-to-cell transport of luminal S<sup>35</sup>-L-cystine (at 100  $\mu$ M) by approximately 75%, from about 528 to 128 fmol min $^{-1}$  (mm tubular length) $^{-1}$ . In addition, the cell-to-lumen ratio of S35-L-cystine was reduced by 90% (30 to 2.1). We conclude from these experiments that the mercuric conjugate Cys-S-Hg-S-Cys is transported by transporters of L-cystine localized in the luminal membrane of the cortical pars recta of the rabbit nephron, perhaps systems  $b^{0,\, +}$  and/or  $B^{0,\, +}$ . We also conclude the affinity of the luminal L-cystine transporter(s) for Cys-S-Hg-S-Cys is greater than that for L-cystine.

COPROPORPHYRINOGEN OXIDASE (CPOX) POLYMORPHISM ALTERS THE EFFECT OF MERCURY (Hg) ON PORPHYRIN EXCRETION IN HUMANS.

<u>I. S. Woods</u><sup>1, 2</sup>, <u>D. Echeverria</u><sup>2, 1</sup>, N. J. Heyer<sup>2</sup>, A. C. Bittner<sup>2</sup> and F. M. Farin <sup>1</sup>. 

<sup>1</sup>Environmental Health, University of Washington, Seattle, WA and <sup>2</sup>Battelle Centers for Public Health Research and Evaluation, Seattle, WA.

Previous studies have documented the efficacy of urinary porphyrin profile changes as a biomarker of Hg body burden in humans and have identified the etiology of this effect as Hg-mediated alteration of CPOX activity in the kidney. This study focused on the genetic etiology of an atypical porphyrinogenic response (APR) seen among 12-16% of Hg-exposed subjects, characterized by substantially excess urinary excretion of CPOX precursors, particularly the atypical porphyrin, most likely keto-isocoproporphyrin (KICP), than is predicted solely on the basis of Hg body burden. Automated DNA sequencing-based assays were developed to examine the 7 exons and flanking intron-exon boundaries of the CPOX gene from 389 subjects with low-level Hg exposure (mean urinary Hg = 1.8(1.7) ug/L). Genetic analysis revealed an A814C polymorphism in exon 4 encoding a N272H substitution that was predominant among subjects with the APR. Overall population frequencies were 73% WT, 26% Het, 2% Mut. Multiple regression analyses suggested that this CPOX polymorphism (β=.08\*\*) preferentially enhanced the specific effect of Hg on KICP excretion, when controlling for gender ( $\beta$ =.03\*\*), the CPOX substrate, 5-carboxylporphyrin (5-CP) (?=.80\*\*), urinary Hg ( $\beta$ =.11\*\*), and the interaction of 5-CP and Hg ( $\beta$ =.09\*\*), where \*\* = p<.05. These data substantiate previous findings of a possible genetic predisposition to an altered biological response to Hg that could affect Hg health risks. The APR, particularly KICP excretion, might therefore serve as a biomarker of both Hg exposure and susceptibility to Hg toxicity. Supported by ES04696 and ES07033

UPTAKE OF BIOLOGICALLY RELEVANT FORM(S) OF INORGANIC MERCURY BY HUMAN ORGANIC ANION TRANSPORTER 1 (hOAT1).

S. Ahmad and R. K. Zalups. School of Medicine, Basic Science, Mercer University, Macon, GA.

The kidney is the primary target affected adversely by inorganic mercury (Hg\*+). Within the kidneys, Hg\*+ accumulates mainly along the three segments of the proximal tubule. Recent findings have implicated indirectly the organic anion transport

systems in the basolateral uptake of thiol-conjugates of Hg++ in proximal tubular epithelial cells. In the present study, we used hOAT1-transfected and non-transfected Madin-Darby Canine Kidney II (MDCK II) cell lines to define more precisely the role of the organic anion transporter 1 (hOAT1) protein in the uptake of thiol-conjugates of Hg\*\*. Significant levels of uptake of Hg\*\* occurred in the hOAT1-transfected cells when the cells were exposed to mercuric conjugates of Homocysteine (hCys-Hg-hCys; 9.97±0.18 pmol x mg protein<sup>-1</sup> x min<sup>-1</sup>), Cysteine (Cys-Hg-Cys; 5.65±0.08 pmol x mg protein x min or N-Acetylcysteine (NAC-Hg-NAC; 3.42±0.08 pmol x mg protein x min by contrast, no significant uptake of Hg++ occurred in the control, non-transfected MDCK II cells when they were exposed to these thiol-conjugates. Intrestingly, uptake of Hg\*\*, in the form of mercuric conjugates of Cysteinylglycine (gly-cys-Hg-cys-gly) or Glutathione (GSH-Hg-GSH) was negligible in both hOAT1-transfected and non-transfected MDCK II cells. The uptake of hCys-Hg-hCys, Cys-Hg-Cys and NAC-Hg-NAC in hOAT1-transfected MDCK II cells was inhibited in a dose dependent manner by p-aminohippurate or the dicarboxylic acids (adipate or glutrate). Transport of hCys-Hg-hCys was time-dependent and temperature-sensitive. Overall, the current transport data indicate that hCys-Hg-hCys has a higher affinity for hOAT1 than Cys-Hg-Cys or NAC-Hg-NAC. Moreover, the findings from the present investigation indicate that OAT1 is likely the primary transporter responsible for basolateral uptake of thiol-conjugates of Hg++ along the proximal tubul in vivo.

#### 392 ALUMINUM TRANSPORT AND UPTAKE IN CACO-2

Y. Zhou<sup>1</sup> and <u>R. A. Yokel<sup>2,1</sup>. <sup>1</sup> Graduate Center for Toxicology, University of Kentucky Medical Center, Lexington, KY and <sup>2</sup> College of Pharmacy, University of Kentucky Medical Center, Lexington, KY.</u>

Aluminum (Al) has been suggested to be a contributor to dialysis encephalopathy, a low-turnover osteomalacia and Alzheimer Disease. However the mechanism by which it is absorbed from the GI tract is uncertain. In the present work, confluent Caco-2 cell monolayers grown 1) on porous membranes which were mounted in vertical diffusion chambers and 2) in 35 mm diameter dishes were used to study apparent Al permeability and uptake kinetics, respectively. For the permeability study, Al citrate or Al maltolate was added to the medium on the apical side of the Caco-2 monolayer and the amount of Al on the basal side measured. The permeability of lucifer yellow and [3H]-propranolol, which pass through the paracellular and transcellular pathways, respectively, were concurrently measured. For the uptake study, Caco-2 cells were incubated with Al citrate or Al maltolate for 5, 10, 30, 60, 120 or 240 min. They were washed in the absence or presence of 2 mM EDTA to determine Al associated with the cell monolayer. The apparent permeabilities of Al citrate and Al maltolate were ~ 30% of, and correlated highly with, the apparent permeability of lucifer yellow (r=0.98, r=0.99). In contrast, Al and propranolol permeabilities did not correlate. The high correlation between Al and lucifer yellow permeation as well as greater Al permeation than uptake suggest Al citrate and Al maltolate apical to basal flux across the Caco-2 cell monolayer is mostly via the paracellular pathway. EDTA washout reduced Al associated with Caco-2 cells after Al citrate but not Al maltolate exposure, suggesting 2 pools of Al citrate and 1 of Al maltolate uptake. Intracellular Al concentration after 240 min of Al citrate and Al maltolate exposure was 0.7- and 2-fold the medium Al concentration, respectively. Al citrate, but not Al maltolate, uptake rate decreased over time. Al citrate and Al maltolate similarly diffuse through the paracellular pathway but enter cells by different rates/processes. Funded by EPA STAR Grant 829783.

## 393 MANGANESE CONCENTRATIONS IN THE AIR OF THE MONTREAL (CANADA) SUBWAY IN RELATION TO SURFACE AUTOMOBILE TRAFFIC DENSITY.

N. Boudia<sup>1</sup>, R. Halley<sup>2</sup>, G. Kennedy<sup>3</sup>, L. Gareau<sup>1</sup> and <u>J. Zayed<sup>1</sup></u>. <sup>1</sup>Environmental and occupational Health, University of Montreal, Montreal, QC, Canada, <sup>2</sup>Transport Montreal Society, Montreal, QC, Canada and <sup>3</sup>Department of Engineering Physics, Ecole Polytechnique de Montreal, Montreal, QC, Canada.

Since its introduction in Canada in 1976, the use of MMT in gasoline increased substantially until it completely replaced tetraethyl lead in 1990. A correlation has been established several times by our research group between atmospheric Mn concentration and automobile traffic density, suggesting that methylcyclopentadienyl manganese tricarbonyl (MMT) in gasoline could play a significant role. This study aims to measure manganese (Mn) concentrations in the air of the underground subway in Montreal (Canada) and to examine the relation with nearby surface automobile traffic density and, by extension, with the use of MMT in gasoline. Three subway stations were chosen for their location in different microenvironments with different traffic densities. Respirable (MnR < 5  $\mu m$ ) and total Mn (MnT) were sampled in the stations about 25 m below ground level, over two weeks, 5 days/week, 12 h/d from 6:00 h to 18:00 h. For the station located in the lower traffic density area, relatively low levels of MnR and MnT were found, with averages of

0.022 µg/m3 and 0.035 µg/m3 respectively. For the other two stations, the concentrations were more than 7 times higher and far exceeded the USEPA reference concentration of 0.05 µg/m3. Although there may be several sources of Mn from the different components of the subway structure and vehicles, no correlation was found between these and the observed Mn concentrations in air. However, a significant correlation (p $\leq$ 0.05) was found between atmospheric Mn concentrations and nearby automobile traffic density. Since the air in the metro is pumped directly from outside without filtration, our findings suggest that the combustion of MMT in automobiles may be an important factor.

## 394 POTENTIAL NEUROLOGICAL EFFECTS OF MANGANESE EXPOSURE DURING WELDING: A "STATE-OF-THE-SCIENCE" REVIEW.

A. Santamaria<sup>1</sup>, A. Li<sup>2</sup>, F. Mowat<sup>3</sup>, C. Cushing<sup>4</sup> and B. Finley<sup>5</sup>. <sup>1</sup>Exponent, Houston, TX, <sup>2</sup>Exponent, Oakland, CA, <sup>3</sup>Exponent, San Francisco, CA, <sup>4</sup>Exponent, Boulder, CO and <sup>5</sup>Exponent, Santa Rosa, CA.

Some recent studies have suggested that exposure to manganese (Mn), an essential component of welding electrodes, can cause neurotoxicity in welders ("manganism" a pattern of neurological effects that bears some similarity to Parkinson's Disease and related syndromes). This review presents a critical analysis of the published data regarding Mn exposure during the welding process and the human health studies evaluating neurotoxicity in welders. Our review indicates that the Mn composition of welding fumes is dependent on the composition of the metal being welded, welding process, and electrodes used. In addition, welders often perform a variety of different tasks with varying degrees of duration and ventilation, and, hence, in order to accurately assess manganese exposures that have occurred in different occupational settings, some specific information on the welder's historical work patterns is desirable. Currently, there is limited information relating airborne Mn levels or Mn exposure biomarkers with specific welding activities, but the data that do exist suggest that Mn exposures in welders are far below those associated with the increased incidence of manganism that has been documented in miners and smelter workers. We believe the available data might support the development of reasonable "worst-case" exposure estimates for most welding activities, and suggest that exposure simulation studies (re-creating a welder's activities and collecting airborne Mn data) would significantly refine such estimates. We also found that, while manganism has been documented in highly exposed populations, there are no epidemiological studies of manganism incidence in welders; the literature to date consists of case reports. Clearly, a well-designed epidemiological evaluation of manganism in welder's would be useful. Such a study (in addition to exposure simulation) could also evaluate the confounding exposures to other potentially neurotoxic compounds that occur during welding.

# 395 PHARMACOKINETIC ANALYSES OF THE EFFICIENCY OF UPTAKE OF INHALED MANGANESE FROM THE OLFACTORY MUCOSA INTO THE CENTRAL NERVOUS SYSTEM IN RATS.

D. B. Rao, D. C. Dorman and M. E. Andersen. CIIT Centers for Health REsearch, Research Triangle Park, NC.

Exposures to high atmospheric concentrations of manganese (Mn) such as in poorly controlled work environments cause neurodegenerative disorders, producing increased concentrations of Mn in specific brain regions including globus pallidum and striatum. Inhaled or instilled Mn can be directly transported from the nasal olfactory mucosa (OM) to the brain. Brain regions showing increased Mn concentrations include the olfactory bulb (OB), the olfactory tract and tubercle (OTT) and to a lesser degree, the striatum (ST). Here, we analyze published time course data from our laboratory for two different forms of Mn; MnCl2 and the less soluble MnHPO4. The time-dependent distribution of Mn in the brain following inhalation in rats was evaluated with a 4-compartment pharmacokinetic (PK) model. The model had deposition of Mn on the ÔM (compartment 1). Subsequent compartments include the OB (compartment 2), OTT (compartment 3) and striatum, ST (compartment 4). The volume of each compartment was characterized by measured weight. Movement among these 4 well-mixed compartments was described as first-order. Optimization in Berkeley Madonna provided estimates for fitted parameters, namely, the rate constants for intercompartmental transfer. Intercompartmental transfer rates were 0.01, 0.03 and 0.07 per hour for k12, k23 and k34, respectively. A proportion of Mn from one compartment moving to the deeper compartments within the CNS (from OB-OTT-ST) was required. All Mn transferred from mucosa through the OTT; however, less than 5% of the OTT Mn moved through to the striatum. PK model structures with deep tissue stores for Mn in the OTT provided a better description of the overall datasets than the single well-mixed OTT compartment. Less Mn was deposited into the olfactory mucosa following MnHPO4 inhalation, although the subsequent disposition was similar to that as MnCl2. This simple PK model will be useful in examining the importance of direct nerve transport as a factor in elevating brain Mn following inhalation in rats and other species.

# 396 DOPAMINE TRANSPORTER LEVELS ARE TRANSIENTLY INCREASED IN THE NON-HUMAN PRIMATE STRIATUM FOLLOWING ACUTE MANCANIESE EXPOSURE, PRELIMINARY ENDINGS

MANGANESE EXPOSURE: PRELIMINARY FINDINGS USING *IN VIVO* BRAIN IMAGING.

M. K. Chen<sup>1</sup>, J. S. Lee<sup>2</sup>, J. L. McGlothan<sup>1</sup>, R. J. Adams<sup>3</sup>, M. Alexander<sup>2</sup>, D. F. Wong<sup>2</sup> and T. R. Guilarte<sup>1</sup>. <sup>1</sup>Environmental Health Sciences, Johns Hopkins University, Baltimore, MD, <sup>2</sup>Radiology, Johns Hopkins University, Baltimore, MD and <sup>3</sup>Comparitive medicine, Johns Hopkins University, Baltimore, MD.

Exposure to high levels of manganese (Mn) causes a Parkinsonian-like syndrome in humans and non-human primates. The exact molecular mechanisms and anatomical loci of Mn-induced dopaminergic dysfunction are not clearly elucidated. We used Positron Emission Tomography (PET) to non-invasively measure the effect of acute exposure to manganese sulfate (MnSO4) on dopamine transporter (DAT) levels in the corpus striatum. Baboons (papio anubis) received [11C]-WIN 35, 428 PET scans to measure dopamine transporter (DAT) levels before and after MnSO4 administration. Binding potential (BP), a measure of DAT binding site availability in the striatum was generated from each PET study using a 2-tissue compartment model with the cerebellum as reference region. In one animal, we measured a 46% increase in DAT BP from a baseline of 6.19 to 9.04 at 1 week after two Mn injections (50 mg/kg S.C. one week apart). DAT levels returned to baseline values at 4 months (BP= 6.75) and remained constant at 10 months (BP= 6.87) after treatment. A subsequent single MnSO4 injection (10 mg/kg I.V.) to the same animal also resulted in an increase in DAT BP from 6.87 to 10.83, two days after administration. In a second animal, a 76% increase in DAT BP was measured from a baseline value of 3.89 to 6.83 at 3 days after Mn injection (20 mg/kg I.V.). In this animal, the BP returned to baseline levels (BP= 4.38) after 1 month. These findings suggest that acute Mn exposure may cause an up-regulation of DAT protein in the non-human primate striatum. An alternative explanation may be that Mn decreases dopamine levels at the synapse increasing the availability of ligand binding to DAT. These preliminary findings provide helpful insights on potential mechanisms of Mn-induced neurotoxicity and indicate that the striatum is a target for Mn in the primate brain [Supported by NIEHS ES07062 to TRG and NIDA K24DA00412 to DFW]

### 397 BRAIN REGIONAL DIFFERENCE IN IRON TRANSPORT AND THE EFFECT OF MANGANESE EXPOSURE.

R. Deane<sup>1</sup> and <u>W. Zheng</u><sup>2</sup>. <sup>1</sup>Center for Aging Research, University of Rochester, Rochester, NY and <sup>2</sup>School of Health Sciences, Purdue University, West Lafayette, IN.

Regulation of brain iron (Fe) homeostasis is still incompletely understood. Using an in situ rat brain perfusion model, we studied the transport Fe, either transferrin (Tf)-bound or free, at the blood-brain/CSF barrier. Data showed that brain capillary endothelia avidly took up circulating <sup>59</sup>Fe (1 nM), at rates (Kin) of 136+/-26 (Tf-bound) and 182+/-23 (free) ml/g/min x10<sup>3</sup>, respectively. However, the rates of <sup>59</sup>Fe entry into brain parenchyma were much reduced, i.e., 1.52+/-0.48 (Tf-bound) and 1.68+/-0.56 (free) ml/g/min x10<sup>3</sup>, respectively, in comparison to the capillary uptake. The pattern of brain Fe uptake shows a regional difference. In <sup>59</sup>Fe-only perfusions, the Kin exhibits in a descending order, cerebellum (CB) > striatum (ST) > brain stem (BS) > hippocampus (HP) > frontal cortex (FC), while with  $^{59}$ Fe-Tf, the order is ST > HP > CB> FC > BS. We further studied regional differences in Tf receptor (TfR) activity on brain capillaries. The Bmax (receptor density) and KD (affinity constant) of Tf binding were significantly higher in capillaries from the HP and ST as compared to FC (n=4, P<0.05), suggesting an uneven distribution of TfR in brain regional capillaries. Patterns of TfR distribution appear to correlate with the observed regional differences in rates of transport of Tf-bound 59Fe. In the absence of perfusate Tf, Mn exposure in rats (6 mg Mn/kg, ip, once daily for 2 wks) significantly increased the influx of 59 Fe to CP, but not the influx to the rest regions examined. In the presence of Tf, however, Mn exposure decreased the Fe uptake to most brain regions, except for a 3-fold increase into CSF compared to controls. Our results suggest that brain endothelia are capable of accumulating Fe and thus limiting the entry of Fe into brain parenchyma. There is a regional difference in Fe transport to brain. The difference in regional endothelial TfR activity may partly underlie the regional differences in Fe transport to brain. (US-NIEHS ES08146 and UK-Burroughs Wellcome Foundation #021366 and #1001670)

#### 398 COMPARATIVE NEUROTOXIC EFFECTS OF MN(II) VERSUS MN(III) IN A RODENT MODEL.

S. H. Reaney<sup>1, 2</sup>, G. Bench<sup>3</sup> and <u>D. R. Smith</u><sup>2</sup>. <sup>1</sup>Chemistry and Biochemistry Department, UCSC, Santa Cruz, CA, <sup>2</sup>Department of Environment Toxicology, UCSC, Santa Cruz, CA and <sup>3</sup>LLNL, Livermore, CA.

Chronic elevated manganese (Mn) exposure has been associated with neurological disorders. Since chronic elevated exposures to Mn may result from the combustion of MMT, and MMT combustion products contain Mn-oxides and phosphates of

various Mn oxidation (ox.) states (Mn(II), Mn(III) and Mn(IV)), there is a need to investigate how the ox. state of Mn exposure mediates toxicity. Recent work from our lab (Reaney and Smith, SOT abst, 2003) substantiates this need. This study evaluated how exposures to Mn as Mn(II) or Mn(III) affected the regional distribution and neurotoxic effects of Mn in the frontal cortex (FC), striatum (STR), globus pallidus (GP), and thalamus (Th) regions of the basil ganglia in Long Evans rats. Rats were exposed (IP) to Mn(II)-chloride or Mn(III)-pyrophosphate over a 5 week period at total cumulative doses of 0, 30 or 90 mg Mn/kg body weight. Results indicate that Mn(III) exposures produced significantly higher blood Mn levels than exposures to Mn(II). Liver Mn levels also increased with dose, but there was no effect of Mn ox state. In the brain, FC Mn levels increased in a dose dependent manner (p<0.05) with high Mn(III) exposures producing significantly higher (~45%) levels than exposures to high Mn(II). Analyses of Mn in other brain regions (STR, GP, Th) are on-going. GABA levels were significantly increased in the GP (p<0.05) and trended to increase in the Th and STR (p>0.05) following exposures to either Mn(II) or Mn(III). In contrast, levels of DA showed no measurable change. TfR expression increased in the GP with Mn dose (p<0.05), and trended up (p>0.05) in other brain regions as well. These data suggest that the oxidation state of Mn exposures mediate acquired blood Mn levels, which in part drives brain Mn uptake, and presumably resultant neurotoxicity.

## 399 MORPHOLOGICAL EVIDENCE OF DIFFERENTIAL CYTOTOXICITY OF MN(II) AND MN(III) IN HUMAN DOPAMINERGIC SH-SY5Y CELLS *IN VITRO*.

C. Zhang¹, J. Li².³, C. Zhou¹ and <u>W. Zheng</u>³. ¹Xinjiang University of Med. Sciences, Urumqi, China, ²Capital University of Med. Sciences, Beijing, China and ³School of Health Sciences, Purdue University, West Lafayette, IN.

Results from this and other laboratories have shown that Mn(III) species appear to be more toxic than Mn(II) in cell killing and cellular biochemical alterations. This study aimed to use morphological approaches to verify the differential toxicity between Mn(II) and Mn(III) in human neuroblastoma dopaminergic SH-SY5Y cells. Cultured cells were exposed to 0.5 mM of either Mn(II) as MnCl<sub>2</sub> or Mn(III) as Mn acetate for 24 or 72 hrs. Changes in cell structure and alterations in cellular apoptotic markers were examined using light microscopy (LM), transmission electron microscopy (TEM), or immunocytochemistry. Following Mn exposure, both Mn species caused cell detachment from culture dishes and shrinkage in cell bodies and nuclei. TEM revealed that Mn exposure resulted in cytoplasmic vacuolation, dense nuclei, chromosome condensation, formation of granules surrounding the nucleus, and decrease in mitochondrial numbers. These morphological damages were evidently much severer in Mn(III)-treated cells than in Mn(II)-exposed cells. In particular, Mn(III) treatment exhibited more profound toxic effect than Mn(II) on cytoplasmic apparatus. To further investigate Mn-induced apoptosis, the expression of caspase-3, a key mediator of apoptosis of mammalian cells, and the activity of nitric oxide synthase (NOS) were studied. Immunocytochemistry showed that incubation with either Mn species equally increased the expression of caspase-3. While Mn treatment did not change the status of neuronal nNOS, it increased the expression of inducible iNOS. Co-incubation with an NO inhibitor (Nmonomethyl-L-arginine) significantly reduced either Mn species-elicited cell killing by a flow cytometry. These data suggest that Mn(III) species causes severer morphological damage than Mn(II). In addition, Mn-mediated apoptosis may be associated with the activity of NOS/NO in cytoplasm and mitochondria. (Supported in part by PRC-NSF #3000140, Beijing Science Committee #9558102800, and US-NIEHS ES08146)

#### 400 MOTOR AND NEUROCHEMICAL EFFECTS OF SUB-CHRONIC LOW MANGANESE EXPOSURES IN A RODENT MODEL.

R. Gwiazda, C. Kern and D. Smith. Environmental Toxicology, University of California, Santa Cruz, Santa Cruz, CA.

The mechanisms and functional outcomes of exposures to Mn from environmental (e.g., from MMT combustion) and more elevated occupational (e.g., welding) sources have sparked interest in elucidating the physiological basis of the neurological effects due to cumulatively low levels of Mn exposure. Particular concern exists for individuals in the early stage of neurological disease who could be further impaired by Mn neurotoxicity. As a first step in evaluating this question 36 Long-Evans female rats were divided in three treatment groups: control, low and high dose, and received 0, 1.6 or 4.8 mg Mn/kg, three times a week for 5 weeks, respectively. The outcomes evaluated at the completion of exposures were spontaneous motor activity using a digitized Video system, latency to fall from an accelerating rotating rod, and the ability to cross a suspended balance beam. Neurotransmitter levels (dopamine, GABA, aspartate, glutamate) in striatum, globus pallidus and motor regions of the thalamus were also evaluated. Animals exposed to the high Mn dose regimen had significantly higher levels of spontaneous motor activity (they

traveled farther and spent less time at rest), and remained on the accelerating rotorod longer before falling compared to animals from either the control or the low Mn dose groups. Animals from the low dose group were significantly impaired in crossing the balance beam compared to animals from the control and high dose groups. Levels of the neurotransmitters dopamine, aspartate, glutamate and GABA were not measurably affected by manganese treatments in striatum and globus pallidus, but the low dose treatment significantly raised aspartate and GABA levels in the motor regions of the thalamus. These effects were elicited at the lowest Mn dose ever administered in a rodent study. Collectively, these results substantiate previous findings that low exposure to Mn induces adverse motor effects and alters aminoacid neurotransmitter levels in brain regions within the basal ganglia without having an effect on striatal dopamine.

# 401 LOCOMOTOR ACTIVITY IN UBIQUITIN MUTANT MICE AFTER NOSE-ONLY INHALATION OF MANGANESE.

J. Karlsson<sup>1</sup>, R. H. Gwiazda<sup>4</sup>, O. Myers<sup>1</sup>, W. Barrington<sup>1</sup>, G. A. Douglas<sup>5</sup>, E. Barr<sup>2</sup>, S. R. Donald<sup>4</sup>, G. Bench<sup>3</sup> and J. Lewis<sup>1</sup>. <sup>1</sup>Community Environmental Health Program, University of New Mexico, Albuquerque, NM, <sup>2</sup>Lovelace Respiratory Research Institute, Albuquerque, NM, <sup>3</sup>Lawrence Livermore National Laboratory, Livermore, CA, <sup>4</sup>Environmental Toxicology, University of California, Santa Cruz, CA and <sup>5</sup>Centre for Cancer Therapeutics, Ottawa Regional Cancer Centre, Ottawa, ON, Canada.

Manganese (Mn) toxicity has been linked to the Parkinsons disease-like syndrome manganism. Mn can be directly transported from the nose into the CNS by the olfactory pathway, and can also be further transported trans-synaptically to deeper brains structures. Ubiquitin plays an important role in tagging damaged proteins for proteosomal degradation. The ubiquitin pathway is implicated in pathogenesis of neurodegenerative diseases such as Parkinsons, Huntingtons, Alzheiemers disease and amyotrophic lateral sclerosis. The aim of the present study was to investigate the role of ubiquitin in behavioral and neuropathological response to inhaled lowdose Mn. Transgenic mice expressing dominant negative mutant (K48R) or wild-type human ubiquitin, as well as FVB/N non-transgenic strain control mice were used as experimental animals. Mice were exposed to air or MnCl2 aerosol (dose of 2.02±0.26 mg/m3, particle size 1.76±0.33 ?m) by nose-only inhalation for 2 weeks (5 days/week, 6h/day to mimic occupational exposures). 18 months after exposure, mouse spontaneous activity, velocity and time spent resting or moving were evaluated over 20 min sessions using a computerized global tracking system. Ubiquitin mutant mice traveled farther, spent less time at rest, spent less time going slow, spent more time going fast, and had higher average velocity when moving than the other genotypes. Activity did not differ between ubiquitin control and FVB/N control mice. When controlled for genotype, Mn-exposed mice traveled less far, spent more time at rest, spent less time going fast, and had a slower velocity when moving compared to air-exposed animals. Ongoing neuropathological evaluation of the brains will shed further light on underlying mechanisms for the altered behavior.

# 402 MANGANESE EXPOSURE ARRESTS CELL PROLIFERATION AND ALTERS SIGNAL TRANSDUCTION ON MAPK'S CASCADES IN PC12 CELLS.

J. Chen<sup>1</sup>, W. Xu<sup>1</sup>, W. Luo<sup>1</sup> and <u>W. Zheng<sup>2</sup></u>. <sup>1</sup>Occupational & Environmental Health Sciences, Fourth Military Medical University, Xian, Shanxi, China and <sup>2</sup>School of Health Sciences, Purdue University, West Lafayette, IN.

Our previous studies suggest that manganese (Mn) exposure leads to cell death by damage to mtDNA and initiation of oxidative stress in cultured PC12 cells (Chen et al., Toxicol Appl Pharmacol 175:160, 2001). This study aimed to test the hypothesis that Mn-induced cellular stress altered the highly conserved MAPK (mitogen-activated protein kinase) signal transduction, particularly on ERK (extracellular signal regulated protein kinase) and p38 pathways, leading to apoptosis. PC12 cells were exposed to Mn at 0, 200, 400, 600, 800 uM as MnCl<sub>2</sub> for up to 4 days. Flow cytometry revealed that the cell proliferation cycle was arrested at the S phase; the cell inhibitory ratio exceeded 50% of the control. Transmission electron microscopy (TEM) and DNA fragment assay confirmed the apoptosis on day 4 following Mn exposure (600 uM). Western-blot showed that Mn treatment decreased phosphorylation of ERK2 in a time-dependent manner, possibly due to a down-regulation of ERK1/2 activity *via* the action on MEK1/2, as attested by studies using PD98059, a specific inhibitor of MEK1/2. Mn exposure, however, increased the phosphorylation of p38 during the same time period. By using SB203580, a specific inhibitor of p38, it was found that the up-regulated p38 activity by Mn treatment may pertain to Mn action on MEK3/6. These data suggest that the apoptosis may underline Mn-induced arrest in cell proliferation. An alteration in intracellular signal transduction appears to occur in a time sequence preceding Mn-induced morphological damage. Further, we demonstrate that Mn acts on MAPK signal transduction cascade by down-regulating ERK2 and up-regulating p38; the combination of both effects may lead to apoptotic cell death in Mn-exposed PC12 cells. (Supported by China National Science Foundation Grant#30100148 and US NIH/NIEHS ES08146)

403 PROTEOLYTIC ACTIVATION OF PROAPOPTOTIC KINASE PKCδ CONTRIBUTES TO MANGANESE-INDUCED APOPTOTIC CELL DEATH IN DOPAMINERGIC NEURONAL CELLS.

C. Latchoumycandane, M. Kitazawa, V. Anantharam and A. Kanthasamy. Department of Biomedical Sciences, Iowa State University, Ames, IA.

The utilization of methylcyclopentadienyl manganese tricarbonyl (MMT) as a gasoline additive has raised health concerns and renewed interest in understanding the neurotoxic effects of manganese in humans (Science 2003, 300:926-928). Chronic exposure to manganese causes Manganism, a neurological disorder similar to Parkinson's disease. However, the cellular mechanism by which manganese induces cell death in dopaminergic neurons remains unclear. We previously reported that manganese induces oxidative stress-dependent apoptotic cell death in the nonneuronal pheochromocytoma (PC12) dopaminergic cell model. In the present study, we investigated apoptotic cell signaling events following chronic exposure to manganese in mesencephalic dopaminergic neuronal (N27) cells. Manganese chloride (300 µM for 24 hr) induced time-dependent cell death in N27 cells, as determined by Sytox green nuclear staining. The cell death was accompanied by sequential activation of mitochondrial-dependent proapoptotic events including mitochondrial membrane depolarization, cytochrome c release, caspase-3 activation and DNA fragmentation, indicating that the mitochondrial-dependent apoptotic cascade primarily triggers the manganese-induced apoptotic cell death. Furthermore, manganese treatment proteolytically activated a member of a novel class of protein kinases, namely protein kinase C8 (PKC8). The caspase-3 specific inhibitor zDEVD-FMK significantly blocked PKCδ cleavage, indicating that caspase-3 mediates the cleavage. Pretreatment with the PKCδ inhibitor rottlerin or the caspase-3 inhibitor zDEVD-FMK almost completely blocked manganese-induced DNA fragmentation. Additionally, N27 cells expressing a catalytically inactive PKCδK376R protein (a PKCδ dominant negative mutant) were resistant to manganese-induced apoptosis. Collectively, the results suggest that the mitochondrialdependent apoptotic cascade mediates apoptosis via proteolytic activation of PKCδ in manganese-induced dopaminergic toxicity [NIH grant ES 10586]

404 ASTROGLIAL-MEDIATED NEURONAL APOPTOSIS FOLLOWING EXPOSURE TO MANGANESE AND CYTOKINES REQUIRES NF-KAPPA B-DEPENDENT PRODUCTION OF NO.

X. Liu, R. Mouneimne and <u>R. Tjalkens</u>. Toxicology Program, Department of Integrative Biosciences, Texas A&M University, College Station, TX.

Neuronal injury in Parkinsons disease is accompanied by regional increases in inflammatory mediators and activation of astroglia, with subsequent overproduction of nitric oxide (NO). The present studies postulate that astroglial-derived NO mediates neuronal apoptosis induced by manganese (Mn) and pro-inflammatory cytokines. PC12 cells were differentiated with nerve growth factor for 5 days and incubated with primary astrocytes grown on permeable cell culture inserts. Following exposure to Mn and interferon-γ (IFN-γ)/tumor necrosis factor-α (TNF-α), neuronal caspase activity was determined by live-cell fluorescence imaging and the number of apoptotic cells determined by terminal deoxynucleotide transferase-mediated dUTP-biotin nick-end labeling (TUNEL) and morphologic analysis of condensed nuclei. Mn synergistically enhanced both production of NO and induction of NOS2 mRNA in primary cortical astrocytes. In co-cultured neurons, apoptosis following exposure to Mn and TNF-α/IFN-γ was only observed in the presence of astrocytes; neurons exposed to Mn and TNF- in the absence of astrocytes did not undergo apoptosis. Overexpression of mutant IkBa (S32/36A) in astrocytes prevented all indices of apoptosis in co-cultured neurons. Inhibition of NOS2 with (±)-2-Amino-5, 6-dihydro-6-methyl-4H-1, 3-thiazine (AMT) significantly reduced neuronal apoptosis. In neurons exposed to Mn and TNF- $\alpha$ /IFN- $\gamma$  in the absence of astrocytes, the apoptotic phenotype was recovered through addition of low concentrations of the NO donor, S-nitroso-N-acetyl penacillamine. It is concluded that Mn- and cytokine-dependent apoptosis in PC12 neurons requires astroglialderived NO and that selective overexpression of mtIkBa in astrocytes prevents apoptosis in co-cultured neurons. Thus, therapeutic strategies that target the molecular signaling pathways regulating NOS2 expression in astroglia may be effective in mitigating neuronal injury in parkinsonian syndromes.

405 MANGANESE NEUROTOXICITY CORRELATES WITH INCREASES IN OXIDATIVE DAMAGE TO DNA IN THE NIGROSTRIATAL PATHWAY BUT NOT WITH CHANGES IN ANTIOXIDANTS

D. Cox, C. Bolin and F. Cardozo-Pelaez. *Biomedical and Pharmaceutical Sciences, University of Montana, Missoula, MT.* Sponsor: A. Holian.

Exposure to Mn can occur from industrial settings such as mining and from drinking water contamination. Environmental levels could increase as more countries use MMT as an additive to gasoline. Chronic exposure to Mn has been associated with the onset of neuropathological changes similar to Parkinsons disease (PD) with effects localized to the basal ganglia. It is believed that Mn neurotoxicity occurs via free radical damage. Antioxidant defenses protect against free radical damage; however exposure to Mn has been shown to deplete antioxidants and lead to increased damage to major cellular macromolecules. Elevated levels of 8-hydroxy-2-deoxyguanosine (oxo8dG), oxidative damage to DNA, have been found in brain regions associated with major neurodegenerative disease in humans, and in brain of animals challenged with various neurotoxicants. However, it is unknown whether DNA damage is responsible for neuronal loss or if it is mere epiphenomena of neurodegeneration. This study has made use of a mouse model genetically engineered to be deficient for the DNA repair enzyme 8-oxoguanine glycosylase (OGĞ1) that is primarily responsible for the removal of oxo8dG. Wild type (WT) and knockout OGG1 (KO) mice were exposed to MnCl<sub>2</sub> in drinking water from gestation to post-natal (PND) 31. Dopamine was measured in caudate putamen (CP) along with oxo<sup>8</sup>dG levels in midbrain (MB) and CP. A correlation between a rise in oxo<sup>8</sup>dG in MB, and a drop in DA in CP was seen in the KO mouse. Although Mn produced changes in endogenous antioxidant systems in both WT and KO mice, DA loss in CP was only associated with increases in oxo8dG levels in the nigrostriatal system. DNA repair activity was assessed in the WT showing a decrease repair capacity in MB and CP as a consequence of Mn exposure. This study has produced some accepted biomarkers for Mn neurotoxicity and it has revealed Mn-induced changes in DNA damage and repair that could enlighten molecular pathways involved in the neuropathological changes seen in Mn neurotoxicity.

406 OXIDATIVE STRESS AND GLOBAL RAT GENE EXPRESSION PROFILES IN PC12 CELLS AFTER MANGANESE TREATMENT.

R. R. Reams<sup>1</sup> and E. Taka<sup>1</sup>. <sup>1</sup>College of Pharmacy, Florida A & M University, Tallahassee, FL and <sup>2</sup>College of Pharmacy, Florida A & M University, Tallahassee, FL.

A Clontech Rat oxidative stress micro array was used to examine manganese chloride induced alteration of gene expression in rat pheochromocytoma cells (PC12 cells). Experimental samples included PC12 cells, which were exposed for 24 hours under control conditions (no added MnCl2) and treated conditions (300mM MnCl2). Two genes, heme oxygenase 1 (HMOX1; HO1) and ribosomal protein S30 40S subunit (RPS30) were upregulated as much as four-fold and three-fold respectively. Five genes, Cu-Zn Superoxide Dismutase, DNA-binding protein inhibitor 1 (ID1), heat shock 27-kDa protein (HSP27), Prothymosin-alpha (PTMA), and Heterogeneous nuclear ribonucleoprotein K (HNRNPK) were partially upregulated, in that they only met one of the two conditions for up regulation. We have confirmed the altered expression of two candidate genes, heme oxygenase 1 and ribosomal protein S30 40S subunit (RPS30) also known as FAU by Reverse Transcription-Polymerase Chain Reaction (RT-PCR) and western blotting analysis, respectively. This is the first report on the direct role of manganese in the global gene expression profile of oxidative stress in PC12 cells. Our findings suggests that 24 hour exposure of PC12 cells to manganese chloride resulted in the upregulation of genes involved in protection against oxidative stress and genes involved in protein synthesis/turnover. In a parallel micro array study, the effect of manganese on global gene expression was examined using Agilents rat global cDNA micro array . The molecular signature after Mn treatment included 405 signature genes. Genes with greater than 4-fold change in gene expression included HOX-1, Diaphorase (NADH/NADPH), rattus norvegicus dithiolethinone-inducible gene-1 mRNA and tartrate-resitant acid phosphatase type 5 mRNA.(Supported by ATS/DR and MHPF #U50/ATU398948-10)

407 ACTIVATION OF NITRIX OXIDE SYNTHASE DURING MODULATION WITH MANGANESE TOXICITY INVOLVES EARLY SIGNALING TRANSCRIPTION FACTOR, NF-KB: IMPLICATION FOR CELL DEATH.

<u>P. G. Gunasekar</u><sup>1</sup>, K. Prabhakaran<sup>2</sup> and D. Ghosh<sup>1</sup>. <sup>1</sup>Biological Sciences, Texas Southern University, Houston, TX and <sup>2</sup>Medicinal Chemistry and Mole. Pharmacology, Purdue University, West Lafayette, IN.

In the treatment of Parkinson's disease (PD), dopamine (DA) modulation has been implicated in the degeneration of dopaminergic neurons. Previously, we reported that modulation of DA enhanced manganese (Mn)-induced cell death which was

mediated by oxidative stress following NMDA receptor activation and involved nitric oxide synthase (NOS). In the present study, mesencephalic cells were used to investigate the early signaling events responsible for the induction of NOS and mediated apoptosis in Mn-induced cell death in the presence and absence of DA. Mn exposure to mesencephalic cells for 24 hr induced minimal apoptotic cell death. However, 2 hr exposure to DA in cell culture potentiated Mn-induced apoptotic cell death significantly in which Nuclear factor Kappa B (NF-KB) was involved. The ability of Mn-induced apoptotic cell death to DA exposure was determined by cell viability assay and Apoptag TUNEL staining. These studies support our hypothesis that greater level of DA in the cellular system interacts with Mn, and may cause cells to be more susceptible. In addition, co-incubation of NF-KB inhibitor (SN50) with Mn and DA protected significantly from cell death especially apoptosis dose dependently, which indicates the involvement of early signaling factor NF-KB during Mn and DA interaction induced dopaminergic toxicity. In order to confirm the role of NF-KB in NOS induction during DA potentiated Mn toxicity, Western blot study was carried out. Mn in the presence of DA (2 hr) markedly induced NOS activation in mesencephalic cells, which was reduced significantly in SN50 pre-treated cells. Taken together, these results indicate that DA modulation at the cellular level strongly interacts with Mn and thereby potentiates NOS mediated dopaminergic cell death. The activation of NF-KB signaling is an upstream event in Mn and DA interaction-induced cell death mechanism (Supported by American Parkinson Disease Association, Inc.).

MANGANESE POTENTIATES LIPOPOLYSACCHARIDE-INDUCED EXPRESSION OF NOS2 IN C6 GLIOMA CELLS THROUGH MITOCHONDRIAL-DEPENDENT ACTIVATION OF NUCLEAR FACTOR KAPPA B.

R. Mounemne, J. Faske, X. Liu and R. Tjalkens. Toxicology Program, Department of Integrative Biosciences, Texas A&M University, College Station, TX.

Excessive accumulation of manganese (Mn) causes a neurodegenerative condition in humans that shares neurologic and pathologic features with idiopathic Parkinsons disease. It has been proposed that increased production of nitric oxide (NO) by inducible nitric oxide synthase (NOS2) in activated astroglia exacerbates neuronal injury. Manganese enhances the effects of proinflammatory cytokines on expression of NOS2 but the molecular basis for this effect is unclear. It was postulated in the present studies that Mn enhances expression of NOS2 through the cisacting factor, nuclear factor kappaB (NF-кВ). Exposure of C6 glioma cells to lipopopolysaccharide resulted in increased expression of NOS2 and production of NO that was dramatically potentiated by Mn and was blocked through overexpression of mutant IκBα (S32/36A). LPS-induced DNA binding of p65/p50 was similarly enhanced by Mn and was decreased by mutant IkBa. Phosphorylation of IκBα was synergistically increased by Mn and LPS and was not blocked by U0126, a selective inhibitor of ERK1/2. Mn decreased mitochondrial membrane potential and increased matrix calcium, associated with a rise in intracellular reactive oxygen species (ROS) that was attenuated by a mitochondrial-specific antioxidant. Blocking mitochondrial ROS also attenuated the enhancing effect of Mn on LPSinduced phosphorylation of IκBα and expression of NOS2, suggesting a link between Mn-induced mitochondrial dysfunction and activation of NF-KB. Overexpression of a dominant-negative mutant of the NF-κB-interacting kinase prevented enhancement of LPS-induced phosphorylation of  $I\kappa B\alpha$  by Mn. These data indicate that Mn augments LPS-induced expression of NOS2 in C6 cells by increasing mitochondrial ROS and activation of NF-κB.

#### 409

COMPARISON OF DIFFERENTIATED AND NON-DIFFERENTIATED PC CELLS RESPONSE TO MNCL2, MPP+, AND ROTENONE.

L. Russell IV. University of Maryland, Baltimore, MD. Sponsor: K. Squibb.

There is an increasing belief that differentiated cells have greater susceptibility than non-differentiated cells following exposure to certain neurotoxicants. Excessive exposure to MnCl2, MPP+, and Rotenone has been shown to produce neurotoxic impairments in dopaminergic neurons of mammalian brains that lead to the development of a Parkinson-like Syndrome. The present study was undertaken to test the hypothesis that differentiated PC12 cells are more sensitive to MnCl2, MPP+, and rotenone than non-differentiated PC12 cells. Non-differentiated cells were differentiated by five-day exposure to 100 ng/mL of nerve growth factor. Differentiated and non-differentiated PC12 cells were evaluated for their response following 24-hour exposure to MnCl2, MPP+, and rotenone. The Alamar Blue cell viability assay was used to measure the metabolic activity of PC12 cells. Differentiated PC12 cells are more metabolically active than non-differentiated PC12 cells. In dose dependent studies MnCl2 decreases the cell viability in a concentration dependent manner in non-differentiated PC12 cells whereas MPP+ and rotenone have no effect. Only MPP+ was able to decrease cell viability in differentiated PC12 cells. In the interaction studies the MPP+ and rotenone interaction in

differentiated cells caused the greatest decrease in cell viability as compared to all other interactions studied in differentiated and non-differentiated PC12 cells. These results suggest that differences in differentiated and non-differentiated sensitivity may involve differences in the expression of genes involved in protection from oxidative damage and dopamine receptor and transporter proteins.

410

MANGANESE AND LEAD DISPLAY DIFFERENT PATTERNS OF NEUROTOXICITY IN HUMAN SY5Y NEUROBLASTOMA CELLS.

Y. Qian, Y. Zheng and E. Tiffany-Castiglioni. Texas A&M University, College

Epidemiologic studies suggest that manganese (Mn) and lead (Pb) contribute to the onset of Parkinson's disease (PD). The α-synuclein-positive Lewy body is a pathological hallmark of PD and its aggregation in dopaminergic neurons may be stimulated by environmental insults that generate the production of reactive oxygen species (ROS). In this report, we used the human SY5Y neuroblastoma cells as a dopaminergic neuronal model to profile effects of Mn and Pb on ROS levels, ROSrelated enzymes and α-synuclein aggregation. In cells exposed to MnCl2 (0-250 μM) for 3 days, both cytotoxicity and ROS levels increased with metal concentration. In contrast, ROS levels decreased while cytotoxicity increased relative to Pb concentration in cells exposed to Pb acetate (0-10 µM). In cells exposed to a mixture of 100 µM Mn and 3 µM Pb, Pb cytotoxicity was partially attenuated by Mn while ROS levels dramatically increased. However, Pb had no effect on Mn cytotoxicity and Mn-induced ROS generation. Mn induced Cu/Zn-SOD expression, as detected by Western blot analysis, but had no effect on Mn-SOD and catalase expression. Whereas Pb did not change SOD expression, Pb and Mn mixture induced CuZn-SOD but not Mn-SOD expression, similar to Mn alone. Effects of Mn, Pb and their mixture on  $\alpha\mbox{-synuclein}$  aggregation were profiled by fluorescence imaging of cells transfected with three chimeric cDNAs containing the transcript for EGFP: WP, A30P or A53T. EGFP was used as a control. In EGFP-, WP-EGFPand A30P-EGFP- transfected cells, no change of protein distribution or aggregation was observed after metal treatment. However, in A53T-EGFP-transfected cells, A53T-EGFP aggregation by Mn, Pb and mixture was observed. These data suggest that Mn, not Pb, cytotoxicity is dependent on ROS generation and Mn can reduce Pb cytotoxicity. Mn-induced ROS generation occurred in the cytosol but not in mitochondria. Therefore, Mn and Pb may have different mechanisms for modifying  $\alpha$ -synuclein distribution and aggregation.

411

HISTOPATHOLOGY, IMMUNOHISTOCHEMISTRY AND ELECTRON MICROSCOPY OF SPONTANEOUS UVEAL MELANOMA IN TWO HAN WISTAR RATS.

C. Barton and A. Moran. Covance Laboratories Ltd., Harrogate, United Kingdom. Sponsor: D. Everett.

Uveal melanomas in rats are unilateral neuroectodermal tumours derived from uveal melanocytes. They occur in numerous species of animals including laboratory animals and are most frequently reported in cats where they are the most common intraocular tumuor. Here we describe the histopathologic, immunohistochemical and electron microscopic characteristics of uveal melanomas in two Han Wistar rats. The tumours occurred in two, one year old Han Wistar rats that were involved in a long term drug study. Fresh tissues were routinely fixed and processed. Paraffin embedded sections were stained with haematoxylin and eosin. Additional sections were immunohistochemically examined for reactivity to Vimentin, S100, Neuron Specific Enolase (NSE), Melan A, Ki-67 and Proliferating Cell Nuclear Antigen (PCNA). In addition sections were also routinely processed for Transmission Electron Microscopy. Histologic examination of the eye in each case revealed an unencapsulated infiltrative densely cellular mass composed of sheets and nests of tumour cells supported by a fine fibrovascular stroma. The tumour cells were round to spindloid with variably distinct cell borders. Occasional cells contained a dark brown granular pigment within their cytoplasm. The tumour cells were positive for Vimentin, S100, NSE and Melan A. Cell proliferation was apparent with Ki-67 and PCNA.

BACKGROUND CHANGES FOLLOWING DAILY INTRAVITREAL INIECTION FOR THREE CONSECUTIVE DAYS IN BEAGLE DOGS AND DUTCH-BELTED RABBITS.

M. Vezina, A. Patel and C. Copeman. CTBR, Senneville, QC, Canada.

Intravitreal injection is becoming more common as a route of administration in the prevention and treatment of diseases in the eye. Previously, multiple intravitreal injections were performed no more than weekly for reasons not only related to the test article, but also to the concern for cumulative trauma caused by the injection procedure. As the injection procedure is becoming more common in the clinic and

clinical ophthalmologists more comfortable with the procedures, the concept of daily injections to maximize exposure and increase efficacy has been investigated. The background data presented is from 12 dogs and 6 rabbits. Intravitreal injections were performed bilaterally once daily for 3 consecutive days in both species using a 27G needle for the dogs and a 29G needle for the rabbits. Ophthalmology was performed predose, on each day of dosing, the day following dosing and 1 and 2 (dogs only) weeks after the first dose. In addition, ERG and tonometry were performed on the dogs the day following Dose 3 and on Days 7 and 14. In both species, background changes were mild and transient, and consisted of subconjunctival hemorrhage in all eyes, with occasional conjunctival hyperemia, chemosis and/or slight aqueous flare, which were associated with manipulation of the eye and the injection. These changes mostly resolved by Day 7 and were completely resolved by Day 14. There were no ERG or tonometry changes in the dogs. It was concluded that a daily intravitreal injection performed over 3 consecutive days was well tolerated in beagles and Dutch-belted rabbits and is a suitable method for multiple intravitreal injection toxicity studies.

# 413 A 14-DAY SYSTEMIC AND OCULAR TOXICITY STUDY IN THE DOG OF INTRAVENOUSLY ADMINISTERED HEAT SENSITIVE LIPOSOMES CONTAINING CARBOXYFLUORESCEIN.

R. E. Rush<sup>1</sup>, S. A. D'Anna<sup>2</sup> and R. C. Zeimer<sup>2</sup>. <sup>1</sup>Charles River Laboratories- Ohio Division, Spencerville, OH and <sup>2</sup>The Wilmer Ophthalmological Institute, Johns Hopkins University, Baltimore, MD.

Vascular diseases, such as age related macular degeneration, are the leading cause of severe vision loss. Local delivery of drugs to the retinal vasculature could allow for interventions not currently feasible. Laser targeted drug delivery (LTD) has been developed to provide a minimally invasive access to this vasculature. Drugs that are encapsulated in heat-sensitive liposomes and injected intravenously can be released by warming the liposome with a laser pulse directed through the pupil. Previous studies in rodents have demonstrated the potential benefits of LTD. In order to further evaluate LTD, a dog toxicology study was performed to explore the potential systemic effects of heat sensitive liposomes containing carboxyfluorescein (CF) and potential ocular toxicity of retinal exposure to blue light (used in angiography) in the presence of CF. Heat sensitive liposomes containing CF were intravenously injected into eight dogs at a dose of 10 ml/kg (10x the intended clinical dose). In each eye, two 20 degree areas of the fundus were exposed to blue (490 nm) light at the intended power density. In one eye, the procedure was performed once with 3x the maximal intended duration (2 sec). In the opposite eye, blue light exposure was performed 10 times at 2x the intended duration (0.2 sec). Four other dogs were administered CF liposomes and returned to their cages without light exposure. A separate group of 8 dogs was similarly treated except that phosphate buffered saline was injected. All animals were observed for signs of systemic toxicity and received ophthalmologic and histopathologic evaluation. The results of this study indicate that intravenous injection of heat sensitive liposomes containing CF at 10x the intended clinical dose along with 490 nm blue light exposure produced no systemic or local toxicity.

#### 414 PHOTOBIOMODULATION ATTENUATES METHANOL-INDUCED RETINAL TOXICITY.

J. T. Eells<sup>1, 3</sup>, M. M. Henry<sup>2</sup>, P. Summerfelt<sup>2</sup>, M. T. Wong-Riley<sup>2</sup>, E. V. Buchmann<sup>3</sup>, M. Kane<sup>3</sup> and H. T. Whelan<sup>3</sup>. <sup>1</sup>Health Sciences, University of Wisconsin-Milwaukee, Milwaukee, WI, <sup>2</sup>Cell Biology, Neurobiology and Anatomy, Medical College of Wisconsin, Milwaukee, WI and <sup>3</sup>Neurology, Medical College of Wisconsin, Milwaukee, WI.

Our laboratory has developed a rodent model of acquired mitochondrial dysfunction produced by the mitochondrial toxin, formic acid, generated during methanol intoxication. Methanol intoxication produces ocular toxicity and blindness. Formic acid inhibits the essential mitochondrial enzyme, cytochrome oxidase. Low energy photon irradiation (photobiomodulation) by light in the red to near infrared spectral range (630-1000 nm) has been demonstrated to enhance mitochondrial activity and promote cell survival in vitro by stimulation of cytochrome oxidase activity. The present studies were undertaken to test the hypothesis that exposure to 670 nm radiation from light-emitting diode (LED) arrays would attenuate the retinotoxic actions of methanol-derived formic acid in this animal model. Using the electroretinogram as a sensitive indicator of retinal function, we demonstrated that that 3 brief (2 min. 24 sec.) 670 nm LED treatments (4 J/cm2), delivered at 5, 25 and 50 h of methanol intoxication, attenuated the retinotoxic effects of methanol-derived formate assessed at 72 h of intoxication. The same treatment protocol administered during the 72 h intoxication period improved the recovery of retinal function assessed following a 72 h recovery period. Our studies document a significant improvement of rod and cone-mediated function in LED-treated methanol-intoxicated rats during intoxication and a complete recovery of rod and cone-mediated function following recovery. We further show that LED treatment protected the retina from formate-induced histopathology. These findings provide a link between the actions of 670 nm light on mitochondrial oxidative metabolism in vitro and retinoprotection *in vivo*. Based on these findings, we suggest that photobiomodulation may represent a novel therapeutic approach for the treatment of retinal diseases including age-related macular degeneration in which mitochondrial dysfunction has been proposed to play a role.

### 415 GENE REGULATION BY THE $\alpha$ -SECRETASE CLEAVED AMYLOID PRECURSOR PROTEIN.

J. A. Johnson<sup>1, 2, 3</sup> and T. D. Stein<sup>1</sup>. <sup>1</sup>Neuroscience Training Program, University of Wisconsin, Madison, WI, <sup>2</sup>Environmental Toxicology Center, University of Wisconsin, Madison, WI, <sup>3</sup>School of Pharmacy, University of Wisconsin, Madison, WI and <sup>4</sup>Waisman, University of Wisconsin, Madison, WI.

Mice engineered to overexpress disease-causing mutant amyloid precursor proteins (APP) display plaque deposition, but lack the hyperphosphorylated tau and massive neuronal loss characteristic of Alzheimer's disease (AD). The Tg2576 mice overexpressing a mutant APP (APPSw) demonstrated increased expression of the amyloid sequestration protein transthyretin (TTR) and the neuroprotective insulin-like growth factor 2 (IGF-2). Both the γ-secretase cleaved COOH-terminal fragment (CTFγ) and the α-secretase cleaved NH2-terminal of APP (sAPPα) can regulate gene expression. While β-amyloid (Aβ) and CTFγ can lead to toxicity and cell death, sAPPa promotes neurite outgrowth, enhances memory, and protects against a variety of insults, including A $\beta$  toxicity. In AD, A $\beta$  levels increase while sAPP $\alpha$ levels decrease. In contrast, sAPPa levels are dramatically increased in the hippocampus of APPSw mice. In mouse hippocampal slice cultures sAPP $\alpha$  treatment completely protects against Aβ toxicity. Furthermore, sAPPα leads to increased expression of a number of neuroprotective genes, including TTR and IGF-2. Blockade of TTR or IGF-2 with either antibodies or siRNAs prevents the protective action of sAPPa, indicating that increased expression of these proteins is necessary for sAPPα protection against Aβ toxicity. Chronic injection of an antibody against transthyretin into the hippocampus leads to increased Aβ, tau phosphorylation, and neuronal death in the CA1 neuronal field of mice overexpressing APPSw. Therefore, elevated expression of transthyretin by sAPP $\alpha$  protects APPSw mice from developing the full neuropathologies observed in AD. Supported by grants from the National Institutes of Environmental Health Sciences (ES08089, ES10042).

# 416 BREVETOXIN-INDUCED COINCIDENT ACTIVATION OF SRC KINASE AND VOLTAGE-GATED SODIUM CHANNELS ENHANCES NMDA RECEPTOR SIGNALING IN NEOCORTICAL NEURONS.

T. F. Murray<sup>1</sup>, D. G. Baden<sup>2</sup> and S. M. Dravid<sup>1</sup>. <sup>1</sup>Physiology and Pharmacology, University of Georgia, Athens, GA and <sup>2</sup>Center for Marine Science Research, University of North Carolina at Wilmington, Wilmington, NC.

Brevetoxins (PbTx) are potent allosteric enhancers of voltage-gated sodium channel (VGSC) function and are associated with periodic Red Tide blooms. These neurotoxins produce neuronal injury and death in cerebellar granule cells (CGC) following acute exposure. In murine neocortical neurons brevetoxin induces calcium influx that is mediated through both glutamatergic and non-glutamatergic pathways. Inasmuch as Src kinase is capable of upregulating the NMDA subtype of glutamate receptors, we determined whether Src kinase participated in PbTx-2-induced calcium influx. Inhibition of Src kinase blocked PbTx-2 induced calcium influx. PbTx-2 treatment moreover increased tyrosine phosphorylation of the NR2B subunit. A rise in intracellular [Na+] and phosphorylation of NMDA receptors by Src kinase is known to increase NMDA receptor activity. We therefore explored the influence of brevetoxin on NMDA receptor function. We found that PbTx-2 augments NMDA receptor mediated calcium influx in both spontaneously oscillating mature neurons and in non-oscillatory immature neurons. PbTx-2 also enhanced the effect of bath applied NMDA on extracellular signal-regulated kinase 2 (ERK2) activation. These results suggest that brevetoxin augments NMDA receptor signaling in neocortical neurons, and this upregulation may be mediated by coincident elevation in intracellular [Na+] and Src kinase activation.

#### 417 CYCLOOXYGENASE-2-CATALYZED OXIDATION OF 6-HYDROXYDOPAMINE IN PC12 PHEOCHROMOCYTOMA CELLS. IMPLICATION FOR PARKINSON'S DESIASE.

A. A. Kapralov<sup>1</sup>, <u>Y. Y. Tyurina</u><sup>1</sup>, G. G. Borisenko<sup>1</sup>, N. F. Schor<sup>4,6</sup>, S. H. Graham<sup>5</sup> and <u>V. E. Kagan</u><sup>1,2,5</sup>. <sup>1</sup>EOH, University of Pittsburgh, Pittsburgh, PA, <sup>2</sup>Pharmacology, University of Pittsburgh, Pittsburgh, PA, <sup>3</sup>Neurology, University of Pittsburgh, Pittsburgh, PA, <sup>6</sup>Pediatrics, University of Pittsburgh, Pittsburgh, PA, <sup>6</sup>Cancer Institute, University of Pittsburgh, Pittsburgh, Pittsburgh, PA, University of Pittsburgh, Pittsburgh, PA.

Parkinson's disease is characterized by a progressive loss of dopaminergic neurons likely associated with dysregulation of dopamine oxidation pathways. It has been suggested that cyclooxygenase-2 (COX-2) is involved in pathogenesis of the disease

although specific pathways have not been identified. We hypothesized that COX-2 enhances the dopamine-induced toxicity by catalyzing its oxidation. To experimentally address the hypothesis in physiologically relevant environments, we used a dopamine analogue - 6-hydroxydopamine (6-OHDA) and COX-2-transfected PC12 pheochromocytoma cells. Using arachidonic acid as a substrate we confirmed that recombinant COX-2 increased the rate of oxidation of 6-OHDA in cell-free systems. COX-2-induced oxidation of 6-OHDA was suppressed by NS-398 (a COX-2 inhibitor) and superoxide dismutase (SOD). In cell homogenates prepared from COX-2-transfected cells, oxidation of 6-OHDA proceeded at a greater rate as compared to homogenates prepared from moc-transfected cells. Addition of NS-398 to homogenates from COX-2 transfected cells resulted in an inhibition of 6-OHDA oxidation. Next we performed cell viability experiments using Trypan blue test. Cells were incubated with 6-OHDA in the presence of SOD to avoid extracellular oxidation of 6-OHDA. Under these conditions, we found that 6-OHDA was toxic to both COX-2-transfected and moc-transfected cells in a concentration dependent manner; COX-2-transfected cells were significantly more sensitive to 6-OHDA than moc-transfected cells. These results suggest that COX-2 contributes to 6-OHDA oxidation. Consequently, inhibitors blocking COX-2-dependent component of 6-OHDA oxidation may be promising for development of new therapeutic approaches. Supported by NIH NS41297.

STRESS AND COMBINED EXPOSURE TO LOW DOSES OF PYRIDOSTIGMINE BROMIDE, DEET, AND PERMETHRIN PRODUCE NEUROCHEMICAL AND NEUROPATHOLOGICAL ALTERATIONS IN CEREBRAL CORTEX, HIPPOCAMPUS, AND CEREBELLUM.

E. M. El-Masry, A. Abdel-Rahman, S. M. Abou-Donia, A. K. Shetty and M. B. Abou-Donia. Pharmacology and Cancer Biology, Duke University Medical Center, Durham NC

Exposure to a combination of stress and low doses of pyridostigmine bromide, (PB), DEET and permethrin in adult rats, a model of Gulf war exposure, produces blood-brain barrier (BBB) disruption and neuronal cell death in the cingulated cortex, dentate gyrus, thalamus and the hypothalamus. In the present study, neuropathological alterations in other areas of the brain where no apparent BBB disruption was observed was studied following the above exposure. Animals exposed to both stress and chemicals exhibited decreased acetylcholinesterase (AChE) activity in the midbrain, brainstem and the cerebellum and a decreased m2 muscarininc ACh receptor ligand binding in the midbrain and cerebellum. These alterations were associated with significant neuronal cell death, reduced MAP-2 expression, and increased GFAP expression in the cerebral cortex, and the hippocampal subfields CA1 and CA3. In the cerebellum, the neurochemical alterations were associated with Purkinje cell loss and increased GFAP immunoreactivity in the white matter. However, animals subjected to either stress or chemicals alone did not show any of the above changes in comparison to vehicle treated controls. Collectively, these results suggest that prolonged exposure to a combination of stress and PB, DEET and permethrin can produce significant damage to the cerebral cortex, hippocampus and the cerebellum, even in the absence of apparent BBB damage. The above alterations could lead to many physiological, pharmacological, and behavioral abnormalities, particularly motor deficits and learning and memory dysfunction. Supported, in part by the US Army Medical and Materiel Command under contract project order DAMD 17-99-1-9020.

419

NEURONAL DEGENERATION AND NEUROBEHAVIORAL DEFICITS FOLLOWING DERMAL EXPOSURE WITH MALATHION, DEET, AND PERMETHRIN, ALONE AND IN COMBINATION IN RATS.

A. Abdel-Rahman, A. M. Dechkovskaia, L. B. Goldstein, S. L. Bullman, W. A. Khan, E. M. El-Masry and <u>M. B. Abou-donia</u>. *Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.* 

In the present study, the neurotoxic effects of malathion, DEET and permethrin, alone or in combination, on the sensorimototor behavior, central cholinergic system and histopathological alterations were studied in male Sprague-Dawley rats following daily dermal dose of 44.4 mg/kg malathion, 40mg/kg DEET and 0.13 mg/kg permethrin for 30 days. Neurobehavioral evaluations for sensorimotor functions included beam-walk score, beam walk time, incline plane and grip time response assessments. Twenty-four hrs after the last treatment with each chemical alone or in combination all behavioral measures were impaired. The combination of DEET and permethrin, malathion and permethrin or the three chemicals together resulted in greater impairments in inclined performance than permethrin alone. Only animals treated with a combination of DEET and and malathion, or DEET and permethrin exhibited significant increases in plasma butyryl-cholinesterase (BChE) activity. Treatment with DEET or permethrin alon,

malathion and permethrin, or DEET and permethrin produced significant increases in cortical acetylcholinesterase (AChE) activity. Combinations of malathion and permethrin or DEET and permethrin produced significant decreases in midbrain AChE activity. Animals treated with DEET alone exhibited a significant increase in cortical m2 muscarinic ACh receptor ligand binding. Quantification of neuron density in the dentate gyrus, CA1 and CA3 subfields of the hippocampus, midbrain, brainstem, and cerebellum revealed significant reduction in the density of surviving neurons with various treatments. These results suggest that exposure to real-life doses of malathion, DEET, and permethrin, alone or in combination, produce no overt signs of neurotoxicity, but induce significant neurobehavioral deficits and neuronal degeneration in brain.

420

LOCOMOTOR PERFORMANCE DEFICITS AND DIFFERENTIAL EFFECTS ON BRAIN REGIONAL ACETYLCHOLINESTERASE ACTIVITY FOLLOWING CO-EXPOSURE TO VARIOUS DOSES OF PYRIDOSTIGMINE BROMIDE WITH DEET, AND PERMETHRIN IN RATS.

A. M. Dechkovskaia, L. B. Goldstein, A. Abdel-Rahman, S. L. Bullman, W. A. Khan and M. B. Abou-Donia. *Pharmacology and Cancer Biology, Duke University Medical Center. Durham. NC.* 

Male Sprague-Dawley rats were treated with pyridostigmine bromide (PB) alone or in combination with DEET (4, 40, 400 mg/kg, dermal) and permethrin (0.013, 0.13 and 1.3 mg/kg, dermal) daily for 60 days. PB (0.13, 1.3, and 13 mg/kg, oral by gavage) was given during the last 15 days. Neurobehavioral performance was assessed on day 60 following the beginning of the treatment with DEET and permethrin. Treatment with PB alone, in combination with DEET, or in combination with DEET and permethrin resulted in deficit in beam-walk score as well as longer beam-walk times as compared with controls. PB alone, in combination with DEET, in combination with permethrin or in combination with DEET and permethrin resulted in impairments in incline plane performance and forepaw grip strength. Treatment with PB alone at all the doses resulted in a slight inhibition of plasma BChE activity, whereas combination of PB with DEET or permethrin resulted in an increase in the activity. AChE activity in brainstem showed a significant increase following treatment with a combination of either DEET or permethrin at all doses. Treatment with PB alone or in combination with DEET and permethrin at all doses resulted in an increase in ligand binding for m2 muscarinic acetylcholine receptors in the cortex. Co-exposure with PB and DEET together or a combination of PB, DEET and permethrin resulted in a significant increase in the ligand binding for nicotinic acetylcholine receptors. These results suggest that exposure to various doses of PB, alone and in combination with DEET and permethrin, leads to neurobehavioral deficits and differential alterations of the cholinergic system in the CNS. Supported, in part by the US Army Medical and Materiel Command under contract project order DAMD 17-99-1-9020.

421

DISTINCT GENE REGULATION EVENTS ACCOMPANY ENHANCED VULNERABILITY IN HIPPOCAMPUS AFTER REPEATED EXPOSURES TO LOW-LEVEL SOMAN.

E. Caba, S. F. Caskurlu, D. M. Boschetto and <u>B. A. Bahr</u>. *Pharmacology Sciences./Center of Drug Discovery, University of Connecticut, Storrs, CT.* 

The organophosphate compound soman (GD) is an irreversible anticholinesterase that produces convulsions, memory impairment, and cell loss in the brain, especially in the hippocampus. The nerve agent is also known to promote release of glutamate that can potentially lower the threshold for excitotoxic damage. Interestingly, we previously found that after repeated exposures to sub-toxic GD levels, hippocampal slice cultures from rat exhibit enhanced vulnerability to brief excitotoxic episodes of glutamate receptor over-stimulation. Here, we assessed such enhanced vulnerability with the Affymetrix neuro-specific microarray. Single daily applications of 150 nM GD were used to produce transient exposure of the slice cultures before rapid GD hydrolysis. The intentionally subtle treatment will help identify gene regulation events that may explain how asymptomatic GD contact increases vulnerability to injury. After 6 days, total RNA was isolated from 2 control and 2 treated slice groups for cDNA and biotin-labeled cRNA synthesis, which was used to inoculate the arrays. Gene induction or repression was tabulated when the change was ±50% with statistical significance confirmed by the Affymetrix software. A group of 11 genes exhibited consistent changes by GD. BDNF and heme oxygenase (HO-1) exhibited 50-60% declines in expression, which could lead to neuronal vulnerability. BDNF reduction, in fact, is one of the pathogenic changes associated with acute excitotoxicity via 20-min NMDA exposure, and neuroprotectants that increase BDNF expression offset excitotoxic damage (Bahr et al. Exp. Neurol. 174:37, 2002). Also of interest is that distinct compensatory events occur in response to the different toxic exposures. NMDA exposure leads to increases in HSP27 and HO-1, whereas these genes are reduced in the GD-slices. Low-level GD causes a 11-fold increase in IL-15, while it is reduced in the NMDA response. Perhaps compensatory pathways identified with microarrays can provide strategies with which to offset GD-induced vulnerability.

### 422 SIGNALING PATHWAYS ASSOCIATED WITH GLIOSIS CAN BE STUDIED USING A BRAIN SLICE PREPARATION

C. L. Damiani and J. P. O'Callaghan. NIOSH, Morgantown, WV.

Damage to the CNS is characterized by activation of microglia and astroglia, a phenomenon termed reactive gliosis. These cellular reactions have been implicated in both regeneration and degeneration of the CNS. Damage-induced production of cytokines and chemokines has been linked to the initiation of gliosis using several injury models, including exposure to known neurotoxicants. The Janus kinase-signal transducers and activators of transcription (JAK-STAT) pathway is a downstream effector of cytokines and activation of this pathway is associated with gliosis. In particular, the transcription factor STAT3 is critical for astroglial response to CNS damage. Here, we used brain slices from mice treated with the dopaminergic neurotoxicant, 1-methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP) to examine astroglial STAT3 activation responses. 12 hours post MPTP (12.5 mg/kg, s.c.) or saline treatment, C57Bl/6 female mice were sacrificed by decapitation and coronal slices of brain were prepared. Striatum was dissected and assayed for activated STAT-3 (Tyr705 phosphorylation). Phospho-STAT3 was present in slices from MPTP treated mice immediately following sacrifice while absent in control mice, recapitulating in vivo observations. These data suggest that activated STAT3 is preserved in brain slices. Striatal slices were then exposed to phosphate free oxygenated buffer for various times. After 45 minutes both MPTP treated and control striata expressed p-STAT3, indicating that MPTP induced phosphorylation is retained ex vivo and that STAT3 activation can also result from slice injury. Production of cytokines upstream of STAT3 was examined by RT-PCR. Messenger RNA for CNTF and IL-6 was not altered while mRNA for MCP-1 and LIF was increased. Finally we determined that AG490, a JAK inhibitor, and lavendustin A, a tyrosine kinase inhibitor, could diminish STAT3 phosphorylation in slices. These data suggest that activation of STAT3 is an early event in both toxicant and slice-induced glial activation. In addition, this investigation establishes the brain slice preparation method as a reliable model to examine reactive gliosis.

# 423 HEXANEDIONE (HD)-INDUCED CHANGES IN THE POLYMERIC AND MONOMERIC STATE OF RAT SPINAL CORD CYTOSKELETAL PROTEINS.

M. L. Reid and R. M. LoPachin. Anesthesiology, Albert Einstein College of Medicine, Bronx, NY.

Accumulating evidence now suggests that axon atrophy in PNS and CNS is the hallmark morphological feature of gamma-diketone neuropathy (e.g., Toxicology. Appl. Pharmacology 135: 58-66, 1995; 165: 127-140, 2000; in press, 2003). Adult axon caliber is maintained by interaction of the cytoskeletal polymer with a mobile pool of exchangeable NF proteins. This interaction can be studied by triton-extraction of nervous tissue followed by differential fractionation. We used this experimental approach to determine how HD intoxication affected NF subunit content in the triton-insoluble cytoskeletal polymer and the soluble monomeric fraction. Lumbar spinal cords from moderately affected HD-intoxicated rats (175 mg/kg/d x 101 days; 400 mg/kg/d x 26 days) or their age-matched controls were homogenized in triton buffer and subjected to differential centrifugation. The low-speed (15, 000g) triton-insoluble pellet (P1 or highly polymerized cytoskeleton), and the high-speed (100, 000g) triton-soluble pellet (P2, or limited NF polymer) and corresponding supernatant (S2, or triton-soluble NF monomer/oligomer) were retained for immunoblot analyses. Results show that, regardless of HD dose-rate, cytoskeletal proteins (tubulin, NF-L, -M and -H) in the P1 fraction were not significantly altered, whereas the NF subunit contents of the P2 and S2 fractions were substantially depleted. Studies with antibodies directed against phosphorylated (RT97) and nonphosphorylated (SMI32) epitopes on NF-H and measurements of corresponding subunit isoelectric point suggest that HD-induced changes in phosphorylation were not involved. These results are consistent with previous published findings regarding NF content in nervous tissue of HD-exposed rats and suggest that atrophy is related to depletion of exchangeable monomeric subunit in the S2 fraction with subsequent impairment of NF turnover. Supported by NIEHS grant ESO7912-7.

SUPRAPHYSIOLOGICAL LEVELS OF THE STRESS HORMONE CORTICOSTERONE ATTENUATE BLOOD-BRAIN BARRIER DISRUPTION AND MICROGLIAL ACTIVATION IN HIPPOCAMPUS OF C57BL/6J MICE TREATED WITH KAINIC ACID.

S. A. Benkovic, <u>J. P. O'Callaghan</u> and <u>D. B. Miller</u>. *TMBB*, *CDC-NIOSH*, *Morgantown*, *WV*.

Kainic acid intoxication in C57BL/6J mice causes neuronal damage and the activation of glial cells. Neurotoxicants can alter blood-brain barrier integrity, and the influx of blood-borne factors may contribute to the total toxicity profile. We evaluated the consequences of kainate treatment on the blood-brain barrier and microglial activation, and the ability of high levels of corticosterone to modulate pathology. Male mice were implanted with a corticosterone pellet (192 mg/kg/d) to mimic the sustained activation of the HPA axis associated with chronic stress, and allowed to recover for seven days. Control and implanted mice were injected intraperitoneally with saline or 25 mg/kg kainic acid, and sacrificed at 1, 3, 6, and 12 hours posttreatment. Kainate-induced seizures were scored at Stage 1 (Racine scale), and corticosterone pretreatment did not alter seizure activity. Analysis of hippocampal IgG levels by Western blotting revealed a kainate-induced breach of the blood-brain barrier, and subsequent influx of plasma-derived IgG by one hour, which continued to increase and achieved significant elevation at six hours posttreatment. Corticosterone pretreatment attenuated the kainate-induced influx of IgG at all time points. Immunohistochemical localization of IgG in hippocampal parenchyma paralleled blot data. Microglial activation following kainate treatment was evaluated by silver staining and revealed activated cells at one hour posttreatment. Staining with Isolectin B4 revealed numerous microglial cells throughout the hippocampal parenchyma at 12 hours posttreatment, and an attenuation in the quantity of microglia by corticosterone pretreatment. The interactions of chronic stress and chemical intoxication, and subsequent effects on neuroanatomy and physiology are complicated, and though many literature reports describe exacerbation of neurotoxicity by stress, our data suggest steroid treatment can be protective.

# 425 USE OF MAGNETIC RESONANCE IMAGING (MRI) TO EXAMINE MORPHINE-INDUCED INTRATHECAL GRANULOMAS.

T. L. Yaksh<sup>1</sup>, J. W. Allen<sup>1</sup>, R. F. Mattrey<sup>2</sup>, J. Corbeil<sup>2</sup>, K. Horais<sup>1</sup> and N. Tozier<sup>1</sup>. <sup>1</sup> Anesthesiology, University CA-San Diego, La Jolla, CA and <sup>2</sup> Radiology, University CA-San Diego, La Jolla, CA.

Continuous intrathecal (IT) delivery of morphine sulfate (MS) for 28 days can produce aseptic subdural extramedullary inflammatory masses (granulomas) localized at the catheter tip. To develop a non-invasive method of assessing the dynamics of granuloma formation and progression we investigated the use of MRI with gadolinium (Gd) enhancement. Beagle dogs were implanted with chronic intrathecal lumbar catheters and received MS infusions via vest mounted pumps for 28 days at a concentration known to produce granuloma formation (12.5 mg/ml, 0.96 ml/day). Animals were assessed for behavior and motor function twice daily. Prior to initiation of morphine infusion, baseline T1 and T2 weighted MRI scans were obtained with a Siemens Symphony 1.5 Tesla system while dogs were anesthetized with propofol. At 7-day intervals dogs underwent repeat MRI scans. If pathology was noted, additional imaging studies were conducted pre and post intravenous gadoversetamide (Optimark), 0.2 mmol/kg. On the day of the final scan, images were made pre and post IT injection of 1 ml of gadopentetate diglumine (Magnavist) 1:400 in saline prior to the intravenous Gd studies. Animals underwent necropsy within 24 hours of the final scan. Animals displaying severe side-effects prior to 28-days were sacrificed to prevent undue suffering. Repeat MRI scans with propofol anesthesia were well tolerated in dogs. There were no apparent abnormalities attributable to the MRI, propofol or Gd exposure. Serial saggittal and axial MRI imaging clearly displayed progression of a mass localized in the area of the catheter tip that was confirmed at necropsy. Intravenous Gd greatly enhanced differentiation of masses from spinal parenchyma. IT Gd displayed irregular distribution indicating probable alterations in cerebral spinal fluid flow patterns and thus morphine distribution. Physical signs were well correlated with the progression and localization of IT masses. MRI with Gd enhancement is a viable method for evaluation of intrathecal mass development on dogs. Supported in part by DA-15353.

### 426 MOLECULAR ACTIONS OF ACRYLAMIDE (ACR) AT THE NERVE TERMINAL.

R. M. LoPachin¹ and D. S. Barber². ¹Anesthesiology, Albert Einstein College of Medicine, Bronx, NY and ²CEHT, University of Florida, Gainsville, FL.

We have provided evidence that nerve terminals in the CNS and PNS are primary sites of ACR action and that compromise of neurotransmission might mediate neurotoxicity (Neurotoxicology 23: 43-59, 2003; Toxicology. Appl. Pharmacology

188: 135-153, 2003). To investigate molecular mechanisms, we used GC-mass spectroscopy to measure levels of the ACR-cysteine adduct, S-carboxyethylcysteine (SEC), in isolated brain synaptosomes exposed to ACR (1mM – 1 M x 60 mins incubation). Previous in vitro studies showed that this concentration range produced graded inhibition of synaptosomal neurotransmitter release that was correlated to a reduction in free sulfhydryl groups (Neurotoxicology, in press, 2003). Results of the present study show that *in vitro* ACR exposure produced concentration-dependent increases in SEC (range  $0.10 \pm 0.03 - 5.6 \pm 1.2$  ng CEC/µg synaptosomal protein), which suggests that ACR impaired transmission by adduction of functionally important cysteine groups on nerve terminal proteins. To identify putative targets, we exposed synaptosomes to  $^{14}$ C-ACR (7  $\mu$ Ci) and then separated proteins by 2-D gel electrophoresis. Labeled proteins were detected by phosphoimaging and subsequently identified by overlay immunoblot analysis. Results show that ACR adducted numerous presynaptic proteins including N-ethylmaleimide sensitive factor (NSF) and SNAP-25, but not synaptobrevin. Inhibition of NSF activity by sulfhydryl alkylation has been shown to impair neurotransmission by preventing disassembly of the 7S SNARE complex. In our studies, in vitro exposure of synaptosomes to ACR (175-700 mM) significantly increased 7S complex levels as determined by immunoblot analysis (mean fold increases =  $1.8 \pm 0.22 - 5.5 \pm 0.81$ ). These results are consistent with the possibility that ACR disrupts neurotransmission by adducting sulfhydryl groups on cysteine residues of presynaptic proteins such as NSF or SNAP-25 which inhibits corresponding function. Supported by NIEHS grant ESO3830-17.

### 427 DEGRANULATION OF DURAL MAST CELLS BY *IN VIVO* AND *EX VIVO* OPIATE EXPOSURE.

<u>J. W. Allen</u>, W. Zielinska, D. Cizkova and <u>T. L. Yaksh</u>. Anesthesiology, University CA-San Diego, La Jolla, CA.

Opiates produce degranulation of some, but not all populations of mast cells (e.g. cutaneous vs mucosal). Recent work showing that continuous intrathecal delivery of high concentration morphine sulfate (MS) leads to inflammatory mass (granuloma) formation localized at the catheter tip in humans and animals led us to focus on the effects of opiates on dural mast cells. We examined dural mast cell degranulation following MS exposure in vivo and ex vivo. For in vivo studies, beagle dogs were implanted with chronic intrathecal lumbar catheters and received MS infusions for 28 days at a granuloma inducing concentration (12.5 mg/ml, 0.96 ml/day). At necropsy dura was harvested from lumbar and cervical regions and stained for biogenic amines with acidic Alcian blue (pH 1.4). For ex vivo studies dura was harvested from opiate naive dogs. Dura was stripped of pia-arachnoid and dissected into 10 mg sections. Sections were incubated in Kreb's-bicarbonate (95%:5% O2:CO2) for 30 minutes in duplicate. The ability of MS or hydromorphone to induce histamine release was examined using Compound 48/80 (0.1 mg/ml) as a positive control. Histamine release was quantified by EIA. Dura samples were then stained with acidic Alcian blue to examine degranulation. In vivo, intrathecal infusions of MS produced degranulation of mast cells in the lumbar, but not cervical regions in dogs receiving 12.5 mg/ml MS. *Ex vivo*, MS (0.1 mM, approximating concentrations in dog CSF following 12.5 mg/ml infusion) more than doubled histamine release over control treatment. This represented over half of the 48/80 sensitive histamine pool. Hydromorphone (0.01 and 0.1 mM) produced an increase of approximately 75% in histamine release. Ex vivo histochemistry displayed mast cell degranulation following MS and hydromorphone incubation. These data suggest opiates produce degranulation of dural mast cells both in vivo and ex vivo. Dural mast cells may be involved in formation of granulomas due to chronic intrathecal opiate infusions and may represent a target for therapeutic intervention to prevent granuloma formation. Supported by DA-15353

## DYSREGULATION OF DOPAMINE HOMEOSTASIS AND OXIDATIVE STRESS IN PCB-EXPOSED NEURONAL CELLS.

D. W. Lee and L. A. Opanashuk. Department of Environmental Medicine, University of Rochester SMD, Rochester, NY.

PCB exposure has been associated with neurological and cognitive impairments. These adverse health effects are thought to arise from disrupted neurotransmission. Previous studies have demonstrated that PCBs can impair dopaminergic (DAergic) systems by inhibiting DA uptake into synaptic vesicles and DA reuptake into presynaptic terminals. This study tests the hypothesis that subtoxic PCB concentrations alter DA homeostasis, increase oxidative stress, and render DAergic neurons vulnerable to subsequent insult. The direct toxicity of PCB treatment was evaluated in MN9D cells, a mesencephalic-derived DAergic cell line. Cultures were exposed to 0-20ppm Aroclor 1254 for 3-48h then assayed for cell viability by measuring LDH release and WST-1 response. Cell viability did not differ significantly between control and treated cells except in response to 20ppm, where approximately 60% cells survived. Additional experiments analyzed whether PCB treatment modulates DA

levels, which could lead to reactive oxygen species (ROS) production and subsequent activation of antioxidant defense systems. Neurochemical studies demonstrated that subtoxic PCB treatments produced a concentration-dependent reduction in intracellular DA levels, which were accompanied by an increase in DA turnover. Furthermore, PCB treatment induced a time- and concentration-dependent elevation in ROS production, as detected by increased dichlorofluorescein staining. Immunoblot analyses revealed that PCB-induced ROS production were accompanied by coincident alterations in antioxidant defense enzyme expression. While MnSOD protein levels exhibited a concentration-dependent decrease with PCB treatment, CuZnSOD protein levels remained unchanged. Additionally, the upregulation of heme oxygenase-1 levels provides supporting evidence that PCBs stimulate an oxidative stress response in dopamine neurons. Although the intracellular source of ROS remains unknown, these results suggest that PCBs activate an oxidative stress-related pathway potentially by disrupting DAergic neuron function. Supported by NIH ES00375 and ES01247.

# OVEREXPRESSION OF BCL-XL ALTERS THE SUSCEPTIBILITY OF PRIMARY RAT ASTROCYTES TO 1, 3-DINITROBENZENE.

A. D. Phelka, M. M. Sadoff, B. P. Martin and M. A. Philbert. Environmental Health Sciences, University of Michigan, Ann Arbor, MI.

Exposure to 1, 3-dinitrobenzene (DNB) produces an edematous, glio-vascular lesion that is initially confined to brainstem nuclei with high energy requirements. Selective vulnerability of brainstem astrocytes to DNB is mediated by a ten-fold lower threshold for opening of the mitochondrial permeability transition pore (mtPTP). Concentrations of 100 µM DNB induce complete loss of mitochondrial membrane potential by 10 min in brainstem astrocytes. Cortical astrocytes remain unaffected by 100  $\mu M$  DNB for at least 1 hour. The BCL family of proteins is known to modulate the open probability state of the mtPTP. It is hypothesized that the balance in expression of BCL-2 agonist and antagonist proteins dictates regional astrocytic susceptibility to DNB. Western blot analyses demonstrate that *in* vivo exposure to 30 or 50 mg/kg 1, 3-DNB does not significantly alter the constitutive expression of BCL-XL, BAX, or BCL-2 in either the brainstem (sensitive region) or cortex (non-sensitive region) of F344 rats or C57/Bl6 mice relative to that observed in the vehicle control (DMSO) animals. In vivo exposure to DNB also fails to induce subcellular translocation of BAX or BCL-XL from the cytosol to the mitochondria, where the proteins are known to interact with one another and the mtPTP. However, overexpression of BCL-XL in primary rat astrocytes significantly reduces DNB-induced loss in cell viability when evaluated by an MTT assay following a 24-hour exposure up to 1 mM DNB. Therefore, while DNB exposure alone is not sufficient to alter the ratio of death promoting to death repressing members of the BCL-2 family, genetic manipulation of this ratio alters the susceptibility of sensitive astrocytes to DNB. Supported by R01 ES08846.

### 430 1, 3-DINITROBENZENE INHIBITS THE PYRUVATE DEHYDROGENASE COMPLEX.

J. A. Miller and <u>M. A. Philbert</u>. Environmental Health Sciences, University of Michigan, Ann Arbor, MI.

Prolonged or repeated exposure to 1, 3-Dinitrobenzene (DNB) produces topographically comparable lesions to those observed in various pathological conditions of energy deprivation including thiamine deficiency, exposure to misonidazole, metronidazole, and inborn errors of metabolism. A key enzyme complex involved in energy metabolism, pyruvate dehydrogenase complex (PDC), acts as the central gateway between glycolysis and the more efficient energy-producing pathway, TCA cycle, through production of acetyl-CoA. A disturbance in PDC activity compromises the brains ability to maintain sufficient ATP levels needed for proper cerebral function. The present study investigated the potential inhibitory effects of DNB on PDC. Purified porcine heart PDC was used to determine the effect of DNB on activity. Kinetic analysis of NADH absorbance showed a rapid dose-dependent inhibition of PDC by DNB (31.25uM-1mM). Approximately 45% inhibition of activity occurred at the lowest dose and greater then 90% inhibition was observed at the highest dose. Inhibition of activity was isomer specific. The para isomer of DNB did not inhibit PDC activity significantly at 250, or 500uM. Consistent with the kinetic analysis, Acetyl-CoA production was also inhibited in a dose-dependent manner by DNB as revealed by HPLC analysis. C6 Gliomas were used to investigate DNB toxicity as a function of energy metabolite levels. Cell morphology, LDH release and lactate production were used as indices of cell damage. Treatment of C6 gliomas with 1mM DNB resulted in cytoplasmic swelling, extensive vacuolation, increased LDH release and nearly a 45% increase in lactate production, relative to controls. Co-treatment with 5mM acetoacetate, which is converted to acetyl-CoA, diminished lactate production by approx. 20% and resulted in complete inhibition of LDH release compared to DNB alone. Morphologically, no swelling or vacuolation was observed in acetoacetate protected cells. The results suggest a potential role for PDC inhibition in the mechanism of DNB induced energy deprivation. Supported by RO1-ES088446.

## 431 N, N-DIETHYLDITHIOCARBAMATE PRODUCES COPPER ACCUMULATION, LIPID PEROXIDATION AND DEMYELINATION IN PERIPHERAL NERVE.

W. Valentine<sup>1</sup>, E. G. Tonkin<sup>1</sup>, H. L. Valentine<sup>1</sup>, D. M. Milatovic<sup>2</sup>, K. Amarnath<sup>1</sup> and V. Amarnath<sup>1</sup>. <sup>1</sup>Pathology and Center in Molecular Toxicology, Vanderbilt University Medical Center, Nashville, TN and <sup>2</sup>Pathology, University of Washington, Seattle, WA.

Human exposure to dithiocarbamates occurs from their many uses in agriculture, industry and medicine. Previous studies have demonstrated the ability of the dithiocarbamate disulfiram to produce a peripheral neuropathy in humans and experimental animals and have provided evidence that N, N-diethyldithiocarbamate (DEDC) is a proximate toxic species of disulfiram. The ability of DEDC to elevate copper levels in the brain suggests that it may also elevate levels of copper in peripheral nerve possibly leading to oxidative stress and lipid peroxidation from redox cycling of copper. The study presented here investigates the potential of DEDC to promote copper accumulation and lipid peroxidation in peripheral nerve. Rats were administered either DEDC or buffered saline by ip osmotic pumps and fed a normal diet or diet containing elevated copper and the levels of metals, F2 isoprostanes and severity of lesions in peripheral nerve and brain assessed by ICP/MS, GC/MS and light microscopy. Copper was the only metal that demonstrated significant elevations relative to controls; and elevations occurred in both brain and peripheral nerve in animals administered DEDC on both diets. In contrast, demyelination and elevated F2 isoprostanes were significantly increased only in the peripheral nerve samples of rats administered DEDC on both diets. Elevated levels of serum homocysteine were also observed in the DEDC animals on both diets. Autometallography staining of peripheral nerve was consistent with increased metal content along the myelin sheath but in brain, focal densities were observed. These data suggest that DEDC chelates copper to form a lipid soluble complex that then accumulates in peripheral myelin and undergoes redox cycling leading to lipid peroxidation and segmental demyelination. # ANATOMICAL AND PHYSIOLOGICAL ASPECTS AND ROUTINE AND SPECIFIC EXAMINATIONS OF MINIPIG EYE AS EXPERIMENTAL MODEL IN NON-CLINICAL SAFETY STUDIES. O. LOGET, F. HOFFMANN-LA ROCHE LTD, BASLE, SWITZERLAND.

O. M. Loget. *PRBN-S, F.Hoffmann-La Roche, Basel, Switzerland.* Sponsor: <u>M. Stephan-Gueldner</u>.

Non-clinical toxicology studies for a new drug are required before EIH (Entry Into Hunan). One of the most important points to consider is the choice of the non-rodent species which should have a metabolic assimilation of the drug under investigation as close as possible to that of Human. For several substances the minipig, which is omnivorous like man and is equipped with similar enzyme systems meets this need. Several minipig organs have also similarities with those of Human. This species is therefore being used more and more as experimental model in non-clinical safety studies in order to replace or to complement the dog or monkey. Notably aspects of the minipig eye, show a number of anatomical and physiological similarities with the human eye. The minipig is therefore considered to be a good experimental model for the assessment of adverse ocular effects. We describe the normal minipig ocular pattern, as well as some ocular findings, in order to define the main variants of the minipig eye. The results of some routine and specific ocular examinations performed in 372 minipigs are also presented. These data are helpful to differentiate between treatment-related and spontaneous findings which may be observed in non-clinical safety studies.

## 433 COMPARISON OF INTERACTIVE CYTOTOXIC EFFECTS OF SELECTED MYCOTOXINS ON RENAL CELLS.

A. H. Heussner, E. O'Brien, J. Haehnlein, M. A. Biester and <u>D. R. Dietrich.</u> Environmental Toxicology, University of Konstanz, Konstanz, Germany.

Of the about 300 mycotoxins identified to date, approximately 30 are found regularly in foodstuffs and animal feed, often in combination. Particularly ochratoxins and citrinin have already been shown to be responsible for porcine nephropathies and are suspected to play a role in the genesis of human urinary tract tumors and BEN (Balkan Endemic Nephropathy). Various animal studies have indicated interactive renal responses to certain mycotoxins. To date *in vitro* data is controversial. In the present study, the mycotoxins citrinin, patulin, ochratoxin A (OTA) and ochra-

toxin B (OTB) were investigated. Porcine (LLC-PK1) and human (IHKE) renal cell lines were used as models and the MTT reduction assay after 48 hours of exposure served as cytotoxicity endpoint. After various range-finding assays, concentration-response curves were generated for each individual toxin. Based on these data, binary mixtures were then tested. Comparison of predicted (additive) and tested mixture effects resulted in higher toxicity of citrinin and patulin in combination with OTA or OTB in LLC-PK1 cells, whereas IHKE cells showed higher than predicted effects only with combinations of citrinin with ochratoxins, predominantely with OTB. Hence, our results support the hypothesis of a superadditive or synergistic mode of action of these mycotoxins in renal cells.

# DETECTION OF ORGANIC ANION TRANSPORTERS (OAT) IN HUMAN KIDNEY HOMOGENATE AND PRIMARY HUMAN KIDNEY CELLS (HKC).

R. Blum, E. O'Brien, A. H. Heussner and D. R. Dietrich. Environmental Toxicology, University of Konstanz, Konstanz, Germany.

Ochratoxin A (OTA), a secondary metabolite of several mould species, is associated with kidney carcinomas in male mice, in rats of both sexes and with nephropathies in pigs, as well as with the human disease, Balkan endemic nephropathy (BEN). The mechanism underlying OTA's toxicity is still unknown. One plausible explanation for the renal specificity of OTA could be accumulation in proximal tubular cells during the course of excretion (transport and/or reabsorption) thereby reaching toxic concentrations within the cells. This study aimed to detect organic anion transporter (OAT1, OAT2, OAT3) proteins in rat renal cortex homogenate, human renal biopsy samples, and primary human kidney cells (HKC). All three transporter isoforms could be detected in human renal cortical tissue via RT-PCR. No signal was detected in HKC (P1, P2). Anti-rat Oat1 antibodies detected both rat (Oat) and human (OAT) in Western blots of cortex homogenates. Anti-Oat2 showed no detection in either rat or human homogenates, while anti-Oat3 showed strong detection in human homogenate. A weaker signal was obtained using the specific anti-human antibody, anti-OAT3. The results show the presence of organic anion transporter proteins in human kidney. Expression of these transporters is, however, lost during passaging of HKC.

### USE OF AN *IN VITRO* HUMAN RENAL CORTICAL CELL MODEL FOR TOXICITY AND TRANSPORT STUDIES.

N. S. Jensen, R. Challmes, L. A. Hyde and <u>P. M. Silber</u>. *In Vitro Technologies, Baltimore, MD*.

Different in vitro models for assessing renal toxicity have been developed and used with variable success. However, renal toxicity can be due to a variety of mechanisms including the ability of the cell to transport and concentrate xenobiotics. We describe the evaluation of cryopreserved human renal cortical cells (HRCC) as a model to determine both transport and cytotoxicity. For toxicity studies three lots of HRCC were thawed and plated on collagen coated 96-well plates and grown to ~80% confluence. Cells were dosed for 48 hours with 0-50 μM cisplatin or transplatin in serum-free medium. MTT was used as an endpoint for toxicity. Organic anion and cation uptake assays were performed on HRCC monolayers that had been 100% confluent for 3 days. [<sup>3</sup>H]p-aminohippuric acid (PAH, 5 µM) was the substrate for organic anion transporter (OAT), while [<sup>3</sup>H]MPP+ (0.1 µM) and [14C]Tetraethylammonium bromide (TEA, 5 μM) were used for organic cation transporter (OCT) assays. Uptake assay incubations were performed by adding substrates to the HRCC monolayers and incubating for 15 minutes in a humidified 37°C, 5% CO<sub>2</sub> incubator. Following incubations, monolayers were washed with buffer, lysed, and radioactivity of samples was measured by liquid scintillation. HRCC toxicity results indicated that incubation with cisplatin, a compound known to have renal toxicity, resulted in a dose dependent decline in viability of >40%, while transplatin showed no loss in *via*bility at up to 40 µM. However, at 50  $\mu M$  cisplatin or transplatin, all cells demonstrated 40-60% loss in  $\emph{via}\mbox{bility}.$  All substrates were successfully transported by HRCC. In addition, inhibitors were added to the different uptake assays to demonstrate that transport could be blocked. Bromosulfophthalein (1 mM) inhibited uptake of PAH by 63.4±21.1%, pseudocyanine iodide (0.1 mM) inhibited MPP<sup>+</sup> uptake by 77.9±3.86%, and procainamide (1 mM) inhibited TEA uptake by 72.5±6.10%. These results indicate that HRCC can serve as a useful model for evaluating various activities that can be associated with renal cytotoxicity.

# TRANSPORT OF MERCURIC CONJUGATES OF HOMOCYSTEINE BY THE AMINO ACID TRANSPORTER, SYSTEM B<sup>0, +</sup>.

C. C. Bridges and <u>R. K. Zalups</u>. Basic Medical Sciences, Mercer University School of Medicine, Macon, GA.

The kidneys, specifically the epithelial cells lining the proximal tubule, are the primary targets where mercuric ions accumulate and exert their toxic effects. Our laboratory has shown recently that mercuric-conjugates of cysteine (Cys), primarily 2-Amino-3-(2-amino-2-carboxy-ethylsulfanylmercuricsulfanyl)-propionic acid

(Cys-S-Hg-S-Cys), are substrates for the luminal, Na+-independent amino acid transporter, system b<sup>0,+</sup>. Homocysteine (hCys), which binds readily to inorganic mercury, is a homolog of Cys that is also present in blood at low micromolar concentrations. Because of structural similarities between Cys and hCys, we hypothesized that mercuric conjugates of hCys, primarily as 2-Amino-4-(3-amino-3-carboxy-propylsulfanylmercuricsulfanyl)-butyric acid (hCys-S-Hg-S-hCys), are taken up by the same system that mediates the uptake of Cys-S-Hg-S-Cys, i.e. system b<sup>0,+</sup>. To test this hypothesis, we analyzed the saturation kinetics, time-dependence, temperature-dependence, and substrate-specificity of the transport of hCys-S-Hg-S-hCys in Madin Darby Canine Kidney (MDCK) II cells stably transfected with system b<sup>0,+</sup>. These data show that hCys-S-Hg-S-hCys is transported across the luminal plasma membrane of renal epithelial cells by the amino acid transporter, system b<sup>0,+</sup>. Furthermore, our data indicate that this transporter likely plays a role in the nephropathy induced following exposure to inorganic forms of mercury. Our data are the first to implicate a specific membrane transporter (present in the luminal plasma membrane of proximal tubular cells) in the transport and toxicity of mercuric conjugates of homocysteine.

## 437 CADMIUM DECREASES MNRA OF MOUSE KIDNEY SODIUM-GLUCOSE COTRANSPORTER 1 (SGLT1) *IN VITRO*.

N. Tabatabai<sup>1</sup>, S. S. Blumenthal<sup>2</sup>, K. Dolan<sup>2</sup> and D. H. Petering<sup>1</sup>. <sup>1</sup>Chemistry, University of Wisconsin-Milwuakee, Milwaukee, WI and <sup>2</sup>Nephrology, VA Medical Center, Milwaukee, WI. Sponsor: J. Eells.

Chronic exposure to cadmium results in glucose malabsorption by kidney. We had shown that exposure of primary cultures of mouse kidney cortical cells to micromolar concentrations of cadmium results in a decrease in uptake of the glucose analogue, a-methylglucopyranoside (AMG). Semiquantitative analysis of sodium-glucose cotransporter 1(SGLT1) mRNA demonstrated that cadmium decreased levels of SGLT1, one of four sodium-glucose cotransporters in the mouse kidney. To investigate the mechanism of cadmium-induced repression of SGLT1, quantitative PCR was performed. Kidneys of mice were removed, cortical cells were cultured, and 5, 7.5, and 10 microM cadmium was added to nearly confluent cultures. Cells grown in media alone were used as controls. After 24 hours, uptake of AMG (0.1 mM) was measured and total RNA was prepared. For quantification of SGLT1 mRNA, RT-PCR was performed with cellular RNA and appropriate dilutions of SGLT1 mimic RNA. Intensities of PCR products were measured and number of SGLT1 mRNA molecules was calculated. Also, to determine the effect of cadmium on stability of SGLT1 mRNA, control and cells exposed to 7.5 microM cadmium were treated with transcription inhibitor Actinomycin D (10 microg/ml) and degradation of SGLT1 mRNA was monitored by RT-PCR. Results show that cells exposed to 5, 7.5, and 10 microM cadmium expressed 57%, 46%, and 28% of control cell SGLT1 mRNA molecules, respectively. We also found that cadmium had no effect on stability of SGLT1 mRNA. In addition, AMG uptake by cadmium treated cells were measured to be 57%, 36%, and 25% of untreated cells. AMG uptake was highly correlated with corresponding number of molecules of SGLT1 mRNA (P< 0.001, R2 = 0.713). These findings suggest that the observed decline in the uptake of AMG by cultured kidney cells in response to cadmium is due to a decrease in the mRNA molecules of SGLT1. Since cadmium did not affect the stability of SGLT1 mRNA, this metal can either directly or indirectly modulate the transcription of SGLT1.

### 438 CADMIUM PORCINE K

CADMIUM DECREASES GLUCOSE UPTAKE IN PORCINE KIDNEY CELLS POSSIBLY BY ALTERING SODIUM-DEPENDENT GLUCOSE TRANSPORTER EXPRESSION.

#### J. R. Pennell and <u>A. R. Villalobos</u>. *University of Rochester, Rochester, NY.*

In humans, chronic exposure to cadmium (Cd) causes several renal abnormalities, such as proteinuria and glycosuria. Animal studies suggest that Cd-induced glycosuria involves a defect in glucose reabsorption by the renal proximal tubule (RPT) and moreover, that the attenuation of glucose reabsorption may be due to decreased levels of sodium-dependent glucose transporters (SGLTs). The goal of this study is to elucidate the mechanism by which Cd decreases SGLT levels, using LLC-PK1 cells, a model for porcine RPT. Cells were treated with 3.5 μM CdCl2 (no FBS) for 24 hrs and various endpoints were examined. Carrier-mediated uptake of α-methyl glucoside (AMG), a non-metabolizable analogue of glucose, was assayed by radio-tracer technique. Total SGLT protein was measured by western blot analysis. mRNA levels of two SGLT isoforms, SGLT1 and pig SGLT3, were determined by RT-PCR. Cytotoxicity was evaluated by trypan blue exclusion and LDH release, and cell *viab*ility was based on WST-1 conversion. Cd did not induce cytotoxicity or adversely affect cell *viab*ility. Kinetics analysis of AMG uptake showed that Cd decreased V<sub>max</sub> by 59% (4.2 vs. 1.7 nmoles/mg<sup>-1</sup>min<sup>-1</sup>; n=2); immunoblot analysis indicated a 50% decrease in total SGLT protein. These observations suggest a pos-

sible loss of active SGLTs in the apical membrane. Interestingly,  $K_{\rm m}$  decreased by 51% (769 vs. 381  $\mu$ M; n=2). Pig SGLT3 mRNA levels decreased by 50%, which is consistent with the observed decrease in V $_{\rm max}$  and SGLT protein (n=2). However, SGLT1 mRNA levels increased by 40% (n=2). Since SGLT1 has a relatively high affinity for AMG, the decrease in  $K_{\rm m}$  may be a subsequent result of the observed increase in SGLT1 mRNA. Collectively, these data suggest that Cd may decrease glucose reabsorption by reducing SGLT expression. Still, the exact molecular mechanism(s) by which Cd modulates SGLT mRNA levels is uncertain. Further investigation will determine whether Cd alters message levels via dysregulation of PKA and PKC signaling. NIEHS-T32-ES07026; NIEHS-P30-ES01247; NIEHS-ES10439; NINDS-NS39452.

### 439 A HUMAN RENAL EPITHELIAL CULTURE MODEL FOR *IN VITRO* NEPHROTOXICITY STUDIES.

M. J. Powers and S. Damian. *Cambrex BioScience, Walkersville, MD.* Sponsor: <u>S.</u> Tannenbaum.

We have developed a cell culture model to re-create human renal tubular function in an in vitro environment. Primary epithelial cells were isolated from human renal cortices and seeded on extracellular-matrix-coated Transwell® membranes, which allow for bi-compartmental (apical and basal) exposure to culture medium. Isolation and culture parameters (e.g., culture medium, matrix coating protocols, cell seeding density) have been optimized for the development of a functional renal tubular epithelial monolayer as assessed through tubule-specific markers. The apical brush border enzyme γ-glutamyl transpeptidase (γ-GTP), specific to proximal tubule epithelium, is consistently and stably expressed in these cultures through 14 days after seeding. Apical concentrations of  $\gamma$ -GTP are typically between 10 and 20 times higher than basal concentrations (p<0.01, Student's t-test), demonstrating the presence both of physiologically accurate polarity and of epithelial barrier properties in the culture model. Consistent ammoniagenesis, critical in renal acid-base homeostasis, is confirmed through at least 14 days in culture. Uptake of rhodamine-123 from the basal chamber is greater than twofold higher than uptake from the apical chamber (p<0.05, Student's t-test), illustrating that an active directional organic ion transport mechanism is present. This culture model therefore provides a polarized, functional renal tubular epithelium in an in vitro environment. In conjunction with specific functional assays such as those described here, the system provides a physiologically relevant platform technology through which the human kidney's response to nephrotoxins and other xenobiotics can be probed for all phases of renal ADME/Toxicology.

ESTROGEN THROUGH ESTROGEN-RECEPTOR INDEPENDENT PATHWAY INDUCES PROLIFERATION OF HUMAN KIDNEY EPITHELIAL CELLS.

K. P. Singh and D. Roy. Environmental Health Sciences, University of Alabama at Birmingham, Birmingham, AL.

Kidney is a target organ of estrogen-induced cancer in animal model. However, the role of estrogen in human renal cell proliferation and carcinogenesis is not clear. In this study, we have examined the influence of 17-b estradiol and diethylstilbestrol (DES) on human embryonic kidney cells, HEK-293, and adult kidney cells, HK-2 of epithelial origin. Cells were treated with six different concentrations (1pg-100 ng/ml) of DES or 17 b-estradiol, and cell growth was measured at 24, 48, and 72 h periods. Both, E2 and DES treatment resulted in significant (p<0.05) stimulation of cell proliferation of embryonic kidney epithelial cells. Co-treatment of HEK-293 cells with E2 and Tamoxifen, an estrogen antagonist, did not inhibit the E2 induced cell growth. Analysis of expression of ERa and ERb by RT-PCR in untreated control as well as in E2-treated HEK-293 cells revealed that the transcripts of these two estrogen-receptors were not detectable. Transcripts of S phase- specific cell proliferation marker Ki-67 and G1-S phase -specific cyclinD1 were increased in E2 treated HEK-293 cells as compared to the untreated control. Based on these data, we conclude that (1) estrogens are mitogenic in human kidney epithelial cells, (2) E2 is more mitogenic in embryonic kidney cells than in adult kidney cells, and (3) estrogen-induced growth in human kidney epithelial cells are mediated by estrogen receptor- independent pathway.

MODULATION OF RENAL GLOMERULAR MESANGIAL AND PODOCYTE CELL NUMBERS CORRELATES WITH FIBRONECTIN ACCUMULATION IN BENZO(A)PYRENE-TREATED SPRAGUE-DAWLEY RATS.

A. Nanez<sup>1, 2</sup> and K. S. Ramos<sup>1, 2</sup>. <sup>1</sup>Center for Genetics and Molecular Medicne, University of Louisville, Louisville, KY and <sup>2</sup>Biochemistry and Molecular Biology, University of Louisville, Louisville, KY.

This laboratory has shown that repeated, weekly exposure of adult Sprague-Dawley rats to benzo(a)pyrene (BaP) (10 mg/kg i.p.) for up to 16 weeks results in loss of renal function, as evidenced by increases in total urinary protein, protein/creatinine

ratios, urinary albumin, structural deficits associated with activation of glomerular mesangial cells, disruption of podocyte foot processes and glomerular hypercellularity. At the cellular level, BaP selectively injures mesangial cells to allow expansion of the podocyte population. The present studies were conducted to determine if changes in glomerular cell numbers in vivo correlate with alterations in extracellular matrix fibronectin deposition. Immunohistochemical markers of cellular identity examined included Wilms' tumor suppressor protein (Wt1) for podocytes, Thy1 for mesangial cells, CD68 for macrophages, CD3 for T cells, and Factor VIII related antigen for endothelial cells. Thy1 expression and fibronectin accumulation were reduced by approximately 20% after 8 weeks BaP treatment. These reductions were transient, as significant increases in both Thy1 and fibronectin immunoreactivity were observed by 16 weeks. Changes in mesangial cell numbers correlated inversely with podocyte numbers at both 8 and 16 weeks, suggesting that BaP influences mechanisms involved in reciprocal control of glomerular cell densities. In contrast, CD68, CD3, and Factor VIII related antigen expression was not altered by BaP exposure. These data suggest that the glomerular hypercellularity induced by BaP involves non-inflammatory mechanisms that are regulated by cell:cell and cell:matrix interactions within the adult rat kidney. (Supported by NIH grants ES04917, ES09106, and CA90301).

### PYRUVATE ATTENUATION OF P-AMINOPHENOL (PAP) TOXICITY IN RENAL SLICES FROM FISCHER 344 (F344) RATS

M. Valentovic and R. Harmon. Pharmacology, Marshall University School of Medicine, Huntington, WV.

The acetaminophen metabolite, PAP is a known nephrotoxicant. The purpose of this study was to investigate the effect of pyruvate on PAP in vitro nephrotoxicity. Renal cortical slices were isolated from F344 rats and washed at 25 degrees Celsis in Krebs buffer. Slices were then incubated with 0 to 0.5 mM PAP for up to 120 min and constant oxygen. Renal slices exposed to 0.1 mM PAP showed toxicity as measured by increased lactate dehydrogenase (LDH) leakage and decreased pyruvatestimulated gluconeogenesis. PAP decreased (p<0.05) both total glutathione (GSH) and glutathione disulfide (GSSG) within 30 min when compared to vehicle controls. Co-incubation with pyruvate (PYR) protected against PAP-induced time and concentration dependent effects on LDH leakage. PYR also reduced PAP effects on GSH and GSSG. Adenine nucleotides were reduced relative to control values within a 30 min exposure to 0.25 and 0.50 mM PAP. Co-incubation with PYR also completely protected renal slices from PAP induced changes in ATP and ADP. PYR also reduced the effects of PAP on 4-hydroxynoneal adduct formation. PYR pretreatment protected renal slices from PAP associated depletion of NADPH. Pretreatment with another energy substrate (5.55 mM glucose) did not provide protection similar to PYR. These data show that PYR protects against PAP in vitro toxicity in renal slices and that PYR protection is mediated by preventing PAP induced oxidative stress.

## PENTAMIDINE-INDUCED INJURY IN LLC-PK1 CELLS IS NOT MEDIATED BY NMDA RECEPTOR ANTAGONISM.

A. L. Piskac and M. A. Smith. Environmental Sciences / Toxicology, University of Texas School of Public Health, Houston, TX.

The aromatic diamidine, pentamidine, is an antimicrobial drug used in the treatment of Pneumocystis carinii pneumonia (PCP) in HIV patients, leishmaniasis, and African trypanosomiasis. The dose-limiting nephrotoxicity restricts the clinical utility of pentamidine. Pentamidine-induced renal injury is targeted to the proximal tubule. Pentamidine is a known antagonist of the N-methyl-D-aspartate (NMDA) receptor, a subgroup of glutamate receptors. NMDA receptor subunits are predominantly expressed in the renal proximal tubule in comparison to the distal tubule. To determine whether the NMDA receptor is involved in pentamidineinduced in vitro cytotoxicity, LLC-PK1 cells (a proximal tubule cell line) were treated with pentamidine at concentrations of 1mM, .5 mM, and .1 mM, as well as 200 uM of D-AP-5, an NMDA receptor competitive antagonist, and 10 uM of MK-801 (dizocilpine), an NMDA channel blocker, or non-competitive antagonist, over a 24-hour period. Cytotoxicity was evaluated morphologically and by LDH leakage. For all time points, control, D-AP-5, and MK-801-treated cells maintained normal morphology, with no evidence of cellular damage or toxicity. Pentamidine induced time and dose-dependent morphological changes associated with apoptosis. The earliest apoptotic changes were observed at the highest concentration at 2 hours. Initial morphologic changes for cells treated with the intermediate concentration of pentamidine were seen at 6 hours. Early apoptotic changes for the lowest concentration of pentamidine were noted at 16 hours after treatment. LDH leakage following treatment with D-AP-5 and MK-801 were comparable to control for all time points. Pentamidine induced a time- and concentration-dependent increase in LDH leakage. The LDH leakage appears to be attributed to secondary necrotic changes following apoptosis. Pentamidine toxicity does not appear to be mediated through the NMDA receptor, as D-AP-5 and MK-801 did not induce morphological changes and toxicity in LLC-PK1 cells.

# ASSESSMENT OF THE MODULATION OF RENAL ANTIOXIDANT DEFENSE MECHANISMS AND CYCLOOXYGENASES BY COMMON RODENT DIETS IN MALE SPRAGUE-DAWLEY RATS.

S. Cooper, B. Blaydes, F. Xin and B. Delclos. NCTR, Jefferson, AR.

Both specific components of the diet and total calorie intake are known to affect responses to toxins. In recent years, considerable attention has been directed to the possible effect of soy-containing diets with variable phytoestrogen levels on the response to estrogenic agents, but often the possible effect of the base diet used in toxicity studies on the measured response is given little consideration. We had previously found that the renal toxicity of nonylphenol appeared to be enhanced when fed to rats in the soy- and alfalfa-free 5K96 diet (Latendresse et al., Toxicol. Sciences. 62: 140, 2001) and that the base diet affected the observed fluctuation of renal cyclooxygenase-2 during the estrous cycle of female rats (Blaydes et al., Toxicologist 72: 348, 2003). As a prelude to our investigation of the modulation of renal toxicity by diet, we examined the effect of four common rodent diets that differ to varying degrees in several components, including soy content, protein composition, and fatty acid and cholesterol levels, on systems potentially involved in renal toxicity. Specifically antioxidant defenses and cyclooxygenases were examined. At weaning on PND21, male rats (five per group) were assigned to one of four diets: NIH-31, Purina 5K96, Purina 5001, or Purina 5002. Food consumption and body weight gain were monitored throughout the study and were found not to differ among the diet groups. On PND51, animals were sacrificed and kidneys removed. Expression of cyclooxygenases-1 and -2 and hemoxygenase-1 was evaluated in cortex and medulla by realtime PCR. Total and oxidized glutathione were determined by colorimetric assays and the activities of superoxide dismutase, catalase, and glutathione peroxidase were measured. Except for marginal differences in superoxide dismutase and oxidized glutathione, no diet-related differences were observed in the endpoints evaluated. While baseline levels of these enzymes did not differ among these diet groups, whether diet modulates the response to toxin exposure remains to be investigated.

# DIFFERENTIAL EXPRESSION OF E-CADHERIN AND N-CADHERIN IN PROXIMAL AND DISTAL SEGMENTS OF THE RAT NEPHRON.

W. C. Prozialeck<sup>1</sup>, P. C. Lamar<sup>1</sup> and D. M. Appelt<sup>2</sup>. <sup>1</sup>Pharmacology, Midwestern University, Downers Grove, IL and <sup>2</sup>Biomedical Sciences, Philadelphia College of Osteopathic Medine, Philadelphia, PA.

E- and N-cadherin are calcium-dependent cell adhesion molecules that play important roles in the development and maintenance of renal epithelial polarity. Recent studies have shown that alterations in cadherin function may be associated with various types of nephrotoxic injury. In the present study, we have employed dual immunofluorescent labeling procedures that utilized specific antibodies against either E- or N-cadherin, along with antibodies that target markers for specific nephron segments, to characterize the patterns of cadherin expression in frozen sections of adult rat kidney. The results showed that N-cadherin was the predominant cadherin in the proximal tubule, but was essentially absent in other nephron segments. By contrast, E-cadherin was abundant in the distal tubule, collecting duct and some medullary segments, but was present only at very low levels in the proximal tubule. Additional results revealed different patterns of N-cadherin labeling along various segments of the proximal tubule; the S1 and S2 segments exhibited a fine threadlike pattern of labeling at the apical cell surface, whereas the S3 segment showed intense labeling at the lateral cell-cell contacts. These findings raise the possibility that differences in cadherin expression may contribute to the differences in the sensitivity of various nephron segments to toxic injury. Supported by Grant #R01 ES006478 from the NIEHS.

# FORMIC ACID EXCRETION IN RATS EXPOSED TO BROMODICHLORO-METHANE: POSSIBLE LINK TO RENAL TUBULE CELL PROLIFERATION IN LONGTERM STUDIES.

E. A. Lock, L. Cottrell, M. Jacobsen, T. Soames and R. Williams. Central Toxicology Laboratory, Syngenta, Macclesfield, United Kingdom.

Bromodichloromethane (BDCM) is a renal carcinogen in male and female F344 rats. The basis for the renal toxicity and carcinogenicity of BCDM is unclear. Several mechanisms have been proposed, oxidation to form phosgene, reduction to

generate a dichloromethyl radical and metabolic activation via glutathione S-transferase theta to form a mutagenic intermediate. This study aimed to provide indirect evidence for a radical mechanism for BDCM-induced renal toxicity by looking for excessive formic acid excretion in urine. Male F344 rats were given BDCM po at 50 or 100mg/kg/day for 5 days/week for 28 days. Controls received corn oil with 5 rats/group. Urine was collected over 24h on days 4-5, 11-12 and 17-18 for 1H-NMR profiling and pH determination. Osmotic minipumps containing 3H-BrDU were implanted on day 24 and animals killed on day 28. Blood was taken for creatinine and urea and kidneys for histopathology and determination of S-phase. Rats exposed to BDCM excreted large amounts of urinary formic acid, accompanied by a change in urinary pH. Formate excretion was dose dependent being elevated >100-fold after 4 doses and remained elevated over the 3 weeks at 100mg/kg. At 50mg/kg formate excretion was elevated 40-fold after 4 doses and declined to 5fold after 3 weeks. Histopathology revealed mild renal tubule injury in 2 rats at 100mg/kg BDCM. Blood urea and creatinine values were normal. Cell proliferation in the renal cortex was markedly elevated at 100 but not 50mg/kg BDCM. Long-term exposure to formic acid is known to cause renal tubule injury. Our study suggests, for the first time, that prolonged excretion of formic acid following BDCM may be a contributory factor to the increased cell proliferation and kidney injury seen in longer term studies. Studies with trichloroethylene, which also leads to excess formic acid in urine, suggest this may occur via a free radical mechanism inducing a B12 deficiency and hence a folate deficiency [Dow & Green (2000) Toxicology) 146, 123].

447

RENAL GLUTATHIONE PEROXIDASE AND GLUTATHIONE REDUCTASE ACTIVITY ARE ALTERED BY 3, 4-DICHLOROANILINE (3, 4-DCA) AND 2-AMINO-4, 5-DICHLOROPHENOL (2A45CP).

G. O. Rankin, M. A. Valentovic, N. Noureddine and B. Dunlap. *Pharmacology, Marshall University, Huntington, WV.* 

Toxic insult to the kidney can result from the generation of free radicals that are deleterious to cell function. The two enzymes glutathione peroxidase and glutathione reductase are involved in cellular detoxification processes. The following studies examined the effect of 3, 4-DCA, an intermediate in the production of propanil (a pre-emergent herbicide extensively used in the United States), and its metabolite, 2A45CP on glutathione reductase and peroxidase activity in the kidney. Renal cortical slices prepared from male Fischer 344 rats were rinsed 3 times each for 3 min in oxygenated Krebs buffer. Renal slices (50-100 mg) were equilibrated in 3 ml oxygenated Krebs at 37oC. Tissues were next incubated for 30-60 min with vehicle (DMSO) or a final concentration of 2 mM 3, 4-DCA or 0.5 mM 2A45CP. DMSO, 3, 4-DCA and 2A45CP were added in a total volume of 30 µl. Upon completion of the incubation period, glutathione peroxidase or glutathione reductase activity was measured in renal cortical slices. A 60 min exposure to 2 mM 3, 4-DCA diminished glutathione reductase activity to 33% of control values (p=0.012) and diminished glutathione peroxidase activity to 50% of vehicle control (p=0.002). Glutathione reductase and glutathione peroxidase were decreased to 54% (p=0.022) and 56% (p=0.005), respectively, of vehicle control values following a 30 min exposure to 0.5 mM 2A45CP. These results indicate that based on concentration, 2A45CP is a more potent nephrotoxicant than 3, 4-DCA. Furthermore, 3, 4-DCA and its metabolite 2A45ĈP decrease glutathione reductase and glutathione peroxidase activity in renal cortical slices, which may contribute to the mechanism of their toxicity.

#### 448 A NOVEL MITOCHONDRIAL MATRIX CALPAIN IN MITOCHONDRIAL INJURY.

D. D. Arrington, T. R. Van Vleet and R. G. Schnellmann. Pharmaceutical Sciences, Medical University of South Carolina, Charleston, SC.

Oncotic cell death is mediated by mitochondrial dysfunction and calpains, Ca<sup>2+</sup>-activated cysteine proteases. Mitochondrial dysfunction is the end result of a variety of cellular insults, with ischemia/reperfusion and toxicant exposure being the most clinically relevant. Previously, we reported that calpain inhibitors protected renal proximal tubular mitochondrial function during hypoxia/reoxygenation and isolated renal cortical mitochondria (RCM) exposed to Ca<sup>2+</sup>. A mitochondrial calpain-like activity was associated with Ca<sup>2+</sup>-exposed RCM. We hypothesized that this calpain-like activity is due to a novel mitochondrial calpain. Rabbit RCM were isolated by differential centrifugation, further purified by sucrose/percoll gradient centrifugation, and sub-fractionated into matrix, inter-membrane space, and inner and outer membrane fractions. All fractions were analyzed for proteolytic activity by FITC-casein and SLLVY-AMC zymography. The addition of Ca<sup>2+</sup> did not induce cleavage of the FITC-casein substrate in any of the RCM fractions. In contrast, Ca<sup>2+</sup>-dependent SLLVY-AMC cleavage was observed in the matrix fraction, one prominent and two minor bands, but not in the other RCM fractions. Purified μ- and m-calpain were used as controls, migrated differentially during zymography,

and cleaved both substrates. The bands of calpain activity in the matrix fraction did not co-migrate with  $\mu$ - or m-calpain. In-gel cleavage of SLLVY-AMC by the matrix fraction calpain was inhibited by the calpain inhibitors E64 (100  $\mu$ M) and calpeptin (100  $\mu$ M) by 70 and 80%, respectively. Additionally, the calpain inhibitors E64 and calpeptin inhibited calpain activity using matrix suspensions with an IC $_{50}$  of 26 and 2 nM, respectively. In summary, we identified a novel mitochondrial calpain activity in the matrix fraction of RCM that is different than cytosolic  $\mu$ - and m-calpain, and is potently inhibited by calpain inhibitors. This mitochondrial matrix calpain appears to play an important role in mediating mitochondrial dysfunction following ischemia/reperfusion or toxicant injury.

#### 449 EFFECT OF CALCIUM OXALATE ON KIDNEY MITOCHONDRIAL FUNCTION.

K. McMartin<sup>1</sup>, C. Guo<sup>1</sup> and K. Wallace<sup>2</sup>. <sup>1</sup>Department of Pharmacology, LSU Health Sciences Center-Shreveport, Shreveport, LA and <sup>2</sup>Biochemisty and Molecular Biology, University of Minnesota-Duluth, Duluth, MN.

Ethylene glycol (EG) poisoning can produce acute renal failure, requiring longterm hemodialysis to restore function. The mechanism of renal failure is unknown, but associated with tubular cell necrosis and EG metabolism. The end metabolite of EG is oxalic acid, the precipitation of which as calcium oxalate monohydrate (COM) crystals in the tubular lumen has been linked with the renal toxicity. Our recent studies suggest that COM is an intracellular toxicant to normal human proximal tubule cells in culture. The present studies were designed to assess whether COM or ionic oxalate alters mitochondrial function so as to lead to renal cell death. Rat kidney mitochondria were prepared by homogenization of cortical tissue, then by differential centrifugation techniques. Substrate-induced respiration was measured in isolated mitochondria using a sealed reaction chamber fitted with Clarktype electrode. Mitochondrial swelling was measured by the decrease in absorbance at 540 nm. COM produced a dose-dependent decrease in State 3 respiration (40% decrease at 0.05 mM COM with either succinate or glutamate/malate as substrate), without affecting either State 4 respiration or the ADP/O ratio. The inhibition of State 3 respiration was not reversed by cyclosporin A (CsA) administration. COM, from 0.01-0.05 mM also dose-dependently increased mitochondrial swelling, which was completely blocked by CsA. Potassium oxalate, at concentrations up to 5 mM did not affect mitochondrial respiration. These results suggest that COM, and not the oxalate ion, damage rat kidney mitochondria and induce the mitochondrial permeability transition, which then leads to renal cell death. Since COM is transported intracellularly by kidney cells, the renal toxicity of EG may result from inhibition of mitochondrial respiratory function in proximal tubular cells by COM crystals. Supported by American Chemistry Council.

# 450 MODULATION OF MITOCHONDRIAL GLUTATHIONE (GSH) TRANSPORT IN NRK-52E CELLS ALTERS SUSCEPTIBILITY TO CHEMICALLY INDUCED APOPTOSIS.

<u>L. H. Lash</u><sup>1</sup>, D. A. Putt<sup>1</sup>, F. Xu<sup>1</sup>, J. Wang<sup>1</sup>, C. S. Wood<sup>1</sup>, J. Hartman<sup>1</sup> and L. H. Matherly<sup>2, 1</sup>. <sup>1</sup>Pharmacology, Wayne State University, Detroit, MI and <sup>2</sup>Karmanos Cancer Institute, Wayne State University, Detroit, MI.

Two anion carriers of the mitochondrial inner membrane, the dicarboxylate carrier (DCC) and oxoglutarate carrier (OGC), are the primary, if not sole, determinants of mitochondrial GSH status. To study the function of this critical GSH pool, NRK-52E cells (an immortalized cell line derived from normal rat kidney proximal tubules) were stably transfected with both wild-type and mutant cDNAs for the DCC and OGC, using total rat kidney RNA as template. Mutants were created by RT-PCR, with targeted residues being those that are conserved across species, are in predicted transmembrane domains, and are thought to be important in catalytic function and/or protein structure. Endogenous mitochondrial transport activity is relatively low, and these cells are highly sensitive to apoptosis induced by either tertbutyl hydroperoxide (tBH; 10 or 50  $\mu$ M) or S-(1, 2-dichlorovinyl)-L-cysteine (DCVC; 50 or 200 µM). Overexpression of either of the wild-type carriers markedly increased the ability of NRK-52E mitochondria to accumulate GSH and markedly protected cells from apoptosis induced by either tBH or DCVC. By contrast, expression of one of three DCC mutants (DCC-H24Q, -P25A, -D120K) or a double-cysteine mutant of the OGC (OGC-C221, 224S) resulted in markedly lower transport of GSH and dicarboxylates, whereas two cysteine mutants of DCC (DCC-C21S, -C211S) exhibited only modestly lower GSH transport activity. NRK-52E cells stably overexpressing OGC-C221, 224S exhibited a similar sensitivity to tBH- or DCVC-induced apoptosis as wild-type cells, indicating absence of protection. These results support the hypothesis that susceptibility to cellular injury from either an oxidant or a mitochondrial toxicant can be directly modulated by mitochondrial GSH status. Moreover, these results show that genetic manipulation of mitochondrial GSH carriers is an effective means to alter cellular susceptibility to toxicants. (Supported by NIH Grant DK40725.)

CELLULAR TOXICITY OF CALCIUM OXALATE: IS IT RELATED TO DISRUPTION OF MEMBRANE INTEGRITY.

C. Guo, <u>T. Dugas</u> and <u>K. McMartin</u>. Department of Pharmacology, LSU Health Sciences Center-Shreveport, Shreveport, LA.

A key metabolite in ethylene glycol (EG) poisoning is calcium oxalate monohydrate [COM], which may be responsible for the EG-related acute renal failure. Previous studies have suggested that COM induces cytotoxicity by producing plasma membrane damage, leading to leakage of cell contents and cell death. For example, COM but not the oxalate ion, produces hemolysis in rat erythrocytes and increase LDH leakage by normal human proximal tubular (HPT) cells in culture. Pretreatment of COM with aluminum citrate, which appears to decrease aggregation of COM, prevents the cellular membrane damage . In the present studies, we have investigated the mechanism of the damage induced by COM. We have used liposomes composed of dipalmitoylphosphatidylcholine (DPPC) as model membranes and calorimetric techniques to explore the COM-lipid interactions. Unilamellar vesicles (ULVs) were prepared in PBS by extrusion through a 0.1 mm polycarbonate membrane. A differential scanning calorimeter (DSC) was used to collect the DSC thermograms by raising the temperature at a constant rate of 0.5oC/min in the range of 25-50oC. COM at 5 and 10 mM did not significantly change the main thermotropic phase transition of DPPC. The effect of COM on the thermotropic phase transition of the other kind of lipid membranes is therefore being explored. These studies suggest that the membrane damaging effect of COM may not result from direct lipid-COM interactions in PBS. Supported by American Chemistry Council.

EVIDENCE FOR THE DIRECT INACTIVATION OF ENDOPLASMIC RETICULUM BOUND  ${\rm CA}^{2+}$ -INDEPENDENT PHOSPHOLIPASE  ${\rm A}_2$  IN RENAL CELLS DURING OXIDATIVE STRESS.

B. S. Cummings<sup>1,3</sup>, G. R. Kinsey<sup>1</sup>, A. K. Gelasco<sup>2</sup>, J. Mchowat<sup>4</sup> and R. G. Schnellmann<sup>3</sup>. Pharmacology and Biomed. Sciences., University of Georgia, Athens, GA, <sup>2</sup>Nephrology, Med. University of South Carolina, Charleston, SC, <sup>3</sup>Pharmacology Sciences., Med. University of South Carolina, Charleston, SC and <sup>4</sup>Pathology, St. Louis University, St. Louis, MO.

While inhibition of endoplasmic reticulum bound Ca2+-independent phospholipase A2 (ER-iPLA2) in primary cultures of rabbit renal proximal tubule cells (RPTC) potentiates oxidant-induced oncosis, the effect of oxidant exposure on ERiPLA2 activity has not been examined. Exposure of RPTC to the model oxidant tert-butylhydroperoxide (TBHP, 0-400 µM) resulted in time- and concentrationdependent decreases in ER-iPLA, activity. Exposure of RPTC to cumene hydroperoxide and cisplatin also decreased ER-iPLA<sub>2</sub> activity. TBHP-induced ER-iPLA<sub>2</sub> inactivation was reversed by the addition of dithiothreitol (DTT, 1 mM) to microsomes isolated from treated RPTC. TBHP also directly inactivated ER-iPLA, in microsomes isolated from untreated RPTC. TBHP-induced microsomal ERiPLA2 inactivation was time- and concentration-dependent with 200 µM TBHP inhibiting microsomal ER-iPLA2 activity 50% after 15 min. Similar to RPTC, DTT (300 µM) prevented TBHP-induced ER-iPLA2 inactivation as did the reactive oxygen scavengers butylated hydroxytolulene (10 µM) and N, N'-diphenyl-pphenylenediamine (2 µM), and the iron chelator deferoxamine (500 µM). These data suggested that TBHP-induced ER-iPLA, inactivation was the result of reactive oxygen species. Electron paramagnetic resonance spin trapping demonstrated that TBHP initiated a carbon-centered radical after 5 min of exposure in microsomes, preceding ER-iPLA, inactivation by 10 min. Further studies suggested that the formation of the carbon-center radical occurred after, or in concert with, the formation of an oxygen-center radical. These data suggest TBHP-induced formation of radical species at the ER is responsible for ER-iPLA, inactivation. These data demonstrate the novel finding that ER-iPLA2 is inactivated by oxidants, and that the mechanism of inactivation involves the oxidation of ER-iPLA, sulfhydryl

# DIABETES PROTECTS FROM LETHAL NEPHROTOXICITY OF S-1, 2-DICHLOROVINYL-L-CYSTEINE (DCVC).

A. V. Dnyanmote<sup>1</sup>, S. P. Sawant<sup>1</sup>, E. A. Lock<sup>2</sup>, J. R. Latendresse<sup>3</sup> and H. M. Mehendale<sup>1</sup>. <sup>1</sup>Toxicology, ULM, Monroe, LA, <sup>2</sup>MUSC, Charleston, SC and <sup>3</sup>Pathology Assoc. Intl., NCTR, Jefferson, AR.

Streptozotocin (STZ)-induced type I diabetic rats show attenuated renal injury from nephrotoxicants such as gentamycin, cisplatin and HgCl<sub>2</sub>. We tested the hypothesis that STZ-induced diabetes protects Swiss Webster mice from a lethal dose (75 mg/kg ip) of DCVC. Diabetes was induced in mice with STZ (200 mg/kg ip) while the controls received only the vehicle. On day 10 the mice received either

DCVC (75 mg/kg ip) or the vehicle alone. Ninety percent of the diabetic (DB) mice given DCVC survived in contrast to only 10% survival of non-diabetic (NDB) mice given DCVC. Time-course measurements of blood urea nitrogen (BUN), creatinine, and histopathology (H&E-stained kidney sections) were performed to assess renal injury. <sup>3</sup>H-thymidine (<sup>3</sup>H-T) incorporation into renal DNA and PCNA immunohistochemistry were carried out to measure S-phase DNA synthesis and cell cycle progression, respectively. Apoptosis was estimated by TUNEL assay. In the NDB mice, DCVC produced a steep temporal increase in BUN and creatinine, which was associated with acute necrosis of proximal tubular cells (PTC) resulting in 90% mortality within 48 h due to acute renal failure (ARF). In contrast, in the DB mice, BUN and creatinine increased till 36 h (albeit less steeply than in the NDB mice) declining thereafter to completely resolve by 96 h. Activity of renal cysteine conjugate β-lyase, the enzyme that bioactivates DCVC, was unaltered in the DB mice, undermining the possibility that lower bioactivation of DCVC led to lower injury in the DB mice. <sup>3</sup>H-T incorporation and PCNA indicated an early and sustained tissue repair in the DB mice treated with DCVC. DB mice also exhibited higher apoptosis after receiving DCVC, further increasing the efficiency of this tissue repair by rapid removal of damaged PTC that might have otherwise died of necrosis extending the progression of injury. These findings suggest that prompt and efficient tissue repair rescues DB mice from DCVC-induced ARF and mortality. (Supported by DK 61650)

NF-kB MEDIATED TRANSACTIVATIONAL MECHANISMS OF G1-TO-S CELL CYCLE PROGRESSION IN AUTOPROTECTION AGAINST S-1, 2-DICHLOROVINYL-L-CYSTEINE INDUCED ACUTE RENAL FAILURE.

M. C. Korrapati<sup>1</sup>, E. A. Lock<sup>2</sup> and H. M. Mehendale<sup>1</sup>. <sup>1</sup>School of Pharmacy, ULM, Monroe, LA and <sup>2</sup>Medical University of South Carolina, Charleston, SC.

Prompt stimulation of nephrogenic cell division and tissue repair were reported to be the mechanisms of protection against a normally lethal dose of S-1, 2dichlorovinyl-L-cysteine (DCVC) in autoprotection. We tested our hypothesis that protection occurs because of up regulated G1 checkpoint genes like cyclin D1 (CD1) mediated by sustained NF-KB binding to nuclear DNA. Male swiss webster mice (n=4) received a priming dose (15 mg DCVC/kg, ip) in distilled water (10 ml DW/kg), 3 days prior to receiving a lethal dose (75 mg DCVC/kg, ip in DW). NFκB binding to nuclear DNA was measured by electrophoretic mobility shift assay, total and phosphorylated IκBα, CD1 and cyclin dependent kinase (cdk4) protein levels were estimated by Western blotting at 3, 6, 12 and 24 h after the lethal dose with or without the priming dose. Autoprotected mice were compared with mice receiving the priming dose+DW, DW+lethal dose & DW+DW. Inhibited phosphorylation of IκBα restricted the nuclear translocation of NF-κB, and decreased levels of CD1 and cdk4 after lethal dose of DCVC alone. However, a prior priming dose led to sustained degradation of IKBa by its phosphorylation, increased translocation and NF-KB binding to nuclear DNA as early as 3 h after receiving the same lethal dose in the autoprotected group. CD1 and cdk4 expression stimulated by the priming dose remained at high levels in the autoprotected group. Therefore up regulated CD1 production facilitated by increased nuclear DNA-binding of NF-κB is the key signaling mechanism behind sustained stimulation of renal cell division in autoprotection. These findings raise the possibility that this signaling mechanism may be availed for potential pharmacotherapeutic modulation to restore lost proximal tubular structure and function. (Supported by DK 61650).

### 455 EFFECT OF MT-3 EXPRESSION ON APOPTOSIS IN THE HUMAN PROXIMAL TUBULE CELL LINE, HK-2.

S. H. Garrett<sup>1</sup>, S. Somji<sup>1</sup>, M. Sens<sup>1</sup> and D. A. Sens<sup>2</sup>. <sup>1</sup>Pathology, University of North Dakota, Grand Forks, ND and <sup>2</sup>Surgery, University of North Dakota, Grand Forks, ND.

Cadmium is a heavy metal known to induce nephrotoxicity in proximal tubule cells of the kidney. Most heavy metals can cause cell death by necrosis or apoptosis. Numerous studies have shown that metallothioneins (MT), a family of low molecular weight metal binding proteins can provide protection against heavy metal toxicity. The third isoform of metallothionein, MT-3, can also bind and sequester cadmium similar to that of the MT-1 and 2 isoforms, and could have the potential to play a role in mediating toxicity that cadmium elicits on the renal proximal tubule cell. The goal of this study was to determine if over-expression of MT-3 in the HK-2 kidney cell line would increase the resistance of these cells to the toxic effects of cadmium. The parental HK-2 cells and the MT-3 transfected cells were exposed to lethal and sub-lethal concentrations of cadmium chloride for various time periods. The effect of cadmium treatment on cell viability was determined by the automated counting of the cell nuclei stained with the nuclear binding dye, 4', 6-diamidino-2phenylindole (DAPI). Continuous exposure of HK-2 cells at various concentrations of cadmium for 8 to 48 hr resulted in cell death with extensive chromatin condensation and DNA fragmentation, features typical for cells undergoing apoptosis. This was further confirmed by agarose gel electrophoresis and caspase-3 assay. The MT-3 transfected cells did not show any increased resistance to cadmium compared to the HK-2 cells with very few cells showing morphological changes typical for apoptosis. These MT-3 transfected cells showed greater release of the enzyme lactate dehydrogenase compared to the parental cells indicating that the cells were undergoing necrosis. These results indicate that although the overexpression of MT-3 does not increase the resistance of the HK-2 cells to the toxic effects of cadmium but makes the cells more sensitive to necrosis.

## 456 STATINS INHIBIT ALBUMIN UPTAKE IN OPOSSUM KIDNEY PROXIMAL TUBULE CELLS VIA REDUCED PRENYLATION OF SIGNALLING PROTEINS.

J. Sidaway<sup>1</sup>, R. G. Davidson<sup>2</sup>, F. McTaggart<sup>2</sup>, <u>T. C. Orton</u><sup>1</sup>, R. C. Scott<sup>1</sup>, G. J. Smith<sup>2</sup> and N. J. Brunskill<sup>3</sup>. 'Safety Assessment, AstraZeneca, Macclefield, Cheshire, United Kingdom, <sup>2</sup>Cardiovascular and Gastrointestinal Discovery, AstraZeneca, Macclefield, Cheshire, United Kingdom and <sup>3</sup>Department of Nephrology, Leicester General Hospital, Leicester, Leicestershire, United Kingdom.

Statins are inhibitors of 3-hydroxy-3-methylglutaryl Coenzyme A (HMG-CoA reductase) and are used for the reduction of cholesterol-containing atherogenic lipoproteins. They also affect cellular processes through depletion of non-sterol metabolites of mevalonate including geranylgeranyl pyrophosphate (GGPP), which is required for the prenylation of many proteins. During phase III studies of a new statin, rosuvastatin, transient proteinuria of tubular origin without impaired renal function was observed in some subjects taking the highest 80mg dose (above the recommended range). We hypothesised that this could be the result of reduced efficiency of protein re-absorption by renal proximal tubule (PT) cells through inhibition of HMG-CoA reductase. Using the PT-derived opossum kidney (OK) cell line, we measured protein uptake by incorporation of FITC-albumin and assessed HMG-CoA reductase activity by conversion of <sup>14</sup>C-acetate into cholesterol. Simvastatin, atorvastatin, rosuvastatin and pravastatin all inhibited albumin uptake into OK cells in a dose-dependent fashion (IC $_{50}$  values at 24hr were 0.3, 1.0, 1.7 and 26.5  $\mu$ M respectively) in the absence of cytotoxicity, and this was related to the degree of inhibition of HMG-CoA reductase. The inhibitory effect of simvastatin on albumin uptake was almost completely prevented by co-addition of mevalonate and GGPP, but not by cholesterol. Inhibition of geranylgeranyl transferase also reduced albumin uptake whilst simvastatin decreased prenylation of Rap1A, a protein associated with endocytosis. These data suggest that statins inhibit protein uptake in OK cells through reduced prenylation of critical signalling/transport proteins and establish the principle that inhibition of HMG-CoA reductase in PT cells may reduce tubular protein re-absorption in vivo providing a mechanistic explanation of statin-associated proteinuria.

## 457 ESTROGEN RECEPTOR $\alpha$ BUT NOT $\beta$ IS A MAJOR MEDIATOR FOR ESTRADIOL INDUCED THYMIC ATROPHY.

Z. Lai<sup>1</sup>, N. C. Fiore<sup>1</sup>, S. C. Hewitt<sup>2</sup>, K. S. Korach<sup>2</sup> and <u>A. E. Silverstone<sup>1</sup></u>.

<sup>1</sup>Department of Microbiology and Immunology, SUNY Upstate Medical University, Syracuse, NY and <sup>2</sup>Lab. Reprod Develop Toxicology, NIEHS/NIH, Research Triangle Park, NC.

It has been shown that estradiol (E2) induces thymic atrophy in all examined mammals. An estrogen receptor (ER) is required to mediate the effects of E2. Our previous study with ERa knockout (ERKO) mice demonstrated that loss of ERa could not completely protect from E2 induced thymic atrophy, suggesting that there may be other mediators for estrogen effects in the immune system. At least one other ER  $(\beta)$  has been identified. To investigate the role of ERB in modulation of E2 induced thymic atrophy; we compared the effects of E2 on C57BL/6 (WT) and ERBKO mice in the present study. Our results show that E2 induced the same degree of thymic atrophy in either WT or ERβKO mice, whose thymii still contain ERα receptors. Analysis of thymocytes for expression of HSA, CD3, CD4, CD8, DP (CD4+8+), DN (CD4-8-) and CD44, CD25, also indicated that there was no difference for the effects of E2 between WT and ER $\beta$ KO mice. Using radiation chimeras reconstituted from WT or ERBKO stem cells into WT mice, we found that there was no significant difference in reduction of the number of total thymocytes and the numbers of CD4, CD8, DP, and DN cells induced by E2 in both types of chimeras. As seen with WT donors, smaller thymii were seen in chimeras reconstituted by ERβKO stem cells into the ERαKO mice compared to those chimeras reconstituted into WT mice. We also found that the effects of E2 on thymocyte subset distribution, were partially inhibited in these ER $\alpha$ KO reconstituted with ER $\beta$ KO BM, which lack thymic stroma ER $\alpha$ . We also did not see an increase of CD3 expression and a decrease of HSA expression in the ERaKO reconstituted with ERβKO BM chimeras; these effects are usually seen in the WT and ERβKO mice. Taken together, our results confirm that ER $\alpha$  but not ER $\beta$  is a major mediator for E2 induced thymic atrophy. (Supported by NIEHS ES 07216 and ES 04862, and Hendricks's fund)

# 458 EVALUATION OF THE POTENTIAL IMMUNOTOXICITY OF 3-MONOCHLORO-1, 2-PROPANEDIOL IN BALB/C MICE.

J. Lee<sup>1</sup>, J. Byun<sup>1</sup>, S. Park<sup>1</sup>, H. Kim<sup>1</sup>, J. Park<sup>1</sup>, J. Eom<sup>1</sup>, M. Ryu<sup>1</sup>, <u>Y. Heo<sup>2</sup></u> and H. Oh<sup>1</sup>. <sup>1</sup>Division of Immunotoxicology, National Institute of Toxicological Research, KFDA, Seoul, South Korea and <sup>2</sup>Daegu Catholic University, Daegu, South Korea.

3-monochloro-1, 2-propanediol (MCPD) is a well-known by-product of acid-hydrolyzed soy sauce during its manufacturing process. MCPD has been reported genotoxic in vitro, and reproductive toxicity and carcinogenicity in rats. However, no previous studies have investigated MCPD-induced alterations in the immune system. In the present study, MČPD was administered by gavage for 14 days at 0, 25, 50, 100, 120mg/kg to female Balb/c mice. The antibody-mediated immune response to sheep red blood cells (SRBC) was assessed using the plaque-forming cell (PFC) assay and splenic cell phenotypes were quantified by flowcytometry. Hematological and histopathological changes were assessed. The T lymphocyte blastogenesis by concanavalin A (Con A) and B-lymphocyte blastogenesis by lipopolyssacharide (LPS) were not significantly changed. The phenotypes of CD3+, CD45R+, CD4+, and CD8+ in spleen of MCPD-treated mice were not significantly changed. There were no significant changes in the hematological and histopathological changes of MCPD-treated mice. However, the significant decrease in thymus weight was observed in 100mg dose group, even though that did not change body weight gain. The cellularites of spleen and thymus were significantly reduced in 100mg dose group. Exposure to 100mg of MCPD decreased the PFC response to SRBC in mice. These results indicate that MCPD could reduce the immune system in Balb/c mice.

### 459 ACETONE: 4-WEEK DRINKING WATER IMMUNOTOXICITY STUDY IN CD-1 MICE.

P. K. Anderson, M. R. Woolhiser and J. M. Waechter. Toxicology & Environmental Research and Consulting. The Dow Chemical Company, Midland, MI.

Acetone exposure occurs from both natural (e.g., food and endogenous production) as well as through anthropogenic sources; previous studies have suggested acetone may modulate humoral immunity (Singh et al. Fund. Applied. Toxicol. 33: 129-139, 1996). This study investigated the immunotoxicity potential of acetone in accordance with the USEPA Immunotoxicology Test Guideline. Acetone was administered to mice at concentrations of 0, 600, 3000 or 6000 ppm (average daily doses of 121, 621, or 1144 mg/kg/day). The highest dose was about equivalent to the estimated dose dermally absorbed for Singh et al., and about 20-fold greater than normal, endogenous production by human adults. Mice were immunized with sheep red blood cells 4 days before the end of exposure to evaluate functional responsiveness of the immune system via the Antibody, Plaque Forming Cell (AFC) assay. Body weights, hematological parameters and thymus weights were also measured. Body weights and hematological parameters showed no treatment-related effects due to acetone consumption. Eosinophil percentages appeared slightly lower than controls in some groups of mice treated with acetone, but the results were neither dose related or statistically different from controls, and all values were within the range of historical controls. Spleen weights were unaltered by treatment while mean thymus weights of mice given acetone at 1144 mg/kg/day were about 25% lower, but not statistically different, than controls. No effects were noted for spleen cellularity as a result of acetone treatment. The AFC responses ranged from 1088-1401 AFC/10<sup>6</sup> splenocytes following acetone administration, and were not statistically different from control (1277  $\mbox{\normalfont\AAFC/10}^6$  cells). The antibody response, WBC numbers, RBC counts, hemoglobin and hematocrit levels, and organ weights for positive controls (CYP) were all reduced. Acetone administration via drinking water for 28 days did not produce immunotoxicity in CD-1 mice at doses as high as 1144 mg/kg/day. This work was sponsored by the Acetone Panel of the American Chemistry Council.

EXPOSURE TO SODIUM DICHROMATE FROM DRINKING WATER DOES NOT ALTER IMMUNE FUNCTION IN B6C3F1 MICE OR SPRAGUE DAWLEY RATS.

R. D. Brown<sup>1</sup>, K. L. White<sup>1</sup>, D. R. Germolec<sup>2</sup>, C. S. Smith<sup>2</sup>, L. X. Zhang<sup>1</sup> and T. L. Guo<sup>1</sup>. <sup>1</sup>Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA and <sup>2</sup>NIEHS, Research Triangle Park, NC.

Hexavalent chromium [Cr(VI)] is a byproduct of chromium plating and as a result of significant use in the industry has resulted in environmental contamination of drinking water surrounding areas where it is produced. Cr(VI) in the drinking water has been associated with cancer clusters and increased incidences of various diseases. The USEPA drinking water standard is 100 mg/l (100 ppb). Studies were conducted by the National Toxicology Program to evaluate the effects of sodium

dichromate, Cr(VI), on the immune system in both rats and mice following exposure from drinking water. Female mice were exposed to Cr(VI) at concentrations of 15.6, 31.3, 62.5, 125, and 250 ppm while rats were exposed to 14.3, 57.3, 172, and 516 ppm in the drinking water for 28 days. Animals were evaluated for toxicological and immune function on day 29. In mice organ weights were not affected, while decreases in body weight and erythroid parameters were observed at the high dose level. Immune parameters such as the mixed leukocyte response, anti-CD3mediated lymphocyte proliferation, splenic phenotypes, and natural killer cell activity were not effected. While a slight stimulation was observed in the plaque assay to sRBC in the middle dose levels, the effect was not dose-responsive in nature. No effect was observed on serum IgM ELISA to the T-dependent antigens, sRBC or KLH. In female rats, body weights, organ weights, and hematological parameters were not affected. Similarly, anti-CD3-mediated lymphocyte proliferation and natural killer cell activity were not affected. A slight increase was observed in the plaque assay at the lowest dose, similar to observations in the mouse. Overall, exposure from Cr(VI) in the drinking water did not produce marked effects on the immune responses of either rats or mice. Supported by NIEHS/NTP Contract ES-

# 461 COMPARISON BETWEEN INTRAPERITONEAL AND ASPIRATION ROUTES OF EXPOSURE TO EVALUATE THE IMMUNOTOXIC EFFECTS OF A MIXTURE OF HERBICIDES.

K. Salazar<sup>1</sup>, M. Chroussis<sup>2</sup>, <u>J. B. Barnett</u><sup>1</sup> and <u>R. Schafer</u><sup>1</sup>. <sup>1</sup> Microbiology, Immunology, & Cell Biology, West Virginia University, Morgantown, WV and <sup>2</sup> Alderson-Broaddus College, Phillipi, WV.

The widespread use of herbicides in agriculture and the accumulation of herbicides in the environment create a need for understanding the mechanism of their toxic effects. Due to the ubiquitous nature of herbicides, exposure is frequently to a mixture. The herbicides 2, 4-D (2, 4-dichlorophenoxyacetic acid) and propanil (3, 4dichloropropionanilide) represent two extensively used herbicides commonly sold as a mixture. Previous experiments in our lab have shown that intraperitoneal (i.p.) exposure to a mixture of these two herbicides produces synergistic immunotoxic effects on the thymus. This study utilized an aspiration model in C57Bl/6 mice to compare the immunotoxic effects on the thymus after i.p. or aspiration exposure to 2, 4-D and propanil. Mice were exposed to either a single 150 or 200 mg/kg dose of propanil or 2, 4-D, or a 150 or 200 mg/kg one to one mixture of the herbicides. Mice exposed via aspiration were lightly anesthetized and administered the herbicides in a DMSO and olive oil vehicle. Thymocyte populations were determined by flow cytometry 2 days post exposure. Mice exposed to a 150/150 mg/kg or 200/200 mg/kg mixture or to 200 mg/kg propanil alone had thymic atrophy following both routes of administration. CD4+CD8+ (DP) thymocytes were decreased approximately 50% compared to vehicle control. Intraperitoneal exposure to 150 mg/kg propanil resulted in thymic atrophy and a decrease in DP thymocytes. However, 150 mg/kg propanil administered via aspiration did not produce any significant thymic toxicity. This suggests that the mechanism inducing thymic toxicity following exposure to the mixture of herbicides is dependent on route of exposure. These data demonstrate that aspiration of the herbicides produce immunotoxic effects on the thymus. These experiments also suggest that the aspiration model is an effective method for evaluating immunotoxicity after herbicide exposure. Supported by the NIH Immunotoxicology Training Grant ES010953.

# 462 INDUCTION OF IFN-G CYTOKINE EXPRESSION BY CHLORPYRIFOS, CHLORPYRIFOS-OXON, AND ENDOTOXIN *IN VITRO*.

P. Duramad and N. Holland. UC Berkeley, Berkeley, CA.

Pesticides and their metabolites are ubiquitous in the environment as a result of widespread agricultural and domestic applications. In addition to pesticides, agricultural workers and their families are also exposed to elevated levels of allergens and endotoxin. Interactions among immunomodulatory agents have only recently become a focus of environmental health research. Few validated immunological markers are currently available to evaluate the immunotoxicity of pesticides. Cytokine profiling is a promising biomarker of the immune response since skewed Th1 and Th2 cytokine secretion is associated with autoimmune disorders, asthma, and cancer. Here, we used an in vitro based method to evaluate the effects of the organophosphate pesticide chlorpyrifos (CP) and its metabolite chlorpyrifos-oxon (CPO) on cytokine secretion by human lymphocytes. We also evaluated the effect of combined exposures to CP/CPO and endotoxin (LPS) in order to model the multiple exposures received by agricultural workers and their families. Human whole blood was treated with CP, CPO (both with doses of 1-10, 000mg/mL), and LPS (1.5-2.5mg/mL) either singly or in combination for 2-72 hours. At 2, 24, 48, and 72 hours supernatants were collected and assayed by ELISA for expression of interferon-g (IFN-g), the Th1 signature cytokine. Whereas no expression of IFN-g was detected in cultures treated with either CP or CPO alone, cultures treated with CP or CPO in combination with LPS expressed higher levels of IFN-g with some combinations inducing greater IFN-g expression than LPS alone (p<0.01). The levels of IFN-g secreted into the supernatants peaked at 48 hours and declined slightly at 72 hrs. In summary, CP and CPO alone do not induce cytokine expression, however the combinations of CP-LPS and CPO+LPS synergistically increased IFN-g expression. These results indicate a potential interaction between endotoxin and organophosphate pesticides. Finally, our results demonstrate that cytokine induction can be a sensitive marker of the immune response to combinations of environmental factors.

### ROLE OF CYTOKINE NETWORKS IN DETERMINING SUSCEPTIBILITY TO DRUG-INDUCED LIVER DISEASE.

M. Bourdi<sup>1</sup>, D. Eiras<sup>1</sup>, M. Holt<sup>1</sup>, T. Reilly<sup>2</sup>, K. Welch<sup>1</sup>, H. Amouzadeh<sup>1</sup> and <u>L. Pohl<sup>1</sup></u>. <sup>1</sup>Molecular and Cellular Toxicology Section/LMI/NHLBI, NIH/DHHS, Bethesda, MD and <sup>2</sup>Immunotoxicology, Drug Safety Evaluation, Bristol-Myers Squibb, Syracuse, NY.

Using interleukin (IL)-10 deficient mice (IL-10-/-), we previously reported that IL-10 plays an important role in protecting the liver against acetaminophen (APAP)induced liver injury. In the current work, we discovered a unique interaction that makes mice deficient in both IL-10 and IL-4 (IL-10/4-/-) highly sensitive to the hepatotoxic effects of APAP. C57BL/6 wild type (WT), IL-10-/-, IL-4-/-, or IL-10/4-/- mice were administered APAP at a dose of 120 mg/kg. Within 24 hours, 90% of the IL-10/4-/- mice died of massive hepatic damage. In contrast, all of the WT, IL-10-/-, and IL-4-/- mice survived and showed minor or no signs of liver injury. The high susceptibility of the IL-10/4-/- mice was associated with elevated levels of hepatic TNF-a mRNA, serum nitrite/nitrate, and hepatic APAP-protein adducts, which appeared to be due in part to depressed levels of hepatic glutathione but not elevated levels of CYP2E1. These findings suggest that hepatocyte homeostasis following drug-induced injury is controlled in part by the activities of both IL-4 and IL-10, which together help maintain adequate levels of glutathione and prevent overexpression of protoxicant factors including TNF-a and nitric oxide. Certain polymorphisms of IL-4 and IL-10 that lead to their under expression may have a role in determining individuals' susceptibility to drug-induced liver disease.

# 464 LIPOPOLYSACCHARIDE PRE-EXPOSURE SENSITIZES THE MOUSE TO DEOXYNIVALENOL -INDUCED PROINFLAMMATORY CYTOKINE EXPRESSION AND LYMPHOCYTE APOPTOSIS.

Z. Islam<sup>1</sup> and J. J. Pestka<sup>1, 2</sup>. <sup>1</sup>Food Science and Human Nutrition, Michigan State University, East Lansing, MI and <sup>2</sup>Institute of Environmental Toxicology, Michigan State University, East Lansing, MI.

Simultaneous exposure to lipopolysaccharide (LPS) and the trichothecene deoxynivalenol (DON, vomitoxin) synergistically induces proinflammatory cytokine gene expression in vitro and in vivo. The purpose of this study was to determine if LPS pre-exposure sensitizes the mouse to DON-induced TNF-alpha, IL-6, IL-1alpha and IL-1beta expression. To test this hypothesis, the effects LPS and/or DON treatment on production of these cytokines were assessed in male B6C3F1 mice using real time PCR and ELISA methods. Initially, mice were treated with LPS (1 mg/kg) for 8 h, orally gavaged with DON (12.5 mg/kg) and cytokine response measured beginning after 1 h. LPS-induced pro-inflammatory cytokines peaked at 2 h and were diminished within 4 to 8 h. However, subsequent DON exposure in LPS-exposed animals caused significant expression and release of proinflammatory cy tokines as compared to DON alone. Expression of TNF-alpha mRNA peaked 5 folds at 1 h but the expression of IL-6, IL-1alpha and IL-1beta mRNAs was increased 5-, 4-, and 3-fold, respectively, 2 h after DON treatment compared to the mean additive responses of LPS alone and DON alone. While TNF-alpha and IL-6 were down regulated 8 h later, IL-1alpha and IL-1beta remained elevated until 24 h and was significantly higher compared to the mean additive responses of LPS alone and DON alone. Plasma levels of these cytokines were also elevated which was consistent with mRNA expression. Amplified cytokine expression was dependent on both LPS and DON dose. Mice pre-treated with LPS for 8 h and DON for 12 h exhibited a massive loss in thymocytes by apoptosis as confirmed by agarose gel electrophoresis and flow cytometry. Based on these and previous results, LPS pre-exposure appeared to sensitize mice to DON with resultant prolonged IL-1 upregulation that might play a major role in subsequent stress-induced lymphocyte apoptosis.

### 465 INFLAMMATION AND TRAUMATIC SKELETAL MUSCLE INJURY.

M. Summan, T. Hulderman, J. M. Matheson and P. P. Simeonova. Toxicology and Molecular Biology, DHHS/CDC/NIOSH, Morgantown, WV.

Traumatic skeletal muscle injuries result in profound histopathological changes and loss of muscle function. These injuries result in local infiltration of large numbers of mononuclear cells, degeneration of injured myofibers and phagocytic removal of

cell debris. Macrophages are critical effector cells in host defense and release a diverse array of cellular mediators including cytotoxic and proinflammatory cytokines that contribute to tissue injury. The present study evaluated the role of systemic macrophages in the injury/repair mechanisms in a traumatic skeletal muscle injury model using liposome encapsulated clodronate, a drug with well characterized monocyte/macrophage depleting qualities. C57BL/6 mice (n = 4 per group) were injected with clodronate liposomes 48 and 2 hours prior to the freeze injury of the left tibialis anterior (TA) muscle and every third day during the post-injury period. Control mice received phosphate buffered saline (PBS) liposomes. At 1, 3, 9 or 14 days post-injury, TA muscles were harvested for histology, immunohistochemistry or gene expression evaluation by quantitative real time RT-PCR. Histopathology revealed less inflammatory cell infiltration in the injured muscle of clodronate treated mice at day 3 post-injury, delayed muscle tissue recovery and impaired clearance of necrotic myofibers at day 9 post-injury; and increased fat infiltration at day 14 post-injury. Immunohistochemical evaluation of injured muscle demonstrated that Mac-1 expression was dramatically reduced in clodronate treated mice at day 3 post-injury. Clodronate treatment also significantly attenuates inflammatory (TNF-alpha, Mac-1 and MCP-1), growth (IGF-BP) factor and antioxidant (thioredoxin) gene expression in injured TA muscle compared to injured non-treated TA muscle. In conclusion, the inhibition of the inflammatory response resulted in delayed phagocytosis of the necrotic myofibers and delayed the repair process of the injured muscle tissue. Selective and time dependent modulation of the innate immune system may provide optimal resolution of skeletal muscle in-

IMMUNOGENICITY OF POLYETHYLENE GLYCOL (PEG)-BASED HYDROGEL SEALANT IN LAPAROSCOPIC PORCINE PARTIAL NEPHRECTOMY.

M. H. French, E. L. Park, W. Y. Ho, J. R. Talley, M. J. White, S. Ramakumar, N. F. Ullrich, J. A. Linehan and J. B. Ulreich. Surgery, University of Arizona,

Our objective was to evaluate potential immunomodulatory effects of a PEG-based hydrogel sealant in a porcine model of laparoscopic partial nephrectomy. Female domestic swine underwent laparoscopic left lower pole guillotine nephrectomy. Hemostasis and tissue sealing were achieved solely by application of a biodegradable PEG-based hydrogel. Humoral and cell-mediated immunity (CMI) to the sealant were evaluated by enzyme linked immunosorbent assay (ELISA) and lymphocyte proliferation assay (LPA) at 0, 2, 6 and 12 weeks. No antibodies to the hydrogel were detected by ELISA in immunized rabbits. There were no significant differences between control and nephrectomized swine in the ELISA at 2, 6 or 12 weeks. Optical density values for all 4 groups of swine in the ELISA were near 0.2, essentially baseline. It is concluded that the presence of the hydrogel in the abdomen did not elicit IgG antibody formation. For the CMI response measured using the LPA, there were significant differences between the log of the stimulation indices for test and control swine for all three mitogens at 2 weeks post-surgery (ConA, p≤0.01; PHA, p≤0.01; PWM, p≤0.05). These differences disappeared at 6 and 12 weeks and may represent a temporal reactivity of the white cells to the surgery undergone by the test, but not the control, swine. For the cellular response to antigens in the LPA, the only significant difference between the test and control groups was a temporal response to Candida albicans at two weeks (p≤0.03). There was no significant difference between test and control pig reactivity to the hydrogel as antigen in the LPA at any time point. The PEG-based hydrogel effectively sealed the cut surface of kidneys following porcine partial nephrectomy. There were no immediate or long term (12 week) complications. There was no humoral or long term cell-mediated immune response to the hydrogel. We conclude that the hydrogel is safe and effective for abdominal use, a novel application. Supported by the ŬA UBRP.

IMMUNOTOXICITY OF A COPLANAR AND NONCOPLANAR POLYCHLORINATED BIPHENYL (PCB) CONGENER IN A FISH MODEL.

J. Duffy, Y. Li and J. Zelikoff. Department of Environmental Medicine, New York University School of Medicine, Tuxedo, NY.

Polychlorinated biphenyls (PCBs) are a well-studied class of environmental contaminants known to be immunotoxic for both mammals and fish. Depending upon the particular structure of a PCB congener (i.e., coplanar or noncoplanar), different degrees and/or types of immunotoxic effects have been observed in exposed species. For this study, the effects of a single intraperitoneal (i.p.) exposure of bluegill sunfish (*Lepomis macrochirus*) to either a coplanar (PCB 126) or noncoplanar (PCB 153) PCB congener on host immunocompetence was determined by examining non-specific and cell-mediated immune parameters. Specifically, phagocyte-mediated intracellular and extracellular superoxide (O<sub>2</sub> ) production as well as mitogenstimulated T- and B-lymphocyte proliferation were examined using kidney or

spleen cells recovered from fish on 7, 14 or 21 d post-exposure. Both PCB congeners acted to depress innate and cell-mediated immune functions at all post-exposure timepoints (compared to controls) with the exception of extracellular  $O_2$ -production which was unaltered following PCB exposure. This study demonstrates that structurally different PCB congeners, thought to act by different mechanisms to produce toxicological effects in exposed species, may actually impact the immune response in a similar manner. This work was supported by a Hudson River Foundation Graduate Fellowship and USACEHR contract no. DAMD 17-99-9011.

### 468 IMPACT OF MATERNAL TOXICITY ON POSTNATAL IMMUNE SYSTEM-RELATED PARAMETERS IN RATS.

A. H. Penninks, M. van Zijverden, F. Kuper, M. M. Tegelenbosch-Schouten, A. P. Wolterbeek and I. D. Waalkens-Berendsen. *Experimental Immunology, TNO Nutrition and Food Research, Zeist, Netherlands.* 

Maternal toxicity during the entire gestation and lactation period might affect the pre-and postnatal development of the immune system of the offspring. As in the absence of a toxicological active substance maternal toxicity can also be mimicked by changes in body weight induced by food restriction, a postnatal developmental study was performed in which next to a control group two groups of pregnant rats were food restricted (approx. 85 and 70% of ad libitum) and two groups were treated with 20-or 100 µg dexamethasone/kg. In order to study the potential immunotoxic effects in these different groups enhanced immunopathology (paying attention to thymus, spleen, various lymph nodes and bone marrow), hematology and lymphocyte subset analysis in blood by flow cytometry was performed in the offspring on various post natal days (PND1, PND 21 and PND 70). Moreover, immune function was studied in offspring on PND 21 and PND 70 by means of a T cell-dependent antibody response to both SRBC (as measured by Plaque Forming Cell assay in spleen cells) and to KLH (as measured by ELISA). During gestation and lactation maternal body weight was affected on almost all days in the food restricted and dexamethasone-treated animals. Pup weights showed some non-significant differences at day 1-4 between the various groups, which became significant in all groups from day 7, except the low dexamethasone-treated group. Subset analysis of blood lymphocytes by flow cytometry revealed that at PND 4 lymphocyte subsets could hardly be determined, and at PND 21 they almost resembled those of adult rats. Mainly in the highest dexamethasone group lymphocyte subset numbers were affected. Immunopathology also revealed the immaturity of lymphoid organs at PND 4 which clearly was improved from PND 21. The further evaluation of the effects in the different treatment groups on immunopathology and the T cell-dependent antibody response on PND 21 and PND 70 (as measured by the SRBC-PFC assay and by KLH-ELISA) will be presented and discussed.

### DEXAMETHASONE-INDUCED IMMUNOTOXICITY FOLLOWING FETAL VS. ADULT EXPOSURE.

R. R. Dietert, J. Lee, J. Olsen, K. Fitch and J. A. Marsh. *Microbiology and Immunology, Cornell University, Ithaca, NY.* 

Immunotoxicity data using adult exposure to toxicants may not reflect perinatal vulnerability. As a result, direct life stage comparisons are needed to establish doseresponse relationships, target organ sensitivities, and expected immunotoxic changes. This study compared gestational vs. adult life stages for suceptibility to dexamethasone-induced immunotoxicity including selected developmental-reproductive endpoints. Dexamethasone-21 phosphate was administered (s.c.) to pregnant CD rats at days 6-21 of gestation (0, 0.0625, 0.125, 0.25, 0.5 mg/kg/day) with identical exposure of non-pregnant adult females. Some reproductive (anogenital distance) and growth (body weight) measures of pups were altered. In the juvenile (5 wk.), the delayed type hypersensitivity response to KLH was significantly reduced at all doses examined and this pattern continued into adulthood (13 wk.). In contrast, the DTH response of adults exposed to DEX was unaltered even at the highest dose. Few DEX-induced changes were seen in offspring or adult blood parameters or in splenocytes analyzed for cell surface makers (by flow cytometry). The thymus of both exposed pups (both ages) and adults showed a marked reduction in the medulla/lobe area beginning with the 0.125 mg/kg/day DEX exposure level. Macrophage production of TNF and NO was only marginally affected as was splenocyte production of IL-4 and IFN gamma. In contrast, pups assessed as juveniles were significantly depressed in splenic IL-2 and IL-10 production. DEX exposure altered serum antibody levels across age groups with an increase of KLH-specific IgG (beginning with the 0.0125 mg/kg/day dose) while total IgE was reduced. These results suggest that while DEX exposure produces some common alterations following *in utero* vs. adult exposure, fetal exposure (even at the lowest doses tested) produces marked and persistent functional loss (DTH) not evident in exposed

adults. Furthermore, there was no apparent advantage in delaying immune assessment until the offspring reached adulthood. Supported by a grant from the American Chemistry Council.

DEVELOPMENTAL EXPOSURE TO A THYROID DISRUPTING CHEMICAL STIMULATES PHAGOCYTOSIS IN JUVENILE SPRAGUE-DAWLEY

A. A. Rooney<sup>1</sup>, R. Matulka<sup>2</sup> and <u>R. W. Luebke<sup>3</sup></u>. <sup>1</sup>CVM Department of Anatomy, Physiological Sciences and Radiology, NCSU/USEPA, Raleigh, NC, <sup>2</sup>Department of Toxicology, UNC, Chapel Hill, NC and <sup>3</sup>USEPA/NHEERL, Research Triangle Park, NC.

During development, exposure to xenobiotics that disrupt the thyroid-axis may adversely impact growth and reproduction through reduced thyroid hormone (TH) concentrations. The regulatory role of THs within the immune system suggests immune function may also be negatively effected. In a previous study we observed increased phagocytic activity of peritoneal macrophages from 7-week-old offspring of Sprague-Dawley (SD) dams exposed to the anti-thyroid drug propylthiouracil (PTU, 2.0 mg/kg/day). The current study tested phagocytic responses in offspring of dams exposed to 0.02, 0.2 or 2.0 mg PTU/kg/day from gestational day 10 through post-natal day (PND) 23. Serum triidothyronine (T<sub>3</sub>) and thyroxine (T<sub>4</sub>) were measured by RIA on PNDs 14, 21, 35, 49 and 101, while peritoneal macrophage phagocytosis was measured during the time frame that offspring recover from a hypothyroid to an euthyroid state (PNDs 21, 35 and 49) to examine the relationship between phagocytic responses and circulating THs. On PND 14, mid dose offspring had lower  $T_4$  and high dose offspring had lower THs. Reduced  $T_4$  persisted in high dose offspring through PND 21 (females) and PND 49 (males). Also in high dose offspring, an increased percentage of macrophages phagocytized latex beads on PNDs 35 and 49; however, phagocytic activity was not correlated to serum THs. These results demonstrate that only developmental exposure to high doses of PTU (sufficient to cause cretinism and severely retard growth) were associated with increased phagocytic response, and that increase was only observed in rats greater than 3 weeks of age. The high doses of PTU necessary to alter phagocytosis and the lack of a clear relationship between serum THs and phagocytosis indicate that phagocytic response of peritoneal macrophages is not a sensitive indicator of developmental hypothyroidism.(This abstract does not reflect EPA policy and was supported in part by the NCSU/EPA Cooperative Training Agreement CT826512010).

471

BOTH ADULT AND DEVELOPMENTAL EXPOSURES TO NEVIRAPINE INCREASED NK CELL ACTIVITY BUT DECREASED SPLEEN ANTIBODY-FORMING CELL (AFC) RESPONSE TO T-DEPENDENT ANTIGEN SHEEP ERYTHROCYTES (SRBC) IN FEMALE B6C3F1 MICE.

T. L. Guo<sup>1</sup>, D. R. Germolec<sup>2</sup>, D. L. Musgrove<sup>1</sup>, R. P. Chi<sup>1</sup> and <u>K. L. White<sup>1</sup></u>.

<sup>1</sup>Virginia Commonwealth University, Richmond, VA and <sup>2</sup>NIEHS, Research Triangle Park. NC.

Nevirapine is a non-nucleotide reverse transcriptase inhibitor of HIV-1, and often used for combination therapy. Nevirapine binds directly to reverse transcriptase and blocks the RNA-dependent and DNA-dependent activities by causing a disruption of the enzyme function. In addition to being used for HIV adult patients, nevirapine has also been applied increasingly to prevent mother-to-child HIV-1 transmission. Thus, the immunotoxicity associated with both adult and developmental exposures to nevirapine is a great concern. We have evaluated the changes in immune responses in female B6C3F1 mice following exposure to nevirapine at dose levels of 0, 88, 176, and 266 mg/kg. In adult mice, exposure to nevirapine by gavage (twice/day) for 28 days had no effects on body weight, hematological parameters, mixed lymphocyte reaction and anti-CD3 mediated proliferation in spleen. However, a dose-related decrease in spleen AFC response to sRBC and an increase in NK cell activity were observed. In developmental exposure, pups were exposed gestationally and lactationally starting at gestation day 5 by dosing dams (gavage) twice a day and by gavage (once/day) starting at PND3. After weaning at PND21, pups continued to be dosed by gavage twice a day until PND45. There was no effect on hematological parameters. However, in agreement with the adult exposure, a dose-related decrease in spleen AFC response to sRBC and an increase in NK cell activity were observed. Furthermore, developmental exposure produced more decreases in spleen AFC response to sRBC than adult exposure. In conclusion, exposure to nevirapine decreases antibody-forming cell responses and increase NK cell activity in both adult and young mice (Supported by the NIEHS Contract ES 05454).

472

THE EFFECTS OF EARLY EXPOSURE OF ENDOSULFAN, PIPERONYL BUTOXIDE AND PERMETHRIN ON IMMUNE FUNCTION OF ADULT MICE.

G. E. Pimentel-Smith¹ and H. P. Misra². ¹ Vet. Med., Virginia Tech, Blacksburg, VA and²Division of Biomedical Sciences, Edward Via College of Osteopathic Medicine, Blacksburg, VA.

Newborns exposed to certain pesticides may not only have immediate effects on immune function but also may develop latent effects at adult life. We studied the effects of permethrin (PR) on adult (11 week-old) mice pre-exposed as juveniles (6-7 days old) with either the insecticide endosulfan (EN; a MFO inducer) or pesticide synergist piperonyl butoxide (PBO; a MFO inhibitor). Groups of 12 juvenile C57Bl/6 mice were injected i.p. with either EN or PBO on days 1 and 3, and allowed to grow up to 11 weeks. At 11 weeks, half of each group was given EN or PBO singly or in mixture with PR, i.p. Control groups received cyclophosphamide (positive) and PBS or corn oil (CO; negative). Doses were 1/8 LD50 (Merck Index) in 10-μl vehicle for juveniles and 1/4 LD50 in 80-μl vehicle for adults. One day after the last dose, all mice were injected with 1ml of 5% sheep red blood cell (SRBC) and sacrificed 4 days later. The immune parameters of splenocytes were analyzed. The results of flow cytometric analysis of cells, using PE- and FITC-labeled monoclonal antibodies, showed higher percentages of splenocytes in early apoptotic stage (P<0.05) in all chemical-exposed groups than the controls. All pesticide treated groups were found to have lower numbers of plaques (P<0.05) using the SRBC-PFC assay, except the EN+PR group. There were no differences observed in spleen weights. The PBO, PR and PBO+PR treatment groups exhibited higher number of total splenocytes (P<0.05). These results indicate that exposure of mice to these pesticides at early life may cause immune dysfunction later in life.

473

PRENATAL MERCURIC CHLORIDE [HGCL2] EXPOSURE IN BALB/C MICE: GENDER-SPECIFIC EFFECTS ON THE ONTOGENY OF THE IMMUNE SYSTEM.

I. A. Silva<sup>1,3</sup>, M. El Nabawi<sup>2</sup>, D. Hoover<sup>2</sup> and E. <u>Silbergeld</u><sup>3</sup>. <sup>1</sup>Institute Molecular Cell Biology, Porto, Portugal, <sup>2</sup>University Maryland Medical School, Baltimore, MD and <sup>3</sup>Environmental Health Sciences, Johns Hopknis University Bloomberg School Public Health, Baltimore, MD.

Mercury (Hg) is a well known developmental toxicant, with devastating effects associated with in utero exposure in humans and animal models. However, this characterization is based exclusively upon the neurodevelopmental effects of prenatal exposures. Because the immune system also undergoes prolonged development preand postnatally, and because Hg is known to be immunotoxic to adult animals, we tested the hypothesis that in utero exposure to HgCl2 would induce persistent immune dysfunction. Pregnant BALB/c females were treated every other day from GD5 for 11 days with s.c. injections of HgCl2 (200mcg/kg body weight); controls received equimolar injections of NaCl2. Offspring were sacrificed at PND10, 14, 21, and 60. Lymph nodes, (LN), spleens, and thymus were harvested for studies of proliferation and cytokine production in vitro. In utero HgCl2 exerted persistent organ specific effects on cell number, proliferation, and cytokine production in LN, spleen and thymus. The effects of prenatal HgCl2 exposure were expressed differently in adult females and males. In adult females, an inhibitory effect was observed on IL-4, IL-10 and IFN-gamma production in thymocytes, IL-2 in LN cells, and IL-10 in splenocytes. In males, a stimulatory effect was primarily observed. Overall, we conclude that in utero exposures to low doses of HgCl2 can induce persistent gender-specific immunotoxic effects, observable in adulthood. Research supported by Heinz Family Foundation and Cure Autism Now Foundation.

### 474 POSTNATAL EXPOSURE TO THIMEROSAL ALTERS IMMUNOLOGICAL FUNCTION IN ADULT MICE.

M. M. Peden-Adams<sup>1</sup>, J. EuDaly<sup>1</sup>, H. Lauren<sup>1</sup>, J. Smythe<sup>1</sup> and <u>D. E. Keil<sup>2,1</sup></u>.

<sup>1</sup>Medical University of South Carolina, Charleston, SC and <sup>2</sup>NIOSH, Morgantown, WV.

Infantile autism (IA) is a neurodevelopmental syndrome found in 1-5 of every 10, 000 children. The cause of IA is unknown; however, exposure to mercury is thought to contribute to this syndrome. More specifically, childrens vaccines containing mercuric compounds such as Thimerosal (TH) have been suggested to increase risk for acquiring neurodevelopmental problems such as autism. Pathophysiological links to autism include effects such as hyperserotoninemia, decreased T-cell proliferative function and activation, increased soluble IL-2 levels in serum, decreased CD8+ cells, decreased NK cells, development of anti-brain autoantibodies, decreased cerebellum volume and Purkinje cell number, and increased brain size. TH contains ethylmercury and the most commonly reported effects include contact hypersensitivity, allergic contact dermatitis, and altered T-cell responses. As several of the reported pathophysiologies are related to altered immunity we assessed the effects of TH on immune function. B6C3F1 mice were injected i.p. with TH (0, 20, 100, or 200  $\mu$ g/kg) at 7, 10, and 12 days of age. A

suite of immune parameters including secondary immune organ weights and cellularity, T- and B-cell proliferation, NK cell function, and T-cell immunophenotyping were assessed along with developmental markers such as eye opening, ear unfolding, body weight and length, and brain weight at 8 weeks of age. Body weight was decreased while brain weight was increased following treatment with 20  $\mu g/kg$  TH. NK cell function was increased after exposure to 200  $\mu g/kg$  TH. Thymus weight and cellularity were not altered; however, splenic cellularity was increased by the 100 and 200  $\mu g/kg$  treatments. Splenic B220 cells were increased by the 100 and 200  $\mu g/kg$  treatments while CD4-/CD8+ and CD4+/CD8- cells were increased after the 200  $\mu g/kg$  exposure. This study identifies that postnatal exposure to TH can modulate the developing murine immune system.

475 DERMAL EXPOSURE TO JP-8 JET FUEL DURING PREGNANCY ALTERS IMMUNOLOGICAL FUNCTION IN F1 MICE.

D. E. Keil<sup>1, 2</sup>, L. Butterworth<sup>1</sup>, S. Azadi<sup>1</sup> and <u>M. Peden-Adams<sup>2</sup>. <sup>1</sup>NIOSH</u>, Morgantown, WV and <sup>2</sup>Medical University of South Carolina, Charleston, SC.

Approximately 5 billion gallons of JP-8 jet fuel (JP-8) are used annually by the United States Department of Defense (DOD) making this the single largest chemical exposure to military personnel. In addition, the aviation industry extensively uses commercial jet fuel which is essentially JP-8 without certain additives for antiicing, corrosion, and static dissipation. Civilian exposure can occur as well through environmentally contaminated sites where jet fuel has been reportedly spilled or leaked from supply lines or storage tanks. Many reports indicate that JP-8 alters immunological function in adult rodents. However, little is known regarding its impact on the developing immune system. Therefore, C57BL/6N pregnant dams (mated with C3H/HeJ males) were dermally exposed with 10, 25, 50, or 75 µL neat applications of JP-8 daily during gestation days 6-15. F1 offspring were evaluated for immunological alterations at 3 and 8 weeks of age. There were no treatment effects on body, liver, kidney, or thymus mass. Although slight, an increase in spleen mass and cellularity was observed at both 3 and 8 weeks. T-cell proliferation following anti-CD3 stimulation was not affected at either age. However, IgM plaque forming cell (PFC) responses were significantly suppressed in 3 week old pups exposed to 50 or 75 µL JP-8 and in all treatment groups at 8 weeks of age. Our data indicate that prenatal dermal exposure to JP-8 can affect the developing murine fetus resulting in impaired humoral immune responses detectable at adulthood.

476 PHENOTYPICALLY ALTERED MURINE BONE MARROW SUBSETS EXPRESS AND ACTIVATE THE AHR IN RESPONSE TO TCDD.

<u>A. Wyman</u> and <u>T. A. Gasiewicz</u>. Environmental Medicine, University of Rochester, Rochester, NY

2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD), acting through the aromatic hydrocarbon receptor (AhR), elicits numerous toxicological effects, including those to the bone marrow (BM). Phenotypic alterations to BM subsets have been demonstrated, but the mechanism for these alterations is unknown. Additionally, the presence and functionality of AhR has been shown in crude BM but not in phenotypically defined subsets. To address this, crude BM from male C57Bl6 mice was harvested, stained with either biotinylated anti-B220 or lineage specific antibodies, and enriched for B220+ cells or Lin- cells using magnetic separation. Real-time RT-PCR and Western blot indicated the presence of AhR in both subsets of BM. The presence of Arnt protein in Lin- subsets was also confirmed by Western blot. Activation of AhR was assessed using a transgenic mouse line expressing LacZ under the control of dioxin responsive elements (DREs) in the promoter region. After 10h treatment, LacZ mRNA was induced in mice treated with TCDD as compared to vehicle. Phenotypic changes in progenitor cells were assessed by dosing C57Bl6 male mice with 30 mg/kg BW TCDD in olive oil (or vehicle alone). BM was harvested at 12, 24, 48, 72 hours, and 5, 7, 9, 11, 13, and 15 days, enriched for Lin- cells by magnetic depletion and stained with a cocktail of antibodies: Sca-1 PE, cKit APC, and either CD34 FITC or TdT-FITC. When compared to vehicle, TCDD-treated cKit hi/Sca-1+ cell populations were significantly increased. The increase peaked at 250% of vehicle at 5 days, and decreased to near vehicle levels by day 15. cKit lo/Sca-1+ cell populations increased less, peaking at 150% of vehicle at 9 days. cKit/Sca-1/34+ cells showed even less of an increase, peaking at approximately 110% at 3 and 9 days post treatment. TdT+ cells decreased with TCDD treatment but recovered to vehicle levels by 13 days. The data suggests a more profound effect of TCDD treatment upon less committed cell populations, mediated by the presence of the AhR. (Funded by NIEHS Grant ES04862, Training Grant ES07026 and Center Grant ES01247)

477 REDUCTION IN THE NUMBER OF SUPERANTIGEN-SPECIFIC T CELL DIVISIONS INDUCED BY 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN RESULTS FROM

INCREASED APOPTOSIS.

L. S. Faulconer<sup>1</sup>, I. A. Camacho<sup>1</sup>, P. S. Nagarkatti<sup>1</sup> and M. Nagarkatti<sup>2</sup>.

<sup>1</sup>Department Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA and <sup>2</sup>Department of Microbiology and Immunology, Virginia Commonwealth University, Richmond, VA.

The precise mechanism by which 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) decreases antigen-specific T cell responsiveness is not clear. In the current study, we investigated the ability of T cells activated with staphylococcal enterotoxin A (SEA) to divide following exposure to TCDD by labeling the cells with 5, 6-carboxyfluorescein diacetate succinimidyl ester (CFSE) and analyzing them using a flow cytometer. To this end, female C57BL/6 mice were injected i.p. with 10 µg/kg bodyweight of TCDD followed by hind footpad injections of 10µg/footpad SEA. The popliteal lymph nodes (LN) were harvested on days one through four, labeled with CFSE and analyzed using a flow cytometer following 1-4 days of in vitro culture. In addition, the lymphocytes were analyzed for cells expressing V $\beta$ 3 or V $\beta$ 11 that become activated by SEA, as well as tested for apoptosis using TUNEL assay. Analysis using CFSE showed that TCDD-exposed lymphocytes exhibited a clear reduction in the number of cell divisions when compared to the vehicle controls. Even after reactivation in vitro with SEA, the lymphocytes from TCDD-treated mice demonstrated a decrease in the number of cell cycle progressions when compared to vehicle-treated mice. Also, exposure to TCDD caused a decrease in the percentage and total numbers of VB3+ and VB11+ cells. Moreover, increased levels of apoptosis were detected in the lymph nodes and in  $V\beta 3/V\beta 11$  T cell subpopulations following TCDD treatment. Together, these data demonstrate that TCDD-induced apoptosis in SEA-activated T cells in vivo may account for decreased cell division and a consequent immunosuppression. (This work was supported in part by grants from National Institutes of Health R01ES09098, R01DA016545, R01AI053703, F31ES11562, R21DA014885, and R01HL058641)

478 EVIDENCE FOR INDUCTION OF APOPTOSIS IN T CELLS FROM MURINE FETAL THYMUS FOLLOWING PERINATAL EXPOSURE TO 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD).

P. S. Nagarkatti<sup>1</sup>, I. A. Camacho<sup>2</sup> and M. Nagarkatti<sup>2</sup>. <sup>1</sup>Department of Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA and <sup>2</sup>Department of Microbiology and Immunology, Virginia Commonwealth University, Richmond, VA.

Perinatal exposure to 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) causes thymic atrophy, but the precise mechanism of such toxicity remains unresolved. The current study investigated the role of apoptosis in TCDD-induced thymic involution following perinatal exposure to TCDD. To this end, C57BL/6 pregnant mice were injected intraperitoneally on gestational day (gd) 14 with a single dose of 10 μg/kg TCDD. Analysis of the thymus on gd-15, gd-16, gd-17, gd-18 and on postnatal day (PD) 1, showed a remarkable reduction in thymic cellularity 3-7 days after TCDD exposure. TCDD treatment also caused marked changes in the proportions of T-cell subsets, particularly on gd-17 and gd-18 thymocytes. In vitro culture of TCDD-exposed fetal or neonatal thymocytes showed increased apoptosis when compared to the controls, which peaked on gd-17. Triple-color staining involving CD4, CD8 and TUNEL showed that all four subpopulations of T cells underwent apoptosis following TCDD exposure, with the double-positive T cells undergoing the highest level. Moreover, increased cleavage of caspase-3 was seen when TCDD-exposed gd-17 thymocytes were directly tested. Furthermore, apoptosis-associated phenotypic changes were found in TCDD-treated neonatal thymocytes, which exhibited an increase in expression of CD3, αβTCR, IL-2R and ĆD44, but a decrease of CD4, CD8 and J11d markers. Finally, TCDD-exposed fetal and neonatal thymocytes had higher levels of Fas, TRAIL and DR5 mRNA, but the levels of Bcl-2, Bcl-xL and Bax were either unaltered or changed moderately. Taken together, these results suggest that TCDD-induced thymic atrophy following perinatal exposure may result, at least in part, from increased apoptosis mediated by death receptor pathway involving Fas, TRAIL and DR5. (This work was funded in part by grants from National Institutes of Health R01ES09098, R01 AI053703, R01 DA016545, F31ES11562, R21DA014885 and R01HL058641).

479 CONSEQUENCES OF TCDD EXPOSURE ON THE MIGRATION, PROLIFERATION, AND SURVIVAL OF ANTIGEN-SPECIFIC T CELLS.

C. Funatake<sup>1</sup>, L. Steppan<sup>1</sup>, E. Spanjaard<sup>2</sup>, A. Marshak-Rothstein<sup>2</sup> and N. Kerkvliet<sup>1</sup>. <sup>1</sup>Oregon State University, Corvallis, OR and <sup>2</sup>Boston University School of Medicine, Boston, MA.

Previous studies have shown that TCDD causes a significant decline in the number of antigen-specific DO11.10 T cells in the spleens of mice following immunization with OVA. The loss of T cells follows what appears to be enhanced T cell activation

(primarily evident as decreased expression of CD62L and, to a lesser extent, enhanced cell cycling) in TCDD-treated mice on days 2 and 3 post-antigen. In the studies presented here, we examined three potential mechanisms for the loss of antigen-activated T cells in TCDD-treated mice: enhanced emigration out of the spleen, premature cessation of proliferation, and induction of cell death. TCDD significantly enhanced the number of antigen-specific T cells in the blood on day 3 post-antigen, which is consistent with TCDD promoting T cell activation. However the activated T cells in TCDD-treated mice failed to upregulate expression of CD11a, which is important for the extravasation of activated T cells. Thus, the T cells may have been trapped in the blood. CSFE staining showed that antigen-activated T cells continued to proliferate in vehicle-treated mice on day 4 after antigen exposure, whereas no additional cycling was observed in T cells from TCDD-treated mice after day 3. TCDD also induced an increase in apoptosis of activated T cells but not until days 5 and 6, arguing against enhanced cell death as the precipitating cause of the decline in T cells. Since T cells from D011.10<sup>lpr/lpr</sup> mice declined in a similar manner as normal T cells, the depletion of antigen-activated T cells by TCDD did not occur by a Fas-dependent process. Gene array analysis on day 3 indicated that TCDD increased the expression of several genes associated with cell survival/death. Taken together, these results suggest that TCDD induces an early but dysregulated activation of T cells, resulting in altered migration, truncated proliferation and reduced survival. Supported by NIH Grants P01ES00040, P30ES00210 and T32ES07060.

## 480 EXAMINING POSSIBLE MECHANISMS UNDERLYING PULMONARY NEUTROPHILIA IN VIRUS-INFECTED MICE TREATED WITH TCDD.

S. Teske<sup>2, 1</sup>, L. Harrison<sup>1</sup>, J. Neumiller<sup>1</sup> and <u>B. Lawrence<sup>1, 2</sup>, <sup>1</sup>Pharmaceutical Sciences, Washington State University, Pullman, WA and <sup>2</sup>Pharmacology/Toxicology Graduate Program, Washington State University, Pullman, WA.</u>

The immune system is one of the most sensitive targets of the pollutant 2, 3, 7, 8tetrachlorodibenzo-p-dioxin (TCDD). Our laboratory studies this immunosuppression using a murine-adapted model of human influenza virus infection. In addition to impairing the adaptive immune response to influenza virus, exposure to TCDD induces pulmonary neutrophilia. Neutrophils release cytotoxic meditors at the site of infection, and excess mediator release can damage healthy tissue. Neutrophil-mediated tissue insult may explain the enhanced mortality that we observe in virus-infected mice treated with TCDD. In fact, *in vivo* depletion of neutrophils improves host resistance in TCDD-treated mice. To determine the mechanism leading to pulmonary neutrophilia, we examined whether neutrophil chemoattractants are enhanced in the lung, adhesion molecules on neutrophils are up-regulated, or neutrophil apoptosis is delayed. Among neutrophil chemoattractants, we evaluated tumor necrosis factor (TNF)-α, interleukin (IL)-1, macrophage inflammatory protein (MIP)-1α, MIP-2, keratinocyte chemoattractant (KC), and lipopolysaccharide-induced CXC chemokine (LIX). Our results show similar levels of these mediators in both treatment groups. Using flow cytometry, we examined the following adhesion molecules on pulmonary neutrophils: CD11a, CD11b, CD11c, CD49d, CD31, CD38, and CD62L. Treatment with TCDD does not enhance the expression of any of these molecules. We studied neutrophil apoptosis using Annexin V and 7-AAD to distinguish viable, apoptotic, and necrotic neutrophils. We also measured CD16 expression, since low levels of CD16 correlate with neutrophils undergoing apoptosis. Although we observed decreased CD16 expression on neutrophils from TCDD-exposed mice, exposure to TCDD did not alter the percent of apoptotic neutrophils. Collectively, our data indicate that TCDD likely promotes neutrophil recruitment via indirect mechanisms, such as changes in adhesion molecules on lung epithelium and endothelium.

### 481 EFFECTS OF SILICA ON *IN VITRO*-GENERATED MACROPHAGE SUBSETS.

C. T. Migliaccio and <u>A. Holian</u>. Department of Biomedical & Pharmaceutical Sciences, Center for Environmental Health Sciences, University of Montana, Missoula, MT.

Inhalation of silica can result in chronic inflammation and fibrosis with a decrease in lung function and an increase in susceptibility to autoimmune diseases. Under normal conditions the lung is considered an immune-suppressed organ; however, following exposure to silica the environment becomes chronically immune-activated. A major component of lung immunology is the pulmonary macrophage. Alveolar macrophages (AM) have been implicated as playing a pivotal role in silicosis, including phagocytic uptake of silica. In general, macrophages have the ability to regulate immune responses by performing the role of intermediary between the innate and adaptive immune systems. Recently macrophage subtypes have been described in the mouse with categories including alternatively activated, classically activated, and type-II activated. The subtypes are defined by surface protein expression (i.e. MHC class II, scavenger receptor) and cytokine profile and have potential

counterparts in the human. Using bone marrow-derived macrophages we generated these three subtypes by culturing with interferon (IFN)-gamma, interleukin (IL)-13, or IL-4 with either soluble or complexed antigen. We then examined the effects of silica exposure on the subtypes for phenotypic changes as determined by flow cytometry and functional assays. Our functional assays include macrophage cytokine ELISA and antigen presenting cell (APC) cultures and cytokine ELISA. Results demonstrated differential surface marker expression among the subtypes, as well as APC capacity. The type II, and to a lesser extent the classic and alternative, subsets have presented with an increase in APC function when exposed to silica. Our current studies suggest that an increase in macrophage function as a result of silica exposure could be an explanation as to the chronic inflammatory environment presented in silicosis. This work is supported by NIH grants ES 04804 and RR-017670

### 482 SILICA STIMULATES PHOSPHORYLATION AND ACTIVATION OF AKT IN MURINE ALVEOLAR

C. A. Wishcamper and <u>A. Holian</u>. *Pharmaceutical and Biomedical Sciences, University of Montana, Missoula, MT.* 

Silicosis is an occupational lung disease caused by the inhalation of silica particles which results in chronic inflammation and progressive pulmonary fibrosis. Phagocytosis of silica by alveolar macrophages (AM) and subsequent activation is a crucial step in the pathogenesis of silicosis. AM release oxygen free radicals and lysosomal enzymes, as well as proinflammatory mediators that propagate inflammation, induce programmed cell death, and promote aberrant cell survival. However, the participation of specific intracellular signaling pathways in regulating the AM response to silica have not been fully elucidated. The serine/threonine protein kinase Akt is activated downstream of phosphatidylinositol 3-kinase and has been shown to regulate diverse cellular processes implicated in mediating a variety of biological responses that include inhibition of apoptosis, promotion of cellular growth, and control of metabolism. To elucidate the role of Akt in silica induced chronic inflammation, we examined lavage fluid and lung sections from Balb/c mice post-silica exposure. Mice received either no treatment or 500µg silica once a week for four weeks. Lavage fluid was collected using 1ml PBS, while whole lungs were fixed and processed for trichrome and immunostained for activated Akt (n=5). Following chronic silica exposure, significantly increased levels of IL-10 and TNF $\alpha$ (p<0.05, p<0.10, respectively) were observed in the lavage fluid of silica exposed mice compared to no treatment. Fluorescence immunostaining demonstrated visible increases in the presence of the activated form of Akt between 0 and 8 weeks, with decreased immunostaining for phospho-Akt observed by 16 weeks. These data emphasize the need to examine the Akt signaling cascade in the AM response to silica exposure. Furthermore, a better understanding of the molecular events involved in regulating the AM response to silica exposure may permit targeting of specific biochemical pathways for more effective diagnosis and treatment of occupational lung diseases.

# REPEATED EXPOSURE TO DIESEL EXHAUST PARTICLES CAUSES SUPPRESSION OF CELL-MEDIATED IMMUNE RESPONSES TO *LISTERIA* INFECTION IN BROWN NORWAY RATS.

X. J. Yin<sup>1</sup>, C. C. Dong<sup>1</sup>, <u>J. Y. Ma</u><sup>2</sup>, <u>J. M. Antonini</u><sup>2</sup>, <u>J. R. Roberts</u><sup>2</sup> and J. K. Ma<sup>1</sup>. <sup>1</sup>School of Pharmacy, West Virginia University, Morgantown, WV and <sup>2</sup>HELD, NIOSH, Morgantown, WV.

Diesel exhaust particles (DEP) have been shown to alter pulmonary immune responses to bacterial infection. However, the in vivo effect of DEP exposure on the T cell-mediated immune responses against bacterial infection has not been clearly demonstrated. Here, we examined the effects of repeated DEP exposure on pulmonary responses to bacterial infection. Brown Norway rats were exposed to DEP by inhalation at  $20.62 \pm 1.31$  mg/m<sup>3</sup>, 4 hr/day for 5 days, followed by intratracheal inoculation with 100, 000 Listeria at 2 hours after the last DEP exposure. DEP-exposed rats showed a significant increase in lung bacterial load at both 3 and 7 days post-infection. The repeated DEP exposure was shown to suppress both the innate, orchestrated by alveolar macrophages (AM), and T-cell mediated responses to Listeria. DEP inhibited production of interleukin-1β (IL-1β), tumor necrosis factor-α, and IL-12 by AM, but enhanced Listeria-induced production of IL-10, which has been shown to prolong the survival of intracellular pathogens such as Listeria. DEP exposure also suppressed the development of bacteria-specific lymphocytes from lung-draining lymph nodes, as indicated by the decreased numbers of T lymphocytes and their  $CD4^{+}$  and  $CD8^{+}$  subsets. In addition, the DEP exposure markedly inhibited the Listeria-induced lymphocyte secretion of IL-2 at day 7, IL-10 at days 3 and 7, and interferon-γ at days 3 to 10 post-infection when compared to air-exposed controls. These results show a sustained pattern of down-regulation of T-cell mediated immune responses by repeated low-dose DEP exposure,

which is different from the results of a single high dose exposure (100 mg/m $^3$ , 4 hours), where the acute effect of DEP aggravated bacteria infection but triggered a strong T cell-mediated immunity.

## 484 PARTICULATE MATTER IMMUNOMODULATORY EFFECT ON THE PROGRESSION OF AUTOIMMUNE DISEASE IN NEW ZEALAND MIXED MICE.

M. Hassani, J. M. Brown and A. Holian. Center for Environmental Health Sciences, The University of Montana, Missoula, MT.

In this study we examined whether particulate matter exposures would impact the progression of autoimmune disease in a lupus-prone New Zealand mixed (NZM) model. NZM mice were intranasally instilled with either 30 µl saline or a 30 µl saline suspension of 500 µg acid washed PM1648, PM1648 or PM2.5 collected in Houston, TX, once a week for 4 weeks. Mortality and proteinuria levels did not significantly change among the groups. Levels of anti-nuclear antibodies (ANA) were evaluated 4 and 16 weeks following PM instillation by ELISA. All three particulates significantly suppressed the natural development of ANA in the NZM mice. There were no significant differences in the serum levels of IFN-γ, IL-12, and IL-4 among the groups 17 weeks post-PM instillation except for IL-10, which was significantly decreased in the particulate-instilled mice. IgG serum levels were significantly decreased in the PM1648 and PM2.5 instilled mice at 6 weeks following particulate instillation as compared to the saline and acid washed PM1648 instilled groups. Serum levels of IgG subclasses were also measured; IgG2b serum levels were significantly increased in the PM2.5 instilled mice as compared to the saline instilled group at 4 weeks following PM instillation, whereas the PM1648 and PM2.5 instilled mice showed significant decrease in IgG3 serum levels as compared to the control at the same time point. Significant reduction in the levels of serum IgM as compared to the saline group was observed in the PM1648 instilled mice during the first 6 weeks post-particulate-instillation period. There were also slight increases in the amount of immune cell infiltration and fibrosis within the PM 1648 and PM2.5 groups in comparison with the control group. Taken together, the results support the notion that PM modulates the immune system towards a Th2 response, thereby decreasing the effect of a Th1 mechanism of autoimmune disease in the NZM model. This work was supported by NIH grants ES 11120 and RR-017670.

### TRICHLOROETHYLENE DOES NOT ACCELERATE AUTOIMMUNE DIABETES IN NOD MICE.

G. Ravel<sup>1, 2</sup>, M. Christ<sup>1</sup>, F. Condevaux<sup>1</sup> and <u>J. Descotes<sup>2</sup></u>. <sup>1</sup>MDS Pharmacology Services, L'Arbresle, France and <sup>2</sup>Poison Center & INSERM University 503, Lyon, France.

Trichloroethylene (TCE) is an environmental contaminant suspected of inducing immunological changes in human after exposure via the drinking water. Previous studies showed that TCE exposure could be linked to autoimmune diseases in susceptible human beings. Increases in antinuclear auto-antibodies and serum immunoglobulin levels, and activation of CD4+ T cells producing Th1-type cytokines have been observed in TCE-treated female MRL +/+ mice. In order to confirm these findings, the effects of TCE exposure were evaluated in another animal model of autoimmune diabetes, the female non obese diabetics (NOD) mouse. Sixty mice were given 0 or 5 mg/ml TCE via the drinking water for 12 weeks starting at 11 weeks of age. Blood glucose levels were measured every two weeks. Blood samples were analysed every 4 weeks for Th1/Th2 cytokine profile including IL-4, IL-5, IL-2, IL-12 and IFN- $\gamma$  by flow cytometry. Cell surface expression of CD44, CD45RB and CD54 on peripheral and splenic CD4+ T lymphocytes was analyzed to evidence possible T cell activation in TCE-treated mice. The mice were killed after 4, 8 or 12 weeks of treatment and a fragment of the spleen was isolated for lymphocyte subset analysis. There were no treatment-related effects on blood glucose levels or on histopathology findings at any time points. TCE did not affect the Th1/Th2 cytokine balance and peripheral and splenic T lymphocyte analysis did not indicate T cell activation. Our results suggest that TCE exposure does not accelerate autoimmune diabetes in female NOD mice. This finding is in sharp contrast with effects previously reported in female MRL +/+ mice. It is also concluded that the selection of relevant animal species or strains for the prediction of autoimmunity in preclinical immunotoxicity evaluation is not straightforward.

ANALYSIS OF TARGET ANTIGENS FOR AUTOANTIBODIES ASSOCIATED WITH ASBESTOS EXPOSURE.

I. Leal, A. Holian and J. Pfau. Biomedical and Pharmaceutical Sciences, University of Montana, Missoula, MT.

Environmental exposures to particles such as asbestos have been associated with systemic autoimmune disease. Previous studies on a population in Libby MT that have been significantly exposed to asbestos have found that these individuals appear

to have an increased frequency of positive ANA (antinuclear antibodies) tests compared to a matched population in Missoula, MT. The goal of this study was to determine if previous positive ANA tests performed in this population were specific for chromatin and double stranded DNA (dsDNA) through the use of Enzyme Linked Immunosorbent assays (ELISAs) and Crithidia luciliae testing, respectively. Our study also aimed to determine if the anti-ENA (Extractable Nuclear Antigen) levels would also be higher in these individuals measured by ELISA, and addressable bead array (LUMINEX). Additionally, mean autoantibody titer for ANAs were performed to determine if there would be a significant change between exposed individuals and those in the control population. The results showed that the percent ANA positive and the mean autoantibody titer for ANAs were significantly higher in the Libby group than those of the Missoula group. The results of tests for antibodies to chromatin and dsDNA on 40 coded samples proved to be negative suggesting that the target for ANA antibodies in these individuals may be histone. The scl-70 ELISA and ENA addressable bead array indicated that those individuals exposed to asbestos had significantly higher ENA scores, particularly for Scl-70, SS-A and SS-B than those in the Missoula control population. These antibodies are commonly seen in autoimmune diseases such as scleroderma and Sjogrens syndrome. These results demonstrate the upregulation of specific autoantibodies in an asbestos-exposed population, and begin to identify some of the specific targets for these autoantibodies. This work was supported by NSF EPSCoR and CDC Grant CCR-822092.

DIFFERENCES IN HEPATOTOXICOLOGICAL PROFILE OF ET-743 BETWEEN SPRAGUE-DAWLEY RATS AND CYNOMOLGUS MONKEYS.

R. De Coster<sup>1</sup>, J. Verbeeck<sup>1</sup>, A. Vynckier<sup>1</sup>, A. Looszova<sup>1</sup>, K. Anciaux<sup>1</sup>, L. Lammens<sup>1</sup>, N. Bode<sup>1</sup>, W. Coussement<sup>1</sup> and P. Aviles<sup>2</sup>. \*Global Preclinical Development, Johnson Johnson Pharmaceutical Research Development, Beerse, Belgium and PharmaMar, Colmenar Viejo, Spain.

Yondelis  $^{\text{TM}}$  (trabectedin, ET-743) is a marine-derived compound under investigation in phase II trials and has shown activity in ovarian, breast and advanced pretreated soft tissue sarcoma. In patients, drug-induced toxicities are non-cumulative neutropenia, reversible increases in transaminases and fatigue. The hepatotoxic potential of Yondelis<sup>TM</sup> was evaluated in repeated dose studies in rodent (Sprague-Dawley rats) and non-rodent models (Cynomolgus monkeys). The latter were chosen as the preferred non-rodent species due to the similarities in metabolic profile to that of humans. In these studies, ET-743 was administered via a 3-hour intravenous infusion every 3 weeks for 3 (rat) or 4 (monkey) cycles, or weekly for 3 weeks followed by 1 week without treatment (3 cycles). After repeated dosing in rats, mortality was observed at 50  $\mu g/kg$  in females and at 50-75  $\mu g/kg$  in males. A pronounced dose-dependent and only partially reversible hepatotoxicity (increased transaminases, hepatocytic necrosis, bile duct inflammation and proliferation, cholangitis) was noted, and toxicity was cumulative and more pronounced in female rats. The difference in gender sensitivity in rats is likely to be linked to differences in the metabolic profile, biliary excretion and/or liver retention. Administration of a weekly 30 µg/kg-dose was better tolerated by Cynomolgus monkeys than dosing 70 µg/kg every 3 weeks. Hepatotoxicity was less pronounced than in rats and non-cumulative (increased transaminases, hepatocellular hypertrophy, hepatocytic degeneration/necrosis and inflammatory cells in the sinusoids and portal tracts). At 50 μg/kg, exposure to ET-743 was higher in monkeys (23-28 μg.h/L) than in rats (1.7-8.6 μg.h/L), without gender difference. The similar profile of hepatic changes induced by chronic ET-743 treatment in humans and monkeys suggest that the Cynomolgus monkey is a more relevant model for human Yondelis <sup>IM</sup> hepatotoxicity than the rat.

PROTECTION OF FUMONISIN B<sub>1</sub> hepatotoxicity by silymarin and myriocin in female balb/c mice.

Q. He, J. Kim and R. P. Sharma. Department of Physiology & Pharmacology, The University of Georgia, Athens, GA.

Fumonisin B<sub>1</sub> (FB<sub>1</sub>) is a toxic and carcinogenic mycotoxin produced by *Fusarium Verticillioides* found on corn. The biological effects of FB<sub>1</sub> are mainly due to disruption of sphingolipid metabolism resulting from its inhibition of ceramide synthase. Silymarin has a strong protective effect against numerous hepatotoxicants. Myriocin is a selective inhibitor of serine palmitoyltransferase (SPT), the first key enzyme in *de novo* synthesis of sphingolipids. Both silymarin and myriocin protected porcine renal epithelial cells from FB<sub>1</sub> toxicity. In the present study we examined the protective effects of silymarin and myriocin on FB<sub>1</sub> hepatotoxicity in female Balb/c mice. Mice were treated daily with 750 mg/kg silymarin by gavage 16 hr prior or 1 mg/kg myriocin intraperitoneally 30 min before subcutaneous injections of either vehicle or FB<sub>1</sub> at 2.25 mg/kg.day for 3 consecutive days. Silymarin, to a greater extent than myriocin, attenuated FB<sub>1</sub>-induced elevation of plasma alanine aminotransferase and aspartate aminotransferase, and hepatocellular apopto-

sis. Both agents reversed  $FB_1$ -induced expression of tumor necrosis factor (TNF) receptor 1, and selected cytokines, TNF  $\alpha$ , TNF-related apoptosis-inducing ligand, lymphotoxin  $\beta$ , and interferon  $\gamma$  to the basal levels, except silymarin did not reduce  $FB_1$  induced transforming growth factor  $\beta 1$ . Silymarin augmented whereas myriocin attenuated  $FB_1$ -induced accumulation of free sphingoid bases. The increase of  $FB_1$ -caused free sphingoid bases by silymarin was not attributed to SPT activation. Both silymarin and myriocin blocked activation of hepatic SPT from  $FB_1$  exposure. Results indicate that silymarin is more effective than myriocin in protecting  $FB_1$  hepatotoxicity; the protective role of silymarin in  $FB_1$  toxicity is likely in part through blocking the effects of free sphingoid bases and prevention of hepatic cytokine induction. Moreover, five-day treatment of mice with myriocin and  $FB_1$  was lethal. (Supported by ES09403 from PHS).

# 489 COCAINE HEPATOTOXICITY AND ITS POTENTIATION BY LIPOPOLYSACCHARIDE: TREATMENT AND GENDER EFFECT.

T. Visalli<sup>1</sup>, R. Turkall<sup>2, 1</sup> and M. S. Abdel-Rahman<sup>1</sup>. <sup>1</sup>Pharmacology/Physiology, UMDNJ, Newark, NJ and <sup>2</sup>Clinical Laboratory Sciences, UMDNJ, Newark, NJ.

The degree of hepatotoxicity after cocaine and lipopolysaccharide (LPS) doubled to tripled after seven-day administration as compared to 5-day administration in male mice. This study was conducted to investigate the effect of a seven-day treatment as well as the influence of gender on cocaine hepatotoxicity (CH) and upon LPS potentiation of CH. Male and female CF-1 mice were orally administered 20mg/kg body weight cocaine hydrochloride once daily for 7 days. Four hours after the last cocaine administration, the mice were administered 12 x 10<sup>6</sup> EU LPS/kg (or equal volume of sterile saline) intraperitoneally. Serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were evaluated as indices of liver injury. Blood and liver glutathione (GSH), glutathione reductase (GRx), and catalase (CAT) activities were also determined to investigate the oxidation stress of the treatment. The results demonstrate that gender has a profound impact on CH and LPS potentiation of CH. Serum ALT and AST concentrations were elevated in all males receiving cocaine alone or cocaine + LPS. Further, blood GSH and CAT were decreased and GRx activity was elevated in the same males. In addition, histological analysis revealed a high degree of focal necrosis in the male cocaine group, and severe sub-massive necrosis in the male cocaine + LPS group. Unlike males, females showed no effect of either cocaine alone or cocaine + LPS treatments. In conclusion, these results indicate that gender plays a significant role in CH and its potentiation by LPS. Also, lengthening the administration by two treatments increased the severity of cocaine + LPS hepatotoxicity dramatically. Investigation regarding the mechanism of action of the gender role is ongoing in our laboratory.

#### 490 TNBS-INDUCED COLITIS IN THE RAT AS A MODEL FOR INFLAMMATORY BOWEL DISEASE.

S. Groom<sup>1</sup>, K. Beard<sup>1</sup>, E. Jacquiner<sup>1</sup> and N. Hamelin<sup>1</sup>. <sup>1</sup>CTBR, Senneville, QC, Canada and <sup>2</sup>IPN, CTBR, Senneville, QC, Canada. Sponsor: M. Vézina.

TNBS-induced colitis in the rat has been widely reported to be an appropriate model for inflammatory bowel disease, although the mechanism responsible for the colitis (i.e. immune-mediated or corrosivity) has remained the subject of discussion. This poster presents data generated from a series of 4-day studies that assessed the relative contribution of TNBS solution corrosivity to the induction of ulcerative colitis. In addition, dexamethasone was validated as a positive control such that this model can be used to screen compounds intended to treat the immune-mediated mechanisms associated with inflammatory bowel disease. Colonic instillation of TNBS doses of 4, 10 and 25 mg/rat each resulted in a severe ulcerative colitis. Colon weight, cytokine profiles and assessments of myeloperoxidase activity within colonic tissue provided data to support the efficacy of dexamethasone as a treatment for inflammatory bowel disease. However, efficacy was not evident within the colon macroscopic damage scores. These data suggest that the colitis induced by colonic instillation of TNBS is primarily one of corrosivity, however, reductions in the immune-mediated responses associated with inflammatory bowel disease were demonstrated by use of dexamethasone. Therefore, we conclude that TNBS-induced colitis in the rat can be used to provide data to support the proposed efficacy of compounds intended to treat inflammatory bowel disease.

#### 491 HYPOXIA IN RAT LIVER AFTER MONOCROTALINE EXPOSURE.

B. L. Copple, P. E. Ganey and R. A. Roth. Department of Pharmacology and Toxicology, Institute for Environmental Toxicology, and National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI.

Monocrotaline (MCT) is a pyrrolizidine alkaloid plant toxin that produces hepatotoxicity in humans and animals. Administration of 300 mg MCT/kg to rats causes rapid sinusoidal endothelial cell (SEC) injury, hemorrhage, pooling of blood and

fibrin deposition in centrilobular regions of liver. These events precede hepatic parenchymal cell (HPC) injury and produce marked changes to the structure of the microvasculature of the liver, which could interrupt blood flow and produce hypoxia in downstream regions. To test the hypothesis that hypoxia occurs in the liver after MCT exposure, rats were treated with 300 mg MCT/kg, and hypoxia was detected immunohistochemically. MCT produced significant hypoxia in centrilobular regions of livers by 8 hours after treatment. Inasmuch as fibrin deposition can impede blood flow, the effect of anticoagulant treatment on MCT-induced hypoxia and hepatocellular injury was determined. Administration of warfarin to MCTtreated rats reduced hypoxia in the liver by approximately 70% and decreased liver injury, suggesting that fibrin deposition plays a causal role in the development of hypoxia in the liver. Conversely, administration of L-NAME, a nonspecific inhibitor of nitric oxide synthases (NOSs), enhanced MCT-induced hypoxia and HPC injury. L-NAME did not, however, affect SEC injury or coagulation system activation. Results from these studies show that hypoxia occurs in the liver after MCT exposure. Furthermore, hypoxia precedes HPC injury, and manipulations that modify hypoxia also modulate HPC injury. (Supported by NIH Grants ES04139 and DK50728)

### 492 MODES OF CELL DEATH IN RAT LIVER AFTER MONOCROTALINE EXPOSURE.

R. A. Roth<sup>1</sup>, B. L. Copple<sup>1</sup>, C. M. Rondelli<sup>1</sup>, J. F. Maddox<sup>1</sup>, N. S. Hoglen<sup>2</sup> and P. E. Ganey<sup>1</sup>. Pharmacology and Toxicology, Michigan State University, East Lansing, MI and <sup>2</sup>IDUN Pharmaceuticals, San Diego, CA.

Monocrotaline (MCT) is a pyrrolizidine alkaloid (PA) plant toxin that produces sinusoidal endothelial cell (SEC) injury, hemorrhage, fibrin deposition and coagulative hepatic parenchymal cell (HPC) oncosis in centrilobular regions of rat livers. Cells with apoptotic morphology have been observed in the livers of animals exposed to other PAs. Whether apoptosis occurs in the livers of MCT-treated animals and whether it is required for full manifestation of pathological changes is not known. To determine this, rats were treated with 300 mg MCT/kg, and apoptosis was detected by transmission electron microscopy and the TUNEL (TdT-mediated dUTP nick end labeling) assay. MCT produced significant apoptosis in the liver by 4 hours after treatment. To determine if MCT kills cultured HPCs by apoptosis, HPCs were isolated from the livers of rats and exposed to MCT. MCT caused a concentration-dependent release of alanine aminotransferase (ALT), a marker of HPC injury. Furthermore, caspase 3 was activated and TUNEL staining increased in MCT-treated HPCs. MCT-induced TUNEL staining and release of ALT into the medium were completely prevented by the pancaspase inhibitors z-VAD.fmk and IDN-7314, suggesting that MCT kills cultured HPCs by apoptosis. To determine if caspase inhibition prevents MCT-induced apoptosis in the liver, rats were cotreated with MCT and IDN-7314. IDN-7314 reduced MCT-induced TUNEL staining in the liver and release of ALT into the plasma. Morphometric analysis confirmed that IDN-7314 reduced HPC oncosis in the liver by approximately 50%. Results from these studies show that MCT kills cultured HPCs by apoptosis but causes both oncosis and apoptosis in the liver in vivo. Furthermore, caspase inhibition reduces both apoptosis and HPC oncosis in the liver after MCT exposure. (Supported by NIH ES04139)

# 493 ALTERED GENE EXPRESSION AS A CONTRIBUTING FACTOR TO LIVER INJURY IN RATS COTREATED WITH RANITIDINE AND LIPOPOLYSACCHARIDE.

J. P. Luyendyk<sup>1</sup>, W. B. Mattes<sup>2</sup>, J. F. Maddox<sup>1</sup>, G. N. Cosma<sup>2</sup>, P. E. Ganey<sup>1</sup> and R. A. Roth<sup>1</sup>. <sup>1</sup>Pharmacology and Toxicology, Michigan State University, East Lansing, MI and <sup>2</sup>Investigative Toxicology, Pharmacia Corp., Kalamazoo, MI.

Studies in rats have suggested a role for underlying inflammation in idiosyncratic liver injury from the histamine 2-receptor antagonist ranitidine (RAN). Coadministration of nonhepatotoxic doses of RAN and the inflammagen, bacterial lipopolysaccharide (LPS), to rats results in hepatocellular injury. We tested the hypothesis that hepatic gene expression changes could distinguish Vehicle-, LPS-, RAN-, and LPS/RAN-treated rats before the onset of significant liver injury in LPS/RAN-treated rats (i.e., 3 h post-treatment). Rats were treated with LPS (44 x 106 EU/kg, iv) or its vehicle, then two hours later with RAN (30 mg/kg, iv) or its vehicle. They were killed 3 h after RAN treatment, and liver samples were taken for evaluation of liver injury and RNA isolation. Hepatic parenchymal cell injury as estimated by increases in serum alanine aminotransferase activity was not significant by 3 h. Hierarchical clustering of gene expression data from Affymetrix U34A rat genome arrays grouped animals according to respective treatments. Relative to vehicle-treated controls, treatment with RAN and/or LPS altered hepatic expression of numerous genes, including ones encoding for products involved in inflammation, hypoxia, and cell death. Some of them were enhanced synergistically by LPS/RAN cotreatment. Within this latter group, real-time PCR confirmed robust changes in expression of B-cell translocation gene 2, early growth response-1, and

plasminogen activator inhibitor-1 (PAI-1) in cotreated rats. Consistent with the antifibrinolytic activity of PAI-1, significant fibrin deposition occurred only in livers of LPS/RAN-treated rats. This result suggests that expression of PAI-1 promotes fibrin deposition in liver sinusoids of LPS/RAN-treated rats and is consistent with the development of localized ischemia and consequent tissue hypoxia.

### 494 COMPARISON OF THE HEPATOCELLULAR TOXICITY OF THE ANTI-ANDROGEN FLUTAMIDE TO CYANO ANALOGS

K. J. Coe<sup>1</sup>, <u>H. K. Ho</u><sup>1</sup>, H. M. Holmes<sup>1</sup>, Y. Jia<sup>1</sup>, N. Fausto<sup>2</sup>, <u>S. A. Bruschi</u><sup>1</sup> and <u>S. D. Nelson<sup>1</sup></u>. <sup>1</sup>Medicinal Chemistry, University of Washington, Seattle, WA and <sup>2</sup>Pathology, University of Washington, Seattle, WA.

Flutamide is an anti-androgen used in the treatment of metastatic prostate cancer. Its use has been curtailed due to its hepatotoxicity in a percentage of patients. Although it has been established that flutamide undergoes a high first-pass metabolism and can result in the formation of covalent adducts to microsomal proteins, the route of hepatocellular injury is not well understood. Flutamide possesses a nitroaromatic group, and it is postulated that this nitro group may mediate its route of toxicity. Two analogs of flutamide, where the nitro group is replaced with the cyano group, including the drug bicalutamide, were used to test this hypothesis in the established murine TAMH cell line. MTT cell viability assays as well as confocal microscopy indicate that cells are more sensitive to flutamide than either of the cyano analogs. Western analysis shows that ATF3, a stress response transcription factor, is highly induced upon flutamide treatment, while HSP70i is not. Furthermore, drug-induced apoptosis does not appear to be a major route of toxicity of flutamide, as neither DNA laddering nor significant PARP cleavage were observed. (Supported by NIEHS Center Grant P30ES07033 and Pfizer Inc.)

## 495 ACETAMINOPHEN-INDUCED MITOCHONDRIAL PERMEABILITY TRANSITION IN ISOLATED MOUSE HEPATOCYTES

A. B. Reid, R. C. Kurten, S. S. McCullough, R. W. Brock, G. Nowak and J. A. Hinson. University of Arkansas for Medical Sciences, Little Rock, AR.

Metabolism of acetaminophen (APAP) to N-acetyl-p-benzoquinoneimine, which depletes GSH and covalently binds to protein, is important in acetaminophen toxicity. However, cellular events leading to APAP-induced necrosis are poorly understood. We have utilized freshly isolated mouse hepatocytes to study mitochondrial permeability transition (MPT) in APAP toxicity. Incubation of APAP (1mM) with hepatocytes resulted in necrosis as indicated by increased permeability of the plasma membrane (measured using ALT release and propidium iodide-DNA binding). To separate metabolic events from later events in APAP toxicity, hepatocytes were preincubated with APAP (1mM) for 2 hr followed by centrifugation of the cells, washing the pelleted cells twice to remove the drug, and reincubation of cells in media. Control cells were treated identically except they were preincubated with media alone. At 2 hr, toxicity was not dramatically different between cells preincubated with APAP or media alone. Preincubation of hepatocytes with APAP followed by 5 hour incubation with media alone resulted in an 11-fold increase in ALT release and a 28-fold increase in propidium iodide fluorescence compared to control. Preincubation of hepatocytes with APAP followed by a 5 hr incubation with media containing cyclosporin A (10µM), a compound known to prevent MPT, resulted in a 79% decrease in ALT release and a 98% decrease in propidium iodide fluorescence. MPT was further analyzed using confocal scanning microscopy. The hepatocytes were preincubated with calcein AM followed by a wash to remove excess calcein AM. Subsequently, cells were incubated in media in the presence or absence of APAP (1mM) and analyzed by confocal scanning fluorescence microscopy. Cells incubated with media alone were shown to exclude calcein AM from the mitochondria. In cells incubated with APAP, the mitochondria did not exclude calcein AM suggesting MPT. These data indicate that MPT is an important event in APAP toxicity.

### 496 S-ADENOSYL-L-METHIONINE (SAME) REDUCES ACETAMINOPHEN HEPATOTOXICITY.

M. Terneus and <u>M. Valentovic</u>. Pharmacology, Marshall University School of Medicine, Huntington, WV.

The over-the-counter analgesic agent acetaminophen (APAP), when taken in excessive amounts induces hepatotoxicity in humans and animal models. The nutraceutical agent SAMe, has been reported to reduce the hepatic damage associated with repeated ethanol ingestion. Information is not currently available regarding the effect of SAMe on the hepatotoxicity of other xenobiotics. The following study examined whether SAMe could reduce APAP hepatic toxicity. Six to eight week old

male C57BL/6 mice were treated with a single dose of 1 g/kg SAMe (intraperitoneal, ip) prior to administration of 500 mg/kg APAP (ip). Hepatic toxicity was evaluated 4 h after APAP administration. Liver weight (g/10g body wt) was increased from a vehicle (VEH) value of  $0.48 \pm 0.01$  to  $0.55 \pm 0.01$  (p<0.05) within 4 h in the APAP treated animals. Liver weight was comparable between the SAMe  $(0.45 \pm 0.01)$  and the SAMe + APAP  $(0.46 \pm 0.01)$  group. Alanine aminotransferase (ALT) activity was increased 70 fold by APAP relative to the VEH group. ALT levels were elevated less markedly in the SAMe + APAP group compared to the SAMe group. Hepatic lipid peroxidation was increased (p<0.05) 2 and 4 h after APAP treatment when compared to the VEH group. Administration of SAMe prevented the APAP induced rise in hepatic lipid peroxidation upon comparison of SAMe and SAMe + APAP groups. The increase in lipid peroxidation induced by APAP was associated with a marked depletion (p<0.05) of glutathione (GSH) at 2 and 4 h after APAP injection when compared to the VEH group. SAMe administration prevented GSH depletion associated with APAP treatment in the SAMe + APAP group at 2 and 4 h post APAP injection. These results indicate that SAMe reduces the hepatotoxicity of APAP. SAMe attenuation of APAP hepatotoxicity is mediated in part by maintaining GSH levels and reducing the extent of lipid peroxi-

# 497 HEPATO-PROTECTIVE EFFECTS OF HC AGAINST ETHANOL-CARBON TETRACHLORIDE-INDUCED LIVER DAMAGE IN RATS.

O. S. El-Tawil<sup>1</sup>, A. M. Mohamadin<sup>2</sup> and A. B. Abdel-Naim<sup>3</sup>. <sup>1</sup>Department of Toxicology and Forensic Medicine, Faculty of Veterinary Medicine, Cairo University, Cairo, Egypt, <sup>2</sup>Tumor Marker Oncology Research Unit, Department of Biochemistry, Faculty of Pharmacy, Al-Azhar University, Cairo, Egypt and <sup>3</sup>Department of Pharmacology and Toxicology, Faculty of Pharmacy, Ain Shams University, Cairo, Egypt.

Liver diseases represent a serious health problem in Egypt. Herbs are known to play a vital role in the management of various liver diseases. HC is a multi-herbal product containing clove, parsley, oak, ginger and cinnamon. The present work was designed to evaluate HC potential to protect against biochemical & histopathological alterations induced by alcohol-carbon tetrachloride (EOH + CCl4) in rats livers. An aqueous extract of HC was administered to rats with liver damage induced by EOH + CCl4. Biochemical parameters including serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), gamma glutamyl transpeptidase (GGT), alkaline phophatase (ALP) and bilirubin were estimated to assess the liver function. In addition, tissue total proteins, triglycerides, total cholesterol, reduced glutathione and thiobarbituric acid reactive substances (TBARS, as an index of lipid peroxidation) were determined. EOH + CCl4 caused profound liver damage, as evidenced by a rise in the levels of serum AST, ALT, GGT, ALP and bilirubin of hepatotoxic rats compared to the control group. Pre-treatment of rats with fresh aqueous extracts of HC reduced the EOH + CCl4- induced elevated levels of the above indices. Furthermore, HC significantly protected against EOH + CCl4-induced adverse effects on liver total proteins, triglycerides and cholesterol. EOH + CCl4  $\,$ administration caused a significant decrease in liver GSH levels and a rise in TBARS concentration. HC pre-treatment restored liver GSH and prevented the elevation in liver TBARS levels. Histopathological examination clearly indicated that HC prevented centrilobular necrosis induced by EOH + CCl4 administration. In conclusion, HC exhibits significant hepatoprotective properties for treating EOH + CCl4-induced toxicity in rats.

#### 498 ONSET OF 3-(3, 5-DICHLOROPHENYL)-2, 4-THIAZOLIDINEDIONE (DCPT)-INDUCED HEPATOTOXICITY IN RATS.

N. N. Patel, C. M. Crincoli and P. Harvison. Department of Pharmaceutical Sciences, University of the Sciences in Philadelphia, Philadelphia, PA.

Previously, we observed that DCPT caused progressive hepatotoxicity in Fischer 344 rats. Hepatic damage was evident within 24 h of administration of this compound. DCPT has a thiazolidinedione (TZD) ring, which is also present in insulinsensitizing drugs, such as troglitazone, that are used for treatment of type II diabetes. Liver damage has been reported in some patients taking these drugs. Since DCPT may be useful for investigating the potential toxicity of TZD ring-containing compounds, it is important to fully characterize its effects in rats. The present study was therefore conducted to determine the onset of DCPT-induced hepatotoxicity. Male, Fischer 344 rats were administered DCPT (0.6 mmol/kg) i.p. in corn oil, and liver and kidney function were assessed at 3, 6, 12 and 24 h after dosing. Control animals received corn oil only. Compared to controls, rats that received DCPT exhibited mild to moderate ketonuria, starting at the 3 h time point. Diuresis was evident within 6 h post-dosing. Serum alanine aminotransferase (ALT) levels in corn oil-treated animals were 53.2±4.6, 51.6±0.8, 25.4±8.4 and 25.6±2.3 Sigma Frankel Unit (SFU) per ml at the 3, 6, 12 and 24 h time points, re-

spectively. In comparison, ALT levels were significantly elevated in DCPT-treated animals, with values of 107.0±12.0 (3 h), 148.7±27.6 (6 h), 407.3±77.9 (12 h) and 281.4±103.0 (24 h) SFU/ml. None of the animals exhibited any changes in liver or kidney weights, except for one DCPT-treated animal at the 12 h time point, which showed an elevated liver weight (8.96 g/100% body weight). Urine glucose and urine protein levels were not altered at any of the time points in either the corn oil or DCPT treatment groups. As serum ALT levels and some other parameters were altered within 3-6 h, absorption and distribution of DCPT is probably rapid. In conclusion, our results suggest that DCPT-induced hepatotoxicity occurs soon after administration of the compound. However, the mechanism behind this rapid onset of liver damage requires further investigation.

499 POTENTIAL ROLE OF CYTOCHROMES P450 IN 3-(3, 5-DICHLOROPHENYL)-2, 4-THIAZOLIDINEDIONE (DCPT)-INDUCED HEPATOTOXICITY IN RATS.

C. M. Crincoli, N. N. Patel and P. Harvison. Department of Pharmaceutical Sciences, University of the Sciences in Philadelphia, Philadelphia, PA.

3-(3, 5-Dichlorophenyl)-2, 4-thiazolidinedione (DCPT) is hepatotoxic in rats. This compound is structurally similar to insulin-sensitizing drugs, such as troglitazone, which have been shown to cause liver damage in some type II diabetic patients. Evidence in the literature suggests that cytochromes P450 may have a role in generating hepatotoxic metabolites from troglitazone. The purpose of this investigation was to determine whether biotransformation of DCPT is critical to induction of its hepatotoxicity. 1-Aminobenzotriazole (ABT) and troleandomycin (TAO) were chosen as non-selective and selective (CYP3A) cytochrome P450 inhibitors, respectively. Male, Fischer 344 rats were administered known hepatotoxic doses of DCPT (0.6 and 1.0 mmol/kg) i.p. in corn oil. Other rats were pretreated with either ABT (100mg/kg) in saline or TAO (500mg/kg) in acidified saline via i.p. injection prior to administration of DCPT. Control animals received equal doses of ABT or TAO, followed by corn oil only. Liver and kidney function were assessed at 24 hours post-dosing. Serum alanine aminotransferase (ALT) levels in rats treated with DCPT at 0.6mmol/kg and 1.0 mmol/kg were 140.0±35.1 Sigma Frankel Units/mL (SFU) and 506.9±99.4, respectively. ABT pretreatment markedly (85-95%) attenuated ALT values at both doses of DCPT; whereas TAO exerted a more modest effect on ALT levels (ca. 52% reduction). Control ALT values were 57.5±14.1 (ABT only) and 48.7±20.4 (TAO only). Liver and kidney weights, and urine protein concentrations were not significantly different among any of the treatment groups. In conclusion, these results suggest that cytochromes P450, including the CYP3A isozymes, are involved in DCPT-induced liver damage in rats. However, the nature of any hepatotoxic metabolites that are produced from DCPT requires further investigation.

500 UNDERLYING AGE-RELATED LIVER PATHOLOGY INCREASES AZOXYMETHANE TOXICITY IN FEMALE F344 RATS IN AN AGING STUDY ON COLON CANCER CHEMOPREVENTION.

S. Francke-Carroll<sup>1</sup>, K. Daly<sup>2</sup>, T. Wang<sup>3</sup> and <u>B. Magnuson<sup>2</sup></u>. <sup>1</sup>OSAS, USFDA, College Park, MD, <sup>2</sup>Department of Nutrition and Food Science, UMD, College Park, MD and <sup>3</sup>Agricultural Research Service, USDA, Beltsville, MD.

The influence of aging and nutrition on the development cancer is of growing interest to the public health. Aging studies in rodents, however, hold many challenges; homogeneously aged laboratory animals are expensive, their availability is limited and they require careful maintenance since they are more stress sensitive than younger animals. Established cancer models, such as the Azoxymethane (AOM) colon cancer model in rats routinely require a standardized dose of AOM for all test groups. Applied to comparative aging studies, where test groups consist of animals that differ significantly in age this means that animals of all age groups receive the same standardized dose of AOM based on body weight, although older animals are potentially more sensitive. We report here inadvertent acute AOM-induced toxicity in female F344 rats due to underlying age related liver pathology. The rats were part of a study investigating the effect of dietary soy and aging on the development of AOM-induced aberrant crypt foci (ACF). Control and test animals of three age groups each (1, 11 and 21 month old), with seven animals per group, received one dose of 20 mg/kg AOM s.q., to induce the ACF. Three 21-month animals and one 11-month animal developed fatal toxic signs within 96 hrs post injection. Histopathological evaluation revealed, acute liver, adrenal gland and the gastro-intestinal toxicity. Preexisting age related changes, including hepatocellular adenomas, were also noted in the livers of all four animals. We conclude that age related liver pathology reduced the organ's ability to compensate, influenced drug metabolism and rendered these animals increasingly more sensitive to drug dosages well tolerated by younger animals in this established cancer research model. We further discuss unknown, underlying age related liver pathology as an additional factor influencing the outcome of aging research in laboratory rodents.

501 IMMUNOHISTOCHEMICAL ANALYSIS OF HEPATIC HEME OXYGENASE-1 EXPRESSION FOLLOWING ADMINISTRATION OF ETHINYL ESTRADIOL TO RATS.

L. A. Morio, A. Leone, J. B. Parker, P. Lord and M. K. McMillian. Mechanistic Toxicology, Johnson & Johnson Pharmaceutical Research & Development, L.L.C., Raritan. NI.

Heme oxygenase-1 (HO-1), also known as heat shock protein 32, is thought to have an important protective role against cellular stress during liver inflammation. Using PCR and microarray analysis we have previously demonstrated that HO-1 gene expression in whole liver tissue is elevated 1 day after administration of ethinyl estradiol to rats (manuscript submitted). In the present studies, we used immunohistochemical methods to analyze hepatic expression of this enzyme following administration of ethinyl estradiol, a steroid hormone which is an effective inducer of cholestasis. Treatment of female Sprague-Dawley rats with a single hepatotoxic dose of ethinyl estradiol (500 mg/kg, po) resulted in increased numbers of HO-1 positive hepatic macrophages at 1 day post-administration, while in parenchymal cells HO-1 expression remained undetectable. Interestingly, HO-1 immunoreactivity disappeared in hepatic macrophages after 4 days of repeated dosing with ethinyl estradiol while the cytoplasm of many hepatocytes now expressed the HO-1 protein. These data suggest a role for HO-1 in ethinyl estradiol-induced hepatotoxicity. The differential expression pattern of HO-1 protein in hepatic macrophages and hepatocytes suggests that HO-1 may play a role in ethinyl estradiol-induced liver injury.

502 INDUCTION OF PEROXISOME PROLIFERATION IN RAT HEPATOCYTES BY A SERIES OF HALOGENATED ACETATES.

J. McMillan, J. E. Walgren and D. J. Jollow. Cell and Molecular Pharmacology, Medical University of South Carolina, Charleston, SC.

Trichloroacetate (TCA) and dichloroacetate are hepatocarcinogenic metabolites of the environmental contaminant trichloroethylene. Induction of peroxisome proliferation via activation of the peroxisome proliferator-activated receptor  $\alpha$  (PPAR $\alpha$ ) has been proposed as a mechanism for their hepatocarcinogenic action. However, it is unclear whether these compounds are direct ligands of PPARa or whether activation occurs by a ligand-independent process. Thus, the present studies were undertaken to determine whether a structure-related pattern of induction of palmitoyl-CoA oxidation could be observed in rat hepatocyte cultures exposed to a series of halogenated acetates. Significant differences were observed in both potency and efficacy of the halogenated acetates. The most potent inducers were the monohalosubstituted acetates, with the order of potency being iodo>bromo>chloro>>fluoro. Significant induction occurred at 50 and 100 µM, respectively for the monoiodo and monobromo derivatives. Cytotoxicity precluded obtaining full concentrationresponse curves for the monoiodo-, monobromo- and monochloroacetates. Trihaloacetates were modest inducers of palmitoyl-CoA oxidation, with no more than 2-fold induction at a concentration of 2 mM for TCA. The dihaloacetates were the most effective inducers of palmitoyl-CoA oxidation. Difluoroacetate (4mM) and dibromoacetate (3mM) induced palmitoyl-CoA oxidation by 10-fold and 7-fold, respectively, while treatment with the dichloro derivative (4mM) resulted in only a 3-fold increase. The slopes of the concentration dependence lines of the difluoro-/dibromoacetates vs. dichloroacetate were markedly dissimilar, suggesting a difference in PPARa activation or a substantial difference in metabolism or transport of these analogs. The disparity in efficacy for the dihalogenated acetates may also suggest a difference in how these peroxisome proliferators activate PPARα. Supported by DOE Cooperative Agreement DE-FC09-02CH11109.

503 ENDOTOXIN POTENTIATES AFLATOXIN B1-HEPATOCELLULAR INJURY BY A MECHANISM WHICH IS DEPENDENT UPON KUPFFER CELLS.

J. L. Wagoner<sup>1, 4</sup>, E. X. Barton<sup>1</sup>, D. F. Klein<sup>2</sup>, T. T. Newton<sup>2</sup>, <u>R. A. Roth</u><sup>3</sup>, L. H. Mortensen<sup>4</sup> and <u>C. Barton</u><sup>2, 4</sup>. Iowa State University, Ames, IA, <sup>2</sup>Iowa Department of Public Health, Des Moines, IA, <sup>3</sup>Michigan State University, East Lansing, MI and <sup>4</sup>Des Moines University, Des Moines, IA.

Exposure to a small, nontoxic dose of bacterial endotoxin potentiates the hepatotoxicity induced by aflatoxin B1 (AFB1), a mycotoxin commonly found in food products. The low level of expression of inflammatory mediators induced by endotoxin appears to be important for this increased susceptibility. In particular, tumor necrosis factor-alpha (TNF) is critical for the potentiation. Inasmuch as TNF is produced primarily by Kupffer cells, this study was conducted to explore the role of Kupffer cells in this pathogenic response. Male, Sprague-Dawley rats (300-400 g) were treated with gadolinium chloride (7.5 mg/kg, i.v.) or its saline vehicle, followed 20 hrs later with AFB1 at 1 mg /kg, i.p., or its vehicle (2% DMSO/water), and 4 hrs later with either endotoxin (E. coli LPS; 7.4 X 106 EU/kg, i.v.) or its

saline vehicle. Inhibition of Kupffer cell function by gadolinium chloride protected against hepatocellular injury as evidenced by alanine aminotransferase (ALT) and aspartate aminotransferase (AST) increases in serum and histological examination of the liver. These results suggest that endotoxin potentiates AFB1 hepatocellular injury by a mechanism which is dependent on Kupffer cells. (Supported by a grant from the Iowa Osteopathic Education Foundation.)

## 503a TRANSCRIPTOMICS OF ACETAMINOPHEN IN RAT LIVER AND IN CULTURED DOG AND RAT HEPATOCYTES

M. Jacquard<sup>1</sup>, M. Renaud<sup>1</sup>, J. Hoflack<sup>1</sup> and <u>N. Claude<sup>2</sup></u>. <sup>1</sup>Drug Safety, Biologie SERVIER, Gidy, France and <sup>2</sup>Drug Safety, IRIS, Courbevoie, France.

Acetaminophen (APAP) induces liver centrilobular necrosis through conjugation routes overwhelming, P450-mediated toxic metabolization, followed by glutathione and macromolecular adduction. Whereas this mechanism is well described, little is known about early cell reactions prefiguring APAP-induced necrosis, and whether it is possible to reproduce the latter in cultured cells. Today, transcriptomics could allow a detection of cellular pre-necrotic status at the molecular level, before blood biochemical or histomorphological hallmarks. Therefore, APAP-induced transcriptomic profiles were monitored in Fischer rat liver and in beagle dog and Fischer rat hepatocyte cultures, under sub-necrotic treatment conditions evidenced by the relevant tissue and cellular parameters. Rats (3 males / group) were administered a single dose i.p. of 250 mg/kg APAP and liver collected at 6, 24, and 72 h time points. Freshly prepared rat and dog hepatocytes were treated for 4 h with 2 mM APAP. Transcriptomics profiles were established using 2color fluorescence microarrays (Phase-1 Molecular Toxicology, USA; 270 genes for dog and 700 genes for rat microarrays) and analyzed using GenePix 5.0 and Acuity 3.1 softwares (Axon Instruments, USA). Comparison of rat in vivo and in vitro transcriptomic profiles showed a partial overlap regarding detoxication routes, but also a number of differences related to culture conditions. Higher APAP concentrations in vitro may have offered a better match between the two conditions. Similar responses were noted for dog and rat hepatocytes cultured in vitro, i.e. same metabolism, and detoxication processes indicative of an oxidative stress. These results show that identifying biomarker sets of genes within transcriptomic profiles may also improve prediction ability of in vitro transcriptomics.

### 504 BLESSINGS OF OLD AGE: PROTECTION FROM CHLORDECONE-POTENTIATED CCL<sub>4</sub> HEPATOTOXICITY.

B. Murali, M. C. Korrapati and H. M. Mehendale. Toxicology, University of Louisiana at Monroe, Monroe, LA.

Objective of the present work was to compare the toxic responses of chlordecone (CD) + CCl<sub>4</sub> between young adults (3 months), middle aged (14 months), and old aged (24 months) male Fischer 344 (F344) rats. After a non-toxic dose of CD (10 ppm in diet) or normal diet for 15 days, rats were challenged with a single nontoxic dose of CCl<sub>4</sub> (100 µl/kg, ip, 1:4 in corn oil) or corn oil (500 µl/kg, ip) alone on day 16. Liver injury was assessed by plasma ALT, AST, and histopathology during a time course of 0 to 96 h. Liver tissue repair was measured by [3H]-thymidine incorporation into hepatic nuclear DNA, and PCNA immunohistochemistry. CYP2E1 protein, enzyme activity and covalent binding assay (2 & 6 h) were carried out in all the age groups with or without CD diet. Plasma glucose and hepatic glycogen were estimated. Exposure to CCl<sub>4</sub> alone did not cause any mortality. The combination led to 100% mortality of young adult rats by 72 h, whereas no mortality occurred in aged rats. Adult and middle aged rats exposed to CD + CCl4 had identical liver injury up to 36 h. Thereafter, liver injury escalated only in young adults while it declined in middle aged rats. In the 24-month-old rats initial liver injury never developed to the level of the other two age groups further declining thereafter as in the 14-month-old rats. Neither hepatomicrosomal CYP2E1 protein nor the enzyme activity or covalent binding differed between the age groups with or without CD diet. Plasma glucose did not change in any age group. Significant depletion of hepatic glycogen was observed only in adult rats exposed to CD + CCl4. Liver tissue repair ([3H]-T, PCNA) was robust in aged rats allowing them to overcome liver injury by compensatory tissue repair. In young adults liver injury progressed due to failed compensatory tissue repair. These findings indicate that the aged rats are resilient to the lethal effect of CD + CCl4 by virtue of early and robust compensatory liver tissue repair. (Supported by NIH/AG19058).

# 505 DEPLETION OF MITOCHONDRIAL COA BY PERFLUOROSULFONIC AND PERFLUOROCARBOXYLIC ACIDS *IN VITRO*.

T. M. O'Brien and K. B. Wallace. Biochemistry and Molecular Biology, University of Minnesota, Duluth, MN.

Perfluorooctanesulfonate (PFOS), perfluorooctanoic acid (PFOA), and the substituted perfluorooctanesulfonamides perfluorooctanesulfonamidoacetate (FOSAA), and N-ethylperfluorooctanesulfonamidoacetate (N-Et-FOSAA) are widely used as

surfactants on fabrics and papers, as anti-corrosion agents and fire retardants, as well as many other commercial applications. Their broad use, global distribution, and environmental persistence has generated considerable interest regarding the metabolic and potentially toxic effects of these compounds. We have previously shown that the perfluorooctanes disrupt mitochondrial bioenergetics and, more specifically, that perfluorinated carboxylic acids induce the mitochondrial permeability transition. The purpose of this study was to determine if, as structural fatty acid analogues, perfluorosulfonic acid and perfluorinated carboxylic acids deplete free coenzyme A. Freshly homogenized rat liver was incubated in the presence of the test compound at 37 C for 40 minutes. Caprylic acid was included as a positive control and the concentration of free coenzyme A determined by reversed-phase HPLC. The concentration of free CoA detected in the control incubations was 92.4 +/- 13.6 nmol/g liver. Incubation with caprylic acid caused a 5% decrease in free CoA, whereas there was a 15%-40% depletion of CoA when liver tissue was incubated with one or another of the perfluorinated acids. We conclude that PFOS and the perfluorinated carboxylic acids deplete free mitochondrial coenzyme A, and that this may contribute to the mechanism by which these compounds interfere with fatty acid metabolism in vivo. (Supported by a grant from the 3M Company).

### 506 EVALUATION OF THE SUBCHRONIC TOXIC POTENTIAL OF CHLOROFORM VIA AQUEOUS

S. S. Anand<sup>1</sup>, P. S. Palkar<sup>1</sup>, M. M. Mumtaz<sup>2</sup> and H. M. Mehendale<sup>1</sup>.

<sup>1</sup>Department of Toxicology, University of Louisiana, Monroe, monroe, LA and <sup>2</sup>ATSDR, Atlanta, GA.

The aim of the study was to develop a dose-response for hepatic, renal injury and tissue repair upon subchronic exposure to CHCl<sub>3</sub>. Swiss-Webster mice were given 3 dose levels of CHCl<sub>3</sub> (150, 225, and 300 mg/kg/day) via aqueous gavage for 30 d. Liver and kidney injury were measured by ALT and BUN, respectively, and by histopathology. Tissue repair was assessed by (<sup>3</sup>H-T) thymidine incorporation into hepato- and nephro-nuclear DNA and by PCNA. These were measured on 1, 7, 15, 21, and 30 d and from 24 to 96 h after the last dose (30 d). Blood, liver and kidney levels of CHCl<sub>3</sub> were quantified over 15 to 360 min. Only the high dose resulted in 20% mortality during the 30 d dosing regimen. After a single dose, CHCl<sub>3</sub> levels in blood, liver and kidney exhibited a dose response, peaking at 1 h and disappearing by 6 h. Upon repeated administration, on 7, 15 and 30 d, the initial levels were higher followed by steeper disappearance. Altered kinetics during repeated administration could be due to a combination of an adaptive response and altered CYP2E1. Moderate liver injury evident with all doses from day 1 to 15 regressed subsequently with the lower doses, whereas injury persisted with the high dose until 24 h after the last dose. Peak liver tissue repair was evident at 7 d with all doses. While the repair was persistent with the high dose, it declined to normal at lower doses. Significant elevation in BUN was evident on 1 d, persisted until 7 d, after which it declined to normal and remained so throughout the 30 d with all doses. Kidney repair peaked at 7 d and was robust with high dose. The biochemical observations were supported by histopathology and PCNA. Regression of injury after the initial rise was consistent with the higher elimination of CHCl<sub>3</sub>. Absence of any significant elevation in liver tissue repair after 7 d excepting high dose, suggests that repeated exposure induces protection from injury at cellular level. The results indicate that subchronic exposure to CHCl, is unlikely to present a threat to humans (supported by ATSDR Û61/ATD 681482).

# 507 PEROXISOME PROLIFERATOR CLOFIBRATE AFFECTS N-6/N-3 POLYUNSATURATED FATTY ACID (PUFA) COMPOSITION DIFFERENTIALLY IN RAT LIVER AND HEART.

J. T. Ahokas<sup>1</sup>, Q. Tian<sup>1</sup>, F. A. Grzemski<sup>1</sup> and S. Panagiotopoulos<sup>2</sup>. <sup>1</sup>Key Centre for Applied and Nutritional Toxicology, RMIT University, Melbourne, VIC, Australia and <sup>2</sup>Austin & Repatriation Medical Centre, University of Melbourne, Melbourne, VIC, Australia.

The peroxisome proliferator, clofibrate (CL) has been used to treat hyperlipidemia. Peroxisome proliferators are a structurally diverse group known to cause hepatocellular carcinoma in rodents with long-term exposure. Peroxisome proliferators act *via* activation of the nuclear receptor, peroxisome proliferator-activated receptor a (PPARO), which is known to play an important role in lipid metabolism The n-6 PUFAs have been shown to enhance tumorigenesis in lipid sensitive carcinogen-induced and tumor transplant tumor models, whereas n-3 PUFAs display anti-tumorigenic effects. This study investigated the effects of CL on PUFA composition in the liver and heart. Sprague-Dawley rats (n=6 / group) were treated with CL 300mg/kg per day or olive oil i.p. for up to 14 days. Fatty acid was then extracted and subjected to gas chromatography. CL pretreatment significantly decreased the plasma levels of all fatty acids except that of C20:3 n-6, which slightly increased after 14 day treatment (P <0.05). In liver, CL administration reduced C18:2n-6,

but C18:3n-6, C20:2n-6, C20:3n-6, C20:4n-6 were significantly increased, . However, n-3 PUFAs including C18:3n-3, C20:5n-3, C22:5n-3 and C22:6n-3 were reduced by CL. These changes together caused a significant increase of hepatic n-6/n-3 ratio (P<0.0001). By contrast in the heart, C20:4 n-6 was reduced to about 50 percent of control level while C22:6n-3 was enhanced by 2-fold. Consequently, CL treatment led to a decrease of myocardial n-6/n-3 ratio (P<0.0001). The different effects of CL on n-6/n-3 ratio may contribute to its distinct actions in liver and cardiovascular system.

508

THE SIGNIFICANCE OF ELEVATED SERUM AMINOTRANSFERASE LEVELS IN THE ABSENCE OF HEPATIC NECROSIS: PRECLINICAL PREDICTIVE VALUE AND RELEVANCE TO HUMAN RISK.

D. D. Wiant<sup>1, 2</sup>. <sup>1</sup>In Vivo Pharmacology, Adolor Corporation, Exton, PA and <sup>2</sup>Department of Health, West Chester University, West Chester, PA.

Serum aminotransferase activities have been used broadly as surrogate markers for tissue injury and disease in human and veterinary settings and in safety assessment of chemicals and pharmaceuticals. This research study was conducted to demonstrate increased aspartate (AST) & alanine (ALT) aminotransferase activity in liver tissue without obvious hepatocyte death or damage and, in plasma as a sequel to hepatic necrosis. Rats were administered 4 or 10 oral doses of 12 mg/kg dexamethasone or 1000 mg/kg acetaminophen, respectively. Terminal plasma and liver samples were assayed by immunoblot and functional assay, while pre and post dose plasma was co-analyzed commercially and necrosis was histologically determined from processed liver slices. Dexamethasone (an aminotransferase inducer) increased liver and plasma AST & ALT levels. Terminal BWs decreased and absolute & relative (%BW) liver weights increased vs. vehicle controls. Dexamethasone group total liver protein decreased, but was similar in the acetaminophen vs vehicle groups. Acetaminophen (a hepatotoxicant) increased plasma ALT levels and slightly decreased liver ALT levels, while plasma AST levels stayed in reference range for age throughout dosing. Contrary to assumptions, acetaminophen liver injury was inconclusive. Dexamethasone induced rapid liver weight gain with necrosis, and increased liver tissue and plasma "liver" aminotransferases. The null hypothesis that there is no significant relationship between the presence of elevated plasma aminotransferase levels and the histologic finding of liver toxicity (necrosis or hepatocyte death) was rejected. Looking at ALT & AST induction in liver tissue by mRNA analysis is the next step in determining if observed liver reactions were toxic in nature, or adaptive. It is strongly suggested that preclinical liver toxicity determinations must include clinical chemistry (plasma ALT & AST), liver histopathology and corroborative liver tissue ALT & AŜT mRNA analyses.

509

IMPORTANCE OF MITOGEN-ACTIVATED PROTEIN KINASES (MAPK) IN ACETAMINOPHEN HEPATOTOXICITY IN MICE AND MURINE HEPATOCYTES.

M. Bajt and H. Jaeschke. Liver Research Institute, University of Arizona, Tucson, AZ.

MAPK (c-Jun kinase, JNK; p44/p42 MAPK, p38 MAPK) are involved in signal transduction and regulation of gene expression in a wide variety of pathophysiological responses of the cell. To evaluate which MAPK signaling pathway is important in acetaminophen (AAP) hepatotoxicity, phosphorylation of the individual MAPK or substrates was assessed after injection of 300 mg/kg AAP in C3Heb/FeJ mice with or without additional treatment of glutathione (200 mg GSH/kg; 1.5 h after AAP) as described (JPET 303: 468, 2002 and JPET 307:67, 2003). None of the MAPK were phosphorylated in untreated controls. However, after AAP alone, phosphorylation of p44 MAPK and p38 MAPK was observed at 6, 12 and 24 h without changes of the total amount of protein. Treatment with GSH, which attenuated liver injury, significantly reduced phosphorylation of p44 and p38 MAPK. In contrast, c-Jun protein levels, not detectable in controls, were moderately increased with AAP alone (6 to 24 h), reaching peak levels at 12 h. Treatment with GSH further increased c-Jun protein expression at all time points after AAP. There was only a minor increase in the phosphorylated form of c-Jun after AAP alone. However, treatment with GSH, substantially enhanced the amount of phosphorylated c-Jun with peak levels at 12 h after AAP. To assess the importance of MAPK activation, cultured murine hepatocytes were treated with 20-50 µM of PD98059 (p44/p42 inhibitor), U0126 (MEK1/2 inhibitor), SB203580 (p38 inhibitor) or \$P600125 (JNK inhibitor) 1 h before adding 5 mM AAP. Cells treated with AAP showed a time-dependent loss of *via*bility (XTT assay: 24% of controls at 12 h; 80% of the cells were trypan blue-positive). Of the MAPK inhibitors used, only the p38 inhibitor SB203580 showed a significant inhibition of cell damage (XTT assay: 70% of controls and 20% trypan blue-positive cells at 12 h). Conclusion: Although AAP treatment differentially up-regulates several MAPK, only p38 MAPK may be involved in the intracellular signaling pathway resulting in necrotic cell death of liver parenchymal cells.

510

INTERLEUKIN-13 PROTECTS AGAINST ACETAMINOPHEN-INDUCED LIVER INJURY.

S. B. Yee, M. Bourdi, M. P. Holt and L. R. Pohl. Molecular and Cellular Toxicology Section, Laboratory of Molecular Immunology, NHLBI, NIH, DHHS, Bethesda, MD.

Recent studies have suggested that one predisposing aspect of idiosyncratic drug-induced liver disease may involve a deficiency of hepatoprotective factors, such as interleukin (IL)-6 and IL-10. In this regard, we tested the hypothesis that IL-13 is another hepatoprotective factor. Following treatment of male C57BL/6 wild type (WT) mice with acetaminophen (APAP; 200 mg/kg), hepatotoxicity, as determined by serum alanine aminotransferase activity, peaked by 24 hours with a concomitant increase in serum IL-13 concentration. Administration of an IL-13 antibody two hours before APAP treatment attenuated serum IL-13 concentration and significantly exacerbated liver injury up to 24 hours after APAP administration. While the qualitative nature of the resulting centrilobular lesions was similar, morphometric analysis revealed that IL-13 antibody pretreatment significantly increased lesion area. APAP administration to IL-13 knockout (KO) mice confirmed the protective role of IL-13 in APAP-induced liver injury. Serum tumor necrosis factor (TNF)-α concentration was significantly elevated in APAP-treated IL-13 KO mice and in WT mice co-administered with IL-13 antibody and then APAP. Protein adduct formation was also increased in IL-13 KO mice compared to WT. This increase, however, was not due to enhanced cytochrome P450 2£1 expression. Taken together, these results suggest that IL-13 is a critical hepatoprotective factor in APAP-induced liver injury and that increased TNF- $\alpha$  and protein adduct formation may be important in the mechanism of enhanced liver injury observed in APAP-treated mice with compromised IL-13 levels.

#### 511 ROLE OF TOLL-LIKE RECEPTOR-4 (TLR-4) IN ACETAMINOPHEN (AA)-INDUCED HEPATOTOXICITY.

C. R. Gardner<sup>1</sup>, L. Chen<sup>1</sup>, J. D. Laskin<sup>2</sup> and D. L. Laskin<sup>1</sup>. <sup>1</sup>Rutgers University, Piscataway, NJ and <sup>2</sup>UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.

Acetaminophen (AA) is a mild analgesic and antipyretic agent known to cause hepatotoxicity at toxic doses. Increasing evidence suggests that that macrophages and inflammatory mediators contribute to acetaminophen-induced tissue injury. Tolllike receptor 4 (TLR-4) is a transmembrane protein expressed on macrophages. It has been shown to mediate endotoxin-induced inflammation and injury. In the present studies, we analyzed the role of TLR-4 in AA induced hepatotoxicity using control C3H/OuJ and TLR-4 mutant C3H/HeJ mice. Treatment of OuJ mice with AA (300 mg/kg) resulted in centrilobular hepatic necrosis and increased serum ALT levels within 3 h. This was correlated with a reduction in liver glutathione (GSH) levels. In HeJ mutant mice, tissue injury was significantly reduced. This was correlated with a delay in AA-induced GSH depletion. Immunohistochemistry showed that expression of proliferating cell nuclear antigen (PCNA), a marker of hepatocyte proliferation and tissue repair, was induced in hepatocyte nuclei 12 h after AA treatment in OuJ mice, but did not appear until 24 h in HeJ mice. Delayed induction of the hepatocyte mitogen IL-6, which is strongly induced at 3 h in OuJ mice, was also noted. TREM-1 is a macrophage receptor that has been implicated in the regulation of endotoxin-induced inflammatory responses. Evidence suggests that TLR-4 is required for TREM-1 expression early in the inflammatory process. We found that TREM-1 mRNA expression was induced in the liver of OuJ mice within 6 h of AA administration peaking at 12 h. In HeJ mice treated with AA, hepatic expression of TREM-1 mRNA was delayed until 12 h and maximal levels were not observed until 24 h. Taken together, these data demonstrate that TLR-4 plays a role in AA-induced hepatotoxicity. Reduced toxicity in TLR-4 mutant mice may be due to delayed generation of cytotoxic inflammatory mediators. Supported by NIH grants GM34310, ES04738 and ES05022.

#### 512 IMPAIRED SIGNAL TRAFFICKING UNDERLIES FAILED ON-DEMAND LIVER TISSUE REPAIR UPON HEPATOTOXIC CHALLENGE IN TYPE 2 DIABETES.

S. P. Sawant<sup>1</sup>, A. V. Dnyanmote<sup>1</sup>, J. R. Latendresse<sup>2</sup> and H. M. Mehendale<sup>1</sup>. Department of Toxicology, School of Pharmacy, The University of Louisiana at Monroe, Monroe, LA and <sup>2</sup>NCTR, Jefferson, AR.

The objectives of this study were to further characterize our type 2 diabetic (DB) model and to investigate mechanisms of increased CCl<sub>4</sub> hepatotoxicity in DB rats. Male SD rats were fed high fat and on day 14 injected streptozotocin (45 mg/kg). On day 24, diabetes was confirmed by hyperglycemia, normoinsulinemia, and oral glucose intolerance, all persisting beyond 6 months. Nonlethal doses of allyl alcohol (35 mg/kg), CCl<sub>4</sub> (2 ml/kg), and thioacetamide (300 mg/kg) yielded 80, 100, and 100% mortality, respectively, in DB rats within 48 h. A time course (0 to 96 h) study of CCl<sub>4</sub> (2 ml/kg)-induced liver damage revealed similar initial bioactivationmediated injury in DB vs non-DB rats, markedly progressing with hyperammonemia and hyperbilirubinemia in the DB rats. Hepatomicrosomal CYP2E1 protein and activity, \$^4CCl\_4\$ covalent binding, and lipid peroxidation did not differ between DB and non-DB rats indicating that higher bioactivation is not the mechanism. Tissue repair was inhibited in DB rats leading to progression of injury, and liver failure. Prompt and robust tissue repair, regression of injury and survival were noted in non-DB rats. Epidermal growth factor receptor- mitogen activated protein kinases (EGFR-MAPK) signal trafficking were investigated. EGFR, MAPKs such as ERK1/2 and p38 expression and activation were downregulated as early as 3 h in the DB rats after CCl\_4 adm. MAPKs facilitate the dissociation of NF-KB, which translocates in the nucleus, binds to DNA, and stimulates the transcription of cyclin D1, required for G1 to S phase checkpoint clearance. In the DB rats, NF-KB-DNA binding and cyclin D1 were down regulated compared to non-DB rats as early as 6 h after CCl\_4 adm. These findings indicate high sensitivity of type 2 diabetes to diverse hepatotoxicants. The mechanism of high sensitivity to CCl\_4 is impaired compensatory tissue repair owing to failed G1 to S checkpoint clearance, allowing unabated progression of liver injury. (Kitty DeGree Endowment)

## PROTECTION AGAINST MECHANISTICALLY DISTINCT HEPATOTOXICANTS IS ASSOCIATED WITH ACUTE PHASE RESPONSE.

K. A. Ewald<sup>1</sup> and E. J. Calabrese<sup>2</sup>. <sup>1</sup>KERA Environmental, LLC, Worthington, MA and <sup>2</sup>Department of Environmental Health Sciences, University of Massachusetts, Amherst, MA.

The acute phase response (APR) is a mechanism of defense associated with a variety of stresses and injuries. Three experiments were conducted to evaluate the relationship between three temporal phases of APR-induction and chemically induced injury: 1) prior-, 2) simultaneous- and 3) post-APR-induction. APR-induction (subcutaneous (sc) injection of turpentine (T)) was tested with 6 toxicants reflecting a range of distinct toxic mechanisms: carbon tetrachloride  $(CCl_4)$ , the chlordecone/carbon tetrachloride interaction (CD/CCl<sub>4</sub>), galactosamine (GalN), allyl alcohol (AA), thioacetamide (TA) and mecuric chloride (HgCl<sub>2</sub>). Each group of Sprague-Dawley rats was administered one of the 6 toxicants (5 hepatotoxicants and 1 nephrotoxicant; prior-induction) or one of 5 hepatotoxicants (simultaneousand post-induction) by intraperitoneal (ip) injection. Serum alanine transaminase (ALT) or blood urea nitrogen (BUN; HgCl, only) and the acute phase protein, haptoglobin (Hp) were evaluated in all groups at 12, 24, 36, 48 and 72 hours after toxicant, along with histological evaluation at selected intervals (prior-induction only). While simultaneous and post APR-induction failed to reduce hepatotoxicity, results indicate that prior APR-induction causes a marked reduction (90 to 97%) in CCl4, CD/CCl4, GalN and TA induced liver toxicity. HgCl2 and AA toxicity were not diminished by prior APR-induction, possibly due to chemical-specific mechanisms of toxicity. Findings suggest that the APR may be a significant adaptive response to a variety of mechanistically diverse hepatotoxicants.

# 514 MECHANISMS REGULATING TREM-1 EXPRESSION IN LIVER MACROPHAGES AND ENDOTHELIAL CELLS DURING ACUTE ENDOTOXEMIA.

L. C. Chen, M. A. Gordon, J. D. Laskin and D. L. Laskin. Joint Graduate Program in Toxicology, Rutgers University and UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.

Acute endotoxemia is associated with excessive release of proinflammatory and cytotoxic mediators in liver macrophages and endothelial cells. TREM-1 (triggering receptors expressed on myeloid cell-1) is a newly identified receptor on myeloid cells implicated in regulating host innate response. In the present studies, we analyzed the effects of acute endotoxemia on TREM-1 expression in liver macrophages and endothelial cells from endotoxin sensitive C3H/OuJ and endotoxin resistant C3H/HeJ mice, which have a mutant toll-like receptor 4 (TLR4). Cells were isolated from livers following perfusion with collagenase, centrifugal elutriation and density gradient centrifugation. Freshly isolated macrophages and endothelial cells from OuJ and HeJ mice constitutively expressed TREM-1 mRNA as determined by semi-quantitative RT-PCR. No major differences were noted between the mouse strains. In both cell types TREM-1 mRNA expression decreased with time in culture. This was overcome by the addition of IL-1 alpha (50 ng) or TNF-alpha (1 ng) to the cultures. Treatment of the mice with endotoxin (3 mg/kg, ip) caused significant induction of TREM-1 mRNA expression in macrophages from OuJ and HeJ mice, which was most prominent at 3 hr. Whereas in OuJ mice, TREM-1 expression remained elevated, in HeJ mice, expression decreased. Endothelial cells from both mouse strains also expressed TREM-1 which was most prominent 3 hr after endotoxin. Subsequently, TREM-1 decreased. To study mechanisms mediating induction of TREM-1, IL-1 beta and TNF-alpha mRNA expression was analyzed since these proinflammatory cytokines were found to induce TREM-1 in the cells. We found that IL-1 beta and TNF-alpha were highly induced 3 hr post endotoxin. These data implicate TREM-1 expression in acute endotoxemia. Moreover, this

may be regulated *via* TLR4, IL-1 beta, and TNF-alpha. Endotoxin-resistance in C3H/HeJ mice may be due to limited expression of the TREM-1 protein. Support: NIH GM34310, ES04738 and ES05022.

#### 515 EXPRESSION OF HEPATIC AND RENAL BILE ACID TRANSPORTERS DURING CHOLESTASIS.

K. Allen<sup>1</sup>, A. L. Slitt<sup>1</sup>, N. J. Cherrington<sup>2</sup>, C. Chen<sup>1</sup>, M. Dieter<sup>1</sup>, J. Maher<sup>1</sup> and C. Klaassen<sup>1</sup>. <sup>1</sup>University of Kansas Medical Center, Kansas City, KS and <sup>2</sup>University of Arizona, Tucson, AZ.

The liver synthesizes and excretes bile acids (BA) to aid in intestinal emulsification and absorption of fats, and also extracts BA from portal blood to complete the enterohepatic cycle. Obstruction of the common bile duct can impede bile flow into the intestine, cause toxic BA to accumulate in liver, and increase urinary BA excretion. In general, the sodium cotransporting polypeptide (Ntcp) and the organic anion transporting polypeptides (Oatps) are thought to transport bile acids into the liver and kidney, whereas the bile salt export pump (Bsep) and the multidrug resistance proteins (Mrps) are thought to export bile acids out of liver and kidney. Therefore, we hypothesized that during cholestasis the liver would alter gene expression to prevent BA accumulation, but the kidney would alter gene expression to enhance urinary excretion of BA. To test this hypothesis, C57BL/6J mice underwent either sham or bile-duct ligation (BDL) surgery. After BDL, liver, kidney, and serum were collected at day 1, 3, 7, and 14. Serum bile acid concentrations were 121µmol/L in sham-operated mice and were elevated to 450, 894, 1687, 1799µmol/L at 1, 3, 7, and 14 days in mice after BDL, respectively. In liver, Ntcp, Oatp1, Oatp3, and Oatp4 mRNA levels decreased, while Bsep, Oatp2, Oatp5, Oatp12, and Mrp1-5 mRNA levels increased. In kidney BDL decreased Oatp1 mRNA levels, and increased kidney Mrp1-5 mRNA levels. The elevated serum BA concentration after 14 days of BDL indicates that liver and kidney are limited in their ability to compensate for the loss of hepatic BA excretion. mRNA expression data indicates that hepatic and renal Oatp and Mrp genes are regulated similarly during cholestasis, favoring a gene expression pattern that lowers cellular BA concentrations. Based on the current knowledge of Oatp and Mrp function, these data suggests that liver and kidney do not work in tandem to protect the mouse during cholestasis. # 516 VOLATILE ORGANIC COMPOUND EXPOSURE ASSESSMENT FOR GOVERNMENT INSPECTORS AT GAS STATIONS.

M. J. Fedoruk<sup>2, 3</sup>, R. Bronstein<sup>3</sup> and <u>B. D. Kerger<sup>1</sup></u>. <sup>1</sup>HSRI, Inc., Tallahassee, FL, <sup>2</sup>Center for Occupational and Environmental Health, University of California-Irvine, Irvine, CA and <sup>3</sup>Exponent, Inc., Irvine, CA.

This study assessed occupational exposure to selected gasoline-derived volatile organic compounds (VOCs) among air quality inspectors at 23 gas stations selected to represent plausible high end exposures based on historical air quality violations. Five inspectors volunteered for the study and followed their normal routine inspection process including review of records, equipment inspection, and in one case calibration tests on selected gas pumps. Each inspector was fitted with three personal air monitoring devices: a full-shift badge monitor (approx. 8 hours) and two active sorbent tube monitors (battery pump, one for full shift and one for am/pm only, 2-3.5 hours each). Monitored analytes included TPH (total petroleum hydrocarbons, gasoline range), MTBE (methyl-tert-butyl ether), benzene, toluene, ethylbenzene and xylenes. TPH, MTBE and toluene were found in nearly all samples while benzene and xylenes were detected infrequently and at low levels, and ethylbenzene was never detected. There was generally good agreement between the badge and active monitoring results when normalized as time-weighted averages and after considering detection limit differences. Gas pump calibration tests were associated with the highest exposure to the VOCs tested, including at-facility-only maximum values of: TPH 29 ppm; MTBE 1.7 ppm; benzene 0.05 ppm; toluene 0.6 ppm; and xylenes 0.3 ppm. All measured VOCs were found at mean and maximum concentrations well below their respective permissible exposure limits set by the Occupational Safety and Health Administration. It is concluded that exposures of these government inspectors to the selected gasoline-derived VOCs at gas stations were relatively low compared to current workplace regulatory limits.

# 517 EXPOSURE ASSESSMENT OF VOLATILE ORGANIC COMPOUNDS AND METALS FOR GOVERNMENT INSPECTORS AT AUTO BODY REPAIR FACILITIES.

B. D. Kerger<sup>1</sup>, R. Bronstein<sup>3</sup> and M. J. Fedoruk<sup>2, 3</sup>. <sup>1</sup>HSRI, Inc., Tallahassee, FL, <sup>2</sup>Center for Occupational and Environmental Health, University of California-Irvine, Irvine, CA and <sup>3</sup>Exponent, Inc., Irvine, CA.

This study assessed occupational exposure to selected volatile organic compounds (VOCs) and metals among air quality inspectors at auto body repair and painting facilities selected to represent plausible high-end exposures based on historical air

quality violations. Four inspectors volunteered for the study and followed their normal routine inspection process including review of records and equipment inspection. Each inspector was fitted with four personal air monitoring devices: a fullshift badge monitor for VOCs (approx. 8 hours), two active sorbent tube monitors for VOCs measured while at each facility (battery pump, one for full shift and one for am/pm only), and one active cassette monitor for metals measured while at each facility. Monitored analytes included a broad scan of metals (28 including all common heavy metals, total hydrocarbons in hexane equivalents, benzene, toluene, ethylbenzene, xylenes and styrene. None of the inspectors had detectable exposures to any of the metals assessed (e.g., Al, As, Be, Cd, Cr, Co., Cu, Pb, Mg, Mn, Se, Sr, Sb, Ti, Zn) at detection limits at or below 0.02 mg/cu.m. Benzene and styrene were not detected (detection limits generally below 0.05 and 0.2 ppm, respectively) in any air samples. Total hydrocarbons as hexane equivalents ranged from 0.4 to 2.9 ppm, toluene from 0.1 to 0.6 ppm, ethylbenzene from 0.006 to 0.03 ppm, and xylenes from 0.03 to 0.9 ppm during inspections only. There was good agreement between the badge and active monitoring results for VOCs when normalized as timeweighted averages and after considering detection limit differences. All measured VOCs were found at mean and maximum levels well below their respective permissible exposure limits set by the Occupational Safety and Health Administration. It is concluded that exposures of these government inspectors to the selected VOCs and metals at auto body repair facilities were relatively low compared to current workplace regulatory limits.

### 518 EXPOSURE CHARACTERIZATION FROM A SURROGATE FINE FRAGRANACE.

D. A. Isola<sup>1</sup>, R. E. Rogers<sup>2</sup>, R. Ansari<sup>3</sup> and <u>L. W. Smith</u><sup>1</sup>. <sup>1</sup>Reaearch Institute for Fragrance Materials, Inc. , Woodcliff Lake, NJ, <sup>2</sup>Toxcon Health Sciences Research Centre, Inc., Edmonton, AB, Canada and <sup>3</sup>Quest International Fragrances Company, Mount Olive, NJ.

This study was designed to assess human respiratory exposure to a surrogate fine fragrance and address concerns about asthma, lung disease, and neurological effects. The test fragrance reflected a product with a low level of scent over time after topical application by an atomizer. The formulation contained 2.2% each of benzyl acetate (BA), eugenol (EU),  $\alpha$ -hexylcinnamaldehyde (HCA), 1, 3, 4, 6, 7, 8-hexahydro-4, 6, 6, 7, 8, 8-hexamethylcyclopenta- $\gamma$ -benzopyran (HHCB), hydroxycitronellal (HO-C), β-ionone (β-I), d-limonene (d-L), linalool (LL), and methyl dihydrojasmonate (MDJ) and 80% of a vehicle (80% EtOH and 20% HOH). The fragrance materials were chosen based on volatility, chemical structure, toxicity, and volume of use. The test product was sprayed toward a manikin at a distance of 3.5 inches. Three different anatomical areas were sprayed with 3 pump actuations each. The concentration of each fragrance material was measured at the adult-breathing zone (5 ft) and the child-breathing zone (1.5 ft) from the start of spray until 5 hrs post-spray. Particle size analysis was also conducted. The samples were collected on thermal desorption tubes and analyzed by GC/MS. The data showed that 0.89 g of test material was released after 9 actuations. Peak total fragrance air concentrations of 1256 mg/m<sup>3</sup> (adult zone) and 850 mg/m<sup>3</sup> (child zone) were seen at 8-18 min post spray. The more volatile fragrance materials (d-L, LL, BA) peaked at that time. The less volatile fragrance materials (β-I, MDJ, HCA, HHĈB, EU, HO-C) peaked at later time periods, generally. Previous studies with air fresheners showed peak fragrance air concentrations of 2550 mg/m<sup>3</sup> (adult zone)/2070 mg/m<sup>3</sup> (child zone) at 1 min for aerosols and 2286 mg/m<sup>3</sup> at 1 hr for plug-ins. The product type and volatility of each fragrance material affect air concentration. The exposure data will be used for clinical study design.

### 519 EVALUATION OF EXPOSURE TO METALS ON REUSABLE SHOP TOWELS.

L. Beyer, M. R. Seeley and B. D. Beck. Gradient Corp., Cambridge, MA.

We evaluated health risks from use of reusable shop towels (RSTs) which may have metal and oil/grease contamination even after being laundered. We estimated oral intake of metals in laundered shop towels for two potential exposure pathways: a) hand contact with laundered shop towels and subsequent transfer to the mouth, and b) direct contact of RSTs with the lips. Because there are no standard methodologies for evaluating exposure to metals in towels, we developed an approach to estimate the amount of metal that could be transferred from the towels, and ultimately ingested. For exposure via hand contact with the laundered shop towels, we estimated transfer of metals from RSTs to hands based on empirical data regarding transfer of pesticide residues from surfaces to hands, using methodology developed by the US Consumer Products Safety Commission for evaluating exposure to dislodgeable residues on treated wood surfaces. We considered the number of RSTs used daily per person, the percentage of the towel surface area that would contact the hand, and the hand-to-mouth transfer efficiency. For exposure via direct contact with the lips, we estimated transfer of metals from laundered shop towels to the lips based on data regarding transfer of pesticide residues from surfaces to hands, the surface area of the lips, as well as estimates of the fraction of the lip surface area contacting the laundered shop towels, fraction of the metal on the lip that is ultimately ingested, and the number of times per day that lips are wiped with RSTs. We compared the results of this analysis to various allowable/recommended levels developed by USEPA, the Agency for Toxic Substances and Disease Registry, and California EPA (under Proposition 65), and concluded that: 1) laundered RSTs contain heavy metals, 2) metals on shop towels may get onto hands and then inadvertently be ingested, and 3) the amount of metals (especially lead) that someone might accidentally ingest from RSTs may potentially exceed regulatory and/or recommended limits. We performed a focused uncertainty evaluation to assess the impact of alternate assumptions on the conclusions.

## 520 POTENTIAL HEALTH EFFECTS OF EXPOSURE TO METHYLENEDIANILINE AND TOLUENEDIAMINE DURING POLYURETHANE FOAM MANUFACTURING.

T. A. Lewandowski<sup>1</sup>, A. Hayes<sup>3</sup> and B. D. Beck<sup>2</sup>. <sup>1</sup> Gradient Corporation, Seattle, WA, <sup>2</sup>Gradient Corporation, Cambridge, MA and <sup>3</sup>School of Public Health, Harvard University, Cambridge, MA.

Methylene diphenylisocyanate (MDI) and toluenediisocyanate (TDI) are used by a wide number of industries to produce polyurethane foam products. Small amounts of methylenedianiline (MDA) and toluene diamine (TDA) are released during MDI and TDI polymerization and may be present in the newly finished polyurethane parts. MDA and TDA concentrations in foam decline exponentially within several hours of demolding. MDA and the 2, 5-isomer of TDA are known animal carcinogens and have also been reported to have significant non-carcinogenic health effects. Neither chemical is commonly found at sites of environmental pollution and thus fall outside the standard risk assessment process. Our goal was to determine whether worker exposures to MDA or TDA in freshly produced polyurethane foams were associated with unacceptable health risks. Unique aspects of this work were the lack of standard toxicity values (i.e., RfDs, CSFs) for these two chemicals and the unusual exposure pathway, which involved dermal transfer of a non-aqueous liquid from the foam surface to the hand; a process which varied across different worker tasks. Sampling and analysis of the fresh foam indicated that MDA and TDA concentrations at demolding varied considerably among production lines but MDA and TDA concentrations in all materials evaluated declined rapidly over time. For example, levels of TDA isomers declined about 4-fold within the first three hours. We found that under a worst-case exposure scenario, cancer risks from TDA exposure were approximately 5x10<sup>-6</sup> whereas cancer risks from MDA exposure resulted in a tumorigenic MOE of 85, 000. Non-cancer hazard indices were also well below 1.0. Thus, we found that estimated cancer and non-cancer risks from MDA or TDA exposure from newly manufactured foam parts would fall well within normal occupational risk criteria. This analysis also suggested that risks for downstream workers and consumers would also likely be below levels of concern.

## 521 IRIDIUM TRACER USED TO MEASURE IN-VEHICLE DIESEL PARTICULATE MATTER CONCENTRATIONS.

M. D. Easter<sup>1</sup>, M. L. Lakin<sup>1</sup>, R. Ireson<sup>2</sup>, C. Lapin<sup>3</sup>, T. Hesterberg<sup>4</sup> and W. Bunn<sup>4</sup>. <sup>1</sup>EnSIGHT, Walnut Creek, CA, <sup>2</sup>AQM Consulting, Greenbrae, CA, <sup>3</sup>Lapin and Associates, Glendale, CA and <sup>4</sup>International Truck and Engine Corporation, Chicago, II.

Previous studies reported diesel particulate matter (DPM) inside diesel-fueled school buses and potential exposure to occupants. These studies did not directly measure DPM, but assumed relationships between DPM and other pollutants present in the air, including black carbon, to estimate DPM. Numerous sources of black carbon other than diesel exhaust exist. This study used an analytical method capable of distinguishing particulate matter (PM) emitted by the study bus from other sources of PM that may enter it. Iridium (Ir) was used as a tracer added to the bus's fuel to identify the PM present in its exhaust and on-board air. Low ambient levels and the availability of sensitive analytical techniques made Ir an ideal tracer. Instrumental neutron activation analysis was used and is capable of measuring Ir to better than +/-1 picogram. Measurements of Ir inside the bus provide a basis for estimating exposure to PM from its own exhaust (DPM<sub>SB</sub>) with high sensitivity. The average DPM  $_{SB}$  concentration inside the study bus was 0.22  $\mu g/m3$  - much less than other reported estimates of DPM. The California Air Resources Board reported that the average concentration of DPM in vehicles in a Los Angeles field study to be 33  $\mu g/m3$  - 150 times greater than the DPM<sub>SB</sub> inside the bus in the current study. The concentrations of total fine particulate matter (PM2.5) and Ir were not correlated. Thus, the use of total PM2.5 as a surrogate for estimating the amount of DPM coming from the bus's own exhaust is inappropriate. The concentration of PM from the bus's own exhaust was a very small percentage of the total PM2.5 inside the bus, ranging from 0.09%-0.77%. Evidence suggests that the levels of PM2.5 and DPM found inside a school bus should be no greater than those found inside any other vehicle traveling on the same roads.

M. Fay. Toxicology, ATSDR, Atlanta, GA. Sponsor: M. Mumtaz.

To determine the need for information on the joint effects of chemicals, the Chemical Mixtures Program of the Agency for Toxic Substances and Disease Registry (ATSDR) seeks to answer, "How often does exposure to chemical mixtures of environmental contaminants occur?" The frequency of exposure to mixtures was studied by analyzing contaminants found in completed exposure pathways (CEPs) in ATSDR's HazDat database (see www.atsdr.cdc.gov). CEPs are documented pathways that have led to exposure at hazardous wastes sites (HWSs). Evaluation of data from 1, 706 HWSs reveals that CEPs occurred at 743 (44%) of the sites. Of these, 588 sites had two or more substances in a CEP. Thus, exposure to mixtures occurred at 79% of the 743 sites with exposure. However, sites often have more than one pathway, and pathways with a single contaminant are common. The number of exposure pathways with two or more chemicals is estimated to be approximately half of all CEPs. This does not include exposure via multiple pathways/routes, so the extent of exposure to multiple chemicals at HWSs might be higher. Further analysis revealed that exposure to simple mixtures consisting of 3, 4, and 5 components occurred at 475, 390, and 321 sites, respectively. Although two chemicals constitute a mixture, 64% of the 743 sites had 3 in a CEP, 52% had 4 in a CEP, and 43% had 5 in a CEP. Exposure to mixtures by specific media was as follows: water, 413 sites; soil, 255 sites; air, 113 sites; and biota (mainly fish), 53 sites. Overall, water pathways had mixtures more often for lower numbers of chemicals (2 to 8 chemicals), but the number of sites with mixtures in soil pathways surpassed the counts for water at (and above) nine chemicals in the mixture. The maximum number of chemicals in a CEP was 62. In conclusion, this study shows that about fourfifths of HWSs with CEPs have chemical mixtures in a CEP, and, more importantly, that about half of all CEPs have a chemical mixture. Thus, exposure to mixtures of chemicals is quite common at HWSs.

## 523 FIBER GLASS AND ROCK/SLAG WOOL EXPOSURE OF PROFESSIONAL INSTALLERS.

L. D. Maxim<sup>1</sup>, W. Eastes<sup>5</sup>, <u>J. G. Hadley</u><sup>2</sup>, C. M. Carter<sup>3</sup>, J. W. Reynolds<sup>4</sup> and R. Niebo<sup>1</sup>. <sup>1</sup>Everest Consulting Associates, Cranbury, NJ, <sup>2</sup>Owens Corning Science and Technology Center, Granville, OH, <sup>3</sup>Johns Manville, Littleton, CO, <sup>4</sup>Certain Teed, Valley Forge, PA and <sup>5</sup>Consultant, Granville, OH.

This study estimates the average cumulative lifetime exposure (fiber-months/cc) of professional installers of fiber glass (FG) and rock/slag wool (RSW) insulation and compares these estimates to the cumulative exposure of workers in plants that manufacture these materials. Key inputs to the exposure model include the frequency and duration of exposures, occupational tenure, mix of insulation types (e.g., FG, RSW) and forms (e.g., blown/loose fill, batts/blankets) installed, workplace concentrations, and extent of respirator usage. Based on best estimates/ranges for these inputs, the average cumulative exposures to FG (from 4 to 7 fiber-months/cc) and RSW (from 2 to 3.3 fiber-months/cc) are considerably less than the cumulative exposures experienced by manufacturing cohorts. Published epidemiological studies of FG and RSW manufacturing cohorts in the United States have shown that there is no significant increase in respiratory system cancer (RSC) compared to appropriate reference populations. The cumulative exposures of the manufacturing cohorts vary with insulation type and plant; maximum (benchmark) values are 23.5 fibermonths/cc for FG plants and 40 fiber-months/cc for RSW plants. Thus, based on fiber exposure, the professional installer cohort is unlikely to experience increased respiratory system cancer. Sensitivity analyses indicate that this conclusion is robust to estimation errors in key inputs.

## 524 AN OCCUPATIONAL EXPOSURE DATABASE FOR SYNTHETIC VITREOUS FIBERS (SVFS).

G. E. Marchant<sup>1</sup>, D. Maxim<sup>3</sup>, J. W. Reynolds<sup>5</sup>, C. M. Carter<sup>4</sup>, A. E. Crane<sup>6</sup> and J. G. Hadley<sup>2</sup>. <sup>1</sup>College of Law, Arizona State University, Tempe, AZ, <sup>2</sup>Owens Corning Science and Technology Center, Granville, OH, <sup>3</sup>Everest Consulting Associates, Cranbury, NJ, <sup>4</sup>Johns Manville, Littleton, CO, <sup>5</sup>CertainTeed Corporation, Valley Forge, PA and <sup>6</sup>North American Insulation Manufacturers Association, Alexandria, VA.

This poster presentation will describe an occupational exposure database for synthetic vitreous fibers that contains the largest number of exposure samples for fiber glass and mineral wool insulation products ever assembled. This exposure database has been created by the North American Insulation Manufacturers Association (NAIMA) and its members as part of the Health and Safety Partnership Program (HSPP), a comprehensive voluntary occupational safety and work practice partnership being implemented by the SVF industry under OSHA's oversight. The database now contains over 10, 000 validated exposure samples, which are individually classified by numerous parameters including fiber type, product type, industrial

sector, job function, and respirator use. This capability to sort the exposure data by particular parameters can be used for several purposes, including (i) to provide a robust estimate of expected exposure levels for a particular occupational exposure scenario; (ii) to track changes in exposure levels over time; and (iii) to identify occupational exposure scenarios where additional protection (e.g., respirator use) may be needed or may no longer be needed. Cumulative exposure data are presented for the manufacturing, fabrication, installation, and demolition sectors for the major fiber types, along with data stratified for some specific product type/job function combinations that may be of particular interest (e.g., installation of blowing wool insulation). The overall and stratified data show that exposure levels in the industry are generally well below the 1 f/cc 8-hour TWA voluntary standard, with a relatively small number of specific exposure scenarios where exposures approach or exceed 1 f/cc.

#### 525

OCCUPATIONAL EXPOSURE TO AIRBORNE CHRYSOTILE ASBESTOS DURING USE AND REMOVAL OF MASTICS, COATING, AND ADHESIVES (CIRCA 1940S-PRESENT DAY).

F. S. Mowat<sup>1</sup>, M. Bono<sup>2</sup> and <u>D. J. Paustenbach<sup>3</sup></u>. <sup>1</sup>Exponent, Menlo Park, CA, <sup>2</sup>Exponent, Hudson, OH and <sup>3</sup>ChemRisk, San Francisco, CA.

In recent years, questions have been raised about the health risks to persons who used asbestos-containing products from the 1940s to present day. Modern era sampling and analytical techniques are often needed to quantify exposure for many of these products, and exposure simulation studies have more frequently been used to estimate the historical airborne concentrations resulting from these products. This research measured the release of chrysotile asbestos during the physical manipulation of coatings, mastics, and an adhesive, which contained 1-8% asbestos within a tarry or a water-based medium. The purpose was to understand whether these products generated any measurable amount of airborne asbestos concentrations that workers or bystanders might be exposed during the use or manipulation of these products. These products were often used to adhere insulation to pipes and boilers or to cover the insulation so as to protect it from direct contact with water, as well as wear and tear. Tests were conducted to evaluate fiber release from such activities as application, spill cleanup, sanding, removal/cutting, and sweep cleaning. Each test activity was performed for 30 minutes, often in triplicate. Personal, area, and background/clearance air samples were collected during the tests, and analyzed for total fiber concentrations using phase contrast microscopy (PCM) and transmission electron microscopy (TEM). No asbestos fibers were identified in 446 of 452 samples collected during these activities. The calculated 8-hour time-weighted average (TWA) airborne concentration for the remaining six samples using hypothetical work scenarios ranged from 0.009 to 0.03 f/cc. Thus, actual and predicted airborne concentrations were well below the current and contemporaneous occupational exposure limits for chrysotile asbestos. Based on these results, these products did not pose an asbestos-related health risk to those who applied or interacted with

#### 526

MERCURY BODY BURDEN AND INTAKE IN TWO CANADIAN COASTAL COMMUNITIES: GRAND MANAN AND ST ANDREWS/ST STEPHEN.

M. Legrand and <u>H. Chan</u>. CINE - McGill University, Ste Anne de Bellevue, QC, Canada.

Mercury exposure in two Canadian costal communities, Grand Manan and St Andrews/ St Stephen, New Brunswick, Canada was assessed with hair samples and sources of exposure through dietary methods identified. Mean arithmetic concentration of total mercury in hair was 0.7 +/- 0.55 mg/Kg at Grand Manan and 0.419 +/- 0.15 mg/Kg for St Andrews/St Stephen. All participants incurred daily total mercury ranging from near zero to 0.286 ug/kgbw/day which is below the 0.73 ug/kgbw/day providional tolerable daily intake of Health Canada. The low intakes and body burdens can be explained by the low level of mercury found in the species being consumed and their frequency of consumption. The top contributors to mercury intake included haddock, canned tuna, lobster, pollock and lake trout. The correlation between hair mercury and intake (defined as micrograms of mercury per spring season) yielded a 0.32 correlation coefficient. This supports the view that estimating mercury levels in hair using a focused food frequency questionnaire coupled with the 24 hour recall is a reliable technique. To our knowledge, this is the first reported study examining mercury body burden in human populations living along the Bay of Fundy and the first to report trends of fish and seafood consumption from that area. Mercury body burden and mercury intake show that, even though fish and seafood are consumed on a regular basis, particularly at Grand Manan, mercury intake is not a serious problem because the species being consumed contain low levels of mercury.

### FETAL EXPOSURE TO PHYTOESTROGENS IN JAPAN: FOCUSING ON EQUOL.

E. Todaka<sup>1, 2</sup>, H. Osada<sup>3</sup>, M. Omori<sup>1, 3</sup>, H. Miyakawa<sup>4</sup>, M. Uzuki<sup>4</sup>, Y. Ikezuki<sup>5</sup>, O. Tsutsumi<sup>5</sup>, K. Sakurai<sup>6</sup>, H. Fukata<sup>7</sup>, T. Iguchi<sup>8, 9</sup> and <u>C. Mori<sup>1, 9, 1</sup> Bioenv</u> Med., Chiba University, Chiba, Japan, <sup>2</sup>Center Env Health, Field Sciences, Chiba University, Chiba, Japan, <sup>3</sup>OB/GY, Chiba University Hospital, Chiba, Japan, <sup>4</sup>SRL Inc., Tokyo, Japan, <sup>5</sup>OB/GY, University of Tokyo, Tokyo, Japan, <sup>6</sup>Clin Cell Biol, Chiba University, Chiba, Japan, <sup>7</sup>Env Med. Science (SRL), Chiba University, Chiba, Japan, <sup>8</sup>Bioenv Research, Center for Integrated Bioscience, Okazaki National Research Institutes, Okazaki, Japan and <sup>9</sup>CREST, Kawaguchi, Japan.

Phytoestrogens are estrogen-like chemicals derived from plants mainly soy. As there is a concern if it is safe when human fetus is exposed to excess amount of phytoestrogens, we investigated the feto-maternal relationship of serum concentration levels of phytoestrogens. We collected 51 maternal and newborn cord serum and measured the concentration level of genistein, daidzein, equol and coumestrol by liquid chromatography/tandem-mass spectrometry. Informed consent from each mother was obtained. This study was approved by the Congress on Medical Bioethics at Chiba University. Genistein was detected from 96% of maternal serum and 100% of cord serum. Daidzen was detected from 75% of maternal serum and 80% of cord serum. Equol was detected from 37% of maternal serum and 35% of cord serum. Coumestrol was detected from only one maternal serum. Equol is a metabolite of daidzein and is reported to be more estrogenic than daidzein or genistein. However, it is well known that there are equol producers and equol non-producers. In our study, the average concentration level of equol of maternal and cord serum were 0.89ng/ml and 2.04ng/ml each. Also, there was a tendency found that the endogenous estrogen level of newborns that were exposed to equol was lower than the newborns that were not exposed to equol. Furthermore, there was another tendency found that the concentration level of E2 was lower in female than male newborns when they were divided as equol exist group and non-exist group. The meaning of this finding should be cleared in the future. (This work was supported by the fund for endocrine disrupters from the Ministry of the Environment, Japan)

## 528 DIALKYL PHOSPHATES (DAP) IN PRODUCE CONFOUND BIOMONITORING IN ORGANOPHOSPHATE RISK ASSESSMENT.

X. Zhang<sup>2,3,1</sup> and <u>R. I. Krieger</u><sup>3,1,2</sup>. <sup>1</sup>Department of Entomology, University of California, Riverside, Riverside, CA, <sup>2</sup>Environmental Toxicology Graduate Program, University of California, Riverside, Riverside, CA and <sup>3</sup>Personal Chemical Exposure Program, University of California, Riverside, Riverside, CA.

Organophosphate (OP) pesticides produce trace residues in fruits and vegetables protected from insect pests. DAPs are important as stable urine biomarkers of OP exposure. OP excretion may be estimated by the back calculation of absorbed daily dosage from urinary DAPs. DAPs may also be formed as a result of plant metabolism. In this study, DAPs were measured in produce for the first time as part of exposure assessment to evaluate whether preformed DAPs from plants could confound OP exposure assessment. Seventy-seven samples from the channels of trade in California were measured for DAPs and the parent OPs. Only produce known to contain an OP residue from routine monitoring by shippers and producers was selected for stduy. The OP pesticides were acephate, azinphosmethyl, chlorpyrifos, diazinon, dimethoate, dimethoate/omethoate, malathion, methamidophos, methidathion, oxydemeton-methyl and phosmet. All residues were below established residue tolerances. Fifty-one out of 77 samples (66%) contained more DAP residue than parent OPs. The mole ratios of DAPs to parent OP residues ranged from 0.1 to 73. The produce contained 4- to 5- times more oxidized APs (dimethylphosphate and diethylphospahte) than sulfurated products (dimethylthiophosphate and diethylthiophospahte). Urine of persons that consume OP treated produce will contain preformed DAPs as well as human metabolites resulting from biotransformation of the OP residue. All preformed DAPs represent false positives in any attempt to back-calculate OP exposure for children or adults. The practice of using urinary DAPs to estimate OP exposure may result in a substantial overestimate of the low dosages of the general population.

## 529 PROBABILISTIC METHODS TO ASSESS WORKER EXPOSURE TO AGRICULTURAL PESTICIDES.

E. Julien and . ILSI RSI Working Group. Risk Science Institute, International Life Sciences Institute, Washington, DC. Sponsor: P. Fenner-Crisp.

Assessing health risk posed by chemical contaminants in the environment requires the integration of data from two distinct disciplines: toxicology and exposure assessment. Methodology for exposure assessment has undergone rapid development over the last decade, particularly in the area of exposure modeling. Software tools now provide the computational power to conduct probabilistic exposure assessments, which explicitly incorporate variability in data for key determinants of ex-

posure (e.g. variability in rate of contact with media containing a contaminant, variability in contaminant concentration). Thus, probabilistic analyses generate, for a specified population, distributions of exposure estimates (external dose estimates) that reflect the full range of potential exposure levels and their probabilities. Regulatory agencies have used probabilistic exposure modeling to assess risk from exposure to a variety of environmental toxicants. Such agencies are now examining probabilistic methods for occupational exposure assessment, specifically, worker exposure to agricultural pesticides. A number of scientific and statistical questions are raised, however, when probabilistic methods are applied in a novel way. To address these questions, ILSI RSI convened a Working Group with experts from diverse disciplines (occupational exposure assessment, dermal absorption assessment, probabilistic modeling, and statistics). This poster will present the Working Group's findings regarding: 1) developing model input distributions to characterize exposure to agricultural pesticides; 2) incorporating absorbed dose in a probabilistic assessment; 3) conducting a 2-dimensional assessment, which separates variability and uncertainty; and 4) interpreting and communicating results of a probabilistic worker exposure assessment. (Project sponsors include: USEPA, European Commission, Crop Life America, NIOSH, Health Canada, Crop Life International, European Crop Protection Association, California Department of Pesticide Regulation and ILSI RSI).

## 530 MEASURING CHILDREN'S HOME EXPOSURE TO TETRACHLORVINPHOS FROM FLEA CONTROL COLLARS APPLIED TO THEIR PET DOG.

J. S. Boone, J. W. Tyler and J. E. Chambers. Center for Environmental Health Sciences, College of Veterinary Medicine, Mississippi State University, Mississippi State, MS.

Family units were chosen to determine the levels of the insecticide tetrachlorvinphos that could be transferred to children from a flea control collar from the family pet dog. One child (3-12 years) from each household wore t-shirts at home 5 different days before the application of the collar and for 5 consecutive days between days 6 and 12-post collar application (5 pre- and 5 post-). The dogs were petted to determine available transferable residues on days 6 and 12 using white cotton gloves. Commercially available flea control collars containing the organophosphate insecticide tetrachlorvinphos (14.55%, 33g collar) were applied to dogs as per package directions. Transferable residues were quantified by petting the dog for 5 minutes in 3 areas (neck with collar, neck, and back), and yielded residues ranging from 1300 to 63000 ug, 900 to 30000 ug, and 2 to 750 ug, respectively. A 100 square inch area was cut out of each t-shirt on the front chest area and weighed. The t-shirt samples were analyzed for tetrachlorvinphos; the pre-application t-shirts averaged <0.05 ng/g t-shirt and the post-application t-shirts averaged 2700 ng/g tshirt. The t-shirt samples worn during the 5 days after placement of the collars ranged from <0.05 ng/g to 47000 ng/g. The variability between and among the families was high. The t-shirts from the child in family 119 averaged 40 ng/g (range 12 to 70 ng/g). The t-shirts from the child in family 120 averaged 13, 000 ng/g (range 290 to 47000 ng/g). The child from family 119 spent less time with the pet dog than the other children, but children from other families spent more time with their pet dog than the one from family 120. The child from family 116 spent the most time with the pet dog and averaged 490 ng/g. The introduction of flea control collars containing tetrachlorvinphos into homes increases the amount of transferable residue of tetrachlorvinphos, to variable extents. (Supported by EPA R-

# THE ASSOCIATION BETWEEN MEDICATION USE AND TAMOXIFEN (TAM) AND TAM METABOLITE CONCENTRATIONS IN WOMEN WITH BREAST CANCER.

L. Gallicchio<sup>1</sup>, K. Tkaczuk<sup>2</sup>, L. Lewis<sup>1</sup> and J. A. Flaws<sup>1, 2</sup>. <sup>1</sup>Department of Epidemiology and Preventive Medicine, University of Maryland School of Medicine, Baltimore, MD and <sup>2</sup>The Greenebaum Cancer Center, University of Maryland School of Medicine, Baltimore, MD.

Tamoxifen (TAM) is a selective estrogen receptor modulator that is metabolized *via* cytochrome P450 enzyme pathways into several major metabolites, including N-desmethyltamoxifen (N-DMT) and 4-hydroxytamoxifen (4-OHT). Since the data regarding the interaction of TAM with other medications are limited, this study was carried out to determine whether other types of medications co-prescribed with TAM significantly influenced the plasma concentrations of TAM, N-DMT, and 4-OHT. Participants were 98 breast cancer patients who had been taking TAM for at least 30 days. Each participant completed a questionnaire and agreed to a medical chart review, which was used to obtain information on medication use at the time of enrollment. In addition, each woman provided a blood sample that was used to

measure plasma concentrations of TAM, N-DMT, and 4-OHT by high performance liquid chromatography. Results of the analysis showed that participants who were taking a diuretic had significantly higher mean plasma concentrations of TAM and N-DMT than participants not taking a diuretic, independent of age, race, body mass index, and months taking TAM. In contrast, arthritis/pain medication intake was negatively associated with plasma TAM concentrations. The use of other types of medications such as chemotherapeutic agents, allergy drugs, anti-depressants, and diabetes medications did not significantly alter plasma TAM, N-DMT, or 4-OHT concentrations. Our findings suggest that treatment with a diuretic or an arthritis/pain medication may significantly affect TAM metabolism. Future studies should investigate the clinical significance of the interaction of these drug types with TAM. This study was supported by DOD Grant DAMD17-00-1-0321 and the University of Maryland, Maryland Statewide Health Network through the Maryland Cigarette Restitution Funds.

532 BRAIN DERIVED NEUROTRPHIC FACTOR (BDNF)
POLYMORPHISM ASSOCIATED WITH INCREASED
SYMPTOM REPORTING AMONG DENTAL
PERSONNEL

N. J. Heyer<sup>1</sup>, <u>D. Echeverria<sup>1, 2</sup></u>, <u>J. S. Woods<sup>1, 2</sup></u>, A. C. Bittner<sup>1, 2</sup> and <u>F. M. Farin<sup>2</sup></u>. <sup>1</sup>Battelle CPHRE, Seattle, WA and <sup>2</sup>Department of Environmental Health, University of washington, Seattle, WA.

Associations were hypothesized between a BDNF polymorphism and increases in self-reported symptoms of poor concentration and memory among 191 male dentists and 231 female dental assistants exposed to mercury (Hg). DNA buccal cell samples were analyzed for the presence of a previously identified SNP at nucleotide 196 (G/A), which produces a valine to methionine substitution at codon 66 (V66M). Genotyping results identified 68% WT, 28% Het, 4% Mut within this population. Self-reported severity, frequency, and duration were collected for 45 symptoms. A priori groups resulted in 14 groups for current symptoms, 16 groups for recent symptoms lasting one month and chronic symptoms lasting more than one year. Alternatively, factor analyses resulted in 6 factors for current symptoms and 10 factors each for recent and chronic symptoms. Regression analyses were conducted for dentists and dental assistants separately controlling for Hg exposure. Among dentists, four factor scores and three a priori ratings were significantly (p<.05) associated with the BDNF polymorphism. Only one was in the unexpected direction. Among dental assistants, three factor scores and seven a priori ratings were significantly associated with the BDNF polymorphism. All associations were in the expected direction. Dentists reported increased symptoms for coordination, muscle weakness, and tremor. Dental Assistants reported increased symptoms for memory, anxiety and tremor. All but one association were within recent and chronic symptoms. Increased reporting for more diverse symptom groups, such as pain, cough and parasthesias were mixed among current, recent and chronic symptoms. These results confirm that the frequency and severity of self-reported symptoms are increased among people with BDNF variants. These symptoms cluster around memory, anxiety and peripheral muscle problems which are not inconsistent with mercury-related health effects. Supported by ES04696 and ES07033.

EFFECT OF TWO COMPLEX ENVIROMENTAL
MIXTURES CONTAINING POLYCYCLIC AROMATIC
HYDROCARBONS (PAHs), DIESEL EXHAUST AND
URBAN DUST, ON THE METABOLIC ACTIVATION OF
CYTOCHROME P450 1A1 IN MOUSE EPIDERMIS.

L. A. Courter, T. Musafia and <u>W. M. Baird</u>. Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR.

Polycyclic aromatic hydrocarbons (PAHs) are widespread environmental pollutants, and are found in complex mixtures such as diesel exhaust and urban dust. We investigated the metabolic activation of cytochrome P450 1A1 (CYP1A1) through the Ethoxyresorufin O-Deethylase (EROD) and Western immunoblot assays. SENCAR mice were topically treated with two Standard Reference Materials (SRM) 1975 (diesel particulate organic extract) or SRM 1649 (urban dust) obtained from the National Institute of Standards and Technology (NIST), and either additional benzo[a]pyrene (B[a]P) or dibenzo[a, l]pyrene (DB[a, l]P for 24 hours. SRM 1975 treatment caused an increase in activity in the epidermis compared to the vehicle control, and a greater increase in activity with the addition of DB[a, l]P. However, with the addition of B[a]P to SRM 1975, there was no CYP1A1 activity. Similarly, SRM 1649 exhibited no activity. However, with the addition of B[a]P, SRM 1649 showed an increase and a greater increase in CYP1A1 activity with the addition of DB[a, l]P. These results indicate that components within PAH-containing environmental mixtures can either inhibit or promote the activation of known carcinogenic PAHs by CYP1A1. (This work was supported by NCI CA28825.)

FORMATION OF *CIS*- BPDE-ADDUCTS AND BASE-STACKED *trans*-BPDE-ADDUCTS IS INCREASED ON SUPERCOILED DNA.

G. Jiang<sup>1</sup>, R. Jankowiak<sup>2</sup>, N. Grubor<sup>2</sup>, M. Banasiewicz<sup>2</sup>, G. Small<sup>2</sup>, M. Skorvaga<sup>3</sup>, B. Van Houten<sup>3</sup> and J. States<sup>1</sup>. <sup>1</sup>University of Louisville, Louisville, KY, <sup>2</sup>Iowa State University, Ames, IA and <sup>3</sup>NIEHS, Research Triangle Park, NC.

534

Benzo[a] pyrene is metabolized to the highly reactive and mutagenic (+)-7R, 8S-dihydroxy-9S, 10R-epoxy-7, 8, 9, 10-tetrahydrobenzo[a]pyrene (BPDE). BPDE forms predominantly N-deoxyguanine DNA adducts in two stereoisomeric configurations (cis and trans). Both eukaryotic and prokaryotic nucleotide excision repair (NER) systems preferentially excise cis-BPDE-adducts. We examined the influence of DNA secondary structure on the stereospecificity of BPDE-adduct formation and on the incision of BPDE-adducts by the prokaryotic UvrABC NER endonuclease. Incision of BPDE-adducts formed at relatively low density (≤ 1 adduct/kb) on supercoiled plasmids by the thermoresistant Bacillus caldotenax UvrABC was 4 - 8-fold better than incision of BPDE-adducts formed on linear DNA. Incision efficiency did not decrease if supercoiled plasmid DNAs were linearized after BPDE adduct formation. These results suggested that adducts formed on linear and supercoiled DNAs differed in configuration and/or conformation. Low temperature fluorescence spectroscopy of adducted supercoiled and linear DNAs confirmed this hypothesis. The spectroscopy results indicated that cis-BPDE-adducts as well as base-stacked trans-BPDE-adducts formed more abundantly in supercoiled DNA than in linear DNA. That the cis to trans-adduct ratio was higher in supercoiled than linear DNA was confirmed by [32P]-postlabeling analyses. The results of these studies indicate that DNA secondary structure influences both the configuration and conformation of BPDE adducts formed at low density, and suggest that the ratio of cis to trans-BPDE-adducts and the amount of base stacked trans-adducts formed under physiological exposure conditions may be higher than inferred from high dose experiments. (Supported in part by NIH Grant 1R01-ES06460 (JCS), the Commonwealth of Kentucky Research Challenge Trust Fund, USDOE contract no. W-7405-Eng-82.) Keyword: UvrABC ; benzo[a]pyrene; stereochemistry

## DNA ADDUCT FORMATION BY DIBENZO(C, P)CHRYSENE IN HUMAN CELL CULTURE.

J. Atkin<sup>1</sup>, H. Garcia<sup>1</sup>, <u>B. Mahadevan</u><sup>1</sup>, T. Musafia<sup>1</sup>, A. Sharma<sup>2</sup>, S. Amin<sup>2</sup> and <u>W. Baird</u><sup>1</sup>. <sup>1</sup>Oregon State University, Corvallis, OR and <sup>2</sup>Institute for Cancer Prevention, Valhalla, NY.

Polyaromatic hydrocarbons (PAH) are ubiquitous environmental pollutanats that have been associated with cancer incidence. PAH are activated in human cells to active metabolites that adduct to DNA. Benzo(a)pyrene (BP) has a bay region that contributes to its carcinogenicity, while more potent dibenzo(a, l)pyrene (DBP) has a fjord region. Dibenzo(c, p)chrysene has both bay and fjord region and we wanted to compare its carcinogenic activation to BP and DBP. We studied the DNA adduct formation by dibenzo(c, p)chrysene and two of its metabolites, dibenzo(cp)C-1, 2-dihydrodiol and dibenzo(c, p) C-11, 12-dihydrodiol, by 33P postlabeling and HPLC analysis. We also assesed the toxicity of these compounds by MTT cytotoxicity assay. Our results show DNA adduct formation by the metabolites of DBC. The MTT assay showed no toxicity with DBC at concentrations up to 30ng/ul, while BP and DBP were toxic to MCF 7 cells at lower concentrations. H.G.P. was supported by ES 007316. The work was supported by grant CA 28825.

### 536 LUNG DNA ADDUCT FORMATION IN MICE EXPOSED TO DIBENZO[*A, L*]PYRENE: A DOSE-RESPONSE STUDY.

B. Mahadevan<sup>1</sup>, J. Atkin<sup>2</sup>, C. Bravo<sup>3</sup>, A. Luch<sup>4</sup>, L. Steppan<sup>5</sup>, N. Kerkvliet<sup>6</sup> and W. M. Baird<sup>7</sup>. <sup>1</sup>Environmental&Molecular Toxicology, Oregon State University, Corvallis, OR, <sup>2</sup>Environmental&Molecular Toxicology, Oregon State University, Corvallis, OR, <sup>3</sup>Environmental&Molecular Toxicology, Oregon State University, Corvallis, OR, <sup>4</sup>MIT Center for Cancer Research, Massachusetts Institute of Technology, Cambridge, MA, <sup>5</sup>Environmental&Molecular Toxicology, Oregon State University, Corvallis, OR, <sup>6</sup>Environmental&Molecular Toxicology, Oregon State University, Corvallis, OR and <sup>7</sup>Environmental&Molecular Toxicology, Oregon State University, Corvallis, OR.

Polycyclic aromatic hydrocarbons (PAH) are environmental carcinogens present in the atmosphere from combustion sources such as cigarette smoke, diesel exhaust, urban dust, as well as industrial coal tar production. To date, dibenzo[a, /]pyrene (DBP) has been found to be the strongest tumor-initiating PAH ever tested in skin and rat mammary glands. In our study we show for the first time that systemic exposure to DBP causes DNA damage in mouse lung tissue. C57B1/6 mice were dosed by gavage with DBP at 1, 5 or 20 mg/kg body weight, daily for 10 days. Results indicated a decrease in body weight only at the highest dose. The lungs from treated mice were removed and DNA was isolated for DNA adduct analysis.

<sup>33</sup>P postlabeling of DNA adducts analyzed by reverse phase high performance liquid chromatography (HPLC) revealed a dose-dependent DNA adduct formation in the mouse lung tissue. A major portion of the DNA adducts formed were contributed by (-)-anti-DB[a, I]PDE (DBP-DE), the ultimate carcinogenic metabolite of DBP. This data is consistent with and also support previous findings that the anti-isomer of DBP is more carcinogenic than the syn isomer.

## 537 ACCELERATED DNA ADDUCT FORMATION IN LUNG, NASAL MUCOSA, AND LIVER OF RATS EXPOSED TO URBAN AIR IN KAWASAKI, JAPAN.

H. Sato<sup>1, 2</sup>, <u>K. T. Suzuki<sup>2</sup></u>, H. Sone<sup>1</sup>, Y. Yamano<sup>3</sup>, J. Kagawa<sup>3</sup> and <u>Y. Aoki<sup>1</sup></u>.

<sup>1</sup>Research Center for Environmental Risk, National Institute for Environmental Studies, Tsukuba, Ibaraki, Japan, <sup>2</sup>Graduate School of Pharmaceutical Sciences, Chiba University, Chiba, Japan and <sup>3</sup>Department of Public Health, Tokyo Women's Medical University, Tokyo, Japan.

Various polycyclic aromatic hydrocarbons (PAHs) generated by the combustion of fossil fuels, such as from diesel engines and industry, have been detected on suspended particulate matter in ambient air in urban areas. Some PAHs, e.g. phenanthrene, benzo(a)pyrene, and related compounds, are potent mutagens. The potency of ambient air for DNA adduct formation in rat organs was estimated by using a 32P-postlabeling method. Wistar rats were maintained in a small-animal facility located beside an intersection of main highways in the city of Kawasaki, Japan, for 4, 12, 24, 48, or 60 weeks, and exposed to roadside air (exposure group, EG) or clean air (control group, CG). The amount of carbon black deposited in EG lungs was 0.475 mg/g wet tissue after exposure for 60 weeks. Compared with CG, the relative adduct levels (RALs) were increased significantly in EG lungs (17.1-fold; P < 0.05), nasal mucosae (4.0-fold; P < 0.01), and livers (4.9-fold; P < 0.01) after exposure for 4 weeks. There were no significant differences in RALs between EG and CG after exposure for 12 weeks, but RALs were elevated again in EG after exposure for 48 or 60 weeks. The level of cytochrome P450 (CYP) 1A2 mRNA in EG rat liver was 2.3 times higher than in CG after 4 weeks of exposure, but gradually decreased with age in both CG and EG. No difference was observed between CG and EG in the levels of CYP 1A2 mRNA in liver after exposure for 60 weeks. These results suggest that roadside air in this region can cause the generation of DNA adducts. This influence of ambient roadside air can be estimated by using experimental animals, indicating that biological monitoring of DNA adduct formation may be a powerful tool for assessing the effect of ambient air on human health.

## 538 KINETICS OF REACTION OF EPOXIDE METABOLITES OF POLYCYCLIC AROMATIC HYDROCARBONS WITH HUMAN AND MOUSE HEMOGLOBIN.

S. R. Myers, C. Cunningham, T. Wright and H. E. Hurst. *Pharmacology and Toxicology, University of Louisville, Louisville, KY.* 

Previous studies from this laboratory have focused on the detection of hemoglobin adducts to tobacco smoke carcinogens in maternal and fetal blood samples. The present study focuses on the kinetics of reaction of selected polycyclic aromatic hydrocarbon (PAH) epoxides with hemoglobin obtained from human and mouse. In this study, we hypothesize that the relative rate and extent of reaction with hemoglobin will be greatest with those PAH epoxides that are more carcinogenic than others. Specifically, we investigated the relative rates of reaction of benz(a)anthracene (BA), benzo(a)pyrene (BP), dibenz(a, h)anthracene (DBA), benzo(ghi)perylene (BghiP), fluoranthene (F), and benzo(b)fluoranthene (BbF) with hemoglobin. The overall carcinogenicity of these compounds is BP > BbF > DBA > F > BghiP > BA. The results obtained are in agreement with the overall carcinogenicity of the parent hydorcarbons with the PAHs having greater carcinogenicity having a greater extent of protein binding to hemoglobin. In addition, those compounds that were weakly carcinogenic diplayed slower kinetics of reaction with hemoglobin and less overall adduct formation. These results suggest that the formation of hemoglobin adducts of carcinogenic PAH serves as a potential biomarker of exposure and carcinogenicity of PAH. Future studies will determine the validity of these correlations in vivo.

### 539 B[A]P AND B[A]P-7, 8-DIOL INDUCED CELL CYCLE ARREST AND APOPTOSIS IN LNCAP CELLS.

O. F. Nwagbara<sup>1</sup>, S. Reed<sup>1</sup> and R. Gragg<sup>1</sup>. <sup>1</sup>Environmental Sciences Institute, Florida A&M University, Tallahassee, FL, <sup>2</sup>Environmental Sciences Institute, Florida A&M University, Tallahassee, FL and <sup>3</sup>Environmental Sciences Institute, Florida A&M University, Tallahassee, FL. Sponsor: R. Thomas.

Carcinoma of the prostate, a steriod hormone dependent organ accounts for 25% of all cancer cases in the United States, is the second cause of death in males in the US it remains incurable once it has metastized. In 2002, there were about 189, 00

new cases of prostate cancer and estimated 30, 200 prostate cancer-related deaths in the US. Polycyclic aromatic hydrocarbons (PAHs) such as benzo[a]pyrene (B[a]P) and Benzo[a]pyrene-7, 8-dihydrodiol (B[a]P-7, 8-diol) are known to act through the aryl hydrocarbon receptor to elicit a variety of cancer and noncancer endpoints in exposed animal and cellular models, and humans. In addition, B[a]P modulates various endocrine functions by enhancing ligand metabolism, altering hormone synthesis, downregulating receptor levels and interfering with gene transcription. PURPOSE: This study investigates the effects of B[a]P and B[a]P-7, 8-diol on lymph node cancer of the prostate (LNCaP)carcinoma cell cycle progression in the presence and absence of synthetic androgen, R1881. METHODS:LNCaP cells were treated for 24 hour with B[a]P and B[a]-7, 8-diol (1.0uM, 5.0uM, 10.0uM, 20.0uM and 50.0uM) in the presence and absence of 0.1uM R1881 or DMSO vehicle. Cell viability was measured by MTT assay. Cell cycle distribution was assessed using flow cytometry technique. RESULTS: Treatment with DMSO and B[a]P in the presence and absence of 0.1uM R1881 had no effect on cell viability. Exposure to increasing concentrations of B[a]P-7, 8-diol alone does not affect cell cycle distribution while exposure to these same concentrations in the presence of Ř1881 induced apoptosis and S phase arrest at 50uM of B[a]P-7, 8-diol. CON-CLUSIONS: These results show that the effects of B[a]P-7, 8-diol is concentrationdependent in the inhibition of G1 to S phase cell cycle progression in the presence of R1881.

## THE PROLIFERATIVE EFFECT OF SELENIUM DIOXIDE AGANIST BENZO(A)PYRENE TOXICITY.

M. R. Smith<sup>1</sup>, J. Ochieng<sup>2</sup> and <u>A. M. Nyanda<sup>1</sup></u>. <sup>1</sup>Pharmacology, Meharry Medical College, Nashville, TN and <sup>2</sup>Biochemistry, Meharry Medical College, Nashville, TN.

The biotransformation of Benzo(a)pyrene [B(a)p], an ubiquitous environmental pollutant, is a two-step process. Initially B(a)p is hydrolyzed by cytochrome  $P_{450}$  and then reduced to form an ultimate metabolite, (±)-benzo[a]pyrene-7, 8-diol-9, 10-epoxide, which will bind to DNA and form an adduct at the  $\hat{N}^7$  guanine residue eventually leading to cellular transformation. Finally, B(a)p is then conjugated by multiple enzymes, particularly glutathione, for elimination. Used as a cofactor, glutathione is a vital component in the biotransformation of selenium compounds; however, selenium dioxide will react with the thiol group of glutathione to form superoxides and reactive oxygen species. We hypothesize that selenium dioxide (SeO<sub>2</sub>) will enhance the formation of 10-selenoether-(±)-benzo[a]pyrene-7, 8, 9triol, thus reducing DNA adduct formation in human mammary and mouse fibroblast cells. Therefore, the objective of this study is to analyze the proliferative effect of SeO, against B(a)p administration in MCF-10A, MDA-MB-435, MDA-MB-468 and 3T3. Preliminary data using CellTiter<sub>96</sub> (Promega) in actively growing cells indicate a dose-dependent decrease in cell proliferation by SeO2 with maximum proliferation at 0.09 x 10<sup>-2</sup> µM. Preliminary data, suggest that prior and subsequent treatment of SeO<sub>2</sub> has an inhibitory effect on B(a)p challenged cells. This study will contribute to the understanding of selenium dioxide in the reduction of xenobiotic associated cancer growth.

# 541 BENZO(A)PYRENE METABOLITES ACTIVATE EGFR PATHWAYS IN HUMAN MAMMARY EPITHELIAL CELLS: A POTENTIAL MECHANISM FOR TUMOR PROMOTION.

A. D. Burdick, K. Liu, L. G. Hudson, H. Shi and S. W. Burchiel. College of Pharmacy, University of New Mexico, Albuquerque, NM.

Polycyclic aromatic hydrocarbons, such as benzo[a]pyrene (BaP), are known mammary carcinogens in rodents and may be involved in human breast cancer. Classically, the carcinogenicity of BaP has been attributed to the formation of the bay-region epoxide, anti-BPDE, which has been shown to stably bind DNA. Our laboratory is interested in the mechanisms by which BaP metabolites may also act as tumor promoters. A hallmark of tumor promotion is the inhibition of cellular apoptosis and/or increased cell proliferation under conditions that would normally be apoptotic, such as growth factor withdrawal. We have reported previously that BaP mimicked growth factor signaling and increased cell proliferation in primary human mammary epithelial cells (HMECs) and the HMEC line, MCF-10A. Diones of BaP (i.e. BaP-quinones, BPQs) are important oxidative metabolites of BaP that have been associated with the production of reactive oxygen species (ROS). In these studies, we demonstrated by electron paramagnetic resonance spectroscopy (EPR) and flow cytometry that BPQs produced ROS in MCF-10A cells. Using a model of epidermal growth factor (EGF) withdrawal in MCF-10A cells, we showed that H2O2 production by BPQs lead to the activation of the EGF receptor (EGFR), resulting in increased cell number in the absence of EGF. Conversely, treatment of MCF-10A cells with anti-BPDE resulted in cell cycle arrest and apoptosis. Thus, the activation of the EGFR signaling pathways by BPQs may represent one pathway by which BaP contributes to tumor promotion, and ultimately the development of breast cancer. This work was supported by NIEHS RO1 ES-07259, P30 ES-012072 and ADB by the US Army CDMRP Grant DAMD17-02-1-0512.

MALIGNANT TRANSFORMATION INDUCED BY BENZO(A)PYRENE AND DISTILLATE MARINE DIESEL FUEL IN HUMAN KERATINOCYTES.

O. Lohitnavy, <u>I. Campain</u> and <u>R. Yang</u>. *Quantitative and Computational Toxicology Group, Center for Environmental Toxicology and Technology, Department of Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO.* 

Some polycyclic aromatic hydrocarbons (PAHs) are known to have carcinogenic properties. To explore the interactions among these PAHs, cytotoxicity and the ability to induce neoplastic transformation by distillate marine diesel fuel (DMA type) and benzo(a)pyrene (BaP) were investigated in an immortalized human keratinocyte cell line, RHEK-1. Cytotoxicity analysis for both DMA and BaP were carried out for this cell line using the clonogenic assay. In transformation studies, RHEK-1 cells were treated repetitively with LC $_5$  BaP, LC $_{50}$  BaP, LC $_{10}$  DMA, the mixture of LC $_5$  BaP and LC $_{10}$  DMA, or DMA: acetone as a solvent control. As RHEK-1 lacks metabolic capabilities, these experiments were carried out in the presence of rat S9 microsomal fraction. Anchorageindependent growth (AIG), an indicator of malignant transformation, was measured in cultures as a function of time. Our results demonstrated that the cells exposed to  $LC_{50}$  BaP and the mixture of  $LC_{50}$  BaP and DMA acquired the ability of AIG in a time-dependent manner. In contrast to AIG-negative control cells, the cloning efficiency in methylcellulose of transformed populations significantly increased from 1-2% at passage 26 to 22-25% by passage 42. Other transformationassociated characteristics being analyzed in AIG+ cultures and negative controls include morphological alterations, saturation density, and serum independent growth. Our findings thus far, based on the endpoints studied, do not demonstrate obvious interactions between DMA and BaP. However, gene expression alterations in these cultures will be characterized to increase our understanding of the process of malignant conversion in keratinocytes through identification of key molecular players. This study was funded by NIEHS Grant #RO1 ES09655.

## TRANSFORMATION-ASSOCIATED CHARACTERISTICS IN CELL GROWTH AND DNA CONTENT IN HUMAN KERATINOCYTES, RHEK-1.

<u>I. Campain</u>, O. Lohitnavy and <u>R. Yang</u>. *Quantitative and Computational Toxicology Group, Center for Environmental Toxicology and Technology, Department of Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO.* 

The ability of benzo(a)pyrene (BaP) alone and a mixture of BaP and five non-carcinogenic polycyclic aromatic hydrocarbons (5PAHs) (anthracene, chrysene, fluoranthene, pyrene and phenanthrene) (Warshawsky et al, Fundam. Appl. Pharmacology 20:376-382, 1993) to induce malignant transformation of an immortalized human keratinocyte cell line (RHEK-1) has been previously demonstrated. To investigate properties of the transformed cells, saturation density, serum independence, cellular DNA content, and cell cycle distribution were analyzed at passages 17, 25, and 33. For comparison, a non-transformed control treated with DMSO was also characterized. Our results showed that the BaP- and BaP+5PAHs - transformed cells had significantly lower saturation density than the DMSO-control cells. This is likely a function of cell size. All transformed cells were still dependent upon fetal bovine serum for maximal growth in cultures. Changes in DNA content of the transformed cells have been demonstrated by staining with bromodeoxyuridine and propidium iodide followed by flow cytometric analysis. Our results demonstrated that the malignant cultures were highly aneuploid, with evidence for at least two different populations present. The DNA content of these populations rapidly increased with time in culture, strongly suggesting a high degree of genetic instability. In order to facilitate characterization of cell cycle parameters in these complex populations, we are currently isolating clones. These clones will be analyzed individually for transformation-associated characteristics, DNA content, and specific gene expression alterations in order to more accurately define correlative (or causal) relationships. This study was funded in part by NIEHS Grant RO1 ES09655 and ATSDR Cooperative Agreement U61/ATU 881475).

## TOXICITY AND METABOLISM OF P-CHLOROANILINE AND P-CHLOROPHENYL UREA: CARCINOGENIC IMPLICATIONS.

R. A. Cardona<sup>1</sup>, G. J. Putterman<sup>1</sup>, D. L. Story<sup>1</sup>, M. M. Gay<sup>1</sup>, V. DeMatteo<sup>1</sup> and E. I. Goldenthal<sup>2</sup>. <sup>1</sup>Crop Protection R&D, Crompton Corporation, Bethany, CT and <sup>2</sup>Department of Toxicology, MPI Research, Mattawan, MI.

In a 1989 National Toxicology Program (NTP) bioassay, p-chloroaniline (PCA) was reported to be carcinogenic in male Fischer 344 rats based on an increased incidence of splenic sarcomas. In the NTP report, it is proposed that PCA undergoes N-hydroxylation to form the corresponding N-hydroxylamine metabolite. N-hy-

droxylation of aromatic amines is a well-known mechanism of aromatic amine carcinogenicity. The resulting hydroxylamine derivative of PCA, or the proximate carcinogen, can then be conjugated by sulfation, acetylation or glucuronidation to form the ultimate carcinogen capable of ionizing to produce a nitrenium ion that reacts with macromolecules (DNA) forming adducts, which result in splenic tumors. N-hydroxy PCA also causes methemoglobinemia in mammals. Consequently, methemoglobin formation can be used as an indicator for the presence of PCA and its N-hydroxy metabolite, or proximate carcinogen. Seven-day dietary and single-dose gavage studies in the Fischer 344 rat with PCA and its urea analog, p-chlorophenylurea (CPU), and a CPU rat metabolism study, were conducted to determine if CPU is metabolized to PCA or, as demonstrated by methemoglobin formation, a N-hydroxylamine derivative. Results demonstrated that CPU is neither metabolized to PCA nor N-hydroxylated, the required first step in the carcinogenic mode of action of PCA and other aromatic amines. Therefore, it can be concluded that CPU does not possess the same toxicity or carcinogenic mechanism of action as PCA. Further, monuron, the 1, 1 dimethyl analog of ČPU, is carcinogenic. Its mode of action involves either formation of a methyl carbonium ion or N-hydroxylation and subsequent formation of a nitrenium ion, as proposed for PCA. Either mechanism is plausible given the presence of a dimethylamine biophore in the monuron molecule and the ability of monuron, like PCA, to produce methemoglobin formation in mammals. In light of the above it can be implied that, unlike PCA and monuron, CPU is not carcinogenic.

## TOXICOLOGY AND CARCINOGENESIS STUDIES OF TRIETHANOLAMINE IN F344/N RATS AND B6C3F1

F. A. Suarez<sup>1</sup>, G. Pearse<sup>1</sup>, M. R. Hejtmancik<sup>2</sup> and J. R. Bucher<sup>1</sup>. <sup>1</sup>NIEHS, Research Triangle Park, NC and <sup>2</sup>Batelle, Columbus, OH.

Triethanolamine is an ingredient in detergents and polishes, textiles, herbicides, pharmaceutical ointments, and in the manufacture of cosmetic products. The carcinogenicity of triethanolamine was evaluated in dermal studies in F344/N rats and B6C3F1 mice. In pre-chronic studies, male and female rats were topically administered 0, 25, 250, 500, or 1000 mg/kg in acetone or 2000 mg/kg neat triethanolamine for 13 weeks. Mice received 0, 25, 250, 500, 1, 000, or 2, 000 mg/kg in acetone or 4, 000 mg/kg triethanolamine (neat). Clinical findings in rats included irritation, scaliness and crustiness of the skin at the site of application. Similar changes were observed in mice but only in the 4, 000-mg/kg dose group. Microscopic examination indicated acanthosis and inflammation at the site of application. Based on the severity of the acanthosis and inflammation at the site of application, doses selected for the 2-year dermal studies in rats were 32, 63, and 125 mg/kg (males), and 63, 125 and 250 mg/kg (females). Mice received 200, 630, and 2, 000 mg/kg (males), and 100, 300, and 1, 000 mg/kg (females). In the 2-year study, the incidences of acanthosis, inflammation and ulceration were increased in female rats. Male rats in the 63-mg/kg dose group had an increased incidence of adenoma of the renal tubule epithelium. This finding was considered an equivocal response. In mice, hepatocellular adenomas occurred with positive trends in females, providing some evidence of carcinogenicity. Males had increased incidences of hemangioma (2, 000 mg/kg), and hemangiosarcomas (630 mg/kg). This finding was considered an equivocal response. Treatment-related lesions observed at the site of application occurred in males from the 300 and 1, 000 mg/kg groups. Microscopically observed changes were associated with the focal crusts observed macroscopically, and included epidermal hyperplasia, suppurative inflammation, and minimal focal ulceration and dermal chronic inflammation.

## 546 AN ORAL CARCINOGENICITY STUDY OF SENNA-MIS IN THE ALBINO RAT.

J. M. Mitchell<sup>1</sup>, S. McPherson<sup>2</sup>, University. Mengs<sup>3</sup>, J. Tigner<sup>1</sup>, J. Zijlstra<sup>4</sup>, P. Dettmar<sup>5</sup>, R. Gregson<sup>2</sup> and I. Lebish<sup>1</sup>. <sup>1</sup>Purdue Pharmacology, Ardsley, NY, <sup>2</sup>CTBR Bio-Research Inc., Senneville, QC, Canada, <sup>3</sup>Madaus AG, Koln, Germany, <sup>4</sup>Novartis Consumer Health SA, Nyon, Switzerland and <sup>5</sup>Reckitt Benckiser Healthcare, Hull, United Kingdom.

Senna-MIS (Madaus Indian Senna), a known laxative derived from plants, was administered by gavage to Sprague-Dawley (Crl:CD(SD)BR) rats once daily at dose levels of 0, 0, 25, 100 and 300 mg/kg/day for up to 104 consecutive weeks. Sixty animals per sex were assigned to the control and dose groups. The primary dose and treatment-related clinical observation was mucoid feces (seen at 300 mg/kg/day). Compared to controls, animals administered 300 mg/kg/day had reduced body weights, increased water consumption and notable changes in electrolytes in serum (increases in potassium and chloride) and urine (decreases in sodium, potassium and chloride) and darker urine. The changes in electrolytes are believed to be physiologic adaptations to the laxative effect of Senna. Dark discoloration of the kidneys was observed in animals in all treated groups. Histological changes were seen in the kidneys of animals from all treated groups and included slight to moderate, tubular basophillia and tubular pigment deposits. In addition, for all treated groups, mini-

mal to slight hyperplasia was evident in the colon and cecum. These histological changes together with the changes seen in the hematology, chemistry and urine parameters evaluated have been shown in previous studies of Senna to be reversible. No treatment-related neoplastic changes were observed. It is concluded that lifetime daily administration of Senna-MIS at dosage levels of up to 300 mg/kg/day did not reveal any evidence of carcinogenicity in Sprague-Dawley rats.

### 547 STABILITY OF Tg.AC PHENOTYPIC RESPONSE ACROSS MULTIPLE BREEDINGS.

<u>G. Moser</u><sup>1</sup>, J. W. Spalding<sup>2</sup>, R. E. Cannon<sup>2</sup>, <u>R. W. Tennant</u><sup>2</sup>, S. Stasiewicz<sup>2</sup>, M. A. Streicker<sup>1</sup> and <u>T. L. Goldsworthy</u><sup>1</sup>. <sup>1</sup> Integrated Laboratory Systems, Research Triangle Park, NC and <sup>2</sup> NIEHS, Research Triangle Park, NC.

Two-stage carcinogenesis in mouse skin has helped define the multistage nature of tumorigenesis. A consistent alteration in mouse skin tumors is activation of the Haras oncogene. The Tg.AC mouse model has an inducible activated v-Ha-ras gene (ζ-globin promoted v-Ha-ras on a FVB background) and has been proposed as an alternative to the conventional two-year bioassay. Historically dermal exposure to 12-O-tetradecanoyl-phorbol-13-acetate (TPA) produces skin papillomas as a predictable reporter phenotype. However, in three studies conducted in 1997 and 1998, the incidence of papilloma-bearing Tg.AC animals was greatly decreased as compared to previous studies. Genomic DNA blots linked an altered genotype to the non-responder phenotype. By selective breeding of mice with the responder genotype, the TPA-induced papilloma response was shown to be consistent and robust in late 1998-1999. To expand upon these findings, we evaluated 19 breedings of hemizygous male and female Tg.AC mice from 2000-2003. After dermal administration of 2.5 µg TPA thrice weekly for at least 12 weeks, the incidence of papilloma bearing mice in male and female Tg.AC mice was greater than 85%. With one exception mean group tumor latency period was <10 weeks, peak number of papillomas was over 20, and tumor multiplicity was greater than 12 papillomas per tumor bearing mouse. The mean multiplicity in male Tg.AC mice was greater than that of female Tg.AC mice. With regard to tumors of odontogenic origin, over 50% of the Tg.AC studies produced animals with odontomas. The incidence of mice with odomotomas within these studies was 5-25%. The success of this selective Tg.AC breeding strategy is evidenced by the recovery of a reproducible and robust phenotypic response in TPA-exposed hemizygous Tg.AC mice over multiple breedings. These studies also validate the importance of positive controls in Tg.AC studies. This work was supported by NIEHS (N01-ES-95442).

## 548 TRANSPLACENTAL CARCINOGENICITY OF AZIDOTHYMIDINE IN B6C3F1 MICE AND F344 RATS.

D. M. Walker<sup>1</sup>, J. F. Hardisty<sup>2</sup>, F. A. Ruecker<sup>3</sup>, K. A. Funk<sup>2</sup>, M. J. Wolfe<sup>2</sup> and <u>V. E. Walker<sup>1</sup></u>. <sup>1</sup>Lovelace Respiratory Research Institute, Albuquerque, NM, <sup>2</sup>Experimental Pathology Laboratories, Inc., Research Triangle ParK, NC and <sup>3</sup>FAR Consulting, L.L.C., Manchester, MO.

AZT has been demonstrated to be incorporated into host cell DNA and to cause DNA chain termination, and thus may act as a mutagen and carcinogen in transplacentally exposed animals and humans. Olivero et al. (JNCI 89:1602, 1997) previously demonstrated that prenatal exposure to clincally relevant cumulative doses of AZT resulted in treatment-related increases in lung, liver, and reproductive organ tumors of CD-1 mice. To evaluate the carcinogenic potential of transplacental AZT exposure in a second mouse strain and a second rodent species, pregnant B6C3F1 mice and F344 rats were exposed by gavage to 0, 80, 240, or 480 mg/kg bw/day AZT for the last 7 days of gestation. Complete necropsies were performed on 680 female and male B6C3F1 mice and 680 female and male F344 rats at 1 or 2 years after birth (40-45 mice and rats/gender/dose group/age group). There was a significant treatment-related increase in the incidence of lung neoplasms (adenoma and carcinomas combined) and a significant dose-related shift from benign to malignant hepatocellular neoplasms (with multiplicity and metastases to lung) in AZT-exposed male mice at 2 years-of-age. These effects in lung and liver are consistent with those reported earlier in CD-1 mice. The major histopathological finding in rats was an increase in the incidence of gliomas in AZT-exposed female rats. The average historical incidence of gliomas in control F344 rats is ~0.5% in females from 2-year bioassays (up to 26 months) versus ~1.5% in females allowed to live out their lifespan (up to 34 months), suggesting that the increased occurrence of gliomas in 2.2 to 4.4% of AZT-exposed female rats may be related to transplacental administration of the drug. Histopatholocial studies of B6C3F1 mice and F344 rats also revealed a treatment related complex of non-cancerous and inflammatory lesions, especially in mitochondrial rich tissues, including the heart.

### 549 PHENOTYPIC BASELINE DATA ON TRANSGENIC MOUSE MODELS FOR TOXICOLOGY.

E. Arlund and S. Swing. Taconic Farms Inc., Germantown, NY.

TG.AC, rasH2, TSG-p53, and mdr1a are genetically engineered (transgenic and knockout) mouse models used in carcinogenicity testing and drug transport study. To better define these models and provide baseline data, these animals in their naïve

state were evaluated in a phenotypic screen. Phenotyping consisted of Urinalysis (a 5 element dipstick), Clinical Chemistry (a 9 component serum analysis), Hematology (a 9 component whole blood analysis), Differential count, organ weights and histology (9 tissues). Genotypes of interest (homozygous TG.AC, heterozygous and wildtype p53 and rasH2) were evaluated and compared to nontransgenic equivalents (FVB, B6). In all cases both males and females, 7 weeks of age, are compared. All of the urinalysis, clinical chemistry and hematology results are within the normal limits for mouse species, though variability is evident between specific models and genotypes. All histologic lesions diagnosed in various tissues during the evaluation were considered to be incidental findings, which are normally described as background pathology. These changes or lesions can usually be attributed to species characteristics, age, dietary influence, or are gender related. This data defines the general physiology of these animals as within normal species range, an important aspect for any genetically altered animal.

## 550 COMPARISON OF THE K6/ODC AND SKH-1 HAIRLESS MICE IN RESPONSE TO PHOTOCARCINOGENICITY OF LOMEFLOXACIN.

J. Bastien, T. O'Brien and Y. Chen. ODC Mouse Group, Inc., Drexel Hill, PA.

K6/ODC mice have been engineered to overexpress the enzyme ornithine decarboxylase (ODC) in skin and some internal organs and are extremely sensitive to tumor induction with both genotoxic chemicals and UV radiation. The Skh-1 hairless mouse strain is the standard mouse model for photocarcinogenesis studies. The purpose of this study was to compare the response of K6/ODC and SKh-1 mice to irradiated lomefloxacin in order to determine the more effective and sensitive model for use in testing photochemical carcinogens. Lomefloxacin and vehicle were administered by gavage to K6/ODC and Skh-1 mice five times every two weeks for a period of 12 weeks. Approximately 1.5 h after oral administration, mice were exposed to UV radiation. Unirradiated vehicle and chemical treated controls were also used. Tumor incidence was recorded weekly for 22 weeks. No signs of phototoxicity were seen in any group. With lomefloxacin plus UV irradiation, the tumor incidence was 100% vs. 37% and multiplicity was 11.4 vs. 1.66 for K6/ODC and Skh-1 mice, respectively. The latency of tumor formation was greatly reduced in K6/ODC mice compared to Skh-1 mice. In animals exposed to UV alone, Skh-1 mice developed no tumors while K6/ODC mice had 4 tumors. There were no tumors in unirradiated control groups of either strain. The majority of the tumors were squamous papillomas in both strains, but some squamous cell carcinomas were also present. These results demonstrate the utility of the K6/ODC model for detecting photochemical carcinogens, especially at low doses and relatively short exposure periods.

## A SUMMARY OF TOXICOLOGICAL AND CHEMICAL DATA RELEVANT TO THE EVALUATION OF CAST SHEET TOBACCO.

R. J. Potts, P. H. Ayres, M. A. Higuchi, K. Shreve, D. R. Meckley, E. R. Bombick, J. E. Swauger, A. T. Mosberg and D. H. Pence. R J Reynolds Tobacco Company, Winston-Salem, NC.

A tiered testing strategy based on a comparative chemical and biological testing program has been developed to evaluate the potential of tobacco processes, ingredients, or other technological developments to change the biological activity that results from burning tobacco. Cast Sheet tobacco is a specific type of reconstituted tobacco sheet currently used in the manufacture of cigarettes. As part of the toxicological evaluation of Cast Sheet tobacco, test cigarettes containing Cast Sheet at a blend level of either 10 or 15% were compared to a reference cigarette that did not contain Cast Sheet. Testing included analysis of mainstream smoke chemistry, in vitro studies using cigarette smoke condensate (CSC) and/or whole smoke (Ames assay, sister chromatid exchange assay, and neutral red cytotoxicity assay), and in vivo studies (13-week inhalation study of mainstream smoke in Sprague-Dawley rats and a 30-week dermal tumor promotion study of CSC in SÊNČAR mice). Compared to the reference cigarette, inclusion of Cast Sheet resulted in significant increases in mainstream smoke levels of "tar" and nicotine, as well as increases in certain target analytes. All analyte values were within the ranges for currently marketed products of similar "tar" category. CSC derived from the cigarettes containing 15% Cast Sheet demonstrated significantly higher Ames activity in strain TA100 on a revertants/cigarette basis but not on a revertants/mg "tar" basis when compared to the reference cigarette. Whole smoke generated from cigarettes containing 10% Cast Sheet was less cytotoxic compared to the reference cigarette. No other statistical differences were observed between the reference and test cigarettes in the remaining in vitro studies. In vivo studies demonstrated that the biological activity of the test cigarettes was comparable to that of the reference cigarette. Collectively, the studies demonstrated that inclusion of Cast Sheet up to 15% in the final blend did not increase the inherent biological activity of cigarette smoke/CSC.

EVALUATION OF THE DBA/2 MOUSE FOR ASSESSING THE DERMAL TUMOR-PROMOTING POTENTIALS OF CIGARETTE SMOKE CONDENSATES.

M. S. Stavanja, D. R. Meckely, P. R. Nelson, G. M. Curtin, P. H. Ayres, A. T. Mosberg and J. E. Swauger. Regulatory Toxicology, R. J. Reynolds Tobacco Company, Winston-Salem, NC.

The DBA/2 mouse has been shown to be as sensitive as the SENCAR mouse to two-stage tumorigenesis when initiated with N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) or high doses of 7, 12-dimethylbenz[a]anthracene (DMBA) followed by 12-O-tetradecanoylphorbol-13-acetate (TPA) promotion. A 30-week dermal tumor promotion study was conducted to evaluate the overall utility of the DBA/2 mouse for assessing the relative tumor-promoting potentials of cigarette smoke condensates (CSC). CSC from the Kentucky 1R4F cigarette was the test article (promoter). Fifteen groups of 40 male DBA/2 mice were used. Seven treatment groups were initiated with single 75 or 150µg dermal applications of DMBA and promoted with 9, 18, 27, 36, or 45 mg "tar"/application. Four treatment groups were initiated with single 300µg dermal applications of MNNG followed by promotion with 9, 18, 27, or 36 mg "tar"/application. CSC was administered three times per week for 29 weeks. Control groups included initiated, non-promoted animals and sentinels. End-points included clinical signs, body weights, and mass tracking data. Neither control groups nor DMBA-initiated/CSC-promoted groups produced masses. The MNNG/1R4F (9mg) CSC group developed one mass-bearing mouse (MBM). The MNNG/1R4F (18mg) CSC group developed 2 MBM and the MNNG/1R4F (36mg) CSC group developed one MBM. These MBM developed only one mass each. This pattern of response indicates no treatment-related effect. The DBA/2 mouse was found to be unresponsive to dermal tumor promotion with CSC and would not be considered a useful substitute for the SENCAR mouse in the standardized dermal tumor-promotion assay used to evaluate CSCs. However, this model could potentially be used for understanding the mechanism by which the DBA/2 mouse is resistant to the tumor-promotion activity of CSC.

## 553 MICROSCOPIC EXAMINATION OF LUNG TUMORS ENHANCES EVALUATION OF TOBACCO SMOKE-INDUCED TUMORIGENICITY IN A/J MICE.

G. M. Curtin, M. A. Higuchi, P. H. Ayres, J. E. Swauger and A. T. Mosberg. Regulatory Toxicology, R.J. Reynolds Tobacco Company, Winston-Salem, NC.

A/J mice were exposed whole-body or nose-only to mainstream tobacco smoke (MTS) from Kentucky 1R4F cigarettes. Whole-body exposed mice received filtered air or 0.20 mg wet total particulate matter (WTPM)/L for 20 weeks (6 hr/d, 5 d/wk), followed by 16 weeks recovery. MTS-exposed mice exhibited statistically significant reductions in body weight relative to shams, with a 2-fold higher weight gain evident during recovery. Gross evaluation of lung tumors post-exposure revealed >50% reductions for multiplicity and incidence compared to shams, with both indices exhibiting non-statistical increases following recovery. Microscopic examination of lungs confirmed tumor reductions during exposure, but revealed statistically significant increases for both multiplicity and incidence post-recovery. Nose-only exposed mice received 0.04, 0.125 or 0.40 mg WTPM/L for 28 weeks (3 hr/d, 5 d/wk), followed by 16 weeks recovery. MTS-exposed mice exhibited dose-related reductions in body weight compared to shams, with statistically significant changes noted for 0.125 and 0.40 mg WTPM/L exposures; body weight gains during recovery were likewise proportional to exposure concentration. Gross determination of tumors post-exposure yielded non-statistical reductions for multiplicity and incidence compared to shams; non-statistical increases for both indices were observed following recovery, but were limited to 0.125 and 0.40 mg WTPM/L exposures. Microscopic examination revealed exposure-related reductions for multiplicity and incidence that were less dramatic than observed grossly, as well as doserelated (non-statistical) increases for both indices post-recovery. These data suggest that microscopic examination of lungs is essential for adequately evaluating MTSinduced tumor formation. Moreover, development of an appropriate lung tumorigenicity model will likely require that the toxicological impact associated with tobacco smoke exposure (i.e., reductions in body weight and tumor formation) be examined more thoroughly.

### 554 NONYLPHENOL INDUCES MAMMARY CANCER IN MMTVNEU MICE.

H. Villanueva<sup>1</sup>, R. Acevedo<sup>1</sup>, P. Parnell<sup>2</sup>, S. L. Gray<sup>3</sup>, T. Gimenez<sup>3</sup> and <u>W. Baldwin<sup>1</sup>. <sup>1</sup>Biological Sciences, University of Texas at El Paso, El Paso, TX, <sup>2</sup>Clemson Veterinary Diagnostics Center, Clemson University, Columbia, SC and <sup>3</sup>Animal and Veterinary Sciences, Clemson University, Clemson, SC.</u>

4-Nonylphenol (4-NP) is a toxic degradation product of alkylphenol ethoxylates, which are nonionic surafactants used in institutional cleaning agents, textiles, agricultural chemicals, plastics, paper products, household cleaning agents and per-

sonal care products. 4-NP has been found in food and drinking water, and is an environmental estrogen that has been shown to increase proliferation of breast cancer cell lines. The threshold dose for increased development and proliferation of mammary tissue in ovariectomized rats is approximately 40mg/kg/day. To determine if 4-NP may increase mammary cancer incidence in mice, FVB/N-TgN(MMTVneu)202Mul mice susceptible to mammary cancer, were fed 4-NP in honey at 0, 30 or 45mg/kg/day, or provided 10µg/kg/day estradiol in honey for 32 weeks. One out of fourteen control mice developed a tumor, while 0/14 and 5/13 mice developed tumors in the 30 and 45mg/kg/day groups respectively. Overall, 4-NP increased both tumor incidence and latency at 45mg/kg/day. This data further supports a threshold dose of 4-NP of no greater than 45mg/kg/day. None of the mice receiving estradiol formed tumors. In addition, metastasis occurred in two of thirteen mice in the 45mg/kg/day group, but metastasis did not occur in other treatment groups. A 7-day pilot study indicated estriol levels were increased by 4-NP, but not estradiol or progesterone levels. Therefore, each month mice were tail bled and steroid hormone levels were analyzed. However, steroid hormone levels were not altered significantly by 4-NP. In conclusion, 4-NP induces mammary cancer formation in MMTVneu mice and has a tumor threshold between 30mg/kg/day and 45mg/kg/day in MMTVneu mice.

## TOXIC AND CARCINOGENIC EFFECTS OF INHALED PROPYLENE GLYCOL MONO-*T*-BUTYL ETHER IN F344/N RATS AND B6C3F<sub>1</sub> MICE.

A. M. Doil<sup>1</sup>, J. H. Roycroft<sup>1</sup>, R. A. Herbert<sup>1</sup>, J. A. Dill<sup>2</sup>, S. L. Grumbein<sup>2</sup>, <u>R. A. Renne</u><sup>2</sup> and <u>J. R. Bucher<sup>1</sup></u>. <sup>1</sup>NTP, NIEHS, Research Triangle Park, NC and <sup>2</sup>Battelle Toxicology Northwest, Richland, WA.

Propylene glycol mono-t-butyl ether (PGMBE) is a solvent used commercially in a wide variety of applications. Because of its high production volume and high potential for human exposure, studies were conducted to evaluate the toxicology and carcinogenicity of PGMBE in rats and mice. Male and female F344/N rats and B6C3F<sub>1</sub> mice were exposed to PGMBE by whole-body inhalation for 2 weeks, 14 weeks, or 2 years. The exposure concentrations of PGMBE in rats and mice were 0, 75, 150, 300, 600, or 1, 200 ppm in the 2-week and 14-week studies, and 0, 75, 300, or 1, 200 ppm in the 2-year studies. The kidney and the liver were sites of PGMBE toxicity in rats. In the 2-week and 14-week studies, renal lesions suggestive of  $\alpha_{2u}$ -globulin nephropathy occurred in male rats. In the 2-year rat studies, exposure-related nonneoplastic renal lesions were accompanied by marginal increases in renal tubular neoplasms in males. Although not significant, the incidences of hepatocellular adenoma were increased in the liver of male rats of the high exposure group, and followed an overall increasing trend with exposure. In mice, the liver was the main target of PGMBE toxicity. In the 2-week and 14-week mice studies, liver weights and/or the incidences of centrilobular hypertrophy were increased in both sexes. In the 2-year studies, the incidences of liver neoplasms in male and female mice were significantly increased in the high exposure group, and followed an overall positive trend with exposure. In summary, PGMBE exposure for 2 years induced kidney lesions characteristic of  $\alpha_{2u}$ -globulin accumulation in male F344/N rats, while the evidence of carcinogenic activity of PGMBE in F344/N male rats was equivocal. There was no evidence of carcinogenic activity of PGMBE in female F344/N rats. In B6C3F<sub>1</sub> mice, PGMBE induced liver neoplasms in males and fe-

## 556 STRAIN-DEPENDENT SUSCEPTIBILITY TO TRANSPLACENTALLY-INDUCED MURINE LUNG TUMORS.

M. S. Miller<sup>1</sup>, J. E. Moore<sup>1</sup>, M. Xu<sup>1</sup>, G. B. Nelson<sup>2</sup>, S. T. Dance<sup>1</sup>, N. D. Kock<sup>1</sup> and J. A. Ross<sup>2</sup>. <sup>1</sup>Wake Forest University, Winston-Salem, NC and <sup>2</sup>USEPA, Research Triangle Park, NC.

Previously, our laboratory demonstrated that fetal mice are more sensitive to in utero exposure to the polycyclic hydrocarbon, 3-methylcholanthrene (MC), than are adults, and that resistant strains had a high incidence of lung tumors 12 months after transplacental exposure to MC. We compared the effects of in utero treatment with MC on lung tumor induction in the offspring of intermediately susceptible Balb/c (Bc), resistant C57BL/6 (B6), and reciprocal crosses between the two strains. Pregnant mice were treated with 45 mg/kg of MC on day 17 of gestation and tumor incidence, multiplicity, and tumor size determined in the offspring 14-18 months after birth. Bc, B6Bc, and BcB6 mice exhibited a 100% tumor incidence whereas the resistant B6 mice had an incidence of 5.3%. B6 mice exhibited 1 small nodule after 18 months whereas Bc mice rarely survived beyond 14 months and BcB6 and B6Bc mice survived to approximately 16 months. Bc, B6Bc, and BcB6 mice exhibited significant tumor involvement in the lungs; in many cases multiple tumors coalesced into single large masses with the majority of lesions classified as adenocarcinomas. Counting only lesions that were discrete, individual nodules, tumor multiplicities in Balb, B6Bc, BcB6, and B6 mice were 7.7±2.9, 5.5±3.3,

6.0±3.0, and <0.1, respectively. Similarly, tumor size in Balb, B6Bc, BcB6, and B6 mice was 1.5±0.7, 1.6±0.9, 1.4±0.7, and <1mm, respectively. These results suggest that, similar to adults, crosses between susceptible and resistant strains results in a susceptible phenotype for lung cancer. We are currently examining differences in MC metabolism, DNA adduct levels and repair, and mutations in Ki-ras as possible mechanistic factors mediating strain susceptibility to lung carcinogens. These studies highlight the important interactions between genetic and environmental factors in determining individual susceptibility to environmental toxicants during development. (Supported by EPA STAR grant R829428-01-0. This abstract does not reflect EPA policy.)

#### 557 INITIATION-PROMOTION STUDIES OF 1, 3-DICHLOROPROPENE (1, 3-D) IN MALE F344 RAT LIVER AND STRAIN A MOUSE LUNG.

S. Reel, L. M. Kamendulis, P. J. Klein and J. E. Klaunig. Division of Toxicology, Indiana University School of Medicine, Indianapolis, IN.

Chronic treatment with the nematocide 1, 3-dichloropropene (1, 3-D) resulted in the induction of neoplasia in the rat liver and mouse lung. While 1, 3-D does not appear to be mutagenic, the mode of action for the induction of these neoplasms has not been established. 1, 3-D may function to promote the growth of preneoplastic lesions. The present study examined the effect of 1, 3-D on hepatic focal lesion growth in the F344 male rat and lung adenoma growth in the male Strain A mouse. In the liver, 1, 3-D (25 mg/kg) had no effect on the number or volume of GSTp positive staining hepatic foci after 30 or 60 days of treatment whereas 1, 3-D increased the number and volume of GSTp negative staining hepatic focal lesions after both 30 and 60 days. In contrast, phenobarbital (PB; 80 mg/kg) significantly increased the number and volume of GSTp positive staining focal lesions at both 30 and 60 days of treatment and increased the number and volume of GSTp negative staining hepatic lesions after 60 days of treatment. Following a 30 day recovery period (treatment for 30 days, followed by no treatment for 30 days), the increases in number and volume of hepatic lesions induced by either 1, 3-D or PB returned to control levels. DNA synthesis in GSTp negative staining hepatic lesions was increased by 1, 3-D after both 30 and 60 days of treatment, and by PB after 60 days of treatment. In the mouse lung, 1, 3-D produced a slight increase in the incidence of grossly visible lung adenomas (26% compared to 10% in control). Treatment with vinyl carbamate (VC)  $\pm$  1, 3-D resulted in a 100% gross adenoma incidence. The total number of adenomas was similar between the VC group and those receiving VC and 1, 3-D (976 vs. 980 adenomas per 20 mice). Analysis of adenoma size distribution showed that 1, 3-D produced a slight increase in the number and size of adenomas compared to control. These results support the premise that 1, 3-D may function at the promotion stage of carcinogenesis.

## 558 CHROMIUM(VI) IN DRINKING WATER INCREASES THE INCIDENCE OF UV-INDUCED SKIN TUMORS IN HAIRLESS MICE.

M. Costa, T. Kluz, T. L. Davidson, T. Rossman, A. Uddin, A. Nadas, Q. Zhang and F. Burns. Department of Env. Med., New York University, Tuxedo, NY.

Hexavalent chromium (Cr(VI)) is a well known human carcinogen with exposures occurring in both occupational and environmental settings. Although lung carcinogenicity has been well documented for exposure via inhalation, the cancer-causing potential of Cr(VI) in drinking water has been much more controversial. Human exposure to chromium compounds alone is not relevant in the scenario of our daily lives, since we are exposed to many different toxicologically active environmental insults. We used a hairless mouse model to study the effects of Cr(VI) exposure via drinking water on ultraviolet radiation(UVR)-induced skin tumors. Hairless mice were divided into seven groups: control, UVR alone, 2.5ppm  $K_2CrO_4$ , 5.0ppm  $K_2CrO_4$ , UVR(1.2 KJ/m2) + 0.5ppm  $K_2CrO_4$ , UVR + 2.5  $K_2CrO_4$ , and UVR + 5.0ppm K<sub>2</sub>CrO<sub>4</sub>. Mice were inspected weekly for the appearance of skin tumors larger than 2mm. Mice were sacrificed on day 182 and skin tumors were removed for histopathological analysis. No skin tumors were observed in the control or chromium only exposure groups. There was a dose dependent increase in the number of skin tumors greater than 2mm for mice exposed to Cr(VI) and UV when compared to mice exposed to UV alone. The increase in tumors larger than 2mm was significant for UV + the two higher doses of K2CrO4. Malignant tumors were observed in all UV treated mice and there was a statistically significant increase in the numbers of malignant tumors for the UVR plus K2CrO4(5ppm) group. Exposure to Cr(VI) via drinking water exposure has been a significant public health concern and drinking water standards have been set based on exposure to chromium alone. The data presented here indicate that Cr(VI) can increase the number of UV induced tumors in a dose dependent manner. This suggests that human exposure to Cr(VI) may increase the risk of carcinogenesis for other agents as well. Our results have important implications for risk assessment and suggest that the current drinking water standards for Cr(VI) exposure should be reassessed and adjusted downward.

### 559 RELIABILITY AND PRACTICALITY OF MEDIUM-TERM LIVER CARCINOGENESIS BIOASSAYS.

S. Tamano<sup>1</sup>, A. Hagiwara<sup>1</sup>, M. Kawabe<sup>1</sup>, H. Yoshino<sup>1</sup>, T. Ichihara<sup>1</sup>, K. Imaida<sup>2</sup>, T. Shirai<sup>3</sup> and N. Ito<sup>4</sup>. <sup>1</sup>Daiyu-kai Institute of Medical Science, Ichinomiya, Japan, <sup>2</sup>Department Onco-Pathology, Kagawa Medical University, Kagawa, Japan, <sup>3</sup>Department Exp. Pathol. And Tumor Biol., Nagoya City University, Nagoya, Japan and <sup>4</sup>Nagoya City University, Nagoya, Japan.

The promoting activities of carcinogens can rise to preneoplastic and neoplastic lesions by stimulating clonal proliferation. We have focused on developing mediumterm liver carcinogenesis bioassays for the detection of carcinogens based on this property. Male F344/duCrj rats, six weeks of age, are initially given a single ip injection of DEN(200mg/kg b.w.) dissolved in saline to initiate hepatocarcinogenesis. After 2 weeks, they received test compounds and are then subjected to twothirds partial hepatectomy (PH) at week 3. The animals are killed for quantitative analysis of glutathione S-transferase placental form (GST-P) positive liver foci at week 8. A positive response is defined as a significant increase in the quantitative values of GST-P-positive foci. Of a total of 314 chemicals examined, 61 out of 66 known hepatocarcinogens (92%) gave positive results. The five hepatocarcinogens which proved negative all belonged to the peroxizome proliferator group that depresses GST-P expression. Therefore, the positive rate for hepatocarcinogens excluding these 5 peroxisome proliferators was 100%. One of the 48 chemicals reported as non-carcinogenic was found to be positive in this assay, but the available information might suggest that it is liver tumor promoter. The results indicated that medium-term liver bioassay system is very useful tools for detection of not only genotoxic but also non-genotoxic carcinogens. Carcinogenicity of carcinogenic agents can be detected primarily by their promoting activity, because the results of the medium-term bioassay clearly mirrored those for long-term carcinogenicity.

## THE MOST APPROPRIATE STRAIN FOR RAT CARCINOGENICITY BIOASSAYS.

L. D. Britton, N. Downes, P. Mullins and <u>D. Mitchell</u>. *Toxicology, Sequani Limited, Ledbury, United Kingdom*.

A lifespan study was initiated to evaluate the Hsd:Sprague-Dawley SD and Hsd:BrlHan:WIST (Han Wistar) rat strains. Data generated was compared with contemporaneous Crl:CD(SD) IGS BR rat data. The objective was to make an informed choice of the most suitable strain to recommend for future carcinogenicity studies. Males (100) and Females (100) of each strain were obtained from Harlan UK and allocated to the study at 6 weeks of age. All strains were housed under the same standard conditions and subject to the same routine handling/observations. The Harlan strains were consistently lighter in weight (mean weight 10%-30% lighter) and routinely consumed less food (up to about 25% less) than Crl:CD rats of the same age. In the second year, the Han Wistar ate around 5%-10% less food than the Hsd:SD but, despite this, ultimately became around 25% heavier (mean weight). Only 33% of Hsd:SD males and 35% of females survived to 104 weeks, which was comparable with the Crl:CD (males 39-40%; females 33-39%) but lower than that for Han Wistar rats (60% / 59% survival for males / females). About half of the Hsd:SD males that died early were found dead without previous indication of ill-health; this contrasts with around 15% of male Han Wistar and Crl:CD decedents. Only one Han Wistar female was found dead in 104 weeks (2%), compared with about 5% of Hsd:SD females and 10% of Crl:CD females. As survival of the Han Wistar rats was good (50% survival at 104 weeks is considered optimal), half the survivors were terminated at 104 weeks and the remainder continued on study for a further 3 months. For the Sprague-Dawley strains, it is clear that standard group sizes of 50 would not have provided optimal numbers for terminal assessment at 104 weeks. It can be concluded that the poor survival and associated pathology of the two Sprague-Dawley derived strains were linked to their common derivation and unaffected by differences in bodyweight and food consumption. Of the three strains assessed, the Harlan Hsd:BrlHan:Wist is considered the most suitable for carcinogenicity bioassays.

## CHARACTERIZATION OF SUBCUTANEOUS TUMOR GROWTH FOR A549, PC3 AND CACO2 HUMAN CANCER XENOGRAFTS IN THE NUDE MOUSE.

A. Adamou, S. Groom and M. Vezina. CTBR, Senneville, QC, Canada.

The human tumor/mouse xenograft system is a recognized model for the in-vivo pre-clinical screening of potential anti-cancer drugs. This poster presents data for the subcutaneous tumor development and growth of 3 tumor cell lines with very different growth characteristics. PC3 prostate cancer is a relatively rapidly growing cell line; CACO2 colon cancer is a slow growing tumor cell line and A549 non-small cell lung cancer was selected as an intermediate. Six week old male and female mice (Crl:Nu/Nu-nuBR) were inoculated with 0.1 mL of the appropriate tumor cell suspension (containing approximately 106 to 107 tumor cells). At a mean

tumor volume of between 100 to 200 mm3, equal numbers of animals were randomly selected to receive paclitaxel treatment or remain untreated. The time taken to reach a mean tumor volume of 100 to 200 mm3 was 4 days for the A549 tumor cell line (117  $\pm$  35 mm3) and 3 days for the PC3 tumor cell line (125  $\pm$  35 mm3). The presence of a tumor was detected for most animals using these cell lines. In contrast, the weakly tumorigenic and slow growing CACO2 tumor cells failed to reach 100 mm3 within 45 days of inoculation despite detection of a tumor in approximately 80% of the animals within that interval. The time to 50% tumor growth inhibition (paclitaxel-treated mice vs untreated mice) was 31 to 32 days for A549 and 23 to 24 days for PC3. Animals inoculated with the CACO2 cell line were not treated with paclitaxel. These data validate A549 and PC3 for use in the nude mouse as effective in vivo models for the screening of potential anti-cancer drugs as well as paclitaxel as an effective reference compound. The suitability of slow growing tumor cell lines for this type of evaluation remains to be evaluated.

#### TIME TO FATAL TUMORS IN P53-/- RAD50S/S MICE.

D. Singh<sup>1</sup>, A. O. Chiu<sup>1</sup>, J. H. Petrini<sup>2</sup>, N. H. Chiu<sup>3</sup> and J. Beaubier<sup>4</sup>. <sup>1</sup>NCEA ORD, USEPA, Washington DC, DC, <sup>2</sup>Mol Biol Prog, MSKCC, New York, NY, <sup>3</sup>OST OW, USEPA, Washington, DC and <sup>4</sup>OPPTS, USEPA, Washington, DC.

Mathematical modeling of individual animal data from established colonies of p53 knockout and rad50 hypomorphic mice were carried out in this analysis. Mre11, Rad50, and Nbs1 are critical for repairing DNA-double-strand-breaks. Rad50s/s mice die mostly with marrow or lymph node depletion, with attrition in spermatogonia. Rad50s/s mice had apoptotic cells in 50% of their seminiferous tubule. Cellular attrition was mitigated by p53 deficiency to 3% in p53+/- Rad50s/s or 6%, p53-/- Rad50s/s mice. Rad50s/s MEFs exhibited a 1.4 - 3.4 fold increases in subG1 DNA content. r-H2AX marker (% in 150 cells, >=3 nuclear foci per cell)increased from approximately 0.45 - 1.1 in Rad50+/+ cells to 0.67- 1.9 for rad50s/s cells. Upon exposure to 12 Gy radiation, r-H2AX increased 1.5- 4.3 fold in Rad50s/s as compared to Rad50+/+ cells. V(D)J recombination was normal in Rad50s/s mice. P53+/- mice developed osteosarcoma after 12 months, whereas p53+/-Rad50s/s died of thymic lymphoma (N=17, p=0.002) with an average of 5 months. The p53-/- strain died within 4.5 months while those with p53-/-Rad50s/s died within 3 months, with the same tumor spectrum. While most Rad50s/s mice died by 4 months with anemia, 20% survived 4-7 months and 20% of this latter group developed thymic lymphoma. In these lymphoma, changes in chromosomal number and structure were signific- antly increased. Our modeling suggests a decrease in critical steps from 6 to either 5 or 4 in p53-/- mouse tumor tissue and from 4 to 3 in p53-/-Rad50s/s carcinogenesis. Anemia development appears to involve 1-2 steps in the cell cycle, whereas the development of lymphoma requires 4 or more steps.

## TIME TO FATAL TUMORS IN P53 +/-, -/- H2AX +/-, -/- KNOCKOUT MICE.

A. Chiu², M. Difilippantonio¹, A. Nussenzweig¹, N. H. Chiu³, <u>D. Singh</u>² and J. Beaubier⁴. ¹NCI, NIH, Bethesda, MD, ²NCEA ORD, USEPA, Washington, DC, ³OSTOW, USEPA, Washington, DC and ⁴OPPTS, USEPA, Washington, DC.

Carcinogenesis is a complex multistage, multipath process. In this analysis intermediate stages in cancer development are identified not only by pathologic changes but also at the cellular-molecular and genetic levels using mice with knockout or targeted-hypomorphic-antioncogenes. Cellular processes affected by antioncogenes include progression of cell-cycle, apoptosis and senescence, which in turn are controlled by gatekeepers such as p53 and Ku70/80. Applying mathematical modeling and computer simulation to individual animal data of established colonies, we found a limited number of critical cell-cycle events (N < 6) associated with p53 +/-, -/- mouse malignant lymphoma, soft- tissue sarcoma and various carcinoma development. This study used a time-to-death analysis of tumor-bearing animals employing parametric and nonparametric statistics. The quadruple knockout p53 -/-H2AX -/- mouse has a shorter latency and requires one less stage for carcinogenesis than the study strain double knockout p53 -/- mouse. We have also begun an analogous study of genes including H2AX focused on genomic stability and homologous and nonhomologous recombination. The number of stages in lymphoma development in p53 -/- H2AX +/- mice is also reduced compared to the p53 -/- strain. The genomic stability-caretaker "H2AX-Rad50-MRE11- BASC" complex plays probably just as an important role in cancer development as the gatekeepers do for poptosis- senescence. Disclaimer: Opinions and conclusions expressed in this abstract are those of the authors and do not necessarily reflect those of the NCEA, OST, OW, ORD, OPPTS, USEPA and NCI, NIH.

## 564 CARCINOGENIC RESPONSE OF K6/ODC MICE TO MELPHALAN.

Y. Chen, J. Bastien and T. O'Brien. ODC Mouse Group, Inc., Drexel Hill, PA. K6/ODC mice have been engineered to overexpress the enzyme ornithine decarboxylase (ODC) in skin and some internal organs and are exquisitely sensitive to skin tumor induction by very low doses of genotoxic carcinogens. This model has

been proposed as a highly sensitive test system for detecting carcinogens. To test the ability of K6/ODC mice to detect a known human carcinogen, the carcinogenicity of melphalan, a genotoxic carcinogen, was evaluated in this model. Groups of 15 female K6/ODC and wild-type control mice, 7 week old, were used in this study. Melphalan was systemically administered by gavage to K6/ODC mice at doses of 0, 1, 4, 16 mg/kg and to wild-type control mice at doses of 4, 16 mg/kg once a week for 20 weeks. Development of skin tumors was monitored weekly. Mean group body weight gain of melphalan-exposed mice was dose-dependently decreased in comparison to the vehicle control mice, for both strains (K6/ODC and wild-type mice). At the highest dose, all mice in both K6/ODC and wild-type control groups were dead at 8 week after treatment. However, at low doses groups, melphalan induced skin tumors were observed in a dose-response manner in K6/ODC mice. The incidence of skin tumors was 7% and 25% at doses of 1 and 4 mg/kg, respectively. The majority of tumors were squamous cell carcinomas. Tumors were not observed in both vehicle and wild-type control groups. Theses results demonstrate that the K6/ODC is a useful model for evaluating the human carcinogenic potential of genotoxic chemicals.

## 565 A NON-ANIMAL ALTERNATIVE CARCINOGENICITY TEST: THE *IN OVO* CARCINOGENICITY ASSAY (IOCA).

M. K. Reeder<sup>1</sup>, M. J. Iatropoulos<sup>2</sup>, G. M. Williams<sup>2</sup>, T. L. Ripper<sup>1</sup>, D. R. Cerven<sup>1</sup> and G. L. DeGeorge<sup>1</sup>. <sup>1</sup>MB Research Laboratories, Spinnerstown, PA and <sup>2</sup>Pathology, New York Medical College, Valhalla, NY.

We have developed a non-animal alternative method to the currently accepted Rodent Chronic Bioassay (RCB), which uses large numbers of rodents over a two year period. The IOCA is similar in concept to the Rodent Liver Focus (RLF) assay in which preneoplastic liver lesions are quantified as indicators of carcinogenicity. In the IOCA, avian embryos are exposed to carcinogens which induce focal lesions in the embryonic liver. Since IOCA is performed in a vian embryos (pre-hatching), it directly addresses the three R's (reduction, refinement and replacement) of animal testing. The advantages of IOCA are numerous; 1) testing time is reduced from 2 years to 24 days, 2) no laboratory animals are required, 3) eggs are kept in small incubators, eliminating the need for costly animal facilities, and 4) dose amounts are small, reducing the amount of chemical needed and human exposure to potential carcinogens. Using IOCA, we have investigated the effects of several well-studied genotoxic and non-genotoxic carcinogens by measuring: (1) induction of preneoplastic lesions in the avian embryonic liver; (2) increase in the size of hepatocellular nuclei in ovo; and (3) damage to avian mitochondrial DNA (mtDNA). Our results demonstrate that the carcinogens, diethylnitrosamine (DEN), N-nitrosomorpholine (NNM), and aflatoxin B1 (AFB), induce preneoplastic lesions in avian liver, manifested as hepatocellular foci and hepatic cord transformation, which correlate to rodent liver preneoplastic lesions. Moreover, a threshold treatment level for lesion development was found for both DEN and AFB. Finally, increased size of hepatocelluar nuclei and damage to liver mtDNA was observed at sub-threshold concentrations of carcinogens, indicating these changes may precede hepatocellular foci and hepatic cord transformation.

## 566 MATERNAL ATRAZINE (ATR) ALTERS HYPOTHALAMIC DOPAMINE (HYP-DA) AND SERUM PROLACTIN (SPRL) IN MALE PUPS.

C. Langdale<sup>1</sup>, T. Stoker<sup>2</sup> and R. Cooper<sup>2</sup>. <sup>1</sup>Cell Biology Department, NCSU School of Veterinary Medicine, Raleigh, NC and <sup>2</sup>Endocrinology Branch, RTD, NHEERL, ORD, USEPA, Research Triangle Park, NC. Sponsor: R. Kavlock.

In rat and mouse, milk-borne PRL (MB-PRL) is important for normal development of the offspring's tuberoinfundibular (TIDA) neurons. The absence of MB PRL on postnatal days (PND) 1-5 leads to impaired TIDA activity and prepubertal hyperprolactinemia in the pups. We previously showed that ATR will block suckling-induced PRL release. Here, we characterized the effect of ATR on sPRL and HYP-DA and DOPAC in the male pups of Wistar rat dams by dosing the dam from PND 1-9 with ATR (0, 12.5, 25 or 50 mg/kg, twice daily). PRL was measured from PND 2-35 and HYPO DA and DOPAC determined on PND 20, 25, 30 and 35. On PND 12-30, PRL was significantly higher in the 12.5 mg/kg group (AUC 22.5 ng/ml control and 32.67 ng/ml for ATR), but not the 25 and 50 mg/kg groups. Posterior HYP, DA was significantly decreased on PND 30, while DOPAC was significantly decreased from PND 20-30 in the 12.5 mg/kg dose but the same as controls in the high dose. In contrast, anterior HYP DA was increased on PND 20 and 30 in the 12.5 mg/kg group and DOPAC was significantly increased in the 12.5 mg/kg dose on PND 20 and 30. DOPAC was significantly decreased in all three dose groups on PND 35. Thus atrazine produced a non-linear dose response for PRL, HYP DA and DOPAC. These results suggest that ATR either induced alterations in the developmental progression of HYP-DA and PRL regulation or compensatory changes in this system in response to increasing doses. (This abstract does not necessarily reflect EPA policy; Supported in part by NCSU/USEPA Coop Agreement).

ATRAZINE INHIBITION OF OVULATION IN IMMATURE RATS TREATED WITH PREGNANT MARE SERUM GONADOTROPIN (PMSG).

C. Eldridge<sup>1</sup>, D. Wynn<sup>1</sup>, C. Breckenridge<sup>2</sup> and <u>J. Stevens<sup>1</sup></u>. <sup>1</sup>Physiology-Pharmacology, Wake Forest University School of Medicine, Winston-Salem, NC and <sup>2</sup>Toxicology, Syngenta Crop Protection, Greensboro, NC.

Treatment with the herbicide atrazine (ATR) has been shown to disrupt estrous cycling and to inhibit ovulation of adult Sprague-Dawley (SD) rats. Effects have been observed with short-term treatment of 2 days-1 week at maximum tolerated doses, and with lower doses after treatment up to 6 months. Although female rats normally begin ovulating at PND 36-40, it is long known that a single injection of PMSG on day 30 will induce a spontaneous LH surge on day 32 and ovulation on day 33. The present studies asked whether the PMSG model is suitable for assessing ATR effects on ovulation and whether these very young animals are more sensitive to ATR than adults. In Study 1, ATR was administered by gavage to groups of SD females on PND 30, 31 and 32. A single sc PMSG dose (4 IU) was given on PND 30. The presence of ova in the oviducts was assessed on PND 33. 76% of controls ovulated and groups treated with 1, 5, 10 and 50 mg/kg ATR produced similar results. Ovulation % was reduced at 100 and 500 mg/kg ATR, but not reduced at 300 mg/kg. The number of ova per ovulation was significantly reduced only at 500 mg/kg. Body weight gains were reduced at all ATR doses of 50 mg/kg and higher. In Study 2, groups were administered ATR by gavage (0, 10, 30, 100 mg/kg) from PND 22-32, and 4 IU PMSG was administered once on PND 30. The percent of animals ovulating in the 4 groups was nearly identical (range = 51-56%), and the mean number of ova per ovulation was unaltered. Body weight gain was retarded only in the 100 mg/kg group. Results suggest (1) the PMSG model could be suitable for testing ovulation blockade, but (2) the model may lack reliability, as many controls did not ovulate, (3) ATR had limited effect on ovulation at doses of 100 mg/kg and higher, (4) many ATR doses that suppressed BW gain did not suppress ovulation, (5) immature rat ovulation seems not to be more sensitive than the adult to ATR treatment, and is possibly more resistant.

### 568 ATRAZINE ALTERS STEROIDOGENESIS IN MALE WISTAR RATS.

W. Modic<sup>1</sup>, J. Ferrell<sup>2</sup>, C. Wood<sup>2</sup>, J. Laskey<sup>2</sup>, R. Cooper<sup>2</sup> and S. Laws<sup>2</sup>. 
<sup>1</sup>Department Mol. Structural Bch., NCSU, Raleigh, NC and <sup>2</sup>RTD, NHEERL, ORD, USEPA, Research Triangle Park, NC. Sponsor: R. Kavlock.

We have reported that atrazine (ATR, 200 mg/kg x 30 d) causes increased serum estrone (E) and estradiol (E2) in male wistar rats (Toxicol. Sciences. 2000, 58:50-59). This study evaluates the short-term effects of ATR on E, E2 and their precursors in the steroidogenic pathway. Sixty-day-old male Wistar rats were gavaged once per day with ATR (0, 50, 200 mg/kg) for 1, 4 or 21 days. Following the single dose, males were killed at 3, 6, or 24 hr. Males receiving multiple doses (4 or 21 days) were killed 3 hr following the last dose. Serum E, E2, testosterone (T), androstenedione (A), progesterone (P), and corticosterone (C) were measured. After one dose of ATR (200 mg/kg), P and C were increased at 3 hr. By 24 hr this dose elevated C and E. A and T were increased at 6 hrs for both doses. After 4 or 21 days of treatment with 200 mg/kg, C, E and E2 were elevated, but A and T remained at control levels. To determine the effect of ATR on adrenal steroidogenesis, ATR treated castrated males were examined. Despite reduced A and T levels in the castrated 200 mg/kg males, increased serum C, E, E2 mirrored previous results. Elevated P was also observed. No change in aromatase CYP19 mRNA was detected by real time RT-PCR in the testicular or hypothalamic tissues at any time point. These data suggest that elevated E and E2 were not strictly due to increased testicular steroidogenesis, altered aromatase mRNA, or substrate availability, but do not rule out a change in steroid metabolism or elimination. Although no CYP19 mRNA was detected in the adrenals, a stress-induced adrenal response may be partially responsible for the increase in steroids. However, in vitro data using a minced testes assay show an increase in T following a  $4\,\mathrm{hr}$  exposure to ATR. Together, these data demonstrate that ATR can alter the steroidogenic pathway in male Wistar rats. This abstract does not necessarily reflect USEPA policy. Supported in part by the NCSU/NHEERL, USEPA Co-op Agreement.

## 569 CARBOFURAN-INDUCED ENDOCRINE DISRUPTION IN MALE RATS.

R. T. Goad<sup>1</sup>, <u>R. C. Gupta</u><sup>1</sup>, J. T. Goad<sup>1</sup>, B. H. Atieh<sup>2</sup> and R. B. Doss<sup>1</sup>.

<sup>1</sup> Toxicology, Murry State University, Hopkinsville, KY and <sup>2</sup>Occup. Safety & Hlth, Murray State University, Murray, KY.

The objective of this investigation was to determine the acute toxic effects of the carbamate insecticide carbofuran on the levels of endocrine hormones in the serum of adult male Sprague-Dawley rats. Using chemiluminescent immunoassay, the hormones determined were progesterone, cortisol, estradiol, testosterone, tiidothy-

ronine (T3), total thyroxine (total T4), and non-protein-bound thyroxine (free T4). Rats exposed to an acute dose of carbofuran (1.5 mg/kg, s.c.) showed the onset of cholinergic signs (salivation, chewing, and fine tremors) within 5-7 minutes. With increasing intensity, toxic signs of maximal severity (severe convulsions and fasiculations) were observed within 30-60 min, and lasted for about 2 to 3 hours. Time courses of hormones for 24 hrs revealed significant alterations in hormone levels during 0.5 to 3 hrs, with the exception of estradiol at 6 hrs. The levels of progesterone, cortisol, and estradiol were significantly increased (1279%, 202%, and 150%, respectively), while the levels of testosterone were decreased by 88%. No significant change occurred in thyroid hormones (T3, total T4, and free T4) at any time during the time course, despite the fact that body temperature was significantly low at 1 to 2 hrs. Carbofuran caused significant increases in glucose (189 to 242%), partly due to > 2-fold increase in cortisol that stimulates gluconeogenesis. In fact, the timings for increases in cortisol and glucose were transient and identical, i.e., 0.5 to 3 hrs. The results suggest that an acute exposure to carbofuran may cause endocrine disruption, which may consequently lead to serious reproductive prob-

## 570 IN VITRO/IN VIVO EVALUATION OF THE (ANTI)ANDROGENIC ACTIVITY OF THE ANTIPROGESTIN R11486

G. Charles, H. L. Kan, M. R. Schisler, B. B. Gollapudi and M. S. Marty. The Dow Chemical Company, Midland, MI.

These experiments are part of an on-going study to evaluate the concordance between in vitro and in vivo Endocrine Disrupter Tier I androgen screening assays. Given that progesterone (PROG) is known to bind the androgen receptor (AR), we examined the anti-androgenic potential of the anti-progestin, RU486 using both in vitro (AR transactivation and AR binding) and in vivo (Hershberger) assays. For the transactivation assay, AR(+) LNCaP prostate carcinoma cells were transfected with an inducible luciferase reporter construct with concatenated androgen-responsive elements (pGudLuc7ARE) and exposed for 24h to concentrations of RU486 and PROG ranging from 1 nM to 10 uM in the presence and absence of 1nM of the AR agonist, R-1881. PROG, but not RU486, produced partial agonist activity (30-45 fold induction) as compared to R-1881 (65-100 fold). However, RU486 produced significant anti-androgenic activity in vitro as evidenced by its 70 and 100% inhibition of agonist responses by PROG (10 nM) and R-1881 (1 nM), respectively. In vitro binding experiments utilizing the recombinant ligand-binding domain of the AR with a fluorescence polarization methodology indicated that RU486 exhibited an IC50 (approx. 24 nM), comparable to that of testosterone (approx.17 nM). For the assessment of anti-androgenic activity in vivo, castrated CD rats (8/group) were dosed for 10 days by gavage with RU486 (0, 1, 5, 10 and 25 mg/kg/day) and by subcutaneous injection with 0.4 mg/kg/day testosterone propionate (TP). Flutamide at 10 mg/kg/day, by gavage, was used as the positive control for anti-androgenicity. At 25 mg/kg/day, RU486 produced significant decreases in ventral prostate, seminal vesicle and Cowpers gland weights without significant effects on body or liver weights. Thus, RU486 showed good concordance between in vitro and in vivo assays, whereas previous screens with other chemicals (BaP and methoxychlor) demonstrated poor concordance. Overall, our results indicate the importance of including in vivo data in assessing endocrine activity of test materi-

### 571 PHOXIM STIMULATE STEROIDOGENESIS IN RAT GRANULOSA CELLS *IN VITRO*.

H. Chen<sup>1, 2</sup> and X. Wang<sup>1</sup>. <sup>1</sup>Institution of Toxicology, Nanjing Medical University, Nanjing, Jiangsu Province, China and <sup>2</sup>Environmental Health Sciences, UCLA School of Public Health, Los Angeles, CA. Sponsor: <u>L. You</u>.

BACKGROUND: Phoxim is a kind of organophosphorus pesticides and is commonly used in agriculture, especially in China. Former studies on the toxicity of this pesticide focused on the nervous system, however, our previous study indicated that phoxim can interrupt the steroidogenesis in whole rat model. The purpose of this study was to determine how phoxim affect the steroidogenesis in rat granulose cells (rGCs) in vitro. METHODS: rGCs was cultured in the serum-free medium and phoxim and/or FSH were added. Progesterone (P4) and estradiol (E2) concentration in the medium were determined by radioimmunoassay (RIA) at 12h and 24h of culture. The effects of phoxim on the mRNA expression of P450scc and 3β-HSD were evaluated by RT-PCR at 24h of culture. Aromatase activity assay was performed at 24h by evaluating the ability of transferring  $^3\text{H-1}\beta\text{-androstenedione}$ to <sup>3</sup>H<sub>2</sub>O. Also, the cellular cAMP concentration was detected by RIA after 24 h of culture. RESULTS: The synthesis of  $P_4$  was stimulated by phoxim in rGC *in vitro*, however it was suppressed by high doses of phoxim (125 and 625  $\mu$ mol/L) with the medium contained FSH (2 mg/L). The synthesis of E2 in rGC in vitro was stimulated by phoxim no matter whether the medium contained FSH (2 mg/L) or not. Although mRNA expression of P450scc and 3β-HSD were induced by phoxim, it

was inhibited by high doses of phoxim (125 and 625  $\mu$ mol/L) with the medium contained FSH (2 mg/L). Phoxim can stimulate cAMP production. No significant effect of aromatase activity was observed in phoxim treated groups. **CONCLUSION:** Phoxim can stimulate the synthesis of  $P_4$  and  $E_2$  in rGC *in vitro* which are related with the mRNA expression alteration of P450scc and 3 $\beta$ -HSD. The effects of phoxim on mRNA expressions of these two emzymes may be caused through cAMP/PKA pathway. Aromatase activity is not involved in the stimulation of  $E_2$  synthesis in rGC *in vitro*.

PROCESS OF VALIDATION OF THE LUMI-CELL™ ER RECOMBINANT BIOASSAY FOR RAPID EVALUATION OF POTENTIAL ESTROGENIC ENDOCRINE DISRUPTOR CHEMICALS.

J. D. Gordon<sup>1</sup>, A. C. Chu<sup>1</sup>, M. D. Chu<sup>2</sup>, C. L. Taylor<sup>1</sup>, <u>M. S. Denison<sup>3</sup></u> and <u>G. C. Clark<sup>1</sup>. <sup>1</sup>Xenobiotic Detection Systems, Inc., Durham, NC, <sup>2</sup>Alta Analytical Perspectives, Wilmington, NC and <sup>3</sup>Department of Environmental Toxicology, University of California, Davis, Davis, CA.</u>

Endocrine disruptor chemicals (EDCs) are a class of compounds, which have tremendous adverse effects on human and wild life populations. The association between the exposure to, and bioaccumulation in the food chain, of EDCs has raised concern worldwide. Identification of ECDs requires a relevant bioassay, which can both detect these chemicals, as well as provide a relevant estimate of their endocrine disrupting potency. Xenobiotic Detection System (XDS) Inc. developed the LUMI-CELL $^{\rm TM}$  ER bioassay in order to detect EDCs using a high-throughput bioassay system. To detect EDCs, BG-1 cells were stably transfected with an estrogen-responsive luciferase reporter gene plasmid (pGudLuc7ere). The resulting cell line responds to estrogenic chemicals in a time-, dose dependent- and chemical-specific manner with the induction of luciferase gene expression. The LUMI-CELL $^{\text{TM}}$ ER bioassay system produced by XDS has tested over 110 chemicals, 53 of these chemicals were recommended by ICCVAM for validation of ER binding and transcriptional activation. Of the 53 chemicals tested, which were recommended by IC-CVAM, all of the 28 compounds having historical data for a positive response demonstrated estrogenic activity. Out of the 110 chemicals tested by LÛMI-CELL<sup>TM</sup> ER bioassay system, 69 demonstrated estrogenic activity, while 41 showed no activity. Of the 57 chemicals tested, which were not included in the ICCVAM requirements for validation, 30 were found to possess estrogenic activity, while 27 showed no activity. This data clearly demonstrates that LUMI-CELL<sup>TM</sup> ER highthroughput bioassay system produced by XDS is a fast, reliable, and relatively inexpensive method for detection of EDCs, meeting many of the requirements mandated by the EPA and ICCVAMs Tier I (screening) requirements for EDC detection assays. Supported by NIEHS SBIR grant ES10533-03, and Superfund Basic Research Grant ES04699.

573 IN VIVO AND IN VITRO ANTI-ANDROGENIC EFFECTS OF DE-71, A COMMERCIAL POLYBROMINATED DIPHENYL ETHER (PBDE) MIXTURE.

T. E. Stoker, R. L. Cooper, C. S. Lambright and <u>L. E. Gray</u>. *EB, RTD, NHEERL, USEPA, Research Triangle Park, NC.* 

PBDEs are synthesized in large quantities as flame retardants for commercial products. The detection of PBDEs in tissues in wildlife species and in human milk and plasma samples has raised concerns about possible health effects. Recently, we showed that DE-71 delayed preputial separation (PPS) and suppressed the growth of androgen-dependent tissues in the Wistar rat following peri-pubertal exposure. These effects occurred concurrently with hypothyroidism and hepatomegaly and suggested that DE-71 may be either inducing steroid hormone metabolism or acting as an androgen receptor (AR) antagonist. To elucidate the anti-androgenic effects of this mixture, we evaluated DE-71 in several in vivo and in vitro assays. In a pubertal exposure study, we observed a delay in PPS with 30, 60 and 120 mg/kg/day of DE-71 (3, 4 and 5 days) and a suppression of ventral prostate (VP) and seminal vesicle growth. In another study, in which adult male rats were exposed to DE-71 for three days, luteinizing hormone, testosterone, androstendione and estrone concentrations were increased following exposure to 60 mg/kg/day. DE-71 and DE-100 (2, 2', 4, 4', 6-pentaBDE), one of the congeners in this mixture, both inhibited AR binding in a competition assay using rat VP cytosol (both with IC50s approximately 5 uM). In addition, both DE-71 and DE-100 inhibited DHT-induced transcriptional activation in MDA-kb2 cells. DE-71 was also positive for anti-androgenic activity in a weanling rat Hershberger assay. In conclusion, DE-71 and -100 have anti-androgenic activity, which appears to be mediated via AR antagonism. This alteration of androgen function may be the mechanism by which DE-71 delayed PPS and suppressed the growth of the androgen dependent tissues in the previous study. Additional studies are in progress to determine the specific (competitive verses noncompetitive) nature of the chemicals in the rat AR binding assays and to repeat the Hershberger assay. (Abstract does not necessarily reflect EPÁ policy.)

574 EFFECTS OF *IN UTERO* EXPOSURE OF DIETHYLSTILBESTROL AND DIBUTYL PHTHALATE ON THE TESTIS DESCENDENT IN RAT OFFSPRINGS.

T. Kim, J. Shin, S. Lee, H. Moon, I. Kang, I. Kim and S. Han. *Endocrine Toxicology Division, National Inst of Toxicol Res, Seoul, South Korea.* Sponsor: <u>I. Yu</u>.

The aims of present study were to compare the effects of in utero exposure to DES and DBP on the development of reproductive organs and to investigate the specific mechanisms of these abnormalities in the male reproductive system. During gestation days 10-19, pregnant Sparague-Dawley rats were administered oraly with corn oil, DÉS (25, 50, or 100 microgram/kg/day) or DBP (250, 500, or 700 mg/kg/day). Animals were killed at 31 or 42 days of age and blood was collected for serum testosterone analysis. Testes and accessory organs (epididymides, seminal vesicles, ventral prostate, LABC, Cowper's glands) were weighed and examined histologically. Steroid hormone receptor (AR and ER) and SF-1 expression levels were also examined in the testes, respectively. At 31 days of age, effects of DBP on the male reproductive tract abnormalities (hypospadias, cryptorchidism) were dose-dependent. DBP treatment significantly decreased the weights of testes and accessory sex organs compared to those of control. In the DBP group, the weights of the testes, epididymides ventral prostate, seminal vesicle, and Cowper's glands were significantly decreased. DBP significantly delayed the testes descent in a dose-dependent manner, whereas DES slightly delayed the testes descent only at the high dose group (100 microg/kg/day). DBP also significantly increased the expression of ER in the testes but DES did not change the expression of AR, ER in the testis compared to those of control. At 42 days of age, the animals of DBP-treated group did not show any different change of testicular and accessory sex organ weights. DBP and DES markedly decreased serum testosterone levels. In addition, DES significantly increased the expression of ER in the testes respectively. In contrast, DBP did not effect the expression of AR, ER in the testis. These results demonstrate that during gestation days 10-19 exposure to DES and DBP causes permanent changes in the endocrine system resulting in abnormal development of male reproductive

575 RAT SPERMATID AND OVARIAN PRIMARY FOLLICLE COUNTS FOLLOWING *IN UTERO* EXPOSURE TO LOW DOSE BISPHENOL A.

C. Talsness, J. Nowak, K. Grote, S. Kuriyama and <u>I. Chahoud</u>. Department of Toxicology, Charite University Medical School, Campus Benjamin Franklin, Institute of Clinical Pharmacology and Toxicology, Berlin, Germany.

Conflicting studies exist whether bisphenol A (BPA), a compound with in vitro estrogenic and anti-androgenic activity, interferes with the developing reproductive system. We evaluated possible effects on gamete numbers in the testis and ovary following in utero exposure to a low dose of BPA. Gravid Sprague-Dawley rats were treated per gavage with either 2 μg/kg/d BPA, 2 μg/kg/d 17-αethinyl estradiol (EE) or cornstarch (one control group for each treatment group) on gestation days 6 -21. Adult female offspring were sacrificed in estrus at approximately four months of age and adult male offspring were killed on PND 170. Paraffin-embedded ovaries were cut in 6µm thick serial sections, stained with hematoxylin and eosin and the number of primary follicles were evaluated in five sections, 240  $\mu m$  apart, taken from the mid portion of the ovary. After removal of the tunica albuginea, the testes were minced and homogenized in 10 ml 0.9 % NaCl containing 0.5 % Triton X-100. After dilution, the number of homogenization-resistant spermatids was counted with a hemocytometer. The preliminary results suggest that there is a decrease in primordial follicle numbers in the ovaries (n=10) exposed to BPA and an increase in primordial follicle numbers in the ovaries (n=8) exposed to EE. A statistically significant decrease in spermatid number was observed following BPA exposure  $(244 \pm 29 \times 10^6 \text{ vs } 207 \pm 33 \times 10^6)$ . The number of ovarian primary follicles may be sensitive to prenatal exposure to endocrine active compounds. In utero exposure to BPA results in decreased spermatid numbers at adulthood in the rat at a dose which may be pertinent to human exposure levels. The study was funded by the Federal Agency for Education and Research (07HORO1/7).

756 REGION-SPECIFIC GLOBAL GENE EXPRESSION
ANALYSIS IN THE MICRODISSECTED
HYPOTHALAMIC MEDIAL PREOPTIC AREA OF RAT
NEONATES INJECTED WITH ESTRADIOL BENZOATE
OR FLUTAMIDE.

M. Shibutani, K. Lee, H. Takagi, N. Kato, S. Takigami and M. Hirose. *Division Pathol., NIHS, Tokyo, Japan.* Sponsor: M. Ema.

To identify genes linked to disruption of brain sexual differentiation, region-specific gene expression profiles in the microdissected medial preoptic area (MPOA) were examined in rat neonates exposed to estrogenic and anti-androgenic drugs utilizing methacarn that we have recently found as a versatile fixation tool for mRNA

expression analysis in the paraffin-embedded tissue specimens. For this purpose, a preliminary validation study on the microarray analysis was performed using the rat liver. With 50 ng of total RNA, up to 0.5 million-fold of antisense RNAs (aRNAs) could be amplified by two-round (2x) in vitro transcription. With the amplified aRNAs, expression profile was compared with those in 1x or 2x-amplified aRNAs from unfixed tissue, and high fidelity was confirmed by a correlation coefficient of 0.91 with 1x-amplified aRNAs from unfixed tissue. In the next experiment, neonatal rats at birth were treated either s.c. with estradiol benzoate (EB; 10 µg/pup) or flutamide (FA; 250  $\mu g/pup$ ), and gene expression profiles in the MPOA were examined 24 hour later. Among 8, 000 probes in the microarray, genes up-regulated twice or more by EB or FA as compared to the control levels were 26 and 6 for males, and 299 and 9 for females, respectively. Genes down-regulated twice or less were 1 and 6 for males, and 125 and 29 for females, respectively. Among them, cyclin G1 showed chemical and sex unrelated up-regulation. By EB, 11 of down-regulated genes in females were up-regulated in males. By FA, each one gene showed opposite expression pattern between males and females. In females, 7 genes were down-regulated both by EB and FA, and 3 genes including GnRH were up-regulated by EB and down-regulated by FA. In summary, we have now established a global expression analysis method in paraffin-embedded histologically defined area by employing methacarn fixation, and genes showing altered expression by EB or FA with sex-dependent manner in the MPOA were identified as candidates to play a role in central endocrine disruption.

## 577 EFFECT OF DDT ON TESTOSTERONE AND AROMATASE ACTIVITY VIA ESTROGEN RECEPTOR IN LEYDIG CELL.

K. Lee<sup>1, 2</sup> and H. Jeong<sup>1, 2</sup>. <sup>1</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and <sup>2</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, Kwangju, South Korea.

Various pesticides known or suspected to interfere with steroid hormone function were screened for effects in leydig cells on catalytic activity and mRNA expression of aromatase. Dichlorodiphenyltrichloroethane (DDT) is a widespread environmental pollutant. In this study, we investigated the effect of DDT on testosterone production through aromatase activity and its molecular mechanism in testicular leydig cell, R2C by using radioimmunoassay (RIA). As the results, the potent leydig cell activator LH increased testosterone production compared to the control. DDT exposure significantly decreased testosterone production in R2C cell. In addition, DDT was found to increase aromatase gene expression and activity in R2C cell in a dose dependent manner. In order to assess whether the suppressive effects of DDT on LH-inducible testosterone (T) production might be influenced by the ER, ICI 182.780 was used, and it was found that these inhibitory effects of DDT were antagonized by ICI 182.780, implying that the estrogen receptor (ER) mediates the suppressive effects of DDT. Furthermore, the inducible effects of DDT on aromatase gene expression might be influenced by the ER, ICI 182.780 was used, and it was found that these enhancing effects of DDT were antagonized by ICI 182.780, implying that the ER mediates the inducible effects of DDT. Our results indicated that DDT inhibition of luteinizing hormone (LH)-inducible T production in R2C cell is mediated through aromatase. The current study suggests the possibility that DDT might act as a modulator aromatase gene transcription.

## 578 CATECHOL ESTROGEN-INDUCED DNA DAMAGE IN MCF-7 CELLS.

M. B. van Duursen, <u>T. Sanderson</u> and <u>M. van den Berg</u>. Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, Netherlands.

Epidemiologic evidence suggests that alterations in estrogen metabolism are associated with breast cancer risk. In breast tissue, estradiol is metabolized to the catechol estrogens (CEs) 2-OHE2 and 4-OHE2 by CYP1A1 and CYP1B1, respectively. A major inactivation step for the CEs is conversion to their inactive methoxy derivatives by catechol-O-methyltransferase (COMT). We have previously shown that several dioxin-like compounds can cause a concentration-dependent increase of CE levels but a decrease in the 4-OHE2/2-OHE2-ratio in MCF-7 and MCF-10A cells. In addition, we have shown that phytochemicals with a catechol structure, like quercetin, have the ability to inhibit methylation of CEs by COMT in cytosol from healthy human breast tissue. In this study, we investigated the effects of altered estrogen metabolism on DNA damage in MCF-7 cells using the comet assay. MCF-7 cells were incubated with 4-OHE2 and 2-OHE2 (total CE concentration held constant at 1 or 10  $\mu$ M) in ratios 0, 0.2, 0.5, 1, 2 or 3. COMT activity was inhibited by the selective inhibitor Ro 41-0960. After a 5h incubation, the cells were lysed and electrophoresed. DNA was stained with ethidium bromide and analysed under a fluorescence microscope. Tail moment (% tail DNA x tail length) as measure of DNA damage was calculated using the PC-image-analysis program Casp. The solvent vehicles, Ro 41-0960 or CEs alone caused no increase in DNA damage compared with control cells. However, when COMT was inhibited by Ro 41-0960, we found a linear correlation between the increase in the 4-OHE2/2-OHE2-ratio and the increase of DNA damage. At 10  $\mu\text{M}$ , there was significantly more DNA damage than at 1  $\mu\text{M}$  CE at each ratio. Quercetin appeared to act like a COMT inhibitor resulting in increased CE-induced damage. These data show that 4-OHE2, but not 2-OHE2, is a potential DNA damaging compound in a concentration-dependent manner. Further, COMT activity appears to be an important factor in determining the genotoxic potential of the CEs and inhibition of COMT might play a role in the etiology of breast cancer.

## 579 ACTIVATION OF HUMAN ESTROGEN RECEPTORS IN HEPG2 CELLS BY GENISTEIN AND ITS CONJUGATED METABOLITES.

S. Borghoff, H. D. Parkinson, S. M. Ross, K. Gaido and M. Sochaski. CIIT Centers for Health Research, Research Triangle Park, NC.

Genistein is a phytoestrogen present in soy and virtually all rodent diets. It has been shown to activate both estrogen receptor (ER)  $\alpha$  and  $\beta$  in vitro. Genistein has also been reported to elicit estrogenic effects in developing rodents. Following oral administration, genistein is found in plasma predominantly conjugated to glucuronic acid (GA) and to a lesser degree to sulphate (S). However, fetal plasma levels of genistein-S and genistein-GA are similar to each other following administration of genistein to pregnant rats. Because these conjugated forms are the major metabolites of genistein in vivo, these metabolites should not be overlooked as possible contributors to estrogenic effects of genistein. The objective of this study was to determine if conjugates of genistein activate ER $\alpha$  or ER $\beta$  as does free genistein. HepG2 human hepatoma cells were transfected with various concentrations of receptor plasmids encoding human ERα or ERβ, and complement 3-luciferase and pĈMV β-galactosidase plasmids. Transfected cells were treated with various concentrations of either estradiol, genistein, genistein-GA (isolated from bile of genistein treated rats), genistein-S (chemically synthesized) or dimethylsulfoxide (control vehicle). Following 24-hr incubation, cell lysates were assayed for luciferase activity (receptor activation) and ?-galactosidase activity (transfection control). Estradiol and genistein activated both ER  $\alpha$  and  $\beta$ , however, neither genistein-GA nor genistein-S activated either receptor or antagonized the ability of estradiol to activate these receptors. These data demonstrate that conjugation eliminates the estrogenic activity of genistein and that it is important to determine the ratio of free genistein to conjugated forms when estimating estrogenic potency. (This study was funded by the American Chemistry Council.)

## 580 INTERACTION ANALYSIS OF SYNTHETIC CHEMICALS AND PHYTOESTROGENS *IN VITRO*.

E. W. Carney<sup>1</sup>, G. D. Charles<sup>1</sup>, C. Gennings<sup>2</sup>, B. B. Gollapudi<sup>1</sup> and T. R. Zacharewski<sup>3</sup>. <sup>1</sup>The Dow Chemical Company, Midland, MI, <sup>2</sup>Biostatistics, Virginia Commonwealth University, Richmond, VA and <sup>3</sup>Biochemistry & National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI.

Humans are potentially exposed to many different estrogenic chemicals including synthetic chemicals (SCs), typically at very low levels, and phytoestrogens (PEs), often present in diets at high levels. In this study we assessed interactions between SCs and PEs using an estrogen receptor-alpha reporter gene assay. Individual concentration-response curves were first generated for each of six SCs [methoxychlor, o, p-DDT, bisphenol A, beta-hexachlorocyclohexane, 2, 3-bis (4-hydroxyphenyl)propionitrile), octylphenol] and for a PE preparation (genistein:daidzein, 2:1). A fixed-ratio mixture of all six SCs was then devised with the proportion of each chemical in the mixture based on its no-effect concentration. The SC mixture was tested at total concentrations of 0.02, 0.2, 1.0, 2.0, or 3.0 uM, with 2.0 uM being the total dose at which each individual chemical in the mixture was at its own response threshold. We then asked whether or not the threshold and slope of the PE concentration-response curve (0, 0.01, 0.025, 0.05, 0.1, 0.15, 0.5 uM) were shifted when the PEs were combined with various concentrations of the SC mixture. In general, the SC mixture significantly increased response thresholds relative to the PEs alone, an effect most likely due to the lower potency of the SCs and their competition with the more potent PEs. Once these thresholds were exceeded, slopes of the PE+SC mixture responses were significantly steeper than that of the PEs alone. Finally, analysis of the SC mixture without PEs indicated an antagonistic interaction between the SC mixture components at the ratio tested. These results highlight the dose-dependency of chemical interactions and also exemplify a novel experimental and statistical approach for assessing complex chemical mixtures at low concentrations. Funded by the American Chemistry Council, Long-Range Research

COMPARATIVE ACTIVATION OF ESTROGEN RECEPTOR  $\alpha$  (ER $\alpha$ ) AND ER $\alpha$ /SP1 IN BREAST CANCER CELLS BY XENOESTROGENS.

F. Wu<sup>1</sup> and <u>S. Safe<sup>2</sup></u>. <sup>1</sup>Biochemistry & Biophysics, Texas A&M University, College Station, TX and <sup>2</sup>Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.

17β-Estradiol (E2) and diethylstilbestrol (DES) are potent estrogenic compounds in vivo and activate estrogen-responsive genes and constructs containing estrogen responsive elements (EREs) in transfection experiments in cell culture. The estrogenic activity of several synthetic "xenoestrogenic" compounds were evaluated in transient transfection assays in breast cancer cells transfected with constructs containing three tandem ERÉs (pERE<sub>3</sub>) or GC-rich motifs (pSp1<sub>3</sub>) that are activated by ERα and ERα/Sp1 respectively. Relatively high concentrations (10-50 μM) of nonylphenol, 2, 2-bis(p-hydroxyphenol)-1, 1, 1-trichloroethane (HPTE), octylphenol, endosulfan and 2', 3', 4', 5'-tetrachlorobiphenol-2-ol induced transactivation in cells transfected with pERE 3, whereas maximal induction was observed for 1 or 10 nM E2 and DES. Ten nM E2 and higher concentrations (up to 75  $\mu M$ ) of the xenoestrogenic compounds also induced 4- to 5-fold increase in reporter gene activity in MCF-7 cells transfected with pSp1<sub>3</sub>, whereas only minimal induction (<50%) was observed in cells treated with 10 nM and higher concentrations of DES. Thus, E2 and DES differentially activated ER $\alpha$ /Sp1. A series of mutant ER $\alpha$ constructs containing selective deletions and mutations were also used in these assay and the results show that DES, E2, antiestrogens and xenoestrogens differentially induced transactivation in MCF-7 cells and other breast cancer cell lines transfected with pSp13. Thus, ER-dependent activation of pSp13 and pERE3 by E2, DES and xenoestrogens in breast cancer cells is ligand structure-dependent, suggesting that these compounds will induce unique in vivo biology. LACK OF SYNERGISTIC OR ANTAGONISTIC EFFECTS OF A MIXTURE OF PHYTOESTROGENS ON CELL PROLIFERATION OF MCF-7 HUMAN BREAST CANCER CELLS (F-SCREEN)

J. van Meeuwen<sup>1</sup>, A. Piersma<sup>2</sup>, <u>M. van den Berg</u><sup>1</sup> and <u>J. Sanderson</u><sup>1</sup>. <sup>1</sup>IRAS, University Utrecht, utrecht, Netherlands and <sup>2</sup>RIVM, Bilthoven, Netherlands.

A normal human diet is known to contain a large number of phytochemicals, of which a minority has shown estrogenic or anti-estrogenic effects in vitro as well as in vivo. It has been suggested that these phytoestrogens may act synergistically or antagonistically in combination with endogenous estrogens, such as  $17\beta$ -estradiol (E<sub>2</sub>). To investigate potential synergism and antagonism, several phytoestrogens were tested individually, in a mixture and as combinations of this mixture with E<sub>2</sub> for cell proliferative effects on MCF7-bus cells (kindly provided by A. Soto). Cell numbers were determined using MTT reduction as a measure of mitochondrial activity. E, caused 50% of maximal cell proliferation at 7pM (EC<sub>50</sub>). Genistein and naringenin produced full concentration-response curves, with EC<sub>50</sub>'s of 0.06µM and 0.8µM respectively. For catechin, coumestrol and quercetin maximal cell proliferation was not reached at concentrations up to 0.1mM, but for coumestrol and quercetin the concentrations 10 µM respectively 0.1mM caused the same proliferative response as the EC<sub>50</sub> of E<sub>2</sub>. For catechin the highest tested concentration (0.1 mM) caused the same proliferative response as the EC<sub>30</sub> of E<sub>2</sub>. Epicatechin did not cause cell proliferation. A phytoestrogen mixture (phytomix) was prepared reflecting measurements of concentrations found in serum from humans consuming a regular diet (genistein=500nM; naringenin=100nM; coumestrol=10pM; quercetin=50nM; catechin=70nM; epicatechin=250nM). Various dilutions (ranging from 0.03 to 10 times the phytomix concentration) produced a full concentration-response curve with an  $EC_{50}$  at 0.16 times phytomix. Binary combinations of the phytomix and  $E_2$  in various ratios, which assuming additivity would result in a proliferative response equal to the  $EC_{50}$  of  $E_2$  alone, were tested. These combinations tions showed no departure from additivity. In conclusion, the tested phytoestrogens appeared to act as full agonists for the estrogen receptor and interacted among each other and with E<sub>2</sub> in an additive manner.

## 583 CELLULAR UPTAKE OF DAIDZIN AND GENISTIN BY MCF-7-ERE CELLS VIA GLUCOSE TRANSPORTER.

I. Kim<sup>1</sup>, Y. Sheen<sup>2</sup> and H. Kwon<sup>1</sup>. <sup>1</sup>Department of Food and Nutrition, college of Human Ecology, Seoul National University, Seoul, South Korea and <sup>2</sup>College of Pharmacy, Ewha Womans University, Seoul, South Korea. Sponsor: Y. Cha.

It has been thought that the metabolism of phytoestrogen glycosides to aglycone is necessary to exert their estrogenic activity due to their poor absorption. However, our previous study suggested estrogenic activity of glycoside is similar to that of aglycone in cultured MCF-7-ERE cells, human mammary cancer cells transfected with reporter genes. The mammary cancer cells appeared to take up glycosides,

since the *in vitro* estrogenic activities of the glycosides apparently were as high as the aglycons. In order to identify the transporter which is responsible for cellular uptake of the glycosides, glucose transporter GLUT blocker cytochalasin B(CytoB) and sodium/glucose cotransporter SGLT blocker phlorizin(PLZ) were employed. Estrogenic activities of glycoside daidzin and genistin were inhibited in a dose-dependent manner by the treatment with 1×10<sup>-7</sup>-2×10<sup>-5</sup>M of cytochalasin B. Phlrorizin inhibited also, but failed to show dose dependency. On the contrary, CytoB and PLZ stimulated estrogenic activities of aglycone daidzein and genistein. These results suggest glycosides daidzin and genistin could be transported into the cell in their intact glycoside form *via* GLUT.

## 584 INTERACTION ANALYSIS OF SYNTHETIC CHEMICALS AND PHYTOESTROGENS *IN VIVO*.

S. D. Seidel<sup>1</sup>, D. R. Boverhof<sup>2</sup>, E. W. Carney<sup>1</sup>, G. D. Charles<sup>1</sup>, C. Gennings<sup>3</sup>, B. B. Gollapudi<sup>1</sup> and T. R. Zacharewski<sup>2</sup>. <sup>1</sup>The Dow Chemical Company, Midland, MI, <sup>2</sup>Biochemistry & Molecular Biology, National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI and <sup>3</sup>Biostatistics, Virginia Commonwealth University, Richmond, VA.

Humans are potentially exposed to many different estrogenic chemicals including synthetic chemicals (SCs), typically at very low levels, and phytoestrogens (PEs), often present in the diet at high levels. In this study we assessed interactions between SCs and PEs using the immature rat uterotrophic assay (UA) coupled with expression analysis of estrogen-responsive genes. All test compounds were administered by gavage once daily for 3 days. 24 h after the last dose, uteri were harvested, wet weights recorded and tissues were snap frozen for real-time RT-PCR analysis. Individual dose-response curves in the UA were first generated for each of six SCs [methoxychlor, o, p-DDT, octylphenol, bisphenol A, beta-hexachlorocyclohexane, 2, 3-bis(4-hydroxyphenyl)-propionitrile)] and for a PE preparation (genistein:daidzein, 2:1) with ethynylestradiol (EE) (10 ug/kg/day) as a positive control. A fixed-ratio mixture of all six SCs was then devised with each chemical in the mixture present at its individual response threshold dose (i.e., a dose causing a 20% increase in uterine wet weight). We then compared the dose-response for the PE preparation alone (total doses of 0, 10, 30 or 120 mg/kg/day) with that of the PEs combined with the SC mixture. Statistical analysis of the UA data indicated that the PEs and SCs, at the tested dose levels, produced an additive response in the uterotrophic assay. Expression of two genes induced by EE, complement component 3 and intestinal calcium-binding protein, also appeared to increase in a doseresponsive manner following treatment with the PEs alone and with the PE+SC mixtures. Studies to further evaluate the estrogenic effects of mixtures of PEs with low levels of SCs are currently in progress. Funded by the American Chemistry Council, Long-Range Research Initiative.

## 585 IN VIVO INTERACTIONS OF THE ENDOCRINE DISRUPTOR ETHINYL ESTRADIOL WITH THYROID HORMONE ACTION.

A. Tindall<sup>1, 3</sup>, I. D. Morris<sup>2</sup>, H. Isaacs<sup>3</sup>, B. Pownall<sup>3</sup>, D. Pickford<sup>4</sup>, T. Hutchinson<sup>4</sup>, R. Schultz<sup>5</sup> and L. Tattersfield<sup>5</sup>. <sup>1</sup>Biological Sciences, Manchester University, Manchester, United Kingdom, <sup>2</sup>Hull York Medical School, York, United Kingdom, <sup>3</sup>Biology, York University, York, United Kingdom, <sup>4</sup>Environmental laboratory, AstraZeneca, Brixham, United Kingdom and <sup>5</sup>Ecological Sciences, Syngenta, Bracknell, United Kingdom. Sponsor: I. kimber.

There is evidence that xenobiotics with estrogenic activity may interact with other endocrine systems. A detailed understanding of these effects may enable more informed evaluation of environmental exposure risk. This study aims to characterise the interactions between environmental estrogens and the thyroid axis. Our model species is Xenopus tropicalis, a sentinel species for environmental thyroid disruption as it is aquatic and the thyroid axis controls metamorphosis which is well studied. Iodothyronine type III deiodinase deactivates thyroid hormones and is regulated by prolactin, which in turn is a physiological/toxicological target for estrogen. X.tropicalis larvae (120/treatment) were continuously exposed to: 100microl/L methanol control with or without 100ng/L 17-alpha ethinyl estradiol (EE2). Exposure began at stage 45-48 and larvae were sampled at stage 53-56 and 61-64. Thyroxine (T4) was measured in larval bodies by RIA at stage 61-64. Whole body expression levels of DI mRNA were quantified by real time PCR in stage 54 larvae. When compared to control EE2 treated larvae had increased snout-vent length at stage 55 (P<0.05) and decreased total length at stage 62 (P<0.05). EE2 accelerated developmental rate between stages 45-48 and 53-56 (log rank P<0.0001), but not between stages 45-48 and 61-64. EE2 treatment increased variability in T4 levels (P<0.005) and increased DI mRNA expression (P<0.005). In this experiment EE2 caused subtle disruption of thyroid hormone action. Developmental rate and 5DI expression increased up to stage 53-56, indicating interaction between the oestrogen and thyroid axes. This is supported by increased variability in T4 levels at stage 61-64 and may be due to modulation of prolactin. Future work will determine whether persistent disruption of the endocrine system occurs which affects later development.

DOSE-DEPENDENT GLOBAL GENE EXPRESSION ANALYSIS IN THE MICRODISSECTED HYPOTHALAMIC MEDIAL PREOPTIC AREA OF RAT NEONATES EXPOSED PERINATALLY TO ETHINYLESTRADIOL.

K. Lee, M. Shibutani, H. Takagi, N. Kato, S. Takigami and M. Hirose. *Division Pathol, NIHS, Tokyo, Japan.* Sponsor: M. Ema.

To identify genes linked to disruption of brain sexual differentiation by exogenous xenoestrogens, a region-specific global gene expression analysis was performed in the medial preoptic area (MPOA) microdissected from hypothalamus of rat neonates following maternal exposure to ethinylestradiol (EE; 0, 0.01, 0.1 and 0.5 ppm in diet) from gestational day 15. At postnatal day 2, brains of offspring (3 males and 3 females per group) were fixed with methacarn and paraffin-embedded. Total RNA (50 ng) extracted from microdissected MPOA was subjected to tworound in vitro transcription, hybridized with Affymetrix GeneChip Rat Genome U34A Array containing 8000 probes, and analyzed the expression data by GeneSpring software ver. 5 (Silicon Genetics). In the MPOA, about 3600 genes showed presence call in both sexes. Among these genes, a total of 5% showed sex difference in the expression (> 2-fold) in untreated controls, with 62 and 124 genes showing up-regulation in males and females, respectively. At 0.5 ppm, a total of 270 and 130 genes were up- or down-regulated (> 2-fold) in males and females, respectively as compared with corresponding controls. Among these genes, dose-dependent up- or down-regulation was revealed in 14 and 146 genes in males, and 6 and 44 genes in females, respectively. Among them, following genes showed strong dose-dependent down-regulation: ribosomal protein S7, S-adenosylmethionine decarboxylase, tyrosine hydroxylase, neurotimin, sodium channel III, GTP binding protein and synaptotagmin in males, and amyloid precursor-like protein 2 and cyclin G in females. At 0.5 ppm, 10 down-regulated genes including GTP binding protein and synaptotagmin observed in male were up-regulated in females. On the other hand, 11 up-regulated genes at 0.5 ppm in males were down-regulated in females. The results suggest that genes showing dose-dependent alteration in the expression with apparent sex difference in response to perinatal exposure to EE can be linked to events in the central endocrine disruption.

587 COMPARISON OF 17β-ESTRADIOL- AND GENISTEIN-INDUCED CELL GROWTH AND PROLIFERATION IN THE RODENT UTERUS.

G. Orphanides, H. Tinwell, F. Lim, D. Moore, I. Pate, <u>I. Kimber</u>, <u>J. Ashby</u> and J. G. Moggs. *Syngenta Central Toxicology Laboratory, Alderley Park, Cheshire, United Kingdom.* 

The xenoestrogen group of endocrine disruptors have the potential to cause reproductive and developmental effects through stimulation or disruption of estrogen receptor signalling. Phytoestrogens have attracted attention due to opportunities for dietary exposure (e.g. soy) and their higher affinity for estrogen receptor (ER)  $\beta$ , which has been proposed to antagonise the effects of ERa. It is, therefore, unclear whether phytoestrogens elicit their estrogenic effects via a mechanism analogous to that of natural estrogens. Using transcript profiling, we have compared the molecular mechanisms through which the phytoestrogen, genistein (GEN), and the natural estrogen, 17b-estradiol (E2), induce growth and maturation of the immature mouse uterus. Mice (19-20 days) received a single subcutaneous injection of either E2 (400  $\mu g/kg$ ) or GEN (250 mg/kg), sufficient to induce a sustained and equivalent increase in uterine weight. Control mice received vehicle (arachis oil) alone. Gene expression levels, uterine weights and histological parameters were analysed 1, 2, 4, 8, 24, 48, and 72hr after exposure. Hierarchical clustering of co-regulated genes, combined with functional classification, revealed that E2 and GEN induce analogous, multi-stage transcriptional programs that drive uterine growth. This involves the sequential induction of genes involved in transcriptional regulation/signal transduction, protein biosynthesis, cell proliferation and epithelial cell differentiation. Our data provide novel insights into the molecular mechanisms that accompany estrogen-regulated uterine growth and, moreover, suggest that GEN is capable of modulating the full spectrum of biological processes associated with the action of E2 in the uterus. Furthermore, we have identified a novel class of estrogen-regulated transcription factors, induced by both chemicals, that appear to be direct targets of ERs and whose function may be linked to the timing of cell cycle progression and proliferation.

ETHYNYL ESTRADIOL ELICITED TEMPORAL AND DOSE-DEPENDENT HEPATIC GENE EXPRESSION PATTERNS IN IMMATURE, OVARIECTOMIZED MICE.

D. R. Boverhof¹, K. C. Fertuck¹, L. D. Burgoon¹, J. E. Eckel², C. Gennings² and T. R. Zacharewski¹. ¹Department of Biochemistry & Molecular Biology, Institute for Environmental Toxicology, and, Department of Pharmacology & Toxicology, National Food Safety & Toxicology Center Michigan State University, East Lansing, MI and ²Department of Biostatistics, Virginia Commonwealth University, Richmond, VA

Temporal- and dose-dependent changes in hepatic gene expression were examined in immature ovariectomized C57BL/6 mice gavaged with ethynyl estradiol (EE). For temporal analysis, mice were gavaged every 24 hrs for 3 days with 100 µg/kg EE or vehicle and liver samples were collected after 2, 4, 8, 12, 24 and 72 hrs. Gene expression was monitored using custom cDNA microarrays containing 3068 cDNA clones of which 393 exhibited a significant change at one or more time points as determined using a model-based t-statistic filtering approach. Functional gene annotation extracted from public databases provided an association between temporal gene expression changes and physiological processes such as growth and proliferation, cytoskeletal and extracellular matrix responses, microtubule based processes, oxidative metabolism and stress, and lipid metabolism and transport. In the 24 hr dose-response study, hepatic samples were collected from mice treated with 0, 0.1, 1, 10, 100 or 250 μg/kg EE. Thirty-nine of the 79 genes identified as differentially regulated at 24 hr in the time course study exhibited a dose response relationship with an average ED50 value of  $47\pm3.5~\mu g/kg$ . Comparative analysis indicated that many of the identified temporal and dose-dependent hepatic responses are similar to estrogen-induced uterine responses reported in the literature and in a companion study using the same animals. Results from these studies confirm that the liver is a highly estrogen responsive tissue that exhibits a number of common responses shared with the uterus as well as distinct estrogen mediated profiles. These data will further aid in the elucidation of the mechanisms of action of estrogens in the liver as well as in other classical and non-classical estrogen responsive tissues. ELUCIDATING THE MOLECULAR PATHWAY FOR REGULATION OF THE STEROIDOGENIC ACUTE REGULATORY PROTEIN BY BETA-SITOSTEROL.

J. Kocerha<sup>1</sup>, K. J. Kroll<sup>2</sup> and <u>N. D. Denslow</u><sup>1, 2</sup>. <sup>1</sup>Biochemistry and Molecular Biology, University of Florida, Gainesville, FL and <sup>2</sup>Biotechnology Program, University of Florida, Gainesville, FL.

The steroidogenic pathway is targeted by some environmental contaminants, resulting in reduced levels of steroid hormone synthesis. Alterations in steroid levels can lead to severe reproductive and physiological abnormalities. The Steroidogenic Acute Regulatory Protein (StAR Protein) is a major rate-limiting step in steroid production and its activity and expression is inhibited by certain toxin exposures. StAR Protein transports cholesterol across the mitochondrial membrane, allowing cholesterol to be metabolized into the various steroids. Using largemouth bass (LMB) as a model, we have begun to examine the molecular mechanism(s) involved in the regulation of StAR by normal endogenous compounds like cAMP, as well as by beta-sitosterol, a common contaminant found in paper mill effluent. We have cloned the entire coding region of LMB StAR and used this sequence to develop a real-time PCR assay for quantitation of changes in StAR mRNA levels in ovarian tissue cultures. We performed dose response experiments with 0.25, 0.5, 0.75, 1 and 4 mM dbcAMP and show increased mRNA production that saturates between 1-4mM dbcAMP. Preliminary results show that cultured ovarian follicles with diameter size ranges of 0.48-0.6mm show about a 3-fold induction with 1mM dbcAMP. These results suggest that LMB and mammalian StAR may be similarly regulated. Preliminary ovarian follicle culture data shows that beta-sitosterol downregulates StAR after 8 hours by 3 to 5 fold. To further analyze the regulation of LMB StAR, a 3 kb portion of the promoter was also cloned. Sequence upstream of the transcriptional start site has been analyzed for consensus sites. Putative binding sites for ER, AHR/ARNT, SF-1, AP-1, C/EBP and GATA transcription factors have been identified. These preliminary results will be used to help elucidate the transcriptional regulation of LMB StAR by beta-sitosterol.

FUNCTIONAL CHARACTERIZATION OF ARYL HYDROCARBON RECEPTOR (AHR) LOCALIZATION AND DEGRADATION IN ZEBRAFISH.

J. Wentworth, R. Buzzeo and <u>R. S. Pollenz</u>. *Biology, University of South Florida, Tampa, FL.* 

The basic-helix-loop-helix/PAS (bHLH/PAS) family of proteins is a group of transcription factors that regulate key pathways in response to stress and in normal development. The aryl hydrocarbon receptor (AHR) is a member of this pathway.

Recently, Danio rerio (zebrafish) has become an important model system in the study of the signal transduction pathway and complement results in mammalian models. However, studies of the AHR protein have been limited by the lack of antibody reagents and thus, little are known condensing the localization and degradation of the zebrafish AHR (zfAHR). In this report, we describe the production and characterization of specific polyclonal antibodies to the zfAHR2 protein and the analysis of AHR-mediated signal transduction in the zebrafish liver cell line (ZFL). The results show that the zfAHR2 is degraded via the 26S proteasome following exposure of cells to Beta-napthoflavone (BNF). Interestingly, the time course is slower and the magnitude of zfAHR2 degradation is not as great as for mammalian AHR. Studies also show the zfAHR2 is rapidly degraded in a ligand independent manner by exposure of cells to geldanamycin (GA) to levels consistent with mammalian AHR. Finally, immunohistochemical staining of the ZFL cells suggest that the unliganded AHR resides in both the cytoplasm and nucleus and appears to undergo active nucleocytoplasmic shuttling in the absence of ligand. These results suggest that there is conservation of function between fish and mammals with respect to ligand dependant and independent degradation of the AHR and that the zfAHR2 is degraded via the 26S proteasome. Sponsored by NIEHS grants ES10991 and

ZEBRAFISH AHR REPRESSOR: CLONING, REGULATORY INTERACTIONS AND INDUCIBILITY BY TCDD.

B. R. Evans<sup>1, 2</sup>, S. I. Karchner<sup>1</sup> and <u>M. E. Hahn</u><sup>1</sup>. <sup>1</sup>Biology, Woods Hole Oceanographic Institution, Woods Hole, MA and <sup>2</sup>Biology, Boston Unviersity, Boston, MA

The aryl hydrocarbon receptor (AHR) is a ligand-activated transcription factor that mediates the effects of 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) and may have roles in the cell cycle and development. Several fish species, including the zebrafish (Danio rerio), possess at least two distinct AHR genes versus a single gene in mammals. Recently, an AHR repressor (AHRR) has been identified in mammals and fish. AHRR and AHR form a negative feedback loop in which AHR activation up-regulates expression of AHRR, which then inhibits transactivation by AHR. This study investigated AHRR structure, function, and regulation in zebrafish, a powerful model in developmental toxicology. We cloned a zebrafish AHRR (zfAHRR) cDNA sequence that encodes a protein of 550 residues and shows high sequence identity to AHRRs from mice, humans, and killifish. The zfAHRR gene maps to linkage group 24, which has regions of conserved synteny with human chromosome 5, the location of the human AHRR gene. The mapping data and phylogenetic analysis show that zfAHRR is an ortholog of the mammalian AHRRs. A single AHRR sequence was also identified in the genome of pufferfish (Fugu rubripes), suggesting that AHRR, unlike AHR, exists as a single gene in fish. In ZF-L zebrafish liver cells dosed with TCDD, real-time RT-PCR showed that expression of AHRR was induced approximately 15-fold, while CYP1A increased by 95-fold and AHR2 by 3.4-fold. În transient transfection assays performed in COS-7 cells, zfAHRR repressed both the constitutive and TCDD-inducible ability of the zebrafish AHR2 to activate expression of a reporter gene under control of AHR response elements. Increasing the amount of transfected ARNT expression construct failed to rescue zfAHR2 activity, suggesting that AHRR inhibition of AHR signaling does not occur solely through sequestration of ARNT. These results indicate that zebrafish possess an AHRR ortholog that acts in a negative feedback loop to repress the AHR signaling pathway downstream of ARNT heterodimerization. ANALYSIS OF LIGAND-DEPENDANT AND INDEPENDENT DEGRADATION OF THE HUMAN ARYL HYDROCARBON RECEPTOR (HAHR) IN HUMAN CELL CULTURE LINES.

C. Buggy and R. S. Pollenz. Biology, University of South Florida, Tampa, FL.

The aryl hydrocarbon receptor (AHR) is a ligand-activated transcription factor that is member of the basic-helix-loop-helix PAS family of proteins. In rodent model systems, the AHR is rapidly degraded following ligand binding via the 26S proteasome resulting in attenuation of AHR-mediated gene regulation. The domains required for degradation and the specific amino acids involved in ubiquitination have not been identified. Since the degradation of the AHR in human is relatively limited, several novel human cell culture lines were characterized following exposure to 2, 3, 7, 8-tetrachlorodibezo-p-dioxin (TCDD) and also to geldanamycin (GA). The cell lines included: kidney adenocarcinoma (A-498), brain carcinoma (DU-145), lung hepatocellular carcinoma (LS-180), normal lung (MRC-9), lung adenosquamous carcinoma (NCI-H596) and breast carcinoma (MCF-7). Each cell line exhibited expression of both the hAHR and hARNT proteins as determined by Western blotting. Interestingly, all cells showed degradation of the hAHR by 70-90 percent following TCDD exposure yet exhibited different time courses. Unlike ro-

dent cells that show maximal degradation between 1-3 hours, LS-180, MRC-9 and NC1-H596 cells show maximal degradation during 4-8 hours. The degradation of the hAHR following exposure to GA also showed differences among the various cell lines. A-498, DU-145, NCI-H596, and MRC-9 cells exhibited >90 percent reduction in the hAHR within 2 hrs of GA exposure. In contrast, GA exposure to LS-180 and MCF-7 cells resulted in < 25 percent reduction of the hAHR after 2 hrs. These results show that the hAHR is degraded in a ligand dependant and independent manner and importantly, identify several novel human cell lines that exhibit reduction in the time course and magnitude of degradation. Future studies will be designed to exploit these cells and to gain information about the enzymes required for the ubiquitination of the AHR and the domains required for this event. TCDD-MEDIATED ACTIVATION OF THE AROMATIC HYDROCARBON RECEPTOR DISPLACES p300 FROM E2F-DEPENDENT PROMOTERS.

J. L. Marlowe and A. Puga. Department of Environmental Health, University of Cincinnati, Cincinnati, OH.

2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) is a ubiquitous environmental pollutant and confirmed carcinogen. The molecular basis for the biological effects of TCDD is largely unknown. TCDD mediates the transcription of the CYP1 family of P450 monooxygenases via activation of the AHR (aromatic hydrocarbon receptor), but this does not adequately explain the diversity of TCDD effects. Transactivation by the AHR can explain gene induction, but not gene repression, which constitutes a major effect of dioxin exposure that has not been characterized at the molecular level. We have shown that complexes formed between the AHR, the retinoblastoma protein RB, and the transcription factor E2F at E2F-regulated promoters result in repression of S-phase-specific genes, and induce cell cycle arrest. Expression of a reporter gene driven by an E2F-dependent promoter shows that TCDD treatment leads to repression of these genes. Relative expression of E2F-dependent genes is largely dependent on the presence of several co-activators and corepressors, including p300/CBP, BRG-1, and HDAC. As the AHR is known to interact with several co-regulators of transcription, we hypothesized that AHR activation may disrupt the activity of such co-regulators at £2F-regulated promoters. TCDD did not affect the activity of the co-repressors BRG-1 or HDAC in transfection assays. However, TCDD was able to reverse the effect of p300 on an E2F-dependent reporter gene. We used chromatin immunoprecipitation assays to analyze this effect at in vivo, E2F-regulated promoters. Such assays show that ÅHR and p300 can be detected at the Cyp1a1 promoter in TCDD-treated cells. However, while p300 associates with E2F-dependent promoters (Dhfr, cyclin E, cdk2) in DMSO-treated cells, TCDD treatment results in the loss of p300 from these promoters. Furthermore, the AHR associates with the promoters of these genes in TCDD-treated cells, but not in DMSO-treated cells. These results suggest a potential mechanism by which TCDD exposure causes gene repression. (Supported by NIH R01 ES06273).

## ALTERED CELL CYCLE REGULATION IN AH RECEPTOR-NULL MOUSE EMBRYO FIBROBLASTS.

X. Chang and A. Puga. Environmental Health, University of Cincinnati, Cincinnati, OH.

2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD) causes diverse toxic effects in animals and humans. Most effects of TCDD result from activation of the cytosolic aryl hydrocarbon receptor (AHR) to a transactivator of Phase I and II drug-metabolizing enzymes. In addition to mediating target gene transcription, AHR causes cell cycle arrest via interacting with the retinoblastoma protein (RB) and potentiating repression of E2F-dependent transcription. To investigate the role of AHR in cell proliferation and differentiation, we developed a tetracycline receptor-regulated Tet-Off system to regulate the expression of mouse AHR and of its deletion mutant D323-494, which lacks the RB-interacting motif "LXCXE" and part of the PAS-B domain. Mouse embryonic fibroblasts (MEFs) derived from AHR null mice were infected with a retrovirus vector carrying the tetracycline receptor gene (tetR). Stable colonies with the highest tetR expression were selected and infected with retroviral vectors carrying either wild type or D323-494 AHR variants, followed by antibiotic selection to obtain double stable cell lines. These cell lines showed complete inhibition of AHR expression after 24-36 hours of treatment with 10 ug/ml doxycycline. In addition, induction of CYP1A1 by TCDD in wild type expressing cells was also suppressed by doxycycline, whereas CYP1A1 expression was constitutively high in D323-494 expressing cells. Doxcycline treatment in both cell lines decreased cell proliferation and removal of doxycycline reversed the effects, suggesting that AHR is critically involved in cell cycle regulation. Supported by NIH grant ES06273 and by a grant from Phillip Morris USA

P. Ramadoss, J. R. Petrulis and G. H. Perdew. Center for Molecular Toxicology and Carcinogenesis, Department of Veterinary Science, The Pennsylvania State University, University Park, PA.

The aryl hydrocarbon receptor (AhR) is a ligand-activated transcription factor that mediates the toxic response induced by TCDD and related compounds. Mouse models are used to study the toxicity of TCDD and estimate risk to humans. Differences between the mouse AhR (mAhR) and human AhR (hAhR) may be important, as these differences could result in altered responses to TCDD exposure. In this study, mAhR and hAhR were compared in terms of their ability to be modulated by the Hepatitis B virus X-associated protein (XAP2), as well as their relative ligand affinities. Fluorescence microscopy studies demonstrated that mAhR localizes predominantly in the nucleus in COS-1 cells, whereas hAhR is mostly cytoplasmic. Co-expressed XAP2 can redistribute and sequester mAhR to the cytoplasm, but appears to have no effect on hAhR's localization. Co-expressed XAP2 also enhances mAhR protein levels, but does not significantly affect hAhR levels; this may be explained in part by XAP2s ability to sequester mAhR to the cytoplasm. An XAP2 construct with an exogenous NLS (XAP2-NLS) was used to target XAP2 to the nucleus. XAP2-NLS can drag hAhR into the nucleus in both ligandbound and ligand-free states, but not mAhR. This indicates that XAP2 is present in the hAhR complex that translocates to the nucleus. Immunoprecipitation experiments showed that the hAhR complex may contain less XAP2 compared to mAhR, and this could, perhaps, explain the differences seen between mAhR's and hAhR's behaviour in cells. Photoaffinity labeling experiments done in vitro and in COS-1 cells showed that the hAhR has a lower affinity for a photoaffinity ligand (2-Azido, 3 [125I]-Iodo 7, 8-dibenzo-para-dioxin) as compared to mAhR. These studies show that there are considerable differences between mAhR and hAhR, and this could result in variations in response to TCDD exposure. This work was supported by NIEHS grant ES04869.

### 596 EPIREGULIN: A POTENTIAL TARGET GENE REGULATED BY AHR

R. D. Patel and <u>G. H. Perdew</u>. Center for Molecular Toxicology and Carcinogenesis, Pennsylvania State University, University Park, PA.

TCDD is known to cause a large number of toxic effects, mediated largely by its binding to the AhR. It is believed that AhR is involved in most of the TCDD induced biological effects like carcinogenesis and teratogenesis through untimely and disproportionate expression of genes. However, the exact mechanism through which TCDD leads to these effects is not known. We have discovered a novel target gene, epiregulin, regulated by TCDD-activated AhR. Epiregulin is a recently discovered growth regulator which belongs to the EGF family and has been shown to stimulate DNA synthesis of primary rat hepatocytes. It is one of the most potent mitogens for hepatocytes and has an additive effect with hepatocyte growth factor and TGF-alpha. On conducting microarray experiments with TCDD treated and untreated temperature sensitive SV-40 virus immortalized mouse hepatocytes, we found that TCDD upregulates epiregulin gene expression. The promoter region of epiregulin has a dioxin responsive element (DRE), 56 nucleotides upstream of the transcription start site, along with three Sp1 binding sites. We performed luciferase reporter assays using NIH/3T3 cells and a vector generated by inserting the first 125 base pairs of the epiregulin rat promoter into pGL3-basic vector. Our results indicate a four-fold induction on TCDD treatment. When a single base of the DRE was mutated, this TCDD mediated induction was lost, establishing the involvement of AhR-ARNT heterodimer. In contrast to this, about 3 fold induction was obtained even when all the Sp1 binding sites were mutated. Our results indicate that epiregulin expression is induced on TCDD exposure through the AhR pathway. Future studies will aim at establishing the significance of epiregulin in TCDD mediated effects such as tumor promotion. (Supported by NIEHS grant ES04869)

### 597 MODULATION OF ARYL HYDROCARBON RECEPTOR FUNCTION BY XAP2 AND P23.

B. D. Hollingshead¹ and <u>G. H. Perdew</u>². ¹ Graduate Program in Biochemistry, Microbiology, and Molecular Biology, Penn State University, University Park, PA and ²Department of Veterinary Science and Center for Molecular Toxicology and Carcinogenesis, Penn State University, University Park, PA.

The AhR is a ligand activated transcription factor that mediates a variety of toxic responses upon exposure to the environmental pollutant TCDD. The unliganded AhR exists as a heteromeric complex consisting of an hsp90 dimer, the immunophilin-like molecule XAP2, and the hsp90 associated protein p23. Different studies have shown that XAP2 can enhance and repress AhR function, and *in vitro* p23 has been observed to enhance DNA binding of the AhR/ARNT heterodimer.

Previously, in an attempt to further understand the role of XAP2 in regulating mouse AhR function a point mutation was introduced in tyrosine 408 changing the residue to alanine. In COS-1 cells this mutation eliminated AhR binding to endogenous levels of XAP2 and showed reduced binding to coexpressed XAP2. Additionally, in AhR regulated luciferase assays this point mutation resulted in a receptor that displayed higher transcriptional activity compared to the non-mutant, and was unable to be repressed with the coexpression of XAP2. Finally, introduction of the Y408A mutation into an AhR-YFP construct showed that that unlike the non-mutant receptor the Y408A mutation renders the AhR incapable of the being redistributed to the cytoplasm when XAP2 is coexpressed. Recent experiments performed using this mutant receptor reveal that increasing transient expression of XAP2 in COS-1 cells reduces the amount of p23 present in the unliganded AhR complex, while having little or no effect on p23 binding in the Y408A mutant receptor complex. Additionally, in the absence of AhR expression p23 association with hsp90 does not appear to be altered by increasing amounts of XAP2. Since p23 is currently believed to be a positive acting factor in AhR function, its dissociation from the unliganded receptor complex in the presence of increased levels of XAP2 provides a mechanistic explanation of how XAP2 expression in COS-1 cells results in repressed AhR transcriptional activity.

MODULATION OF ARYL HYDROCARBON RECEPTOR NUCLEAR TRANSLOCATOR ACTIVITY & PHOSPHORYLATION STATUS BY PKCE.

I. A. Murray<sup>1</sup>, M. S. Denison<sup>2</sup> and G. H. Perdew<sup>1</sup>. <sup>1</sup>Vet. Science, Pennsylvania State University, University Park, PA and <sup>2</sup>Environmental Toxicology, Uuniversity of California, Davis, CA.

Aryl Hydrocarbon Receptor Nuclear Translocator (ARNT), a member of the basic Hélix-Loop-Helix/PAS transcription factor family, has been widely reported as the obligate dimerization partner required for the transcriptional activities of both the Aryl Hydrocarbon Receptor (AhR) and Hypoxia-Inducible Factor-1alpha (HIF-1α). Transfection of hepa1c1c7 cells with a constitutively active mutant of Protein Kinase C ε (PKCε) enhanced TCDD-dependent induction of an AhR-dependent reporter gene above that observed with wild type PKCE, no enhancement was with PKCα. Transient transfection/reporter assays in Cos-1 cells demonstrated that ARNT is transcriptionally active in the context of a homodimer; stimulating E-box mediated transcription (1.8-fold). Furthermore, the activity of ARNT is potentiated (4-fold) by phosphorylation through co-transfection with the novel calciumindependent PKCE and further enhanced (20-fold) with a constitutively active mutant of PKCE, an effect not observed with PKCa. We report through immunoprecipitation studies with exogenously expressed human ARNT (hARNT) that the phosphorylation status of hARNT increases (17-fold) in the presence of active PKĈε relative to control. PKCα induces a moderate (6-fold) enhancement of phosphorylation status. Coimmunoprecipitation studies reveal that hARNT physically interacts with endogenous PKC $\epsilon$ . Using phospho-amino acid analysis, we demonstrate that phosphorylation of hARNT occurs exclusively at serine residues. 2D tryptic phospho-peptide mapping has revealed at least three hARNT tryptic peptides, which are predominantly phosphorylated in response to activated PKCE exposure. Phospho-peptide mapping in conjunction with MADLI-TOF mass spectrometry and radiometric Edman sequencing will allow the identification of the precise serine residues modified in response to PKCE. These data suggest an important role for phosphorylation in the modulation of ARNT activity and that PKCE is involved in this regulation.

#### 599

A POSSIBLE ROLE FOR THE MAP KINASES IN DIOXIN-INDUCED ARYL HYDROCARBON RECEPTOR PHOSPHORYLATION.

Z. Tan, A. Puga and Y. Xia. Department of Environmental Health, University of Cincinnati, Cincinnati, OH.

2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) exposure causes the induction of mitogen-activated protein (MAP) kinases involved in aryl hydrocarbon receptor (AHR) activation and up-regulation of gene expression. Post-translational modification of AHR is known to modulate its activities as a transcription factor, but a direct connection between specific protein modifications, such as phosphorylation, and receptor activation has yet to be established. The objective of the present studies was to characterize the phosphorylation status of the Ah receptor upon ligand activation and to determine the involvement of MAP kinases in the activation process. We find that TCDD treatment of mouse hepatoma Hepa-1 cells causes a rapid induction of AHR phosphorylation at tyrosine and threonine residues. Twodimensional analyses of the AHR protein immunoprecipitated from control and TCDD-treated cells show isoelectric point changes corresponding to charge differences consistent with receptor phosphorylation caused by TCDD exposure. To determine whether the Extracellular signal Regulated Kinase (ERK) MAP kinase directly catalyzes AHR phosphorylation, we measured AHR phosphorylation by active-ERK in an in vitro kinase assay. We find that ERK is able to phosphorylate

AHR. MALDI-TOF analyses of the phosphorylated AHR reveal two potential ERK phosphorylation sites in the PAS domain of the receptor, in a sequence evolutionarily conserved. Our studies suggest that AHR phosphorylation by MAP kinases is a likely complement to TCDD regulation of receptor activity. ACTIVATION OF THE AH RECEPTOR CAN PROMOTE BENZO(A)PYRENE-7, 8-DIHYDRODIOL INDUCED APOPTOSIS IN THE ABSENCE OF MAP KINASE ERK1/2 ACTIVITY

S. Chen, T. Operana, J. Bonzo, N. Nguyen and R. H. Tukey. Pharmacology, University of California, San Diego, La Jolla, CA.

Exposure of hepatoma cells to B[a]P-7, 8-dihydrodiol activates the Ah receptor (AhR) resulting in oxidative metabolism to B[a]P-7, 8-dihydrodiol epoxide (BPDE-2) and cell death. We have demonstrated that inhibition of MAP kinase signaling through ERK1/2 and p38 by BPDE-2 blocks cellular apoptosis. In contrast, inhibition of MEK1/2 by U0126 synergizes apoptosis when cells are treated with B[a]P-7, 8-dihydrodiol. To elucidate the role of U0126 in B[a]P-7, 8-dihydrodiol induced apoptosis, studies were carried out to examine the functional properties of the AhR. Û0126 was shown to activate the AhR, leading to nuclear translocation and induction of CYP1A1 transcription. However, in comparison to TCDD activation of the AhR, we observed dramatic differences in the cellular properties of the AhR. As previously observed by others, TCDD leads to a dose and time dependent reduction in the abundance of total cellular AhR, a property that is linked to ubiquitination. In contrast, AhR activation by U0126 is followed by a significant increase in total cellular AhR, which is also apparent by enhanced accumulation of nuclear AhR. The increase in cellular AhR is dependent upon protein synthesis, since treatment of cells with cycloheximide blocks U0126 accumulation of total cellular AhR with no apparent effect on nuclear translocation. Thus, AhR accumulation results from an imbalance of synthesis and degradation. Since the inhibition of MAP kinases correlates with a reduction in BPDE-2 induced apoptosis, these results indicate that B[a]P-7, 8-dihyrodiol induced apoptosis in the absence of functional MAP kinases ERK1/2 is linked to AhR activation (Supported by USPHS grant ES10337).

### A NOVEL MECHANISM FOR REGULATION OF CHOLESTEROL BIOSYNTHESIS.

Q. Tan<sup>1</sup>, S. Ke<sup>1</sup>, <u>M. A. Gallo<sup>2</sup></u> and <u>Y. Tian<sup>1</sup></u>. <sup>1</sup>Vet. Physiology and Pharmacology, Texas A&M University, College Station, TX and <sup>2</sup>Environmental & Community Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.

Aryl hydrocarbon receptor (AhR) complex consists of the ligand-binding subunit and AhR nuclear translocator (ARNT) which is also known as the hypoxia inducible factor 1β. The AhR complex has been well characterized for its roles in mediating toxic effects of dioxin and related environmental contaminants. However, these evolutionarily conserved proteins also play important roles in normal physiological responses that are beginning to be understood. Recent studies from our laboratory revealed a potential novel mechanism for regulation of cholesterol biosynthesis: activation of AhR by prototype agonist 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) suppressed the HMG-CoA reductase mRNA levels in mouse liver cells (Hepa1c1c7) in a time and dose-dependent manner as determined by real-time RT-PCR. In mice (C3H/HeNCr, 3 wk old, 14-24 g), TCDD treatment (20 and 100  $\mu g)$  caused suppression of the serum cholesterol levels. Using chromatin immunoprecipitation assay, we found that binding of the sterol response element binding protein 1a (SREBP1a) to the HMG-CoA reductase promoter region was markedly inhibited by TCDD treatment (10 nM, 2 hr) in Hepa1c1c7 cells. Furthermore, in collaboration with J. A, Gustafsson (Karolinska Institute, Sweden), we found that ARNT interacts with sterol response element binding protein (SREBP1a) in two hybrid assays. These results suggest a novel mechanism for regulation of cholesterol biosynthesis by AhR and its agonists such as TCDD and indole-3-carbinol (I3C), the former is an environmental contaminant and the later is a plant compound, which has documented beneficial effects, such as the hypocholesterolemic effects. Supported in part by NIEHS grants ES09859, ES09106 and a grant from the American Heart Association (0355131Y).

MODULATION OF ARYL HYDROCARBON RECEPTOR-REGULATED GENES BY TUMOR NECROSIS FACTOR- $\alpha$  AND LIPOPOLYSACCHARIDES BY AHR-DEPENDENT MECHANISMS.

N. Gharavi and A. O. El-Kadi. Faculty of Pharmacy, University of Alberta, Edmonton, AB, Canada.

Little is known about the mechanisms involved in the modulation of aryl hydrocarbon receptor (AHR)-regulated genes during pathophysiological conditions such as inflammation. In the present study the effect of TNF- $\alpha$  and lipopolysaccharides

(LPS) on the constitutive and inducible expression of the AHR-regulated genes: cytochrome P450 1a1 (cyp1a1), glutathione S-transferase Ya (GST Ya), and NAD(P)H:quinone oxidoreductase (QOR) were determined. Murine hepatoma Hepa 1c1c7 (WT), AHR-deficient (C12) and AHR nuclear translocator protein (ARNT)-deficient (C4) cells were incubated with recombinant murine TNF-α (1, 5 and 10 ng/ml) or LPS (1 and 5μg/ml) with or without β-naphthoflavone (βNF, 10μM). We found that TNF-α and LPS had no apparent cellular toxicity effects on WT, C12 and C4 cells at all concentrations tested. In WT cells, in the absence of  $\beta$ NF, TNF- $\alpha$  and LPS dose-dependently inhibited the constitutive activities and mRNA levels of cyp1a1, GST Ya and QOR. QOR activity was significantly induced by TNF-α and LPS in C12 and C4 cells respectively, while other enzymes remained unchanged. Treatment of WT cells with BNF alone resulted in significant increase in the cyp1a1, GST Ya and QOR activities, as well as their mRNAs levels. When WT cells were treated with TNF- $\alpha$  or LPS with  $\beta$ NF, the  $\beta$ NF-mediated induction of cyp1a1, GST Ya and QOR at their activities and mRNA levels were significantly reduced in a dose-dependent manner. There were no changes in C12 and C4 cells. In addition, a significant increase in reactive oxygen species (ROS) was observed in WT, C12 and C4 cells with TNF-α and LPS treatment. These results show that both TNF-α and LPS strongly repress the constitutive expression and inducibility of cyp1a1, GST Ya and QOR in WT but not in AHR- or ARNT-deficient cells. Therefore, down-regulation of AHR-regulated genes by inflammation are dependent on the presence of both heterodimeric transcription factors, AHR and ARNT. Furthermore, ROS may directly or indirectly be involved in down-regulation of AHR-regulated genes.

AFFYMETRIX MICROARRAY AND REAL-TIME PCR ANALYSIS OF BENZO(A)PYRENE INDUCE CHANGES IN GENE EXPRESSION IN RAT LIVER.

A. University. N'jai, A. Jelaso, C. Ide and J. Means. Chemistry/Environmental Institute, Western Michigan University, Kalamazoo, MI.

Benzo(a)pyrene (BaP), an environmental contaminant produced from combustion, is associated with a variety of adverse health effects, including cancer. In order to elucidate the BaP-induced health effects prior to cell transformation, we used realtime PCR and Affymetrix microarray analysis to measure gene expression changes associated with early molecular mechanisms occurring in response to BaP dietary exposures. Preliminary results with our affymetrix genechips show regulation of several gene families. For instance, after two weeks, exposure to 0.01mg/g-diet increased expression (>=3-fold) of 266 genes and decreased expression of 66 genes vs. controls, at 0.1 mg/g-diet increased expression of 53 genes and decreased expression of 79 genes. After 3-months, a dose-dependent trend occurred in genes that were up-regulated, 28 genes were increased (>=3-fold) in rats exposed at 0.01mg/g-diet vs. controls, 64 genes in rats at 0.1mg/g-diet and 102 genes in rats at 1.0mg/g-diet. Similarly, a large number of genes were down-regulated after exposure to BaP for 3 months (185 genes decreased at 0.01mg/g-diet; 30 in rats exposed to 0.1mg/g-diet; 76 in rats exposed to 1.0mg/g-diet). Our affymetrix data revealed changes in gene expression of several biochemical pathways such as cyp450 detoxification, redox, metabolism, steroid hormone, transcription regulators and so on. We used our affymetrix data as a screen to select genes for further quantitative analysis using realtime PCR. Gene candidates selected for real-time PCR include Cyp1a1, Cyp1a2, glutathione-s-transferase, glutathione peroxidase, NADPH cytochrome p450 reductase, Zinc finger protein, protein Kinase C, ras-related protein p23, c-myc and aldehyde dehydogenase. The real-time PCR results were used to both validate and to provide quantitative estimate of our Affymetrix genechip data. Also, analysis of BaP metabolites in rat liver samples were carried using an LC/MS method developed in our lab.

#### 604

COMPARATIVE ANALYSIS OF DIOXIN REGULATORY ELEMENTS IN HUMAN, MOUSE AND RAT GENOMIC SEQUENCES.

Y. Sun<sup>1</sup>, D. R. Boverhof<sup>1</sup>, M. R. Fielden<sup>2</sup> and <u>T. R. Zacharewski</u><sup>1</sup>. <sup>1</sup>Biochemistry & Molecular Biology, National Food Safety & Toxicology Center, Institute for Environmental Toxicology, Michigan State University, East Lansing, MI and <sup>2</sup>Iconix Pharmaceuticals, Mountain View, CA.

Dioxin is a highly toxic compound produced as a by-product of modern industry and causes a wide range of health problems. Most, if not all, of the effects elicited by dioxin and related compounds are mediated *via* ligand activation of the aryl hydrocarbon receptor which forms a heterodimer with the AhR nuclear translocator. This complex modulates gene expression through specific binding to dioxin response elements (DREs) in the regulatory regions of responsive genes. The purpose of this study is to identify conserved DREs through the analysis of available human, mouse and rat genomic sequences, corresponding to nucleotide RefSeq accessions (17882, 11697, and 3896 promoters respectively), obtained from the UCSC Genome Browser (http://genome.ucsc.edu/). Thirteen bona fide DRE sequences, each included the 5bp core sequence (GCGTG) and the 7bp flanking sequences.

were used to establish a position weight matrix. Human, mouse and rat genomic sequences were scanned for the presence of DREs in both upstream and transcribed regions. Identified DREs were disproportionately distributed in the upstream regulatory regions, close to transcription start site, in all three species. Conserved DREs were identified in 365 out of 8872 orthologous human and mouse genes, 140 out of 3379 orthologous human and rat genes, 133 out of 2840 orthologous rat and mouse genes, and 48 out of 2437 orthologous genes across the three species. These findings corroborate many previously published reports, including the well characterized dioxin responsive genes Cyp1a1 and Cyp1b1. This in silico approach to identifying DREs will complement ongoing microarray studies of dioxin-mediated alterations in gene expression and suggests that dioxin-mediated effects on gene expression may not be well conserved across species, which could have significant implications towards human risk assessment. This work was supported by National Institute of Health Grant ES012245

TRANSCRIPTIONAL PROFILES FOLLOWING LIGAND-ACTIVATED AHR SIGNALING IN THE DEVELOPING KIDNEY: A ROLE FOR WT1 AND IGF SIGNALING.

M. Falahatpisheh<sup>1,2</sup>, C. D. Johnson<sup>1,2</sup> and <u>K. S. Ramos<sup>1,2</sup>, <sup>1</sup>Biochemistry and Molecular Biology, University of Louisville, Louisville, KY and <sup>2</sup>Center for Genetics and Molecular Medicine, University of Louisville, Louisville, KY.</u>

Ligand-activated aryl hydrocarbon receptor (Ahr) signaling induces accumulation of (–)KTS splice variants of the Wilms' tumor suppressor gene (Wt-1) and inhibits nephrogenesis. The present studies were conducted to define global patterns of gene expression following ligand-activated Ahr signaling during the course of kidney morphogenesis in vitro. In these experiments, organ cultures of E11.5 metanephric blastema from C57BL/6J mice were treated for four consecutive days with 3 uM benzo(a)pyrene (BaP), a hydrocarbon ligand of the Ahr. Genes involved in cellular differentiation, proliferation, apoptosis, cell cycle progression, stress signaling, matrix remodeling and transcriptional control were identified as Ahr targets during the course of disrupted nephrogenesis. Many of these genes are involved in nephrogenesis (glial derived neurotrophic factor, frizzled receptor, insulin-like growth factor (Igf), insulin-like growth factor binding protein (IgfBP), syndecan, and laminin), while others, such as *Sry*, oncostatin M, pinin, GATA-3, CCAAT/enhancer-binding protein, *Sox-18*, *Nrf-2*, FBG-MuSV, *Gro1*, cyclin G and fibulin are novel targets of developmental dysregulation. Because the Igf signaling pathway is pivotal in renal organogenesis via activation of mitogen activated protein kinase (MAPK) signaling, further studies were conducted to examine protein kinase cascades during the course of nephrogenesis. Activation of Ahr signaling altered the expression of extracellular signal-regulated protein kinase. Immunostaining for PCNA, TUNEL and Apaf showed massive hyperplasia coupled to increased apoptosis in distinct regions of the developing kidney. Collectively, these results suggest that altered Wt1 splicing following ligand-activated Ahr regulates differentiation and apoptosis of mesenchymal cells through the Igf signaling pathway. (Supported by NIH grants ES04917 and ES09106).

MECHANISMS OF CARDIOVASCULAR TOXICITY BY 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN AND RELATED POLYHALOGENATED AROMATIC HYDROCARBONS.

M. K. Walker. College of Pharmacy, University of New Mexico, Albuquerque, NM. Previously, the cardiovascular system has not been considered to be a primary target

Previously, the cardiovascular system has not been considered to be a primary target of toxicity induced by 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) and other structurally related polyhalogenated aromatic hydrocarbons (PHAHs), particularly in mammalian species. However, considerable research in the past 5-10 years has demonstrated that TCDD and related PHAHs exhibit significant impacts on both the developing and adult cardiovascular system and these effects are apparent across vertebrate classes, including piscine, avian, and mammalian species. Furthermore, occupational exposure of humans to TCDD and related PHAHs has been linked to an increased risk of mortality from ischemic heart disease, demonstrating that humans are not impervious to the cardiovascular risk posed by TCDD/PHAH exposure. This symposium will cover the recent advances in understanding the mechanisms underlying TCDD/PHAH-induced cardiovascular toxicity. The speakers will present data on the effects of TCDD/PHAHs on both cardiac and vascular development and function, providing unique comparisons across vertebrate classes.

607

TCDD CARDIOTOXICITY IN DEVELOPING ZEBRAFISH.

W. Heideman, D. K. Sieprawska and <u>R. E. Peterson</u>. Molecular and Environmental Toxicology and School of Pharmacy, University of Wisconsin, Madison, WI.

2, 3, 7, 8-Tetrachlorodibenzo-p-dioxin (TCDD) causes cardiac defects in developing fish, birds, and mammals. While it is well known that TCDD is an aryl hydrocarbon receptor (AHR) agonist, and that AHR activation mediates toxic effects of

TCDD, we know little about the mechanism by which AHR causes cardiotoxicity, or the role that AHR plays in normal heart development. The zebrafish (Danio rerio) has emerged as an attractive vertebrate model for studying cardiovascular development. In addition to ease of observation, zebrafish do not require a functional circulatory system during the first week of life. This allows the study of cardiac defects that would be immediately lethal in other organisms. TCDD exposure (1ppb) immediately after fertilization does not appear to affect basic heart morphogenesis: atrium, ventricle, bulbus arteriosis and sinus venosus are all formed in TCDD treated fish. Thereafter, TCDD exposure produces reductions in heart rate, cardiac output, and heart size. The change in heart morphology caused by TCDD is characterized by a pattern in which the atrium and ventricle are stretched out with altered looping, and the sinus venosus fails to migrate dorsally as the heart matures. TCDD treated fish have hearts with thin walls and reduced myocardium. Morpholino knockdown of zfAHR2 expression indicates that the cardiotoxic effects of TCDD are mediated by zfAHR2. The earliest signs of carditoxicity are observed before the formation of pericardial and yolk sac edema. Furthermore, while osmotic support with mannitol can relieve the edema produced by TCDD, mannitol does not block the cardiotoxicity. These results indicate that the cardiotoxic effects of TCDD in zebrafish larvae are not secondary to edema formation. The ability to manipulate the AHR/ARNT pathway in developing zebrafish through transgenic, morpholino, and genomic approaches provides an excellent opportunity for studying both AHR-mediated TCDD cardiotoxicity and the role of the AHR/ARNT pathway in normal heart development. (Supported by UW Sea Grant)

FETAL DIOXIN EXPOSURE INHIBITS CORONARY VASCULOGENESIS. A POTENTIAL RISK FACTOR FOR ISCHEMIC HEART DISEASE.

M. K. Walker. College of Pharmacy, University of New Mexico, Albuquerque, NM.

Epidemiology studies show a strong association between exposure to 2, 3, 7, 8tetrachlorodibenzo-p-dioxin (TCDD) and structurally related polyhalogenated aromatic hydrocarbon and an increased risk of mortality from ischemic heart disease (IHD); however, the potential contribution of fetal exposure to these chemicals to IHD risk is unknown. IHD mortality inversely correlates with the ability to induce vascular endothelial growth factor-A (VEGF-A) and stimulate coronary collateral growth. Since coronary collateral growth recapitulates fetal coronary development, we studied the effects of fetal TCDD exposure on (1) cardiac VEGF-A expression and endothelial signaling, (2) coronary vascular development, and (3) myocardial ischemia post natally. In the avian embryo, TCDD reduces coronary vascular outgrowth by 50% and this reduction is associated with a 50 and 65% decrease in cardiac VEGF-A mRNA and protein, respectively, and reduced activation of VEGF receptor 2. The cause-and-effect relationship between reduced VEGF-A and reduced coronary vasculogenesis is revealed by the ability of exogenous VEGF-A and hypoxia-stimulated endogenous VEGF-A to rescue the reduced vascularization, and that the rescue is blocked by VEGF-A neutralizing antibody. Further, VEGF-A neutralizing antibody alone reduces coronary vasculogenesis in control hearts by 50%, but fails to effect coronary vascular outgrowth from TCDD hearts, suggesting that the VEGF-A component of coronary vasculogenesis is impaired significantly by TCDD. In the murine fetus, TCDD reduces cardiac VEGF-A mRNA by 50% and leads to reduced coronary capillary density on postnatal day 21. In addition, fetal TCDD exposure increases the sensitivity to stress-induced myocardial ischemia after birth. While the mechanism by which TCDD reduces cardiac VEGF-A and alters VEGF-A signaling, leading to reduced coronary vascular development, remains to be fully elucidated, these studies suggest that TCDD exposure early in life may represent a previously unidentified risk factor for IHD. Supported by NIH R01 ES09804.

PROINFLAMMATORY MECHANISMS OF PCB TOXICITY IN THE VASCULAR ENDOTHELIUM.

B. Hennig<sup>1</sup>, M. Toborek<sup>1</sup> and <u>L. W. Robertson</u><sup>2</sup>. <sup>1</sup>University of Kentucky, Lexington, KY and <sup>2</sup>University of Iowa, Iowa City, IA.

There is now increasing evidence that exposure to polyhalogenated aromatic hydrocarbons can contribute to the development of inflammatory diseases such as atherosclerosis. Activation, chronic inflammation and dysfunction of the vascular endothelium are critical events in the initiation and acceleration of atherosclerotic lesion formation. Because of its constant exposure to environmental contaminants and other blood components, including prooxidants, the vascular endothelium is extremely vulnerable to chemical insult, as well as to necrotic and apoptotic injury. Our data demonstrate that coplanar polychlorinated biphenyls (PCBs), and possibly other aryl hydrocarbon receptor (AhR) ligands and environmental contaminants, can compromise normal functions of vascular endothelial cells by activating oxidative stress-sensitive signaling pathways and subsequent proinflammatory

events critical in atherosclerosis and cardiovascular toxicity. Our studies indicate that an increase in cellular oxidative stress and an imbalance in antioxidant status are critical events in PCB-mediated induction of inflammatory genes and endothelial cell dysfunction. Furthermore, we found that specific dietary fats (e.g, linoleic acid, the parent unsaturated fatty acid of the omega-6 family) can further increase endothelial dysfunction induced by selected PCBs, probably by contributing to oxidative stress and the production of toxic lipid metabolites such as leukotoxins. We also observed that antioxidant nutrients (such as vitamin E and dietary flavonoids) can protect against endothelial cell damage mediated by PCBs or polyunsaturated dietary fats by interfering with oxidative stress-sensitive and proinflammatory signaling pathways. Even though the concept that nutrition may modify or ameliorate the toxicity of environmental chemicals is provocative and warrants further study, the implications for human health could be significant. Supported in part by grants from NIH/NIEHS (ES 07380), and the Kentucky Agricultural Experimental Station.

EXPRESSION PROFILES OF CULTURED VASCULAR SMOOTH MUSCLE CELLS AND AORTA ARE WIDELY DIFFERENT, BUT SHOW COMMON RESPONSES TO DIOXIN EXPOSURE.

A. Puga, M. Sartor, M. Huang, J. Kerzee, Y. Wei, C. R. Tomlinson and M. Medvedovic. Department of Environmental Health, University of Cincinnati, Cincinnati, OH.

Environmental toxicants may play a role in the onset or progression of cardiovascular disease, the main cause of mortality and morbidity in industrialized countries. Many environmental agents, such as dioxin, may be risk factors because they alter gene expression and exacerbate an underlying disease through deregulation of critical genes. Expression profiling of vascular tissues may provide predictive information particularly useful during early stages of heart disease. Often, however, direct experimentation is unfeasible for logistic or ethical reasons. In these cases, extrapolation from cultured cells is necessary, although there is no assurance that cultured cells and live tissues share common global responses. We compared gene expression profiles of C57BL/6 mice aortas and cultured vascular smooth muscle cells from the same mice to determine if gene responses to dioxin exposure in the one would predict responses in the other. Using microarrays with sequences from 13, 400 genes, aorta tissues and vSMCs were found to differ in the expression of more than 4, 500 genes, many showing differences greater than 1000-fold. We used GenMAPP (Gene Microarray Pathway Profiler), a program to analyze microarray data on profiles representing biological pathways, to integrate Gene Ontology Project annotations and organize the data on the basis of known biological processes. The resulting GenMAPPs showed that many of the genes differentially expressed belonged to the same biological process or metabolic pathway and were coordinately deregulated. Notwithstanding, a subset of 20-30 genes were equally altered by dioxin exposure in both systems. Genes in this subset encode phase I and phase ÍI detoxification enzymes as well as signal transduction kinases and phosphatases and proteins involved in cell cycle and DNA damage repair. We conclude that vSMCS can be used as aorta surrogates for the study of early responses to dioxin exposure provided that the analyses focus on this subset of predictive genes.

## 611 CARDIOVASCULAR CHANGES FOLLOWING CHRONIC RODENT EXPOSURE TO DIOXIN-LIKE COMPOUNDS.

M. P. Jokinen<sup>4</sup>, <u>N. J. Walker</u><sup>2</sup>, D. M. Sells<sup>5</sup>, A. E. Brix<sup>2</sup> and A. Nyska<sup>2</sup>. <sup>1</sup>ETP, NIEHS, Research Triangle Park, NC, <sup>2</sup>NIEHS, Research Triangle Park, NC, <sup>3</sup>EPL, Research Triangle Park, NC, <sup>4</sup>Pathology Associates - A Charles River Company, Durham, NC and <sup>5</sup>Battelle Columbus, Columbus, OH.

Polyhalogenated aromatic hydrocarbons (PHAHs ) comprise a large class of compounds including polychlorinated dibenzodioxins (PCDDs), polychlorinated dibenzofurans (PCDFs), polychlorinated biphenyls (PCBs), polychlorinated naphthalenes (PCNs), and polybrominated diphenyl ethers (PBDEs). Certain PCDDs, PCDFs and co-planar PCBs, have the ability to bind to the aryl hydrocarbon (Ah) receptor and exhibit biological actions similar to 2, 3, 7, 8-tetrachlorodibenzo-pdioxin (TCDD) and are commonly referred to as dioxin-like compounds (DLCs). Recent epidemiologic studies have linked dioxin exposure to increased mortality caused by ischemic heart disease (IHD). The Department of Health and Human Services, National Toxicology Program has recently conducted multiple 2-year lifetime rat bioassays to evaluate the chronic toxicity and carcinogenicity of dioxin-like compounds, structurally-related PCBs, and mixtures of these compounds. Chronic administration of dioxin-like compounds to female rats was associated with treatment-related increases in the incidence of cardiomyopathy, a degenerative myocardial change seen commonly in rats, and of chronic active arteritis. Chronic active arteritis occurred primarily in the mesentery and pancreas, although other tissues, including rectum, liver, heart, ovary, uterus, or glandular stomach in the PCB 126 (3, 3', 4, 4', 5-PCB) study, and liver or ovary in the TCDD study were affected in a few dosed animals. These studies indicate that the cardiovascular system is a target for dioxin exposure in the adult rat, exacerbating the incidence and severity of spontaneous cardiomyopathy and arteriopathy.

NEW DEVELOPMENTS IN OXIDATIVE PHOSPHOLIPID SIGNALING IN APOPTOSIS AND PHAGOCYTIC REGULATION OF INFLAMMATORY RESPONSE.

V. Kagan<sup>2</sup> and D. Jones<sup>1</sup>. <sup>1</sup>Department of Biochemistry, Emory University, Atlanta, GA and <sup>2</sup>Environment and Occupational Health, University of Pittsburgh, Pittsburgh, PA.

Apoptosis eliminates unwanted or irreparably damaged cells by orderly phagocytosis in the absence of inflammatory responses. Oxidative stress is one of the most common factors that induce apoptosis. In addition, apoptosis itself is often accompanied by the generation of reactive oxygen species (ROS) and oxidative stress, resulting from departure of cytochrome c (cyt c) from mitochondria and attendant disruption of electron transport with enhanced production of one-electron reduced oxygen intermediates. Until recently, it was not known whether this apoptosis-associated oxidative stress is a meaningless but unavoidable side effect or an important component of the final common pathway for apoptosis. Findings from several laboratories implicated ROS production and oxidative stress in the execution of apoptotic program via activation of two essential mechanisms: mitochondrial permeability transition pore and caspases. The latest discoveries indicate that oxidative modifications of two types of phospholipids are critically involved in the execution of apoptotic program. In mitochondria, oxidation of cardiolipin loosens its association with cyt c and facilitates release of the latter into the cytosol, the central event in intrinsic apoptosis. In the cytosol, cyt c plays a redox-dependent catalytic role in selective oxidation of phosphatidylserine (PS) a signaling molecule of the pathway culminating in recognition of apoptotic cells by phagocytes. PS-dependent signaling involves externalization of PS on the outer leaflet of plasma membrane, its interactions with specialized adapter molecules, and tethering to specific receptor(s) on the surface of phagocytes. Cyt c-catalyzed PS oxidation in the cytosolic leaflet of plasma membrane is essential for both its externalization and recognition by macrophages. These exciting new developments in oxidative control of apoptosis, clearance of apoptotic cells, and regulation of inflammatory response will be discussed by leading researchers of the field.

#### 13 REACTIVE OXYGEN SPECIES IN ACTIVATION AND EXECUTION OF APOPTOSIS.

D. Jones. Department of Biochemistry, Emory University, Atlanta, GA.

Early studies revealed that thiol antioxidants such as N-acetylcysteine are effective inhibitors of apoptosis in many systems, suggesting that oxidative reactions serve a central function in this conserved pathway. However, other studies provided evidence that oxidative events are not essential for initiation of apoptosis. This presentation will describe accumulating mechanistic data on apoptosis signaling which show that key oxidative events occur at both activation and execution steps. An increase in reactive oxygen species can be detected in many systems in early in activation of apoptosis. Oxidation of thioredoxin allows activation of apoptosis signalregulating kinase 1 (ASK-1). Oxidants activate the mitochondrial permeability transition in mitochondria with associated release of cytochrome c and other apoptogenic factors. Over-expression of antioxidant systems in mitochondria, including mitochondrial thioredoxin, glutathione reductase and superoxide dismutase, result in protection against apoptosis. Opposing models of apoptosis activation by lipidderived oxidation products and direct oxidation of critical apoptosis-signaling proteins will be presented. Evidence will also be presented to describe a switch in electron transport, which occurs upon release of cytochrome c from mitochondria. This switch results in inhibition of normal respiration, increased ROS generation and activation of downstream oxidation reactions, which function in execution of apoptosis. A comparison of possible mechanisms indicates that lipid oxidation processes at least provide a functional redundancy to protein oxidation in signaling the terminal phases of apoptosis and may, in fact, be the key components signaling the final phagocytic elimination of apoptotic bodies.

#### **614** LIPOCALINS AND APOPTOSIS.

J. P. Kehrer. Pharmacology and Toxicology, The University of Texas at Austin, Austin, TX

In recent years, studies on the cancer preventing and treating activities of aspirin, indomethacin and related cyclooxygenase (COX) inhibitors have indicated that the anticancer/apoptosis-inducing activity of these agents is in many systems independent of COX. Our work on the mechanism(s) by which inhibitors of lipoxygenase (LOX) enzymes induce apoptosis has similarly shown independence from LOX inhibition. Specifically, a number of LOX inhibitors, as well as MK886, a structural analog of indomethacin that inhibits the activity of 5-LOX by binding to the 5-

LOX-activating protein (FLAP), have strong pro-apoptotic activity that is not mediated through the inhibition of FLAP, LOX or COX. Changes in polyunsaturated fatty acid protein binding, possibly leading to fatty acid oxidation may be involved. An interesting and diverse family of lipid binding proteins are the lipocalins. Their biological functions are not fully understood. However, one member of this family, murine 24p3, binds fatty acids and retinoids, enhances the activity of the c-AMPdependent protein kinase, delivers iron to the cytoplasm, and plays a crucial role in IL3-deprivation-induced apoptosis. This latter activity suggested that apoptosis-inducing xenobiotics, particularly those affecting lipid pathways, might also function via 24p3. We have found that 24p3 is profoundly induced by MK886, as well as related compounds. The extent of apoptosis closely parallels this induction. MK886 and related apoptosis-inducing xenobiotics also upregulate the human analog of 24p3, neutral gelatinase associated lipocalin (NGAL). Importantly, over- and under-expressing 24p3/NGAL levels by transfection and antisense strategies leads to changes in levels of apoptosis. These data suggest 24p3/NGAL represent a new upstream signaling pathway for apoptosis regulation/initiation. (Supported by CA83701 and NIEHS Center Grant ES07784.)

## 615 PHOSPHATIDYLSERINE OXIDATION DURING INTRINSIC AND EXTRINSIC APOPTOSIS: CATALYTIC AND SIGNALING MECHANISMS.

V. E. Kagan. Environmental and occupational Health, University of Pittsburgh, Pittsburgh, PA.

Release of cytochrome c from mitochondria is central to successful progression and completion of intrinsic apoptotic program. Evidence will be presented for a new role for cytochrome c in the cytosol as a competent redox catalyst of phosphatidylserine (PS) peroxidation on the inner leaflet of plasma membrane. Experimental data will be shown to illustrate an important role of cytochrome ccatalyzed PS peroxidation in trans-membrane export of PS and its externalization on the outer surface of apoptotic cells. Because externalized PS acts as a unique eatme-signal for phagocyte clearance of apoptotic cells, participation of cytochrome c in apoptosis is not limited to its activation of caspases but includes PS signaling cascades. Catalytic redox mechanisms of cytochrome c, based on its specific interactions with anionic PS leading to activation of its peroxidase activity and responsible for selective PS oxidation, will be discussed. Because extrinsic apoptotic pathways in type II cells include disruption of mitochondria and release of cytochrome c, we hypothesize that this additional cytochrome c-dependent loop is utilized not only for enhanced caspase-8 activation but it is also essential for PS-dependent signaling. Finally, interruption of cytochrome c-catalyzed PS oxidation by different antioxidant enzymes and free radical scavengers will be considered in lieu of their potential effects on PS-dependent signaling pathways, clearance of apoptotic cells by phagocytes. Supported by NIH HL 70755.

### 616 BRIDGING PROTEINS IN LIPID DIRECTED PHAGOCYTOSIS.

A. Schroit and K. Balasubramanian. Cancer Biology, The University of Texas, M. D. Anderson Cancer Center, Houston, TX. Sponsor: V. Kagan.

Many studies have established the unifying concept that plasma membrane phospholipids are asymmetrically distributed across membrane bilayers. The majority of the aminophospholipids reside in the cell's inner membrane leaflet and most of the choline-containing phospholipids are in the outer membrane leaflet. If cells fail to maintain this asymmetry, phosphatidylserine (PS) appears at the cell surface and marks the cell for disposal. Analysis of proteins recovered from PS-containing liposomes injected into mice showed that beta-2-glycoprotien 1 ( $\beta$ 2GP1), a normal plasma protein, bound to the vesicles. This raised the possibility that B2GP1 participates in the recognition and phagocytosis of PS-expressing apoptoic cells to phagocytes. In vitro experiments showed that  $\beta$ 2GP1 dramatically enhanced the uptake of PS-containing vesicles through a specific macrophage receptor that binds the bridging protein only after first binding to its lipid ligand. Additional in vivo experiments indicated that cells undergoing Fas-induced apoptosis bind endogenous  $\beta$ 2GP1. These data support the concept that  $\beta$ 2GP1 marks apoptotic and dying cells for clearnace by the reticuloendothelial system.

PROGRAMMED CELL CLEARANCE: STUDIES ON THE MECHANISM AND IMPORTANCE OF PHOSPHATIDYLSERINE EXPOSURE AND PLASMA MEMBRANE BLEBBING DURING FAS-TRIGGERED APOPTOSIS.

B. Fadeel. Institute of Environmental Medicine, Division of Toxicology, Karolinska Institutet, Stockholm, Sweden. Sponsor: V. Kagan.

Apoptosis is essential during development and for the maintenance of tissue homeostasis in the adult organism. Considerable efforts have been made in recent years to elucidate the molecular mechanisms that govern this mode of cellular demise; however, the process of programmed cell clearance, i.e. the subsequent recognition and removal of apoptotic corpses by neighboring phagocytes, has received less attention. The current presentation will address studies on the mechanism of programmed cell clearance in a model of death receptor (Fas/APO-1/CD95)-induced apoptosis. Fas-triggering results in the selective oxidation and externalization of phosphatidyserine (PS) on the surface of the apoptotic cell, and oxidized as well as non-oxidized species of PS mediate recognition and engulfment of effete cells by macrophages. Moreover, recent studies indicate that plasma membrane blebbing (zeiosis) and the concomitant aggregation of PS molecules on the cell surface is an important determinant of phagocytic clearance of Fas-triggered cells. The co-expression on the cell surface of other "eat me" signals, such as annexin I, and the opsonization of apoptotic cells by soluble factors, including milk-fat globule epidermal growth factor-8 (MFG-E8), may also serve to facilitate macrophage clearance. Macrophages, in turn, employ an array of receptors that mediate tethering and ingestion of dying cells. Taken together, these specific interactions between phagocyte and prey ensure that inflammation and tissue scarring due to secondary necrosis and lysis of neglected apoptotic cells is limited.

#### 618

## PUBLIC TOXICOGENOMIC DATABASE RESOURCES AND THEIR ROLE IN THE TOXICOLOGY COMMUNITY.

W. B. Mattes<sup>1</sup> and S. D. pettit<sup>2</sup>. <sup>1</sup>Pfizer, Kalamazoo, MI and <sup>2</sup>Health and Environmental Sciences Institute, ILSI, Washington, DC.

Over the last several years, the volume of microarray data generated in studies of toxicology has been steadily increasing. Likewise, the expectations of the toxicology community with respect to the information buried in this volume of data has also been increasing, and with those expectations, an appreciation for more sophisticated approaches to data housing, sharing, and analysis. Thus, public microarray databases are now considering the need to include appropriate biological context (i.e., linked toxicology data) in conjunction with array data. However, the ultimate scientific value and utility of public toxicogenomic databases, such as those developed by HESI-EBI and NIEHS-NCT will depend upon a clear assessment of how the community (both public and private sector) hopes to utilize these resources. This workshop will include presentations about the status of, challenges in, and expectations for current public toxicogenomic database development efforts by leading developers. Discussions will cover issues around whether these databases are or will meet the needs and interests of the toxicology community.

#### 619

### DEVELOPMENT OF TOXICOGENOMIC GENE EXPRESSION DATA INFRASTRUCTURE.

S. Sansone, S. Contrino, M. Shojatalab, N. Abeygunawardena, University. Sarkans, G. Garcia Lara, H. Parkinson, P. Rocca-Serra and A. Brazma. *Microarray Informatics, EMBL-EBI, Cambridge, United Kingdom.* Sponsor: S. Pettit.

The ArrayExpress infrastructure<sup>1</sup> for microarray gene expression data has been established at the EMBL-EBI. ArrayExpress provides the community with easy access to high quality gene expression data and associated metadata (e.g. histopathology, clinical chemistry) in a standard format, serves as repository for data in publications, and facilitates the sharing of array designs and experimental protocols. The meaningful exchange of information is supported by the use of standard contextual information (MIAME and MIAME/Toxicology)<sup>2</sup>, a standard data exchange format (MAGE-ML)<sup>2</sup> and a team of curators. ArrayExpress infrastructure consists of the database itself, a high-throughput data submission route via ftp in MAGE-ML format or via a web-based annotation/submission tool MIAMExpress, an online database query interface, the web-based analysis tool Expression Profiler and query optimised data warehouse. Following an agreement with ILSI HESI<sup>3</sup>, the infrastructure has undergone further development according to the specifics of toxicogenomics experiments. To integrated gene expression data with conventional toxicology metadata, a toxicogenomics-specific version of the annotation/submission tool has been developed. Toxicology-MIAMExpress enforces the use of controlled vocabularies and complies with MIAME/Toxicology, an effort initiated by the EBI, NIEHS-NCT and ILSI-HESI to fulfill the need of capturing and exchanging toxicogenomics and similarly pharmacogenomics, chemogenomics experiments. The use of common terminologies, the consistent annotation and a standard data exchange format bewteen ArrayExpress and Chemical Effects in Biological Systems (CEBS), the toxicogenomics knowledgebase at NCT, are the first steps towards the establishment of an international infrastructure for toxicogenomics data. 1=Brazma et al. ArrayExpress a Public Repository for Microarray Gene Expression Data at the EBI. Nucleic Acids Res. 31(1):68-71(2003) 2=MIAME and MIAME/Toxicology: http://www.mged.org 3=Toxicogenomic project: http://www.ebi.ac.uk/microarray/Projects/ilsi/index.html

### THE CHEMICAL EFFECTS IN BIOLOGICAL SYSTEMS KNOWLEDGE BASE.

M. Waters<sup>1</sup>, P. Bushel<sup>1</sup>, W. Eastin<sup>1</sup>, S. Gustafson<sup>2</sup>, P. Hurban<sup>3</sup>, A. Merrick<sup>1</sup>, G. Nehls<sup>1</sup>, J. Selkirk<sup>1</sup>, S. Stasiewicz<sup>1</sup>, N. Stegman<sup>1</sup>, K. Tomer<sup>1</sup>, H. Wan<sup>1</sup>, B. Weis<sup>1</sup>, J. Yost<sup>2</sup>, S. Xirasagar<sup>2</sup> and <u>R. Tennant</u><sup>1</sup>. <sup>1</sup>NIEHS, Research Triangle Park, NC, <sup>2</sup>SAIC, Germantown, MD and <sup>3</sup>Paradigm Genetics, Research Triangle Park, NC.

The Chemical Effects in Biological Systems (CEBS) knowledge base is under development as a public information resource combining datasets from transcriptomics, proteomics, metabonomics, and conventional toxicology for environmental exposures. CEBS will facilitate data integration across multiple sources, centers, and technology platforms. CEBS is designed to meet the information needs of systems toxicology, involving study of chemical or stressor perturbations, monitoring changes in molecular expression, and iteratively integrating biological response data to describe the functioning organism. International database content guidelines, minimal information about a microarray experiment, MIAME and MIAME/Toxicology, and microarray gene expression markup language, MAGE-ML, are used to assemble and exchange high quality datasets with the goal of creating a system of predictive toxicology. Toxicogenomics experiments performed using validated NCT and NTP methodologies are captured in their entirety via a unique extended implementation of the MAGE-OM object model. Dictionaries and metadata will introduce and guide interpretation of publicly available datasets using open source statistical analysis tools and scripted data workflows. CEBS creates the capability to relationally link toxicogenomics data to animal effects data so as to evaluate global changes in molecular expression as a function of dose, time, and target cell type. By analogy to GenBank, CEBS will support global sequence-based query using probe sequence of differentially expressed genes or analytically determined proteins. CEBS also supports conventional query for compound/ structure/class, toxic/pathologic effects, gene annotation, gene groups, pathways and phenotypes. CEBS links to the NTP Toxicology Database Management System and the NTP Studies Database leveraging these OracleTM systems in experimental design and interpretation of phenotypes. CEBS will serve the scientific community in both discovery and hypothesis-driven research.

### **621** dbZach - AN INTRALABORATY TOXICOGENOMIC SUPPORTIVE DATABASE.

T. Zacharewski. Biochemistry & Molecular Biology, National Food Safety & Toxicology Center, and Institute for Environmental Toxicology, Michigan State University, East Lansing, MI.

In order to fully assess the adverse effects of subchronic and chronic exposure to drugs, chemicals, natural products and their mixtures, an integrated systematic understanding of the molecular, cellular and physiological effects is required within the context of a whole organism its genome, proteome and metabonome. Consequently, bioinformatics and global assessment technologies, including genomics, proteomics, and metabonomics, are being incorporated into existing mechanistic and safety assessment paradigms. These technologies generate vast quantities of data that must be properly indexed and integrated with traditional toxicological data in order to facilitate comprehensive assessments. Failure to consider all available data may lead to poor product development decisions, incorrect conclusions and inaccurate risk predictions resulting in significant health, social and economic consequences. Relational databases provide an effective solution for indexing large amounts of information and can unify disparate chemical, toxicological, pathological and omic databases. Although many existing databases support discovery research, their utility for toxicogenomic efforts is limited since issues specific to toxicology such as multiple dose levels, time course, replicate data sets and extrapolation between species are not adequately addressed. This presentation will describe dbZach (http://dbzach.fst.msu.edu), a MIAME compliant relational database running under Windows 2000/Oracle 9i that supports ongoing toxicogenomic studies and provides data management. It also facilitates data analysis, storage, retrieval and querying. dbZach consists of four core subsystems (i.e. Clones, Genes, Protocols, and Sample Annotation), four Experimental Subsystems (i.e. Microarray, Affymetrix, Protein, Real-Time PCR, and Toxicology), and two In Silico Subsystems (i.e. Pathway and Gene Regulation) as well as a number of data analysis tools. Examples of the utility of dbZach will also be discussed. Development of dbZach is supported by ÉS11271.

## 622 MICROARRAY DISCOVERY: INTEGRATING BIOLOGY WITH EXPRESSION.

J. Quackenbush<sup>1</sup>. <sup>1</sup> The Institute for Genomic Research, Rockville, MD and <sup>2</sup>ILSI Health & Environmental Sciences Institute, Washington, DC. Sponsor: W. Mattes.

Over the last several years, the volume of microarray data generated in studies of toxicology has been steadily increasing. Likewise, the expectations of the toxicology community with respect to the information buried in this volume of data has also

been increasing, and with those expectations, an appreciation for more sophisticated approaches to data housing, sharing, and analysis. Thus, public microarray databases are now considering the need to include appropriate biological context (i.e., linked toxicology data) in conjunction with array data. However, the ultimate scientific value and utility of public toxicogenomic databases, such as those developed by HESI-EBI, NIEHS-NCT, Stanford, will depend upon a clear assessment of how the community (both public and private sector) hopes to utilize these resources. This workshop will include presentations about current public toxicogenomic database development efforts by leading developers and then discussion about such outstanding issues as: a) Which portions of the scientific community are mostly like to utilize a public toxicogenomic database resource and for what purposes? and b) What are the hurdles to data submission to these databases?

#### 623

### THE ROLE OF METHYLATION IN ARSENIC TOXICITY & RISK: THE ENIGMA CONTINUES.

M. Waalkes<sup>2</sup>, B. D. Beck<sup>1</sup>, D. Thomas<sup>3</sup>, M. Kadiiska<sup>2</sup> and M. Del Razo<sup>4</sup>.

<sup>1</sup> Gradient Corporation, Cambridge, MA, <sup>2</sup>NIEHS, Research Triangle Park, NC,

<sup>3</sup> USEPA, Research Triangle Park, NC and <sup>4</sup> Instituto Poletecnico Nacional, Mexico City, Mexico.

Methylation of inorganic arsenic was originally considered to be solely a detoxification pathway. Recent studies have demonstrated that, in vitro, the trivalent monoand di-methylated species of inorganic arsenic are both highly cytotoxic and genotoxic. However, the relationship of these findings to in vivo responses and to risk assessment remains an area of on-going investigation and debate. This workshop will address toxicological differences among different states of arsenic as a function of methylation status and valence, and will consider how the role of methylation in toxicity may vary according to endpoint, tissue type, exposure duration, and animal species. Recent investigations into the enzymology of arsenic methylation including the role of co-factors will be described. The importance of reactive oxygen species in cytotoxicity and genotoxicity of inorganic versus methylated arsenic, both in vivo and in vitro, will be addressed. The use of human biomonitoring data, specifically arsenic species in urine, to elucidate the role of methylation in toxicity and to inform the role of methylation differences in susceptibility to arsenic will be discussed. Pharmacokinetic and toxicological differences between methylated species of arsenic as generated in the body via metabolism versus the same species when ingested will be discussed. Finally, the significance of these recent developments will be considered in the context of risk assessment for arsenic; the implications for the shape of dose-response curve as well as inter and intra-species variability will be discussed.

#### **624** ENZYMOLOGY OF ARSENIC METHYLATION.

D. J. Thomas. USEPA, Res. Tri. Pk., NC.

A remarkable aspect of arsenic metabolism in many species is its conversion from inorganic species into methylated species. Thus, individuals ingesting inorganic arsenic excrete in urine inorganic and methylated arsenicals containing trivalent or pentavalent arsenic. Cyt19, an S-adenosyl-L-methionine-dependent-arsenic(III) methyltransferase purified from rat liver converts inorganic arsenic into methylated arsenicals. The protein is encoded by a cyt19 gene orthologous to mouse and human genes. Although exogenous reductants (dithiothreitol or tris (2-carboxylethyl) phosphine) support catalysis by recombinant rat cyt19 (rrcyt19), endogenous reductants that support its activity are unknown. Glutathione (GSH), the most abundant endogenous reductant, does not support catalysis by rrcyt19. However, the endogenous reductants, thioredoxin, glutaredoxin, and dihydrolipoic acid, coupled with thioredoxin reductase or glutathione reductase and NADPH, support its activity. Glutaredoxin and dihydrolipoic acid support its function in the presence of GSH. Aurothioglucose, an inhibitor of thioredoxin reductase, decreases arsenic methylation by rrcyt19 in thioredoxin-supported reactions. Endogenous reductants in guinea pig liver cytosol, a poor source of arsenic methyltransferase activity, support its catalytic activity. Dependence of enzyme activity on reductants is consistent with its function as an arsenate reductase. A CX7R motif in rrcyt19 resembles a CX5R motif of the P-loop structure in known arsenate reductases; like these proteins, cyt19 activity is stimulated by the presence of an oxyanion, phosphate. Endogenous reductants may be required by rrcyt19 to catalyze the reduction of a methylarsonic (MAs(V)) intermediate to trivalency as a prerequisite for its conversion to a dimethylated product. Thus, cyt19 encodes a protein possessing both As(III) methyltransferase and arsenate reductase activities. Variation in cyt19 genotype may underlie phenotypic variation in the capacity to metabolize arsenic and interindividual differences in susceptibility to arsenic-induced diseases. (This abstract does not represent policies of the USEPA.)

ARSENIC METHYLATION AND OXIDANT INJURY BY ESR IN VIVO AND IN VITRO.

M. B. Kadiiska<sup>1</sup>, S. Nesnow<sup>2</sup>, J. Liu<sup>3</sup>, M. Waalkes<sup>3</sup> and R. Mason<sup>1</sup>.

<sup>1</sup>NIEHS/NIH, Research Triangle Park, NC, <sup>2</sup>USEPA, Research Triangle Park, NC and <sup>3</sup>NCI at NIEHS, Research Triangle Park, NC.

Arsenic is a serious environmental concern worldwide, because of the large number of known contaminated sites and millions of people at risk from drinking arseniccontaminated water. Inorganic arsenic undergoes metabolic conversion from pentavalent arsenate (As V) to trivalent arsenite (As III) with subsequent methylation to generate organometallic forms of arsenic such as MMAV, MMAIII, DMAV, DMAIII and trimethylarsine oxide. Studies have shown that As III metabolites MMAIII and DMA<sup>III</sup> are quite toxic and cause extensive damage to DNA. It has been postulated that the in vivo toxicity and carcinogenicity result from the catalysis of free radical generation. Using electron spin resonance (ESR) in conjunction with the spin traps phenyl-N-tert-butylnitrone (PBN), α (4-pyridyl 1-oxide)- N-tert-butylnitrone (POBN) and 5, 5-dimethyl-1-pyrroline-N-oxide (DMPO) we investigated free radical production by sodium arsenite (As<sup>III</sup>) and sodium arsenate (As<sup>V</sup>) in a mouse model of acute poisoning. In addition, the role of free radicals in in vitro cytotoxicity of DMAIII using murine TRL 1215 liver cells was examined. And, in order to define the mode of action of DNA damage induced by DMA<sup>III</sup>, this study investigated free radical generation by DMA<sup>III</sup> in *in vitro* experiments with supercoiled \$\phi X174 DNA. Simultaneous administration of PBN and As III to adult male 129/Sv mice resulted in the generation of free radical metabolites detected in the liver lipid extract by ESR. Free radical generation was subsequently observed in TRL 1215 liver cells subjected to an acute high dose of DMA<sup>III</sup> exposure. Finally, ESR was used to identify the nature of the radical being trapped by DMPO in the DMA<sup>III</sup>-DNA-damage studies. The complete system gave a characteristic spectrum of a DMPO-hydroxyl radical adduct. In conclusion, the present study provides the most direct ESR evidence for the generation of free radicals by both inorganic and biomethylated forms of arsenic in vivo and in vitro. The relationship of these metabolites to effects of arsenic in humans will be discussed. This abstract does not reflect EPA policy

626

USE OF HUMAN BIOMONITORING TO ASSESS ARSENIC METHYLATION.

L. M. Del Razo<sup>1</sup>, O. L. Valenzuela<sup>1</sup>, G. G. Garcia-Vargas<sup>2</sup> and E. S. Calderon-Aranda<sup>1</sup>. <sup>1</sup>Toxicology, Cinvestav-IPN, Mexico City, Mexico and <sup>2</sup>UJED, Medical School, Gomez Palacio, Durango, Mexico.

Metabolism of inorganic arsenic (As;) in humans produces monomethylarsenic (MAs<sup>V</sup>), dimethylarsenic(DMA<sup>V</sup>), monomethylarsenic (MAs<sup>III</sup>), and dimethylarsenic (DMA<sup>III</sup>), which can be found in human urine. The concentration of arsenicals in urine is used as a biological indicator of As, exposure, because excretion via kidney is the major route for elimination of most As species. As, methylation is often evaluated by the relative distribution of urinary As species. Due to increased recognition of trivalent methylated and dimethylated arsenicals (MAsIII and DMAIII) as more cytotoxic and more genotoxic than As<sub>i</sub>, we studied the relationship of trivalent methylated metabolites to skin signs of arsenicism in humans chronically exposed to As. A cross-sectional study was conducted in central Mexico (about 220 km NE of Mexico City). Seventy-six residents (ages 15-51) from an endemic As-area have been exposed to very high levels of As, in drinking water (150 to 1, 350 ppb) for at least 10 years. The participants answered a questionnaire and were clinically examined. Fifty-five individuals presented skin signs of arsenicism, such as keratosis and hyper- or hypo-pigmentation. Participants provided drinking water and spot urine samples. Due to instability of methylated As species in urine, samples were immediately frozen in dry ice and trivalent As species were analyzed approximately 6 hrs after collection. Trivalent methylated arsenic species were presapproximately of its after concentric introduction in the internated abeliance present in almost all the urine samples (99 %), DMA<sup>III</sup> being the major metabolite (51.2%), followed by DMA<sup>V</sup> (22.6%), MAs<sup>III</sup> (7.2%), MAs<sup>V</sup> (2.7%) As<sub>i</sub><sup>III</sup> (8.8%) and As<sub>i</sub><sup>V</sup> (7.5%). Urinary MAs<sup>III</sup> and DMA<sup>III</sup> were directly correlated with As<sub>i</sub> in water. Individuals with skin-lesions had higher concentration of MAs<sup>III</sup> in urine than those without skin lesions. The main factor associated with arsenicism was cumulative  $As_i$  exposure. More studies are necessary to determine if the urinary excretion of  $MAs_i^{III}$  or  $DMAs_i^{III}$  provides a new biomarker of the effects of chronic exposure to As<sub>i</sub>. Study supported by Conacyt-Mexico (grant 38471-M).

ARSENIC METHYLATION: CONSIDERATIONS FOR RISK ASSESSMENT.

B. D. Beck and A. Schoen. Gradient Corporation, Cambridge, MA.

Recent studies have demonstrated significant cytotoxicity and genotoxicity in vitro of the trivalent forms of methylated arsenic species (specifically monomethyarsonic acid or MMA and dimethylarsinic acid or DMA), often orders of magnitude more

potent than the corresponding pentavalent forms. These studies have raised doubts about earlier understanding of methylation being a detoxification pathway. However, an analysis of both in vivo and in vitro studies indicates that generalizations about the toxicological significance of arsenic methylation are not appropriate for several reasons. First, a cell's capacity to methylate arsenic does not correlate with resulting toxicity or ability to undergo transformation. Moreover, distinctions must be made between MMA and DMA that are generated internally via methylation of inorganic arsenic versus MMA and DMA, which are directly administered. In the latter case, MMA and DMA are excreted rapidly from the body nearly unchanged and demonstrate relatively low toxicity. High doses of DMA cause bladder cancer in rats, possibly through oxidative damage from DMA<sup>III</sup> formation and subsequent generation of trimethyl arsine oxide (TMAO); these metabolites are believed to cause urothelial cell necrosis followed by regenerative cell proliferation and tumorigenesis; however, this response appears to be unique to the rat, with hamsters, mice and humans forming much less (if any) TMAO than rats. It may also be necessary to make distinctions between acute and chronic exposure to arsenic. More research is required to clarify the toxicological significance of arsenic methylation. In particular, a better understanding of the amount and persistence of trivalent metabolites present in vivo at critical target sites would help clarify the role of such forms in injury and disease. Risk assessment considerations about arsenic methylation, the role of trivalent forms, and dose response implications must be made on a case-by case basis with emphasis on species-specific and dose and duration-specific responses.

CONTRIBUTION OF NEUROBEHAVIORAL ASSESSMENT OF OFFSPRING TO HAZARD IDENTIFICATION AND CHARACTERIZATION.

D. L. Shuey<sup>1</sup> and L. D. Middaugh<sup>2</sup>. <sup>1</sup>Preclinical Safety Assessment, Endo Pharmaceuticals Inc., Chadds Ford, PA and <sup>2</sup>Department of Psychiatry and Behavioral Sciences, Medical University of South Carolina, Charleston, SC.

Neurobehavioral assessment of offspring following maternal exposures during gestation and lactation have long been a routine part of preclinical safety assessment during pharmaceutical development (Peri/Postnatal Development Study). Similar studies have recently become more common for agricultural and industrial chemicals (USEPA Developmental Neurotoxicity Study). Recently, the Health and Environmental Sciences Institute of ILSI collected data from 174 studies to retrospectively evaluate the contribution of these assessments to hazard identification (i.e., definition of a NOEL) and characterization. A similar retrospective analysis of developmental neurotoxicity studies submitted for EPA review has also recently been updated. In June 2003, a workshop was held to review and evaluate current behavioral test methods. The outcomes of these activities will be presented to provide a basis for discussion of the overall contribution of these assessments to hazard identification and characterization, as well as study design and methodologic considerations for consistent and effective conduct and interpretation of these studies.

629

NEUROBEHAVIORAL ASSESSMENT: A SURVEY OF USE AND VALUE IN SAFETY ASSESSMENT STUDIES.

L. D. Middaugh. Psychiatry and Behavioral Sciences/ CDAP, Medical University of South Carolina, Charleston, SC. Sponsor: D. Shuey.

A survey designed to evaluate the contribution of F1 neurobehavioral testing to hazard identification and characterization in safety assessment studies was distributed to industrial laboratories in the United States, Europe, and Japan. The survey provided information about studies completed since 1990 on 174 compounds. General categories of compounds included pharmaceuticals (81%), agricultural (7%), industrial (1%), or were undefined (10%). Information collected included: 1) intended use of the test agent, 2) general study design and methodology, 3) types and characteristics of F1 behavioral evaluations, and 4) the frequency with which agents affected neurobehavioral parameters in comparison to other F0 and F1 generation parameters. F1 general toxicology parameters such as mortality, pre- and post-weaning body weight, and food intake were assessed in most studies and were affected more frequently than other parameters by the test agents. F1 behavioral parameters were assessed less consistently across studies, and were less frequently affected by the agents tested. Although affected by agents less often than general toxicology parameters, F1 behavioral parameters along with other parameters defined the no-observed-effect level (NOEL) in 17/113 (15%) studies, and solely defined the NOEL in 3/113 (2.6%) studies. Thus, the F1 behavioral parameters sometimes improved on the standard toxicological measures of hazard identification. While not detecting agent effects as readily as some measures, the F1 behavioral parameters provided information about agent effects on specialized functions of developing offspring that were not provided by other standard measures of toxicity. The survey results emphasize the need for further research into the methods of behavioral assessment as well as the mechanisms underlying the neurobehavioral alterations.

A RETROSPECTIVE ANALYSIS OF DEVELOPMENTAL NEUROTOXICITY STUDIES SUBMITTED TO THE USEPA.

#### S. L. Makris. OPPTS/OPP/HED (7509C), USEPA, Washington, DC.

Over the past decade, a number of developmental neurotoxicity (DNT) studies have been submitted to the USEPA in support of pesticide registration. These studies, conducted in rats, include detailed neurobehavioral and neuropathological assessments, following in utero and postnatal exposures. An analysis was conducted retrospectively on the DNT study data that have been received and reviewed by OPP staff scientists between 1991 and 2003, and of the influence of these data on regulatory decisions for pesticides. The DNT study has been found to be a sensitive study for characterizing hazard and dose-response in the young, particularly for chemicals with known neurotoxic potential. Primary contributions of the DNT study in pesticide risk assessment have been: 1) for some chemicals, the DNT study has been used as a source of endpoints and doses for the calculation of risk following various durations and routes of potential human exposure, and 2) the presence or absence of the DNT study in some pesticide databases has been a critical factor in determining the magnitude of the uncertainty factors applied in the risk assessment. The analysis of these DNT studies also included inter-laboratory comparisons of control data, and has identified a number of issues and problems in study conduct and data interpretation. (This abstract does not necessarily reflect the policy of the USEPA.)

#### 631 BEHAVIORAL TEST METHODS WORKSHOP.

W. Slikker. Division of Neurotoxicology, NCTR/FDA, Jefferson, AR.

The overall goal of the Behavioral Test Methods Workshop, conducted June 20 and 21, 2003 as a satellite meeting just preceding the Teratology, Neurobehavioral Teratology and Behavioral Toxicology annual meeting in Philadelphia, was to improve the sensitivity and quality of behavioral testing thereby enhancing the utility of behavioral data as a reliable index of neurotoxicity in safety evaluation. Several objectives were determined including 1) understanding better the scientific rationale underlying high quality behavioral toxicity testing, 2) identifying the primary practical elements in the conduct of behavioral toxicity testing and analysis that optimize the development of high quality, scientifically creditble, and interpretable data, and 3) providing expert input from academia, industry and government to assist the Inter Agency Committee on Neurotoxicology (ICÓN) in finalizing its behaviroal test methods primer. After presentations by several experts on the fundamentals of behavioral assessment and statistical design, breakout groups were charged to address selected topics and to focus on several well-developed questions. The outcome of the breakout groups' discussions provided several recommendations including 1) the need for determining the purpose of behavioral screen or characterization, and factors that determine appropriate experimental design and data quality, 2) the need for appropriate technical training, logistical support, selection and validation of methods and equipment, and 3) need for appropriate statistical design and clarity of terminology. These and other important findings of the Workshop will be presented and discussed in terms of improving behavioral test methods.

## 632 INTERPLAY OF P53 AND P63 IN TRANSCRIPTIONAL RESPONSE AFTER CELL STRESS.

### J. A. Pietenpol. *Biochemistry, Vanderbilt University, Nashville, TN.* Sponsor: J. Kramarik

The p53 homologue, p63 shares structural similarity with p53 but exhibits functions that are quite distinct from those of p53. Six splice variants of p63 have been identified. They are similar to p53 in that they contain a central DNA binding domain and an oligomerization domain; however, differential transcriptional initiation results in proteins that contain a transactivation domain (TAp63) or lack the N-terminal transactivation domain (deltaNp63). Additionally, alternative splicing results in alpha, beta, and gamma transcripts that each display unique C-termini. deltaNp63 forms are considered to be a dominant negative form of the protein. Since they retain the ability to bind DNA, they may compete for DNA binding sites or they may bind the TA forms and render them inactive. In adult epithelium, we find that deltaNp63alpha is the predominantly expressed form of the protein. While p53 has a well-established role in tumor suppression, we find elevated levels of deltaNp63alpha in squamous cell carcinomas and it is hypothesized to have oncogenic properties. Conservation of the DNA binding domain between p53 and the p63 suggests that they bind a common subset of promoters. We have found this to be the case using chromatin IP-based assays to analyze p53 and p63 occupancy at target gene promoter sites in primary cultures of normal human keratinocytes and mammary epithelial cells under normal and stress conditions. We discovered that deltaNp63alpha acts as a transcriptional repressor, presumably to allow for maintenance of proliferation in these regenerative cells. Further, using several gene discovery approaches, we identified subsets of gene promoters that p53 can bind to after genotoxic stress, but to which deltaNp63alpha cannot and vice versa. Our results suggest that p53 and p63 coordinately regulate subsets of genes in a given cell type after stress; however, each p53 family member can regulate a distinct subset of genes as well. Determining mechanism(s) that dictate differential gene regulation by p53 family members will lend great insight to how cells reprogram gene expression in response to insult.

## 633 MAPPING THE REGULATORY SURFACES OF MEDIATOR WITH ARTIFICIAL TRANSCRIPTION FACTORS.

A. Mapp. University of Michigan, Ann Arbor, MI. Sponsor: J. Kramarik.

Regulated gene expression forms the basis of an organisms response to environmental stress. The metabolism of many xenobiotics, for example, relies upon the controlled production of cytochrome P450 oxidizing enzymes, and the proliferation of cells containing severely damaged DNA is checked by the selective up-regulation of the p53 tumor suppressor gene. Disruptions or faults in the regulatory network of gene expression are thus directly linked to a variety of human diseases and in many cases, the altered gene expression profiles are due to malfunctioning transcriptional regulators. As a result, the design and synthesis of artificial transcription factors, molecules that target specific genes and regulate their expression positively or negatively, has taken on renewed significance. Such factors will be powerful tools for defining the macromolecular interactions that dictate gene expression patterns and in the long term, serve as prototypes for the development of transcription-based therapeutics. Towards that end, we developed an approach for selecting molecules from synthetic combinatorial libraries that interact with individual transcriptional machinery proteins and employ these ligands in artificial transcriptional regulator construction. These regulators are then used to map key protein binding events that lead to a gene being turned on or off. The first generation ligands, short peptides, were used to identify binding sites within the Mediator complex that are used for gene up-regulation in S. cerevisiae. The ligands function as activators of transcription, and unexpectedly, their potency as activators is linked to the binding site location rather than binding affinity for the target protein. The binding site location and potency of these novel activators can be tuned by making small sequence changes, providing compelling evidence that assembly of the transcriptional machinery can be mediated by targeting a relatively small binding surface area. Using this information, organic molecules mimicking the activator characteristics were designed and indeed function as transcriptional activators in vitro.

## 634 INHIBITION OF SMAD TRANSCRIPTION ACTIVITY AND ANTIPROLIFERATIVE FUNCTION BY CDK PHOSPHORYLATION.

F. Liu. CABM and LCR, Rutgers University, Piscataway, NJ. Sponsor: J. Kramarik.

Cell cycle progression from the G1 to S phase is governed by G1 cyclin-dependent kinases CDK4 and CDK2. Transforming growth factor-beta, a secreted polypeptide growth factor, exerts potent growth-inhibitory effects on many different cell types by causing cell cycle arrest at the G1 phase, which enables it to function as a potent tumor suppressor during the early stages of tumorigenesis. TGF-beta also regulates differentiation, cell adhesion, extracelluar matrix deposition, cell motility, cell death and other activities. Many environmental agents, such as reactive oxygen species hydrogen peroxide, and antioxidant treatments, also regulate TGF-beta expression, and their effects, at least in part, may be mediated by TGF-beta. TGFbeta binds to transmembrane serine/threonine kinase receptors. We and others have shown that Smad proteins can transduce the TGF-beta signal from the receptors to the nucleus. Smad proteins can be directly phosphorylated by activated TGF-beta receptor kinases. Following phosphorylation, Smad proteins form heteromeric complexes, accumulate in the nucleus, and regulate transcription of target genes. Smad proteins can mediate TGF-beta growth-inhibitory effects by regulating the expression of cell cycle components. For example, Smad proteins can upregulate the expression of CDK inhibitors p15 and p21 and downregulate the expression of the c-myc protooncogene. Through phosphorylation studies, we have recently discovered that CDK4 and CDK2 can phosphorylate Smad proteins. Except for the retinoblastoma (Rb) family members, Smad proteins are the only demonstrated substrates for CDK4. We have further shown that CDK phosphorylation of Smads inhibits their transcription activity and antiproliferative function. Since tumor cells often contain high levels of CDK4 and CDK2 activities, inactivation of Smad proteins by extensive CDK phosphorylation may provide an important mechanism for the resistance to the growth-inhibitory effect of TGF-beta in cancers.

J. M. Ford, S. Adimoolam and M. Fitch. *Medicine & Genetics, Stanford University School of Medicine, Stanford, CA.* Sponsor: J. Kramarik.

The p53 tumor suppressor gene is involved in multiple aspects of cellular physiology, including DNA repair and the response to DNA damage. The function of the p53 gene is due to its role as a transcription factor regulating expression of genes involved in DNA damage response pathways and affecting apoptosis, cell cycle regulation and DNA repair. We have shown that wild-type p53 is required for proficient mammalian nucleotide excision repair (NER) of UV-irradiation induced DNA damage, and that p53 dysfunction or loss results in a DNA repair defective phenotype, specifically affecting the global genomic NER pathway. The dependence of global genomic NER, but not transcription-coupled NER, on p53 function suggests that the mechanism involves those NER enzymes specifically required for GGR. Using gene expression profiling techniques we identified the DNA damage recognition factors p48 (protein product of the DDB2 gene) and XPC as DNA damage inducible in a p53-dependent manner. Both genes contain consensus p53 responsive regulatory elements in their promoters domains. These promoter elements can activate p53-dependent transcription when placed in a promoter-reporter construct, and bind p53 protein following UV-irradiation, in vivo, as measured by chromatin immunoprecipitation assays. Both p48 and XPC proteins localize within minutes of UV-irradiation to sites of DNA damage in vivo, and this does not require the presence of wild-type p53. p53 protein itself does not co-localize to DNA damage sites in cells, but p48 activates the binding of XPC to these sites. Stable ectopic expression of a p48 cDNA results in complementation of the NER defect associated with p53 deficiency in human cells, demonstrating that efficient NER does not require the presence of wild-type p53 protein, but can be restored through expression of damage-inducible, p53-regulated downstream genes. Therefore, the DNA damage recognition of NER is highly regulated, by transcriptional and post-transcriptional means. Impaired NER due to loss of p53 may play a crucial role in the pathogenesis of human cancers.

636

USING DNA MICROARRAYS TO DEFINE TRANSCRIPTIONAL PATTERNS ASSOCIATED WITH AGING AND OXIDATIVE STRESS IN THE MOUSE HEART.

T. Prolla. University of wisconsin, Madison, WI. Sponsor: J. Kramaric.

To examine molecular events associated with aging and its retardation by caloric restriction (CR), we have employed high-density oligonucleotide arrays providing data on 9, 997 genes to define transcriptional patterns in cardiac muscle. Male B6C3F1 mice were either fed normally or subjected to CR. To investigate aging, 5 month (young adult) and 30 month-old normally fed mice were compared. To study CR, 30 month-old control and CR mice were compared. Aging was associated with specific transcriptional alterations that are prevented by ČR. Specifically, aging was associated with a transcriptional pattern associated with a metabolic shift from fatty acid to carbohydrate metabolism, increased expression of extracellular matrix genes and reduced protein synthesis. CR was associated with a transcriptional pattern consistent with reduced oxidative damage and apoptosis. To investigate the transcriptional response to oxidative stress in the heart and how it changes with age, we examined the cardiac gene expression profiles of young (5-mo-old), middle-aged (15-mo-old), and old (25-mo-old) C57BL/6 mice treated with a single intraperitoneal injection of paraquat (50 mg/kg). Genes commonly induced in all age groups include those associated with stress, inflammatory, immune, and growth factor responses. Interestingly, only young mice displayed a significant increase in expression of all three isoforms of GADD45, a DNA damage-responsive gene. Additionally, the number of immediate early response genes (IEGs) found to be induced by paraquat was considerably higher in the younger animals. These results demonstrate that, at the transcriptional level, there is an age-related impairment of specific inducible pathways in the response to oxidative stress in the mouse heart.

#### 637

REPROGRAMMING GENE EXPRESSION WITH OXIDATIVE STRESS AND STRESS HORMONES: A PARADOX OF ANTIOXIDANT RESPONSES.

Q. M. Chen. Department of Pharmacology, University of Arizona, Tucson, AZ.

Oxidative stress and mental stress have been considered as two different types of health hazards in the modern world. While oxidants have been shown to contribute to the toxicity of a large number of chemicals, aging and a number of diseases, the role of the stress hormone corticosterone remains controversial among various tissues. We have utilized several *in vitro* experimental systems to understand the

mechanisms of oxidative stress. With normal human diploid fibroblasts (HDFs) in culture, oxidants induce a phenotype indistinguishable from replicatively senescent cells. However gene array analyses revealed only a few genes overlapping between H2O2 treated cells and replicatively senescent cells. Nevertheless antioxidant/redox genes were upregulated in both H2O2 treated HDFs (metallothioneins) and replicative senescent cells (thioredoxin reductase-1, peroxiredoxin-6). Induction of antioxidant genes was also observed with H2O2 treated cardiomyocytes [NAD(P)H:quinone oxidoreductase (NQO1)] or cardiac fibroblasts (NQO1, glutathione S-transferases  $\alpha$ 1, metallothionein1). While the expression of these antioxidant genes appear to be contradictory to observed deleterious effects of H2O2, corticosterone was found to be cytoprotective and inhibit apoptosis in cardiomyocytes. Gene array analyses found that corticosterone caused upregulation of metallothioneins, glutathione peroxidase-3 and glutathione S-transferase mu2. These data suggest that although expression of antioxidant genes can contribute to cytoprotection, the cellular outcome of oxidative stress is a balance of multiple factors.

### 638 EFFECTS OF TRANSSPECIES CARCINOGENS IN AVIAN EMBRYOS.

H. G. Enzmann<sup>1</sup>, C. Goetze<sup>1</sup>, K. Spicher<sup>1</sup> and H. Korr<sup>2</sup>. <sup>1</sup>Preclinical Pharmacology and Toxicology, Federal Institute for Drugs and Medical Devices, Bonn, Germany and <sup>2</sup>Department of Anatomy and Cell Biology, RWTH University of Aachen, Aachen, Germany.

A high number of chemicals are carcinogenic in the chronic rodent bioassay. Not all of them however may be considered transspecies carcinogens and are a cancer hazard to humans. The distinction between chemicals that are carcinogenic in rodents only and chemicals that are transspecies carcinogens requires non-rodent experiments. Long term carcinogenicity studies in non-rodents or even primates will usually not be possible for reasons of study duration, cost and ethical considerations. The use of a vian embryos is a rapid and inexpensive approach to study the effects of chemicals on non-rodent tissues. Turkey or quail eggs are injected with the test chemicals into the white of the egg prior to incubation. Control eggs are injected with an equivalent volume of the vehicle. After an incubation period of up to 24 days for turkey eggs and up to 21 days for quail eggs, the embryos are removed from the eggs and tissue samples are fixed in 4% phosphate buffered formaldehyde and processed for histological examination. For autoradiography 3H -thymidine is administered on the chorion allantois membrane 90 minutes before termination. For hepatocyte culture, in situ instillation of embryonic livers with collagenase is used before hepatocytes are plated on collagen-coated dishes. In liver samples, hepatocellular tumors, bile duct proliferations and hematological neoplasia are induced by the transspecies carcinogen diethlynitrosamineamine (DEN). In the kidney storage of PAS positive material is observed in tubular cells after exposure to ochratoxin A. Cell cultures from nitrosamine-treated livers (DEN, N-Nitrosomorpholine, NNK) exhibit persistent morphological alterations (megalocytosis). DNA synthesis in megalocytes is increased in situ and in vitro. We suggest that induction of tumors in avian embryos by a chemical that is carcinogenic in rodents may be considered conclusive evidence of a transspecies carcinogen.

#### 639

MODEL SYSTEMS FOR COMPARING THE ROLES OF AKR1A1 AND CPY1A1 IN THE METABOLIC ACTIVATION OF THE PROXIMATE CARCINOGEN BENZO(A)PYRENE-7, 8-DIOL.

H. Jiang, Y. Shen, A. Quinn, S. Gopishetty and T. M. Penning. *Department of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA.* Sponsor: S. Burchiel.

Benzo[a] pyrene (BP) is a representative polycyclic aromatic hydrocarbon (PAH) which is metabolically activated to exert its carcinogenic effects. One potential pathway of BP activation involves aldo-keto reductases (AKRs), which convert potent proximate carcinogen trans-dihydrodiols to their corresponding reactive orquinones. Another pathway of activation involves CYP1A1 and CYP1B1 which oxidize trans-dihydrodiols to form reactive diol-epoxides. However, the relative contribution of these competing pathways is unknown. To address this issue, model in vitro and transfection systems in vivo were established. In vitro results verified that BP-7, 8-diol was oxidized by both recombinant AKR1A1 and human bronchoalveolar cells (H358) transfected with AKR1A1 to form the reactive BP-7, 8-dione which was trapped by ten- to twenty-fold mercaptoethanol as a stable BP-7, 8-dione thioether conjugate. To examine the competing roles of AKR1A1 and CYP1A1, CYP1A1 expression was induced with 2, 3, 7, 8-TCDD in parental bronchoaveolar cells (H358 and H441) and breast carcinoma MCF7 cells, and in cells transfected with AKR1A1. 10 nM 2, 3, 7, 8-TCDD was the optimal concentration for CYP1A1 induction in parental and transfected H358 and MCF7 cells

over 3-24 h, but no CYP1A1 induction was observed in H441 cells. These models provide the basis for comparison of trans-dihydrodiol activation *in vivo via* the AKR1A1 and CYP1A1 pathways. (Supported by RO1-CA-092537/awarded to T.M.P.)

ASSESSMENT OF THE ROLE OF CYP2E1-MEDIATED METABOLISM OF URETHANE ON THE EXPRESSION OF P53, PCNA, AND KI-67 USING CYP2E1-NULL AND WILD-TYPE MICE.

University. Hoffler<sup>1, 2</sup>, <u>D. Dixon</u><sup>2</sup> and <u>B. I. Ghanayem</u><sup>1, 2</sup>. <sup>1</sup>Meharry Medical College, Nashville, TN and <sup>2</sup>NIEHS/NIH, Research Triangle Park, NC.

Urethane is a known multi-site carcinogen capable of inducing tumors in various organs and animal species. Recent work in this laboratory demonstrated that cytochrome P450 2E1 (CYP2E1) is the principal enzyme responsible for urethane metabolism. Earlier reports showed no immunoreactive cells for p53 in pulmonary proliferative lesions of mice treated with urethane. However, positive immunoreactions for proliferating cell nuclear antigen (PCNA) were observed and as the lesions progressed from hyperplasias to carcinomas, PCNA labeling indices also increased. In an attempt to evaluate the relationship between CYP2E1-mediated urethane metabolism and the pathogenesis of urethane-induced tumors, the expression of PCNA, Ki-67, and p53 were assessed using CYP2E1-null (KO) and wild-type (WT) mice. Mice were administered urethane via gavage at 0, 1, 10, or 100 mg/kg/day, 5 days/week for 6 weeks. At the end of the dosing regimen mice were euthanized and tissues were collected, fixed and processed for immunohistochemical staining. Present work supports earlier findings in that no immunoreactive cells for p53 were detected in the liver or lung of either genotype of mice. Further, no significant increase in PCNA expression was detected in the lung or liver of either genotype of mice. In contrast, however, a 4-fold increase in the expression of Ki-67 was exhibited in the livers of WT mice administered 100 mg urethane/kg in comparison to their vehicle-treated wild-type controls. Similarly, an approximate 2.5 and 4-fold increase in Ki-67 expression were observed in the alveolar regions and bronchioles (including terminal bronchi) of high-dosed WT mice, respectively. In contrast, KO mice administered 100 mg urethane/kg exhibited no significant alterations in Ki-67 expression in lungs compared to lungs of vehicle-treated KO mice. In conclusion, this study demonstrates that CYP2E1-mediated metabolism is a prerequisite for the induction of Ki-67 in the liver and lungs of urethane-treated mice.

641

INCREASED DNA METHYLATION IN THE HOXA5 PROMOTER REGION CORRELATES WITH DECREASED EXPRESSION OF THE GENE DURING TUMOR PROMOTION.

R. E. Watson<sup>1</sup>, G. M. Curtin<sup>2</sup>, G. M. Hellmann<sup>2</sup>, D. J. Doolittle<sup>2</sup> and J. I. Goodman<sup>1</sup>. <sup>1</sup>Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI and <sup>2</sup>Regulatory Toxicology, R. J. Reynolds Tobacco Co., Winston-Salem, NC.

Methylation of cytosine residues of DNA constitutes an epigenetic mechanism for regulating gene transcription, with increased methylation of promoter regions often leading to decreased gene expression. HoxA5 has characteristics of a tumor suppressor gene, with HOXA5 binding to the promoter of the p53 tumor suppressor gene to increase its expression. Thus, a decrease in HoxA5 might contribute to carcinogenesis by decreasing the expression of p53. In this study, we used a SENCAR mouse skin initiation/promotion model to examine changes in gene expression and DNA methylation during tumor promotion. Skin was initiated with 75 ug 7, 12dimethylbenz[a]anthracene and promoted with 27 or 36 mg cigarette smoke condensate (CSC) for 9 wks. Gene array analysis using a BD Biosciences Clontech Atlas<sup>TM</sup> mouse 1.2 nylon array indicated an average decreased expression for HoxA5 of 61% and 66% following treatment with 27 or 36 mg CSC, respectively. To determine if increased methylation plays a role in the decreased HoxA5 expression, we used the enzymatic regional methylation assay to assess the average methylation level in the promoter region. DNA was bisulfite modified and PCR amplified with primers containing dam sites (GATC), and incubated with [14C-methyl] S-adenosyl-L-methionine (SAM) and dam methyltransferase (internal control) to standardize DNA quantity. DNA was then incubated with [3H-methyl] SAM and SssI methylase (methylates C's 5' to G's) to quantify methylation status. A high 3H/14C ratio compared to control is indicative of hypermethylation. HoxA5 in animals promoted with 27 or 36 mg CSC was hypermethylated compared to initiated-only controls. The 3H/14C ratio in controls versus promoted with 27 or 36 mg CSC was 12.4±0.34, 48.2±6.9 and 24.2±6.1, respectively. These data indicate that DNA methylation may contribute to the decreased expression of HoxA5, which might then contribute to tumorigenesis.

IDENTIFICATION OF MOLECULAR PATHWAYS THAT MAY PROMOTE CELL GROWTH AND PROLIFERATION IN RESPONSE TO NONGENOTOXIC CARCINOGENS.

V. Bombail<sup>1</sup>, R. Currie<sup>1</sup>, J. Oliver<sup>1</sup>, A. Morsi<sup>2</sup>, <u>I. Kimber</u><sup>1</sup>, K. Chipman<sup>2</sup> and G. Orphanides<sup>1</sup>. <sup>1</sup>Syngenta Central Toxicology Laboratory, Alderley Park, Cheshire, United Kingdom and <sup>2</sup>School of Biosciences, University of Birmingham, Birmingham, United Kingdom.

A diverse group of industrial chemicals cause liver tumors in rodents without damaging DNA directly. Species differences in response to these nongenotoxic carcinogens question the relevance of such rodent tumors for human risk assessment. It is believed that these chemicals induce carcinogenesis through regulation of cell growth, proliferation and apoptosis. Assessment of the likely risk to humans posed by these chemicals will be facilitated by identification of the molecular pathways through which these compounds control cell proliferation. We have attempted to identify these pathways using global gene expression profiling. Mice were dosed with the model rodent nongenotoxic carcinogen and peroxisome proliferator di-ethylhexylphthalate (DEHP; 1150 mg/kg/day) or corn oil (control) by gavage for three days. Gene expression levels were measured 1, 2, 4, 8, 24, 48 and 72 hr following first exposure using Affymetrix MG-U74v2A GeneChips. 1, 257 genes showed statistically significant alterations in expression level between control and DEHP groups. Gene ontology analysis revealed significant alterations in gene expression in genes involved in peroxisomal function, the acute phase response, xenobiotic responses, prostaglandin metabolism, the regulation of apoptosis, and cholesterol biosynthesis. Analysis of components of signal transduction pathways revealed coordinated changes in the expression of genes of the TNF- $\alpha$ , IL-1, IL-6, EGF and TGF-β pathways. In addition, DEHP induced the expression of a family of protease inhibitors implicated in cell proliferation and of a novel protein that may regulate cell cycle progression in hepatocytes. These data shed light on the mechanisms by which nongenotoxic carcinogens control hepatocyte growth and proliferation and will facilitate assessment of the likely risk posed by these chemicals to humans.

### 643 AHR REGULATION OF C-MYC IN HUMAN BREAST

X. Yang, T. J. Murray, D. Liu and <u>D. H. Sherr</u>. Enviormental Health, Boston University School of Public Health, Boston, MA.

It has long been suggested that ubiquitous environmental chemicals, such as PAH, contribute to human breast cancer. The preferential targeting of breast tissue by orally administered PAH in rodent breast cancer models supports this contention. Most of the biologic activity of PAH and related dioxins is mediated by the AhR. Previously, we demonstrated that the AhR and CYP1B1, an AhR-regulated gene, are dramatically up-regulated in rodent and human breast tumors. Here, we investigated the possible consequences of this apparent constitutive AhR activation. In specific, we tested if constitutively active AhR in a human breast cancer cell line, regulates c-myc, an important breast cancer oncogene which contains six AhR binding sites (AhREs) in its promoter. Luciferase reporter vectors containing the cmyc promoter with its six AhREs was constructed. Variants with mutations in NFkB and/or AhR binding sites were generated by site-directed mutagenesis. These constructs were transfected into Hs578T cells and subsequently assayed for luciferase activity in the presence or absence of TCDD, a strong AhR agonist. The results indicate that: 1) there is a significant baseline level of wildtype c-myc promoter driven reporter activity in these tumor cells which was not affected by inclusion of TCDD, 2) the baseline reporter activity was not affected by deletion of the NF-kB site, 3) while mutation of single AhRE sites had no effect on baseline reporter activity, mutation of all six sites resulted in a five fold increase in reporter activity; a similar increase in reporter activity was seen when the wildtype reporter construct was co-transfected with an AhR repressor plasmid, 4) c-myc-specific real time PCR indicated that AhR repressor transfection increased background levels of endogenous c-myc mRNA. These results suggest that the AhR represses c-myc transcription and that AhR up-regulation in tumor cells may represent a failed growth feedback mechanism.

2, 3, 7, 8-TETRACHOLODIBENZO-P-DIOXIN (TCDD) INDUCES MMP EXPRESSION AND INVASION IN A2058 MELANOMA CELLS.

L. A. White<sup>1</sup>, K. Murphy<sup>1</sup>, A. Akintobi<sup>1</sup> and C. Villano<sup>2</sup>. <sup>1</sup>Biochemistry and Microbiology, Rutgers University, New Brunswick, NJ and <sup>2</sup>Joint Graduate Program in Toxicology, Rutgers University, New Brunswick, NJ.

The incidence of metastatic melanoma is increasing in industrialized nations, and we propose that environmental contaminants, such as the polycyclic and halogenated aromatic hydrocarbons (PAH/HAH), stimulate melanoma progression by altering matrix metalloproteinase (MMP) expression and activity. MMP activity is necessary for cell migration through matrix barriers, and expression of these en-

zymes correlates with aggressive and invasive tumors. Our data in melanoma cells demonstrate that though both non-invasive and invasive melanoma lines are responsive to TCDD, only the invasive cells (A2058) express MMPs following TCDD exposure. In addition, our data show that TCDD exposure results in a concomitant down-regulation of PAI-2 (plasminogen activator inhibitor-2), an inhibitor of matrix remodeling. Finally, in vitro invasion assays demonstrate that TCDD treatment results in an increase in invasion of the melanoma cells through a basement membrane barrier. These data suggest that TCDD directly increases melanoma invasion by stimulating degradation of the protein barriers between cells and tissues. In order to determine the mechanism of TCDD-induced MMP-1 expression in these cells, we performed transient transfection of 4.4 kb of the promoter linked to a reporter gene (luciferase; pGL3). Data from these experiments demonstrate that TCDD-induced MMP expression in melanoma cells is mediated, at least in part, through activation of the sequences in the enabncer region of MMP-1. A deletional series was used to identify a TCDD-responsive region of the MMP-1 promoter. Interestingly, the identified region contains no sequences homologous to the consensus binding site (xenobiotic responsive element: XRE) for the known receptor for TCDD, the Aryl hydrocarbon receptor (AhR). As no consensus XREs sequences have been identified in this distal region, the results of these experiments may reveal novel TCDD-responsive cis-acting element(s).

HEPATOMA MITOCHONDRIA RESIST THE MITOCHONDRIAL PERMEABILITY TRANSITION: POSSIBLE INVOLVEMENT OF HEAT SHOCK PROTEIN-25 (HSP25).

E. Bustamante, L. He and <u>J. J. Lemasters</u>. Cell and Developmental Biology, University of North Carolina School of Medicine, Chapel Hill, NC.

Opening of mitochondrial permeability transition (MPT) pores plays a causative role in cell death by committing cells to either apoptosis or necrosis, and increased expression of HSP25 after heat shock is associated with a capacity to resist the MPT and cell killing. We investigated the MPT in mitochondria isolated from three lines of rat hepatoma cells (AS-30D, N1-S1, and RH7777) and from rat liver using a mitochondrial swelling assay at 540 nm and 25°C. Mitochondrial Ca<sup>2+</sup> uptake and membrane potential were also monitored with Fluo-5N and tetramethylrhodamine methyl ester (TMRM), using a fluorescence plate reader at 25°C. Mitochondrial functional and structural integrity were assessed by oxygen consumption, electron microscopy, and confocal microscopy (after loading live cells at 37°C with TMRM, propidium iodide, or MitoTracker Red). In Mg<sup>2+</sup>-free medium, 200 μM Ca<sup>2</sup> caused swelling of liver mitochondria within 10 min, but hepatoma mitochondria did not swell after 30 min even with over 500 µM Ca<sup>2+</sup>, although the membranepiercing peptide alamethicin did induce swelling. Lack of swelling in tumor mito-chondria was not due to a defect of ruthenium red-sensitive  $\mathrm{Ca}^{2^+}$  uptake, which occurred at a similar rate as liver mitochondria, or to differences of mitochondrial membrane potential. Mitochondria from neonatal liver and regenerating liver behaved similarly to normal liver. The uptake of Ca<sup>2+</sup> by hepatoma mitochondria caused temporary mitochondrial depolarization as measured by TMRM fluorescence and mitochondria subsequently repolarized, strongly suggesting that the mitochondrial membranes were physiologically intact. Immunoblot analysis revealed HSP25 in hepatoma mitochondria, whereas HSP25 was not detectable in liver mitochondria. Resistance of hepatoma mitochondria to induction of the MPT may contribute to the relative insensitivity of tumor cells to pro-apoptotic stimuli. Expression of HSP25 in mitochondria may play a role in the resistance to the MPT of hepatoma mitochondria.

POSSIBLE ROLE FOR CHEMOTHERAPY IN THE UPREGULATION OF MITOCHONDRIAL BIOGENESIS IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS.

J. S. Carew, Y. Zhou, M. J. Keating and P. Huang. UT M.D. Anderson Cancer Center, Houston, TX. Sponsor: D. McConkey.

Chronic lymphocytic leukemia (CLL) is the leading form of adult leukemia in the Western hemisphere. In spite of its prevalence, many of the biochemical and molecular features of this disease remain unclear. Previous studies by our group established that CLL cells from patients with prior chemotherapy had significantly higher basal levels of reactive oxygen species (ROS) and mtDNA mutation frequencies than cells from untreated patients. These findings led us to speculate that chemotherapy may also contribute to other mitochondrial (mito) aberrations. Considering that oxidative stress has been proposed to activate mito biogenesis, we hypothesized that treatment with certain anticancer agents may be associated with increased cellular mito mass. To test this hypothesis, we obtained clinical specimens from CLL patients with and without prior chemotherapy. Previously treated patients primarily received a regimen of fludarabine, cyclophosphamide, and rituxan. Basal superoxide (O2-) generation of primary CLL cells was assessed using hydroethidine. As expected, cells from previously treated patients generated higher

levels of basal O2- than those from untreated patients. Cellular mito mass was determined by flow cytometry using Mitotracker Green. The mito mass of CLL cells from patients with prior chemotherapy was significantly higher (p=0.0313) than that of cells from untreated patients. Electron microscopy showed that CLL cells contained significantly higher numbers of mitochondria per cell than normal B lymphocytes, suggesting that increased mito biogenesis may play a key role in oncogenesis or disease progression. Analysis of a direct relationship between O2- generation and mito mass revealed a weak correlation. However, certain cells with especially high levels of O2- also had a very high mito mass, indicating that ROS may contribute to the increased mito mass observed in cells from treated patients. Taken together, the data suggest that treatment with anticancer agents is associated with elevated mito mass, possibly due to increased mito biogenesis.

## 647 EFFECTS OF RAT GENDER AND STRAIN ON ELUCIDATING LIVER TOXICITY.

B. W. Higgs, A. L. Castle, W. Zeng, M. W. Porter and <u>D. L. Mendrick</u>. *Toxicogenomics, Gene Logic Inc., Gaithersburg, MD.* 

We examined the effects of gender and strain on our ability to use a reference database built mostly on male Sprague-Dawley rats. The differences in baseline gene expression for these factors were compared to see how they might affect our capabilities in building predictive models and in elucidating mechanism of toxicity. To address the effects of these two factors, we examined those genes that show significant changes between genders and between strains. The study design consisted of 59 vehicle-treated rat liver samples. Four groups of animals were compared: Male Sprague-Dawley (MSD), female Sprague-Dawley (FSD), male Wistar (MWS), and female Wistar (FWS). The expression intensities were generated with the Affymetrix RGU34 GeneChip® microarray using standard protocols. Differences between baseline expression across gender and strain and the resulting impact of both predictive models and mechanistic analysis were examined. The results show that the effects due to gender are much greater than that of strain, as many more genes were differentially regulated due to gender, including some known to be me-diators of the toxic response. Examples of such genes showing high gender specificity include sulfotransferase, hydroxyacid oxidase 3, and carbonic anhydrase 3. These genes show significant modulation in signal intensities between male and female rats. Interestingly, the strain effects are greater in female rats than in male rats, when taken in context of liver toxicity markers identified by Gene Logic. Results also show that removal of the few most gender-specific genes from the toxicity marker set greatly improves the predictive accuracy. These results give us confidence in the ability to both predict a general toxic response and identify the mechanism of toxicity (MOT) across strain much better than gender. However, better overall success in prediction and MOT can be achieved if one discounts the most gender-specific genes. These strategies support our ability to accurately predict female-and Wistar-derived data.

LIVER EFFECTS AT THE GENE EXPRESSION LEVEL OF FOOD-FASTING, WATER DEPRIVATION, AND ANESTHETIC AGENT ADMINISTRATION IN UNTREATED RATS.

M. W. Porter, <u>C. G. Chang</u>, M. W. Orr and <u>D. L. Mendrick</u>. *Toxicogenomics, Gene Logic Inc., Gaithersburg, MD*.

Animal-based gene expression experiments reveal a large amount of information relating to the toxic mechanism of compounds. In addition, gene expression has been shown to be a more sensitive predictor of toxicity when measured at the whole transcriptome level than when measured by classical assays. The ability of gene expression-based methods to correctly characterize a toxic response is also dependent on its ability to separate toxicity from other experimental confounding factors such as food-fasting, water deprivation, and anesthetic agent administration within the organ of interest. We recently performed a study where male Sprague-Dawley rats were purposely fasted, deprived of water, and administered one of three anesthetic agents (Carbon Dioxide, Pentobarbital, and Halothane) to determine the gene expression-level changes in the liver. Food-fasting induced a relatively large number of changes that were localized to several metabolic pathways; most notably, Sterol Biosynthesis and Fatty Acid Metabolism (KEGG). Gene expression was also modified by the individual anesthetic agents across time. For example, GADD45-alpha shows no significant changes in gene dysregulation within 30 min of pentobarbital treatment, but is significantly upregulated at 60 min of exposure. In contrast, methallothionein is upregulated by a 5 min exposure and remains upregulated throughout the 60 min exposure period. These results illustrate that in-life standard operating procedures are critical for evaluating gene expression responses and demonstrate that animal husbandry processes and anesthesia selection can influence the expression of genes that are often modulated by cellular perturbations sometimes associated with adverse effects. In addition, the results suggest that the separation of a true test compound-induced toxic response from experiment-derived factors is essential before gene-level predictive and mechanistic assessments can be pursued.

CONCORDANCE OF TOXICOGENOMIC PREDICTIONS AND MECHANISTIC ANALYSIS FOR COMPOUNDS TESTED IN BOTH RAT LIVER AND PRIMARY RAT HEPATOCYTES.

M. S. Orr, B. W. Higgs, K. R. Johnson and <u>D. L. Mendrick</u>. *Toxicogenomics, Gene Logic Inc., Gaithersburg, MD*.

Even with an assortment of cell based assays available today, early detection of compounds capable of inducing liver toxicity is still a significant problem. A cell based assay that was able to identify multiple types of liver toxicity and provide richer information regarding the mechanisms of toxicity would improve upon current technologies. Comparisons between toxicogenomic data derived from rat liver or primary rat hepatocytes were evaluated to determine the feasibility of using the combination of rat hepatoyctes and microarray analysis for detecting liver toxicity. Predictive models used in this study were developed based on gene expression information from the ToxExpress® database that is derived from rat liver or primary rat hepatocytes analyzed with the Affymetrix RGU34 GeneChip® set following treatment with a large number of compounds. For the in vivo to in vitro comparisons, 42 compounds that had been used in both systems were evaluated. A concordance of 74% was observed for the 42 compounds examined, as 31/42 compounds studied were correctly identified as either human/rat liver toxicants or non-toxic agent by the respective predictive models. Notably, the rat hepatocyte models were able to identify a pharmacologically diverse set of compounds capable of inducing steatosis and/or hepatitis such as Valproic acid, Amiodarone, Tetracycline, and Diclofenac, agents that are difficult to detect by conventional techniques. In addition, a comparative analysis of microarray data from rat liver and hepatocytes treated with Clofibrate indicated a very similar response in beta oxidation genes such as Ratacoa1, Cpt1a, Cpt2, Crot, and Ech1 and peroxisome proliferation genes such as Pex11a, Hsd17b4, Decr2, and Abcd3, suggesting a similar biologic response in both biological systems. These results provide evidence that primary rat hepatocyte system in conjunction with microarray analysis is a valuable in vitro assay tool for detecting liver toxicants and it also provides precious mechanistic information regarding the observed toxicity.

## 650 EVALUATION OF THE BIOLOGICAL VARIATION IN GENE EXPRESSION PROFILES IN CULTURED PRIMARY RAT HEPATOCYTES

C. Wang<sup>1</sup>, S. M. Hussain<sup>2</sup>, V. Chan<sup>2</sup> and J. M. Frazier<sup>3</sup>. <sup>1</sup>Microarray Core, Cedars-Sinai Medical Center, UCLA, Los Angeles, CA, <sup>2</sup>ManTech Environ Technology, Inc., Dayton, OH and <sup>3</sup>AFRL/Wright-Patterson AFB, Dayton, OH.

Cultured primary rat hepatocytes are valuable tools for toxicological research. They are used widely for testing toxicological and pharmacological effects of chemicals and drugs. Although it is known that variation may exist in data generated in animal models, the biological variation exhibited by time-course gene expression profiles has not been fully evaluated. Hepatocytes were harvested from male Fisher 344 rats, plated in 6-well plates and allowed to recover for 24 h. To evaluate biological variations in mRNA expression profiles, total RNA was extracted from cultured primary hepatocytes derived from four different rats over a 24 h period (0, 2, 5, 8, 14 and 26 h) following the recovery period. Gene expression profiles were obtained using the Affymetrix RatTox U34 array. To evaluate the intra-animal reproducibility, gene expression data were obtained for 2 replicate samples at all time points for each rat. Our results indicated that: (1) mRNA levels were above the detection limit (present or marginal calls) for 367 out of 1031 probe sets across all time points in all four animals and 58% (212/367) of these probe sets exhibited statistically significant differences among the four rats (one-way ANOVA, p < 0.05), indicative of biological variation in gene expression; (2) for 250 out of 367 detectable probe sets (68%), the mRNA expression levels exhibited statistically significant time-dependent pattern in all four rats using one-way ANOVA (p < 0.05); (3) on the other hand, the gene expression for most genes (801 out of 1031 probe sets) were constant across all time points in all four rats; (4) no significant differences in gene expression were found at any time points in replicate samples (ANOVA, P> 0.05). Overall, these results strongly suggest that replicate samples of rat hepatocytes for gene expression profiling are highly consistent, however, inter-animal variability is a confounding factor and must be carefully evaluated to make sense of microarray gene expression studies.

## CLASSIFYING CHEMICAL INDUCED LIVER PATHOLOGY USING GENE EXPRESSION PROFILING IN VITRO IN PRIMARY HEPATOCYTES.

S. Baumhueter, L. Brady, G. Day, S. Dunlea, B. Eynon, J. Ferng, S. Fujimoto, R. Idury, K. Jarnagin, <u>K. Kolaja</u>, M. Lee, R. Nair, C. Pearson, A. Roter and A. Tolley. *Iconix Pharmaceuticals, Mountain View, CA*.

We have investigated rat primary hepatocytes as an alternative to *in vivo* studies for the characterization of the toxic liability of various environmental chemicals, therapeutics and toxicants. We have chosen to use global gene expression profiling in this

in vitro system to identify sets of transcripts (signatures) whose regulation is closely correlated with compound group effects, either mechanism of activity or toxicity, from treated rat livers in vivo. Our results show that transcript sets derived from expression profiles in vitro and characteristic of Peroxisome proliferator receptor alpha activating compounds can be used to correctly identify the corresponding gene expression profiles generated from liver tissue of rats treated with compounds of the same activity class. This in vitro gene set is highly specific in that it recognizes 23 in vivo profiles from a database containing over 1500 gene expression profiles. Additionally we have used this in vitro system to derive transcript sets that are correlated with a chemicals propensity of inducing cholestasis in vivo.

#### 652 CROSS-SPECIES ANALYSIS OF PHENOBARBITAL-INDUCED GENE EXPRESSION CHANGES IN DOG AND RAT.

W. B. Mattes, M. S. Orr and D. L. Mendrick. Toxicogenomics, Gene Logic Inc., Gaithersburg, MD.

A fundamental concept in toxicological hazard identification is the evaluation of findings in several different species and the extrapolation of these findings to humans. Adverse findings common to several species would suggest a hazard for humans. On the other hand, a finding unique to one non-human species must be evaluated in the context of whether the underlying mechanism is relevant to humans. Genomic information and technology offers the hope of providing a molecular and cellular basis for evaluating cross-species mechanisms of toxicity. With the advent of microarrays capable of querying canine mRNA such comparisons between dog and rat, the two most common test species, become possible. In a preliminary test of such a comparison, the gene expression responses to phenobarbital treatment were examined in livers from male and female dogs treated for 7 days, and in male rats treated for 2 days. Liver RNA from individual animals was analyzed with Affymetrix microarrays and gene expression changes meeting statistical cutoffs were evaluated. Probeset sequences on the canine array were annotated based upon public domain canine sequences and homology to human and mouse sequences. Despite the obvious hurdles in establishing biologically equivalent treatments and unambiguous homologies between genes across species, clear similarities in gene expression changes were seen. On an individual gene basis, induction of several cytochrome P450 mRNAs, notably those in the Cyp3A family, were seen in both species. When the regulated gene sets were analyzed using Gene Ontology analysis, concordance across species was found in the induction of genes involved in electron transport. Hierarchical cluster analysis clearly identified regulated gene sets within each species, and in the case of the dog, could differentiate males and females. These results point to the value and potential of gene expression analysis for comparing contrasting the mechanisms of toxicity for a compound in several species.

## USE OF EXPRESS PROFILING™ TO CHARACTERIZE GENE EXPRESSION BIOMARKER SETS FOR LIVER TOXICITY.

J. Monforte<sup>1</sup>, G. Vansant<sup>1</sup>, P. Pezzoli<sup>1</sup>, F. Ferre<sup>1</sup>, S. Baumhueter<sup>2</sup>, G. Day<sup>2</sup>, S. Dunlea<sup>2</sup>, B. Eynon<sup>2</sup>, M. Fielden<sup>2</sup>, S. Fujimoto<sup>2</sup>, B. Ganter<sup>2</sup>, R. Idury<sup>2</sup>, K. Jarnigan<sup>2</sup>, <u>K. Kolaja<sup>2</sup></u>, M. Lee<sup>2</sup>, R. Nair<sup>2</sup>, G. Natsoulis<sup>2</sup>, S. Nicholson<sup>2</sup>, C. Pearson<sup>2</sup>, A. Roter<sup>2</sup> and A. Tolley<sup>2</sup>. <sup>1</sup> Althea Technologies, Inc., San Diego, CA and <sup>2</sup> Iconix Pharmaceuticals, Inc., Mountain View, CA.

There is a continuing need for improved methods to predict the toxicological liabilities of new drug candidates. In order to provide more informed methods for evaluating compounds during drug discovery and development, we have identified a large library of biomarkers for important toxicities and mechanisms of action. Gene expression profiles have been generated from tissues from rats treated with more than 580 drugs and environmental chemicals. Analysis of this extensive dataset has revealed specific gene expression patterns or signatures associated with specific mechanisms of toxicity. Relatively small sets of genes, typically 20-50, are adequate to diagnose many toxicities. A number of these gene signatures have been converted into high-throughput gene-expression assays using eXpress Profiling, a quantitative, highly-multiplexed rtPCR process. Using this format we have developed gene sets and assayed a number of specific toxicological endpoints, including DNA damage, bile duct hyperplasia, PPAR-alpha agonist activity and severe liver weight increase, and demonstrated the validity of this method for predicting these specific mechanisms of response in rats. Furthermore, the expression profiles show good correlation with phenotypic evidence. The expression signatures offer the advantage of early stage activity detection and may ultimately provide higher sensitivity than existing histopathological and pharmacological endpoints. The high throughput nature of the eXpress Profiling method offers a practical means for converting a process that we have validated *in vivo* into high throughput *in vitro* screening applications.

## EARLY CHANGES IN HEPATIC GENE EXPRESSION FOLLOWING EXPOSURE TO THE RODENT CARCINOGEN METHYLEUGENOL.

J. T. Auman, R. D. Fannin, S. O. Sieber, M. L. Cunningham and R. S. Paules. National Center for Toxicogenomics, NIEHS, Research Triangle Park, NC.

Methyleugenol is a potent, nongenotoxic rodent carcinogen used widely as a fragrance and flavoring additive that caused liver tumors in both rats and mice in a 2year exposure study. To determine if the indications of tumorigenic potential of methyleugenol could be detected earlier, we compared hepatic gene expression in male Fischer rats following exposure for 2 weeks with hepatocellular carcinomas obtained from the 2-year rat study. Methyleugenol was administered by gavage for 1 to 14 days, with hepatic gene expression measured at various times during the treatment regimen, as well as 6 months after the last dose. Hepatic gene expression of treated samples or tumors was measured with an Agilent rat 60-mer oligonucleotide microarray compared to time matched controls. We found that during the course of administration, methyleugenol elicited marked changes in hepatic gene expression especially of genes involved in xenobiotic detoxification, stress response and cholesterol homeostasis which were accompanied by changes in clinical chemistry parameters and histopathology indicating biliary and hepatic dysfunction. Following six months without exposure to methyleugenol after the initial daily dosing for 14 days as described above, differentially expressed genes were still detected, with several of the gene changes having been previously associated with hepatocellular carcinomas. We also detected gene changes in common between methyleugenol-induced hepatocellular carcinomas and those found during methyleugenol treatment and 6 months after the last dose. This study clearly demonstrates long-lasting changes in hepatic gene expression following exposure to methyleugenol, suggesting that the tumorigenic potential of a compound might be predicted before the emergence of neoplastic lesions.

## 655 IDENTIFICATION OF MOLECULAR TARGETS OF CURCUMIN IN RAT LIVER BY OLIGONUCLEOTIDE MICROARRAY.

V. Misra<sup>1</sup>, R. Thimmulappa<sup>1</sup>, K. Mai<sup>1</sup>, <u>L. L. Adams-Campbell<sup>2</sup></u> and <u>S. Biswal<sup>1</sup></u>.

<sup>1</sup> Johns Hopkins University, Baltimore, MD and <sup>2</sup> Howard University, Washington DC, WA.

Curcumin is an important component of turmeric, a rhizome of the plant Curcuma longa. It is commonly used as a spice, flavoring agent, food preservative, and coloring agent. The FDA has classified turmeric among substances as Generally Recognized as Safe (GRAS). In vitro and in vivo studies have demonstrated anti-inflammatory, antioxidant, antifungal, and anticarcinogenic properties of curcumin. Human phase I trials found no toxic effect of curcumin even at a dose as high as 8000 mg/day for 3 months. Deciphering the molecular targets of curcumin in liver will aid in its development as a chemopreventive agent. After feeding rats on 1% curcumin for 14 days, liver was excised and processed for RNA extraction. Gene expression study was done by oligonucleotide microarray analysis using Affymeterix Genechip Rat expression set 230A. The data was analyzed using MAS 5.0 and Data Mining Tool 3.0 (Affymetrix, CA). The results revealed the upregulation of genes coding for antioxidants and detoxification enzymes. Detoxification enzymes included UDP-glucuronosyltransferase, glutathione-S-transferase, aflatoxin B1 aldehyde reductase, epoxide hydrolase, NAD(P)H:menadione oxidoreductase. Among the antioxidants, glutathione related enzymes such as glutathione reductase, glutathione synthetase, and glutamate-cysteine ligase were elevated. In addition, heat shock proteins and several genes encoding for proteins associated with lipid metabolism were increased. Moreover, curcumin repressed certain genes associated with detoxification (CYP1A2, sulfotransferase), inflammation, fatty acid metabolism (carnitine palmitoyltransferase 1 alpha, hydroxysteroid dehydrogenase, 11 beta type 1) and cell cycle. In conclusion, the result provides a comprehensive list of molecular targets of curcumin in rat liver and underscores its beneficial effects. (Supported by Howard/Hopkins Partnership grant)

## NORMAL HUMAN DENDRITIC CELLS: A TOOL TO STUDY ALLERGIC AND IMMUNOLOGICAL REACTIONS *IN VITRO*.

M. Klausner, S. Ayehunie, S. Lamore, K. Bellavance, R. Lappen, P. Hayden and J. Sheasgreen. R & D, MatTek Corporation, Ashland, MA.

Dendritic cells (DC) or Langerhans cells (LC) are immunological cells of the body which play a key role in allergic reactions and infectious diseases. However, widespread experimental use of DC has not occurred since previously-used methods of harvesting DC directly from tissue result in poor yields, short survival time, and rapid phenotypic changes. Currently, we have developed a new method of generating DC from CD34+ progenitor cells harvested from human umbilical cord blood. This method resulted in an average increase of  $205 \pm 86$  fold (n = 15) in DC num

ber versus previous methods. The DC express CD1a, HLA-DR, and co-stimulatory molecules (CD40 and CD80), and can be cultured for up to 36 days with no significant change in cell number or phenotype. Transmission electron microscopy showed the presence of Birbeck granules, a key ultrastructural marker of DC, over the duration of the culture period. The DC contain plasmacytoid (CD123+/cd11c-) and myeloid (CD11c+/cd123+) populations and can be frozen and recovered with a viability of 80-90%. Exposure of the DC to external stimuli such as lipopolysaccharide (LPS), phorbol-12-myristate-13-acetate (PMA), and interferon- $\gamma$  (IFN- $\gamma$ ), caused a reproducible (n = 4), high level of gene and protein responsiveness in terms of IL-12, macrophage inflammatory protein (MIP)-1α, MIP-3α, IL-6, and TNF- $\alpha$  expression. DC pulsed with the neo-antigen, keyhole-limpet hemocyanin (KLH), or the recall-antigen, tetanus toxoid, induced autologous Tcell proliferation as measured by 5-bromo-2-deoxyuridine (BrdU) incorporation. Functionally, the DC were also shown to: 1) express foreign genes following transfection, 2) migrate in response to chemotactic factors such as granulocyte/monocyte colony stimulating factor (GM-SCF) and MIP-3 $\alpha$ , 3) become infected following exposure to HIV-1. Thus, these cells are likely to be useful in a broad variety of allergic and immunological studies.

### DOSE RESPONSE ANALYSIS OF ALLERGEN-INDUCED GENE EXPRESSION CHANGES IN DENDRITIC CELLS.

L. A. Gildea<sup>1</sup>, <u>C. A. Ryan</u><sup>1</sup>, B. C. Hulette<sup>1</sup>, <u>R. J. Dearman</u><sup>2</sup>, <u>I. Kimber</u><sup>2</sup> and <u>F. Gerberick</u><sup>1</sup>. 'Procter & Gamble, Cincinnati, OH and Syngenta CTL, Macclesfield, United Kingdom.

Allergen uptake and processing by resident skin dendritic cells are critical steps in the induction of allergic contact dermatitis (ACD) and therefore are ideal events to model for study of the allergic immune response. Microarray analysis of human peripheral blood-derived dendritic cells (PBMC-DC), a surrogate for skin DC, has revealed many changes in gene expression following allergen treatment. Genes identified via this approach are potential targets for the development of an in vitro method for skin sensitization testing as well as provide a mechanistic understanding of the immune recognition phase of ACD. However, prior to final gene selection, analysis of their sensitivity, selectivity, and dynamic range must be evaluated. Therefore, we analyzed a select number of genes by real-time PCR analysis to determine their usefulness as markers for contact allergy and to reproduce previous microarray data using additional blood donors. PBMC-DC were treated for 24 hours with various doses of the contact allergen, dinitrobenzene sulfonic acid (DNBS), and RNA was extracted for use in real-time PCR reactions. Specific primers were designed for selected genes and mean relative fluorescence units (RFU) were calculated using individual well readings within a given PCR run and then converted to mean fold changes comparing mean RFU in control (vehicletreated)samples versus mean RFU in treated samples. DNBS treatment induced changes in the expression of numerous genes associated with immune function, such as interleukin (IL)-8, CD86, IL-1 receptor antagonist, CD1E, interferon stimulated gene 20, and cathepsins H and L. Similar expression profiles were seen with other allergens, such as 3, 4-diethoxy-3-cyclobutene-1, 2-dione, NiSO4, oxazalone, and propyl gallate. Real-time PCR analysis of dose response studies has identified a number of additional genes whose role in immune regulation are unclear yet fit the selection criteria for sensitivity, dynamic range, and reproducibility and thus will be analyzed further for their specificity for contact allergy.

# COMPARISON OF THE RESPONSE OF DENDRITIC CELLS DERIVED FROM CORD BLOOD CD34+ AND FROM CD14+ MONOCYTES TO THE CONTACT SENSITIZER NICKEL.

F. Boisleve<sup>1</sup>, N. Aubert<sup>2</sup>, J. Bernard<sup>2</sup>, <u>M. Pallardy</u><sup>1</sup> and S. Roemer<sup>1</sup>.

<sup>1</sup> Immuntoxicology, Inserm U461, Chatenay-Malabry, France and <sup>2</sup>laboratoire de therapie cellulaire, Institut Jean Godinot, Reims, France.

Dendritic cells (DCs) consist of a heterogeneous population. Two distinct hematopoietic lineages, CD14+ monocytes and CD34+ stem cells, when cultured under desirable conditions, differentiate into DCs. These immature DCs can be activated *in vitro* by a variety of simple chemicals such as haptens and several metals. The purpose of this work was to compare three differents DCs models in order to know if they respond identically to such stimuli (1) CD34+ cells differentiated with GM-CSF, TNF-α and Flt-3L during 7 days (CD34+-DCs), (2) CD14+ cells differentiated with GM-CSF, and IL-4 during 6 days (MoDCs) and (3) CD14+ cells differentiated with GM-CSF, TGF-? and IL-4 during 6 days (TGF-α+-MoDCs). We examined, *in vitro*, the effects of a metal, Nickel (Ni2+) known to be involved in contact allergy, on the expression of different markers: CD86, a co-stimulatory molecule, CD83 and CCR7 which is known to participate in the emigration of DCs from peripheral tissue to lymph nodes. Flow cytometric analysis revealed that immature DCs derived from monocytes expressed more CD86 than CD34+-DCs. When these cells were stimulated with Ni2+, CD86 was expressed at higher levels

on CD34+-DCs (13 fold) and on MoDCs (10 fold) than on TGF- $\alpha$ +-MoDCs (5 fold). CD83 was expressed at higher levels on immature TGF- $\alpha$ +-MoDCs (14.5 %) compared to immature CD34+-DCs (1.6 %) or immature MoDCs (5.3 %). Interestingly, Ni2+ induced a strong expression of CD83 in all three models [CD34+-DCs (48.6 %), MoDCs (93.6 %), TGF- $\alpha$ +-MoDCs (97.8 %)]. Moreover, CCR7 was also induced after Ni2+ stimulation and was more expressed on CD34+-DCs (34.4%) than on other models [TGF- $\alpha$ +-MoDCs (20.3%), MoDCs (9.1 %).].

## 659 INTRACELLULAR CYTOKINE STAINING PATTERNS OF ALLERGEN ACTIVATED LYMPH NODE CELLS (LNC).

N. Humphreys, R. Skinner, R. J. Dearman and I. Kimber. Syngenta CTL, Macclesfield, United Kingdom.

Topical exposure of BALB/c strain mice to the contact allergen 2, 4-dinitrochlorobenzene (DNCB), or to the respiratory allergen trimellitic anhydride (TMA) induces selective type 1 or type 2 cytokine secretion profiles, respectively. The contributions of CD4 and CD8 cells to these cytokine phenotypes have been investigated using flow cytometry for intracellular cytokine staining. Thirteen days following the initiation of exposure to chemical, auricular lymph nodes were excised, a single cell suspension prepared and cells cultured for 3h in the presence of mitogen and brefeldin A. Cells were stained with anti-CD4 or CD8 antibodies, fixed, permeabilized with saponin and stained with anti-cytokine antibodies. An increased frequency of interleukin (IL-4)+CD4+ LNC was recorded following TMA exposure compared with DNCB treatment (2.4% +/-0.5 and 0.5% +/-0.3, respectively, n=5 experiments). In all LNC populations less than 0.1% of CD8+ LNC expressed IL-4. Exposure to both TMA and DNCB resulted in marked increases in interferon (IFN)-7+ CD8+ cells (47% +/-7.3 and 48.4% +/-9, respectively), compared with vehicle-treated controls (19.5% +/-3.9). In all populations, less than 5% CD4+ LNC expressed detectable IFN-γ. This pattern of cytokine staining was also observed for a further pair of contact and respiratory allergens; formalin and fluorescein isothiocyanate (FITC). Relatively low levels of IL-4+CD4+ LNC were recorded following treatment with formalin, whereas exposure to FITC resulted in increased frequency of these cells (0.9% +/-0.3 and 8.5% +/-0.6, respectively; mean and range of 2 experiments). Similar numbers of IFN-γ+ CD8+ cells were observed following topical application of either chemical (52% +/-18 and 65% +/- 11, respectively). Thus, topical exposure of mice to either class of chemical allergen results in increased numbers of IFN-γ+CD8+ cells, but treatment only with respiratory allergens is associated with an elevated frequency of IL-4+CD4+ cells. The vigorous ÏFN-γ production by contact allergen-activated LNC is likely to be regulated at the level of secretion.

## THE SENSITIZING POTENTIAL OF PEANUT PROTEINS IN FOUR DIFFERENT MICE STRAINS.

L. M. Knippels<sup>1</sup>, A. H. Penninks<sup>1</sup> and <u>G. A. Bannon</u><sup>2</sup>. <sup>1</sup>Experimental Immunology, TNO Nutrition and Food Research, Zeist, Netherlands and <sup>2</sup>Product Characterisation Center, Monsanto, St. Louis, MO.

One aspect of the evaluation of genetically engineered crops prior to introduction to the public involves the determination of the potential allergenicity of the newly introduced protein(s). While present methods can identify known allergens or proteins with allergen characteristics, validated animal models to study the potential allergenicity of novel proteins are not yet available. In this study, four mice strains (Balb/C, C3H/HeJ, A/J, and C57/BL6) were compared for their ability to mount an IgE response to a peanut protein extract. Mice (n=5) were intraperitoneally (ip) sensitized with 0.1, 0.5 or 2.5 mg peanut-proteins with or without alum at days 0, 7 and 21. Serum samples obtained at day 0, 14 and 28 were tested for antigen specific IgE, IgG1 (both T-helper-2 mediated) and IgG2a (T-helper-1 mediated) antibody levels using a passive cutaneous anaphylaxis assay and enzyme-linked immunosorbent assay (ELISA). Clinical symptoms were also obtained by performing an active systemic anaphylaxis (ASA) test at day 45. Parenteral administration of peanut proteins, with or without alum, resulted in peanut protein-specific IgE, IgG1 and IgG2a antibody responses in all strains tested, although the responses were more pronounced upon co-administration with alum. In all strains the Thelper-2 mediated antibody responses (IgE and IgG1) were more vigorous compared to the IgG2a responses. The best antibody responses were observed in the C3H/HeJ mice followed by the A/J, Balb/C and C57/BL6 mice. In addition, a good correlation between the levels of specific IgE and the clinical symptoms, as determined by the ASA test, was observed in the C3H/HeJ, A/J and C57/BL6. Sera from peanut protein sensitised Balb/C mice elicited strong PCA reactions but little or no clinical reactions. From these studies it was concluded that the most sensitive strains were the C3H/HeJ and A/J mice. Whether these strains will also be able to distinguish between strong-, weak-, and non-allergenic proteins will be part of future research.

## 661 EVALUATION OF PROTEIN ALLERGENIC POTENTIAL: STUDIES IN MICE.

S. Stone, H. Caddick, R. J. Dearman and I. Kimber. Syngenta CTL, Macclesfield, United Kingdom.

There is a growing interest in the development of approaches for the characterization of the allergenic potential of proteins. Although most foreign proteins are immunogenic (able to induce IgG antibody responses), relatively few are important food allergens with the capacity to provoke IgE antibody production and immediate type hypersensitivity responses. The majority (90%) of food allergic reactions are due to ingestion of 8 main foodstuffs; eggs, cows milk, peanuts, nuts, shellfish, tree nuts, wheat and soybeans. We have examined the allergenic potential of a range of proteins as a function of the induction of IgE antibody responses following systemic (intraperitoneal; ip) exposure of BALB/c strain mice. Animals were exposed to proteins from the major allergenic food groups peanut, egg and cows milk (peanut agglutinin, ovalbumin [OVA] and bovine serum albumin [BSA]); to patatin, the major allergen in potato, a foodstuff with a relatively low allergenic potential, and to potato agglutinin, a material considered to lack allergenicity. Specific IgE antibody was measured by homologous passive cutaneous anaphylaxis assay and specific IgG antibody measured by enzyme-linked immunosorbant assay. Each of the proteins induced IgG antibody responses at all doses tested (0.2% to 10%), although there was some variation with respect to vigor of IgG responses. High titer IgE antibody was provoked by peanut agglutinin, OVA and BSA whereas patatin stimulated relatively low titer IgE antibody over the dose ranges examined. Potato agglutinin stimulated low titer IgE antibody at the highest dose (10%) only. Importantly, differences in IgE antibody production were observed against a background of equivalent immunogenicity (IgG antibody responses), with the vigor of the IgE response broadly reflecting the relative sensitizing potential of human allergens. These data suggest that the measurement of antibody (IgE) responses in BALB/c mice may allow discrimination between allergens and those materials that apparently lack significant allergenic potential.

# PROGRESS IN THE EVALUATION OF AN IN-BRED RAT STRAIN ("ASTHMATIC RAT") FOR PREDICTING THE ALLERGIC POTENTIAL OF FOOD AND OTHER PROTEINS.

D. M. Hinton, M. Lorenzo, S. B. Harper and S. Francke-Carroll. CFSAN, USFDA, Laurel, MD.

Inbreeding of the Sprague-Dawley rat strain for dyspenic reactions to challenge with egg albumin (OVA) was first reported by Holme and Piechuta (Immunology, 42, 1981) for evaluation of the efficacy of anti-asthmatic drugs. Using a protocol consisting of subcutaneous sensitization with one mg of protein in alum followed by i.p. challenge at two to three weeks, we evaluated respiratory and other physiologic changes as well as the histopathology after challenge to various food proteins, i.e. purified ara-H2 from peanuts, glycinin and beta-conglycinin from soy, tropomyosin (TROPO) from chicken muscle, and OVA. Also, we have compared the respiratory responses of the Asthmatic rat to the normal out-bred Sprague-Dawley strain using the Buxco Electronics (Troy, NY) non-invasive whole body plethysmograph after challenge with 10  $\mu g$  of OVA. The respiratory responses are typically characterized by rapid or labored breathing 10 to 20 min after challenge. Asthmatic female rats are considered to be more sensitive than males responding maximally to one µg of OVA compared to 10 µg for male Asthmatic rats. Neither female nor male normal Sprague-Dawley rats responded to the 10 µg OVA challenge. Using a time/incremental dose protocol (one to ten µg) for the four proteins, greater responses were seen for OVA than with ara-H2, the soy proteins, and tropomyosin with female rats at the one  $\mu g$  dose. Tentative ranking at the low doses would be OVA>ara-H2>SOY>>TROPO. At the 10 ug dose, a tentative ranking would be ara-H2>OVA>SOY>>TROPO. The tropomyosin was chosen as a nonallergen protein control. No responses were seen at any of the doses tested with this protein. In conclusion, the Asthmatic rat is a promising animal model for evaluating the allergic potential of proteins.

## influence of endotoxin on ige responses to protein allergens.

R. J. Dearman and I. Kimber. Syngenta CTL, Macclesfield, United Kingdom.

Specific IgE antibody is the key biological mediator of immediate type hypersensitivity reactions including food allergy and asthma. It has been demonstrated previously that the endotoxin content of protein allergen can impact significantly on the quality of immune response provoked. Thus, intranasal (in) exposure of mice to the food allergen and asthmagen ovalbumin (OVA) in the presence of low levels of endotoxin (0.1 $\mu$ g per mouse) enhanced type 2 responses including IgE production and airway hyperreactivity. Identical treatment in the presence of high dose endotoxin (100 $\mu$ g per mouse) resulted in a type 1 response, with inhibition of IgE anti-

body expression. We have demonstrated previously that systemic (intraperitoneal; ip) administration of OVA to BALB/c strain mice stimulates a vigorous IgE antibody response. We have now investigated the impact of exogenous endotoxin on the induction of anti-OVA IgE antibody production. Animals (n=5) received 1% OVA supplemented with various concentrations of endotoxin (lipopolysaccharide from E coli serotype 055 B5) by ip injection on days 0 and 7. Seven days later, serum samples were analyzed for specific IgE antibody by homologous passive cutaneous anaphylaxis assay. Exposure to 1% OVA resulted in high titer IgE antibody (1 in 32) that was unaffected by co-administration of endotoxin (0.025 to 6.25µg per mouse), doses that encompass those reported to influence IgE antibody responses induced by in exposure to OVA. Endogenous endotoxin content of OVA preparations was measured by Limulus Ambeocyte Lysate (LAL) assay with a chromogenic end point. There was some inter-batch variation in endotoxin content of OVA, with samples varying from approximately 0.1 to 1µg per mg of protein. These concentrations equate to an endogenous endotoxin dose of 0.25 to 2.5µg per mouse. These data suggest that IgE responses to protein allergen administered by the ip route are less affected by endotoxin content than are those induced by in exposure to protein. Furthermore, the amounts of endogenous endotoxin contained within the protein preparation are unlikely to affect IgE responses.

FUNCTIONAL REGULATION OF HUMAN MICROSOMAL EPOXIDE HYDROLASE BY ALTERNATIVE GENE PROMOTERS AND SPLICING VARIANTS

S. Liang, C. Hassett and <u>C. Omiecinski</u>. Veterinary Science, The Pennsylvania State University, University Park, PA.

The human microsomal epoxide hydrolase (EPHX1) is a key enzyme involved in bioactivation or detoxification of environmental and pharmaceutical compounds. Previously, we identified two alternative splicing variants in human tissues that differ in the noncoding exon 1 (Ex1 and Ex1b) region. The Ex1 variant is specifically expressed in the liver whereas the Ex1b variant is expressed in most human tissues. In this study, the alternative promoters for Ex1 and £1b were cloned and characterized. Transient transfection of the reporter constructs demonstrated that Ex1 promoter was active in the human hepatoma cell lines HepG2 and Huh7 but not in transformed kidney cells 293A, whereas the Ex1b promoter was active in all cells. These results are in accordance with our finding that the Ex1 variant is specifically expressed in the liver tissue, suggesting that HepG2 and 293A can be used as model systems to study the differential regulation of Ex1 and Ex1b variants. Mutagenesis analyses indicated that 200 bp and 300 bp regions upstream of Ex1 and Ex1b, respectively, contributed to the basal transcription of these two variants. Multiple ciselements in the -200-Ex1 region were further identified as associated with the control of Ex1 variant expression. The cis-elements include a potential GATA binding site (-118 to -98), a CCAAT-binding factor site (-88 to -68), and a GC-rich site (-48 to -28). Several other EPHX1 splicing variants are reported in NCBI AceView data base. In the process of further characterizing these variants, we identified two other EPHX1 splicing variants by RT-PCR. One variant possesses an alternative exon 1 (Ex1b'), representing an extended sequence of Ex1b, and was detected in all cell lines tested. Another variant detected only in Huh7 cells contains Ex1b as exon 1 and possesses a deletion of exon 4. Together with our previous studies, these results indicate that functional regulation of EPHX1 is subjected to a complex program involving genetic polymorphism and altered regulation of gene expression. MOLECULAR MECHANISMS OF SUBCELLULAR LOCALIZATION OF HUMAN GLUTATHIONE REDUCTASE.

L. K. Rogers, T. Tamura, B. J. Rogers, T. N. Hansen, <u>S. E. Welty</u> and <u>C. V. Smith</u>. Columbus Children's Research Institute, Columbus, OH.

Human Glutathione reductase (hGR) is encoded by a single nuclear gene, but GR protein and activities are found in cytoplasmic, mitochondrial, and nuclear compartments. Mitochondrial localization is attributed to an N-terminal, 43 amino acid mitochondrial targeting signal (MTS) that is coded by a 129 bp sequence immediately 5′ to the GR coding sequence, but the mechanisms involved in nuclear localization are unknown. Transfections of 293T cells with hGR cDNA without the MTS increased GR activities in cytoplasm only, whereas constructs including the MTS increased GR activities in the mitochondria and nuclei as well as the cytoplasm. A fusion protein consisting of MTS-GFP directed GFP immunofluorescence to the mitochondria. Examination of the GR amino acid sequence revealed a putative NLS in the C-terminal region of GR (416KRKTK420), but mutation of this sequence did not abolish nuclear GR localization. Deletion mutations of the MTS-hGR were prepared and transfected into 293T cells, GR activities were measured, and cells were analyzed by confocal microscopy. The (aa 2 to 15) MTS deletion gave lower mitochondrial GR activities than did MTS-hGR, but nuclear activ-

ities were not affected. The (aa 2 to 30) deletion gave higher cytoplasmic GR activities than did MTS-hGR, but the nuclear and mitochondrial activities were not increased above the activities in native cells. The deletion of (aa 42 to 50) which omits the last aa of the MTS and first 8 aa of hGR, including the second ATG, gave lower cytoplasmic, higher mitochondrial, and equivalent nuclear activities than did MTS-hGR. In contrast, a construct containing a point mutation of the second ATG gave lower cytoplasmic, unchanged mitochondrial and higher nuclear activities than did MTS-hGR. In conclusion, mitochondrial expression of GR is directed by the MTS, but nuclear localization of GR is determined in part by elements of the MTS between aa 15 and 30. The mechanisms through which cells may modulate subcellular expressions of GR, as in response to metabolic or toxicant-induced stresses remain to be studied.

CHARACTERIZATION OF FOUR MERCAPTURIC ACID URINARY METABOLITES OF 3-BUTENE-1, 2-DIOL.

S. L. Christopher and A. A. Elfarra. Center for Molecular and Environmental Toxicology and Department of Comparative Biosciences, University of Wisconsin-Madison, Madison, WI.

3-Butene-1, 2-diol (BDD) is a major metabolite of 1, 3-butadiene (BD), a known rodent and human carcinogen. In vitro studies showed BDD can be readily oxidized to yield hydroxymethylvinylketone (HMVK), a Michael acceptor. In this study, male B6C3F1 mice and Sprague-Dawley rats were given BDD (25 - 200 mg/kg, i.p.) and the amounts of four HMVK derived mercapturic acids (4-(Nacetyl-L-cystein-S-yl-)-1-hydroxy-2-butanone [HB], 4-(N-acetyl-L-cystein-S-yl-)-1, 2-dihydroxybutane [DHB], 3-(N-acetyl-L-cystein-S-yl-)propan-1-ol [POH], and 3-(N-acetyl-L-cystein-S-yl-)propanoic acid [PA]) were measured. Mercapturic acids were extracted from urine, derivatized, and then quantified by GC/MS. In previous studies, urine DHB levels were measured to assess human BD exposure. While DHB, POH and PA have been reported as mouse or rat urinary BD metabolites, HB has not been previously identified as a metabolite of BD or its metabolites. The total amounts of the mercapturic acids excreted after BDD exposure were dose-dependent and similar between mice and rats given equivalent doses of BDD. The percentage of the dose present as the total mercapturic acids significantly increased with decreasing the dose in both species. The major mercapturic acid excreted by mice was DHB whereas rats excreted equivalent amounts of DHB and HB. The urine POH and PA amounts increased after BDD treatment but the levels of these two mercapturic acids were significantly lower in both species relative to DHB and HB and mice excreted more POH than PA. The results provide evidence that HMVK formation represents a prominent route for BDD metabolism in both mice and rats. This finding is significant because HMVK has potential to bind to macromolecules and disrupt cellular function thus contributing to BD toxicity. The observed species difference in BDD metabolic profile is consistent with the reported variability of the human DHB biomarker data. Collectively, the results may improve human biomonitoring studies. (supported by ES06841)

MECHANISTIC INVESTIGATION ON CYTOTOXICITY OF STYRENE.

J. Zheng, J. Chung and W. Yuan. Pharmaceutical Sciences, Northeastern University, Boston, MA.

Styrene (ST) is one of the most important industrial chemicals widely used in the production of many commercial polymers. Human exposures occur from such diverse sources as automobile exhaust, cigarette smoke, carpets, heating systems, painting and even food packaging. ST has been found to be toxic to respiratory system. Formation of styrene epoxide has been suggested to be initial step for cytotoxicity of ST, and CYP2E1 has been speculated as one of possible cytochrome P450 enzymes responsible for bioactivation of ST. To probe the role of CYP2E1, we exposed transgenic cell line expressing CYP2E1 and cHo1 cell line (wild-type <2E1-/->) to ST and found CYP2E1 cells were more susceptible to ST than wild-type cells, indicating participation of CYP2E1 in ST cytotoxicity. To investigate the structure-activity relationships of ST, CYP2E1 cells were exposed to ST analogs ethyl benzene (EB), vinylcyclohexane (VH), and ethylcyclohexane (EH). EB and VH were found as toxic as ST, but EH showed no toxicity to the cells. This indicates that unsaturation (i.e. olefins) of ST analogs is required for their toxicity. Epoxides are known to be derived from olefins. We propose that EB and VH are metabolized to corresponding epoxides, and the resulting epoxide metabolites cause cell injury. To probe the role of epoxide metabolites in their cytotoxicity, we used glutathione derivatives and epoxide hydrolaes inhibitors as modulators. Ethyl glutathione ester was found to decrease cytotoxicity of ST, EB and VH, while soluble epoxide hydrolase inhibitors as well as microsomal epoxide hydrolase inhibitors dramatically increased cytotoxic effect of ST and the derivatives. In conclusion, CYP2E1 is an enzyme responsible for bioactivation of ST. Unsaturation is a critical structure required for ST cytotoxicity, and epoxide metabolites may play an important role in ST-induced cytotoxicity.

G. Chen. Physiological Sciences, Oklahoma State University, Stillwater, OK.

Phase I and phase II drug metabolizing enzymes are responsible for the detoxification of toxic compounds in food and drugs. Sulfotransferases (STs) belong to the phase II drug metabolizing enzymes. ST catalyzed sulfation is an important pathway in the metabolism of hydroxyl containing chemicals. Studies on drug metabolizing enzymes have focused mainly on the liver. Relatively less is known regarding detoxification processes in non-hepatic tissues. There have been reports on hormone regulation of STs since the 1980's. Xenobiotic induction of STs, especially intestinal STs, has not been well studied compared to other drug metabolizing enzymes. We have recently studied hepatic and intestinal STs induction by anti-cancer drugs tamoxifen (TAM), retinoic acid (RA), and methotrexate (MTX). Enzymatic assay, Western blot, and RT-PCR methods have been used to study changes in protein and mRNA levels after drug treatment in male and female Sprague-Dawley rats (10-12 weeks old) and in human Hep G2 and Caco-2 cell lines. The anti-folate, apoptosis inducing drug MTX was shown for the first time to be a novel xenobiotic inducer of rat liver and intestinal STs and human STs in Hep G2 and Caco-2 cells. The induction was found to be in transcription level. MTX has not been shown to induce other drug metabolizing enzymes. Like TAM and RA, intestinal inductions were found to be greater than the inductions found in liver. Further more, folic acid effects on MTX induction of STs were studied. Folic acid does not induce STs, but it can inhibit MTX induction of STs in a concentration-dependent manner. Currently, possible roles of folate receptor (FR) in the MTX induction of STs are being investigated.

BIOCHEMICAL COMPARISON OF ZEBRAFISH AND HUMAN ALDH2: USE OF ZEBRAFISH AS A MODEL FOR HUMAN ACETALDEHYDE METABOLISM AND TOXICITY.

N. Lassen<sup>1</sup>, T. Estey<sup>1, 2</sup>, <u>V. Vasiliou<sup>1, 2</sup></u>, <u>R. Tanguay<sup>3</sup></u> and A. Pappa<sup>1</sup>.

<sup>1</sup>Pharmaceutical Sciences, UCHSC, Denver, CO, <sup>2</sup>Pharmaceutical Biotechnology, UCHSC, Denver, CO and <sup>3</sup>Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR.

Ethanol is metabolized to acetaldehyde mainly by the alcohol dehydrogenase pathway (ADHs) and to a lesser extent by microsomal oxidation (CYP2E1) and the catalase-H<sub>2</sub>O<sub>2</sub> system. Acetaldehyde, which is responsible for some of the deleterious effects of ethanol, is further oxidized to acetate by aldehyde dehydrogenases (ALDHs). The mitochondrial ALDH2 is the most effective ALDH that metabolizes acetaldehyde. The aim of this study was to clone, express and characterize the biochemical properties of the zebrafish (Danio rerio) ALDH2, in order to validate the use of this freshwater teleost as a model for human ethanol toxicity. We have cloned and sequenced the zebrafish ALDH2 cDNA, which is 1, 892 bp excluding the poly (A\*) tail, and has 5' and 3' untranslated regions of 5 bp and 335 bp, respectively. Zebrafish ALDH2 encodes a protein of 516 amino acids, including the first methionine (MW = 56, 562), which is approximately 75% identical to mammalian ALDH2 proteins. Western blot analysis showed that zebrafish ALDH2 is expressed at high levels in muscle, heart and brain with moderate expression in liver, eye and swim bladder. Recombinant zebrafish and human ALDH2 proteins were expressed using the baculovirus system and purified using single-step affinity chromatography with Sepharose-5'AMP 4B. Purification of human and zebrafish ALDH2 revealed single protein bands at the expected molecular weight of 56 kDa on SDS-PAGE. The zebrafish ALDH2 was found to be catalytically active with acetaldehyde ( $K_m$  = 11.5  $\mu$ M) and propionaldehyde ( $K_m$  = 6.1  $\mu$ M), and similar kinetic constants were found with the human recombinant ALDH2 protein ( $K_m$  =  $3.2 \,\mu\text{M}$  and  $2.4 \,\mu\text{M}$ , respectively). Based on the results of this study, the zebrafish is a reasonable model for studying acetaldehyde metabolism and toxicity. This work was supported by NIH R01 AA11885 and NIH R21 AA12783 Grant.

REGIO-SPECIFIC ( $\omega$  TO  $\omega$ -6) LAURIC ACID HYDROXYLATION IN HUMAN RECOMBINANT AND PEROXISOME PROLIFERATOR-TREATED JUVENILE CATFISH MICROSOMES.

M. L. Haasch<sup>1, 2</sup>, A. W. Ford<sup>1</sup> and J. C. Allgood<sup>1</sup>. <sup>1</sup>RIPS, ECHR, Environmental Toxicology Research Program, The University of Mississippi, University, MS and <sup>2</sup>Pharmacology, The University of Mississippi, University, MS.

Most studies of lauric acid hydroxylation have focused on only two hydroxylation products,  $\omega$  and  $\omega$ -1. Modifications of an HPLC method (Lemaire et al., 1992) to include GC-MS (Buhler et al., 1997) have allowed more sub-terminal hydroxylation products including  $\omega$ -2 to  $\omega$ -6 to be quantified. Previously we have shown that in male rat liver microsomes,  $\omega$  to  $\omega$ -2 hydroxylation products of lauric acid, significantly increase in response to peroxisome proliferator chemicals (PPCs).

Interestingly, adult catfish exposed by i.p. injection, to the PPCs, clofibrate (CLO) or the more potent ciprofibrate (CPR), did not exhibit any changes in hepatic microsomal lauric acid hydroxylase (LA-OHase) activities, although kidney microsomal  $\omega$  and  $\omega\text{--}6$  products were increased significantly. In rainbow trout,  $\omega\text{--}1$  lauric acid hydroxylation is catalyzed by CYP2K1 and  $\omega$ -6 by CYP2M1 (Buhler and Wang-Buhler, 1998). Induction of CYP2K1/2M1-like immunoreactive proteins in catfish by 48 hr i.p. injection of CLO and CPR has been shown (Haasch, 1996). Waterborne, 48 hr exposure of juvenile channel catfish (*Ictalurus punctatus*; size range 7.24 g to 34.32 g) to 1 ppm CLO (4.12 nM) or 2, 4-dichlorophenoxyacetic acid (2, 4-D; 4.52 nM) produced significant increases in both ω-1 and ω-5 hydroxylation products. Unexpectedly,  $\omega$ -1 activity was absent in juvenile control and vehicle (DMSO) treated fish although we have previously shown that adults have relatively high  $\omega$ -1 activity (Haasch, 1998). Regio-specific lauric acid hydroxylation was also investigated in human recombinant microsomes for isozyme control, CYP4A11 and CYP2E1. There is potential for sub-terminal hydroxylation products to act as second messengers in cellular signal transduction or to interfere with steroid biotransformation. These hypotheses will be investigated in future research. (Work supported by ES07929)

METABOLISM OF TATTOO PIGMENT YELLOW 74 USING RAT LIVER MICROSOMAL PROTEIN OR XANTHINE OXIDASE.

Y. Cui<sup>1,3</sup>, N. V. Gopee<sup>1,3</sup>, F. E. Evans<sup>2</sup>, L. H. Couch<sup>1,3</sup>, M. I. Churchwell<sup>1</sup>, D. R. Doerge<sup>1</sup> and P. C. Howard<sup>1,3</sup>. <sup>1</sup>Division of Biochemical Toxicology, NCTR, USFDA, Jefferson, AR, <sup>2</sup>Division of Chemistry, NCTR, USFDA, Jefferson, AR and <sup>3</sup>NTP Center for Phototoxicology, NCTR, USFDA, Jefferson, AR.

Tattooing has increased in popularity in the past decade and is now considered a common form of personal artistic expression. Recent publications point out the increase in tattoo popularity has been accompanied by a change in the colorant in tattoo inks from inorganic salts to organic-based pigments. Very little is known concerning the pigments or combination of pigments in tattoo inks, or the biological availability, metabolism or toxicity of these pigments. In these initial studies, we examined the metabolism of Pigment Yellow 74 (PY74; CI 11741), a common monoazo pigment in yellow tattoo inks. Oxidative metabolism of PY74 was determined following aerobic incubation of PY74 with liver microsomes isolated from 3-methylcholanthrene treated male F344 rats. PY74 solubility in the incubations was increased by inclusion of bovine serum albumin to 10 mg/mL. Consumption of PY74 and formation of metabolites was linear for up to 30 min at 0.1 mg/mL microsomal protein. The predominant metabolite was isolated by HPLC and identified as a ring hydroxylation product (4-hydroxylation on the 2-methoxyaniline ring) using NMR and mass spectral (MS) methods. The identification of the second metabolite and determination of the CYP450 specificity of PY74 metabolism are in progress. PY74 contains a nitro group on the 2-methoxy-4-nitroaniline group that should be available for nitroreduction. PY74 was incubated with 0.2 University/mL xanthine oxidase under hypoxic conditions and the products were extracted. The nitroreduction of PY74 to the amino-derivative (NH2-PY74) of PY74 was detected by comigration on HPLC (UV-VIS and fluorescence detection) with authentic NH<sub>2</sub>-PY74, and additionally confirmed by MS analysis. These results demonstrate that PY74 can be metabolized by both aerobic oxidative and anaerobic nitroreductive pathways, and that these monoazo tattoo pigments should not be considered as inert chemicals.

672

REGULATION OF GLUCOCORTICOID-INDUCIBLE RAT HYDROXYSTEROID SULFOTRANSFERASE GENE EXPRESSION BY LIVER-ENRICHED TRANSCRIPTION FACTORS.

M. Alipour, J. R. Smigelski, A. Weckle and M. Runge-Morris. Inst. Environment Health Sciences., Wayne State University, Detroit, MI.

Rat hepatic hydroxysteroid sulfotransferase (SULT2A-40/41) is involved in the detoxication of bile acids and xenobiotics. Therefore, understanding its molecular regulation is essential. We previously showed that physiological doses of glucocorticoid (10<sup>-7</sup>M) induce SULT2A-40/41 gene transcription *via* a glucocorticoid receptor (GR)-mediated mechanism. Since the proximal promoter region of the SULT2A-40/41 gene contains consensus binding sites for the CCAAT enhancer binding protein (C/EBP) liver-enriched transcription factors, the hypothesis is that ligand activation of the GR induces the nuclear expression of C/EBP transcription factors that in turn, transactivate SULT2A-40/41 gene expression. We determined that incubation of primary cultured rat hepatocytes with dexamethasone (DEX, 10<sup>-7</sup>M) produced early increases in C/EBPα and C/EBPβ at 3h to 6h following DEX treatment. Subsequent inductions of SULT2A-40/41 mRNA and protein levels occurred at 24h and 48h, respectively. Transient transfections in primary cultured rat hepatocytes using SULT2A-40/41 reporter constructs demonstrated that cotreat-

ment with triamcinolone acetonide (TA,  $10^{-7} M$ ) and an expression plasmid containing dominant negative C/EBP effectively blocked TA-inducible SULT2A-40/41 transcription. These data implicate a role for GR-inducible C/EBP $\alpha$  and C/EBP $\beta$  in the transactivation of SULT2A-40/41 expression by physiological concentrations of glucocorticoid. Supported by NIH grant ES05823 and NIEHS Center Grant ES06639. Dominant negative C/EBP expression plasmid was a generous gift from Dr. Charles R. Vinson, National Cancer Institute, Bethesda, MD.

### 673 ONCOGENICITY EVALUATION OF NELFINAVIR MESYLATE IN RATS.

M. Zorbas<sup>1</sup>, M. McClain<sup>2</sup>, B. Jessen<sup>1</sup>, W. Evering<sup>1</sup>, G. Stevens<sup>1</sup>, R. Gasser<sup>3</sup> and L. Burns Naas<sup>1</sup>. <sup>1</sup>Pfizer Global Research & Development, San Diego, CA, <sup>2</sup>McClain Associates, Randolph, NJ and <sup>3</sup>Hoffmann-LaRoche, Basel, Switzerland.

The oncogenic and immunotoxic potential of nelfinavir mesylate (NFV) were evaluated in a 2 year oral (gavage) carcinogenicity study in SD rats at dose levels of 100, 300, and 1000 mg/kg/d. At the end of treatment, increased incidences of thyroid follicular cell hyperplasia and neoplasms were observed at 300 (07) and 1000 (0'/2) mg/kg/d. No other adverse effects were observed, including immunotoxicity evaluated at 1 & 6 mo. Results from previous studies indicated a number of effects in the liver and thyroid as well as metabolic profiles that suggested NFV may cause thyroid hyperplasia/neoplasia secondary to hormone imbalance by altering thyroid hormone disposition. To confirm this hypothesis, the effects of NFV on gene expression in rat hepatocytes and liver slices (in vitro), thyroxin plasma clearance, and thyroid gland function were evaluated. Compared to controls, gene expression analyses demonstrated an increased expression of glucuronyltransferase (UGT) and CYP450 3A1 in NFV-treated rat hepatocytes and liver slices. In rats treated with NFV (1000 mg/kg/d) for 1 month, liver weights and centrilobular hepatocellular hypertrophy were increased and minimal to mild diffuse thyroid follicular cell hypertrophy and early follicular cell hyperplasia were evident in the thyroid gland. TSH levels were significantly increased (3 fold), while T3/T4 and reverse T3 levels were unchanged indicating that a compensated state to maintain homeostasis of T3/T4 had been achieved. Plasma <sup>125</sup>I-thyroxin clearance was increased and the plasma thyroxin AUC $_{0.48}$  was reduced by 24% compared to control. In conclusion, these data indicate that thyroid neoplasms observed in the NFV treated rats are secondary to thyroid hormone imbalance. Increased thyroxine disposition contributes to the effects of NFV on thyroid gland function and is likely a result of UGT induction. These results are consistent with a well-recognized rat-specific mechanism for thyroid neoplasms.

### 674 SAFETY EVALUATION OF STEALTH® LIPOSOMAL CKD-602.

B. E. Stewart<sup>1</sup>, C. M. Engbers<sup>1</sup>, N. B. Modi<sup>1</sup> and A. P. Mould<sup>2</sup>. <sup>1</sup>ALZA Corporation, Mt View, CA and <sup>2</sup>Covance Laboratories, Madison, WI.

The safety of STEALTH® liposomal CKD-602 (S-CKD602) was evaluated in IV single and repeat dose GLP toxicity studies in CD® (SD) IGS rats and beagle dogs. CKD-602 is a topoisomerase I inhibitor that is being developed by Chong Kun Dang Pharmaceutical Corporation in South Korea as an antitumor treatment. ALZA Corporation is developing a liposome formulation of CKD-602 in order to prolong the circulation time and target drug exposure to tumor tissue. In repeat dose studies S-CKD602 was administered for six cycles of single IV doses two and three weeks apart in rats (0.05 to 0.6 mg/kg·dose; n=12/sex·grp) and dogs (0.025 to 0.070 mg/kg dose; n=6/sex grp), respectively. Control groups included saline and placebo liposomes, and in some cases, nonliposomal (free) CKD-602. One treatment-related death occurred in the rat after five repeat doses of 0.6 mg/kg dose of S-CKD602. In the dog, one death occurred after a single dose of 0.050 mg/kg S-CKD602, however, no deaths occurred with six administrations at the highest dose of 0.070 mg/kg·dose. Clinical signs of toxicity included fecal abnormalities, tooth abnormalities (rat only), and in the dog, rapidly reversible signs of a liposomal infusion reaction. Weight loss, decreased weight gain and decreased food consumption were seen after each dose administration in both species. Toxicokinetics were similar in males and females of both species, with increases in Cmax and AUC with increasing S-CKD602 dose. In the dog, the elimination half-life was approximately 1.3 h with free CKD-602 and approximately 9 to 18 h with S-CKD602. Dose-related, reversible myelotoxicity was seen in rats and dogs with administration of S-CKD602, with reticulocytes, white blood cells, and platelets most affected. Reversible microscopic changes in the rat and dog identified bone marrow (femur and sternum), thymus, gastrointestinal tissues and spleen as the target organs for toxicity by S–CKD602. The starting dose for Phase I Clinical studies, 0.1 mg/m², is one fifth the non–severely toxic dose in the dog of 0.025 mg/kg-dose  $(0.50 \text{ mg/m}^2 \cdot \text{dose}).$ 

#### 675 2-[4-AMINO-3-METHYLPHENYL] 5-FLUORO BENZOTHIAZOLE, 5F-203, A DRUG USED IN BREAST CANCER TREATMENT UP-REGULATES NAG-1

EXPRESSION: A POSSIBLE MECHANISM OF ACTION.

J. M. Martinez<sup>1</sup>, T. Sali<sup>2</sup>, R. Okazaki<sup>2</sup>, M. Hollingshead<sup>3</sup>, C. Hose<sup>4</sup>, <u>N. Walker</u><sup>1</sup>, A. Monks<sup>4</sup>, S. Baek<sup>2</sup> and T. Eling<sup>2</sup>. <sup>1</sup>LCBRA, NIEHS, Research Triangle Park, NC, <sup>2</sup>LMC, NIEHS, Research Triangle Park, NC, <sup>3</sup>Developmental Therapeutics Program, NCI, Frederick, MD and <sup>4</sup>SAIC Frederick Inc., NCI, Frederick, MD.

A candidate anti-tumor drug 5F-203 to be evaluated in the treatment of breast cancer inhibits cell proliferation and has potent anti-cancer activity. 5F-203 activates the AhR that results in the induction of CYP1A1 and CYP1B1 in the human breast cell line, MCF-7. However, microarray analysis revealed the most highly induced gene was NAG-1/MIC/PLAB that has pro-apoptotic activity and anti-cancer activity in several models suggesting that NAG-1 may mediate the anti-cancer activity of 5F-203. In an orthotopic mouse model for breast cancer, treatment with the L-lysylamide prodrug, Phortress, reduced the size of the breast tumors in a dose-dependent manner. Furthermore, expression levels of NAG-1 as measured with realtime RT-PCR and the size of the tumors appeared to be inversely correlated. MCF-7 cells, constructed to express NAG-1, yielded smaller tumors as compared to control cells in the mouse orthotopic model. In cultured MCF-7 cells, 5F-203 at nanomolar concentrations greatly enhanced NAG-1 protein expression in a time dependent manner and was the most potent inducer of NAG-1 expression when compared to other anti-cancer chemicals. NAG-1 expression in HCT-116 human colorectal tumor cells, and in LNCaP human prostate tumor cells, was increased by 5F-203 indicating the response was not restricted to breast tumors. In contrast to other anti-cancer drugs, 5F-203 does not increase the transcriptional activity of the NAG-1 gene as measured in luciferase promoter constructs but appears to increase the half-life of NAG-1 mRNA. These results provide a rationale for the increase in protein expression by this drug. This study supports the hypothesis that the anti-cancer activity of 5F-203 is mediated by NAG-1 that in part, may be dependent on the stimulation of apoptosis. NAG-1 may be a suitable marker for estimating the efficacy of 5F-203.

## 676 PIFITHRIN-α IS A POTENT ARYL HYDROCARBON RECEPTOR AGONIST.

M. S. Hoagland, E. M. Hoagland, G. M. Ziegler and H. I. Swanson. Molecular and Biomedical Pharmacology, University of Kentucky, Lexington, KY.

Pifithrin- $\alpha$  (PFTa), chemical inhibitor of p53-dependent apoptosis, is currently being developed to be used in chemotherapies to limit drug-induced toxicity in normal, p53+/+ cells. The mechanism by which PFTa inhibits p53, however, is unknown. Upon observing the structural similarities of PFTa to b-naphthoflavone as well as indole-containing compounds, we hypothesized that PFTa may act as an aryl hydrocarbon receptor (AhR) ligand. AhR activation induces gene expression of xenobiotic-metabolizing enzymes including CYP1A1 through dioxin response elements (DREs). We have found that PFTa acts as an AHR agonist that induces CYP1A1 expression in a DRE-dependent manner. Using gel shift and ligand binding assays, we have also shown that PFTa directly interacts with the AhR and induces formation of the AhR/ARNT DNA binding complex. Ongoing studies will determine whether inhibition of apoptosis by PFTa requires activation of the AhR signaling pathway.

## 677 PULMONARY FUNCTION EFFECTS OF A THREE-HOUR TOXICITY STUDY OF AMINOFLAVONE PRODRUG (NSC-710464) IN DOGS.

I. M. Grossi<sup>1</sup>, M. Lynch<sup>1</sup>, J. Merrill<sup>1</sup>, <u>J. Tomaszewski<sup>2</sup></u> and J. O. Peggins<sup>2</sup>. 
<sup>1</sup>Toxicology, Battelle, Columbus, OH and <sup>2</sup>NCI, NIH, Bethesda, MD.

Aminoflavone prodrug NSC-710464 exhibits excellent antineoplastic activity against the Caki-1 and A498 renal, MCF-7 breast, and OVCAR-5 ovarian cancer cell lines *in vitro* and *in vivo* against Caki-1 and A-498 xenografts. The objective of this study was to determine the effect of aminoflavone prodrug on pulmonary function in dogs treated once a week for three weeks. Dogs were administered a 3-hour continuous IV infusion of NSC-710464 at 0, 5.7 or 11.5 mg/kg (114 and 230 mg/m2) once per week for 3 weeks. Drug-related emesis occurred primarily after administration of the second and third doses. Increased respiratory rates with associated respiratory sounds were noted in the 11.5 mg/kg group. Swollen infusion sites were also noted in all NSC-710464 dosed animals. Dogs receiving aminoflavone had a 24% to 43% decline in diffusion lung capacity of CO (DLCO) values following the third dose. There was a similar decline in these animals diffusion constant of CO (KCO). At recovery, the DLCO and KCO values returned towards baseline values. There was no apparent change in total lung capacity (TLC-STPD), indicating no impairment of overall mechanical ventilation capacity. WBC

counts of treated dogs were consistently elevated in response to each infusion of the drug, and increased fibrinogen values were also noted in treated dogs. This was consistent with the thrombosis of the veins used for the infusions noted histopathologically. The increased fibrinogen response was also noted after recovery, but WBC values trended toward normal. Treatment related thrombosis was noted microscopically in all treated dogs and one vehicle dog. Drug-related histopathological lesions in the lung included multifocal chronic-active inflammation and thromboembolism. Thus, administration of the aminoflavone prodrug NSC-710464 by a three-hour continuous intravenous infusion at 5.7 or 11.5 mg/kg once a week for 3 weeks produced pulmonary toxicity in dogs.

## 678 EFFECT OF HUMAN APOB-100 ANTISENSE OLIGONUCLEOTIDE (ISIS 301012) ON THE EXPRESSION OF APOB-100 MNRA IN MONKEY.

T. Kim<sup>1</sup>, T. Zanardi<sup>2</sup>, M. Graham<sup>1</sup>, R. Crooke<sup>1</sup>, A. Levin<sup>1</sup> and <u>S. Henry</u><sup>1</sup>.

Toxicology/PKM, ISIS Pharmaceuticals, Carlsbad, CA and <sup>2</sup>Charles River Laboratories (SBi Division), Sparks, NV.

ISIS 301012 is an antisense inhibitor of human ApoB-100. In humans, ApoB-100 plays a critical role in controlling cholesterol biosynthesis and is the principal apolipoprotein of triglyceride rich, VLDL and LDL-cholesterol. This apolipoprotein is synthesized exclusively in the liver of non-human primates and man. ISIS 301012 is also complementary with the cynomolgus monkey mRNA with the exception of two base pair mismatches. It has been shown to inhibit ApoB-100 expression both human and monkey hepatocytes in vitro. We characterized toxicity and the pharmacological activity of ISIS 301012 on liver ApoB-100 mRNA expression in monkeys after 4 weeks of treatment. ISIS 301012 was administered by 1hour i.v. infusion at doses of 2, 4, and 12 mg/kg or s.c. injection at 2 and 20 mg/kg to monkeys. Doses were given on alternate days for the first 4 doses (loading) and every fourth day thereafter (maintenance). Results from this study reveal that acute and transient 1.2 to 1.3-fold increase in APTT was noted with high doses only during the first 4 hours after dosing. Basophilic granules containing oligonucleotide were observed in numerous tissues and are evidence of drug uptake by cells. After 1 week of treatment with 4 mg/kg, ApoB-100 mRNA expression in liver was reduced and the reduction was sustained up to 16 days after the cessation of treatment, consistent with the long half-life of the drug. There was a dose-dependent reduction in expression in liver after 4 weeks of treatment with up to 90% reduction of liver ApoB-100 mRNA in the highest dose group. When serum ApoB-100 protein was measured by serum ELISA, a dose-dependent decrease in ApoB-100 was observed. At the 12 mg/kg dose, \$\sigm40\%\$ reduction in monkey ApoB-100 was noted. Collectively, these data suggest that ISIS 301012 is a potent inhibitor of ApoB-100 that produced minimal alterations in clinical pathology or histopathology at 20 mg/kg. The prolonged target reduction by ISIS 301012 suggests that weekly or biweekly dosing in humans will be possible.

## 679 CJC-1295, A LONG-ACTING GROWTH HORMONE RELEASE FACTOR ANALOGUE, IS WELL TOLERATED IN RATS UP TO 14 DAYS.

V. Iordanova<sup>1</sup>, B. Lawrence<sup>1</sup>, <u>S. Morseth</u><sup>2</sup> and J. Castaigne<sup>1</sup>. <sup>1</sup>ConjuChem, Montreal, QC, Canada and <sup>2</sup>Milestone Biomedical Associates, Frederick, MD.

CJC-1295 is a synthetic modification of growth hormone releasing factor (GRF), the active core of growth hormone releasing hormone (GHRH) which predominately stimulates the pulsatile release of growth hormone (GH). By applying the Drug Affinity Complex technology to GRF, the peptide selectively and covalently bonds to circulating albumin after parenteral administration, thus prolonging its  $t_{1/2}$ , as seen in rats administered CJC-1295 ( $t_{1/2}$ =-20 h). The acute toxicity of CJC-1295 was evaluated in CD rats following single intravenous (IV) doses of 2, 4 and 8 mg/kg. CJC-1295 was generally well tolerated with transient decreases in food consumption at ≥2 mg/kg (↓62-90%), soft/mucoid stools (≥4 mg/kg), and decreased activity (8 mg/kg). Similar clinical signs were noted in a sub-chronic study in CD rats with every other day IV injections for 14 days at 0.25, 1 and 4 mg/kg, including transient decreases in food intake at ≥1 mg/kg (↓10-72%) and water consumption at 4 mg/kg (\$\psi 13-60\%), seen on dosing days only; feces soft/mucoid/watery (≥0.25 mg/kg), absent stool (≥1 mg/kg), decreased activity (≥1 mg/kg), lacrimation (4 mg/kg), and decreases in weight gain in males at ≥1 mg/kg (\$\scrip\*8-26%). There were no effects on survival, ophthalmology, urinalysis, bone marrow, and gross pathology. Hematologically, red blood cell counts, hemoglobin and hematocrit were slightly reduced at ≥0.25 mg/kg (↓5-15%). Clinical chemistry changes included mild increases in calcium, cholesterol, albumin, globulins and total proteins at all doses. Although liver weight increases were seen at ≥0.25 mg/kg (18-25%), there were no corresponding microscopic changes. Microscopic finding consisted of minimal injection site hemorrhage/inflammation/necrosis at all doses. There was partial or complete recovery of the findings after a 14-day treatment-free period. In conclusion, CJC-1295 was well tolerated in rats following IV doses up to 4 mg/kg for up to 14 days.

## 680 CJC-1131, A LONG-ACTING GLP-1 ANALOGUE, EXHIBITS SAFETY AND TOLERABILITY IN RATS AND DOGS UP TO 91 DAYS.

S. Wen<sup>1</sup>, B. Lawrence<sup>1</sup>, <u>S. Wilson</u><sup>2</sup> and J. Castaigne<sup>1</sup>. <sup>1</sup>ConjuChem, Montreal, QC, Canada and <sup>2</sup>Milestone Biomedical Associates, Frederick, MD.

CJC-1131 is an anti-diabetic compound being developed for the control of type 2 diabetes and is currently in Phase II clinical trials. By applying the Drug Affinity Complex (DAC) technology to glucagon-like peptide-1 (GLP-1), the hormone selectively and covalently bonds to circulating albumin after parenteral administration. The safety of CJC-1131 was evaluated in CD rats by subcutaneous (SC) every other day (q2d) administration at doses ranging from 0.05-1.8 mg/kg and in Beagle dogs by SC every three days (q3d) injections at doses of 0.04-4 mg/kg for 91 days. The toxicity profile was similar in both species. The primary test article-related effects included transient altered fecal output (e.g. few or absent feces, watery stools), decreased food and water consumption, and subsequent decreased body weight and/or body weight gains. Decreases in body weight gain in rats and dogs ranged from ~10-40% and ~25->100%, respectively, over 91 days with 4 mg/kg/q3d female dogs exhibiting a slight mean weight loss. Decreased activity was also observed in rats with secondary effects of salivation and material around nose. Occasional emesis was noted in dogs. Most changes in hematology and clinical chemistry parameters were not of biological or toxicological significance, and were consistent with those secondary to decreased food and water intake and decreased body weight. There was no consistent pattern to these changes that indicated any target organ toxicity and no histopathological findings that were attributed to treatment. The majority of the treatment-related findings exhibited reversibility during the four-week recovery periods in both species. In conclusion, with the exception of body weight effects, sub-chronic administration of CJC-1131 for 91 days was generally well tolerated up to 1.8 mg/kg/q2d in rats and up to 4 mg/kg/q3d in dogs with primarily exaggerated pharmacology-related effects.

## FOUR-WEEK COMBINATION TOXICITY STUDY OF ANTI-VLA4 ANTIBODY ADMINISTERED IV AND IFN β-1A ADMINISTERED IM IN THE RHESUS MONKEY.

M. Cooper<sup>1</sup>, V. Palmer<sup>2</sup>, G. Beattie<sup>4</sup>, J. Green<sup>2</sup>, P. Martin<sup>2</sup> and N. G. Wehner<sup>3</sup>.

<sup>1</sup>Biomarker Development, Biogen, Cambridge, MA, <sup>2</sup>Preclinical and Clinical Development Sciences, Biogen, Cambridge, MA, <sup>3</sup>Safety Evaluation, Elan, South San Francisco, CA and <sup>4</sup>Sierra Biomedical, Sparks, NV.

The objective of this study was to evaluate the potential toxicity of an anti-VLA4 antibody and IFN β-1a when administered alone and in combination to rhesus monkeys. Anti-VLA4 Ab is an anti-α4-integrin monoclonal antibody currently being developed for the treatment of multiple sclerosis. IFN β-1a is currently marketed for the treatment of this disease. Weekly administration of 30 or 60 mg/kg anti-VLA4 Ab I.V. for 4 weeks alone, or in combination with 30  $\mu g$  IFN  $\beta\text{-1a}$  IM, followed by an 8-week recovery period was well tolerated. Test-article-related effects were limited to anti-VLA4 Ab-related alterations in hematology parameters. These effects likely reflect the pharmacologic activity of anti-VLA4 Ab and did not occur in animals administered only IFN  $\beta$ -1a. There was no evidence of an additive effect on hematology parameters when the drugs were co-administered. Hematology effects were generally reversible; some alterations persisted in high dose anti-VLA4 Ab animals, probably due to the persistence of the antibody. The individual PK profiles for Anti-VLA4 Ab and IFN β-1a were not affected by co-administration. Histologic findings consisted of lymphoid hyperplasia in the spleen and peripheral lymph nodes, and leukocytosis and focal leukocyte aggregates in the liver. These findings often appeared to be more prominent in animals administered anti-VLA4 Ab. Changes in the intramuscular injection sites were possibly related to IFN  $\beta$ -1a administration. The findings are consistent with hyperplasia of both T-lymphocyte and B-lymphocyte populations in the spleen. After an 8-week recovery period, spleen weights were considered fully or partially recovered and histological changes were resolved. Because the test article related histologic changes were of minimal or mild severity and reversible, they were considered to be of minor toxicologic significance under the conditions of this study.

## RISING-DOSE TOLERABILITY STUDY OF A LYMPHOTOXIN BETA RECEPTOR AGONIST IN CHIMPANZEES.

M. Cooper<sup>1</sup>, V. Palmer<sup>2</sup>, T. J. Rowell<sup>3</sup> and J. Green<sup>2</sup>. <sup>1</sup>Biomarker Development, Biogen, Cambridge, MA, <sup>2</sup>Preclinical and Clinical Development Sciences, Biogen, Cambridge, MA and <sup>3</sup>New Iberia Research Center, New Iberia, LA.

LTBR mAb is a humanized monoclonal antibody that acts as an agonist to the lymphotoxin beta-receptor (LTBR). The LTBR is expressed on both neoplastic and normal tissues. Activation of the LTBR is expected to induce cell death or differentiation of neoplasms. LTBR mAb, which is being developed for treatment of

human solid tumors, is biologically active in humans and chimpanzees, but not macaques or other common laboratory species. The objective of this study was to determine the effects of LTBR mAb when administered intravenously in the chimpanzee and to determine basic pharmacokinetic parameters of LTBR mAb. Three male and three female chimpanzees were separated into two groups. Group 1 consisted of two males and two females. Group 2 contained one male and one female that had not been previously exposed to exogenous monoclonal antibodies. Group 1 was administered a single bolus intravenous infusion of LTBR mAb Placebo on Day 0 and were monitored for seven days post dose. Group 1 animals were then administered escalating doses of LTBR mAb at 1.0, 3.0, and 10.0 mg/kg at weekly intervals. Group 2 animals were administered a single bolus intravenous infusion of LTBR mAb Placebo on Day 21 then administered a single dose of LTBR mAb at 30 mg/kg on Day 28 to assess the effects of a single dose of LTBR mAb. This dose was selected as it represents an approximate 30-fold increase over the projected clinical dose of 1 mg/kg and would thus provide a reasonable assessment of potential toxicity. Samples were collected at various time points for pharmacokinetics, antibody concentrations, complete hematology panel, serum chemistries, coagulation profiles, cardiac parameters, and serum electrophoretic profiles. All animals survived the study. No clinical signs of test article-related toxicity were noted in any of the study parameters. LTBR mAb is thus concluded to be safe and well-tolerated when administered intravenously at doses up to 30 mg/kg in chimpanzees.

### 683 INTRAVENOUS PERI-POSTNATAL REPRODUCTION STUDY OF RHAT IN RATS.

M. S. Christian<sup>1</sup>, E. M. Lewis<sup>2</sup>, A. M. Hoberman<sup>2</sup> and R. A. Scotland<sup>3</sup>. <sup>1</sup>Argus International, Inc., Horsham, PA, <sup>2</sup>Charles River Discovery and Development Services, Argus Division, Horsham, PA and <sup>3</sup>GTC Biotherapeutics, Inc., Framingham, MA.

AT III deficiency, a rare hereditary disease, causes thromboembolic complications during pregnancy and childbirth. This study was conducted to support safe use of a transgenically-produced antithrombin human blood protein, rhAT, in pregnant women administered IV rhAT 3 days before and 3 days after delivery of an infant and to determine reproducibility of previous findings. In a previous study, in which female rats were treated IV with rhAT on DG 6 through DL 20 (~37 daily dosages), maternal body weights and feed consumption were increased and postnatal pup mortality to DL 5 was significantly increased at 210 mg/kg/day. Although these findings potentially were associated with prolonged treatment, it was more probable that they were associated with the techniques (purchased pregnant rats) and number and extent of maternal and pup observations. In the current study, pregnant Crl:CD®(SD)IGS BR VAF/Plus® rats (30/group) were given rhAT or sodium citrate buffer (diluent) IV on DG 20 through DL 5, a more relevant treatment period (~8 daily dosages), at 0, 52.5, 105 or 210 mg/kg/day. Additional procedural differences from the previous study included onsite mating, multiple detailed daily clinical observations, a 24-hour litter watch (dams and pups), individual identification of pups, with daily clinical observations and body weights, and hematology and clinical chemistry parameters (dams and pups). Previous findings were not replicated. rhAT 105 and 210 mg/kg/day dosages produced transient increases in limb and/or facial swelling and pharmacologic increases in PT and APTT during gestation and/or lactation; maternal body weight and feed consumption were unaffected, findings consistent with studies in virgin female rats. rhAT dosages as high as 210 mg/kg/day did not adversely affect maternal reproductive parameters or pup viability or growth. Thus, the previous findings were not replicated when a more appropriate, detailed study design was used.

## 684 SINGLE AND 28-DAY REPEATED INTRAMUSCULAR DOSE TOXICITY STUDIES OF BOTULINUM TOXIN TYPE A IN RATS.

W. S. Koh<sup>1</sup>, M. K. Chung<sup>1</sup>, Y. B. Kim<sup>1</sup>, C. S. Ha<sup>1</sup>, G. H. Yang<sup>2</sup>, H. H. Chung<sup>2</sup> and T. C. Jeong<sup>3</sup>. Korea Institute of Toxicology, Daejeon, South Korea, <sup>2</sup>Medy-Toxicology, Asan, South Korea and <sup>3</sup>College of Pharmacy, Yeungnam University, Kyungsan, South Korea.

Botulinum toxin type A was intramuscularly administered to Sprague-Dawley rats in both single and 28-day repeated dose toxicity studies. In the single dose toxicity study performed at 25, 50, 100, and 200 ng/kg, LD50 was estimated to be 70.71 ng/kg for males and 97.63 ng/kg for females. The major clinical signs observed were paralytic gait, decrease of locomotor activity, ananastasia, and death. The 28-day repeated dose toxicity study performed at dose levels of 1, 3, and 9 ng/kg/day showed an attenuation of body weight gain in a dose-dependent manner. This attenuation of body weight gain was considered due to the decrease of food and water consumption observed in the animals treated at 9 ng/kg/day and continued throughout a 4-week withdrawal period on completion of dosing. Paralytic gait was a common clinical sign observed in the animals treated at 3 ng/kg/day and muscle atrophy as well as paralytic gait were monitored at 9 ng/kg/day. Serum aspartate an-

imotransferase in males treated at 9 ng/kg/day was significantly higher than that of the vehicle-control males. No changes attributable to the administration of the botulinum toxin were observed in organ weight, ophthalmologic and hematological examinations. Histopathological examination of femoral muscle, which was the test substance-application site, revealed an atrophy of skeletal muscle. It showed a decrease in myofibre diameter and an increase of myofibre nuclei and intermyofibre connective tissue. The NOAEL of botulinum toxin type A is 1 ng/kg for 28-day repeated intramuscular dose toxicity in rats.

# A HUMANIZED ANTI-TISSUE FACTOR MONOCLONAL ANTIBODY DOES NOT INCREASE THE RISK OF SURGICAL BLEEDING IN A CYNOMOLGUS MONKEY

P. J. Bugelski<sup>1</sup>, E. C. Martin<sup>2</sup>, V. Mendenhall<sup>2</sup>, A. R. Soderman<sup>1</sup>, S. H. Tam<sup>1</sup>, K. M. Picha<sup>1</sup>, V. S. Khandekar<sup>1</sup> and <u>G. Treacy</u><sup>1</sup>. <sup>1</sup> Centocor, Inc., Malvern, PA and <sup>2</sup> Charles River Labs, Worcester, MA.

A humanized IgG4 monoclonal antibody (mAb) that blocks human and cynomolgus monkey tissue factor (TF)-mediated coagulation was evaluated in a surgical bleeding model in cynomolgus monkeys. The purpose of the study was to determine if the anti-tissue factor mAb is associated with a significant risk of uncontrollable bleeding. Doses of 0.006, 0.06, 0.6, 6 and 60 mg/kg of the anti-tissue factor mAb caused a dose-dependent prolongation of PT and inhibited the LPS-induced up-regulation of prothrombin fragment F1+2 and fibrin D-dimer. Monkeys were anesthetized and a laparotomy performed. Four 6 mm diameter x 2 mm deep biopsies were cut from the liver, kidney and spleen and the resultant wounds covered with Surgicel®. Blood loss over a 1 hr observation period was quantified by weight and was the data expressed as % total blood volume. Anti-tissue factor mAb at a dose of 60 mg/kg did not inhibit the ability of Surgicel® to control bleeding. In contrast, heparin (300 University/kg) and activated protein C (25 mg/kg) significantly increased blood loss. Anti-tissue factor mAb may be a safe and effective means to control the undesirable activation of the coagulation system mediated by tissue factor.

## A 4-WEEK SUBCUTANEOUS INJECTION TOXICITY STUDY OF PTH-FC WITH A 4-WEEK RECOVERY PERIOD IN THE ALBINO RAT.

<u>I. E. Atkinson<sup>1</sup></u>, <u>C. Alcalde<sup>1</sup></u>, <u>M. E. Cosenza<sup>1</sup></u>, S. Y. Smith<sup>2</sup>, N. Doyle<sup>2</sup>, C. R. Dunstan<sup>3</sup>, C. Zimmermann<sup>1</sup> and P. Kostenuik<sup>4</sup>. <sup>1</sup>Toxicology, Angen Inc., Thousand Oaks, CA, <sup>2</sup>CTBR, Senneville, QC, Canada, <sup>3</sup>ANZAC Research Institute, Concord, NSW, Australia and <sup>4</sup>Metabolic Disorders, Angen Inc., Thousand Oaks, CA

To determine the toxicity of PTH-Fc, Sprague-Dawley rats received subcutaneous injections twice weekly for 4-weeks. Upon completion of the dosing period a 4week treatment-free recovery period was employed to determine the reversibility of any findings. Two hundred eighty-eight rats were assigned to 4 groups receiving 0, 0.2, 2 or 8 mg/kg/dose. Clinical observations, hematology, clinical biochemistry, toxicokinetic and antibody sampling were routinely performed throughout the experiment. Gross pathology, histopathology and organ weights were evaluated. Clinical observations seen in the high dose group only included, but were not limited to, lethargy (decreased activity, lateral recumbency), inappetence and abnormal breathing. Treatment-related mortality on Days 13 and 14 likely associated with hypercalcemia and/or uremia led to early euthanasia of the high dose group. Tissue mineralization was noted in, but not limited to, the heart, kidney and pancreas and is considered secondary to the hypercalcemia seen in the mid- and high-dose groups. Treatment-related changes were seen in the hematological parameters for both the mid- and high-dose groups. Biochemical parameters, including BUN and electrolyte values, notably changed for all groups receiving test article. Generally, changes seen in hematology and biochemistry parameters were reversible at the end of the recovery period and correlated to the histopathological findings upon the completion of the study. The high dose group exhibited a relative increase of heart, kidney and spleen weights in males and females when compared to controls. These differences are considered to be treatment-related. Based on findings of hypercalcemia, pathology changes in tissues, and changes in hematology and biochemistry parameters the NOAEL was 0.2 mg/kg.

### DOSE RANGE-FINDING STUDY OF HALOFUGINONE (NSC-713205) IN RODENTS.

D. Kobs<sup>1</sup>, P. J. Tosca<sup>1</sup>, L. Bollinger<sup>1</sup>, I. M. Grossi<sup>1</sup>, <u>J. Tomaszewski<sup>2</sup></u> and J. O. Peggins<sup>2</sup>. <sup>1</sup>Toxicology, Battelle, Columbus, OH and <sup>2</sup>NCI, NIH, Bethesda, MD.

Angiogenesis inhibitors such as halofuginone have shown great potential in the treatment of various cancers. They possess anti-metastatic and anti-proliferative properties due to their ability to suppress extracellular matrix deposition, cell proliferation and angiogenesis. Rats were utilized to determine the maximally tolerated

dose and relative drug toxicity of halofuginone when administered twice weekly for 4 consecutive weeks. Thirty male Fischer 344 rats received intravenous doses of 0, 0.75, 1.5, 3.0, 3.5, or 4.0 mg/kg halofuginone. A high incidence of drug-related mortality occurred in rats at the two highest dose levels. Dosing was suspended following the third dose administration for the 3.5 and 4.0 mg/kg groups due to the moribund condition of the animals. A drug related effect at 3.5 and 4.0 mg/kg was noted by marked clinical observations (lethargy, hunched posture, red eye/nasal discharge, unresponsive, alopecia, thin appearance, soiled anal region and urine stain) and group mean body weight decreases. Changes in hematology and serum chemistry parameters were also noted. Histological review of the bone marrow and spleens of all 3.5 and 4.0 mg/kg rats indicated toxicologically significant hematopoietic depression. Several serum chemistry parameters were also decreased in the 3.5 and 4.0 mg/kg groups. Decreases in TP and ALB were attributed to gastrointestinal toxicity (diarrhea), which corresponded to intestinal lesions seen microscopically (necrosis, edema, dilation, hyperplasia, and/or ulcers). Elevated BUN and CREA were noted in many unscheduled-death rats, related to dehydration secondary to the reported diarrhea. Rats in the 3.0 mg/kg group and lower had few or no clinical signs (non-drug related). Based on these findings, doses of halofuginone at 3.5 mg/kg and higher produced high mortality, bone marrow depletion and gastrointestinal toxicity. Findings at doses of 1.5 and 3.0 mg/kg were not as severe and reversible. The maximally tolerated dose in rats appears to be between 3.0mg/kg and 3.5mg/kg.

#### 688 28-DAY ORAL (GAVAGE)TOXICITY STUDY OF SE-METHYLSELENOCYSTEINE IN DOGS.

<u>W. Johnson</u><sup>1</sup>, J. Lopez<sup>1</sup>, R. Morrissey<sup>2</sup>, C. Ip<sup>3</sup>, I. Kapetanovic<sup>4</sup> and <u>D. McCormick</u><sup>1</sup>. <sup>1</sup>IIT Research Institute, Chicago, IL, <sup>2</sup>Pathology Associates, Chicago, IL, <sup>3</sup>Roswell Park Memorial Institute, Buffalo, NY and <sup>4</sup>National Cancer Institute, Bethesda. MD.

Se-Methylselenocysteine (MSC) is an organoselenium compound being developed for breast cancer prevention. This study was conducted to characterize the toxicity of subchronic oral administration of MSC in dogs. Beagle dogs (4/sex/group) received daily oral (gavage) exposure to MSC (in purified water) at doses of 0, 0.15, 0.3, or 0.6 mg/kg/day for 28 days. Toxicology endpoints included body weight, food consumption, clinical observations, clinical chemistry, hematology, coagulation, urinalysis, ophthalmology, electrocardiography, organ weights, gross pathology, and microscopic pathology. The high dose of MSC induced weight loss in two male dogs; one of these dogs also exhibited hypoactivity, hypothermia, salivation, and decreased food consumption. No other effects on body weight, food consumption, or other clinical signs of toxicity were observed in any dog exposed to MSC. Modest anemia was observed in both sexes exposed to the high dose of MSC; slight anemia was seen in males exposed to the middle dose. Fibrinogen levels were increased in high dose males. No treatment-related alterations in clinical chemistry or urinalysis parameters were observed, and the results of ophthalmic and electrocardiographic evaluations were within normal limits. Absolute and relative thymus weights were decreased in males receiving the high dose of MSC; no other organ weight changes were seen. Treatment-related microscopic lesions were observed in the liver, duodenum, ileum, thymus, and epididymides of MSC-treated dogs. Although changes in one or more organs were seen in all dose groups, only hepatic changes (peliosis hepatic and midzonal vacuolar degeneration) present in high dose males were considered to be toxicologically significant. On the basis of body weight loss, clinical signs, anemia, and microscopic liver toxicity seen in high dose males, the No Observed Adverse Effect Level (NOAEL) for MSC in beagle dogs in this study was defined as 0.3 mg/kg. (NCI N01-CN-15140)

## ACUTE AND SUB ACUTE ORAL TOXICITY OF VEGPANZYME IN MICE AND RATS.

S. N. Shah<sup>1</sup>, A. University. Burhan<sup>1</sup>, S. L. Bodhankar<sup>1</sup>, S. P. Risbud<sup>2</sup> and S. Kurundkar<sup>3</sup>. <sup>1</sup>Pharmacology, Bharati Vidyapeeth Deemed University, Pune, Maharashtra, India, <sup>2</sup>Advanced Biochemicals Ltd.,, Thane, Maharashtra, India and <sup>3</sup>Raj Biotech (India) Pvt. Ltd.,, Satara, Maharashtra, India. Sponsor: <u>H.</u> Mehendale.

Vegpanzyme, a mixture of proteolytic enzymes is used to treat GIT disorders. The objective of the study was to evaluate the acute and subacute oral toxicity of Vegpanzyme in mice and rats. Wistar rats of either sex weighing 100 to 150g and Swiss Albino mice weighing 18 to 22g were used. Mice received 50, 300, 2000 and 5000mg Vegpanzyme/kg(AOT 425, OECD guidelines). In subacute toxicity study 4 groups of each gender (4M&4F) received distilled water, 100, 200 or 400mg Vegpanzyme/kg/day for 28 days. Body weight and food consumption was recorded. On day29, the animals were sacrificed. Haematological and clinical chemistry parameters were measured. Histology of rat organs was performed. No clinical signs of toxicity or mortality was seen during the 14 days after the end of treatment period. The LD50 was >5000 mg Vegpanzyme/kg and the animals were free from any

toxic effect on haemoglobin, RBC, WBC, DLC and ESR at the doses of 100, 200 and 400mg/kg. At 400mg/kg a weak (non significant) hypoglycemic effect was observed. Vegpanzyme did not alter Blood cholesterol, triglycerides, HDL and VLDL compared to vehicle treatment. Vegpanzyme 400 and 100mg/kg decreased serum urea, potassium concentration and creatinine respectively. Vegpanzyme(100, 200&400 mg/kg) produced increase in plasma alkaline phosphatase (ALP) and decrease in ALT and AST. The histopathology of liver and kidneys indicated minimal changes. Histopathology indicated consistent but insignificant changes of haemorrhage and congestion in spleen. At 100 and 400mg/kg Vegpanzyme caused minimal, focal MNC in myocardial tissue. No abnormality was detected in stomach. At the lower doses of 100 and 200mg Vegpanzyme/kg did not alter the body weight of rats. However, at higher doses of 400mg/kg a nonsignificant reduction in body weight was observed. Vegpanzyme did not alter organ weight of rats. It was thus concluded that Vegpanzyme at the doses of 100 and 200mg/kg is non-toxic. However, at higher dose, the drug is likely to alter function of spleen and heart.

#### 690

A NON-HUMAN PRIMATE MODEL OF COLLAGENINDUCED ARTHRITIS: ITS ONSET AND THE EFFECTS OF METHOTREXATE.

H. Kasai, H. Sameshima, H. Tsusaki, N. Horai, S. Kojima, H. Tokado and R. Nagata. DSR Laboratories, SNBL, Kagoshima, Japan.

Collagen-induced arthritis (CIA) has been used in several species, primarily rodents, in order to evaluate rheumatoid arthritis. However, little data exists of CIA in non-human primates, and most data is from rhesus monkeys. In this study, we selected cynomolgus monkeys, which are commonly used in safety and efficacy studies. The objectives were to identify whether they can be employed in a CIA model by investigating the onset to arthritis and any effects of methotrexate (MTX, Wako Pure Chemical Industries, Ltd., Japan). Forty-five females, weighing 2.0 to 3.5 kg, were sensitized with an emulsion of type II bovine collagen and Freund's complete adjuvant. The emulsion was administered 3 times at 3-week intervals. The area of the interphalangeal (IP) joints of all limbs were measured sequentially using calipers. The mean IP area was measured in order to evaluate the onset of CIA. Animals in which the mean IP area increased 105% or greater from the 1st sensitization were defined as CIA animals. Five animals were selected from this group and were treated with MTX at 0 (control), 3, or 10 mg/animal twice weekly for 8 weeks. CIA was induced in 32/45 animals (72%) at 2 weeks after the final sensitization. The 3rd sensitization produced a marked increase in the IP area, whereas the 1st and 2nd sensitization did not. When the CIA animals were treated with MTX, increased IP area in control group did not change or slightly decreased during the treatment period. In the MTX groups, percentile changes in IP area were decreased 55% and 71% at 3 mg/animal (n=2) and 10 mg/animal (n=2), respectively, compared with the pre-treatment values. The histopathological results of the MTX groups showed repair of the destroyed joint. It is concluded that the CIA model in cynomolgus monkeys can be used for the evaluation of efficacy for rheumatoid arthritis when changes in IP area are used as primary end point as an established drug demonstrates a therapeutic effect in this model.

REAL-TIME PCR ASSAY FOR THE QUANTITATION OF SEROTYPE 5 ADENOVIRUS VECTOR DNA IN GENOMIC DNA EXTRACTED FROM TISSUES AND FILIDS

M. Wu<sup>1</sup>, M. Subramanyam<sup>2</sup> and D. Enke<sup>1</sup>. <sup>1</sup>Biomarker Development, Biogen, Cambridge, MA and <sup>2</sup>Biogen, Cambridge, MA. Sponsor: J. Green.

The FDA has mandated that quantitative PCR-based assays be developed to assess the safety of gene therapy viral vectors. Specifically, these assays are to be used to determine the biodistribution of the vector distal to the site of injection and in germline tissues. A TaqMan® real-time PCR assay was developed for the quantitation of adenovirus type 5 gene therapy vector viral genome copy number. The assay is specific for a target sequence in the d1309 region of the adenoviral vector genome. A standard curve is generated by plotting the threshold cycle (CT) number versus the log of copy number, and the standard vector copy number in each test sample is determined from the sample CT number by interpolation from the standard curve. The standard curve ranges from 10 to 1x106 copies of standard vector in a background of genomic DNA. Intermediate assay precision averaged 0.8% CV by CT value (14.4% CV by interpolated copy number) across the standard curve range. Based on the tightness of the assay precision, a decision was made to test samples in duplicate on a single plate. Plate acceptance criteria are based on the acceptance criteria of the standard curve. According to acceptance criteria set by the manufacturer Applied Biosystems, TaqMan® standard curves should have a slope of  $-3.32 \pm 0.5$  and a correlation coefficient (R2) of > 0.99. In addition, No Template Control (NTC) wells should return a value of zero copies as a control for contamination. Sample acceptance criteria are based on the CV of sample copy number returned. Samples which return copy numbers with >20% CV between duplicates should be retested. This assay satisfies the current Food and Drug Administration (FDA) guidelines for PCR-based biodistribution assays as defined by Biological Response Modifiers Advisory Committee (BRMAC).

## APOPTOSIS INDUCED BY INTERACTIONS BETWEEN MOLDY HOUSE MICROBES.

P. Penttinen<sup>1, 2</sup>, J. Pelkonen<sup>2, 3</sup>, K. Huttunen<sup>1</sup> and M. Hirvonen<sup>1, 1</sup>Department of Environmental Health, National Public Health institute, Kuopio, Finland, <sup>2</sup>University of Kuopio, Kuopio, Finland and <sup>3</sup>Kuopio University Hospital, Kuopio, Finland. Sponsor: M. Viluksela.

Exposure to complex mixture of bacteria and fungi in moldy buildings is a potential cause of inflammatory related symptoms among the occupants. In this study, capability of these microbes to cause apoptotic cell death was investigated in more details. In addition, microbial interactions on apoptosis was identified in mouse macrophages, when the microbes were cultured separately and together on the same culture plate. The fungal strain Stachybotrys chartarum and the gram-positive bacterial strain Streptomyces californicus were selected in this study based on their characteristic occurrence in water damaged buildings. These microbes were co-cultivated on the same agar plate. The both strains were also cultured separately and the strains were combined at the same proportion as the co-cultivated combination of S. chartarum and Str. californicus (1:5). Mouse macrophages (RAW264.7) were exposed to combination of spores and spores individually. In the dose response study the macrophages were exposed to six doses  $(1\times10^4-3\times10^6 \text{ spores/ml})$  for 24 hours. For the time course study the macrophages were exposed to the dose of 3×10<sup>5</sup> spores/ml for 4, 8, 16 and 24 hours. Apoptosis was measured by flow cytometry using propidium iodide (PI) staining of permeabilized cells. Changes of caspase-3 activity in mouse macrophages were detected by fluorometric substrate cleavage assay. Flow cytometric analysis of DNA fragmentation showed, that there was 2.6±0.1 % apoptotic cells when exposed (3×10<sup>5</sup> spores/ml at 24 hr) to separately cultured combination, but the amount of apoptotic cells increased to 12.4±1.3 % when exposed to co-cultivated combination. Furthermore co-cultivation increased the caspase-3 activity by 2.4-fold compared to separately cultured combination. Altogether, this data suggests that co-culture of S. chartarum and Str. californicus leads to microbial interactions, which significantly affect on the ability of microbes' spores to cause apoptosis in mammalian cells.

DIFFERENCES IN THE ONSET OF APOPTOSIS IN OLFACTORY SENSORY CELLS OF MICE, RATS AND MONKEYS GIVEN AN INTRAVENOUS INJECTION OF MAXIMUM TOLERATED DOSE (MTD) OF VINCRISTINE, A VINCA-ALKALOID ANTITUMOR DRUG.

K. Kai, H. Satoh, T. Suzuki, M. Yoshida, Y. Shikanai, T. Kajimura, M. Kato and K. Furuhama. Drug Safety Research Laboratory, Daiichi Pharmaceutical Co., Ltd., Tokyo, Japan.

We have previously reported that vincristine sulfate (VCR) causes apoptosis in the olfactory sensory cells of male mice following an intravenous injection. In the present study, we investigated differences in the onset of apoptosis in the olfactory epithelium of BALB/c mice and Crj:CD(SD)IGS rats given an intravenous injection of VCR at a MTD and estimated 10% lethal dose (LD10), and of common marmoset monkeys receiving MTD. Namely, VCR was intravenously administered once to mice (1.17 and 1.95 mg/kg), rats (0.21 and 0.35 mg/kg) and monkeys (0.35 mg/kg) of both sexes. The dosing day was designated as Day 1 in this study. The animals were serially necropsied on Days 2, 5 and 10, and the nasal tissue and sciatic nerve were examined light-microscopically. The olfactory sections of mice on Day 2 were subjected to the terminal deoxyribonucleotidyl transferase-mediated dUTP-digoxigenin nick-end labeling (TUNEL) assay and electron-microscopic observation. In mice, VCR elicited cell deaths with condensation and fragmentation of nuclei in the olfactory epithelia and vomeronasal organs in males given 1.95 mg/kg and in females receiving 1.17 mg/kg or more from Day 2. On Day 10, demyelination in the sciatic nerve was noted in both sexes at 1.17 mg/kg or more. TUNEL-positive cells were also recognized in the basolateral olfactory epithelium. Ultrastructurally, condensation and margination of chromatin were observed in sensory cells of the basolateral olfactory epithelium. However, no morphological changes related to VCR treatment were observed in rats and monkeys of either sex. In conclusion, these results demonstrate that MTD of VCR evokes severe olfactory apoptosis only in mice, especially in females.

#### 694

EFFECTS OF STAINLESS STEEL MANUAL METAL ARC WELDING FUMES ON DNA DAMAGE AND APOPTOSIS INDUCTION *IN VITRO* AND *IN VIVO*.

M. D. Taylor, J. R. Roberts, C. E. Solano-Lopez, S. S. Leonard, X. Shi and J. M. Antonini. HELD/PPRB, NIOSH, Morgantown, WV.

Epidemiological studies examining the potential association of occupational inhalation of welding fumes and increased incidence of lung cancer have not reached definite conclusions. Stainless steel (SS) welding fumes are of particular interest be-

cause they contain potential human carcinogens, such as chromium and nickel. Animal studies addressing toxicological responses related to carcinogenicity are currently lacking, although SS welding fumes have been shown to be mutagenic in vitro. The goals of this study were to examine the potential for SS welding fumes to damage DNA and induce apoptosis, events that are associated with possible carcinogenic activity. In a previous study using electron spin resonance, the generation of hydroxyl radicals from Cr(VI) in the SS fume (1.0 mg/ml) was observed. In the current study, SS fume at the same concentration caused plasmid DNA strand breakage in vitro under similar conditions. To examine the effects of SS fumes on apoptosis in vivo, male Sprague-Dawley rats were intratracheally instilled with SS fumes from manual metal arc welding (1.0 mg/100 g bw), Cr(VI) (0.2 mg/100 g bw) as a positive control, or the saline vehicle. On days 1, 3, 6, 8, and 10, the rats were euthanized and their left lungs were excised and cryo-sectioned. Apoptosis was examined in the tissue sections by TUNEL assay. Increased numbers of apoptotic cells were found in lung tissue treated with either the SS fume or the positive control, Cr(VI), as compared to lungs from saline-treated animals. These preliminary studies indicate that SS welding fumes can damage DNA in vitro and induce apoptosis in vivo. Studies are ongoing to determine if the apoptotic event is associated with an increase in oxidative DNA damage in lung tissue.

#### 695 INHALED OZONE INDUCES DNA-DNA CROSS-LINKING IN EXPOSED RAT LUNG.

D. H. Bowser<sup>1</sup>, M. Sisco<sup>1</sup>, K. Baker<sup>1</sup>, <u>K. Salnikow<sup>2</sup></u>, <u>R. B. Schlesinger<sup>3</sup></u>, <u>M. D. Cohen<sup>1</sup> and J. T. Zelikoff<sup>1</sup>. <sup>1</sup> Environmental Medicine, New York University School of Medicine, Tuxedo, NY, <sup>2</sup>NCI, Frederick, MD and <sup>3</sup> Biology, Pace University, Pleasantville, NY.</u>

Ozone (03) exposure has been shown to cause a variety of debilitating respiratory disturbances including possibly cancer. The prevalence of 03 as the dominant oxidant of world-wide photochemical smog, its occupational utilization and its application as a direct or adjunct therapy for treatment of various diseases make it a global human health concern. As the major target of 03 inhalation, lung tissue has been reported to sustain both cytotoxic and genotoxic damage as well as cause neoplastic transformation in vivo and in vitro. However, whether exposure to O3 can cause DNA-DNA cross-linking is as of yet unknown. Thus, this study examined whether long-term /chronic 03 exposure could induce pulmonary genomic DNA-DNA cross-linking. Adult male rats were exposed nose-only, 5h/d, 5d/wk for 4, 8, 12, 24 and 48 wks to filtered air or one of three different O3 concentrations (i.e., 0.1, 0.3 and 0.6 ppm). Rats were sacrificed 3d after the cessation of exposure lungs were removed and flash frozen and DNA-DNA cross-links determined by gel electrophoresis. Effects of 03 appeared to be time- and dose- dependent. Animals exposed to 0.3 ppm 03 for 8 wks demonstrated significantly elevated levels of crosslinking compared to controls and 0.1 and 0.6 ppm 03 exposed rats; exposure for twelve wks to 0.3 and 0.6 ppm 03 resulted in greater DNA cross-linking than controls or the 0.1 ppm 03 group; inhalation exposure of rats for twenty four wks to all three concentrations caused a significant dose-related increase in cross-linking; at 48 wks rats exposed to 0.3 ppm O3 demonstrated significantly elevated levels of cross-linking (compared to air controls). These findings suggest that long-term inhalation of 03 can produce genotoxic events that could be associated with neoplastic changes. NIOSH # OH03607.

#### 696

ROLE OF INDUCIBLE NITRIC OXIDE-DERIVED NITRIC OXIDE IN SILICA-INDUCED PULMONARY INFLAMMATION AND INJURY.

P. C. Zeidler<sup>1, 2</sup>, A. F. Hubbs<sup>1, 2</sup> and <u>V. Castranova<sup>1, 2, 1</sup>PPRB</u>, NIOSH, Morgantown, WV and <sup>2</sup>West Virginia University, Morgantown, WV.

Our lab has demonstrated previously that exposure of rats to silica resulted in induction of inducible nitric oxide synthase (iNOS) in alveolar macrophages (AM) and alveolar type II epithelial cells (TII). The production of nitric oxide (NO) by these pneumocytes and resultant NO-dependent damage (nitrotyrosine residues) have been related temporally and anatomically with silica-induced inflammation and granuloma formation (Am J Physiol Lung Cell Mol Physiol 283:L485, 2002). The objective of the present study was to determine if these associations represent a causal role for NO in silica-induced lung disease. To address this question, the subchronic response of C57BL/6J wild type (WT) mice and iNOS knockout (KO) mice to aspiration of silica (40 mg/kg) was compared 42 days post-exposure. Exposure of WT mice to silica was marked by the following sub-chronic responses: pulmonary damage (increased LDH and albumin levels in lung lavage fluid, and increased lung weight), inflammation (increased lung lavage polymorphonuclear leukocytes, TNF-alpha, MIP-2 and TGF-beta, and histological evidence of alveolitis and lipoproteinosis), oxidant stress (increased zymosan-stimulated chemiluminescence from AM, and decreased total antioxidant levels in lung lavage fluid), and

fibrosis (increased lung hydroxyproline levels). Absence of the iNOS gene in KO mice resulted in a significant decrease in markers of pulmonary damage, inflammation, oxidant stress and fibrosis 42 days after silica exposure. These data indicate that NO production plays a causal role in the progression of silica-induced lung disease.

ROLE OF NITRIC OXIDE IN MEDIATING ALVEOLAR MACROPHAGE RESPONSES TO DIESEL EXHAUST PARTICLES.

<u>I. Y. Ma</u><sup>1</sup>, H. Zhao<sup>1</sup>, M. W. Barger<sup>1</sup>, J. K. Ma<sup>2</sup> and <u>V. Castranova</u><sup>1</sup>. <sup>1</sup>HELD, NIOSH, Morgantown, WV and <sup>2</sup>School of Pharmacy, WVU, Morgantown, WV.

Diesel exhaust particles (DEP) are known to suppress the innate immune responses of alveolar macrophages (AM) against bacterial infection. In particular, although DEP induce AM production of nitric oxide (NO) through particle stimulation, the organic component of DEP strongly inhibits pathogen-induced NO production by AM. The present study examined whether NO may affect the secretion of pro- and anti-inflammatory cytokines by AM resulting in suppression of the host defense in response to DEP exposure. Male Sprague-Dawley rats were intratracheally (IT) instilled with saline or DEP (35 mg/kg body weight). To inhibit DEP-induced inducible nitric oxide synthase (iNOS), another group of rats were treated with an iNOS inhibitor, aminoguanidine (AG), by i.p. injection of 100 mg/kg AG, 30 min prior to and 3, 6 and 9 h after IT instillation of DEP or saline. Rats were sacrificed at 1 day post-DEP exposure, and AM were harvested. The results show that DEP induced iNOS expression in AM, which was not affected by AG. AG did not affect DEP-induced inflammatory markers in the lung (neutrophil infiltration and protein content), but significantly lowered the DEP-induced iNOS activity in AM. The production of nitrite by DEP-exposed AM was reduced from  $52 \pm 16$  to  $18 \pm$  $4~\mu \text{M}$  by AG treatment. AG treatment inhibited the secretion of TNF- $\alpha$  , pro-inflammatory cytokine, by AM in response to DEP exposure (from  $3424 \pm 676$  to 1511 ± 428 pg/ml). DEP exposure induced AM production of IL-10, an anti-inflammatory cytokine that is often induced by intracellular pathogens to dampen the host defense mechanism. Inhibition of iNOS activity by AG further enhanced this DEP-induced IL-10 production (from  $38 \pm 20$  to  $199 \pm 86$  pg/ml), suggesting that NO, by inhibiting IL-10, plays an important anti-bacterial role. In summary, this study shows that inhibition of NO by AG significantly decreases TNF-α secretion, while further enhancing IL-10 production by DEP-exposed AM. This change in pro-/anti-inflammatory cytokine balance may make the lung more susceptible to bacterial infection.

IN-VITRO INFLAMMATORY AND CYTOTOXIC RESPONSES TO AMBIENT AIR PARTICULATE SAMPLES COLLECTED DURING LONG-RANGE TRANSPORT (LRT) OF FOREST FIRE SMOKE TO HELSINKI, FINLAND.

P. Jalava<sup>1,3</sup>, R. O. Salonen<sup>1</sup>, A. I. Halinen<sup>1</sup>, M. Sillanpaa<sup>2</sup>, S. Saarikoski<sup>2</sup>, R. Hillamo<sup>2</sup> and M. Hirvonen<sup>1,1</sup> Department of Environmental Health, National Public Health Institute (KTL), Kuopio, Finland, <sup>2</sup>Air Quality Research, Finnish Meteorological Institute, Helsinki, Finland and <sup>3</sup>University of Kuopio, Kuopio, Finland. Sponsor: M. Viluksela.

Ambient air particulate (PM) samples from three different air pollution situations in autumn 2002 were studied: normal seasonal sample and two episodes of LRT forest fire smoke. The samples were collected with a high volume cascade impactor in three size fractions: Fine2 (F2, PM1-0.2), Fine1 (F1, PM2.5-1) and Coarse (CO, PM10-2.5). Episodes affected mostly the F2 fraction: the total mass concentration increased 5-10 times and the PM<sub>2.5</sub> mass concentrations for K+, oxalate and malonate increased also strongly. Cultures of mouse macrophage cell line (RAW 264.7) were exposed in a dose-related manner (15, 50, 150 and 300  $\mu g/ml$ ) to the PM samples for 8 or 24h. We measured nitric oxide (NO) production by the Griess method, production of cytokines (TNFα, IL-1, IL-6, IL-10 and MIP-2) immunochemically (ELISA) and cytotoxicity with the MTT test. Both the size fraction and the air pollution situation affected the PM induced cytotoxic and proinflammatory responses. The CO and F1 fractions were roughly equipotent but at the same time more potent inducers of cytotoxicity and cytokine production than the F2 fractions. The potency difference in TNFa production was 100-fold. The first forest fire episode increased TNFa production most within F2 fractions, whereas within F1 fractions, the second forest fire episode and the normal seasonal sample gave the larger responses. In NO and MIP-2 production, and cytotoxicity, the normal seasonal F2 fraction was more potent than the forest fire episodes. Thus, the PM chemistry changes caused by the LRT-episodes of forest fire smoke were differently reflected in the toxicity of the F2 and F1 fractions.

699

NRF2 PLAYS A CRITICAL ROLE IN CONFERRING PROTECTION AGAINST INFLAMMATION IN A MOUSE MODEL OF ASTHMA.

T. Rangasamy<sup>1</sup>, J. Guo<sup>2</sup>, S. Srisuma<sup>1</sup>, S. N. Georas<sup>2</sup>, T. W. Kensler<sup>1</sup>, W. A. Mitzner<sup>1</sup> and <u>S. Biswal</u><sup>1</sup>. <sup>1</sup>Environmental Health Sciences, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD and <sup>2</sup>Department of Medicine, Johns Hopkins University, Baltimore, MD.

The critical role of Nrf2, a b-zip transcription factor that positively regulates several antioxidant enzymes and cytoprotective proteins, against inflammatory response in lung was investigated in a murine model of asthma. Both Nrf2 +/+ and -/- mice were sensitized (on day 0 and 14) and challenged (on day 24th, 26th and 31 st) with ovalbumin (OVA). In response to OVA challenge, there was a progressive increase in the infiltration of inflammatory cells, particulary eosinophils (80 %) into the lungs of Nrf2 -/- than Nrf2 +/+ mice from 1st to 3rd OVA challenge. Staining of the lung sections with PAS and H&E also showed increased mucus cell metaplasia and infiltration of eosinophils into the lungs of the OVA treated Nrf2 -/- mice. There was an elevated level of of TH-2 cytokines (IL-4 and IL-13) in the BAL fluid of OVA treated Nrf2 -/- mice. In response to acetylcholine, OVA treated Nrf2 -/mice showed increased airway hyperresponsiveness than Nrf2 +/+ mice. Activation of Nrf2 in the lungs of Nrf2 +/+ mice in response to OVA was confirmed by EMSA. Real Time PCR analysis showed the increased transcriptional induction of an array of antioxidant genes in the lungs of OVA treated Nrf2 +/+ mice. Increased eosinophilia, mucus cell metaplasia, airway hyperresponsiveness and elevated level of TH-2 cytokines in Nrf2-deficient mice in response to allergen suggests the pivotal role of Nrf2 in the protection of lungs against ovalbumin induced asthmatic response. (This work was supported by grants: P50 CA058184-09 and NIEHS center grant P30 ES 03819)

## 700 LACK OF NRF2 AUGMENTS LIPOPOLYSACCHARIDE INDUCED INFLAMMATION IN MICE LUNGS.

S. Srisuma, R. Thimmulappa, <u>T. Rangasamy</u>, K. Mai, <u>T. W. Kensler</u> and <u>S. Biswal</u>. *Johns Hopkins University, Baltimore, MD*.

Lung inflammatory diseases such as acute lung injury and chronic obstructive pulmonary disease are predominantly associated with oxidative stress. Recent findings on the transcriptional targets of Nrf2 revealed its regulatory role on several detoxifying enzymes, antioxidants and NADPH-regenerating enzymes suggest its protective function against a wide spectrum of toxicants. To evaluate the protective role of Nrf2 against inflammation in lungs, we employed the murine model of lipopolysaccharide (LPS) induced acute lung injury. LPS caused greater increase in wet/dry lung weight, inflammatory cells, TNF-a level in bronchoalveolar lavage fluid of Nrf2 -/- mice than those of Nrf2 +/+ mice. Electrophoretic mobility shift assay showed greater increase of NF-KB activity in the Nrf2 -/- lungs than Nrf2 +/+ lungs in response to LPS, which may be responsible for differences in inflammation. LPS treatment also resulted in higher oxidative stress in the lungs of Nrf2 -/than Nrf2 +/+ mice as determined by the ratio of GSH/GSSG. mRNA levels of antioxidant genes such as g-glutamylcysteine synthetase (regulatory subunit), glutathione reductase, heme oxygenase and the specific activity of glutathione peroxidase, gluathione reductase, and glucose-6-phosphate dehydrogenase were significantly higher in the lungs from Nrf2 +/+ mice compared to Nrf2 -/- mice after LPS challenge. Results demonstrated that Nrf2 plays a significant role in protection against endotoxin-induced lung inflammation and resulting lung injury by elevating antioxidant defense systems (supported by P50 CA058184-09 and NIEHS Center grant-P30-ES03819).

ROLE OF TOLL LIKE RECEPTOR-4 IN OZONE-INDUCED PRODUCTION OF INFLAMMATORY MEDIATORS AND TOXICITY.

A. J. Connor, J. D. Laskin and D. L. Laskin. Joint Graduate Program In Toxicology, Rutgers University and UMDNJ/Robert Wood Johnson Medical School, Piscataway, NJ.

Studies from our laboratory have demonstrated that the toxicity of inhaled ozone is due, in part, to cytotoxic inflammatory mediators including nitric oxide, generated from inducible nitric oxide synthase (NOSII), tumor necrosis factor alpha (TNF\$\alpha\$), and PGE2 produced via cyclooxygenase-2 (COX-2) released from activated alveolar macrophages. Toll like receptor-4 (TLR-4) is a transmembrane protein important in macrophage-mediated inflammatory responses initiated by lipopolysaccharide. Engagement of TLR-4 leads to activation of the transcription factor NF-\$\alpha\$B which regulates NOSII, COX-2 and TNF\$\alpha\$. In the present studies we analyzed the role of TLR-4 in ozone-induced macrophage activation, inflammatory mediator production, and toxicity. Treatment of control C3H/OuJ mice with ozone (0.8 ppm, 3 hr) resulted in alveolar epithelial injury as measured by protein accumulation in bronchoalveolar lavage fluid (BAL). In contrast, BAL fluid protein

was at control levels in C3H/HeJ which possess a mutated TLR-4, demonstrating that they are protected from ozone-induced injury. In OuJ mice, ozone inhalation caused a time-dependent induction of NOSII and COX-2 protein expression in the lung which was detected in histologic sections. Whereas NOSII was localized mainly in alveolar macrophages, COX-2 staining was noted throughout the alveolar epithelial regions. Ozone-induced expression of NOSII and COX-2 was markedly attenuated in lungs from HeJ mice. Taken together these data demonstrated that TLR-4 plays an important role in the pathogenesis of inflammation and tissue injury induced by ozone. Supported by NIH grants ES04738, GM34310, ES007148 and ES05022.

## **702** GENOMIC ANALYSIS OF PHOSGENE-INDUCED LUNG INJURY.

A. M. Sciuto<sup>2</sup>, J. F. Dillman<sup>1</sup>, C. S. Phillips<sup>1</sup>, L. M. Dorsch<sup>1</sup>, A. I. Hege<sup>1</sup> and T. S. Moran<sup>2</sup>. <sup>1</sup>Applied Pharmacology, USAMRICD, Aberdeen Proving Ground, MD and <sup>2</sup>Neurotoxicology, USAMRICD, Aberdeen Proving Ground, MD.

Phosgene is a toxic gas used widely in industry for the production of many synthetic products, such as polyfoam rubber, plastics, and dyes. Exposure to phosgene results in a latent (3-24 hr) potentially life-threatening pulmonary edema and irreversible acute lung injury. A genomic approach was utilized to investigate the molecular mechanism of phosgene-induced lung injury. CD-1 male mice were exposed whole-body to either air or a concentration x time (c x t) amount of 32 mg/m3 (8 ppm) phosgene for 20 min (640 mg x min/m3). Lung tissue was collected from airor phosgene-exposed mice at 0.5, 1, 4, 8, 12, 24, 48, and 72 h post-exposure. RNA was extracted from the lung and used as starting material for the probing of oligonucleotide microarrays to determine changes in gene expression following phosgene exposure. The data were analyzed using principal component analysis (PCA) to determine the greatest sources of data variability. A two-way analysis of variance (ANOVA) based on agent exposure and time was performed to identify the genes most significantly changed as a result of phosgene exposure. These genes were rank ordered by p-values and categorized based on molecular function and biological process. Some of the most significant changes in gene expression reflect changes in glutathione synthesis and redox regulation of the cell, including upregulation of glutathione S-transferase alpha-2, glutathione peroxidase 2, and glutamate-cysteine ligase, catalytic subunit (also known as gamma-glutamyl cysteine synthetase). This is in agreement with previous observations describing changes in redox enzyme activity after phosgene exposure. We are also investigating other pathways that are responsive to phosgene exposure in order to identify mechanisms of toxicity and potential therapeutic targets.

# 703 TRANSCRIPTIONAL REGULATION IN RESPONSE TO CARBON NANOTUBES IN HUMAN BRONCHIAL EPITHELIAL CELLS AS DETECTED BY MICROARRAY ANALYSIS.

N. Keshava<sup>1</sup>, A. R. Murray<sup>2</sup>, O. Gorelik<sup>4</sup>, S. Arepalli<sup>4</sup>, V. Z. Gandelsman<sup>5</sup>, <u>V. Castranova<sup>2,3</sup></u> and <u>A. A. Shvedova<sup>2,3</sup>. <sup>1</sup>TMBB, NIOSH, CDC, Morgantown, WV, <sup>2</sup>PPRB, NIOSH, CDC, Morgantown, WV, <sup>3</sup>Physiology & Pharmacology, WVU, Morgantown, WV, <sup>4</sup>Materials & Processes Branch, Lockheed Martin Corporation, Engineering Directorate, Houston, TX and <sup>5</sup>Nanotube Team, GBTech, Inc., NASA-JSC, Houston, TX.</u>

Carbon nanotubes are new members of carbon allotropes with unique physical properties used for novel applications in the electronics, aerospace and computer industries. Previously, we have reported that exposure of BEAS-2B cells to single wall carbon nanotubes (SWCNT) caused ultra-structural and morphological changes, cytotoxicity, apoptosis, and induced oxidative stress as shown by the formation of free radicals, accumulation of peroxidative products, and depletion of antioxidants. In this study, we have investigated the effect of SWCNT on alterations in gene expression. Exponentially growing human bronchial epithelial cells were exposed to 0.06, 0.12 or 0.24 mg/ml of SWCNT for 18 h. Total RNA was used for the preparation of double stranded cDNA. A biotin labeled cRNA transcript was synthesized, fragmented and hybridized to Affymetrix U133A oligonucleotide microarray. The arrays were stained with streptavidin-phycoerythrin and biotinylated anti-streptavidin antibodies. The differential gene expression data analysis was performed using Affymetrix microarray suite 5.0 software. The 3'/5' cRNA transcript ratios for both GAPDH and ?-actin were found to be consistent between control and treatment groups over a period of 18 h exposure. Altered gene expression patterns were observed in 187 RNA transcripts with a signal log ratio of at least 0.8 (1.7 fold change). Altered genes include genes involved in metabolism (CYP1B1, aspargine synthetase, NNMT), cell cycle control (p21, CD24, GAS1, PA26) and others (matrix metalloproteinase, ferrodoxin reductase, cathepsin L2). In conformity with our earlier study, it appears that SWCNT alter a variety of genes that include those involved in oxidative stress.

## 704 IN VIVO EXPOSURE TO DRINKING WATER ARSENIC MODIFIES EXPRESSION OF GENES IN THE MOUSE LUNG.

A. S. Andrew<sup>1</sup>, A. Barchowsky<sup>2</sup>, J. C. Davey<sup>1</sup>, N. V. Soucy<sup>1</sup>, D. D. Mayka<sup>1</sup>, <u>C. R. Lantz<sup>3</sup></u>, A. Hayes<sup>3</sup> and <u>J. W. Hamilton<sup>1</sup>. <sup>1</sup> Pharmacology & Toxicology, Dartmouth Medical School, Hanover, NH, <sup>2</sup> Environmental & Occupational Health, University of Pittsburgh, Pittsburgh, PA and <sup>3</sup> Cell Biology & Anatomy, University of Arizona, Tucson, AZ.</u>

Chronic ingestion of arsenic has been associated with increased incidence of vascular and cardiovascular disease, diabetes, hyperkeratosis, and cancer in multiple organs, including the lung. However, the disease risks and biological effects associated with arsenic ingestion at lower levels commonly found in the US remain unclear. To investigate these effects, C57BL/6 mice ingested drinking water with or without 50 ppb arsenic (the previous US maximum contaminant level) for five weeks. RNA from three control and three arsenic exposed animals was labeled and hybridized independently on six independent Affymetrix mouse 430(A) arrays, each containing over 14 k full length genes. Signals were normalized using Robust Multichip Analysis (RMA) and statistical analysis for differential gene expression between the control and arsenic exposed groups was assessed using a Bayesian approach. We ranked differentially expressed genes in ascending order by the p-values and our initial focus was placed on the 30 genes with p-values <0.005. As we have observed previously, the levels of expression for the majority of the genes in the arsenic exposed group were decreased in comparison to controls. Genes involved in transcriptional regulation, DNA repair, and T-cell mediated immune response showed significant decreases in expression, while increases were observed in insulin regulating and xenobiotic metabolism genes. These data indicate that significant biological effects occur at drinking water arsenic concentrations routinely found throughout the US The specific pattern of gene changes that were observed will also guide further mechanistic studies of arsenic-induced disease. Supported by NIEHS SBRP grants ES07373 and ES04940.

## **705** ESTROUS CYCLE ALTERS PULMONARY METABOLISM OF NAPHTHALENE (NA).

L. S. Van Winkle<sup>1</sup>, G. L. Baker<sup>1</sup>, R. L. Stelck<sup>1</sup>, C. D. Brown<sup>1</sup>, C. G. Plopper<sup>1</sup> and A. R. Buckpitt<sup>2</sup>. <sup>1</sup>VM:APC, UC Davis, Davis, CA and <sup>2</sup>VM:Molecular Biosciences, UC Davis, Davis, CA.

Tobacco smoke exposure is causally associated with pulmonary diseases in both men and women. However, risk for cancers of the peripheral lung is higher in women and suggests gender and lung region-specific differences in pulmonary epithelial responses to tobacco smoke. NA is the most abundant PAH in sidestream tobacco smoke. Random cycling female mice are more susceptible than males to NA-induced pulmonary cytotoxicity. NA lung toxicity has been shown to depend on bioactivation to a toxic intermediate by cytochrome P450s. This study addressed the issue of whether metabolism of NA in proximal and distal airways of female mice differed by estrous cycle stage and from male mice. Intact cycling female mice separated into three categories by estrous cycle stage: proestrus (estradiol low, progesterone low), estrus (estradiol high, progesterone low) and noncycling diestrus (estradiol moderate, progesterone high). Cycle stage was determined using vaginal cytology. NA metabolic products were measured in microdissected proximal (bronchi and trachea) and distal (bronchioles) airways using HPLC. In both proximal and distal airways, total NA metabolism as well as formation of NA glutathione conjugate 2 (derived from the 1R, 2S-epoxide) were significantly greater (P< 0.05) in mice at the proestrus stage of the estrous cycle compared to females in estrus, to noncycling females or to males. Formation of NA dihydrodiol increased significantly in the distal airways of the proestrus mice (P< 0.05) compared to all other groups. However, in the proximal airways, estrus and proestrus mice had similar rates of NA dihydrodiol formation which differed significantly from the rates in noncycling females and in males. We conclude that NA metabolism is influenced by the estrous cycle in the lungs of female mice and varies by airway level. Further, the pattern of changes suggests that NA conjugate formation may be influenced by estradiol, but dihydrodiol formation in proximal airways is influenced by progesterone. SITE-SPECIFIC INDUCTION OF PULMONARY CYTOCHROME P450 ISOZYME 3A1 BY 1-NITRONAPHTHALENE IN NEONATAL RATS.

K. C. Day, G. L. Baker, <u>C. G. Plopper and M. V. Fanucchi</u>. *Center for Comparative Respiratory Biology and Medicine, University of California, Davis, Davis, CA*.

Neonatal rats are more susceptible to severe pulmonary injury by bioactivated environmental cytotoxicants than adult animals. Cytochrome P450 (CYP) monooxygenases play an important role in the bioactivation of these environmental cytotoxicants such as nitropolyaromatic compounds. 1-Nitronaphthalene (1NN), a

by-product of diesel exhaust and cigarette smoke, produces pulmonary injury at lower doses in neonatal rats than adult rats. To determine whether 1NN alters the expression of pulmonary CYP monooxygenases, we examined RNA expression in laser capture microdissected and blunt microdissected airways, protein expression and CYP3A1 activity during the first 24 hours post 1NN treatment in 7-day old and adult male Sprague-Dawley rats. Rats were injected IP with 0 or 100 mg/kg of 1NN dissolved in corn oil and killed at 0, 1, 2, 3, 6, 24 hours post-treatment. CYP3A1 RNA expression was significantly induced at 6-hrs post treatment in proximal airway epithelium and pulmonary vein of 7-day old rats, but not in adult rats. CYP3A1 protein expression increased 2-hrs post treatment in 7-day old rats but not in adult rats. Proximal airways of 7-day old and adult rats were heavily labeled with immunoreactive CYP3A1. There was little to no labeling in the distal airways. The vascular smooth muscle surrounding the proximal airway was heavily labeled throughout the time course. Differences in CYP3A1 activity levels were also determined from both neonatal and adult lung microsomes using the substrate Midazolam. We conclude that elevation in gene and protein expression for pulmonary CYP isozyme 3A1 is induced by the bioactivated cytotoxicant 1NN in neonatal rats but not adult rats. This suggests that a potential mechanism for the increased susceptibility of neonatal rats to pulmonary injury by a bioactivated cytotoxicant (1NN) is by induction of a key isozyme CYP3A1. **707** 

THE EFFECT ON PUP VIABILITY AND GROWTH DURING NOSE-ONLY INHALATION EXPOSURE OF WISTAR-HAN RATS FOR PRE AND POST NATAL STUDIES.

M. Stoute<sup>1</sup>, S. Maquire<sup>2</sup>, K. Robinson<sup>1</sup>, A. Viau<sup>1</sup> and <u>C. Banks<sup>1</sup>. <sup>1</sup>CTBR</u>, Senneville, QC, Canada and <sup>2</sup>GlaxoSmithKline, Ware, United Kingdom.

Due to the increased focus on the effects of inhaled pharmaceutical products on reproduction, a study was undertaken to determine the effects on the viability and growth of pups when their dams were placed in restraint tubes (for nose only inhalation exposure) for 60 minutes starting from Day 15 of gestation to parturition and again from Day 1, 2, 3 or 4 to Day 10 post partum. Fifty mated female Wistar Han rats were randomized into 5 groups of 10. Group 1 animals were used as a room control. Groups 2 to 5 animals were acclimatized to restraint tubes over a period of 3 days (15, 30 and 60 minutes, respectively), from Day 13 of gestation, followed by a period of 60 minutes each day in the restraint tubes until Day 20 of gestation. Following parturition, the Group 2, 3, 4 and 5 dams were restrained for 60 minutes daily, from Day 1, 2, 3 and 4 post partum (pp), respectively. Tube restraint continued to Day 10 pp for each group. The dams were checked daily for mortality, signs of poor health, abnormal behavior and signs of parturition. Detailed clinical examinations were performed weekly on the dams and the pups were checked daily. Body weights and food intake were measured during gestation until Day 10 pp for the dams and pup body weights were measured on Days 0, 1, 4, 7 and 10 pp. The dams and pups were euthanized at the end of the study. There were no deaths or adverse clinical signs and no effect upon body weights, food intake or maternal performance including numbers of live pups for the restrained F0 dams. There were no adverse effects upon pup viability, pup body weight or clinical condition due to the pups separation from their dams. Daily tube restraint for 60 minutes starting from Day 15 of gestation to parturition and again from Day 1, 2, 3 or 4 to Day 10 pp had no effects upon maternal performance or pup viability and growth.

## 708 INHALATION TOXICITY OF GASOLINE & FUEL OXYGENATES: NEUROTOXICITY.

<u>I. P. O'Callaghan</u><sup>1</sup>, C. M. Felton<sup>1</sup>, B. K. Mutnansky<sup>1</sup> and <u>W. C. Daughtrey</u><sup>2</sup>.

<sup>1</sup> Molecular Neurotoxicology, Centers for Disease Control and Prevention-NIOSH, Morgantown, WV and <sup>2</sup>211b Research Group, American Petroleum Institute, Washington, DC.

In compliance with the Clean Air Act Section 211b for fuel and fuel additive registration, petroleum and oxygenate manufacturers have conducted comparative toxicology testing of evaporative emissions of gasoline alone, and gasoline plus ether and alcohol oxygenates. Here we present results from the neurotoxicity component of this program. The functional observation battery (FOB) with the addition of motor activity (MA) testing, hemotoxylin and eosin staining of brain tissue sections, and brain regional analysis of glial fibrillary acidic protein (GFAP) were used to assess behavioral changes, neuropathology and gliosis, respectively, following inhalation exposure to the test agents. Seven vapor condensates of gasoline (GVC) or gasoline+ether [MTBE (G/MTBE), ethyl t-butyl ether (G/ETBE), t-amyl methyl ether (G/TAME), diisopropyl ether (G/DIPE)] or alchohol [ethanol (G/EtOH), t-butyl alcohol (G/TBA)] oxygenates were evaluated. Sprague-Dawley rats of both sexes were exposed to the test agents (2000-20, 000 mg/m³)by inhalation for 13 weeks (6 hrs/day, 5 days/week). FOB and MA were conducted on non-exposure days, at least 16 days post-initiation of exposures; neuropathology and GFAP analyses were conducted at the study termination (13 weeks). A recovery group was in-

cluded to monitor resolution of behavioral changes. FOB and MA data for all agents, except G/TBA, were negative. G/TBA behavioral effects resolved during recovery. Neuropathology was negative for all groups. Analyses of GFAP revealed multi-brain region increases (as great as 150% of air controls) limited largely to males of the G/EtOH group. Small changes (mostly increases) in GFAP were observed for other test agents but these effects were not consistent across sex, brain region or exposure concentration. The results are consistent with the incidence of a mild gliosis in males of the G/EtOH group. Results of these studies will be used for comparative risk assessments of gasoline/oxygenate blends.

709

INHALATION TOXICITY OF GASOLINE & FUEL OXYGENATES - REPRODUCTIVE TOXICITY ASSESSMENT

T. M. Gray<sup>1</sup>, K. P. Hazelden<sup>3</sup>, D. R. Steup<sup>1</sup>, J. P. O'Callaghan<sup>2</sup>, G. M. Hoffman<sup>3</sup> and <u>L. G. Roberts<sup>1</sup>. <sup>1</sup>API, 211b Research Group, Washington, DC, <sup>2</sup>Molecular Neurotoxicology, CDC-NIOSH, Morgantown, WV and <sup>3</sup>Reproductive Toxicology, Huntingdon Life Sciences, Inc., East Millstone, NJ.</u>

In compliance with the Clean Air Act Section 211b for fuel and fuel additive registration, the petroleum industry and oxygenate manufacturers conducted comparative toxicology testing on evaporative emissions of gasoline alone and gasoline containing ether or alcohol oxygenates. Seven vapor condensates of gasoline (GVC), or gasoline-ether [MTBE (G/MTBE), ethyl t-butyl ether (G/ETBE), t-amyl methyl ether (G/TAME), diisopropyl ether (G/DIPE)], or alcohol [ethanol (G/EtOH), tbutyl alcohol (G/TBA)] were evaluated for reproductive toxicity in Sprague-Dawley rats. G/ETBE, G/TAME, G/DIPE, G/EtOH, and G/TBA were assessed for one-generation; GVC and G/MTBE were assessed over two generations. Additionally, GVC and G/MTBE offspring were evaluated for quantitative changes in regional brain glial fibrillary acidic protein (GFAP) content. All inhalation exposures were 6 h/d, 7 d/w, at levels of 2000 - 20, 000 mg/m3. All exposures increased male kidney weight consistent with light hydrocarbon nephropathy. In adult rats, frequent findings across exposure groups included decreased body weight gain and increased liver weight, most commonly in males. Spleen weight decreased with G/TBA. G/EtOH and G/TBA exposure resulted in higher prostate weight, but no pathological changes occurred to reproductive organs in any study. Except for decreased food consumption during lactation (G/TAME) and a minor increase in time to mating (G/TBA), there were no reproductive findings. Offspring effects included reduced weight gain during lactation (G/TAME) and decreased spleen weight (G/TBA). Results of these studies will be used for comparative risk assessments of gasoline and gasoline/oxygenate blends.

710 ANALYTICAL CHARACTERIZATION OF AEROSOLIZED JET PROPELLANT 8 (JP-8) IN AN EXPOSURE CHAMBER

K. Frank<sup>1</sup>, J. Campbell<sup>1</sup>, <u>M. Witten<sup>2</sup></u>, M. Bartlett<sup>3</sup> and <u>J. Fisher<sup>1</sup></u>.

<sup>1</sup>Interdisciplinary Toxicology Program, University of Georgia, Athens, GA, <sup>2</sup>Pediatrics, University of Arizona, Tuscon, AZ and <sup>3</sup>Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA.

Jet propellant 8 (JP-8) is a kerosene-based fuel that is composed of hundreds of hydrocarbons and is used by the military. The most common route of JP-8 exposure is through inhalation. Our laboratory is constructing a physiological model for JP-8 to understand its uptake, deposition at target organs, and clearance in animals exposed to JP-8 aerosol and vapor. Analytical methods were developed to identify and quantify JP-8 hydrocarbons in the vapor and aerosol phases of animal exposure chambers. Using a nose-only (mouse) exposure chamber at the University of Arizona, samples of JP-8 aerosol were collected on glass fiber filters and vapor on charcoal tubes. Aerosol samples were also collected on cascade impactor plates. Five samples were collected from 60 minute exposures and three samples were collected from 15 minute exposures. Each exposure was conducted with no animals in the chamber. The impactor plates were analyzed gravimetrically to determine the aerosol chamber concentration of JP-8 in mg/m3. In addition, charcoal tubes, glass fiber filters, and impactor plates were extracted with chloroform and analyzed by GC/MS. Preliminary results indicate that this aerosol exposure system produces a JP-8 chamber atmosphere that consists of 5-10% aerosol and the remainder is vapor. Analysis of the hydrocarbon composition of the aerosol and vapor phases is ongoing. The composition of JP-8 hydrocarbon aerosol fraction collected on glass wool fibers compares favorably with that of the cascade impactor plates. Funded by AFOSR [grant no F49620-03-1-0157].

## 711 INHALATION TOXICITY OF GASOLINE & FUEL OXYGENATES: TEST SAMPLE PREPARATION.

W. C. Daughtrey, M. Henley, D. M. Burnett, P. Podhasky and R. D. White. API 211(b) Research Group, Washington, DC.

In compliance with the Clean Air Act Section 211b requirements for fuel and fuel additive registration, the petroleum industry and oxygenate manufacturers conducted comparative toxicology testing on evaporative emissions of gasoline alone

and gasoline containing ether or alcohol oxygenates. To mimic real world exposures, a distillation method was employed that produced test material similar in composition to the headspace vapor from an automotive fuel tank at near maximum in-use temperatures. Gasoline vapor was generated by a single-step distillation from a 1000-gallon Pfaudler glass-lined kettle wherein approximately 15 to 20 % of the starting material was slowly vaporized, separated, condensed and recovered as test sample. This fraction was termed gasoline vapor condensate (GVC) and was prepared for each of the seven test samples, namely: gasoline alone (GVC), or gasoline + an ether (MTBE, ETBE, TAME, or DIPE), or gasoline + an alcohol (EtOH or TBA). Oxygenate concentrations were generally higher in the vapor phase than the liquid fuel starting material. Additional details about the methodology for generating the GVCs and data on their respective chemical compositions will be presented in the poster. The GVCs were analyzed under GLP conditions using capillary GC or GC MS methods. These materials were used as test samples for the subsequent inhalation toxicology studies described in the accompanying series of abstracts. These studies included evaluations for subchronic toxicity, neurotoxicity, immunotoxicity, genotoxicity, reproductive and developmental toxicity, and chronic toxicity / carcinogenicity. Results of these studies will be submitted to the USEPA and be used for comparative risk assessments of gasoline and gasoline/oxygenate blends.

# 712 A SIMPLE METHOD FOR COMPARING THE TOXICOLOGIC POTENTIAL OF EMISSIONS FROM VEHICLES USING DIFFERENT FUELS.

C. A. Lapin<sup>1</sup>, W. B. Bunn<sup>2</sup> and T. W. Hesterberg<sup>2</sup>. <sup>1</sup>Lapin & Associates, Glendale, CA and <sup>2</sup>International Truck and Engine Corporation, Chicago, IL.

In June 2000, the South Coast Air Quality Management District (SCAQMD) of southern California sought to improve air quality through a series on rules promoting the purchase of alternative fueled vehicles over diesel fueled vehicles for local government fleets. With some exceptions, diesel fueled vehicles can only be purchased if their exhaust emissions meet 1) required nitrogen oxides and particulate matter levels and 2) equivalent "toxic risk" to alternative fueled vehicles. The SCAQMD has a proposed procedure for determining "toxic risk" equivalency that focuses solely on cancer potency weighted emissions. This paper describes simple method that builds upon the SQAQMD proposal by also looking at all emissions that have potential air health concerns at ambient levels, not just those with cancer unit risk factors (URF). For emissions with a URF, because of the controversy surrounding the California Office of Environmental Health Hazard Assessment diesel exhaust URF, this paper uses three different potency weighted comparisons: mixed, PM based, and chemical specific. For emissions with Reference Exposure Levels, mass emission rates for each compound are compared. Other measures, such as in vitro mutagenicity are also compared when available. The resulting comparisons provide a summary matrix for use by decision makers. The method in this paper was used to compare recent emissions tests of diesel and compressed natural gas (CNG) transit buses (Ayala et al., Diesel Engine Emissions Reduction Conference, 2003). Trapped-equipped diesel transit buses were found to have equivalent potential "toxic risk" when compared to CNG buses equipped with oxidation catalysts. In conclusion, a simple method is described that provides decision makers with a comprehensive and clear way to use available emission data to facilitate a straightforward comparison of the "toxic risk" potential of vehicles using different fuels.

## 713 INHALATION TOXICITY OF GASOLINE & FUEL OXYGENATES - CHRONIC TOXICITY.

<u>J. Benson</u><sup>1</sup>, <u>C. R. Clark</u><sup>2</sup>, E. B. Barr<sup>1</sup>, A. P. Gigliotti<sup>1</sup>, T. H. March<sup>1</sup>, C. A. Elliott<sup>1</sup>, A. P. Gomez<sup>1</sup>, <u>B. M. Tibbetts</u><sup>1</sup> and R. White<sup>2</sup>. <sup>1</sup>Lovelace Respiratory Research Institute, Albuquerque, NM and <sup>2</sup>API 211(b) Research Group, Washington, DC.

In compliance with the Clean Air Act Section 211(b) for fuel and fuel additive registration, the petroleum industry and oxygenate manufacturers have conducted comparative toxicology testing of evaporatve emissions from gasoline alone, and gasoline plus ether and alcohol oxygenates. This abstract presents results from chronic toxicity testing of inhaled baseline gasoline vapor condensate (gasoline) and gasoline containing MTBE (G/MTBE). Groups of 50M/50F F344 Crl BR rats were exposed in H2000 whole body inhalation chambers to gasoline or G/MTBE at vapor concentrations of 2000 mg/m3 (low level), 10, 000 mg/m3 (mid level) and 20, 000 mg/m3 (high level) 6 hr/day, 5 d/wk for 104 wk. There were no clinical signs of toxicity attributable to inhalation of either vapor condensate. Survival was not adversely affected by chronic inhalation of either vapor condensate. Mean group body weights of mid and high level male and female gasoline-exposed rats were significantly below control values for most of the study. Group mean terminal body weights of high level and mid level gasoline exposed rats and high level G/MTBE

exposed rats were significantly below control values. Kidney-to-brain weight ratios for high and mid level gasoline exposed females and for high level G/MTBE-exposed males were significantly greater than control. Gross observations at necropsy were chiefly related to lesions commonly present in aged F344 rats. Information on target organ effects and carcinogenicity is pending histopathological evaluations.

# 714 INHALATION TOXICITY OF GASOLINE & FUEL OXYGENATES: 13-WEEK SUBCHRONIC/NEUROTOXICITY STUDY.

G. Hoffman<sup>1</sup>, C. A. Schreiner<sup>2</sup>, C. Parker<sup>2</sup> and T. Gray<sup>2</sup>. <sup>1</sup>Huntingdon Life Sciences Inc., East Millstone, NJ and <sup>2</sup>API 211(b) Research Group, Washington, DC.

In compliance with the Clean Air Act Section 211(b) for fuel and fuel additive registration, the petroleum industry has conducted comparative toxicology testing of evaporative emissions of seven vapor condensates of gasoline (GVC), or gasoline+ether [methyl tertiary butyl ether (G/MTBE), ethyl t-butyl ether (G/ETBE), t-amyl methyl ether (G/TAME), diisopropyl ether (G/DIPE)], or alcohol [ethanol (G/EtOH), t-butyl (G/TBA)] oxygenates. Here we present results of a 13-week inhalation study. Results of satellite studies evaluating genetic toxicity, GFAP and immunotoxicity are addressed in accompanying abstracts. Sprague-Dawley rats were exposed to target concentrations of 0, 2000, 10000, or 20000mg/m3 of each test material, 6 hr/day, 5d/wk for 13 wks. Air-control and 20000mg/m3 groups contained 20 rats/sex; 10/sex terminated at wk 13; 10/sex maintained for 4wk untreated recovery. Other groups contained 10 rats/sex. At wk 13 necropsy, 5 rats/sex/group were transcordally perfused and nervous system tissues prepared for neuropathology; all other rats were prepared for routine microscopy. Body wt gain and food consumption were comparable to concurrent controls for all test materials except at the high dose of G/EtOH (both sexes) and G/ETBE (males only) where decreased gain was seen during exposure but was resolved in recovery rats. Neurobehavioral test results (motor activity [MA], functional observational battery [FOB]) were comparable to controls for all test materials except for G/TBA where dose-related trends in MA and grip strength were observed during exposure but were not seen in recovery rats. Neuropathology was negative in all animals. Increased kidney wt and light hydrocarbon nephropathy (LHN) were observed in treated male rats in all studies. Effects were reversible or nearly reversible after 4wk recovery. LHN is unique to male rats and is not relevant to human toxicity. Results of these studies will be used for comparative risk assessment of gasoline and gasoline/oxygenate blends.

# 715 INHALATION TOXICITY OF GASOLINE & FUEL OXYGENATES: MICRONUCLEUS AND SISTER CHROMATID EXCHANGE TESTS.

C. Schreiner<sup>1</sup>, G. Hoffman<sup>2</sup>, C. Mason<sup>2</sup> and R. Gudi<sup>3</sup>. <sup>1</sup>API 211(b) Research Group, Washington, DC, <sup>2</sup>Huntingdon Life Sciences Inc., East Millstone, NJ and <sup>3</sup>BioReliance, Rockville, MD.

In compliance with the Clean Air Act Section 211(b) for fuel and fuel additive registration, the petroleum industry has conducted a series of comparative multi-endpoint studies of evaporative fractions of seven vapor condensates of gasoline (GVC), or gasoline+ether [methyl t- butyl ether (G/MTBE), ethyl t-butyl ether (G/ETBE), t-amyl methyl ether (G/TAME), diisopropyl ether (G/DIPE)], or alcohol [ethanol (G/EtOH), t-butyl (G/TBA)] oxygenates. Here we present results from micronucleus (MN) and sister chromatid exchange (SCE) tests. Sprague-Dawley rats (5/sex/group used for both studies) were exposed to target concentrations of 0, 2000, 10000, or 20000mg/m3 of each test material, 6 hr/day, 5d/wk for 4 weeks. Positive control groups (5 rats/sex/group) were used for each study; rats were given cyclophosphamide IP, 24hr prior to sacrifice at doses of 5mg/kg for the SCE study and 40mg/kg for the MN study. At treatment end, blood was collected from the abdominal aorta for the SCE test [cultures established within 24 hr of collection], and femurs removed for the MN test. Femoral bone marrow was prepared and stained using a modified Feulgen method. Approx. 21hr after initiation of culture, cells were exposed to 5ug/ml bromodeoxyuridine (BrdU); colcemid was given at 68hr of culture. Cells were harvested after 72hr in culture and processed for SCE evaluation. No significant increased incidence of micronuclei in polychromatic erythrocytes was observed for any test material. Statistically significant increases in SCE over several doses were observed in rats given GVC alone or G/MTBE; females appeared more sensitive than males. G/TAME induced increased SCE in both sexes at the highest dose only. Although several instances of increased SCE were observed in cultured lymphocytes, gasoline and gasoline/oxygenate blends did not induce cytogenetic effects in bone marrow of exposed animals. Results of these studies will be used for comparative risk assessment of gasoline and gasoline/oxygenate blends.

### INHALATION TOXICITY OF GASOLINE & FUEL OXYGENATE: IMMUNOTOXICITY.

K. L. White<sup>1</sup>, V. L. Peachee<sup>1</sup>, S. R. Armstrong<sup>2</sup> and L. E. Twerdok<sup>2</sup>. <sup>1</sup>Immuno Tox, Inc., Richmond, VA and <sup>2</sup>API 211(b) Research Group, Washington, DC.

In compliance with the Clean Air Act Section 211b for fuel and fuel additive registration, the petroleum industry and oxygenate manufacturers have conducted comparative toxicology testing of evaporative emissions of gasoline alone, and gasoline plus ether and alcohol oxygenates. Here we present results from the immunotoxicity component of this program. The antibody-forming cell (AFC) response to the T-dependent antigen, sheep erythrocyte (sRBC), was used to determine the affects of the gasoline vapor condensates on the humoral immune component of the immune system. Seven vapor condensates of gasoline (GVC) or gasoline + an ether [MTBE (G/MTBE), ethyl t-butyl ether (G/ETBE), t-amyl methyl ether (G/TAME), diisopropyl ether (G/DIPE)] or an alcohol [ethanol (G/EtOH), tbutyl alcohol (G/TBÂ)] oxygenates were evaluated. Female Sprague-Dawley rats were exposed to the test agents (2, 000, 10, 000 and 20, 000 mg/m<sup>3</sup>) by inhalation for 4 weeks (6 hrs/day, 5 days/week). Animals were immunized with sRBC four days prior to sacrifice. Spleens were removed the day after the last exposure and were shipped overnight express to ImmunoTox, Inc. where the plaque assays were conducted. Exposure to GVC, G/MTBE, G/TAME, and G/TBA did not result in significant changes in the IgM AFC response to sRBC, when evaluated as either specific activity (AFC/10<sup>6</sup> spleen cells) or as total spleen activity (AFC/spleen). However, exposure to G/EtOH and G/DIPE resulted in a dose-dependent decrease in the AFC response when evaluated as either AFC/10<sup>6</sup> spleen cells or AFC/spleen. The decrease, ranging from 63-86% reached the level of statistical significance at the high (20, 000 mg/m $^3$ ) exposure level. Exposure to G/ETBE resulted in a statistically significant decrease in the AFC response when evaluated as either AFC/10 $^6$ spleen cells or AFC/spleen, which reached the level of statistical significance at the middle (10, 000 mg/m<sup>3</sup>) and high (20, 000 mg/m<sup>3</sup>) exposure levels, ranging from 70-76%. Results of these studies will be used for comparative risk assessments of gasoline and gasoline/oxygenate blends.

## 717 BIOCHEMICAL CHANGES IN RESPIRATORY TISSUES OF RATS EXPOSED TO ETHYL TERT-BUTYL ETHER.

K. M. Broadwell and R. Schatz. Northeastern University, Boston, MA.

Ethyl tert-butyl ether (ETBE), a fuel oxygenate, is added to gasoline to improve combustion and reduce automobile emissions. Studies assessing ETBE respiratory effects are limited. Analysis of bronchoalveolar lavage fluid (BALF) and nasal lavage fluid (NLF) are sensitive tools in assessing suspected respiratory toxicants. In this study, rats were exposed to ETBE (500 and 250 ppm for 6 hours) and sacrificed both immediately and 24 hours following exposure. Significant increases in sialic acid (SA) (93%) and lactate dehydrogenase (LDH) (162%) were seen in NLF of rats sacrificed 24 hours post-exposure to 500 ppm ETBE. Significant increases were observed in protein content (101% and 174%) and acid phosphatase (ACP) (31% and 117%) at 0 and 24 h post exposure in NLF, respectively. There were significant increases in LDH activity (98%), gamma-glutamyl transferase (GGT) (149%), and ACP (86%) at 24 h post-exposure in BALF following a 500 ppm exposure. Following exposure to 250 ppm, there were significant increases in SA (46%), LDH (78%), and ACP (89%) 24 h post-exposure in NLF. ETBE is metabolized to acetaldehyde, a known respiratory irritant and free radical inducer. In vitro incubation with acetaldehyde (0.1mM -1mM) with liver, lung, and nasal mucosa microsomes was investigated in a reactive oxygen species (ROS) assay. Acetaldehyde addition produced dose-dependent increases in ROS formation in hepatic, pulmonary, and nasal microsomes (maximal values of 153%, 154%, and 217% for each organ system, respectively). Following an in vivo exposure to ETBE, there was a significant increase in ROS formation in lung microsomes (172% at 500 ppm) and nasal mucosa microsomes (181% and 140 % at 500 and 250 ppm, respectively) immediately following exposure. Biochemical changes in lavage fluid parameters indicate that ETBE is a respiratory toxicant. A possible mechanism of toxicity may be bioactivation of ETBE in target organs and subsequent formation of ROS.

## 718 CATEGORIZING SIGNS AND SYMPTOMS FOR EMERGENCY RESPONSE PLANNING LEVELS.

G. V. Alexeeff and W. D. Wang. OEHHA, Cal/EPA, Oakland, CA.

The National Advisory Committee for Acute Exposure Guideline Levels for Hazardous Substances (NAC/AEGLs) reviews the scientific literature and identifies adverse effects that may be discomforting (AEGL-1), disabling (AEGL-2), or increasing the likelihood of death (AEGL-3). These levels are to assist emergency response planning. In this analysis, 91 chemical documents were reviewed to evaluate their consistency in classifying signs and symptoms to discrete severity levels. The starting points and adverse effects associated with specific AEGLs were identified. AEGL-1 values based on human data include effects such as headaches, nausea,

vomiting, and mild nervous system responses. AEGL-1 values based on animal signs primarily included eye and respiratory irritation. An emphasis on notable discomfort for the AEGL-1 resulted in a lack of reliance on irritation and other mild adverse effects in humans. The signs and symptoms encountered often did not easily conform with AEGL definitions. Some human effects found to occur below the AEGL-1 included mild eye and respiratory irritation, chest tightness, cough, and slight headache. AEGL-2 values were primarily identified based on animal data such as bronchiolar lesions, pulmonary edema, irreversible ocular lesions, incapacitation, ataxia and malformations. Some AEGL-2 values were identified based on human effects and included exposures producing unbearable irritation or considered intolerable by experimental subjects. AEGL-3 values were almost exclusively based on animal lethality studies. AÉGLs are derived for once-in-a-lifetime exposures during chemical emergencies. In contrast, most air toxics standard setting is designed to address exposures of the susceptible public to routine emissions from facilities or motor vehicles where mild adverse effects become more important due to repeated or prolonged exposures. Consequently, the adverse effects categories and the AEGLs themselves should not be applied as protective standards in situations other than emergency response planning.

# 719 ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR THREE ALIPHATIC AMINES: ALLYLAMINE (AA), CYCLOHEXYLAMINE (CYC), AND ETHYLENEDIAMINE

S. Milanez<sup>1</sup>, L. Koller<sup>2</sup>, M. McClanahan<sup>3</sup>, D. Krewski<sup>4</sup> and K. Bakshi<sup>5</sup>. <sup>1</sup>Oak Ridge National Laboratory, Oak Ridge, TN, <sup>2</sup>Loren Koller & Associates, Corvallis, OR, <sup>3</sup>Centers for Disease Control and Prevention, Doraville, GA, <sup>4</sup>University of Ottawa, Ottawa, ON, Canada and <sup>5</sup>National Research Council, Washington, DC.

AA, CYC, and EDA are basic compounds with ammonia-like or fishy odors. AEGLs are airborne concentrations above which toxic effects of specified severity could occur in humans from one-time exposure for 10 min to 8 hrs: AEGL-1 (discomfort), AEGL-2 (disability), and AEGL-3 (death). AEGLs were developed from animal and human inhalation studies by exponential scaling ( $C^n \times t = k$ ) and use of interspecies and intraspecies uncertainty factors and modifying factors. AEGL-1 values for 10 min to 8 hrs were based on the endpoint of sensory irritation for AA and CYC (0.42 ppm; 1.8 ppm), but were not developed for EDA due to lack of data. AEGL-2 values were associated with respiratory irritation as well as cardiovascular lesions (AA), ocular irritation (CYC), and kidney swelling (EDA). The AEGL-2 values for CYC and EDA for 10 min to 8 hrs (11-2.7 ppm; 12-4.8 ppm) were similar, but values were ~3-fold lower for AA (3.3-1.2 ppm). This indicates that AA will elicit non-lethal toxic effects in humans at lower air concentrations than CYC or EDA. The AEGL-3 endpoint for all three amines was the lethality threshold. Animals that died had lung edema and hemorrhage (AA); ocular opacity and lung and bladder lesions (CYC); but no toxic effects were described for EDA (just death). AEGL-3 values for 10 min to 8 hrs were comparable for CYC (38-9.4  $\,$ ppm) and EDA (25-10 ppm) but spanned a greater range for AA (150-2.3 ppm). The greater values for AA at <4 hrs may have been due to limiting AA metabolism (to acrolein and H<sub>2</sub>O<sub>2</sub>, known to occur in mammals). The developed AEGL values reflect the similarities and differences in the chemical structure and mode of action of the three amines. [This abstract presents Interim AEGL values that are subject to change pending further review.] ORNL is managed by UT-Battelle LLC for the US Department of Energy under contract DEAC0500OR22725.

## 720 ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR URANIUM HEXAFLUORIDE.

C. Bast<sup>1</sup>, <u>G. Rusch<sup>2</sup></u>, D. Krewski<sup>3</sup> and <u>K. Bakshi<sup>4</sup></u>. <sup>1</sup>Oak Ridge National Laboratory, Oak Ridge, TN, <sup>2</sup>Honeywell, Morristown, NJ, <sup>3</sup>University of Ottawa, Ottawa, ON, Canada and <sup>4</sup>National Research Council, Washington, DC.

AEGL values represent one-time exposures for increasingly severe effects with AEGL-1 being least and AEGL-3 being most severe. Uranium hexafluoride (UF<sub>6</sub>) is a volatile solid. When airborne, it hydrolyzes immediately on contact with moisture to form hydrofluoric acid (HF) and uranyl fluoride (UO<sub>2</sub>F<sub>2</sub>). Thus, an inhalation exposure to uranium hexafluoride is actually an inhalation exposure to a mixture of both fluorides. Pulmonary irritation, corrosion, or edema may occur from the hydrofluoric acid component. Renal injury may be observed from the uranium component. In the absence of chemical-specific data, a stoichiometric adjustment factor of 4 was applied to the hydrogen fluoride AEGL-1 values to obtain AEGL-1 values for uranium hexafluoride (3.6 mg/m³). AEGL-1 values were derived only for the 10-minute, 30-minute, and 1-hour time points. AEGL-2 values (28 mg/m³, 19 mg/m³, 9.6 mg/m³, 2.4 mg/m³, and 1.2 mg/m³, for 10-min, 30-min, 1-hr, 4-hr, and 8-hr, respectively) were based on renal pathology in dogs exposed to 192 mg/m³ UF<sub>6</sub> for 30 minutes. AEGL-2 values were adjusted by interspecies and intraspecies UFs of 3 each. In the absence of an empirically derived chemical-specific scaling exponent for renal effects, temporal scaling was performed using n=3 when

extrapolating to shorter time points and n = 1 when extrapolating to longer time points using the equation,  $c^n \ x \ t = k$ . The AEGL-3 values (216 mg/m³, 72 mg/m³, 36 mg/m³, 9.0 mg/m³, and 4.5 mg/m³ for 10-min, 30-min, 1-hr, 4-hr, and 8-hr, respectively) were based on an estimated lethality threshold in rats. Values were divided by a total uncertainty factor of 10 and scaled across time using the exposure-concentration duration relationship  $c^1 \ x \ t = k$ , shown to be valid for lethality in rats from pulmonary effects of UF6. [This abstract presents Interim AEGL values subject to change pending further review.]  $^1$ Oak Ridge National Laboratory, managed by UT-Battelle, LLC, for the US Department of Energy under contract DEAC0500OR22725.

### 721 ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR HYDROGEN CHLORIDE.

R. Young<sup>1</sup>, C. Bast<sup>1</sup>, J. Hinz<sup>2</sup>, D. Krewski<sup>3</sup> and K. Bakshi<sup>4</sup>, <sup>1</sup>Oak Ridge National Laboratory, Oak Ridge, TN, <sup>2</sup>USAF, Brooks AFB, TX, <sup>3</sup>University Ottawa, Ottawa, ON, Canada and <sup>4</sup>National Research Council, Washington DC, DC.

AEGL values represent one-time exposures for increasingly severe effects with AEGL-1 being least and AEGL-3 being most severe. Hydrogen chloride is an upper respiratory irritant at relatively low concentrations and may cause damage to the lower respiratory tract at higher concentrations. Regression analyses of the exposure-concentration duration relationship for lethality in rats and mice determined that the relationship is  $c^{1} x t = k$ . The AEGL-1 values were based on a 45 minute no-adverse-effect-level of 1.8 ppm in exercising adult asthmatics. No uncertainty factors were applied because the study population consisted of sensitive humans. The 1.8 ppm value was held constant across all exposure durations because there is adaptation to the slight irritation that defines AEGL-1. The 10-minute AEGL-2 value (100 ppm) was derived by dividing the mouse RD50 of 309 ppm by a factor of 3 to estimate an irritation threshold. AEGL-2 values for 30-min, and 1-hr (43 ppm, 22 ppm, respectively) were based on severe nasal or pulmonary histopathology in rats exposed to 1300 ppm for 30 minutes. The values were adjusted by intraspecies and interspecies Uncertainty Factors (UFs) of 3 each and a modifying factor of 3, for a total of 30. Time scaling utilized the regression relationship above. The 4- and 8-hour values (11 ppm) were derived by applying a modifying factor of 2 to the 1-hr AEGL-2 value. The 10-min, 30-min, 1-hr, and 4-hour AEGL-3 values (620 ppm, 210 ppm, 100 ppm, 26 ppm, respectively) were based on an estimated lethality threshold in rats. Values were divided by a total uncertainty factor of 10 and time-scaled using the regression relationship above. The 8-hour value (26 ppm) was set equal to the 4-hour value because low concentrations of HCl are well scrubbed in the nasal passages. These Interim AEGL values are subject to change pending further review. <sup>1</sup>Oak Ridge National Laboratory, managed by UT-Battelle, LLC, for the US Department of Energy under contract DEAC0500OR22725.

## 722 ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR HYDROGEN FLUORIDE.

S. Talmage<sup>1</sup>, L. Gephart<sup>2</sup>, D. Krewski<sup>3</sup> and <u>K. Bakshi<sup>4</sup>. <sup>1</sup>Oak Ridge National Laboratory, Oak Ridge, TN, <sup>2</sup>Exxonmobil Biomedical Sciences, Inc., Annandale, NJ, <sup>3</sup>University of Ottawa, Ottawa, ON, Canada and <sup>4</sup>National Research Council, Washington, DC.</u>

AEGL values represent one-time exposures for increasingly severe effects with AEGL-1 being least and AEGL-3 being most severe. AEGL values were developed for hydrogen fluoride (HF), a colorless, highly irritating gas. Data on irritant effects in humans and lethal and sublethal effects in six species of mammals were available for development of AEGL values. Regression analyses of the exposure durationconcentration relationship for lethality for the animal species determined a relationship of  $C^2$  x t = k. The AEGL-1 value was based on a clinical study in which 3 ppm was the threshold for irritation. The 3 ppm value was divided by an intraspecies uncertainty factor (UF) of 3 to protect sensitive individuals. The resulting 1 ppm value was used across all exposure durations because there is adaptation to the slight irritation that defines the AEGL-1. The 10-minute AEGL-2 and AEGL-3 values were based on 10-minute no-effect (950 ppm) and lethal threshold (1700 ppm) values, respectively, in cannulated rats. The values were adjusted by intraspecies and interspecies UFs of 3 each for a total of 10. The 30-minute through 4-hour AEGL-2 values were based on a 1-hour exposure to 243 ppm in which dogs showed signs of sensory irritation. The value was divided by a total UF of 10 and time scaled to the longer exposure durations using the regression relationship above. The 8-hour value was set equal to the 4-hour value because at this concentration (12 ppm), HF is well scrubbed in the nasal passages. The 10-minute through 4-hour AEGL-3 values were based on the threshold for lethality in mice, a 1-hour exposure to 263 ppm. Adjustment was by an uncertainty + modifying factor of 6; time-scaling used the regression relationship above. The 8-hour value was set equal to the 4-hour value. [This abstract presents interim AEGL values subject to change pending further review.] <sup>1</sup>ORNL, managed by UT-Battelle, LLC, for the US Department of Energy under contract DEAC0500OR22725.

## 723 ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR TOLUENE DIISOCYANATE.

C. S. Wood<sup>1</sup>, S. J. Barbee<sup>2</sup>, D. Krewski<sup>3</sup> and K. Bakshi<sup>4</sup>. <sup>1</sup>Oak Ridge Nat. Lab., Oak Ridge, TN, <sup>2</sup>Arch Chemicals Inc., Norwalk, CT, <sup>3</sup>University of Ottawa, Ottawa, ON, Canada and <sup>4</sup>National Research Council, Washington, DC.

2, 4- and 2, 6-Toluene diisocyanate (TDI) cause irritation and sensitization of the respiratory tract. Only irritation effects were considered in establishing AEGL values. AEGLs represent threshold exposure limits for the general public and are applicable to emergency exposure periods of 10 min, 30 min, 1 hr, 4 hr, and 8 hr. AEGL-1 (discomfort) values (0.02, 0.02, 0.02, 0.01, 0.01 ppm, respectively) were based on exposure of fifteen asthmatics to 0.01 ppm TDI for 1 hr, then after a rest of 45 min, to 0.02 ppm TDI for 1 hr. No statistically significant differences in lung function parameters were observed, but nonpathological bronchial obstruction was measured in several individuals; eye and throat irritation, cough, chest tightness, rhinitis, dyspnea, and/or headache were reported. AEGL-2 (disability) values (0.24, 0.17, 0.083, 0.021, and 0.021 ppm, respectively) were based on human data. Exposure of volunteers to 0.5 ppm for 30 minutes resulted in severe eye and throat irritation and lacrimation. A higher exposure concentration was intolerable. Extrapolations were made with the equation  $C^n \times t = k$  using default values of n = 3for extrapolating to shorter durations and n = 1 for extrapolating to longer durations. An uncertainty factor of 3 was applied to account for sensitive individuals. Animal data were used to derive AEGL-3 (death) values (0.65, 0.65, 0.51, 0.32, and 0.16 ppm, respectivley). The 4-hr mouse LC<sub>50</sub> of 9.7 ppm was divided by 3 to estimate a threshold of lethality and scaled as described for AEGL-2. A total uncertainty factor of 10 was applied which includes 3 to account for sensitive individuals and 3 for interspecies extrapolation. [This abstract presents Interim AEGL values that are subject to change pending further review.] Oak Ridge National Laboratory, managed by UT-Battelle, LLC, for the US Department of Energy under contract DEAC0500OR22725.

## 724 ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR ETHYLENIMINE (EI) AND PROPYLENIMINE (PI).

J. H. Moyer<sup>1</sup>, <u>K. A. Davidson</u><sup>1</sup>, M. A. McClanahan<sup>2</sup>, D. Krewski<sup>2</sup> and <u>K. S. Bakshi<sup>4</sup></u>. <sup>1</sup>Oak Ridge National Laboratory, Oak Ridge, TN, <sup>2</sup>CDC (retired), Atlanta, GA, <sup>3</sup>University of Ottawa, Ottawa, ON, Canada and <sup>4</sup>National Res. Council, Washington, DC.

AEGL values represent threshold exposure limits for the general public and are applicable to emergency exposure periods of 10, 30, and 60 min, 4 hrs, and 8 hrs. The three AEGL levels (discomfort, disability, and death, respectively) are distinguished by varying degrees of severity of toxicity. EI PI are very reactive alkylating agents that cause blistering similar to that of nitrogen mustard. EI and PI vapors are irritating to the skin, eyes, and respiratory tract; PI, however, is less toxic than EI. The effects of both chemicals may be delayed depending upon the concentration. Data were not available for deriving AEGL-1 values for either EI or PI. Death and/or extreme respiratory difficulty occurred at EI concentrations ≥25 ppm for 1 to 8 hrs. Therefore, AEGL-2 values for EI (33, 9.8, 4.6, 1.0, and 0.47 ppm, respectively) were based a no-observed-effect-level (NOEL) for extreme respiratory difficulty (10 ppm for a 4-hr exposure) in guinea pigs. AEGL-3 values for EI (51, 19, 9.9, 2.8, and 1.5 ppm, respectively) were based on an estimation of the lethality threshold (LC<sub>01</sub>) of 15 ppm for rats exposed to EI for 8 hrs. AEGL-2 values for PI (83, 25, 12, 2.5, and 1.2 ppm, respectively) were based on the relative potency factor of 5 for PI compared with EI. AEGL-3 values for PI (170, 50, 23, 5.1, and 2.4 ppm, respectively) were based on the NOEL for lethality (500 ppm for 30 min) in guinea pigs. Interspecies and intraspecies uncertainty factors of 3 and 3, respectively, (total UF = 10) were applied to the NOEL to derive the AEGL values. The equation  $\mathrm{C}^{\mathrm{n}}\,\mathrm{x}$ t = k, where n = 0.91 for the guinea pig studies and n = 1.1 for the rat study, was utilized for time scaling across the 10-min to 8-hr time frames. [This abstract presents interim AEGL values that are subject to change pending further review.] Oak Ridge National Laboratory, managed by UT-Battelle, LLC, for the US Department of Energy under contract DEAC0500OR22725.

## 725 INTERIM ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR ETHYLENE OXIDE.

 $\underline{K.\ A.\ Davidson}^1 \ and \ K.\ Blackman}^2. \ ^1Life\ Sciences\ Division,\ Oak\ Ridge\ National\ Laboratory,\ Oak\ Ridge,\ TN\ and\ ^2FEMA,\ Washington,\ DC.$ 

AEGL values represent threshold exposure limits for the general public and are applicable to emergency exposure periods of 10 min, 30 min, 60 min, 4 hrs, and 8 hrs, and the three levels are distinguished by varying degrees of severity of toxicity. Ethylene oxide (EO) is a direct alkylating agent that is readily absorbed from the respiratory tract of both humans and animals. Inhalation of ethylene oxide vapor has been shown to affect the eyes, respiratory tract, central and peripheral nervous systems, hematopoietic system, and the developing fetus of humans and/or animals. AEGL-1 values were not developed for EO because the odor detection

threshold (\$\geq 260\$ ppm) and concentrations causing mild sensory irritation would be above the AEGL-2 levels. AEGL-2 values (80, 80, 45, 14, and 7.9 ppm for 10 min, 30 min, and 60 min, 4 hrs, and 8 hrs, respectively) were based on a developmental toxicity study in rats. Uncertainty factors (UFs) of 3 for interspecies sensitivity and 3 for intraspecies variability (total UF = 10) were applied to the exposure concentration of 100 ppm for 6 hrs that caused growth retardation in rat fetuses. The equation, C<sup>n</sup> x t = k, where n = 1.2, was utilized for time scaling across the relevant exposure durations. The 10-min value is set the same as the 30-min value because of the uncertainty of scaling from a 6-hr study to 10 min. AEGL-3 values (360, 360, 200, 63, and 35 ppm, respectively) were based on an estimation of the lethality threshold (LC01 = 628 ppm) utilizing a 4-hr acute inhalation study in rats. Application of UFs and the time scaling method were the same as described for AEGL-2 values. [This abstract presents interim AEGL values that are subject to change pending further review.] Oak Ridge National Laboratory, managed by UT-Battelle, LLC, for the US Department of Energy under contract DEAC0500OR22725.

## 726 INTERIM INDOOR HEALTH GUIDANCE LEVEL FOR FORMALDEHYDE.

R. Lam, R. J. Blaisdell and M. A. Marty. CalEPA/OEHHA, State of California, Oakland. CA.

Since 2000 the California Department of Health Services (CDHS) has been using OEHHA's chronic Exposure Reference Levels (RELs) as guidance levels in controlling the release of pollutants from indoor products. The chronic REL for formaldehyde is 2 ppb (3 \*mu\*g/m3) and is often found above that level in indoor air. OEHHA's chronic RELs are intended to protect the general public who could be exposed to a pollutant continuously for a 24-hour time period. CDHS requested OEHHA to provide an 8-hour indoor health standard for formaldehyde with consideration that at present time it is impossible to completely eliminate formaldehyde emission from wood products. The acute 1-hour REL of 76 ppb (94 \*mu\*g/m3) for formaldehyde was derived from a human study with eye irritation as the adverse health effect. An 8-hour interim indoor REL (IREL) of 27 ppb (33 \*mu\*g/m3) was derived directly from this human study using a modification of Haber's Law, Cn \* T = K, where n=2. An uncertainty factor of 10 was used to account for intraindividual variability in the human population. This interim number has been used for assessing human exposure to formaldehyde on a typical 8-hour workday or school day. The interim IREL for formaldehyde represents the current best scientific judgment, but there may be need for periodic revision of the number when new scientific data become available. It is believed that inhalation of formaldehyde at 27 ppb or below, will not have adverse noncancer health effects, primarily irritation, for most people. However, highly sensitive groups especially those that respond immunologically to the chemical may be effected at levels below this concentration. Health effects at or below this level can also result from combined exposures to various chemicals or from exposure to the same chemical by multiple routes.

## 727 UPDATING USEPA'S AMBIENT WATER QUALITY CRITERIA FOR ARSENIC (AS): TOXICITY AND BIOACCUMULATION.

T. R. Henry<sup>1</sup>, T. Linton<sup>2</sup>, W. Clement<sup>2</sup>, D. McIntyre<sup>2</sup> and C. Abernathy<sup>1</sup>.

<sup>1</sup> Office of Water, USEPA, Washington, DC and <sup>2</sup> Great Lakes Environmental Center, Columbus, OH.

The Clean Water Act requires the USEPA (EPA) to develop, publish and periodically revise AWQC. Human health AWQC are numeric values for pollutant concentrations in ambient waters considered to be protective of human health. In 2000, USEPA updated the methodology for deriving AWQC to reflect advances in key areas such as risk assessment, exposure assessment and bioaccumulation. EPA published partial updates to AWQC, incorporating new information on toxicity and fish consumption, for 83 chemicals in 2000 and proposed updates to 15 chemicals in 2002. As, for which a major reassessment is ongoing, was not included in the 2000 or 2002 updates. Key components of the As criterion reassessment are the toxicology and bioaccumulation inputs. The toxicological basis for the existing As criteria is skin cancer. EPA has considered recent information on target tissues and dose-response relationships for As toxicity and concluded that the cancer potency factor should be based on bladder and lung cancers and therefore, is currently revising the slope factor. To assess the bioaccumulation potential of As, a literature review was conducted to identify data on the relative amounts of inorganic and organic As in aquatic organisms and surface waters. The literature search results have been reviewed for applicability in deriving trophic-level specific bioaccumulation factors, as per the 2000 human health methodology. The present data set is insufficient to derive bioaccumulation factors for any As species other than total As. The proportion of total As in freshwater fish that is inorganic appears to be considerably higher than that previously reported for marine fish and shellfish, and indicates that

As speciation data from marine species should not be used for freshwater species. The statements expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of EPA.

# 728 ARSENIC SPECIATION AND BIOACCUMULATION STUDIES SUPPORT HIGHER AMBIENT WATER QUALITY CRITERION (AWQC).

R. A. Schoof<sup>1</sup>, L. Williams<sup>1</sup> and J. W. Yager<sup>2</sup>. <sup>1</sup>Integral Consulting, Inc., Bellevue, WA and <sup>2</sup>Electric Power Research Institute, Palo Alto, CA.

The AWQC for protection of human health for arsenic (As) is currently 0.14 µg/L for fish ingestion. Two principal assumptions used to derive the current arsenic AWQC need to be reevaluated when these studies are revised, including the assumption that all arsenic in fish has toxic potential comparable to inorganic As (Asi), and the use of a bioaccumulation factor (BAF) of 44. The majority of the arsenic in fish is composed of complex organic arsenicals that are relatively nontoxic. Available studies of As speciation in seafood support the following assumptions regarding the fraction of total As (As-tot) that is As-i in various kinds of seafood: freshwater fish, 0.1, marine and estuarine fish, 0.01, crustaceans, 0.01, and molluscs, 0.02. The fractional contribution of these seafood categories to the total fish consumption value of 17.5 g/day is as follows: freshwater fish, 0.19, marine and estuarine fish, 0.37, crustaceans, 0.41 and molluscs, 0.03. Multiplying these intake fractions by the corresponding As-i fraction indicates that an average of 2.7% of Astot in seafood consumed is As-i. The BCF of 44 was intended for broad application to freshwater and estuarine environments, and is based on consumption-weighted values for oysters (350) and fish (1). However, available studies of As bioaccumulation in seafood suggest that no increases in tissue As concentrations occur in freshwater fish exposed to water As concentrations less than 100 μg/L. Additional studies are needed to verify this finding and to assess bioaccumulation in estuarine species and shellfish. On an interim bases, a BAF of 1 should be used to derive a revised As AWQC for fish consumption. When this BAF and an adjustment of 0.027 to reflect the average fraction of As-tot that is As-i and the current oral cancer slope factor are incorporated into the AWQC equation, the resulting value is 99  $\mu\text{g/L}.$ This analysis demonstrates that the current As AWQC for fish consumption may be more than 700-fold lower than needed to protect human health.

## 729 ESTIMATING A RELATIVE SOURCE CONTRIBUTION FOR DRINKING WATER IN ARSENIC (AS) RISK ASSESSMENTS.

I. S. Dooley<sup>1</sup>, <u>C. O. Abernathy</u><sup>1</sup>, M. Devitt<sup>2</sup> and A. Kotros<sup>2</sup>. <sup>1</sup>Environmental Protection Agency, Washington, DC and <sup>2</sup>The Cadmus Group, Watertown, MA.

In 1996, the EPA charged the National Academy of Sciences/National Research Council (NRC) to review the Agency's draft risk assessment of As in food and drinking water, considering the available studies. NRC issued a report in 1999 and EPA used many of the NRC's recommendations and data to quantify bladder and lung cancer risks for its 2001 arsenic drinking water regulation. After publishing the final arsenic rule on January 22, 2001, the Agency asked the NRC to re-evaluate the Agency's risk assessment, available studies, and the effect of data uncertainties and differences in populations related to As. One uncertainty examined is water consumption. The 2001 NRC report commented on the Taiwanese water consumption rates applied in the 1999 NRC report and EPA's 2001 drinking water risk assessment and characterization. In this paper, we use US Army data to examine some parameters that can affect water consumption to estimate drinking water consumption in Taiwan. We used both temperature and relative humidity to develop heat categories along with 3 different levels of work (light, medium or heavy activity) to estimate the water intake levels for Taiwanese (adjusted to 50 kg). During the warm season (or growing season), water intake estimates ranged from 4.3 L/day (light activity) to 6.4 L/day (medium to heavy activity). During the cooler months, the lower bound estimates were taken from the Army's minimum recommendations of 1.7 to 2.1 L/day. These calculations were based on only "working" hours and average temperatures to calculate water needs. For most of the year, water intake is near 2 L/day, but during growing season, they may reach 2 to 3 times the 2 L/day rate generally used by EPA to estimate water consumption. This methodology needs to be further validated prior to its use in risk assessments. [These views are those of the authors and do not necessarily represent the views of EPA or the Cadmus Group.]

# 730 RISK ASSESSMENT FOR CHEMICALS IN DRINKING WATER: ESTIMATION OF RELATIVE SOURCE CONTRIBUTION.

R. A. Howd, J. P. Brown and A. M. Fan. Office of Environmental Health Hazard Assessment, CallEPA, Oakland, CA.

In estimating health-protective levels of chemicals in drinking water, one of the factors that should be considered is the proportion of the total permissible dose that is derived from water, versus other exposure routes. This is applied only for chemicals

or toxic effects presumed to involve a toxicity threshold (primarily non-cancer effects), in which the combined daily dose from all exposure routes is used for calculation of allowable exposure levels. However, the calculation of the relative source contribution (RSC) is usually rather crude due to a lack of appropriate data, and the methods for estimation of an RSC in the absence of good data involve a large component of professional judgment. USEPA (USEPA) policy provides limited guidance on calculating RSC. Values in the range of 0.2 to 0.8 (20 to 80%) are allowed, with a default value of 0.2 (20%) of total permissible exposure in the absence of data. OEHHA has generally followed this guidance, although it has also used a value of 1.0 (100%) in its derivation of Public Health Goals (PHGs) for drinking water when human data were used, which was uncontrolled for environmental exposures. Application of the principles for development of RSCs can be illustrated by examining the values and rationale used in the development of PHGs. Examples of the range of values include aluminum (1.0, acute human study), beryllium (0.2, animal study), cadmium (0.2, chronic human study), copper (0.8, acute human study), ethylbenzene (0.2, chronic animal study), fluoride (1.0, chronic human studies), Freon-11 (0.4, subchronic animal study), nickel (0.3, animal reproductive study), simazine (0.2, chronic animal study), thallium (0.2, subchronic animal study), 1, 2, 4-trichlorobenzene (0.2, subchronic animal study), and xylene (0.4, chronic human study). The entire set of 69 chemicals for which PHGs have so far been finalized provides a larger database for illustration of the application of RSC development principles.

## 731 INTERACTION PROFILE FOR CHEMICALS IN RURAL WELL WATER.

J. Colman<sup>1</sup> and H. Pohl<sup>2</sup>. <sup>1</sup>Syracuse Research Corp., Syracuse, NY and <sup>2</sup>ATSDR, Atlanta, GA. Sponsor: P. McGinnis.

Atrazine, deethylatrazine, simazine, diazinon and nitrate frequently occur together in rural well water. The potential impact of this mixture on public health was evaluated using an approach developed by ATSDR. Because pertinent data were not available for the whole mixture, evaluation of health effects, mechanistic and joint toxic action data for individual components and various combinations of components was performed in the ATSDR Interaction Profile. The profile recommends that reproductive health hazard of atrazine, deethylatrazine and simazine be assessed with the hazard index (HI). Neurological effects of diazinon and hematological effects of nitrate are to be assessed with separate hazard quotients (HQs). This approach is used when HQs of components are ≥0.1. The Weight of Evidence (WOE) for interactions indicates high confidence in the dose additivity assumption (HI) for triazine components and uncertainty regarding potential effects of diazinon or nitrate on reproductive toxicity of these components. WOE analysis suggests that the triazine components may potentiate neurological toxicity of diazinon such that the HQ may underestimate the hazard. No information regarding impact of interactions on hematological toxicity of nitrate was available so uncertainty is high for this endpoint. Although components of this mixture have not been classified as carcinogens, triazines may interact with nitrate (as the metabolite nitrite) to form N-nitrosoatrazine and N-nitrososimazine, which are more genotoxic than the parent triazines. Confidence in the WOE prediction that this chemical interaction may result in carcinogenicity is medium because although adequate cancer data are lacking for these compounds, data for other N-nitrosamines and their precursors support the prediction. When screening criteria are exceeded (HI>1 for reproductive effects of triazine components, HQ close to or >1 for neurological effects of diazinon, and/or HQ>1 for nitrate), further evaluation is needed using biomedical judgment and community-specific health outcome data and taking into account potential carcinogenicity of nitrosamines that may be formed.

## 732 REGULATORY DETERMINATION FOR HEXACHLOROBUTADIENE IN DRINKING WATER.

D. Wong and J. Du. USEPA, Washington, DC.

The 1996 Safe Drinking Water Act Amendment (SDWA) requires EPA to establish a list of contaminants to aid the Agency in regulatory priority setting for its drinking water program. The first Contaminant Candidate List (CCL) was published on March 2, 1998; and hexachlorobutadiene (HCBD) was one of the 19 chemicals in the regulatory determination priority category. The SDWA requires EPA to make regulatory determinations for no fewer than five contaminants in the regulatory determination priority category. Regulations are only recommended when all the following three criteria are satisfied: 1) The chemical must have adverse health effects, 2) It must occur or is likely to occur in drinking water at concentrations of health concern, and 3) Regulation of this chemical provides a meaningful opportunity to reduce human risk. The available toxicological data indicate that HCBD can cause adverse health effects in animals, and probably also in humans at high dose. In rodents, there is clear evidence of renal damage resulting from acute, subchronic, and chronic exposures to HCBD by the oral route. Under EPAs 1999 draft Guidelines for Carcinogen Risk Assessment, HCBD is classified as likely to be carcinogenic to

humans by the oral route of exposure. However, the available data on occurrence, exposure, and other risk considerations suggest that, because HCBD does not occur in public water systems at frequencies and levels of public health concern, regulating HCBD will not present a meaningful opportunity for health risk reduction for persons served by public water systems. (The opinions expressed in this abstract are those of the author and not necessarily those of EPA.)

## 733 DERIVATION OF A DRINKING WATER ACTION LEVEL FOR 2-MERCAPTOBENZOTHIAZOLE.

<u>A. Gebhart</u><sup>1</sup>, <u>M. H. Whittaker</u><sup>2</sup> and F. Hammer<sup>1</sup>. <sup>1</sup>Water Program, Underwriters Laboratories, Northbrook, IL and <sup>2</sup>ToxServices, Washington, DC.

2-Mercaptobenzothiazole (MBT) is used as a vulcanization accelerator in rubber products that come into contact with potable drinking water. When such products are submitted for ANSI/NSF Standard 61 certification, any chemical extracting from these products must be below an appropriate action level. As defined by Standard 61, a Total Allowable Concentration (TAC) is the maximum concentration of a nonregulated contaminant allowed in a public drinking water supply, and the Single Product Allowable Concentration (SPAC) is 10% of the TAC. În order to determine an action level for MBT, a comprehensive health effects evaluation was performed. Epidemiological investigations indicate that occupational exposure to MBT results in an increased risk of death from bladder cancer. Genotoxicity investigations provide evidence indicating that MBT has the potential to induce mutations and chromosome aberrations. Studies in rats and mice chronically exposed to MBT identified increases in tumors, such as adrenal, pituitary, liver, and renal pelvis tumors. The biological significance of most of these tumors is questionable due to a lack of dose-response, and the effect of test article vehicle (corn oil) upon tumor rates. A review of the epidemiological and toxicological datasets for MBT indicates that the induction of renal pelvis transitional cell tumors is the most sensitive health effects endpoint upon which to base a TAC and SPAC. A linearized multistage model was used to extrapolate to low-dose MBT exposure due to the genotoxicity of MBT. A TAC of 100  $\mu g/L$  was derived for MBT, and is based upon an LED10 of 164.18 mg/kg/day and a 20% relative source contribution factor. A SPAC of 10  $\mu$ g/L was derived by multiplying the revised TAC by 0.10. These action levels are based upon the most sensitive health effects endpoint, as well as current risk assessment methodologies.

## 734 HUMAN HEALTH RISK ASSESSMENT OF FURFURAL TO DETERMINE DRINKING WATER ACTION LEVELS.

A. Ewing<sup>1</sup>, A. Phelka<sup>2</sup>, G. Ball<sup>3</sup> and C. McLellan<sup>4</sup>. <sup>1</sup>NSF International, Ann Arbor, MI, <sup>2</sup>NSF International, Ann Arbor, MI, <sup>3</sup>NSF International, Ann Arbor, MI and <sup>4</sup>NSF International, Ann Arbor, MI. Sponsor: M. Dourson.

A human health risk assessment was conducted by NSF International to determine acceptable levels of furfural in drinking water according to NSF/ANSI Standard 60/61, Annex A. The scientific literature relating to human and laboratory animal exposure to furfural was reviewed. Significant treatment-related responses were limited to liver lesions in high-dose male rats. A chronic rat bioassay completed by the NTP (1990) was selected as the key study from which oral risk values were derived. Groups of 50 F344/N rats of each sex were administered furfural by gavage at adjusted doses of 0, 21 or 43 mg/kg-day. Significant liver lesions were observed at each of the two administered doses, preventing the identification of a NOAEL. However, the available data suggested that a dose level should exist below which no significant treatment-related responses were observed. Benchmark dose modeling after conversion to human equivalent doses, was used to derive a BMDL10 of 2.9 mg/kg-day using centrilobular necrosis of the liver as the critical, treatment-related and precursor response. The logistic model provided the best fit, although five other dichotomous models gave similar results. Uncertainties of 3x for interspecies variability, 10x for intraspecies variability, 3x for database deficiencies and 1x each for less-than-lifetime extrapolation and LOAEL to NOAEL extrapolation were incorporated into the oral RfD derivation. An oral RfD of 0.03 mg/kg-day, with a 20% relative source contribution for drinking water was used to derive NSF-specific risk management values, including a Total Allowable Concentration of 0.2 mg/L and a Single Product Allowable Concentration of 0.02 mg/L.

#### 735 HUMAN HEALTH RISK ASSESSMENT FOR *p*-CHLORO*m*-CRESOL TO DETERMINE DRINKING WATER ACTION LEVELS.

J. Durham, V. S. Bhat, G. L. Ball and C. J. Mclellan. *Toxicology Services, NSF International, Ann Arbor, MI.* Sponsor: M. Dourson.

A risk assessment to determine acceptable levels of *p*-chloro-*m*-cresol in drinking water was conducted according to Annex A of NSF/ANSI Standard 60/61. Scientific literature in humans and animals was reviewed. *p*-Chloro-*m*-cresol tested

positive in one Salmonella reverse mutation assay in Strain TA97 with metabolic activation but tested negative in all tested strains in four other Salmonella studies. Chloro-m-cresol tested negative in chromosomal aberration and unscheduled DNA synthesis assays. The weight of evidence suggested p-chloro-m-cresol is not genotoxic. In a developmental study, a NOAEL of 100 mg/kg-day was chosen based on clinical signs of toxicity and decreased mean body weight gain in dams and also based on a statistically significant decrease in mean fetal weight per litter. The critical study chosen for this risk assessment was a two-year feeding study in which rats were administered p-chloro-m-cresol at 0, 21, 103.1, or 558.9 mg/kg-day in males and 0, 27.7, 134.3, or 743.5 mg/kg-day in females, as indicated by the authors of the study. In mid-dose females and low-dose males, a statistically significant increase in the number of pituitary adenomas was observed. In mid- and high-dose males, a statistically significant increasing trend of testicular interstitial cell adenomas was observed. Since all neoplastic effects were within historical control ranges, they were not considered relevant. In high-dose males, an increased incidence of unilateral papillary necroses, truncated papillae, and cortical dilations and fibrosis of the kidneys were observed. These renal effects were considered to be the critical effects. Using a NOAEL of 103.1 mg/kg-day and an uncertainty factor of 1000x to account for interspecies extrapolation, intraspecies variability, and database deficiencies, an oral RfD of 0.1 mg/kg-day was calculated. The resulting Short-Term Exposure Level was calculated to be 1 mg/L, and the chronic exposure levels, Total Allowable Concentration and Single Product Allowable Concentration, were calculated to be 0.7 mg/L and 0.07 mg/L, respectively.

736

RISK ASSESSMENT FOR DRINKING WATER CONTAMINANTS: ASBESTOS, BARIUM, BERYLLIUM, CHLOROBENZENE, 1, 1- DICHLOROETHANE, DIETHYLHEXYLADIPATE, ETHYLENE DIBROMIDE, HEXACHLOROBENZENE, SILVEX, 1, 1, 2, 2-TETRACHLOROETHANE AND TOXAPHENE.

A. M. Fan, R. A. Howd, G. Alexeeff, M. Sullivan, T. Parker, J. Avalos, P. Painter, D. Ting, N. Butler, C. Vidair and L. Jowa. Office of Environmental Health Hazard Assessment, California Environmental Protection Agency, Oakland/Sacramento, CA.

Risk assessments were performed for 11 chemicals for development of public health goals (PHGs) in drinking water. PHGs are non-regulatory concentrations in water that are not anticipated to produce adverse health effects following a lifetime exposure, based on health considerations. Toxicological evaluations included both animal and human studies, and carcinogenic and non-carcinogenic endpoints. The PHGs established based on carcinogenic endpoints are: Asbestos, 7E6 fibers/L (>10 um), mice; 1, 1-dichloroethane, 3 ppb, rats; ethylene dibromide, 10 ppb, rats and mice; hexachlorobenzene, 0.03 ppb, rats; 1, 1, 2, 2-tetrachloroethane, 0.1 ppb, mice; and toxaphene, 0.03 ppb, mice. PHGs based on non-cancer endpoints are: Barium, 2000 ppb, absence of cardiovascular effects (hypertension), human; beryllium, 1 ppb, gastrointestinal tract lesions, dog; diethylhexyladipate, 200 ppb, fetotoxicity, rat; chlorobenzene, 200 ppb, liver pathology, dog; and silvex, 25 ppb, liver pathology, dogs. The assessments included the consideration of sensitive populations, cancer potency values, relative source contribution, uncertainty factors, and water consumption intake. These PHGs were finalized September 2003 after extensive periods for scientific peer review and public input.

#### 737

HEALTH RISKS TO FETUSES, INFANTS AND CHILDREN (PROPOSED STAGE 2 DISINFECTANT/DISINFECTION BYPRODUCTS): A REVIEW.

Q. Zhao<sup>1</sup>, N. Chiu<sup>2</sup>, J. Du<sup>2</sup>, A. Bathija<sup>2</sup>, J. Donohue<sup>2</sup> and <u>D. Wong</u><sup>2</sup>. <sup>1</sup>TERA, Cincinnati, OH and <sup>2</sup>USEPA, Washington, DC.

The 1996 Safe Drinking Water Act requires that any new regulations for a drinking water contaminant must address the risk to sensitive populations, including children. In the development of Stage 1 regulations for the disinfectants and disinfectant by-products (DBPs), a children's risk report was developed in 1998 entitled "Health Risks to Fetuses, Infants, and Children (Final Stage 1 D/DBP Rule)." A corresponding Stage 2 D/DBP document updates the Stage 1 document on health risks to fetuses, infants, and and includes a number of new developmental, reproductive and cancer studies in animals, in addition to new epidemiology data on developmental and reproductive effects. The new document includes proposals for new Maximum Contaminant Level Goals (MCLGs) for three DBPs: monochloroacetic acid (MCA), trichloroacetic acid (TCA), and chloroform. MCLGs and Maximum Residential Disinfectant Level Goals (MRDLGs) promulgated in 1998 for six DBPs and three disinfectants are unchanged, but the health effects data base as it relates to the fetuses, infants and children has been updated. At the present time, the data necessary for quantifying risks are not available for four DBPs, these are: monobromoacetic acid (MBA), bromochloroacetic acid (BCA), dibromoacetic acid (DBA) and 3-chloro-4-(dichloromethyl)-5-hydroxy-2(5H)-furanone (MX).

#### 738

DERIVATION OF A LITRE-EQUIVALENT MODIFYING FACTOR TO ACCOUNT FOR MULTIROUTE EXPOSURES IN SETTING DRINKING WATER GOALS FOR TRIHALOMETHANES (THMS)

K. Krishnan<sup>1</sup> and R. Carrier<sup>2</sup>. <sup>1</sup>Occupational and Environmental Health, Universite de Montreal, Montreal, QC, Canada and <sup>2</sup>Water Quality and Health Bureau, Health Canada, Ottawa, ON, Canada.

In establishing the drinking water goals for THMs, the importance of inhalation and dermal routes associated with showering and bathing should be evaluated. The objective of the present study was to derive a modifying factor, in terms of L-equivalent, for each of the THMs by evaluating the relative contribution of inhalation and dermal exposures associated with household use of tap water. The approach involved the derivation of an overall L-equivalent for dermal and inhalation exposures to THMs during showering/bathing as follows: L-equivalent = (Kp x A x t x F x 0.001) + (Pw/a x Qp x t x F x 0.001), where Kp = skin permeability coefficient (cm/hr), A = area of skin exposed (sq. cm), t = duration of exposure (hr), F = fraction of the dose that is absorbed (unitless), Pw/a = water-to-air factor (L/cub. metre), Qp = alveolar ventilation rate (L/hr), and 0.001 = conversion factor (L to cubic metre, or cubic cm to L). To solve the above equation for chloroform (CLFM), bromoform (BROM), bromodichloromethane (BDCM), and dibromochloromethane (DBCM), the numerical values of Kp, A, Pw/a and Qp were obtained from the published literature, whereas t was set to 30 min (duration of bathing) and F was estimated using a physiologically-based pharmacokinetic model. The L-equivalents, reflective of the contribution of dermal and inhalation exposures during 30-min bathing, were 2.6, 2.1, 2.1 and 2.2 for CLFM, BDCM, DBCM and BROM, respectively. These numbers for a 6-yr old child were 1.5, 1, 1, and 1.1 for CLFM, BDCM, DBCM and BROM, respectively. Whereas contribution of the inhalation route was more important than dermal route for CLFM, the opposite was true for the three other THMs. The litre-equivalent modifying factors derived in this study, based on the consideration of the relative importance of dermal and inhalation routes during bathing, should be useful for setting drinking water goals for THMs.

### HUMAN HEALTH RISK ASSESSMENT FOR ENVIRONMENTAL RESIDUES OF ATOMOXETINE.

<u>I. P. Bercu</u>, J. M. Fiori and R. D. Meyerhoff. *Toxicology and Drug Disposition, Eli Lilly and Company, Greenfield, IN*.

Atomoxetine (Strattera®) is a selective norepinephrine reuptake inhibitor recently approved by the FDA for the oral treatment of attention-deficit/hyperactivity disorder. A risk assessment was performed for the impact on human health from possible trace atomoxetine residues in surface water. This included calculations of representative atomoxetine levels in the environment and safe levels for children and adults. Assessment of a possible exposure level was derived from FDA guidance for estimating the amount of atomoxetine that could be eliminated and enter publicly owned treatment works. Based on the calculations, the upper level of residual atomoxetine that might be in the surface water is about 46 ng/L. In order to determine safe levels for atomoxetine, nonclinical and clinical safety endpoints were reviewed. The recommended starting doses for atomoxetine are 0.5 mg/kg/day for children and 40 mg/day for adults. Doses are increased after a minimum of 3 days to a target daily dose of 1.2 mg/kg/day for children and 80 mg/day for adults. Based on levels of water and fish consumption, exposure to atomoxetine is at least 100, 000 times lower than the recommended starting dose for therapy. Thus, there is no concern for human health resulting from exposure to residues of atomoxetine in water.

#### 740

EVALUATION OF NONCANCER HEALTH RISK ASSOCIATED WITH EXPOSURE TO CHEMICAL MIXTURES IN FISH.

S. J. Baird<sup>1</sup> and T. S. Bridges<sup>2</sup>. <sup>1</sup>Menzie-Cura & Assoc., Inc., Winchester, MA and <sup>2</sup>US Army Engineer Research and Development Center, Vicksburg, MS. Sponsor: <u>L.</u> Hicks.

Bioaccumulative chemicals found in contaminated sediments move through the aquatic food chain and result in PCBs, TCDD, pesticides, metals and PAHs in fish tissue. Evaluation of the human health noncancer hazard from exposure to these mixtures of chemicals typically considers one chemical at a time, with the total noncancer hazard index (HI) evaluated by summing the individual chemical hazard quotients (HQ) based on the critical effect. When an estimated HI is >1, the mixture is reevaluated based on the target organs (TO) of the critical effect (Risk Assessment Guidance for Superfund, USEPA, 1989). However, effects of toxicological significance can occur in additional TOs at doses similar to that eliciting the critical effect. Ignoring these additional effects may lead to an underestimate of noncancer hazard associated with an exposure. We evaluated the potential health impact of not considering these effects. We calculated TO-HIs by dividing an esti-

mated average daily dose for each chemical by the toxicologic target organ doses (TTD) (i.e., TO specific RfDs) for all significant effects for all chemicals in a mixture typically found in fish tissue. We used TTDs developed by ATSDR, presented in Interaction Profiles (ATSDR, 2001), as well as TTDs developed following USEPA guidance for the derivation of RfDs. The influence of dose rate and timing of the exposures, and the potential for interactions within the exposure-dose-response pathway (i.e., toxicokinetics, toxicodynamics) were considered. The TO-HIs were 3 to 5 times higher than HIs based on critical effects only for neurological, hematological, reproductive, and hepatic TO systems for a mixture of PCBs, DDE, methylmercury, zinc, arsenic, cadmium and chromium(VI). Our results suggest that human health risk from exposure to a mixture of chemicals typically found in fish could be underestimated when effects other than the critical effects are omitted from the hazard evaluation. These results support the need for continued efforts to understand the risk from chemical mixtures.

# 741 FACTORS AFFECTING EXPOSURE AND RISK TO DOMOIC AID VIA SHELLFISH CONSUMPTION FOR HIGH RISK POPULATIONS.

N. L. Judd<sup>1, 2</sup>, W. C. Griffith<sup>1, 2</sup> and <u>E. M. Faustman<sup>1, 2, 1</sup> Environmental Health, University Washington, Seattle, WA and <sup>2</sup> Institute for Risk Analysis and Risk Communication, Seattle, WA.</u>

The Pacific Northwest is a unique location for study of health risks associated with shellfish contaminated with domoic acid because there are groups with diverse diets who consume high levels of seafood, and domoic acid contamination is a common phenomenon in this region. Our studies have evaluated which groups may be most at risk and the importance of different dietary and behavioral factors for determining domoic acid health risks for these groups. Recent reports of total seafood consumption by some tribal groups and recent Asian and Pacific Islander (API) immigrants are 5X the national average, and average shellfish consumption by tribal groups may be 25X the national average. Tribal members also collect shellfish where domoic acid contamination is common. In both tribal and API communities, cultural practices result in consumption behaviors, like drinking shellfish cooking water and consumption of the crab hepatopancreas, which may make them more vulnerable to both acute high level and chronic low-level domoic acid exposure. We have previously shown that these dietary behaviors may increase risk from some contaminants (e.g. PCBs) by more than 10X. Shellfish monitoring practices may not be sufficient to evaluate risk from chronic exposures. The limit of detection is high (1 mg/kg) relative to the tolerable limit for domoic acid acute toxicity (20 mg/kg). Thus, there may be potential for chronic health risks from low level (nondetected) domoic acid exposure for these high consumption groups. This contributes to uncertainties about exposure and toxicity which limit ability to assess risk. We have evaluated four additional dietary and behavioral factors which influence domoic acid exposure from shellfish. To prioritize data needs identified for these dietary and behavioral factors, we have developed a model for evaluating domioc acid health risks from shellfish consumption. Supported by the Center for the Study and Improvement of Regulation at Carnegie Mellon University.

# 742 BIOACCESSIBILITY TESTING OF PAH CONTAMINATED SOIL AND ITS APPLICATION IN HUMAN HEALTH RISK ASSESSMENT.

M. J. Chappel<sup>1</sup>, B. Birmingham<sup>1</sup>, B. Gizyn<sup>1</sup>, B. Leece<sup>3</sup>, University. Klee<sup>3</sup>, J. Bestari<sup>2</sup> and K. Solomon<sup>2</sup>. Standards Development Branch, Ontario Ministry of the Environment, Toronto, ON, Canada, <sup>2</sup>CNTC, University of Guelph, Guelph, ON, Canada and <sup>3</sup>Risk Assessment, Dillon, Cambridge, ON, Canada.

In human health risk assessment, ingestion of soil is considered to be a major route of exposure for soil-borne contaminants. However, only a fraction of a chemical measured in soil may be available to impact human health. Bioaccessibility (in vitro) studies are designed to estimate the fraction that may be accessible for absorption following ingestion. A bioaccessibility study was conducted on polycyclic aromatic hydrocarbon (PAH) contaminated soils collected from a community in S. Ontario where elevated levels of carcinogenic and non-carcinogenic PAH have been detected. The objectives were to estimate a location-specific bioaccessibility factor value for a PAH mixture in soil to determine more accurate exposure point concentrations and to refine the exposure assessment portion of the risk assessment based on site-specific considerations. Soil samples were tested using a modified in vitro digestion process. Soil characteristics and properties were also evaluated. Results indicated that PAHs were consistently recovered from the digestive fluid. Average recovery ranged from 53 to 67% (+/-3%). The average bioaccessibility factor (BAF) values for unfiltered non-carcinogenic PAH samples was 0.09 (+/- 0.04), while BAF for unfiltered carcinogenic PĂH samples was 0.07 (+/- 0.04). The BAF values were, on average, 20% higher for non-carcinogenic PAHs when compared to carcinogenic PAHs, and 20% higher between unfiltered and filtered samples. Although individual sample PAH BAFs ranged from 0.01 to 0.20 for the soil type tested, the combined average BAF for all PAHs was 0.08. The effect of other variables, including soil concentration were also assessed. Although the results of the *in vitro* bioaccessibility study were used for adjusting intakes of soil component, the results should be interpreted with caution, as *in vivo* validation has not taken place.

# 743 MODELING RISKS FROM INTERMITTENT EXPOSURES TO LEAD: EFFECT OF EXPOSURE MODEL AVERAGING TIME.

M. H. Follansbee<sup>1</sup>, R. M. Lorenzana<sup>2</sup>, R. Troast<sup>3</sup>, J. M. Klotzbach<sup>4</sup> and <u>G. L. Diamond<sup>1</sup>. <sup>1</sup>Environmental Science Center, Syracuse Research Corp., Syracuse, NY, <sup>2</sup>R10, USEPA, Seattle, WA, <sup>3</sup>OSRTI, USEPA, Washington, DC and <sup>4</sup>Syracuse Environmental Research Associates, Syracuse, NY.</u>

Lead exposures often involve both long-term exposures to relatively constant exposure levels (e.g., yard soil) and intermittent exposures elsewhere (e.g., seasonal visits to a park), resulting in blood lead concentrations (PbB) that vary on a temporal scale with the intermittent exposure pattern. Prediction of short-term PbB arising from intermittent exposures requires a model that can reliably simulate lead exposures and biokinetics on a temporal scale equivalent to the exposure events. If exposure model averaging times (EMATs) exceed the shortest exposure duration that characterizes the intermittent exposure, uncertainties will be introduced into risk estimates because the exposure concentration must be time-averaged. The International Commission of Radiological Protection (ICRP) model simulates lead intakes that can vary over time spans as small as one day, allowing for simulation of intermittent exposures to lead, and resulting PbB, as a series of discrete daily exposure events. The ICRP model was used to explore the potential magnitude of uncertainty introduced into risk estimates (expressed as the probability of a specified PbB) from time averaging of exposures. Results of these analyses suggest that standard approaches to time averaging that estimate the long-term daily exposure concentration can, in some cases, produce substantial under-prediction of short-term variations in PbB predicted for intermittent exposures. In general, risk estimates will be improved by simulation of exposure and biokinetics of lead on shorter time scales that more closely approximate the actual temporal dynamics of the exposure. In applications of existing regulatory models that implement EMATs of 1 year or more, however, alternative approaches to time averaging approaches that more reliably predict short-term elevations in PbB are recommended. [Views expressed in this report are those of the authors and do not represent the views of the USEPA.]

# 744 LEAD AND COPPER AT MILITARY SMALL ARMS RANGES; EVALUATION, RISK ASSESSMENT, AND BIOAVAILABILITY ISSUES.

D. Bannon<sup>1</sup> and B. R. DeShields<sup>2</sup>. <sup>1</sup>Center for Health Promotion and Preventive Medicine, US Army, APG, Aberdeen, MD and <sup>2</sup>Blasland, Bouck, and Lee, Inc., Engineers and Scientists, San Rafael, CA. Sponsor: G. Reddy.

An estimated 2000-3000 military small arms ranges exist in the continental US, ranging in size from a few to hundreds of firing lanes. These sites are all commonly contaminated with lead (Pb) and copper (Cu) from copper-jacketed lead bullets. Bullets can be entire, fragmented, or oxidized, and risk assessment methods attempt to address the health and environmental effects of these varied forms. Over time the ultimate fate of the metals is oxidation to compounds of Pb and Cu that interact with the soil particles, forming a vehicle for metal ingestion. Human health and ecological concerns primarily stem from exposure to Pb, although copper can also pose a hazard. How risk is assessed depends on whether the targeted use is residential, industrial, or continued military. For Pb, well established human models of soil ingestion and absorption are used into which default parameters are placed, while ecological risk assessment relies on less precise exposure estimates and toxicity values, including the hazard quotient (a ratio of the estimated ingested dose of a metal to the dose of a metal supplied in a controlled laboratory toxicity study) for indicator species such as small mammals or birds. For Cu, no such models exist, and the hazard quotient is used. Relative bioavailabilty (RBA) measurements adjust the absorption of metals to account for chemical forms of the metal and soil properties of the site, using soluble salts as a reference. For Pb, this adjustment factor is based on in vivo swine surrogates of human digestion and absorption, allowing the setting of realistic and cost-effective cleanup goals. Current research focuses on the establishment of reliable in vitro methods for bioavailability assessment. A modified method for ecological receptors is also examined. For small arms ranges, rapid in vitro methods for bioavailability measurement would expedite decision making and remedia-

## 745 EFFECTS OF LEAD BIOAVAILABILITY ON OUTCOME OF ADULT AND CHILD BIOKINETIC MODELS.

I. S. Chaudhuri and M. Garcia. Risk Assessment, ENSR International, Westford, MA.

A risk evaluation was conducted to develop lead remedial goals for lead present in thermally treated foundry sand. The foundry used a method that involved roasting waste foundry sand at a temperature of 800C. for about 45 minutes. Roasting waste

foundry sand results in the formation of insoluble lead silicate. This roasting method results in reducing leachable lead concentrations to less than 5 mg/L as measured by USEPA's Toxicity Characteristic Leaching Procedure (TCLP). The lead leachate from foundry sand before thermal treatment is approximately 30 mg/L, therefore this technique significantly reduces the amount of leachable lead. Information in the literature and the TCLP data indicate that lead silicate has very low bioavailability in the body. USEPA's Adult Lead Exposure Model (ALEM) for adults and Integrated Exposure Uptake Biokinetic (IEUBK) model for children assumes the form of lead to be soluble lead acetate, which is a much more bioavailable form of lead than lead silicate. The ALEM assumes that soluble lead acetate in water and food has 20% absolute bioavailability. The relative bioavailability of lead bound in a soil matrix is 60%. Therefore, the absolute bioavailability of lead in soil is 12% (i.e., 60% x 20%) in the ALEM. The IEUBK model assumes that soluble lead acetate in water and food has 50% absolute bioavailability. The relative bioavailability of lead bound in soil is 60%, similar to the ALEM. Therefore, the absolute bioavailability of lead in soil is 30% (i.e., 60% x 50%) in the IEUBK model. Information from the literature indicates that the relative bioavailability of 60% is too high for lead silicate. Based on various studies, we determined a more appropriate relative bioavailability of 20%. Using this factor resulted in an absolute bioavailability of 4% in the ALÉM and 10% in the IEUBK model. These factors resulted in remedial goals of 2, 800 mg/kg lead in sand using the ALEM, and 1040mg/kg lead in sand using the IEUBK model, which are higher than remedial goals calculated using the default bioavailability factors (929 and 400 mg/kg, respectively).

746

PEDIATRIC BIOAVAILABILITY OF LEAD IN SOIL AND DUST: ESTIMATES FROM SOIL, HOUSE DUST, AND BLOOD AT THE BUNKER HILL SUPERFUND SITE.

M. L. Stifelman<sup>1</sup>, S. Spalinger<sup>2</sup> and I. H. von Lindern<sup>2</sup>. <sup>1</sup>Region X, Office of Environmental Assessment, USEPA, Seattle, WA and <sup>2</sup>TerraGraphics, Inc., Moscow, ID

More than a century of mining and smelting at Bunker Hill contaminated soil and interior dust with lead and other metals. Following closure of the smelter in 1981, lead in soil and dust were identified as primary exposure pathways for children. Soil and dust have been sampled annually as contaminated soil was replaced with clean soil at schools, parks, businesses, and approximately 2, 200 residences. Annual voluntary blood lead screening has recruited over 50% of exposed children every year since 1988. Blood lead levels have decreased as soil and dust lead levels have declined as the soil cleanup progressed. Bioavailability was estimated by comparing lead uptake from over 5, 000 blood lead measurements paired with estimates of lead intake from thousands of soil and dust measurements. Lead intakes were estimated using a range of assumptions of the relative importance of lead levels in 1) house dust, 2) residential soil from a child's own yard, 3) soil from neighboring yards, and 4) the mean concentration from all yards in a town. The impact of various exposure assumptions on the estimated intake was minimal because of intercorrelations among the four sources of exposure. From 1988 to 2002, the estimated aggregate bioavailability of soil and dust averaged 18% over a range of 12-23%. Higher bioavailability coincided with increased intakes of dust relative to soil, suggesting that lead in dust is more bioavailable than soil. Attempts to separate soil and dust bioavailability were sensitive to soil and dust ingestion rate assumptions. However, assuming 12% soil and 24% dust bioavailability explains the annual variation in aggregate soil/dust bioavailability observed from 1988 to 2002. Greater bioavailability of dust may be caused by smaller particles in dust relative to soil which may account for an increase in bioavailability (due to greater surface area) and ingestion rate (smaller particles are more likely to cling to hands and fingers).

ASSESSMENT OF METALS EXPOSURE ASSOCIATED WITH SUBSISTENCE USE OF CARIBOU COLLECTED NEAR A MINING TRANSPORT ROAD IN NORTHWEST ALASKA.

M. R. Garry<sup>1, 2</sup>, L. J. Yost<sup>2</sup>, S. S. Shock<sup>2</sup> and W. J. Shields<sup>2, 1</sup>University of Washington, Seattle, WA and <sup>2</sup>Exponent, Bellevue, WA.

Caribou have historically been, and remain, an integral part of life for native northern Alaskans, for both subsistence and cultural reasons. Historical transport of ore concentrate over a 50-mile haul road from the Red Dog lead/zinc mine in northwest Alaska to the seaport has been associated with elevated concentrations of lead on moss growing near the road, and with concerns regarding subsistence foods. Although caribou herds range widely, they sometimes overwinter in areas near the road. As part of a comprehensive assessment of potential impacts to human health and the environment associated with metals released during overland transport of ore concentrate, caribou were evaluated for their potential contribution to dietary metals exposure during subsistence use. In spring 2002, 10 caribou were harvested from near the mine and the haul road. Muscle, liver, and kidney tissues were dis-

sected at the time of harvest, frozen immediately, and shipped for analysis of lead, zinc, cadmium, and arsenic. Caribou metals concentrations were compared to concentrations in caribou collected from the Red Dog mine area in 1996, and concentrations in caribou harvested from other areas of northern Alaska without known anthropogenic sources. There were no consistent elevations of metals in the 2002 Red Dog caribou relative to the comparison groups. Lead was slightly elevated (two- to three-fold) in liver (2.70±1.72 mg/kg) relative to the other northern Alaska herds, but was two- to eight-fold lower in muscle tissue (0.104±0.088 mg/kg). Muscle lead was similar to the typical lead concentrations in meat, fish, and poultry in the United States, which range from 0.002 to 0.159 mg/kg. Zinc was lower in all tissues sampled. Cadmium and arsenic were similar in all tissues sampled. Based on the lack of consistent differences and the results of preliminary health risk estimates, there appear to be little or no potential human health impacts from subsistence use of caribou in the area of the Red Dog mine.

748

RELATIVE BIOAVAILABILITY OF ARSENIC FROM SOIL AFFECTED BY CCA-TREATED WOOD AND DISLODGEABLE ARSENIC FROM CCA-TREATED WOOD COLLECTED FROM RESIDENTIAL STRUCTURES.

S. W. Casteel, T. J. Evans, M. A. Miller and S. E. Turnquists. Veterinary Medical Diagnostic Laboratory, University of Missouri, Columbia, MO.

Assessment of health risks from oral exposure to arsenic in chromated copper arsenate (CCA)-treated wood requires knowledge of the amount of arsenic absorbed from the gastrointestinal tract into the body. The enteric absorption of arsenic from soil adjacent to CCA-treated wood utility poles, placed in service in 1988, was measured in a juvenile swine model. In a related study the swine model was also used to measure the absorption of arsenic from dislodgeable material obtained from the surface of weathered (1-3 years) residential structures composed of CCA-treated wood. The arsenic concentrations in the test materials were 320 ?g/g in the utility pole soil and 3500 ug/g in the dislodgeable material. In each dosing trial, groups of five semi-fasted swine were orally dosed with sodium arsenate (0, 30, or 60 ug/kg/day), soil (60, or 120 ug/kg/day) or dislodgeable material (30, 60, or 120  $\,$ ug/kg/day) twice a day for either 12 (dislodgeable material) or 15 (soil) days. The amount of arsenic absorbed by each pig was estimated by measuring the amount excreted in the urine during 48 hour collections on days 6 to 7, 8 to 9 and 10 to 11. The amount of arsenic excreted by each pig was plotted as a function of the amount administered and the slope of the best-fit straight line through the data approximated the urinary excretion fraction (UEF). The relative bioavailability (RBA) of arsenic in a test material was calculated as a ratio (UEFtest/UEFref) of the UEFs. Using sodium arsenate as a soluble reference form of arsenic in each independent study, the RBA estimates for both test materials were 49% for soil and 29% for dislodgeable material. Both estimates are significantly lower than the default value of 80%-100% employed when reliable site-specific data are lacking. Use of these data will improve the accuracy of risk estimates for humans who may incidentally ingest soil adjacent to CCA-treated wood or dislodgeable material from CCA-treated wood structures.

749

DEVELOPMENT OF A RISK ASSESSMENT TO EVALUATE HUMAN HEALTH RISKS FROM EXPOSURE TO TEBUCONAZOLE USED AS A WOOD PRESERVATIVE.

B. K. Shipp<sup>1</sup>, E. M. Dube<sup>1</sup>, B. D. Beck<sup>1</sup>, M. R. Seeley<sup>1</sup>, K. A. Radloff<sup>1</sup>, S. Schettler<sup>1</sup> and C. Petito Boyce<sup>2</sup>. <sup>1</sup> Gradient Corporation, Cambridge, MA and <sup>2</sup> Gradient Corporation, Seattle, WA.

Background: Copper azole Type B (CA-B) is a new pressure-applied, waterborne wood preservative, consisting of copper and tebuconazole (TEB). TEB is an effective fungicide used to protect the integrity of wood used primarily for outdoor structures. Objective: Risk assessments have rarely been conducted for preservatives used in treated wood applications. Our objective was to apply toxicity criteria for TEB used as a treated wood preservative to a human health risk assessment (HHRA). Approach: We reviewed animal studies to identify no observed effect levels (NOELs) for acute and chronic exposures to TEB via ingestion, dermal contact, and inhalation. Results: Based on animal studies, developmental effects are the main toxicological concern regarding high-dose exposure to TEB. We identified an acute oral NOEL of 10 mg/kg-day, based on a developmental toxicity study in mice; an acute/chronic dermal NOEL of 1, 000 mg/kg-day, based on no effects observed at the highest dose tested in developmental studies in mice, rats, and rabbits; a chronic oral NOEL of 3 mg/kg-day based on adrenal gland effects in dogs; and an acute/chronic inhalation NOEL of 1.9 mg/m³-day (adjusted for continuous exposure) based on the induction of liver microsomal enzymes in rats. Doses up to and including the maximum tolerated dose do not appear to be carcinogenic in animals. We assessed potential human health risks from occupational and non-occupational

exposures to TEB used as a wood preservative based on these NOELs and a margin of exposure (MOE) approach. Using reasonable maximum exposure (RME) assumptions, MOEs for residential exposures to TEB ranged from  $1.1 \times 10^4$  for a child (from dermal contact with soil) to  $2.4 \times 10^7$  for an adult handler (from incidental ingestion of dislodgeable residue). Conclusion: No appreciable risk of adverse health effects from exposures to TEB in CA-B-treated wood are expected based on the sufficiently large MOEs calculated for the exposure scenarios in our HHRA

# 750 PROBABILISTIC CANCER RISK ASSESSMENT OF WORKERS EXPOSED TO CREOSOTE DURING PRESSURE TREATMENT OF WOOD.

T. Long<sup>1</sup>, C. R. Kirman<sup>1</sup>, <u>J. Butala<sup>3</sup></u> and <u>R. Tardiff<sup>2</sup></u>. <sup>1</sup>The Sapphire Group, Beachwood, OH, <sup>2</sup>The Sapphire Group, Bethesda, MD and <sup>3</sup>Toxicology Consultants, Gibsonia. PA.

Creosote is a complex coal tar-derived mixture consisting of polynuclear aromatic hydrocarbons (PAHs) used as a preservative in pressure-treated commercial wood products. A cancer risk assessment was conducted for occupational exposure associated with pressure-treatment of wood. For exposure assessment, a recent exposure study in creosote workers served as the primary source of information and dose estimation. In the exposure study, measurements with personal air samplers and passive, whole-body dosimeters were made for 108 dermal and 88 inhalation work shifts job activities involving creosote exposure. Total dermal doses ranged from 0.0141 to 49.6 mg/kg, and were lognormal in distribution. No carcinogenic PAHs were identified in air samples and CTPV's were detected in only one of 88 samples (<0.1mg/m3). For the toxicity assessment, cancer potency was estimated based on a study of coal tar mixtures in mice exposed orally for two years. In this study, doserelated increases in hepatocellular adenomas and carcinomas, alveolar and bronchiolar adenomas and carcinomas, forestomach papillomas and carcinomas, small intestine adenocarcinomas, and other tissue tumors were reported. For dose-response relationships, the tissue sites were grouped into two categories: (1) point-of-contact tumors, consisting of forestomach and small intestines; and (2) systemic tumors, consisting of all other tissue sites. Monte Carlo methods were used to characterize the variability and uncertainty associated with exposure and dose-response components. The estimates of cancer risk generally fall within the range of USEPA acceptable risk levels (5x10-6 to 1x10-4). It is concluded that over the course of a working lifetime, wood treating workers exposed to creosote will experience no more than one additional cancer per 10, 000 workers. In a population of about 600 to 3700 workers, the number actually involved in pressure treatment of wood, less than one new cancer case could be expected to occur as a result of occupational creosote ex-

# 751 GEOSPATIAL ANALYSIS OF THE EFFECTIVENESS OF THE RESIDENTIAL DUST CLEANUP PROGRAM IN LOWER MANHATTAN FOLLOWING THE ATTACK ON THE WORLD TRADE CENTER.

M. Maddaloni<sup>1</sup>, C. Nace<sup>1</sup>, W. Thayer<sup>2</sup>, E. Gabriel<sup>2</sup>, M. Ramsey<sup>2</sup>, B. Allen<sup>2</sup>, P. Goodrum<sup>2</sup> and <u>G. Diamond</u><sup>2</sup>. <sup>I</sup>Region 2, USEPA, New York, NY and <sup>2</sup>Environmental Science Center, Syracuse Research Corporation, Syracuse, NY.

In response to the concerns of the residents of Lower Manhattan regarding the potential presence of residual contamination from the collapse of the World Trade Center (WTC) buildings, the USEPA (EPA) and its federal, state and city partners developed a comprehensive plan to ensure that residences potentially affected by the collapse of the WTC had been properly cleaned. Upon the request of residents located in Lower Manhattan (south of Canal Street), USEPA and its partners arranged for the cleanup of residential units, using certified contractors, with follow-up testing for air-borne asbestos and total fibers. In a subset of residences, data on metals loading in settled dust (ug / sq. ft. of sampled surface area) were collected prior to and following cleanup. As part of the assessment of the effectiveness of the cleanup effort, we analyzed the data, using methods from point pattern analysis, to determine if the post-cleanup data exhibited any spatial pattern that might support the hypothesis that exceedance of health-based benchmarks were attributable to residual contamination from the collapse of the WTC buildings. We tested the hypothesis using Monte Carlo-type statistical tests that are appropriate for data that were not collected using random sampling methods (cleanups and sampling were performed at the request of residents of Lower Manhattan); the tests consider the geographic location of the sampled buildings and the number of samples collected from each building. The point pattern analysis was performed using GeoSEM: GIS software that was developed by SRC for the application of spatial statistics in human and ecological risk assessment. The results of our analysis do not support the hypothesis that post-cleanup exceedance of the health-based benchmarks are related to the collapse of the WTC buildings.

## 752 REENTRY CRITERIA FOR DIOXIN AND DIOXIN-LIKE COMPOUNDS FOR BUILDING SURFACES.

<u>I. Greene<sup>1</sup></u>, G. Brorby<sup>1</sup> and <u>D. Paustenbach<sup>2</sup></u>. <sup>1</sup>Exponent, Oakland, CA and <sup>2</sup>ChemRisk, San Francisco, CA.

Building reentry criteria for dioxin TEQ, as measured by surface wipes, have varied greatly over the past 15 years, from as low as 1 ng/m<sup>2</sup> to as high as 125 ng/m<sup>2</sup>. While these values have all been derived from either the cancer slope factor (CSF) or relatively high no observable adverse effect levels, they are highly variable, inconsistent in their use of exposure parameters, and lacking complete transparency in the calculations. Recently, the World Trade Center Indoor Air Taskforce calculated a reentry criterion of 2 ng TEQ/m<sup>2</sup> for a residential exposure. This number was based on the EPA's draft CSF of 1 x 10<sup>6</sup> (mg/kg-day)<sup>-1</sup>, various exposure parameters, dermal absorption values, and a cancer risk criterion of 1 x 10-4. An indoor 'degradation' parameter was also included in the calculations. However, a single criterion based on a single set of assumptions cannot, and should not, be universally applied. Reentry criteria that consider a wider range of exposure scenarios, exposure pathways, bioavailability, and behavioral parameters would be very useful to risk managers who may have to address multiple diverse situations in the coming years. This paper describes our recommended reentry building surface criteria for four exposure scenarios: 1) adult occupational, 2) adult residential, 3) childhood 'occupational' (i.e., school), and 4) childhood residential. Using a cancer risk criterion of 1 x 10<sup>-5</sup>, USEPA's current CSF of 1.56 x 10<sup>5</sup> (mg/kg-day)<sup>-1</sup>, and updated exposure and bioavailability parameters, we calculated reentry criteria of approximately 100, 50, 10, and 5 ng TEQ/m<sup>2</sup> for the four scenarios, respectively. These criteria result in dose levels of approximately 0.001-0.02 pg TEQ/kg-day and thus could plausibly produce daily intakes in the vicinity of 1/100 to 1/1000 of the 70 pg/kg-month level (based on non-cancer endpoints) considered acceptable by the joint FAO/WHO committee. Therefore, they should be protective for both cancer and non-cancer effects.

## 753 MALIGNANT TRANSFORMATION OF HUMAN UROTHELIAL CELLS BY ARSENITE AND CADMIUM.

S. Somji<sup>1</sup>, V. Gurel<sup>1</sup>, S. Park<sup>1</sup>, M. Sens<sup>1</sup>, <u>S. H. Garrett</u><sup>1</sup> and <u>D. A. Sens<sup>2</sup></u>.

<sup>1</sup>Pathology, University of North Dakota, Grand Forks, ND and <sup>2</sup>Surgery, University of North Dakota, Grand Forks, ND.

Cadmium and arsenite are human carcinogens and exposure to either of them has been associated with the development of bladder cancer. Neither cadmium or arsenite has been shown to elicit the malignant transformation of human urothelial cells under in vitro conditions, although such a model would be of value in elucidating the mechanism of carcinogenesis of both compounds. This laboratory has characterized an immortalized cell culture model of human urothelial cells (UROtsa) that does not form colonies in soft agar or produce tumor growth in nude mice. The goal of the present study was to determine if exposure of UROtsa cells to cadmium or arsenite would result in malignant transformation. UROtsa cells were grown on both serum-free and serum-containing growth medium to confluency and then exposed to cadmium and arsenite concentrations that produced greater than 90% cell death over a 30 to 60 day period. Surviving cells were allowed to grow back to confluency in the continued presence of cadmium or arsenite. At passage 4, 8, 12 and 16, the cultures were tested for their ability to form colonies in soft agar. At passage 4 and 8 no colonies were formed, at passage 12 a few colonies were formed, and at passage 16 a large number of colonies were formed in the soft agar assay. Cells at passage 16 from each treatment group were injected into nude mice and all 4 groups formed tumors. Control UROtsa cells of equal passage failed to form colonies in soft agar and did not form tumors in nude mice. Histological examination of the tumors demonstrated characteristics expected of transitional cell carcinoma of the bladder. Tumors produced from cells grown in serum tended to have features associated with high grade tumors while those from serum-free cells had features associated with low grade tumors. These studies show that both cadmium and arsenite can cause malignant transformation of human urothelial cells.

#### 754 ARSENIC TOXICITY IN HUMAN KERATINOCYTES.

M. A. Ngo, T. J. Patterson and <u>R. H. Rice</u>. Environmental Toxicology, University of California, Davis, CA.

Arsenic, a human carcinogen and drinking water contaminant, is encountered in the environment in the trivalent (AsIII) and pentavalent (AsV) oxidation states. AsV, the most prevalent form, usually appears much less toxic with its potency being enhanced by reduction to AsIII. To understand the importance of reduction in elucidating arsenic mechanisms we evaluated the responsiveness of human keratinocyte cultures to different oxidation states using Northern and quantitative PCR analysis of heme oxygenase-1 induction. We found AsV to be as efficacious as AsIII; however a longer time was required for AsV to reach maximal effect. These observations were correlated with ICP-MS measurements of cellular uptake and conversion rates. In parallel experiments, we found pentavalent antimony (SbV) to

have limited biological activity, uptake, and conversion compared to the trivalent form (SbIII). These findings emphasize the importance of intracellular reduction of metalloids for biological activity.

## 755 CYTOTOXICITY OF METALS ON CULTURED MORTAL AND IMMORTAL HUMAN MAMMARY CELLS.

C. M. Schmidt, M. B. Anderson and F. A. Barile. Pharmaceutical Sciences, St. John's University College of Pharmacy, Jamaica, NY.

An in vitro study was conducted to determine the effects of metals on human cultured mammary cells. Monolayers of human mortal (MCF-12A) and immortal (MDA-MB231) mammary epithelial cells were incubated in the absence or presence of increasing concentrations of arsenic, mercury and copper for 24-hrs, 72hrs, 4-days, and 7-days. The MTT assay was used to assess cytotoxicity for all time periods and cell proliferation was monitored for 4-day and 7-day studies. The data suggest that both cell lines have similar sensitivities to arsenic and mercury at 24and 72-hr exposures. Cell viability of MCF-12A cells, however, is stimulated by otherwise equivalent inhibitory concentrations of copper on MDA-MB231 cells at 24-hrs. Similarly, arsenic and mercury suppress proliferation and viability in both cell lines, whereas copper enhances cell proliferation and *via*bility of MCF-12A cells after 4-days and 7-days of exposure. The immortal cells, however, recover better after 4-days of toxic insult to the metals than the finite cells. In combination with previous reports, it appears that a basal cytotoxic phenomenon may not be appropriate to explain differences between finite or continuous cell lines, particularly in response to trace metal exposure. In addition, sensitivity of immortal cells to slightly higher concentrations of copper, a biologically important trace metal, may play an important role in controlling unregulated cellular processes and proliferation. (Supported by NIH/NIEHS/AREA R15 ES012170-01).

## 756 SODIUM CHROMATE AND CADMIUM CHLORIDE TOXICITY IN STELLER SEA LION CELLS.

C. Goertz<sup>1</sup>, S. Wise<sup>1</sup>, L. Dunn<sup>3</sup>, F. Gulland<sup>4</sup>, A. Morin<sup>1</sup>, N. Jayasundara<sup>1</sup>, M. Bozza<sup>2</sup>, S. Atkinson<sup>2</sup> and J. P. Wise<sup>1</sup>. <sup>1</sup>Wise Laboratory of Environmental and Genetic Toxicology, Center for Integrated and Applied Environmental Toxicology, University of Southern Maine, Portland, ME, <sup>2</sup>Alaska Sea Life Center, Seward, AK, <sup>3</sup>Mystic Aquarium, Mystic, CT and <sup>4</sup>The Marine Mammal Center, Sausalito, CA.

The Western population of the Steller sea lion is endangered and the cause is unknown. We are investigating the hypothesis that metals might be a factor in this decline. We find that metals are toxic to Steller sea lion cells in an organ and metal specific manner. For example, chromium induced concentration-dependent cytotoxicity in dermal, renal, bronchial and testicular fibroblasts. 2.5, 5, 10, and 25 uM sodium chromate induced 92, 73, 29, and 1% relative survival in kidney cells; 76, 64, 37, and 24% relative survival in dermal fibroblasts; and 54, 41, 25, and 1% relative survival in bronchial cells. Testicular cells had 22 and 1% relative survival at 2.5 and 5uM, and no survival at higher doses. Thus, testicular cells were the most sensitive, dermis most resistant, and bronchial and renal cells were intermediate. Cadmium was generally less toxic than chromium at all doses studied in these tissues. Cadmium chloride concentrations of 2.5, 5, 10, and 25 uM induced 77, 53, 40, and 30% relative survival in kidney cells; 121, 98, 82, and 81% relative survival in dermal fibroblasts; 84, 76, 57, and 52% relative survival in bronchial cells; and 65, 63, 54, and 27% survival in testicular cells. It is noteworthy that testicular cells were the most sensitive to both of these metals which has implications concerning possible transgenerational effects of metal exposure. Current efforts include evaluating tissue loads of metals in Steller sea lion tissue to compare with the intracellular loads in cell lines at toxic concentrations, and understanding the genotoxic effects of metals. Further research is aimed at testing additional metals and extending the lifespan of these cells in culture with telomerase. This work was supported by a grant from National Oceanic and Atmospheric Administration, NA16FX1412 (IPW).

# 757 METAL TOXICITY OF SODIUM CHROMATE IN STELLER SEA LION BRONCHUS AND DERMIS COMPARED TO HUMANS.

A. Morin<sup>1</sup>, C. Goertz<sup>1</sup>, S. Wise<sup>1</sup>, L. Dunn<sup>3</sup>, F. Gulland<sup>4</sup>, N. Jayasundara<sup>1</sup>, M. Bozza<sup>2</sup>, S. Atkinson<sup>2</sup> and J. P. Wise<sup>1</sup>. <sup>1</sup>Wise Laboratory of Environmental and Genetic Toxicology, Center for Integrated and Applied Environmental Toxicology, University of Southern Maine, Portland, ME, <sup>2</sup>Alaska Sea Life Center, Seward, AK, <sup>3</sup>Mystic Aquarium, Mystic, CT and <sup>4</sup>The Marine Mammal Center, Sausalito, CA.

Hexavalent chromium (Cr(VI)) is a known carcinogen to humans. Some species of marine mammals are known to be more resistant to the effects of this and other xenobiotics than humans. For example, Cr(VI) has been shown to cause cancer in

humans, but relatively higher levels of chromium and other metals have been found in tissues from many populations of marine mammals without increasing incidences of pathologies. Therefore, the focus of this investigation was to explore the possibility that sea lion cells respond differently than human cells to the cytotoxic effect of Cr(VI). We found that concentrations of 1, 2.5, 5, 10, and 25 uM sodium chromate induced 63, 42, 8, 0, and 0% relative survival in human bronchial fibroblasts (WTHBF-6) when compared to untreated controls, and that these same concentrations induced 67, 54, 41, 25 and 1% relative survival in Steller sea lion bronchial fibroblasts. Similarly, concentrations of 1, 2.5, 5, 10, and 25 uM sodium chromate induced 56, 28, 11, 0, and 0% relative survival in human dermal fibroblasts (BJ-htert) when compared to untreated controls; whereas the same concentrations induced 89, 76, 64, 37, and 24% relative survival in Steller sea lion dermal fibroblasts. This suggests that at low and moderate concentrations Sea lion cells may have protective mechanisms for the cytotoxic effects of Cr(VI). Further research is aimed at understanding the mechanism of this.

## 758 CYTOTOXICITY OF ORGANO-TIN COMPOUNDS IN DIFFERENT CULTURED CELL LINES.

C. Siegers<sup>2</sup>, A. Hoth<sup>2</sup>, S. Syed Ali<sup>2</sup> and J. B. Schulze<sup>1</sup>. <sup>1</sup>Office of the Dean, Frankfurt/Main, Germany and <sup>2</sup>Inst. Exp. Clin. Pharmacology Toxicol., Frankfurt/Main, Germany.

Organo-tin as monobutyltin (MBT), dibutyltin (DBT) and tributyltin (TBT) are used as fungizides and antifouling compounds. Little is known about their toxicological profile. We therefore studied the cytotoxicity of these agents in different human and animal cell lines. As a measure of cell death and cell growth the neutral red assay and the release of LDH into the medium was used. The hepatoma-derived cell line HepG2, the renal tubular cell line LLC-MK2 from monkey kidney and the cornea epithelial cell line (CE cells) was investigated. As a measure of growth inhibition the IC50-value were calculated for the different tin compounds: TBT-chloride 160 nmol/L in LLC-MK2, 150 nmol/L in HepG2 and 180 nmol/L in CE cells; for DBT the corresponding values were higher, i.e 500 nmol/L DBT for LLC-MK2 cells and 220 nmol/l for CE cells. ED50 values for LDH release indicating disturbances of the outer cell membrane was higher than 250 nmol/l in LLC MK2 cells for both TBT acetate and TBT chloride addition. We conclude that all three organo-tin compounds tested are equally effective. Significant cytotoxicity (LDH release) was not observed in the concentration range tested, whereas growth inhibition as indicated by decreased neutral red uptake was affected at organo tin concentrations between 150 and 500 nmol/l. This concentration is appr. 70 to 200 fold higher than values observed in environmental samples.

## 759 COMPARATIVE CHROMIUM TOXICITY IN CULTURED BOWHEAD WHALE AND HUMAN LUNG CELLS.

S. S. Wise<sup>1</sup>, A. Holmes<sup>1</sup>, M. Thompson<sup>1</sup>, B. Smith<sup>1</sup>, T. O'Hara<sup>2</sup> and J. P. Wise<sup>1</sup>.

Management, Barrow, AK.

Bowhead whales live 150-200 years and yet do not appear to get cancer. This is remarkable given that bowhead whales are routinely exposed to, and bioaccumulate, high levels of metals. We have established bowhead whale lung cell lines to compare their cellular responses to metals to those of human cells. Hexavalent chromium (Cr(VI)) is a metal of particular concern and has long been recognized to cause human lung cancer. Studies have shown that it is the insoluble forms of Cr(VI) that are the most potent carcinogens. In humans, these particles dissolve outside the cell. We found that the particulate form of Cr(VI) was more cytotoxic to bowhead cells than to human cells. For example, 0.1, 0.5, 1 and 5 ug/cm $^2$  lead chromate induced 39, 20, 7 and 0% relative survival in bowhead cells and 90, 71, 43 and 15% relative survival in human cells at the same concentrations. By contrast, we found that the soluble form of Cr(VI) was more cytotoxic to human cells than to bowhead cells. 1, 2.5, 5 and 10 uM sodium chromate (SC) induced 63, 42, 8 and 0% relative survival in human cells and 98, 96, 62 and 3% relative survival in bowhead cells. Human cells treated with SC had intracellular chromium concentrations of 1.81, 3.84, 7.71 and 15.41 uM at treatment concentrations of 1, 2.5, 5 and 10uM, while bowhead cells had intracellular concentrations of 3.54, 9.16, 14.99 and 29.25 uM at the same treatment concentrations. By measuring the toxicity of chromium in human and bowhead lung cells we can start to understand the differences in these species biological response to environmental insult. Further research is needed to elucidate the differences in the cellular responses to soluble versus insoluble chromium and to look at the biochemical mechanisms in the responses of both cell types to chromium. # LEAD CHROMATE-INDUCED CYTOTOXICITY IN HUMAN BRONCHIAL CELLS IS MEDIATED BY EXTRACELLULAR CHROMIUM.

A. Holmes<sup>1</sup>, N. Gordon<sup>2</sup> and <u>J. P. Wise</u><sup>1</sup>. <sup>1</sup>Wise Laboratory of Environmental and Genetic Toxicology, Center for Integrated and Applied Environmental Toxicology, University of Southern Maine, Portland, ME and <sup>2</sup>Department of Chemistry, University of Southern Maine, Portland, ME.

Hexavalent chromium (Cr(VI)) compounds are established human lung carcinogens and solubility plays a key role in the carcinogenicity of Cr(VI), with the most potent carcinogens being the particulate Cr(VI) compounds. Lead chromate (LC) is often used as a prototypical particulate Cr(VI) compound since it is the most insoluble of these compounds; however, it is unknown whether chromium (Cr), lead (Pb), or a combination is responsible for the cytotoxic effects of LC. We compared the cytotoxicity and ion uptake of LC with sodium chromate (SC) and lead glutamate (LG) in WTHBF-6 cells, and the effects of co-treating LC, SC and LG with vitamin C to evaluate changes in cytotoxicity and ion uptake since vitamin C is known to reduce Cr(IV) to Cr(III) and prevent chromium uptake. LC and SC both induced concentration-dependent increases in cytotoxicity at similar intracellular Cr concentrations. LC at 0.1 and 5 ug/cm<sup>2</sup> induced 85 and 3% relative survival at intracellular concentrations of 1.3 and 16.7 uM respectively, while 1 and 5 uM SC induced 75 and 3% relative survival with intracellular concentrations of 1.7 and 15.2 uM respectively. Co-treating LC or SC with vitamin C dramatically reduced intracellular Cr concentrations and cytotoxicity. LG also induced a concentrationdependent increase in cytotoxicity, but 200 and 1000 uM LG induced 86 and 62%relative survival at an intracellular Pb concentration of 4.4 and 48.3 uM respectively, while 5 ug/cm<sup>2</sup> LC induced 3% relative survival with an intracellular Pb concentration of only 2.9 uM. Co-treating LG with vitamin C had no effect on the cytotoxicity or intracellular Pb concentrations. Cytotoxicity and intracellular Pb concentrations decreased when LC was co-treated with vitamin C 5 ug/cm<sup>2</sup>. These data indicate that Cr and not Pb mediates LC-induced cytotoxicity in human bronchial cells. This work was supported by NIEHS grant 1R01 ES10838-01

## 761 BRONCHIOLAR EPITHELIUM CHANGES AFTER PB, CD OR ITS MIXTURE INHALATION.

T.I. FORTOUL<sup>1</sup>, L. Saldivar<sup>3</sup>, G. Espejel<sup>3</sup>, L. Colin-Barenque<sup>2</sup>, A. Zepeda<sup>1</sup>, F. Pasos<sup>1</sup> and M. Avila-Costa<sup>2</sup>. <sup>1</sup>Biologia Celular Y Tisular, Universidad Nacional Autonoma De Mexico, Mexico City, Mexico, <sup>2</sup>Fes Iztacala, Universidad Nacional Autonoma De Mexico, Tlalnepantla, Mexico and <sup>3</sup>Facultad De Quimica, Universidad Nacional Autonoma De Mexico, Mexico, Mexico.

Pollutants are present as mixtures and limited information about its behavior is available. Pb and Cd are some of the most frequently metals found in the air and both enter together into the respiratory tract. The objective of this study was to identify the interaction that the inhalation of Pb, Cd and its mixture has on the bronchiolar epithelium evaluated by scanning electron microscopy (SEM) and its correlation with metal's tissue concentration. CD-1 male mice were exposed by inhalation to Pb (0.01M), Cd (0.006M) or its mixture twice a week, four weeks. Animals were sacrificed each week; the right lung was processed for SEM and the left for metal determination by atomic absorption spectrometry. Pb maintained its concentration, while Cd increased abruptly, while in the mixture, Pb was notoriously decreased, and Cd had values like those found in Cd single inhalation. Changes in morphology indicated that Cd was more aggressive than Pb alone, and in the mixture the predominant changes were similar to those observed with single Cd inhalation. It is very difficult to predict what the behaviour of a mixture might be, because of the interactions with enzymes, receptors, other metals, etc., but it is urgent to increase studies of this type because in real world exposures to mixtures predominate. P.O.S. Institute

## 762 THROMBOCYTOSIS INDUCED IN MICE AFTER ACUTE AND SUBACUTE V205 INHALATION.

Reports about vanadium (V) inhalation toxicity on the coagulation system are limited, so we decided to evaluate the effects of this element on this system through complete blood count and morphologic analysis of platelets in blood smears. CD-

1? mice inhaled V2O5 0.02M one hour, twice a week during 6 weeks. Blood samples were obtained by direct heart puncture, Wright stained smears were used to platelet quantification. At 5th and 6th weeks thrombocytosis with megaplatelets were found and correlation of platelets counts and time of exposure was positive (r=0.45; r2=0.20). Hypercoagulability is associated with metal exposure and this is linked with an increased risk of thromboembolic diseases. Until now no reports were found of thrombocytosis associatiated with metal exposures. Further analysis is needed to evaluate the functionality of these platelets as well as the cause of its increase. PAPIIT 210301

# 763 UPREGULATION OF CELLULAR THIOLS BUT DOWNREGULATION OF LYSYL OXIDASE IN LONG TERM CADMIUM (CD) EXPOSED LUNG FIBROBLASTS.

Y. Zhao<sup>1</sup>, I. Chou<sup>1</sup>, P. Toselli<sup>2</sup>, P. Stone<sup>2</sup>, H. Kagan<sup>2</sup> and W. Li<sup>2</sup>. <sup>1</sup>Microbiology, Boston University School of Medicine, Boston, MA and <sup>2</sup>Biochemistry, Boston University School of Medicine, Boston, MA.

Lysyl oxidase (LO), a Cu-dependent enzyme, oxidizes lysine residues in collagen and elastin leading to crosslinking of these proteins, thus stabilizing the extracellular matrix (ECM). Chronic inhalation of Cd, a toxic metal for humans, induces emphysema. To probe mechanisms of Cd injury to the lung we developed Cd-resistant (CdR) cells from rat fetal lung fibroblasts (RFL6) by long-term Cd exposure and further examined their relative capacities to synthesize LO and Cu scavenging thiol components, e.g., metallothionein (MT) and glutathione (GSH). Cellular levels of MT and GSH in CdR cells were elevated to 8- and 2.5-fold of the parental control, respectively, whereas LO activity in the CdR cell-conditioned medium was much less than that in parental cells amounting to 12% of the latter. Addition of Cu into CdR cell cultures restored LO activity suggesting limitation of Cu bioavailability for LO occurred in these cells. Immunoprecipitation assays indicated that in addition to a decrease in the 46 kD preproenzyme of LO in the cell extract, both the 50 kD proenzyme and 32 kD mature enzyme of LO were essentially undetectable in the CdR cell extract and conditioned medium. Instead, a conspicuous 52 kD band appeared in the CdR cell extract but not in the conditioned medium. Immunofluorescent staining revealed the 52 kD species colocalized with the ER marker [DiOC5(3)] within the cell. These results suggest that the Cd-induced 52 kD protein is a product of abnormal LO processing which was not secreted extracellularly. In view of the roles of MT and GSH in Cu metabolism and the function of LO in ECM stability, downregulation of LO by Cd due to limited Cu bioavailability following elevated cellular thiol levels coupled with perturbed LO processing may weaken the deposition of collagen and elastin, the substrates of LO, destabilizing the lung ECM, a critical event to emphysema development (supported in part by NIH grants R01-ES 11340 and R01-ES 11164 and Philip Morris foundation).

## 764 MORPHOLOGICAL CHANGES IN TESTES. AFTER MANGANESE INHALATION. STUDY IN MICE.

P. BIZARRO<sup>1</sup>, I. SANCHEZ<sup>1</sup>, I. LOPEZ<sup>1</sup>, F. PASOS<sup>1</sup>, V. DELGADO<sup>1</sup>, A. GONZALEZ-VILLALVA<sup>1</sup>, L. COLIN-BARENQUE<sup>2</sup>, S. ACEVEDO<sup>1</sup>, G. NINO-CABRERA<sup>1</sup>, P. MUSSALI-GALANTE<sup>1</sup>, M. AVILA-COSTA<sup>2</sup> and T. I. FORTOUL<sup>1</sup>. <sup>1</sup>BIOLOGIA CELULAR Y TISULAR, UNIVERSIDAD NACIONAL AUTONOMA DE MEXICO, MEXICO CITY, Mexico and <sup>2</sup>NEUROCIENCIAS, FES IZTACALA UNAM, TLALNEPANTLA, Mexico.

Manganese (Mn) has been used as an antiknocking agent in gasoline. Its increase in the atmosphere enhances the risk of its inhalation and the induction of systemic damage. Some reports mention that oral administration of MnCl2 induces reproductive delay in male mice. Prostatic cancer has been identified among exposed workers. The objective of this study was to identify in a murine inhalation model in CD-1 male mice. Animals inhaled MnCl2 0.02M, 1h, twice a week, for 4 weeks, sacrificed once a week and processed for light and electron microscopy. Light changes evidenced necrosis of stem cells, binucleated spermatocytes and dense nuclear structures. Ultrastructural changes in Leydig cells consisted in hyperplastic endoplasmic reticulum forming whorl-like structures. As a consequence of these modifications the function of the testes might be altered, as well as its endocrine function.

## 765 ADVERSE EFFECT OF COPPER TOXICITY ON SOME BLOOD PICTURE AND CELLULAR CONSTITUENTS OF A TELEOST.

A. Panigrahi, A. K. Dasmahapatra and A. K. Medda. Department of Physiology, Basirhat College, West Bengal, India. Sponsor: M. Ehrich.

The heavy metal toxicity is the inherent capacity of the metal to affect adversely any biological activity due to the non-degradation of metals leading to accumulation in tissue and an interaction of the metal with a protein or enzyme leading to changes in physiologic and metabolic processes. Copper if the most potent toxic and heavy metal in trace amounts. It was evident from results that a single injection of cupric acctate at the dose of 5.10 and  $20x10^{-9}$  mole/g decreased RBC count, Hb content

and the PCV in an Indian Teleost (<u>Clairas batrachus</u> L.) on days 7, 14, 28, 42. In cupric acetate injected fish MCV increased but MCHC decreased with some exceptions. The MCH decreased only on day 14 with 10 and 20x10<sup>-9</sup> mole/g but increased on days 28 and 42 with the said dose. It was also evident from the results that a single injection of cupric acetate at the dose of 5, 10 and 20x10<sup>-9</sup> mole/g exerted reducing influence on protein, RNA and DNA metabolism of the liver of the said fish on different days of the experiment, i.e., on days 7, 14, 28, and 42. Liver protein content was significantly reduced on day 14 only compared to control but no change was observed on the other days of the experiment. Liver RNA content was found to be reduced on all the days, except with the lower dose (5x10<sup>-9</sup> mole/g) of the cupric acetate which reduced the RNA content from day 7 to day 28 only. The higher dose (20x10<sup>-9</sup> mole/g) caused maximum reduction in liver DNA on day 7 and day 14, particularly with medium and the higher dose. No significant change in DNA content was observed on days 28 and 42.

#### 766 A JUVENILE SWINE MODEL FOR COPPER OVERLOAD.

T. J. Evans<sup>1</sup>, S. W. Casteel<sup>1</sup> and K. V. Katti<sup>2</sup>. <sup>1</sup>Veterinary Medical Diagnostic Laboratory, University of Missouri, Columbia, MO and <sup>2</sup>Radiopharmaceutical Sciences Institute, University of Missouri, Columbia, MO.

Cu overload occurs in various human disease conditions, including Wilson's disease, and often results in liver damage. Novel chelating agents and animal models for testing the efficacy of these compounds are needed since current chelation regimens cause adverse health effects. Although there are many similarities between the metabolism of metals in humans and swine, there have previously not been any experimental protocols which consistently induce Cu overload in pigs. In the first of two studies, 6 to 8-week-old, male swine were assigned to one of three treatment groups. Pigs received no IV Cu (n=4) or were given 1 mg Cu/kg BW IV (as CuCl<sub>2</sub> in a solution containing 0.1% Cu), either once daily (n=3) or twice daily (n=3), for 3 consecutive days. Twenty-four hours after the final treatment, pigs were sacrificed and samples of liver and kidney were collected for Cu analysis by AAS. Statistical comparisons were performed using ANOVA. Cu-treated pigs had 3-fold higher mean hepatic concentrations of Cu than negative controls. Twice daily administration of Cu did not result in higher mean liver concentrations of Cu than once daily Cu administration, but Cu given twice daily did result in mean renal Cu concentrations that were greater than those of the other two treatment groups. In a second study, similarly aged, male pigs were administered either saline (n=3) or 1 mg Cu/kg BW (n=4) IV, once daily, for 5 consecutive days. Beginning 48 hours after the final treatment, urine was collected from each of the pigs for 96 hours and analyzed for Cu using AAS. Following urine collection, pigs were sacrificed and samples of liver and kidney were collected and analyzed for Cu as before. Comparisons were performed using the *t*-test. There were no differences in the urinary excretion of Cu between groups, but the mean concentrations and total amounts of Cu were 6-fold greater in the liver and 2-fold greater in the kidney in Cu-treated pigs than in pigs treated with saline. These results form the basis for the development of reliable swine models for Cu overload.

## 767 TOXICOLOGICAL EVALUATION OF EXPANDED SHREDDED TOBACCO STEMS.

E. H. Theophilus, D. R. Meckley, M. A. Higuchi, B. R. Bombick, M. F. Borgerding, P. H. Ayres, D. H. Pence and J. E. Swauger. R&D, R. J. Reynolds Tobacco Company, Winston-Salem, NC.

A tiered testing strategy has been developed to evaluate the potential of tobacco processes, ingredients, or technological developments to change the biological activity resulting from burning tobacco. The strategy is based on comparative chemical and biological testing. Expanded shredded tobacco stems (ESS) constitute an example of a common tobacco components expansion process currently used in the manufacture of cigarettes to increase the tobacco blend filling capacity. As part of the toxicological evaluation of ESS, test cigarettes containing 9.5%, 18.5%, and 25% ESS were compared to control cigarettes containing 0% ESS. Testing included mainstream cigarette smoke chemistry studies, genotoxicity studies (Ames and sister chromatid exchange), a 13-week inhalation study in Sprague-Dawley rats, and a 30-week dermal tumor promotion study in SENCAR mice. Although statistically significant differences in several smoke constituent yields were observed, the yields of most constituents from cigarettes containing ESS were within the range observed for cigarettes in the US market. Collectively, data indicated that cigarettes with and without ESS had a similar toxicological profile in this test battery.

## 768 TOXICOLOGICAL EVALUATION OF PROPANE EXPANDED TOBACCO.

<u>I. E. Swauger</u>, <u>E. H. Theophilus</u>, B. R. Bombick, D. R. Meckley, M. A. Higuchi, M. F. Borgerding, M. J. Morton and <u>P. H. Ayres</u>. *R&D*, *R. J. Reynolds Tobacco Company, Winston-Salem, NC.* 

A tiered testing strategy has been developed to evaluate the potential for tobacco processes, ingredients, and other technological developments to increase or decrease the biological activity resulting from burning tobacco. The strategy is based on comparative chemical and biological testing. Propane expanded tobacco is an example of a processed tobacco that may be used in the manufacture of cigarettes to increase the tobacco blend filling capacity. Test cigarettes containing propane expanded tobacco were compared to control cigarettes containing tobacco expanded with a previous expansion agent (Freon-11). The toxicological evaluation included chemistry studies with mainstream cigarette smoke (determination of selected constituent yields), in vitro studies with cigarette smoke condensate (Ames study in Salmonella typhimurium and sister chromatid exchange study in Chinese hamster ovary cells) and in vivo studies (13-week inhalation study of mainstream cigarette smoke in Sprague-Dawley rats and 30-week dermal tumor promotion study of cigarette smoke condensate in SENCAR mice). Although statistically significant differences in several smoke constituent yields were observed, the yields of most constituents from cigarettes containing 100% propane expanded tobacco were within the range observed for cigarettes in the US market. Collectively, biological tests indicated that the cigarettes containing propane or Freon-11 expanded tobacco had a similar toxicological profile in this test battery.

#### **769** TESTING INGREDIENTS ADDED TO CIGARETTES.

D. M. Byrd, M. C. Falk, R. S. Feldman, K. D. Lewis, P. Nixon and N. P. Royaee. *Life Sciences Research Office, Bethesda, MD.* 

The Life Sciences Research Office (LSRO), a nonprofit, biological research organization, has embarked on a three-phase project to assess the health risks of smoking cigarettes with added ingredients relative to smoking comparable cigarettes without added ingredients. The project includes an evaluation of the feasibility of testing (Phase One), development of the scientific criteria to apply in testing (Phase Two), and assessments of specific ingredients (Phase Three). LSRO assembled a multidisciplinary committee of experts, which has met eleven times. LSRO staff and the advisory committee reviewed more than 3, 000 scientific publications, including books, clinical studies, and governmental reports. Phase One comprised an analysis of the relevant scientific literature about cigarette smoke, including its chemistry and physics, exposures, morbidity and premature mortality, issues in testing, and potential testing programs. LSRÓ concluded that although challenging, testing is feasible and worthwhile. Work on Phase Two (Scientific Criteria) is underway. LSRO is developing a framework to guide the process of testing the ingredients added to cigarettes. LSRO will make recommendations about pyrolysis, smokers' exposures, pharmacokinetics, biological effects, research needs, and human smoking behaviors. The Phase Two report will discuss the data necessary to evaluate an added ingredient and the limitations of reviews. LSRO has held two open meetings, the second one on November 5, 2003 in Bethesda, MD about Phase Two. The meetings provide public fora, encourage inputs from different organizations and individuals, maintain transparency during a long process, and facilitate discussion of the relative health risks, if any, attributable to ingredients. LSRO advertised the meetings in Science magazine and invited external attendees. For additional information or to request LSRO reports, go to www.LSRO.org. Philip Morris USA sponsored this work.

# 770 EFFECT OF 4-DAY FOOD RESTRICTION AND CORN OIL STIMULATION ON SERUM ALKALINE PHOSPHATASE ACTIVITY IN THE FISCHER 344 RAT.

D. K. Ness, J. M. Sullivan and W. P. Hoffman. Eli Lilly and Company, Greenfield, IN

Rationale: Toxicity to the gastrointestinal (GI) mucosa is difficult to monitor. This study begins examining the potential use of serum intestinal alkaline phosphatase (iALP) as an indicator of mucosal injury by studying the effect of decreased food intake, a common confounding toxicity. Methods: Female Fischer 344 rats (10/group) were assigned to four treatment conditions: ad libitum (AD)-fed (Group 1); AD-fed, corn oil stimulated (CO) (Group 2); food restricted (FR) (Group 3); and FR, CO (Group 4). The treatment period was 4 days, animals were fasted overnight, and euthanasia and necropsy occurred on the 5th day. Food was restricted to 50% of baseline consumption during the treatment phase for the two FR groups. One mL of corn oil was given orally 5 hours prior to necropsy for the two CO groups. Blood was collected at termination for ALP fractionation (intestine, liver, bone isozymes). Liver and the GI tract were weighed at necropsy. Intestine, liver, and bone were evaluated histologically. Results: Rats in the FR groups (Groups 3 and 4) lost approximately 15% of their pre-study body weight during the treatment period. Body weights increased 8% in AD-fed rats (Groups 1 and 2) during this period. FR significantly decreased total ALP (-17%), decreased iALP (-43%), and increased liver ALP (+23%) relative to AD-fed rats. Predictably, CO significantly increased total ALP (+32%) and iALP (+118%) relative to unstimulated groups. FR resulted in a decrease, compared to AD-fed groups, in both GI tract and liver weights, both on an absolute basis (39-40%) and relative to body weight (21-22%). Microscopic changes in the GI mucosa included an increased incidence of villous atrophy in FR animals. Liver effects in these rats consisted of centrilobular hepatocellular atrophy attributed to decreased glycogen. Conclusions: 1) Serum concentrations of iALP decrease with the development of villous atrophy in the GI tract. 2) Total ALP measurements may be difficult to interpret accurately if effects, in opposite direction, are observed in multiple isozymes.

## 771 TOXICITY EVALUATION OF A FLUORINATED NORBORNENE COMPOUND.

M. DeLorme<sup>1</sup>, G. S. Ladics<sup>1</sup>, M. Donner<sup>1</sup>, V. O. Wagner<sup>2</sup>, C. Finlay<sup>1</sup> and S. E. Loveless<sup>1</sup>. <sup>1</sup>DuPont Haskell Laboratory, Newark, DE and <sup>2</sup>BioReliance, Rockville, MD.

The object of this study was to evaluate the toxicity of the fluorinated norbornene compound 2[(bicyclo[2.2.1]hept-5-en-2-yloxy)methyl]-1, 1, 1, 3, 3, 3-hexafluoro-2-propanol (NBFOH), which is used as an intermediate in the production of fluorinated monomers and polymers. NBFOH was evaluated acutely for dermal sensitization using the LLNA, for mutagenesis by the Ames assay and for subchronic toxicity in a 4wk inhalation rat study. NBFOH produced dermal sensitization but did not cause bacterial mutagenicity either in the presence or absence of S9 activation. Male and female rats were exposed nose only to airborne NBFOH at levels of 0, 410, 1400 and 1500 mg/m³, 6hr/day, 5days/wk for 4wk with clinical and histopathology specimens collected 1d following the final exposure. Due to the vapor pressure of NBFOH the 1500 mg/m<sup>3</sup> atmosphere was 27% aerosol and 73% vapor, the 1400 mg/m³ atmosphere was 5% aerosol and 95% vapor, while the 410 mg/m<sup>3</sup> level was pure vapor. No test substance-related mortality or clinical signs of toxicity were observed over the course of the study. However, male rats demonstrated significant weight loss and decreased food consumption at 1400 mg/m<sup>3</sup> or greater during the exposure period. Male rats from the 1500 mg/m<sup>3</sup> group demonstrated an 11% increase in prothrombin time that was significantly higher than the control value of 15.7 sec. Urine fluoride did not demonstrate a concentration-response relationship, with minimal elevations observed in male rats at all exposure levels and sporadic increases in females. Both male and female rats exposed to 1400 mg/m<sup>3</sup> or greater had squamous metaplasia of the laryngeal mucosa and degeneration of the nasal olfactory and respiratory mucosa. The severity of the laryngeal squamous cell metaplasia correlated with the aerosol concentration of NBFOH while the nasal and respiratory lesions did not. Therefore, NBFOH demonstrates the potential to produce allergic dermatitis and subchronic studies indicate a noobserved-effect-level (NOEL) of 410 mg/m<sup>3</sup>.

## 772 SAFETY OF TINOSORB® S, A NEW ORGANIC SUNSCREEN FOR BROAD SPECTRUM UV PROTECTION.

J. R. Plautz<sup>2</sup> and <u>W. F. Salminen</u><sup>1</sup>. <sup>1</sup>Product Safety and Regulatory, Ciba Specialty Chemicals Corporation, High Point, NC and <sup>2</sup>PSR, Ciba Specialty Chemicals, Basel, Switzerland.

Tinosorb® S (CASRN 187393-00-6: Phenol, 2, 2'-[6-(4-methoxyphenyl)-1, 3, 5triazine-2, 4-diyl]bis[5-[(2-ethylhexyl)oxy]-) is a new active sunscreen ingredient that provides broad spectrum UVA and UVB protection and is highly photostabile. Tinosorb S is currently approved for use as an active sunscreen ingredient in the European Union, Switzerland, and many other countries with the major exception being the US. We present here the results showing Tinosorb S to be safe as an active sunscreen ingredient when tested in standard (OECD) protocols. Tinosorb S is of low acute toxicity with rat dermal and oral LD50 values >2, 000 mg/kg. Tinosorb S caused none to minimal irritation when applied to rabbit eyes and skin. Tinosorb S did not cause skin sensitization, photoirritation, or photosensitization when applied to the skin of guinea pigs or humans. Tinosorb S was not genotoxic or mutagenic in standard *in vitro* and *in vivo* assays and in tests using UV exposure protocols. In a percutaneous absorption assay with ex vivo human skin, Tinosorb S exhibited low penetration across the skin (<0.1%). Rats given doses of radiolabelled Tinosorb S showed very low systemic uptake after a single oral dose (<1% of dose) or after dermal dosing (<1% of dose). In a 90-day subchronic oral gavage study in the rat, the NOEL was 1, 000 mg/kg/day, which was the highest dose tested (HDT). In a developmental toxicity study, the maternal and fetal NOEL was 1, 000 mg/kg (HDT). Reproductive effects did not occur in Segments I and III studies. Tinosorb S did not show binding affinity or competitive inhibition of natural hormone binding to either estrogen or androgen receptors in vitro and effects did not occur in the uterotrophic assay with immature rats given Tinosorb S orally. Additional safety tests are underway to assess the long-term photo(co)carcinogenicity and dermal carcinogenicity of Tinosorb S. In conclusion, Tinosorb S is a safe UV filter sunscreen ingredient that can be used to make highly photostabile, broadspectrum sunscreens.

773 PHYSIOLOGICAL PARAMETERS AND BACKGROUND HISTOPATHOLOGY FINDINGS FROM CHRONIC (2 YEAR) CARCINOGENICITY STUDIES IN THE HAN

WISTAR RAT

C. Barton and C. Springall. Covance Laboratories Ltd., Harrogate, United Kingdom. Sponsor: D. Everett.

The HAN Wistar rat is becoming increasingly popular for use on regulatory toxicology studies. This strain tends to have a lower incidence of spontaneous background histopathology, when compared with some other rat strains; most notably those tumours involving endocrine and hormone-associated tissues. The HAN Wistar rat generally has a low mortality rate, with good survival over the course of a 2 year study and the potential for reducing group sizes. In addition, the small adult body weight can result in considerable reductions in bulk drug requirement. There are few publications detailing basic physiological data: bodyweight gain, food consumption, survival data and spontaneous tumour incidences for the HAN Wistar rat in chronic (2 year) carcinogenicity studies. The control data in this poster presentation are from carcinogenicity studies conducted recently at Covance Laboratories, Harrogate, England

774 TOXICOLOGICAL EVALUATION OF LEACHABLES AND EXTRACTABLES IN INHALATION DRUG PRODUCTS: RISK ASSESSMENT OF DI(2-ETHYLHEXYL)PHTHALATE (DEHP).

L. A. Haighton<sup>1</sup>, K. L. Bibeau<sup>1</sup>, N. N. Kim<sup>2</sup> and J. M. Daniels<sup>1</sup>. <sup>1</sup>CANTOX HEALTH SCIENCES INTERNATIONAL, Mississauga, ON, ON, Canada and <sup>2</sup>Sepracor Inc., Marlborough, MA.

Container closure systems may be used for nasal spray and inhalation solutions, suspension, and spray drug products. The US Food and Drug Administration (FDA) requires that a toxicological evaluation be completed for chemicals that can be extracted from the container components. DEHP, a commonly used plasticizer, is an example of an extractable that was identified in extraction studies of a novel container closure system. Although the level extracted was very low (approximately 0.0088 mg per container closure system) there is currently no regulatory threshold for extractables. Therefore, a detailed toxicological evaluation of DEHP was conducted including consideration of liver tumor mechanistic data (peroxisome proliferation) and potential Sertoli cell vacuolation. Exposure to DEHP was calculated using the highest concentration determined from the extraction testing and assuming the maximum dosing regimen for the drug product. This is very conservative, since extraction testing conditions do not reflect normal use and storage conditions. As the majority of toxicology data were generated using the oral route of administration, the exposure limit derived from oral studies was adjusted to account for differences in absorption. The results of the evaluation showed that the maximum theoretical exposure to DEHP through use of the inhalation spray drug product of 0.0037 micrograms/kg bodyweight/day was approximately 400 times lower than the inhalation exposure limit of 1.5 micrograms/kg bodyweight/day. Thus, no adverse effects attributable to exposure to DEHP from use of the drug product would be expected to occur. Furthermore, the results of this assessment indicate that, as long as future extraction testing indicated that the concentration of DEHP was below 3.6 mg per closure system, there would be no concern with regard to potential health effects.

## 775 DIETARY INCLUSION OF NOVASIL: SUBCHRONIC TOXICITY EVALUATION IN SPRAGUE-DAWLEY RATS.

E. Afriyie-Gyawu<sup>1</sup>, J. Mackie<sup>2</sup>, B. Dash<sup>1</sup>, M. Wiles<sup>1</sup>, H. J. Huebner<sup>1</sup>, K. E. Lee<sup>3</sup> and <u>T. D. Phillips</u><sup>1</sup>. <sup>1</sup> Faculty of Toxicology (VAPH), Texas A&M University (TAMU), College Station, TX, <sup>2</sup> Veterinary Pathobiology, TAMU, College Station, TX and <sup>3</sup> Statistics, TAMU, College Station, TX.

NOVASIL (NS) clay, commonly added to animal feeds, has been reported to diminish the bioavailability and toxicity of aflatoxins. To investigate the potential toxicity of subchronic exposure to NS, a 90-day study was conducted using male and female Sprague-Dawley rats (4-5 week old) fed rations containing 0, 0.25, 0.5, 1.0, and 2.0 % levels of NS. Doses were based on the lowest and highest levels recommended in animal feeds for the prevention of aflatoxicosis. Treatments consisted of 3 females and 3 males in five groups. Body weights, body weight gain, organ weights, histopathology, plasma biochemistry, serum vitamins A and E and micronutrients (Fe and Zn) were measured, standardized and compared to determine toxicity and any interactions of NS with critical nutrients. No morbidity or mortality was observed among treatment groups throughout the duration of the study. Among the males there were no significant differences in feed intake (FI), body weight gain (BWG), and FI/BWG. In females, FI/BWG was significantly higher at the 2.0% level suggesting impaired feed utilization. At necropsy, no changes in the major organs were observed. The ratios of organ weight to final body weight for the

liver, kidneys, lungs, heart, brain, spleen, and tibia among the treatment groups in each sex were not significantly different. Histopathological analysis of the liver and kidneys indicated no differences between controls and clay treatments. No significant reductions were observed in Zn and Fe. Other serum biochemical parameters were also unaffected. However, serum vitamin A and E levels in females were reduced at 2.0% clay, which may be associated with an increase in FI/BWG. Long-term studies (using larger sample sizes) are ongoing to confirm these preliminary findings. Results suggest that inclusion of NS at levels less than 2.0 % (w/w) in the diet should not result in overt toxicity (Supported by USAID LAG-G-00-96-90013-00, NIEHS P42-ES04917, and NIEHS Center Grant ES09106).

# 776 QUANTITATIVE CELL CYCLE INFORMATION COMPARED TO CYTOCHALASIN B BLOCKAGE IN CELL LINE MICRONUCLEUS ASSAYS.

E. Luther and M. Lee. *Strategic Research Development, CompuCyte Corp., Cambridge, MA.* Sponsor: <u>S. Zhao</u>.

The in vitro micronucleus assay is routinely performed to detect clastogenic and other chromosomal damage as a result of test samples being exposed to toxic substances. Typically it is performed by manual scoring of the test slides by microscope observation, often using cytochalasin B to identify binucleate cells that have completed DNA replication and are thus able to allow drug effects to manifest themselves. We investigated if DNA content per cell, the nuclear area, the number of cells per test well, expression of apoptotic markers, combined with the micronucleus count would be a suitable replacement for the cytochalasin B cell blockage method. CHO cells were seeded in microtiter wells, incubated with test substances (etoposide, mitoycin C, ) in increasing dosages, with and without cytochalasin B, fixed in situ, and stained with DNA specific dyes, and a protein marker. The plates were analyzed with the iCyte Automated Imaging Cytometer (CompuCyte, Cambridge, MA). Dosage response curves were obtained for multiple cellular factors. In experiments without cytochalasin B, control wells are characterized by an exponential cell cycle distribution, less than .5% micronuclei, and normal nuclear morphology. With an increase in drug concentration we saw a progression of formed micronuclei (up to 12%), blockage of cells in S-phase in the cell cycle, and a decrease in cell count. An increase in nuclear area was observed at the highest dosages. In cytochalasin B treated experiments, control wells exhibited a large proportion of binucleate cells. Increases in drug dosages were accompanied by increased amounts of micronuclei, a decrease in the percentage of binucleate and total number of and the appearance of sub-G2 phase cells in the cell cycle distributions. A moderate increase in nuclear area was registered. Both methods gave equivalent results in terms of the dosage presenting the maximum micronuclei, however, the non-cytochalasin B treated sets had a higher signal to noise level, indicating greater sensitivity.

## 777 SAFETY OF GLYCOLIC ACID IN CLEANING PRODUCTS.

A. W. Hayes<sup>1</sup> and J. C. Stadler<sup>2</sup>. <sup>1</sup>Department of Environmental Health, Harvard School of Public Health, Boston, MA and <sup>2</sup>DuPont Haskell Laboratory, Newark, DE.

Glycolic acid occurs widely in nature, and is in a number of edible fruits, vegetables and meat products. It is also manufactured by several processes and used in a broad range of industrial and consumer products. The concentrated acid produced industrially is significantly diluted in end use products. Calculated estimates indicate that exposure to glycolic acid through household products is less than 1/10 the naturally occurring amount typically ingested on a daily basis. It has been used by dermatologists for years to treat skin disorders and is a component of many over-the-counter personal care products. No systemic toxicity has been noted as a result of these uses. Toxicity results indicate that glycolic acid (70%) causes effects that are typical of a strong acid, such as dermal and eye irritation; however, concentrations of < 5%, typically used in cleaning formulations, are not irritating to the skin. Extremely high doses given orally (~3000 mg/kg) will cause liver and kidney damage. In repeated dose testing, a no-effect level (NOEL) of 150 mg/kg/day was established for subchronic toxicity and for developmental effects. No effects to the immune system, neurological function or to reproductive parameters were observed. Genetic toxicology studies were negative. A safety margin may be calculated based on the repeated dose NOEL and estimated daily exposures during institutional cleaning. Glycolic acid biodegrades quickly and, therefore, does not persist or bioaccumulate in the environment. When chemicals containing glycolic acid are used on a daily basis, protection for the skin and eyes is advised to prevent localized irritation. Child-proof packaging is available to prevent children from ingesting these products. Overall, the evidence indicates there is minimal risk of adverse health effects from glycolic acid during the normal use of commercially available cleaning products

### 778 REPEATED DOSE ORAL TOXICITY OF 8-2 TELOMER B ALCOHOL RANGE-FINDING STUDY IN RATS.

G. L. Kennedy<sup>1</sup>, G. S. Ladics<sup>1</sup>, J. O'Connor<sup>1</sup>, S. Gannon<sup>1</sup>, R. Jung<sup>2</sup>, H. Iwai<sup>3</sup> and S. Shin-ya<sup>4</sup>. <sup>1</sup>DuPont Haskell Laboratory, Newark, DE, <sup>2</sup>Clariant, GmbH, Sulzbach, Germany, <sup>3</sup>Daikin Industries, Ltd.,, Osaka, Japan and <sup>4</sup>Asahi Glass Co., Ltd.,, Tokyo, Japan.

8-2 Telomer B Alcohol is a fluorinated chemical intermediate used to manufacture specialty polymers and surfactants. Preliminary to a repeated dose toxicity assessment, a range-finder study involving repeated oral doses of 8-2 Telomer B Alcohol was conducted in rats to determine the time needed to reach steady-state as determined by total organofluorine blood fluoride levels. Groups of 10 male and 5 female Crl:CD®(SD)IGS BR rats were each dosed daily by gavage with either 0 (control), 5, 25, or 125 mg 8-2 Telomer B Alcohol/kg/day. A number of toxicology end-points, such as body weights, liver and kidney weights were recorded during and at the end of the study. Blood samples were analyzed for total fluorine levels weekly. Steady-state concentrations were reached between test days 60 and 84. At steady-state, pooled plasma samples obtained from males and females over the duration of the study were analyzed for 8-2 Telomer B Alcohol (parent compound), 8-2 Telomer B acid, perfluorooctanoate acid (PFOA), perfluorononanoic acid (PFNA), and total fluorine levels. The level of parent compound detected did not exceed 0.074 ppm in either males or females. In males, PFOA represented approximately 85% of the total plasma fluorine. In females, PFOA represented approximately 5%. The 8-2 acid of Telomer B Alcohol and PFNA were also found in plasma of both males and females. Significantly lower mean body weights and increased liver weights compared to control were observed in male rats administered 125 mg/kg/day. Based on these data, the following doses were chosen for the 90day oral toxicity study with the 8-2 Telomer B Alcohol: 0, 1, 5, 25, and 125 mg/kg/day. This study was sponsored by the Telomer Research Program.

# 779 A SUBCHRONIC TOXICITY STUDY IN RATS AND GENOTOXICITY TESTS WITH SURELEASE® AQUEOUS ETHYLCELLULOSE DISPERSION.

C. C. DeMerlis<sup>1</sup>, D. R. Schoneker<sup>1</sup>, <u>C. Kelly</u><sup>2</sup> and <u>J. Borzelleca</u><sup>3</sup>. <sup>1</sup>Colorcon, West Point, PA, <sup>2</sup>Huntingdon Life Sciences, East Millston, NJ and <sup>3</sup>Medical College of Virgina, Richmond, VA.

C C DeMerlis, D R Schoneker, C M Kelly and J F Borzelleca. 1Colorcon, West Point, PA, USA, 2Huntingdon Life Sciences, E. Millstone, NJ, USA; 3Medical College of Virginia, Richmond, VA, USA. Surelease® is an excipient used as a modified release coating for beads, granules, non-pariels, drug crystals and tablets and for taste masking applications for drug products and dietary supplement products. A study was conducted to assess the toxicity of spray dried Surelease when administered orally, via dietary admixture, to Sprague-Dawley CD® rats (20/sex/group) at dose levels of 0, 2000, 3500, and 5000 mg/kg/day for a period of at least 3 months. After 3 months of treatment, all survivors were sacrificed and selected organs were weighed. Complete macroscopic examinations and histopathological evaluation of selected tissues were conducted on all animals. Neuropathological evaluations were performed on 5 animals/sex/group. No mortality occurred during the study. Clinical observations, ophthalmology, body weight and food consumption, hematology, coagulation, clinical chemistry, urinalysis, functional observational assessments, motor activity, organ weights and ratios and macroscopic and microscopic observations did not reveal any test article-related effects. The NOAEL (no-observable-adverse-effect-level) is 5000 mg/kg/day, the highest dose tested. A series of genotoxicity tests were conducted with Surelease. Surelease showed no evidence of mutagenic activity in the bacterial reverse mutation test with and without metabolic activation and in the in vitro cell mutation assay under the experimental conditions employed. Surelease did not show any evidence of causing chromosome damage or bone marrow cell toxicity when administered orally by gavage in the mouse micronucleus in vivo test procedure. These findings support the safety of Surelease for use as an excipient.

# 780 P450-GLO™LUMINESCENT ASSAYS DETECT CYP450 ACTIVITIES IN RECOMBINANT FRACTIONS, LIVER MICROSOMES AND CULTURED HEPATOCYTES.

J. J. Cali, S. Ho, D. Ma and R. Bulleit. Research and Development, Promega Corporation, Madison, WI.

P450-Glo<sup>TM</sup> is a luminescence-based technology for assaying cytochrome P450 (CYP450) activities. We used P450-Glo<sup>TM</sup> to measure CYP450 activities in recombinant fractions, liver microsomes and cultured hepatocytes. The approach is based on a series of D-luciferin derivatives that are not substrates for firefly luciferase but are metabolized by CYP450s to the firefly luciferase substrate D-luciferin. When

CYP450 reactions with the derivatives are combined with a luciferase reaction an amount of light is produced that is directly proportional to the amount of CYP450-generated D-luciferin. Light is therefore used to measure CYP450 activity. Luminogenic substrates reacted with recombinant human CYP1A1, 1A2, 1B1, 2C8, 2C9, 3A4 and 3A7 and detected known CYP450 inhibitors of these activities with IC50s similar to those reported using conventional assays. The assays also detected CYP450 activities in liver microsomes. Two substrates, luciferin benzyl ether and deoxyluciferin were highly specific for CYP3A4 and CYP2C9, respectively. The luminogenic CYP450 substrates are cell permeable and therefore provided a basis for luminescent assays that measured CYP450 induction in cultured hepatocytes. Because P450-Glo™ Assays do not rely on fluorescent substrates data analysis was not confounded by overlap of the fluorescent properties of probe and analyte. P450-Glo™ Assays were homogenous, highly sensitive and robust. The assays were readily configured in multi-well plate formats for rapid screening of multiple compounds against CYP450 activities.

# 781 EVALUATION OF THE SUBCHRONIC, REPRODUCTIVE, AND DEVELOPMENTAL TOXICITY OF A FLUORINATED ACRYLIC COPOLYMER.

N. E. Everds, J. C. Stadler, S. A. MacKenzie, L. A. Malley, S. M. Munley and G. P. Sykes. *DuPont Haskell Laboratory, Newark, DE.* 

The objective of these studies was to evaluate the subchronic, reproductive, and developmental toxicity of a fluorinated acrylic copolymer in rats. The test substance was suspended in methylcellulose and administered by oral gavage at dosages of 0, 10, 100, or 1000 mg/kg/day (90-day subchronic toxicity and one-generation reproduction), and at the same dosages on gestation days 6-20 (developmental toxicity). The NOEL for subchronic toxicity was 100 mg/kg/day in males and females, based on reversible, minimal to mild thyroid follicular hypertrophy observed at 1000 mg/kg/day. Other non-adverse, test substance-related effects, observed in males and/or females at 1000 mg/kg/day, were mild clinical pathology alterations, increased liver and kidney weights, minimal liver hypertrophy, and increased hepatic b-oxidation activity. All effects were reversible after a one-month recovery, except the thyroid hypertrophy, which was still present but at reduced incidence and severity. No test substance-related effects were observed on in-life, neurobehavioral, ophthalmological, or anatomic pathology parameters, or on any reproductive parameter in P1 or F1 rats dosed up to 1000 mg/kg/day. In the developmental toxicity study, the NOEL for both maternal and fetal toxicity was 1000 mg/kg/day, based on a lack of test substance-related effects on any maternal or fetal parameter. No fetal malformations were observed. Overall this polymer, which is used in stain and soil-resistance applications, is considered to have low potential to produce human health effects.

## 782 DOSE RANGE-FINDING STUDY OF HALOFUGINONE (NSC-713205) IN BEAGLE DOGS.

K. Veley<sup>1</sup>, B. Sparrow<sup>1</sup>, J. W. Merrill<sup>1</sup>, I. M. Grossi<sup>1</sup>, <u>J. Tomaszewski<sup>2</sup></u> and J. O. Peggins<sup>2</sup>. <sup>1</sup>Toxicology, Battelle, Columbus, OH and <sup>2</sup>NCI, NIH, Bethesda, MD.

Halofuginone is a botanical quinazolinone alkaloid capable of inhibiting tumor progression through its ability to suppress extracellular matrix deposition, cell proliferation and angiogenesis. Beagle dogs were utilized to determine the maximally tolerated dose and relative drug toxicity of halofuginone when administered as a biweekly 1hr infusion for 4 consecutive weeks. Dose concentrations delivered over the 1hr period were 0, 0.025, 0.05, 0.1, 0.5 and 1.0mg/kg. Following the completion of the first infusion dose on Day 1, animals in the 0.5 and 1.0mg/kg dose groups displayed signs of toxicity in the form of extreme emesis and diarrhea. On Day 2, emesis and diarrhea continued in conjunction with altered hematology and serum chemistry parameters. Dehydration subsequent to the diarrhea was considered responsible for increases in RBC, HEM and HCT levels. Increased AST, ALT and CK values may have been related to cardiac or skeletal muscle damage, however hepatic alteration could not be ruled out. Elevated ALP may have been a secondary response to either the stress of diarrhea or possibly to increased mineral resorption from bones, which invariably accompanies renal dysfunction. Additionally, elevated BUN and CREA values indicated renal dysfunction with dehydration/poor renal perfusion and was proposed to have contributed to the moribundity of these animals. The affected animals in the 0.5 and 1.0mg/kg dose groups were euthanized moribund on Day 2, and additional infusions at these levels were suspended. With the exception of elevated nRBC on Day 9 in the 0.05 and 0.1mg/kg groups, there were no other effects noted at the 0.1mg/kg dosage and lower. Based on these results, the maximum tolerated dose for intravenously dosed halofuginone when administered bi-weekly to beagle dogs appears to be between 0.1mg/kg and 0.5mg/kg.

## 783 NOGATOXIN ISOLATED FROM NON-AXENIC CULTURES OF PFIESTERIA.

D. Baden<sup>1</sup>, E. Noga<sup>3</sup>, K. Rein<sup>2</sup>, J. Benson<sup>5</sup>, W. Abraham<sup>4</sup>, R. Belas<sup>6</sup> and C. Tomas<sup>1</sup>. <sup>1</sup>UNCW, Wilmington, NC, <sup>2</sup>FIU, Miami, FL, <sup>3</sup>NCSU, Raleigh, NC, <sup>4</sup>Mt Sinai Medical Center, Miami, FL, <sup>5</sup>Lovelace Respiratory Research Institute, Albuquerque, NM and <sup>6</sup>UMd, Baltimore, MD.

An ichthyotoxic lipid-soluble extract has been isolated from mixed cultures of fishkilling Pfiesteria spp. Nogatoxin was purified by column and thin-layer chromatography (TLC), using fish bioassay-guided fractionation. Crystalline material was subjected to NMR and toxicologic testing methods. MW was estimated at <500 amu and a cyclopropane ring is suggested. Gambusia fish exposed to TLC fractions developed obvious skin damage after 4 hrs of exposure, indicated grossly by cloudiness which was prominent on the fins. Sometimes, fish behaved normally and in other cases they died after developing the skin damage. Histological examination of fish revealed skin erosion and ulceration. There were no deaths in mice by oral or ip injection (up to 1.26 mg/kg body weight) and no clinical signs of toxicity were noted. Some organ lesions were noted, but did not correlate with dose. Organ weights between control and experimental mice did not differ. Airway responsiveness after Nogatoxin challenge (20 breaths at 100 pg/mL), measured in naive sheep, was 107 +/- 27% (mean +/- sem). There was no induced hyper-responsiveness and no changes in inflammatory response. Extracted cultures were a taxonomically diverse microbial community. Denaturing gradient gel electrophoresis and quantitative real-time PCR methods were used to identify and quantify microorganisms. Multiple ciliate species and one species of rotifer were detected in addition to Pfiesteria piscicida and P. shumwayae. The ciliate Chilodonella, a fish gill parasite, was also found. The complex eukaryotic microbial community may have influenced both Pfiesteria dinoflagellate abundance and the occurrence of fish deaths due to the extracted toxic fraction. Nogatoxin is not present in our clonal cultures of Pfiesteria. The lack of potency in mammalian toxicological assays may reflect our use of fish bioassay for purification. Supported by NIH ES05705 and ES09563, Sea Grant NA46-RG-0087, and Saltonstall-Kennedy NA67FD00500.

# 784 UP-REGULATION OF CYCLOOXYGENASE-2 EXPRESSION BY GELATIN IN MURINE MACROPHAGES.

J. Kim<sup>1, 2</sup> and <u>H. Jeong<sup>1, 2</sup>. <sup>1</sup> Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and <sup>2</sup> Research Center for Proteineous Materials, Chosun University, Kwangju, Kwangju, South Korea.</u>

Gelatin is derived from animal collagen tissues and is therefore present in many kinds of animal protein food. The biological origin and biocompatibility of gelatin has led to wide-ranging applications in the pharmaceutical and medical fields; for example, as sealants for vascular prostheses, bone-repairing materials, wound healing agents and scaffolds for tissue engineering purposes. In the present study, we investigated the effects of gelatin and collagen on the cyclooxygenase-2 (COX-2) gene expression in the mouse macrophage cell line RAW 264.7. Gelatin and gelatin significantly increased the prostaglandin E2 production and the expression of COX-2 mRNA and COX-2 protein in a dose-dependent manner. To investigate the significant cis-acting regions which COX-2 promoter, transient transfection experiments were carried out using reporter vectors harboring deleted COX-2 promoters. The transcriptional factor binding sites for activator protein 1 (AP-1) and NF-kB between -574 and -51 could be important for the induction of COX-2 by gelatin and collagen. The results of these studies suggest that induction of transcriptional activation of COX-2 by gelatin and collagen might be mediated through the AP-1 and NF-kB activation.

# 785 INDUCTION OF INDUCIBLE NITRIC OXIDE SYNTHASE AND TUMOR NECROSIS FACTOR-A EXPRESSION BY GELATIN VIA NUCLEAR FACTOR-KB TRANSACTIVATION IN MACROPHAGES.

D. Oh<sup>1, 2</sup>, J. Kim<sup>1, 2</sup> and <u>H. Jeong<sup>1, 2</sup></u>. <sup>1</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and <sup>2</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, Kwangju, South Korea.

As biological polymer, gelatin employed as backbones in the construction of hydrogels or cell/tissue scaffoldings for various biomedical applications. In the present study, we investigated the effect of collagen and gelatin on the inducible nitric oxide synthase (iNOS) gene expression in the mouse macrophage cell line RAW 264.7. The nitric oxide production and iNOS expression were induced by both of gelatin and collagen in dose-dependent manner. Gelatin and collagen also increased the production of TNF-a and its expression level in a dose-dependent manner. The effects of gelatin and collagen on the transcriptional activity of NF-kB were examined, since the transcriptional regulation of iNOS has been shown to be under the control of the NF-kB. Transient expression assay with the luciferase reporter vector

containing three-copies of NF-kB binding site revealed that the increased level of iNOS mRNA induced by collagen or gelatin could be mediated by the NF-kB transcription factor complex. Furthermore, gelatin and collagen activates the DNA binding ability of NF-kB, in the result of electrophoretic mobility shift analyses using the NF-kB binding sequence within iNOS promoter as a probe. These results demonstrated that nitric oxide and TNF-a production in the gelatin- and collagen-stimulated macrophages might be induced by the up-regulation of these genes expression through NF-kB transactivation.

# 786 GROWTH INHIBITION AND INDUCTION OF APOPTOSIS BY DIHYDRO-N-CAFFEOYLTYRAMINE ON HUMAN LEUKEMIA CELLS.

E. Woo<sup>2, 3</sup>, C. Choi<sup>1</sup> and <u>H. Jeong<sup>2, 3</sup></u>. <sup>1</sup>Food Science, Jinju International University, Jinju, South Korea, <sup>2</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and <sup>3</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, Kwangju, South Korea.

Lycii Radicis Cortex, the root bark of Lycium chinense Miller (Solanaceae) is used in oriental medicine as a tonic and is reported to exhibit hypotensive, hypoglycemic, and antipyretic activity. Recently, we have isolated dihydro-N-caffeoyltyramine, a phenolic amide, from the Lycii Radicis Cortex. Treatment with dihydro-N-caffeoyltyramine significantly inhibited the proliferation of human leukemia cell lines HL-60 in a dose-dependent manner. We found also that the growth inhibition of HL-60 by dihydro-N-caffeoyltyramine is associated with induction of apoptosis of cells. Dihydro-N-caffeoyltyramine induced the apoptosis of HL-60 such as apoptotic body and DNA fragmentation. In addition, the flow cytometric analysis revealed dihydro-N-caffeoyltyramine dose-dependently increased apoptotic cells with hypodiploid DNA contents. These results indicate that dihydro-N-caffeoyltyramine can control growth of leukemic HL-60 cells through apoptosis and may have a possibility of potential anticancer activities.

#### 787 PLATYCODON GRANDIFLORUM SUPPRESSED PDGF-DRIVEN PROLIFERATION AND COLLAGEN SYNTHESIS IN HEPATIC STELLATE CELLS.

K. Jung<sup>1,2</sup>, K. Lee<sup>1,2</sup>, Y. Chung<sup>3</sup>, C. Choi<sup>3</sup>, S. Roh<sup>4</sup>, Y. Cho<sup>4</sup> and <u>H. Jeong<sup>1,2</sup></u>. 

<sup>1</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea, <sup>2</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, Kwangju, South Korea, 

<sup>3</sup>Food Science, Chinju International University, Jinju, South Korea and <sup>4</sup>R&D, Jangsaeng Doraji Co., Ltd.,, Jinju, South Korea.

Activation of hepatic stellate cells has been identified as a critical step in hepatic fibrogenesis and is regulated by several factors including cytokines and oxidative stress. Although the underlying mechanisms remain incompletely understood, it is widely accepted that oxidative stress plays a critical role in liver fibrogenesis. We investigated an aqueous extract from the roots of Platycodon grandiflorum A. DC (Campanulaceae), Changkil (CK)-mediated signaling pathway involved in hepatic stellate cell line (HSC-T6) inactivation. CK significantly inhibited in PDGF-driven HSC-T6 cell growth by inducing cell cycle arrest in a dose- and time-dependent manner. CK suppressed the expression of collagen and alpha-smooth muscle actin expression in PDGF-driven HSC-T6 cell. Furthermore, CK induced cell arrest at G1 *via* a relative protein of cell arrest pathway, p53 and a cell cycle-dependent kinase inhibitor, p21Cip1/WAF1 in PDGF-driven HSC-T6 cell. These results suggested that the protective effects of CK on the hepatic fibrosis in stellate cells may, at least in part, be due to its ability to reduce proliferation and collagen synthesis.

# 788 MATRIX METALLOPROTEINASE GENE EXPRESSION IN RAT MICROGLIA EXPOSED TO THE MARINE TOXIN DOMOIC ACID.

A. M. Mayer<sup>1</sup>, M. J. Fay<sup>1</sup> and A. M. Romanic<sup>2</sup>. <sup>1</sup>Pharmacology, Midwestern University, Downers Grove, IL and <sup>2</sup>Cardiovascular Pharmacology, Glaxo SmithKline, King of Prussia, PA. Sponsor: W. Prozialeck.

The pathology of Amnesic Shellfish Poisoning, one of the shellfish poisoning syndromes in the United States caused by the marine glutamate analog domoic acid (DOM), is incompletely understood. Our working hypothesis is that DOM may activate rat neonatal microglia (BM\$\phi\$), cause generation of matrix metalloproteinases (MMP), and toxicity to the nervous system. We have reported that *in vitro treatment of BM\$\phi\$with DOM lead to MMP-9 protein release (Mayer et al.* BioMedCentral Pharmacology 1:7-19, 2001). The purpose of our study was to investigate MMP gene expression in 4-24 hour DOM [1mM]-treated BM\$\phi\$using a MMP-specific cDNA array (SuperArray Inc., Bethesda, MD). Through side-by-side hybridization with cDNA probes prepared from mRNAs of control or 4, 8, 16 and 24 hour

DOM-treated BM\$\phi\$, the expression of 18 MMP and 4 tissue inhibitor of metalloproteinase (TIMP) genes was determined. Control BM\$\phi\$ expressed 4 MMP and 2 TIMP genes constitutively at high levels in vitro: collagenase-like A (MMP-1), MMP-2, -9, -19 and TIMP-2 and -4. Over a 24-hour observation period, DOM increased expression of MMP-2, -9, TIMP-2 and -4, by 242, 226, 144 and 163 % of control expression, respectively. Concomitantly, DOM decreased expression of MMP-1 and -19 in a time-dependent manner. Our current data, while providing additional experimental evidence to support of our working hypothesis, also extends our recent observations (Mayer A. et al. The Toxicologist 72(S1): 346, 2003) by generating new evidence that suggests that DOM has a time-dependent effect on BM\$\phi\$ MMP and TIMP gene expression in vitro. Supported by Midwestern University (AMM) and Glaxo SmithKline (AMR).

## 789 14-DAY AND 90-DAY MELATONIN TOXICITY STUDIES IN FISCHER 344(F344) AND LONG-EVANS(LE) RATS.

D. Gerken<sup>1</sup>, M. Ryan<sup>1</sup>, M. Hejtmancik<sup>1</sup>, A. Wiechmann<sup>3</sup>, G. Boorman<sup>2</sup>, M. Vallant<sup>2</sup>, J. Roberts<sup>4</sup> and <u>R. Chhabra<sup>2</sup></u>. <sup>1</sup> Battelle Science and Technology, Inc., Columbus, OH, <sup>2</sup>NIEHS, Research Triangle Park, NC, <sup>3</sup>University of Oklahoma Health Sciences Center, Oklahoma City, OK and <sup>4</sup>Fordham University, New York, NY.

Melatonin(MEL), a pineal gland hormone and "nutritional supplement", was administered by gavage in 0.5% methylcellulose containing 0.25% ethanol to male(M) and female(F) LE and F344 rats at dosages of 0, 5, 50, 5000, 50, 000, and 200, 000 ug/kg in both studies. In the 14-day study, 10/sex/dosage/strain were administered 12 daily doses (weekdays only) and subjected to one of three lighting and dosing regimes. Group I rats were exposed to full-spectrum fluorescent lighting (F-SFL) during the 12-hour light cycle (10-40 lux at cage level) and were dosed during the 4th and 5th hour of the light cycle. Group II rats were exposed to F-SFL during the 12-hour light cycle (10-40 lux at cage level) and were dosed during the 3rd and 4th hour of the 12-hour dark cycle. Group III rats were exposed to F-SFL during the 12-hour light cycle (10-40 lux at cage level) plus either 1000 lux(F344) or 1500 lux(LE) during the 6th and 7th hour of the light cycle approximately every other day and were dosed during the 4th and 5th hour of the light cycle. Weekly body weights, weekly clinical observations, organ weights, morphometric measurements of the outer nuclear layer (ONL) retinal thickness and histopathology were collected. No MEL related effects were noted in this study. In the 90-day study, 10/sex/dosage/strain were administered 68 daily doses (excluding weekends). Weekly body weights, weekly clinical observations, clinical pathology assessments including thyroid hormone analyses, organ weights, morphometric measurements of the ONL retinal thickness and histopathology were performed. MEL administration resulted in a mean weight decrease (10-15%) in F344 M and LE F compared to control, dark colored feces (200, 000 and 50, 000 ug/kg M and F LE and F344), increases in serum thyroid hormones (200, 000 ug/kg LE and F344 M and F, 50, 5, 000, 50, 000 ug/kg F344 F) and cystic uterine endometrial hyperplasia (all dosages in LE F).

# 790 CYTOTOXIC AND APOPTOSIS-INDUCING PROPERTIES OF *GUALACUM SANCTUM L.* (ZYGOPHYLLACCEAE) ON BREAST CANCER CELL

K. J. Chavez<sup>1</sup>, I. Delgado<sup>3</sup>, M. T. Laux<sup>2</sup>, J. A. Flanders<sup>2</sup> and E. Rodriguez<sup>3</sup>.

<sup>1</sup>Institute for Comparative and Environmental Toxicology, Cornell University, Ithaca, NY, <sup>2</sup>Department of Clinical Sciences and Molecular Medicine, Cornell University, Ithaca, NY and <sup>3</sup>Department of Plant Biology, Cornell University, Ithaca, NY.

Guaiacum sanctum L. (Zygophylacceae) is a medicinal and ornamental plant from tropical America and the West Indies. The heartwood and bark is widely used in South American folk medicine for the treatment of rheumatism, gout, boils, and gonorrhea. Extracts of the plant have been shown to possess anti-inflammatory activity, including immunomodulatory and analgesic properties. However, to date no studies have been carried out to verify the direct antitumor activity of the extracts. The present investigation was initiated to study the direct effect of organic extracts from the root and bark of Guaiacum sanctum L. on the growth of human breast cancer cell lines (SKBR-3, BT20, MB-MDA-468, MB-MDA-453, and MB-MDA-231) in addition to cervical cancer cell line (A-431) and simian kidney cell line (COS). Antiproliferative in vitro assays were based on both metabolic activity (Alamar Blue Assay) and determination of bound protein [Sulforhodamine B Assay (SRB)]. Indication of apoptosis was studied utilizing fluorescence microscopy "double stained" with propidium iodide and Hoechst 33342. Our results indicate that  $Guaiacum\ sanctum\ L$  exerts a direct antiproliferative effect on the growth of human breast cancer cell lines with inhibition ranging from 1000 ppm-15.6 ppm with Alamar Blue Assay and IC50 ranging between 200-20 μg/ml as determined by SRB, but had no effect on cell line A-431 and showed inhibition of (COS) only at the highest concentration. Apoptosis was induced in a dose-dependent manner.

IC50 for cell death was detected at  $50\mu g/ml$  for cell lines MB-MDA-231 and SKBR-3. Morphologic features (chromatin condensation and apoptotic bodies formation) were seen as low as 12.5  $\mu g/ml$  as early as 6 hrs. The study provides preliminary information that *Guaiacum sanctum L*. contains chemicals with chemotherapeutic potential. The study was supported by MIRT/NIH T37TW00076.

## 791 THE USE OF ELISA IN DIFFERENTIAL DIAGNOSIS OF THE GENUS TRIMERESURUS SNAKE BITES IN TAIWAN

D. Hung¹ and M. Liau². ¹ Toxicology Center, Taichung Veterans General Hospital, Taichung City, Taiwan and ² Department of Biotechnology, Fooyin University, Kaohsiung Hsien, Taiwan. Sponsor: S. Lin-Shiau.

In Taiwan, Trimeresurus mucrosquamutus (Taiwan habu) and T. stejnegeri (green bamboo habu) are the two most important poisonous snakes and half of the snakebite cases are afflicted by these Trimeresurus snakes. Their venoms are thought to be similar in toxicity despite of outstanding differences in their appearances. As reported, some distinct clinical pictures have been noted with more bleeding diathesis in T. stejnegeri snakebites. However, in many cases the afflicting snake is not witnessed. Here, we developed the method of Sandwich enzyme-linked immunosorbent assay (Sandwich-ELISA) to differentiate and detect snake venom in biological samples with the 1ng/ml of detection limit. In cases of definite T. stejnegeri or T. mucrosquamutus snakebite (snakes witnessed or caught), the cross reactivity of these two venoms and antivenoms was found to be only 1.8-13.5% by ELISA, which proved that Sandwich-ELISA method is useful to differentiate these two snake bites clinically. Key Words: ELISA, snake bites, Trimeresurus

# 792 TOXICITY EVALUATION OF KAVA KAVA EXTRACT IN FISHER 344 RATS AND B6C3F<sub>1</sub> MICE FOLLOWING REPEAT DOSING BY ORAL GAVAGE.

B. Sparrow<sup>1</sup>, M. Hejtmancik<sup>1</sup>, M. Ryan<sup>1</sup>, A. Skowronek<sup>1</sup>, P. Chan<sup>2</sup> and D. Orzech<sup>2</sup>. <sup>1</sup>Battelle, Columbus, OH and <sup>2</sup>NIEHS, Research Triangle Park, NC.

Kava kava extract is a nutraceutical promoted as a natural relaxant to treat nervous anxiety, stress and restlessness. Recently, severe hepatotoxicity including hepatitis, cirrhosis and liver failure was associated with kava kava products. This study investigated the toxicological effects of kava kava extract in rats and mice. Kava kava extract in corn oil was administered by oral gavage to Fischer 344 rats and B6C3F mice at dosages of 0, 0.125, 0.25, 0.5, 1.0 or 2.0 g/kg. Doses were administered daily (excluding weekends) for up to 13 doses. Clinical observations were recorded daily and food and water consumption monitored. Body weights were recorded weekly. At study termination, animals were humanely euthanized and necropsied. Liver, heart, lung, kidney, thymus and testis weights were recorded. Brain, liver, kidney and lung tissues were processed for microscopic examination. One 2.0 g/kg male mouse was moribund on Day 2 and was euthanized. One 2.0 g/kg female rat and male mouse died on Day 3. Treatment-related clinical observations included abnormal breathing, ataxia and lethargy, which occurred in both the rat and mouse 1.0 and 2.0 g/kg groups. No notable body weight changes occurred. Food and water consumption for the 2.0 g/kg groups were initially low, but eventually recovered to control values. For rats, organ-to-body weight changes attributed to kava kava extract included increased liver-to-body weight ratio for the 1.0 and 2.0 g/kg male rats and the 0.5, 1.0 and 2.0 g/kg female rats. Similarly, liver-to-body weight ratio changes attributed to kava kava extract occurred in mice, with increases noted in 1.0 and 2.0 g/kg male mice and 0.25, 0.5, 1.0 and 2.0 g/kg female mice. Microscopically, hepatic cellular hypertrophy was noted for the 2.0 g/kg male rats, the 0.25, 0.5, 1.0 and 2.0 g/kg female rats and the 2.0 g/kg male and female mice. Based on this study, further investigation of kava kava extract toxicology is recommended. (Supported by NIEHS Contract NO1-ES-25484).

USE OF THE AFRICAN GREEN MONKEY (CHLOROCEBUS AETHIOPS) MODEL TO DETERMINE PATHOPHYSIOLOGICAL RESPONSES TO INHALED RICIN TOXIN AND EFFICACY OF RICIN VACCINES.

R. W. Wannemacher, R. Dinterman, J. Hewetson, M. Pitt, R. Tammariello, R. Rietcheck, C. Klages and C. Millard. *USAMRIID, Frederick, MD.* 

In rodent models, inhaled ricin (R) causes severe lung injury that can result in death. Preliminary observations in the rhesus macaque indicated that inhaled doses of R that resulted in death were associated with severe lung damage. In this study, the African green monkey (AGM) was chosen because of freedom from Cercopitheane herpes virus 1 infection, non-aggressive behavior, and more uniform in weight and size as adults. To date, 5 monkeys have been exposed to various doses of aerosolized R with 3 deaths and 2 survivors. The median lethal inhaled dose

(MLID) appears to be ~  $7 \mu g/kg$ . Death occurred in to 2 to 3 days (D), with a gross pathology of moderate pulmonary edema and hemorrhage. Lung histology included inflammation, fibrin, edema, and hemorrhage. Surviving monkeys had persistent lung damage as measured by chest X-ray. They had elevated body temperature on D 1, which became subnormal for the next 5 to 6 D. The monkeys became anorexic for 10 to 14 D and on D 14 had lost weight; had an increased white blood, neutrophil, eosinophil, basophile, and platelet count; decreased total serum protein and albumin; and elevated serum LDH. The survivors will be monitored for 10 weeks (W). Twenty-two additional AGM are being used in an efficacy study for 2 vaccine candidates, deglycosylated R A-chain (dgRTA), and recombinant truncated (1-198) deletion (34-43) mutation of R A-chain (33/198 rRTA), plus 2 controls. At 0, 4, & 8 W, 10 monkeys in each vaccine group were vaccinated IM with 20 µg of antigen protein + 0.2% Alhydrogel. The dgRTA group developed serum anti-R IgG titers of 1:40, 000 by 4 W after the first vaccination, while it took 2 W after the second vaccination for the 33/198 rRTA group to develop titers of 1:4, 000. Six W after the third vaccination the monkeys will be exposed to 5 MLID of R. The AGM appears to be an excellent model to study the effects of inhaled R toxicity and efficacy of R vaccines.

# 794 DOWN-REGULATION OF CYCLOOXYGENASE-2 EXPRESSION BY CAFFEOYL-4-DIHYDROCAFFEOYL QUINIC ACID IN MACROPHAGES.

Y. Chung<sup>1</sup>, C. Choi<sup>1</sup> and <u>H. Jeong<sup>2,3</sup></u>. <sup>1</sup>Food Science, Jinju International University, Jinju, South Korea, <sup>2</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and <sup>3</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, Kwangju, South Korea.

Inducible cyclooxygenase-2 (COX-2) has been implicated in the processes of inflammation and carcinogenesis. Thus, the potential COX-2 inhibitors have been considered as anti-inflammatory or cancer chemopreventive agents. In this study, we investigated the effect of Caffeoyl-4-dihydrocaffeoyl quinic acid (CDCQ) isolated from Salicornia herbacea on the expression of cyclooxygenase (COX-2) in lipopolysaccharide (LPS)-activated RAW 264.7 macrophages. When CDCQ was treated with LPS, the prostaglandin E2 production and COX-2 gene expression induced by LPS were markedly reduced in a dose-dependent manner. Transient transfection experiments showed that LPS-induced increase in COX-2 promoter activities was suppressed by CDCQ. Moreover, transient transfection experiments using reporter vectors harboring deleted COX-2 promoters revealed that the transcriptional factor AP-1, but not NF-kB, between -574 and -51 in COX-2 promoter could be important for the inhibition of LPS-induced COX-2 mRNA by CDCQ. This study suggests that modulation of COX-2 by CDCQ may be important in the prevention of carcinogenesis and inflammation.

# 795 SUPPRESSION OF LIPOPOLYSACCHARIDE-ACTIVATED CYCLOOXYGENASE-2 EXPRESSION BY DIHYDRO-N-CAFFEOYLTYRAMINE IN MURINE MACROPHAGE RAW 264.7 CELLS.

H. Kim<sup>1,3</sup>, J. Kim<sup>1,3</sup>, C. Choi<sup>2</sup>, K. Jung<sup>1,3</sup>, E. Woo<sup>1,3</sup>, S. Han<sup>1,3</sup> and <u>H. Jeong<sup>1,3</sup></u>. <sup>1</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea, <sup>2</sup>Food Science, Jinju International University, Jinju, South Korea and <sup>3</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, Kwangju, South Korea.

Lycii Radicis Cortex, the root bark of Lycium chinense Miller (Solanaceae) is used in oriental medicine as a tonic and is reported to exhibit hypotensive, hypoglycemic, and antipyretic activity. A phenolic amide, dihydro-N-caffeoyltyramine was isolated from the Lycii Radicis Cortex. In the present study, we investigated the effects of dihydro-N-caffeoyltyramine on the cyclooxygenase-2 (COX-2) gene expression, which plays a crucial role in many physiological and pathological processes in macrophages. Treatment with dihydro-N-caffeoyltyramine significantly decreased the production of LPS-induced prostaglandin E2 and the expression of COX-2 mRNA in lipopolysaccharide (LPS)-activated RAW 264.7 macrophages in a dose-dependent manner. Transient transfection experiments also showed that LPS-induced increase in COX-2 promoter activities was suppressed by dihydro-N-caffeoyltyramine. This study suggests that modulation of COX-2 expression by dihydro-N-caffeoyltyramine may be important in the prevention of inflammation.

# 796 AN AQUEOUS EXTRACT ISOLATED FROM PLATYCODON GRANDIFLORUM SUPPRESSED IN B16F10 MELANOMA CELL METASTASIS.

K. Lee<sup>1, 2</sup> and H. Jeong<sup>1, 2</sup>. <sup>1</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and <sup>2</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, Kwangju, South Korea.

Metastasis of cancer cells to distant sites is one of the major deciding factors in cancer outcome. In fact, prognosis of cancer is mainly determined by the invasiveness of the tumor and its ability to metastasize. In this study, we assayed the preventive

and therapeutic effects of aqueous extract from the roots of Platycodon grandilflorum A. DC, Changil (CK) on the experimental lung metastasis induced by melanoma cell (B16F10) in C56BL6 mice. CK clearly inhibited both B16F10 melanoma cell adhesion to the extracellular matrix proteins as well as invasion through Matrigel-coated filter. In addition, CK significantly inhibited the proliferation of B16F10 melanoma cells in a dose-dependent manner. In B16F10 melanoma lung metastasis experiment, CK showed remarkable inhibitory effects on the lung tumor colonization in a dose-dependent manner. These results demonstrate that anti-metastatic and anti-angiogenetic activity of CK resulted from blocking of proliferation and invasion of the melanoma cells. Taken together, the results of our study provide evidence that CK possess an anti-metastatic activity.

## 797 PLATYCODON GRANDIFLORUM SUPPRESSED INVASION AND ANGIOGENESIS.

D. Shin<sup>1, 2</sup>, K. Lee<sup>1, 2</sup> and <u>H. Jeong<sup>1, 2</sup></u>, <sup>1</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and <sup>2</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, Kwangju, South Korea.

Medical plants contain pharmacological substances including flavonoids and saponin, and their extracts have been therapeutically administered for cancer therapy in vitro and in vivo. In this study, we assayed the preventive and therapeutic effects of aqueous extract from the roots of Platycodon grandiflorum A. DC, Changil (CK) on the in vitro angiogenesis using human microvessel endothelial cell-1 (HMEC-1). CK inhibited cell migration and proliferation of HMEC-1 in a dose-dependent manner. CK also inhibited the tube formation of HMEC-1 in a dose-dependent manner. Furthermore, in an in vivo matrigel plug assay, CK reduced B16F10 tumor melanoma cell-induced angiogenesis compare with control. These results demonstrated that prevention of angiogenesis by CK was mediated by inhibition of proliferation and migration of endothelial cells. Taken together, the results of our study provide evidence that CK possess an anti- angiogenetic potential that is a new insights and previously unrecognized biologic activity.

# 798 PROTECTIVE EFFECT OF PLATYCODON GRANDIFLORUM ON THE ACETALDEHYDEINDUCED ACTIVATION OF HEPATIC STELLATE CELLS.

H. Jeong<sup>1, 2</sup> and K. Lee<sup>1, 2</sup>. <sup>1</sup>Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and <sup>2</sup>Research Center for Proteineous Materials, Chosun University, Kwangju, Kwangju, South Korea.

The increased deposition of extracellular matrix by hepatic stellate cells following liver injury in a process known as activation is considered a key mechanism for increased collagen content of liver during the development of liver fibrosis. In this study, we investigated the protective effects of an aqueous extract from the roots of Platycodon grandiflorum A. DC (Campanulaceae), Changkil (CK), on hepatic fibrosis in hepatic stellate cells. We report that CK reduces the accumulation of collagen in acetaldehyde-induced hepatic stellate cells. The accumulation and synthesis of collagen were measured by Marson-Trichrom stain and pulse-labeling with [3H]-proline, respectively. As the results, CK inhibited collagen accumulation and incorporation of proline in a dose dependent manner. Furthermore, the effects of CK on expression of alpha-smooth muscle actin (a-SMA) and collagen type I were evaluated utilizing immunocytochemistry. CK reduced a-SMA and collagen type I expressions compared with acetaldehyde-induced hepatic stellate cells. These results suggested that the protective effects of CK on the hepatic fibrosis in stellate cells might, at least in part, be due to its ability to reduce the accumulation of collagen and blocked activation of hepatic stellate cells by acetaldehyde.

# **799** STUDY OF THE MUTAGENIC ACTIVITY OF *LUPINUS termis* ALCOHOLIC EXTRACT IN *SALMONELLA typhimurium* STRAINS.

M. R. Santiago<sup>1</sup>, M. D. Antoun<sup>2</sup> and <u>D. Herreno-Saenz</u><sup>1</sup>. <sup>1</sup>Pharmacology and Toxicology, School of Medicine, University of Puerto Rico, San Juan, Puerto Rico and <sup>2</sup>School of Pharmacy, University of Puerto Rico, San Juan, Puerto Rico.

Higher plants that have served as source of several lead compounds for drugs are used in modern medicine. The genus Lupinus (Leguminosae) is represented by about two hundred species in the New World and a smaller in the Mediterranean region and Africa. *Lupinus termis* Forsk, also known as Tirmus or Turmuz, is widely cultivated in Sudan and has been widely used as an aqueous extract in folklore medicine due to its beneficial effects on a variety of dermatological disorders. Previous studies have shown the efficacy of the alcoholic extract of *Lupinus termis* seeds in the treatment of chronic atopic dermatitis. The study of the genotoxic potential of *Lupinus termis* alcoholic extract is important to determine if this extract is a safe

natural product, which could have a potential of being developed as a new treatment for chronic atopic dermatitis in United States. The mutagenic potential of this alcoholic extract was studied using the Salmonella typhimurium reverse mutation assay (Ames assay). The study was performed using six Salmonella typhimurium strains, TA97a, TA98, TA100, TA102, TA1535 and TA1538. Three concentrations (5 μg/plate, 20 μg/plate and 100 μg/plate) of the alcoholic extract of Lupinus termis, as well as its main alkaloid, Lupanine, were studied using the plate incorporation method in the presence and absence of metabolic activation (S9). Three replicates were done for each concentration, and the assay was performed in triplicate. 2-Aminofluorene (20 µg/plate) and Benzo(a)pyrene (5 µg/plate) were used as positive controls and DMSO was used as the solvent and as the negative control. For each concentration treatment, the revertants per plate obtained in the presence and absence of metabolic activation (S9), were statistically lower compared with controls. The results obtained show that at these concentrations, the alcoholic extract of Lupinus termis and Lupanine, do not have any mutagenic activity in the Salmonella typhimurium tester strains.

## **800** MALDI-TOF/MS IN THE CHARACTERIZATION OF NUTRACEUTICALS.

J. R. Guthrie<sup>1</sup>, H. A. Weber<sup>1</sup>, D. E. Gray<sup>1</sup>, R. K. Harris<sup>1</sup>, A. P. Clark<sup>1</sup>, J. W. Algaier<sup>1</sup> and <u>C. S. Smith<sup>2</sup></u>. <sup>1</sup>Midwest Research Institute, Kansas City, MO and <sup>2</sup>NIEHS, Research Triangle Park, NC.

Matrix-assisted laser desorption ionization time-of-flight mass spectrometry (MALDI-TOF/MS), traditionally used in the study of large biomolecules and polymers, was used in the chemical characterization of various nutraceuticals. Powdered kava kava extract (KKE), goldenseal root powder (GSRP), comfrey root (CR), powdered Ginkgo biloba extract (GbE), grape seed extract (GSE), and pine bark extract (PBE) have been selected for toxicological evaluation by NIEHS. The analysis of these herbal products, which contain a wide variety of chemical constituents, poses a number of significant analytical challenges. An overall investigative approach to MALDI-TOF/MS analysis of nutraceuticals was developed, including evaluation of different sample preparation procedures, various MALDI matrices, different matrix/sample ratios, and the use of reflector- and linear-mode TOF/MS. The developed approach was applied to the above nutraceuticals. During analysis of KKE, 20 kava-related ions were observed, all of which were \( \) 360 Da. Alkaloids, including berberine and hydrastine, were observed during analysis of GSRP using 2, 5-DHB and CHCA as MALDI matrices. Analysis of CR extract led to the observation of polysaccharides \( \rangle 3, 900 Da. Ginkgolides and flavonol glycosides were observed during MALDI-TOF/MS analysis of GbE. Linear- and reflector-mode methods were developed for the analysis of GSE and PBE, which led to the identification of up to tridecamer proanthocyanidins.

## 801 CHEMICAL CHARACTERIZATION OF GINKGO BILOBA EXTRACT.

J. E. McClintock<sup>1</sup>, H. A. Weber<sup>1</sup>, M. D. Armstrong<sup>1</sup>, B. M. O'Brien<sup>1</sup>, D. Logan<sup>1</sup>, R. A. Swaney<sup>1</sup>, J. R. Guthrie<sup>1</sup>, R. K. Harris<sup>1</sup>, A. P. Clark<sup>1</sup>, J. W. Algaier<sup>1</sup> and <u>C. S. Smith<sup>2</sup></u>. \*\**Imidwest Research Institute, Kansas City, MO and PNIEHS, Research Triangle Park, NC.* 

Ginkgo biloba L. leaf extract, which is an extremely popular dietary supplement and is consumed to improve memory and mental alertness, has been selected for toxicological evaluation by the NIEHS. Millions of consumers use powdered Ginkgo biloba extract (GbE), which is standardized to contain \( \sigma 24\% flavonol glycosides \) (mainly based on kaempferol, quercetin, and isorhamnetin) and \( \sigma 6\% \) terpene lactones (ginkgolides and bilobalide). A strategy, which included HPTLC, HPLC, GC/MS, LC/MS, and MALDI-TOF/MS analyses, was developed for overall characterization of GbE. Two HPTLC methods were used to analyze GbE; one was used to identify terpene lactones and the other to identify flavonol glycosides. After GbE was hydrolyzed with HCl at 90°C for 1 hr, the resulting solutions were analyzed using gradient RPHPLC with UV and ELSD detection to determine aglycone and terpene lactone content, respectively. Quercetin dihydrate standards were used to quantitate the aglycones, while bilobalide standards were used to quantitate terpene lactones. Using UV detection, quercetin, kaempferol, and isorhamnetin glycosides were observed at 16.71%, 12.20% and 2.37%, respectively. Using ELSD detection, bilobalide was observed at 6.94%, while ginkgolides A, B, and C were observed at 3.74%, 1.62%, and 3.06%, respectively. The HPLC method was transferred to positive electrospray LC/MS, which was used to identify 18 components in nonhydrolyzed GbE and 10 components in hydrolyzed GbE. LC/MS analyses verified that GbE did not contain colchicine, a reported Ginkgo contaminant, and that ginkgolic acids were present at  $10.45 \pm 2.40 \,\mu\text{g/g}$ . Ten volatile components were identified during GC/MS analyses. Reflector mode MALDI-TOF/MS analyses were conducted using CHCA as the matrix and led to the identification of 22 GbE components.

NEUROPROTECTION BY GINKGO BILOBA EXTRACT EGR761

J. T. Kern, A. D. Kraft and J. A. Johnson. Department of Pharmaceutical Sciences, University of Wisconsin-Madison, Madison, WI.

Oxidative stress plays an important role in cell death and has been implicated in the development of a number of neurological diseases, including Parkinsons and Alzheimers (AD). The plant extract Ginkgo biloba EGb761 contains a number of chemical constituents that counteract these oxidative-stress induced effects in standardized neurophysiological tests. The cellular mechanisms underlying the beneficial effects, however, remain unclear. Here, we demonstrate that ginkgo treatment induces two distinct neuroprotective pathways, including activation of the antioxidant response element (ARE) and increasing transthyretin (TTR) levels. The ARE is an enhancer element commonly found in the flanking region of a number of phase II detoxifying enzymes, including heme oxygenase I and NAD(P)H:quinone reductase I. Induction of the ARE protects cells from glutamate, dopamine, and hydrogen peroxide induced cytotoxicity. TTR is a protein involved in the transport of retinol-binding protein in the cerebrospinal fluid. In vitro, TTR has been shown to bind beta amyloid and prevent the formation of fibrils, a species of beta amyloid found in human AD plaques. Utilizing chemical and genetic inhibitors against phosphatidylinositol 3-kinase, as well as other known enzymes in the ARE signaling cascade, we demonstrate that the signaling events leading to ARE activation and increased TTR levels are distinct from one another. Interestingly, in an ARE-luciferase reporter assay comparing ginkgo treatment (50 micrograms/mL) to treatment of the ARE-activating antioxidant tert-butylhydroquinone (10 micromolar) in IMR-32 human neuroblastoma cells, we observe that ginkgo induces the ARE only one-fourth as well as tBHQ but affords similar, if not better, protection from 250 or 500 micromolar hydrogen peroxide-induced cytotoxicity. Overall, these data suggest that Ginkgo biloba extract EGb761 activates at least two neuroprotective pathways and paves the way for future studies into the neuroprotective role of the constituents of the extract and a detailed examination of the signaling events involved in ARE and TTR activation.

# 803 THE BRAIN HOMEOSTASIS IS AFFECTED BY INTRACEREBRAL BUT NOT SUBCUTANEOUS INFUSION WITH FUMONISIN B, IN BALB/C MICE.

M. F. Osuchowski and R. P. Sharma. Physiology and Pharmacology, The University of Georgia, Athens, GA.

Fumonisin B $_1$  (FB $_1$ ) is a mycotoxin produced by Fusarium verticillioides, a wide-spread contaminant of corn. FB $_1$  is a causative agent of leukoencephalomalacia, a fatal neurodegenerative condition affecting equide. This study investigated the neurotoxicity of FB $_1$  in a mouse model after its intracerebral or systemic administration. Female BALB/c mice (5/group) were continuously infused (0.5  $\mu$ II/hi) with the total doses of 10 or 100  $\mu$ g FB $_1$  or saline over 7 days via osmotic pumps implanted either sub-

cutaneously or *via* intracerebral cannulation of the lateral ventricle in brain bypassing the blood-brain barrier. One day after the treatment mice were killed; their brains dissected fresh or after intracardiac fixation with paraformaldehyde. High performance liquid chromatography indicated increased free sphinganine in both intracerebral FB<sub>1</sub>-treated groups in cortex, cerebellum and midbrain (also free sphingosine in the cortex after 100 µg but not in medulla oblongata. Increase of cerebellar sphinganine in the 100 µg group was substantially cortex as a constant of the 100 µg group was substantially cortex as a constant of the 100 µg.

the <sup>100</sup> μg group was substantially greater compared to other two regions. Real-time polymerase chain reaction assessed the expression of proinflammatory cytokines in brain. Intracerebral administration of FB<sub>1</sub> induced expression of tumor necrosis factor  $2^{\alpha_i \text{ interfleukin}^{-1}}$ β, interleukin-6 and interferon γ in the whole brain. FluoroJade B staining detected neuronal degeneration in hippocampus of mice treated intracerebrally with high dose. The subcutaneous administration of FB<sub>1</sub> had no effect on the brain sphingolipid metabolism, cytokine gene expression or morphology. Results indicated the intracerebral FB<sub>1</sub> treatment inhibited de novo synthesis of sphingolipids, stimulated inflammatory cytokines and inflicted neuronal damage in the murine brain. Results indicate the lack of fumonisin permeability into brain is responsible for the absence of its neurotoxicity in mouse. (Partially supported by ES09403).

## 804 CHEMICAL CHARACTERIZATION OF POWDERED KAVA KAVA EXTRACT.

H. A. Weber<sup>1</sup>, A. E. Hodges<sup>1</sup>, S. M. Barnes<sup>1</sup>, L. A. Moody<sup>1</sup>, R. A. Swaney<sup>1</sup>, J. R. Guthrie<sup>1</sup>, R. K. Harris<sup>1</sup>, A. P. Clark<sup>1</sup>, J. W. Algaier<sup>1</sup> and <u>C. S. Smith</u><sup>2</sup>.

<sup>1</sup> Midwest Research Institute, Kansas City, MO and <sup>2</sup> NIEHS, Research Triangle Park, NC.

Powdered kava kava (*Piper methysticum*) extract (KKE) is an herbal supplement that has been selected for toxicological evaluation by the NIEHS. Kava, which is a traditional beverage of various Pacific Basin countries, has psychoactive properties and is used as a treatment for anxiety. A strategy, which included extraction, HPLC,

GC/MS, LC/MS, and MALDI-TOF/MS was developed for overall characterization of KKE. KKE was extracted under ambient conditions and the extracts were analyzed using an isocratic HPLC method with UV detection at 220 nm to determine the weight percentages of six kavalactones. Samples containing between  $\backsim 5$ and 500 mg of KKE were extracted by sonicating for 60 minutes at ambient temperature with 50 mL of methanol. All samples were diluted to a final analytical concentration of \sim 0.1 mg KKE/mL methanol in order to obtain more reproducible results. Kavain, a major kavalactone, was used to prepare quantitation standards ( $\backsim 3-393~\mu g/mL)$  to quantitate weight percentages of kavain and five other kavalactory. tones in KKE. The extraction of methysticin, dihydromethysticin (DHM), kavain, dihydrokavain (DHK), yangonin, and desmethoxyyangonin (DMY) from KKE proved to be linear (r ) 0.9999) and precise, with RSDs  $\langle$  1.9% for 10 replicates. The HPLC method was transferred to positive electrospray LC/MS, which was used to identify 14 KKE components. Twenty KKE components were identified using GC/MS analyses. MALDI-TOF/MS analyses were conducted using three matrices, which led to the observation of 20 kava-related ions. Contaminant testing indicated that N-nitrosopyrrolidine was present at 30.9 ppb; all other nitrosamines were less than the detection limit of 1.0 ppb. All organophosphate and organochlorine pesticide levels, except for pentachloronitrobenzene (PCNB) which was present at 16.6 ppb, were below the detection limit. Aflatoxins, heavy metals, and microbial contaminants were all below the reported detection limits.

# 805 POLYSACCHARIDE ISOLATED FROM PORIA COCOS SCLEROTIUM INDUCES INOS EXPRESSION THROUGH THE ACTIVATION OF NF-KB/REL IN MURINE MACROPHAGES.

Y. J. Jeon. *Pharmacology, Chosun University, Kwangju, South Korea.* Sponsor: <u>H. Kim.</u>

We show that PCSC, a polysaccharide isolated from the sclerotium of Poria cocos with one percent sodium carbonate, significantly induces nitric oxide (NO) production and inducible NO synthase (iNOS) transcription through the activation of nuclear factor-kB/Rel (NF-kB/Rel). In vivo administration of PCSC induced NO production by peritoneal macrophages of B6C3F1 mice. PCSC also dose-dependently induced the production of NO in isolated mouse peritoneal macrophages and RAW 264.7, a murine macrophage-like cell line. Moreover, iNOS protein and mRNA transcription were strongly induced by PCSC in RAW 264.7 cells. To further investigate the mechanism responsible for the induction of iNOS gene expression, we investigated the effect of PCSC on the activation of transcription factors including NF-kB/Rel and Oct, whose binding sites were located in the promoter of iNOS gene. Treatment of RAW 264.7 cells with PCSC produced strong induction of NF-kB/Rel-dependent reporter gene expression, whereas Oct-dependent gene expression was not affected by PCSC. DNA binding activity of NF-kB/Rel was significantly induced by PCSC, and this effect was mediated through the degradation of IkB . In conclusion, we demonstrate that PCSC stimulates macrophages to express iNOS gene through the activation of NF-kB/Rel.

# 806 SYNERGISTIC EFFECTS OF OCHRATOXIN A AND FUMONISIN B1 IN C6 GLIOMA CELLS: CYTOTOXICITY AND DNA SYNTHESIS INHIBITION.

E. E. CREPPY<sup>1</sup>, M. CARRATU<sup>2</sup>, P. CHIARAPPA<sup>2</sup>, I. BAUDRIMONT<sup>1</sup>, P. BORRACCI<sup>2</sup>, T. A. MOBIO<sup>1</sup> and S. M. MOUKHA<sup>1</sup>. <sup>1</sup> Toxicology, University Bordeaux 2, Bordeaux, France and <sup>2</sup> Pharmacology and Human Physiology, University of Bari, Medical School, Bari, Italy.

Ochratoxin A (OTA) and Fumonisin B1 (FB1) are mycotoxins detected as contaminants in animal feed and food. These mycotoxins are produced by Aspergillus and/or Penicillium and by Fusarium species respectively. In vitro studies, so far available, focusing on the effects of each toxin, show that both are cytotoxic and inhibit the synthesis of cellular macromolecules 1-2. Since multi-mycotoxins contamination of feed and foodstuffs occurs more frequently than a single mycotoxin contamination, the aim of the present study was to investigate possible synergistic or antagonistic effects of these two mycotoxins on both cell viability and DNA synthesis in the rat glioma cells, C6. Cell viability and DNA synthesis were studied by the methods previously described 1-2. The results show that OTA inhibits cell viability (IC50 -18 microM, for 48h incubation) and DNA synthesis (IC50 -8 microM, for 24h incubation) in C6 glioma cells. The combination of OTA with different concentrations of FB1 significantly enhances OTA-induced inhibition of both cell viability and DNA synthesis. DNA synthesis inhibition was increased from <5% for 2.5 microM of FB1 to >50% when combined to 5 microM OTA while this OTA concentration induces solely less than 20% of inhibition. The present findings underline that multi-mycotoxins contamination must be carefully considered when assessing the risk for humans exposed to mycotoxins. ochratoxin A. J. Toxicol. Sciences. 23, 165-172, 1998. [2] Mobio TA, Anane R, Baudrimont I, Carratu MR, Shier TW, Dano SD, Ueno Y, Creppy EE., Epigenetic properties of fumonisin B1: cell cycle arrest and DNA base modification in C6 glioma cells. Toxicol. Appl. Pharmacology 164, 91-96, 2000

### 807 TOXIC BREVETOXIN COMPLEXES ARE IN AQUEOUS SOLUTIONS

A. J. bourdelais and D. G. Baden. Center for Marine Science, University of North Carolina at Wilmington, Wilmington, NC.

Florida red tides are caused by blooms of the marine dinoflagellate Karenia brevis which produce brevetoxins. These toxins are associated with massive fish kills, marine mammal poisoning and human health problems. There are 9 natural brevetoxins with two different polyether backbones. This study presents the structure and characterization of three new compounds (AJB29.0psp, AJB29.5psp and AJB31.5psp) produced by *K. brevis*. These compounds are believed to be complexes of brevetoxins and are more toxic to fish. The brevetoxin-complexes were purified from cultures of K. brevis. Structure elucidation was perfrormed using LC-Mass Spectrometry and NMR. 1-D and 2-D NMR experiments were run. Fish bioassays using mosquito fish were run as follows: fish were placed in 100 ml beakers containing 20 ml tank water. The fish received one of the following: 200 ml of ethanol, 20  $\mu g$  PbTx-2 in 200 ml ethanol or 20  $\mu g$  of one of the new complexes in 200 ml ethanol. Fish were then observed until death. NMR spectra suggest a polyether ladder structure for all three compounds. The AJB29.0psp 1H-spectrum contains an aldehyde moiety . The AJB29.5psp 1H-spectrum contains no aldehyde or exomethylene and the LC-MS showed masses of 866, 868, 892, 894, 898 and 910. The AJB31.5psp NMR spectrum shows and aldehyde and exomethylene with 50 carbons, LC-MS data showed masses of 876, 892, 894, and 910. The easiest explanation for the brevetoxin-complexes is that they are mixtures. However, after the NMR runs in CDCl3 the complexes were dried and rerun on the HPLC. The resulting chromatograph indicated several different peaks. When collected separately and rerun on the HPLC these peaks eluted as individual peaks which eluted at retention times for known brevetoxins. However, if the peaks were collected together, dried and rerun on the HPLC only one peak would appear. These results suggest that the new compounds are complexes in aqueous solutions and dissociate in nonaqueous solutions. This work was supported by NIEHS grants ES05853 and E\$10594

THE EFFECTS OF (-)-HYDROXYCITRIC ACID EXTRACT AND FLUOXETINE ON RAT BRAIN CORTEX NEUROTRANSMITTERS AFTER 30, 60 AND 90 DAYS TREATMENT.

M. Shara<sup>1</sup>, S. J. Stohs<sup>1</sup>, D. Bagchi<sup>1</sup>, M. Bagchi<sup>3</sup> and S. Ohia<sup>2</sup>. <sup>1</sup>Pharmacy Science, Creighton University, Omaha, NE, <sup>2</sup>Pharmacology, University of Houston, Houston, TX and <sup>3</sup>InterHealth USA, Benicia, CA.

This study examined the effects of a novel (-)-hydroxycitric acid (HCA) extract and fluoxetine on rat brain cortex neurotransmitters. Previous studies have demonstrated that HCA use is associated with significant decreases in food consumption and body weight in animals and humans. The effects of HCA on brain cortex serotonin (5-HT), its metabolite 5-hydroxyindoleacetic acid (HIAA), dopamine (DA) and its metabolites 3, 4-dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) have not been examined. Methods: HCA was administered as 0.2, 2 and 5% of the diet and 15 mg/kg/day of fluoxetine was administered orally. The 5% HCA dose is 25 fold the recommended dose. Animals were killed after 30, 60 and 90 days. Brain cortices were analyzed for 5-HT, HIAA, DA, DOPAC and HVA content utilizing reverse phase HPLC with electrochemical detection. Results: HCA (0.2, 2, and 5%) increased cortex 5-HT by 11, 9, and 12% after 90 days (p <0.05). In contrast, fluoxetine treatment decreased cortex 5-HT by 9, 7 and 8% on days 30, 60 and 90, respectively (p <0.05). Fluoxetine also decreased cortex HIAA by 19, 15 and 17% (p<0.05) 30, 60 and 90 days post-treatment, respectively. No changes in HIAA were observed in any of the HCA treatment groups. After 90 days, HCA (0.2, 2 and 5%) increased cortex DA by 10, 15 and 18 % (p <0.05) and increased DOPAC by 23, 26 and 29% (p<0.05), respectively. In contrast, fluoxetine decreased DA by 18, 15 and 19% (p<0.05), respectively. No changes in cortex DOPAC were observed in all fluoxetine groups. On day 90, HCA (0.2, 2 and 5%) increased cortex HVA by 12, 15 and 13% (p<0.05), respectively. Fluoxetine decreased cortex HVA by 17, 13 and 14% (p<0.05), respectively. Conclusions: The results for fluoxetine agree with previous reports. The changes in 5-HT, DA and their metabolites due to HCA have not been previously reported. The changes in these neurotransmitters may play a role in the weight loss and appetite suppressing effects of HCA.

EFFECTS OF KAVA KAVA EXTRACT ON HEPATIC PHASE I AND PHASE II DRUG METABOLIZING FNZYMFS

A. B. Cadwallader and M. R. Franklin. Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.

South Pacific Islanders have long utilized aqueous extracts of kava kava (Piper methysticum) for relaxation and feelings of satisfaction and until recent suspicions of hepatotoxity, its use has been on the upswing in other populations. Kava kava has been shown to both inhibit and induce P450 suggesting the potential for drug interactions with OTC or prescription medicines. Using the rat as an experimental model, we investigated the effects of in vivo administration of kava kava extract on hepatic Phase II in addition to Phase I drug metabolizing enzymes. Both enzyme activity and mRNA levels were monitored, and the effects were compared with two known inducing agents, \( \beta \)-naphthoflavone (\( \beta NF \)) and dexamethasone. Following kava kava treatment, increases were seen in the mRNA levels of CYP2B and CYP3A and no changes were seen in CYP1A2. Compared to dexamethasone effects, the increase in the cytochrome P450 concentration and CYP3A mRNA was smaller and the increase in CYP2B mRNA was greater. Increases in UDP-glucuronosyltransferases (UGT), glutathione S-transferases, quinone oxidoreductase, and microsomal epoxide hydrolase were also seen. Microsomal p-nitrophenol glucuronidation activity and ÚGT1A6 and UGT2B1 mRNAs were all increased following kava kava treatment but UGT1A1 mRNA was not. The UGT2B1 increase was similar to that elicited by dexamethasone treatment and the UGT1A6 increase was less than elicited by  $\beta NF$ . The increases in glutathione S-transferase (CDNB) activity and GSTA2 mRNA and quinone oxidoreductase activity and its mRNA, were not as large as elicited by  $\beta NF$  treatment. The results indicate that the effects of kava kava on drug metabolizing enzymes extend beyond P450 and include many of the Phase II enzymes.

KAVA EXTRACT MODULATES EXPRESSION OF DRUG-METABOLIZING ENZYMES AND TRANSPORTERS IN MICE AND HEPA-1 CELLS.

M. Z. Dieter, J. M. Maher, A. L. Slitt and C. D. Klaassen. University of Kansas Medical Center, Kansas City, KS.

Severe hepatic toxicity in humans has been associated with consumption of dietary supplements containing Piper methysticum (kava), prompting a consumer advisory by the USFDA. To explore the possibility that kava may alter the expression of genes involved in drug metabolism and transport, mRNA levels of several genes were examined in male mice treated with kava extract. A single 300 mg/kg intraperitoneal dose of kava extract (standardized to 30 mg kavalactones/ml) caused no significant alterations in liver mRNA levels of any of the genes examined. In male mice treated for 1 week with an oral dose of 300 mg/kg kava twice a day, significant increases in liver NQO1 (2.1 fold), MRP3 (2.3 fold), and MRP4 (4 fold) mRNA were observed, whereas CYP1A1/2, CYP3A11, MRP2, UGT1A6, and OATP2 were unchanged. Oral gavage of kava also increased CYP1A1/2 mRNA expression in mouse duodenum more than 15 fold, with minor changes in other genes. In mouse hepatoma (Hepa-1) cells, kava extract caused concentration-dependent increases in mRNA levels of NQO1, CYP1A1/2, MRP3, and MRP4, with maximal inductions of 7.6, 26, 2.4, and 4.3 fold, respectively, at 90 ng/ml for 12 hours. These results indicate that repeated administration of kava can cause significant increases in gene expression in both liver and duodenum of mice. The more marked induction of CYP1A1/2 in duodenum compared to liver suggests that metabolism of kavalactones may occur in intestinal mucosa. The gene expression changes observed in mice and cells suggest that a kava component could mediate its effects through activation of the aromatic hydrocarbon receptor- and/or Nrf2- responsive drug metabolism pathways. Changes in expression of drug-metabolizing enzymes and transporters could result in changes in metabolism and disposition in humans regularly consuming kava-containing supplements, possibly contributing to drug-drug interactions and/or hepatotoxicty. (Supported by NIH grants ES-09716 and ES-07079)

## 811 IMMUNOMODULATORY EFFECTS OF NUTRACEUTICALS ON MOUSE PHAGOCYTIC CELLS.

S. Navarro<sup>2, 1</sup>, A. Rhule<sup>1</sup>, J. M. Wilham<sup>2, 1</sup>, B. Seaver<sup>1</sup>, J. R. Smith<sup>1</sup> and <u>D. M. Shepherd<sup>2, 1</sup>. <sup>1</sup>Department of Biomedical & Pharmaceutical Sciences, University of Montana, Missoula, MT and <sup>2</sup>Center for Environmental Health Sciences, University of Montana, Missoula, MT.</u>

Herbals have been used by many ancient civilizations to treat illness and boost general well-being. Furthermore, phytomedicines have been reported to enhance the function of the immune system. However, information to support the efficacy and/or toxicity of herbal extracts is severely lacking. To address this deficiency, we have evaluated the effects of a select group of nutraceuticals on the activity of cul-

tured dendritic cells (DC2.4 cells) and macrophages (RAW264.7 cells). Based on the selective action of a panel of herbals on the enzymatic activity of COX-2, but not COX-1, we chose to evaluate the immunomodulatory effects of andrographis, amentoflavone, notoginseng, ostivone, thunder god vine and white willow bark. In a concentration-dependent manner, notoginseng and thunder god vine suppressed the LPS-induced production of TNF-alpha by DC2.4 and RAW264.7 cells. Conversely, white willow bark and andrographis increased TNF-alpha production by the dendritic cells, and ostivone increased the production of this pro-inflammatory cytokine by the macrophages. The LPS-stimulated induction of both COX-2 and IL-1B mRNA in RAW264.7 cells was inhibited by thunder god vine, amentoflavone, and notoginseng. Delayed exposure of DC2.4 cells to notoginseng failed to suppress LPS-induced TNF-alpha production whereas exposure at or before LPS activation resulted in significant decreases. Similar effects were observed following the LPS activation of macrophages that had been treated with thunder god vine. These results demonstrate that herbal extracts can modulate the inflammatory responsiveness of cultured immune cells and suggest that these phytochemicals may be useful for the treatment of inflammatory diseases. Future investigations will assess the potential immunomodulatory effects of these nutraceuticals on ex vivo immune cells and in vivo models of inflammatory disease.

# 812 HISTOPATHOLOGICAL CHANGES OCCURRING IN THE ORGANS OF RATS FOLLOWING SUBCHRONIC TOXICITY OF ZEARALENONE.

R. M. kadry, M. Abdel-Wahab and N. A. El-Danaf. *Animal Reproduction Research Institute, ARC, Giza, Egypt.* Sponsor: <u>A. Kadry</u>.

Contamination of the food supply by drugs, synthetic chemical and naturally occurring toxins, poses a threat to public health. Although toxicosis resulting from ingestion of residue-contaminated food products is a relatively rare occurrence, the long-term health effects from repeated exposure to low concentrations of certain chemicals may be of much greater concern. Zearalenone is a mycotoxin that exhibits strong estrogenic properties when fed to domestic animals. When present in sufficient quantities in the ruminant diet, this toxin may cause infertility, vaginal prolapse, enlargement of the uterus and mammary glands and could lead to abortion. Anabolic agents such as zearalenone are suspected to cause morphologic tissue response. In the current study, Zearalenone was orally administered daily to SD rats at three dose levels 0, 1 and 10 mg/kg B.W. for 14 days. Gross signs of toxicity or mortality were recorded five days/ week. Following the conclusion of the exposure period, the liver, kidney, lung, uterus and ovaries were examined for tissue distribution and for histopathological changes. Tissues slides from all animals were prepared by routine procedure and stained with hematoxylin and eosin. High dose exposure to Zearalenone caused hydropic degeneration, sinusoidal congestion and lymphocyte infiltration in liver. Marked cloudy swilling and hydropic degeneration were observed in the kidney tissues. Focal aggregation of lymphocytes and macrophages were observed in lung tissues. Examination of the heart showed subendocardial infiltration with lymphocytes and macrophages. These data suggest that subchronic exposure results in deleterious effects from zearalenone toxin.

# PROTECTION BY METALLOTHIONEIN INDUCTION FROM CYTOTOXICITY INDUCED BY HIGH LEVELS OF GLUCOSE AND TRIGLYCERIDE.

J. Wang, Y. Jiang, Y. Kang and L. Cai. Medicine, University of Louisville, Louisville, KY.

Previous studies have shown that the cardiac damage caused by diabetes was significantly inhibited in a cardiac-specific metallothionein (MT)-overexpressing transgenic mouse model. The present study was undertaken to investigate the determinant factor of MT protection; MT itself versus the metal species bound to MT. Cardiac myoblast cell line (H9C2) was treated with high levels of glucose and triglyceride (Tg) to mimic the model of diabetes in vitro. Before incubated with 50 μg/ml of Tg and 22 mM of glucose in culture media for 60 h, the cell line was pretreated with 50 µM of ZnSO<sub>4</sub> or 1.0 µM of CdCl<sub>2</sub> for 24 hours. The cell *via*bility was measured by a colorimetric MTT. Compared with controls in the presence of 5.5 mM of glucose, cells without Zn-pretreatment exposed to both high levels of glucose and Tg survived only 42%, but cells with Zn-pretreatment survived 70% (P<0.01). The survival rate of Cd-pretreated cells (80%) was also significantly higher than that of cells without Cd-pretreatment (46%) (p<0.01). Western blot revealed that both Zn and Cd pretreated groups had a significant high level of MT. We concluded that MT induction, regardless of the metal species, provides protection from myocardial injury by high levels of glucose and Tg. (Supported in part by American Diabetes Association, Philip Morris USA Inc. and Jewish Hospital Research Foundation, NIH grant 59225).

# 814 DIABETES-INDUCED CARDIAC MT SYNTHESIS: INDEPENDENT OF METAL ALTERATIONS OR OXIDATIVE DAMAGE, BUT LIKELY RELEVANT TO INFLAMMATORY FACTORS.

L. Cai<sup>1</sup>, Y. Song<sup>1</sup>, L. Zhang<sup>1</sup>, Y. Jiang<sup>1</sup>, J. T. Saari<sup>2</sup> and <u>Y. Kang<sup>1</sup></u>. <sup>1</sup>Medicine, University of Louisville, Louisville, KY and <sup>2</sup>Grand Forks Human Nutrition Research Center, Grand Forks, ND.

Diabetic complications are associated with oxidative stress. We have shown that both hepatic and renal MT expression increased in the diabetic rats, independent of metal alterations, suggesting that MT induction in different organs is a diabetes-related response. In this study, we investigated cardiac MT induction in streptozotocin (STZ)-induced diabetic mice. We found a significant increase in cardiac MT content without significant changes of cardiac metals including zinc, copper, iron, calcium and magnesium at 2 months after STZ-treatment. We also found that the cardiac MT induction did not resulted from cardiac oxidative damage (lipid peroxidation measured by TBARS), but was correlated with an increase in systemic inflammation such as marked increases in serum endotoxin and TNF- $\alpha$  levels. This study suggests that diabetes-induced MT in the heart is not related to metal alterations, but may be a systemic response to diabetic changes such as hyperglycemia, hyperlipidemia and systemic inflammation. (Supported in part by American Diabetes Association, Philip Morris USA, Inc., Jewish Hospital Research Foundation and NIH grant 59225).

# PREVENTION OF DIABETIC CARDIOMYOPATHY BY ZINC SUPPLEMENTATION CORRELATES WITH METALLOTHIONEIN INDUCTION.

Y. Song, J. Wilkerson, Y. Kang and L. Cai. Medicine, University of Louisville, Louisville, KY.

Using a cardiac-specific metallothionein (MT)-overexpressing transgenic mouse model, we have demonstrated that MT significantly prevented cardiomyopathy in diabetic mice. The present study was undertaken to determine whether zinc can induce MT production in the heart to an efficient level for pretection against diabetic cardiomyopathy in C57BL/6J mice. Diabetic mice, induced by streptozotocin (STZ), were treated intraperitoneally with zinc sulfate (5mg/kg) 3 times a week over a period of 3 months. At 3 month after the last injection, cardiac function was examined and myocardial tissue was collected for morphological study along with serum cardiac enzyme analysis. Diabetic mice exhibited cardiomyopathy characterized by significant increases in serum creatine kinase, morphological abnormalities, and reduced contractility. These changes were significantly inhibited by zinc-treatment. Immunohistological staining showed an increased expression of cardiac MT in zinc-treated mice. These results suggest that zinc supplementation significantly suppresses diabetic cardiomyopathy, probably through MT induction. (Supported in part by American Diabetes Association, Philip Morris USA, Inc., Jewish Hospital Research Foundation and NIH Grant 59225).

## 816 ALCOHOL-INDUCED MYOCARDIAL FIBROSIS IN A METALLOTHIONEIN-NULL MOUSE MODEL.

L. Wang, Z. Zhou and Y. Kang. Medicine, University of Louisville School of Medicine, Louisville, KY.

Alcohol-induced cardiomyopathy is both exposure time- and dose-dependent and myocardial fibrosis has been found in alcoholic patients but seldom reported in animal models. The present study was undertaken (1) to develop a mouse model resembling clinical observation of alcohol-induced myocardial fibrosis and (2) to define the role of zinc depletion in the pathogenesis. Because metallothionein (MT) may participate in the regulation of cellular zinc homeostasis, MT-knockout (MT-KO) mice along with their wild-type (WT) 129/Sv controls were used and fed alcohol-containing Lieber-DeCarli liquid diet following a 2 X 2 factorial design: Ethanol versus zinc. An improved alcohol feeding protocol was established as follows: 1) The alcohol content (%, w/v) in the diet started from 3.2, with an increment of 0.2 every week, reached 5.0 at the end, and 2) an one-day-stop of alcohol feeding on the last day of each week was introduced. Zinc was supplemented at a level of 100 mg zinc ion/l. Both WT and MT-KO mice fed ad libitum for 10 weeks showed significant cardiac injury, as indicated by increased serum creatine phosphokinase activity, myocardial histopathological and ultrastructural alterations, and disturbance in signaling pathways. However, a severe and massive collagen deposition was observed only in the MT-KO myocardium along with increased ventricular volume. Zinc supplementation significantly attenuated alcohol-induced myocardial injury in both WT and MT-KO mice and inhibited alcohol-induced fibrosis in the MT-KO myocardium. These results thus demonstrate that (1) alcohol-induced myocardial fibrosis can be produced in the MT-KO mouse model, providing a valuable tool for understanding alcoholic cardiomyopathy, and (2) zinc is an important modulator in alcoholic myocardial pathogenesis. (Supported in part by NIH grants AA13601 and HL59225).

DOSE AND TIME RESPONSE OF ALCOHOL-INDUCED HYPERTENSION AND CARDIOVASCULAR INJURIES IN RATS

K. Husain. Pharmacology and Toxicology, Ponce School of Medicine, Ponce, Puerto Rico.

Alcoholic beverages (ethanol) are consumed by most human societies regularly or at least occasionally. Low dose of ethanol ingestion has been shown to be beneficial but chronic high dose of ethanol is harmful to the cardiovascular system. Therefore, the aim of this study was to investigate the dose and time response of alcohol-induced hypertension and associated cardiovascular injuries in a rat model. Male Fisher 344 rats were divided into different groups of 24 rats each and treated as follows: 1) Control (5% sucrose, p.o.) daily for 12 weeks), 2) Ethanol (1g/kg, p.o.) daily for 12 weeks, 3) Ethanol (2g/kg, p.o.) for 12 weeks, 4) Ethanol (4g/kg, p.o.) for 12 weeks, 5) Ethanol (6g/kg, p.o.) for 12 weeks. The blood pressure (BP) was recorded weekly by tail-cuff method and rats were sacrificed at 6, 8, 10 and 12 weeks post-treatment. The heart and thoracic aorta were isolated and analyzed. Ethanol at a dose of 1 g/kg did not alter BP, nitric oxide (NO), glutathione (GSH), antioxidant enzymes: superoxide dismutase SOD), catalase (CAT), and glutathione peroxidase (GSH-Px); lipid peroxidation (malondialdehyde and 8-isoprostane levels) and protein oxidation (carbonyl contents) in the heart and aorta of rats at 6, 8, 10 and 12 weeks post-treatment compared to control. Ethanol at a dose of 2g/kg caused mild hypertension (BP=140-145 mm of Hg), depletion of cardiovascular NO, GSH and antioxidant enzymes (SOD, CAT, and GSH-Px) as well as augmentation of lipid peroxidation and protein oxidation at 8, 10 and 12 weeks post-treatment. Higher doses of ethanol (4 and 6 g/kg) significantly elevated BP (145-155 mm of Hg), depleted cardiovascular NO, GSH and antioxidant enzymes (SOD, CAT, and GSH-Px) and enhanced lipid peroxidation and protein oxidation at 8, 10 and 12 weeks post-treatment. The data suggest that alcohol-induced hypertension is related to the down regulation of NO and antioxidant systems and oxidative injuries to the cardiac and vascular tissues of rats in both dose and time dependent manner (supported in part by NIH grant #2 G12 RR03050-19).

818 CHEMICAL INDUCTION OF ENDOGENOUS ANTIOXIDANTS AFFORDS PROTECTION AGAINST OXIDATIVE AND ELECTROPHILIC INJURY IN CARDIOVASCULAR CELLS.

 $\underline{Z.~Cao}$ , M. Tsang and  $\underline{Y.~Li}$ . Pharmaceutical Sciences, St. John's University, Jamaica, NV

Reactive oxygen species (ROS) and electrophiles are critically involved in the pathogenesis of various forms of cardiovascular diseases, including atherosclerosis, ischemia-reprfusion injury, and drug-induced cardiomyopathy. Accumulating evidence suggests that exogenous antioxidative compounds provide protection against oxidative cardiovascular injury. However, whether induction of endogenous antioxidants by pharmacological agents can also exert protective effects on ROS- and electrophile-mediated cardiovascular injury has not been carefully investigated. In this study, using rat aortic smooth muscle A10 cells and rat cardiomyocyte H9C2 cells as the in vitro systems, we have characterized the induction of cellular antioxidants by the chemical inducers, 3H-1, 2-dithiole-3-thione (D3T), resveratorl, and alphalipoic acid (LA), and determined the cytoprotection of the chemically-elevated endogenous antioxidative defenses against oxidative and electrophilic cardiovascular cell injury. Incubation of cardiovascular cells with the above chemical inducers results in a remarkable induction of a battery of cellular antioxidants, including reduced glutathione, glutathione reductase, glutathione S-transferase, NAD(P)H:quinone oxidoresuctase 1, catalase, and/or superoxide dismutase. Moreover, pretreatment of cardiovascular cells with these chemical inducers leads to a marked protection against the cytotoxicity elicited by various oxidative and electrophilic insults, including xanthine oxidase-derived ROS, peroxynitrite, acrolein, 4-hydroxy-2-nonenal, and doxorubicin. Taken together, this study demonstrates for the first time that a scope of endogenous antioxidants in cardiovascular cells can be induced by exposure to the chemical inducers, D3T, resveratrol and LA, and such chemically-induced cellular antioxidative defenses are accompanied by a significantly increased resistance to oxidative and electrophilic cardiovascular cell injury. The results of this study may have important implications for chemical protection of oxidative cardiovascular disorders.

819 CHEMICAL INDUCTION OF ENDOGENOUS ANTIOXIDANTS IN MOUSE CARDIAC TISSUE: IMPLICATIONS FOR CARDIOPROTECTION.

Y. Li and Z. Cao. Pharmaceutical Sciences, St. John, Jamaica, NY.

The critical involvement of reactive oxygen in cardiac disorders has led to extensive investigation on the protective effects of exogenous antioxidants on oxidative cardiac injury. On the other hand, another strategy for protecting against oxidative

cardiac injury may be through induction of endogenous antioxidants in myocardium. However, our understanding of the chemical inducibility of endogenous cardiac antioxidants in vivo is limited. In addition, studies on the basal levels of a scope of antioxidants in myocardium as compared with other tissues, such as liver are lacking. Accordingly, this study was undertaken to determine the basal levels of endogenous antioxidants, including superoxide dismutase (SOD), catalase, glutathione (GSH), GSH peroxidase (GPx), glutathione reductase (GR), GSH Stransferase (GST) and NAD(P)H:quinone oxidoreductase 1 (NQO1), and investigate the inducibility of endogenous antioxidants by 3H-1, 2-dithiole-3-thione (D3T) and resveratrol in mouse heart as well as liver. Our results demonstrated that the levels of catalase, GSH, GPx, GR and GST were significantly lower in cardiac tissue than in hepatic tissue. Total SOD activity did not differ between mouse heart and liver. Notably, heart contained a much higher NQO1 activity than liver. Imuunobloting and RT-PCR analyses further confirmed the high expression of NQO1 protein and mRNA in the heart. Oral administration of D3T resulted in a significant induction of cardiac SOD, catalase, GR, GST and NQO1. Only GR, GST and NQO1 in the liver were induced by the D3T treatment. Oral administration of resveratrol also caused a significant induction of catalase and NQO1 in mouse cardiac and hepatic tissues. Taken together, this study demonstrates that expression of NQO1 is remarkably high in the heart though other cardiac antioxidants are relatively lower as compared with liver, and a number of antioxidants in mouse heart can be induced by D3T and/or resveratrol. This study provides a basis for future investigation of the cardioprotection of chemically-induced antioxidants in myocardium in animal models of oxidative cardiac disorders.

820 INCREASED FORMATION OF MITOCHONDRIAL REACTIVE OXYGEN SPECIES CAUSES MITOCHONDRIA PERMEABILITY TRANSITION-DEPENDENT KILLING OF CULTURED ADULT RAT MYOCYTES AFTER ISCHEMIA/REPERFUSION.

J. Kim, Y. Jin and J. J. Lemasters. UNC-Chapel Hill, Chapel Hill, NC.

BACKGROUND: Opening of high conductance permeability transition pores in the mitochondrial inner membrane is a causative event precipitating ischemic damage to heart and other tissues upon reperfusion. Cellular factors contributing to onset of the mitochondrial permeability transition (MPT) in myocardium are unknown. The AIM of this study was to characterize the role of mitochondrial reactive oxygen species (ROS) in the MPT after ischemia/reperfusion of myocytes. METHODS: Cultured adult rat ventricular myocytes were incubated in anoxic Krebs-Ringer-HEPES buffer at pH 6.2 for 3 h to simulate tissue ischemia. Reperfusion was then simulated by reoxygenating cells at 7.4 for 2 h. In some experiments, myocytes were treated with 1 µM cyclosporin A (CsA), a MPT blocker, and antioxidants including 0.5 mM desferal, 1 µM diphenylphenylene diamine (DPPD), and 5 mM 2-mercaptopropionyl glycine (2-MPG), beginning 20 min prior to reperfusion. Cell killing was assessed by propidium iodide fluorometry. To monitor formation of ROS, cells were labeled with 10  $\mu$ M chloromethyl dichlorodihydrofluorescein (cmH2DCF) diacetate for 30 min at 37 °C before reperfusion. cmDCF fluorescence was also assessed by a multiwell fluorometry. Confocal images of green fluorescence (cmDCF) were collected with a Zeiss LSM 510 microscope. RESULTS: Cell killing increased to 74.5% after 2 h of reoxygenation at pH 7.4, which was blocked by CsA, desferal, and 2-MPG. cmDCF fluorometry showed 1.7-fold increase in ROS formation after 30 min of reperfusion, compared to normoxia. All three antioxidants blocked the reperfusion-induced increase in ROS formation, whereas CsA did not. Confocal microscopy revealed that reperfusion caused hypercontracture and subsequent cell death after a substantial increase in ROS formation. CsA did not block increased ROS generation, but prevented hypercontracture and cell death. CONCLUSION: Mitochondrial ROS generation is a key event promoting the MPT and subsequent cell killing after reperfusion.

821 OPENING OF MITOCHONDRIAL PERMEABILITY TRANSITION PORES PRIOR TO REPERFUSION DURING PROLONGED ISCHEMIA TO CARDIAC MYOCYTES.

J. R. Blattner and J. J. Lemasters. Curriculum in Toxicology and Department of Cell and Developmental Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Opening of non-specific high conductance pores in the mitochondrial inner membrane causes the mitochondrial permeability transition (MPT). Cyclosporin A (CsA) blocks MPT pores in their regulated state but not in their unregulated state. In ischemia/reperfusion injury, controversy exists whether PT pores open during ischemia or only during reperfusion. Here, our aim was to assess regulated and unregulated pore opening during I/R stress to neonatal rat cardiomyocytes. Myocytes were exposed to 2 or 3 h of anoxia at pH 6.2 in Krebs-Ringers-HEPES buffer con-

taining 5 mM 2-deoxyglucose to simulate ischemia. Subsequently, myocytes were re-oxygenated with minimal essential media at pH 7.4 to simulate reperfusion. Cell killing determined by propidium iodide fluorimetry did not increase during either 2 or  $\bar{3}$  h of ischemia, but progressively increased to  $48 \pm 2\%$  and  $75 \pm 1\%$ , respectively, during 2 h of reperfusion. After 2 h of ischemia, the non-immunosuppressive analog of CsA, NIM811 (5 µM), added 15 min prior to and during reperfusion suppressed cell killing to  $26 \pm 2\%$ . NIM811 added at reperfusion did not protect after 3 h of ischemia (73  $\pm$  2%). Protection did occur after 3 h ischemia when NIM811 or the unregulated pore inhibitor, 2-aminoethoxydiphenyl borate (2-APB), was added from the beginning of ischemia (47  $\pm$  6% and 43  $\pm$  4%). Confocal microscopy of MitoTracker Red (500 nM)-labeled myocytes revealed mitochondrial swelling during ischemia. Moreover, mitochondrial repolarization after reperfusion assessed by tetramethylrhodamine methyl ester (200 nM) became increasing less frequent as the time of ischemia increased. These results suggest that MPT pore opening may occur before reperfusion after longer periods of ischemia, possibly developing to an unregulated state causing irreversible mitochondrial in-

# 822 INDUCTION OF P21 WAF1/CIP1/SDI1 BY DOXORUBICIN IN CARDIOMYOCYTES: FUNCTIONAL IMPLICATIONS OF P21 WAF1/CIP1/SDI1 IN POSTMITOTIC CELLS.

J. Terrand<sup>1</sup>, S. K. Williams<sup>2</sup> and Q. M. Chen<sup>1</sup>. <sup>1</sup>Pharmacology, University of Arizona, Tucson, AZ and <sup>2</sup>Biomedical Engineering, University of Arizona, Tucson, AZ

The p21 WAF1/Cip1/Sdi1 (p21) protein is known as a cyclin dependent kinase inhibitor. Chemical and physical stresses can induce the expression of the p21 gene in proliferating cells as well as in non-proliferating cells. The biological function of p21 induction in non-proliferating cells remains unclear. Cardiomyocytes cease proliferation in most species of mammals after birth. During the process of heart failure, cardiomyocytes often develop hypertrophy to compensate for the loss of cardiomyocytes. When treated with doxorubicin, a cancer chemotherapy drug known to induce dilated cardiomyopathy, cardiomyocytes show an elevation of p21 protein. Time course studies indicate that the elevation of p21 is delayed but sustained, following the expression of the hypertrophy biomarker Atrial Natriuretic Factor. Hypertrophy inducers angiotensin II (50-200 nM), phenylephrine (100-200 nM) and endothelin-1 (100-200 nM) can also induce the expression of p21, although the induction is transient by angiotensin II and is less pronounced with all the hypertrophy inducers as compared to doxorubicin. While the mechanism of p21 induction by hypertrophy inducers is under investigation, we have used p21 gene knockout (p21KO) mice to study the function of p21 in heart failure induced by doxorubicin. Doxorubicin treated wild type mice showed a reduction of cardiac contractility and an increase in the ratio of heart weight over body weight. In contrast, the p21KO mice showed little alterations in cardiac contractility and in heartto-body weight ratios with doxorubicin administration. These data suggest the possibility that the p21 gene exhibits biological functions irrelevant to cell cycle regulation.

# 823 BOTH SPHINGANINE AND SPHINGOSINE ARE CYTOTOXIC TO H9C2[2-1] CARDIOMYOCYTES AND HEPG2 HEPATOCYTES.

S. V. Hsiao<sup>1</sup>, P. D. Constable<sup>2</sup>, M. Tumbleson<sup>3</sup> and W. M. Haschek<sup>1</sup>. <sup>1</sup>Veterinary Pathobiology, University of Illinois at Urbana-Champaign, Urbana, IL, <sup>2</sup>Veterinary Clinical Medicine, University of Illinois at Urbana-Champaign, Urbana, IL and <sup>3</sup>Veterinary Biosciences, University of Illinois at Urbana-Champaign, Urbana, IL.

Cardiotoxicity and cell death induced by doxorubicin and TNF- $\alpha$  have been linked to increased concentrations of sphingolipid molecules such as ceramide and sphingosine. In fumonisin B1 toxicity, sphinganine (another sphingoid base in de novo sphingolipid synthesis) concentration increases in parallel with sphingosine. However, the role of sphinganine in such cytotoxic events remains poorly understood. Here we compared the cytotoxic effects of exogenous sphinganine and sphingosine in rat embryonic cardiomyocytes (H9C2[2-1]) and hepatocellular carcinoma cells (HepG2), using the MTT assay. Sphinganine was a more potent cytotoxic agent than sphingosine for both H9C2[2-1] and HepG2 cells. The ED<sub>50</sub> in H9C2[2-1] and HepG2 cells for sphinganine was 35.2 and 45.1 μM and for sphingosine was 50.3 and 64.4  $\mu\text{M},$  respectively. Cytotoxicity was detectable at 1 hour after exposure with a plateau after 12 hours. In addition, cells in suspension were more susceptible to sphinganine and sphingosine than cells in adherent monolayers. The ED<sub>50</sub> in suspended H9C2[2-1] and HepG2 cells for sphinganine was 24.8 and 11.9 µM, and for sphingosine was 37.5 and 26.5 µM, respectively. These findings suggest a possible role for both sphinganine and sphingosine in doxorubicin, fumonisin B<sub>1</sub> and TNF-α-induced cardiotoxicity and cell death. Additionally, cell adhesion may be one of several targets for the cytotoxic effects of sphinganine and sphingosine. Supported by Society of Toxicologic Pathology/Abbott Laboratories Clinical Research Award and C-FAR (02E-082-4VR).

# 824 MITOCHONDRIAL AND CARDIOVASCULAR PATHOLOGY IN MICE EXPOSED TRANSPLACENTALLY TO ZIDOVUDINE (AZT) ALONE OR WITH LAMUVIDINE (3TC).

V. E. Walker<sup>1</sup>, D. M. Walker<sup>1</sup>, M. J. Campen<sup>1</sup>, R. L. Divi<sup>2</sup>, O. A. Olivero<sup>2</sup> and M. C. Poirier<sup>2</sup>. <sup>1</sup>Lovelace Respiratory Research Institute, Albuquerque, NM and <sup>2</sup>NCI, NIH, Bethesda, MD.

Antiretroviral drug combinations including nucleoside analogues are remarkably effective in preventing vertical transmission of HIV-1, but accumulating evidence suggests long-term risks for mitochondrial dysfunction in children exposed in utero. Our research team is investigating the temporal relationships between mitochondrial damage in mice exposed in utero to AZT or AZT-3TC and the onset of cardiomyopathy. During transplacental cancer bioassays of AZT in B6C3F1 mice and F344 rats (0, 80, 240, or 480 mg AZT/kg bw/day by gavage to dams during the last 7 days of gestation), non-cancerous lesions included a significant dose-dependent cardiac enlargement that was most pronounced in AZT-exposed female mice (when, at 2 years-of-age, heart weight was normalized to body weight and compared to control animals). Studies are in progress to determine the nature and extent of AZT- and AZT-3TC-induced mitochondrial damage in transplacentally exposed female mice by evaluating levels of mtDNA incorporation of these drugs, mtDNA depletion, ultrastructural pathology, and change in cardiac function. Transmission electron microscopy (EM) evaluation of hearts from newborn mice following *in utero* exposure to 100 mg AZT + 50 mg 3TC/day during the last 7 days gestation showed substantial damage to mitochondria (characterized by swelling, fragmentation of membranes, loss of normal central architecture, and occurrence of occasional inclusion bodies), with the loss of mitochondria ranging from 20% to 50% in cardiomyocytes of different animals. EMs of hearts from control mice showed normal appearing densely packed clusters of mitochondria be-tween cardiac myofibrils. Our initial results demonstrated clear mitochondrial insult in cardiac tissue of newborn mice exposed transplacentally to AZT-3TC, while data from echocardiographic screening of (AZT-3TC-exposed) litter mates at 7 weeks of age were consistent with our findings of cardiomyopathy in adult mice following in utero exposure to AZT.

# ALLYLAMINE-INDUCED VASOSPASM *IN VITRO*: ROLE OF ACROLEIN, HYDROGEN PEROXIDE, SEMICARBAZIDE-SENSITIVE AMINE OXIDASE ACTIVITY, AND EXTRACELLULAR Ca<sup>++</sup>.

D. J. Conklin<sup>1</sup>, H. R. Cowley<sup>2</sup>, N. Xiong<sup>2</sup>, G. H. Johnson<sup>3</sup>, R. J. Wiechmann<sup>3</sup>, L. M. Sayre<sup>4</sup>, M. B. Trent<sup>5</sup> and <u>P. J. Boor<sup>5</sup></u>. <sup>1</sup>Department of Medicine, Division of Cardiology, University of Louisville, Louisville, KY, <sup>2</sup>Department of Biology, University of Wisconsin-Eau Claire, Eau Claire, WI, <sup>3</sup>Department of Cardiothoracic Surgery, Luther Hospital/Midelfort Clinic, Eau Claire, WI, <sup>4</sup>Department of Chemistry, Case Western Reserve University, Cleveland, OH and <sup>5</sup>Department of Pathology, University of Texas Medical Branch, Galveston, TX.

Allylamine (AA; 3-aminopropene) is a cardiovascular toxicant that induces vasospasm in vitro and hypothetically in vivo. To understand the mechanism of AAinduced vasospasm we determined: 1) the sensitivity of isolated human blood vessels (internal mammary artery, IMA; saphenous vein, SV) to AA, acrolein, and hydrogen peroxide (1-1, 000 µM; H<sub>2</sub>O<sub>2</sub>), 2) the dependence of AA-induced vasospasm on semicarbazide-sensitive amine oxidase activity (SSAO) using SSAO inhibitors (semicarbazide, 1 mM; MDL 72274-E, active isomer; MDL 72274-Z, inactive isomer; 100 µM), and 3) the role of extracellular Ca++. Vasospasm (sustained, intractable hypercontraction) was evidenced by maintenance of elevated tension resistant to sodium nitroprusside addition (100 µM) and AA removal. AA, acrolein, and  $H_2O_2$  similarly altered tension in norepinephrine-precontracted (1  $\mu M$ ) vessels in a concentration-dependent manner but only AA and acrolein led to vasospasm. AA-induced vasospasm and vessel SSAO activity were inhibited by semicarbazide or MDL 72274-E but not by MDL 72274-Z pretreatment. AA-induced responses were significantly attenuated in the absence of extracellular Ca<sup>++</sup> but not overall AA toxicity. The return of normal [Ca++] buffer gradually increased tension that was sustained in AA-treated but not in untreated vessels. Thus, AA-induced vasospasm in human IMA and SV was dependent on SSAO activity, acrolein formation, and extracellular Ca<sup>++</sup> influx. We propose that AA metabolism by SSAO triggers vasospasm via a Ca++ overload mechanism. This work supported by the Ronald McNair Program at UWEC and NIEHS AREA #1 R15 ES011141-01.

# IN VITRO CHARACTERIZATION OF THE MECHANISMS INVOLVED IN CARDIOVASCULAR TOXICITY OF ULTRAFINE PARTICULATE.

M. Marinovich<sup>1</sup>, E. Corsini<sup>1</sup>, C. L. Galli<sup>1</sup>, R. Pieters<sup>3</sup>, S. Bellosta<sup>2</sup>, K. Remedios<sup>2</sup> and A. Corsini<sup>2</sup>. <sup>1</sup>Department Pharmacological Sciences, University of Milan, Milan, Italy, <sup>2</sup>Laboratory of Cellular Pharmacology of Atherosclerosis, University of Milan, Milano, Italy and <sup>3</sup>IRAS, University of Utrecht, Utrecht, Netherlands.

A major issue in modern environmental toxicology is to find a scientific explanation for the epidemiological effects of air pollution. A particularly puzzling point is that fine particulate matter affects not only respiratory but also cardiovascular morbidity and mortality. Most research is centered around the possible consequences of particle-induced pulmonary inflammation on the heart and other systems. Another hypothesis considers the possible "direct" effects of particles that may pass from the lung into the blood stream. The present knowledge of the pathogenesis of the atherosclerotic process allowed the identification of the key processes involved in atherosclerotic plaque formation. Smooth muscle cells (SMC) proliferation and apoptosis in the vessel wall drive the formation of the plaque, while cytokines production and proteolytic enzymes secretion such as the matrix metalloproteinases (MMP) by inflammatory cells like activated macrophages, facilitates plaque fissuration and rupture. Plaque rupture and the subsequent thrombosis cause the fatal complications of atherosclerosis. The purpose of this study was to highlight proatherogenic mechanism/s of action of the ultrafine particulate. To this purpose the proliferation and apoptosis of SMC, and the release of MMP was evaluated. Replication of SMC isolate from rat aorta or human femoral artery was evaluated either by direct cell count or by thymidine incorporation into nuclear DNA. Apoptosis was measured by cytofluorimetry. MMP activity was evaluated by zymography. Our data suggest that a direct effect of ultrafine particulate on SMC vitality is likely to contribute to plaque fissuration and rupture. This study provides an understanding of fine particulate matter effects on cardiovascular morbidity and mortality.

# 827 ARTERIAL CARCINOGEN METABOLISM COULD INITIATE THE ACCELERATED ATHEROSCLEROSIS SEEN IN SMOKERS.

J. L. Holtzman<sup>1</sup>, L. M. Dunning<sup>1</sup>, W. Carter<sup>3</sup> and R. J. Edwards<sup>4</sup>. <sup>1</sup>Pharmacology, University of Minnesota, Minneapolis, MN, <sup>2</sup>Pharmacology, University of Minnesota, Minnapolis, MN, <sup>3</sup>Edina Plastic Surgeions, Edina, MN and <sup>4</sup>Imperial College, London, United Kingdom.

HYPOTHESIS: The accelerated atherosclerosis seen in smokers may be initiated by the toxic products formed during the arterial metabolism of the 2 major carcinogens of tobacco smoke, the polycyclic aromatic hydrocarbons (PAHs) and N-nitroso-amines (NNAs). BACKGROUND: Numerous laboratories have reported that arteries from various animals metabolize the PAHs to form the ultimate carcinogens. These reactions are catalyzed by cytochrome P450s, CYP1A1 and 1B1. The 1A1 is present in the aortas of various animal after PAH induction. We previously reported the possible presence of the P450s catalyzing NNAs activation, CYP2A6 and 2E1. OBJECTIVES: We have sought to determine whether these P450s are present in human arterial walls. METHODS: We prepared microsomes by standard procedures from the arteries of patients undergoing abdominal plasties. The P450s were determined by immunoblotting by enhanced chemoluminescence detection. RESULTS: We obtained 125 ug of microsomal protein from each artery. Three of the 4 CYPs were observed at concentrations comparable to those found in hepatic microsomes after PAH induction. Due to an artifact in our assay procedure, contrary to our previous report, we did not detect any 2A6. CYP 1A1 1B1 2A6 2E1 pmol/mg protein 21.4 2.1 5.2 1.0 N/D 33.7 3.7 SIGNIFICANCE: These data support the hypothesis that the accelerated atherosclerosis seen in smokers is due to the metabolism of the PAHs and possibly the NNAs in the arterial wall leading to toxic injury. Similarly, estradiol is metabolized by 1B1 to toxic catechols, suggesting a mechanism for the increased disease seen in women with postmenopausal hormone replacement.  $\mu$ 

## 828 CARDIOVASCULAR EFFECTS OF CHRONIC FUMONISIN B1 INGESTION IN SINCLAIR MINIPIGS.

G. W. Smith<sup>1</sup>, P. Constable<sup>2</sup>, R. L. Fredrickson<sup>1</sup>, M. E. Tumbleson<sup>3</sup>, R. M. Eppley<sup>4</sup> and <u>W. M. Haschek</u>. <sup>1</sup> Veterinary Pathobiology, University of Illinois, Urbana, II., <sup>2</sup> Veterinary Clinical Medicine, University of Illinois, Urbana, II., <sup>3</sup> Veterinary Biosciences, University of Illinois, Urbana, IL and <sup>4</sup> Center for Food Safety and Applied Nutrition, USFDA, Laurel, MD.

Fumonisins are a group of mycotoxins primarily produced by the fungus Fusarium verticillioides, one of the most prevalent fungi associated with corn intended for human and animal consumption. Acute ingestion of fumonisin B1 (FB1) induces

hypercholesterolemia in many species, including non-human primates, and has caused cardiovascular toxicity in pigs and horses. Chronic ingestion of FB1 has induced right ventricular hypertrophy in pigs and congestive heart failure in a baboon. Because the potential exists for chronic fumonisin ingestion to induce cardiovascular changes in humans, the main purpose of this study was to evaluate the cardiovascular effects of chronic FB1 ingestion in Sinclair minipigs (barrows, 7 to 14 wk of age). Treated pigs (n=7) were fed a diet containing FB1 at 10 ppm for 18 wk followed by a diet containing FB1 at 30 ppm for 8 wk. Control pigs (n=6) were fed a diet free of fumonisins for the 26 wk experimental period; at the end, serum was obtained for biochemical analyses and pigs were anesthetized and instrumented for cardiovascular function studies. Pigs fed FB1 had significant (P < 0.05) increases in sphinganine and sphingosine concentrations in serum, heart, and ascending aorta. There were no differences in serum cholesterol, low-density lipoproteins, high-density lipoproteins or triglyceride concentrations between the two groups. The only hemodynamic difference between the 2 groups was a decrease in systolic aortic pressure in FB1 treated pigs. Chronic ingestion of FB1 may increase the risk of cardiovascular disease in humans by increasing serum, heart, and aortic sphinganine and sphingosine concentrations. These effects were seen in pigs ingesting FB1 at 10 to 30 ppm; it is likely that humans consuming a corn-based diet ingest lower amounts of FB1. Supported by USDA-CSREES #928-39453, USFDA, and ILSI.

#### 829 CHRONIC ARSENIC EXPOSURE ENHANCES FGF-2-STIMULATED ANGIOGENESIS *IN VIVO* AND TISSUE EXPRESSION OF ANGIOGENIC GENES.

<u>A. Barchowsky</u><sup>1, 2</sup>, L. R. Klei<sup>1</sup>, D. D. Mayka<sup>2</sup>, J. C. Davey<sup>2</sup>, <u>I. W. Hamilton</u><sup>2</sup> and <u>N. V. Soucy</u><sup>2, 1</sup>Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA and <sup>2</sup>Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH.

Chronic exposures to low levels of arsenic are associated with increased incidence of cardiovascular diseases in humans. However, there few studies have examined the effects of these chronic exposures on vascular development, despite evidence that arsenic stimulates proliferative responses in vascular cells. Therefore, the hypothesis that arsenic enhances neovascularization following chronic exposure through drinking water was examined in C57BL/6 mice. Dose-dependent, synergistic enhancement of FGF-2-stimulated angiogenesis in Matrigel implants was observed after 5 wk exposures to 5-500 ppb of arsenite (AsIII). Significant enhancement of angiogenesis was also observed after 10 and 20 wk exposures; however, the responses to 250 and 500 ppb were desensitized relative to responses to the same doses at 5 weeks. Gene screens and RT-PCR in cardiac and lung tissues were used to investigate systemic changes in cardiovascular genes that contribute to enhanced angiogenesis. The mRNA levels for several angiogenic genes increased and significant increases were confirmed for induction of plasminogen activator inhibitor-1 (PAI-1) and the endothelial specific transcription factor, pigpen. Circulating levels of active PAI-1 protein also increased with chronic exposure. The response of primary smooth muscle cells in culture to arsenic were used to demonstrate the dose-dependence for PAI-1 gene induction. Inhibitor studies suggested that this induction required both PI3K and PKC activation. These studies indicated that low levels of arsenic (including the current MCL in drinking water) potentiated angiogenic responses and suggested that this potentiation involved stimulation of specific signaling processes and gene activation. Supported by NIEHS SBRP grant ES07373.

# 830 EXPRESSION OF PROCOAGULANT ACTIVITY BY LYSOPHOSPHATIDIC ACID IN HUMAN ERYTHROCYTES.

S. Chung, M. Lee, O. Bae and <u>J. Chung</u>. *College of Pharmacy, Seoul National University, Seoul, South Korea.* 

Lysophosphatidic acid (LPA), an important mediator in blood clotting and wound healing, has been recently reported to induce influx of extracellular calcium into erythrocytes (RBC). This elevation in intracellular calcium level may cause destruction of membrane asymmetry and microvesicle formation, resulting in procoagulant activity of RBC. Thus, we investigated if LPA could induce phosphatidylserine (PS) exposure and microvesicle formation as a result of extracellular calcium influx in human RBC. Treatment with LPA to RBC resulted in microvesicle generation in a time-, and concentration-dependent manner. Consistent with these findings, scanning electron microscopy studies revealed that LPA treatment changed normal discocytic shape into echinocyte followed by spherocyte. Both microvesicles and remnant erythrocytes expressed procoagulant PS on their surface membrane. Chelation of extracellular calcium with EGTA did not affect vesiculation and PS exposure, suggesting that calcium influx into RBC was not responsible for these events. Suramin that can block the interaction of LPA with its receptor did not inhibit microvesicle formation, indicating that this LPA-induced response in RBC might not be mediated by the known receptor. LPA-exposed RBC potentiated the

generation of thrombin by recombinant human thromboplastin in plasma. These results suggest that LPA-exposed erythrocytes can contribute to clot formation or thrombosis by expressing procoagulant activity.

# 831 ELEVATED MEAN ARTERIAL BLOOD PRESSURE IN ARYL HYDROCARBON RECEPTOR (AHR) NULL MICE IS ASSOCIATED WITH ENDOTHELIN-1.

A. Lund<sup>1</sup>, J. L. Born<sup>1</sup> and M. K. Walker<sup>1,2</sup>. <sup>1</sup> College of Pharmacy, University of New Mexico, Albuquerque, NM and <sup>2</sup> Cell Biology and Physiology, University of New Mexico, Albuquerque, NM.

AhR is a ligand-activated transcription factor that mediates the toxicity of environmental pollutants such as TCDD. The role of the AhR in physiological homeostasis is still uncertain, however functional inactivation of AhR (AhR null mice) results in profound effects on the cardiovascular system. We have previously reported AhR null mice exhibit cardiac hypertrophy associated with elevated mean arterial blood pressure (MAP) and increased levels of vasoactive peptides endothelin-1 (ET-1) and angiotensin II (Ang II). However, chronic treatment of AhR null mice with an ACE-inhibitor did not normalize either MAP or ET-1, compared to age-matched C57Bl6 mice. To better understand the role of ET-1 in MAP regulation, we tested the hypothesis that the observed MAP results from increased ET-1 and that this increase is age-progressive. Time-course assessment of MAP in AhR null mice, measured by indwelling catheters, showed elevated MAP by age 2 mo (AhR null: 110.0, C57Bl6: 100.6 mmHg), with a progressive increase seen at 5 mo (AhR null: 123.1, C57Bl6: 102.0 mmHg). Corresponding with these findings, time course analysis of plasma ET-1 levels as determined by RIA, showed significantly increased levels in AhR null mice at age 2 mo (AhR null: 9.9, C57Bl6: 7.7 fmol/ml) with further elevations at 5 mo (AhR null: 12.3, C57Bl6: 7.7 fmol/ml). Real-time PCR of lung tissue showed that ET-1 mRNA levels were approximately 8-fold higher in AhR null mice compared to AhR wildtype. To examine the role of ET-1 in MAP, 5 mo old AhR null and C57Bl6 mice were treated with ET<sub>A</sub> receptor antagonist BQ-123, delivered via osmotic minipumps for a period of 7 days, and resulting MAP was measured. BQ-123-treated AhR null mice had significantly reduced MAP compared to untreated AhR null mice (treated: 105.1; untreated: 120.8, C57Bl6 controls: 100.8 mmHg). Such findings indicate that MAP in AhR null mice is mediated by ET-1. Supported by ES10433 to MKW, ES12072 (NM NIEHS Center), and ÉPA fellowship U91621501 to AKL.

## 832 EFFECTS OF CHLORODIBROMOMETHANE ON THE DEVELOPING HEART OF MEDAKA.

S. Palit<sup>1</sup>, W. R. Hartley<sup>1</sup>, L. K. Teuschler<sup>2</sup>, C. Gennings<sup>3</sup>, O. Conerly<sup>4</sup> and <u>A. Thiyagarajah<sup>1</sup>. <sup>1</sup> Environmental Health Sciences, Tulane University Health Sciences Center, New Orleans, LA, <sup>2</sup>NCEA, USEPA/ORD, Cincinnati, OH, <sup>3</sup>MCV, VCU, Richmond, VA and <sup>4</sup> Office of Water, USEPA, Washington, DC.</u>

We observed a variety of cardiovascular lesions induced by trihalomethanes, a class of disinfection byproducts, in medaka embryos. The purpose of this presentation is to report the sequential development of the cardiovascular malformations induced by chlorodibromomethane (CDBM), one of the trihalomethanes. Medaka embryos at stage 10 (N= 60 per concentration) were exposed individually in 5 ml of embryo rearing solution to nominal concentrations of 0, 10, 25, 40, 55 or 70 mg/L CDBM for 15 days. The test solutions were renewed daily. Embryos were evaluated daily for mortality and cardiovascular abnormalities. The heartbeat count was made for one full minute from day 3-10. The earliest lesion observed was the tubular heart on day 4 of exposure. Lack or incomplete chambers formation often began on day 5. Diathesis or pooling of blood in various tissues began to appear staring on day 5 of exposure, followed by slowing of blood flow and complete stasis usually on day 10. At this time pericardial edema began to develop and progressed to other organs and interfered with hatching which resulted in partial hatching. In addition, low incidence of the following lesions were observed: non-development of heart, absence or reduced numbers of vitelline vessels, reduced numbers of blood cells, and ruptured blood vessels. We proposed a sequential development of the pericardial edema in the developing medaka embryos caused by CDBM, which lays the foundation for the future mechanistic studies of cardiovascular malformations.

# 833 SAFETY EVALUATION OF E5564, A TOLL-LIKE RECEPTOR 4 (TLR4) ANTAGONIST, ON CARDIOPULMONARY BYPASS (CPB) SURGERY IN DOGS BY INTRAVENOUS INFUSION.

A. Suganuma<sup>1</sup>, H. Mendenhall<sup>2</sup>, J. P. Sites<sup>3</sup>, K. Kaneko<sup>1</sup>, M. Nedelman<sup>2</sup> and W. D. Kerns<sup>4</sup>. <sup>1</sup>Drug Safety and Disposition, Eisai Co., Ltd.,, Tsukuba, Japan, <sup>2</sup>Discovery and Development Services, Charles River Laboratories, Worcester, MA, <sup>3</sup>Cardiovascular and Extracorporeal Technologies, Plymouth, MN and <sup>4</sup>Pharmacology Consulting Inc., Harvard, MA.

E5564, a TLR4 antagonist is expected to block LPS-mediated diseases. To support use during CPB surgery, E5564 was evaluated to determine if there was an adverse effect on oxygenation, heparin reversal, and to determine plasma concentrations in

mongrel dogs. Blood was collected for 18 days prior to surgery by the Domino method for autotransfusion at surgery. The animals (3 males/group) received either E5564 (1 mg/kg/hr) or its vehicle (2% lactose/4% dextrose-phosphate buffer) by IV infusion at 2 mL/kg/hr, starting at the time surgery commenced. The heart was arrested and the animal's core body temperature was cooled to ~28°C for 60 min, while on bypass. The animal was warmed to 35-38°C, resuscitated and taken off bypass. The dogs were ventilated with room air and their condition monitored for another 30 min. During the surgery, the following parameters were assessed: anesthesia time, surgery time, CPB time, heparin dose, protamine dose, ECG, heart rate, systolic, diastolic and mean arterial pressure, central venous pressure, pulmonary artery pressure, oxygen saturation, end-tidal carbon dioxide,  $P_{O2}$ ,  $P_{CO2}$  base-excess,  $HCO_3$ , pH, hematocrit,  $Na^*$ ,  $K^*$ , Ca, activated clotting time, rectal and esophageal body temperature, total volume of lactated Ringer's solution administered, urine output, defibrillation attempts, hematology, coagulation, blood chemistry, and pharmacokinetics. All animals tolerated the cardiopulmonary bypass procedure well. There were no differences observed between E5564 and vehicle groups in all parameters tested. Similar plasma levels of E5564 from all three treated dogs were obtained and comparable to those seen in a 72-hour infusion toxicity study in the dog. In conclusion, E5564 did not compromise any CPB process or measured parameter. CPB did not interfere with the pharmacokinetics of E5564.

# 834 A UNIQUE CARDIOVASCULAR TOXICITY IN RATS FOLLOWING ADMINISTRATION OF PYRAZOLE KINASE INHIBITORS IN FISCHER 344 RATS.

A. J. Stauber, J. L. Zimmerman, B. W. Main, S. T. Adams and G. Bricker. Lilly Research Laboratories, Eli Lilly and Company, Greenfield, IN.

Escalating doses of pyrazole kinase inhibitors were administered to Fischer 344 rats to determine their toxicity profile. After 2-3 doses at 100 mg/kg or greater, rats began to show clinical signs of increased and/or labored respiration. Physical examination of the rib cage revealed an indentation of the sternum towards the chest cavity. Mortality occurred in rats with the most severe signs of respiratory distress. These clinical observations became the best indicator of the toxicity and predictor of mortality. Minimal to moderate amounts of fluid in the pleural cavity was found in some, but not all treated rats, and was not sufficient to be considered the cause of death. Analysis of thoracic fluid revealed a modified exudate containing high protein levels and infiltration of inflammatory cells. No morphologic changes were present in the heart, lungs, sternum, rib cage or diaphragm. Cardiovascular effects were determined in conscious Sprague-Dawley rats after a single dose and resulted in acute hypotension followed by reflex tachycardia that was sustained for up to 24 hours. This data does not identify the primary target organ, yet suggests a functional effect on the cardiovascular system may be responsible for the clinical signs and mortality that are observed after multiple doses. Several compounds from the pyrazole class exhibiting structural diversity were evaluated. Based on administered dose, the data indicated a difference in potency (relative to the toxicity) between the molecules. This suggests a structure activity relationship between this unique toxicity and an, as yet, unidentified target.

# 835 ALPHA GLUTATHIONE S-TRANSFERASE AS A NOVEL BIOMARKER FOR MONITORING CHRONIC METHOTREXATE HEPATOTOXICITY.

M. C. Shaw<sup>1</sup>, P. R. Maxwell<sup>2</sup> and D. Burden<sup>3</sup>. <sup>1</sup>Biotrin International, Dublin, Ireland, <sup>2</sup>Biochemistry, Stobbill Hospital, Glasgow, United Kingdom and <sup>3</sup>Dermatology, Western Infirmary, Glasgow, United Kingdom. Sponsor: R. Chandra Gupta.

Methotrexate is a commonly used drug for treating severe psoriasis and other severe immunological diseases. It is a known hepatotoxin and it is recommended that liver function be monitored in patients and that liver biopsies are performed on patients after they have received fixed cumulative doses of 1-1.5g of the drug. Improved monitoring of liver status could reduce the need for routine biopsies, saving costs and reducing patient morbidity while identifying those most at risk Alpha glutathione S-transferase (\alpha GST) is a more sensitive indicator of acute hepatocyte injury than transaminases, but it has not previously been studied as an indicator of chronic toxicity. 44 subjects receiving low dose methotrexate for psoriasis were monitored using  $\alpha$ GST, ALT, AST, GGT, ALP and serum albumin. Alpha GST was assayed using the Biotrin HEPKIT-Alpha GST EIA kit. AST, ALT, GGT, ALP, Albumin and total protein were assayed using the Bayer ADVIA 1650. Data were compared with that obtained from 20 healthy controls. Data for  $\alpha GST$  and GGTis presented as mean±SEM. αGST µg/L Control 3.6±1.0, Patients 9.0±7.0 p< 0.01 GGT, University/L Control 23±7.0 Patients 36±27, p < 0.05 Values for AST, ALT, ALP serum albumin and total protein were similar in both patients and controls. Only 5% of patients (2/44) showed elevated ALT levels, but  $\alpha$ GST levels were above normal in 25% (11/44) of cases. In the immediate period after a dose of

methotrexate, (24-48 hours) AST and  $\alpha GST$  were elevated but  $\alpha GST$  was elevated to a greater degree (~5fold compared with ~2fold for AST). Other liver biomarkers were unchanged.  $\alpha GST$  is more often elevated and to a greater degree than other biomarkers in subjects receiving chronic methotrexate therapy. Since subjects with normal transaminases would not normally be biopsied,  $\alpha GST$  has the potential to identify those most at risk of hepatic injury.

## 836 BIOSENSOR DETECTION OF BLOOD NTE INHIBITION.

V. V. Malygin¹, G. F. Makhaeva¹, N. N. Strakhova¹, L. V. Sigolaeva², L. G. Sokolovskaya², A. V. Eremenko², I. N. Kurochkin² and R. J. Richardson³. ¹Institute of Physiologically Active Compounds, RAS, Chernogolovka, Russian Federation, ²Faculty of Chemistry, M.V. Lomonosov Moscow State University, Moscow, Russian Federation and ³Toxicology Program, University of Michigan, Ann Arbor. MI.

To enable NTE to be assayed in whole blood, an electrochemical method was developed, based on detection of phenol with a tyrosinase carbon paste electrode. The biosensor was used to establish correlations of NTE inhibition in blood with that in lymphocytes and brain 24 hr after dosing hens with di-1-propyl-2, 2-dichlorovinyl phosphate (PrDChVP). To improve sensitivity, the initial electrode was optimized to achieve a detection limit of 25 nM phenol in a flow cell, allowing NTE activity to be measured in blood diluted 1:500. The new electrode had improved operating stability and a working life >12 mo. Using the biosensor, the *in vitro* sensitivity of hen blood and brain NTE to OP compounds was compared. I50 values for inhibition of NTE with  $RO(C_6H_5)P(O)ON=CCH_3Cl$  (R = Me, Et, n-Pr, n-Bu) were obtained amperometrically for blood and colorimetrically for brain. A good correlation was found between pI50 values for blood and brain NTE inhibition by the phenylphosphonates, as well as 3 other OP compounds (r = 0.988, n = 7). To assess the time dependence of blood NTE inhibition after OP compound exposure, NTE activity was measured in brain and blood 4 hr after dosing hens with PrDChVP (0.32-1.0 mg/kg, im), as well as 4, 24, 48, 72 and 96 hr after 1.0 mg/kg. Brain and blood NTE inhibition was dose related 4 hr after dosing, and highly correlated between brain and blood (r = 0.997). NTE activity in brain and blood of hens killed 4, 24, 48, 72, and 96 hr after dosing with 1 mg/kg PrDChVP differed significantly from respective control values. During all measured times, NTE inhibition relative to controls (mean  $\pm$  SE, n = 5) was  $72 \pm 4\%$  in brain and  $75 \pm 3\%$  in blood. The results demonstrate that whole blood NTE is a reliable biomarker of exposure to neuropathic OP compounds during 96 hr between exposure and measurement. (Supported by CRDF grants #RB2-2035, #RB2-2488).

# 837 COMPARATIVE GENE EXPRESSION PROFILING OF EPOTHILONE B AND PACLITAXEL TO SEARCH FOR BIOMARKERS OF EFFICACY AND TOXICITY.

M. Saulnier, F. Staedtler, P. McSheehy, A. Mahl, J. Schaffner, D. Roman, P. Ulrich, M. Wartmann, S. Chibout, H. Firat and L. Mueller. *Novartis Pharmacology AG, Basel, Switzerland.* Sponsor: <u>V. Nogues</u>.

Epothilone B (EPO906) is a novel microtubule stabilizer developed for the treatment of solid tumors, including tumors insensitive and refractory to paclitaxel, a Pgp substrate. In preliminary clinical studies designed to define the optimal dose and schedule of the drug, diarrhea represents the most common dose-limiting side-effect of EPO906 so far. In preclinical models, diarrhea occurs in rats treated with 1.75 mg/kg EPO906. In the present study, EPO906 was compared to paclitaxel to understand the mechanism of diarrhea after EPO906 treatment, and identify specific biomarkers. Both compounds were injected i.v. into groups of Lewis rats at roughly equipotent doses (EPO906: 1.75 mg/kg, paclitaxel: 10 mg/kg) with regard to suppression of tumor growth in a rat tumor model. Caecum samples were collected after 2, 24, and 48 hours post-injection; RNA was extracted and analyzed using rat DNA microarrays. Caecum transcript profiles showed that both compounds induced dose- and time-dependent changes related to their pharmacological effects on stabilization of microtubules, leading to cell-cycle arrest. With paclitaxel, most of the changes in terms of number and mRNA expression levels were weak and transient. An EPO906-specific expression pattern was observed, which included genes encoding acute phase proteins, coagulation cascades, tissue remodeling, angiogenesis, lipid metabolism and, particularly, the arachidonic acid pathway, indicating a strong inflammatory response. These data suggest that induction of diarrhea by EPO906 may be related to the expected antiproliferative and cytotoxic activity, which may, in turn, be exacerbated by the presence of a strong inflammatory response, leading to the loss of the intestinal electrolyte/water barrier function. In EPO906-treated animals, early, differentially expressed genes were defined as potential biomarkers for the prediction of EPO906-induced diarrhea.

# 838 ENVIRONMENTAL TOBACCO SMOKE INDUCED REACTIVE OXYGEN SPECIES GENERATION IN MICE BRAIN REGIONS.

K. C. Wise<sup>1</sup>, T. Rangasamy<sup>2</sup>, S. Biswal<sup>2</sup> and R. Govindarajan<sup>1</sup>. <sup>1</sup>Department of Biology, Texas Southern University, Houston, TX and <sup>2</sup>Department of Environmental Health Sciences, Johns Hopkins University, Baltimore, MD.

Environmental tobacco smoke (ETS) is a key culprit in indoor air pollution. Tobacco smoke contains a mixture of over 4700 chemical components many of which are toxic and have been implicated in the etiology of oxidative stress related diseases such as chronic obstructive pulmonary disease, Parkinsons disease, asthma, cancer and cardiovascular disease. However, the mechanism of action of cigarette smoke in the onset of these diseases is still largely unknown. Previous studies have revealed that the free radicals generated by cigarette smoke may contribute to many of these chronic health problems and this study sought to address the role of environmental tobacco smoke in oxidative stress related damage in different brain regions of a mouse model. In this study, male strain A/J mice were exposed for 7 h/day, 7 days/week, for six months to an atmosphere of ETS consisting of 89% side stream smoke and 11% mainstream smoke produced by burning reference cigarettes using a smoke machine. Chamber atmosphere was monitored for total suspended particulates (TSP) and carbon monoxide (CO). Our preliminary findings from this study indicates that exposure to tobacco smoke leads to increased generation of reactive oxygen species with a concomitant decrease in the level of glutathione, a natural antioxidant utilized to combat oxidative stress. Gel shift analysis also revealed the elevated level of the oxidative stress sensitive, proinflammatory transcription factor NF-kappa-B in different regions of the brain of cigarette smoke exposed AJ mice. Research is in progress to determine the cigarette smoke induced oxidative lesions in different regions of the brain of AJ mice. [This work was supported by grant: RCMI/NIH #G12RR03045-16].

# 839 IDENTIFICATION OF BIOMARKERS FOR OXYCHLORDANE-EXPOSURE IN RODENT LIVER USING MICROARRAYS.

I. Curran, A. Hierlihy, K. Smith, J. Green and G. Bondy. *Toxicology Research Division, Health Canada, Ottawa, ON, Canada.* 

Oxychlordane (OXY) is the primary metabolite of the toxic mixture, technical chlordane. Such persistant organo-pollutants were widely used as pesticides until the 80s and thus have accumulated in the food chain. Recent reports indicate that the formation of this metabolite is more toxic and bioaccumulative than the parent contaminants. The goal of this study was to elucidate possible genetic markers that may be used in identifying toxic exposure before overt physiological effects are evident. Female and male rats were gavaged with 2.5mg/kg body weight/day OXY for 28 days; control animals were gavaged with corn-oil vehicle only. Total RNA was isolated from liver and pooled, followed by comparison of gene expression levels using microarray analysis. Three trials using Mergen chips (contain oligos of 1152 known rat genes and ESTs) were performed. Microarray data was verified using semi-quantitative RT-PCR on individual samples. Microarray analysis on female rat liver RNA showed that 31 targets were expressed at >2-fold increase in treated vs. control animals. Classification of these genes identified several membrane transport genes, as well as cytochrome p450 genes. RT-PCR confirmed increased levels of gene expression in treated female rats in such genes as sodium-dicarboxylate cotransporter (SDCT1), Na+, K+ ATPase-gamma subunit. Interestingly, sex-specific differences were detected in gene expression of 4 of the target genes. These included proton-coupled peptide transporter-2, Na+, K+ ATPase- gamma, SDCT1, and putative potassium channel. While female expression levels were shown to increase in these genes, transcript levels were observed to decrease in male OXY-treated livers. Results indicate that OXY elicits an effect on membrane proteins. This corresponds with previous studies that report depressed organic-ion transport to be an effect of chlordane, trans- and cis-nonachlor on membrane channel, ion transport and other membrane-related proteins. Further testing is currently underway to screen larger gene arrays at lower dose groups to identify additional gene targets.

# 840 MEETING GUIDELINES FOR CHOLINESTERASE MONITORING BY CLINICAL LABORATORIES IN CALIFORNIA.

B. W. Wilson<sup>1</sup>, J. D. Henderson<sup>1</sup>, D. E. Arrieta<sup>1</sup> and M. A. O'Malley<sup>2,3</sup>.

<sup>1</sup>Environmental Toxicology, University of California, Davis, CA, <sup>2</sup>Employee Health, University of California, Davis, CA and <sup>3</sup>Department of Pesticide Regulation, California Environmental Protection Agency, Sacramento, CA.

California (CA) is the only state with a long standing formal monitoring program for mixers, loaders and applicators of pesticides. When we found commercial clinical kits were not optimal for assaying blood cholinesterases (ChEs), CA regulations were revised to specify use of optimal Ellman ChE assay conditions. Alternate

methods were allowed if a correlation (r²) of 0.9 was achieved in a comparison with the specified method. We were enlisted to work with the clinical laboratories. Only 2 of 7 participating laboratories achieved an acceptable correlation for red blood cell acetylcholinesterase (AChE) and 4 of 5 laboratories for plasma ChE. When the CA Department of Pesticide Regulation (DPR) reiterated the need to meet this requirement we used bovine ghost RBC AChE as a standard to work with several of the clinical laboratories. Only 3 of 10 participating laboratories had acceptable correlations. Some said their instruments lacked the sensitivity to assay the bovine AChE samples. Next, we provided all interested laboratories with human blood and plasma samples to perform a comparison study outlined in the regulation (Section 6728f). Fourteen laboratories participated; 9 met the criterion for whole blood, 14 for plasma and 6 for RBC AChE. Based on such data, DPR notified the CA Agricultural Commissioners on July 8, 2003 that 9 clinical laboratories were approved for ChE testing. We continue to work with laboratories interested in being on the approved list. The current list may be seen at: www.cdpr.ca.gov/docs/whs/lablist.htm. Supported by NIOSH (#CDC U07/CCU906162-06) and NIEHS (#ESO5707).

### 841 BIOLOGICAL MONITORING OF BISPHENOL A IN CHILDREN

S. Park<sup>1</sup>, C. Shin<sup>2</sup>, S. Kim<sup>3</sup> and <u>M. Yang</u><sup>1</sup>. <sup>1</sup>Preventive Medicine, Seoul National University College of Medicine, Seoul, South Korea, <sup>2</sup>Pediatric Endocrinology, Seoul National University Hospital, Seoul, South Korea and <sup>3</sup>Preventive Medicine, Eulji University School of Medicine, Taejon, South Korea.

Health risk of bisphenol A (BPA) among potential endocrine disrupters (EDs) is not clear, yet. In addition, children are thought to be more sensitive to BPA than adults. Therefore, we studied exposure levels of BPA and association between the exposure levels and endocrine disorders in Korean children (N= 168; 9.1  $\pm$  2.2 yrs; male, 41.1 %) to provide safe exposure levels of BPA. Cases of endocrine disorders included short stature, precocious puberty, hyperthyroidism, etc. Controls were 94 healthy children. Using our established analysis method of BPA in urine (HPLC/FD), we measured conjugated BPA as a biomarker for BPA exposure. As results, range of BPA was 0.04- 83.5  $\mu g/L$  in detectable urine samples (N=149). When we gave half of the lowest level, 0.02, to the other 19 non-detectible samples, the median of BPA levels was 5.85  $\mu g/L$ . The level of BPA was higher in cases (N=65) than controls (N=94): geometric mean (geometric standard deviation) in cases and controls, 3.9  $\mu g/L$  (5.8) and 1.9  $\mu g/L$  (12.0), respectively: p = 0.13. When we considered age and sex for BPA levels, the odd ratio for case was 4.7 (95% CI, 1.3-19.4). Even though our results should be confirmed in enlarged populations, our results suggest that exposure to BPA may affect endocrine disorder in children. In addition, approximate 3  $\mu$ g of BPA is thought to be daily exposed to the children. Our results will be useful for establishment of future safe levels of RPA

## 842 METABOLOMIC ANALYSIS OF THE MECHANISMS OF ACETAMINOPHEN LIVER TOXICITY IN RATS.

A. J. Higgins, T. J. Colatsky, B. R. Bullard and <u>S. S. Sumner</u>. *Paradigm Genetics, Inc., Research Triangle Park, NC.* 

Acetaminophen (APAP) overdose remains one of the most common causes of hospital admissions for acute liver toxicity. The initiating mechanism is believed to involve hepatic metabolism of APAP to a reactive oxidative species, NAPQI, which subjects the liver to oxidative stress, resulting in depletion of glutathione. Oxidative stress is also believed to play a pivotal role in the hepatotoxicities of a wide range of chemical and pharmaceutical agents, and APAP may therefore serve as a useful model agent. Single oral doses of APAP, ranging from 50 mg/kg (no histopathological changes) to 2000 mg/kg (frank necrosis) were administered to rats. Groups of 6 rats were serial sacrificed up to 48h and livers were snap frozen. Samples were extracted and analyzed by LC/MS (ToF) with an ESI source in either positive or negative mode. Mass spectra at each retention time were matched to a library of around 500 known standards using proprietary software and linked to metabolic pathways. Data were reduced and visualized by principle component analysis. As early as 6h after the acute administration, changes in biochemical profiles could be clearly observed with doses of 1500 mg/kg and above. The time-related trajectories were similar for the 1500 and 2000 mg/kg groups. A similar qualitative trend was also apparent at 150 mg/kg, a dose that produced only minimal histopathological changes. Analysis of individual metabolites revealed major perturbations in pathways associated with known injury and repair mechanisms - e.g. depletion of glutathione and cystathionine (oxidative stress), decreases in NAD and various nucleotides (nucleic acid repair), and a decrease in CDP-choline (phospholipid turnover). Several of these decreases in liver metabolites were also reflected in urine, suggesting that they might serve as useful biomarkers for early detection of liver disease. Time and doserelated changes were also observed in various other biochemicals that were not predicted by current knowledge. Samples for this study were kindly provided by

## 843 METABOLOMICS: URINE AND SERUM BIOMARKERS FOR ACETAMINOPHEN HEPATOTOXICITY IN RATS.

T. J. Colatsky, A. J. Higgins, B. R. Bullard and <u>S. C. Sumner</u>. *Paradigm Genetics, Inc., Research Triangle Park, NC.* 

Acetaminophen (APAP) is a common cause of liver toxicity in humans. Standard markers of liver toxicity are relatively insensitive to the effects of APAP and have limited value in predicting outcomes for patients who have overdosed with the drug. Biochemical profiling (metabolomics) is a zero-based diagnostic approach (i.e. requiring no prior assumptions) that has the potential to simultaneously map changes in multiple biochemical processes that serve as novel biomarkers of liver disease. APAP was administered to groups of 6 rats in a single oral dose of either 50 or 1500 mg/kg. Urine was collected during various periods up to 48h and a single serum sample was also obtained at 48h. Biochemical profiles were determined in urine and serum by LC/MS (ToF) with an ESI source in either positive or negative mode. Mass spectra at each retention time were matched to a library of around 500 known standards using proprietary software. Data were reduced and visualized by principle component analysis (PCA). Results from urine showed separation of the 1500 mg/kg group from the control and low dose groups within the first 6h collection period. Progressively greater separation occurred from 6-24h and 24-48h. PCA analysis of serum showed similar classifications at 48h. The mechanisms underlying the changes in urine included decreases in homocysteine and cystathione, reflecting protection against oxidative stress. Amongst the other changes observed, some were representative of effects on phospholipid and nucleic acid turnover. Others mainly involved various pathways of amino acid metabolism. The most striking alteration in urine was a large, rapid increase in cAMP at the high dose and a smaller, transient increase at the low dose. A large increase in cAMP was also observed with the high dose in serum. These results suggest a basis for development of a novel panel of biomarkers for early detection and monitoring of liver toxicity. Samples for this study were kindly provided by NIEHS.

## **844** GENE EXPRESSION PROFILING IN A RAT CARDIAC ISCHEMIA MODEL.

P. H. Koza-Taylor<sup>1</sup>, B. Lu<sup>1</sup>, M. Wenfang<sup>3</sup>, S. Eustis<sup>2</sup>, X. Li<sup>2</sup> and <u>M. Lawton</u><sup>1</sup>. <sup>1</sup>Molecular and Investigative Toxicology, Pfizer, Groton, CT, <sup>2</sup>Pathology, Pfizer, Groton, CT and <sup>3</sup>Comparative Medicine, Pfizer, Groton, CT.

Cardiotoxicity in preclinical animal species is a common finding during development of vasoactive or cardiotonic pharmaceutical agents. There are multiple mechanisms of cardiotoxicity, with cardiac ischemia being the most common cause for cardiac injury. We have utilized a rodent model of cardiac ischemia to search for biomarkers for the early prediction and/or identification of cardiac injury. In this model, male Sprague-Dawley rats were anesthetized with isoflurane, and a left thoracotomy was performed aseptically to expose the heart and the left coronary artery. For ligation, the left anterior coronary artery was tied completely to occlude the blood flow. For sham control, the needle/suture were passed through under the artery, but was not tied. The heart and whole blood samples were collected for gene expression profiling at 3, 6, 9, 24 and 48 hours after coronary artery ligation or sham surgery. Moderate acute cardiomyocyte necrosis at 3-9 hours and necrosis with mixed inflammatory cell infiltration at 24 -48 hours were observed in the left free ventricular wall after ligation. Principal component analysis (PCA) of the global gene expression data showed clear separation between the sham and treated animal groups. An immediate-early stress response was observed starting the early time points and increasing at the later time points. The genes differentially expressed in the ischemia-induced animals fell into distinct clusters: the down-regulated genes included metabolism, glycolysis and catalase pathway members whilst up-regulated genes included acute phase and inflammatory response, heme oxidation pathway members, heat shock proteins, matrix metalloproteinases and fibronectin. Using both hierarchical clustering and Gene Logic's linear discriminant analysis (LDA)-based predictive models, the transcriptional profile in the hearts of ischemic rats was similar to catecholamine- and minoxidil-like responses, suggesting common mechanisms of ischemic cardiac injury.

## METABOLISM AND HEMOGLOBIN ADDUCTS OF [1, 2, 3-13C<sub>3</sub>] ACRYLAMIDE IN HUMANS.

T. Fennell<sup>1</sup>, R. Snyder<sup>1</sup>, J. P. Burgess<sup>1</sup> and <u>M. A. Friedman</u><sup>2</sup>. <sup>1</sup>RTI International, Research Triangle Park, NC and <sup>2</sup>UMDNJ, Newark, NJ.

Acrylamide (AM), which is used in the manufacture of polyacrylamide and grouting agents, is produced during the cooking of foods. Exposure to AM in the workplace can occur through dermal and inhalation exposure. The objectives of this study were to evaluate the metabolism of AM in humans on oral administration, and to compare hemoglobin adduct formation on oral and dermal administration. The study protocol was reviewed and approved by IRBs at both the laboratory performing the analysis of samples, and the clinical research center conducting the

study. 1, 2, 3-<sup>13</sup>C<sub>3</sub> AM was administered in an aqueous solution either orally (single dose of 0.5, 1.0, or 3.0 mg/kg), or dermally (3 daily doses of 3.0 mg/kg) to sterile male volunteers. Blood and urine samples were obtained before and after administration of AM. Urine samples from the 3 mg/kg oral dose group were analyzed for AM metabolites using <sup>13</sup>C NMR spectroscopy. Approximately 34 % of the administered dose was recovered in urine by 24 hr, and 75% of the urinary metabolites were derived from direct GSH conjugation. Glycidamide, its hydrolysis product, glyceramide, and one unidentified metabolite were detected in urine. Hemoglobin adducts derived from AM (*N*-(2-carbamoylethyl)valine, AAVal) and glycidamide (*N*-(2-carbamoyl-2-hydroxyethyl)valine, GAVal) were measured by the modified Edman method, with quantitative analysis by LC-MS/MS. On oral administration, a linear dose response was observed for both <sup>13</sup>C<sub>3</sub> AAVal (514, 914, and 2488 fmol/mg globin at 0.5, 1 and 3 mg/kg, respectively) and <sup>13</sup>C<sub>3</sub> GAVal (186, 344, and 1136 fmol/mg). Dermal administration resulted in lower levels of <sup>13</sup>C<sub>3</sub> AAVal (116, 292 and 440 fmol/mg) and <sup>13</sup>C<sub>3</sub> GAVal (55, 167, and 292 fmol/mg) following 1, 2 and 3 days of dosing (3 mg/kg). <sup>13</sup>C<sub>3</sub> AAVal normalized for dose for all of the oral dose groups was 924 fmol/mg globin/mg AM/kg. These data indicate that humans metabolize AM less than rodents *via* glycidamide, that there is a linear dose response for AAVal and GAVal, and that dermal uptake was approximately 5 % of that observed with oral uptake.

# ANALYSIS OF HEMOGLOBIN N-VALINE ADDUCTS FROM (1-CHLOROETHENYL)OXIRANE, A METABOLITE OF CHLOROPRENE.

H. Hurst and M. Y. Ali. Pharmacology and Toxicology, University of Louisville, Louisville, KY.

Chloroprene (2-chloro-1, 3-butadiene, CAS 126-99-8, CP) is a colorless volatile liquid used in manufacture of polychloroprene, a synthetic rubber polymer. National Toxicology Program inhalation studies of CP in rats and mice gave clear evidence of carcinogenic activity in multiple organs including lung, oral cavity, thyroid, mammary glands, and kidney. CP is metabolized by CYP 2E1 to an electrophilic epoxide, (1-chloroethenyl)oxirane (CEO), which forms adducts with nucleic acids and other nucleophiles such as glutathione and hemoglobin (Hb). CEO-Hb adduct measurement may provide a biomarker of exposure to this air pollutant. This study presents GC/MS measurement of N-terminal CEO-valine Hb adducts. Mouse (C57Bl/6) red cells were exposed in pH 7.4 phosphate-saline to 25 or 100 ppm CEO vapor in septum capped vials at 37°C for 1 to 72 hr. Reactions were stopped with ice-cold acidified acetone to precipitate globin containing CEOadducts. Precipitates were washed with pure acetone, dried, and stored at -20°C. CEO-valine-tyrosine-valine (CEO-VYV) was synthesized and purified by HPLC as a quantitative standard. Precipitated CEO-globin samples or CEO-VYV and CEO-13C<sub>5</sub>-Val (internal standard, IS) were dissolved in formamide. NaOH and pentafluorophenylisothiocyanate (PFPITC) were added. Samples were shaken overnight at 25°C and incubated for 2 hours at 50°C. Edman derivatives were extracted with ether, dried, re-dissolved with toluene, washed with aqueous sodium carbonate, dried, and incubated with N, O-bis-(trimethylsilyl)trifluoroacetamide (BSTFA) in acetonitrile. GC separation used a DB-1 capillary column with temperature programming. An AutoSpec mass spectrometer (70eV ionization energy and 1000 resolving power) detected ions of m/z 465 [M-Cl]+ and 470 (IS). Identical spectra were observed in two resolved GC/MS peaks at 13.6 and 13.7 min. Low - high CEO and Hb reactions followed 1st order kinetics with yields of 2.0 - 6.2, 11 - 27 picomoles adduct/mg globin and formation half-lives of 5.8 - 7.6, 7.2 - 7.8 hr for isomers 1 and 2, respectively.

# 847 A SIMULTANEOUS DETERMINATION OF THE THREE EPOXYMETABOLITE-HEMOGLOBIN ADDUCTS OF 1, 3-BUADIENE.

K. Peltonen¹ and T. Anttinen-Klemetti². ¹EELA, Helsinki, Finland and ²FIOH, Helsinki, Finland. Sponsor: S. Kai.

1, 3-Butadiene (BD) is produced from petroleum as a co-product of steam cracking. BD is used as a monomer in the manufacturing of a wide range of polymers and copolymers. In 1996 BD was among the 40 most produced chemical in the USA. About 30.000 workers in Europe and 50.000 workers in the USA are potentially exposed to BD. BD is metabolized mainly in the liver to electrophilic epoxymetabolites: monoepoxybutene (BMO) epoxybutanediol (EBD) and diepoxybutane (DEB). In a reaction with N-terminal valine of globine all epoxymetabolites forms adducts. We have prepared and characterized 33 modified peptide standards which we will use in human biomonitoring purposes. These include alkylated hepta and octapeptide (alpha chaing), nona and oktapeptide (beta chaing) and corresponding deuterated analogs. The progress of the reaction was monitored with HPLC, the products were isolated and spectroscopically identified. At present the markers were utilized to look the adducts at animals inhalation exposed to 1, 3-butadiene. The simultaneous measurements of all adducts allow a reliable estimation of the adduct ratio formed *in vivo* 

### DRUG SIGNATURES THAT PREDICT A VARIETY OF

C. Pearson, A. Roter, A. Tolley, B. Eynon, B. Ganter, G. Natsoulis, G. Day, K. Jarnagin, K. Kolaja, M. Fielden, M. Lee, R. Nair, S. Dunlea, J. Yang, L. Gong, S. Nicholson, S. Tugendreich, S. Fujimoto and S. Baumhueter. *Iconix Pharmaceuticals, Inc., Mountain View, CA*.

To improve compound selection during drug discovery we have developed a large library of biomarkers, Drug Signatures  $^{\mathrm{TM}}$ , for important toxicities and mechanisms of action. These signatures come from a comprehensive database that marries ~13, 000 microarray gene expression results derived from treating rats with 580 drugs at two doses and four time points in triplicate with traditional measurements of toxicity, pathology and pharmacology. Drug Signatures allow rapid, accurate interpretation of a drug's toxicity and mechanism, potentially hastening drug discovery and approval. Iconix has developed about 100 signatures that predict future pathologies based on early gene expression data in liver, kidney and heart. Pathologies that appear between 5 and 7 days after drug administration can be predicted with 40 to 95% accuracy using gene expression results from 6 and/or 24 hours. These pathologies include decreases in serum cholesterol; serum albumin; body weight; the numbers of neutrophils, lymphocytes and platelets; and increases in liver, kidney and heart weights; serum alkaline phosphatase and total bilirubin, markers of cholestasis; serum blood urea nitrogen and creatinine, markers of kidney injury; and liver pathologies such as hypertrophy, bile duct hyperplasia, apoptosis and centrolobular hydropic change. Genes in these signatures include those that encode proteins that act early in a process, such as transcription factors and signaling molecules. Other genes include those that are also in diagnostic signatures that indicate a concurrent pathology. These findings show that gene expression changes associated with a toxic response can be detected early before overt pathology occurs. Thus, predictive Drug Signatures allow identification of those drugs that may be toxic very early in preclinical studies, saving time and expense during drug discovery decision making.

## THE CONTRIBUTION OF AGE AND GENOTYPE TO SENSITIVITY TO ENVIRONMENTAL GENOTOXINS.

F. M. Williams, E. L. Davis, A. E. Daly and D. Morgan. Toxicology Unit, The Medical School, University of Newcastle, Newcastle upon Tyne, United Kingdom.

The aim of this study was to determine the influence of age and exposure to environmental genotoxins on DNA damage measured in freshly isolated human lymphocytes and to determine whether the genotype for xenobiotic metabolism was a factor contributing to susceptibility. Rural young (n=33) and elderly (n=52) and urban young (n=57) and elderly (n=116) volunteers were recruited in rural Northumberland and urban Newcastle upon Tyne. Lymphocytic DNA damage was determined by the COMET assay, genotype by PCR and haemoglobin adducts of arylamines measured as markers of environmental exposure. DNA damage measurements (tail density moment, median, 25th and 75th percentile) were in the elderly rural 28.45(25.53, 30.65), elderly urban 26.78 (23.9, 30.28) compared to the young rural 23.08(21.5, 25, 42)and young urban 25.98 (23.74, 28.59). The levels in the elderly were higher than the young and in the urban compared to the rural volunteers. There was no significant influence of the following genetic polymorphisms (Ah receptor (Lys 554), CYP1A1\*2A, epoxide hydrolase His 113 and Arg139, NAT2\*5, \*6, \*7, GSTM1\*0, GSTT1\*0 and GSTP1\*B and \*C) on DNA damage. Arylamine levels were highest in the urban population although only 2naphthylamine was significantly higher. However, there was no relation between haemoglobin arylamine levels and DNA damage between individuals. The greater DNA damage in the elderly was probably due to increased oxidative stress and reduced repair. Environmental genotoxin exposure influenced lymphocyte DNA damage but to a lesser extent than age but the elderly urban population was not more susceptible to DNA damage.

# 850 NEURO-SPECIFIC PROTEINS IN REPRODUCTIVE ORGANS AS POSSIBLE BIOMARKERS FOR ASSESSING ADVERSE EFFECTS OF 1-BROMOPROPANE.

H. Wang<sup>1</sup>, H. Ito<sup>2</sup>, K. Kato<sup>2</sup>, W. Li<sup>1</sup>, Y. Takeuchi<sup>1</sup>, T. Nakajima<sup>1</sup> and <u>G. Ichihara</u><sup>1</sup>. <sup>1</sup>Occupational and Environmental Health, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan and <sup>2</sup>Biochemistry, Institute for Developmental Research, Aichi Prefectural Colony, Kasugai, Aichi, Japan.

Our previous studies revealed that 1-bromopropane (1-BP), an alternative to ozone-depleting solvents, has reproductive toxicity in male and female rats, in addition to its neurotoxicity. As a considerable amount of neuro-specific proteins also exist in the reproductive organs, we considered that they might be related to a common basis for reproductive toxicity and neurotoxicity. The present study investigated neuro-specific proteins in reproductive organs in rats exposed to 1-BP and evaluated their possibility as markers of adverse effects. Thirty-six Wistar male rats were divided into four groups of twelve each and exposed to 1-BP at 200, 400 and

800 ppm, and fresh air for eight hrs per day for 2 wks. At the end of the experiment, the rats were euthanized, the testes and epididymides were dissected out and the right cauda epididymidis was minced for evaluation of sperm count and motility. The remaining organs were used for determination of CK-B,  $\alpha$ -S100,  $\beta$ -S100,  $\alpha$ -enolase, and  $\gamma$ -enolase with the sandwich-type enzyme immunoassay method. The sperm count did not change significantly, but sperm motility decreased dose-dependently with a significant change at 800 ppm.  $\gamma$ -enolase (per weight of wet tissue) significantly increased in the epididymides in a dose-dependent manner at 200 ppm or over, but did not change in the testes. In contrast,  $\alpha$ -enolase significantly increased in the testes at 400 ppm and 800 ppm, but did not change in the epididymides.  $\alpha$ -S100 significantly decreased only in the epididymides at 800 ppm, while  $\beta$ -S100 increased in the epididymides at 800 ppm.  $\gamma$ -enolase in the epididymides and  $\alpha$ -enolase in the estess were more sensitive than sperm indices. Neuro-specific proteins might serve as sensitive and organ-specific biomarkers for assessing adverse effects of 1-BP on reproductive organs.

## 851 EFFECT OF L-CARNITINE PRETREATMENT AGAINST 3-NITROPROPIONIC ACID (3-NPA) INDUCED NEUROTOXICITY.

Z. K. Binienda<sup>1</sup>, J. L. Summage<sup>1</sup>, S. Dufour<sup>2</sup>, B. Przybyła-Zawislak<sup>1</sup>, A. Virmani<sup>3</sup>, <u>W. Slikker<sup>1</sup></u> and L. C. Schmued<sup>1</sup>. <sup>1</sup>Neurotoxicology, NCTR, Jefferson, AR, <sup>2</sup>Milieux et Peuplements Aquatiques, Museum National d, Paris, France and <sup>3</sup>Scientific Affairs, sigma-tau Health Science s.p.a., Rome, Italy.

A plant and fungal toxin, 3-NPA, acts as an inhibitor of mitochondrial function via irreversible inhibition of the mitochondrial inner membrane enzyme succinate dehydrogenase (SDH). Inhibition of SDH disturbs the electron transport and leads to cellular energy deficit and neuronal injury. We have shown that pretreatment with L-carnitine, while not significantly attenuating SDH inhibition, prevented hypothermia and oxidative stress-associated increase in activity of free radical-scavenging enzymes. Here, a neurohistological method was applied to examine the effect of carnitine pretreatment against 3-NPA-induced neurotoxicity. Twenty adult male Sprague-Dawley rats were randomly divided into two groups (n=10/group). Rats in the first group were injected with 3-NPA at 30 mg/kg, s.c. twice, two days apart and the second group of animals received L-carnitine pretreatment at 100 mg/kg 30-40 min before 3-NPA administration. Rats in both groups were perfused seven days later and their brains harvested. Degenerating neurons were identified and localized via the fluorescent marker Fluoro-Jade B. Briefly, tissue sections were pretreated with 0.06% potassium permanganate followed by incubation in 0.0001% Fluoro-Jade B in 0.1% acetic acid vehicle. Examination of the stained sections with an epifluorescent microscope revealed the following results: Of the three animals that survived 3-NPA dosing, one exhibited no pathology, one exhibited moderate unilateral damage to the striatum and the third exhibited extensive bilateral neuronal degeneration in multiple forebrain regions. Of the seven-surviving animals that received L-carnitine prior to 3-NPA insult, six exhibited no lesions, while one exhibited a modest unilateral lesion of the striatum. It appears that L-carnitine is protective against 3-NPA-induced toxicity, as reflected by both reduced mortality and significantly reduced neuronal degeneration.

## 852 ANALYSIS OF MOLECULAR INTERACTIONS FOR PROTEIN-LIGAND COMPLEXES: INVERSE DOCKING AND TARGET IDENTIFICATION.

<u>J. Wang</u> and <u>R. Richardson</u>. Environmental Health Sciences, University of Michigan, Ann Arbor, MI.

Computational studies of molecular interactions are important for drug design and toxicological research. Docking is widely used in drug discovery to screen small molecule ligands using a target macromolecule as a template. In contrast, inverse docking is designed to identify potential macromolecular targets for a small molecule and has been little studied. The present work used computer experiments to investigate the promise of inverse docking in predictive toxicology by analyzing molecular interactions for 50 protein-ligand complexes. Proteins represented diverse biological functions, and ligands varied in structural flexibility and hydrophobicity. Protein-ligand structures were extracted from the Protein Data Bank (PDB). Ligands and proteins were separated to form a small molecule set and a macromolecular target set. Autodock was used to dock small molecules into macromolecules in the target set to find potential targets. Based on computed interaction energies generated by docking, inferences were drawn about the potential of a protein to be a target for a ligand. The results showed that some small molecules interacted with one or a few targets, while others had the potential to interact with many targets. Nevertheless, in 48 of 50 cases, the computed interaction energies of small molecules with their assumed targets (based on the PDB complexes) ranked within the top 3. Furthermore, for 32 of 50 small molecules, computed interaction energies with their assumed targets were ranked first. Thus, inverse docking was relatively effective for identifying potential targets for small molecules. Moreover, this technique has the potential to discover alternative targets for toxicities and mechanisms beyond those originally assumed for small molecules. Finally, this study suggests that a database of targets could be formed using the records of the PDB. This database could be designed for virtual docking evaluations of small molecules, thereby furnishing a rapid screening approach for high-throughput predictive toxicology. (Supported in part by ARO grant DAAD19-02-1-0388).

# 853 EFFECT OF PHYSICAL EXERTION ON THE BIOLOGICAL EXPOSURE INDICES OF TOLUENE FOLLOWING EXPOSURE BY INHALATION IN HUMAN VOLUNTEERS

V. Nadeau<sup>1</sup>, G. Truchon<sup>2</sup>, M. Brochu<sup>3</sup> and R. Tardif<sup>1</sup>. <sup>1</sup>Occupational and Environmental Health, University of Montreal, Montreal, QC, Canada, <sup>2</sup>Occupational Health, IRSST, Montreal, QC, Canada and <sup>3</sup>Kinesiology, University of Montreal, Montreal, QC, Canada.

Physical exertion (workload) has been recognized as one of the several factors that can influence the kinetics of xenobiotics within the human body. This study was undertaken to evaluate the impact of physical exertion on the biological exposure indices (BEIs) of TOL in human volunteers exposed under controlled conditions in an inhalation chamber. A group of 4 volunteers (1 woman, 3 men) were exposed to TOL (50 ppm) according to the following scenarios involving either aerobic (AERO), muscular (MUSC) or both (AERO/MUSC) types of physical exercises (exercise bicycle, treadmills, pulleys): REST, 50W AERO, 100W AERO and 50W AERO/MUSC during 7 h; 50W MUSC and 100W MUSC during 3 and 21/2 h, respectively. Alveolar air and urine samples were collected at different time intervals before, during and after exposures for the measurement of unchanged TOL in expired air and of urinary o-cresol. Overall, results showed that unchanged concentrations of TOL in expired air measured during and after all scenarios involving physical activities were higher (approximately 1.4 - 2 fold) compared to exposures at rest. However, there was no difference between levels measured at 50W AERO and 100W AERO. All scenarios involving physical exertion also resulted in increased urinary levels of o-cresol (umol/mmol creatinine) (mean ± standard error): creased urmary levels of o-cresol (umol/mmol creatinine) (mean  $\pm$  standard error): REST<sub>0.3h</sub>: 0.2  $\pm$  0.05, REST<sub>3.7h</sub>: 0.6  $\pm$  0.06; 50W AERO<sub>0.3h</sub>: 0.63  $\pm$  0.09, 50W<sub>3.7h</sub>:  $1.32\pm0.25$ ; 50W AERO/MUSC<sub>0.3h</sub>:  $0.48\pm0.07$ , 50W AERO/MUSC<sub>3.7h</sub>:  $0.88\pm0.25$ ; 50W MUSC<sub>0.3h</sub>:  $0.39\pm0.06$ ). Muscular activity was less effective compared to aerobic exercise. In conclusion, this study showed that BEI values of TOL vary according to the level (W) and type (AERO or MUSC) of physical exertion. Additional experiments aimed at characterising the impact of workload on the BEIs of 4 other solvents are underway. (Supported by IRSST, Quebec)

## THE USE OF METABONOMICS TO DIFFERENTIATE THE TOXICITY OF TWO MAPK KINASE INHIBITORS IN MICE

A. P. Brown<sup>1</sup>, L. Robosky<sup>3</sup>, C. V. Okerberg<sup>1</sup>, R. Merriman<sup>2</sup>, C. Howard<sup>2</sup>, H. Tecle<sup>4</sup> and M. Reily<sup>3</sup>. <sup>1</sup>Safety Sciences, Pfizer Global Research and Development, Ann Arbor, MI, <sup>2</sup>Cancer Pharmacology, Pfizer Global Research and Development, Ann Arbor, MI, <sup>3</sup>Discovery Technologies, Pfizer Global Research and Development, Ann Arbor, MI and <sup>4</sup>Chemistry, Pfizer Global Research and Development, Ann Arbor, MI.

Analysis of biofluids, such as urine, by nuclear magnetic resonance (NMR) spectroscopy (metabonomics) can serve as a tool for identifying drug-induced alterations in homeostasis and provide a mechanism for screening compounds for toxicity. This study was conducted to determine whether metabonomics could detect potential differences in toxicity of the structurally related MAPK kinase (MEK) inhibitors PD 254552 and PD 320125-2, which differ only by a methyl group on the imidazole ring. Female Balb/C mice were dosed by gavage twice daily, approximately 12 hours apart, at 400 mg/kg/day for up to 7 days. The control group received vehicle (0.5% hydroxypropylmethylcellulose/0.2% Tween 80) alone. Urine samples, collected pretest and once daily during the dosing period, were analyzed by 600 MHz 1H NMR spectroscopy. Four mice/group were sacrificed on Days 4 and 8, and serum chemistries were measured. Select tissues collected on Day 8 were examined microscopically. PD 254552 produced one mortality, body weight loss, increased serum AST and ALT levels (4- to 10-fold), decreased serum total protein and albumin levels (24% to 48%), and hepatic (degeneration, necrosis) and GI tract lesions (gastric erosion/ulcers, mucosal changes). These changes were not produced by administration of PD 320125-2. Principle components analysis demonstrated a difference between the NMR spectra of PD 254552-treated mice from the other dose groups, which increased with time. Analysis of urinary endogenous metabolites indicated that PD 254552-dosed mice had decreased levels of hippurate, oxoglutarate, and trimethylamine-N-oxide. NMR data in the control and PD

320125-2 groups were similar. In conclusion, metabonomics data correlated with indices of toxicity and differentiated between exposures to structurally related compounds.

ASSESSMENT OF GLOBIN S-PROPYLCYSTEINE
ADDUCTS AND URINARY N-ACETYL SPROPYLCYSTEINE AS INTERNAL EXPOSURE MARKERS
OF 1-BROMOPROPANE.

<u>G. Ichihara</u><sup>1</sup>, K. Amarnath<sup>2</sup>, V. Amarnath<sup>2</sup>, H. I. Valentine<sup>2</sup>, W. Li<sup>1</sup>, H. Wang<sup>1</sup> and <u>W. M. Valentine</u><sup>2</sup>. <sup>1</sup>Occupational and Environmental Health, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan and <sup>2</sup>Pathology, Vanderbilt University Medical Center, Nashville, TN.

1-Bromopropane(1-BP), an alternative to ozone-depleting solvents, is neurotoxic and is a reproductive toxicant in animals and humans. We previously reported the detection of N-acety S-propylcysteine in the urine of workers exposed to 1-BP. The present study investigated the dose response of urinary N-acetyl S-propylcysteine and of S-propylcysteine in globin and neurofilament preparations as a function of exposure level and duration. Thirty two Wistar male rats were randomly divided into four groups of eight and exposed to 1-BP at 0, 50, 200, or 800 ppm for eight h/day for two wks. The urine was collected both during and after the exposure on the first and final exposure days. At the end of the experiment, blood and spinal cord were obtained. Secondly, 24 male rats were divided into two groups of twelve and exposed to 1-BP at 50 ppm or filtered air for eight h/day, five days/wk for four wks. The urine was collected for 15 h during the night before the first exposure and after the fifth exposure each week. Blood (0.5 mL) was also obtained after the last exposure in every week. After 4 wks 6 exposed and 6 control rats were euthanized and blood and spinal cord obtained. The remaining rats were euthanized 1 wk after the end of exposure to examine the elimination kinetics of the metabolites and protein adduct. Urinary N-acetyl S-propylcysteine was measured with two methods using GC-MS and LC-MS/MS. S-Propylcysteine in globin and neurofilaments were determined using LC-MS/MS. S-propylcysteine adducts were correlated with both the level and duration of exposure whereas the urinary metabolite was correlated to exposure level but did not increase after 1 wk of exposure. These results support the potential of urinary N-acetyl S-propylcysteine and globin S-propylcysteine adducts as biomarkers of 1-BP exposure and demonstrate the ability of 1-BP to covalently modify proteins within the nervous system.

856 DETERMINATION OF BIOLOGICAL REFERENCE VALUES FOR CHLORPYRIFOS METABOLITES IN HUMAN URINE USING A TOXICOKINETIC APPROACH.

M. Bouchard<sup>1</sup>, G. Carrier<sup>1</sup>, R. C. Brunet<sup>2</sup>, N. H. Gosselin<sup>1</sup> and Y. Bonvalot<sup>1</sup>.

<sup>1</sup>Environmental & Occupational Health, University of Montreal, Montreal, QC, Canada and <sup>2</sup>Mathematics & Statistics, University of Montreal, Montreal, QC, Canada.

Urinary biomarkers of chlorpyrifos (CPF) exposure are increasingly being measured in field studies although biological guidelines are not yet available to assess health risks in workers. In this study, a toxicokinetic approach is proposed for the determination of biological reference values for CPF metabolites in urine. As a first step, a toxicokinetic model for CPF and its metabolites was developed and validated using the human kinetic time course data available in the literature. The model was built to link the absorbed dose of CPF under a variety of exposure routes and temporal scenarios to the urinary excretion of its major metabolites, 3, 5, 6-trichloro-2pyridinol (3, 5, 6-TCP) and alkyl phosphates (AP). The model was then used to predict guidance values of urinary biomarkers of CPF exposure below which workers should not experience adverse health effects, whatever their exposure conditions. This was achieved by linking i) a literature reported repeated CPF no-observed-effect level (NOEL) daily dose for the inhibition of red-blood-cell acetylcholinesterase to a corresponding absorbed daily dose on the one hand and ii) the absorbed daily dose to the urinary excretion of CPF metabolites on the other hand. Model simulations under a variety of exposure scenarios showed that the safest biological reference values are obtained from a dermal exposure scenario with the slowest possible absorption rate rather than from respiratory or oral exposure scenarios. Also, model simulations showed that, for a given total absorbed dose, absorption over 8 hours results in smaller 3, 5, 6-TCP and AP urinary excretion rates than those obtained from shorter exposure durations. From these considerations, biological reference values were derived by simulating an 8-h dermal CPF exposure such that the total absorbed daily dose corresponds to the absorbed NOEL. These guidance values are proposed in the form of total amounts of 3, 5, 6-TCP and AP metabolites collected in urine over conveniently chosen time periods.

857 DNA ADDUCT FORMATION AND TOXICITY OF TRANS-2-HEXENAL IN MALE F344 RATS.

M. D. Stout<sup>1</sup>, E. Bodes<sup>1</sup>, Y. Li<sup>2</sup>, P. B. Upton<sup>2</sup>, R. Schoonhoven<sup>2</sup>, J. Nakamura<sup>2</sup>, Y. Jeong<sup>2</sup>, R. Sangaiah<sup>2</sup> and J. A. Swenberg<sup>1, 2</sup>. <sup>1</sup>Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC and <sup>2</sup>Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC.

Trans-2-hexenal (hexenal) has been given generally regarded as safe (GRAS) status as a flavoring agent by the Flavor and Extracts Manufacturers Association (FEMA) expert panel, even though it is genotoxic in vitro. Hexenal also forms exocyclic 1, N<sup>2</sup>-propanodeoxyguanosine adducts (H-dGuo) upon reaction with DNA. Since hexenal exerts its biological effects without metabolic activation, we hypothesized that the dose-response of both H-dGuo formation and its toxicity would be sub linear, due to saturation of detoxification. We have developed a highly sensitive and specific mass spectrometry based method for quantitating H-dGuo in DNA. Eightweek old male F344 rats were exposed to single doses of 0, 50, 200, or 500 mg hexenal/kg b.w. by oral gavage, as in a previous study (Schuler and Eder (1999) Carcinogenesis 20, 1345-1350). In that study, no toxicity was reported and the highest concentrations of H-dGuo were found in the forestomach, liver, esophagus, and kidney when measured by <sup>32</sup>P-postlabeling of DNA from rats sacrificed two days after dosing. We observed moderate to severe lesions in the forestomachs of hexenal-exposed rats, with coagulative necrosis and severe edema at the high dose. Furthermore, in preliminary experiments, we were not able to quantify H-dGuo in liver DNA (n=4) of rats exposed to 500 mg hexenal/kg b.w. or forestomach DNA (n=2) of rats exposed to 200 mg hexenal/kg b.w. two days after dosing. Thus, we were not able to confirm the results of the previous report. We are continuing to analyze samples from additional time points and exposing F344 rats to repeated doses of hexenal, in order to characterize toxicity and H-dGuo formation under these conditions. This work was supported in part by grants from the NIEHS (T32ES07126, ES11746, P30ES10126), the NCI (P30CA16086, T32CA72319) and the Flavor and Extract Manufacturers Association (FEMA).

ORAL TREATMENT WITH 13-CIS-RETINOIC ACID (13-CIS-RA) OR ALL-TRANS-RETINOIC ACID (ALL-TRANS-RA) ALTERS SERUM LEVELS OF ALBUMIN (ALB), TRIGLYCERIDES (TRIG), TOTAL PROTEIN AND GLUCOSE OF RATS.

F. J. Cisneros<sup>1</sup>, B. J. Gough<sup>1</sup>, R. E. Patton<sup>2</sup> and <u>S. A. Ferguson<sup>1</sup>. <sup>1</sup>Division of Neurotox, NCTR/FDA, Jefferson, AR and <sup>2</sup>Charles River Laboratories, Jefferson, AR.</u>

13-cis-RA has been used to treat acne vulgaris since 1982. Its dermatological effect seems to occur via isomerization to all-trans-RA. Although the package insert suggests followup lab testing, recent reports indicate that except for teratogenicity, it is safe and effective. Thus, some suggest there is no need for routine lab followup. We evaluated the effects of 13-cis-RA and all-trans-RA on serum chemistry, leptin and adiponectin levels. Adult male and female Sprague-Dawley rats were gavaged daily for 7 days with 13-cis-RA (7.5 or 15 mg/kg), all-trans-RA (10 or 15 mg/kg) (n=24/sex/dose), or soy oil (n=16/sex) and blood collected after the last gavage. Body weight was unaffected by RA treatment. There were no RA treatment effects on levels of blood urea nitrogen, aspartate amino transferase, leptin, or adiponectin. Sex differences were noted for levels of cholesterol, creatinine, TRIG, ALB, alanine amino transferase (ALT), and total protein. Despite an RA treatment effect on ALT levels, no treated group was statistically different from controls. However, all-trans RA treatment (10 & 15 mg/kg) reduced ALB levels to ≈90% of control (p<0.05) and reduced total protein levels to ≈93% of control (p<0.05) while substantially elevating TRIG levels ≈66-99% above control (p<0.05). Additionally, TRIG levels of the 15 mg/kg 13-cis RA group were  $\approx$ 62% higher than controls (p<0.05) and total protein levels were  $\approx$ 5% less (p<0.05). Glucose levels were impacted by sex and RA treatment in that males treated with 15 mg/kg of 13-cis-RA or 10 mg/kg all-trans-RA had lower levels than same-sex controls (13-19% lower) (p<0.05); however, females were not affected. As expected, all-trans-RA is more potent than 13-cis-RA on a mg/kg basis. Our results suggest that in addition to recommended followups in blood lipid analysis and hepatic function, glucose levels should be monitored with special attention in males.

859 EVALUATION OF THREE SERUM BIOMARKERS OF HEPATOTOXICITY: MALATE DEHYDROGENASE, PARAOXONASE, AND PURINE NUCLEOSIDE PHOSPHORYLASE.

S. J. Schomaker, D. E. Amacher, I. M. Pruimboom-Brees and M. L. Mirsky. Safety Sciences Groton, Pfizer Global Research and Development, Groton, CT.

The objective of these studies was to evaluate three potential serum biomarkers of hepatotoxicity: malate dehydrogenase, paraoxonase, and purine nucleoside phosphorylase. These markers were originally identified in the Pfizer/OGS collaboration

and are targeted as those serum proteins with the greatest potential to serve as sensitive, early indicators of dose-dependent liver toxicity including steatosis, hepatocellular necrosis, or hepatobiliary injury. In the first study, male and female CD rats were dosed with acetaminophen, α-naphthylisothiocyanate, phenobarbital, or galactosamine. All of the compounds, at the specified doses, have been shown in the literature to cause increases or decreases in one or more of the proposed biomarkers. Clinical pathology and histopathology procedures were completed for correlation of the serum biomarker results to physiological toxicity. The results from the serum samples from the four rat studies paralleled the results from studies with the same compounds published in the literature. All three assays showed detectable protein levels in normal rat serum from both males and females, had a low coefficient of variation in control populations, and were easily adapted to the Cobas Fara (a clinical chemistry autoanalyzer). In a second study, male and female CD rats were dosed with acetaminophen, α-naphthylisothiocyanate, galactosamine, thioacetamide, or allyl alcohol. Clinical pathology and histopathology analyses were completed for correlation of the serum biomarker results to physiological toxicity. In general, the assays are at least as sensitive as traditional clinical chemistry hepatotoxicity assays. With allyl alcohol and α-naphthylisothiocyanate, both associated with periportal necrosis, the assays appear to be more sensitive than traditional clinical chemistry hepatotoxicity assays.

860

HEMOGLOBIN ADDUCTS OF 3, 4-EPOXY-1, 2-BUTANEDIOL IN RODENTS EXPOSED TO 3-BUTENE-1, 2-DIOI

M. W. Powley<sup>1</sup>, P. B. Upton<sup>1</sup>, V. E. Walker<sup>2</sup> and J. A. Swenberg<sup>1</sup>. <sup>1</sup>Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC and <sup>2</sup>Lovelace Respiratory Research Institute, Albuquerque, NM.

1, 3-Butadiene (BD) is a rodent carcinogen and may also be a human carcinogen. BD metabolism yields several mutagenic epoxides whose contribution to carcinogenicity is not fully understood. 1, 2:3, 4-diepoxybutane and 1, 2-epoxybutene cannot completely account for the mutagenic effects of BD, suggesting that other reactive metabolites may be involved. Two potential sources arising from 3-butene-1, 2-diol (BD-diol) are 3, 4-epoxy-1, 2-butanediol (EB-diol), a known mutagen, and hydroxymethylvinyl ketone (HMVK), a compound expected to be mutagenic. Recent experiments have shown that BD-diol increases the frequency of Hprt mutations in splenic T-cells from rodents. Furthermore, based on a comparison of mutagenic potencies the BD-diol pathway may account for most mutagenicity in rats exposed to 625 ppm BD and contributes to the mutagenicity in mice. The objective of our current research was to measure N-(2, 3, 4-trihydroxybutyl)valine (THB-Val), an EB-diol derived hemoglobin adduct, to understand the involvement of this metabolite in BD-diol induced mutagenicity. To accomplish this, female B6C3F1 mice and female F344 rats were exposed to 0, 6, 18, and 36 ppm BD-diol for 4 weeks (6 hr/day x 5 days/week). Globin samples were processed and analyzed by GC-MS/MS according to a published method. Results showed that mice formed 1.01  $\pm$  0.74, 12.3  $\pm$  2.2, 29.2  $\pm$  1.2, and 35.8  $\pm$  1.6 pmol THB-Val/mg globin (mean ± SD, n≥3) at 0, 6, 18, and 36 ppm BD-diol, respectively. At the same exposure concentrations rats formed  $0.37 \pm 0.23$ ,  $5.8 \pm 1.2$ ,  $14.75 \pm 0.98$ , and 20.9± 1.3 pmol adduct/mg globin (mean ± SD, n≥3). The adduct dose-response mimicked the increase in Hprt mutation frequency observed in rodents following exposure to BD-diol. While the contribution to mutagenicity made by HMVK must still be determined, the results of our current study, along with earlier studies using BD or other metabolites, show that EB-diol may in part be responsible for the mutagenicity observed in rodents exposed to BD-diol or BD.

# ACB-PCR MEASUREMENT OF p53 MUTATION: A POTENTIAL BIOMARKER OF SKIN CANCER DEVELOPMENT.

T. L. Verkler<sup>1</sup>, L. H. Couch<sup>2</sup>, B. J. Miller<sup>2</sup>, <u>P. C. Howard</u><sup>2</sup> and B. L. Parsons<sup>1</sup>. <sup>1</sup>Division of Genetic and Reproductive Toxicology, NCTR, USFDA, Jefferson, AR and <sup>2</sup>Division of Biochemical Toxicology, NCTR, USFDA, Jefferson, AR.

*p53* codon 270 CGT to TGT mutation is frequently detected in mouse squamous cell carcinomas (SSCs) induced by simulated solar light (SSL). Measurement of this mutation is being developed as an early biomarker for skin carcinogenesis. Allelespecific Competitive Blocker-PCR (ACB-PCR) is a sensitive, DNA-based method for the detection of rare point mutations. The method relies on selective PCR amplification of a mutation using a primer with more mismatches to wild-type than mutant DNA. ACB-PCR also uses a non-extendable blocker primer with more mismatches to mutant than wild-type DNA to reduce the signal produced from wild-type template. Mutant and wild-type PCR products were mixed in ratios corresponding to mutant fractions of 10<sup>-2</sup> to 10<sup>-4</sup> and compared with a no-mutant control of only wild-type PCR product. Reaction conditions were varied systematically until the assay routinely distinguished between the no-mutant control and the 10<sup>-4</sup> mutant faction. Thus, the ACB-PCR assay can quantify *p53* mutation

within a 10, 000-fold excess of wild-type allele. To characterize the utility of the assay, eight SSL-induced SSCs were analyzed for p53 codon 270 CGT to TGT mutation. Genomic DNA from tumors was used to synthesize a PCR product identical to the mutant and wild-type standards. Equivalent copies of each PCR product were then analyzed in parallel with mutant fraction standards. In three independent ACB-PCR experiments, the p53 mutant fraction in each sample was measured relative to a standard curve constructed from the mutant fraction standards. The p53 mutation was detected as a subpopulation in each of the eight tumor DNAs analyzed. Specifically, three SSCs had p53 mutant fractions between  $10^{-3}$  and  $10^{-3}$ . Five SSCs had p53 mutant fractions between  $10^{-3}$  and  $10^{-2}$ . These results demonstrate that ACB-PCR can be used to quantify p53 codon 270 CGT to TGT mutation and this mutation may be a useful biomarker for studying tumor induction and progression in response to SSL.

## 862 CYCLIC N-TERMINAL HEMOGLOBIN ADDUCT IN HUMANS, RATS AND MICE EXPOSED TO BUTADIENE.

N. I. Georgieva, G. Boysen, Y. Li and J. A. Swenberg. Environmental Sciences and Engineering, UNC, Chapel Hill, NC.

1, 3-Butadiene (BD) is an industrial chemical that is carcinogenic in rodents and probably humans. BD is oxidized by P450 to 1, 2:3, 4-diepoxybutane (DEB), the most mutagenic BD metabolite. DEB reacts with N-terminal valine in hemoglobin, forming the cyclic adduct (2, 3-dihydroxypyrrolidin-1-yl)-3-methybutanoic acid (pyrV), a potential biomarker that is specific for DEB. Sensitive isotope dilution mass spectrometric assays were developed to measure pyrV in globin from mice, rats and humans, exposed to BD or DEB. The procedure uses trypsin hydrolysis of globin, immunoaffinity (IA) purification of peptides (with antibodies specifically raised against the adducted human peptide), and quantitation of the N-terminal heptapeptides by capillary LC-ESI-MS/MS. The necessary internal standards (IST, D<sub>3</sub> labeled) for each species were synthesized and characterized by ESI-MS/MS sequencing. Quantitation was performed by LC-ESI-MS/MS in SRM mode, using both singly and doubly charged ions. This method readily detects 25 fmol of human analytical standard on column. The overall recovery was 50-90% for in vivo samples. Preliminary results show that the pyrV adduct was below the detection limit in 10 BD workers with exposures ranging from 0.1 to 4.2 mg/m<sup>3</sup> when 200 mg of globin was processed. In samples from rats exposed to 2.5 and 5 ppm DEB (4 weeks), the adduct was measured at 1.6 and 2.5 pmol/mg globin, respectively (using the human IST). In rats exposed to 1000 ppm BD (90 days) the amounts of pyrV adducts were 3-4 times lower than in the DEB exposed rats. In mice exposed to 62.5 ppm BD (4 weeks) and 1250 ppm BD (10 days) the amounts were 0.1 and 2.5 pmol/mg globin, respectively. These results provide preliminary data on the use of pyr-V as a specific and selective biomarker for internal exposure to DEB. This novel biomarker represents a useful tool to study differences in the metabolism and carcinogenicity of BD in mice, rats and humans, as well as potential gender differences and possible effects of genetic polymorphisms.

# 863 DETERMINING A REFERENCE VALUE FOR BLOOD CHOLINESTERASE USING US DEFENSE DEPARTMENT PERSONNEL.

S. A. McCurdy<sup>1</sup>, J. D. Henderson<sup>2</sup>, D. E. Arrieta<sup>2</sup>, L. J. Lefkowitz<sup>3</sup>, R. E. Reitstetter<sup>4</sup> and <u>B. W. Wilson<sup>2</sup></u>. <sup>1</sup>Epidemiology and Preventative Medicine, University of California, Davis, CA, <sup>2</sup>Environmental Toxicology, University of California, Davis, CA, <sup>3</sup>US Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD and <sup>4</sup>Clinical Investigation, Brooke Army Medical Center, San Antonio, TX.

The use of pesticides and threats of chemical warfare establish the need for high throughput reliable standardized determinations of blood cholinesterase (ChE) as early warnings of exposure. The US Army Center for Health Promotion and Preventive Medicine (CHPPM) uses a  $\Delta pH$  method based on that of Michel for the determination of red blood cell cholinesterase levels in humans. With it they monitor approximately 25, 000 DOD personnel annually. Our goal is to establish a normal range of blood ChE using ΔpH data. Blood specimens from 991 Department of Defense personnel without a potential exposure to anticholinesterase agents enrolled in a required occupational health screening program were statistically analyzed. The median age was 43 years (range 18-76). 823 specimens (82.1 %) were from men. Men were on average older than women (median age 44 vs 37 years, p<0.0001, Wilcoxon test). The mean  $\pm$ SD for  $\Delta$ pH was 0.75  $\pm$ 0.06 units.  $\Delta$ pH values were greater for men than for women (0.74 vs. 0.73, p<0.0006, Wilcoxon test). Multivariate linear regression analysis showed an association for  $\Delta pH$  with age (slope +0.0008  $\Delta pH$  units for each year of age, p<0.001). There was a small, but statistically significant, reduction in  $\Delta pH$  associated with test date (-0.006  $\Delta pH$  units per 100 days, p<0.001). A multiple regression model incorporating age, gender, and test date explained only 3.4% of the observed variance. The small magnitude of these effects and their minimal role in accounting for

the observed variability suggest it appropriate to ignore such factors when evaluating  $\Delta pH$  data. The next step in our project is to correlate the  $\Delta pH$  values with those from the more commonly used colorimetric Ellman test. Supported by DOD (DAMD17-01-1-0772), NIOSH (#CDC U07/CCU906162-06) and NIEHS (#ESO5707).

# 864 IDENTIFICATION OF INTER-INDIVIDUAL VARIATION IN AFLATOXIN METABOLIZING ENZYMES USING HUMAN URINARY DNA.

B. Dash, E. Afriyie-Gyawu, W. Porter, H. J. Huebner and T. D. Phillips. Faculty of Toxicology (VAPH), Texas A&M University, College Station, TX.

Aflatoxin B<sub>1</sub>(AFB<sub>1</sub>) is a factor in the etiology of hepatocellular carcinoma (HCC). Xenobiotic metabolizing enzymes (XMEs) such as mixed-function oxidases, microsomal epoxide hydrolases (mEH) and glutathione S-transferases (GSTs) are involved in the metabolism of AFB<sub>1</sub>. It has been shown that AFB<sub>1</sub>-albumin adduct levels may be modified by mEH and GST genotypes. Moreover, it has been hypothesized that inherited differences in DNA sequence of mEH and GST genes influence an individual's risk of HCC in response to AFB<sub>1</sub>. In order to study genetic differences in these XMEs, a simple and non-invasive DNA extraction procedure was followed. Quantifiable amounts of DNA (9.5-573 ng ml-1 urine) were extracted from ≤4.5 ml of urine from AFB<sub>1</sub>-exposed individuals and amplicons of 162 bp and 357 bp were generated for single nucleotide polymorphism (SNP) analysis of mEH exon 3 (Y113H) and exon 4 (H139R), respectively, by PCR-RFLP. In a single run, 49 (55%) and 71 (79%) of 89 samples were genotyped for mEH exon 3 and exon 4 polymorphisms, respectively. For mEH exon 3 SNP typed, there were 37 wild types (113YY), 11 heterozygotes (113YH) and 1 homozygote (113HH). All individuals SNP typed for mEH exon 4 were heterozygotes (139HR). Urinary DNA was also analyzed by multiplex-PCR to identify deletion polymorphisms in GSTM1 and GSTT1 genes using a fragment of the albumin gene as an internal control. Presence or absence of amplicons of 215 bp (GSTM1) and 450 bp (GSTT1) were indicative of gene polymorphisms. A total of 62 of 89 individuals were genotyped for GSTM1 and GSTT1 polymorphisms. Twenty-one and 48 individuals were found to be GSTM1 and GŜTT1 null respectively, while 20 individuals were doubly null. These results suggest that exfoliated nucleated cells in urine can be a significant source of DNA and may be useful as a non-invasive method for assessing the genetic susceptibility of AFB, exposed populations to HCC (Supported by USAID LAG-G-00-96-90013-00, NIEHS P42-ES04917, and NIÊĤS Center Grant ES09106).

## 865 NEW APPROACH FOR MONITORING EXPOSURE TO ENVIRONMENTAL TOXIC AGENTS.

T. Berman-Shlomovich and <u>University. Wormser</u>. Institute of Life Sciences, Ierusalem, Israel.

One of the major limitations of the current methods of biological detection of exposure to hazardous environmental agents is their inability to detect long-term exposures, and exposures that occurred in the past without immediate clinical effects. In the current study we examined the potential of a new bioassay that is based on the hypothesis that serum of exposed individuals contains a toxic factor or factors produced by an affected cell or tissue in response to an exposure. In the present study PC12 cell cultures were exposed to serum samples of rats treated with the organophosphate chlorpyrifos. We observed a decrease of up to 31.8% and 40% in cell viability and nerve growth factor-induced neurite outgrowth, respectively, in PC12 cells treated with serum of chlorpyrifos-exposed rats, in comparison to cells treated with serum of control rats. Maximal effect was observed for both parameters 4 weeks after exposure whereas motor activity and cholinesterase activity returned to normal levels within one week after the exposure; thereafter the rats showed no signs of toxicity, including 4 weeks post-exposure. These results demonstrate the potential of the proposed method to detect environmental exposures long after they have occurred.

EVALUATION OF TWO COMMERCIALLY AVAILABLE CARDIAC TROPONIN IMMUNOASSAYS FOR THE DETECTION OF DRUG-INDUCED CARDIOTOXICITY IN RATS.

C. Bozynski<sup>1</sup>, A. Lambert<sup>2</sup>, J. Lugo<sup>2</sup>, J. D. VanNess<sup>2</sup>, C. LaBare<sup>2</sup>, J. R. Sibley<sup>2</sup> and D. B. Walker<sup>2</sup>. <sup>1</sup>Faculty of Veterinary Medicine, University of Montreal, Saint Hyacinthe, QC, Canada and <sup>2</sup>Drug Safety, Wyeth Research, Chazy, NY. Sponsor: <u>F. Kirchner</u>.

Cardiac troponin I (cTnI) and T (cTnT) are established tissue-specific biomarkers of acute myocardial injury in humans. To determine the relative value of cTnI (DPC Immulite) or cTnT (Roche Elecsys) for detection of drug-induced car-

diotoxicity in rats, serum concentrations of these analytes were measured in male rats given doxorubicin using both acute and chronic dosing protocols. These levels were compared with concentrations of standard serum chemical markers of tissue injury (e.g., LDH, CPK), light microscopic findings and immunohistochemical staining of cTn1 and cTnT in the myocardium. Results demonstrated good correlation between measurable serum TnT levels and doxorubicin-induced myocardial degeneration in rats. Correlations were less robust between histologically observed cardiac lesions and serum Tn1 levels, or the other serum markers evaluated. Immunohistochemistry of heart sections for either Tn1 or TnT demonstrated diffuse staining of the myocardium with attenuated, or absent staining of the degenerate myofibers indicating that cTn1 and cTnT immunostaining of the myocardium can complement light microscopy in delineating foci of injury. In summary, evaluation of serum cardiac troponin T appears to be valuable for detection of some types of drug-induced cardiotoxicity in rats.

#### 867

COMPARISON OF UNCHANGED n-HEXANE IN ALVEOLAR AIR AND 2, 5-HEXANEDIONE IN URINE FOR THE BIOLOGICAL MONITORING OF n-HEXANE EXPOSURE IN HUMAN VOLUNTEERS.

G. Hamelin<sup>1</sup>, G. Truchon<sup>2</sup> and <u>R. Tardif</u><sup>1</sup>. <sup>1</sup>Occupational and Environmental Health, University of Montreal, Montreal, QC, Canada and <sup>2</sup>IRSST, Montreal, QC, Canada.

Biological monitoring of exposure to n-hexane (HEX) is based on the measurement of free urinary 2, 5-hexanedione (2, 5-HD) (no hydrolysis). The current ACGIH biological exposure index (BEI) value (3.5 µmol/L) was derived from 4 field studies involving worker exposures to variable concentrations of HEX and to other solvents. This study was undertaken to characterize, for 5 consecutive days, the relationship between HEX exposure (25 and 50 ppm) and 1) 2, 5-HD urinary excretion and, 2) HEX in alveolar air. Five volunteers (3 women and 2 men) were exposed to HEX in an exposure chamber for 2 non consecutive weeks (7 hours/day). They were exposed to 50 ppm HEX, during the first week, and to 25 ppm during the second week. Unchanged HEX in alveolar air, and urinary 2, 5-HD (with or without acid or enzymatic hydrolysis) were measured. Concentrations of HEX in alveolar air were 18 ppm (25 ppm) and 37 ppm (50 ppm) which shows that 73% of inspired HEX was excreted unchanged. The urinary 2, 5-HD concentrations (mean ± standard de viation) for the last 4 hours of exposure (day 5) following exposure to 50 ppm HEX were  $30.4 \pm 7.8 \,\mu \text{mol/L}$  (acid hydrolysis),  $5.8 \pm$ 1.0  $\mu$ mol/L (enzymatic hydrolysis) and 6.2  $\pm$  0.9  $\mu$ mol/L (without hydrolysis). Following exposure to 25 ppm HEX, the urinary concentrations were 15.2  $\pm$  1.9  $\mu mol/L$ ,  $3.1\pm0.7~\mu mol/L$  and  $3.7\pm0.5~\mu mol/L$ , respectively. The 2, 5-HD value measured in this study following exposure to 50 ppm (6.2  $\mu$ mol/L), which is higher (X1.8) than the average value reported in field studies better reflects the levels of exposure to HEX alone. Inter-ethnic differences caused by genetic polymorphism, and/or metabolic interferences due to co-exposure to other solvents are likely responsible for the lower 2, 5-HD values measured in previous field studies. In conclusion, the current BEI value for HEX is most likely more protective than what has been believed up until now. (Supported by IRSST, Quebec, Canada)

#### 868

URINARY 3-BROMOPROPIONIC ACID: AN EFFECTIVE GAS CHROMATOGRAPHIC TEST METHOD FOR OUANTIFICATION.

C. B'Hymer<sup>1</sup> and <u>K. L. Cheever</u><sup>2</sup>. <sup>1</sup>BHAB, NIOSH, Cincinnati, OH and <sup>2</sup>BHAB, NIOSH, Cincinnati, OH.

3-Bromopropionic acid is a metabolite and possible biomarker for exposure to 1bromopropane. 1-Bromopropane is used as an industrial solvent and exposure is a health concern for industrial workers due to its toxicity. Central neurological disorders and peripheral neuropathy has been reported in workers chronically exposed to materials composed of 1-bromopropane in the United States and animal studies have shown reproductive toxicity. Occupational exposure to this widely used industrial solvent is likely, since it is readily absorbed through the skin. A simple and effective general test method for 3-bromopropionic acid in urine samples was developed to monitor any exposed population. Urine specimens were first spiked with 3-chloropropionic acid which was used as a procedural internal standard. The samples were extracted with ethyl acetate, concentrated, and treated with N-methyl-N-[tert-butyldimethylsilyl] trifluoroacetamide (MTBSTFA) to produce the corresponding t-butyldimethylsilane derivatives of 3-bromopropionic acid and the internal standard. Quantification was by means of a gas chromatograph (GC) equipped with a mass selective detector (MSD) using a 50-m X 0.20-mm (id) HP-1 capillary column. A temperature program of 60 to 255oC was used for the gas chromatographic measurement. Ion m/z 211 was monitored for the derivative of 3bromopropionic acid and ion m/z 165 was monitored for the internal standard. Average recovery of known 3-bromopropionic acid fortified blank urine samples was between 93-98% with relative standard deviations as high as 5.7% using samples at 3-bromopropionic concentrations of 2, 10, 20 and 50  $\mu g/ml$  . The limit of detection (LOD) for the developed procedure was found to be approximately 0.01 μg/ml in urine.

CREATININE ADJUSTED URINARY EXCRETION OF 3, 5, 6-TRICHLOROPYRIDINOL (TCP) BY CHILDREN AGED 4 TO 12 AND THEIR PARENTS.

R. I. Krieger<sup>3,1,2</sup>, M. R. Oliver<sup>3,1</sup>, R. L. Williams<sup>2,3,1</sup> and X. Zhang<sup>2,3,1</sup>.

<sup>1</sup>Department of Entomology, University of California, Riverside, Riverside, CA,

<sup>2</sup>Environmental Toxicology Graduate Program, University of California, Riverside, Riverside, CA and <sup>3</sup>Personal Chemical Exposure Program, University of California, Riverside, Riverside, CA.

Complete 24-h urine samples are less often available in exposure studies than spot samples, especially for young children. Thus urinary creatinine (Cn) is useful to estimate 24-h urine volume with norms of 1.7 g/day for adult males and 1.0 g/day for adult females (ICRP, 1994). With biomarker expressed as ug /g Cn and Cn norms, daily biomarker excretion can be estimated. The relationship of daily urinary Cn excretion and age for children is not verified in exposure assessment. Cn excretion to age 12 increases at a rate of 0.08 g/year of age (Krieger, 2001). This study will clarify the relationship of Cn excretion to age and evaluate its use in pesticide exposure studies. In 2001, 42 children below 12 yrs from 13 California and 10 Missouri families and 36 California persons (>12 years of age) were recruited to participate a pesticide exposure study in which 6 consecutive 24-h urine specimens were collected. Urinary Cn was measured for all samples and TCP as a biomarker of chlorpyrifos (CP) was analyzed for the California samples. The increase of Cn excretion rate for children aged 4 to 12 was 0.075 g/year of age. The linear regression equation is urinary Cn =  $0.075 \times age - 0.035$  (R2 = 0.71). Using this factor, urinary TCP was adjusted and the absorbed daily dosage (ADD) of CP equivalents was calculated. ADD of CP equivalents based on 24-hour urine volumes correlates with the Cn-adjusted ADD (R2 = 0.80). The ADDs for Cautrorna addus and Simple Secretion for children aged 4 to 12 increased 0.075 g Cn/yr. This factor can be used to estimate 24-h urine volume from spot samples. This procedure may help resolve ongoing concerns about children's pesticide exposures.

DETERMINATION OF ETHYL GLUCURONIDE IN BIOLOGICAL MATRICES USING REVERSED-PHASE HIGH PERFORMANCE LIQUID CHROMATOGRAPHY COUPLED WITH ELECTROCHEMICAL DETECTION.

R. Kaushik<sup>1, 2, 3</sup>, W. R. LaCourse<sup>2</sup>, B. Levine<sup>3, 1</sup> and <u>K. Squibb<sup>1</sup>. <sup>1</sup> Toxicology, University of Maryland, Baltimore, Columbia, MD, <sup>2</sup> Chemistry, University of Maryland, Baltimore County, Baltimore, MD and <sup>3</sup> Office of the Chief Medical Examiner, Baltimore, MD.</u>

Currently no method exists to distinguish between ethanol levels detected in biological matrices due to alcohol consumption versus ethanol production after death as a result of decomposition. Ethyl glucuronide (EtG) is a non-volatile, water-soluble metabolite of ethanol that can serve as a biological marker of alcohol consumption. It is a highly sensitive and specific alcohol consumption marker that can be detected for up to 80 hours after alcohol elimination from the body. This has very important clinical and forensic applications. The current study involved developing a method for the detection of EtG in postmortem urine and blood samples using reversed-phase liquid chromatography with electrochemical detection. Methyl glucuronide served as the internal standard. The mobile phase consisted of 1% acetic acid/water and acetonitrile (98:2), with a 600mM sodium hydroxide post-column system attached to enable pulsed electrochemical detection (PED). This amperometric detection technique applies alternated positive and negative potential pulses at a noble metal electrode. The analyte is oxidized followed by oxidative and reductive cleaning steps. The analyte concentration is determined by measuring the electric current resulting from the molecule gaining or losing electrons. In order to separate EtG from the biological matrix a solid-phase extraction (SPE) was developed using aminopropyl columns after deproteination with hydrochloric acid. EtG was found to have a retention time of 5.3 minutes with LOQ and LOD values of 58 and 11 ug/mL respectively. The range of EtG found in postmortem samples was 3 to 700 ug/mL. Compound recovery following SPE was approximately 50%. This method showed good reproducibility and sensitivity. It is now available as a tool to clinical and forensic toxicologists for determining levels of alcohol consumption in live and deceased individuals.

871 2'-MOE ANTISENSE OLIGONUCLEOTIDES STIMULATE A PROINFLAMMATORY RESPONSE BY A TLR9-INDEPENDENT MECHANISM.

J. J. Senn, S. Burel, R. Kadri, T. Pham and <u>S. Henry</u>. *Toxicology, ISIS Pharmaceuticals, Carlsbad, CA*.

Oligos with a bacterial-like "CpG" have been shown to trigger proinflammatory responses by activating the Toll-like receptor (TLR)-9. Oligos with CpG motifs have been developed to exploit this process for use as adjuvant and cancer therapies. However, oligos intended for antisense applications (ASOs) are designed to avoid

these proinflammatory responses by avoiding CpG motifs and using chemical modifications (i.e., 2'-MOE sugars and methylated cytosine residues). Although modified, ASOs are capable of eliciting a proinflammatory response in rodents at high doses. To determine if this phenomena is TLR-mediated, wild type, TLR9 and MyD88 knockout mice were treated with a CpG optimal oligo 12449, and several non-CpG ASOs. The non-CpG ASO compounds appear to have a lower potency to induce proinflammatory effects requiring a 10-fold higher dose. The inflammatory response in knockout animals to 12449 was TLR9 dependent while non-CpG ASO compounds still activated a proinflammatory response indicated by increased spleen weight and the expression of proinflammatory genes. These data implicate a TLR9-independent mechanism of action by non-CpG ASO at high concentrations. Isolated bone marrow from wild type and knockout animals treated with non-CpG ASOs responded similar to the whole animal, with production of MIP-2 and activation of MAPK pathways. We have characterized an *in vitro* system using mouse macrophage cell line RAW 264.7, that exhibit a dose-dependent increase in both ERK1/2 and p38 activation in response to treatment with ASOs, suggesting a receptor-mediated event. After 3 hr of exposure, RAW 264.7 cells release MIP-2 and MIG, and TNF $\alpha$  into the culture media. Also, to begin to investigate species specificity, we have examined a human macrophage cell line, U937, this cell line responds in a dose-dependent manner to ASOs treatment by activating ERK1/2 and JNK. These data suggest that there is a TLR9-independent mechanism for the stimulation of a proinflammatory response in mice to high dose non-CpG ASO treatment and that this mechanism is likely a receptor-mediated phenomenon.

872

DISTINCTIVE EFFECTS OF TOLL-LIKE RECEPTOR LIGANDS AND ETHANOL *IN VIVO*, *IN VITRO*, AND IN A MACROPHAGE CELL LINE: IMPLICATIONS FOR SIGNALING MECHANISMS.

Q. Zheng, R. Fan, C. Schwab and <u>S. B. Pruett</u>. Cell. Biol. & Anatomy, LSU Health Sciences. Center, Shreveport, LA.

A number of important events in innate immunity are initiated through toll-like receptors (TLRs), and the macrophage-like cell line RAW 264.7 has been extensively used to delineate signaling pathways involved in the induction of various responses. Thus, it is important to determine if the responses of these cells correspond to responses of normal macrophages (or other cell types) in vivo or in vitro. In other studies, we have determined that most of the cytokines measured in peritoneal lavage fluid are not derived from blood and were likely produced locally in the peritoneal cavity. Thus, the effects of two TLR ligands (LPS, a TLR 4 ligand and poly I:C, a TLR 3 ligand) and an inhibitor of TLR signaling (ethanol) were examined in vivo, with peritoneal macrophages in vitro and with RAW 264.7 cells in vitro. The results suggest that there are important differences in TLR signaling between peritoneal macrophages in vivo and in vitro compared to RAW 264.7 cells in vitro. In response to poly I:C, peritoneal fluid IL-10 was low (20-100 pg/ml), and IL-12 was higher (150-300 pg/ml). Ethanol given at the same time as poly I:C had no effect or increased IL-10 and decreased IL-12 concentrations. In contrast, IL-10 concentrations from peritoneal macrophages or RAW 264.7 cells in culture were much higher than IL-12 concentrations in response to poly I:C (4000-7500 pg/ml vs. <100 pg/ml). A similar pattern was noted at earlier time points in culture (4 vs. 24 hr), and a similar pattern was noted for serum concentrations of IL-10 and IL-12 in comparison with concentrations in spleen cell cultures. Ethanol did not produce the same types of effects on cytokine concentration in vivo as in vitro. These results suggest that there are fundamental differences in regulation of cytokine production in vivo and in vitro and that this should be considered in interpreting results from experiments using in vitro systems. This work was supported by a grant from NIAAA (ES09505).

873

PRE-ACTIVATION OF TOLL-LIKE RECEPTORS SENSITIZE MACROPHAGES TO INDUCTION OF PROINFLAMMATORY CYTOKINE GENE EXPRESSION BY DEOXYNIVALENOL AND OTHER MICROBIAL TOXINS.

J. J. Pestka<sup>1, 2</sup> and H. Zhou<sup>1</sup>. <sup>1</sup>Food Science and Human Nutrition, Michigan State University, East Lansing, MI and <sup>2</sup>Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI.

Stimulation of the innate immune response has the potential to increase sensitivity to xenobiotics. Asynchronous sensitization by LPS and/or other Toll-Like Receptor (TLR) agonists to induction of the proinflammatory cytokines IL-1 beta, IL-6, and TNF-alpha expression by the trichothecene deoxynivalenol (DON) and other biological toxins was investigated in primary and cloned murine macrophage models. Pretreatment of peritoneal murine macrophages or RAW 264.7 cells with the TLR-4 agonist LPS (100 ng/ml) for 16h markedly increased DON-induced IL-1 beta mRNA expression and to a lesser extent IL-6 and TNF-alpha mRNA expression. The effects of DON were dose-ldependent. In addition to LPS, similar results were

observed for other TLR agonists including zymosan (TLR2), poly [I:C] (TLR3), flagellin (TLR5), R848 (TLR 7/8) and ODN 1826 (TLR9). Furthermore, increased IL-1 beta and IL-6 mRNA expression was found in LPS-sensitized RAW 267.4 cells that were exposed to microbial toxins satratoxin G, zearalenone, ochratoxin A and Shiga toxin as compared to cells treated with LPS or the toxins alone. Taken together, the results indicate that a TLR activation sensitizes macrophages to trichothecenes and other natural toxins.

## 874 GALLIUM ARSENIDE EXPOSURE UPREGULATES INFLAMMATORY CYTOKINE EXPRESSION.

K. McCoy, S. Becker, T. Harrison and C. Hartmann. Microbiology & Immunology, MCV Campus/Virginia Commonwealth University, Richmond, VA.

The semiconductor, gallium arsenide (GaAs), is classified as an immunotoxicant and a carcinogen. We previously showed that GaAs in vivo induces several phenotypic changes in macrophages located at the exposure site, indicative of an activated state. To discern primary consequences, macrophage cell lines and murine peritoneal macrophages were exposed to the chemical in vitro. In culture, GaAs augmented invariant chain protein expression, and proteolytic activities and mRNA expression of cathepsins L and B. However, GaAs did not alter cell surface expression of major histocompatibility complex class II molecules on the macrophages, nor influence their ability to stimulate antigen-specific helper T cell s to respond to intact antigens that require processing. In vitro GaAs exposure did not completely mirror in vivo exposure, suggesting that other cells or factors may be involved. We examined the role of cytokines in GaAs-mediated macrophage activation. Blood monocytes were rapidly recruited to the exposure site, and the chemokine MCP-1 was present in the sera of exposed mice. The mRNA of seventeen chemokines and inflammatory cytokines were upregulated, while transcripts of three inhibitory cytokines diminished. Administration of latex beads caused less cytokine induction than GaAs, indicating that changes in mRNA levels could not be attributed to phagocytosis alone. Four cytokine proteins examined were mainly produced by myeloid cells. In vivo GaAs exposure alters cytokine gene expression which may lead to an inflammatory reaction and contribute to pathological tissue damage. This work was supported by NIEHS grant ES07199, and M. T. Harrison was supported by training grant T32 ES07087.

# 875 ETHANOL IS A GENERALIZED MODULATOR OF CYTOKINE PRODUCTION INDUCED THROUGH TOLL-LIKE RECEPTORS AND INHIBITS EARLY AS WELL AS LATE SIGNALING EVENTS.

C. Schwab, R. Fan, Q. Zheng, Q. Dai and <u>S. B. Pruett</u>. Cell. Biol. & Anatomy, LSU Health Sciences. Center, Shreveport, LA.

Toll-like receptors play an important role in the recognition and eventual elimination of pathogens. Once a ligand is recognized a series of signaling events begin resulting in the synthesis of proinflammatory cytokines. Previous experimentation has shown that ethanol can inhibit the ability of toll-like receptor 3 (TRL3) to induce cytokines in response to poly I:C. In this study, the effects of ethanol on cytokine production induced through TLR2, TRL3, TLR4, TLR6, TLR7, and TLR9 were examined and the mechanism by which ethanol inhibits the production of proinflammatory cytokines was examined. ELISA data indicate that serum and peritoneal cytokine levels (IL-12 and IL-6) were elevated in mice treated with a ligand alone, however, when ethanol is given in conjunction with the ligand proinflammatory cytokine production was suppressed. RNAse protection assay results indicate that in both purified and unpurified peritoneal macrophages IL-12, IL-6, IL-10, IL-15, INF-alpha, INF-beta, and INF-gamma levels are increased upon exposure to the ligand poly I:C, and this is significantly decreased, with the exception of IL-10, by ethanol. Proteins isolated from peritoneal macrophages were analyzed by Western blot. Western blot data suggest that ethanol decreases signaling early in the toll like receptor pathway. Inter/extra cellular flow cytometric data also suggest phosphorylation of p38, a kinase activated late in the signaling pathway, is decreased in macrophages exposed to ethanol. These data have implications with regard to human health, as the consumption of ethanol is prevalent, and the exposure to TLR ligands is unavoidable. This work was funded by a grant from NIAAA (AA09505).

## 876 METALLOTHIONEIN CAN FUNCTION AS A CHEMOTACTIC FACTOR.

X. Yin, D. A. Knecht and M. A. Lynes. Molecular and Cell Biology, University of Connecticut, Storrs, CT.

Mammalian cells respond to environmental stress by producing an array of stressresponse proteins. One of these (metallothionein, MT), is a low molecular weight, cysteine-rich protein that can be induced by a variety of stressors, including heavy metals, organic solvents, free radicals, irradiation, and acute phase cytokines. MT sequesters toxic heavy metals, serves as a reservoir of essential divalent metal cations, regulates cellular redox status, and can modulate transcription factor activity. As a consequence, MT can regulate specific immune functions. We have noticed that the human and mouse genes which encode MT map close to the chemokines Ccl17 and Cx3Cl1. CC, CXC, and CX3C motifs that characterize chemokines are also found in the MT sequence. These observations suggested that MT might also act as a chemokine. In the experiments reported here, we show that MT can act as a chemokine for both Jurkat T cells and by cloned myeloid cells (WBC 264 9-C cells) using both the microBoyden chamber assay and the ECIS/taxis assay. This response can be blocked by two different monoclonal anti-MT antibodies (clones UC1MT and E9). Pre-incubation of Jurkat T cells with MT suppresses the response of these cells to SDF-1a, but MT does not change CXCR4 levels (the receptor for SDF-1a) on the surface of those cells. We interpret these results to suggest that MT may compete with SDF-1a and thus interfere with the SDF-1a chemotactic response. Incubation of Jurkat T cells with 2mg/ml Cholera toxin completely abrogates the chemotactic response of those cells to MT. This suggests that MT may bind to G-protein coupled receptors as it stimulates chemotaxis. These results indicate that MT that is produced in the context of exposure to environmental toxicants and released from cells may alter immune capacity in part by disturbing normal chemotactic responses. Thus, inappropriate MT synthesis may represent an important susceptibility factor in toxicant-mediated immunomodulation.

# 877 ENHANCED PROINFLAMMATORY CYTOKINE PRODUCTION BY ACTIVATED MICROGLIAL AND MACROPHAGE CELL LINES EXPOSED TO MANGANESE *IN VITRO*.

P. L. Crittenden and N. M. Filipov. CEHS, Basic Sciences, Mississippi State University, Mississippi State, MS.

Activated microglia and/or astrocytes have been proposed to play a role in the mechanism of manganese (Mn) neurotoxicity such that neurons adjacent to activated microglia could be injured by proinflammatory cytokines and reactive oxygen species elaborated from the microglia. Recently, we demonstrated that Mn greatly potentiated the LPS (lipopolysaccharide)-induced proinflammatory cytokine (IL-Îβ, IL-6, and TNF-α) production by the microglial cell line, N9. Because (i) Mn exposure may also potentiate proinflammatory cytokine production in the periphery, (ii) there are functional differences between brain microglia and peripheral macrophages, and (iii) peripheral inflammation contributes to/modulates the inflammatory response in the brain, our objective was to compare the influence of Mn on proinflammatory cytokine production by N9 microglia and J774 macrophage cell lines. Cells were exposed in vitro to increasing concentrations (up to 500 µM) of Mn (as MnCl<sub>2</sub>) in the presence or absence of LPS (up to 1000 ng/ml). Following 24 h incubation, supernatants were collected and IL-1β, IL-6, and TNF-α concentrations were determined by ELISA. Similar to the effects already observed in N9 microglia, LPS-induced proinflammatory cytokine production was potentiated dose-dependently by Mn in the J774 macrophage cell line. This finding suggests that Mn augments proinflammatory cytokine production through a common mechanism which is now the subject of investigation. Considering that Mn exposure is not confined to the nervous system, increased inflammatory response in the periphery may be contributory to the mechanism of Mn neuro- and, possibly, systemic toxicity. (Supported by NIEHS ES11654).

## 878 THE EFFECTS OF INDIRUBIN ON GENE EXPRESSION PROFILES IN U937 HUMAN MONOCYTE/MACROPHAGES.

A. E. Becker and C. D. Rice. Biological Sciences, Clemson University, Clemson, SC.

The AhR is a ligand-activated transcription factor that alters the expression of a variety of genes relevant to toxicology and immunology. Although the AhR remains an orphan receptor, many synthetic ligands, including co-planar HAHs and TCDD, activate its specific signaling pathways. The immunotoxicity of TCDD and coplanar HAHs is fairly well characterized. However, the immunomodulatory properties of plant-based AhR ligands are just now being characterized. Indirubin (IR), a metabolite of tryptophan, can be synthesized by gut flora and is the active ingredient in an ancient Chinese remedy from Polygonum tinctgorium used to treat leukemia, used as an anti-inflammatory agent, and used to enhance detoxification processes. Despite its historical use, little is known about the effects of IR on immune function. Since TCDD and coplanar PCBs are potent immunotoxic agents, IR may have similar effects on the immune system. We treated U937 cells with IR in four different regimes representing both undifferentiated and differentiated steps in macrophage development, then monitored gene expression profiles using a macroarray for select stress and toxicity related genes. We monitored (1.) un-differentiated U937 cells treated with IR or carrier control (CC), (2.) IR or CC followed by PMA-induced differentiation to macrophages, (3.) differentiated cells activated with LPS treated with IR or CC, and (4.) differentiated cells treated with IR or CC. Regimes 1, 2 and 3 resulted in CYP1A1 inductions of 12.7, 3.24, and 4.52 fold, respectively, supporting other findings that IR is a potent AhR ligand. COX-2 was significantly decreased in regime 2, as was iNOS in regime 3, suggesting that IR has anti-inflammatory properties. Macroarray validity was confirmed by RT-PCR on select genes. We also show that IR also induces indoleamine diooxygenase in differentiated U937 cells, suggesting an indirect of IR on immune function. Overall, our data provide evidence that IR may be a highly immunotoxic plant-based AhR ligand.

879 EFFECTS OF SELECT PARTICULATE MATTER (PM)ASSOCIATED METALS ON MACROPHAGE (Μφ) IRON
HOMEOSTASIS.

S. P. Doherty<sup>1</sup>, C. Prophete<sup>1</sup>, <u>J. Zelikoff</u><sup>1</sup>, P. Maciejczyk<sup>1</sup>, <u>K. Salnikow</u><sup>2</sup>, T. Gould<sup>3</sup>, T. Larson<sup>3</sup>, P. Jaques<sup>4</sup>, <u>J. Koenig</u><sup>3</sup>, C. Sioutas<sup>5</sup>, M. Lippmann<sup>1</sup> and <u>M. Cohen</u><sup>1</sup>. <sup>1</sup>Env Med., NYU, Tuxedo, NY, <sup>2</sup>NCI, Bethesda, MD, <sup>3</sup>University of Washington, Seattle, WA, <sup>4</sup>UCLA, Los Angeles, CA and <sup>5</sup>USC, Los Angeles, CA.

Analyses of fine airborne PM25 samples collected during fall 2001 indicate significant differences between the average daily PM levels in New York City (NYC), Los Angeles (LA), and Seattle (S). XRF analyses indicated that the inorganic composition of the PM varied from city to city, both in terms of absolute amounts of individual elements and their mass relationships to one another. Sulfur levels (as ng/m<sup>3</sup>) were consistently the highest of 29 elements measured in each city's samples; however, concentrations of all other elements were very dissimilar. In NYC PM, the next most present elements were Fe, Si, Na, Ca, Al, and K. The second most prominent metal in LA and S PM was Na, followed by Si, Fe, Al, K, Ca and Cr in LA, and Fe, K and equal amounts of Cl and Si in S. We hypothesized that relative molar/mass relationships between select PM metals and Fe might govern the pulmonary immunotoxic potential of a given day's (or city's) PM by affecting alveolar Mφ iron status, thereby altering their antibacterial/general functions. To test this, binding activity of iron response proteins (IRPs) in NR8383 rat Mø was assessed after exposure to select PM-associated metals (Fe, V, Mn and/or Al in the presence of apotransferrin). In all studies, relevant molar ratios of these metals, as found in a 500 µg sample of NYC PM for a specified day, were used. Results indicated that V, Mn and Al significantly changed the expression of IRP activity, although the effects were not consistently dose-dependent. Analysis of intracellular Fe status paralleled the IRP data for Mn and V, but not Al. The disruption in IRP binding activity, possibly as a result of competition for binding to the transferrin carrier, indicates that certain PM-associated metals might alter pulmonary immune competence in exposed hosts by impacting upon the Fe status of deep lung major defense cells. This work was supported by EPA/PM Center Grant R82735101.

## 880 EFFECTS OF PROPANIL (DCPA) ON THE NF-κB ACTIVATION PATHWAY IN MURINE MACROPHAGES.

I. Ustyugova<sup>1</sup>, K. M. Brundage<sup>1, 2</sup>, R. Schafer<sup>1</sup>, C. L. Walton<sup>1</sup> and J. B. Barnett<sup>1, 2</sup>. <sup>1</sup>Microbiology, Immunology and Cell Biology, West Virginia University, Morgantown, WV and <sup>2</sup>Mary Babb Randolph Cancer Center, West Virginia University, Morgantown, WV.

DCPA (3, 4-dichloropropionalide) is a post-emergent herbicide used extensively to control weeds in rice. Previous studies have demonstrated that treatment of the IC-21 macrophage cell line with DCPA resulted in changes of critical macrophage functions, such as decreases in cytokine production (TNF- $\alpha$ , IL-1 $\beta$  and IL-6). This appears to be due inhibition of the important transcription factor, NF-кB, as evidenced by reduced nuclear levels of NF-κB p65/p50 heterodimers as well as NF-κB p65/p50 DNA binding levels. To determine the cause of the decrease in nuclear levels of NF-κB, the molecules involved in the activation of NF-κB were studied. In unstimulated cells, NF-κB is bound to IκBα, IκBβ or IκBε, which conceal the nuclear localization sequence (NLS) of NF-кВ required for nuclear import. Upon activation, these IkBs are phosphorylated, ubiquitinated and then degraded by 26S proteosomes to expose the NLS of NF-KB, which is then actively translocated into the nucleus. Inhibition of IKB phosphorylation would prevent ubiquitination and subsequent proteosomal degradation of IkB that would result in decreased nuclear levels of NF-KB. Therefore, LPS-induced phosphorylation and degradation of  $I\kappa B\alpha$  in the cytosol was studied in DCPA treated cells by Western Blot. No differences in phosphorylation or degradation of  $I\kappa B\alpha$  were seen in DCPA-treated versus vehicle-treated cells, however, the kinetics of IκBβ degradation was delayed in DCPA-treated cells versus vehicle-treated cells. Moreover, the hypophosphorylated form of IkB $\beta$  is less pronounced in DCPA treated cells. These data provide evidence that DCPA affects the NF-KB activation pathway by changing the phosphorylation state of IκBβ, thereby interfering with its degradation and preventing NFκB shuttling to the nucleus. Supported by NIEHS grant ES11311.

881 SMAD3 MEDIATES SUPPRESSION OF T CELL RECEPTOR-INDUCED BUT NOT IL-2-INDUCED T CELL PROLIFERATION BY TGF-β1.

S. C. MCKARNS<sup>1</sup>, N. E. Kaminski<sup>2</sup> and R. H. Schwartz<sup>1</sup>. <sup>1</sup>Laboratory of Cellular and Molecular Immunology, NIAID/NIH, Bethesda, MD and <sup>2</sup>Deptartment of Pharmacology and Toxicology, Michigan State University, East Lansing, MI.

TGF-\$\beta\$1 plays a critical role in regulating immune homeostasis. It is well documented that TGF-\$\beta\$1 can impair T cell proliferation and IL-2 production; however, the mechanisms of suppression remain elusive. TGF-\$\beta\$1 signals through a transmembrane serine/threonine kinase receptor complex to activate Smad-dependent and -independent intracellular signaling cascades. We have previously shown that Smad3 is critical for suppression of IL-2 production by TGF-\$\beta\$1. Utilizing Smad3-deficient mice and CFSE labeling, we now demonstrate that \$\beta\$-CD3 \$\beta\$-CD28-stimulated Smad3-\$^{f\_0}\$ splenic T cells and thymocytes are partially resistant to growth inhibition by TGF-\$\beta\$1. However, in striking contrast, TGF-\$\beta\$1 suppresses IL-2-induced proliferation independent of Smad3. Our data implicate critical roles for TCR-induced Smad3-dependent and IL-2-induced, Smad3-independent signaling pathways in the regulation of T cell homeostasis by TGF-\$\beta\$1. These differential immune suppressive properties of TGF-\$\beta\$1 may allow for selective regulation of T cell expansion during an immune response.

882 INHIBITION OF INTERLEUKIN-2 (IL-2) SECRETION BY ANANDAMIDE IS MEDIATED BY A CYCLOOXYGENASE (COX) METABOLITE.

C. E. Rockwell and N. E. Kaminski. Pharmacology & Toxicology, Michigan State University, East Lansing, MI.

The putative endogenous cannabinoid, arachidonoyl ethanolamine, which is commonly known as anandamide (AEA), is an arachidonic acid derivative that has been shown through radioligand binding studies to bind to the cannabinoid receptors, CB1 and CB2. Anandamide mimics many of the immunomodulatory effects of the plant-derived cannabinoids, including inhibition of cytokine production. Specific to the present studies, AEA inhibits IL-2 secretion that has been induced by the phorbol ester, phorbol-12-myristate-13-acetate (PMA), and the calcium ionophore, ionomycin. The objective of the present studies was to determine the mechanism for this effect and the role of the CB1 and CB2 receptors. The CB1 and CB2 antagonists, SR141716A and SR144528, when used in combination, did not antagonize the inhibition of IL-2 secretion by AEA. Furthermore, neither AM404, the inhibitor of the putative AEA membrane transporter (AMT), nor methyl arachidonoyl fluorophosphonate (MAFP), the inhibitor of fatty acid amidohydrolase (FAAH), attenuated the effects of AEA upon IL-2 secretion. Interestingly, arachidonic acid caused a similar concentration-dependent inhibition of IL-2 secretion (IC<sub>50</sub>=12.3 $\mu$ M) as structurally-related AEA (IC<sub>50</sub>=14.1 $\mu$ M). The nonselective COX inhibitor, flurbiprofen, reversed inhibition of IL-2 mediated by AEA as well as by arachidonic acid. The COX-2 specific inhibitor, SC58125, had no effect upon the inhibitory activity of either AEA or arachidonic acid on IL-2 secretion. These data suggest that inhibition of IL-2 by AEA is independent of CB1/CB2 and the AMT/FAAH system. These data also suggest that inhibition of IL-2 is mediated by a COX-1 metabolite of arachidonic acid rather than AEA itself and that the enzyme responsible for the hydrolysis of AEA is not FAAH. (Supported by NIH grants DA12740 and DA15276).

ROLE OF EXTRACELLULAR SIGNAL-REGULATED PROTEIN KINASE 1/2 (ERK1/2) IN THE INHIBITION OF T-CELL FUNCTION BY ALKENYLBENZENES.

S. Yea<sup>1, 2</sup>, H. Jeong<sup>1</sup>, C. Kim<sup>1</sup>, Y. Park<sup>1</sup>, S. Lee<sup>2</sup>, J. Shin<sup>2</sup> and C. Yun<sup>3</sup>.

Human may consume alkenylbenzenes as natural components of certain spices, essential oils or vegetables. However, the potential of alkenylbenzenes for immune modulation and their mechanism have not known. In the present study, we investigate the effect of several naturally occurring alkenylbenzenes on T lymphocytes that play an important role in immune response through the action of cytokines they elaborate. Anethole, eugenol, isoeugenol and myristicin produced inhibition of concanavalin A-induced lymphoproliferation in B6C3F1 mouse splenocytes. In light of the fact that IL-2 is responsible for the clonal expansion of T-cells, effect of the alkenylbenzenes on IL-2 expression was determined. PMA plus ionomycin (Io) induced IL-2 mRNA expression and protein secretion in EL4.IL-2 T-cells, which were inhibited by anethole, eugenol, isoeugenol and myristicin as determined by real-time RT-PCR and ELISA, respectively. Electrophoretic mobility shift assay was performed to evaluate the effect of the alkenylbenzenes on binding activity of transcription factors for IL-2 gene expression, and the alkenylbenzenes decreased the

NF-AT and AP-1 binding activity in PMA/Io-stimulated EL4.IL-2 cells. Western blot analysis showed that the alkenylbenzenes inhibited the phosphorylation of extracellular signal-regulated protein kinases 1 and 2 (ERK1/2). These results suggest that the alkenylbenzenes have the potential for immune modulation, which is due to the inhibition of IL-2 expression and is mediated, at least in part, through the blocking of ERK1/2 signaling.

## 884 SODIUM ARSENITE INHIBITS ERK1/2 PHOSPHORYLATION IN MICE LYMPHOCYTES STIMULATED WITH PHYTOHEMAGGLUTININ.

P. Conde-Moo<sup>1</sup>, L. C. Acosta-Saavedra<sup>1</sup>, <u>M. E. Cebrian</u><sup>1</sup> and E. S. Calderon-Aranda<sup>1, 2</sup>. <sup>1</sup>Seccion Externa de Toxicologia, Cinvestav, Mexico, DF, Mexico and <sup>2</sup>Department of Environmental Health Sciences, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD.

Arsenic immunotoxic effects include inhibition of the proliferative responses elicited by mitogens such as phytohemagglutinin (PHA) în humans and animal lymphocytes, although the molecular mechanism remains to be defined. Previous studies have shown that arsenite induces activation of mitogen-activated protein kinase (MAPK) in non-stimulated lymphocytes, but the effect on PHA-stimulated lymphocytes has not been evaluated. The aim of this study was to establish the possible role of ERK on the inhibition of PHA-induced proliferation of mice T lymphocytes, produced by arsenite. For this purpose, T lymphocytes from female C57BL/6 mice spleen were used. The effects of arsenite on proliferative response of T lymphocytes induced by PHA (10 ug/ml) were measured by incorporation of [3H]-Thymidine and the phosphorylation of ERK1/2 was determined by immunoblotting using an anti-phosphorylated-ERK antibody. The simultaneous treatment of PHA-stimulated lymphocytes with 10 uM arsenite had an inhibitory effect (80%) on PHA-induced proliferation. The phosphorylation of ERK normally elicited by PHA, was inhibited by arsenite at the concentration of 10 uM, but not by 1.0 uM. These results suggest that the MAPK family members, such as ERK, could be involved in the inhibitory effect of sodium arsenite on T-cell proliferation which probably explains in part, immunosupression. Whether this effect is mediated by other MAPK member remains to be determined. This work was partially supported by the Mexican Council for Science and Technology (Conacyt 34508-M) to ES Calderon-Aranda.

## PRETREATMENT WITH CIGARETTE SMOKE EXTRACT DECREASES CELL DEATH IN PMA-TREATED NEUTROPHILS.

H. C. O'Neill<sup>2</sup> and <u>K. A. Stringer</u><sup>1, 2</sup>. <sup>1</sup>Department of Pharmaceutical Practice, UCHSC, Denver, CO and <sup>2</sup>Department of Pharmaceutical Sciences, UCHSC, Denver, CO.

Neutrophil (PMN) accumulation in the lung is implicated in the pathogenesis of inflammatory pulmonary diseases such as COPD and emphysema. Cigarette smoke (CS) recruits PMNs into the lungs and may alter PMN function. Timely PMN apoptosis is necessary for resolution of inflammation. We have previously determined that pre-treatment of normal, human PMNs with Camel CS extract (CSE) reduces phorbol 12-myristate 13-acetate (PMA)-induced reactive oxygen species (ROS) production. Because of the important relationship between PMN ROS production and lifespan, we investigated the ability of CSE to influence PMN survival. Peripheral neutrophils were isolated from normal healthy volunteers and treated with PMA, Camel CSE, or CSE and PMA and incubated for 0, 4, 8, 12, or 24 hr. Pretreatment with CSE slowed PMA-induced cleavage of caspase 3 as measure by Western immunoblotting. However, morphological fluoresent microscopy studies (Hoeschst 33258 dye) showed PMA-induced necrosis rather than apoptosis which was prevented by pre-treatment with CSE. There was no difference between CSE alone and untreated control cells either morphologically or as measured by caspase 3 immunoblotting. These data suggest that CSE is capable of modulating PMA-induced necrosis in human PMNs. Whether this translates to apoptotic mediated events and its relationship to PMN ROS production are currently under investigation. If CSE interferes with activator-induced apoptosis, it may limit resolution of inflammation which could contribute to the pathogenesis of inflammatory lung diseases such as COPD and emphysema. Research described in this article was supported by Philip Morris USA Inc.

#### 886 GW7845, A PPARγ AGONIST, INDUCES MAP KINASE-DEPENDENT APOPTOSIS IN PRO/PRE-B CELLS.

D. Liu<sup>1</sup>, J. Emberley<sup>2</sup>, <u>D. H. Sherr</u><sup>1</sup> and <u>J. J. Schlezinger</u><sup>1</sup>. <sup>1</sup>Environmental Health, Boston University School of Public Health, Boston, MA and <sup>2</sup>Microbiology, Boston University, Boston, MA.

Peroxisome proliferator-activated receptor  $\gamma$  (PPAR $\gamma$ ) is expressed highly in the immune system and influences multiple aspects of immune function. Previously we have shown that activation of PPAR $\gamma$  by the high affinity agonist GW7845 results

in apoptosis in pro/pre-B lymphocytes. PPARy agonists are known to influence MAP kinase cascades, therefore we investigated the activation of these casades in pro/pre- B cells and their role in apoptosis induction. Treatment of a non-transformed murine pro/pre-B cell line (BU-11) with GW7845 (40 µM) strongly induced the phosphorylation of p38 MAPK, while the phosphorylation of p44/42 MAPK and JNK was induced minimally. This is in contrast to the pattern of phosphorylation seen following treatment with hydrogen peroxide (200 µM), which strongly induced the phosphorylation of all of the kinases. Phosphorylation of p38 MAPK was accompanied by induction of its kinase activity as evidenced by a significant increase in the phosphorylation of its substrate ATF-2 by p38 MAPK immunoprecipitated from GW7845-treated BU-11. No change in AP-1 DNA-binding was observed following treatment with GW7845, suggesting that the small increase in JNK phosphorylation did not lead to significant induction of its kinase activity. Pre-treatment with the p38 MAPK inhibitor SB202190 (30 µM), but not JNK (SP600125) or p44/42 (PD98059) inhibitors, prevented GW7845-induced B cell apoptosis. Activation of PPARy appears to initiate apoptotic signaling in B cells in early maturation stages, potentially through the activation of a p38 MAPK cas-

AN ENVIRONMENTAL PPAR $\gamma$  AGONIST, MONO-(2-ETHYLHEXYL) PHTHALATE, INDUCES PRO/PRE-B CELL TOXICITY: INTERACTIONS WITH 9-CIS-RETINOIC ACID AND 15-DEOXY- $\Delta^{12, 14}$ -PROSTAGLANDIN J,.

J. J. Schlezinger<sup>1</sup>, G. Howard<sup>1</sup>, C. H. Hurst<sup>2</sup>, T. Webster<sup>1</sup>, D. J. Waxman<sup>2</sup> and D. H. Sherr<sup>1</sup>. <sup>1</sup>Environmental Health, Boston University School of Public Health, Boston, MA and <sup>2</sup>Biology, Boston University, Boston, MA.

The common industrial and commercial use of phthalate esters has resulted in significant human exposure to these bioactive compounds. The facts that phthalate ester metabolites are peroxisome proliferator-activated receptor (PPAR) agonists and that PPARy agonists induce lymphocyte apoptosis suggest that phthalate esters may be immunotoxicants. Here, we examined the effects of a metabolite of one such environmental phthalate, mono-(2-ethylhexyl) phthalate (MEHP), on developing B cells. MEHP inhibited thymidine incorporation by primary bone marrow pro/pre-B cells and by a non-transformed pro/pre-B cell line (BU-11). Co-treatment with a retinoid X receptor α (RXRα) ligand, 9-cis-retinoic acid, decreased thymidine incorporation synergistically, a characteristic feature of PPARy-mediated apoptosis. These results were similar to those obtained with the natural PPAR $\gamma$  ligand 15-deoxy- $\Delta^{12, 14}$ -prostaglandin J<sub>2</sub> (15d-PGJ<sub>2</sub>). At moderate doses of MEHP (150-200 µM), the inhibition of thymidine incorporation resulted primarily from induction of pro/pre-B cell apoptosis, while at low doses (50-100 μM), the inhibition reflected growth arrest in the absence of apoptosis. Co-treatment of bone marrow B cells with 15d-PGJ, and MEHP significantly enhanced the inhibition of thymidine incorporation seen with MEHP alone, potentially mimicking exposures in the bone marrow microenvironment where prostaglandin concentrations are high. MEHP and 15d-PGJ<sub>2</sub> activated PPARγ and induced a significant increase in NF-κB. These data demonstrate that an environmental phthalate ester can inhibit proliferation of and induce apoptosis in developing bone marrow B cells *via* PPARγ activation. The activation of NF-κB suggests a signaling pathway through which these are effected. Finally, the data suggest that bone marrow B cells are particularly susceptible to phthalate toxicity.

#### 888

INDUCTION OF COMPETING PRO-APOPTOTIC AND PRO-SURVIVAL SIGNALING PATHWAYS IN THE MACROPHAGE BY THE TRICHOTHECENE DEOXYNIVALENOL.

H. Zhou<sup>1</sup> and J<u>. J. Pestka<sup>1, 2, 3</sup>. <sup>1</sup>Food Science and Human Nutrition, Michigan State University, East Lansing, MI, <sup>2</sup>Department of Microbiology and Molecular Genetics, Michigan state University, East Lansing, MI and <sup>3</sup>Institute for Environmental Toxicology, Michigan state University, East Lansing, MI.</u>

Deoxynivalenol (DON) and other trichothecene mycotoxins cause immune suppression by inducing apoptosis in leukocytes. The capacity of DON to activate proapoptotic and pro-survival signaling pathways was assessed in the murine RAW macrophage model. Induction of the Bax/Mitochondira/Caspase-9 pathway was first investigated. DON at 250 ng/ml readily induced the phosphorylation and the binding activity of p53 as determined by Western analysis and electrophoretic mobility shift assay, respectively. DON exposure also resulted in translocation of Bax, altered mitochondrial membrane potential and release of cytochrome C. PFT- $\alpha$  (Pifithrin- $\alpha$ ), an inhibitor of p53, reduced DON-induced phosphorylation of p53 as well as the p53 binding activity. Moreover, PFT-α decreased DON-induced caspase-3 activity and subsequent apoptosis in a dose dependent manner. Interestingly, DON concurrently activated an anti-apoptotic pathway as evidenced by induction of Akt and p90Rsk phosphorylation and, subsequently, Bad . Taken together, the results demonstrate the DON competing apoptotic (p53/Bax/Mitochondrial/Caspase-9) and survival (Akt/p90Rsk/Bad) pathways in the macrophage.(Supported by NIH Grant ES-03358 and USDA-ARS Grant 59-070-060).

## 889 Ahr Ligands inhibit proliferation of Activated human B cells.

L. L. Allan<sup>1</sup>, <u>H. Ryu</u><sup>2</sup>, J. K. Emberley<sup>1</sup>, <u>J. J. Schlezinger</u><sup>2</sup> and <u>D. H. Sherr</u><sup>2</sup>. <sup>1</sup>Microbiology, Boston University School of Medicine, Boston, MA and <sup>2</sup>Environmental Health, Boston University School of Medicine, Boston, MA.

Polycyclic aromatic hydrocarbons (PAHs) and halogenated aromatic hydrocarbons (HAHs), ubiquitous environmental contaminants, are immunosuppressive AhR ligands. Previous studies suggested that several types of activated cells, including lymphoid tumors, have high AhR levels. Here, the consequences of this putative up-regulation, with regard to normal human B cell function and susceptibility to AhR ligands, were studied. In vitro activation of primary human B lymphocytes with either CpG (a TLR-9 ligand) or CD40 ligand, stimuli that model B cell activation during innate and adaptive immune responses respectively, dramatically upregulated AhR mRNA and protein levels. Furthermore, constitutive AhR activation was suggested by its nuclear translocation and by an increase in CYP1A1 mRNA levels. Treatment of activated B cells with B[a]P or TCDD further augmented CYP1A1 expression, suggesting that these cells with high AhR levels would remain or become more sensitive to environmental AhR agonists. To test this hypothesis, the consequences of PAH or HAH exposure on the proliferation of CD40L and CpG-activated B cells were assessed. B[a]P (10-5 to 10-7 M) significantly reduced the proliferation of CD40L-activated B cells while B[e]P, a B[a]P congener and weak AhR agonist, had no effect. Conversely, TCDD (10-8 to 10-10 M) greatly inhibited proliferation of human B cells activated with CpG. Collectively, these data demonstrate that activated human B cells express high AhR levels, making them extremely sensitive targets of AhR-mediated PAH/HAH immunotoxicity.

## 890 HEMATOTOXIC EFFECTS OF HEPTACHLOR ON B LYMPHOPOIESIS.

S. V. Dodson, D. A. Piktel, J. B. Barnett and K. S. Landreth. Microbiology, Immunology, and Cell Biology, West Virginia University, Morgantown, WV.

Hematotoxicity has been documented in adults exposed to high levels of organochlorine pesticides. We previously evaluated effects of prenatal heptachlor exposure on development of embryonic hematopoiesis and observed that embryonic exposure consistently resulted in altered numbers of fetal liver lymphoid progenitor cells. Prenatal heptachlor exposure did not affect development of myeloid progenitor cells. To further investigate mechanisms of lymphoid hematotoxicity, we evaluated direct effects of heptachlor on lymphoid cell lines at different stages of maturation. Following exposure, 70Z/3 pre-B cells withdrew from cell cycle and expressed immunoglobulin kappa chains, indicative of maturation in these cells. Nuclear factor-kappa B (NF-κB), a transcription factor known to promote kappa light chain transcription, was increased in nuclei of pre-B cells exposed to heptachlor. Exposure of the pro B cell line, C1.92, to heptachlor resulted in failure to proliferate and onset of apoptosis. We determined that NF-κB is decreased in nuclei of pro-B cells following exposure to heptachlor. Pro-B cells require stromal cell contact and cytokines produced by stromal cells for normal development. Pro-B cells cultured with stromal cells were more resistant to onset of apoptosis following heptachlor exposure than pro-B cells treated in the absence of stroma. In order to determine whether hematotoxicity was limited to direct effects on developing lymphoid cells, we exposed stromal cells to heptachlor. Heptachlor pretreatment of stroma resulted in decreased stem cell factor mRNA, VCAM-1 protein, and pro-B cell proliferation. Taken together, these data suggest that heptachlor directly alters lymphoid cell development by interrupting expansion of pro-B cells and causing premature differentiation of pre-B cells through alterations of NF-KB. Additionally, heptachlor exposure affects hematopoiesis through alteration in stromal cell function. Supported by NIEHS ES010953

## **891** 2, 3, 7, 8-TETRACHLORODIBENZO-*P*-DIOXIN ALTERS THE REGULATION OF PAIRED BOX GENE 5 (*PAX5*) IN B CELLS

D. Shnaider<sup>1, 3</sup>, B. S. Yoo<sup>5, 1</sup>, D. R. Boverhof<sup>2, 3</sup>, R. B. Crawford<sup>1</sup>, <u>T. R. Zacharewski<sup>2, 3, 4</sup></u> and <u>N. E. Kaminski<sup>1, 3, 4</sup>. <sup>1</sup>Pharmacology & Toxicology, Michigan State University, East Lansing, MI, <sup>2</sup>Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI, <sup>3</sup>Institute of Environmental Toxicology, Michigan State University, East Lansing, MI, <sup>4</sup>National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI and <sup>5</sup>Biology, Kyonggi University, Paldal-gu, Suwon-Si, South Korea.</u>

The environmental contaminant, 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD), produces a suppression of the primary immunoglobulin-M (IgM) antibody response. The suppression of IgM production by TCDD can occur through direct in-

teractions with the B cell, is aryl hydrocarbon receptor-dependent and results from interference with the differentiation of B cells to plasma cell stage. Pax5, also known as B cell-lineage-specific activator protein, is a crucial repressor of B cell differentiation. The objective of the present investigation was to characterize the effects of TCDD on the regulation of Pax5 and its downstream targets: immunoglobulin heavy chain (IgH), light chain (Igk), *J chain* and X box protein-1 (XBP-1). Lipopolysaccharide (LPS)-activation of CH12.LX cells induced a time-dependent decrease in cellular Pax5 mRNA, protein and Pax5 DNA binding activity during a 72 hour culture period, which was almost completely blocked in the presence of TCDD. Concordant with sustained *Pax5* expression, *IgH*, *Igk*, *J chain* and XBP-1 mRNA levels were strongly suppressed in LPS-activated CH12.LX cells treated with TCDD. Collectively, these studies suggest that the suppression of the primary IgM antibody response by TCDD is intimately related to altered Pax5 cellular levels and function. (NIH Grant ES02520)

### 892 TCDD-INDUCED MODULATION OF THE $3'\alpha$ ENHANCER.

C. Sulentic<sup>1</sup>, W. Zhang<sup>2</sup>, Y. Na<sup>3</sup> and N. Kaminski<sup>2</sup>. <sup>1</sup>Pharmacology & Toxicology, Wright State University, Dayton, OH, <sup>2</sup>Pharmacology & Toxicology, Michigan State University, East Lansing, MI and <sup>3</sup>Korea Advanced Institute of Science and Technology, Daejon, South Korea.

Transcriptional regulation of the immunoglobulin heavy chain gene involves several regulatory elements including the 3'a enhancer, which is composed of four distinct regulatory domains. DNA binding sites for several transcription factors, including B cell-specific activator protein, NF- $\kappa$ B and Oct have been identified within the 3'a enhancer domains and are believed to be important in regulating 3'a enhancer activity. We have identified an additional DNA binding motif, the dioxin responsive element (DRE) which can contribute to 3'a enhancer regulation. 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD), a known disruptor of B cell differentiation (i.e., decreased plasma cell formation, inhibition of mu heavy chain expression and suppression of IgM secretion), induces binding of the aryl hydrocarbon receptor (AhR) nuclear complex to DREs. TCDD also induces AhR binding to the hs4 domain of the 3'a enhancer. Interestingly, TCDD enhances LPS-induced activation of the hs4 domain but profoundly inhibits LPS-induced activation of the complete 3'\alpha enhancer. Furthermore, site-directed mutational analysis demonstrated that a DRE and KB element in the hs4 domain is modulated by TCDD in LPS-activated B cells. We propose that the AhR is a novel transcriptional regulator of the 3' $\alpha$  enhancer, which can mediate, at least in part, the effects of TCDD on the 3'α enhancer and its domains, putatively contributing to a marked suppression of IgM production (Supported by NIH ES02520 and NIEHS 1F32ES05914).

## 893 DEVELOPMENTAL LEAD EXPOSURE IMPACTS ON SPATIAL LEARNING AND MEMORY: CHOLINERGIC AND GLUTAMATERGIC INVOLVEMENT.

E. D. Levin<sup>1, 2</sup>, K. Sato<sup>2</sup>, J. H. Freedman<sup>2</sup>, J. Skene<sup>3</sup> and G. Harry<sup>4</sup>. <sup>1</sup>Psychiatry, Duke University Med. Ctr, Durham, NC, <sup>2</sup>Nicholas School of Earth and Environmental Sciences, Duke University, Durham, NC, <sup>3</sup>Neurobiology, Duke University Med. Ctr, Durham, NC and <sup>4</sup>NIEHS, Research Triangle Park, NC.

Developmental lead exposure has been shown to cause persisting neurobehavioral effects in various species including humans, non-human primates, and rats. To provide data concerning a mouse model for lead effects, CD1 mice (dams with their litters) received lead acetate (0.2 percent in drinking water) upon parturition of pups until weaning at day 21. No lead-induced changes in body weight or developmental landmarks were evident. One male and one female from each litter were trained as adults for 18 sessions on the 8-arm radial maze. During the initial block of 3 sessions a paradoxical lead-related improvement in choice accuracy was noted. For the rest of the training period no lead-induced effects were seen with choice accuracy. Response latency during acquisition training was affected by lead with a significant decrease in lead-exposed females, but not males. After acquisition, the mice received amnestic pharmacological challenges with scopolamine, a muscarinic cholinergic antagonist and dizocilpine, an NMDA glutamate antagonist. Scopolamine challenge uncovered a significant choice accuracy impairment in the lead-exposed female offspring relative to controls. There was also evidence for complex lead-induced alterations in response to the amnestic effects of dizocilpine challenge. This mouse model can facilitate genetic analysis to determine the molecular mechanisms of persisting lead-induced neural damage. Preliminary cDNA array studies have suggested specific effects on a very limited number of genes. An early induction of the transthyrethrin gene suggests either an early maturation of the choroid plexus or a disruption in the thyroid hormone status with developmental lead exposure. The mouse model provides the opportunity to determine the relationship between lead effects on genetic expression and neurobehavioral function. (Supported by Duke University and NIEHS.)

NEUROGENESIS IN THE RAT DENTATE GYRUS IS DECREASED BY CHRONIC DEVELOPMENTAL LEAD EXPOSURE.

T. Verina<sup>1</sup>, C. A. Rohde<sup>2</sup> and <u>T. R. Guilarte<sup>1</sup>. <sup>1</sup> Environmental Health Sciences, Johns Hopkins University, Baltimore, MD and <sup>2</sup> Biostatistics, Johns Hopkins University, Baltimore, MD.</u>

Developmental Pb2+ exposure impairs spatial learning and synaptic plasticity in the hippocampus of young adult rats [Nihei et al., Neurosci. 99:233, 2000]. We have previously reported preliminary evidence of decreased neurogenesis in the dentate gyrus (DG) of Pb2+ exposed rats [Verina et al., Toxicology. Sciences., 66(S1) 129, 2002]. DG neurogenesis is important for some forms of hippocampaldependent learning and memory [Shors et al., Nature 410: 372, 2001]. Changes in hippocampal neurogenesis may serve as a novel cellular mechanism of cognitive deficits caused by Pb2+. To further investigate this question in a larger cohort of animals, we counted newly generated cells labeled with the thymidine analog bromodeoxyuridine (BrdU) using stereology. The phenotype of BrdU-labeled cells was assessed by using doublecortin (DCX), a marker of immature neurons, or the glial marker GFAP. Pb2+-exposed or control rats were injected daily with BrdU (100mg/kg) from postnatal days (PN) 45 to 49 and sacrificed by transcardial perfusion at PN50. Systematically selected sections from the dorsal aspects of the DG were processed for either BrdU immunohistochemistry or triple-immunofluorescence with BrdU, DCX, and GFAP. BrdU-positive cells were analyzed using a Poisson regression model with count as the response variable, area as an offset, and group (control & lead) as a factor. We measured a 13% decrease (p < 0.001) in BrdÛ-labeled cells in the granular layer and subgranular zone of the DG from Pb2+-exposed rats relative to controls (1673 vs 1915 total cells, respectively). Approximately 78% of the BrdU cells were colocalized with the immature neuronal maker DXC, 2% with the astrocytic marker GFAP, and 18% did not label with either marker. No treatment effects on the percent distribution of cellular phenotypes were found. These findings indicate that chronic exposure to Pb2+ during development reduces neurogenesis in the rat DG and may form the basis for learning impairments associated with Pb2+ exposure [supported by NIEHS ES06189 to TRG].

## 895 CAMKII ACTIVITY, PROTEIN AND GENE EXPRESSION IN THE HIPPOCAMPUS OF LEAD-EXPOSED RATS.

C. D. Toscano, J. R. Moss and <u>T. R. Guilarte</u>. Environmental Health Sciences, Johns Hopkins University, Baltimore, MD.

The NMDA receptor (NMDAR) is a ligand-gated calcium channel essential for learning and memory. We have shown previously that developmental Pb2+ exposure alters the expression of NMDAR subunits in the rat hippocampus (Toscano et al, Dev. Brain Res. 139(2):217, 2002), a brain region essential for some forms of learning and memory. The calcium-calmodulin dependent kinase II (CAMKII) is directly activated by NMDAR-mediated calcium signaling in the post-synaptic membrane. Further, CAMKII is an important kinase in the propagation of calcium-sensitive signaling essential for learning and memory. We hypothesized that developmental Pb2+ exposure alters NMDAR-mediated calcium signaling and affects the activity of key kinases such as CAMKII. Control and Pb2+-exposed rats were used at 50 days of age, a time point at which deficits in spatial learning, synaptic plasticity, and NMDAR subunit expression are observed (Nihei et al, Neuroscience 99:233-42, 2000). Hippocampal CAMKII activity was measured in the presence of activators. Kinetic analysis showed that Pb2+-exposed rats exhibit a 55% decrease in Vmax [Control =192.9  $\pm$  92.1 pmol/µg/min vs. Pb2+= 88.1  $\pm$ 31.2 pmol/ $\mu$ g /min; p<0.02] with no change in Km [Control = 34.2  $\pm$  17.2  $\mu$ M vs. Pb2+=  $20.5 \pm 7.0 \,\mu\text{M}$ ; p>0.05] of hippocampal CAMKII activity. The decrease in Vmax cannot be explained by a direct effect of Pb2+ on CAMKII since incubation of hippocampal homogenates with Pb2+ [10<sup>-8</sup> to 10<sup>-5</sup>M] did not significantly affect CAMKII activity. In addition, the decrease in Vmax is not due to an alteration in the gene or protein expression of CAMKII as demonstrated by in situ hybridization and immunoblot analysis. While the nature of the Vmax decrease is unknown, it is possible that an alteration in the expression of CAMKII isoforms or posttranslational modifications occurs with Pb2+ exposure. A decrease in CAMKII activity could alter its ability to effectively phosphorylate substrates in an activity-dependent manner affecting neuronal function, synaptic plasticity, learning and memory [Supported by NIEHS ES06189 to TRG]

THE INFLUENCE OF LEAD ON THE EXPRESSION OF OCT-2 AND THE REGULATION OF ITS TARGET GENES.

S. A. Bakheet and N. H. Zawia. Biomedical Sciences, University of Rhode Island, Kingston, RI.

The nervous system is the principal target for a number of environmental metals, which are well known for their neurological and behavioral effects in humans. Lead (Pb) exposure is highly neurotoxic, particularly to the developing central nervous

system. Exposure to lead may alter developmental gene expression and brain development through selective effects on the transcriptional machinery. In this study macroarray analysis was used in an attempt to identify transcription factors that are involved in the response to Pb-exposure. Rat pups were exposed to Pb-acetate (0.2 %) from birth to weaning via lactating dams. On various postnatal days the hippocampi of control and Pb-exposed pups were examined by macroarray analysis for changes in the developmental profiles of approximately 30 transcription factors, belonging to known transcription factor families. A number of transcription factors appear to be altered following lead exposure and have distinctive temporal patterns of expression. The most prominent changes were exhibited by the Sp and Oct families. The results of macroarray screening were validated by using alternative methods (RT-PCR). Also the functional properties of Oct transcription factor were tested by using EMSA. We found that Oct-2 mRNA expression and DNA-binding follow a similar pattern after lead exposure. The expression of the nitric oxide synthase (NOS) gene was examined to test whether Pb-induced changes in Oct-2 DNA-binding translate into alterations in the expression of its target genes. We found that NOS mRNA levels and Oct-2 DNA-binding were inversely related consistent with the predominant inhibitory effects of Oct-2 on NOS expression in neuronal cells. In the future, we plan to examine other target genes regulated by Oct-2 transcription factor along with the signaling pathways involved following lead exposure in order to determine the role of Oct-2 transcription factor in lead

#### 897

DEVELOPMENTAL EXPOSURE TO LEAD AND RESPOSIVNESS OF THE APP GENE IN THE SENESCENT BRAIN.

N. Benitez, N. H. Zawia and M. Basha. Biomedical Sciences, University of Rhode Island, Kingston, RI.

Although AD is a disease of the elderly, environmental influences that impact the onset and severity of neurodegeneration may occur much earlier in life. A potential mechanism through which Pb could promote neurodegeneration is by interfering with programmatic regulation of the APP gene established during early development. The regulatory region of the APP gene contains elements recognized by the transcription factor Spl, which is essential for the activation of the APP gene. An induction in the activity of Spl would consequentially increase the expression of the APP gene, subsequently increasing the supply of APP substrates which could be processed to generate higher levels of AP associated with the neuropathological symptoms of AD. The DNA-binding and transcriptional activity of Spl was found to be induced following neonatal exposure of rats to Pb. Long-term analysis of Spl DNA-binding of the same progeny of rats exposed to Pb during the postnatal stage revealed that Spl activity is maintained at resting levels for more than a year but exhibits a rise in activity 20 months later, when compared to unexposed controls. Furthermore the expression of the APP gene follows a pattern that is similar to that of Sp1 DNA-binding and Sp1 MNRA expression, while the levels of a house keeping gene are not changed. These delayed elevations of both Sp1 DNA-binding and APP expression are exacerbated when postnatally-exposed animals are challenged by renewed Pb-exposure during their old age. Interestingly, none of these effects are observed if exposure occurred only during old age, strongly suggesting that Pb interferes with gene imprinting which is established during development and which is critical for the responsiveness of the gene regulatory apparatus in the adult.

### 898 INTERACTIVE EFFECTS OF CHRONIC POSTWEANING PB EXPOSURE AND ENVIRONMENTAL STRESS.

D. A. Cory-Slechta<sup>1</sup>, M. B. Virgolini<sup>1</sup> and D. Weston<sup>2</sup>. <sup>1</sup>Env Comm. Med., EOHSI, Piscataway, NJ and <sup>2</sup>University of Rochester, Rochester, NY.

Lower socioeconomic status (SES) children in the US also sustain the highest blood lead (Pb) levels. Low SES itself is a known risk factor for adverse health outcomes and behavioral dysfunctions, a phenomenon attributed to higher levels of stress and prolonged cortisol elevation. Pb exposure and elevated cortisol are associated with similar behavioral alterations and target mesolimbic dopamine (DA) systems. The hypothesis that Pb interacts with environmental stress was examined here in male rats subjected to chronic postweaning Pb exposure (0, 50 or 150 ppm in drinking water) with or without environmental stress (groups: control no-stress (C-NS), control stress (C-S), Pb50 no-stress (50-NS), Pb50 stress (50-S), Pb150 no-stress (150-NS) & Pb150 stress (150-S)). As in our past studies, Pb increased response rates on a fixed interval (FI) schedule of food reward by 38% and 58% at 50 and 150 ppm, respectively. Functionality of the HPA axis was measured via blood corticosterone (CORT) levels. Pb itself decreased basal CORT levels at 50 ppm (31%) with less pronounced effects (18%) at 150 ppm. Introduction into a novel environment increased ambulatory and horizontal activity only in the 150-S group and suppressed FI response rates only in the Pb groups, even though equivalent increases in CORT were observed across all groups. Brief exposure to a cold environment increased CORT levels only in the 50-S and 150-S groups but did not differentially influence FI performance. Interactions of Pb and stress cannot be easily ascribed to changes in brain monoamine alterations since changes in levels of DA and serotonin and metabolites in striatum and frontal cortex were primarily due to Pb alone, and no changes were found in nucleus accumbens. These results indicate that Pb exposure can modulate responses to stress situations and stress can unmask effects of Pb. These findings raise questions about stress-related mechanisms of Pb effects as well as the adequacy of risk assessments based on the study of Pb in isolation. Supported by ES05017, ES01247.

899

LONG-LASTING BEHAVIORAL AND NEUROCHEMICAL CONSEQUENCES OF MATERNAL LEAD (PB) EXPOSURE AND STRESS IN FEMALE OFFSPRING.

M. B. Virgolini and D. A. Cory-Slechta. EOHSI, UMDNJ and Rutgers University, Piscataway, NJ.

Elevated Pb body burden is a particular problem for low socioeconomic status children in the US, populations also considered to sustain the highest levels of environmental stress. Since both Pb and stress target the same brain sites and behavioral functions, their potential interactions were examined here. Dams exposed to 150 ppm Pb in drinking water during gestation and lactation were subjected to restraint stress 3 times per day on gestational days 16-17 yielding 4 groups: control no-stress (C-NS), control stress (C-S), Pb no-stress (Pb-NS) and Pb stress (Pb-S). In assessments of fixed-interval (FI) schedule controlled behavior of adult female offspring, stress alone (C-S) increased overall response rates and decreased pause time, while Pb exposure alone (Pb-NS) had no effect. In contrast, Pb-S significantly decreased response rates. To assess impacts on the HPA axis, blood basal and stress-induced corticosterone (CORT) levels were measured. Prenatal Pb exposure alone permanently increased CORT levels (Pb-NS and Pb-S groups). Restraint stress resulted in maximal CORT levels in all groups and no differences in subsequent FI performance. However, a brief exposure to a cold environment increased CORT levels above baseline in all groups except the Pb-S group. Finally, monoamines and metabolites were determined to evaluate long-lasting effects of the combined Pb/stress exposure in mesolimbic and nigrostriatal terminals. In nucleus accumbens, Pb-induced changes in levels of dopamine (DA) and 5-HT and metabolites were not altered by stress. However, in striatum, multiple interactions between Pb and stress were found in which generally Pb increased but Pb-S decreased neurotransmitter levels. A significant elevation in frontal cortex DA levels was observed only in the Pb-S group. Since Pb and stress can modulate each other's effects, the study of Pb as a risk factor in isolation may be unrepresentative of its actual adverse effects. ES05017 and ES01247.

EFFECTS OF EARLY LEAD EXPOSURE ON DOPAMINERGIC AND GLUTAMATERGIC NEURONAL MARKERS IN THE AGING RAT BRAIN.

J. L. McGlothan, T. Verina, C. D. Toscano and T. R. Guilarte. Environmental Health Sciences, Johns Hopkins University, Baltimore, MD.

Childhood lead (Pb2+) intoxication is a major public health problem with thousands of children exposed each year in the US. It is well recognized that childhood Pb2+ exposure results in long-term changes in brain chemistry leading to deficits in cognitive function. Although these changes have been known to persist for years, little is known about the effects of Pb2+ exposure during early life on the aging brain. We examined the effects of chronic Pb2+ exposure on the dopaminergic and glutamatergic neuronal systems in the aging rat. Rats exposed to Pb2+ from gestation until 235 days of age were euthanized for neurochemical assessment at 1.3 years of age. Analysis of tyrosine hydroxylase (TH) immunoreactive neurons in the substantia nigra (SN) indicate a significant decrease (22.8%; p < 0.05) in Pb2+-exposed animals relative to controls. We also measured the levels of dopamine transporters (DAT) in the corpus striatum and SN using 125I-RTI quantitative autoradiography. Consistent with the loss of TH-positive neurons in the SN of Pb2+-exposed rats, we found a 41.4% decrease (p < 0.01) in the levels of DAT in the SN. On the other hand, there was a 19.4% (p < 0.05) increase in the levels of DAT in the striatum of Pb2+-exposed rats. We also measured the expression of NMDA receptor subunit genes in the hippocampus of the same animals. We found no significant differences in the NR1 or NR2A mRNA levels in the hippocampus of Pb2+-exposed rats. However, there was a significant decrease in NR2B subunit mRNA in the CA1 (12.6%; p < 0.05) and CA4 (13.1%; p < 0.05) subfields of the pyramidal cell layer and in the granule cell layer of the dentate gyrus (13.6%) in Pb2+-exposed rats. In summary, these studies provide evidence that early exposure to Pb2+ produces changes in dopaminergic and glutamatergic neuronal markers in the aging brain. These molecular and cellular changes may be associated with deficits in neurological function in the aging animal [Supported by NIEHS ES06189 to TRG]

PRENATAL EXPOSURE TO METHYLMERCURY ALTERS NEUROBEHAVIOR AND BRAIN MONOAMINE OXIDASE ACTIVITY IN SPRAGUE-DAWLEY RAT OFFSPRING

C. J. Stamler<sup>1</sup>, P. Beyrouty<sup>3</sup>, K. M. Loua<sup>1</sup> and <u>L. Chan<sup>2</sup></u>. <sup>1</sup>Dietetics and Human Nutrition, McGill University, Montreal, QC, Canada, <sup>2</sup>Centre for Indigenous Peoples' Nutrition and Environment, McGill University, Montreal, QC, Canada and <sup>3</sup>Natural Resource Sciences, McGill University, Montreal, QC, Canada.

Epidemiological data have shown that prenatal chronic low dose exposure to methylmercury (MeHg) is a risk factor for neurobehavior alterations in infants. Monoamine oxidase (MAO) regulates serotonin and dopamine levels in the developing brain and has recently been shown to play a critical role in neurodevelopment. The objective of this study was to evaluate the effects of gestational MeHg exposure on neurobehavior and brain MAO activity in different brain regions in rat offspring. Adult female rats were treated by gavage with saline or MeHg (0.5 or 1.0 mg/kg/d) for four weeks prior to mating and throughout pregnancy. Tests to assess cognitive, sensory and motor function were performed on the offspring between postnatal day (PND) 20 and 38. Auditory startle tests performed on offspring (PND 23) revealed a marked augmentation of the startle reflex amplitude at both dose levels. In addition, there was a gender difference in responses. Male offspring in the 1.0 mg/kg/d exposure group displayed a shorter response time for the hot plate test, an increased state of arousal and memory deficits as assessed by the passive avoidance tasks. Female offspring in the 0.5 mg/kg/d exposure group showed an increase in conditioning latency time. The offspring exhibited no significant alterations in motor activity, swim performance, Cincinnati water maze test or rotorod test. MAO activity in the offspring (PND 41) was significantly (p<0.01) decreased in the cerebral cortex of the 0.5 and 1.0 mg/kg/d exposure groups (22%) and 19%, respectively) and in the striatum of the 1.0 mg/kg/d exposure group (24%) when compared to controls. Our data demonstrates a low-level gestational exposure to MeHg results in altered neurobehavioral function and a disruption in brain MAO activity in rat offspring. These neurochemical changes may be one of the underlying mechanisms of MeHg neurotoxicity.

#### 902

EFFECTS OF EARLY POSTNATAL METHYLMERCURY ADMINISTRATION ON EPH RECEPTOR EXPRESSION AND SPATIAL LEARNING IN THE MOUSE.

<sup>4</sup> Department of Psychology, Rutgers University, Piscataway, NJ.

The appropriate spatio-temporal expression of the Eph family of tyrosine kinase receptors and their ligands is critical for neural migration and establishment of proper topographic projections in the central nervous system. Dysregulation of Eph tyrosine kinase receptor expression results in cognitive and motor impairments, as well as misguided axonal projections. Previous studies demonstrated that gestational and lactational administration of methylmercury (MeHg) produced an increase in the expression of Ephrin-A5, an Eph ligand involved in hippocampal development. In order to examine these effects of early postnatal MeHg exposure on Eph receptor expression as well as habituation and hippocampal-dependent spatial learning, mice were treated with either PBS or MeHg on alternate postnatal days 3-15 and allowed to explore an open field and trained on the water maze on days 24 and 25. Compared to PBS treated mice, MeHg treatment resulted in increased exploration following dishabituation in an open field. PBS-treated mice learned the water maze task after several trials, while MeHg treatment produced a significant, persistent deficit in escape latency throughout training. Using a RNase Protection Assay to examine Eph receptor mRNA levels in the hippocampus, an increase in EphA4 and A5 RNA was detected following repeated spatial navigation training trials, an effect attenuated by MeHg pretreatment. These results suggest that induction of Eph receptor expression may participate in morphological changes that underlie learning events in the hippocampus; and may partially underlie MeHg-induced cognitive deficits in rodent models. (Supported by NIH ES05022, NIH/EPA ES011256 and NIH ES11279)

## 903 ENVIRONMENTAL MERCURY EXPOSURE AND COGNITIVE FUNCTION IN OLDER ADULTS.

M. E. Weil<sup>1</sup>, <u>J. Bressler</u><sup>1</sup>, T. Glass<sup>1</sup>, P. Parsons<sup>2</sup>, J. Hidalgo<sup>3</sup> and <u>B. Schwartz</u><sup>1</sup>. <sup>1</sup>Johns Hopkins University, Baltimore, MD, <sup>2</sup>New York State Department of Health, Albany, NY and <sup>3</sup>Autonomous University of Barcelona, Bellaterra, Spain.

The neurotoxicology of low-level mercury (Hg) exposure has not been adequately studied in the general adult population. We evaluated associations of blood Hg with neurobehavioral test scores, and effect modification by factors that could influence the toxicology of Hg. Toxicokinetic differences might be due to differential

binding of Hg; metallothionein (MT) and hemoglobin (Hb) bind Hg avidly and both exhibit inter-individual variability. Toxicodynamic differences could be mediated by apolipoprotein (ApoE) genotype; previous studies have reported that the ApoE ε-4 allele may make the nervous system more susceptible to lead. We performed cross-sectional analysis of data from a longitudinal study of cognitive decline in 1, 140 50-70 year old Baltimore residents. A total of 474 subjects were randomly selected for a sub-study examining neurobehavioral test scores (NBT), blood Hg (cold-vapor atomic absorption spectrometry), fish consumption (Block 98.2), blood MT (radio-immunoassay) and Hb (cyanmethemoglobin). The sub-study consisted of 31% men, 54% whites and 39% blacks. The median Hg level was 2.1 μg/L (range: 0-16 μg/L). Linear regression was used to model NBT adjusting for age, gender, race, education and technician. Results indicate that higher Hg was associated with worse performance on Rey Complex Figure Delayed Recall (visual memory; p = 0.04) and Rey Auditory Verbal Learning Test Delayed Recall (verbal memory; p = 0.08). In contrast, higher Hg was associated with better performance on Purdue Pegboard (manual dexterity; p < 0.01), Finger-Tapping tests (manual dexterity; p < 0.02) and Category Fluency Score (language; p = 0.04). MT, Hb and ApoE genotype were not associated with NBT; nor did these factors modify the relation between Hg and test scores. Analysis of fish consumption data is ongoing. Overall the data suggest that blood Hg, a biomarker of relatively recent dose, was associated with poorer performance on memory tests and improved performance on tests of eye-hand coordination.

## 904 ASSESSMENT OF POSTNATAL EXPOSURE TO THIMEROSAL AND METHYL MERCURY USING A MORRIS WATER MAZE PROCEDURE IN B6C3F1 MICE.

J. Smythe, J. EuDaly, W. C. Griffin, <u>D. E. Keil</u> and <u>M. Peden-Adams</u>. *Medical University of South Carolina, Charleston, SC.* 

The National Institute of Mental Health has stated that autism affects approximately 1 in 1000 children with an ever-increasing rate of diagnosis; however, the cause(s) of autism is unknown. Current attention has lead to the examination of thimerosal (TH) containing vaccines administered to infants. While the toxicity of TH has not been previously examined, mercury and other mercury containing compounds are known to affect the developing nervous system. Thus, we performed comparative studies to assess spatial learning and memory after postnatal exposure to either methylmercury (MeHg) or TH in male B6C3F1 using the Morris Water Maze (MWM). The MWM procedure required mice to learn the location of an escape platform hidden just below the surface in a pool of opaque water using spatially arranged visual cues. The mice were given 4 daily trials of 90 seconds each for 9 days. The first experiment compared adult male B6C3F1 mice with the parental strains of adult male C3H and C57 mice. The B6C3F1 mice readily acquired the maze problem as indicated by significantly greater declines in escape latency and steeper slopes than the parental strains. In the second experiment, male pups were exposed to either MeHg (0, 10, or 50 ug/kg) or TH (0, 20, 100, or 200 ug/kg) on postnatal days 7, 10, and 12 and examined in the MWM procedure at 8 weeks of age. No treatment effect was observed due to exposure to MeHg or TH. Although no treatment effects were observed after postnatal exposure to MeHg or TH, this study demonstrated that B6C3F1 mice readily learn under the conditions of the MWM procedure.

## 905 AGE-DEPENDENT SENSITIVITY OF STRIATAL MITOCHONDRIA TO MANGANESE-INDUCED CYTOTOXICITY.

J. Li<sup>1,2</sup>, R. Geng<sup>1</sup>, J. Chu<sup>1</sup> and <u>W. Zheng<sup>2</sup></u>, <sup>1</sup>School of Public Health & Family Medicine, Capital University of Medical Sciences, Beijing, China and <sup>2</sup>School of Health Sciences, Purdue University, West Lafayette, IN.

The mitochondrion is a known target for manganese (Mn) toxicity. However, the question as to whether the mitochondria in different ages may have the differential sensitivity to Mn insults remained unclear. The purpose of this study was to test the hypothesis that the mitochondria of the aged animals were more vulnerable to Mn cytotoxicity than those from the young ones. The mitochondrial fractions were collected from the striatal area of Wistar rats aged either 4 months old (the young group) or 18 months old (the aged group). Mitochondrial preparations were incubated with Mn at various concentrations at 37°C for 10 min. The functions of mitochondria were examined for the activities of Complex-I/III and Complex-II, mitochondrial membrane potential (MP), and mitochondrial superoxide dismutase (SOD) activity. The results showed that following Mn exposure (50, 100, 200, and 400 uM as MnCl<sub>2</sub>), there was a dose-dependent inhibition of Complex-I/III in the young group (14, 24, 36, and 45% of inhibition) as well as in the aged group (15, 28, 41, and 49% of inhibition). In comparison to the control group, Mn exposure caused 57% inhibition of Complex-II in the young, whereas it caused 66% inhibition in the aged group. The age factor did not seem to affect the sensitivity of mitochondrial MP to Mn exposure, as determined by laser scanning confocal microscopy; a Mn dose-dependent decrease (50-400 uM) in the mitochondrial MP was observed in both age groups with 15-49% decrease in the aged group vs. 14-51% in the young group. Mn treatment at 20 uM, however, significantly inhibited SOD activity, and the effect was more profound in the aged group (93% inhibition) than in the young group (69% inhibition) (p<0.05, n=15). These data suggest that the age plays a significant role in the sensitivity of brain mitochondria to Mn-induced cytotoxicity. ## 906 IRON DEFICIENCY (ID) INCREASES MANGANESE (MN) ACCUMULATION IN THE DEVELOPING RAT BRAIN

S. J. Garcia<sup>1</sup>, T. Syversen<sup>2</sup>, E. Steinnes<sup>3</sup>, K. Gellein<sup>3</sup> and M. Aschner<sup>1</sup>.

<sup>1</sup>Physiology and Pharmacology, Wake Forest University School of Medicine, Winston-Salem, NC, <sup>2</sup>Neuroscience, Norwegian University of Science and Technology, Trondheim, Norway and <sup>3</sup>Chemistry, Norwegian University of Science and Technology, Trondheim, Norway.

ID is a prevalent nutritional disorder, affecting ~2 billion people, particularly pregnant and lactating women and children. Since iron (Fe) and Mn share similar transport mechanisms, ID enhances Mn accumulation even in the absence of excess dietary Mn. While Mn neurotoxicity in adults results in neurological disturbances, little is known regarding Mn toxicity during brain development. Moreover, few studies have considered the interactions of ID and Mn throughout early brain development, a time when the brain is most vulnerable to change. Pregnant Sprague-Dawley rats were fed either control (35 mg Fe/kg, 10 mg Mn/kg diet) or low Fe (3 mg Fe/kg, 10 mg Mn/kg diet) semi-purified diets (AIN-93-G) from gestational day (GD) 7 until weaning at postnatal day (PN) 21. Neonates were cross-fostered from control dams to control or low Fe dams on PN4 and were exposed to the diets via maternal milk until PN21. To evaluate the relationship between systemic Fe status and Mn accumulation within the brain, we assessed hematological parameters and metal levels, including Mn, by inductively coupled plasma mass spectrometry (ICP-MS). Measurement of hematological parameters confirmed ID in dams and pups fed a low Fe diet. Hemoglobin was reduced in the Fe-deficient dams throughout lactation and in pups at PN21. Furthermore, Fe-deficient rats had decreased plasma Fe and increased plasma transferrin and total iron binding capacity. In Fedeficient pups, Fe, chromium (Cr), and molybdenum (Mo) brain levels decreased while Mn and copper (Cu) levels increased. Surprisingly, no regional differences were detected in the striatum, hippocampus, midbrain or cerebellum. These data demonstrate that ID increases brain Mn during early development and that ID is a risk factor for Mn as well as Cr, Mo, and Cu alterations in the brain. Supported by NIEHS 07331 (MA) and 12768 (SJG)

## 907 THE EFFECTS OF TRIBUTYLTIN (TBT) ON NEUROTRANSMITTERS AND NMDA RECEPTORS IN THE BRAINS OF ICR MOUSE OFFSPRING.

M. Tsunoda<sup>1</sup>, N. Konno<sup>2</sup> and Y. Sugita-Konishi<sup>3</sup>. <sup>1</sup>Public Health, Fukushima Medical University, Fukushima, Japan, <sup>2</sup>Koriyama Women's University and College, Koriyama, Japan and <sup>3</sup>Division of Microbiology, National Institute of Health Sciences, Tokyo, Japan.

Tributyltin (TBT) compounds have been widely used as biocides and antifouling agents. TBT compounds have been detected in marine waters, fish and shellfish. The central nervous system is one of the target organs of TBT. TBT-induced modulations of neurotransmitters and binding to NMDA receptors in the brains of adult mice have been reported. However, little is known about the developmental neurotoxicity of TBT. In this study, we evaluated the neurotoxic effects of TBT on the offspring in ICR mice. Pregnant ICR mice were exposed to TBT chloride at concentrations of 0, 15, and 50 ppm in water and 125 ppm in diet. Exposure was continued until the time offspring were weaned (3 weeks). Male offspring were sacrificed at 1, 2 and 3 weeks after birth. Brain samples were dissected into the cerebrum, cerebellum, medulla oblongata, midbrain, corpus striatum and hypothalamus. The concentrations of norepinephrine, dopamine, dihydoxyphenylacetic acid(DOPAC), homovanillic acid (HVA), serotonin (5-HT), and 5-hydroxyindolacetic acid (5-HIAA) were determined in different brain regions by HPLC. The binding of [3H]MK-801, which is the NMDA non-competitive antagonist, was also investigated in membrane preparations from the cerebrum. Since all offspring from the 125 ppm group died immediately after birth, comparisons were made among living groups only. Decreases in mean body weight were observed in TBTexposed groups most notably at the first week. A significant increase in TBT-treated groups compared to the control was observed for HVA in the cerebrum and 5-HT in the medulla oblongata at the third week. The significant decrease in the binding of [3H]MK-801 was observed in TBT-treated groups at the third week. For neurotransmitters and binding to NMDA receptors in the brain of offspring, the effects of TBT were observed at the third week at the relatively lower levels than those observed in previous studies for adult mice.

## 908 BEHAVIORAL CONSEQUENCES OF PERINATAL MONOMETHYLTIN EXPOSURE IN RATS.

K. D. Ehman<sup>2</sup>, K. L. McDaniel<sup>1</sup>, P. M. Phillips<sup>1</sup> and <u>V. C. Moser</u><sup>1</sup>.

<sup>1</sup>NTD/NHEERL, USEPA, Research Triangle Park, NC and <sup>2</sup>Curriculum in Toxicology, UNC/USEPA, Research Triangle Park, NC.

Organotins, such as monomethyltin (MMT), are widely used as heat stabilizers in PVC and CPVC piping, which results in their presence in drinking water supplies. Concern for neurotoxicity produced by organotin exposure during development has been raised by published findings of a deficit on a runway learning task in rat pups perinatally exposed to either MMT or trimethyltin. The objective of the first study was to replicate the earlier publication and further define the dose-response characteristics of MMT. Female Sprague-Dawley rats were exposed via drinking water to MMT (0, 10, 50, 245 ppm) before mating and throughout gestation and lactation (until weaning at postnatal day, or PND, 21). Behavioral assessments included: the runway test (PND 11) in which the rat pups learned to negotiate a runway for dry suckling reward; motor activity habituation (PNDs 13, 17, and 21); and learning in the Morris water maze (as adults). Contrary to the earlier finding, there were no effects on any measure of growth, development, or cognitive function following MMT exposure. These findings were confirmed in a subsequent study in which the developmental effects of 500 ppm MMT in drinking water were explored in pregnant rats exposed from gestational day 7 until weaning. The behavioral assessments included the runway task (PND 11) and motor activity habituation (PND 17). In this second study, MMT-exposed females consumed significantly less water than the controls throughout both gestation and lactation, although neither dam nor pup weights were affected. As in the first experiment, MMT-exposure did not alter pup runway performance or motor activity habituation. These results indicate that perinatal exposure to MMT, even at concentrations which decrease fluid intake, does not result in significant neurobehavioral or cognitive deficits. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

#### 909 COMBINED EFFECTS OF FLUTAMIDE AND β-ESTRADIOL 3-BENZOATE ON ADULT MOUSE TESTES.

R. Anahara<sup>1</sup>, Y. Toyama<sup>2</sup> and C. Mori<sup>1,3</sup>. <sup>1</sup>Bioenviron Med., Grad Sch Med., Chiba University, Chiba, Japan, <sup>2</sup>Anat Devel Biol, Grad Sch Med., Chiba University, Chiba, Japan and <sup>3</sup>CREST, JST, Kawaguchi, Japan.

Many reports on endocrine disrupting chemicals (EDCs) were investigated using single compounds. Little information is available about the combined effect of hormone active compounds. The present study investigated the combined-effect of βestradiol 3-benzoate (E2B) and flutamide (Flu) on mouse testes by electron-microscopic observation. Both E2B and Flu were subcutaneously and simultaneously administrated to adult ICR mice (12-week-old) for 5 days. The combination of the doses was 20µg/kg/day (histological LOEL) of E2B and any one of 0.01, 0.1, 1 or 10μg/kg/day of Flu. Single treatments of Flu were also examined. Testes (n=5) were fixed on the 6th day for electron microscopy. The number of abnormal spermatids in the treated-mice and normal-mice were counted on semi-thin sections. Deformation of acrosomes and/or nuclei of spermatids and complete or partial deletion of the ectoplasmic specialization between the Sertoli cell and spermatids were observed. There were no differences in ultrastructure between the combinedtreatment and single-treatments of Flu. Disarrangements of seminiferous cycles were observed in combined-treatment by light microscopy, but these changes were not seen in single-treatments. Moreover, the percentages of abnormal spermatids were increased at histological NOEL in combined-treatments. The effects of combined treatment on testes of spermatids have tendencies with no linear-correlation in accordance with dose. There were no differences in the observed histological change between the single-treatment and combined-treatment, even though in the combined & treatment of E2B and the highest-dose of Flu (10µg/kg/day). In this study, the dose of histological NOEL of Flu was decreased in the presence of exogenous estrogen, and also xenoestrogenic actions were observed in the combinedtreatments than in single-treatments. In conclusion, the combined treatments of both estrogen (histological LOEL) and low-dose-Flu on mouse testes induced synergic effect and strengthened the effect of Flu.

## 910 VALIDATION OF A METHOD OF INTRAPROSTATIC ADMINISTRATION OF TEST MATERIAL TO THE MOUSE.

S. Grainger and G. Hale. *Covance Laboratories Ltd.*, *Harrogate, United Kingdom.* Sponsor: <u>D. Everett</u>.

The dorsal and lateral prostate glands of the mouse are composed of branching ducts and glands surrounded by loose connective tissue and adipose tissue situated around the dorsal and lateral aspects of the proximal urethra. A method was devel-

oped to deliver test material (in this case, a viral gene vector) to the dorsal prostate of the mouse. The method and its validation for use are described. Mice are anaesthetised with isoflurane in oxygen. Antibiotics and analgesics are administered and the animal placed on a heated pad. Using aseptic surgical technique the urinary bladder is exposed at laparotomy. The ventral prostate is visualised by gentle traction on the bladder and, if necessary, section of the middle ligament of the bladder and blunt dissection of fatty tissue around the bladder neck. Using the ventral prostate as a guide, test material (50 µl) is deposited in the area of the dorsal prostate by transurethral injection using a 300 µl insulin syringe with a 30 gauge needle. Surgical repair is routine. For validation purposes the administration procedure was carried out on ten male CD-1 mice freshly killed by exposure to a rising concentration of carbon dioxide in a chamber.  $50 \,\mu\text{l}$  of indian ink was injected into the area of the dorsal prostate. Immediately after injection the bladder, proximal urethra, prostate, seminal vesicles and coagulating glands were removed in one piece and fixed in 10% neutral buffered formalin prior to processing to paraffin wax blocks, sectioning and staining with haematoxylin and eosin. During organ removal and histological processing care was taken to maintain anatomical relationships as closely as possible. The distribution and density of indian ink particles was assessed in the histological sections and correlated with observations made at the time of injection. When the administration had been thought satisfactory, there was a clear concentration of indian ink particles in the loose connective and adipose tissues surrounding the lobules of the dorsal and lateral prostate and the base of the anterior prostate (coagulating glands).

# 911 EFFECTS OF GESTATIONAL AND LACTATIONAL EXPOSURE TO 17 ALPHA-ETHYNYLESTRADIOL ON SPERM QUALITY AND EGG FERTILIZING ABILITY OF MALE OFFSPRING IN MICE.

J. HAN<sup>1,3</sup>, P. M. Saama<sup>1</sup>, T. R. Zacharewski<sup>2,3,4</sup> and K. Chou<sup>1,3,4</sup>. <sup>1</sup> Animal Science, Michigan State University, East Lansing, MI, <sup>2</sup> Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI, <sup>3</sup> Institute for Environmental Toxicology, Michigan State University, East Lansing, MI and <sup>4</sup> National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI.

Previously, we reported decreases in sperm production and fertilizing ability in utero and lactational exposure to high doses (1 and 10 ug/kg of maternal BW) of diethylstilbestrol (DES) and increases in fertilizing ability after low dose exposure. The objective of this study was to examin the effect of 17 alpha-ethynylestradiol (EE2), the major estrogenic component of oral contraceptives, on sperm production and fertilizing ability in male offspring. Pregnant C57BL/6 mice (F-0), bred with DBA/2 male, were gavaged with 0, 0.1, 1, or 10 ug EE2/kg of BW per day from gestational day 12 to postnatal day (PND) 20. The male offspring (F-1), at 15-17 or 45-48 weeks of age, were examined for sperm quality by using sperm motion analysis and in vitro fertilization (IVF) assay. The anogenital distance (AGD) of the male offspring in the 1 and 10 ug dose groups was shorter than that of the control animals on PND21. Sperm concentration from 45-48 week-old male offspring was lower in the 10 ug dose group than that in the control (P<.05), but not at 15-17 weeks of age. However, when equal sperm concentrations were used in IVF assay, no treatment effect on fertilization in either age group was observed. Results from this study suggest that exposure to high doses of EE2 during gestation could decrease sperm production, body weight, and AGD, while there is no apparent effect on sperm fertilizing ability. Similar to the observation in our DES study, low dose exposure, 0.1 ug/kg of maternal body weight, had no detrimental effect on sperm production of offspring. The median dose tested, 1 ug/kg, is about 1.5 to 2 times of the dosage used in oral contraceptives. (Acknowledgement: EPA, R827-420-01-0, and Michigan Agricultural Experiment Station)

# 912 DISRUPTION OF MALE REPRODUCTIVE DEVELOPMENT IN THE RAT BY A SINGLE DOSE OF THE ANTIANDROGEN, FLUTAMIDE, ADMINISTERED ON DIFFERENT GESTATIONAL DAYS.

P. M. Foster and M. W. Harris. DHHS, NIH, NIEHS, Research Triangle Park, NC.

Previous studies have indicated that the antiandrogen, flutamide, can produce a suite of reproductive malformations in the rat when administered daily on gestation days (GD) 12-21. The objective of this study was to investigate the time dependence for the induction of these malformations to establish a robust animal model for future studies of gene expression related to specific malformations. Groups of timed-pregnant Sprague-Dawley rats (GD 0 = day of mating) were administered flutamide as a single gavage dose (50 mg/kg) on GD 16, 17, 18, or 19 with 10 dams per group. Control animals (5 dams / time group) were administered corn oil vehicle (1ml/kg). Dams were allowed to litter and their adult male offspring were killed at postnatal day (PND) 100±10. Anogenital distance was measured at PND 1 and 100. Areolae were scored at PND 13 and permanent nipples evaluated at PND 100. No reproductive tract malformations were found in control male offspring. In

the treated groups, malformations were noted following exposure at every GD, although the incidence of specific malformations varied by GD. At GD 16, the highest incidence was noted for permanent nipples (46% pups, 60% litters), epispadias (12% pups, 30% litters), and missing epididymal components (5% pups, 20% litters). The highest incidences for hypospadias (58% pups, 80% litters), vaginal pouch (49% pups, 70% litters), cleft prepuce (29% pups, 60% litters) and missing prostate lobes (12% pups, 60% litters) were noted at GD 17. At GD 18 the highest incidence of malformations noted were epispadias (5% pups, 30% litters), reduced prostate size (32% pups, 90% litters) and abnormal kidneys (3% pups, 30% litters) and bladders (7% pups, 30% litters), while on GD 19 70% of the litters had animals with abnormal seminal vesicles. Thus, a single gestational exposure of flutamide induced numerous reproductive tract malformations consistent with previously reports following multiple exposures, with the timing of the exposure producing marked tissue selectivity in the response noted in adult offspring.

## 913 EFFECTS OF SULFASALAZINE ON SPERM ACROSOME REACTION AND GENE EXPRESSION IN THE REPRODUCTIVE ORGANS.

T. Fukushima<sup>1, 2</sup>, M. Kato<sup>1</sup>, T. Adachi<sup>3</sup>, Y. Hamada<sup>1</sup>, M. Horimoto<sup>1</sup>, M. Komiyama<sup>2</sup>, C. Mori<sup>2</sup> and I. Horii<sup>1</sup>. <sup>1</sup>PGRD Nagoya Lab., Pfizr.Inc., Taketoyo, Aichi, Japan, <sup>2</sup>Department of Bioenvironmental Mdedicine, Graduate School of Medicine, Chiba university, Inohana, Chiba, Japan and <sup>3</sup>Center for Research and Development of Bioresources, Reserch Institute for Advanced Sciences and Technology, Osaka Prefecture University, Sakai, Osaka, Japan. Sponsor: M. Kurata.

Sulfasalazine (SASP) has been reported to depress the fertility in men. This study was undertaken to investigate the mechanism by which SASP affects fertility. After we confirmed the effect of SASP on the fertility of rats administered the drug at the dose of 600 mg/kg/day for 28 days, we investigated its effects on sperm motion and acrosome reaction using FITC-concanavalin A lectin stain and on gene expression using cDNA microarray and real-time RT-PCR in the reproductive organs. We observed a decrease in sperm velocity and a depression of acrosome reaction in the SASP treated group. În the testes, acrosome membrane related genes (CD59) expression was slightly altered in the SASP treated group. There were, however, no changes in the expression of the genes related to spermatogenesis. In the epi-didymides, the expression of CD59 and other acrosome membrane related genes, membrane cofactor protein (MCP) and decay accelerating factor (DAF), were decreased in the SASP treated group. It is known that CD59, MCP and DAF have biological functions related to sperm motion and that MCP is involved in the acrosome reaction or binding of the sperm with the egg. From these findings, it was elucidated that the effects of SASP on fertility were mediated by a depression of sperm velocity and acrosome reaction. These findings correlated with the decreased expression of CD59, MCP and DAF gene in the epididymides.

## 914 METHYL TERTIARY-BUTYL ETHER INDUCES ALTERATIONS IN MOUSE TESTIS WEIGHT, TESTOSTERONE PRODUCTION AND MORPHOLOGY.

L. Almeida and E. Hall. Biology, Rhode Island College, Providence, RI.

Methyl tertiary-butyl ether (MTBE) is the most common fuel oxygenate used today. Oxygenating fuel serves to induce a more complete combustion reaction, thus reducing CO and hydrocarbon emissions. Because of the high water solubility and widespread use of MTBE, there is a high risk of exposure through groundwater that has been contaminated with MTBE oxygenated fuel from leaking, underground storage tanks and pipelines. In this study, mice were exposed to doses of 80, 800, and 8000 ppb MTBE in drinking water for 28 days. Results demonstrated a significant, dose-dependent increase in mean combined testis weight, mean seminal vesicle weight, mean seminiferous tubule diameter, and incidence of abnormal tubules. Serum testosterone was substantially decreased by exposure to 800 and 8000 ppb of MTBE. These results indicate that MTBE may act *via* a disruption in endocrine-mediated Leydig cell testosterone production. Supported by NIH RR16457 from the BRIN Program of the NCRR and a grant from the Rhode Island College Faculty Research Committee.

IN VIVO EXPOSURE OF YOUNG ADULT RATS TO METHOXYCHLOR (M) REDUCES SERUM TESTOSTERONE (T) LEVELS, BASAL LEYDIG CELL (LC) T FORMATION, LC CYTOCHROME P450 CHOLESTEROL SIDE-CHAIN CLEAVAGE (P450SCC) ACTIVITY AND SERUM DEHYDROEPIANDROSTERONE (DHEA) LEVELS.

E. P. Murono and R. C. Derk. *Pathology and Physiology Research Branch, CDC/NIOSH, Morgantown, WV. Sponsor:* V. Castranova.

M is a pesticide developed as a replacement for dichlorodiphenyltrichloroethane (DDT). Although its metabolite, 2, 2-bis(p-hydroxyphenyl)-1, 1, 1-trichloroethane (HPTE), is thought to be the active compound, both M and

HPTE have been reported to exhibit weak estrogenic and/or antiandrogenic activities and thereby produce adverse reproductive effects in rodents. In the current studies young adult male rats (at least 11 animals per each treatment group) were gavaged once daily between days 54-60 days of age with 0, 5, 40 or 200 mg M/kg body weight in corn oil. Animals were sacrificed ~24 h after the last exposure to assess the effects of M on LC steroidogenic competence. Serum T levels declined from  $4.40 \pm 0.52$  ng/ml (control) to  $1.82 \pm 0.27$  ng/ml at the 200 mg/kg dose. Similarly, both wet and expressed seminal vesicle weights declined to 44 and 60%of control, respectively, at the highest exposure dose. However, serum LH and FSH levels were unaffected by M. In addition, testicular LC isolated from exposed animals produced less T under basal conditions following a 4 h incubation period  $(2.20 \pm 0.13 \text{ ng T/4 h/}10^5 \text{ cells in LC from 200 mg/kg exposed animals vs } 4.50 \pm$ 0.31 ng/4 h/10<sup>5</sup> cells in control cells). Also, P450scc activity of isolated LC declined from  $20.44 \pm 0.92$  ng side-chain/h/10<sup>5</sup> cells (control) to  $16.10 \pm 1.29$  and  $10.15 \pm 0.98$  ng/h/10<sup>5</sup> cells in LC from animals exposed to 40 and 200 mg/kg M, respectively. Although serum corticosterone levels were unaffected by M, serum DHEA levels declined from  $0.11 \pm 0.01$  ng/ml (control) to  $0.05 \pm 0.01$  ng/ml in 200 mg/kg exposed animals. Whether this decline in DHEA represents adrenal or LC androgen remains to be determined. These studies suggest that in vivo exposure of M to young adult male rats directly reduces LCT formation and that this decline is due to inhibition of LC P450scc activity.

DI(*N*-BUTYL) PHTHALATE RAPIDLY REPRESSES STEROIDOGENESIS IN THE FETAL TESTIS AND INTERFERES WITH ADRENAL STEROIDOGENESIS THROUGH AN ALTERNATIVE MECHANISM.

C. Thompson, S. M. Ross, S. Heinze and <u>K. W. Gaido</u>. CIIT Centers for Health Research, Research Triangle Park, NC.

The phthalate ester di(n-butyl) phthalate (DBP) produces antiandrogenic effects on reproductive development in male rats by interfering with testosterone production. We have shown that several genes involved in steroidogenesis are downregulated in the fetal testis following in utero exposure to DBP. Expression of these genes returns to control levels within 48 hours of DBP withdrawal. Our aim was to determine how rapidly testosterone synthesis is affected following exposure to DBP. Also, since several genes repressed by DBP are expressed in other steroidogenic tissues, we evaluated the effects of DBP exposure on steroidogenesis in the fetal adrenal. Pregnant Sprague-Dawley rats were dosed via oral gavage with 500 mg/kg/day DBP or corn oil from gestational day (gd) 12 to 19. The start of DBP dosing was shifted from gd 12 one day later in gestation for each treatment group, so that the final group was dosed only on gd 19. On gd 19, testes were removed for testosterone, RNA, and protein isolation. Testosterone production was significantly repressed in all groups exposed to DBP. The mean testosterone concentration in the fetuses dosed only on gd 19 was 44% of control. Mean testosterone concentration of all other dose groups was 13% of control. mRNA and protein levels for StAR, SR-B1, P450<sub>SCC</sub>, and CYP17 were correspondingly repressed at all time points. In the adrenal gland, corticosterone content was decreased 42% in male fetuses and 48% in female fetuses following DBP treatment from gd 12-19, although only the decrease observed in the females was statistically significant. mRNA expression of SR-B1, StAR, and  $P450_{SCC}$  were not significantly altered in the adrenal following DBP treatment. Our results show that DBP rapidly leads to transcriptional repression in the fetal testis resulting in diminished testosterone production. Diminution of steroid concentrations in the fetal adrenal occurs through a mechanism distinct from the transcriptional repression caused by DBP in the fetal testis.

## 917 THE EFFECTS OF NEONATAL EXPOSURE TO DIETHYLSTILBESTROL AND 17β-ESTRADIOL IN MOUSE EPIDIDYMIS.

K. Yamazaki<sup>1</sup>, Y. Ono<sup>1</sup>, T. Adachi<sup>2</sup>, H. Fukata<sup>3</sup>, K. Kojima<sup>4</sup>, K. Chiba<sup>4</sup>, <u>C. Mori<sup>1, 5</sup></u> and M. Komiyama<sup>1, 6</sup>. <sup>1</sup> Department of Bioenvironmental Medicine, Graduate School of Medicine, Chiba University, Chiba, Chiba, Japan, <sup>2</sup> Center for Research and Development of Bioensources, Research Institute for Advanced Science and Technology, Osaka Prefecture University, Sakai, Osaka, Japan, <sup>3</sup> Department of Bioenvironmental Medicine (SRL), Graduate School of Medicine, Chiba University, Chiba, Chiba, Japan, <sup>4</sup> Laboratory of Biochemical Pharmacology and Toxicology, Graduate School of Pharmaceutical Sciences, Chiba University, Chiba, Chiba, Japan, <sup>5</sup> Core Research for Evolutional Science of Technology (CREST), Japan Science and Technology Corporation (JST), Kawaguchi, Saitama, Japan and <sup>6</sup> Center for Environment, Health and Field Sciences, Chiba University, Kashiwa, Chiba, Japan.

Recently, several studies have reported that semen quality has decreased. Endocrine disruptors (EDs) have been thought to be one of the possible causes. Epididymis is an important organ for maturation of spermatozoa. Perinatal exposure to EDs has induced morphological changes in epididymis. However, there is little information about the effects of EDs on epididymal gene expression. In this study, we examined

morphological changes and alteration of gene expression using in house cDNA microarray in epididymis after neonatal exposure to diethylstilbestrol (DES) or  $17\beta$ -estradiol (E2). Male newborn ICR mice were treated with DES or E2 (5  $\mu g/mouse/day)$  for 5 successive days, and their epididymides were dissected at 2, 4, and 8 weeks of age. Morphological observation revealed that the height of epithelial cells was lower than control, and unusual supranuclear vesicles were observed in the initial segment of epididymal duct at 2, 4 and 8 weeks of age in both groups. In microarray analysis, the expression of 340 and 196 genes was altered at 4 and 8 weeks of age in DES group, respectively, as compared with control. In E2 group, 5350 and 985 genes were different in expression from control at 4 and 8 weeks of age, respectively. These results suggest that neonatal exposure to exogenous estrogen alters the expression of several genes and induces the morphological changes in epididymis.

## 918 IMPACT OF METHODS OF EUTHANASIA ON SPERM MOTILITY OF OLDER ADULT SPRAGUE-DAWLEY

S. L. Lohrke<sup>1</sup>, S. A. Stutler<sup>1</sup>, E. W. Johnson<sup>1</sup>, J. E. Miller<sup>1</sup>, K. Carnes<sup>2</sup>, <u>R. A. Hess<sup>2</sup></u>, D. L. Schaeffer<sup>2</sup> and <u>D. P. Arfsten<sup>1</sup></u>. <sup>1</sup>Naval Health Research Center Toxicology Detachment, Wright-Patterson AFB, OH and <sup>2</sup>College of Veterinary Medicine, University of Illinois at Urbana-Champaign, Urbana, IL.

There are several agents and methods that are approved by the American Veterinary Medical Association for administering euthanasia. Most involve administering an overdose of inhaled or injectable anesthetic. It is known that the administration of drugs or chemicals can have an impact on sperm motility and viability. NHRC scientists carried out studies to compare the effects of euthanasia on sperm motility in the interest of determining whether reported absolute sperm motility/viability were comparable across studies in situations where the methods or agent of euthanasia were different. In this study, the impacts of different euthanasia methods on sperm motility and viability were determined in 22 week-old Sprague-Dawley rats. Agents tested in this study were CO<sub>2</sub>, halothane, isoflurane, enflurane, sevoflurane sodium pentabarbitol, and Buthansia D solution. Sperm motility and viability were compared with those of animals euthanized by rapid decapitation (negative controls) or treated with α — chlorohydrin (positive controls) prior to rapid decapitation. Sperm motility and viability was measured using a Hamilton Thorne sperm analyzer (HTM-IVOS Version 12). Preliminary results suggest that there does not appear to be significant differences in sperm motility or viability between animals euthanized rapid decapitation versus those euthanized by CO<sub>2</sub> asphixiation or an overdose of sodium pentobarbital. Work is continuing on determining the effects (if any) of halothane, isoflurane, enflurane, and sevoflurane on sperm motility and viability as compared with controls.

## 919 *IN VITRO* EXPOSURE TO 8-MOP DAMAGES MALE REPRODUCTIVE CELLS.

M. M. Diawara and J. Carsella. Biology, Colorado State University - Pueblo, Pueblo, CO.

The psoralens occur naturally in many plants. Synthetic forms of 8-methoxypsoralen (8-MOP) have been widely used to treat skin disorders. Studies have shown that Wistar rats have low birth rates when both male and female are dosed with 8-MOP or when only female in a mated pair is exposed. Reduced sperm counts, reduced litter size, decreased weight of individual pups and birth defects were also exhibited when only the male is dosed. This was accompanied by other teratogenic effects such as missing limbs and discolored fetuses in offspring of naive females mated to dosed males, suggesting adverse effect on the sperm in dosed males. Therefore, the current study was initiated to see if 8-MOP exposure would damage the DNA of rat spermatozoa. A modified comet assay protocol was used to test spermatozoa DNÂ for 8-MOP-induced damage. Spermatozoa samples were collected from the testes of mature Wistar rats and reacted with varying concentrations of 8-MOP (0, 2, 4, 6, 8, 10 mg/ml Acetone solution). Some of the treated samples were exposed to long-range UVA radiation and some were not. Samples were then digested with proteinase K in 1% SDS and TES buffer for 60 minutes. The cells were then placed in a low melting point gel and lysed. DNA damage in the samples was scored. Images were gathered using a fluorescence microscope and analyzed by computer. The moments (ratio of nucleus to tail for each gamete) of comets were statistically analyzed. Treated, irradiated sperm samples sustained significantly more damage than untreated, irradiated samples. The treated, non-irradiated sperm samples also sustained significantly more damage than the untreated, non-irradiated samples. The damage in these sperm samples occurred in a dose-dependant manner in both irradiated and non-irradiated groups. These results, which are consistent with previous findings, provide evidence that the linear furanocoumarins could compromise the reproductive function in a naive female by indirect effect on the sperm in the seminal fluid. (Supported by NIGMS grant 2S06 GM008197-20 MPRC-B)

### 920 FUNCTIONAL EXPRESSION OF PPAR GAMMA IN SERTOLI CELLS.

Y. Ye and J. H. Richburg. College of Pharmacy, The University of Texas at Austin, Austin, TX.

Recently, mono-2-ethylhexyl phthalate (MEHP) has been shown to activate the PPAR gamma receptor in granulosa cells and is likely responsible for the MEHPinduced suppression estradiol production by the ovary. Since the Sertoli cell is the primary target cell of MEHP in the testis, we hypothesized similar mechanisms of action may contribute to MEHP-induced testicular injury in the testis. To test this hypothesis, we examined the expression of PPAR gamma receptor in primary Sertoli cell cultures and the mouse TM4 Sertoli cell line. We also utilized 15-deoxy-Delta12, 14-PGJ2 (15d-PGJ2), an endogenous ligand for PPARgamma, to examine the functional consequences of PPAR gamma receptor activation in TM4 cells. Using immunohistochemical staining, a nuclear localization of PPAR gamma receptor was detected in both primary Sertoli cells and TM4 cells. Staining was not observed in germ cells of primary Sertoli-germ cell co-cultures. Incubation of TM4 cells with 15d-PGJ2 (10 µM) for 24 hours significantly inhibited the proliferation of TM4 cells (a decreased of 64 percent). However, the growth inhibition effect of 15d-PGJ2 was not reversed by GW9662, a specific PPAR gamma antagonist. 15d-PGJ2 (10 µM) was able to rapidly (1h) increase the phosphorylation of the kinase ERK1/2 by 127 percent in TM4 cells. In contrast, MEHP (200  $\mu$ M) caused only marginal ERK1/2 increases (27 percent) that were maximal at 30 minutes. These novel findings indicate that Sertoli cells express PPAR gamma receptor and that 15d-PGJ2 is capable of triggering an ERK1/2 response. These observations provide for a foundation for our future investigations on the role of PPAR gamma in Sertoli cells and its possible modulation by MEHP. (Supported, in part by grants from NIH/NIEHS ES09145 & ES07784).

# 921 CRITICAL WINDOWS OF VULNERABILITY FOR EFFECTS OF 2, 3, 7, 8-TETRACHLORODIBENZO-p-DIOXIN (TCDD) ON PRENATAL PROSTATE DEVELOPMENT IN MICE.

S. M. Hicks, T. Lin and R. E. Peterson. School of Pharmacy, University of Wisconsin. Madison. WI.

A single maternal dose of TCDD on gestation day (GD) 13 impairs prostate development in C57BL/6J mice. The effect is most severe in ventral prostate where TCDD causes complete agenesis by inhibiting formation of epithelial buds. TCDD does not appear to inhibit early bud formation in dorsolateral and anterior prostate but alters number and patterning of buds leading to smaller adult organs. A time course study was performed to define critical windows of vulnerability to TCDD for the various prostate lobes. Pregnant mice were dosed orally with 0, 5, or 25 μg/kg TCDD on GD 13, 14, 15, 16, or 17. Urogenital sinus (ÚGS) from male fetuses was collected on GD 18 and evaluated for epithelial bud formation by scanning electron microscopy. In all cases, the 25 µg/kg dose slightly enhanced the effects seen in male fetuses from dams exposed to 5  $\mu g/kg$  TCDD on the same GD, which are detailed below. Ventral budding was completely inhibited in fetuses exposed on or before GD 15 but was normal in those exposed on GD 17. There was some ventral budding in fetuses exposed on GD 16, but buds were laterally dislocated. In fetuses exposed on or before GD 14, lateral buds moved up to the anterior-dorsal surface and dorsal buds crowded along the dorsal-posterior ridge. There was moderate recovery of dorsolateral bud position if TCDD exposure occurred on GD 15 or 16 and full recovery if exposure occurred on GD 17. Anterior buds appeared normal in all samples. However, the buds were proportionally larger in males exposed later in gestation, a trend also apparent in dorsolateral buds. In summary, UGS regions that develop into the lobes of the adult mouse prostate are vulnerable to disruption by TCDD at different times during gestation. The anterior region is susceptible beginning on or before GD 13 to changes affecting bud growth. Maximum vulnerability of the dorsolateral regions begins on GD 14, though some effect remains in mice exposed later in gestation. Ventral budding can be completely inhibited by exposure as late as GD15. (NIH grant ES 01332)

## 922 PROTEOME ANALYSIS OF THE EFFECTS OF *IN UTERO* 2, 3, 7, 8- TETRACHLORODIBENZO-*P*-DIOXIN EXPOSURE ON MALE C57BL/6 MOUSE UROGENITAL

R. Karjanlahti<sup>1,2</sup>, University. Simanainen<sup>1,2</sup>, M. Tuomainen<sup>2</sup>, S. Ryhanen<sup>2</sup>, T. Lin<sup>3</sup>, J. Tuomisto<sup>1,2</sup>, S. Karenlampi<sup>2</sup>, R. E. Peterson<sup>3</sup> and M. Viluksela<sup>1</sup>. 
<sup>1</sup>National Public Health Institute, Kuopio, 70701, Finland, <sup>2</sup>University of Kuopio, Kuopio, 70211, Finland and <sup>3</sup> University of Wisconsin, Madison, WI.

The earliest visible stage of prostate development is bud formation from the urogenital sinus (UGS) epithelium. This early stage of prostate development is vulnerable to environmental disturbances. *In utero* 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin

(TCDD) exposure on gestational day (GD) 13 disrupts prostate development in a lobe-specific manner by preventing ventral bud formation, reducing dorsolateral bud number and delaying dorsolateral and anterior bud formation in male mice. This effect of TCDD is aryl hydrocarbon receptor (AHR) dependent. In UGS gene expression analysis mRNA levels were altered on GD 16 after a single maternal dose of 5 µg TCDD/kg on GD 13. Using proteomics as a tool we analyzed the effect of a single maternal dose of TCDD on the pattern of UGS protein expression. Pregnant C57BL/6 mice were administered po. 5  $\mu g$  TCDD/kg or vehicle on GD 13 and the UGS from male fetuses were collected on GD 16. Five to eight UGS per sample were pooled and lysed directly into rehydration solution containing protease free Dnase/Rnase. For each gel, 150 µg of protein was first applied to a 24 cm, pH 4-7 IPG strip (Amersham Biosciences) using Ettan<sup>TM</sup> IPGphor<sup>TM</sup> Isoelectric Focusing System and the second dimension was run by Hoefer<sup>TM</sup> Dalt vertical system according to manufacturer's instructions. The gels were stained with SYPRO<sup>TM</sup> Ruby fluorescence dye and imaged on an FLA3000 reader. In total about 700 proteins were analyzed with PDQuest (7.0.1, Bio-Rad) and statistical analysis with SPSS (version 11.5). The expression of 65 proteins were significantly altered. Of those, 24 were up-regulated after TCDD exposure. Determining the identity of the altered proteins will provide greater insight into mechanism by which TCDD disrupts prostate development. EXAMINING THE POSSIBILITY THAT CHRONIC AZATHIOPRINE TREATMENT POTENTIATES GERMLINE TRANSMISSION OF *HPRT* MUTATIONS IN C57BL/6 MICE.

S. Bendre<sup>1, 2</sup>, J. G. Shaddock<sup>2</sup>, V. N. Dobrovolsky<sup>2</sup> and R. H. Heflich<sup>2, 1</sup>.

Azathioprine (Aza), a pro-drug of 6-mercaptopurine, is used in human medicine to prevent transplant rejection and for the treatment of autoimmune diseases. Patients undergoing chronic Aza therapy can have extremely large increases in Hprt lymphocyte mutant frequency (MF) (up to 10 x 10<sup>-2</sup>) that may be caused by selection and amplification of pre-existing Hprt mutant lymphocytes. We have developed a mouse model to test the hypothesis that in vivo selection by Aza increases germ cell, as well as somatic cell Hprt MFs. 55 male C57BL/6 mice were treated with 10 mg/kg Aza for 23 weeks; 10 control mice were treated with the vehicle. Each of the treated animals then was bred with 3 females, and each of the controls with 1 female for a total period of 8 weeks. The resulting litters were sexed, weighed and counted, and the female offspring were sacrificed at 28 days of age to measure splenic lymphocyte *Hprt* MFs. Since the *Hprt* gene is on the X-chromosome, female mice with a germline *Hprt* mutation should have lymphocyte *Hprt* MFs between 1 and 5 x  $10^{-1}$ . The results indicate that 335 of the female offspring have Hprt MFs of 0-6 x  $10^{-6}$  (the normal range for mice this age), but 5 of the offspring have slightly elevated lymphocyte Hprt MFs of 15-30 x 10<sup>-6</sup>. Since one of these mice was fathered by a control male, these relatively high MFs may be part of the normal variation in lymphocyte Hprt MFs for mice this age. The mutants from these mice are being analyzed for alterations in the Hprt gene to determine if they were due to clonal expansion of single mutations or are independent events. The males treated with Aza were also evaluated for *Hprt* mutants, and 12 had lymphocyte MFs of 0.01-25 x 10<sup>-2</sup>, indicating that the Âza treatment successfully selected somatic cell mutants. Although data continue to be collected on additional offspring of Aza-treated mice, the present results indicate that Aza therapy does not promote high levels of germline *Hprt* mutation transmission.

TRANSPLACENTAL EXPOSURE TO  $17-\alpha$ -ETHYNYL ESTRADIOL INDUCES A SPECIFIC GENE EXPRESSION PROFILE IN THE DEVELOPING MALE RAT REPRODUCTIVE SYSTEM.

J. M. Naciff, K. A. Hess, S. M. Torontali, J. P. Tiesman, G. J. Overmann, G. J. Carr and G. P. Daston. Central Product Safety, Procter & Gamble Company, Cincinnati. OH.

Exposure of developing fetal rodents to estrogenic compounds at relatively high doses induces abnormalities in the male reproductive system and causes a predisposition to abnormal function during adulthood. We hypothesize these latent developmental effects are preceded by immediate changes in the fetal gene expression. Thus, an approach to address the potential impact on the physiology of the male reproductive system to estrogenic exposure is the evaluation of the gene expression changes elicited in this system. In this study, high-density oligonucleotide arrays were used to determine the transcriptional program produced by transplacental exposure to  $17~\alpha$ -ethynyl estradiol (EE), in the developing rat testis and epididymis on gestation day (GD) 20, following EE exposure from GD11 to GD20. At the highest dose (10 µg EE/kg/day) less than 1% of the detected mRNAs (83 genes;
