LIME

By M. Michael Miller

Lime is an important chemical with hundreds of chemical, industrial, and environmental uses in the United States. Its history probably dates back at least 4,000 to 6,000 years. The ancient Egyptians utilized lime as an ingredient in mortar and plaster. The Greeks, Romans, and Chinese utilized lime for construction, agriculture, bleaching, and tanning. Its uses began expanding with the advent of the industrial revolution, but it remained primarily a construction commodity until the rapid growth of the chemical process industries at the beginning of the 20th century. At the turn of the century, over 80% of lime consumed in the United States went for construction uses, but now over 90% of lime is consumed for chemical and industrial uses.

Lime is a basic chemical that ranked fifth in total production in the United States in 1995. It was produced in 33 States and Puerto Rico, and its major uses were in steelmaking; pulp and paper manufacturing; construction; and the treatment of water, sewage, and smokestack emissions.

Total lime sold or used by domestic producers, excluding that from Puerto Rico, increased by about 1.12 million metric tons (1.24 million short tons) to 18.5 million tons (20.4 million short tons) in 1995. Production included the commercial sale or captive consumption of quicklime, hydrated lime, and deadburned refractory dolomite. These products were valued at more than (\$1.1 billion). Commercial sales increased by 864,000 tons (952,000 short tons) to a record high of 16.3 million tons (18.0 million short tons), and captive consumption increased 264,000 tons (291,000 short tons) to 2.18 million tons (2.40 million short tons). (See table 1.)

Production

The term "lime," as used throughout this chapter, refers primarily to six chemicals produced by the calcination of highpurity calcitic or dolomitic limestone followed by hydration where necessary. They are (1) quicklime, calcium oxide (CaO); (2) hydrated lime, calcium hydroxide [Ca(OH)₂]; (3) dolomitic quicklime (CaOMgO); two types of dolomitic hydrate, (4) type N [Ca(OH)₂MgO] and (5) type S [Ca(OH)₂Mg(OH)₂]; and (6) dead-burned dolomite. Nondolomitic quicklime and hydrated lime are also called high-calcium lime. Lime also can be produced from a variety of calcareous materials such as aragonite, chalk, coral, marble, and shell. Lime is also regenerated; that is, produced as a byproduct, by paper mills, carbide plants, and water treatment plants; however, regenerated lime is beyond the scope of this report.

Domestic production data for lime are developed by the U.S. Geological Survey from two separate, voluntary surveys of U.S.

operations. The survey used to prepare this report is the annual "Lime" survey. Of the 108 operations to which the annual survey request was sent, 96 responded, representing 74% of the total sold or used by producers shown in table 2. Production for 11 nonrespondents was provided based on the monthly survey. Production for six nonrespondents was estimated using reported prior-year production figures.

In 1995, 61 companies produced lime. Leading producing companies, in descending order, were Dravo Lime Co., with two plants in Kentucky and one plant in Alabama; Chemical Lime Co., with two plants each in Alabama, Arizona, Nevada, and Texas and one each in California, Idaho, Missouri, and Utah; Marblehead Lime Co., with two plants in Illinois and one each in Indiana and Michigan; Mississippi Lime Co. in Missouri; Continental Lime Inc., with one plant each in Montana, Nevada, Utah, and Washington; Martin Marietta Magnesia Specialties in Ohio; APG Lime Co., with one plant each in Texas and Virginia; Bellefonte Lime Co., with two plants in Pennsylvania; Tarmac America, Inc. (formerly Wimpey Minerals PA), with two plants in Pennsylvania, and U.S. Lime & Minerals, Inc., with one plant each in Arkansas, Pennsylvania, and Texas. These 10 companies operated 35 plants and accounted for 71% of commercial sales and 64% of total lime production.

Domestic lime plant capacity is based on 365 days minus the average number of days for maintenance times the average 24-hour capacity of quicklime production, including quicklime converted to hydrated lime, and reported in short tons per year. In 1995, there were 38 commercial lime companies operating 61 lime plants; excluding combined captive and commercial producers, hydrating plants, and Puerto Rico. Capacity data were available from 32 commercial companies operating 52 plants. Based on the available data, the U.S. lime industry operated at 88% of capacity in 1995. Capacity utilization would be slightly lower if the capacity of several idle or mothballed plants were factored into the calculations.

On a regional basis, capacity utilization ranged from 82% to 97%. In the Mid-Atlantic Region (plants in eastern and central Pennsylvania, West Virginia, and northern Virginia) capacity utilization was 94%, based on data from seven companies operating eight plants. In the Southeastern Region (plants in Alabama, eastern Tennessee, and southern Virginia) capacity utilization was 92%, based on data from seven companies operating seven plants. In the Eastern Midwest Region (plants in Michigan, northern Kentucky, Ohio, and western Pennsylvania) capacity utilization was 90%, based on data from five companies operating six plants. In the Western Midwest Region (plants in Illinois, Indiana, Iowa, Missouri, and Wisconsin) capacity utilization was 82%, based on data from 9

companies operating 12 plants. In the South Central Region (plants in Arkansas, Louisiana, Oklahoma, and Texas) capacity utilization was 88%, based on data from six companies operating seven plants. In the Western Region (plants in Arizona, Colorado, Idaho, Montana, Nevada, Oregon, South Dakota, Utah, and Washington) capacity utilization was 86%, based on data from 6 companies operating 13 plants. (See tables 2 and 3.)

The lime industry continued the expansion of capacity begun in 1993. From 1993 to 1995, the commercial lime industry added over 1.9 million tons (2.1 million short tons) of new capacity, while losing 190,000 tons (210,000 short tons) of capacity. The lost capacity was the result of the closure of Warner Lime Co. in 1993. In 1995 alone, the industry added 1.5 million tons (1.7 million short tons) of new capacity. An additional 2.0 million tons (2.2 million short tons) of new capacity is planned for 1996 and 1997. Not included is the additional capacity planned by Martin Marietta Magnesia Specialties, a large combined captive and commercial producer of dolomitic lime in Ohio. Some of the announced new capacity will replace existing plant capacity, i.e., replacing older kilns with larger and more efficient new kilns, and may be partially offset by the closure or mothballing of some older plants.

Chemical Lime Co. started production at its new lime plant near Ste. Genevieve, MO, in December 1995. The first of two 1,100-ton-per-day (1,200-short-ton) Kennedy Van Saun (KVS) preheater rotary kilns went on-line. The second kiln was due on-line during the first quarter of 1996.¹

Dravo Lime Co. completed the capacity expansion at its Black River Division at Carntown, KY. The expansion included the installation of two 1,000-ton-per-day (1,100-short-ton) KVS preheater rotary kilns; two lime storage silos; a barge loadout system; three coal storage silos; and a limestone processing, storage, and reclaim system. Dravo completed construction of a limestone byproducts processing plant at its Longview Division at Saginaw, AL.² The company announced expansion plans at its Maysville Division at Maysville, KY, including the addition of a new preheater rotary kiln and the upgrade of the underground mining operation. The new Maysville kiln will have a capacity of 1,000 tons per day (1,100 short tons per day) or about 330,000 tons per year (350,000 short tons per year).³

Global Stone Corp. of Canada purchased St. Clair Lime Co., a producer of quicklime, hydrate, and chemical-grade limestone located in Sequoyah County in northeastern Oklahoma. St. Clair Lime was subsequently renamed Global Stone St. Clair Inc.⁴ Global Stone also purchased the assets of two Pennsylvania stone companies, Delta Carbonate Inc. and PenRoc Inc., located in York County, PA. The assets comprised three high-calcium limestone quarries producing construction aggregates and ground calcium carbonate, including high-brightness white fillers.⁵

Effective March 30, 1995, Bellefonte Lime Co. purchased the assets, real property, and mineral rights for the production of lime and limestone of its nearby competitor Centre Lime and Stone Co.⁶ Acquisition of Centre Lime and Stone doubled Bellefonte's lime production capacity and strengthened its

position in the Mid-Atlantic and Northeastern markets.

Greer Industries' Germany Valley Limestone Co., Riverton, WV, started up its new 450-ton-per-day (500-short-ton) KVS preheater rotary kiln in November 1995. This second kiln more than doubled the plant's production capacity.⁷ In a subsequent development, Greer Industries announced the renaming of Germany Valley Limestone to Greer Lime Co. and the opening of a new sales office in Charlotte, NC.⁸

Continental Lime Inc. continued the major expansion at its Pilot Peak plant near Wendover, NV. The company began work on a third kiln for the plant due on-line during the second quarter of 1996. The newest kiln will have a capacity of 900 tons per day (1,000 short tons per day) and bring the total plant capacity to 1,900 tons per day (2,100 short tons per day).

Consumption

Lime was consumed in every State, with the largest consuming States being Ohio, Pennsylvania, Indiana, Texas, and Michigan. Some States were net exporters, such as Alabama, Virginia, and Wisconsin. Some States were net importers, such as Ohio, Michigan, and Pennsylvania. (See tables 2 and 4.)

The breakdown of consumption by major end uses was as follows: 62% for chemical and industrial uses, 28% for environmental uses, 8% for construction uses, and 2% for refractory dolomite. Captive lime was used mainly in the production of steel in basic oxygen furnaces, in sugar refining, and in magnesia production.

In steel refining, quicklime was used as a flux to remove impurities such as phosphorus, silica, and sulfur. Dolomitic lime was often substituted for a fraction of the high-calcium lime to extend refractory life. Dead-burned dolomite, also called refractory lime, was used as a component in tar-bonded refractory brick used in basic oxygen furnaces. Despite an increase in U.S. raw steel production of more than 4% (more than 2% for basic oxygen furnace output and more than 7% for electric arc furnace output), lime consumption by the steel industry was essentially unchanged at 5.2 million tons (5.8 million short tons). The steel industry accounted for about 28% of all lime consumed in the United States.

The failure of lime consumption to increase in proportion to increases in steel production may have been the result of the use of larger amounts of scrap in basic oxygen furnaces, increased hot metal desulfurization, increased use of fluxed pellets, and improved efficiencies in steel production and energy consumption. Increased imports of quicklime from Canada were also part of the explanation. In 1995, imports of quicklime through the Detroit Customs District increased by 201% to 87,200 tons (96,200 short tons). This was undoubtably the result of the regional shortages experienced in 1995, when demand temporarily outstripped supply in the Western Midwest, Eastern Midwest, and Mid-Atlantic Regions.

In nonferrous metallurgy, lime was used in the beneficiation of copper ores to neutralize the acidic effects of pyrite and other iron sulfides and maintain the proper pH in the flotation process. It was used to process alumina and magnesia, to extract uranium from gold slimes, and in the recovery of nickel by precipitation. It was used in gold and silver recovery operations to control the pH of the sodium cyanide solution used to leach the gold and silver from the ore. Such leaching processes are called dump leaching when large pieces of ore are involved, heap leaching when small pieces of ore are involved, and carbon-in-pulp cyanidation when the ore is leached in agitated tanks. Dump and heap leaching involve crushing the ore, mixing it with lime for pH control and agglomeration, and stacking the ore in heaps for treatment with cyanide solution. Lime is used to maintain the pH level of the cyanide solution between 10 and 11 to maximize precious-metals recovery and to prevent the generation of hydrogen cyanide gas.

The tailings that result from the recovery of precious metals may contain elevated levels of cyanides. Three of the four major treatment processes (Cyanisorb, alkaline chlorination, and SO₂/air) used to recover these cyanides used lime in the process.

In the environmental sector, lime was used in the softening and clarification of municipal potable water. Lime was used to neutralize acid mine and industrial discharges. In flue gas desulfurization (FGD) systems serving utility and industrial plants, lime was used to react with sulfur oxides in the flue gas, and was used to stabilize the resulting sludge before disposal. In 1995, the FGD market exhibited the large increase expected due to the startup of lime scrubbers at American Electric Power's Gavin powerplant in Ohio and Monongahela Power Co.'s Harrison powerplant in West Virginia. Consumption for FGD use in utility powerplants, industrial boilers, and incinerators grew an aggregate 37% to nearly 2.7 million tons (3.0 million short tons).

In sewage treatment, lime was used to control pH in the sludge digester, which removes dissolved and suspended solids that contain phosphates and nitrogen compounds. It also aided clarification and killing of bacteria. Lime also was used to stabilize sludges from sewage treatment plants.

Sewage sludge stabilization, also called biosolids stabilization, has as its goal the reduction of odors, pathogens, and putrescibility of the solids. In lime stabilization, the basic process involves mixing quicklime with the sludge to raise the temperature and pH of the sludge to minimum levels for a specified period of time. In 1995, the sewage treatment market increased by nearly 29%. This probably reflects the expected growth in the sewage sludge stabilization market, generated by the 40 CFR 257 part 503 sewage sludge regulations.

The paper industry used lime as a coagulant aid in the clarification of plant process water. It was used, generally in conjunction with soda ash, for softening plant process water. This is a precipitation process to remove bivalent soluble calcium and magnesium cations (and to a lesser extent manganese, ferrous iron, zinc, and strontium), which contribute to the hardness of water. This process also reduces carbonate alkalinity and dissolved solids content.

In the basic Kraft pulping process, wood chips and an aqueous solution (called liquor) of sodium hydroxide and sodium sulfide are heated in a digester. The cooked wood chips (pulp) are discharged under pressure along with the spent

liquor. The pulp is screened, washed, and sent directly to the paper machine or for bleaching. Lime is sometimes used to produce calcium hypochlorite bleach for bleaching the paper pulp. The spent liquor is processed through a recovery furnace where dissolved organics are burned to recover waste heat and where sodium sulfide and sodium carbonate are recovered. The recovered sodium sulfide and sodium carbonate are diluted with water and then treated with slaked lime to recausticize the sodium carbonate into sodium hydroxide (caustic soda) for reuse.

Lime was used to make precipitated calcium carbonate (PCC), a specialty filler used in premium-quality coated and uncoated papers. The most common PCC production process used in the United States is the carbonation process. Carbon dioxide is bubbled through milk-of-lime, a suspension of hydrated lime in water, to form a precipitate of calcium carbonate and water. The reaction conditions determine the size and shape of the resulting PCC crystals.

The chemical industry used lime in the manufacture of alkalies. Quicklime was combined with coke to produce calcium carbide, which was used to make acetylene and calcium cyanide. Lime was used to make calcium hypochlorite, citric acid, petrochemicals, and other chemicals.

In sugar refining, milk of lime, a suspension of hydrated lime in water, was used to raise the pH of the product stream, precipitating colloidal impurities. The lime itself was then removed by reaction with carbon dioxide to precipitate calcium carbonate. Carbon dioxide was obtained as a byproduct of lime production.

Dolomitic quicklime was used as a flux in the manufacture of glass. Quicklime was used to make calcium silicate building products such as sand-lime brick; hydrated lime was used to produce silica refractory brick.

In construction, lime was used for soil stabilization to upgrade clay soils into satisfactory base and subbase materials. Common applications included the construction of roads, airfields, building foundations, earthen dams, and parking areas. Quicklime was used in autoclaved aerated concrete to produce building materials that could be cut, drilled, and nailed like wood, but with the advantages of a concrete product. Hydrated lime was used with fly ash to make a base material, in asphalt mixes to act as an antistripping agent, and in plaster, stucco, and mortar to improve durability. (See table 5.)

Although most lime is manufactured and sold or used as quicklime, there are some significant markets for hydrated lime. Total hydrated lime production was 2.37 million tons (2.61 million short tons), the vast majority of which was commercial sales. The construction and environmental markets were the largest consumers of hydrated lime. Sales of hydrate for construction uses (mainly asphalt, finishing lime, masonry, and soil stabilization) totaled 996,000 tons (1,098,000 short tons), which accounted for nearly 43% of total hydrate sales. Specific construction sales figures were as follows: asphalt, 206,000 tons (227,000 short tons); finishing lime, 82,000 tons (90,400 short tons); masonry, 161,000 tons (178,000 short tons); soil stabilization, 455,000 tons (502,000 short tons); and other

construction, 92,000 tons (101,000 short tons). Sales of hydrated lime for environmental uses (mainly acid neutralization, sewage treatment, and water purification) totaled 781,000 tons (861,000 short tons), which accounted for 33% of total hydrated lime sales. Specific sales figures for major environmental markets were as follows: acid neutralization, 132,000 tons (145,000 short tons); sewage treatment, 237,000 tons (261,000 short tons); and water purification, 285,000 tons (314,000 short tons).

Prices

Despite regional shortages in the lime supply and corresponding increases in spot prices, the overall average values for quicklime were essentially unchanged in 1995. Expected increases in the average values appear to have been reined in by the fierce competition between producers to aquire new powerplant FGD contracts and the moderating effect on prices of existing long-term steel and FGD contracts.

The average value of lime sold or used by producers, as reported to the U.S. Geological Survey on an f.o.b. plant basis, increased only slightly in 1995 to \$59.42 per ton (\$53.90 per short ton). Average values per ton were \$58.63 (\$53.18 per short ton) for chemical and industrial lime, \$55.93 (\$50.74 per short ton) for environmental lime, \$71.15 (\$64.54 per short ton) for construction lime, \$79.48 (\$72.11 per short ton) for agricultural lime, and \$91.44 (\$82.95 per short ton) for refractory dolomite.

The average value of quicklime sold was essentially unchanged at \$56.77 per ton (\$51.50 per short ton). Average values per ton sold were essentially unchanged for the following: chemical and industrial lime at \$57.67 (\$52.31 per short ton), environmental lime at \$53.39 (\$48.43 per short ton), and construction lime at \$58.51 (\$53.08 per short ton). The average value per ton of refractory dead-burned dolomite sold increased by 19% to \$95.46 (\$86.60 per short ton). Almost no quicklime was sold as aglime.

The average value of hydrated lime sold increased by 6% to \$72.09 per ton (\$65.40 per short ton). Average values per ton were essentially unchanged for chemical and industrial lime at \$64.97 (\$58.94 per short ton) and for environmental lime at \$70.50 (\$63.95 per short ton). The average value per ton of hydrate sold for construction increased by nearly 14% to \$77.06 (\$69.90 per short ton), and the average value for agricultural use increased 3% to \$78.81 (\$71.49 per short ton). The increase in the construction hydrate value may be partially the result of increased sales of hydrated lime slurry, which is considered a value-added product.

Foreign Trade

According to the Bureau of the Census, exports of lime were essentially unchanged at 71,900 tons (79,200 short tons). Imports of lime increased by 42% to 289,000 tons (318,000 short tons). Most U.S. trade was with Canada and Mexico, which together accounted for nearly 100% of the U.S. exports

and imports of lime. Canada was the major trading partner, receiving 85% of U.S. exports and shipping 95% of U.S. imports. (See table 1.)

World Review

Canada.—Based on preliminary data, lime shipments totaled 2.5 million tons (2.8 million short tons) in 1995 at a value of about C\$210 million. Commercial sales accounted for about 65% of the total. The industry was composed of 13 companies operating 19 plants in Alberta, British Columbia, Manitoba, New Brunswick, Ontario, and Quebec Provinces. Effective capacity utilization was approximately 70%. Apparent consumption decreased for the fourth year in a row and at 2.30 million tons (2.54 million short tons) was at the lowest level since 1987. 10

Mexico.—Cal de Torreon S.A. de C.V., located in Coahuila State, placed an order for an oil-fired 400 ton-per-day (440-short-ton-per-day) MAERZ vertical shaft kiln. The new kiln was due on-line during the first quarter of 1996.¹¹

South Africa.—Anglo Alpha's Union Lime Division was given approval to install a new kiln at its Ouplaas operation in the northern Cape. Installation of the new kiln is expected to be complete by the end of 1996, and the new kiln is expected to boost the plant's capacity by approximately 450,000 tons per year (500,000 short tons per year).¹²

The country's two largest lime producers, Union Lime and PPC Lime, ended their two-party lime cartel. The cartel agreement had the approval of the Government's Competitions Board, but the companies chose to voluntarily end the agreement. Termination of the agreement should boost competition with potential benefits to lime customers.¹³

United Kingdom.—In 1995, RMC Industrial Minerals Ltd. began work on a 5-year expansion program at its Hindlow lime plant located near Buxton, Derbyshire. The program called for the replacement of existing lime production facilities, while maintaining lime production. Phase I of the expansion program was scheduled for completion by the end of 1996, and consisted of replacement of the stone handling plant, installation of a MAERZ parallel flow regenerative vertical shaft kiln, replacement of the lime handling and lime grinding plants, and additional site work and infrastructure. Subsequent phases will include a stone washing plant, a second kiln, and replacement or upgrade of the hydration plant. ¹⁴ (See table 6.)

Current Research and Technology

An economic evaluation of the lime stabilization process for the treatment of sewage sludge (biosolids) was run comparing it to aerated-static pile composting and thermal drying. The study evaluated the competing Class A stabilization processes ability to handle sludge from facilities with varying capacities. Class A sludges can be distributed and marketed or land applied without the restrictions associated with Class B sludges. The economic evaluation included capital costs, annual operating and maintenance costs, and a present worth analysis. The study concluded that lime stabilization had the lowest unit costs of the three processes evaluated.¹⁵

Lime manufacturing utilizing rotary kilns loses 16% to 18% of the stone charge to dust. If practical, such fines are generally sold for a few dollars per ton as aglime or for acid neutralization, or given away at no charge. Unfortunately, the majority has to be disposed of by the producer, generating a negative plant value. A possible alternative to disposal is the compaction of fines into briquets of similar size as pebble lime targeting traditional pebble lime markets. The basic equipment includes the roll-type press, screw feeder, binders or lubricants to increase the strength of the briquets, a troughed conveyor, and a vibrating screen. Builders of briquetting machinery maintain test facilities to determine compaction characteristics and are able to supply the data necessary to determine the type of roll press, feeder, additives, and briquetting conditions to deliver the best machine performance and product benefits to the lime producer.16

The basic concern of marketing such fines remains, whether they are sold as fines or as briquets. Lime producers do not want to impact their high-quality lime markets by offering a less expensive product to the same customers. But if capacity utilization remains high, it may be worth consideration by some producers to investigate briquetting as a means to produce additional lower-grade product.

Outlook

Lime has dozens of end uses in the chemical, industrial, and construction industries, but over 65% of consumption comes from six major markets: steel, FGD, water purification, pulp and paper, soil stabilization, and precipitated calcium carbonate.

Steelmaking is still the largest single end use for lime. The steel industry is continuing to add capacity in the form of flat roll minimills. Most of this new capacity is being built in the Southeast or Midwest. U.S. steel production should continue to increase as long as the economy stays out of a recession. Lime consumption will probably increase also, but may lag steel increases due to industry changes in raw materials and flux usage, the latter including greater use of flux pellets and hot metal desulfurization.

In 1995, the FGD market exhibited the large increase expected due to the startup of lime scrubbers at the General Gavin and Harrison powerplants in Ohio and West Virginia, respectively. Although future growth is not expected to be as dramatic, there are a number of positive factors influencing this market. There are the favorable economics of using lime in dry scrubbers used with small utility boilers (less than 25 megawatts), which will be regulated in Phase II of the Clean Air Act Amendments. Regulations covering small municipal incinerators and waste to energy incinerators favor the use of lime scrubbers. Major FGD lime producers are investing in research and development to lower the capital and operating costs associated with lime scrubbing and to produce salable byproducts. The goal of such research ultimately is to provide environmentally sound and economic technologies designed

attract customers from powerplants currently utilizing limestone scrubbers and/or low sulfur coal. One negative is the evidence that the utility industry has been so successful in reducing SO₂ emissions that they have accumulated a large surplus of emissions allowances, which will allow them to delay installing scrubbers or closing older less efficient powerplants. Demand for FGD lime is expected to increase at a modest rate over the next few years.

Soil stabilization sales increased by 13% in 1995, but still fell substantially below the record year of 1993. The soil stabilization market fluctuates depending on the level of highway and related types of construction, the weather, and competition from competing products like cement. The use of lime in asphalt paving decreased by 12% in 1995, and although long-term growth is expected in this market, it is affected by the same uncertainties as soil stabilization.

Lime's traditional pulp and paper market was flat in 1995, as producers are apparently regenerating more lime from their carbonate sludge for environmental and cost reasons. The market will remain a large, mature market for lime, but growth is expected to be flat. The PCC market increased slightly in 1995 and should continue to grow as PCC attempts to expand into the groundwood paper and paper coating markets.

Overall, commercial lime sales are expected to grow at about 3% per year over the next several years. Any price increases expected because of shortages or increased demand will probably be negated by increased competition resulting from the addition of new capacity.

e/ Estimated. r/ Revised.

- $1/\,\mbox{Data}$ are rounded to three significant digits; may not add to totals shown.
- 2/ To convert metric tons to short tons multiply metric tons by 1.10231.
- 3/ Excludes regenerated lime. Excludes Puerto Rico.
- 4/ Selling value, f.o.b. plant, excluding cost of containers.
- 5/ Bureau of the Census.
- 6/ Calculated by sold or used plus imports minus exports.

r/ Revised.

^{1/} Excludes regenerated lime.

 $^{2\!/}$ Data are rounded to three significant digits; may not add to totals shown.

^{3/} To convert metric tons to short tons multiply metric tons by 1.10231.

 $^{4/\,}Less$ than 1/2 unit.

^{5/} Revised to zero.

^{6/} Includes other countries and U.S. possessions.

e/ Estimated. r/ Revised. XX Not applicable.

- 5/ Less than 1/2 unit.
- 6/ Dissolved Dec. 31, 1992.
- 7/ Eritrea became independent from Ethiopia in 1993.
- 8/ Includes hydraulic lime.
- 9/ Data are lime produced for steel production and do not include the widespread artisanal production of lime for whitewash and sanitation purposes.
- 10/ Dissolved in Dec. 1991.
- $11/\,Total\ production\ of\ the\ former\ U.S.S.R..\ Information\ was\ inadequate\ to\ formulate\ reliable\ estimates\ for\ individual\ countries.$
- 12/ Dissolved in Apr. 1992.

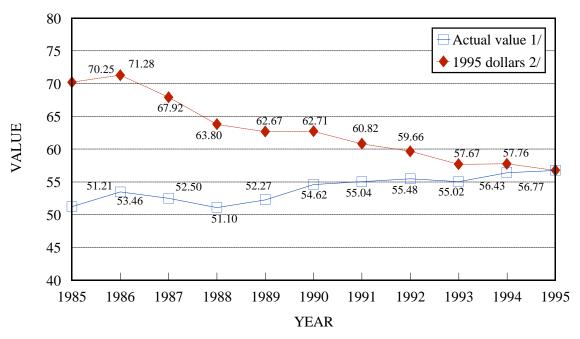

^{1/}World totals, U.S. data, and estimated data are rounded to three significant digits; may not add to totals shown.

^{2/} Table includes data available through Aug. 1, 1996.

^{3/} Lime is produced in many other countries besides those listed. Argentina, Iraq, Pakistan, and Syria are among the more important countries for which official data are not available. Venezuela does not report production of lime, which is thought to be produced in very small amounts on individual farms. Previous estimates of lime production in Venezuela have lacked any basis, and will not be reported in the future.

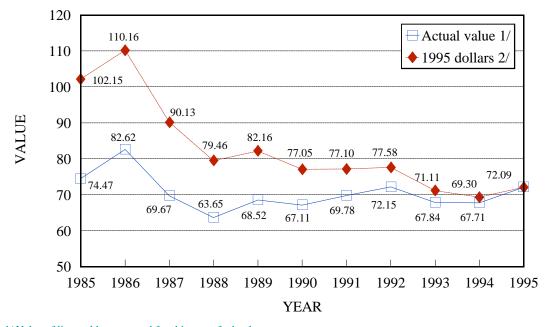

^{4/} Reported figure.

FIGURE 1
TIME-VALUE RELATIONSHIPS FOR QUICKLIME SOLD
(Dollars per metric ton)

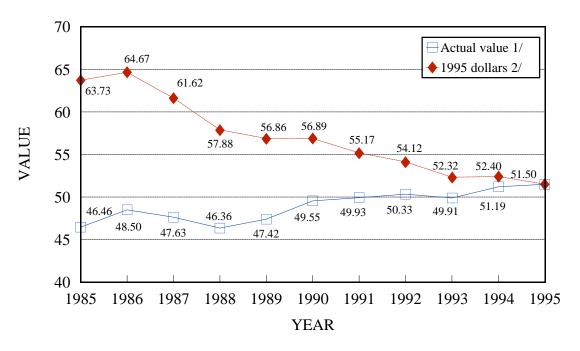

- 1/ Value of lime sold as prepared for shipment, f.o.b. plant.
- 2/ Based on implicit price deflator for gross domestic product of nonfinancial corporate business.

FIGURE 2
TIME-VALUE RELATIONSHIPS FOR HYDRATED LIME SOLD
(Dollars per metric ton)

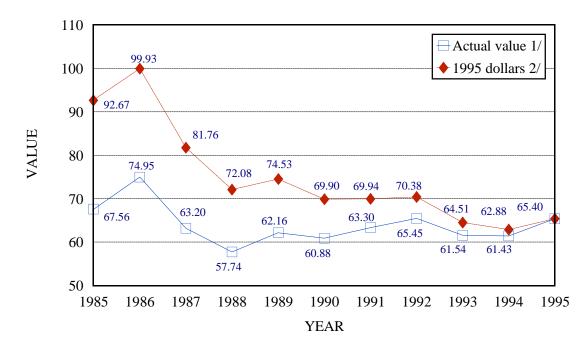

- $1/\ Value\ of\ lime\ sold\ as\ prepared\ for\ shipment,\ f.o.b.\ plant.$
- 2/ Based on implicit price deflator for gross domestic product of nonfinancial corporate business.

FIGURE 3
TIME-VALUE RELATIONSHIPS FOR QUICKLIME SOLD
(Dollars per short ton)

- 1/ Value of lime sold as prepared for shipment, f.o.b. plant.
- 2/ Based on implicit price deflator for gross domestic product of nonfinancial corporate business.

FIGURE 4
TIME-VALUE RELATIONSHIPS FOR HYDRATED LIME SOLD
(Dollars per short ton)

- 1/ Value of lime sold as prepared for shipment, f.o.b. plant.
- 2/ Based on implicit price deflator for gross domestic product on nonfinancial corporate business.
