

# COPPER

By Daniel L. Edelstein

**Domestic survey data and tables were prepared by Janet D. Richards and Deana Demichelis, statistical assistants, and the world production tables were prepared by Regina R. Coleman, Linder Roberts, and Glenn J. Wallace, international data coordinators.**

In 2000, mine production of recoverable copper in the United States continued its downward slide that began in 1998, falling by more than 150,000 metric tons (t) to the lowest level since 1988. In addition to mine closures and cutbacks carried forward from midyear 1999, high energy costs coupled with low copper prices led to unanticipated cutbacks and closures. Some rationalization of capacity occurred following consolidation of ownership at the end of 1999. Three companies, Phelps Dodge Corp., ASARCO Inc. (owned by Mexico's Grupo Mexico S.A. de C.V.), and Kennecott Utah Copper Corp. (owned by Rio Tinto plc of the United Kingdom), accounted for more than 95% of U.S. copper mine production.

While the United States maintained its position as the world's second largest mine producer of copper, accounting for about 11% of world production, its share of global production continued to decline from its 19% share in 1994. Chile, where mine production increased by 5% in 2000, and by 85% since 1995, was the largest mine producer and accounted for 35% of world production. World mine production grew by about 3.5% in 2000 and by 30% since 1995. The world reserves and reserve base for copper were estimated to be 340 million metric tons (Mt) and 650 Mt, respectively. The United States had about 13% each of reserves and reserve base. In the 1998 National Mineral Resource Assessment conducted by the U.S. Geological Survey (U.S. Geological Survey, 2000), the estimated copper

contained in undiscovered resources in the United States ranged from greater than 170 Mt at a 90% probability to greater than 440 Mt at a 10% probability. The mean estimate of copper in undiscovered deposits was 290 Mt. According to the assessment, more than two-thirds of the copper was thought to be contained in undiscovered porphyry copper deposits. Other major deposit types were sediment-hosted and volcanogenic massive sulfide deposits. About 50% of the undiscovered resource was believed to be in Great Basin and Southern Basin and Range regions (portions of Arizona, California, Nevada, New Mexico, and Utah). The identified copper resource was estimated to be 260 Mt. Coupled with past production of about 91 Mt, the total discovered copper resource in the United States was estimated to be 350 Mt.

U.S. copper smelter and refinery production also continued to fall and were down by 23% and 16%, respectively, from 1999 production levels, and 42% and 33%, respectively, from production in 1998. Owing to the combined impact of mine cutbacks and low prices, three of seven primary smelters had closed in 1999. Primary refined production declined owing to a downstream shortage of anode for refining. With the three smelters remaining closed in 2000, the United States became a net exporter of copper in concentrates. Contraction of the secondary copper industry continued with the closure in May of one of the Nation's two remaining secondary smelters and its

## Copper in the 20th Century

At the beginning of the 20th century, following patenting of the electric lightbulb and initial development of electric power distribution infrastructure late in the 19th century, the United States was experiencing a prolonged period of expansion in copper use for electrical generation, distribution, and industrial applications. U.S. mine production rose from 27,000 metric tons in 1880 to 275,000 tons in 1900 and 490,000 tons in 1910. Most of the copper produced came from high-grade vein deposits that predominantly yielded ore for direct shipping to smelters (80 smelters operated in 1907). By 1900, Montana and Arizona had emerged as the leading producing States, accounting for 45% and 20% of domestic production, respectively. The United States was by far the world's largest producer in 1900, accounting for 55% of world production and exporting about 160,000 tons of refined copper and consuming about 160,000 tons.

The United States retained its position as the largest producer and consumer of copper through most of the century. Domestic copper mine production peaked in 1997 at 1.94 million tons. Froth flotation and large-scale open pit mining methods introduced during the first decade of the century had revolutionized copper mining, and production was derived

increasingly from low-grade porphyry copper deposits. Industrialization, rural electrification, and growing infrastructure all contributed to the growth in copper demand. Electrical applications accounted for an increasing share of domestic consumption (about 75% in 2000).

By the start of the 21st century, however, the United States had relinquished its role as the world's largest copper producer to Chile (35% of global production). U.S. mine production in 2000 fell to about 1.4 million tons and accounted for only about 11% of world production. Technology advances made in the 1980s resulted in one-third of U.S. mine output in 2000 coming from the leaching and solvent extraction-electrowinning of acid soluble ores. The combined impact of environmental regulation and industry restructuring left only four smelters operating. The United States remained the world's largest user of refined copper (about 3 million tons, 20% of world total) and was dependant on imports for about one-third of its refined copper supply. Copper recovered from old scrap (500,000 tons in 1997) also fell victim to industry consolidation and offshore processing and declined to only 350,000 tons in 2000.

captive electrolytic refinery. Electrowon production, which accounted for a record 36% of primary refined production and 38% of mine production, declined by about 5%. Though it retained its position as the second largest refiner and third largest smelter, the U.S. share of world smelter and refinery production fell to 9% and 12%, both down from 15% in 1998. In 1998, the United States had been the largest smelter and refiner of copper.

Twenty-seven mines operating in 7 States, down from 33 in 1999, reported recoverable quantities of copper in 2000. Fourteen mines located in Arizona, Utah, New Mexico, and Montana, in descending order, accounted for more than 99% of production. The remaining 13 mines were either small leach operations or byproduct producers of copper. Despite the decline in production, capacity utilization at domestic mines rose, as capacity was adjusted downward to reflect the long-term closure of mines that were not expected to reopen without significant capital investment.

During the year, 4 primary and 2 secondary smelters, 6 electrolytic and 3 fire refineries, and 14 solvent extraction-electrowinning (SX-EW) facilities operated in the United States. By yearend, however, one secondary smelter and associated electrolytic refinery had closed. Following closure of three primary smelters in 1999, which were not anticipated to reopen in the short term, smelter capacity for 2000 was revised downward from 1.75 million metric tons per year (Mt/yr) in 1999 to 1.18 Mt/yr. Consequently, smelter capacity utilization rose from 74% in 1999 to 85% in 2000. Capacity at refineries declined by about 200,000 metric tons per year (t/yr) to 2.4 Mt/yr and the utilization rate fell to 74%. The conversion of old scrap to alloys and refined copper, declined by 47,000 t (12%), contributed 334,000 t of copper to the market, and accounted for 11% of apparent industrial demand. Lower copper prices in 2000 and closure of a secondary copper smelter led to the continued downward trend in recovery.

Copper was consumed as refined copper and as direct melt scrap at about 35 brass mills, 13 wire-rod mills, and 600 foundries, chemical plants, and miscellaneous operations. According to data compiled by the Copper Development Association Inc. (CDA) (Copper Development Association, Inc., 2001, p. 18), mill and foundry product shipments to the U.S. market, including net imports of mill products, continued their upward trend, rising by 170,000 t (4%) to 4.33 Mt, and were 43% higher than shipments in 1990.

The net import reliance for refined copper, as a percentage of apparent consumption, rose sharply to a record-high 37% (from 14% in 1998) following cutbacks in domestic production and growth in demand. Peru emerged as the largest source of refined copper, and, along with Canada and Chile, accounted for about 80% of refined imports. Canada remained the largest U.S. source for unwrought copper, accounting for 27% of total imports of unwrought copper. China (including Hong Kong), owing to a large growth in U.S. scrap exports, became the largest recipient for unwrought exports, accounting for 58% of refined exports and 38% (copper content) of total exports.

### **Legislation and Government Programs**

On January 26, 2000, as authorized by the Coin Act of 1997, the U.S. Mint began releasing its new Golden dollar coin to replace the Susan B. Anthony dollar coin that had been

introduced in 1979. In its report to Congress, the Mint outlined details of a promotional campaign aimed at helping the public build a strong awareness for the coins. According to the Mint, about 700 million Golden Dollars were placed in circulation during 2000, 7 times initial expectations. The new coins also generated an \$800 million profit for the Mint (U.S. Mint, 2001). At a coin weight of 8.1 grams and overall composition of 88.5% copper, 6% zinc, 3.5% manganese, and 2% nickel, the 700 million coins contained about 5,000 t of copper.

In January, the U.S. Department of Labor, Division of Trade Adjustment and Assistance, rejected a petition by the United Steel Workers of America seeking transitional adjustment assistance for workers producing copper rod at the Pauline, KS, plant of Superior-Essex Inc. In rejecting the petition, the department found that criterion 3 (the subject firm increased imports of like products from Canada or Mexico) and criterion 4 (the firm shifted production to Canada or Mexico) of the act had not been met. The Division of Trade Adjustment and Assistance concluded that copper rod production at Pauline had been shifted to other domestic plants of the subject firm and that Superior-Essex had neither increased its imports from Mexico or Canada nor shifted production to those countries (U.S. Department of Labor, 2000).

In June, the U.S. Environmental Protection Agency (EPA) proposed a change to its proposed national emissions standards for hazardous air pollutants (NESHAP) for primary smelters (smelting furnaces, slag cleaning furnaces, and batch converters). In April 1998, under section 112 of the Clean Air Act, which directs EPA to establish NESHAPs to control emissions from major stationary sources, EPA had proposed an equipment-based standard. The new proposed rule for the control of process emissions would establish a numerical emissions standard for particulate matter of 23 milligrams of total particulate matter per dry standard cubic meter (0.010 grains per dry standard cubic foot). In EPA's judgment, the proposed standard reflects "a level of total particulate matter emissions that can be achieved consistently by a properly operated and maintained sulfuric acid plant used to control process offgas from primary smelting and converting operations." The proposed standard also specifies that a furnace will be in violation of the standard if leak detector alarms installed on baghouses indicate higher than allowable emissions more than 5% of the operating time over a 6-month period. Copper smelting was 1 of 170 categories selected for regulation under the Clean Air Act (U.S. Environmental Protection Agency, 2000b).

In November, in response to an industry petition, EPA issued a final rule exempting the need for a residue tolerance test, in accordance with the Federal Food, Drug, and Cosmetic Act (as amended by the Food Quality Protection Act of 1996), when copper sulfate pentahydrate is used as a fungicide on raw agricultural commodities after harvest. This regulation eliminates the need to establish a maximum permissible level for residues of copper sulfate pentahydrate. While use of copper compounds has been exempted from tolerance tests when applied to growing crops, they had not been exempted when applied to crops at the time of or after harvest. Copper compounds are already exempted from testing when used on harvested fish, meat, poultry, eggs, and irrigated crops. In granting its exception, EPA noted relevant scientific data indicating that it is unlikely that excessive amounts of copper

ion from this use would be ingested, that copper is ubiquitous in nature and naturally occurring in ingested water and plants, is an essential nutritional element in animals (including humans) and plants, not readily absorbed when ingested, and that most of absorbed copper is excreted (U.S. Environmental Protection Agency, 2000a).

## Production

Mine production capacity was adjusted downward by about 250,000 t/yr to about 1.75 Mt/yr, reflecting the sustained closure of BHP Copper Co. mines and reduced capacity at several other mines that had shifted mining strategies or plans. Phelps Dodge closed its Metcalf concentrator at its Morenci Mine in Arizona during August in anticipation of switching to an all leach operation in 2001. In response to lower average prices, mine closures, and higher than anticipated utility rates, production declined by about 160,000, t and capacity utilization rose slightly to about 84%. With the exception of its small Arizona leach SX-EW operations at San Manuel, Pinto Valley, and Miami, BHP's mines remained shuttered.

Primary smelter production declined by 21% following the closure of three of the seven primary domestic smelters during 1999 and was down by 42% from that in 1998. Smelter capacity was revised downward to reflect the indefinite closure of these smelters. Secondary smelter production continued its downward trend, declining by 31%. In May, Southwire Co. closed its secondary smelter and associated electrolytic refinery, in Carrollton, GA. Southwire continued to operate its rod mill housed within its Copper Division Southwire (CDS). Sixteen months prior, as part of a restructuring plan aimed at lowering its costs, Southwire had unsuccessfully placed its Carrollton copper smelter/refinery operations on the market. Southwire cited economic factors, including the continued cost of compliance with environmental regulations in the metro-Atlanta area, for the closure of copper smelting operations. CDS was constructed in 1972, at a time when primary producers exerted greater control over copper prices. As part of the closure justification, Southwire cited the advent of worldwide commodity prices and their own "strong buying position" as leverage in meeting future raw material needs (Southwire Co., 2000). Closure of CDS secondary copper facilities, which have a capacity to produce 140,000 t/yr of refined copper, had a significant impact on the U.S. scrap copper market. Southwire processed a mixture of imported blister and copper scrap at its smelter to produce anode for electrolytic refining. Southwire was one of two remaining secondary smelters in the United States, two other smelters having closed in the preceding 3 years. Southwire closed its other secondary copper smelter in Gaston, SC, at the end of 1994, also citing the high cost of environmental compliance as the reason for closure.

Primary and secondary refinery production declined by 16% and 9%, respectively. The aforementioned smelter closures led to downstream shortages of anode for refining. Electrowon production declined by only about 3% and accounted for a record 36% of primary refined production. The Warrenton fire refinery, which had closed in March 1999, was reopened under different management, mitigating some of the lost secondary refinery capacity.

Following acquisition of the assets of Cyprus Amax Minerals Co. at yearend 1999, Phelps Dodge Corp. reported record

copper production of 1.32 Mt, including minority participants share of 235,000 t, from its worldwide operations. U.S. production amounted to 850,000 t. In the United States, production and costs were adversely affected by unusually heavy precipitation during the fourth quarter of the year and high energy costs, including electricity, diesel fuel, and natural gas. According to Phelps Dodge, its domestic electricity costs during the fourth quarter averaged \$0.11 per kilowatthour, more than three times their 5-year average cost, and total energy costs rose by \$0.08 per pound of copper production, a 65% increase over the comparative 1999 period. Total energy costs increased copper unit costs in 2000 by approximately \$0.04 per pound compared with unit costs in 1999. Beginning in the spring of 2000, the impact of a power supply/demand imbalance in California, drought in the Pacific Northwest, and higher natural gas prices caused a shortage of electricity and higher spot market electricity costs. Approximately 27% of Phelps Dodge's electricity requirements in 2000 was purchased on the spot market (Phelps Dodge Corp., 2001a, p. 15-16; 2001b, p. 3).

At its Morenci Mine, production of copper in concentrate declined from 177,000 t to 120,000 t following placement of the Metcalf concentrator on standby in June. In September 1999, Phelps Dodge had announced its intent to reduce production costs by converting all Morenci production to mine-for-leach by early 2001 and permanently shut both the Metcalf and Morenci concentrators. The \$220 million conversion proceeded throughout 2000 and was completed during the first quarter of 2001. New facilities included an expanded crushing and conveying system, mobile stackers to disperse the ore on leach piles, expanded solvent extraction facilities, and construction of a new electrowinning tankhouse. Electrowon production in 2000 of 258,000 t was unchanged from that of 1999 (Phelps Dodge Corp., 2001a, p. 3-9).

At its Miami, AZ, leach operations acquired with the purchase of Cyprus Amax, a new mine plan was instituted in June that suspended stripping in a higher cost section of the mine and allowed redistribution of equipment to other Phelps Dodge operations. Production in 2000 of 54,000 t of cathode was not impacted by the mine plan change, though production in 2001 and 2002 was expected to fall by 16,000 t and 39,000 t, respectively. At its newly acquired Bagdad Mine in Arizona, Phelps Dodge reported production of 101,000 t of copper in concentrate and 10,700 t of electrowon copper. Electrowon production at its Tyrone, NM, mine was essentially unchanged at 72,000 t (Phelps Dodge Corp., 2001a, p. 3-9).

In March, Phelps Dodge ended speculation on the fate of its newly acquired Sierrita Mine in Arizona when it announced that it intended to invest \$13 million to upgrade the mine (\$2.9 million), the crushing and conveying system (\$2.5 million), the solvent extraction circuit (\$1.3 million), as well as other upgrades and land purchases (\$3.0 million) (Platt's Metals Week, 2000c). Production in 2000 amounted to 87,000 t of copper in concentrate and 24,000 t of electrowon copper (Phelps Dodge Corp., 2001a, p. 8).

At its Hidalgo, NM, smelter, closed in September 1999, Phelps Dodge announced its intention to reconfigure the smelter to produce sulfuric acid for its leaching operations. While Phelps Dodge had a near-term surplus of concentrate, the company announced at midyear that it intended to stop exporting surplus concentrates and to stockpile them in anticipation of conversion of Morenci to all leach operation,

resulting in a future concentrate shortfall. Prior to closure of the Hidalgo smelter, Phelps Dodge had been a net importer of copper concentrates from its South American operations (Phelps Dodge Corp., 2000). In 2000, Phelps Dodge smelters produced 449,000 t of copper. As a result of the upstream curtailment in smelting, Phelps Dodge's refineries in El Paso, TX, and Miami, AZ, operated at only 72% of their combined capacity, producing 427,000 t of copper cathode (Phelps Dodge Corp., 2001a, p. 9).

In July, Asarco, a wholly owned subsidiary of Mexico's Grupo Mexico S.A. de C.V., announced plans to consolidate all corporate functions in Phoenix, AZ, by yearend. Following acquisition by Grupo in November 1999, Asarco had already transferred many of its corporate functions from New York City to Arizona (ASARCO Inc., 2000a). Grupo reported that operating and cost savings from the integration of Asarco and Southern Peru Copper Corp. following acquisition in 1999 amounted to more than \$171 million. Asarco's share of mine production declined from 293,000 t in 1999 to 261,000 t in 2000 (Grupo Mexico S.A. de C.V., 2001b).

At Asarco's Ray Operations in Hayden, AZ, production of copper in concentrate and electrowon cathode declined to 99,300 t and 38,800 t, respectively, down from 144,000 t and 40,000 t, respectively, in 1999. The Ray mining unit consists of a 227,000-metric-ton-per-day (t/d) open pit mine with a 27,000-t/d concentrator (Ray) and a 23,500-t/d concentrator (Hayden), a 13,600-t/d silicate leaching system, a low-grade sulfide dump leaching system, and a SX-EW operation. The Hayden oxygen flash smelter, with an annual capacity of 650,000 t/yr of concentrates, produced 191,000 t of copper anode. Asarco's El Paso smelter remained on standby throughout the year, and production at its Silver Bell Mine and SX-EW operation in Arizona declined by about 2,000 t to 18,300 t (Grupo Mexico S.A. de C.V., 2001a, p. 10-13).

In November, Asarco initiated a new mine plan at its Mission Mine Unit in Arizona. Under the plan, ore production was reduced from 56,000 t/d to 37,000 t/d, while total material mined was increased by 25%, thus increasing the stripping ratio and extending the reserve life at the mine from 14 to 22 years. The new plan was expected to boost average ore grades, increase recovery rates, and reduce unit production costs. Annual production of copper in concentrate was expected to decline by 22,000 t (ASARCO Inc., 2000b).

Montana Resources Inc. (49% owned by Asarco) suspended milling operations at its Continental Mine in Montana on June 30, citing "a dramatic escalation in power prices" as the reason for the shutdown. Stripping operations continued after the mill closed, and the company had anticipated resuming operations by yearend when it had expected utility rates to abate after the peak summer demand (Platt's Metal's Week, 2000b). At yearend, however, the mine remained closed and was not anticipated to reopen in the near term.

Despite numerous setbacks and limited interest by investment companies, Summo Minerals Corp. continued predevelopment work on its Lisbon Valley Copper Project, San Juan County, UT. The company resumed a drilling program early in the year in the Centennial SE Extension deposit and updated reserve calculations for a revised "final feasibility study," approved in September, for submission to banks for solicitation of financing. The plan design is for an open pit, heap-leach, SX-EW project producing 18,000 t/yr of cathode during a minimum 8.5-year

period at anticipated cash and full operating costs of below \$0.50 and \$0.75 per pound of copper, respectively. Reserves were estimated at 333 Mt of ore grading an average 0.54% copper with a stripping ratio of 2.25 (Summo Minerals Corp., 2000a; 2000b).

At Kennecott Utah Copper Corp.'s Bingham Canyon Mine, production of copper increased by 5.9% to 296,000 t, and gold output rose 44% to 529,000 ounces compared with production in 1999. A 4% increase in ore milled, combined with a 4% and 44% increase, respectively, in copper and gold grades, accounted for the production growth. Copper ore grades had fallen from 0.62% copper in 1998 to 0.55% in 1999 and recovered, beginning midyear, to an annual average of 0.57% in 2000, still below the expected life-of-the-mine average. Kennecott anticipated that large-scale underground mining would extend mine life by 15 years when open pit reserves are exhausted around 2015. Refinery output increased nominally to 269,000 t with the smelter reportedly operating in excess of rated capacity (Rio Tinto plc, 2001, p. 37).

Nord Resources Corp. was seeking financing to return the Johnson Camp copper mine to full production. Nord acquired Johnson Camp in June 1999. In the first 6 months of 2000, the company incurred losses related to the planned redevelopment of the mine but operated on a close to break-even basis after that (Nord Resources Corp., 2000b). The Johnson Camp Copper Mine, 105 kilometers east of Tucson, AZ, is currently being operated on a maintenance basis. Since 1975, the mine has produced more than 68,000 t of cathode copper from open pit mining, heap leaching, and SX-EW processing of oxide ores. Although significant reserves remain, mining operations ceased in 1997. Heap leaching continues and the mine is producing 1 to 2 million pounds of copper annually. A detailed feasibility study to restart the Johnson Camp Mine demonstrated that the mine could produce 8,900 t per year of copper cathode for 11 years at an average cash cost of \$0.63 per pound. Startup costs would total \$13.5 million, including \$7.9 million of capital investment and \$5.6 million of working capital and other costs. Current reserves are placed at 3.2 Mt grading 0.417% copper (Nord Resources Corp., 2000a).

## Consumption

Reported consumption of refined copper by domestic manufacturers continued its upward trend, rising by 1.6%, to 3.03 Mt. In addition to refined copper, domestic manufacturers directly consumed (melted or processed into chemicals) 1.3 Mt of copper-base scrap containing about 1 Mt of recoverable copper. An additional 75,000 t of copper was recovered in the consumption of aluminum-, nickel-, and zinc-base scrap.

Consumption of refined copper at wire-rod mills increased nominally and accounted for about 74% of domestic consumption of refined copper. For the third consecutive year, consumption growth at wire-rod mills was moderated by increased imports of wire rod, principally from Canada and Mexico, from which imports rose by 45,000 t to 225,000 t in 2000. Total imports rose by 63,000 t. Capacity utilization at domestic mills remained high following closure of two wire-rod mills in 1999. According to industry reports, despite increased imports, the U.S. wire-rod market was tight and at midyear experienced supply shortages. Wire-rod inventories in June fell to their lowest levels in recent years. An extended maintenance

shut down at Grupo Minero Mexico S.A.'s Mexican wire-rod mill led to a 20% cutback in shipments in June, and production difficulties were also reported at Southwire Co., which had closed its secondary smelter and electrolytic refinery at the end of May (Platt's Metals Week, 2000d). In response to limited U.S. capacity and expectations of continued demand growth, Alcatel, a French-owned communications company with wire-rod mills in Canada, France, and Germany, announced plans to construct a 200,000-t/yr wire-rod mill in the southeastern United States. Commissioning was anticipated in 2 to 3 years (Platt's Metals Week, 2000a).

At brass mills, which were the second largest consumers of refined copper, consumption of refined copper rose by about 5%, while consumption of copper-base scrap rose by less than 2%, reflecting the continued impact of relatively low copper prices that reduced the cost of using refined copper and reduced the availability of scrap for processing. Brass mills still remained the largest consumers of scrap, accounting for about two-thirds of the total copper recoverable from scrap.

According to data compiled by the CDA (2001, p. 18), the supply of copper and copper-alloy products to the U.S. market by fabricators (wire mills, brass mills, foundries, and powder producers), including net imports, rose by about 4% to 4.3 Mt, up from the revised total of 4.16 Mt in 1999, and contained an estimated 3.9 Mt of copper. About 71% of these shipments was as unalloyed copper products. Wire mill products accounted for about 49% of total shipments to the domestic market; brass mill products, 47%; and foundry and powder products, 4%. In building construction, the largest end-use sector, shipments were essentially unchanged and accounted for about 39% of the market, down from 41% the previous year. Building construction included products used for building wire, plumbing and heating, air conditioning and commercial refrigeration, builders hardware, and architectural applications. Shipments for electric/electronic products and consumer/general products rose by 9% and 11%, respectively, and accounted for 28% and 11% of the market, respectively. Shipments for transportation equipment, 11%, and industrial machinery, 11%, rose slightly.

In May, Cerro Copper Products Co. announced that it had broken ground on a new "flagship" tube manufacturing and distribution center in Cedar City, UT. The tube mill was expected to be commissioned in 2001. The facility is part of a 3-year, \$125 million expansion program. In addition to employing a unique, Cerro-developed process to produce both plumbing and air conditioning tube, the mill will be the only tube mill in the western United States (Cerro Copper Products, 2000). According to the Copper Development Association Inc. data (2001, p. 17), though down slightly in 2000, plumbing and commercial tube shipments to the U.S. market have risen 14% since 1995.

## Prices and Stocks

Despite growing global inventories, copper prices in January continued the upward trend begun in mid-1999 and rose to their highest level in almost 2 years. The Commodity Exchange (COMEX) spot price averaged \$0.85 per pound in January. With global inventories held on the commodity exchanges continuing to rise in February, prices began to weaken. Despite a sharp reversal in the upward trend in global inventories beginning in March, prices remained lower, the COMEX price

averaging only \$0.80 per pound in the March to June period. According to data compiled by the International Copper Study Group (2001a, p. 6), monthend inventories of refined copper on the global exchanges (LME, COMEX, and Shanghai Futures Exchange) peaked in February at 990,000 t before beginning a sustained slide that lasted through November when monthend inventories fell to 495,000 t. Prices began to respond to the decline in global stocks in May, and the average monthly COMEX price climbed to \$0.91 per pound in September. Prices weakened and fluctuated during the fourth quarter of the year, the COMEX price averaging \$0.86 per pound and finishing the year at \$0.85 per pound. At yearend, inventories of copper held on the metals exchanges totaled 530,000 t, and total reported inventories, as reported by the International Copper Study Group (ICSG), decreased to 1.31 Mt, down from 1.62 Mt in 1999. At the prevailing rate of consumption, global inventories at yearend represented only about 31 days of supply, down from 41 days in 1999.

## Trade

Net imports of refined copper rose sharply for the fifth consecutive year to 962,000 t, compared with 812,000 t in 1999. General imports of refined copper (1,025,000 t) were 30,000 t lower than imports for consumption as bonded material was removed from U.S.-located London Metal Exchange Ltd. (LME) warehouses. Beginning in March, LME inventories declined steadily and at yearend totaled 204,000 t, down from 412,000 t at yearend 1999. Exports of refined copper rose to 94,000 t, up from 25,000 t in 1999, and accounted for some of the drawdown in LME inventories.

Reduced domestic capacities led to shifts in the trade pattern for several copper products. Continuing the trend begun during the second half of 1999 following the closure of three primary smelters, the United States reverted to being a net exporter of copper in concentrates during 2000. The United States exported 175,000 t of copper in concentrate while having only negligible imports. Prior to 1998, the United States had been a long-term net exporter of concentrates. Reduced secondary processing capacity led to a surge in scrap exports; combined scrap exports of 486,000 t for 2000 exceeded exports of 315,000 t in 1999. China, including Hong Kong, was the largest recipient, accounting for 223,000 t, 46%, of total scrap exports. Owing to reduced capacity at domestic wire-rod mills, growth in industrial demand for wire rod was met by increased imports. Wire-rod imports (as reported by the U.S. Census Bureau and adjusted by the U.S. Geological Survey) rose to 247,000 t, up from 197,000 t in 1999 and 108,000 t in 1998.

According to U.S. Census Bureau data compiled by the Copper and Brass Fabricators Council Inc. (2001, p. 1-9), the United States imported 394,000 t of copper and copper-alloy semifabricated products, excluding wire-rod mill products, and exported 158,000 t. Net imports rose to 236,000 t, up from 139,000 t in 1999 and 86,000 t in 1998. Canada and Mexico accounted for 75% of semifabricated copper exports and 30% of imports.

Each year during the anniversary month of the publication of an antidumping or countervailing duty order, finding, or suspension of investigation, interested parties may request that the Department of Commerce conduct a review of the prevailing ruling. Numerous copper products for which antidumping or

countervailing duties have been imposed were subject to review in 2000. In May, the International Trade Administration (ITA) ruled that revocation of antidumping duty orders against brass sheet and strip from the Republic of Korea, the Netherlands, and Sweden was not likely to lead to recurrence or continuation of material injury to the domestic industry and that it was revoking the duties effective January 1, 2000 (U.S. Department of Commerce, 2000b). Conversely, the ITA ruled to maintain antidumping and countervailing duty orders for brass sheet and strip from Brazil, Canada, France, Germany, Italy, and Japan (U.S. Department of Commerce, 2000a).

## World Review

The global production oversupply for refined copper that developed at midyear 1997, and continued into 1999, began to shift during the first quarter of 2000. According to data compiled by the ICSG, reported world inventories of refined copper by the end of June had declined 220,000 t from those held at yearend 1999, and by yearend 2000 were down by 310,000 t to 1.3 Mt. At the prevailing rate of consumption, yearend world inventories represented a 31-day supply of refined copper, down from about 42 days at the end of 1999. Inventories held in LME warehouses declined by 433,000 t, overshadowing increases in reported consumer and Shanghai Futures Exchange inventories. The transition from production surplus in 1999 to production deficit in 2000 reflects a slowdown in refined production growth and an almost 8% growth in world refined copper consumption to 15.3 Mt. While consumption grew only about 2% in North America to 3.74 Mt, consumption by European Union countries grew by about 7% to 4.1 Mt, and Asian countries by about 11% to 6.1 Mt. Growth was particularly strong in China, where usage grew by about 25% to 1.88 Mt (International Copper Study Group, 2001a).

In 2000, despite the decline in U.S. capacity, estimated world mine capacity rose by 470,000 t/yr, or 3.4%, to 14.4 Mt/yr, extending the strong growth trend that began in 1995. Chile, Indonesia, and Kazakhstan accounted for most of the capacity expansion, their capacities having grown by 270,000 t/yr, 145,000 t/yr, and 90,000 t/yr, respectively. Capacity also increased significantly in Australia (33,000 t/yr) and China (30,000 t/yr). World smelter capacity, which had trended upward over the preceding 5 years, declined by about 150,000 t/yr. Indefinite closures of U.S. smelters were partially offset by expanded capacity in Australia (110,000 t/yr), where the Mount Isa smelter reached full capacity and the new Port Kembla smelter was commissioned during the year. In Korea, incremental expansions of the Onsan smelters boosted capacity by about 40,000 t/yr; in Bulgaria, expansion of the UM Pirdop smelter increased capacity by 45,000 t/yr; and in China, installation of an Isasmelt furnace at the Yunnan smelter boosted capacity by about 50,000 t (International Copper Study Group, 2001c, p.1-56). According to CRU International Ltd. (2001, p. 54-55), the supply of copper concentrates for smelting exceeded demand by about 230,000 t/yr of contained copper, and contract treatment (smelting) and refining charges assessed by smelters averaged about \$0.18 per pound of recoverable copper, essentially unchanged from that in 1999.

World refinery capacity rose by about 140,000 t/yr, less than 1%, principally owing to expansion of electrowinning capacity in Chile. The decline in U.S. electrolytic refining capacity was

offset by increased capacity in Australia, where the Port Kembla refinery was commissioned (60,000 t/yr expanding to 120,000 t/yr) and the Olympic Dam refinery was expanded by about 50,000 t/yr. In Indonesia, capacity increased by about 30,000 t/yr at the Gresik refinery, commissioned in 1999 (International Copper Study Group, 2000c, p. 57-98).

## Outlook

U.S. mine production is expected to decline by about 100,000 t in 2001 as the full impact of 2000 mine plan changes is realized and new cost saving programs are implemented. Production is expected to decline by an additional 40,000 t in 2002. The Morenci Mine in Arizona already closed its remaining concentrator and converted to an all leach operation during the first quarter 2001, reducing its total output but increasing production of electrowon copper. At Miami, suspension of stripping in 2000 was expected to reduce output in 2001 and 2002 by 16,000 t and 38,000 t, respectively. The mine plan implemented by Asarco at its Mission Mine at yearend should further reduce production in 2001 by about 20,000 t. In June 2001, Kennecott announced that it would suspend operations from its higher cost North concentrator, reducing ore throughput by about 18% (Kennecott Utah Copper Corp., 2001). Following cutbacks in concentrate output, the three primary smelters closed in 1999 are expected to remain shuttered.

Primary refined production in 2001 is expected to decline only slightly owing to a decrease in net exports of concentrate and increased electrowon production. Secondary refined production is expected to fall following the May closure of Southwire Co.'s secondary smelter.

Domestic consumption of refined copper during the first 6 months of 2001 was down by about 10% from the same period in 2000. In addition to a more than 100,000 t decline in copper consumption at wire-rod mills, weakness in the wire-rod market was indicated by a 20,000-t decline in net imports of wire rod for the first 6 months of the year. Economic slowdown during the second half of 2001 was expected to keep demand at or below first half levels.

At the Annual General Session of the ICSG, held in June 2001, in Lisbon, Portugal, a consensus view of the world balance of copper supply and use for refined copper was developed by Government and industry delegates. According to the consensus, world production of refined copper from both primary and secondary sources in 2001 (adjusted to reflect primary feed shortages and disruptions to operations) is projected to increase by about 500,000 t (3.4%), while world refined copper use is expected to decline by about 100,000 t (less than 1%). This forecast follows a 10-year period of sustained demand growth. Consequently, the production deficit that developed in 2000 was expected to be reversed, and a small surplus of about 130,000 t of refined copper was anticipated. At the prevailing rate of use, this surplus represents only about a 3-day supply of copper. Projections by the ICSG for 2002 indicate that refined production, adjusted to reflect feed shortages and disruptions, will increase by only about 0.5% and will not keep pace with the projected 3.7% growth in demand. As a result, a production deficit is expected for 2002 (International Copper Study Group, 2001b).

Total	2,730,000	23,800	101,000	176,000	3,030,000

r/ Revised. W Withheld to avoid disclosing company proprietary data; included with "Wirebar, billets, other." -- Zero.

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

2/ Includes items indicated by symbol W.

3/ Includes consumers of copper powder and copper shot, iron and steel plants, primary smelters producing alloys other than copper, and other manufacturers.

TABLE 6  
COPPER RECOVERED FROM SCRAP PROCESSED IN THE UNITED STATES,  
BY KIND OF SCRAP AND FORM OF RECOVERY 1/

(Metric tons)

	1999	2000
Kind of scrap:		
New scrap:		
Copper-base	903,000	906,000
Aluminum-base	46,200 r/	45,500
Nickel-base	94	18
Total	949,000 r/	952,000
Old scrap:		
Copper-base	349,000	334,000
Aluminum-base	31,200 r/	28,400
Nickel-base	44	170
Zinc-base	31	32
Total	381,000	363,000
Grand total	1,330,000	1,310,000
Form of recovery:		
As unalloyed copper:		
At electrolytic plants	156,000	128,000
At other plants	81,800	88,400
Total	238,000	217,000
In brass and bronze	1,000,000	1,010,000
In alloy iron and steel	599 r/	549
In aluminum alloys	78,200 r/	74,900

See footnotes at end of table.

TABLE 6--Continued  
COPPER RECOVERED FROM SCRAP PROCESSED IN THE UNITED STATES,  
BY KIND OF SCRAP AND FORM OF RECOVERY 1/

(Metric tons)

	1999	2000
Form of recovery--Continued:		
In chemical compounds	11,800 2/	11,700
Total	1,090,000	1,100,000
Grand total	1,330,000	1,310,000

r/ Revised.

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

2/ 1999 data reflects expanded coverage to include copper sulfate and other copper chemical producers.

TABLE 7  
COPPER RECOVERED AS REFINED COPPER AND IN ALLOYS AND OTHER FORMS  
FROM COPPER-BASE SCRAP PROCESSED IN THE UNITED STATES, BY TYPE OF OPERATION 1/

(Metric tons)

Type of operation	From new scrap		From old scrap		Total	
	1999	2000	1999	2000	1999	2000
Ingot makers	34,700	29,900	94,700	90,700	129,000	121,000
Refineries 2/	48,800	39,000	181,000	169,000	230,000	208,000
Brass and wire rod mills	804,000	822,000	25,900	22,200	830,000	844,000
Foundries and manufacturers	11,400	10,800	40,000	44,500	51,400	55,400
Chemical plants 3/	3,940	3,880	7,840	7,840	11,800	11,700
Total	903,000	906,000	349,000	334,000	1,250,000	1,240,000

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

2/ Electrolytically refined and fire-refined scrap based on source of material at smelter level.

3/ 1999 data reflects expanded coverage to include copper sulfate and other copper chemical producers.

TABLE 8  
PRODUCTION OF SECONDARY COPPER AND COPPER-ALLOY PRODUCTS  
IN THE UNITED STATES, BY ITEM PRODUCED FROM SCRAP 1/

(Metric tons)

Item produced from scrap	1999	2000
Unalloyed copper products:		
Electrolytically refined copper	156,000	128,000
Fire-refined copper	73,700	80,000
Copper powder	7,420	7,510
Copper castings	647	839
Total	238,000	217,000
Alloyed copper products:		
Brass and bronze ingots:		
Tin bronzes	15,800 r/	14,600
Leaded red brass and semired brass	97,300 r/	93,500
High leaded tin bronze	13,000	12,700
Yellow brass	6,010	5,650
Manganese bronze	7,060 r/	6,240
Aluminum bronze	6,870	7,030
Nickel silver	2,050	2,260
Silicon bronze and brass	4,530	4,680
Copper-base hardeners and master alloys	13,200 r/	13,800
Miscellaneous	169 r/	3,500
Total	166,000 r/	164,000
Brass mill and wire-rod mill products	1,030,000	1,060,000
Brass and bronze castings	43,400	45,600
Brass powder	214	198
Copper in chemical products	11,800 2/	11,700
Grand total	1,490,000 r/	1,490,000

r/ Revised.

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

2/ 1999 data reflects expanded coverage to include copper sulfate and other copper chemical products.

TABLE 9  
COMPOSITION OF SECONDARY COPPER-ALLOY PRODUCTION IN THE UNITED STATES 1/

(Metric tons)

	Copper	Tin	Lead	Zinc	Nickel	Aluminum	Total
<b>Brass and bronze ingot production: 2/</b>							
1999 r/	137,000	4,850	7,900	15,700	267	19	166,000
2000	136,000	5,240	8,430	14,400	252	14	164,000
<b>Secondary metal content of brass mill products:</b>							
1999	830,000	950	7,840	188,000	W	W	1,030,000
2000	844,000	1,650	7,450	199,000	W	W	1,060,000
<b>Secondary metal content of brass and bronze castings:</b>							
1999	39,100	708	1,100	2,260	112	119	43,400
2000	42,200	633	837	1,700	85	98	45,600

r/ Revised. W Withheld to avoid disclosing company proprietary data; included in "Total."

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

2/ Includes about 97% from scrap and 3% from other than scrap in 1999 (revised) and about 96% from scrap and 4% from other than scrap in 2000.

TABLE 10  
CONSUMPTION AND YEAREND STOCKS OF COPPER-BASE SCRAP 1/

(Metric tons, gross weight)

Scrap type and processor	1999		2000	
	Consumption	Stocks	Consumption	Stocks
<b>No. 1 wire and heavy:</b>				
Smelters, refiners, ingot makers	106,000	2,360 r/	86,000	2,260
Brass and wire-rod mills	431,000	(2/)	438,000	(2/)
Foundries and miscellaneous manufacturers	41,200	2,520	45,500	2,650
<b>No. 2 mixed heavy and light:</b>				
Smelters, refiners, ingot makers	137,000	6,020 r/	133,000	2,120
Brass and wire-rod mills	21,200	(2/)	13,800	(2/)
Foundries and miscellaneous manufacturers	3,230	226	3,320	193
<b>Total unalloyed scrap:</b>				
Smelters, refiners, ingot makers	243,000	8,380 r/	219,000	4,370
Brass and wire-rod mills	452,000	20,300	452,000	17,600
Foundries and miscellaneous manufacturers	44,500	2,740 r/	48,800	2,840
<b>Red brass: 3/</b>				
Smelters, refiners, ingot makers	50,200	2,150 r/	52,700	2,120
Brass mills	10,400	(2/)	9,330	(2/)

Foundries and miscellaneous manufacturers	1,740	(2/)	1,680	(2/)
<b>Yellow and low brass, all plants</b>				
Cartridge cases and brass, all plants	76,600	1,160 r/	105,000	713
Auto radiators:	79,400	(2/)	72,600	(2/)
Smelters, refiners, ingot makers	53,400	2,130 r/	48,300	1,610
Foundries and miscellaneous manufacturers	4,650	(2/)	2,750	(2/)
<b>Bronzes:</b>				
Smelters, refiners ingot makers	16,100	886 r/	11,100	1,130
Brass mills and miscellaneous manufacturers	10,600	(2/)	11,800	(2/)
<b>Nickel-copper alloys, all plants</b>				
Low grade and residues:	23,000	369 r/	28,100	314
Smelters, refiners, miscellaneous manufacturers	111,000	13,100 r/	88,600	7,670
<b>Other alloy scrap: 4/</b>				
Smelters, refiners, ingot makers	12,100	839 r/	11,300	324
Brass mills and miscellaneous manufacturers	6,740	(2/)	7,600	(2/)
<b>Total alloyed scrap:</b>				
Smelters, refiners, ingot makers	258,000	21,200 r/	221,000	15,300
Brass mills	593,000	35,500	620,000	39,500
Foundries and miscellaneous manufacturers	35,500	3,030 r/	34,200	2,360
<b>Total scrap:</b>				
Smelters, refiners, ingot makers	501,000	29,600 r/	440,000	19,600
Brass and wire-rod mills	1,050,000	55,700	1,070,000	57,200
Foundries and miscellaneous manufacturers	79,900	5,770 r/	83,000	5,210

See footnotes at end of table.

TABLE 10--Continued  
CONSUMPTION AND YEAREND STOCKS OF COPPER-BASE SCRAP 1/

r/ Revised.

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

2/ Individual breakdown is not available; included in "Total unalloyed scrap," "Total alloyed scrap," and "Total scrap."

3/ Includes cocks and faucets, commercial bronze, composition turnings, gilding metal, railroad car boxes, and silicon bronze.

4/ Includes aluminum bronze, beryllium copper, and refinery brass.

TABLE 11  
CONSUMPTION OF PURCHASED COPPER-BASE SCRAP 1/ 2/

(Metric tons, gross weight)

Type of operation	From new scrap		From old scrap		Total	
	1999	2000	1999	2000	1999	2000
Ingot makers	46,300	44,000	132,000	125,000	178,000	169,000
Smelters and refineries	71,100	58,800	252,000	212,000	323,000	271,000
Brass and wire-rod mills	1,020,000	1,050,000	26,800	23,000	1,050,000	1,070,000
Foundries and miscellaneous manufacturers	27,200	26,200	52,700	56,800	79,900	83,000
Total	1,160,000	1,180,000	464,000	417,000	1,630,000	1,600,000

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

2/ Consumption at brass and wire-rod mills assumed equal to receipts.

TABLE 12  
FOUNDRIES AND MISCELLANEOUS MANUFACTURERS  
CONSUMPTION OF BRASS INGOT, REFINED COPPER AND  
COPPER SCRAP IN THE UNITED STATES 1/

(Metric tons)

Ingot type or material consumed	1999	2000
Tin bronzes	33,200	29,900
Leaded red brass and semired brass	70,100 r/	71,000
Yellow, leaded, low brass 2/	8,520 r/	8,510
Manganese bronze	4,720	4,590
Nickel silver 3/	2,710	3,480
Aluminum bronze	4,140	4,650
Hardeners and master alloys 4/	2,100	2,260
Lead free alloys 5/	141 r/	145
Total brass ingot	126,000 r/	125,000
Refined copper	52,200 r/	59,800
Copper scrap	79,900	83,000

r/ Revised.

1/ Data are rounded to no more than three significant digits; may not add to totals shown.

2/ Includes brass and silicon bronze.

3/ Includes brass, copper nickel, and nickel bronze.

4/ Includes special alloys.

5/ Includes copper-bismuth and copper-bismuth-selenium alloys.

TABLE 13  
AVERAGE PRICES FOR COPPER SCRAP AND ALLOY-INGOT, BY TYPE

(Cents per pound)

Year	Brass mills No. 1 scrap	Refiners No. 2 scrap	Dealers' buying (New York)		Alloy-ingot (New York) 1/	
			No. 2 scrap	Red brass turnings and borings	No. 115 brass (85-5-5-5)	Yellow brass (405)
1999	70.88	57.53	42.97	37.74	138.50	135.25
2000	80.67	64.99	51.43	39.95	138.50	135.25

e/ Estimated. r/ Revised. -- Zero.

1/ World totals, U.S. data, and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ Data represent copper content by analysis of concentrates produced except where otherwise noted. Table includes data available through July 20, 2001.

3/ Reported figure.

4/ Copper content of pelletized nickel-copper matte produced in smelter.

5/ Reported by Comision Chilena del Cobre. Includes recoverable copper content of nonduplicative mine and metal products produced from domestic ores and concentrates and leach production for electrowinning.

6/ Recoverable content.

7/ Less than 1/2 unit.

8/ Excludes copper content of pyrite.

9/ Data are for fiscal years beginning April 1 of year stated. Zambian-mined copper reported recovered during smelting and electrowinning.

e/ Estimated. r/ Revised. W Withheld to avoid disclosing company proprietary data; included in total. -- Zero.

1/ World totals, U.S. data, and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ This table includes total production of copper metal at the unrefined stage, including low-grade cathode produced by electrowinning methods. The smelter feed may be derived from ore, concentrates, copper precipitate or matte (primary), and/or scrap (secondary). To the extent possible, primary and secondary output of each country is shown separately. In some cases, total smelter production is officially reported, but the distribution between primary and secondary has been estimated. Table includes data available through July 20, 2001.

3/ Reported figure.

4/ Copper content of nickel-copper matte exported to Norway for refining.

5/ Data are for year beginning March 21 of year stated. Secondary production is estimated to be about 5% of total.

6/ Secondary production is estimated to be about 5% to 10% of total.

7/ For fiscal year beginning April 1 of year stated. Electrowon is total electrowon production reported less the quantity reported as "finished production, leach cathodes."

8/ Includes impure cathodes produced by electrowinning in nickel processing.

9/ U.S. production undifferentiated in 2000.

Total	100,000	110,000	94,930	77,000	80,000
Zambia, primary: 8/					
Electrowon	58,000	63,736	80,709	57,000 e/	55,000
Other	276,000	268,553	248,820	176,000 e/	170,000
Total	334,000	332,289	329,529	233,000 e/	225,000
Zimbabwe: e/					
Electrowon	3,200	2,900	2,400	1,020 r/	--
Primary	10,900	4,990	2,940	7,000 r/	7,200
Secondary	6,000	--	--	--	--
Total	20,100	7,890	5,340	8,020 r/	7,200
Total, primary	10,700,000	11,400,000	12,200,000	12,700,000 r/	13,000,000
Total, secondary	1,980,000	2,090,000	1,940,000 r/	1,880,000	1,960,000
Total, primary and secondary, undifferentiated	39,000	43,400 r/	36,100 r/	33,000 r/	32,000
Grand total	12,700,000	13,500,000	14,200,000 r/	14,600,000 r/	15,000,000

e/ Estimated. r/ Revised. -- Zero.

1/ World totals, U.S. data, and estimated data are rounded to no more than three significant digits; may not add to totals shown.

2/ This table includes total production of refined copper, whether produced by pyrometallurgical or electrolytic refining methods and whether derived from primary unrefined copper or from scrap. Copper cathode derived from electrowinning processing is also included. Table includes data available through July 20, 2001.

3/ Reported figure.

4/ Includes reprocessed leach cathode from Congo (Kinshasa).

5/ Excludes leach cathode exported for processing in Belgium.

6/ Data are for Iranian years beginning March 21 of that stated.

7/ May include secondary.

8/ Data are for fiscal year beginning April 1 of that stated. Electrowon covers only presumably high-grade electrowon cathodes reported as "finished production leach cathodes." Other, in addition to electrowon cathodes, includes a smaller amount of "finished product shapes" presumably cast from electro-refined cathodes, or any blister-anodes and low-anodes and low-grade electrowon cathodes that were furnace- or fire-refined.
