

Analysis of the MJO in the Super-CAM

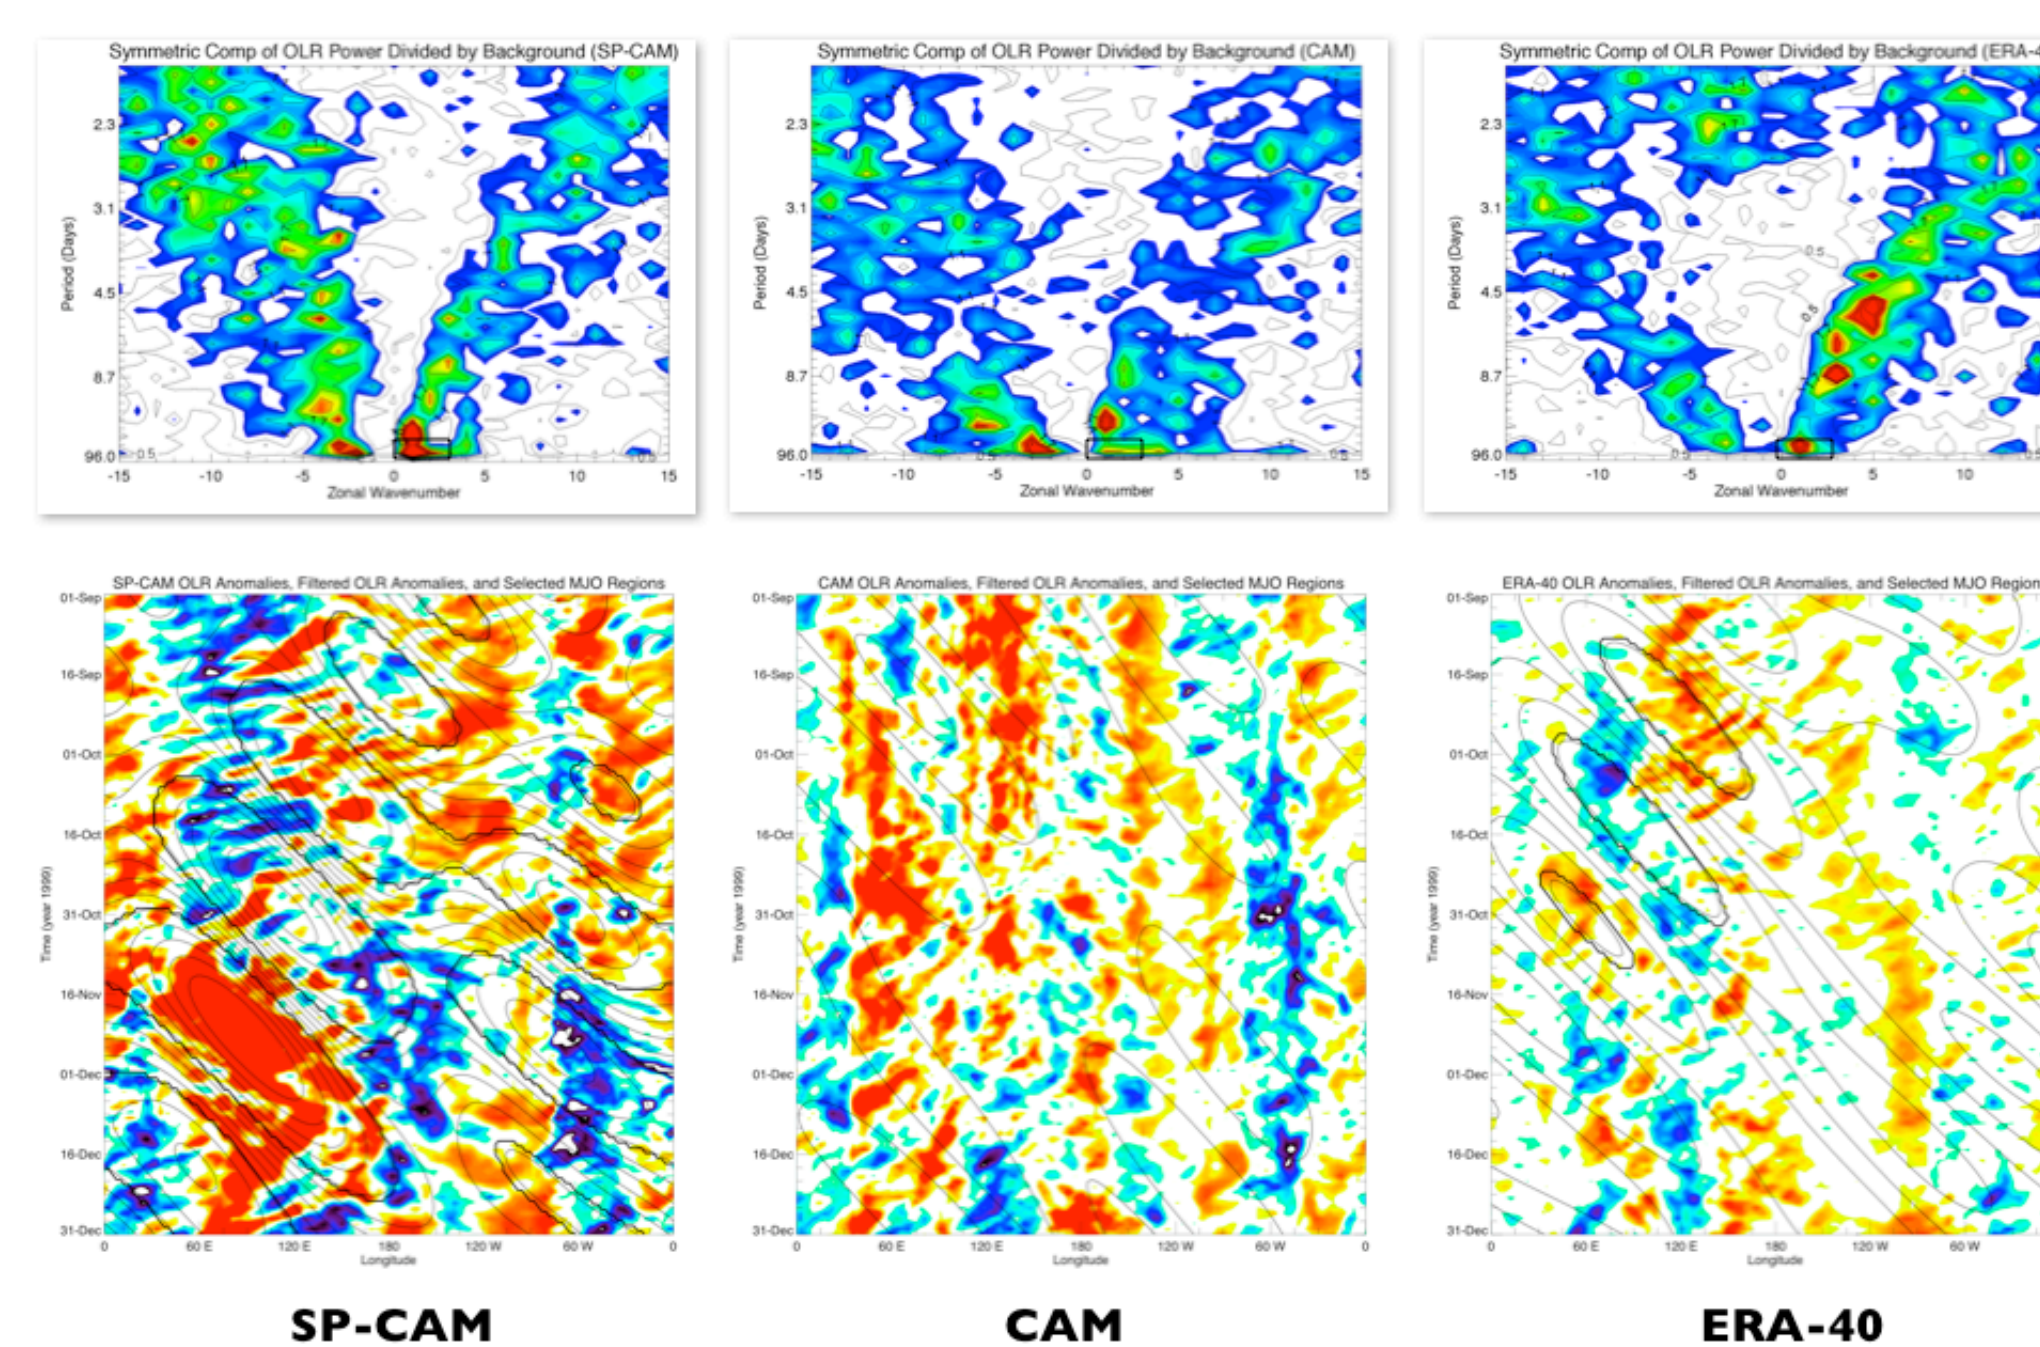

David Randall, James Benedict, Kate Thayer-Calder

Super-Parameterization (a.k.a. the Multiscale Modeling Framework, or MMF)

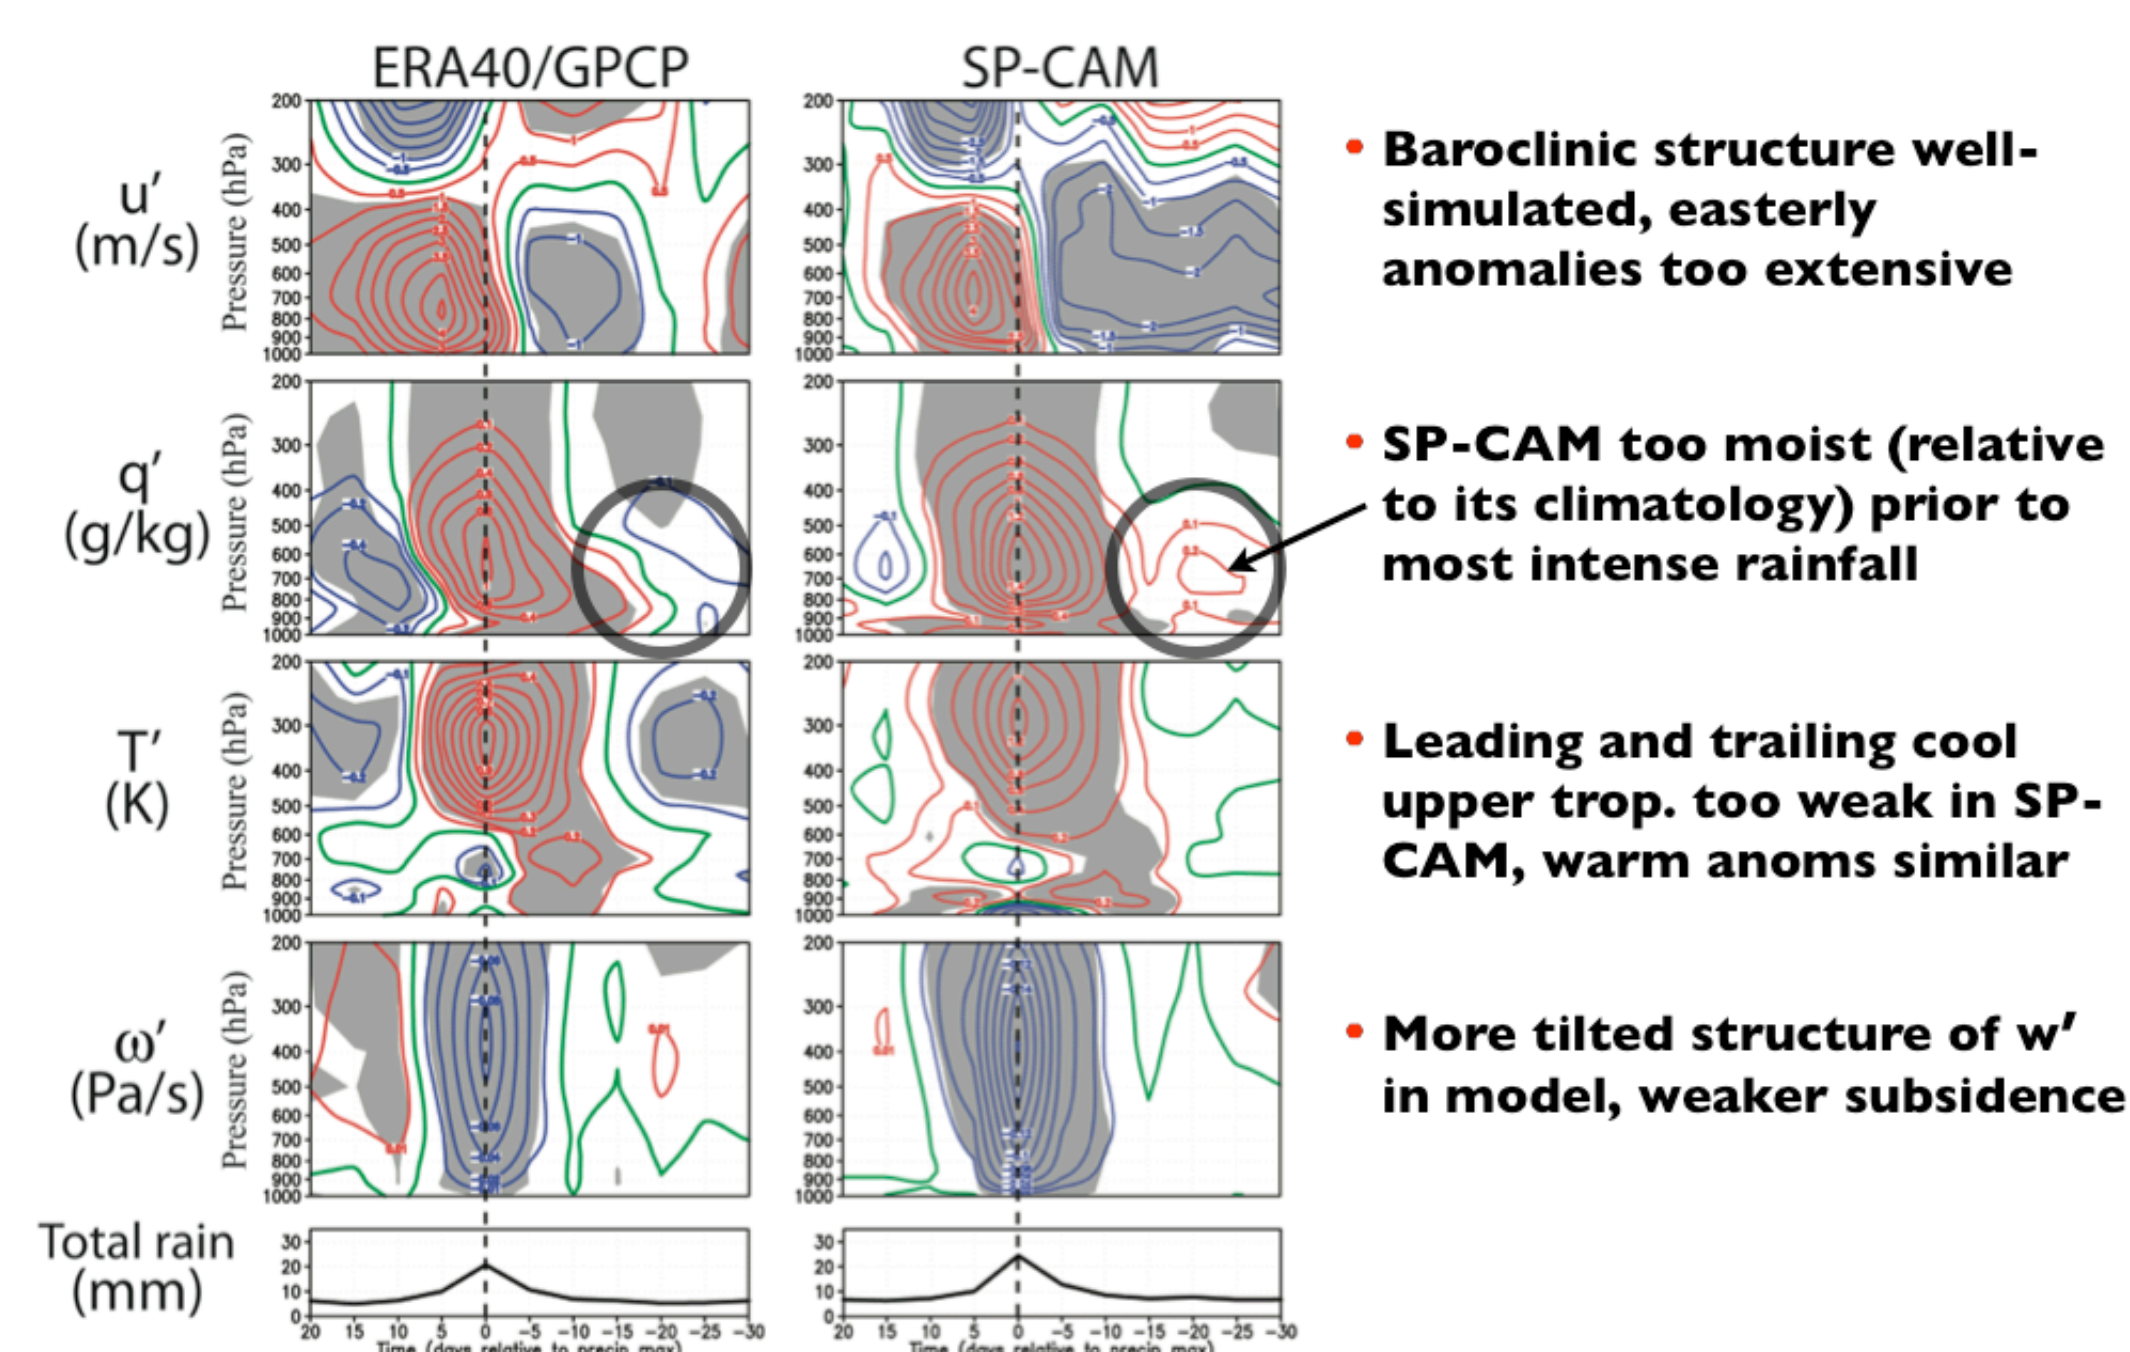

Idea proposed by W. Grabowski

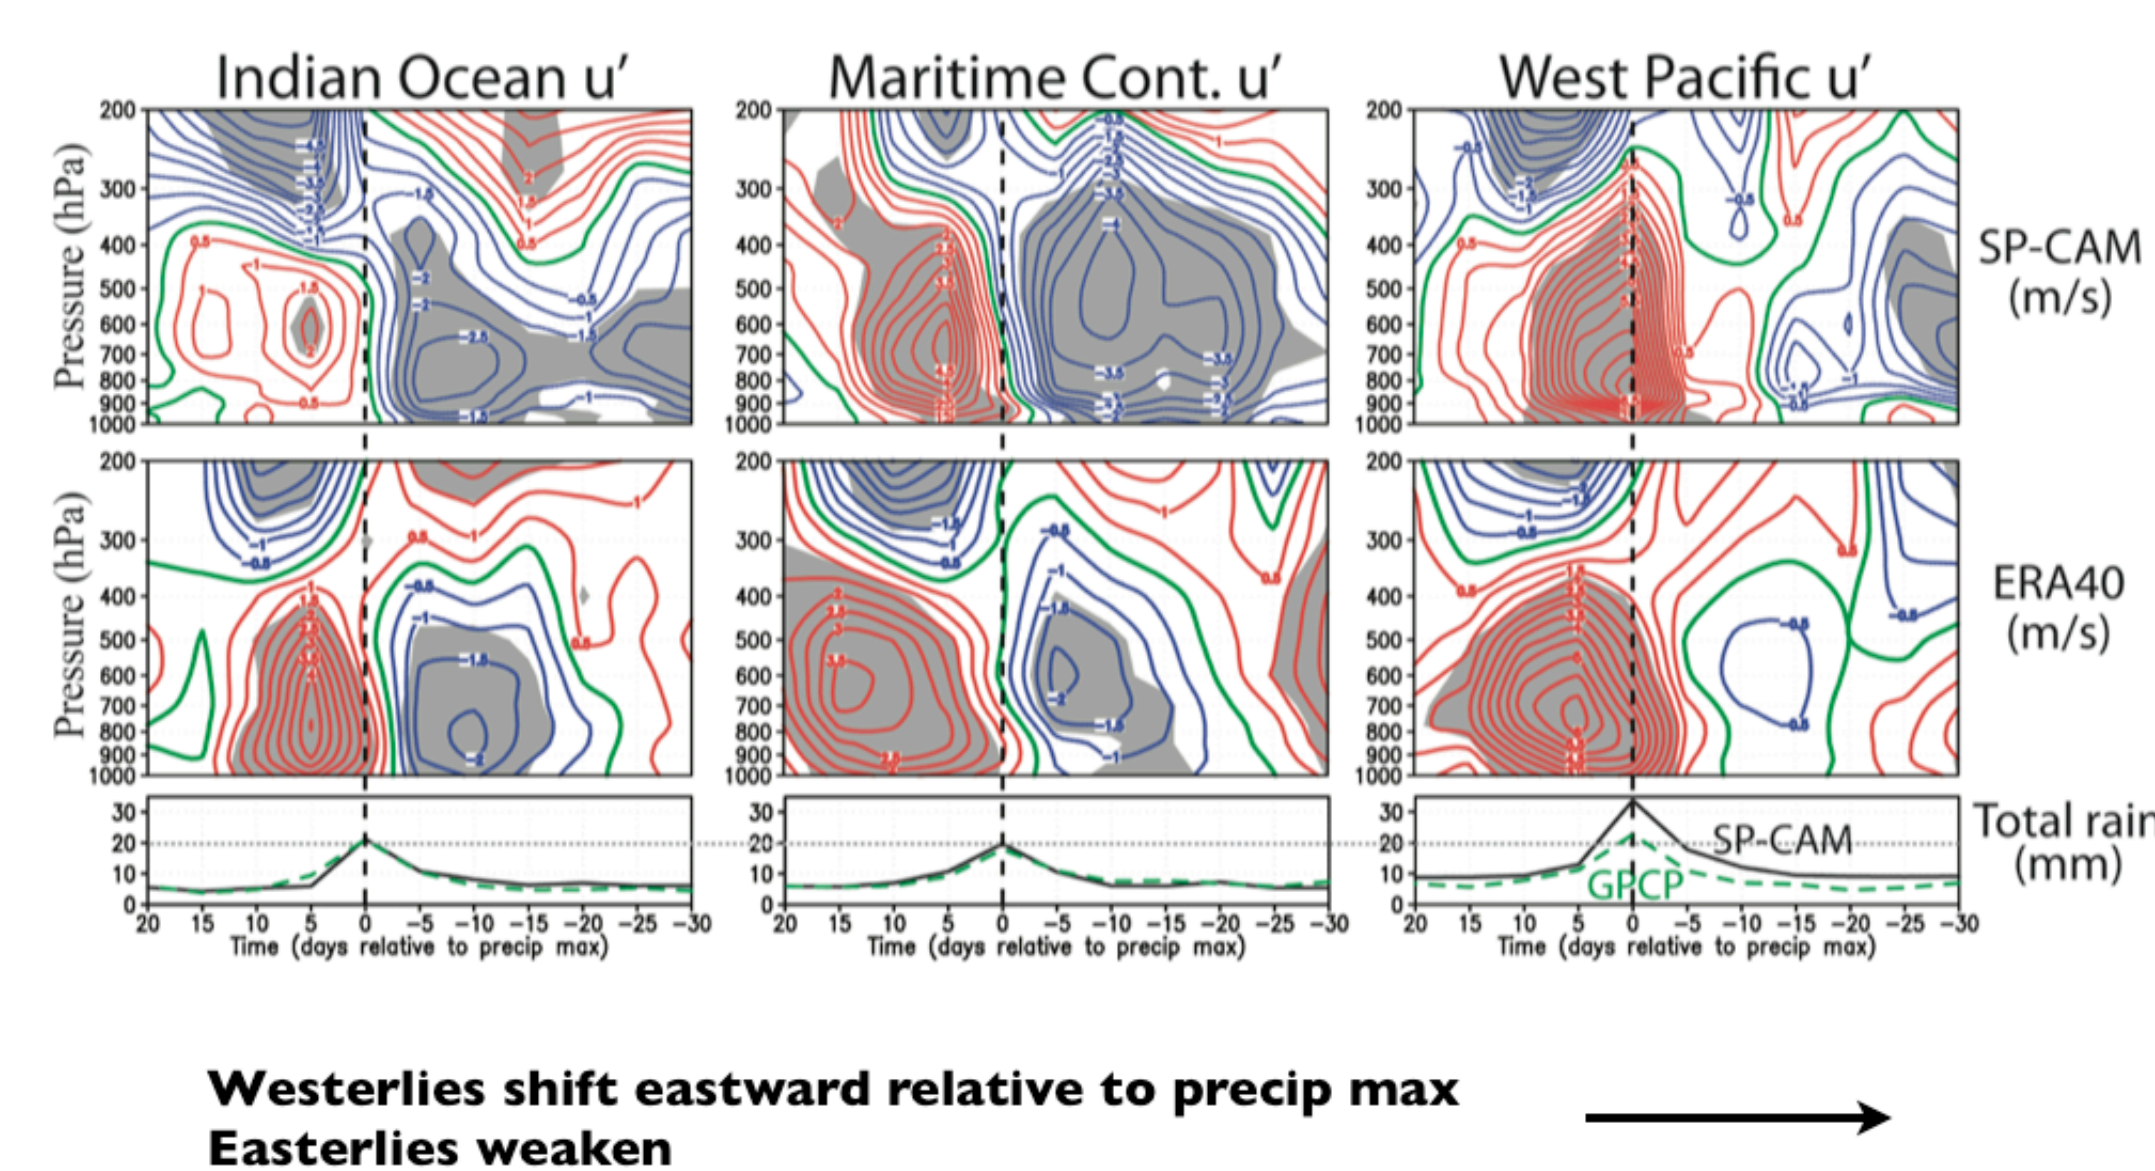

OLR: WKs and Hovmöllers

State variables

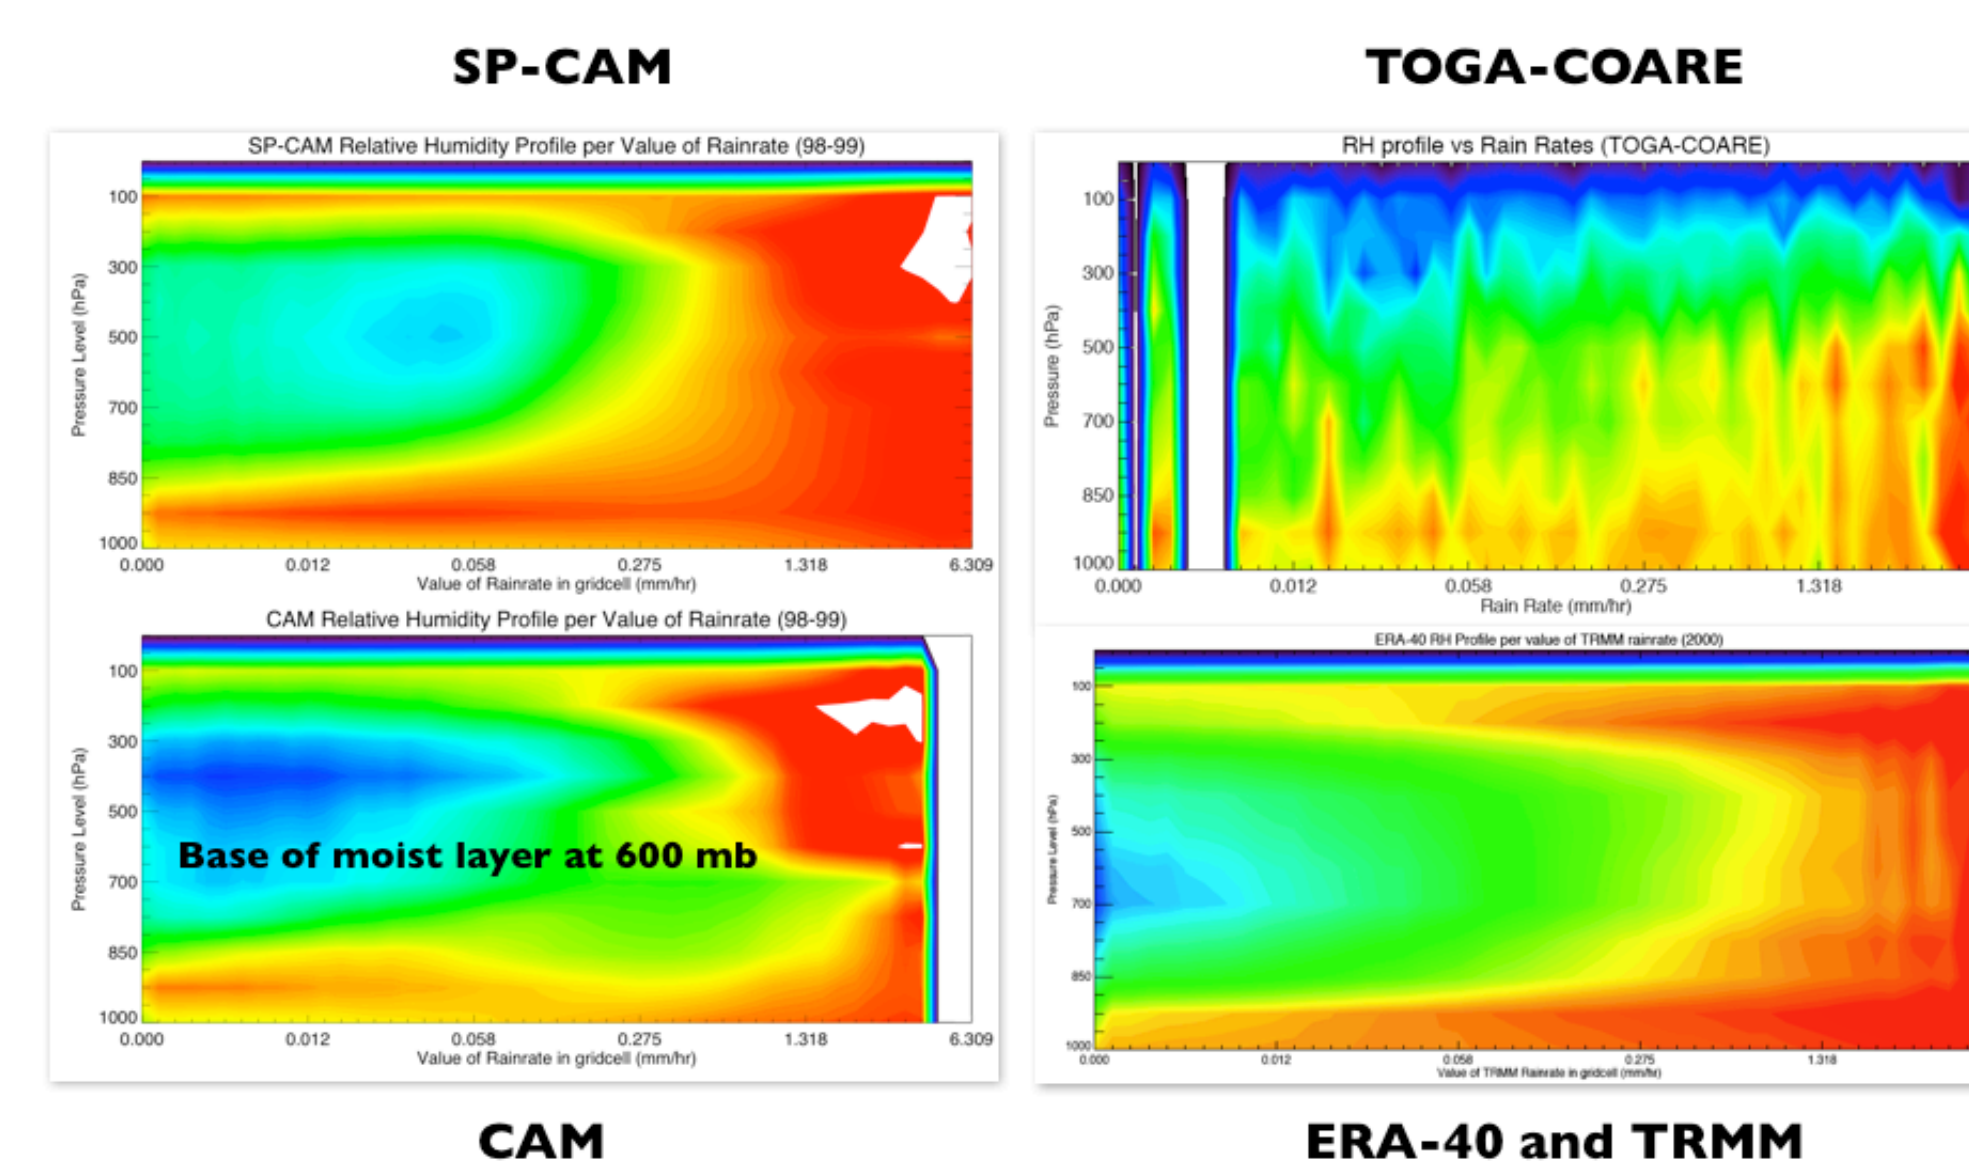

Geographical differences

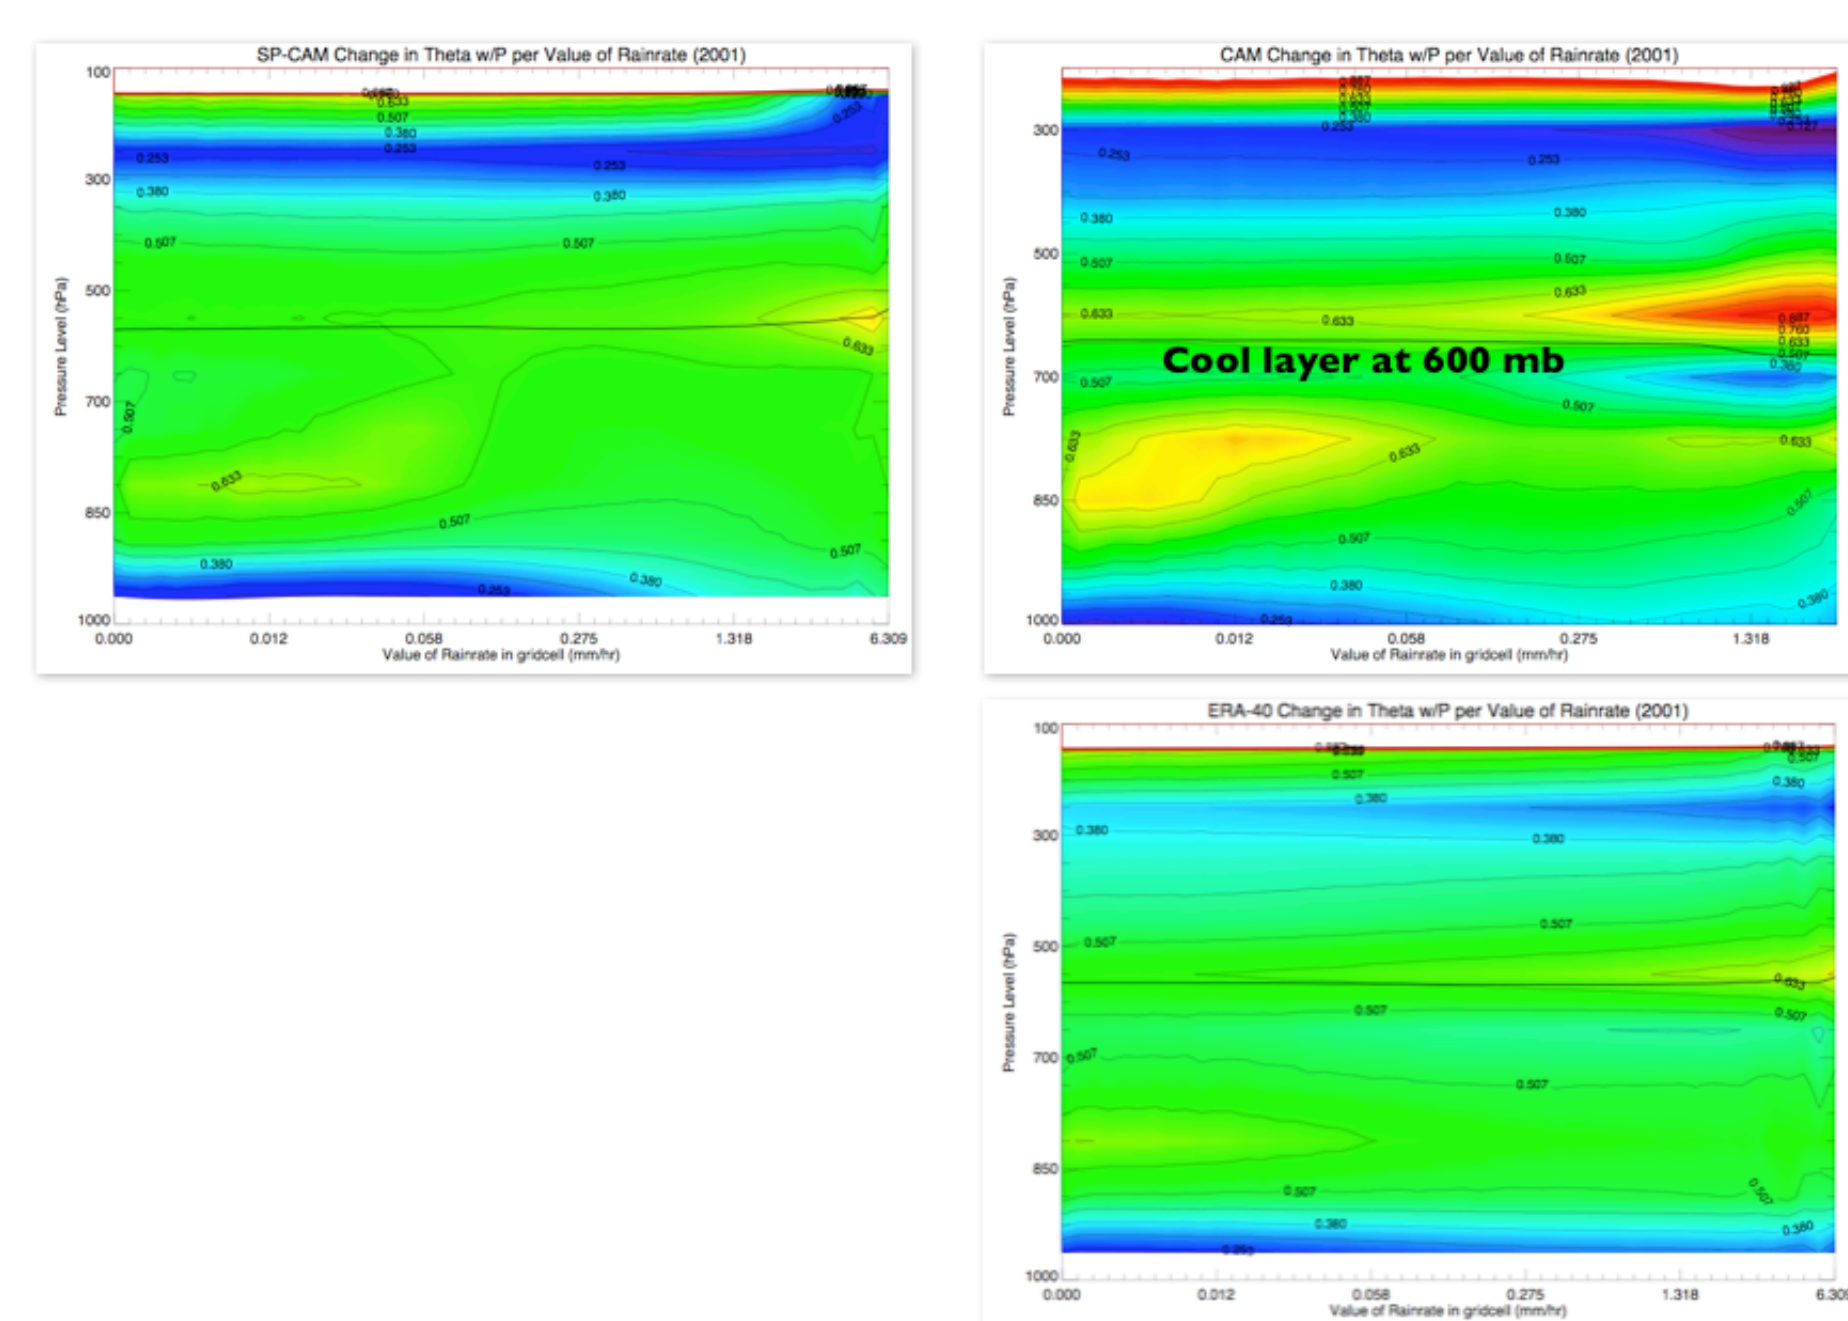

Seasonal Change, 1986-2003

Rainfall-humidity composites

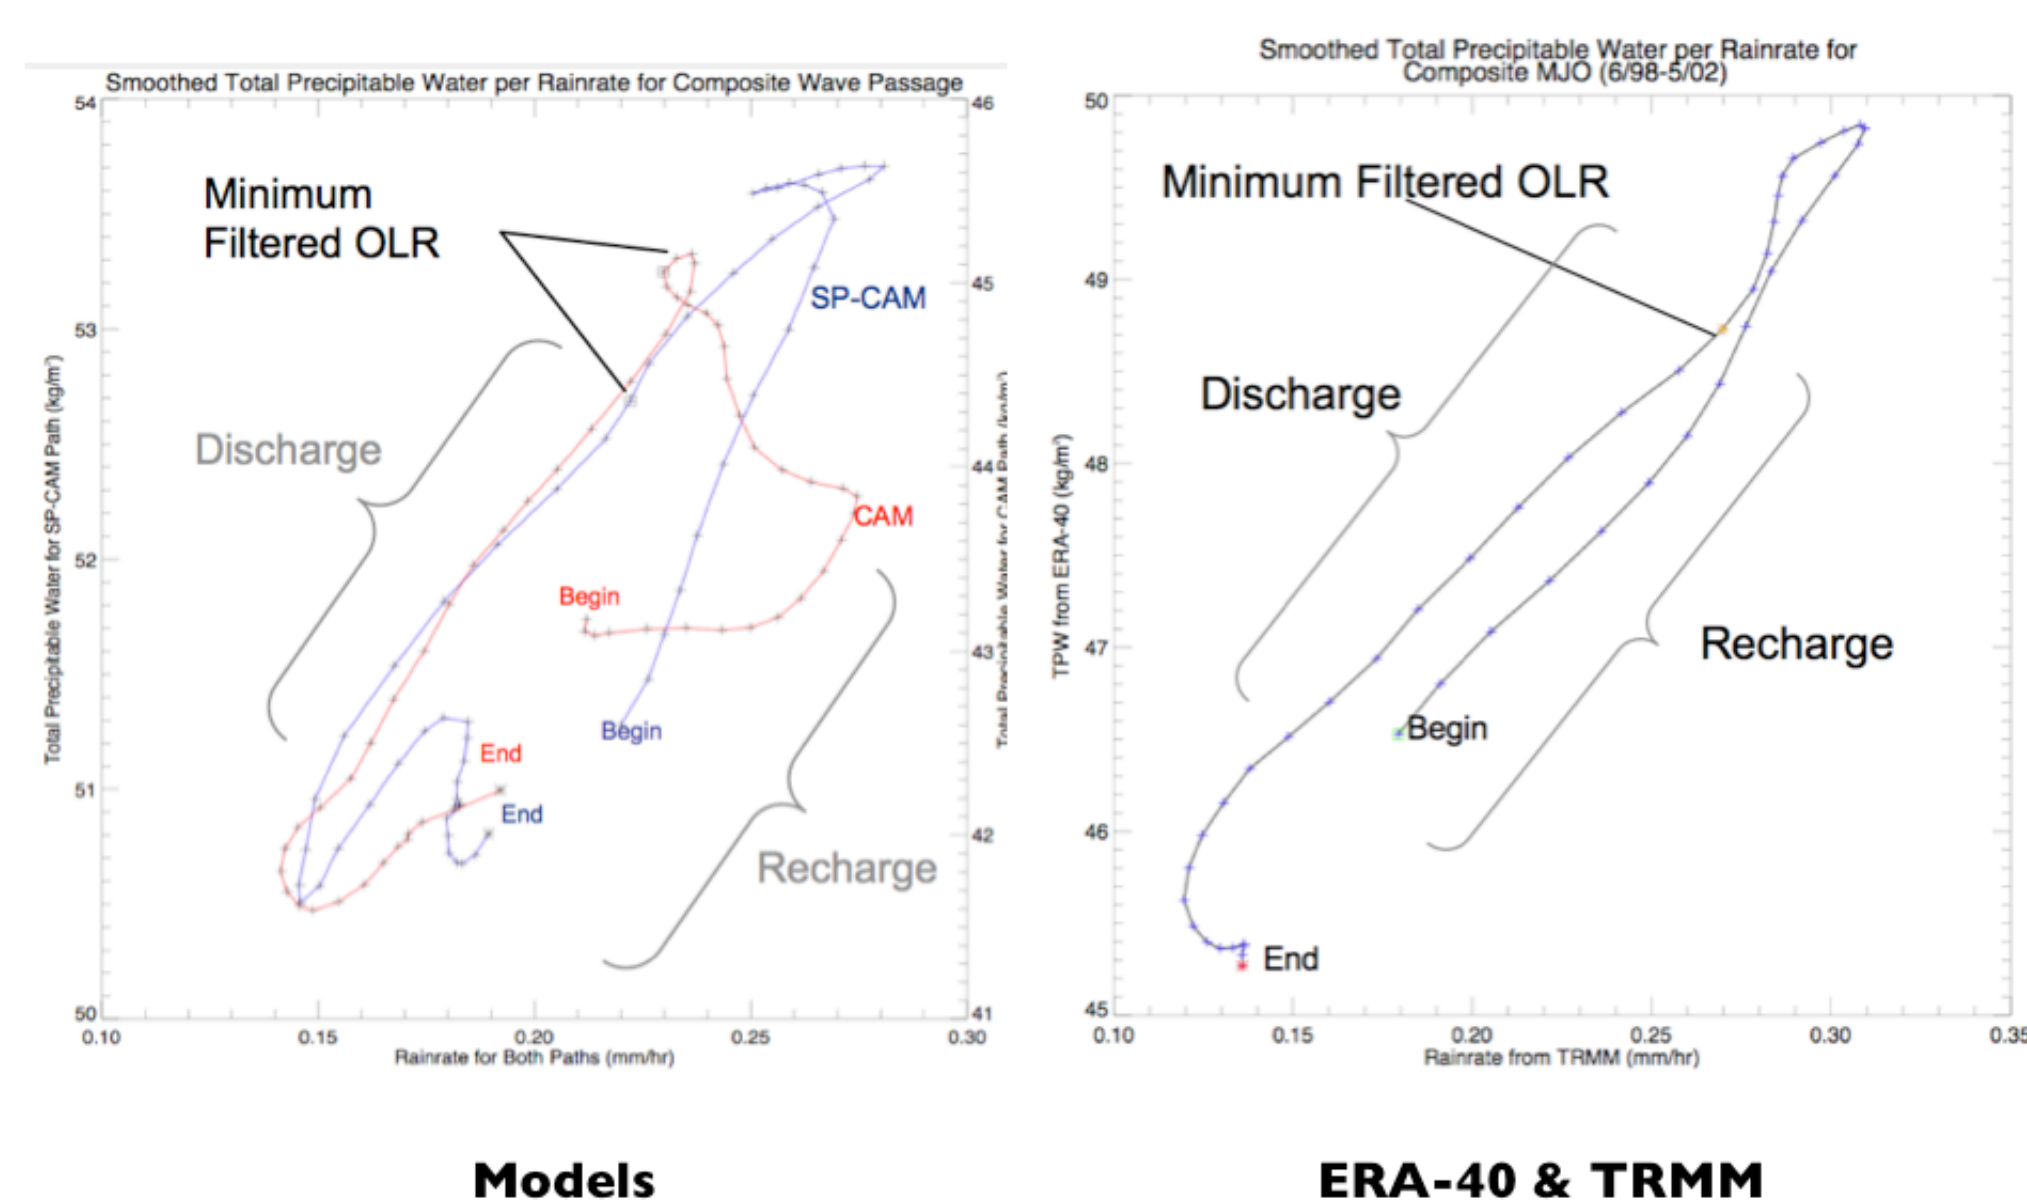

Static stability vs. rain rate

Wind-Evaporation Feedback

Discharge and Recharge

What I think is going on

- During the "recharge" phase, convective stabilization occurs mainly through the effects of downdrafts on the PBL moist static energy.
- When the troposphere becomes very moist, this mechanism does not work well.
- Convection then intensifies, exciting a large-scale disturbance.
- Warming aloft and strong dry advection west of the heating shut off the deep convection.
- Recharge resumes.
- This is generally consistent with the model of Bony and Emanuel (JAS, 2005), who discussed a "moisture-convection feedback."
- For this mechanism to work, a model needs:
 - ▲ A tendency to moisten a deep layer as the rainfall rate increases
 - ▲ Downdrafts that modify the PBL
