#### 3. A GLS Method of Accounts Reconciliation

The objective here is to reconcile the Input-Output and Income-by-industry data with expenditure based benchmark GDP. Because the expenditure based GDP estimate was from the 2003 comprehensive revision, it was considered the correct measure of GDP. Therefore, the initial estimates of final demand by expenditure category, exports, and imports were not to be adjusted. The mathematical problem is to minimize the reliability weighted sum of squares of adjustments of initial estimates in all components of gross output, intermediate inputs, and value-added of all industries and commodities, subject to accounting constraints and restrictions.

Let x, z, v denote estimates of gross output, intermediate input, and value-added. Let wx, wz and wv denote reliabilities of the corresponding initial estimates, where reliabilities are measured by variances of initial estimates. Let y, e and m denote final demand by expenditure category, exports and imports. Let  $Y^{E}$  and  $Y^{I}$  denote aggregate GDP and GDI. Formally, the reconciliation problem is

$$(1) \quad \text{Min } S_{\{x, z, v\}} = \sum_{i=1}^{65} \sum_{k=1}^{69} \frac{(x_{ik} - x_{ik}^0)^2}{wx_{ik}} + \sum_{i=1}^{65} \sum_{k=1}^{69} \frac{(z_{ik} - z_{ik}^0)^2}{wz_{ik}} + \sum_{i=1}^{65} \sum_{f=1}^{3} \frac{(v_{if} - v_{if}^0)}{wv_{if}},$$

(2) s.t. 
$$\sum_{k=1}^{69} x_{ik} - \sum_{k=1}^{69} z_{ik} - \sum_{f=1}^{3} v_{if} = 0$$
,  $i = 1, ..., 65$ ,

2

(3) 
$$\sum_{i=1}^{65} x_{ki} - \sum_{i=1}^{65} z_{ki} - \sum_{d=1}^{11} y_{kd}^o - e_k^o + m_k^o = 0, \qquad k = 1, ..., 69,$$

(4) 
$$\sum_{i=1}^{65} \sum_{f=1}^{3} v_{if} = \sum_{k=1}^{69} \sum_{d=1}^{11} y_{kd}^{o} - e_{k}^{o} + m_{k}^{o},$$

with the initial conditions satisfying

(5) 
$$\sum_{k=1}^{69} \left[ \sum_{d=1}^{11} y_{kd}^{o} - e_{k}^{o} + m_{k}^{o} \right] = Y^{E0},$$

$$(6) \qquad \qquad \sum_{i=1}^{65} \sum_{f=1}^{3} v_{if}^{o} = \Upsilon^{I0}.$$

Letters i, k, f and d are indexes for industry, commodity, component of value-added and category of final demand, and superscript "0" indicates initial estimates.

The accounting constraint (2) states that for each industry, final estimates of intermediate inputs and value-added must sum up to final estimate of industry gross output. Constraint (3) says that for each commodity, final estimates of commodities used as intermediate inputs and commodities sold as final demand must sum up to final estimate of commodity output. Constraint (4) states value-added estimates from 65 industries must

sum up to total GDP, removing aggregate statistical discrepancy. Equation (5) and (6) are initial conditions indicating that initial estimate of total GDP differs from initial estimate of total GDI. The difference between the two,  $Y^{E0} - Y^{I0}$ , is the aggregate statistical discrepancy.

The system of accounts described here consists of 100062 variables and 135 accounting constraints. Because the 11 final uses, exports and imports are held as fixed, there are 9165 final estimates to be solved for. The reconciliation model is solved with an optimization software package GAMS using its CPLEX solver, a powerful tool for handling large linear or quadratic programming models. One reason that reconciliation of disaggregated system of accounts has not received wide attention since its inception by Byron (1978) was because of the computer technology available at the time and the large memory requirement of reconciliation. Under the current technology of computer and software, the system of accounts described can be successfully reconciled in about .5 second.

### 4. Measure Reliability of Initial Data

To correct errors such as double-counting, misallocation, misreporting, misspecification and omission, various types of adjustments are made to the source data. Figure 1 provides a glimpse of adjustments relative to initial estimates.

4

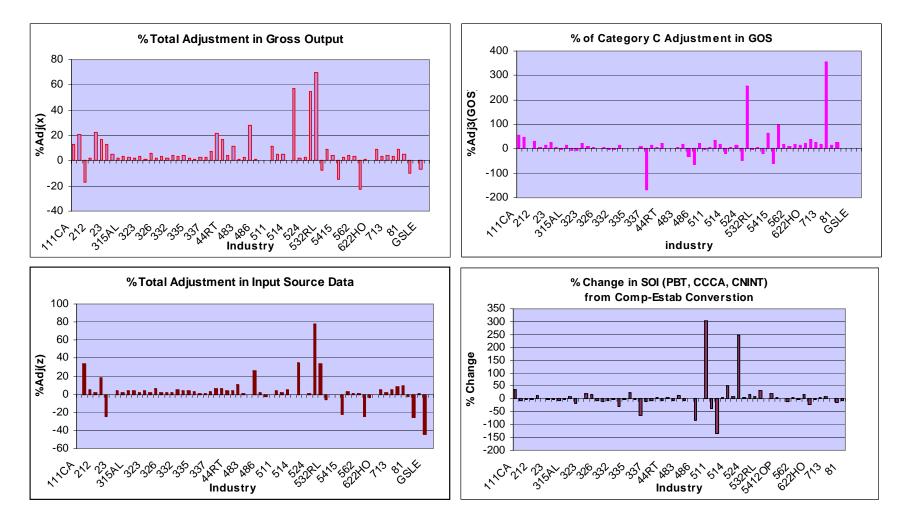

Figure 1: Percentage Adjustment in Gross Output, Total Inputs and Some Items of Value Added Source Data from Income-by-Industry

#### Acknowledgement:

This project has received strong support from NEA and Industry Accounts management since the proposal was submitted. During the time I have worked on the project, I have received assistance and support from staff members from different divisions. Some have provided data needed for the project, some with whom I have had helpful discussions about the project, and some have helped process data or with my SAS programming questions. I would like to express my appreciation to the following people,

<u>Nation Economic Account</u>: Brent Moulton, Brian Moyer, Brooks Robinson, Steve Andrews, Greg Keys, Kurt Kunze, Nicole Mayerhauser, Julia Nguyen, Marshall Reinsdorf, Charles Robinson, Dave Wasshausen.

<u>Industry Accounts</u>: Sumiye Okubo, Ann Lawson, Karen Horowitz, George Smith, Felicia Candela, Tom Howells, Sarah Mattingly, Doug Meade, Gabe Medeiros, Mark Planting, Dylan G. Rassier, Carol Robbins, Conrad E. Roesch, Erich Strassner, Mary Streitwieser, Bob Yuskavage.

Regional Division: Bettina Aten, Zoe Ambargis.

Office of Chief Statistician: Ruth A. Bramblett.

Census Bureau: Stacy Cole.

IRS: Kimberly A. Henry, Thomas Petska, Valerie Testa, Ahmed Z. Yahia.

My special thanks go to Karen Horowitz and George Smith. George has helped obtain and process data on sampling errors from the IRS. He also provided Income-by-industry data and helped analyze adjustment data on the income side of the accounts. Karen Horowitz has taught me everything I understand about I-O account, explained the data problems in the 1997 data set, and always provided timely answers to my questions. She provided large I-O data sets from the databank and helped analyze adjustment data on the I-O side of the accounts. I would also like to express my sincere thanks to my former colleague Zhi Wang for bringing this subject to me and for his help with computer programs in the early stage of the project.
