

measure exposure to the hands. The goal of this evaluation is to identify issues associated with the use of this technique and to make recommendations with regard to how these data should be interpreted for exposure assessment purposes based on factors such as chemical properties and exposure duration.

- *Predictive Capability Of Exposure Monitoring Techniques.* Most exposure data that are currently available are based on the use of passive dosimetry techniques (e.g., whole-body dosimeters and handwash). These data quantify the residues that result on the surface of the skin after completing a job task of some sort. The purpose of this evaluation is to characterize the performance of passive dosimetry as a predictive tool for risk assessment purposes (e.g., through comparison with biological monitoring data and other possible analyses).

- *Clustering Of Hand Labor Tasks For Exposure Assessment Purposes.* The crops in the United States that require hand labor for successful production are extremely varied and range from field crops such as lettuce (e.g., harvest is a key labor requirement) to tree fruit such as apples (e.g., thinning and harvest are key labor requirements). Based on the currently available data and a need to address exposures related to hand labor across agriculture, the Agency has created clusters or groups which represent categories of exposures that are believed to be similar for assessment purposes. These categories allow the Agency to develop risk estimates for a wide range of crops and were defined based on agronomic and ergonomic similarities in crops and workers, respectively. The purpose of this evaluation is to characterize the methods used to define a representative cluster and analyze the monitoring data that pertains to that group which are then used for exposure assessment purposes. An example, based on vineyard and trellis crops will be used for illustrative purposes.
