# Shares of Income Received by Quintiles When Equivalent Income Is Used as the Measure of Income 

John McNeil<br>Special Assistant

Housing and Household Economic Statistics Division
U.S. Census Bureau

## SHARES OF INCOME RECEIVED BY QUINTILES WHEN EQUIVALENT INCOME IS USED AS THE MEASURE OF INCOME

Data on the shares of aggregate income received by the various income quintiles are frequently calculated using households as the reference unit. That is, households are ranked by their level of income in order to determine which households are in the bottom quintile of the income distribution, and which are in the second, third, fourth, and top quintiles. It is then possible to determine the share of aggregate income that is received by each group of households.

A criticism of this method of measuring income shares is that the the average size and composition of households may change over time. For example, if there is a very large increase in the proportion of households with only one member, it may be that an observed change in the share of income received by households in the bottom quintile may be a reflection of this change rather than a real change in the distribution of economic well-being.

The tables below attempt to control for the effect of changes over time in the size and composition of households by adopting a modified measure of income. In this document, the modified measure is called Aequivalent income.@The modified measure assigns to each individual (regardless of age), the income of his or her family. The income that is assigned to each individual is then modified by applying a value from an equivalence scale.

For the purpose of presenting a time series of average equivalent income that can be compared to more traditional income time series, the equivalent income assigned to each individual in each year has been raked by a factor equal to median household income in $1969(\$ 8,241)$ divided by the median unraked equivalent income in 1969 (\$3,936).

For additional information on the calculation of equivalent income, see the appendix following the two tables of data. The appendix is taken from a 1999 paper by John McNeil presented at the Annual Meeting of the Western Economic Association, AChanges in the Economic Status of Children: 1969 to 1997.@

# TABLE 2. MEAN EQUIVALENT INCOME BY INCOME QUINTILE AND WHETHER IN TOP FIVE PERCENT OF INCOME DISTRIBUTION 

(In 1999 dollars)

The equivalent income of an individual is defined as the family income of the individual adjusted for differences in family size. Unrelated individuals are considered to be 1-person families. Each member of a given family has the same equivalent income, regardless of age or family relationship.

The assumption underlying an equivalent income measure is that larger families need more income than smaller families to reach a given level of economic well-being. It would then follow that a four-person family with an income of $\$ 40,000$ has a lower level of economic well-being than a two-person family with the same income level.

A critical element in the calculation of equivalent income is the equivalence scale that is used to adjust family incomes so that the incomes of the members of one family of a given size can be compared directly with the incomes of another family of a different size. When the equivalent income measure used in this report was developed, three equivalence scales were considered. The first was the scale that is used to calculate the official poverty thresholds, the second was a scale suggested by Patricia Ruggles in her book, Drawing the Line (The Urban Institute Press, Washington, D. C., 1990), and the third was a version of a scale suggested by the Panel on Poverty and Family Assistance in their report, Measuring Poverty: A New Approach (National Academy Press, Washington, D. C., 1995).

The scale used to calculate the official poverty thresholds cannot be described by an equation. The scale is based primarily on the cost of basic food plans for families of given sizes and compositions. The scale has been used for many years but does have some peculiarities that have long been noticed. For example, the poverty threshold for a couple who are both 65 years of age is considerably lower than the poverty level for a 65 year old individual and his or her grandchild (in 1997, the first threshold was \$9,701 and the second threshold was $\$ 11,021$ ).

The other two scales can be described by equations:

$$
\text { Ruggles=FAMSIZE }{ }^{.5}
$$

$$
\text { Poverty Panel= (ADULTS + .7 KIDS) }{ }^{.7}
$$

The table on the next page (Appendix Table 1) shows the official poverty thresholds for families of varying sizes and composition for 1997 and also shows the relative equivalence scales that are obtained from the three scales discussed above. Each of the three has one or more characteristics that seem undesirable. An oddity in the equivalence scale used for poverty thresholds has already been noted. A problem with the Ruggles scale is that it goes rather flat as family size increases. For example, the scale used in the poverty definition implies that a 7-person family that included 5 children would need 48 percent more income than a 4-person family that included 2 children to

TABLE 2. MEAN EQUIVALENT INCOME BY INCOME QUINTILE AND WHETHER IN TOP FIVE PERCENT OF INCOME DISTRIBUTION
(In 1999 dollars)

| Size of family, age of householder, and number of related children | Official poverty thresholds for 1997 |  | Relative equivalence scales |  |  |

| 7 related children | $\$ 26,185$ | $\$ 3,273$ | 1.61 | 1.41 | 1.47 |

Ruggles scale=Number of family members to the power of .5 .
Poverty panel scale=Number of adults plus .7 times number of children, all to the power of .7 .
reach an equivalent level of well-being. But the Ruggles scale puts the differential at only 32 percent.
The Poverty Panel scale produces an equivalence factor for 1-person families that presents a serious problem. The scale implies that a 1-person family would need only 42 percent of the income of a 4-person family that included two children to reach the same level of economic well-being. In 1997, the poverty threshold for the latter type of family was $\$ 16$, 276, so the Poverty Panel scale would set the poverty threshold for a 1-person family at $\$ 6,836$, a level that seems unreasonably low.

The scale chosen for the equivalent income data shown in this paper is a slightly modified version of the Poverty Panel scale. The only modification is the use of a replacement value for 1-person families. The modification brings the relative equivalence scale value for 1-person families up to .5 , the same as the Ruggles scale and very close to the value produced by the scale used in the poverty definition.

In the calculation of an equivalent income level, actual family income is divided by a factor determined by the equivalence scale. For example, the actual income of a 4-person family that includes 2 children is divided by $(2+.7 * 2)^{.7}$ or 2.355 . This operation results in a set of equivalent incomes, but the level of incomes will be lower than the level of actual incomes because actual incomes are being divided by a number larger than 1 . To bring the level of equivalent incomes up to a level
similar to actual incomes, a raking factor was developed. The raking factor was set equal to median household income in 1969 divided by median equivalent income (unraked) in 1969
(\$8,241/\$3,936=2.09375).

The table below shows the relationship between actual and equivalent incomes for several types of families.

TABLE A2. RELATIONSHIP BETWEEN ACTUAL AND EQUIVALENT INCOME

| Family type | Actual income <br> (Col. 1) | Equivalence <br> factor <br> (Col. 2) | Column 1 divided by Column 2 | Raking <br> factor | Equivalent <br> income |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1-person | \$40,000 | 1.178 | \$33,956 | 2.09375 | \$71,095 |
| 2 adults | \$40,000 | 1.625 | \$24,615 | 2.09375 | \$51,538 |
| 4 adults | \$40,000 | 2.639 | \$15,157 | 2.09375 | \$31,735 |
| 2 adults, 2 children | \$40,000 | 2.355 | \$16,985 | 2.09375 | \$35,562 |
| 2 adults, 4 children | \$40,000 | 2.998 | \$13,342 | 2.09375 | \$27,935 |
