# Access Denied: Changes in Computer Ownership and Use: 1984-1997 

Robert Kominski Eric Newburger

Population Division
U.S. Census Bureau

Washington, D.C.

Presented at the Annual Meeting of the American Sociological Association Chicago, Illinois<br>August 1999

This paper reports research and analysis undertaken by Census Bureau staff. It has undergone a more limited review than official Census Bureau publications. This report is released to inform interested parties of research, and to encourage discussions.

## Introduction

There has been perhaps no single technological tool during the last half of this century that has touched so many lives and their social organization so quickly, than that of the personal computer. Derived from the development of large-scale computers, which became commonplace in the 1950's, the personal computer utilized advances in microelectronics to achieve immense reductions in the physical size and monetary cost of computing equipment. What filled entire buildings in the 1950's, costing millions of dollars, was reduced to the size of a single computer chip, manufactured for a few dollars, by the late 1980's. Advances in hardware and software technology took the computer from a cumbersome but dedicated unidimensional operating tool to an elegant complex task processor, capable of handling literally thousands of unique and individual operations simultaneously. In current Western society, virtually no life is left completely untouched by computer-driven technology. Computers and computing applications are tightly integrated into many aspects of daily life, and are becoming more so each day.

The transition of computing from an organizational to a personal level is in large part a technological triumph. But its acceptance and integration into daily life is a social phenomenon, one which is still not well-understood. In this paper we look at national survey data to create a picture of the diffusion and integration of computer technology into the personal lives of the U.S. population. Just as large-scale computing was initially controlled and owned by a small group of corporations, the spread of personal computing also can be shown to be highly variable across specific population subgroups.

The focus in this paper is on two distinct but related aspects of diffusion - access and use. The data utilized, collected over a 14-year period, allow us to examine the pace at which personal computing has spread across the population, and to identify those segments which are differentially affected and involved. Because the impact of computing technology has different significance for adults and children, we examine these groups separately. In the final section of the paper we examine use patterns in one area of computing that appears to have particular social significance - the growing use of the Internet.

## Data

The data for this analysis comes from a series of questionnaire supplements conducted as part of the Current Population Survey (CPS). The CPS is a large nationally-representative survey of approximately 50,000 households, conducted each month by the U.S. Census Bureau. The survey has been conducted by the Census Bureau, for the Bureau of Labor Statistics, on a routine basis, since 1942. BLS's sponsorship stems from the fact that the CPS is the tool by which the government measures the monthly unemployment rate in the United States. As such, the CPS has been designed to investigate the employment circumstances of the members of U.S. households.

Over time, the CPS has come to be used as a tool for measuring a wide variety of economic, demographic and social conditions of the U.S. population on a recurring basis. Routine reporting on topics such as income, poverty, job searches, health insurance, family structure, migration patterns, educational attainment, school enrollment and voting turnout are but a few examples of the many issues CPS has routinely come to address. In most Octobers since the late 1940's, a special supplement has been added to the survey to determine the school-
going population and its' characteristics. The school enrollment supplement is cosponsored by the Census Bureau and the National Center for Education Statistics (NCES). Issues covered in this supplement touch not only on basic issues of school enrollment (part-time/full-time status; two-year/four-year college), but occasionally address other relevant issues on education. In developing the supplement for 1984, we discussed the possibility of including questions on computer ownership and use with NCES. The supplement developed for and administered as part of the October 1984 CPS has since been repeated in October 1989, 1993 and 1997. While each supplement has been modified slightly to reflect emerging topics regarding computers, the basic questions assessing ownership and use have remained fairly constant, thus providing a unique time-series of data points that allow us to examine changes over the 14 -year period.

Questions in the supplement address both home ownership and use (see Attachment A.) Other items collect information about use at school and at work. Follow-up items focus on the degree of involvement, and the kinds of specific uses computers are used for. Census Bureau reports were issued for the 1984 and 1989 collections (U.S. Census Bureau, Robert Kominski, Current Population Reports, Series P23, No. 155, Computer Use in the United States: 1984, U.S. Government Printing Office, Washington, D.C., 1988., and U.S. Census Bureau, Current Population Reports, Series P-23, No. 171, Computer Use in the United States: 1989, U.S. Government Printing Office, Washington, D.C., 1991). Detailed tabulations only were issued for 1993 (PPL-22, Computer Use in the United States, http://www.census.gov/population/www/socdemo/computer/comp1.txt). A report for the 1997 data collection is in print preparation at this time. Public use data files of all four surveys are available from the Census Bureau.

The strategy of analysis in this paper is to focus on several of the basic dimensions in the data. First, we examine changes over time in the levels of home computer access ("who has them?") and use. Then, because school and work constitute two other important access and use points, we examine the roles of these venues in facilitating use, for children and adults respectively. In each of these analyses we concentrate on critical factors underlying variation in access/use. Finally, we conclude by looking at data from our most recent data point to address a topic of most recent emerging interest - access to the Internet.

## Analysis

## Overview of the Trends

Table 1 and Figure 1 portray the dramatic growth of computer ownership and use during the period 1984-1997. In the fall of 1984 , just 7.9 percent of U.S. households reported that they owned a home computer; by 1997 this had more than quadrupled to 36.6 percent. Patterns of access and use at the individual level reflect these general household patters. About half of all children ages 3 to 17 had access to a computer at home by 1997, as did about 40 percent of all adults (ages 18+). Growth rates are even more impressive at school (for children) and work (for adults). About 71 percent of children in school had some use of a computer, while 50 percent of working adults report that they now use a computer in their job.

Considering all three venues (home, school and work), three-fourths of children reported they used a computer somewhere in 1997, up from just about a third, fourteen years earlier. For adults, there is also an impressive rate of growth, but at lower levels. While in 1984 just 18 percent of adults had reported they used a computer somewhere, by 1997 this level had risen to

47 percent. For the entire population ages 3 and older, in 1997 over 53 percent of all persons reported using a computer somewhere in their daily life.

## Household Access

Table 2 details variation in the patterns of computer access in U.S. homes, and some changes that have occurred over time. It is clear from table 2 that at all four measurement points in time, computer ownership is strongly related to family income. That is, affordability is a serious hurdle for many households. Even in 1997, fewer than 1 in 4 households with family incomes below $\$ 35,000$ owned a computer, an income threshold which reaches far into the $3^{\text {rd }}$ quintile of all households.

Other variations in household ownership are not quite as dramatic, but are still large, even in 1997. People of white and 'other' races have much higher levels of ownership than blacks or Hispanics. Education is also a strong correlate of ownership, with over 60 percent of households where the reference person has a Bachelor's degree or higher. Age differences have flattened considerably; household with a reference person between the ages of 25 and 54 all have similar probabilities of ownership (in the 40-49 percent range). Householders either older or younger than this have significantly lower likelihoods. In general, the data indicate that while the relative level of difference has dampened over time, the absolute level of difference has in many cases actually increased.

## Use by Children

Computer use by children has grown dramatically during the period of time covered by the four surveys. Where in 1984 just 30 percent of children ages 3-17 used a computer in some location, by 1997 this level had risen to about 75 percent. Both Table 3 and Figure 2 illustrate this growth, and the dimensions along which it has occurred. Across age groups for youths there is also a consistent level of use. Only at the very youngest ages (3-6) are usage levels substantially below the remainder of the youth population. Even for the very youngest children, however, there has been sizable growth over time. In the 1984 survey, just 8 percent of 3-5 yearolds used a computer someplace; today the level is nearly five times that at 38 percent. In 1984, white children were about twice as likely as blacks or Hispanics to use a computer; in 1997 while there were still real differences favoring whites, the relative difference was much smaller. Income differences still persist: in 1984 children from the lowest family income group had usage rates of about 16 percent, while those from the highest were around 50 percent. While usage has increased for all groups, there is still a sizable difference: in 1997 the lowest income children had a rate around 57 percent, while those from the highest incomes had a rate of 90 percent.

The role of schools in acting as an "equalizing" force for children should not be discounted. As Figure 2 indicates, through 1993 it appears that access and use for children in schools was rising at a faster rate than for children at home. Only since 1993 has the rate of growth for home use appeared to have risen to that of use in schools. Nevertheless, levels of school use for children are over 20 percentage points higher than those for children's use at home.

Table 4 focuses on the use of computers in school for children. In schools alone, 70 percent of all children had some kind of use of computers in 1997, over twice the access level in 1984. While demographic and socioeconomic differentials exist, they are considerably dampened from what is observed for home use levels. For example, while there are racial differences, they are on the order of fewer than 10 percentage points when comparing whites, blacks and persons of other races. Most importantly, the effect of family income appears to be considerably less critical than at home. Differences in school use range from 62 percent for the children from the lowest family income group, to 75 percent for those from the highest income group. In short, schools provide at least some point of access for many people who would otherwise have no access, and do it in a more equitable fashion than in the home arena, as one might expect. Nevertheless, the data show that even after 15 years of computer dissemination, there are still some differences in usage levels even in schools.

## Use by Adults

As with children, the levels of computer usage by adults have risen strongly over the four survey administrations we have conducted. Table 5 shows that in 1984 just 18 percent of the adult population said they were using a computer someplace - for many of these people, work was the primary - or sole - point of access. By 1997, 47 percent -- nearly half of adults -- said they used a computer someplace - at home, work or school. As with children's trends, we can see that growth has occurred across all segments of the population, and that some differentials have moderated over time. For example, in the 1984 survey, usage rates for persons $25-44$ were about 25 percent; for older ages there was a serious drop off - just 1 percent of persons ages 65 and
older reported using a computer anywhere. By 1997 sizable growth and change had occurred 58 percent of those $25-44$ used a computer, but nearly 50 percent of those $45-64$ did so as well. While use by the elderly was still low at 10 percent, this is a sizable relative increase from the level in 1984.

Interestingly, there is no difference between adult men and women in the level of overall computer use. This has been true almost from the start of our measurements in 1984. However, as we shall see in the data on use at work, there are probably major differences across locales, which act to mask the estimates that consider use in all places. Race differences are still quite substantial. White and black usage levels have risen about three-fold, but this means that the relative difference between the groups is about the same, with whites about 40 percent more likely than blacks to use a computer.

Across education groupings, usage levels have risen for all persons. In 1984, individuals with a Bachelor's degree or more were about 8 times as likely as those with some high school to be using a computer - by 1997 this ratio has dropped to less than 5 times, a large improvement, until one recognizes that the current absolute levels of use are 76 and 16 percent for the two groups.

The pattern across income groupings is a bit less clear. While relative increases at the very lowest income groups indicate change in the neighborhood of 3 or 4 times the 1984 levels, for most middle income groups the increase is somewhat less than a doubling from the first time period, and for the highest income group it is about twice the original level.

Figure 3 shows the levels of use and access across time for adults in various contexts. The data indicate growth in all areas, with perhaps an additional increase in overall use since 1993,
coinciding perhaps with home ownership and use. School use affects only a small proportion of all adults. The trend line for use at work is perhaps most interesting. Still on the increase, but perhaps at a slower rate than in previous years, the gap between home use and work use levels among all adults has declined noticeably, separated now only by 3.8 percent, compared to a 9.6 percent difference in 1984.

While home use for adults does appear to be on a significant rise, it is clear that for many people, the main point of access is in the workplace. About a quarter of all workers in 1984, and about half in 1997, use a computer in their job. Gender differentials are quite sizable, and have been so during all four surveys, actually increasing over time, such that women currently have about a 12 percentage point advantage over men in computer use in the workplace.

Usage levels for workers across ages reveal an interesting pattern. The level of use for persons ages 25-64 are fairly high, exceeding 50 percent. But while usage levels for older workers exceeds that seen for the elderly in general ( 24 vs 10 percent), the level of use at work for young people (18-25) is substantially less than their level at home ( 37 vs 58 percent). These data probably tell us far more about the kinds of jobs held by persons in various age groups than the actual need or desire to use a computer in the job. As Table 6 shows, there are still very wide differences across various occupational categories in the levels of computer use. Most of the use, and most of the growth, occurs in occupation such as managerial, professional technical or administrative jobs. Positions in the service, craft, and laborer occupations require relatively little use of computers. A more thorough multivariate analysis is needed to disentangle the significant interactions at play between occupations and the characteristics of the people in these jobs.

## Use of the Internet

Historically, most applications of computers have been dedicated, single-activity, singleuser functions. Programming languages and application tools (such as word processors, spreadsheets) generally require a single user to "interact" with the functional capacity of the computer they are using to achieve some desired end result. The development of large-scale electronic mail systems, multi-user applications, and the interconnected wise-area network of computers for them to ride on, is the realization of the environment we have come to know simply as the Internet. In its current configuration, the Internet is host to literally millions of computers across the world, allowing users to access information on virtually any topic. During the past few years, use of the Internet has accelerated even faster, as a new use, focusing on the buying and selling and goods and services, has emerged. "E-commerce", as this phenomenon has been tagged, could quite possibly be the leading form of financial transactions within the next decade. In short, the Internet has rapidly become a critical, not optional, tool for many people in their day-to-day activities.

In the 1997 survey we were able to ask questions about the Internet for the first time. (Previous surveys had asked about activities such as "email" in the uses questions, but not the Internet specifically.) Persons were asked about Internet use at home, work, and school. These data indicate that most of the differentials that exist in computer use are also present in Internet use. Table 7 shows that about 23 percent of all children used the Internet someplace - home or school. Home use levels ( 22 percent of those with computers) are not much higher than school use levels (17 percent of those in school). Strong differences are apparent in terms of both race
and family income; however, there is virtually no gender difference. Strong gradations in use across age groups reflect the nature of the Internet - high levels of interactive and searching activity are not likely to be something that small children can routinely undertake. Questions about specific Internet uses confirm this notion: the top two uses among children are "email" (58 percent) and "chatrooms" (32 percent).

The data for adults are equally as informative (Table 8). Overall, about 22 percent of all adults use the Internet somewhere - home, work or school. Interestingly, this is about the same level of use that children demonstrate. Unlike the actual use of computers, which is much higher among children ( 74 vs .47 percent), it appears that at this point in time the Internet is more equally accessed by adults and children. Nevertheless, among adults there are sizable differences, much as there are for computer use itself. Men hold about a 5 percentage point advantage in use ( 25 vs 20 percent). Age data point to younger persons as much more likely users. Whites are twice as likely as blacks or Hispanics to be on the Internet. As with computer use, very strong differences across educational and income levels are clear. Perhaps most importantly, of those adults with computers at home, a third - 35 percent are using the Internet; work use remains relatively low - just 17 percent of those using a computer at work are also using the Internet. The "uses" question, while somewhat limited, also reveals one interesting result--perhaps a harbinger of things to come. Even in 1997, 15 percent of adults using the Internet at home said one of their uses was for "shopping".

## Summary

The impact of technology on human society can be far reaching and pervasive. Just a century ago, the automobile was in its infancy, and most major cities struggled to deal with the large number of horses and the waste they produced. Today, much of the U.S. social organization has been structured around, and presumes the presence of, automobiles for virtually everyone. Persons without automobiles are at the mercy of public transportation (or selfpropulsion). In short, people without personal vehicles lead very different lives than those with them.

A different technology has taken central stage in the back half of this century. In less than two decades, personal computing devices have gone from being interesting playthings of the technically capable and financially able, to practical, useful and sometimes essential tools of the general public. The trend data discussed in this paper, and supported by many other data collections all point to this inevitable conclusion.

Nevertheless, the march forward into a "computer facile and literate" society is not one in which all persons participate equally. Despite sizable reductions in cost, and considerable improvements in technical efficiency, not all people have access to, or use of, computers. A piece of this 'unequal' access may be due to choice alone, an issue not examined in these data. However, despite improvements in differentials from our first survey measurement in 1984 there are still serious gaps in computer ownership and use, especially across racial, age, economic and educational levels. A multivariate analysis of these data might work well to clarify these differences. Only in terms of gender do gaps appear small or nonexistent. These gaps are closing, but not at an especially rapid pace. Gaps among children, while not as large, still remain. Finally,
in one "leading edge" indicator of technology - use of the Internet - it is clear that many of the gaps still exist.

The new and different of today may well become the routine of tomorrow. With regard to computing technology this seems to be somewhat likely to be the case. Those late starting the race will find it difficult to catch up; still others may not be given the opportunity to enter the race at all.

Table 1. Levels of Access and Use of Computers: 1984, 1989, 1993, 1997.

| (ln percent) |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Access, use, and Age | 1984 | 1989 | 1993 | 1997 |
| Households with computers | 7.9 | 14.4 | 22.8 | 36.6 |
| 3 to 17 years: |  |  |  |  |
| Access to a home computer. | 15.3 | 24.2 | 31.9 | 49.7 |
| Use home computer/1 | 74.2 | 71.1 | 74.7 | 82.4 |
| Use computer at school/2 | 28.0 | 46.0 | 60.6 | 70.8 |
| Use computer at home or school | 30.2 | 46.0 | 58.5 | 74.4/4 |
| 18 years and over: |  |  |  |  |
| Access to a home computer | 9.1 | 17.3 | 25.6 | 40.7 |
| Use home computer/1 | 53.3 | 58.4 | 65.6 | 70.9 |
| Use computer at school/2 | 30.8 | 43.6 | 53.8 | 62.3 |
| Use computer at work/3 | 24.6 | 36.8 | 45.8 | 49.8 |
| Use computer at home, school, or work | 18.3 | 28.1 | 36.0 | 47.1 |

1/Among people with a computer at home.
2/Among those enrolled in school.
3/Among employed individuals.
4/1997 figure includes 62,000 at work users.

The next set of questions has to do with your direct or hands on use of computers. These computers may be personal or home computers, laptops, mini computers or mainframe computers. These questions do not refer to hand-held calculators or games, electronic video games, notepads, WebTV, or systems which do not use a typewriter-like keyboard.

## >COMP-I<

The information you provide is very important. These questions will provide valuable information about the quantity and quality of computer use at home, school, and
work. This information is used to do research into expanding computer ownership and use, some of which did not even exist 4 years ago.
