## Executive Summary

A reconnaissance was undertaken by EPA-New England (EPA-NE) and Massachusetts Department of Environmental Protection (MADEP) of the Ten Mile River watershed which runs through the City of Attleboro in southeastern Massachusetts. Seven discrete sediment sampling locations were identified as being representative of the past and current pollutant history of the river. Sampling was undertaken by OEME staff on March 25, 1998 following a previously approved QAPP which is appended to this document (Appendix F). All sample collection, handling and analysis was consistent with the requirements in the QAPP.

Eight sediment samples (Wetherell Pond was sampled twice at the same location) were analysed at the OEME laboratory for a full suite of analytical parameters including inorganics (metals), volatile and semi-volatile organic compounds, chlorinated pesticides, polychlorinated biphenyls (PCBs), total organic carbon (TOC), grain size, acid volatile sulfides (AVS) and simultaneously extractable metals (SEM). Chemistry analytical results are given in Appendix A. These sediments are highly contaminated with complex mixtures of inorganic chemicals (metals), volatile and semi-volatile organic compounds, chlorinated pesticides and PCBs. Given the history of this river during and subsequent to the Industrial Revolution in New England, including jewelry, tannery, and electroplating works, such remnant contamination is not unexpected. Should any remediation of this river, such as dredging be proposed, further study would be warranted.

These results were then screened using a new tool recently developed at OEME, the Sediment Ecotoxicological Screening Benchmark (SESB) tables (Appendices D and E). These SESB tables screen inorganics (primarily metals), chlorinated pesticides and polychlorinated biphenyls and volatile and semi-volatile organic hydrocarbons (SVOCs) relative to ecotoxicological screening benchmark values derived from the published scientific and technical literature. These results are depicted in Figures 7-30 and Tables 6-29 and summarized in Appendix D and Tables 30-32. Contamination of potential ecotoxicological concern was observed at all sample locations.

An exploratory multivariate data analysis including clustering and ordination techniques was undertaken of the chemistry data sets. Graphical and numerical results are shown in Appendix B. These depict similarity and dissimilarity between sample sites based on observed contaminants.

Biological tests of these sediment samples were undertaken in which two freshwater invertebrate species (chironomids and amphipods) were exposed under controlled laboratory conditions. The amphipod test failed to meet test acceptability criteria with excessive mortality in the control animals. Thus these results could not be statistically analyzed and interpreted further. However, the chironomid test observed significant impairment of survival in three test site replicates: Dodgeville Pond Dam (DODG01), Rt. 15 Pond Dam (RESE01) and Wetherell Pond Dam (WETH01/02). No significant impairment in the growth endpoint was observed. However, one site, Hebronville Pond Dam (HEBR01), displayed significantly enhanced growth relative to the control. The implications of this are unclear. Moreover, the potential for adverse effects from

these sediments could be underestimated since, for example, tests did not measure subchronic effects, such as reproduction and emergence.

The chemical and physical characterization of river bed sediments is of interest as sediment quality is often a good indicator of aquatic system “health”. Persistent contaminants associated with past and present cultural and natural influences enter aquatic systems and may be adsorbed onto or absorbed into sediments. These contaminated sediments may pose an ecotoxicological and human health risk if their contaminants are able to enter the aquatic food chain, or if people or organisms are otherwise exposed to them.

### **Introduction, Purpose and Scope**

The Massachusetts Department of Environmental Protection Office of Watershed Management (OWM) requested EPA-New England’s Office of Environmental Measurement and Evaluation (OEME) assistance in evaluating the sediment quality in the Ten Mile River. The Ten Mile River has a history of physical alteration and chemical contamination, particularly from jewelry, tannery, and electro-plating industries. The purpose of this investigation is to determine chemical concentrations of inorganic chemicals (primarily metals), chlorinated pesticides and polychlorinated biphenyls (PCBs), and volatile and semi-volatile organic chemicals (SVOCs), in the river sediment upstream of several impoundments and a Waste Water Treatment Plant (WWTP), to evaluate the potential ecotoxicity of these sediments to benthic invertebrates and other organisms, and to determine ambient surface water quality conditions associated with the sampling locations.

## Field Reconnaissance and Sampling

Table 1 and Map 1 identify the seven sample locations. Wetherell Pond Dam was sampled twice, with two co-located sediment samples. All samples were taken, tagged, and transported as per the QAPP (Appendix F).

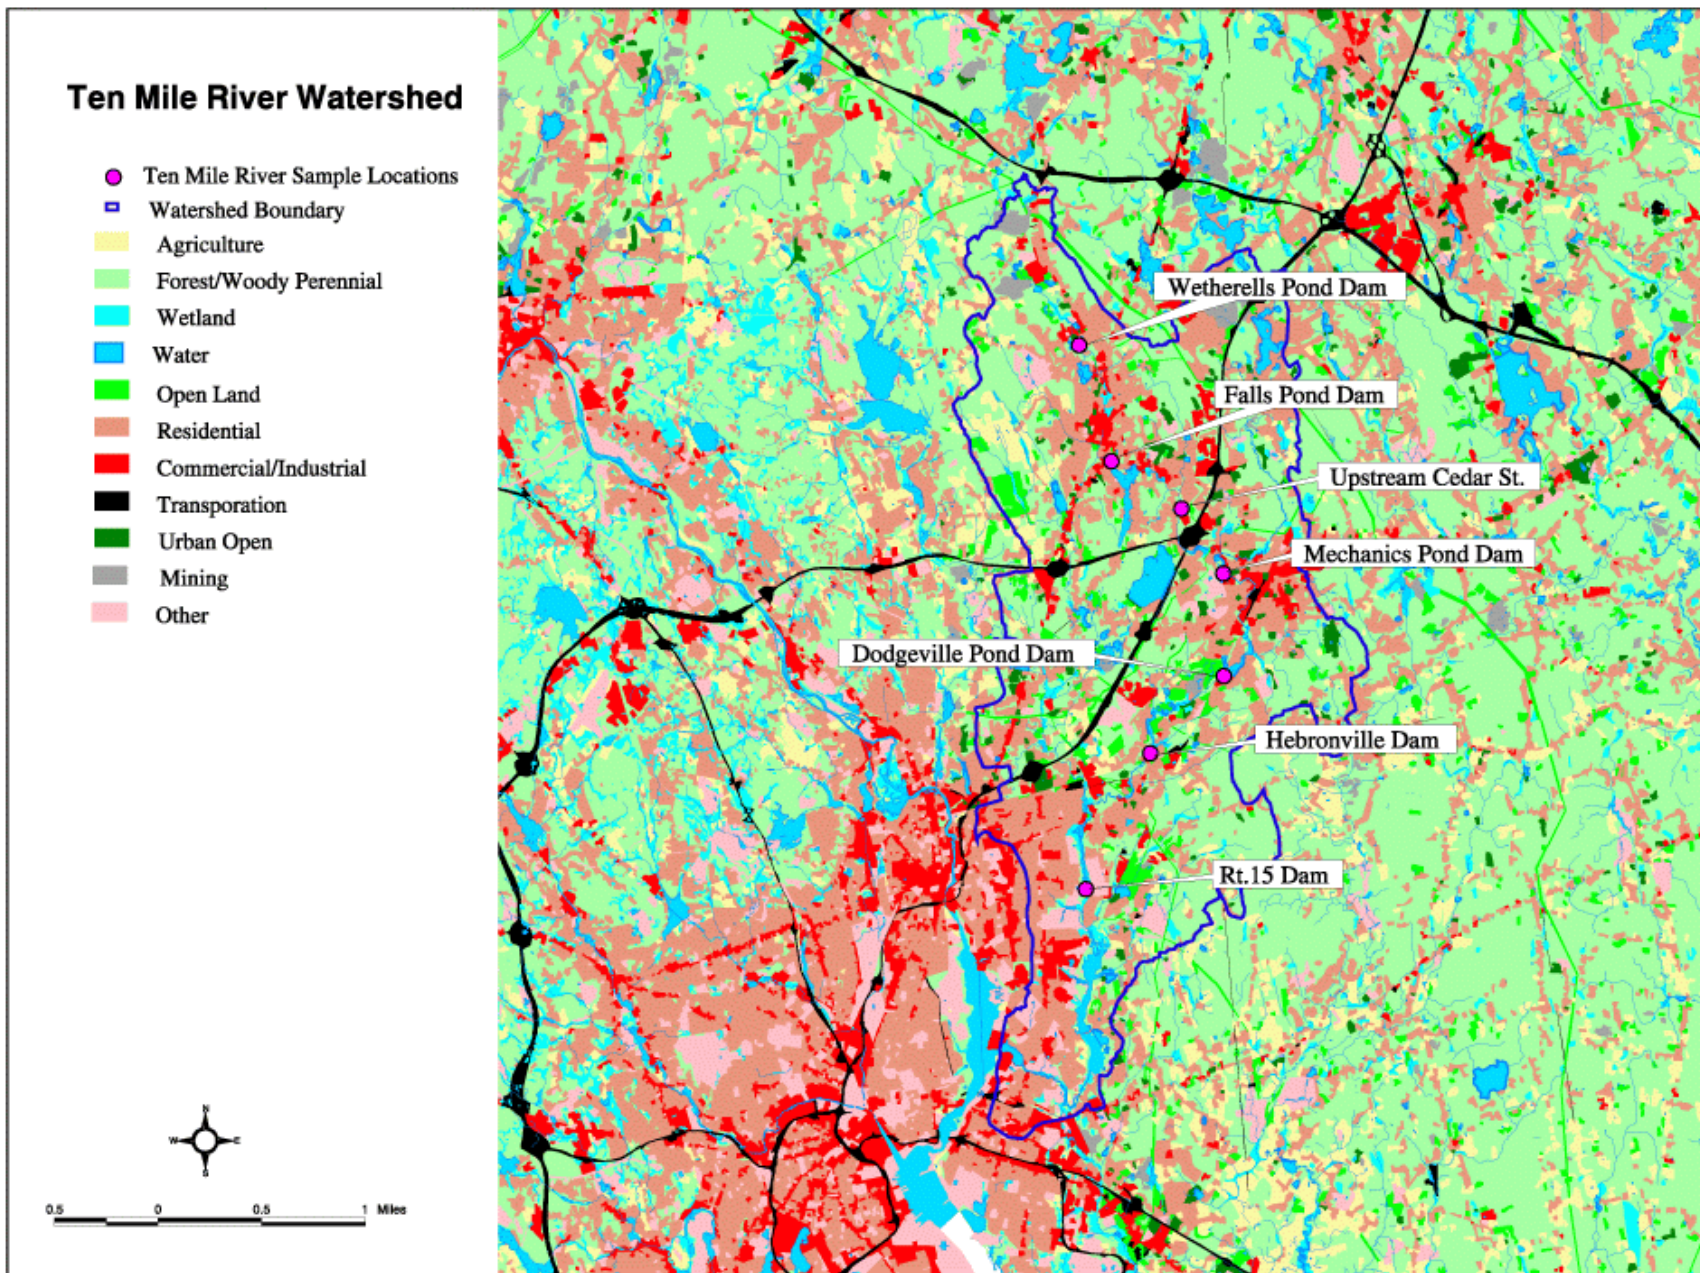

## GPS (Global Positioning System) Locations and Ambient Water Quality Parameters

Table 1 documents the GPS locations and ambient water quality parameters taken at each sample location pH, dissolved oxygen, conductivity, and temperature.

**Table 1.** Ten Mile Watershed Sample Site GPS (Global Positioning System) Locations and Ambient Water Quality Parameters

Ambient water quality parameters at all sample sites indicated very similar circumneutral, well oxygenated water of similar conductivity.

**Map 1.** Map of the Ten Mile River Watershed showing land use/land cover and sediment sampling stations.

## Laboratory Analyses - Chemistry and Biology

An evaluation of the quality of the Ten Mile River sediment was attempted using a multidimensional approach. This approach includes the use of bulk sediment chemistry data, bulk sediment toxicity testing, comparison to sediment quality guidelines and an attempt to explain any correlation of chemical and toxicological findings, or lack of, through the use of bioavailability information i.e. site specific SEM/AVS and TOC normalization.

### Simultaneously Extractable Metals and Acid Volatile Sulfides

**Table 2. Acid Volatile Sulfides/Simultaneously Extractable Metals (AVS/SEM)<sup>1</sup> (*umole/gm*, dry weight)**

---

<sup>1</sup>AVS - "An extractable reactive pool of solid-phase sulfide that is associated with and available from the mineral surfaces of sediment to bind metals and may render that portion unavailable and non-toxic to biota. Metals associated with the sulfide fraction of suspended matter and sediments in anaerobic environments include zinc, lead, copper, cobalt, nickel, cadmium, arsenic, antimony, mercury, manganese, and molybdenum" (Rand 1995:939).

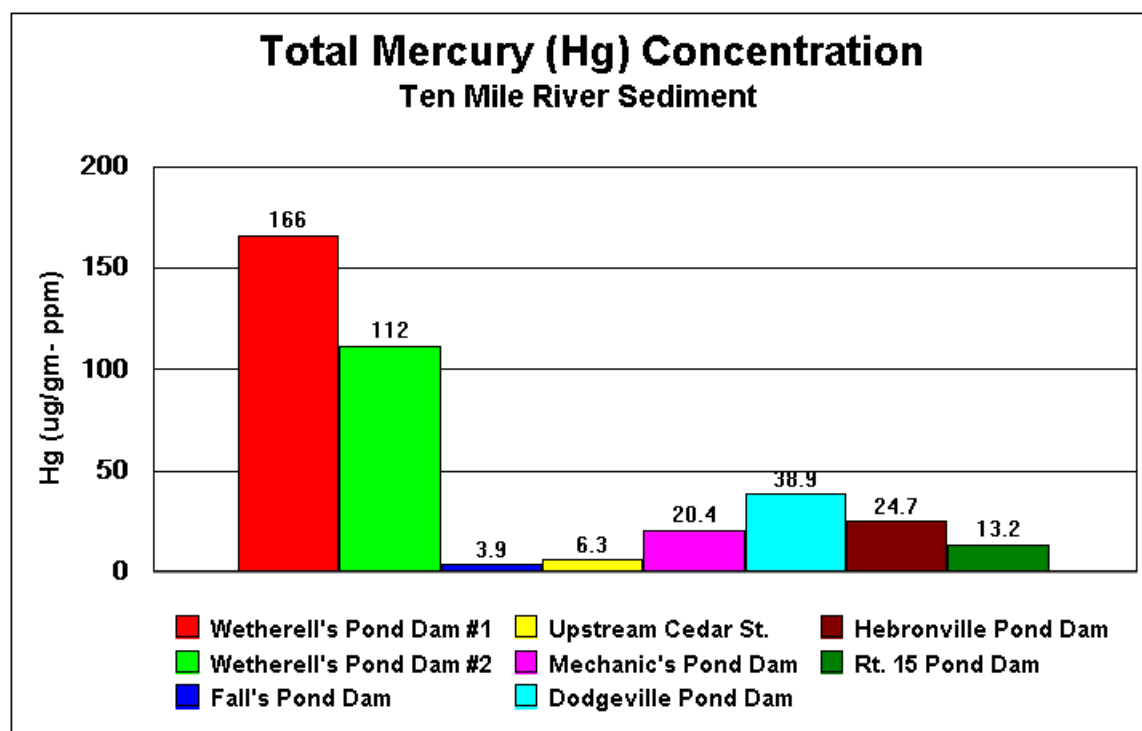

**Figure 1.** Acid Volatile Sulfides and Simultaneously Extractable Metals of Ten Mile River Watershed Sediment Samples

When AVS exceeds SEM, with a ratio of 1 or less, such as at Fall Pond Dam (TENM01) and Mechanic Pond Dam (MECH01), it is assumed that metals will be less available to biota and therefore less toxic. When AVS is not detected above reporting limits, as in the case of the Upstream Cedar St. site (NATP01), metals are assumed to be more bioavailable. The Ten Mile river sites vary widely in SEM/AVS levels, however, all sites except those mentioned above exhibit ratios greater than 1 suggesting that metals are more bioavailable than if higher levels of AVS were observed in these sediments.

## Total Mercury

**Table 3.** Mercury Analysis in Ten Mile Sediment Samples

SITE	Wetherell Pond Dam #1 (WETH01)	Wetherell Pond Dam #2 (WETH02)	Fall Pond Dam (TENM01)	Upstream Cedar St. (NATP01)	Mechanic Pond Dam (MECH01)	Dodgeville Pond Dam (DODG01)	Hebronville Pond Dam (HEBR01)	Rt. 15 Pond Dam (RESE01)

**Figure 2.** Total Mercury Concentration in Ten Mile Watershed Sediment Samples

sediment and *not* water concentrations.

Notes: Dry sample results in *ug/gm* (ppm)

\* Results on a dry weight basis

A metal whose bioavailability is affected by the SEM/AVS ratio and which is of the highest ecotoxicological and human health concern is Hg. High levels were observed, especially at Wetherell Pond Dam (WETH01/02). We have no analytical knowledge of whether the mercury is in inorganic or methylated (bioavailable) states. Given the extremely high observed mercury values at all sampled sites in this watershed, this contaminant is of both potential ecotoxicological and human health concern. Furthermore, the toxicity test endpoints of growth and survival do not account for possible bioaccumulation. Methyl mercury may bioaccumulate in aquatic organisms from 10,000 to 100,000 times the ambient water concentration (Rand 1995). It should be noted that the values in Figure 2 are for

## Total Organic Carbon

Samples were analyzed for Total Organic Carbon (TOC)<sup>2</sup> according to the methods identified in the QAPP. The SESBs in Appendix D adjust ecotox thresholds of SEL, SQAL and SQC for the percent of TOC. The ecotox values were developed for a normalized TOC concentration of 1%. Adjustment is applied to TOC values between .2%(.2) and 10%(10). Samples with TOC >10% default to 10% and <.2% to .2%. As Rand (1995:498) notes, “[O]rganic carbon-based partitioning provides a good estimate of the amount of organic chemical sorbed to natural particles, even though the actual sorption mechanism may involve a variety of adsorption (surface binding) and partitioning processes.”

**Figure 3.** Total Organic Carbon content (unadjusted) of 10 Mile River Watershed Sediment Samples

<sup>2</sup> “Total Organic Carbon (TOC) is the total amount in the water column and represents the sum of contributions from truly dissolved, colloidal, and suspended particulate organic carbon (POC)” (Rand 1995:496).

## Sediment Grain Size Analysis

Figure 4 and Table 4 indicates a large percentage of the grain size of the Ten Mile River sediment samples is in silts and clays, from 31-64%. Mechanic Pond (MECH01), Dodgeville Pond (DODG01), Hebronville Pond (HEBR01) and Rt. 15 Pond (RESE01) Dams all have similar grain size distributions. Upstream Cedar St. (NATP01) has a larger percentage of material in the finer and finest sand categories. Finer sediments, such as silts and clays, tend to bind contaminants more than sand.

**Table 4.** Sediment Grain Size Analysis for Ten Mile Sediment Samples

	<b>Wetherell Pond Dam #1 and #2 (WETH01/02)</b>	<b>Fall Pond Dam (TENM01)</b>	<b>Upstream Cedar St. (NATP01)</b>	<b>Mechanic Pond Dam (MECH01)</b>	<b>Dodgeville Pond Dam (DODG01)</b>	<b>Hebronville Pond Dam (HEBR01)</b>	<b>Rt. 15 Pond Dam (RESE01)</b>

# Ten Mile River Sediment Grain Size

(as % retained)

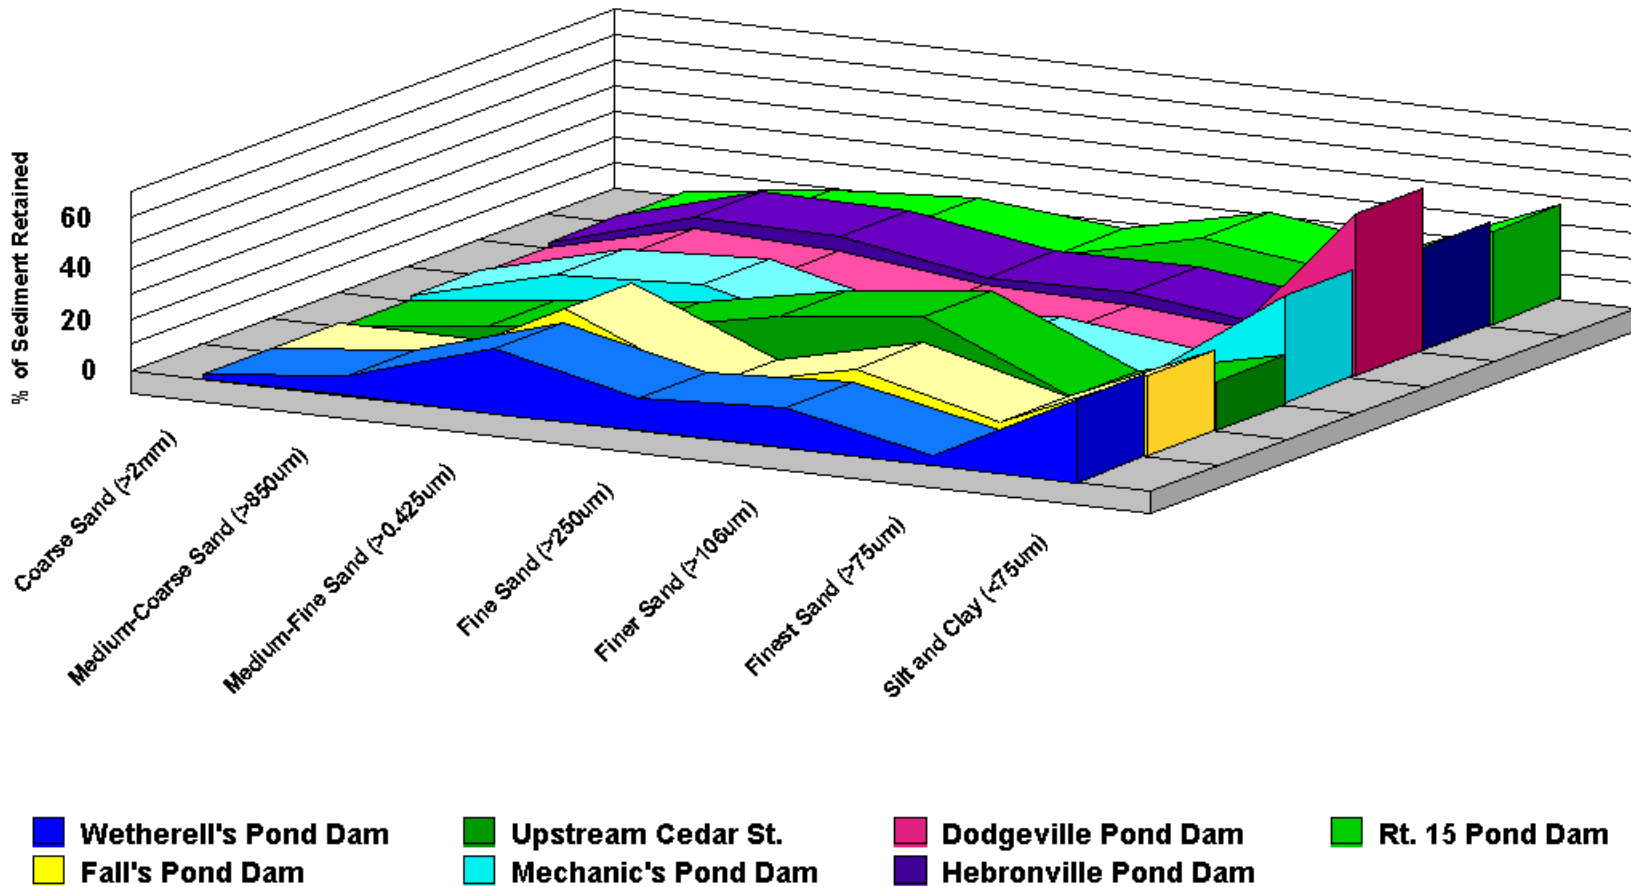

Figure 4. Sediment Grain Size Analysis for the Ten Mile River Watershed

## Statistical Analysis of Sediment Toxicity Data

Bulk sediment toxicity testing was successful for chironomids (*Chironomus tentans*) exceeding test acceptability criteria of 70% survival in the laboratory control. However the ARTSED laboratory control for amphipods (*Hyallela azteca*) only achieved a survival of 61%, considerably below the 80% required for test acceptability for this species. Given that we have no way of knowing the cause for impairment of the controls we must exclude this test from statistical analysis and further discussion. For example, the control results might indicate impaired health of the amphipod test organisms.

The acute endpoints selected for statistical analyses for chironomids were survival and growth. Statistical analyses performed using the TOXSTAT Version 3.0 DOS software package are shown in Appendix C (Gulley and others, N.D.). Test replicates were first compared at all locations relative to the laboratory control (Artificial Sediment) for survival. The survival data set was tested for normality using the Chi-Square test and for homogeneity of variance using Hartley's and Bartlett's tests. It passed all three tests allowing analysis of the data using Dunnett's Test, given the equal number of replicates. Dunnett's test identified statistically significant impairment in survival ( $p=0.05$ , one-tailed;  $df=40,7$ ; T Stat=2.42) at Dodgeville Pond Dam (DODG01), Rt. 15 Pond Dam (RESE01) and Wetherell Pond Dam (WETH01/02).

Figure 5. Sites with significant and non-significant effects on chironomid survival.

**Figure 6.** Sites with significant and non-significant effects on chironomid growth.

These sites were then removed from further statistical analysis for growth impairment, as impaired survival precludes this analysis. The growth data set was also tested for normality using the Chi-Square test and for homogeneity of variance using Hartley's and Bartlett's tests. It passed all three tests allowing analysis of the growth data using Dunnett's Test, given the equal number of replicates. Dunnett's test identified no statistically significant impairment in growth ( $p=0.05$ , one-tailed;  $df=30,4$ ;  $T \text{ Stat}=2.25$ ). When the two-tailed Dunnett's test value is used in the analysis then statistically enhanced growth ( $p=0.05$ ; two-tailed;  $df=30,4$ ;  $T \text{ Stat}=2.58$ ) is observed at Hebronville Pond Dam (HEBR01) (Zar, 1974).

### Contaminant Levels of Potential Ecotoxicological Concern

Tables 6-29 and Figures 7-30 document the presence and absence of potential ecotoxicological effects from observed contaminants at each site. Potential effects are highlighted in red. Specific thresholds exceeded are shown in the Sediment Ecotoxicological Screening Benchmark (SESB) tables (Table 5). Appendix E provides a thorough discussion of the derivation, strengths and limitations of the SESB tables.

Chromium, total	OWSER, Region IV, AEL-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Copper	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Lead	OSWER, Region IV, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA

Mercury, total	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEL-C, TEL-F, PEL-C, PEL-F
Nickel	OSWER, Region IV, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Silver	Region IV, AET-L, AET-H, ERL, ERM, TEL-F, PEL-F
Zinc	OSWER, Region IV, AET-L, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA

**Figure 8.** Sediment Ecotoxicity - Wetherell Pond #2 (WETH02) (Inorganic Chemicals - Metals)

**Table 7.** Wetherell Pond #2 (WETH02) Inorganic Chemicals (Metals) exceeding Ecotoxicological Threshold (SEM/AVS = 19.3)

Contaminant	Ecotox Thresholds Exceeded
Arsenic	OSWER, Region IV, LEL, MEL, ERL, TEL-C, TEL-F
Cadmium	OSWER, Region IV, AET-L, LEL, MEL, TOEL, ERL, TEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Chromium, total	OWSER, Region IV, AEL-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Copper	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Iron	LEL
Lead	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA

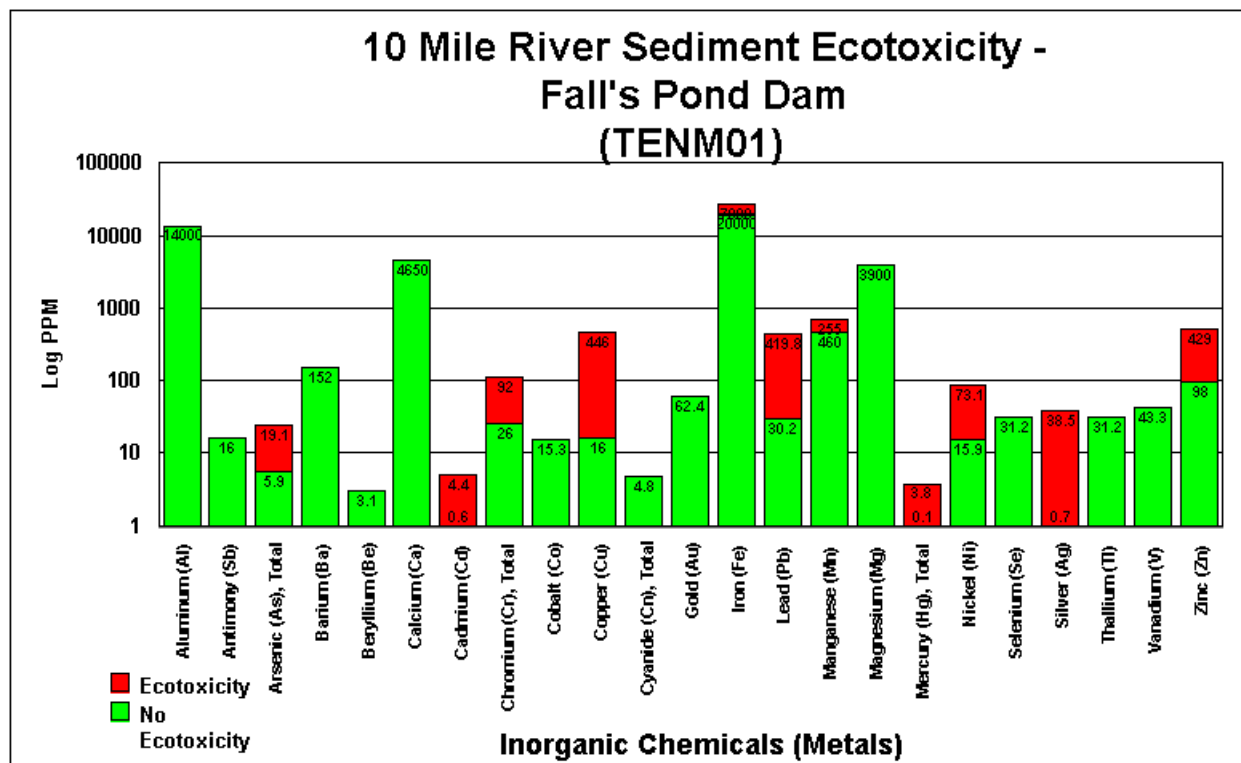

Mercury, total	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEL-C, TEL-F, PEL-C, PEL-F
Nickel	OSWER, Region IV, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Silver	Region IV, AET-L, AET-H, ERL, ERM, TEL-F, PEL-F
Zinc	OSWER, Region IV, AET-L, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA

The Wetherell Dam Pond (WETH01) and Wetherell Pond #2 (WETH02) sites are most notable because of the high levels of mercury detected there (166 and 112 ppm., respectively). Other inorganic chemicals which exceeded ecotoxicological thresholds at these sites included cadmium, chromium<sup>3</sup>, copper, lead, nickel, silver and zinc. Silver, nickel, copper, and chromium were present at high levels compared to the other Ten Mile sites. Further, the high SEM/AVS ratios observed in both samples (29.2 and 19.3), by far the highest in the watershed, indicates the potential for bioavailability of zinc, lead, copper, nickel, cadmium, arsenic, and mercury.

---

<sup>3</sup> We have no analytical knowledge of the speciation of chromium at any of the Ten Mile sites. Clearly the much more toxic Cr<sup>+6</sup> form, if present, would be of greater ecotoxicological concern than the less toxic Cr<sup>+3</sup> form.

**Figure 9.** Sediment Ecotoxicity - Fall Pond Dam (TENM01) (Inorganic Chemicals - Metals)

**Table 8.** Fall Pond Dam (TENM01) Inorganic Chemicals (Metals) exceeding Ecotoxicological Thresholds (SEM/AVS = 0.24)

Contaminant	Ecotox Thresholds Exceeded
Arsenic	OSWER, Region IV, LEL, MEL, TOEL, ERL, TEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C
Cadmium	OSWER, Region IV, LEL, MEL, TOEL, ERL, TEC-ARC, . TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Chromium, total	OSWER, Region IV, LEL, SEL, MEL, TOEL, ERL, TEL-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C
Copper	OSWER, Region IV, AET-L, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Iron	LEL
Lead	OSWER, Region IV, AET-L, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA

Manganese	LEL
Mercury, total	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEL-C, TEL-F, PEL-C, PEL-F
Nickel	OSWER, Region IV, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Silver	Region IV, AET-L, AET-H, ERL, ERM, TEL-F, PEL-F
Zinc	OSWER, Region IV, AET-L, LEL, MEL, ERL, ERM, TEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA

The low SEM/AVS ratio of 0.24 indicates greater binding and less bioavailability of zinc, lead, copper, nickel, cadmium, arsenic, mercury, and manganese at the Fall Pond Dam site.

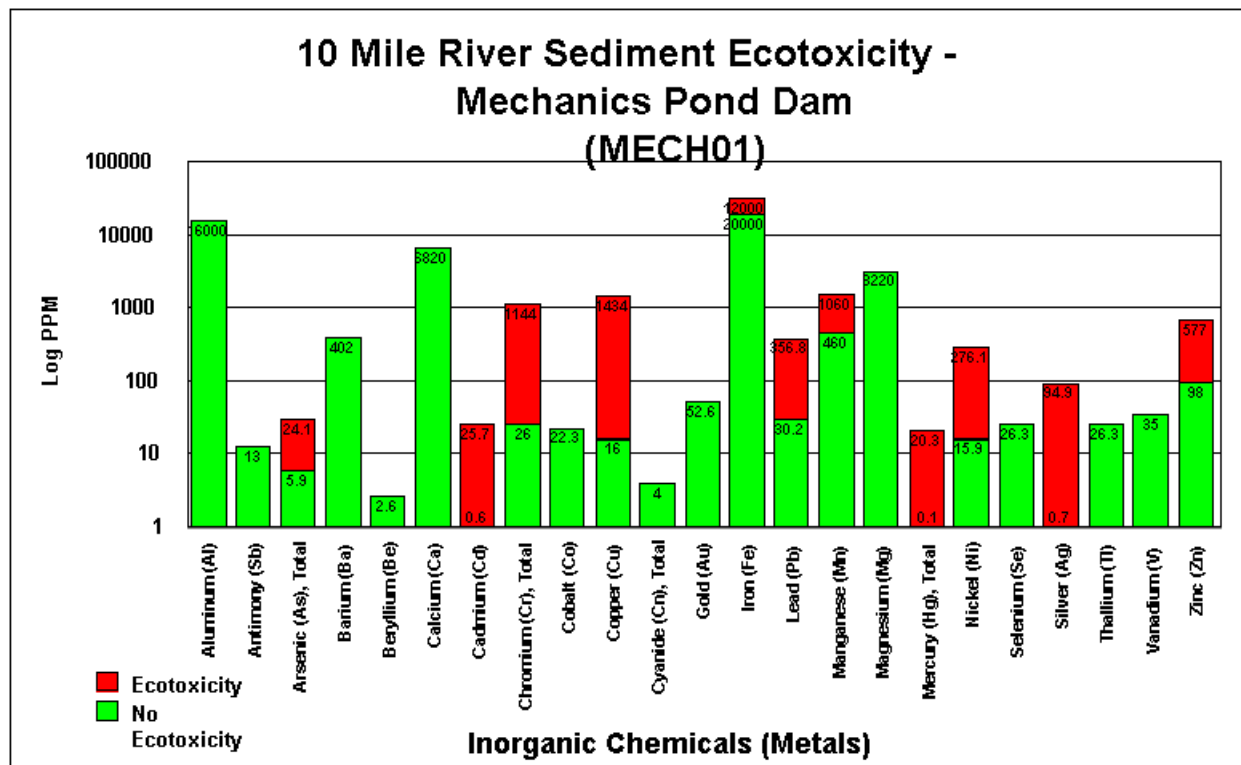

Figure 10. Sediment Ecotoxicity - Upstream Cedar St.(NATP01) (Inorganic Chemicals - Metals)

Table 9. Upstream Cedar St. (NATP01) Inorganic Chemicals (Metals) exceeding Ecotoxicological Thresholds (SEM/AVS = 0.00)

Contaminant	Ecotox Thresholds Exceeded
Arsenic	OSWER, Region IV, LEL, MEL, ERL, TEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Cadmium	OSWER, Region IV, LEL, MEL, TOEL, ERL, TEC-ARCS, TEL-C, TEL-F, TEL-HA
Chromium, total	Region IV, LEL, MEL, TEC-ARCS, TEL-C, TEL-F, TEL-HA
Copper	OSWER, Region IV, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Iron	LEL
Lead	OSWER, Region IV, LEL, MEL, ERL, TEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Manganese	LEL, SEL, TEC-ARCS, PEC-ARCS, NEC-ARCS

Mercury, total	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEL-C, TEL-F, PEL-C, PEL-F
Nickel	OSWER, Region IV, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Silver	Region IV, AET-L, AET-H, ERL, ERM, TEL-F, PEL-F
Zinc	OSWER, Region IV, LEL, MEL, ERL, TEC-ARCS, TEL-C, TEL-F, TEL-HA

The low SEM/AVS ratio of 0.00 suggests the greater binding in the sediment and lesser bioavailability of zinc, lead, copper, cobalt, nickel, cadmium, arsenic, mercury and manganese at the Upstream Cedar St. site (NATP01). The strongly associated Fall Pond Dam (TENM01) and Upstream Cedar St. sites were distinguished by relatively low levels, although still of potential ecotoxicological effect, of cadmium, chromium, copper, mercury, nickel, and silver. Other inorganics observed at values more similar to the other Ten Mile sites and exceeding ecotoxicological thresholds included iron, lead, manganese and zinc

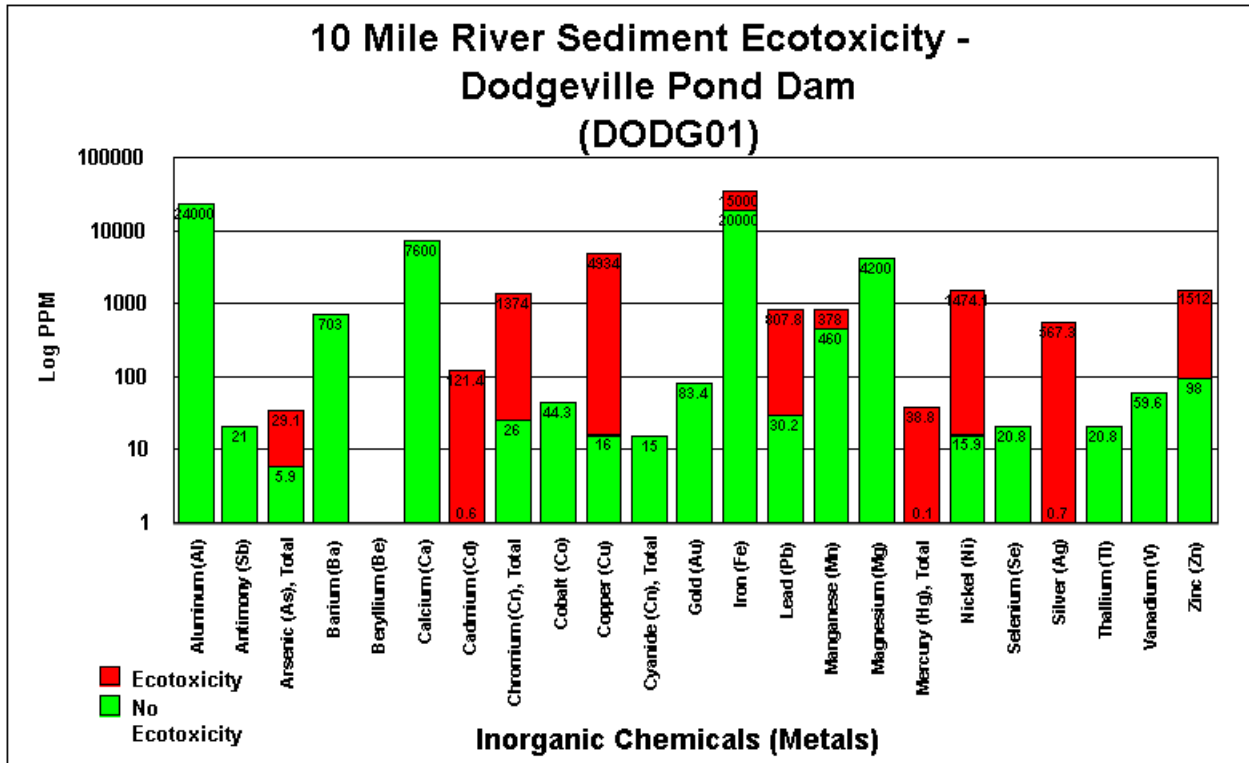

**Figure 11.** Sediment Ecotoxicity - Mechanic Pond Dam (MECH01) (Inorganic Chemicals - Metals)

**Table 10.** Mechanic Pond Dam (MECH01) Inorganic Chemicals (Metals) exceeding Ecotoxicological Thresholds (SEM/AVS = 0.24)

Contaminant	Ecotox Thresholds Exceeded
Arsenic	OSWER, Region IV, LEL, MEL, TOEL, ERL, TEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C
Cadmium	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Chromium, total	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Copper	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Iron	LEL

Lead	OSWER, Region IV, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Manganese	LEL, SEL, PEC-ARCS, NEC-ARCS
Mercury, total	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEL-C, TEL-F, PEL-C, PEL-F
Nickel	OSWER, Region IV, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Silver	Region IV, AET-L, AET-H, ERL, ERM, TEL-F, PEL-F
Zinc	OSWER, Region IV, AET-L, LEL, MEL, TOEL, ERL, ERM, TEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA

The low SEM/AVS ratio of 0.24 at Mechanic Pond suggests greater binding to sediment and less bioavailability of zinc, lead, copper, nickel, cadmium, arsenic, mercury and manganese.

**Figure 12.** Sediment Ecotoxicity - Dodgeville Pond Dam (DODG01) (Inorganic Chemicals - Metals)

**Table 11.** Dodgeville Pond Dam (DODG01) Inorganic Chemicals (Metals) exceeding Ecotoxicological Thresholds (SEM/AVS = 2.4)

Contaminant	Ecotox Thresholds Exceeded
Arsenic	OSWER, Region IV, LEL, SEL, MEL, TOEL, ERL, TEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C
Cadmium	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Chromium, total	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Copper	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Iron	LEL

Lead	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Manganese	LEL, NEC-ARCS
Mercury, total	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEL-C, TEL-F, PEL-C, PEL-F
Nickel	OSWER, Region IV, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Silver	Region IV, AET-L, AET-H, ERL, ERM, TEL-F, PEL-F
Zinc	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PERL-HA

The high SEM/AVS ratio of 2.4 at Dodgeville Pond suggests less binding in sediment and greater bioavailability of zinc, lead, copper, nickel, cadmium, arsenic, mercury and manganese.

**Figure 13.** Sediment Ecotoxicity - Hebronville Pond Dam (HEBR01) (Inorganic Chemicals - Metals)

**Table 12.** Rt. 15 Hebronville Pond Dam (HEBR01) Inorganic Chemicals (Metals) exceeding Ecotoxicological Thresholds (SEM/AVS = 2.4)

Contaminant	Ecotox Thresholds Exceeded
Arsenic	OSWER, Region IV, LEL, SEL, MEL, TOEL, ERL, TEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C
Cadmium	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Chromium, total	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Copper	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Iron	LEL

Lead	OSWER, Region IV, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Manganese	LEL, SEL, TEC-ARCS, PEC-ARCS, NEC-ARCS
Mercury, total	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEL-C, TEL-F, PEL-C, PEL-F
Nickel	OSWER, Region IV, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Silver	Region IV, AET-L, AET-H, ERL, ERM, TEL-F, PEL-F
Zinc	OSWER, Region IV, AET-L, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA

The high SEM/AVS ratio of 2.4 suggests less sediment binding and greater bioavailability of zinc, lead, copper, nickel, cadmium, arsenic, mercury and manganese at the Hebronville Pond Dam site. The aggregation of Dodgeville Pond Dam (DODG01), Hebronville Pond Dam (HEBR01), and Mechanics Pond Dam (MECH01) were distinguished by the high levels of cadmium, chromium, nickel, and relatively high level of mercury. Other ecotoxicological exceedances at these sites included copper, iron, lead, manganese, silver and zinc. However, the much lower SEM/AVS of Mechanic Pond Dam site suggests a considerable difference between these sites in bioavailability of zinc, lead, copper, nickel, cadmium, arsenic, mercury and manganese.

**Figure 14.** Sediment Ecotoxicity - Rt. 15 Pond Dam (RESE01) (Inorganic Chemicals - Metals)

**Table 13.** Rt. 15 Pond Dam (RESE01) Inorganic Chemicals (Metals) exceeding Ecotoxicological Thresholds (SEM/AVS = 3.5)

Contaminant	Ecotox Thresholds Exceeded
Arsenic	OSWER, Region IV, LEL, SEL, MEL, TOEL, ERL, TEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Cadmium	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Chromium, total	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Copper	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Iron	LEL
Lead	OSWER, Region IV, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA

Manganese	LEL, SEL, TEC-ARCS, PEC-ARCS, NEC-ARCS
Mercury, total	OSWER, Region IV, AET-L, AET-H, LEL, SEL, MEL, TOEL, ERL, ERM, TEL-C, TEL-F, PEL-C, PEL-F
Nickel	OSWER, Region IV, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA
Silver	Region IV, AET-L, AET-H, ERL, ERM, TEL-F, PEL-F
Zinc	OSWER, Region IV, AET-L, LEL, SEL, MEL, TOEL, ERL, ERM, TEC-ARCS, PEC-ARCS, NEC-ARCS, TEL-C, TEL-F, TEL-HA, PEL-C, PEL-F, PEL-HA

The high SEM/AVS ratio of 3.5 at the Rt. 15 Pond Dam (RESE01) site suggests less sediment binding and greater bioavailability of zinc, lead, copper, nickel, cadmium, arsenic, mercury and manganese.

Wetherell Dam Pond (WETH01) and Wetherell Pond #2 (WETH02) samples differ as to the presence of naphthalene and benzo(e)pyrene and the absence of diethyl phthalate and dimethyl phthalate in the Wetherell Dam Pond site. Otherwise these sites have very equivalent volatile and semi-volatile contaminant profiles with ecotoxicological exceedances.

Dodgeville Pond Dam (DODG01) and Mechanic Pond Dam (MECH01) are highly similar sites on SVOCs in addition to other contaminants. As Map 1 shows these sites are close to one another which likely accounts for the similar contaminant histories.

## Multivariate Exploratory Data Analysis

Statistical analysis of the chemical data was undertaken using the Multivariate Statistical Package (MVSP, Version 3.1, Kovach Computing Services, [www.kovcomp.co.uk](http://www.kovcomp.co.uk)) which performs clustering and ordination. Results are shown in Appendix B. All data for cluster analysis was  $\text{Log}_{10}$  transformed to correct for the effects of extreme values. Cluster Analysis similarity coefficients were calculated using four algorithms (Percent Similarity, Jaccard's Similarity Coefficient, Gower General Similarity Coefficient, and Average Distance). Similarity Coefficients use mathematical means to assess the degree of similarity and difference between a set of samples.

“Cluster analysis is an exploratory data analysis tool for solving classification problems. Its object is to sort cases (people, things, events, etc) into groups, or clusters, so that the degree of association is strong between members of the same group and weak between members of different groups. Each such cluster thus describes, in terms of the data collected, the class to which its members belong; and this description may be abstracted through use from the particular to the general class or type.

Cluster analysis is thus a tool of discovery. It may reveal associations and structure in data which, though not previously evident, nevertheless are sensible and useful once found.”(Clustan 1999)

The cluster analyses of the metals, VOCs/SVOCs, pesticides/PCBs and total chemistry reveal similar patterns. For metals the general order of the clusters of sites are highly similar independent of the similarity coefficient used. The Jaccard Coefficient did not yield a discrimination of the sites and was discarded from the analysis for metals.

For pesticides/PCBs the results were very similar for all four clustering algorithms. Ordination provided discrimination from nominally similar sites such as the cluster of Upstream Cedar St. (NATP01) and Wetherell Pond Dam (WETH01/02). Axis 1 of each of the three ordinations clearly distinguishes these sites from each other together with other proximal sites such as Fall Pond Dam.

These patterns are further clarified by the ordinations. Dodgeville Pond Dam (DODG01) and Mechanic Pond Dam (MECH01) are highly similar sites in all three ordinations.

The patterns observed in all four SVOC cluster analyses were also very similar and were further elucidated by the ordinations.

For total chemistry similar clusters of sites were observed, although specific sites changed position, as for the other parameters, depending on the similarity coefficient used in the analysis. Similar patterns were observable in the ordination graphs, for example, the close association of Hebronville Pond Dam (HEBR01) and Rt. 15 Pond Dam (RESE01) in three of the clusterings

and in the Correspondence Analysis. The other two ordinations and the other cluster analysis differentiated the Rt. 15 Pond Dam site from the Hebronville Pond Dam site.

Ordination was also performed on these data sets using three algorithms in the MVSP 3.1 program (Principal Components, Principal Coordinates and Correspondence Analysis).

### **Ordination Techniques**

Ordination may be defined as, “[T]he ordering of a set of data points with respect to one or more axes. Alternatively, the displaying of a swarm of data points in a two or three-dimensional coordinate frame so as to make the relationships among the points in many-dimensional space visible on inspection” (Pielou 1984). “Ordination primarily endeavors to represent sample and species relationships as faithfully as possible in a low-dimensional space” (Gauch 1982).

### **Principal Components and Detrended Correspondence Analysis**

The axes in Principal Components Analysis are uncorrelated with (orthogonal to) one another and have the characteristic of explaining more of the data variance than subsequent axes (Helsel and Hirsch 1993). “The resulting  $p$  axes are thus new ‘variables’, the first few of which often explain the major patterns of the data in multivariate space. The remaining principal components may be treated as residuals, measuring the ‘lack of fit’ of observations along the first few axes” (Helsel and Hirsch 1993:59). The percentage of data variance explained by successive axes in all three ordinations are given in the attached quantitative ordination output tables.

Palmer (1998) observes that, “[A]lthough PCA is often useful for the analysis of samples in species space, it is still quite appropriate for the analysis of samples in environmental space. This is because it is likely for most environmental variables to be monotonically related to underlying factors, and to each other. Also, PCA allows the use of variables which are not measured in the same units (e.g. elevation, concentration of nutrients, temperature, pH, etc.).”

Kovach (1999) provides background information on PCA:

“Principal components analysis (PCA) is one of the best known and earliest ordination methods, first described by Karl Pearson (1901). Mathematically, PCA consists of an eigenanalysis of a covariance or correlation matrix calculated on the original measurement data. Graphically, it can be described as a rotation of a swarm of data points in multidimensional space so that the longest axis (the axis with the greatest variance) is the first PCA axis, the second longest axis perpendicular to the first is the second PCA axis, and so forth. Thus these first few PCA axes represent the greatest amount of variation in the data set and hopefully contain some patterns of significance.

“When a PCA is calculated, first the covariance or correlation matrix is calculated for the variables. The correlation matrix is used if standardization is desired; this

is useful if the variables have been measured on different scales or are of different orders of magnitude. Otherwise the covariance matrix should be used. An eigenanalysis is then performed on the matrix.

“There are several sets of results. First the eigenvalues are given. In PCA these equal the variance accounted for by each PCA axis. The eigenvalue for the first axis will be the largest, the second the second largest, and so on. The percentage of the total variance of each axis will also be calculated. Hopefully the first two or three axes will account for a large proportion of the variance, say 50-60% or more. In some cases the first axis might account for over 90-95% of the variance. In all but the most simple data sets this result should be looked at with skepticism. This may occur, for instance, when a few variables have very large values that are one or two orders of magnitude greater than the others. The analysis will be dominated by these few large variables. In these situations you may want to consider using a correlation matrix instead or transforming the data to logs or square roots.

“Also provided will be the eigenvectors for each PCA axis. Each eigenvector is composed of values called the component loadings for that axis. Each variable in the original data matrix has a component loading associated with it in the eigenvector. These loadings may be considered a measure of the relative importance of each variable in the extracted PCA axis. The sign of the value indicates which end of the axis the variable is associated with. If, for example, variables A, C, and F have high positive loadings on the first PCA axis and variable H has a high negative loading, this means that the largest proportion of the variance in the data can be accounted for by the trends in these four variables. The different signs indicate that variable H has high values in a certain set of cases whereas A, C, and F have high values in a completely different set of cases.

The third set of results is a matrix of component scores. Again, one set of scores is provided for each PCA axis and each score corresponds to one case. These are computed by simply multiplying the component loadings by the original data. The resulting scores may be plotted on a scatterplot so that the first two PCA axes, for example, may be plotted against each other and the individual points would indicate the cases. In the example above, those cases that have high values of variables A, C, and F would be plotted at the positive end of the first axis, whereas those with variable H would be at the negative end” (Kovach 1999).

However, Palmer (1998) notes at <http://www.okstate.edu/artsci/botany/ordinate/PCA.htm> one of the central problems with PCA is that, “PCA produces an artifact known as the Horseshoe Effect (similar to the Arch Effect), in which the second axis is curved and twisted relative to the first, and does not represent a true secondary gradient.”

Kovach (1999) similarly notes,

“CA is also susceptible to two faults that are common to many ordination methods. The first and most prominent is what is called the arch effect or alternatively the horseshoe effect. With this effect, the points are arranged in an arched pattern along the first two axes, rather than a linear pattern as would be expected....This arch is a result of the data reduction process and represents a mathematical relationship between the first two axes, which are supposed to be independent. The effect is particularly pronounced when a long environmental gradient has been sampled, so that cases from one end are mostly or completely different from those at the other.

The second fault, which is a result of the first, is the compression of data points at the ends of the axes. Pairs of cases that are equally dissimilar will appear closer together at the ends of the axes than in the middle, thus misrepresenting the distance between these pairs. Both of these faults can be corrected with detrended correspondence analysis (DCA).

DCA corrects the arch effect in the following manner: After the first two axes are extracted with the reciprocal averaging technique the first axis is divided into several segments. The scores on the second axis for each point are then adjusted so that the mean score of the points within each segment is the same as that in other segments. This is like cutting the scatterplot into a number of vertical strips and moving each up and down until the points are in a straight line. The scores are then adjusted along the first axis so that they are more evenly spaced.

This method can often give more interpretable results, but it can also introduce distortion or instability of its own. The method can be viewed as using a hammer to smooth out distortions in a sheet of metal. It may work but it may also remove some embossed patterns that were supposed to be there. Therefore it is always a good idea to try both regular and detrended correspondence analysis on a data set and compare the results.”

## Discussion and Recommendations

This study has estimated, at a survey level, the spatial distribution and magnitude of anthropogenic contamination in the Ten Mile River watershed sediments for inorganic chemicals (primarily metals), chlorinated pesticides and polychlorinated biphenyls, and volatile and semi-volatile organic compounds. All sites demonstrated heavy contamination of complex mixtures of these contaminants. Given the history of this river during and subsequent to the Industrial Revolution in New England, including jewelry, tannery, and electroplating works, such remnant contamination is not unexpected. Should any remediation of this river, such as dredging be proposed, further study would be warranted.

These results were then screened using a new tool recently developed at OEME, the Sediment Ecotoxicological Screening Benchmark (SESB) tables (Appendices D and E). These SESB tables screen inorganics (primarily metals), chlorinated pesticides and polychlorinated biphenyls and volatile and semi-volatile organic hydrocarbons (SVOCs) relative to ecotoxicological screening benchmark values derived from the published scientific and technical literature. These results are depicted in Figures 7-30 and Tables 6-29 and summarized in Appendix D and Tables 30-32. Contamination of potential ecotoxicological concern was observed at all sample locations.

An exploratory multivariate data analysis including clustering and ordination techniques was undertaken of the chemistry data sets. Graphical and numerical results are shown in Appendix B. These depict similarity and dissimilarity between sample sites based on observed contaminants. Clearly spatial contiguity and exposure history are related although not entirely predictive.

Biological tests of these sediment samples were undertaken in which two freshwater invertebrate species (chironomids and amphipods) were exposed under controlled laboratory conditions for a 10 day period. The amphipod test failed to meet test acceptability criteria with excessive mortality in the control animals. Thus these results could not be statistically analyzed and interpreted further. However, the chironomid test observed significant impairment of survival in three test site replicates: Dodgeville Pond Dam (DODG01), Rt. 15 Pond Dam (RESE01) and Wetherell Pond Dam (WETH01/02). No significant impairment in the growth endpoint was observed. However, one site, Hebronville Pond Dam (HEBR01), displayed significantly enhanced growth relative to the control. The implications of this are unclear. Moreover, the potential for adverse effects from these sediments could be underestimated since, for example, tests did not measure subchronic effects, such as reproduction and emergence. Longer term (45-60 day exposure) tests might identify sub-chronic effects.

The chemical and physical characterization of river bed sediments is of interest as sediment quality is often a good indicator of aquatic system "health". Persistent contaminants associated with past and present cultural and natural influences enter aquatic systems and may be adsorbed onto or absorbed into sediments. These contaminated sediments may pose an ecotoxicological and human health risk if their contaminants are able to enter the aquatic food chain, or if people or organisms are otherwise exposed to them.

The 2000-2001 Edition of the Massachusetts Natural Heritage Atlas (MANHESP 2000) identifies estimated habitats of rare wildlife and priority habitats of rare plant and animal species. The Attleboro 7 ½ x 7 ½ minute USGS quadrangle maps cover the area of this study. These quad maps identify estimated and priority habitat proximal to or overlaying the study sites and the Ten Mile watershed. These would be the ecological receptors of greatest concern and requiring the highest level of conservation concern and management in this landscape.

Data Quality Statements

Chemists who reviewed data: Mike Dowling, Scott Clifford

Method modifications: The volume of hydrochloric acid used in the digestion was doubled.

Limitations of data: Sb results are approximated due to the low MS recovery.

Comments: The Ag and Cd LFB recoveries are outside the  $\pm 20\%$  criteria; however, the LCS and MS/MSD recoveries are acceptable. The Tl LCS recovery is high; however, the LFB and MS/MSD recoveries are acceptable.

Instrument performance: Excellent

Matrix spike recovery problems: Sb

Unusual visual characteristics: None

### MEMORANDUM

**DATE:** April 28, 1998  
**SUBJECT:** TEN MILE RIVER  
**FROM:** William J. Andrade, Ph.D.  
Chemist, EIA  
**TO:** Greg Hellyer  
ECA

Project Number : 98177

### Analytical Procedure

New England Regional Laboratory Standard Operating Procedure (SOP)  
14.1

Equipment

Dohrmann DC-190 TOC Analyzer

The analytical support for this project was performed by the ESAT contractor, Paul Bedrosian.

Date samples received: March 26, 1998

Date samples analyzed: April 8-9, 1998

file name: 98177SO.TOC

---

Data Quality Statement

-Chemist who reviewed the data: William J. Andrade, Ph.D.  
-Method modification: none  
-Instrument performance:  
-Spike recovery problem: ok  
-Limitations to the data: none  
-Unusual visual characteristics:  
Chain of Custody abnormalities: none

Comments:

The percent recovery for one set of data for the low level (61.6 mg/kg) laboratory control sample ERA 29003 was slightly elevated. The recovery for the higher level (3750 mg/kg) laboratory control samples ERA was within the acceptance range.

Data Quality Statements

Chemists who reviewed data:	Mike Dowling, Scott Clifford, William Andrade, Dan Curran
Method modifications:	None
Limitations of data:	None
Comments:	The Cr values are not used in calculating the SEM/AVS ratio.
List of method contaminants:	None
Instrument performance:	Excellent
Matrix spike recovery problems:	None
Unusual visual characteristics:	None
Chain of custody abnormalities:	None

**Volatile and Semi-Volatile Organic Compounds  
(GC/MS Extractable Organic Analysis)**

DATE: April 24, 1998  
SUBJ: TEN MILE RIVER  
FROM: Dick Siscanaw, Chemistry Section  
THRU: Dr. William J. Andrade, Advanced Analytical Chemistry  
Specialist  
TO: Greg Hellyer

PROJECT NUMBER: 98177

ANALYTICAL PROCEDURE:

All samples were received and logged in by the laboratory according to the SOP for Sample Log-in (EIA-ADMLOGN1.SOP, 7/97).

EPA Region I Procedure for Polyaromatic Hydrocarbons in Sediment Samples PAHSELL1.SOP. The extracts were analyzed on the gas chromatograph/mass spectrometer using the selected ion monitoring.

The analytical support for this report was performed by ESAT contractors.

Date(s) Samples Received by the Laboratory: 03/26/98

Date Analysis Started: 03/27/98

File: J:\CHEMISTRY\REPORTS\BNA\98177SO.PAH

QUALITY CONTROL:

1. A laboratory blank was analyzed before the sample analysis.
2. Each sample was spiked with the following surrogate compounds, fluorobiphenyl and p-terphenyl,d14, at 2 ppb. The results for the surrogate recoveries are reported out for each sample.
3. One sample, 07697, was spiked with the following compounds at 2 ppb.

MS

MSD

**US ENVIRONMENTAL PROTECTION AGENCY  
REGION I LABORATORY  
GC/MS EXTRACTABLE ORGANIC ANALYSIS**

Compound	Rec. (%)	Rec. (%)	RPD %
Acenaphthene	92	81	12.7
Acenaphthylene	85	73	13.9
Fluorene	84	72	15.4
Naphthalene	96	85	12.2

SAMPLES ANALYZED: BLANK, 07697, 07697MS, 07697MSD, 07698, 07699,  
07700, 07701, 07702, 07703, 07704

Chemist who reviewed data: Dick Siscanaw

Holding times meet (Y/N): Yes

Extraction (Water - 7 days, Soils - 14 days)

Analytical (40 days after extraction)

Method modifications: None

Limitations of data: None

Laboratory blank problems: None

Instrument performance problems: None

Surrogate and spike recovery problems:

The sample 07697 had concentrations higher than the spiked level. The analyses requested was a low level method. Only 4 PAH'S could be reported out in which the matrix spike was higher than the sample's concentration.

Additional comments: None

SUBJ:            Gas Chromatography-Mass Spectrometry Analysis of  
Extractable Organics in Soils and Sediments - TEN  
MILE RIVER

FROM:            Dick Siscanaw, Chemistry Section

THRU:            Dr. William J. Andrade, Advanced Analytical Chemistry  
Specialist

TO:              Greg Hellyer

PROJECT NUMBER:    98177

ANALYTICAL PROCEDURE:

All samples were received and logged in by the laboratory according

**US ENVIRONMENTAL PROTECTION AGENCY  
REGION I LABORATORY  
GC/MS EXTRACTABLE ORGANIC ANALYSIS**

to the SOP for Sample Log-in (EIA-ADMLOGN1.SOP, 7/97).

Sample processing and analysis was done following the EPA Region 1 Standard Operating Procedures BNASOLL2.SOP and BNAENV11.MOD. The methods are based on the US EPA, Contract Laboratory Program, Statement of Work for Organic Analysis, Multi-Media, Multi-Concentration, Low Level Preparation for Screening and Analysis of Semivolatiles (BNA), OLM01.2, 1/91. The sample extracts were screened on a gas chromatograph prior to the gas chromatography-mass spectrometry analysis. All values are reported out on a dry weight basis.

The analytical support for this report was performed by ESAT contractors.

Date(s) Samples Received by the Laboratory: 03/26/98

Date Analysis Started: 04/02/98

cc:

File: J:\CHEMISTRY\REPORTS\BNA\98177SO.BNA

**QUALITY CONTROL:**

1. A laboratory blank was processed with the samples.
2. Each sample was spiked with 100 ug of base/neutral and 200 ug of acid surrogate compounds. The results for the surrogate recoveries are reported out for each sample.
3. One sample, 07700, was spiked with 100 ug of base/neutral and 200 ug of acid matrix spike compounds. The results for the analyses are reported on the following page.

GC/MS EXTRACTABLE ORGANIC ANALYSIS**

GC/FID Screening Conditions:

Gas: Hydrogen  
Capillary Column: DB-1, 30m, 0.32mm ID, 0.10 micron film thickness  
Injection Mode: Splitless  
Temperature Program: Isothermal for 3 min at 40°C, programmed at 15°C/min to 320°C for 3 min

GC-MS Conditions:

Gas: Helium  
Capillary Column: DB-5, 60m, 0.25mm ID, 0.25 micron film thickness  
Injection Mode: Splitless  
Temperature Program: Isothermal for 4 min at 40°C, programmed at 7°C/min to 300°C  
  
Injector, Transfer  
Temperatures: 300°C, 290°C  
Electron Energy: 70 V  
Mass Range: 35-550  
  
Scan Rate: 0.9 seconds

Chemist who reviewed data: Dick Siscanaw

Holding times met (Y/N): Yes

Extraction (Water - 7 days, Soils - 14 days)  
Analytical (40 days after extraction)

Method modifications:

Two 30 g extractions were done. The extracts were combined for one sample because of the high moisture content.

Limitations of data: None

### Chlorinated Pesticides and PCBs

DATE: May 15, 1998

SUBJ: Analysis of Chlorinated Pesticides and Polychlorinated Biphenyls (PCBs) in Soil Samples - TEN MILE RIVER

FROM: Peter Philbrook, Chemistry Section

THRU: Dr. William J. Andrade, Advanced Analytical Chemistry Specialist

TO: Greg Hellyer

PROJECT NUMBER: 98177

ANALYTICAL PROCEDURE:

All samples were received and logged in by the laboratory according to the SOP for Sample Log-In (EIA-ADMLOGN1.SOP, 7/97).

Sample preparation was done by the EPA Multi-Media Consensus Organics Protocol - Revised 8/87. A macro-Florisil column elution and GPC was used for the sample cleanup. The analysis was carried out using high resolution capillary column chromatography. The 30-m dual capillary system consists of J&W DB-1701 and J&W DB-5, both with a 0.25mm ID and a 0.25 micron film thickness. Results are reported out in dry weight.

Date Samples Received by the Laboratory: 03/26/98

Date Analysis Started: 03/31/98

File: J:\CHEMISTRY\REPORTS\PCB-PEST\98177SO.PES  
QUALITY CONTROL:

1. One method blank was included in the analysis.
2. Each sample was spiked with the surrogate compounds, tetrachloroethylene and decachlorobiphenyl, at approximately 17 ug/Kg. The results for the surrogate recoveries are reported out with each sample.
3. One sample, 07699, was spiked as a matrix spike and a matrix spike duplicate at the following concentrations: Aldrin, gamma-BHC (Lindane), and Heptachlor at ~3 ug/Kg. DDT, Dieldrin, and Endrin at ~13 ug/Kg. The recoveries are listed below.

Pesticide	Matrix Recovery (%)	Matrix Dup Recovery (%)	QC Limits (%)	RPD (%)
gamma-BHC	56	44	46-127	24
Heptachlor	64	65	35-130	2
Aldrin	123	103	34-132	18
Dieldrin	80	60	31-134	29
Endrin	99	125	42-139	23
pp-DDT	148	100	23-134	39

Other targeted Compounds Quantitated:

Compound	MS Conc. ug/Kg	MSD Conc. ug/Kg	RPD %
alpha-Chlordane	9.1	10	9
endrin ketone	12	10	18

**US ENVIRONMENTAL PROTECTION AGENCY  
REGION I LABORATORY  
CHLORINATED PESTICIDES AND POLYCHLORINATED BIPHENYLS**

DDD	16	16	0
DDE	18	15	18

4. One sample, 07698, was analyzed in duplicate. The results are listed below.

Compound	07698 ug/Kg	07698 Dup. ug/Kg	RPD %
alpha-BHC	15	14	7
alpha Chlordane	34	33	3
gamma-Chlordane	28	26	7
DDD	84	78	7
DDE	65	60	8
DDT	65	57	13
Aroclor 1254	140 P*	290	70 *
Aroclor 1260	90	130	36

\* = The reported value (140 ug/Kg) for sample 07698 was qualified as a 'P'. The value determined on the primary GC column exceeded 35% difference compared to that of the confirmatory column. The values had less than a 100% difference so the lower value was reported. The value for 07698 DUP (290 ug/Kg) had no such limitations and the average of the 2 columns was used. This would explain the high (70%) relative percent differences when comparing the two values.

SAMPLES ANALYZED: BLANK, 07697, 07698, 07698 DUP, 07699, 07699 MS, 07699 MSD, 07700, 07701, 07702, 07703, 07704

Chemist who reviewed data: Paul Carroll

Holding times meet (Y/N): Yes

Extraction (Water - 7 days, Soils - 14 days)

Analytical (40 days after extraction)

Method modifications:

Samples were air dried prior to extraction.

Limitations of data: None

Laboratory blank problems: None

Instrument performance problems: None

Surrogate and spike recovery problems:

**US ENVIRONMENTAL PROTECTION AGENCY  
REGION I LABORATORY  
CHLORINATED PESTICIDES AND POLYCHLORINATED BIPHENYLS**

Decachlorobiphenyl (DCB) surrogate recoveries for samples 07702, 07703 were high due to the compound DCB in the samples. Aroclor 1268 was found in each of these samples. Aroclor 1268 contains the compound decachlorobiphenyl.

Additional comments: Clean-ups for sample extracts included a macroflorisil column elution followed by a Gel Permeation Chromatography clean-up. The extracts were split one aliquot was used for the pesticides analysis, and one portion was further cleaned with a sulfuric acid clean-up for the PCB analysis.

ANALYTICAL RESULTS CONT.

Sample Recovery for Surrogate Compound:	Observed Recoveries (%)	QC Range
Decachlorobiphenyl	108	60-150
2,4,5,6-Tetrachloro-m-xylene	97	60-150

Notes:

RL = Reporting limit  
(6E+00 = 6, 1E+01 = 10, 4E-01 = 0.4)

ND = None detected

~ = Approximate

< = Less than

> = Greater than

NA = Not available due to dilution or interference

E = Estimated value exceeds the calibration range

L = Estimated value is below the calibration range

B = Analyte is associated with the lab blank or trip blank contamination. Values are qualified when the observed concentration of the contaminant in the sample extract is less than ten times the concentration in the blank.

P = The confirmation value exceeded 35% difference and is less than 100 %. The lower value is reported.

D = Detected but too low to quantitate.

C = The identification has been confirmed by GC/MS.

## Appendix B: Multivariate Graphical and Numerical Chemistry Data Analysis

### Graphical Analysis -- Inorganic Chemicals (Metals)

**Graphical Analysis -- Inorganic Chemicals (Metals)**

# Graphical Analysis -- Inorganic Chemicals (Metals)

## 10 Mile River Metals Correspondence Analysis

## 10 Mile River Metals Correspondence Analysis

## Graphical Analysis -- Inorganic Chemicals (Metals)

### 10 Mile River Metals Principal Coordinates (Average Distance)

### 10 Mile River Metals Principal Coordinates (Average Distance)

# Graphical Analysis -- Inorganic Chemicals (Metals)

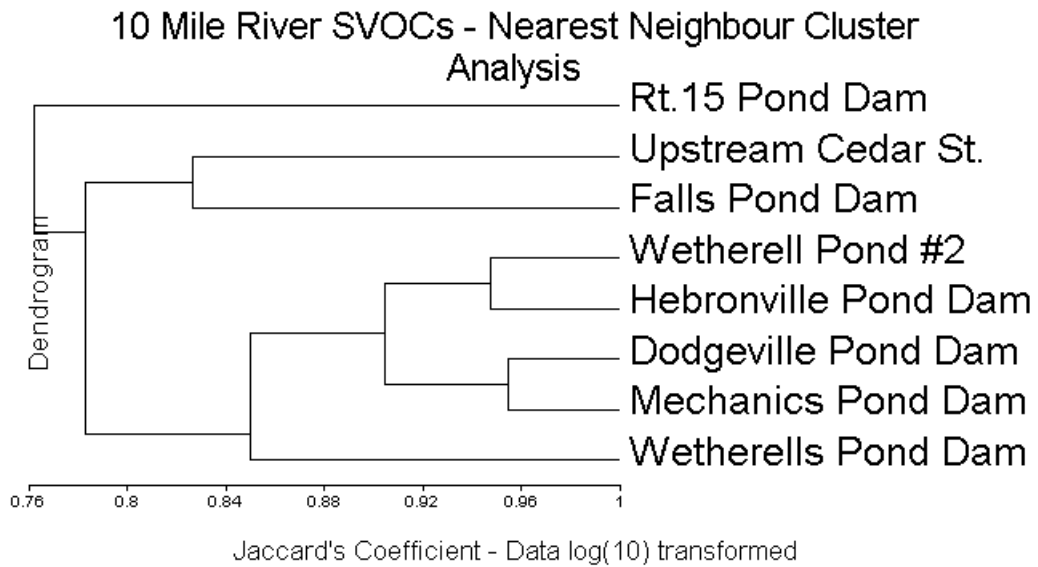

### 10 Mile River Metals Principal Components Analysis

### **Graphical Analysis -- Inorganic Chemicals (Metals)**

The Principal Components and Principal Coordinates metals analyses yielded identical ordinations with the only difference being the particular values along the axes case scores. The Falls Pond and Upstream Cedar St. sites formed a discrete highly associated cluster. The Wetherell Pond sites were even more strongly associated under the metals analysis. The Route 15 Pond Dam site was strongly associated in all three ordinations with the Dodgeville Pond Dam, Hebronville Pond Dam, and Mechanics Pond Dam sites.

## Graphical Analysis -- Volatile and Semi-Volatile Organic Compounds Data

## Graphical Analysis -- Volatile and Semi-Volatile Organic Compounds

# Graphical Analysis -- Volatile and Semi-Volatile Organic Compounds

### 10 Mile River SVOCs Correspondence Analysis

# Graphical Analysis -- Volatile and Semi-Volatile Organic Compounds

## 10 Mile River SVOCs - Detrended Correspondence Analysis

# Graphical Analysis -- Volatile and Semi-Volatile Organic Compounds

## 10 Mile River SVOCs Principal Coordinates Analysis (Average Distance)

## 10 Mile River SVOCs Principal Coordinates (Average Distance)

# Graphical Analysis -- Volatile and Semi-Volatile Organic Compounds

## 10 Mile River SVOCs Principal Components

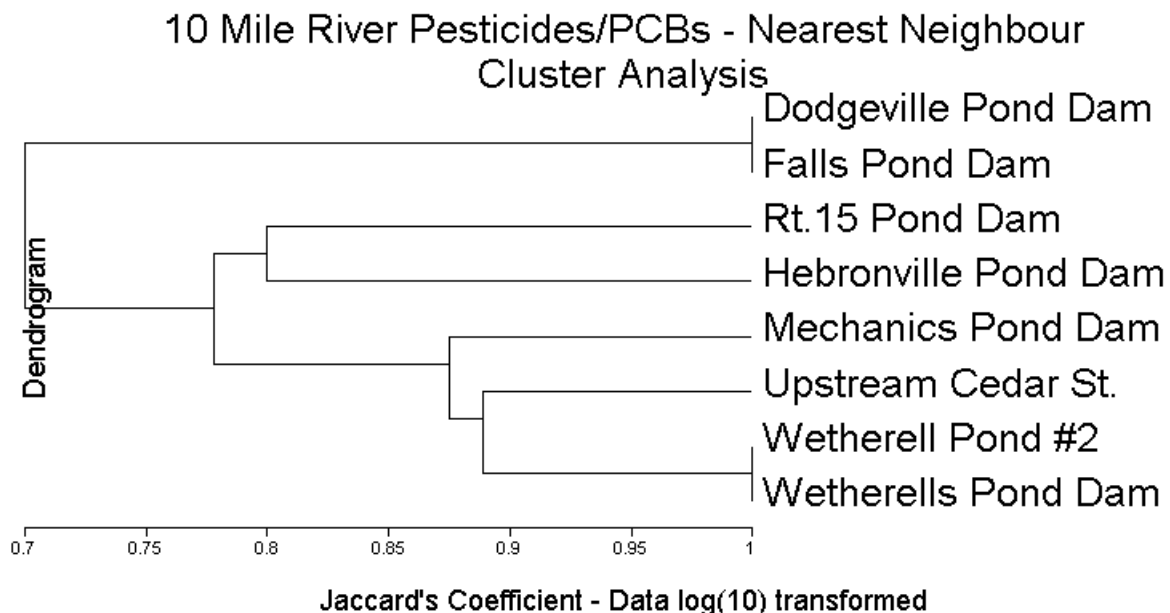

## 10 Mile River SVOCs Principal Components Analysis

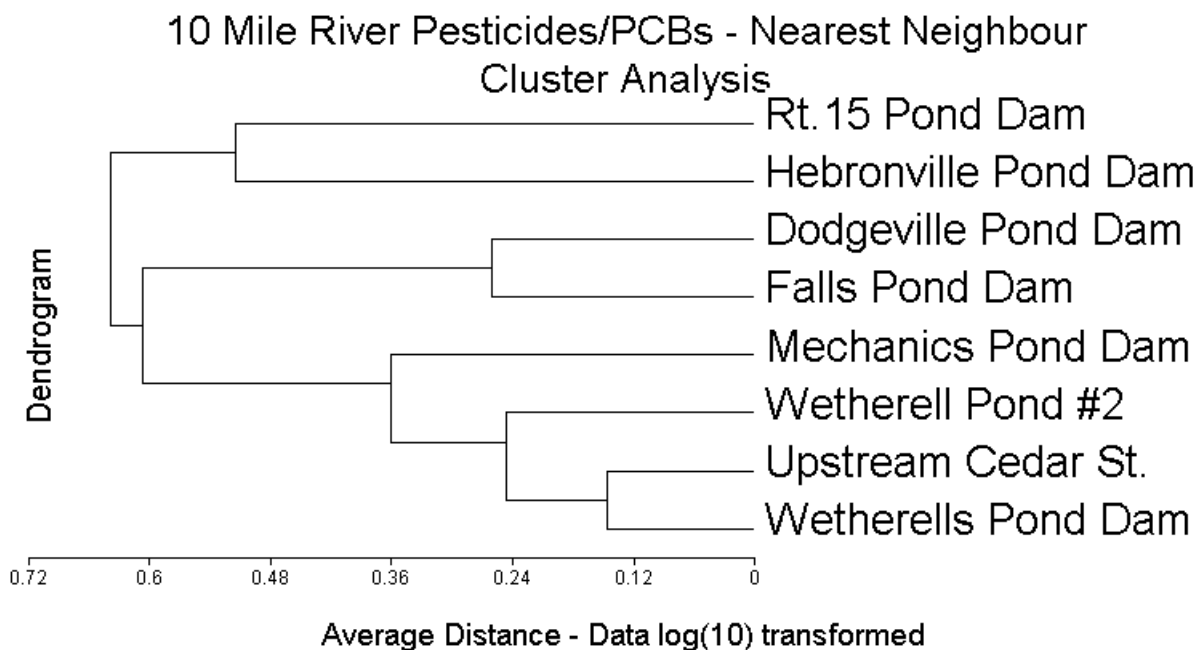

## **Graphical Analysis -- Volatile and Semi-Volatile Organic Compounds**

All of the ordinations and cluster analyses for SVOCs reveal an aggregation of Mechanic Pond Dam and Dodgeville Pond Dam sites. Hebronville Pond Dam is also strongly associated with the two Wetherell Pond sites. However, in the Correspondence Analysis the Wetherells Pond Dam site is quite divergent from the other sites, including Wetherell Pond #2. Upstream Cedar Street and Fall Pond Dam also form a distinct association. The Route 15 Pond Dam site appears somewhat anomalous being the most dissimilar from other sites.

**Graphical Analysis -- Chlorinated Pesticides and PCBs**

## Graphical Analysis -- Chlorinated Pesticides and PCBs

## Graphical Analysis -- Chlorinated Pesticides and PCBs

### 10 Mile River Pesticide/PCB Correspondence Analysis

### 10 Mile River Pesticide/PCBs Correspondence Analysis

# Graphical Analysis -- Chlorinated Pesticides and PCBs

## 10 Mile River Pesticides/PCBs Principal Components Analysis

## 10 Mile River Pesticides/PCBs Principal Components Analysis

# Graphical Analysis -- Chlorinated Pesticides and PCBs

## 10 Mile River Pesticides/PCBs Principal Coordinates (Average Distance)

## 10 Mile River Pesticides/PCBs Principal Coordinates (Average Distance)

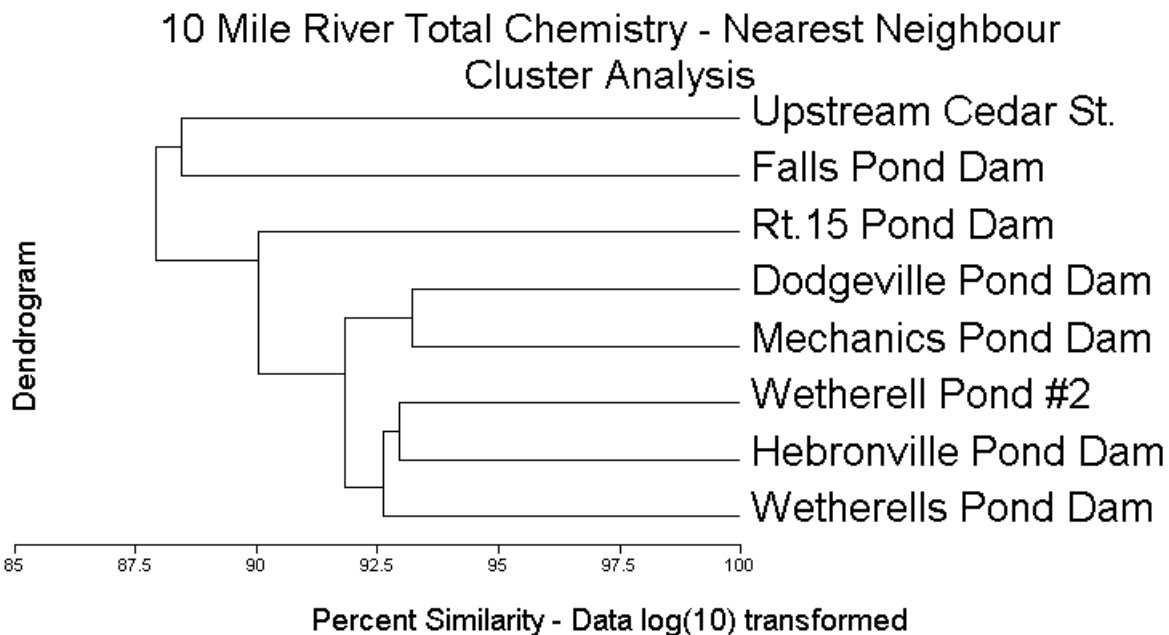

## **Graphical Analysis -- Chlorinated Pesticides and PCBs**

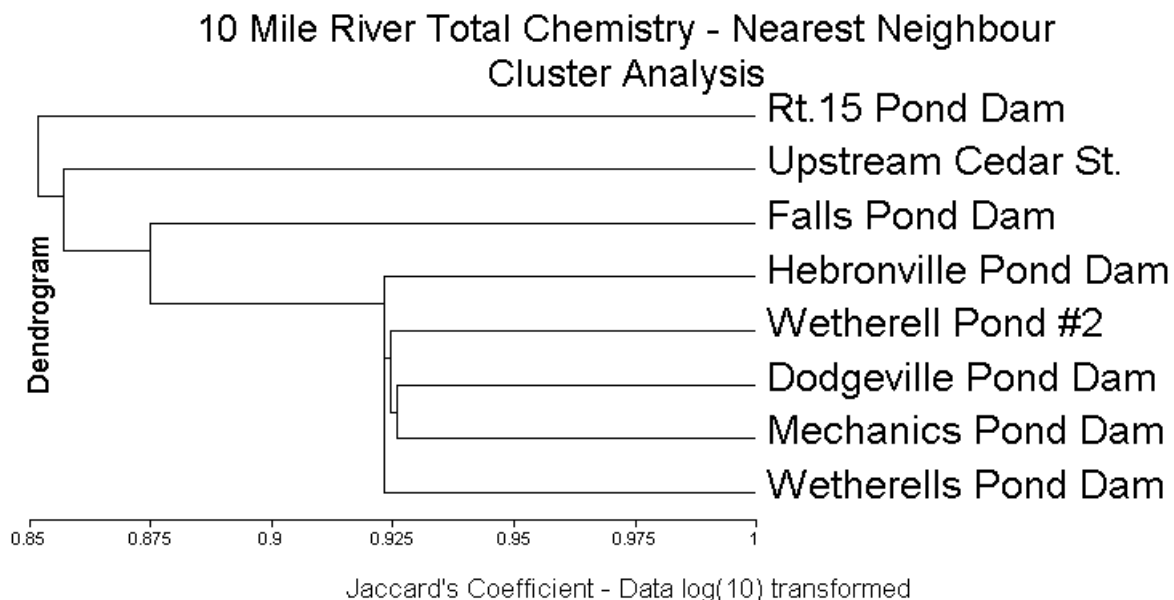

Results of the ordinations for Pesticides/PCBs are somewhat more anomalous than those for metals and SVOCs. All three ordinations yielded highly similar results for Pesticides/PCBs. The Dodgeville Pond Dam and Falls Pond Dam sites are highly associated in all three ordinations for these contaminants. The Route 15 Pond Dam site is somewhat of an outlier and the Hebronville Pond Dam is also to a lesser degree. A strong cluster is formed by Mechanics Pond Dam, Upstream Cedar St., and the two Wetherell Pond Dam sites.

**Graphical Analysis Total Chemistry**

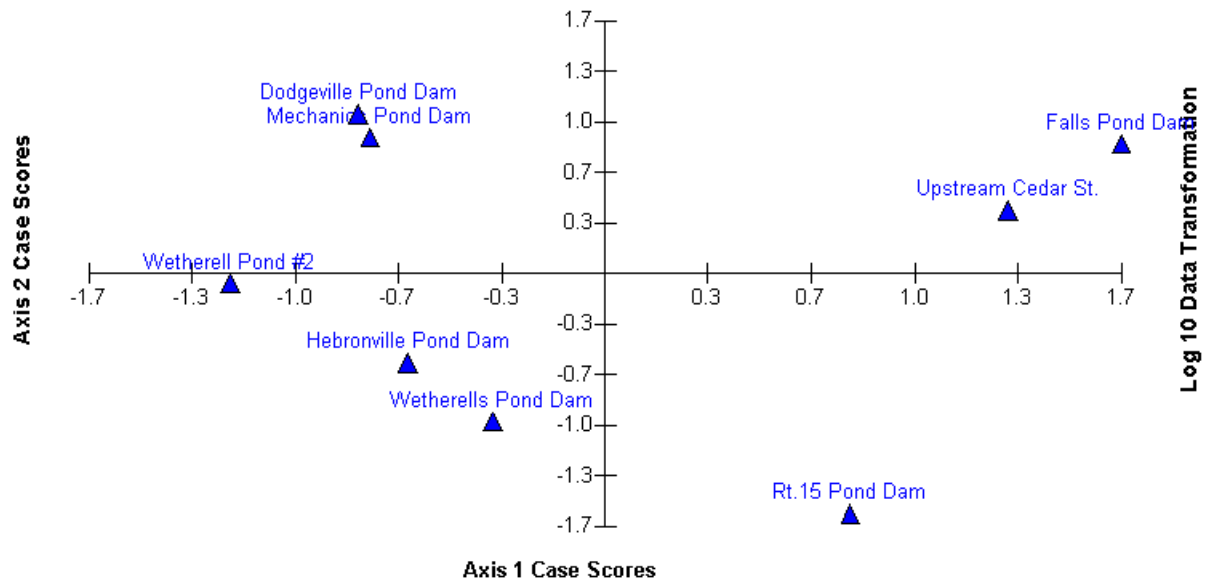

**Graphical Analysis Total Chemistry**

# Graphical Analysis Total Chemistry

## 10 Mile River Total Chemistry - Principal Components Analysis

## 10 Mile River Total Chemistry Principal Components Analysis

**Graphical Analysis Total Chemistry**

**10 Mile River Total Chemistry Correspondence Analysis**

**10 Mile River Total Chemistry Correspondence Analysis**

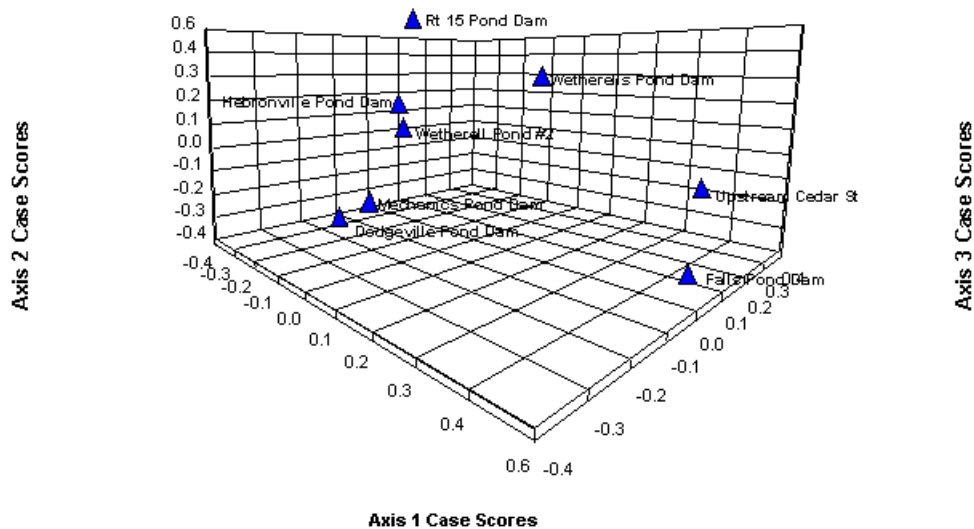

## Graphical Analysis Total Chemistry

### 10 Mile River Total Chemistry Principal Coordinates Analysis (Average Distance)

Note: Results of this analysis are identical, except for scaling, when calculated using Euclidean Distance which methodologically equals Principal Components Analysis (Palmer, 1998).

### 10 Mile River Total Chemistry Principal Coordinates (Average Distance)

## **Graphical Analysis Total Chemistry**

The ordination results for total chemistry are, of course, highly similar to those observed for each separate class of contaminant. The Falls Pond Dam and Upstream Cedar St. sites are highly associated in all three ordinations. The Route 15 Pond Dam site is an outlier without any close affinity to any other sites. The Dodgeville Pond Dam and Mechnics Pond Dam sites are more highly associated than the two Wetherell Pond Dam sites. The two Wetherell Pond Dam sites are highly associated with the Hebronville Pond Dam site.

## Chironomid (*C. tentans*) Growth and Survival Data Statistical Analysis

### Ten Mile Sediment *C. tentans* Survival Data

File: 10ctsurv            Transform: NO TRANSFORMATION

Chi-square test for normality: actual and expected frequencies

---

INTERVAL	<-1.5	-1.5 to <-0.5	-0.5 to 0.5	>0.5 to 1.5	>1.5
EXPECTED	4.288	15.488	24.448	15.488	4.288
OBSERVED	4	16	17	26	1

---

Calculated Chi-Square goodness of fit test statistic = 11.9612

Table Chi-Square value (alpha = 0.01) = 13.277

Data PASS normality test. Continue analysis.

Hartley test for homogeneity of variance

---

Calculated H statistic (max Var/min Var) = 16.37

Closest, conservative, Table H statistic = 22.0 (alpha = 0.01)

Used for Table H ==>    R (# groups) = 8,    df (# reps-1) = 7

Actual values        ==>    R (# groups) = 8,    df (# avg reps-1) = 7.00

---

Data PASS homogeneity test. Continue analysis.

NOTE: This test requires equal replicate sizes. If they are unequal but do not differ greatly, the Hartley test may still be used as an approximate test (average df are used).

## Chironomid (*C. tentans*) Growth and Survival Data Statistical Analysis

Bartlett's test for homogeneity of variance

#### Abstract

Sediment Ecotoxicological Screening Benchmark (ESB) templates (Lotus and Excel spreadsheets) were developed using available technical references for (1) inorganic chemicals (primarily metals) (2) volatile and semi-volatile organic compounds and (3) chlorinated pesticides and polychlorinated biphenyls (PCBs). Formulas for Total Organic Carbon (TOC) adjustment are provided for the latter two tables. Graphing templates depict exceedance of ecotoxicological thresholds.

Derivation, strengths, and limitations of various sediment benchmarks are briefly discussed. Some benchmarks were derived through analysis of data from a combination of spiked sediment bioassays, chemical analysis, and bulk sediment toxicity testing. Other benchmarks were derived using a combination of sediment chemistry and benthic species presence/absence data. Others utilize models that predict the exposure of benthic organisms based on sediment chemistry data. These equilibrium partitioning models predict the interstitial (pore) water concentration of a sediment based on bulk sediment contaminant concentration and sediment TOC.

Application of ESBs to river sediment data is illustrated.

Ten Mile Watershed Ecotoxicity Report

## Introduction

Determining the ecotoxicological implications of sediment contamination continues to remain a central concern in ecological risk assessment. In its comprehensive report to Congress EPA [1, adapted from 2] concluded that sediment ecotoxicology was important for the following reasons:

- “Various toxic contaminants found only in barely detectable amounts in the water column can accumulate in sediments to much higher levels.
- Sediments serve as both a reservoir for contaminants and a source of contaminants to the water column and organisms.
- Sediments integrate contaminant concentrations over time, whereas water column contaminant concentrations are much more variable and dynamic.
- Sediment contaminants (in addition to water column contaminants) affect bottom-dwelling organisms and other sediment-associated organisms, as well as both the organisms that feed on them and humans.
- Sediments are an integral part of the aquatic environment that provide habitat, feeding, spawning, and rearing areas for many aquatic organisms.”

Numerous criteria and quantitative thresholds have been derived for inorganic chemicals (primarily metals), volatile and semi-volatile organic compounds, and chlorinated pesticides and polychlorinated biphenyls (PCBs) [3, 4, 5, 6, 7, 8, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28]. However, no comprehensive compilation or method has hitherto been available to apply these ecotoxicological screening benchmarks (ESBs) in assessing sediment contaminants. This paper describes a method of screening sediment for ecotoxicological risk using Lotus 1-2-3<sup>®</sup> and Excel<sup>®</sup> spreadsheet templates based on available technical references for (1) inorganic chemicals (primarily metals) (2) volatile and semi-volatile organic compounds and (3) chlorinated pesticides and polychlorinated biphenyls (PCBs). Formulas for Total Organic Carbon (TOC) adjustment are provided for the latter two tables. Graphing templates depict exceedance of ecotoxicological thresholds. These ESBs are available with a written review document, which is expanded in this article, from the Sediments Research Web at:

[www.sediments.org](http://www.sediments.org) Links to Resources Downloads.

A wide range of methods were used to develop these ESBs. Some benchmarks were derived through analysis of data from a combination of spiked sediment bioassays, chemical analysis, and bulk sediment toxicity testing. Other benchmarks were derived using a combination of sediment

G. Hellyer and G. Balog, *Derivation, Application, Strengths and Limitations of Sediment Ecotoxicological Screening Benchmarks (ESBs)*

chemistry and benthic species presence/absence data. In general, these “associative” measures involve a review of biological effects associated with various concentrations of a chemical or group of chemicals. Their value is influenced by the size of the available data set.

Other benchmarks were derived using models that predict the exposure of benthic organisms based on sediment chemistry. Equilibrium partitioning models predict the interstitial (pore) water concentration of a sediment based on bulk sediment contaminant concentration and the total organic carbon (TOC) of the sediment. The two organic compound tables allow adjustment of several ecotoxicological thresholds based on site-specific TOC.

### Ecotoxicological Screening Benchmarks

Discussion of the derivation, strengths and limitations of the ESBs used in the screening templates follows. In conclusion, an application of this method to a historically contaminated watershed in south-eastern Massachusetts is provided.

### Interstitial Water Concentrations: Sediment/Water Equilibrium Partitioning (EqP)

The equilibrium partitioning (EqP) approach is used to calculate a sediment quality benchmark (SQB) using site-specific organic carbon, chemical-specific partitioning data, and water quality benchmarks [23]. The principal assumptions used in this model are as follows:

- Organic chemicals in sediment tend to be partitioned between interstitial water and sediment particles. This partitioning is assumed to be in a state of equilibrium determined primarily by the organic carbon content of the sediment and the partitioning behavior of each chemical.
- Sediment-dwelling organisms will be exposed to an organic chemical in sediment primarily through exposure to the fraction of the chemical in interstitial water, as opposed to the fraction bound to sediment particles; therefore the concentration of organic chemicals in interstitial water should correlate with biological effects.
- Sediment-dwelling organisms have a range of sensitivities to organic chemicals that is similar to the range of sensitivities exhibited by the aquatic organisms used to develop water quality benchmarks.

It follows from these assumptions that a water quality benchmark can be used to predict the concentration in sediment associated with biological effects, provided the organic carbon content of the sediment and the partitioning behavior of each chemical is known. It must be noted that this methodology applies primarily to non-polar organic compounds. The partitioning behavior of the chemical with respect to organic carbon ( $K_{oc}$ ) can be predicted from the octanol-water partition coefficient of the chemical ( $K_{ow}$ ) using the formula [29]:

G. Hellyer and G. Balog, *Derivation, Application, Strengths and Limitations of Sediment Ecotoxicological Screening Benchmarks (ESBs)*

$$\text{Log}_{10}(K_{oc}) = (0.00028 + 0.983 \log_{10}(K_{ow})) \quad (1)$$

The sediment benchmark can be calculated using the following formula:

$$\text{SQB} = \text{WQB} \times f_{oc} \times K_{oc} \quad (2)$$

Where:

SQB = Sediment Quality Benchmark ( $\mu\text{g}/\text{kg}$ )

WQB = Water Quality Benchmark ( $\mu\text{g}/\text{L}$ )

$f_{oc}$  = the fraction organic carbon of the sediment (unitless)

$K_{oc}$  = the partitioning coefficient of the chemical in sediment (L/Kg)

$K_{ow}$  = octanol-water partition coefficient

Any water quality benchmark, such as a Federal Ambient Water Quality Criterion (AWQC), or a Tier II Secondary Chronic Value (SCV), can be used in this model to calculate a sediment benchmark for non-polar organic compounds.

The bulk sediment concentrations measured at a site can be compared directly to the Sediment Quality Benchmarks (SQBs) [22]. However, these benchmarks should be adjusted by multiplying the SQB by the site-specific percent TOC. The EqP methodology and subsequent benchmarks are appropriate for sediments with 0.2% to 10% TOC. The ESB templates standardize TOC of sediment samples outside these limits to these values.

The EqP approach has the following strengths:

- Benchmarks can be developed for any non-polar organic compound if a WQB value and the  $K_{ow}$  of the chemical are available.
- EqP-derived benchmarks are site-specific if they are derived using a site-specific TOC value.

The EqP approach has the following limitations:

- The theory that chemicals exist at equilibrium in sediment is not universally accepted.
- Factors other than TOC that may influence the availability of chemicals to benthic organisms are not accounted for.
- EqP-derived benchmarks may not be protective with regard to biomagnification.

EqP has been widely used in the development of sediment benchmarks [9, 16, 22, 23, 25]. The

G. Hellyer and G. Balog, *Derivation, Application, Strengths and Limitations of Sediment Ecotoxicological Screening Benchmarks (ESBs)*

volatile and semi-volatile organic compound template lists several benchmarks developed using EqP-based approaches. These include benchmarks developed for the Oak Ridge National Laboratory (ORNL) [9, 16, 31], and EPA Sediment Quality Advisory Levels (SQALs) and Sediment Quality Criteria (SQC) [22, 23, 25]. A template for adjusting these values for site-specific TOC, within the 0.2% and 10% limits noted above, is provided. Similar TOC adjustment is provided for the SQAL/SQC and SEL sediment benchmarks in the chlorinated pesticides and PCBs template.

## Field Survey Methods

### Screening Level Concentration (SLC)

The screening level concentration (SLC) was designed to estimate the highest concentration of a particular contaminant in sediment that can be tolerated by approximately 95% of benthic infauna, as measured by species abundance [14].

The SLC is derived from synoptic data on sediment chemical concentrations and benthic invertebrate distributions [14]. First, the species screening level concentration (SSLC) is calculated by plotting the frequency distribution of the contaminant concentrations over all sites (at least 10) where the species is present. The 90<sup>th</sup> percentile of this distribution is taken as the SSLC for that species. Next a large number of SSLCs are plotted as a frequency distribution to determine the contaminant concentration above which 95% of the SSLCs occur. The final concentration is the SLC.

The SLC approach has the following strengths:

- The approach can be used with any chemical contaminant.
- SLCs can be developed using existing databases and methodologies.
- The method does not require assumptions concerning mechanisms of interaction between organisms and contaminants.

The SLC approach has the following limitations:

- A large amount of field data is required.
- A precise level of infaunal taxonomic identification is required.
- Calculation of SLCs is affected by the range and distribution of contaminant concentrations and species.
- Selection criteria for species used in this approach have not been established.

G. Hellyer and G. Balog, *Derivation, Application, Strengths and Limitations of Sediment Ecotoxicological Screening Benchmarks (ESBs)*

- No mechanism has been established to separate single contaminant effects from multiple contaminant effects.

Various benchmarks developed using the SLC approach are discussed in the following sections.

#### Specific SLC-Derived Benchmarks

##### Provincial Sediment Quality Guidelines (PSQGs)

The Ontario Ministry of the Environment (OMOE) has prepared Provincial Sediment Quality Guidelines (PSQGs) [8] using the SLC approach [14]. These values are based on sediments and benthic species from a wide range of geographical areas within the province.

The PSQGs are numerical sediment guidelines using a tiered approach, that were developed for the protection of sediment dwelling organisms. These guidelines also protect against biomagnification of contaminants through the food chain. The PSQGs define three levels of ecotoxicological effects and are based on chronic, long term effects of contaminants on benthic organisms. The three levels are as follows:

- No Effect Level (NEL) is the concentration at which no toxic effects have been observed on aquatic organisms, or at which biomagnification is not expected. Sediments at this level are considered to be clean.
- Lowest Effect Level (LEL) is a level of contamination which can be tolerated by a majority of benthic organisms. Sediments at this level are considered clean to marginally contaminated.
- Severe Effect Level (SEL) is a level at which pronounced disturbance of a sediment-dwelling community is expected; the sediment concentration would be detrimental to a majority of benthic organisms. Sediments at this level would be considered heavily contaminated.

The PSQGs are often referred to as the Ontario Ministry of the Environment (OMOE) sediment guidelines [8]. The following is a brief description of how the guidelines were developed.

The Low Effect Level (LEL) is derived using field-based data on the co-occurrence of sediment concentrations and benthic organisms. Calculation of the SLC is a two step process, and is calculated separately for each parameter. The procedure is based on the Screening Level Concentration (SLC) method [14]:

- Individual SLCs are calculated for each of the benthic species. Sediment concentrations at all locations where the species was present are plotted in order of increasing concentration. The 90<sup>th</sup> percentile of this concentration distribution is determined. The 90<sup>th</sup> percentile was

G. Hellyer and G. Balog, *Derivation, Application, Strengths and Limitations of Sediment Ecotoxicological Screening Benchmarks (ESBs)*

chosen to provide a conservative estimate of the tolerance range for that species.

- The 90<sup>th</sup> percentiles for all of the species present are plotted in order of increasing concentration. From this plot, the 5<sup>th</sup> percentile is calculated; this level becomes the contaminant-specific LEL guideline.

The Severe Effect Level (SEL) is identical to the calculation of the LEL, except that the 95<sup>th</sup> percentile of the SLC (the level below which 95% of all SSLCs fall) is calculated in the second step of the SLC calculation; this level becomes the SEL guideline.

The strengths of using PSQGs include:

- The SEL values for organic chemicals can be normalized to site-specific TOC.
- The approach is based on chronic population-level effects on indigenous biota.

The limitations of using PSQGs include:

- Species “absence” endpoint used to derive the OMOE values is considered insensitive [5, 13]. Therefore, the SLC values may not be adequately protective.
- No direct cause-and effect relationship is established between a single contaminant and benthic organism survival.
- Values were derived to be applicable to sediment types throughout the Province of Ontario. Thus, differences between Ontario and other sediments and biota introduce a level of uncertainty.

The metals template lists the LEL and SEL values for inorganic chemicals (metals). The volatile and semi-volatile organic compound template provides LEL and SEL values. The SEL values are adjusted for site-specific TOC. LELs are not adjusted for TOC. The same sediment benchmarks and TOC adjustments are contained in the chlorinated pesticides/PCBs template.

#### Interim Criteria for the Evaluation of Sediment of the St. Lawrence River

These benchmarks were developed by the St. Lawrence Center of Environment Canada and the Québec Ministry of the Environment for the purpose of agency sediment management [19]. Periodic updates are expected as a result of future sampling efforts and further developments in ecotoxicology. Values are derived from the OMOE data base [8]. However, a higher percentile is used for the minimal (lowest) effect level, and a lower percentile for the toxic (severe) effect level. The result is that these benchmarks are less restrictive at the minimal level, and more restrictive at the toxic level. The following levels are assumed to correlate with acute and chronic, long-term

G. Hellyer and G. Balog, *Derivation, Application, Strengths and Limitations of Sediment Ecotoxicological Screening Benchmarks (ESBs)*

effects on benthic organisms:

- Minimal Effect Level (MEL) is the concentration of a substance at which some effects are noticeable, but are tolerated by most organisms. Most of the MELs are derived by 15<sup>th</sup> percentile screening level concentrations (SLCs).
- Toxic Effect Level (TOEL) is the concentration of a substance that will cause adverse effects in most living organisms. The TOELs are derived by 90<sup>th</sup> percentile SLC.

The strengths of this approach are similar to those for the OMOE sediment quality guidelines [8]. The MEL and TOEL values are not adjusted for TOC, which is a disadvantage of these benchmarks. These benchmarks were developed for inorganic chemicals (metals), volatile and semi-volatile organic compounds and chlorinated pesticides/PCBs.

#### Apparent Effects Threshold (AET)

The Apparent Effects Threshold (AET), developed by the Puget Sound Estuary Program [3], uses data from matched sediment chemistry and biological effects measures (i.e., benthic community survey, sediment toxicity tests). The narrative definition of an AET is the sediment concentration of a selected chemical above which statistically significant biological effects always occur. Barrick et al. [3] prepared specific AET values for several different species which are cited in EPA [1]. Chemical specific AET values were derived for amphipods, oysters, and benthic organisms, in order to represent a range of potentially sensitive receptors. The Apparent Effects Threshold-Low (AET-L) is defined as the lowest AET among applicable biological indicators. The Apparent Effects Threshold-High (AET-H) value is defined as the highest AET among applicable biological indicators. These values have been normalized to dry weight. No adjustment is made for site-specific TOC when AETs are used.

The strengths of AET approach are as follows:

- There are no constraints on the type of contaminant or biological effects that can be used.
- Contaminants most likely associated with observed biological effects are identified on a site-specific basis.
- Values are based on non-contradictory evidence of biological impacts [31].

The limitations of the AET approach include:

- The correlation between chemical concentrations and the biological effects measured in the field may vary from site to site, complicating and confounding widespread applicability of the AETs.

G. Hellyer and G. Balog, *Derivation, Application, Strengths and Limitations of Sediment Ecotoxicological Screening Benchmarks (ESBs)*

- AET benchmarks may be under protective; biological effects may be observed at chemical concentrations well below AET values.
- AET development requires, at a minimum, a large chemical database and one biological indicator.
- Combined contaminant effects cannot be separated from single contaminant effects.

The AET values were developed for inorganic (metals) and organic chemicals (volatile and semi-volatile organic compounds, pesticides/PCBs), however, no adjustment is made for site-specific TOC.

#### Washington State Sediment Quality Standards

The Washington State Department of Ecology has developed various regulatory standards for designating sediments that have acute or chronic adverse effects on aquatic organisms, or pose a significant risk to human health [4]. The sediment quality standards are based on the AET approach, using amphipod (*Rhepoxynius abronius*) mortality, bivalve (*Crassostrea gigas*) larval abnormality, and Microtox<sup>®</sup> (*Photobacterium phosphoreum*) bacterial luminescence bioassay endpoints, as well as abundance of major taxa of indigenous benthic infauna. The AET values were developed for Puget Sound.

The AET values adopted by Washington State are defined by Ginn and Pastorok [6] as

“...the concentration of a single chemical (or chemical class) in sediments above which a particular biological effect has always been observed (and thus is predicted to be observed in other areas with similar concentrations of that chemical.”

The strengths of the Washington State Sediment Quality Standards are as follows:

- The list of standards includes several polar (ionizable) organic compounds for which benchmark values are rare.
- The standards were developed using a range of potentially sensitive indicator species.
- Adjustment of the standards for site-specific TOC is possible for non-polar organic compounds.

The Washington State Sediment Quality Standards have the following limitations:

- The standards were developed on a site-specific basis for Puget Sound, therefore they may

G. Hellyer and G. Balog, *Derivation, Application, Strengths and Limitations of Sediment Ecotoxicological Screening Benchmarks (ESBs)*

not adequately predict chemical-associated effects in other areas.

- Application of the standards to freshwater may be unreliable because the standards were developed using marine species.

Only the Washington State Sediment Quality Standards for seven ionizable organic compounds are listed in the volatile and semi-volatile organic compound ESB template. No TOC adjustment is provided or appropriate for these compounds.

### Integrative Methods

The following sections briefly describe several approaches that integrate laboratory and field-measured biological effects with chemical contaminant concentrations. These approaches are similar in the types of data needed to produce benchmarks, but differ in the exact calculations of the benchmarks.

#### National Oceanic and Atmospheric Administration (NOAA)

The National Oceanic and Atmospheric Administration (NOAA) annually collects and chemically analyzes sediment samples from sites located in coastal marine and estuarine environments throughout the United States [12]. These data were used to evaluate three basic approaches (i.e., EqP, spiked-sediment toxicity, synoptically collected biological and chemical data in field surveys) to the establishment of effects-based criteria. Chemical concentrations observed or predicted by these methods to be associated with biological effects were ranked. The lower 10<sup>th</sup> percentile called the Effects Range-Low (ER-L) and median identified as the Effects Range-Median (ER-M) concentration were identified from this ranking. The ER-L and ER-M values were recalculated by Long et al. [11] after omitting a small amount of freshwater data included in the Long and Morgan [12] calculations and adding more recent data.

The major strength of these benchmarks is that they integrate several different types of biological effects data. The major disadvantage is that synoptically-collected biological and chemical data might have included groups of chemicals, and the NOAA method is not capable of accounting for possible antagonistic and synergistic effects of multiple chemicals.

The NOAA ER-L and ER-M values are listed in the templates for inorganic chemicals (metals), and organic chemicals (volatile and semi-volatile organic compounds, pesticides/PCBs). No site-specific TOC adjustments are made to these benchmarks.

#### Florida Threshold Effects Level (TEL-F) and Probable Effects Level (PEL-F)

The Florida Department of Environmental Protection (FDEP) approach, developed by MacDonald [5, 13], is similar to the NOAA approach [11, 12]. The updated and revised data set used by Long

G. Hellyer and G. Balog, *Derivation, Application, Strengths and Limitations of Sediment Ecotoxicological Screening Benchmarks (ESBs)*

et al. [11] was used by MacDonald [5, 13] to calculate Threshold Effects Levels (TEL-Fs) and Probable Effects Levels (PEL-Fs). However, unlike the ER-Ls and ER-Ms, the TEL-Fs and PEL-Fs also incorporate chemical concentrations observed or predicted to be associated with no adverse biological effects.

The TEL-F is the geometric mean of the 15<sup>th</sup> percentile in the effects data set and the 50<sup>th</sup> percentile in the no effects data set. Thus, the TEL-F represents the upper limit of the range of sediment contaminant concentrations dominated by the no effects data.

The PEL-F is the geometric mean of the 50<sup>th</sup> percentile in the effects data set and the 85<sup>th</sup> percentile in the no effects data set. Thus, the PEL-F represents the lower limit of the range of contaminant concentrations that are usually or always associated with adverse biological effects.

The strengths of this approach include:

- The FDEP values may be used to help identify sites with potential to cause adverse biological effects.

The limitations of this approach include:

- Data compiled by MacDonald et al. [5] are from marine and estuarine locations. Application of these benchmarks to freshwater systems may be inappropriate.
- Values are for single chemicals, although sediments containing chemical mixtures were used for their derivation

The TEL-F and PEL-F values are listed in the templates for inorganic chemicals (metals), and organic chemicals (volatile and semi-volatile organic compounds, pesticides/PCBs). No site-specific TOC adjustments are made to these benchmarks.

Canadian Freshwater Threshold Effect Level (TEL-C) and Probable Effect Level (PEL-C)

Smith et al. [17, 18] describe a procedure to develop TEL-Cs and PEL-Cs based on a large freshwater data set known as the Biological Effects Database for Sediment (BEDS). BEDS incorporates much of the work done in the Assessment and Remediation of Contaminated Sediments (ARCS) program [20, 21, 27] as well as the Ontario sediment data set [8].

The TEL-Cs and PEL-Cs are determined only for chemicals having at least 20 data entries for both effect and no effect. The TEL-C is derived by calculating the geometric mean of the 15<sup>th</sup> percentile of the effect data and the 50<sup>th</sup> percentile of the no effect data. The TEL-C was intended to estimate the concentration of a chemical below which biological effects only rarely occurred. The PEL-C was derived by calculating the geometric mean of the 85<sup>th</sup> percentile of the no effect data and the 50<sup>th</sup>

G. Hellyer and G. Balog, *Derivation, Application, Strengths and Limitations of Sediment Ecotoxicological Screening Benchmarks (ESBs)*

percentile of the effect data. The PEL-C was intended to estimate the concentration of a chemical above which biological effects frequently occurred.

The TEL-Cs and PEL-Cs can be used as tools in assessing sediment by delineating three distinct effects ranges:

- Minimal effect ranges; concentrations equal to or below the TEL-C.
- Occasionally possible effect ranges; concentrations above the TEL-C but below the PEL-C.
- Frequently detected effect ranges; concentrations equal to or greater than the PEL-C.

The confidence in the TEL-Cs, or alternatively the degree of internal reliability, is high based on the very low incidence (<10%) of biological effects below the TEL-C. The one exception is the value for total DDT which was most likely influenced by a small data set containing few no-effect entries.

The confidence in the PEL-Cs is generally lower than for the TEL-Cs. Several pesticides benchmarks showed high reliability, especially those for p,p'(4,4')-DDD and total DDT. However, the reliability of PEL-Cs for all trace metals, all individual SVOCs, and two pesticides was less than 50%.

The strengths of the approach is primarily the high internal reliability of the TEL-Cs. This means that the TEL-Cs, when applied to the data used to develop the benchmarks, correctly identified samples in which no effects would be observed for most chemicals. Hence the TEL-Cs are reliable screening benchmarks.

There are several limitations in the use of these benchmarks. The PEL-Cs were not as reliable as the TEL-Cs for meeting their narrative purpose. The authors state that the TEL-Cs and PEL-Cs are currently too conservative for use as a screening tool in cases where it is necessary to identify high priority sites. In the case of the PEL-Cs, however, the relatively lower internal reliability indicates that they may not adequately identify sediment-associated chemical concentrations above which adverse effects biological effects are expected to frequently occur.

The freshwater TEL-C and PEL-C values are listed in the templates for inorganic chemicals (metals), and organic chemicals (volatile and semi-volatile organic compounds, pesticides/PCBs). No site-specific TOC adjustments are made to these benchmarks.

#### Screening Benchmark Compilations

Various agencies have compiled sediment screening benchmarks, including some of the benchmarks discussed in this report, and recommended screening benchmarks for ecological risk assessments. Several of these compilations are listed in the ESB tables. One of these, the State of Washington

G. Hellyer and G. Balog, *Derivation, Application, Strengths and Limitations of Sediment Ecotoxicological Screening Benchmarks (ESBs)*

Sediment Quality Standards [4], contains a few benchmarks that are unique, notably those for phenolic compounds. The following sections discuss the various compilations listed in the ESB tables.

#### Ecotoxicological Thresholds

In 1996 EPA [26] published Ecotoxicological Thresholds (ETs) intended to be used for screening contaminants at CERCLA (Superfund) sites. Sediment values are available for selected metals and organic compounds. The preferred method for determining sediment ETs was the proposed EPA Sediment Quality Criteria (SQC) values derived using the EqP method [22, 23, 25]. In the absence of SQC values, sediment quality benchmarks (SQB) were calculated using EqP and substituting Tier II Secondary Chronic Values for Ambient Water Quality Criteria. Four of the SQBs were from the Great Lakes Water Quality Initiative [20, 21], twelve were from Suter and Mabrey [31], and seventeen were calculated by EPA [25]. The NOAA ER-L value [11, 12] listed in the template is used if neither an SQC nor an SQB is available.

These benchmarks have the advantage of having been peer-reviewed and recommended by the EPA. The benchmarks are also based upon the widely-accepted EqP approach. EPA [25] notes that there is a relatively low correlation between the incidence of effects and values above the ER-L for mercury, nickel, total PCBs, and DDT [11] and that the ETs for these chemicals should be used cautiously.

The freshwater TEL and PEL values are listed in the templates for inorganic chemicals (metals), and organic chemicals (volatile and semi-volatile organic compounds, pesticides/PCBs). No site-specific TOC adjustments are made to these benchmarks.

#### USEPA Region IV Screening Values

Region IV has published ecological screening values for sediments [15]. The selected effect level is the lower of the ER-L [11] and TEL-F [5, 13]. The ER-L for antimony is taken from Long and Morgan [12]. When the Contract Laboratory Program's Practical Quantitation Limit (PQL) is above the effect level, the screening values default to the PQL. However, if concentrations below the PQL are reported, they should be compared with the effect level.

There are few strengths to this compilation of benchmarks. They are highly conservative for chemicals using the ER-L and TEL-F values. On the other hand, the PQL is not risk-based in any way, therefore adverse effects may be seen at levels below the PQL for some chemicals.

The Region IV values are listed in ESB templates for inorganic chemicals (metals), VOCs and SVOCs, and chlorinated pesticides/PCBs. No site-specific TOC adjustments are made to these benchmarks.

G. Hellyer and G. Balog, *Derivation, Application, Strengths and Limitations of Sediment Ecotoxicological Screening Benchmarks (ESBs)*

Assessment and Remediation of Contaminated Sediments (ARCS) Program

Under the aegis of EPA's ARCS program, sediments were collected and toxicity tests were performed from a number of locations throughout the Midwestern and south-central United States. The ARCS program [20, 21, 27] describes the procedures for calculating and evaluating sediment effect concentrations (SECs) using lab data on the toxicity of field-collected sediments to the amphipod, *Hyalella azteca* and the midge fly, *Chironomus riparius*.

SECs were calculated primarily for total metals, simultaneously extracted metals, PCBs, and volatile and semi-volatile organic compounds. The ranges of concentrations were too narrow in the ARCS database to adequately evaluate SECs for butylins, methyl mercury, polychlorinated dioxins and furans, or chlorinated pesticides. The SECs are further subdivided into three categories: (1) Effects Range Low (ERL) and Effects Range Median (ERM) (2) Threshold Effects Level (TEL) and probable effect level (PEL) and (3) no effect concentration (NEC). These acronyms refer to the methods employed by the original authors and also used in this ARCS program to derive benchmarks.

The SECs can be used as sediment assessment tools to:

- interpret historical sediment chemical data.
- identify chemicals or areas of concern.
- identify the need for more detailed studies.
- identify a potential problem before a chemical is discharged.
- establish a link between contamination source and sediment quality.
- trigger regulatory action.
- establish target remediation objectives.

The SECs are based on endpoints for amphipods (*H. azteca*) that include survival, growth (length), and sexual maturation. Endpoints for midges (*C. tentans*) include survival and growth (length). A sample was designated as toxic in replicated tests if there was a significant reduction in an endpoint relative to the response of the control sediment. Or, a sample was deemed toxic if there was greater than 50% reduction in response relative to the control sediment in non-replicated tests. Furthermore, SECs were derived only if five or more samples were toxic for the chemical and the number of toxic samples with concentrations above the SEC was greater than the number of toxic samples with concentrations below the SEC.

G. Hellyer and G. Balog, *Derivation, Application, Strengths and Limitations of Sediment Ecotoxicological Screening Benchmarks (ESBs)*

The authors note that if a chemical concentration exceeds an SEC threshold it does not necessarily mean that the chemical *caused* the observed effect. Rather, the SEC is the concentration of a chemical that is *associated* with the effect. Correlation is not causation.

One of the limitations of this method the authors mention is the complex nature of field collected sediments versus lab controlled spiked sediments. There are many variables which can effect the toxicity of a sediment to a benthic organism such as the chemicals acting independently, additively, synergistically, or antagonistically. Therefore, the application of SECs is associated with uncertainty in field collected sediments. Paradoxically, one of the strengths of this type of approach is that, to a point, it mimics natural conditions, and can predict potential toxicity in field collected sediments.

The freshwater TEL and PEL values are listed in the ESB template for inorganic (metals) and organic chemicals (volatile and semi-volatile organic compounds, pesticides/PCBs). No site-specific TOC adjustments are made to these benchmarks.

#### Sediment Effect Concentrations for Amphipods and Midges

Ingersoll et al. [7] describe a method to determine the toxicity in sediments of inorganic and organic chemicals. This study is an offshoot of the ARCS program [20, 21, 27] where sediments were collected from a number of locations throughout the Midwestern and south central United States and toxicity tests were performed. Sediment effect concentrations (SECs) were determined based on these toxicity tests. The authors developed benchmarks based on each individual toxicity test in the same manner as presented in ARCS. The SECs are further subdivided into three categories: (1) Effects Range Low (ER-L) and Effects Range Median (ER-M) (2) Threshold Effects Level (TEL-HA) and probable effect level (PEL-HA) and (3) no effect concentration (NEC).

Like the ARCS program, the SECs are based on endpoints for the amphipod that include survival, growth (length), and sexual maturation. Endpoints for the midges include survival and growth (length). A sample was designated as toxic in replicated tests if there was a significant reduction in an endpoint relative to the response of the control sediment.

The strengths of this method include the use of field collected sediments. However, because of the complex nature of these sediments if a chemical exceeds an SEC it does not necessarily mean that the chemical *caused* the observed effect. Rather, the SEC is the concentration of a chemical that is *associated* with that effect. Another advantage of this method is the reliance of SECs on dry weight concentrations which, according to the authors, are generally more reliable than ECs calculated using sediment concentrations normalized to organic carbon for non-polar organic chemicals and SECs calculated using pore-water metals concentrations.

One of the limitations also happens to be one of the strengths of the method in that determining the toxicity of field collected sediments is complex because of the many factors which influence toxicity and can act either independently, additively, synergistically, or antagonistically.

G. Hellyer and G. Balog, *Derivation, Application, Strengths and Limitations of Sediment Ecotoxicological Screening Benchmarks (ESBs)*

The PEL-HA and TEL-HA values for *H. azteca* are listed in ESB templates for inorganic chemicals (metals), volatile and semi-volatile organic compounds, and chlorinated pesticides/PCBs. No site-specific TOC adjustments are made to these benchmarks.

#### Canadian Sediment Quality Guidelines

The Canadian strategy for developing sediment quality guidelines involves two separate approaches, as described by Smith et al. [17, 18]. The spiked sediment toxicity test approach uses dose-response information from sediments spiked with known concentrations of a chemical and adverse biological effects observed in the exposed organisms.

The second approach, the National Status and Trends Program (NSTP), uses field-collected data in which chemical mixtures occur that establish associations between chemical concentrations in the sediments and adverse biological effects that are classified as effects range low (ER-L) and effects range median (ER-M). These two values defined concentration ranges that attempted to identify the frequency associated with adverse effects. This approach was also used by the state of Florida to support the development of sediment quality guidelines.

The original derivation procedure was modified to calculate two guidelines, the lower value, or, lower Threshold Effects Level (TEL-C), representing the concentration below which adverse effects were expected to occur rarely. The upper value, or, probable effect level (PEL-C), represented the concentration above which adverse effects were expected to occur frequently.

The derivation of interim guidelines using the modified NSTP approach, as described in Smith et al. [18], involves the evaluation of data from studies conducted throughout North America, as noted above. Chemical and biological data as well as equilibrium partitioning models, were compiled in the biological effects database for sediments, (BEDS). Each entry included information on the measured chemical concentration, sample location, test approach, duration, presence or absence of adverse effects and life stage used. This information was sorted by chemical and sediment type and effect descriptors were assigned where adverse effects were noted. Adequate toxicological data were available to support the calculation of TEL-Cs and PEL-Cs for thirty-one substances in marine sediments and twenty-three substances in freshwater sediments.

Quantification of the incidence of adverse biological effects was used to estimate the degree to which the objective of the TEL-Cs and PEL-Cs were met. The TEL-Cs for all chemical in both freshwater and marine sediments adequately defined the concentration below which adverse effects occurred within the data compiled in BEDS. Similarly the PEL-Cs for most chemicals found in marine sediments were adequately defined as well. The PEL-Cs for most chemicals in freshwater sediments did not satisfy the narrative definition of the PEL-C. This problem may be corrected through further expansion of the database to include more toxicological information from sites covering a larger range of chemical concentrations.

The TEL-C and PEL-C values are listed in ESB templates for inorganic chemicals (metals), volatile and semi-volatile organic compounds, and pesticides/PCBs. No site-specific TOC adjustments are made to these benchmarks.

G. Hellyer and G. Balog, *Derivation, Application, Strengths and Limitations of Sediment Ecotoxicological Screening Benchmarks (ESBs)*

Conclusions

A comprehensive, easy to use and interpret, method has been developed and illustrated using available ecotoxicological screening benchmarks (ESBs) for inorganics (metals), volatile and semi-volatile organic compounds, and chlorinated pesticides/polychlorinated biphenyls (PCBs). It allows rapid screening of sediment contaminants for potential ecotoxicological risk. It complements and readily integrates with other biological and chemical information, including sediment bioassays, grain size determination, and SEM/AVS data. Sites identified by this method may be investigated further with more rigorous chemical and biological sampling and modeling techniques, particularly focusing on potential exposure pathways to organisms of ecological or societal concern.

Acknowledgments: We appreciate review, support and comments provided by our colleagues, Patti Lynne Tyler, Alan VanArsdale, and Peter Nolan.

## 1.0 Project Objective

The Massachusetts Department of Environmental Protection Office of Watershed Management (OWM) has requested Office of Environmental Measurement and Evaluation (OEME) assistance in evaluating the ambient water/sediment quality in the 10 Mile River. The 10 Mile River has a history of physical alteration and chemical contamination, particularly from jewelry and electro-plating industries. The purpose of this investigation is to determine chemical concentrations in the river sediment upstream of several impoundments and a Waste Water Treatment Plant (WWTP), to evaluate the potential toxicity of these sediments to benthic invertebrates, and to determine current surface water quality conditions associated with the sampling locations.

Chemical constituents (metals, mercury, SVOCs, PCBs, pesticides, TOC, and AVS/SEM (Cu, Zn, Pb, Cd, Cr, Hg, Ni) in sediments will be determined for 7 stations. These sediment concentrations will be compared to biological effects guidelines and laboratory control toxicity results and will be used to evaluate the sediment contamination and screen for potential ecological risk in the river.

## 1.1 Project Organization

The organizational hierarchy for this project includes the MADEP project manager (MADEP/PM) Robert Maietta (MADEP/OWM) and the EPA project manager (EPA/PM) Greg Hellyer (EPA/OEME/ECA). Chemical Analyses will be performed at EPA's New England Regional Laboratory (NERL) under the direction of Robert Maxfield (EPA/EIA). Field activities will take place as a cooperative effort with teams comprised of both EPA and MADEP personnel. Interpretation of data and the evaluation of useability will be provided by EPA's PM.

## 2.0 Data Usage

The sediment toxicity test results will be used to determine if exposure to contaminants in the sediments has adverse biological effects (i.e. mortality) to benthic organisms. The sediment chemical concentrations will be evaluated against the survival responses from the whole sediment toxicity tests. As part of that evaluation, results from Simultaneously Extracted Metals and Acid Volatile Sulfide (SEM/AVS) analysis and TOC will be compared with the toxicity test data in an attempt to identify mechanisms possibly controlling the bioavailability of toxic contaminants. In addition, Any outstanding ecological concerns noted from the site visits will be recorded in the final report.

### 3.0 Design and Rationale

This project will take place in an effort to provide evidence of degradation and the need for possible future remedial action. This project will include monitoring at seven sites in the 10 Mile River. The sites selected will be determined by the MADEP and EPA PMs. A site reconnaissance visit will take place in March, 1998 to determine access points in the river and sampling locations.

Sampling locations will in part be based on accessibility, historical information and areas of low energy (depositional environments). Each sampling location will be documented through the use of the Global Positioning System (GPS) using the OEME SOP (Standard Operating Procedure in Attachment E).

Surface water chemistry will be performed at each location. Sediment samples will be collected at each of the sites for chemical and physical analyses, as well as toxicity testing. A list consisting of sampling site descriptions, medium for analyses and analytical parameters can be found in Table 1.

If toxicity occurs in any of the biological assays, the chemical analysis may assist in identifying the causal agent responsible for toxicity. If chemical analysis indicates high concentrations of various toxicants, and no toxicity occurs, then the bioavailability or toxicity of the contaminants may be altered by other physical or chemical parameters such as elevated levels of total organic carbon (TOC) or acid volatile sulfides (AVS).

### 4.0 FIELD SAMPLING

#### 4.1 Water Collection

Field water quality measurements will be performed with a YSI 6000 Sonde operated with portable computer or an equivalent method at all 7 field sites listed in Table 1. The measurements recorded will consist of pH, dissolved oxygen (DO), temperature and specific conductance. See Attachment B for YSI 6000 calibration procedures.

Field water quality measurements will be made prior to sediment collection just below the surface of the water where the depth is less than 0.3 meter (1 ft) in depth. If the water depth is greater than 1 meter, measurements will be collected at 1 meter depth intervals. Table 2 contains information on parameters and analytical methods.

## 4.2 Sediment Collection

Sediment samples will be collected from the bioactive layer (< 10 cm.) from 7 locations in the 10 Mile River. A petit ponar dredge will be used to collect sediment samples. If a problem with the substrate is encountered, a hand corer may be used instead. Sediments will be collected from the upper six inches of bottom substrate. The dredge may be used several times in slightly different spots at each sampling station to obtain adequate sample volume. Sediments will be emptied from the dredge into a precleaned 5 gallon HDPE container for each location. The sampling containers for Simultaneously-Extracted Metals (SEM)/AVS analysis will be filled immediately prior to homogenization with no head space in the sample container using a plastic scoop. Aliquots for analyses of PAH, PCB, pesticide, TOC and grain size will be taken next. Containers for total metals will then be filled using a plastic scoop. The toxicity sample will be taken last from the homogenized sample. The dredge will be decontaminated between sampling stations with soapy water, tap water and a deionized (DI) water rinse. All sampling containers for chemical and physical analyses will be appropriately pre-cleaned plastic or glass (amber when necessary) bottles.

Every effort will be made in the field to meet the 30 % solids requirement for sediment analysis. This will consist of initially allowing adequate time for excess water to drain from the dredge. Once the sample settles in the 5 gallon container, overlying water will again carefully be poured off (avoiding loss of fines), prior to distribution into individual sample containers. If necessary, special arrangements may be made with OEME's Chemistry Section for possible sample filtration in the laboratory should there be any questions with respect to meeting this requirement. Samples will not be dried prior to analysis.

NOTE Sediments will be sampled during the reconnaissance and analyzed at OEME to assess the % of solids. If sediments are not expected to meet 30% solids, analyst should meet with EPA/PM and NERL Chemistry Section Chief to determine next steps to be taken, including, if necessary, additional sampling of the apparent problematic sites.

For more information on sediment collection see OEME/ECA, Sediment Sample Collection Methods SOP #2.25 (Attachment E).

Sediment samples will be analyzed for: total organic carbon (TOC), polychlorinated biphenyls (PCBs), semivolatile organic compounds (SVOCs), pesticides, grain size, total metals analysis, SEM/AVS and toxicity. Table 4 lists specific analytes of interest, appropriate sample containers and analytical methods.

Whole sediment toxicity tests will be conducted utilizing the two freshwater macroinvertebrate species, *Chironomus tentans* and *Hyalella azteca*. Toxicity testing procedures will follow EPA's *Methods for Measuring the Toxicity and Bioaccumulation of Sediment-Associated Contaminants with Freshwater Invertebrates* (EPA/600/R-94/024)

and OEME/ECA Standard Operating Procedure # 2.7 ( Attachment A).

### 5.0 Interferences and Potential Problems

Sampling will be conducted at low energy depositional areas. Every effort will be made to collect depositional sediment rather than sand or gravel. Sand and gravel does not bind the contaminants that may be present. In addition, sediment samples should be collected upgradient of major bridge and roadways so as to avoid contaminants from road runoff.

### 6.0 Sample Handling and Preservation

Samples will be preserved on ice in a cooler for transport to the EPA Region 1 laboratory. Proper paperwork including labeling and chain of custody will be maintained at all times. Upon arrival at the laboratory, all samples will be logged in and then refrigerated at 4 degrees Celsius. Table 2 and 4 list the holding time and preservation necessary for each parameter collected.

The sample label will contain the following information:

1. Sample number
2. Sample location or identifier
3. Date and time of collection
4. Sampling personnel

A bound field notebook will be maintained by field personnel to record sample collection information. A chain of custody form will be used to document the types and numbers of samples collected and logged. The storage coolers and refrigerators will be taped with signed chain-of-custody tape while the samples are being stored.

ADDITIONAL INFORMATION

9.0 Schedule of Task and Products

- 1)Collect water and sediment samples ..... 4/1/98
- 2)Complete all chemical analysis and toxicity testing ..... 4/30/98
- 3)Complete all analytical and toxicity reports ..... 5/31/98
- 4)Meet with MADEP to discuss data ..... 6/30/98

10.0 Field Safety

All field samplers will be approved by their immediate supervisors to perform field work. The supervisors are responsible for assuring the field samplers are trained (OSHA 1910-120) in safety issues regarding field work.

All boat operation and safety protocol will adhere to EPA Environmental Studies Section, Standard Operating and Safety procedures.

11.0 Data Quality Requirements and Assessments

*Precision and Accuracy:*

The precision and accuracy of the data is to be within ranges associated with the specific approved protocols. See Tables 4 and 5 for QC goals and reporting limits. For the sediment toxicity test to be acceptable, survival at 10 day must equal or exceed 80% for *H. azteca* and 70% for *C. tentans* in the laboratory formulated sediment (negative control). Refer to parameter methods and standard operating procedures for more information.

*Data Representativeness:*

\_\_\_ Samples must be representative of conditions existing at the time of sample collection. Standardized procedures will be used at all times in an effort to insure representativeness of conditions preent at the site. Samples must be preserved immediately according to protocol in Tables 2 and 4. The metals rinseate blank will be preserved with nitric acid at

the time of collection. Field and laboratory conditions which may affect sample integrity are to be documented on the field collection forms or laboratory logs.

*Data Comparability and Completeness:*

Data must be comparable for all samples within each media, i.e. all analyzed with the same detection limits and method for each parameter. Again, standardized procedures will be used at all times in an effort to insure representativeness of conditions present at the site which allows for a higher level of comparability. Data will be compared with existing databases and water quality criteria. Analytical methods will be those cited in the parameter tables. At least 90% of the data must be determined to be valid/useable for the project to be considered complete. This will be determined by comparing the ratio of the total number of valid/useable samples to the total number of samples analyzed and multiplying by 100 to convert to a percentage value.

*Data Validation and Useability:*

All analytical results will be reviewed and the QC requirements evaluated by the primary analyst and a second laboratory QC chemist before they are released. Data reports will then be evaluated by the EPA/PM for use in obtaining project objectives.

*Corrective Action*

When it is found that data is incomplete or that results are unacceptable, the Project Officer may determine that one or more of the following procedures for corrective action shall be undertaken:

1. Incomplete data: Omissions from logs, notebooks and worksheets place the entire analysis in question. If data does not meet the 90% data completeness requirement, a meeting will be held with the analyst and QA officer to determine an appropriate response. Incomplete field sampling data may require resampling of the questionable location. Incomplete laboratory data usually calls for reintroduction or reanalysis of the questionable sample if feasible.
2. Conflicting or poor quality data: When results from duplicates, spikes, blanks, etc. do not meet the described QC goals, the available data will be reviewed by the project officer and QA officer. Upon examination, all or some of the following actions may be applied:
  - a. Systems audit for analyte in question.
  - b. Determination of matrix interference.
  - c. Re-sampling of the questionable sample.

- d. Reconsideration of acceptable limits with statements explaining the results of the action/rationale taken.
- e. Rejection of data and exclusion from the report with written explanation.
- f. Rejection of the entire sample/site location with recommendation of relocation of sample site or reconsideration of results.

#### 12.0 Final Report

The final report will include all analytical results and water/sediment quality evaluations. The report will be sent to the MADEP for future decision making. A meeting will be scheduled after the final report is released to discuss the results and future monitoring or management activities.

ATTACHMENT A

STATIC BULK SEDIMENT TOXICITY TESTING PROCEDURES

Biology Section

New England Regional Laboratory

SOP number: 2.7  
Revision number: 1  
March 9, 1998

Filename:G:\allshare\bio-sops\busedtes.sop

### 1.0 Purpose of Method

This procedure is used to evaluate the toxicity of freshwater bulk sediments to the benthic community. A two species test is prescribed due to species sensitivity differences.

### 2.0 Summary of Method

Two species of benthic macroinvertebrates are exposed to sediments for a 10 day period. Sediment and overlying water are placed in each of 8 replicates/sample/species and allowed to settle overnight. The following day, after water renewal, test organisms are introduced to each test vessel. Test chemistry is performed on the overlying water on a daily basis for the duration of the test. The test is ended, determining the number of surviving organisms. Subsequent to test termination, survival and growth endpoints are examined statistically. Procedures follow those described in the EPA document, Methods For Measuring The Toxicity and Bioaccumulation of Sediment-associated contaminants with Freshwater Invertebrates, EPA/600/R-94/024, June 1994.

### 3.0 Apparatus/Materials

- a. 300 ml lipless test vessels
- b. turbulence reducers
- c. aluminum pans
- d. drying oven
- e. muffle oven
- f. analytical balance
- g. pH/specific ion electrode meter, DO meter and conductivity meter
- h. ammonia probe
- i. pH probe
- j. DO probe

k. environmental chamber

l. precleaned nalgene trays

3.0 Apparatus/Materials (cont'd)

m. precleaned spatulas

n. crystallizing dishes

o. 6.0 ml disposable transfer pipets

p. forceps

q. light table

r. # 35 sieves

s. *Hyallela azteca*, 3rd and 4th instar (<7 days old): 2-3 mm in length

t. *Chironomus tentans*, 2nd and 3rd instar larvae, 50% of which are 2nd instar

4.0 Reagents

a. laboratory control sediment (see artificial sediment SOP)

b. deionized (DI) water

c. pH buffers

d. conductivity standards

e. ammonium chloride standard

f. 0.02N H<sub>2</sub>SO<sub>4</sub>

g. calmagite

h. 10N NaOH

i. 0.01M EDTA

## 5.0 Procedure

### 5.1 SEDIMENT STORAGE

a. Solid-phase sediment will be stored at 4<sup>0</sup>C in air-tight containers in the dark. All samples must be accompanied with proper identification and sample tracking information. Storage of sediments will be for no longer than 2 weeks prior to testing.

### 5.2 ENVIRONMENTAL CONTROLS WHILE TESTING

See the EPA method referenced for the specified environmental controls.

### 5.3 SAMPLE PREPARATION and DISTRIBUTION

a. The day before the toxicity test starts (Day -1), sediments are poured from the 2 liter Nalgene (or equivalent) containers and homogenized to a uniform distribution, in a large precleaned Nalgene tray, making sure that complete mixing is achieved. Excess sediments will be returned to the sample containers and held in the biology refrigerator until testing is complete.

b. One hundred ml. of each test sediment, reference sediment, and laboratory control sediment is added to each of 8 replicates per species. The sediment in each test vessel should be smoothed using a spoon or spatula. Next, carefully add 175 ml of overlying water to each vessel. The sediments are then allowed to settle for 12-24 hours. Water quality parameters should be measured prior to the addition of the test organisms.

### 5.4 ORGANISM INTRODUCTION

a. Test organisms are randomly selected from the test population for inoculation into the test. Each replicate will receive 10 organisms. No more than 5 individuals should be placed in a vessel during a complete pass of all sample replicates.

With a 6 ml. disposable transfer pipet, test organisms are very carefully transferred from the test population into the test vessel, being sure to release the organisms below the surface of the overlying water.

Note: If the test overlying water hardness is 1/2 or less than the culture water, then acclimating with a 1:1 dilution of the test population with overlying water on a 2 hour schedule until the overlying water is approximated is required.

Note: Inspect the test chambers <2 hours after introduction to insure that organisms are not

trapped in the surface tension of the water. If floaters are detected, replace with new organisms.

#### 5.5 TEST CHEMISTRY (See test chemistry SOP for details)

a. Test chemistry will be performed on a daily basis and results will be recorded in the test chemistry log book.

1) Initial test chemistry is performed on an overlying water composite from each sample prior to the introduction of test organisms. Chemical analyses will consist of the determination of pH, temperature, conductivity, dissolved oxygen(DO), hardness, alkalinity and ammonia.

2) Daily test chemistry consisting of a DO, temperature and conductivity measurement of overlying water will take place in the morning after renewal.

3) Final test chemistry will be done on a composite of replicates for each sample per species. Parameters tested will be identical to initial parameters.

Note: In order to accurately measure chemical parameters under test conditions, beakers of water to be tested should be kept in the environmental chamber until ready to perform the analyses.

Note: If the DO concentration on any sample falls below 40% of saturation, that species specific set of replicates must be aerated.

#### 5.6 FEEDING

a. Feeding of each replicate is performed daily following the morning renewal.

1) *C. tentans* is fed 1.0 ml of Tetramin of a 20 g/L suspension daily. *Feeding for all replicates is suspended for a day or more if fungus appears on sediment.*

2) *H. azteca* is fed 1.5 ml of YAT daily. *Feeding for all replicates is suspended for a day or more if fungus appears on sediment.*

#### 5.7 RENEWAL

a. A 50% renewal using turbulence reducers to minimize resuspension is performed in the early morning and late afternoon. Renewal water is transferred from the drum in the Wet Lab to the environmental chamber between renewal so that the water will be at the test temperature.

### 5.8 TERMINATING SEDIMENT TESTS

- a. Removal of sediment from the test chambers will be handled with the same protective garb used in setting up the test.
- b. There are various techniques that can be used for retrieval of test organisms. *H. azteca* are counted. *C. tentans* are counted and then are rinsed clean and placed on muffled, preweighted, and numbered aluminum pans. The replicate #, species, sample ID and number of organisms recovered are documented on tally sheets. The retrieval process should take place in a white plastic tray on a light table for increased visibility. Approximately 50% of the overlying water is poured into a white translucent tray on the light table. All organisms detected are counted and, in the case of *C. tentans*, placed on aluminum trays. Next, since the majority of organisms dwell in the upper few millimeters of sediment, the beakers can be swirled to lift this layer into water column and then poured into the sieve or translucent tray placed on a light table. Again organisms are retrieved as prescribed. This suspension process is repeated, adding additional water to the beaker if necessary, with a thin layer at a time being poured into the tray.
- c. Once all organisms are retrieved or the test vessel finished, and the total number of organisms tallied, the label can be removed, the vessel is rinsed, with the rinsate being poured into a waste bucket, and the vessel is placed on the wash table in the Wet Lab.
- d. All tally sheets are to be copied and the copies stapled into the specific project section of the sample project log book.

### 5.9 ENDPOINTS and OBSERVATIONS

Endpoints for this test are survival (both species) and growth (*C. tentans*) as ash free weight. Make notes of behavioral changes during the conduct of the test i.e. floating on surface, sediment avoidance.

### 6.0 Safety

- a. All workers involved with handling and testing contaminated sediment must undergo health monitoring annually.
  - b. Hands should always be kept away from the eyes and mouth ie. no fingernail biting. After removing gloves, and possibly contaminated lab clothing, dispose of it in a trash bag marked non-hazardous, and wash hands with soap.
  - c. Lab coats must be worn at all times when working with sediments. Tyvec may be worn during sediment manipulation and mixing. The sediment may be checked with an HNU to
- Ten Mile Watershed Ecotoxicity Report

determine if respirator use is necessary. Gloves must be worn to avoid skin contamination. Latex, rubber and vinyl gloves however may not provide full protection. Wear latex liners with nitrile or other protective glove if necessary. Safety glasses must be worn during the manipulation of sediments. If mixing is messy, face shields may be worn.

d. Mixing of sediment will occur under a hood if the potential for generating toxic aerosols, fumes or dusts exist.

#### 7.0 Waste

a. Overlying water waste can be placed in the “dirty tank” unless suspected of being toxic or otherwise hazardous. If suspected of being hazardous, the overlying water waste should be isolated in a properly labeled drum and the EIA and chemistry groups contacted to schedule sampling of the drum and analyses. When the analytical data is made available, it is to be forwarded to the H&S officer for review and ultimate disposal.

b. Sediment waste should be collected in labeled drums put into the Wet Lab next to the “dirty tank” and the biology lab manager contacted when sed waste is available for disposal.

c. Chemical waste from test activities is disposed of as per the test chem SOP (testchem.sop)

#### 8.0 QA/QC

a. An artificial sediment is prepared and used as a laboratory control for each species during each test. The material used are of high quality. Test acceptability criteria for survival of each species must be met on exposure to this control or the test may be invalidated.

b. Facility QC is documented through the monitoring and recording of temperature in the environmental chamber.

c. Organisms provided by this laboratory undergo water column only reference toxicant testing for each tank of cultures to document the quality of the test organisms. Organisms from outside laboratories have documentation of QC testing available upon request.

d. Test chemistry is performed on overlying waste water on a daily basis. Based on the results, response would include, aeration of all beakers associated with the specific sample and species or for problems indicated by the development of fungi, food would be reduced or eliminated.

e. Calibration of instrumentation used during the test is performed and documented. If

problems are identified they are corrected prior to test measurement being performed or so noted if impossible to correct.

ATTACHMENT B:  
YSI 6000 CALIBRATION PROCEDURES

Standard Operating Procedure      5/23/96

For: YSI 6000 Sonde with Omnidata Polycorder

Calibration and Measurements of: Dissolved Oxygen, pH, Temperature, Conductivity, Depth.

CALIBRATION

Dissolved Oxygen

1. Inspect D.O. probe for air bubbles, or damaged membrane. If air bubbles or damage, repair according to manufacturer suggestions.
2. Insert Sonde in calibration cup with wet sponge, and wait 15 minutes to assure equilibration with water saturated air is complete. Place the probe with the cup attached into water that is approximately at the temperature of the water to be sampled.
3. Attach Sonde to Omnidata Polycorder. Turn on the Polycorder and enter PC6000 software. (Type "CD PC6000" <enter>, and "PC6000" <enter>)
4. Position the cursor and enter "SONDE"  
\* If an error or a not communicating message appears, check the cable connections, check batteries (dead or inserted incorrectly), make sure all battery and cable connections are dry, and finally type "setup" at the C:> and make sure Serial Ports are set "ON".
5. At the Main Menu, type "1" 3 times to enter the Discrete Sampling Mode.  
  
Wait for the temperature to become stable and using the YSI D.O. (10-15 min).  
Return to main menu.
6. Select 2 Calibrate

7. Select D.O%
8. Enter the current Barometric Pressure in mm of Hg. (760 mmHg is Standard conditions).
9. Press enter after approx. 1 minute calibration will be complete (note calibration in DO% also results in calibration of DO mg/l).

YSI D.O. Solubility Table (to check calibration)

<u>Temp. (°C)</u>	<u>Solubility mg/L</u>	<u>Temp. (°C)</u>	<u>Solubility mg/L</u>
16.0	9.87	23.0	8.58
16.3	9.81	23.3	8.53

22.9	8.60	29.9	7.57

Alt.(ft.) mmHg Corr. Factor

0	760	1.00
278	752	0.99
558	745	0.98
841	737	0.97
1126	30	0.96

10. Press "0" 3 times to return to the Main Menu.
11. At the Main Menu, type "2" , (Calibration Menu)  
\* The left side of the screen cannot be easily viewed. The screen can be moved left by pressing the RED KEY and the ARROWS. The menus are attached on the printed sheets.
12. Wait for "Calibration Accepted" message and press any key to continue.
13. Press "0" to the Main Menu and 2 for the Calibration Menu.

pH

1. At the Calibration Menu, type "6" (pH 2 Point)
2. Unscrew the hex nuts and remove the shield. Be very careful not to touch the D.O. membrane. Place the pH probe into a low ionic strength pH buffer of 6.97.
3. Press any key to begin calibration.
4. Wait for "Calibration ACCEPTED" message. If an "Out of Range" message appears, do not accept, and re-calibrate in the 6.97 buffer. If the error continues check the probe condition, accept the error and make note on the field forms.
5. Rinse probe with D.I. water and wipe dry with a paper towel.
6. Place the pH probe into a low ionic strength pH buffer of 4.10.

7. Press any key to "continue calibration"
  8. When prompted, enter the pH of the second buffer.
  9. Wait for "Calibration Accepted" message, and press any key to continue.
  10. Press "0" 1 time to return to the Main Menu. At the Main Menu type "1" 3 times to enter into the Discrete Sampling Mode.
11. Make sure the probe is reading the second buffer correctly ( $\pm 0.05$ ).
12. Rinse probe with D.I. water and dry.
13. Insert probe into pH 7 buffer and make sure it is reading correctly ( $\pm 0.05$ ). If either of the buffer readings are not correct, repeat the calibration procedure. If the second calibration does not check correctly, make note on the field form.
- \* Write the meter reading on the field note form.
14. If the river sample has a pH greater than 7.0, recalibrate the meter using a second buffer of 10.00.

#### Conductivity

1. At the Calibration Menu, press 1, (Conductivity)
2. Place Sonde into a conductivity standard that is typical of the sample expected, (i.e., 718 umhos/cm (0.718mS/cm) for fresh water).
3. Enter the standard specific conductance in mS/cm (0.718).
4. Wait for "Calibration Accepted" message, and press any key to continue.
5. Return to the Main Menu by pressing "0".
6. Enter "1" 3 times to run and write the meter reading on the field note form.
7. Rinse probe with D.I. water after calibration is complete.

#### Depth

**Project Work/QA Plan**  
**Ten Mile River Sediment/Water Quality Assessment**

Page -26-

1. Depth calibration must be performed at the site with the Sonde in the air. This is only necessary at sites with expected depths greater than 2 meters.
2. At the Calibration Menu, press 4, (Depth)
3. Press any key to zero depth.
4. Wait for "Calibration Accepted" message, and press any key to continue.
5. Press "0" and <enter> to return to the previous menu, (Main Menu).

**MEASUREMENTS**

Measurement procedures below are for discrete sample measurements. If timed or conditional samples are to be measured, follow the procedures outlined in the YSI 6000 Operating and Service Manual.

1. At the Main Menu, press "1", (Run).
2. At the Run Menu, press "1", (Discrete).
3. At the Run Discrete-sample Menu, press "2", (Site description).
4. Enter the Site number. (see Team List for site #).
5. At the Run Discrete-sample Menu, press "1", (Start discrete sample).
6. Within 15 seconds measurements should be displayed on the screen.  
If measurements do not begin to appear on the screen, press "0" to return to the previous menu and re-enter "1" to begin discrete sampling.
7. Place the Sonde into the water to be analyzed, and watch the variations in temperature, D.O., pH and conductivity.
8. When the variations are less than: 0.1°C temperature  
0.02su pH  
0.02mg/l D.O.  
5 uS/cm conductivity  
Press "2" -to begin logging  
  
\* Make note of the readings on the Field Note Form.
9. After approximately 15 readings, Press "2" -to end logging.
10. Press "0" to return to the Run Discrete-sample Menu.
11. Press "4" and <enter>, (Close file). Confirm with "y".  
If a "NO OPEN FILE" message appears, re-run the sampling and logging procedures.

12. Press "0" twice to return to the Main Menu.
13. Turn off Omnidata between sites to save batteries.

After all of the samples have been collected for the day, check the probe readings in the conductivity standard and the pH buffers.

1. Insert probe in pH buffer 6.97, press "1" 3 times from the Main Menu to enter into the discrete sample mode.
2. Make note on the final Field Note Form, the probe reading in this buffer (wait for readings to stabilize -2 minutes).
3. Rinse and dry probe. Insert in pH buffer 4.10 and wait for stable readings. Make note on the final Field Note Form.
4. Rinse and dry probe. Insert in the conductivity standard and wait for stable readings. Make note of true probe reading on the final Field Note Form.
5. Rinse probe and exit from sampling mode by pressing "0" 3 times. Turn off Polycorder.

SOP #:2.25  
Revision #:1  
Date: March 11, 2003  
Filename  
G:/allshare/bio.sops/sedsamp.sop

### 1.0 Purpose of Method

This procedure is developed to document protocols used with the collection of representative sediment samples. Sediment samples will be taken for the purposes of chemical and physical analyses and toxicity testing. Please note; a Quality Assurance Project Plan (QAPP) is necessary for sediment sampling projects.

### 2.0 Summary of Method

The method described below involves the taking of sediment samples. Sediment for the purpose of this SOP, is defined as one of a solid matrix made up of inorganic and/or organic components and is located underwater in either a lotic or lentic system. Samples are taken from the benthic substrate of either system by means of a coring or dredging technique. Depending on the purpose of sampling, as defined in a workplan, sediments are homogenized in a large precleaned holding container of sufficient volume to contain all replicates. If necessary, to minimize % moisture, the sample is allowed to settle for a short time and any free standing water is decanted off prior to homogenization. Volatiles are taken prior to homogenization. Acid volatile sulfide subsamples are taken immediately after homogenization. Using a precleaned scoop or spoon the homogenized sample is subsampled into the designated properly labeled sample containers. The containers are sealed with a chain of custody seal, put into a "ziploc" bag and placed in a cooler on ice.

### 3.0 Apparatus

a. sample containers - precleaned clear /amber glass or plastic bottles

- b. coring tubes
- c. hand corer
- d. Phleger corer
- e. dredges e.g. Ekman, Ponar
- f. new 5 gallon plastic bucket (1 per sampling station)
- g. new plastic scoops, spoons or spatulas (1 per sampling station)
- h. cleaning brush
- i. chemical waste cubetainers

3.0 (cont'd)

- j. 250 ml squirt bottles
- k. waders
- l. boat, motor, oars ( if necessary)
- m. rubber stoppers
- n. GPS unit
- o. COC seals
- p. coolers
- q. ice
- r. COC sheets
- s. waterproof writing utensils
- t. "zip loc" bags
- u. cellular phone

#### 4.0 Reagents Required

- a. Laboratory grade, non-phosphate detergent
- b. Deionized water
- c. 5% Nitric Acid (HNO<sub>3</sub>) solution
- d. Isopropanol
- e. Baking soda (acid neutralizer)
- f. boat motor fuel ( if necessary)

#### 5.0 Procedures

##### 5.1 Cleaning procedures

- a. Sampling containers for metals, extractable organics, pesticides, and PCB's are purchased precleaned. Sampling containers for extractable organics, PCBs and pesticides are to be amber colored glass. Metals sample containers may be either of HDPE or glass, but preferably HDPE for safety purposes.
- b. Sampling containers for volatile organics are glass vials with a Teflon septum and are purchased precleaned.
- c. Homogenizing containers are to be only new 5 gallon HDPE pails cleaned prior to use with non-phosphate soap and water followed by a tap and DI rinse.
- c. All sampling equipment must be cleaned prior to use and in between sampling stations.
- d. For chemical analysis, sampling equipment used to collect any combination of metals, extractable organics, volatile organics, pesticides, PCBs, TOC and toxicity testing must be cleaned according to the following procedure.
  - a. Wash with laboratory grade, non-phosphate detergent
  - b. Rinse 3 times with tap water
  - c. Rinse with 5% HNO<sub>3</sub> (only for sampling metals)
  - d. Rinse 3 times with deionized water

- e. Isopropanol rinse (only for sampling organics )
- f. Rinse 3 times with deionized water
- g. Air dry in contaminant free area
- e. sampling equipment for grain size analyses require only soap and water wash with a tap water rinse.

## 5.2 Volume Requirement

- a. Refer to the appropriate section of the tables based on the test being performed.

**TABLE 1 - SAMPLING CONTAINERS, PRESERVATIVES AND HOLDING TIMES**

PARAMETER	MATRIX	CONTAINER <sup>1</sup>	PRESERVATIVE	HOLDING TIME <sup>2</sup>
MERCURY	SED	8 OZ. (P,G) <sup>3</sup> (1/2 full)	ICE TO 4°C (±2°C)	28 DAYS
ALL OTHER METALS	SED	8 OZ. (P,G) (1/2 full)	ICE TO 4°C (±2°C)	180 DAYS
CYANIDE	SED	8 OZ. (P,G)	ICE TO 4°C (±2°C)	14 DAYS
VOA	SED	2 X 40 ML VOA VIALS	ICE TO 4°C (±2°C)	14 DAYS
TOC	SED	1 40 ML VOA VIAL	ICE TO 4°C (±2°C)	28 DAYS
GRAIN SIZE	SED	8 OZ (P,G)	NA	NA
AVS/SEM	SED	20 ml vial	ICE TO 4°C (±2°C)	7days
TOX TESTING	SED	1 GAL <sup>4</sup> (PLASTIC)	ICE TO 4°C (±2°C)	14 DAYS
EXTRACTABLES	SED	8 OZ. (GLASS)	ICE TO 4°C (±2°C)	14 DAYS
PESTICIDE/PCBS	SED	8 OZ. (GLASS)	ICE TO 4°C (±2°C)	14 DAYS

**NOTES:**

1. SAMPLE CONTAINERS MUST BE FILLED COMPLETELY, UNLESS SPECIFIED OTHERWISE
2. HOLDING TIMES ARE MEASURED FROM THE TIME OF SAMPLE COLLECTION.
3. P,G = PLASTIC OR GLASS
4. 2 SPECIES TEST

**5.3 Sediment sampling procedure**

- a. Vertical sediment sampling depths should be based on the projects data quality objective

which are described in the QAPP. Typically, the Ponar and Ekman dredges will collect sediments from the first 6 inches of sediment. However, this will vary greatly based on technique and sediment characteristics. A corer can be used to collect sediments of greater depths. A dredge or a corer should always be used when collecting sediments.

- b. When collecting samples for worst case scenarios an attempt should be made to collect from areas that have depositional sediment with silty organic substrate. Notation should be made of the actual extent of depositional areas in relation to the substrate as a whole.
- c. When collecting sediment at a site, the location where the dredge or corer is dropped should be moved slightly each time in order to avoid collecting in a pocket where sediment has already been removed.
- d. Prior to sampling, samplers should become familiar with the operation of the particular sampling device and proper technique. For example, a Ponar dredge is set for sampling by opening the jaws and inserting the spring loaded pin completely through both holes in the scissor bracket located above the jaws. The Ponar is then lowered below the surface of the water and allowed to drop. Once the Ponar is on the bottom the rope is quickly “jerked” to release and close the jaws. Once at the surface, the water is allowed to drain from the dredge. If coring is required it can be done by hand if water depth allows. The core is driven into the sediment either manually or attached to a corer and then slowly retrieved. When the bottom of the corer is still below the surface, and as soon as it can be reached, a rubber stopper is plugged into the bottom of the core tube. The core is brought to the surface overlying water is decanted off and the specified depth of sediment is taken for subsampling.
- e. Every attempt should be made to reduce the water content in the sample by pouring off overlying water before homogenizing the sample. This should be done by letting the sample settle then slowly and carefully decanting preventing loss of fine particle. A goal of at least 30% solids should be attempted.

#### 5.4 Homogenization and subsampling for analyses

- a. When metals, extractable organics, pesticides, TOC, grain size, PCBs, AVS/SEM and toxicity testing are requested, homogenize the sample in a new pre cleaned 5 gallon plastic pail with a disposable plastic spatula or spoon or cleaned according to procedure 5.1.d. Samples are transferred to the appropriate container using new or precleaned plastic spatulas or spoons.
- b. AVS/SEM samples should be collected immediately after samples have been taken and homogenized. Containers should be filled with no head space.
- c. VOA samples should be taken immediately prior to homogenized filled completely with no

head space.

#### 6.0 Safety

- a. Extreme care should be taken when handling any chemicals. Proper PPE should be worn. Follow OEME's procedure for acid washing and the Health and Safety Plan (HASP) for the project .
- b. When using a boat, refer to OEME's boat operation SOP and follow the HASP for the project.
- c. Be extremely careful when handling and transporting dredges. Always place the storage pin in the dredge when they are not being used. Keep hands away from jaws or scissor bracket.
- d. Always wear proper equipment for the job including waders, PFDs, etc.
- e. When sampling around water be aware of unsafe conditions caused by water depth and speed or slippery substrates.
- f. Take adequate precautions when sampling in extreme weather. Always wear and bring enough clothing and be aware of water temperatures and hypothermia potential.

#### 7.0 Waste Disposal

- a. All isopropanol and acid rinsate from the decontamination procedures is collected in separate labeled waste containers and disposed of according to proper OEME waste disposal procedures .
- b. Soap and water rinsate may be disposed of on site by pouring it onto the soil surface at a reasonable distance from any water body.

#### 8.0 Quality Assurance and Quality Control

- a. Follow all procedures in this SOP and the project specific QAPP.
- b. Consult with the Quality Control officer or designee before deviating from any procedures.
- c. Pay particular attention to the need for rinsate blanks, field duplicates and extra sample volumes for duplicate and spike analyses.

## Standard Operating Procedure

### Trimble Navigation GeoExplorer GPS Receiver

#### On Site

Hold the receiver at eye level with the antennae part horizontal.

Turn the unit on by pressing bottom black button at the bottom of the keypad once.

Go to "3. GPS Status", then select "1. Sat Tracking".

When 4 Satellites are being received, press "ESC,ESC" to the Main Menu

From the "Main Menu", press go to "1. Data Capture" hit yellow diamond key in middle, when Data Capture is flashing.

Press "1. Open Rov. File" once.

Record file name on field sheet.

File name will be created automatically, you can not change file name.

If the number next to "Pts." does not increase, check SV's by pressing "ESC,ESC" to main menu and going into "2. Position"

Make sure 4 SV's are being tracked.

If not signals may be blocked.

Try moving to a different area, there may be tree canopy or buildings blocking the signals.

After 85 Pts. are logged Press "3. Close File", "yes".

ESC to Main Menu and go to 2. Position, record position on field sheet.

To turn unit off, Hold down bottom black button for 5 seconds to turn off.
