Executive Summary

This report presents the results of a post-demolition residual risk assessment (RA) for the entire Reynolds Metals Company (RMC) facility, including Fairview Farms, in Troutdale, Oregon. This work was conducted under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and *Memorandum WP No. 67: Post-Demolition Residual Risk Assessment Scoping Document for RMC-Troutdale* (CH2M HILL, 2005a).

Purpose of This Report

The post-demolition RA documents the final condition at the RMC-Troutdale site after completion of plant demolition and extensive remediation of the property. The site will be developed as a mixed-use general industrial complex consistent with the general industrial zoning currently designated for the property. This report addresses the reasonably anticipated future land uses at the site and considers exposure scenarios for direct contact pathways associated with soil for the most plausible future site users: site trespassers, recreational users, construction workers, excavation/trench workers, and standard occupational workers. An updated ecological risk assessment is also presented for the south wetlands area using current data representative of final conditions.

Background

The *Baseline Risk Assessment* (BLRA) (CH2M HILL, 2000) addressed potential human and ecological exposure pathways associated with soil, surface water, sediment, and biota for conditions existing before the extensive removal and remedial actions were conducted at the site. Since the preparation of the BLRA, removal and remedial actions and plant demolition have significantly reduced contaminated materials on the site, reduced potential sources of exposure, and eliminated certain exposure pathways. Removal of source material also has eliminated sources of contamination to groundwater. In addition, projected future land use changes required consideration of exposure scenarios different from those assumed in the BLRA.

This post-demolition RA builds on the previous BLRA work and evaluates residual risks now that removal and remedial actions are complete. Exposure to groundwater, surface water, sediment, and historical soil sources have been addressed by the BLRA and by the *Reynolds Metals Company Record of Decision for Interim Action* (U.S. Environmental Protection Agency [EPA], 2002) and are not addressed in this report.

Purpose of the Post-Demolition Risk Assessment

The purpose of this post-demolition RA is to estimate the realistic potential for risk to human health and ecological receptors posed by chemicals of potential concern present at the site following plant demolition and extensive remediation.

This post-demolition RA was conducted using standard EPA methodologies as well as additional approaches and assumptions agreed to by RMC, EPA, and the Oregon

Department of Environmental Quality (DEQ). The resulting risk estimates, along with other factors, serve as the basis of risk management decisions for the RMC-Troutdale site.

The main objective of the human health RA is to determine whether residual concentrations of chemicals in soil result in cancer or noncancer risks that exceed regulatory risk threshold levels. A consideration of reasonably anticipated future land uses provides identification of the most feasible human exposure pathways for future use of the RMC-Troutdale site.

The main objective of the ecological RA is to update the south wetlands ecological risk assessment that was presented in the BLRA, using characterization data representative of final site conditions and the most current regulatory guidance. The purpose is to document the effectiveness of a polychlorinated biphenyl (PCB) removal action in this area in September 1999, and to consider additional sampling data (since the BLRA) from the railroad embankment, south landfill, north landfill, and Company Lake. Ecological evaluations for other areas at the RMC-Troutdale site were documented in the BLRA.

Revised Conceptual Site Model

The physical setting of the site has changed since the BLRA because significant removal actions have been performed and plant buildings and structures have been demolished. In addition, a considerable amount of contamination has been removed, and projected land use conditions have been clarified.

Projected Future Land Uses

The RMC-Troutdale site will be developed as a mixed-use general industrial complex consistent with the general industrial zoning currently designated for the property. The site will be subdivided and built out over an extended period of time.

Proposed Exposure Areas

This post-demolition RA evaluates the entire RMC-Troutdale site, including Fairview Farms to the west and areas outside the dike to the north. The risk assessment was performed on four discrete exposure areas. These four areas are as follows:

1. Fairview Farms
2. Outside the dike
3. South wetlands
4. East Area (former plant area east of Sundial Road)

Human Receptors and Exposure Routes

The exposure scenarios appropriate for each of the identified areas are presented in Table ES-1.

Table ES-1 Summary of Scope						
Exposure Area	Human Health					Ecological
	Short-Term Trespasser	Recreational User	Construction Worker	Excavation/Trench Worker	Occupational Worker	
Outside the Dike	X	X				
Fairview Farms	X		X	X	X	
East Area	X		X	X	X	
South Wetlands	X		X	X		X

Human Health Risk Assessment Findings

Risk Quantification Results

The exposure assessment component of the risk assessment identifies the means by which individuals on or near the Troutdale site may contact chemicals in environmental media. The estimation of potential exposure requires specific assumptions to describe potential exposure situations. Upper-bound exposure assumptions are used to define reasonable maximum exposure (RME) conditions to provide a bounding estimate on exposure. In accordance with *Guidance for Conduct of Deterministic Human Health Risk Assessments* (DEQ, 2000a), deterministic risk assessments should also define central tendency estimates (CTEs) of exposure and risk. The results of the human health risk assessment are presented in Table ES-2.

Table ES-2 Human Health Risk Assessment Results Summary					
Exposure Area	Exposure Scenario	Excess Lifetime Cancer Risk		Noncancer Hazard Index (RME and CTE)	Primary Excess Lifetime Cancer Risk Contributors (approximate percent contribution)
		CTE	RME		
Fairview Farms	Short-Term Trespasser	1×10^{-8}	2×10^{-7}	<1	None
	Construction Worker	3×10^{-8}	2×10^{-7}	<1	None
	Excavation/Trench Worker	1×10^{-9}	6×10^{-9}	<1	None
	Occupational Worker	2×10^{-7}	2×10^{-6}	<1	None
Outside the Dike	Short-Term Trespasser	1×10^{-7}	2×10^{-6}	<1	None
	Recreational User	1×10^{-7}	2×10^{-6}	<1	None
South Wetlands	Short-Term Trespasser	8×10^{-7}	1×10^{-5}	<1	Benzo(a)pyrene ELCR = 3×10^{-6} (32%) Dibenzo(a,h)anthracene ECLR = 2×10^{-6} (21%)
	Construction Worker	4×10^{-7}	3×10^{-6}	<1	None
	Excavation/Trench Worker	4×10^{-8}	3×10^{-7}	<1	None

Table ES-2
Human Health Risk Assessment Results Summary

Exposure Area	Exposure Scenario	Excess Lifetime Cancer Risk		Noncancer Hazard Index (RME and CTE)	Primary Excess Lifetime Cancer Risk Contributors (approximate percent contribution)
		CTE	RME		
East Area	Short-Term Trespasser	9×10^{-8}	1×10^{-6}	<1	None
	Construction Worker	4×10^{-7}	2×10^{-6}	≤ 1	None
	Excavation/Trench Worker	1×10^{-8}	9×10^{-8}	<1	None
	Occupational Worker	1×10^{-6}	1×10^{-5}	<1	Benzo(a)pyrene ELCR = 5×10^{-6} (38%) Arsenic ELCR = 2×10^{-6} (17%)

This table provides the excess lifetime cancer risk and noncancer hazard index results for each exposure area and exposure scenario evaluated in this report. Also provided in Table ES-2 is a summary of the primary risk contributors and their respective contributions to the total area-specific risk estimate, when appropriate.

Comparison with Target Risk Levels

Risks for each exposure area are evaluated relative to goals established by DEQ that define acceptable risk for individual carcinogenic compounds to be set at one in one million (1×10^{-6}) excess risk for cancer and one in one hundred thousand (1×10^{-5}) for cumulative risks from carcinogenic compounds. Acceptable risk for noncarcinogenic constituents is set at a hazard index equal to 1. If calculated risks within an exposure area are below these target risk levels, risks are assumed to be acceptable and no further evaluation or action will be taken. This comparison is provided in Table ES-3.

Table ES-3
Comparison of Human Health Risk Results with Regulatory Risk Criteria

Exposure Area	Exposure Scenario	DEQ Target Risk Exceedance—Is Total ELCR > 1×10^{-5}?		Is Total HI for RME and CTE > 1.0?	Are Individual Chemical ELCRs > 1×10^{-6}?
		CTE	RME		
Fairview Farms	Short-Term Trespasser	No	No	No	No
	Construction Worker	No	No	No	No
	Excavation/Trench Worker	No	No	No	No
	Occupational Worker	No	No	No	No
Outside the Dike	Short-Term Trespasser	No	No	No	No
	Recreational User	No	No	No	No
South Wetlands	Short-Term Trespasser	No	No	No	Yes. ^a Two polynuclear aromatic hydrocarbons (PAHs)
	Construction Worker	No	No	No	No
	Excavation/Trench Worker	No	No	No	No

Table ES-3 Comparison of Human Health Risk Results with Regulatory Risk Criteria					
Exposure Area	Exposure Scenario	DEQ Target Risk Exceedance—Is Total ELCR $> 1 \times 10^{-5}$?		Is Total HI for RME and CTE > 1.0 ?	Are Individual Chemical ELCRs $> 1 \times 10^{-6}$?
		CTE	RME		
East Area	Short-Term Trespasser	No	No	No	No
	Construction Worker	No	No	No	No
	Excavation/Trench Worker	No	No	No	No
	Occupational Worker	No	No	No	Yes. One PAH and arsenic. Arsenic concentrations are at background levels.

^a Individual chemical ELCRs do not exceed 1×10^{-6} when assuming a more realistic trespass frequency of less than 11 days per year at south wetlands, as described in Section 4.6.2 of the main report.

The Troutdale site meets DEQ's 1×10^{-5} cumulative target risk and total hazard index (less than 1.0) for the CTE case for all human health exposure scenarios. The site also meets the 1×10^{-6} individual target risk criterion for the CTE case for all human health exposure scenarios.

For the RME case, the Troutdale site meets DEQ's 1×10^{-5} cumulative target risk and total hazard index (less than 1.0) for all human health exposure scenarios. The site also meets the 1×10^{-6} individual target risk criterion, except for the RME site trespasser scenario at south wetlands and the RME occupational worker scenario at the East Area. However, the individual target risk criterion is not exceeded for these two areas under the CTE scenario. The slight exceedance of the 1×10^{-6} individual target risk for the RME site trespasser scenario at south wetlands is not considered significant in light of the results seen for the CTE case for this site. An additional calculation indicated that even if the trespass frequency were assumed to be 11 days per year, there would be no exceedances of the 1×10^{-6} individual target risk for this area. For trespass exposure at south wetlands, an exposure frequency of about 5 days per year (assumed under the CTE case) is more reasonable than the 26 days per year assumed under the RME case,¹ and results in acceptable risk. In addition, the thick vegetation and standing water would serve to minimize direct contact with soil at south wetlands.

In addition to the above risk estimates, all soil samples in the Fairview Farms area, outside the dike area, south wetlands, and East Area met the risk-based screening levels identified in DEQ's *Risk-Based Decision Making for the Remediation of Petroleum-Contaminated Sites* (DEQ, 2003), except one sample in south wetlands.

South Wetlands Ecological Risk Assessment Findings

A post-demolition residual ecological RA was performed for south wetlands to document the effectiveness of a PCB removal action in this area in September 1999, and the addition of

¹ The exposure frequency of 26 days per year was used as a high-end default in the BLRA and was carried over here for consistency, but it does not reflect actual trespass observed at south wetlands.

sampling data (since the BLRA) from the railroad embankment. The ecological RA provides an assessment of the potential impacts on wildlife of residual concentrations at south wetlands, assuming that site development does not occur. If the area is developed in the future, then the ecological risk results will become invalid at that time. Additional areas at the RMC site where ecological exposures could occur were previously addressed during the BLRA.

This ecological RA for south wetlands was conducted using a tiered approach, structured to focus the ecological RA on the contaminants of potential ecological concern and receptors with the greatest potential for ecological exposure. Tier 1 consists of a screening-level ecological assessment that serves to narrow the field of chemicals detected in site media to those that are of most concern to ecological receptors. Tier 2 uses site-specific information to provide more realistic exposure estimates and to better characterize risk for south wetlands, but only for those chemicals and receptors that were not screened out during Tier 1.

The previous BLRA indicated that the contaminants of potential ecological concern with the highest potential for ecological exposure were PCBs, primarily in south wetlands, and fluoride and polynuclear aromatic hydrocarbons (PAHs), primarily within Company Lake. Since the BLRA, these constituents have been addressed by the remedial actions at Company Lake (as outlined in the interim Record of Decision [EPA, 2002]) and the PCB removal action in September 1999 at south wetlands.

The results of the Tier 2 ecological RA presented here indicate that these actions have been effective in further reducing ecological risk in south wetlands within acceptable levels. The removal action at south wetlands was effective at reducing the PCB exposure point concentration in surface soil by 65 percent.

Conclusion

Using the results of this post-demolition residual risk assessment, RMC has demonstrated that acceptable risk levels have been achieved for the property such that deed restrictions on soil are not required for the potential exposure scenarios evaluated, except as presupposed in the evaluation. These presuppositions include prohibiting residential use of the site and requiring that clean fill is placed over south wetlands prior to occupational use. RMC has accomplished this level of risk reduction by eliminating sources of contamination to the groundwater and to human and ecological receptors through soil removal, capping, offsite disposal, and grading. No further remedial action is anticipated.

SECTION 1

Introduction

This report presents the results of a post-demolition residual risk assessment (RA) for soil at the Reynolds Metals Company (RMC) facility in Troutdale, Oregon. This work was conducted under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and *Memorandum WP No. 67: Post-Demolition Residual Risk Scoping Document for RMC-Troutdale* (Risk Scoping Document) (CH2M HILL, 2005a).

The post-demolition RA documents the final condition at the Troutdale site following plant demolition and extensive remediation, prior to the sale and development of the property. It addresses the reasonably anticipated future land uses at the site and considers exposure scenarios for direct contact pathways associated with soil for the most plausible future site users: site trespassers, recreational users, construction workers, excavation/trench workers, and standard occupational workers. An updated ecological risk assessment is also presented for the south wetlands area using current data representative of final conditions.

This report contains the following sections:

- Section 1 presents the background and overall purpose of the post-demolition RA
- Section 2 presents the revised conceptual site model
- Section 3 describes the process used to select representative data for use in the post-demolition RA
- Section 4 is the human health risk assessment (HHRA)
- Section 5 is the updated ecological risk assessment (ERA) for the south wetlands area
- Section 6 identifies major uncertainties and assumptions
- Section 7 presents the conclusions of the post-demolition remedial investigation/risk assessment (RI/RA) process
- Section 8 presents the references cited in this report

1.1 Background

The *Baseline Risk Assessment* (BLRA) (CH2M HILL, 2000) addressed potential human and ecological exposure pathways associated with soil, surface water, sediment, and biota for conditions existing before the extensive removal and remedial actions were conducted at the site over the past 6 years. Since the preparation of the BLRA, removal and remedial actions and plant demolition have significantly reduced contaminated materials on the site, as well as potential sources of exposure. Removal of source material also has eliminated sources of contamination to groundwater. In addition, projected future land use changes require consideration of exposure scenarios different from those assumed in the BLRA.

This post-demolition RA builds on the previous BLRA work and evaluates residual risks from soil now that removal and remedial actions are complete. Current soil conditions and a history of removal and remedial actions conducted at the site are provided in the *Post-Demolition Remedial Investigation Report* (Post-Demolition RI) (CH2M HILL, 2006).

Groundwater risks have been addressed by the interim Record of Decision (ROD) (U.S. Environmental Protection Agency [EPA], 2002) and are not addressed in this report.

Removal and remedial actions resulted in removing sources of contamination for human and ecological exposure, as well as sources of contamination to groundwater. In total, soil removal and remedial actions removed more than 348,000 tons of material. This tonnage contained over 7,300 tons of fluoride that was disposed of offsite in approved landfills. Historical (pre-demolition) soil remedial actions and those removal actions undertaken as part of the interim ROD accounted for over 232,000 tons of material that were the major source of contamination to the intermediate and deep groundwater zones. Removal of this material significantly reduces the migration of fluoride to these zones. These historical actions (and dates of action) included:

- Carbon Bake Sumps (1997)
- Casthouse/PCB Spill Area (1995, 1998-1999)
- Company Lake (2001, 2003-2005)
- Cryolite Ponds (1995-1996)
- Diesel Spill Area (1994-1995)
- East Potliner (1995-1996)
- North Landfill (2003)
- Scrap Yard (2002, 2004)
- South Ditch (1995, 1998-1999)
- South Landfill (2003-2004)
- South Wetlands (1999)
- Wet Electrostatic Precipitator (1997)

These actions are identified in Section 7.1.1 of the Post-Demolition RI, with references provided in Table 7-2 and quantities provided in Table 7-4.

The most recent actions taken during the demolition phase of the project are described in Section 7.1.2 of the Post-Demolition RI, with references provided in Table 7-3, quantities in Table 7-4, and locations in Figure 7-2. Recent actions (and dates of action) have been taken at the following locations:

- Building 97, Building 98, and Building 34 (2005)
- Bunker C Area (2005)
- Cryolite Plant Area (2005)
- East of Building 52 (2006)
- East Plant Area at or near buildings and structures (2004-2005)
- Field West of Potline 5 (2005-2006)
- Rectifier Yard (2005)
- Sample Area 12 and ADD3 (2005)
- Scrap Yard Area Road (2005-2006)
- South Ditch and Banks (2005)

- Storage Areas 1 Through 7 (2005-2006)
- West Railroad Fill/Embankment (2006)

1.2 Purpose of the Risk Assessment

The purpose of this post-demolition RA is to estimate the realistic potential for risk to human health and ecological receptors posed by chemicals of potential concern (COPCs) present at the site following plant demolition and extensive remediation. This post-demolition RA was conducted using standard EPA methodologies, as well as additional approaches and assumptions agreed to by RMC, EPA, and the Oregon Department of Environmental Quality (DEQ) in a series of meetings in 2004 and 2005. The methodology and assumptions used in this post-demolition RA were documented in the Risk Scoping Document, which was accepted by EPA and DEQ.

The main objective of the HHRA is to determine whether residual concentrations of chemicals in soil result in cancer or noncancer risks that exceed regulatory risk threshold levels. A consideration of reasonably anticipated future land uses provides identification of the most feasible human exposure pathways for future use of the RMC-Troutdale site.

The main objective of the ERA is to update the south wetlands ecological risk assessment that was presented in the BLRA, using characterization data representative of final site conditions and the most current regulatory guidance. The purpose is to document the effectiveness of a polychlorinated biphenyl (PCB) removal action in this area in September 1999, and to consider additional sampling data (since the BLRA) from the railroad embankment, south landfill, north landfill, and Company Lake. Ecological evaluations for other areas at the RMC-Troutdale site were documented in the BLRA.

SECTION 2

Revised Conceptual Site Model

This section provides the revised conceptual site model (CSM) for the RMC-Troutdale site, considering changes that have taken place since the BLRA. The physical setting of the site has changed since the BLRA because significant removal and remedial actions have been performed and plant buildings and structures have been demolished. In addition, a considerable amount of contamination has been removed, and projected land use conditions have been clarified.

2.1 Projected Future Land Uses

The RMC-Troutdale site will be developed as a mixed-use general industrial complex consistent with the general industrial zoning currently designated for the property. The site will be subdivided and built out over an extended period of time. The planned development will likely cover virtually all of the current RMC-Troutdale property within the dike with buildings, asphalt, concrete, fill material, rail beds, and landscaping. The development plans consider that the RMC-Troutdale site will consist of the following types of land uses:

- Green Open Space (north of the dike)
- Mixed General Industrial (Fairview Farms, east plant areas, and the south wetlands area)

The potential exposure scenarios considered for the assessment of residual risk (described below) are consistent with the current and future land uses anticipated for the site.

2.2 Proposed Exposure Areas

This post-demolition RA evaluates the entire RMC-Troutdale site, including Fairview Farms to the west and areas outside the dike to the north. The risk assessment was performed on four discrete exposure areas (as outlined in the approved Risk Scoping Document), delineated on the basis of similar historical uses and associated contaminant releases. In addition, these exposure areas are anticipated to provide risk estimates that would adequately represent reasonably anticipated future uses of the site. These four areas are as follows:

- Fairview Farms
- Outside the dike
- South wetlands
- East Area (former plant area east of Sundial Road)

Table 2-1 summarizes the components of each of these categories. Table 2-1 also lists areas where early actions have been completed. The *Post-Demolition Remedial Investigation Report* (CH2M HILL, 2006) contains a summary of these actions and references for further

information. The boundaries of these four exposure areas are shown on Figure 2-1 and are described in the following subsections.

2.2.1 Exposure Area 1: Fairview Farms

The Fairview Farms area (essentially all areas west of Sundial Road, comprising approximately 277 acres) is planned for industrial development.² This area has not been previously used for industrial purposes, and verification sampling indicates very low levels of site constituents. On the basis of the projected future land use, the most plausible exposure scenarios at Fairview Farms are site trespasser (short term), construction worker (near term), and excavation/trench worker (long term). The trespasser exposure scenario would apply before development. The construction worker exposure scenario would apply during development, and the excavation/trench worker exposure scenario would apply after construction (assuming that, because of development, contact with site soil could occur only during excavation).

The conceptual development plans for the Troutdale site include development of the Fairview Farms area as part of a mixed-use general industrial complex. With this planned use, virtually all of the area would be covered with structural fill, railways, rail bed ballast (crushed rock), paved roadways and parking areas, structures, and landscaping. Because of the size of the complex and the potential spatial differences in historical releases, the western portion of the complex (the Fairview Farms area) is considered separately from the eastern portion. In addition to the site-specific scenarios mentioned above, an occupational worker exposure scenario is included to demonstrate whether controls may be necessary to ensure acceptable risk.

2.2.2 Exposure Area 2: Outside the Dike

The area outside the dike (approximately 177 acres) is located within a floodplain and could not be built upon unless it were rezoned and filled. If filled, the area would be considered capped, greatly reducing any existing risk. Additionally, source materials in Company Lake have been removed as a part of the interim ROD actions. Company Lake and portions of the area adjacent to Company Lake will be restored and set aside for open space under the Natural Resource Damage Assessment (NRDA) settlement with the natural resource trustees. Therefore, the trespasser exposure scenario would apply for areas outside the dike until the area becomes available for recreational use, and the recreational exposure scenario would apply thereafter.

2.2.3 Exposure Area 3: South Wetlands

The south wetlands area (approximately 28 acres) is considered separate and distinct from other areas because it is currently a wetland and would need to be covered by considerable fill material in order to develop the property. In addition, because of the presence of existing habitat, a residual risk evaluation for potential ecological pathways was conducted for this area to document the effectiveness of a PCB removal action that occurred in September 1999, and the addition of sampling data (since the BLRA) from the railroad embankment. Plausible human exposure scenarios include a site trespasser scenario under current conditions, a

² Although recent land use at the westernmost end of Fairview Farms has been agricultural, this area is to be incorporated into industrial property for redevelopment.

construction worker (modified) scenario for development and fill preparation, and a potential future excavation/trench worker scenario if a pipeline or utilities are laid through the area when (and if) the area is filled for development. An occupational worker scenario was not evaluated for this area because extensive filling of the south wetlands area would be required before traditional construction or industrial use could begin.

2.2.4 Exposure Area 4: East Area, Comprising Former Plant Area East of Sundial Road

The East Area (approximately 254 acres) includes the former plant area and areas to the east and south outside the current plant fenceline. On the basis of the projected future land uses, the most plausible exposure scenarios are site trespasser (short term), construction worker (near term), and excavation/trench worker (long term). The trespasser exposure scenario would apply before development. The construction worker exposure scenario would apply during development, and the excavation/trench worker exposure scenario would apply after development since contact with site soil could occur only during an excavation. The conceptual development plans for the Troutdale site include development of the East Area as part of a mixed-use general industrial complex. These areas would be covered with structural fill, railways, rail bed ballast (crushed rock), roadways, parking areas, structures, and/or landscaping as part of development. In addition to the site-specific scenarios mentioned above, an occupational worker exposure scenario is included to demonstrate whether controls may be necessary to ensure acceptable risk.

2.3 Conceptual Exposure Model

The conceptual exposure model for the RMC-Troutdale site is shown in Figure 2-2. The model indicates that the following three general pathways of exposure to residual constituents in soil are potentially complete:

- Direct contact with contaminant in surface soil (before and during development)
- Direct contact with contaminant in subsurface soil (during and after development)
- Dust generated from wind (before and during development)

All other pathways are addressed in the BLRA and the interim ROD, including those associated with exposure to groundwater, surface water, and sediment, or soil sources that have been remediated as a part of the interim ROD. This post-demolition RA addresses existing soil under current conditions.

2.3.1 Human Receptors and Exposure Routes

On the basis of current and potential future land uses at the site, potentially complete human exposure pathways for each of the exposure areas exist for the following receptors and exposure routes:

- Incidental ingestion of and dermal contact with surface soil by trespassers, recreational users, and/or construction workers (depending on exposure area)
- Incidental ingestion of and dermal contact with subsurface soil by excavation and construction workers (depending on exposure area)

- Inhalation of dust in ambient air by trespassers, recreational users, and/or excavation and construction workers (depending on exposure area)

Once the area inside the dike is developed, direct contact pathways for surface soil are anticipated to be incomplete, therefore minimizing the potential for future exposure under the standard occupational worker scenario. However, an occupational scenario is evaluated to demonstrate the potential need for institutional controls on soil to ensure acceptable risk. The exposure scenarios appropriate for each of the identified exposure areas are summarized in Table 2-2. The locations where these exposure scenarios apply are shown in Figure 2-1. The exposure assumptions associated with each exposure scenario are described in Section 4.

The ecological risk assessment has already been performed in the BLRA for all appropriate areas at the site. Ecological evaluations are not appropriate where the land is disturbed, such as at the former plant site or where the land will be developed in the future (for example, the Fairview Farms area).³ The south wetlands area requires an ecological evaluation update because remediation and additional data collection have occurred in this area since the BLRA, and the residual risk remaining at the site has decreased as a result of that removal action. The ecological conceptual exposure model provided in Figure 2-4 of the BLRA still applies to south wetlands.

³ At the request of EPA and DEQ, a comparison of submerged Company Lake verification sediment samples to applicable sediment regulatory benchmarks will document current, post-remediation conditions.

SECTION 3

Selection of Representative Data

The analysis of health risks uses chemical data generated during the post-demolition remedial investigation (PDRI), as well as from previous investigations and removal and remedial actions. These data were evaluated to determine the degree to which they represent current conditions at the site, and whether they are usable for assessing the residual risk remaining at the Troutdale facility. Soil analytical data were obtained from the vast number of references provided in the *Post-Demolition Remedial Investigation Report* (CH2M HILL, 2006).

The data were reviewed for completeness and representativeness. The available soil sample data collected at the site since 1994 initially were sorted according to the four exposure areas identified. The data for each exposure area were then evaluated for exclusion from the post-demolition RA for the following reasons:

- Sample was not soil⁴
- Sample was not on RMC property or along the adjacent shoreline and was not considered representative of site releases
- Sample was in an area where excavation has occurred to remove the contaminated soil
- Sample is currently more than 10 feet below ground surface, and therefore not subject to direct contact exposure
- Sample is beneath a cap placed over the contaminated material, making it inaccessible to a receptor

In cases where excavation or soil capping had occurred, the original sample depth was adjusted to reflect the current depth. This may have resulted in the inclusion or exclusion of some samples as their depths changed. Duplicate samples were processed in accordance with the procedure described in Section 4.3. On the basis of this sample selection process, the number of samples found usable for the risk assessment are as follows:

- Fairview Farms – 49 samples
- Outside the dike – 104 samples
- South wetlands – 142 samples
- East plant – 875 samples

Tables 3-1 through 3-4 list the station identifications (IDs), sampling dates, and depths for soil samples considered representative of final site conditions and that were used in the post-demolition RA. Figure 3-1 shows the locations of these samples.

⁴ Samples for waste characterization analyses were excluded from the risk assessment data set.

SECTION 4

Human Health Risk Assessment

4.1 Organization of This Section

The human health risk assessment for the Troutdale facility is composed of the following components:

- **Human Health Risk Assessment Guidance.** Lists the guidance documents used for the risk assessment.
- **Chemicals of Potential Concern and Data Evaluation.** Identifies the constituents considered to be most important to the human health risk quantification process.
- **Human Exposure Assessment.** Identifies the pathways by which potential human exposures could occur, describes how they are evaluated, and evaluates the magnitude, frequency, and duration of these exposures.
- **Toxicity Assessment for Human Health.** Summarizes the toxicity of the selected chemicals and the relationship between magnitude of exposure and the occurrence of adverse health effects.
- **Human Health Risk Characterization.** Integrates information from the exposure and toxicity assessments to characterize the risks to human health from potential exposure to chemicals in environmental media.

4.2 Human Health Risk Assessment Guidance

The procedures used for the human health risk assessment are consistent with those described in the following guidance documents:

- *Guidance for Conduct of Deterministic Human Health Risk Assessments* (DEQ, 2000a)
- *Risk-Based Decision Making for the Remediation of Petroleum-Contaminated Sites* (DEQ, 2003)
- *Risk Assessment Guidance for Superfund – Volume I: Human Health Evaluation Manual, Part A (Interim Final)* (RAGS), EPA/540-1-89/002 (EPA, 1989)
- *Human Health Evaluation Manual, Supplemental Guidance: Standard Default Exposure Factors* (EPA, 1991)
- *Exposure Factors Handbook* (EPA, 1997a)
- *Risk Assessment Guidance for Superfund – Volume I: Human Health Evaluation Manual, Part E Supplemental Guidance for Dermal Risk Assessment (Final)* (EPA, 2004a)
- *Guidelines for Carcinogen Risk Assessment* (EPA, 2005a)

The first two guidance documents were released by DEQ after the BLRA was completed. Pertinent exposure assumptions for the construction worker, excavation/trench worker, and occupational worker scenarios are used from these sources.

4.3 Chemicals of Potential Concern and Data Evaluation

COPCs are those chemicals that should be carried through the human health risk quantification process. Data sources, identification of usable laboratory data, and methodology of identification of COPCs are consistent with methods used in the BLRA (CH2M HILL, 2000).

Soil to a depth of approximately 10 feet (ft) below ground surface (bgs) was considered for the excavation/trench worker and construction worker scenarios, in accordance with DEQ guidance (DEQ, 2003). Soil to a depth of approximately 1 ft bgs was considered for the trespasser, recreational user, and occupational worker scenarios.

Laboratory analytical data were reviewed to determine their reliability for use in the risk assessment. The data review consisted of the following checks to identify usable data:

- Estimated values flagged with a "J" qualifier were treated as qualified detected concentrations.
- Data for detected constituents that were also detected in method blanks were not used in the risk assessment, in accordance with EPA guidance.
- For duplicate samples, the following procedure was applied: (a) if there were two detections, the average detection value was used; (b) if there was one detection and one nondetection, the detected value was used; (c) if there were two nondetections, the lowest detection limit was used.
- Data qualified with an "R" (rejected) were not used in the risk assessment and were not included in the total count of samples analyzed for a constituent.

4.3.1 Identification of COPCs for Human Health

Soil samples collected during the life of the RMC-Troutdale project have been analyzed for constituents based on knowledge of plant processes and RMC's long history of site investigation and remediation at this and other aluminum reduction plants around the world. The confirmation sampling conducted as part of the PDRI focused on those constituents that were anticipated to be historically used or released at that specific location that could have resulted in localized releases to soil. To supplement this focused sampling, a full suite of laboratory analysis was performed on 5 percent of the samples to document the absence or presence of other COPCs. This effort proved that the COPCs identified below are the correct subset of compounds for the site.

The COPCs for the human health risk assessment were identified for each exposure area using three main criteria:

- The chemical was detected in at least 5 percent of the samples
- Concentrations exceeded background values for inorganics
- Agency-derived toxicity values exist for the chemical

Concentrations of each metal detected were compared with background levels for the same soil types. Background levels were obtained from the BLRA. Inorganic chemical concentrations detected at or below background levels are excluded as COPCs. Table 4-1 summarizes the COPCs identified for each of the exposure areas, for both surface soil (0 to 1 ft bgs) and subsurface soil (0 to 10 ft bgs). The reason for elimination of a chemical as a COPC is provided for chemicals not retained for further evaluation.

Petroleum compounds were not evaluated in the same manner as other COPCs in this risk assessment. Rather, for each exposure area where they occurred, gasoline, diesel, and total petroleum hydrocarbon (TPH) concentrations were compared with the risk-based screening levels in DEQ's *Risk-Based Decision Making for the Remediation of Petroleum-Contaminated Sites* (DEQ, 2003).

4.3.2 Calculation of Exposure Point Concentrations

For each exposure area, exposure point concentrations (EPCs) for COPCs in surface soil and subsurface soil were calculated as the lesser of either the maximum value or the 95th percentile upper confidence limit (UCL) of all results, in accordance with EPA guidance. Summary statistics were calculated for each chemical and each exposure area. The EPA statistical tool, ProUCL, was used to calculate the EPCs and identify the statistical distribution type for each analyte including normal, lognormal, or nonparametric distribution types. For cases where risk estimates only slightly exceed DEQ's regulatory target risk thresholds using the 95th percentile UCL, the EPCs for the major contributing chemicals were recalculated to determine the 90th percentile, in accordance with DEQ guidance (DEQ, 2000a). The summary statistics and EPCs for each of the exposure areas are provided in Tables 4-2 through 4-9.

4.4 Human Exposure Assessment

The exposure assessment component of the risk assessment identifies the means by which individuals on or near the Troutdale site may contact chemicals in environmental media. It addresses exposures that may result under current site conditions and from reasonably anticipated potential uses of the site and the surrounding areas in the future. The exposure assessment also identifies the populations that may be exposed, the routes by which these individuals may become exposed, and the magnitude, frequency, and duration of potential exposures.

The estimation of potential exposure requires specific assumptions to describe potential exposure situations. Upper-bound exposure assumptions are used to define reasonable maximum exposure (RME) conditions to provide a bounding estimate on exposure. In accordance with DEQ guidance (DEQ, 2000a), deterministic risk assessments should also define central tendency estimates (CTEs) of exposure and risk. The exposure parameters used for generating RME and CTE risk estimates are as listed in Tables 4-10 and 4-11, respectively, and are described in the following subsections. The equations used to calculate direct contact exposures to contaminants in site soil are the same as those provided in Sections 3.4.2 and 3.4.3 of the BLRA (CH2M HILL, 2000).

4.4.1 Trespasser Scenario

For the trespasser scenario, it is assumed that this person would be exposed to site contaminants for 5 days per year for 5 years under the CTE scenario and for 26 days per year for 5 years under the RME scenario (CH2M HILL, 2000). It is assumed that this person is a 35-kilogram [kg] adolescent and could be exposed to chemicals in surface soil via dermal contact, incidental ingestion, and inhalation of particulates.

4.4.2 Recreational User Scenario

For the recreational user scenario, it is assumed that this person would be exposed to site contaminants for 5 days per year for 5 years under the CTE scenario and for 26 days per year for 5 years under the RME scenario. It is assumed that this person is a 35-kg adolescent and could be exposed to chemicals in surface soil via dermal contact, incidental ingestion, and inhalation of particulates.

4.4.3 Construction Worker Scenario

For the construction worker scenario, it is assumed that this worker would be exposed to site contaminants for 250 days per year for 0.5 year under the CTE scenario and for 250 days per year for 1 year under the RME scenario. These assumptions are consistent with *Risk-Based Decision Making for the Remediation of Petroleum-Contaminated Sites* (DEQ, 2003). However, the DEQ default exposure frequency for a construction worker scenario (250 days per year) was modified for south wetlands to a site-specific value of 90 days per year to reflect a 3- to 4-month working timeframe of July through October.⁵ It is assumed that this worker is a 70-kg adult that could be exposed to chemicals in soil via dermal contact, incidental ingestion, and inhalation of particulates.

4.4.4 Excavation/Trench Worker Scenario

For the excavation/trench worker scenario, it is assumed that this worker would be exposed to site contaminants for 9 days per year for 0.5 year under the CTE scenario and for 9 days per year for 1 year under the RME scenario, following *Risk-Based Decision Making for the Remediation of Petroleum-Contaminated Sites* (DEQ, 2003). It is assumed that this worker is a 70-kg adult that could be exposed to chemicals in subsurface soil via dermal contact, incidental ingestion, and inhalation of particulates.

4.4.5 Occupational Worker Scenario

As previously noted, use of any portion of the site for industrial purposes would require extensive development of infrastructure, including railways, roadways, parking areas, buildings, or associated landscaping. Actual post-development exposures will be significantly reduced by the placement of these infrastructure materials. Because of the limited access to surface soil after development, standard occupational exposures are not anticipated. However, an occupational worker scenario is evaluated for the Fairview Farms area and East Area under a worst-case assumption that workers would occupy the site before placement of infrastructure and be potentially exposed to the entire exposure area

⁵ The south wetlands area is below the seasonal water table, supports dense hydrophytic vegetation, and has standing water for a significant portion of the year.

without any barrier materials. It is assumed that an occupational worker would be exposed to site contaminants for 250 days per year for 6 years under the CTE scenario and for 250 days per year for 25 years under the RME scenario, following *Risk-Based Decision Making for the Remediation of Petroleum-Contaminated Sites* (DEQ, 2003).

4.5 Toxicity Assessment for Human Health

This toxicity assessment evaluates the relationship between the magnitude of exposure to a chemical at the former site and the likelihood of adverse health effects to potentially exposed human populations. This assessment provides, where possible, a numerical estimate of the increased likelihood of adverse effects associated with chemical exposure (EPA, 1989). In accordance with EPA guidance, toxicity values (cancer slope factors and noncancer reference doses) to be used were obtained from the following sources (EPA, 2003):

- Integrated Risk Information System (IRIS), an electronic database available through the EPA National Center for Environmental Assessment (NCEA) in Cincinnati, Ohio (EPA, 2005b). The IRIS database is prepared and maintained by EPA and contains of health risk and EPA regulatory information on specific chemicals.
- Provisional Peer Reviewed Toxicity Values (PPRTVs), provided by the EPA Superfund Health Risk Technical Support Center. The PPRTVs are developed on a chemical-specific basis when requested under EPA's Superfund program.
- Health Effects Assessment Summary Tables (HEAST), provided by the EPA Office of Solid Waste and Emergency Response. HEAST is a compilation of toxicity values published in health effects documents issued by EPA and is intended for use in Superfund and Resource Conservation and Recovery Act (RCRA) programs.
- U.S. EPA Region IX Preliminary Remediation Goal (PRG) Table (EPA, 2004b) available at <http://www.epa.gov/region09/waste/sfund/prg/index.htm>.

The primary source of toxicity values is the EPA IRIS database. If a toxicity value is not available from IRIS, then the latest available values from the other sources are used. Toxicity values for COPCs present at the Troutdale facility are shown in Tables 4-12 and 4-13, for the oral and inhalation routes, respectively.

4.6 Human Health Risk Characterization

The risk characterization for each exposure area provides estimates of risk to human health based on the identified COPCs, the exposure scenarios, and toxicity information. The assessment includes excess lifetime cancer risk (ELCR) estimates and noncancer hazard index (HI) calculations (a comparison of intake of noncarcinogenic compounds with acceptable intake rates). Risk characterization considers the nature and weight of evidence supporting these estimates, as well as the magnitude of uncertainty surrounding such estimates. The human health risk posed by each exposure area is calculated using a two-step process as described in Section 3.5 of the BLRA (CH2M HILL, 2000): (1) calculate chemical-specific risk (either ELCR or hazard quotient [HQ]) from the EPCs for each contaminant, and (2) sum the risk

estimates from all contaminants to estimate the aggregate ELCR or HI for each exposure area.

4.6.1 Target Risk Levels

Risks for each exposure area are evaluated relative to goals established by DEQ in Oregon Administrative Rule (OAR) 340-122-0115(1) and Oregon Revised Statute (ORS) 465.315 (1)(b) A and B in recognition of state regulations as applicable or relevant and appropriate requirements (ARARs). Oregon law defines that acceptable risk for individual carcinogenic compounds be set at one in one million (1×10^{-6}) excess risk for cancer and one in one hundred thousand (1×10^{-5}) for cumulative risks from carcinogenic compounds. Acceptable risk for noncarcinogenic constituents is set at an HI equal to 1. If calculated risks within an exposure area are below these target risk levels, risks are assumed to be acceptable and no further evaluation or action will be taken.

4.6.2 Summary of Risk Estimates

This section summarizes the risk estimates for soil at each of the four exposure areas identified for the Troutdale facility. The risk calculation data sheets used to develop the risk summary tables for the area-specific evaluations described below are provided by area of concern in Appendix A.

Fairview Farms

Fairview Farms includes essentially all areas west of Sundial Road and comprises approximately 277 acres (Figure 2-1). The exposure media evaluated for Fairview Farms are surface and subsurface soil containing site-related constituents. In accordance with the CSM, the exposure scenarios evaluated for Fairview Farms are site trespasser (short-term exposure), construction worker (near-term exposure), and excavation/trench worker (long-term exposure). In addition to these site-specific scenarios, an occupational worker exposure scenario is included to demonstrate whether controls may be necessary to ensure acceptable risk. The exposure assumptions are summarized in Tables 4-10 and 4-11. The ELCR and HI estimates for these exposure scenarios at Fairview Farms are summarized in Table 4-14. The risk calculation data tables are provided in Appendix A, Tables A-1 through A-16.

Trespasser Scenario. The ELCR estimates for the trespasser scenario are 2×10^{-7} for the RME case and 1×10^{-8} for the CTE case. The HI estimates for the trespasser scenario are 0.02 for the RME case and 0.002 for the CTE case.

Construction Worker Scenario. The ELCR estimates for the construction worker scenario are 2×10^{-7} for the RME case and 3×10^{-8} for the CTE case. The HI estimates for the construction worker scenario are 0.1 for the RME case and 0.02 for the CTE case.

Excavation/Trench Worker Scenario. The ELCR estimates for the excavation/trench worker scenario are 6×10^{-9} for the RME case and 1×10^{-9} for the CTE case. The HI estimates for the excavation/trench worker scenario are 0.005 for the RME case and 0.0008 for the CTE case.

Occupational Scenario. The ELCR estimates for the occupational worker scenario are 2×10^{-6} for the RME case and 2×10^{-7} for the CTE case. The HI estimates for the occupational worker scenario are 0.05 for the RME case and 0.03 for the CTE case.

The risk estimates for all four exposure scenarios evaluated for Fairview Farms do not exceed the DEQ acceptable risk target ELCR of 1×10^{-5} for cumulative contaminant exposure or an HI of 1. Also, no carcinogens exceed the DEQ target risk level for single carcinogens of 1×10^{-6} . The maximum detection of lead in soil in this exposure area is 34.3 milligrams per kilogram (mg/kg), well below the EPA Region IX PRGs (EPA, 2004b).

Outside the Dike

The exposure medium evaluated for the area outside the dike (Figure 2-1) is surface soil containing site-related constituents. This approximately 177-acre area is located within a floodplain and could not be built upon unless it were rezoned and filled. In accordance with the CSM, the exposure scenarios evaluated for the area outside the dike are short-term exposures, including the site trespasser and recreational user scenarios. The trespasser scenario assumes exposure to surface soil (0 to 1 ft bgs), whereas the recreational user scenario assumes exposure to both surface soil and surface sediments where surface water is typically less than 6 feet deep in areas of Company Lake, East Lake, and along the Sandy and Columbia rivers. The exposure assumptions are summarized in Tables 4-10 and 4-11. The ELCR and HI estimates for these exposure scenarios at the area outside the dike are summarized in Table 4-15. The risk calculation data tables are provided in Appendix A, Tables A-17 through A-24.

Trespasser Scenario. The ELCR estimates for the trespasser user scenario are 2×10^{-6} for the RME case and 1×10^{-7} for the CTE case. The HI estimates for this scenario are 0.3 for the RME case and 0.02 for the CTE case.

Recreational User Scenario. The ELCR estimates for the recreational user scenario are 2×10^{-6} for the RME case and 1×10^{-7} for the CTE case. The HI estimates for this scenario are 0.3 for the RME case and 0.02 for the CTE case.

The risk estimates for the area outside the dike do not exceed the DEQ acceptable risk target ELCR of 1×10^{-5} for cumulative contaminant exposure or an HI of 1. Also, no carcinogens exceed the DEQ target risk level for single carcinogens of 1×10^{-6} . The maximum detection of lead in surface soil in this exposure area is 123 mg/kg, well below the EPA Region IX PRGs (EPA, 2004b).

South Wetlands

The exposure media evaluated in the south wetlands area (comprising approximately 28 acres) are surface and subsurface soil containing site-related constituents (Figure 2-1). The purpose of assessing risk in this area is to determine the effectiveness of a PCB removal action in this area in September 1999, and to include additional sampling data from the railroad embankment since the BLRA. In accordance with the CSM, the exposure scenarios evaluated for the south wetlands area are site trespasser (short term), construction worker (near term), and excavation/trench worker (long term). The exposure assumptions are summarized in Tables 4-10 and 4-11. The ELCR and HI estimates for these exposure scenarios at the south wetlands area are summarized in Table 4-16. The risk calculation data tables are provided in Appendix A, Tables A-25 through A-36.

Trespasser Scenario. The ELCR estimates for the trespasser scenario are 1×10^{-5} for the RME case and 8×10^{-7} for the CTE case. The HI estimates for the trespasser scenario are 0.5 for the

RME case and 0.04 for the CTE case. These risk estimates are based on EPCs calculated as the 90 percent UCL for the primary contributing constituent (benzo(a)pyrene), in accordance with DEQ guidance, and as outlined in Section 4.3 of the Risk Scoping Document.

Construction Worker Scenario. The ELCR estimates for the construction worker scenario are 3×10^{-6} for the RME case and 4×10^{-7} for the CTE case. The HI estimates for the construction worker scenario are 0.7 for the RME case and 0.1 for the CTE case. These risk estimates are based on EPCs calculated as the 90 percent UCL for the primary contributing constituents (benzo(a)pyrene, dibenzo(a,h)anthracene, PCBs, fluoride, and vanadium), in accordance with DEQ guidance, and as outlined in Section 4.3 of the Risk Scoping Document.

Excavation/Trench Worker Scenario. The ELCR estimates for the excavation/trench worker scenario are 3×10^{-7} for the RME case and 4×10^{-8} for the CTE case. The HI estimates for the excavation/trench worker scenario are 0.09 for the RME case and 0.01 for the CTE case. These risk estimates are based on EPCs calculated as the 90 percent UCL for the primary contributing constituents (benzo(a)pyrene, dibenzo(a,h)anthracene, PCBs, fluoride, and vanadium), in accordance with DEQ guidance, and as outlined in Section 4.3 of the Risk Scoping Document.

The risk estimates for all three exposure scenarios evaluated for the south wetlands area do not exceed the DEQ acceptable risk target ELCR of 1×10^{-5} for cumulative contaminant exposure, or an HI of 1. Also, no carcinogens exceed the DEQ target risk level for single carcinogens of 1×10^{-6} for the construction worker and excavation/trench worker exposure scenarios. The maximum detection of lead in soil in this exposure area is 259 mg/kg, which is below the EPA Region IX PRGs (EPA, 2004b).

For the trespasser scenario, RME risk estimates slightly exceed the DEQ acceptable risk target ELCR of 1×10^{-6} for individual contaminant exposure for the south wetlands area. Under this scenario, benzo(a)pyrene (3×10^{-6}) and dibenzo(a,h)anthracene (2×10^{-6}) are above the DEQ target risk level for a single carcinogen of 1×10^{-6} .

It should be noted that the trespass exposure frequency of 26 days per year was used as a high-end default in the BLRA and was carried over to this risk assessment for consistency, as requested by EPA during scoping meetings. This exposure frequency does not reflect actual trespass observed at south wetlands. To provide further clarification of this issue, an additional calculation was conducted to identify what trespass frequency would result in acceptable risk for individual carcinogens (that is, the “critical exposure frequency”) at south wetlands. This evaluation indicated that if the trespass frequency were assumed to be 11 days per year, there would be no exceedances of the 1×10^{-6} individual target risk for this area. For trespass exposure at south wetlands, an exposure frequency of less than 11 days per year (probably about 5 days per year, as assumed under the CTE case) is more reasonable than the 26 days per year assumed under the RME case, and results in acceptable risk under DEQ statutory rules.

East Area, Comprising Former Plant Area East of Sundial Road

The exposure media evaluated for the East Area (comprising approximately 254 acres) are surface and subsurface soil containing site-related constituents (Figure 2-1). In accordance with the CSM, the exposure scenarios evaluated for the East Area are site trespasser (short term), construction worker (near term), and excavation/trench worker (long term). In

addition to these site-specific scenarios, an occupational worker exposure scenario is included to demonstrate whether controls may be necessary to ensure acceptable risk. The exposure assumptions are summarized in Tables 4-10 and 4-11. The ELCR and HI estimates for these exposure scenarios at Fairview Farms are summarized in Table 4-17. The risk calculation data tables are provided in Appendix A, Tables A-37 through A-52.

Trespasser Scenario. The ELCR estimates for the trespasser scenario are 1×10^{-6} for the RME case and 9×10^{-8} for the CTE case. The HI estimates for the trespasser scenario are 0.1 for the RME case and 0.007 for the CTE case. These risk estimates are based on EPCs calculated as the 90 percent UCL for the primary contributing constituents (benzo(a)pyrene, arsenic, benzo(k)fluoranthene, and dibenzo(a,h)anthracene), in accordance with DEQ guidance, and as outlined in Section 4.3 of the Risk Scoping Document.

Construction Worker Scenario. The ELCR estimates for the construction worker scenario are 2×10^{-6} for the RME case and 4×10^{-7} for the CTE case. The HI estimates for the construction worker scenario are 1 for the RME case and 0.2 for the CTE case. These risk estimates are based on EPCs calculated as the 90 percent UCL for the primary contributing constituents (PCBs), in accordance with DEQ guidance, and as outlined in Section 4.3 of the Risk Scoping Document.

Excavation/Trench Worker Scenario. The ELCR estimates for the excavation/trench worker scenario are 9×10^{-8} for the RME case and 1×10^{-8} for the CTE case. The HI estimates for the excavation/trench worker scenario are 0.04 for the RME case and 0.01 for the CTE case. These risk estimates are based on EPCs calculated as the 90 percent UCL for the primary contributing constituents (PCBs), in accordance with DEQ guidance, and as outlined in Section 4.3 of the Risk Scoping Document.

Occupational Scenario. The ELCR estimates for the occupational worker scenario are 1×10^{-5} for the RME case and 1×10^{-6} for the CTE case. These risk estimates are based on EPCs calculated as the 90 percent UCL for the primary contributing constituents (benzo(a)pyrene, arsenic, benzo(k)fluoranthene, and dibenzo(a,h)anthracene), in accordance with DEQ guidance, and as outlined in Section 4.3 of the Risk Scoping Document. The HI estimates for the occupational worker scenario are 0.2 for the RME case and 0.09 for the CTE case.

The risk estimates for all four exposure scenarios evaluated for the East Area do not exceed the DEQ acceptable risk target ELCR of 1×10^{-5} for cumulative contaminant exposure or an HI of 1. Also, no carcinogens exceed the DEQ target risk level for single carcinogens of 1×10^{-6} for the trespasser, construction worker, and excavation/trench worker scenarios.

For the RME occupational worker scenario, only benzo(a)pyrene (5×10^{-6}) and arsenic (2×10^{-6}) are above the DEQ target risk level for a single carcinogen of 1×10^{-6} . The EPC for arsenic, however, is 3.8 mg/kg, well within the range anticipated for natural background (less than 11.9 mg/kg). The maximum detection of lead in soil in this exposure area is 338 mg/kg, well below the EPA Region IX PRGs (EPA, 2004b).

4.6.3 Risk-Based Screening for Petroleum

Petroleum hydrocarbon values from each area were compared with risk-based screening levels in DEQ's *Risk-Based Decision Making for the Remediation of Petroleum-Contaminated Sites* (DEQ, 2003), for gasoline, diesel, heavy oil, and mineral oil, on a sample-by-sample basis for

each exposure scenario. When a detection was reported generically as TPH, the most conservative risk-based concentration for gasoline, diesel, or oil was used for that sample.

Fairview Farms

Gasoline, diesel, and TPH by 418_1 were compared with DEQ screening levels for the occupational worker, construction worker, and excavation worker scenarios. No TPH values exceeded the screening levels.

Outside the Dike

In order to evaluate TPH values from this area, residential scenario screening levels were used in the comparison, since no screening levels exist for recreational or trespasser scenarios. None of the gasoline, diesel, heavy oil, and TPH by 418_1 values exceeded the residential screening levels.

South Wetlands

Gasoline, diesel, heavy oil, and TPH by 418_1 were compared with DEQ screening levels for the construction and excavation worker scenarios. Only one sample (SW-SB29) had a TPH by 418_1 value that exceeded the diesel screening levels (most conservative) under the construction worker scenario.

East Area, Comprising Former Plant Area East of Sundial Road

Gasoline, diesel, heavy oil, motor oil, and oil were compared with DEQ screening levels for the occupational worker, construction worker, and excavation worker scenarios. No TPH values exceeded the screening levels.

SECTION 5

Updated Ecological Risk Assessment for South Wetlands

5.1 Introduction

A post-demolition residual ERA was performed for south wetlands to document the effectiveness of a PCB removal action in this area in September 1999, and the addition of sampling data (since the BLRA) from the railroad embankment. This ERA provides an assessment of the potential impacts on wildlife of residual concentrations at south wetlands, assuming that site development does not occur. If the area is developed in the future, then the ecological risk results will become invalid at that time.

Specifically, this ERA includes the following updates to the BLRA (CH2M HILL, 2000):

- Revision of PCB data from the former high concentration area where excavation at south wetlands occurred, substituting data from the post-excavation confirmation samples
- Inclusion of new sampling data from railroad embankment areas
- Consideration of the remedial actions at Company Lake, north landfill, and south landfill during the Tier 2 ERA⁶

Additional areas at the RMC site where ecological exposures could occur were previously addressed during the BLRA.

5.2 The Tiered Approach for the Ecological Risk Assessment

The BLRA and ERA were conducted in accordance with approaches described in EPA (EPA, 1992, 1997a, 1998) and DEQ guidance (DEQ, 2000b) and the tiered framework described below was used.

5.2.1 Tier 1 Approach

Tier 1 consists of a screening-level ecological assessment that serves to narrow the field of chemicals detected in site media to those that are of most concern to ecological receptors. These identified chemicals are called chemicals of potential ecological concern, or COPECs. Tier 1 conservatively assumes that completely suitable habitat is provided, and that representative wildlife receptors exclusively use the south wetlands area for their food source (that is, regional home range use is not considered). These assumptions are intended to provide a conservative identification of COPECs, which are carried forward into Tier 2

⁶ The purpose of considering the remedial actions at Company Lake is specifically to allow for a sitewide (that is, Tier 2) risk estimate for south wetlands, and not to provide post-remedial risks for Company Lake, since the remedial actions there occurred as part of the interim ROD for the site. The potential ecological risk at Company Lake was evaluated in *Memorandum No. 36: RMC-Troutdale Company Lake: Post-Remediation Data Evaluation Relative to Sediment Benchmarks* (CH2M HILL, 2005b).

where more realistic, site-specific assumptions are applied. Following Tier 1, chemicals with ecological HQs exceeding the background ecological HQ by 1.0 or more were designated COPECs, and were carried forward to Tier 2. The results of the south wetlands Tier 1 ERA are provided in Section 5.4.2 of this report.⁷ Chemicals screened out during Tier 1 were discussed in the risk characterization step, but no further risk assessment is needed because they pose minimal (if any) risk and are excluded from further consideration.

5.2.2 Tier 2 Approach

Tier 2 uses site-specific information to provide more realistic exposure estimates and to better characterize risk for south wetlands, but only for those chemicals and receptors that were not screened out during Tier 1. The Tier 2 ERA provides additional evaluation of four primary considerations, as follows:

- **Exposure from multiple areas:** The possibility that receptors using the Troutdale site could use and potentially be exposed at multiple areas at the site is accounted for.
- **Habitat quality:** The quality of the available habitat within and surrounding each evaluated area of concern is weighted in order to identify its relative suitability for wildlife use. This evaluation is conducted for each selected receptor carried forward from Tier 1 for each area of concern.
- **Species home range:** A consideration is made of the availability of more suitable foraging or feeding habitat in areas surrounding the site but within each selected receptor's documented home range or foraging area.
- **Toxicological uncertainty:** For COPECs exceeding an ecological HQ of 1.0, the Tier 2 ERA provides a more detailed evaluation of the toxicity of COPECs to site receptors. Because the actual chemical-specific toxicity falls between the no observed adverse effect level (NOAEL) and lowest observed adverse effect level (LOAEL), a consideration is made on the range between the NOAEL and LOAEL.

These four considerations serve to ground-truth the risk assessment results from Tier 1. The methods employed to conduct these additional Tier 2 refinements, and the results of the south wetlands Tier 2 ERA, are discussed in Section 5.4.3.⁸

5.3 Ecological Risk Assessment Guidance

The procedures used for this ERA are consistent with those described in the following EPA and DEQ guidance documents:

- *Guidelines for Ecological Risk Assessment* (EPA, 1998)
- *Framework for Ecological Risk Assessment* (EPA, 1992)

⁷ Tier 1 BLRA risk results were provided in Section 4.6.2 of the *Baseline Risk Assessment, Part 1—Nongroundwater Media* (CH2M HILL, 2000).

⁸ Tier 2 BLRA risk results were provided in Section 4.6.3 of the *Baseline Risk Assessment, Part 1—Nongroundwater Media* (CH2M HILL, 2000).

- *Supplemental Ecological Risk Assessment Guidance for Superfund: EPA Region 10* (EPA, 1997b)
- *Wildlife Exposure Factors Handbook* (EPA, 1993)
- *ECO Updates, Volumes 1 through 3* (EPA, 1991-96)
- *Guidance for Ecological Risk Assessment – Level III Baseline* (DEQ, 2000b)

In addition to these published agency guidance documents, monthly meetings of RMC and EPA, DEQ, and the U.S. Fish and Wildlife Service (USFWS) were held from May through August 1998 to develop consensus on ERA methodologies, endpoints, assumptions, and sampling needs. This ERA uses approaches and assumptions consistent with the agreements made at that time.

5.4 Ecological Risk Characterization for South Wetlands

The problem formulation components related to south wetlands are the same as those presented in Section 4.4 of the BLRA. The methods, receptors of potential concern, exposure parameters, toxicity reference values (TRVs), and equations used to compute potential exposure and risk to wildlife are also the same as those used in the BLRA. Exposure point concentrations that serve as input to the intake equations are developed using the same approaches described for the HHRA in Section 4.3.2 of this report. Summary statistics and EPCs for south wetlands are provided in Appendix B. The numerical results of exposure quantification at south wetlands are provided in the ecological risk calculation data sheets (Appendix B).⁹

On the basis of the habitat and potential species present at the Troutdale facility, two general food web types were distinguished during the BLRA for the purpose of intake calculation, and both types occur at south wetlands. The general habitat types considered are upland and open water/wetland areas. Appropriate avian and mammalian endpoint species for food chain uptake, as identified in Section 4.4.5.3 of the BLRA, are considered. Figures 4-4 and 4-5 of the BLRA schematically present the food webs for both upland and open water/wetland habitats, respectively.

5.4.1 Derivation of Ecological Hazard Quotients

The primary means for quantifying ecological risk is to determine the ratio of the estimated chemical intake level for the endpoint species of concern (per the equations described in the BLRA) with the chemical-specific TRV.

$$\text{Ecological } HQ = I/TRV$$

⁹ As a result of remedial and restoration activities at Company Lake, revised risk estimates for Company Lake are also included in Appendix A and used as part of the Tier 2 ERA.

where:

Ecological HQ	= Ecological hazard quotient (unitless)
I	= Medium-specific intake level (mg/kg-day ¹⁰)
TRV	=Toxicity reference value (mg/kg-day)

When this ratio (that is, the ecological HQ) exceeds unity ($HQ > 1$), there is a potential for ecological risk. Conversely, if $HQ \leq 1$, it is assumed that ecological risks are not present. The TRV and intake estimates for Tier 1 are intentionally conservative (reasonable worst case), whereas Tier 2 uses more realistic, site-specific assumptions. Following Tier 1, chemicals with ecological HQs exceeding the background ecological HQ by 1.0 or more were designated COPECs, and are carried forward to Tier 2.

5.4.2 Results of the Tier 1 Ecological Risk Assessment for South Wetlands

Table 5-1 provides a summary of the Tier 1 ecological risk characterization for south wetlands. A total of 59 surface soil samples and 24 surface water samples collected in this area were used in the evaluation. Because south wetlands is largely identified as a wetland area (CH2M HILL, 1997), selected ecological receptors of concern included the robin, mink, great blue heron, mallard, coyote, red-tailed hawk, and deer. Of the 36 detected chemicals that were evaluated for ecological risk, aluminum, antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, fluoride, lead, mercury, nickel, selenium, vanadium, zinc, polynuclear aromatic hydrocarbons (PAHs), and PCBs occur at concentrations resulting in an ecological HQ that exceeds 1.0 for one or more of the selected endpoint species.

Also provided in Table 5-1 are the ecological HQ estimates for the corresponding background soil samples (as calculated during the BLRA). A comparison of the south wetlands and background ecological HQ estimates indicates that all chemicals that resulted in an ecological HQ exceeding 1.0 (with the exceptions of antimony, arsenic, and beryllium) also exceeded the background ecological HQ¹¹ by 1.0 or more (highlighted by boldface type in Table 5-1). Aluminum, barium, cadmium, chromium, cobalt, copper, fluoride, lead, mercury, nickel, selenium, vanadium, zinc, PAHs, and PCBs are therefore identified as COPECs and are carried forward to be addressed in the Tier 2 ERA.

5.4.3 Results of the Tier 2 Ecological Risk Assessment for South Wetlands

Tier 2 uses site-specific information and more realistic exposure estimates to better characterize risk for those chemicals and receptors of highest priority (those identified as COPECs during Tier 1). Tier 2 provides additional evaluation of four primary considerations described in Section 5.2.2 (exposure from multiple areas, habitat quality, species home range, and toxicological uncertainty) to help ground-truth the risk assessment results from Tier 1. The methods used to conduct these additional Tier 2 refinements, and the results of the Tier 2 ERA for south wetlands, are provided in this section.

¹⁰ Milligrams of chemical contacting the body per kilogram body weight per day.

¹¹ Background ecological HQ results were as provided in Appendix G of the *Baseline Risk Assessment, Part 1—Nongroundwater Media* (CH2M HILL, 2000).

Consideration of Additive Exposure from Areas Outside of South Wetlands

During Tier 1, to select COPECs for south wetlands, the endpoint species were conservatively assumed to obtain 100 percent of their diet specifically from the south wetlands area. For Tier 2, it is assumed that endpoint species obtain their forage from all of the same areas of concern at RMC-Troutdale that were previously considered in the BLRA.¹² The fraction of total dietary intake is assumed proportional to the areal size (in acres) of each area of concern, relative to the total acreage of all areas of concern.¹³ This approach allows for a more realistic accounting for multiple site exposures at the Troutdale facility.

The specific areas at the Troutdale facility considered collectively are grouped on the basis of habitat and receptor types, as follows:

- Open water/wetland habitats where the heron, mallard, and mink could occur. In addition to south wetlands, these areas include Company Lake, the depression east of the outfall ditch, East Lake, east South Ditch, Salmon Creek/West Drainage, and river shoreline areas along the RMC-Troutdale property.
- In addition to south wetlands, upland areas where upland species could occur include the north landfill, south landfill, Fairview Farms, and east potliner areas. Receptors considered for these areas include the red-tailed hawk, American robin, mule deer, and coyote.

It should be noted that this aggregate intake approach still assumes that foraging occurs only within the RMC areas of concern, and thus is still considered conservative for ecological receptors with home ranges larger than the property. This factor is further addressed in the section below on endpoint species home range.

Consideration of Area-Specific Habitat Suitability

In addition to consideration of intake from multiple areas of concern, Tier 2 provides consideration of the general degree to which habitat at each area of concern is suitable for attracting wildlife use and providing food for foraging. These judgments were based on knowledge of the site obtained during reconnaissance visits and field surveys.

During the BLRA, each area of concern was rated on a five-step scale according to whether the area is believed to provide excellent, good, average, poor, or unsuitable foraging habitat for the endpoint species selected for that area. These ratings correspond to assigned weighting factors, expressed as a fraction, with which the Tier 1 ecological HQs are multiplied to provide an adjustment based on habitat suitability. The ecological rationale for these habitat suitability ratings, based on preferences for each endpoint species, was provided in Appendix I of the BLRA. The habitat suitability ratings assigned for each area of concern are listed in Section 4.6.3 of the BLRA. Habitat restoration at Company Lake following the remedial action activities has resulted in a higher quality habitat. As a result, the habitat suitability weighting factor at Company Lake has been increased from 0.75 to 1.0 for the Tier 2 ERA for south wetlands.

¹² These are areas determined to have habitat suitable for ecological use, and therefore exclude the east plant area.

¹³ For example, the area of south wetlands is 44.2 percent of the total area of open water/wetland areas, and therefore has an areal weighting factor of 0.442.

Tier 2 Ecological Hazard Quotients

The consideration of both multiple area exposures and habitat suitability results in interim numerical adjustments to the risk estimates. Tables 5-2 and 5-3 provide summaries of these Tier 2 adjustments to the Tier 1 ecological HQs for open water/wetland and upland habitat types, respectively.¹⁴ Each table lists by area the Tier 1 ecological HQs, the habitat suitability weighting, the area weighting, and the calculated Tier 2 ecological HQs. The areal size weightings are calculated at the bottom of each table. The Tier 2 ecological HQs for all areas are summed in the last column to estimate the sitewide Tier 2 ecological HQ for each COPEC.

Open Water/Wetland Areas. For open water/wetland areas, the list of south wetlands COPECs with total Tier 2 ecological HQs exceeding 1.0 is reduced to aluminum, fluoride, selenium, vanadium, and PCBs. It is still possible, however, that a substantial portion of this calculated risk is the result of background levels of naturally occurring chemicals. To evaluate this possibility, Table 5-4 provides a comparison of the total Tier 2 ecological HQs with ecological HQs calculated for background areas with similar habitats sampled for the RI. This comparison indicates that, for the open water/wetland areas, the total Tier 2 ecological HQs for only fluoride (for heron) and PCBs (for heron and mink) exceed corresponding background values by at least 1.0. Table 5-5 summarizes the area-specific contribution to the total sitewide Tier 2 HQ for fluoride and PCBs. These results indicate that south wetlands is the highest risk-contributing area of concern for fluoride and PCBs, contributing 88 percent and more than 100 percent, respectively, of the sitewide risk for these COPECs. These COPECs are therefore carried forward for further evaluation by considering the home ranges of these endpoint species of concern and the toxicological uncertainty of these COPECs to birds and mammals.

Upland Areas. For upland areas, the list of south wetlands COPECs with total Tier 2 ecological HQs exceeding 1.0 is reduced to aluminum, chromium, fluoride, zinc, and PCBs.

Table 5-6 provides a comparison of the sitewide Tier 2 ecological HQs with ecological HQs calculated for the similar habitat background area. This comparison reveals that, for the upland areas, only aluminum (for the robin), fluoride (for the robin), and PCBs (for the red-tailed hawk) have a total Tier 2 ecological HQ that exceeds the corresponding background value by at least 1.0. Table 5-7 summarizes the area-specific contribution to the total sitewide Tier 2 HQ for fluoride and PCBs. These results indicate that south wetlands is the highest risk-contributing area of concern for fluoride and PCBs, contributing 58 percent and 89 percent, respectively, of the sitewide risk for these COPECs. These COPECs are therefore carried forward for further evaluation by considering the home ranges of these endpoint species of concern and the toxicological uncertainty of these COPECs to birds.

For aluminum, more than 90 percent of the sitewide risk for upland areas is contributed by the Fairview Farms area (see Table 4-29 of the BLRA), primarily because of its large areal weighting. Because releases of aluminum across Fairview Farms have not occurred, these results suggest that the aluminum risk estimate for Fairview Farms is being contributed largely by naturally occurring concentrations. The maximum background aluminum concentration (14,600 mg/kg) measured in 14 samples during the RI is about 73 percent of

¹⁴ It should be noted that the Tier 1 and Tier 2 HQs for upland areas are likely lower than reported in Table 5-3 due to the remedial actions that have taken place at north and south landfills since the BLRA.

the level measured in Fairview Farms (19,900 mg/kg as lognormal UCL of 35 samples). A more thorough regional background evaluation conducted by the Washington Department of Ecology (WDOE, 1994) for Clark County, Washington (just across the Columbia River from RMC) reported background aluminum concentrations ranging from 13,740 to 54,550 mg/kg, with a 90th percentile 52,276 mg/kg. The geologic conditions just across the river would not intuitively be expected to differ from those found on the Oregon side. The Washington statewide median concentration is reported to be 21,956 mg/kg (versus 31,192 mg/kg for Clark County). In light of this information, the aluminum risk estimates for the robin are not interpreted to be the result of a release or to indicate unacceptable risk, and this constituent is not identified as a COPEC.

Consideration of Endpoint Species Home Range

As stated earlier, Tier 2 evaluations to this point in the ERA conservatively assume that all foraging of endpoint species occurs only at the areas of concern within or along the property boundaries. However, it is known that for most of the endpoint species, the home range and foraging areas extend well beyond the areas of concern and property boundaries. The available foraging areas and home ranges for the endpoint species, as documented in literature sources, were summarized in Table 4-30 of the BLRA.

In the vicinity of the Troutdale property, it is unknown exactly how much suitable habitat actually exists within each species' documented home range. Without extensive habitat identification in areas surrounding the facility, the exact acreage of suitable habitat for each species remains uncertain. In addition, the potential for exposure to COPECs from offsite sources and their contribution to total exposure is uncertain.

In lieu of specific knowledge of the amount of offsite foraging habitat and potential offsite exposures, an alternative evaluation approach was used. By knowing the magnitude of the estimated total Tier 2 ecological HQs for site COPECs (from Tables 5-4 and 5-6) and the total size of the open water/wetland (about 60 acres) and upland (about 259 acres) areas of concern, it is possible to back-calculate the minimum amount of needed suitable offsite habitat (with zero exposure) that would result, when combined with areas of concern, in site exposures posing acceptable risk (ecological HQ = 1). The resulting acreage estimates can be compared with general knowledge of surrounding habitat areas in order to give a rough idea of the likelihood that unacceptable risk exists. If the calculated amount of required offsite suitable habitat is (1) within the total home range of the species of concern and (2) believed to be locally available, then it is postulated that ecological risks for that COPEC at the Troutdale facility are acceptable. This approach is used for each remaining COPEC (fluoride and PCBs, but not aluminum, which was eliminated as a COPEC) and endpoint species identified in Tables 5-4 and 5-6 as exceeding corresponding background risk levels. Each of these potentially affected endpoint species (mink, great blue heron, and red-tailed hawk)¹⁵ is discussed in the following subsections.

Mink. Mink are closely associated with aquatic and wetland habitats, including the banks of rivers, streams, lakes, and ditches, as well as wooded swamps, freshwater marshes, coastlines, and backwater areas. Their home range includes both their foraging areas around

¹⁵ Because of the relatively small home range for the American robin, no discussion of a home range refinement to the risk estimates for this species is provided in this section. Rather, this species is addressed further in the consideration of toxicological data in the following subsection.

these waterways and their dens. Most mink activity occurs within a few meters of water and mink rarely stray more than several hundred meters from water. Den sites are within 100 meters of open water, typically closer (Allen, 1986; EPA, 1993). However, more than one den may be used by an individual mink. Home range shape depends on habitat type, with riverine home ranges being basically linear.

For the mink, the documented home range from seven studies (see Table 4-30 of the BLRA) ranges from 19.2 to 4,520 acres, with an average of 1,270 acres and a median of 790 acres. The sitewide Tier 2 ecological HQ for this species is calculated to be 5.8 for PCBs (Table 5-2). The total acreage of the open water/wetland areas of concern considered for the mink is about 60 acres. Therefore, within the median documented home range for the mink of about 790 acres, if approximately 288 additional acres [$(5.8 \times 60) - 60 = 288$] of offsite habitat exists that is suitable for foraging by mink, then it can be concluded that the RMC-related exposures to PCBs are not high enough to pose unacceptable risk (ecological HQ > 1). The availability of actual suitable surrounding habitat is sufficient, as discussed below.

Great Blue Heron. For the great blue heron, the documented home range from literature sources is generally expressed in terms of linear foraging distance from the colony. Great blue herons will forage relatively far from nesting colonies, averaging several kilometers (km), but they may go as far as 30 km on occasion (EPA, 1993; Table 1). Maximum distances of between 15 and 20 km are the farthest great blue herons will regularly travel between foraging areas and colonies (Gibbs et al., 1987). The principal determinant of adequate foraging habitat is the availability of shallow water with available small fish (Henning et al., 1999).

The documented foraging distance for the great blue heron, from seven studies (see Table 4-30 of the BLRA), ranges from 1.8 to 29 km, with an average of 9.5 km and a median of 7.5 km. For the purposes of converting linear distance to area, it was assumed that the heron uses a zone of approximately 100 meters wide along its documented foraging distance, consistent with that documented for the mink. For the median reported foraging distance of 7.5 km, this results in an estimated home range size of about 185 acres.

The sitewide Tier 2 ecological HQs for this species are calculated to be 2.2 for fluoride and 4.5 for PCBs (Table 5-2). The total acreage of the open water/wetland areas of concern considered for the heron is about 60 acres. Therefore, if approximately 210 additional acres [$(4.5 \times 60) - 60 = 210$] of nearby offsite habitat exists that is suitable for foraging by piscivorous birds, then it can be concluded that the RMC-related exposures to fluoride and PCBs are not high enough to pose unacceptable risk (ecological HQ > 1). The availability of actual suitable surrounding habitat is sufficient, as discussed below.

Red-tailed Hawk. The size of the red-tailed hawk home range depends on the type of habitat and availability of forage. Hawks inhabit large open or semi-open areas, often near woodlands. Trees or other elevated sites are a requirement for nesting and perching. This species occupies large territory areas and defends its area throughout the year. Hawks are primarily sit-and-wait predators and are opportunistic feeders.

For the red-tailed hawk, the documented home range from eight studies (see Table 4-30 of the BLRA) ranges from 210 to 964 acres, with an average of 408 acres and a median of 346 acres. The sitewide Tier 2 ecological HQ for PCBs is calculated to be 1.1 (Table 5-3) for this species. The total acreage of the upland areas of concern considered for the red-tailed

hawk is about 259 acres. Therefore, within the documented home range for the red-tailed hawk of about 346 acres, if approximately 26 additional acres [(1.1×259) – 259 = 26] of nearby offsite habitat exists that is suitable for foraging by upland raptors, then it can be concluded that the RMC-related exposures to PCBs are not high enough to pose unacceptable risk (ecological HQ > 1). The availability of actual suitable surrounding habitat is sufficient, as discussed below.

Surrounding Habitat. Because the property is located at the confluence of two of Oregon's largest rivers, and because of regional climatological conditions, an abundance of suitable nearby habitat exists for the types of endpoint receptors evaluated for this post-demolition ERA. Areas directly across the Sandy River (including the U.S. Forest Service Sandy River Delta Restoration Project), and on Lady Island within the Columbia River near RMC, provide several thousand acres of high-quality habitat and foraging for great blue herons, mink, and red-tailed hawks. Also, adjacent properties provide usable habitat, such as those along the shorelines of the two rivers and within the unused areas of RMC property north of the dike. The availability of abundant habitat in these nearby areas makes sole use of the areas of concern by wildlife unlikely.

Consideration of Toxicity Data

The Tier 1 risk estimates use NOAELs to develop TRVs (the highest tested dose shown to be without adverse effects). For south wetlands COPECs, the lowest observed adverse effect levels (LOAELs, the lowest tested dose shown to produce adverse effects) is considered, in order to provide a perspective on the uncertainty associated with the NOAEL-based HQs. In addition, the LOAEL is considered more relevant than the NOAEL for identifying acceptable risk to animal populations under DEQ statutory rules.¹⁶

Fluoride. Fluoride is identified as a COPEC for the great blue heron (wetland/open water areas) and robin (upland areas), each with an NOAEL-based Tier 2 HQ of about 2. The LOAEL for fluoride was identified from the same study from which the NOAEL was derived (Pattee et al., 1988). The difference between the reported LOAEL and NOAEL for the selected avian toxicity study is about four-fold. The LOAEL and NOAEL from this study are 32 and 7.8 mg/kg-day, respectively. This study was considered very relevant for this risk assessment because it tested effects in a wildlife species, screech owls. Another available avian study (Guenter and Hahn, 1986) reported a LOAEL of >49 mg/kg-day in chickens. Given the range of available avian LOAELs reported for fluoride (Table 5-8), the LOAEL from the Pattee et al., 1988 study is considered adequately protective.

The LOAEL-based HQs for fluoride in birds are provided in Tables 5-5 and 5-7 for the heron (HQ = 0.5) and robin (HQ = 0.5), respectively. Considering collectively the foraging areas for these species (discussed above), the availability of nearby suitable habitat, and the uncertainties in the toxicity data, fluoride levels at RMC-Troutdale are not high enough to pose meaningful risk to any of the endpoint species evaluated.

Total PCBs. Total PCBs are identified as a COPEC for the great blue heron (wetland/open water areas), red-tailed hawk (upland areas), and mink (wetland/open water areas). The NOAEL-based Tier 2 HQs are 4.5, 1.1, and 5.8 for the heron, hawk, and mink, respectively

¹⁶ Because DEQ guidance specifies that the median lethal dose should be used as an ecological benchmark value to assess population risk (OAR340-122-0115(21), the LOAEL is still considered very conservative.

(Tables 4-5 and 4-7). The avian LOAEL for PCBs was identified from the same study from which the NOAEL was derived (Dahlgren et al., 1972). The difference between the reported LOAEL and adjusted NOAEL for the selected avian toxicity study is five-fold. The LOAEL and NOAEL from this study are 1.8 and 0.36 mg/kg-day, respectively. This study was considered very relevant for this risk assessment because it tested effects in a wildlife species, pheasants. Another available avian study (Bird et al., 1983, as cited in Eisler, 1986) reported an LOAEL of 9 to 10 mg/kg-day in American kestrels. Given the range of available avian LOAELs reported for PCBs (Table 5-8), the LOAEL from the Dahlgren et al., 1972 study is considered adequately protective.

The mammalian LOAEL for PCBs was identified from the same study from which the NOAEL was derived (Aulerich and Ringer, 1977). The difference between the reported LOAEL and adjusted NOAEL for the selected mammalian toxicity study is also approximately five-fold. The LOAEL and NOAEL from this study (are 0.69 and 0.14 mg/kg-day, respectively. This study was considered very relevant for this risk assessment because it tested effects in mink, a wildlife species known to be very sensitive to PCBs. Other available mink studies reported LOAELs of 0.69 mg/kg-day (McCoy et al., 1995) and 3.43 mg/kg-day (Aulerich and Ringer, 1980). Given the range of available mink LOAELs reported for PCBs (Table 5-8), the LOAEL from the Aulerich and Ringer, 1977 study is considered adequately protective.

The LOAEL-based HQs for PCBs are provided in Tables 5-5 and 5-7 for the heron (HQ = 0.9), hawk (HQ = 0.2), and mink (HQ = 1), respectively. Considering collectively the foraging areas for these species (discussed above), the availability of nearby suitable habitat, and the uncertainties in the toxicity data, total PCB levels at RMC-Troutdale are not high enough to pose meaningful risk to any of the endpoint species evaluated.

5.4.4 ERA Conclusions

This ERA for south wetlands was conducted using a tiered approach, structured to focus the ERA on the COPECs and receptors with the greatest potential for ecological exposure. The previous BLRA indicated that the COPECs with the highest potential for ecological exposure were PCBs, primarily in south wetlands, and fluoride and PAHs, primarily within Company Lake. Since the BLRA, these constituents have been addressed by the remedial actions at Company Lake (as outlined in the interim ROD) and the PCB removal action in September 1999 at south wetlands. The results of the Tier 2 ERA presented here indicate that these actions have been effective in further reducing ecological risk in south wetlands within acceptable levels. The removal action at south wetlands was effective at reducing the EPC for PCBs in surface soil by 65 percent.

SECTION 6

Identification of Major Uncertainties and Assumptions

Several sources of uncertainty affect the overall estimates of human health and ecological risk presented in this RA. The sources are generally associated with the following:

- Sampling, analysis, and data evaluation
- Chemical fate and transport
- Exposure estimation
- Toxicological data

These sources of uncertainty are discussed in the following subsections.

6.1 Sampling, Analysis, and Data Evaluation

Uncertainty associated with sampling and analysis includes the inherent variability (standard error) in the analysis, representativeness of the samples, sampling errors, and heterogeneity of the sample matrix. The quality assurance/quality control (QA/QC) program used during the Post-Demolition RI serves to maintain acceptable precision and accuracy in measurement of chemical concentrations, but it cannot eliminate all sampling and analysis errors. The degree to which sample collection and analyses reflect real exposure point concentrations will influence the reliability of the risk estimates. Many of the sample data used for this RA were generated from samples collected at known or suspected areas of concern, rather than randomly. Because exposure is not likely to be limited solely to higher concentration areas, risk estimates for these areas may be conservatively high.

A key uncertainty for this RA is that many of the sample data used were generated from samples collected at known or suspected areas of concern, rather than randomly. Because exposure is not likely to be limited solely to higher concentration areas, risk estimates for these areas are likely conservatively high.

In addition, the statistical methods used to identify potential EPCs have inherent uncertainty. The 95 percent UCL (or, in a few cases, the 90 percent UCL) was selected to project the high end of potential exposure, and could in some instances overestimate exposure. In some cases, exposure estimates defaulted to maximum detected concentrations, also adding to conservatism.

In some cases, the reported detection limits for chemicals in environmental media were higher than concentrations of concern derived from TRVs, resulting in possible undetected risk. This occurred either because the required laboratory program detection limits exceeded concentrations of concern, or because a particular sample was diluted due to the presence of high concentrations of other constituents (usually PAHs). In the former case, the detection limits were unavoidable, because of the limitations of the instruments, the methods used, or both. The latter case generally occurred when another risk-contributing chemical was

present, reducing the impact of any undetected risk. However, the risk estimates in these situations are less certain and may be underestimated as a result of the higher detection limits.

6.2 Chemical Fate and Transport

This RA makes simplifying assumptions about environmental fate and transport of COPCs in order to estimate exposure; specifically, that no chemical loss or transformation will occur. It is assumed that the chemical concentrations detected in site media remain constant during the assessed exposure duration. In cases where natural attenuation processes are high, the analytical data chosen to represent exposure point concentrations may overstate actual long-term exposure levels. This uncertainty is likely to be more relevant for organic constituents that biodegrade (for example, PAHs) than for inorganic constituents (for example, fluoride).

6.3 Exposure Estimation

Uncertainties introduced into risk characterization during exposure assessment include assumptions made about future land and water use and chemical intake. Since the BLRA, projected land use conditions have been clarified. The RMC-Troutdale site will be developed as a mixed-use general industrial complex consistent with the general industrial zoning currently designated for the property. The estimation of intake requires many assumptions to describe potential exposure situations. There are uncertainties about the frequency and extent of contact with contaminated media, the concentration of constituents at exposure points, and the total duration of exposure. To address these, the estimation of exposure requires numerous assumptions to describe potential exposure situations. The use of upper bound exposure assumptions to estimate RME exposures provides a bounding estimate on exposure. The use of CTE parameters in estimation of exposure provides a perspective on some of the uncertainties due to use of RME assumptions. The uncertainties regarding the trespass exposure frequency at south wetlands are described in Section 4.6.2. Based on past observations, an exposure frequency of less than 11 days per year (probably about 5 days per year, as assumed under the CTE case) is more reasonable than the 26 days per year assumed under the RME case, and results in acceptable risk under DEQ statutory rules.

For the Tier 1 ERA, the assumption was made during risk characterization that the selected endpoint species (and their representative functional groups) use only onsite areas of concern, and are potentially exposed to the chemical concentrations in media directly onsite. A discussion of the potential for offsite habitat use is provided in Section 5.4.3. The fact that many of the Tier 1 risk estimates presented are below regulatory concern in the face of these conservative assumptions provides an added level of confidence in the conclusions for COPECs.

6.4 Toxicological Data

Uncertainties in toxicological data can influence the reliability of risk management decisions. The toxicity values used for quantifying risk in this HHRA and ERA have varying

levels of uncertainty that may affect the confidence in the resulting risk estimates. The sources of uncertainty include the following:

- Extrapolation from high to low doses, from species to species, and from short to long exposure durations
- Gender, age, and strain differences in uptake, metabolism, organ distribution, and target site susceptibility
- Variability with respect to diet, environment, activity patterns, and ecosystem factors

The use of uncertainty factors in the derivation of human and ecological toxicity factors, while striving for protectiveness, may result in an overestimate of risk. However, by using health-conservative estimates throughout this process, a margin of safety is allowed to account for uncertainty in this assessment, giving a margin of safety to the conclusions drawn.

For the HHRA, the levels of uncertainty for RfDs, judged by EPA on the basis of uncertainty factors and modifying factors, are listed in Tables 4-12 and 4-13 for the COPCs at RMC. For COPCs suspected of resulting in human cancer effects, uncertainty is in part expressed in terms of EPA's weight-of-evidence classification, also listed in Tables 4-12 and 4-13. For the ERA, similar use of uncertainty factors was made in the derivation of ecological TRVs, as listed in the table in Appendix B. Only a few of the TRVs for terrestrial/avian species were based on toxicity studies using the actual endpoint species (for example, mink for PCBs). For many chemicals, data on toxicity to wildlife are limited. Most wildlife toxicity information is generated by laboratory studies evaluating inbred animals under controlled laboratory conditions. This requires that the toxicity information be extrapolated to native species in the wild. For the most important COPECs identified (fluoride and PCBs), the toxicity information came from studies using actual wildlife species, increasing confidence in the results.

The following bullets describe some of the other sources of toxicological uncertainties that need to be considered when interpreting the results of this RA:

- One primary source of uncertainty in the ERA is the use of default inter-taxa uncertainty factors to extrapolate between species, per EPA Region 10 guidance (EPA, 1997a). An alternative scientifically sound approach is the use of a physiological scaling factor based on body weight. In some instances (for example, extrapolation between bird species), the use of the EPA default uncertainty factors for interspecies extrapolation could result in risk estimates higher than when using the body-weight scaling approach.
- Another major uncertainty for this RA is the bioavailability of the forms of metals that occur in soil at the site. Because the toxicity of many elements is greatly influenced by the chemical state in which they occur in an animal's food or water, total concentrations of these elements in water or soil are not generally accurate indicators of potentially toxic exposure. For most chemicals, however, site-specific bioavailability data were unavailable. The HHRA and ERA conservatively assume that bioavailability from soil is the same as that in the toxicological studies from which the toxicity values were derived, with the exception of aluminum, copper, fluoride, and vanadium. The uncertainty in bioavailability for these four elements is reduced through use of the adjustment (ERA

only) described in Section 4.5.1.1 of the BLRA. If the chemical form occurring in soil at the site is less bioavailable than assumed, actual risk would be proportionately lower.

- The use of the NOAEL to derive human and ecological toxicity factors also provides a margin of conservatism for the HHRA and ERA. If toxicity factors were based on exposure levels where actual adverse effects would occur (that is, at the LOAEL), risk estimates could be up to four times lower than when calculated using the NOAEL. To address this uncertainty, LOAEL-based ecological HQs were computed for the primary risk contributors, fluoride and PCBs (see Section 5.4.3).
- Because some of the constituents detected at the Troutdale facility did not have available human or wildlife toxicity information on which to quantify risks, these constituents could not be evaluated. However, most of the constituents that have no available toxicity data are generally considered less toxic, because most of the toxicological literature focuses on those constituents considered more toxic to human and ecological receptors. In some cases where adequate toxicity data were unavailable, structurally similar surrogates were used. The use of surrogates for these chemicals may lead to overestimates or underestimates of risk to ecological receptors. Because surrogates considered to have greater toxicity were chosen (for example, benzo(a)pyrene for high-molecular-weight PAHs in the ERA), the risk estimates for these chemicals are likely to be conservatively high.

In the HHRA risk characterization phase, the assumption is made that the total risk of developing an adverse effect from aggregate exposure to site constituents is the sum of the hazard quotients or cancer risks estimated for exposure to each individual constituent. This approach does not account for the possibility that chemicals act synergistically or antagonistically.

SECTION 7

Conclusions of the Post-Demolition RI/RA Process

Currently, the RMC-Troutdale site is on the National Priorities List (NPL) and has been remediated as a Superfund site under CERCLA since 1995. RMC has conducted a significant number of owner-initiated removal actions and CERCLA removal and remedial actions, independent of and during the plant demolition process. These actions have removed structures and contaminated materials from the site, resulting in the removal of sources of contamination for human and ecological exposure and to groundwater. Soil removal and remedial actions have resulted in the offsite disposal of over 348,000 tons of material that contained more than 7,300 tons of fluoride.

The Troutdale site meets DEQ's 1×10^{-5} cumulative target risk and total hazard index (less than 1.0) for both the RME and CTE case for all human health exposure scenarios. The site also meets the 1×10^{-6} individual target risk criterion, except for the RME site trespasser scenario at the south wetlands and the RME occupational worker scenario at the East Area. However, the individual target risk criterion is not exceeded for these two areas under the CTE scenario. The slight exceedance of the 1×10^{-6} individual target risk for the RME site trespasser scenario at south wetlands is not considered significant in light of the results seen for the CTE case for this site. An additional calculation indicated that even if the trespass frequency were assumed to be 11 days per year, there would be no exceedances of the 1×10^{-6} individual target risk for this area. For trespasser exposure at south wetlands, an exposure frequency of about 5 days per year (assumed under the CTE case) is more reasonable than the 26 days per year assumed under the RME case¹⁷, and results in acceptable risk. In addition, the thick vegetation and standing water would serve to minimize direct contact with soil at south wetlands. For occupational exposure at the East Area, the exceedance of the individual target risk for a single PAH is not anticipated to be meaningful once site development occurs. The site is expected to be covered with buildings, parking lots, or landscaping prior to occupational use.

The results of the ERA indicate that the removal action in south wetlands was effective in further reducing ecological risk within acceptable levels.

Using the results of this post-demolition residual risk assessment, RMC has demonstrated that acceptable risk levels have been achieved for the property such that deed restrictions on soil are not required for the potential exposure scenarios evaluated, except as presupposed in the evaluation. These presuppositions include prohibiting residential use of the site and requiring that clean fill is placed over south wetlands prior to occupational use. RMC has accomplished this level of risk reduction by eliminating sources of contamination to the groundwater and to human and ecological receptors through soil removal, capping, offsite disposal, and grading. No further remedial action is anticipated.

¹⁷ The exposure frequency of 26 days per year was used as a high-end default in the BLRA and was carried over here for consistency, but it does not reflect actual trespass observed at south wetlands.

Deed restrictions on future activities at the site have been drafted in consultation with EPA and DEQ and will be finalized and included in the upcoming final Record of Decision (ROD). RMC has the goal of obtaining a final ROD and Consent Decree from EPA by September 30, 2006. This post-demolition residual risk assessment, ROD, and Consent Decree serve as the foundation for removing the Troutdale site from the NPL.

East Plant Area	Buildings 30, 32, 32A, 32C, 34, 36, 37A, 41A, 52/52B, 52A, 54, 54A, 54A-62 Trench, 55, 58, 60, 55A/58C/66A Basements, 56, 60, 62, 62A, 64, 66, 71, 83 Complex, 97 Subarea, 98 Area, 44, 46, 53 Cryolite Ponds Diesel Spill East Field East Parking Lot East Potliner Former Cryolite Plant Mineral Oil Spill North Field North Parking Lot North Property Old West Ditch and Forebay Potline 1-5 & Courtyard Railroad Fill/Embankment (West) ^a Railroad (Center, East, West) Rectifier Building – Filter Room Rectifier Yard Scrap Yard and Road South Landfill South Property Storage Areas 1, 2, 3, 4, 5, 6, 7 West of Potline 5 West South Ditch
^a Includes central and eastern portion of railroad embankment within the south wetlands boundary. The western portion of the railroad embankment is within the East Area.	

Table 2-2
Post-Demolition Residual Risk Assessment Exposure Scenarios

Exposure Area	Human Health					Ecological
	Short-Term Trespasser	Recreational User	Construction Worker	Excavation/Trench Worker	Occupational Worker	
Outside the Dike	X	X			a	b
Fairview Farms	X		X	X	X ^c	d
East Area	X		X	X	X ^c	
South Wetlands	X		X ^e	X	e	X

Notes:

- ^a The area outside the dike is located within a floodplain and could not support occupational uses unless it were filled. Therefore, present and future occupational uses in this area are highly unlikely.
- ^b As part of the interim Record of Decision (ROD), remedial actions for Company Lake and the north landfill area removed significant source materials, reducing terrestrial ecological risk for the area outside the dike. At the request of the U.S. Environmental Protection Agency (EPA) and the Oregon Department of Environmental Quality (DEQ), a comparison of submerged Company Lake verification sediment samples with applicable sediment regulatory benchmarks served to document current, post-remediation conditions. This evaluation is provided in *Memorandum No. 36: RMC-Troutdale Company Lake: Post-Remediation Data Evaluation Relative to Sediment Benchmarks* (CH2M HILL, 2005b).
- ^c Development of areas for planned industrial use will require placement of railways, roadways, buildings, fill, or landscaping, significantly reducing the potential for exposure to surface soil at the site (without excavation). However, an occupational scenario is evaluated to demonstrate whether controls may be necessary to ensure acceptable risk. Specification of barriers may be included in deed restrictions that would ensure placement of such barriers as part of development before occupational use could ensue.
- ^d The Fairview Farms area was evaluated for ecological risk in the *Baseline Risk Assessment, Part 1—Nongroundwater Media* (CH2M HILL, 2000) (BLRA), and risk was found to be acceptable. In the event that some localized areas of Fairview Farms remain to be used for green or open space, it is anticipated that these baseline ecological risk estimates would still apply.
- ^e The south wetlands area is below the seasonal water table, supports dense hydrophytic vegetation, and has standing water for a significant portion of the year. An occupational worker scenario was not evaluated for this area because extensive filling of the south wetlands area would be required before traditional construction or industrial use could begin. Potential exposures associated with future occupational use would need to assume direct contact with fill material, not the material currently in place, because placement of fill will preclude direct contact with south wetlands soil. A construction worker exposure scenario is evaluated to assess potential risks to construction workers, specifically survey crews or other workers who might conduct tasks in advance of filling. The exposure assumptions for this task may be modified to reflect the limited working season in the wetland. The excavation/trench worker scenario evaluates potential exposures resulting from penetration of the fill material for building foundations or from placing utility lines in existing soil. RMC will prepare a deed restriction that will be filed for this area, to be recorded with the property title, prohibiting future moving or altering of the current soil elevations, or any filling within the south wetlands area, without DEQ approval. This will effectively involve DEQ in any future plans that could conceivably result in human exposures. Draft language for a deed restriction was submitted to EPA for approval as part of the post-demolition project in support of a final Record of Decision.

✓ = Constituent was selected as a chemical of potential concern and used in the risk assessment.

1. Frequency of detection is less than 5%.

2. Chemical is an essential nutrient.

3. Exposure point concentration (EPC) does not exceed background levels.

4. No toxicity factor exists for chemical.

NT = Analyte was not tested for at this exposure area.

ND = Analyte was not detected at site.

^a Background values from Technical Memorandum DS No. 12: Background Data Summary for RMC-Troutdale (CH2M HILL, December 3, 1996).

Reasons:

1. Frequency of detection is less than 5 percent.
2. Chemical is an essential nutrient.
3. Maximum detected volume does not exceed background levels.
4. No toxicity factor exists for chemical.

Table 4-3

^a These risk estimates are based on EPCs calculated as the 90 percent upper confidence limit (UCL) for the primary contributing constituents (aroclors 1232, 1242, 1248, 1254, 1260, 1262, and 1268, and polychlorinated biphenyls), in accordance with DEQ guidance, and as outlined in Section 4.3 of Memorandum WP No. 67: Post Demolition Residual Risk Assessment Scoping Document for RMC-Troutdale (CH2M HILL, 2005a).

^b Background values from Technical Memorandum DS No. 12: Background Data Summary for RMC-Troutdale (CH2M HILL, December 3, 1996).

Reasons:

1. Frequency of detection is less than 5 percent.
2. Chemical is an essential nutrient.
3. EPC does not exceed background levels.
4. No toxicity factor exists for chemical.

^a Primary contributors to the total risk are listed when chemical-specific ELCR > 10⁶ or HQ > 1.0, and when that chemical contributes 10 percent or greater to the overall risk.

CTE = central tendency estimate.

ELCR = excess lifetime cancer risk.

HI = hazard index.

N/A = Not applicable since none identified.

RME = reasonable maximum exposure.

Total	2.1	0.5	100%	1.1	0.2	100%

Bold indicates the area with the greatest contribution to the ecological hazard quotient.

Table 5-8
Available LOAELs for Fluoride and PCBs

Chemical	Chemical Form Tested	Principal Study	Test Species	Exposure Route	Exposure Duration	Measured Effect	LOAEL (mg/kg-bw-day)
Fluoride	Sodium Fluoride	Patte et al., 1988 in Sample et al., 1996	Screech owl	Oral in diet	5-6 months/critical stage	Reproduction	32
Fluoride	Sodium Fluoride	Guenter and Hahn, 1986	Leghorn chicken	Oral in diet	252 days	Feed consumption, growth, egg quality, hen-day production	>49.3 ^a
PCBs	Aroclor 1254	Dahlgren et al., 1972 in Sample et al., 1996	Ring-necked pheasant	Oral gelatin capsule	17 weeks/critical stage	Reproduction	1.8
PCBs	Aroclor 1254	Bird et al., 1983 in Eisler, R. 1986	American kestrel	Oral in diet	62 to 69 days	Sperm reduction	9-10
PCBs	Aroclor 1254	Aulerich and Ringer, 1977 in Sample et al., 1996	Mink	Oral in diet	4.5 months/critical lifestage	Reproduction	0.69
PCBs	Aroclor 1242	McCoy et al., 1995 in Sample et al., 1996	Mink	Oral in diet	7 months/critical lifestage	Reproduction	0.69
PCBs	Aroclor 1016	Aulerich and Ringer, 1980 in Sample et al., 1996	Mink	Oral in diet	18 months/critical lifestage	Reproduction	3.43

Notes:

Values in bold were used in the Ecological Risk Assessment.

a. Based on a dietary fluoride intake of 700 mg/kg; dosage was calculated assuming leghorn body weight of 1.5 kg and food ingestion rate of 0.106 kg/day.

a. Conceptual development of areas for planned industrial use include covering the areas with structural fill, railways, rail bed ballast (crushed rock), roadways, parking areas, structures, and/or landscaping as part of development. However, the occupational worker exposure scenario is included to demonstrate whether controls may be necessary to ensure acceptable risk.

NOTES:

- 1) PLANT STRUCTURES SHOWN IN THESE PHOTOGRAPHS ARE FOR REFERENCE ONLY.
- 2) PLANT DEMOLITION IS COMPLETE. ALL STRUCTURES HAVE BEEN REMOVED BY ALCOA IN ACCORDANCE WITH THE DEMOLITION WORK PLAN AND EPA REQUIREMENTS.
- 3) AERIAL PHOTOGRAPHS WERE TAKEN IN 2003.
- 4) ALL SAMPLE LOCATIONS ARE IN SOIL. SAMPLES THAT APPEAR ON OR IN BUILDINGS WERE COLLECTED FROM SOIL ADJACENT TO BUILDINGS OR AFTER BUILDINGS WERE DEMOLISHED.
- 5) TABLES 3-1 THROUGH 3-4 IDENTIFY WHICH SAMPLE LOCATIONS ARE IN EACH EXPOSURE AREA. SOME FIGURES SHOW SAMPLE LOCATIONS IN MORE THAN ONE EXPOSURE AREA.

A horizontal scale bar representing distance in feet. The scale is marked at 0, 25, 50, 75, and 100. A thick black segment starts at 0 and ends at 25, with a thin white segment extending from 25 to 50. Another thick black segment extends from 50 to 100.

Note:

Cancer WOE Classifications:

Group A: Human carcinogen

Group B (B1, B2): Probable human carcinogen

Group C: Possible human carcinogen

Group D: Not classifiable

Group E: No evidence of carcinogenicity

ABS_d = Dermal Absorption Factor

ABS_{gi} = Gastrointestinal Absorption Factor

CDI = Chronic Daily Intake

ELCR = Excess Lifetime Cancer Risk

EPC = Exposure Point Concentration

mg/kg-day = milligrams per kilogram per day

SF_d = Dermal Slope Factor

SF_o = Oral Slope Factor

SF_i = Inhalation Slope Factor

WOE = Weight of Evidence

Note:

Cancer WOE Classifications:

Group A: Human carcinogen

Group B (B1, B2): Probable human carcinogen

Group C: Possible human carcinogen

Group D: Not classifiable

Group E: No evidence of carcinogenicity

ABS_d = Dermal Absorption Factor

ABS_{gi} = Gastrointestinal Absorption Factor

CDI = Chronic Daily Intake

ELCR = Excess Lifetime Cancer Risk

EPC = Exposure Point Concentration

mg/kg-day = milligrams per kilogram per day

SF_d = Dermal Slope Factor

SF_o = Oral Slope Factor

SF_i = Inhalation Slope Factor

WOE = Weight of Evidence

Note:

Cancer WOE Classifications:
 Group A: Human carcinogen
 Group B (B1, B2): Probable human carcinogen

Group C: Possible human carcinogen

Group D: Not classifiable

Group E: No evidence of carcinogenicity

ABS_d = Dermal Absorption Factor

ABS_{gi} = Gastrointestinal Absorption Factor

CDI = Chronic Daily Intake

ELCR = Excess Lifetime Cancer Risk

EPC = Exposure Point Concentration

mg/kg-day = milligrams per kilogram per day

SF_d = Dermal Slope Factor

SF_o = Oral Slope Factor

SF_i = Inhalation Slope Factor

WOE = Weight of Evidence

Note:

ABS_d = Dermal Absorption Factor
 ABS_{gi} = Gastrointestinal Absorption Factor
 CDI = Chronic Daily Intake
 EPC = Exposure Point Concentration
 HI = Hazard Index
 HQ = Hazard Quotient;
 mg/kg-day = milligrams per kilogram per day
 RfC = Reference Concentration
 RfD_d = Dermal Reference Dose;
 RfD_o = Oral Reference Dose
 RfD_i = Inhalation Reference Dose

APPENDIX B

**Area-Specific Ecological Risk
Calculation Data Sheets**

	Mink	7.50E+01	Mouse	4	1.88E+01	1.41E+00	0.08

a) Value is as calculated in Tables G-2 and G-3 of the BLRA; dose divided by the uncertainty factor for the toxicity endpoint

b) Uncertainty factors (UFs) used to extrapolate from the test species to the receptor; UFs are based on EPA Region 10 guidance (EPA, 1997)

c) Reference toxicity value is the NOAEL divided by the interspecies (taxa) uncertainty factor

a) During the BLERA, open water areas with available sediment, surface water, and biota tissue data included only Company Lake, and only for fluoride and PAHs. For these constituents, the intake equation for Company Lake included biota tissue data.

Because the biota tissue data were collected prior to restoration activities at Company Lake, the tissue data are no longer representative of current conditions.

Instead, the PDERA calculates bioaccumulation and intake rates at Company Lake using the same equations as other open water areas.

a) Value is as calculated in Tables G-2 and G-3 of the BLRA; dose divided by the uncertainty factor for the toxicity endpoint

b) Uncertainty factors (UFs) used to extrapolate from the test species to the receptor; UFs are based on EPA Region 10 guidance (EPA, 1997)

c) Reference toxicity value is the NOAEL divided by the interspecies (taxa) uncertainty factor

Table B-7

Fairview Farms Tier 1 Ecological Risk Assessment
 Intake Estimation for Ecological Endpoint Species
 RMC - Troutdale Facility

Chemical	Receptor Species	Body Weight (kg)	Daily Food Intake (kg/day)	Area Use Factor	Migration Factor	Daily Food Ingestion from Site (kg/day)	Daily Water Intake from Site (L/day)	Fraction of Diet as Prey	Sediment to Prey Transfer Factor	Fraction of Diet as Invertebrates	Sediment to Invertebrate Transfer Factor	Fraction of Diet as Plants	Sediment to Plant Transfer Factor	Fraction of Diet as Sediment	Sediment Conc. (mg/kg)	Bioavailability	Water Conc. (mg/L)	Chemical Intake (mg/kg-d)

a) Value is as calculated in Tables G-2 and G-3 of the BLRA; dose divided by the uncertainty factor for the toxicity endpoint

b) Uncertainty factors used to extrapolate from the test species to the receptor; UFs are based on EPA Region 10 guidance (EPA, 1997)

c) Reference toxicity value is the NOAEL divided by the interspecies (taxa) uncertainty factor

a) Value is as calculated in Tables G-2 and G-3 of the BLRA; dose divided by the uncertainty factor for the toxicity endpoint

b) Uncertainty factors used to extrapolate from the test species to the receptor; UFs are based on EPA Region 10 guidance (EPA, 1997)

c) Reference toxicity value is the NOAEL divided by the interspecies (taxa) uncertainty factor

a) Value is as calculated in Tables G-2 and G-3 of the BLRA; dose divided by the uncertainty factor for the toxicity endpoint

b) Uncertainty factors used to extrapolate from the test species to the receptor; UFs are based on EPA Region 10 guidance (EPA, 1997)

c) Reference toxicity value is the NOAEL divided by the interspecies (taxa) uncertainty factor
