

2003 Kentucky Small Grain Variety Trials

G. C. Claywell, C.S. Swanson, J. Connelley, R. Green, and D.A. Van Sanford

The 2003 wheat growing season ended with Kentucky farmers harvesting 300,000 acres of soft red winter wheat resulting in 17.7 million bushels of grain. An average yield of 59 bushels per acre was recorded, which is up six bushels per acre from the 2002 growing season (Table 1).

Small grain performance tests were conducted in six of the seven agroclimatic regions of Kentucky (Figure 1). Agricultural areas within each region are considered to have similar soil types and climatic conditions. Each region having a substantial acreage of a small grain commodity will have a trial conducted in that region for that commodity.

The objective of the Kentucky small grain variety trials is to evaluate varieties of barley and wheat that are commercially available or may soon be available to Kentucky farmers. New varieties are continually being developed by agricultural experiment stations and commercial firms. Annual evaluation of small grain varieties and selections provides seedsmen, farmers, and other agricultural workers with current information to help them select the varieties best adapted to their locality and individual requirements.

Because weather, soil, and other environmental factors will alter varietal performance from one location to another, tests are grown in six locations (Figure 1) in the state.

July 1, 2003, Kentucky Crop and Livestock Reporting Service

Experimental Methods

Beginning in 1998, varieties were evaluated under both conventional and no-till cultural practices. No-till tests were grown at three locations in addition to the conventional tests, which were grown at all locations.

The plots were planted with specially built multi-row conventional and no-till cone seeders. Conventional test plots consisted of six rows to form a plot 4 feet wide and 15 feet long, which was later trimmed to 10 feet in length. No-till plots consisted of seven rows to form a plot 4.5 feet wide and 40 feet long, which was later trimmed to 20 feet in length. Each variety was grown in four replications, and the data presented are the average response from the four replications. Plots were harvested with a small plot combine. Planting dates of all trials for the past three years are listed in Table 2.

** No-till wheat trial not harvested.

In some instances, uncontrollable factors—such as excessive rainfall, winter killing, high winds, hail, grazing cattle, etc.—adversely affected an experiment so that the results were judged unreliable. When this occurred, results are not given for that location and year. Data averaged over a period of years give a more accurate picture of varietal performance than do annual data.

Results and Discussion

Because genetic expression of a variety is greatly influenced by environmental conditions, it is best to have several years' data from which to draw conclusions. Performance of a variety tested for only one year should not be compared with a three-year average of another variety since it is possible that results in one of the other years were extremely good or poor and thus not comparable.

The yield of a variety is relative and should be compared with the yields of the other varieties in the same experiment and at the same location. Small differences in yield of only a few bushels per acre between two varieties from an individual test should not be interpreted to indicate the superiority of one variety over another. However, if one variety consistently outyields another over a period of several years, the chances are that the differences are real.

Lodging data are very difficult to interpret. A high-yielding variety should not necessarily be downgraded because of a high percentage of lodging for a given year at a given location. Local weather conditions, such as wind and rain, may cause a variety to lodge much more than it normally does. Variety trials normally have a greater degree of lodging than do farmer fields. It should also be emphasized that a variety reported to be 50 percent lodged does not imply that only 50 percent of the

grain could be harvested. With good equipment, almost all of the grain can often be saved. Lodging data for a period of years should receive more consideration than annual lodging data because they will give a more accurate picture of varietal performance.

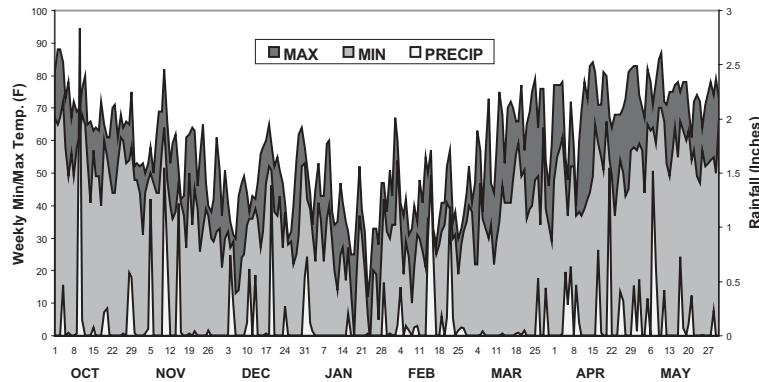

2003 Test Conditions

Wet weather in October hampered planting the 2003 wheat crop. Much of the wheat crop was planted in late October and on into November. Some intended wheat acreage was not planted at all as a result of the wet conditions. However, the 2003 small grain variety trials were planted within an approximate time window of 10 days from the middle to latter parts of October. As the wet conditions continued throughout the fall, colder temperatures prevailed also. As a result of cold, wet temperatures, tillering was reduced, but snow cover in some instances helped protect the crop. Very cold temperatures covering the plot growing regions of Kentucky for a few days in December seem to have had a slight effect on early planted wheat, but most wheat was planted later and not as negatively affected by the cold temperatures. January was the fourteenth coldest and eighteenth driest in 108 years of records.

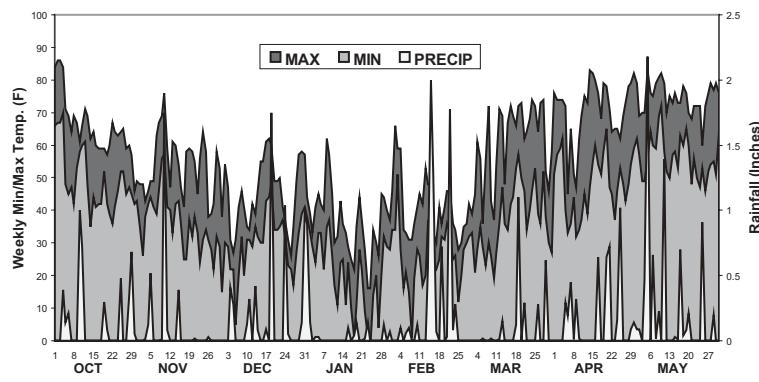

Wheat began to tiller and green up nicely in February with fairly moderate moisture available. In March and April, more than adequate rain fell on the crop. Going into flowering, precipitation continued in abundance. Temperatures during this period were much cooler than normal, and the grain filling period was extended.

Head scab was observed in some plot areas; however, cool temperatures limited the spread of the disease and reduced its impact. All no-till plots had insecticide and fungicide applications. Insecticides were used in the fall and spring to control aphids on the conventional plots.

Henderson Weekly Weather Data

Lexington Weekly Weather Data

Small Grain Varieties for 2003

Varieties eligible for certification include (1) varieties that may have potential for Kentucky and (2) older varieties that are still acceptable for production in Kentucky. The characteristics of wheat and barley varieties are summarized in Tables 3 and 13, respectively.

Soft Red Winter Wheat Varieties

Kentucky's climate and soils are well suited for the production of high-quality soft red winter wheat. No single variety has all the desirable characteristics, but each has certain advantages. Yielding ability, straw strength, height, earliness, grain quality, and disease resistance are important in choosing a variety. Varietal performance is presented in Tables 3 through 11.

Winter Barley Varieties

Winter barleys are less winter-hardy than winter wheat but more hardy than winter oats. The degree of winter-hardiness, straw strength, and maturity are important characteristics when choosing a variety. Varietal performance data are presented in Tables 13 through 15b.

Certified Seed

Planting certified seed is one of the first steps in ensuring a good small grain crop. The extra cost of certified seed is justified in view of the high quality of seed obtained. Certified seed is seed that has been grown in such a way as to ensure the genetic identity and purity of a variety. Certified seed also helps to maintain freedom from weed and other crop seed and, in some cases, freedom from disease. The Kentucky Agricultural Experiment Station recommends that Kentucky-certified seed be used whenever possible for growing commercial crops of small grains.

Acknowledgment is made to the following individuals for their contributions to this report: Brittany Edelson, Joanna Coles, Lloyd Weatherly, and Rankin Powell, county Extension agents for agriculture, for assistance in locating test sites and collecting data; D. Hershman and A. J. Stewart for disease ratings; V. Verges, C. Knott, A. J. Stewart, B. O'Daniel, H. Peden, B. Hilton, K. Liagre, T. Taylor, A. Balut, C. McCarty, J. Gray, W. Randolph, and Dottie Call for data collection; Mary Ann Kelley, Sandie Waddell, and Kay Cotton for text and table preparation; Freddie Higgins for data analysis.

Lexington and Princeton data were collected in an irrigated, inoculated nursery. The FHB index reflects both incidence and severity. Logan County data were based on natural infection.

Deoxynivalenol (vomitoxin) concentration, Lexington only.

* Variety not rated.
