Preface

The Long Term Resource Monitoring Program (LTRMP) was authorized under the Water Resources Development Act of 1986 (Public Law 99-662) as an element of the U.S. Army Corps of Engineers' Environmental Management Program. The LTRMP is being implemented by the Environmental Management Technical Center, an office of the National Biological Service, in cooperation with the five Upper Mississippi River System (UMRS) States of Illinois, Iowa, Minnesota, Missouri, and Wisconsin, with guidance and Program responsibility provided by the U.S. Army Corps of Engineers. The UMRS encompasses the commercially navigable reaches of the Upper Mississippi River, as well as the Illinois River and navigable portions of the Kaskaskia, Black, St. Croix, and Minnesota Rivers.

The mission of the LTRMP is to provide decision makers with information for maintaining the UMRS as a sustainable large river ecosystem given its multiple-use character. The long-term goals of the Program are to understand the system, determine resource trends and effects, develop management alternatives, manage information, and develop useful products.

This report was prepared under Strategy 1.2.3, *Determine Effects of Water Levels and Discharges on the Upper Mississippi River Ecosystem*, and Goal 3, *Develop Alternatives to Better Manage the Upper Mississippi River System*, as specified in the Operating Plan of the LTRMP for the Upper Mississippi River System (USFWS 1992). The purpose of the report is to provide requested information to the Pool 25 Natural Resources Management Committee concerning historical water level management practices.

This report was developed with funding provided by the Long Term Resource Monitoring Program.

Additional copies of this report may be obtained from the National Technical Information Service, 5285 Port Royal Road, Springfield, Virginia 22161 (1-800-553-6847 or 703-487-4650).

Pool 25: Analysis of Water Levels and Discharge

By Joseph H. Wlosinski

Abstract

Analysis of water level elevations and discharges was performed for Pool 25 on the Upper Mississippi River as part of a study to increase ecological benefits of the operation of Lock and Dam 25. This dam was placed in operation in May 1939. Since that time, the operating plan for managing water levels has undergone several changes. Discharges for Pool 25 were estimated using data from the closest gaging stations, with corrections accounting for changes in watershed area. Discharge estimates since 1939 were used to compute exceedence frequencies on a weekly, monthly, and yearly basis. They were also used to calculate the percentage of time discharges were within specified ranges for the three time scales. Water level measurements at five in-pool stations were used to calculate the percentage of time water levels were above specific elevations for the same three time scales. Only data for the period between 1952 and 1993 were used for this part of the analysis because different water level management plans were in use before 1952. The results of this work, along with a companion study, show the expected frequencies when alternative water level plans may be utilized and the amount of habitat that would be affected by alternative plans.

Introduction

Conservation agencies in Illinois and Missouri have requested assistance from the Environmental Management Technical Center (EMTC) in preparing an ecosystem management plan for Pool 25 on the Upper Mississippi River (UMR). The objective of the work to be performed by the EMTC is to evaluate management alternatives to minimize negative effects and increase ecological benefits of the operation of Lock and Dam 25 (Fig. 1). The purpose of this report is to provide requested information to the Pool 25 Natural Resources Management Committee concerning historical discharges and water level management practices. Results from historical analyses will be used to estimate the percentage of time that alternative plans could be utilized. The Committee requested that most analyses be conducted using three time scales: yearly, monthly, and weekly. A companion report (Wlosinski and Rogala 1996) includes information on water levels in Pool 25 and the types and amounts of habitat affected by various management alternatives. Related reports have been issued by the U.S. Army Corps of Engineers (1991), Wilcox and Willis (1993), Wlosinski and Hill (1995), and Wlosinski and Koljord (1996).

Water Level Management

Legal Authorities

Congress authorized a 9-ft channel for the Mississippi River by way of the River and Harbor Act of July 3, 1930, as modified by the act of August 30, 1935 (U.S. Army Corps of Engineers 1980a). These Acts provide for a channel depth of 9 ft at low water level with widths suitable for long-haul, common-carrier service. However, other laws, executive orders, and regulations also pertain to water level regulation. The information below was excerpted from reports by the U.S. Army Corps of Engineers (1991) and Wilcox and Willis (1993). The broad authority of the Secretary of the Army to prescribe regulations for the use, administration, and navigation of navigable waters of the United States (33 United States Code [U.S.C.] 1) could be exercised to impact water levels. Investigations and improvements of rivers must include a "due regard for wildlife conservation" (33 U.S.C. 540). According to para. 21, subpara. c of Engineering Manual 1110-2-3600, November 30, 1987, Management of Water Control Systems, even in single-purpose projects, operations "must be tuned to produce the benefits for environmental

and social goals such as flood control, instream quality, in-lake quality, recreation, power, or any other attainable goals a project can achieve without compromising the authorized project purpose." The Fish and Wildlife Coordination Act, 16 U.S.C. 661, et seq. provides that fish and wildlife receive equal consideration with other project purposes.

Historical Plans

Water level management on Pool 25 has changed since construction of the lock and dam system on the UMR. Previous plans are included here to provide possible alternatives within the original laws and regulations. Historical plans were obtained from Appendix 25, Master Water Control Manual (U.S. Army Corps of Engineers 1980b). Lock and Dam 25 was placed in use on May 18, 1939, and reached full pool on July 11, 1939. The dam backs up water on the Mississippi River from river mile (measured from the confluence of the Mississippi and Ohio Rivers) 241.4 to river mile 273.4. The authorized project pool elevation is 434.0 ft above sea level (1929 National Geodetic Vertical Datum).

The water level management plan adopted when Lock and Dam 25 was constructed limited pool regulation to the navigation season of March 10 to December 1 of each year, with open river conditions during the remainder of the year. Open river conditions exist when all dam gates are out of the water, and water levels on the upriver and downriver side of the dam are nearly equal. Under this plan, water levels in Pool 25 were regulated as follows: Water stage would be allowed to recede as discharges fell from relatively high values, until elevation 435.75 ft was reached at the Mozier Landing gage (river mile 260.3; Fig. 1). It was thought this stage would be reached coincidental with a maximum drawdown at the dam of 427.0 ft. As flows continued to decrease, an elevation of 435.75 ft was maintained on the Mozier Landing gage by closing dam gates until an elevation of 434.0 ft was reached at the dam. This procedure was

reversed during increasing river flows. This scheme is known as the mid-pool control point method or the hinge point method.

The major benefit of this plan is that it required a minimum amount of land to be acquired by the Government. On navigable streams, the area between the plane of ordinary high water and the plane of highest backwater produced by regulation of a dam is a measure of damages for which the U.S. Government is liable. For Pool 25, the limiting land acquisition lines were drawn 2 ft higher than the maximum calculated backwater elevation at the dam site and at the towns of Sterling and Hamburg, and 2 ft above elevation 436.0 ft at the mouth of the Sny River (river mile 261.5). From elevation 438.0 ft at the mouth of the Sny River, a horizontal line was drawn to the intersection with ordinary high water, about river mile 264.4. The lands purchased totaled about 12,000 acres, with 7,000 acres in Calhoun County, Illinois, and 4,000 and 1,000 acres, respectively, in Lincoln and Pike Counties, Missouri.

Regulation of the pool on a year-round basis was commenced in the early 1940s, with the maximum drawdown elevation at the dam changed from 427.0 to 428.0 ft. Sterling Landing (river mile 250.8) was established as an auxiliary control point in 1945. Under that plan as discharge fell from relatively high values, an elevation of 428.0 ft was maintained at the dam by placing dam gates in the water. This elevation was held until an elevation of 431.0 ft was reached at Sterling Landing. An elevation of 431.0 ft was maintained at Sterling Landing by adjusting the dam gates until an elevation of 434.0 ft was reached at Mozier Landing. An elevation of 434.0 ft was maintained at Mozier Landing until an elevation of 434.0 ft was reached at the dam. This procedure was reversed during increasing river flows.

About 1950, use of the auxiliary control point at Sterling Landing was abandoned, and an elevation of 429.7 ft at the dam was established as the maximum drawdown elevation. A modified drawdown schedule was implemented in 1971 as an aid to waterfowl hunters. The new maximum

drawdown and waterfowl season changes are still in effect and are further described below.

When discharge, as estimated at Lock and Dam 25, is between 0 and 95,000 ft³ per second (cfs), the target water level is maintained between 434.0 and 435.75 ft at Mozier Landing (mid-pool control point). To maintain the target water level at this location as the discharge increases up to 95,000 cfs, gates are raised at the dam, causing the water level to fall just upriver of Dam 25. However, the water level at the dam cannot be lowered past a maximum drawdown elevation without affecting the 9-ft navigation channel. At 95,000 cfs, the water level at Dam 25 is lowered to its maximum drawdown (429.7 ft), or 4.3 ft below the project pool elevation. Between 0 and 95,000 cfs, water levels rise in parts of the pool upriver of Mozier Landing and drop downriver of this location. Between 95,000 and 135,000 cfs, the target water level is maintained at 429.7 ft at Dam 25, and in all locations of the pool upriver of the dam the water surface rises with an increase in discharge. As discharge increases from 0 to 135,000 cfs, water levels rise in the tailwater of Dam 25. Above 135,000 cfs, water elevations on both sides of the dam will be nearly the same and all gates are raised above the water surface (known as open river conditions). Above 135,000 cfs, a 9-ft channel exists naturally, and the dam is not needed; the reverse operation occurs as discharge falls. The modified schedule begins October 1 of each year and is in effect only during the waterfowl season, when discharge is between 70,000 and 135,000 cfs. This modification was implemented so that hunters would not be stranded on mud flats. The present plan is shown in Figure 2. Navigation is officially possible during the entire year. However, from December into March, ice forms on the pool, which at times makes navigation nearly impossible. Ice may be passed from the pool by rapidly raising and lowering water levels (U.S. Army Corps of Engineers 1980b).

Methods

Historical water level measurements were obtained from the U.S. Army Corps of Engineers, St. Louis District, at six stations: the tailwater at Lock and Dam 25 (river mile 241.2), the headwater of Lock and Dam 25 (river mile 241.5), Sterling Landing (river mile 250.8), Mozier Landing (river mile 260.3), Rip Rap Landing (river mile 265.0), and the tailwater at Lock and Dam 24 (river mile 273.2). Measurements were obtained as daily water level readings, usually taken between 6 and 8 a.m. Each water level observation includes a five-character station name, year, Julian day, the time the observation was made, and the water level, reported as feet above sea level using the 1929 National Geodetic Vertical Datum. Additional information concerning the water level and discharge databases maintained at the EMTC appear in the LTRMP Procedures Manual (Wlosinski et al. 1995).

Discharge estimates were also needed for the study because water levels are managed as a function of discharge. However, discharge estimates are not routinely measured at Lock and Dam 25. The closest U.S. Geological Survey (USGS) discharge station on the Mississippi River upriver of Dam 25 is at Keokuk, Iowa, and downriver at Grafton or Alton, Illinois. The USGS moved their monitoring station from Alton to Grafton in 1986. Dam 25 is 123 river miles from Keokuk, 23 river miles from Grafton, and 39 river miles from Alton. Grafton and Alton have a much larger watershed than Dam 25, but measured discharge at either Meredosia or Valley City on the Illinois River accounts for most of the difference. Because travel time is much shorter to Grafton and Alton, data from these stations were used to estimate discharge at Dam 25. Discharges for the tailwater of Lock and Dam 25 were estimated using the following equations:

October 1939 to September 1986

$$Q_{25} = Q_a - Q_m - (0.0202 Q_a)$$

October 1986 to September 1993

$$Q_{25} = Q_g - Q_{vc} - (0.0149 Q_g)$$

where:

- Q_{25} = Discharge estimate for Lock and Dam 25 tailwater
 Q_a = Discharge at Alton (from USGS)
 Q_g = Discharge at Grafton (from USGS)
 Q_m = Discharge at Meredosia (from USGS)
 Q_{vc} = Discharge at Valley City (from USGS)

The parameter 0.0202 represents the percentage of the watershed area at Alton not included in the Pool 25 watershed. Similarly, 0.0149 represents the percentage of the watershed area at Grafton not included in the Pool 25 watershed. Two equations were needed because gaging station locations were changed on both the Mississippi and the Illinois Rivers. If the calculated Pool 25 discharge from either equation was lower than the discharge at Keokuk, Iowa, three days before, the Keokuk discharge was used. Each discharge observation includes a five-character station name, year, Julian day, and discharge, reported in cubic feet per second as a daily average.

Linear trends for yearly minimum, mean, and maximum discharges were developed using autoregressive error correction procedures (SAS Institute, Inc. 1993). Significance for these procedures was set at $P \leq 0.05$.

Discharge estimates were used to compute exceedence frequencies on a weekly, monthly, and yearly basis. They were also used to calculate the percentage of time discharges were within specified ranges on a weekly, monthly, and yearly basis.

Water level measurements at the five in-pool stations were used to calculate the percentage of time water levels were above specific elevations on a weekly, monthly, and yearly basis. Only data for the period between 1952 and 1993 were used because different water level management plans were in use before 1952.

All analyses were conducted at the EMTC using the Statistical Analysis System (Version 6.09) on a Sun workstation and Fortran programs on a personal computer.

Results and Discussion

Minimum, mean, and maximum yearly discharges for Pool 25 from 1940 to 1993, inclusive, are presented in Figure 3. A linear trend line is also presented for each relationship. Although all trends are increasing, only the trends for minimum and mean yearly discharges are statistically significant. The R^2 values were 0.22, 0.12, and 0.03 for the minimum, mean, and maximum trends, respectively. Other statistics for the discharge database are presented in Table 1. The minimum, mean, and maximum estimated discharges for the period of record were 12,700, 91,200, and 524,000 cfs, respectively. The mean daily discharge for the period of record is presented in Figure 4.

A discharge exceedence curve for the tailwater of Pool 25, based on estimates from 1939 to 1993, is presented in Figure 5. Similar curves are presented for the months of January through December in Figures 6 through 17, respectively. Discharge exceedence values (1,000 cfs), by week, are listed in Table 2. Discharges are above the listed value for a specified percentage of time.

The percentage of time discharges were within certain ranges in the tailwater (river mile 241.2) of Pool 25, based on estimates from 1939 to 1993, is presented in Figure 18. Similar curves are presented for the months of January through December in Figures 19 through 30, respectively. The percentage of time discharges were within certain ranges, calculated on a weekly basis, is presented in Table 3.

Yearly statistics for water surface elevations at the headwater of Lock and Dam 25, Sterling Landing, Mozier Landing, Rip Rap Landing, and the tailwater at Lock and Dam 24 are presented in Tables 4 through 8, respectively. The

percentages of time water levels are above specific elevations at the above five stations, calculated on a monthly and yearly basis, are presented in Tables 9 through 13. Similarly, the percentages of time water levels are above specific elevations at the above five stations, calculated weekly, are presented in Tables 14 through 18. The mean yearly water surface elevations at Sterling Landing are presented in Figure 31 (Sterling Landing is the station with the most data). Water level fluctuations are greatest in the upriver portions of the pool on the Upper Mississippi River because of the way the dams are managed. At Pool 25, water level fluctuations from 1952 to 1993 averaged 14.9 ft at the tailwater of Lock and Dam 24 to 7.9 ft at the headwater of Lock and Dam 25.

Discharge is an unpredictable variable that may allow or disallow any planned water level management alternative. However, some idea is needed as to how often discharge remains within predefined limits. Figures 18 through 30 and Table 3 provide information on discharge frequencies averaged over the historical record. For some purposes, it may be more useful to know the percentage of years when discharge remained at certain levels for a particular time period. For example, in August, discharge is between 35,000 and 55,000 cfs 30% of the time (Fig. 26), but during only 1 of 54 years of record it remained within that range for the entire month. A table or graph displaying this information cannot be developed because of the infinite number of possible alternatives. A program that calculates the percentage of years discharge would be expected to be between certain ranges for certain time periods has been developed, based on historical discharge estimates from October 1939 to October 1993. To run the program, the user must have access to the Sun computer system at the EMTC. After logging on to the Sun04 computer, enter the string:

```
sas /home/jhw0/getp25q
```

The program then queries the user for a discharge range and a time period and returns the percentage of years that discharge remained

within that range. For example, let us assume that discharge must be between 40,000 and 160,000 cfs to keep the water level lower than 433.0 ft at the headwater of Pool 25 in July. By running the program, we see that discharge is within the specified range for the entire month, for 33% of the years.

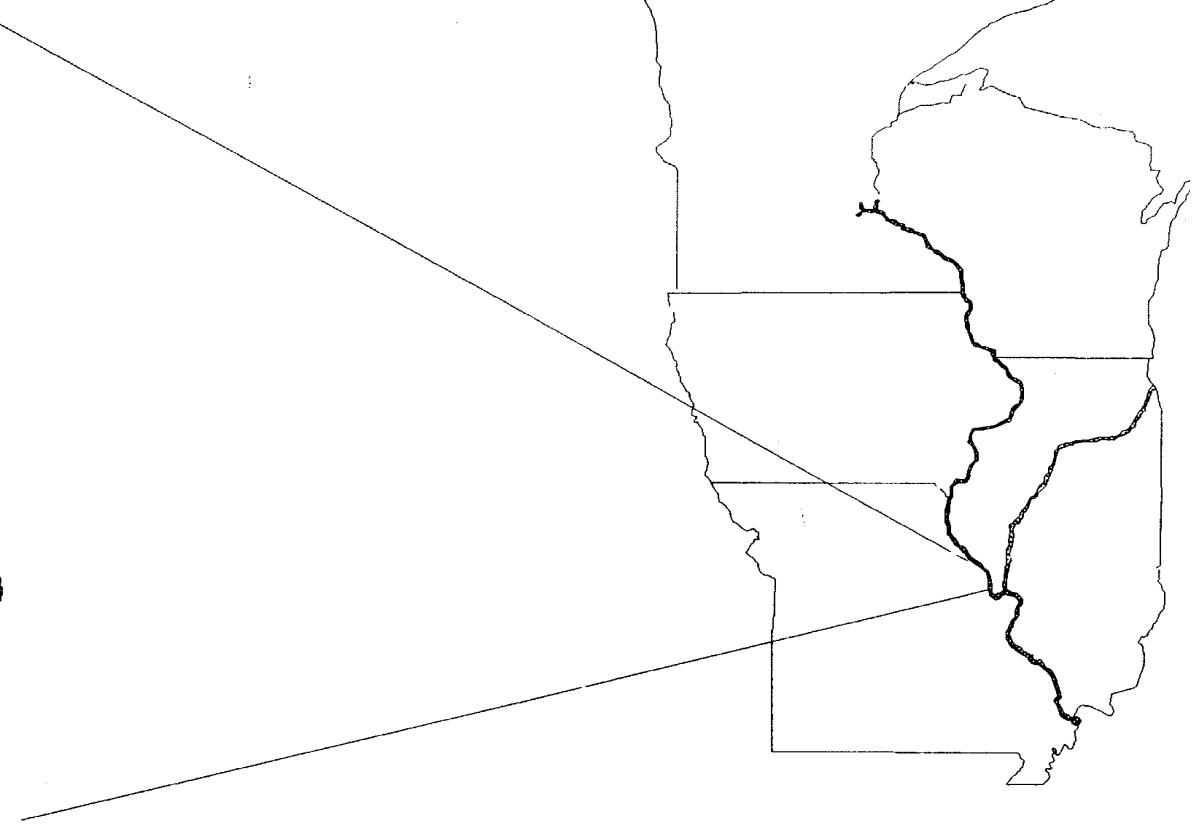

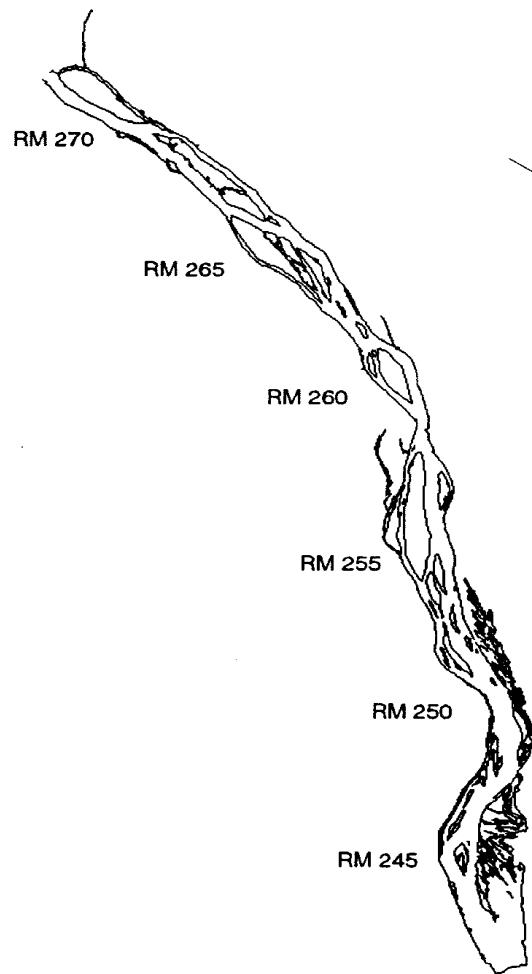

Figure 1. Pool 25 on the Mississippi River

RM = River Mile

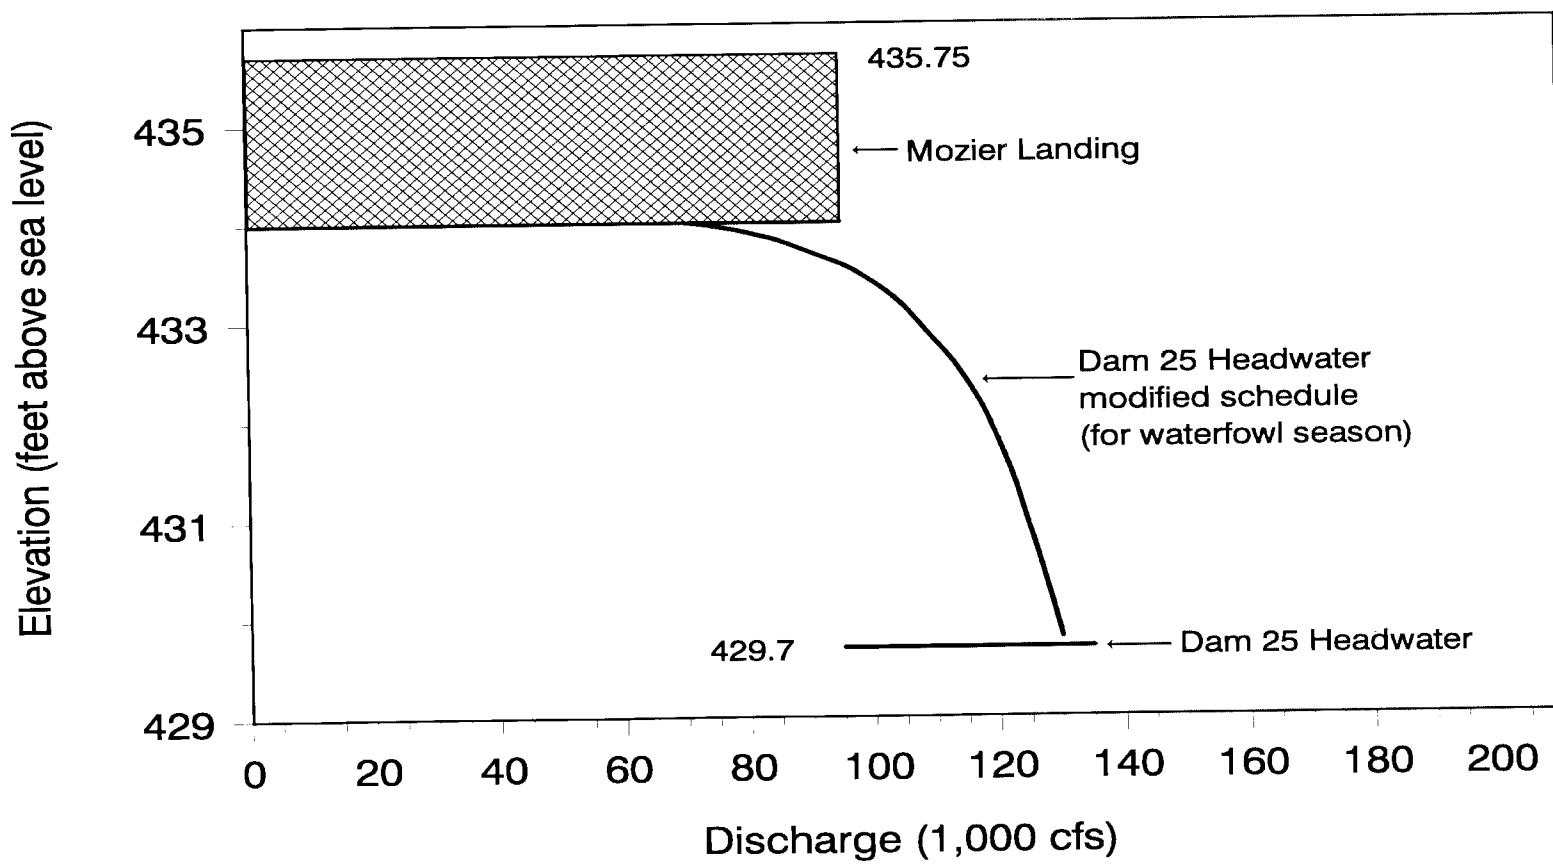

Figure 2. The present water level management plan for Upper Mississippi River System Pool 25. Water levels are kept within the hatched areas at Mozier Landing (river mile 260.3) when discharges are under 95,000 cubic feet per second (cfs).

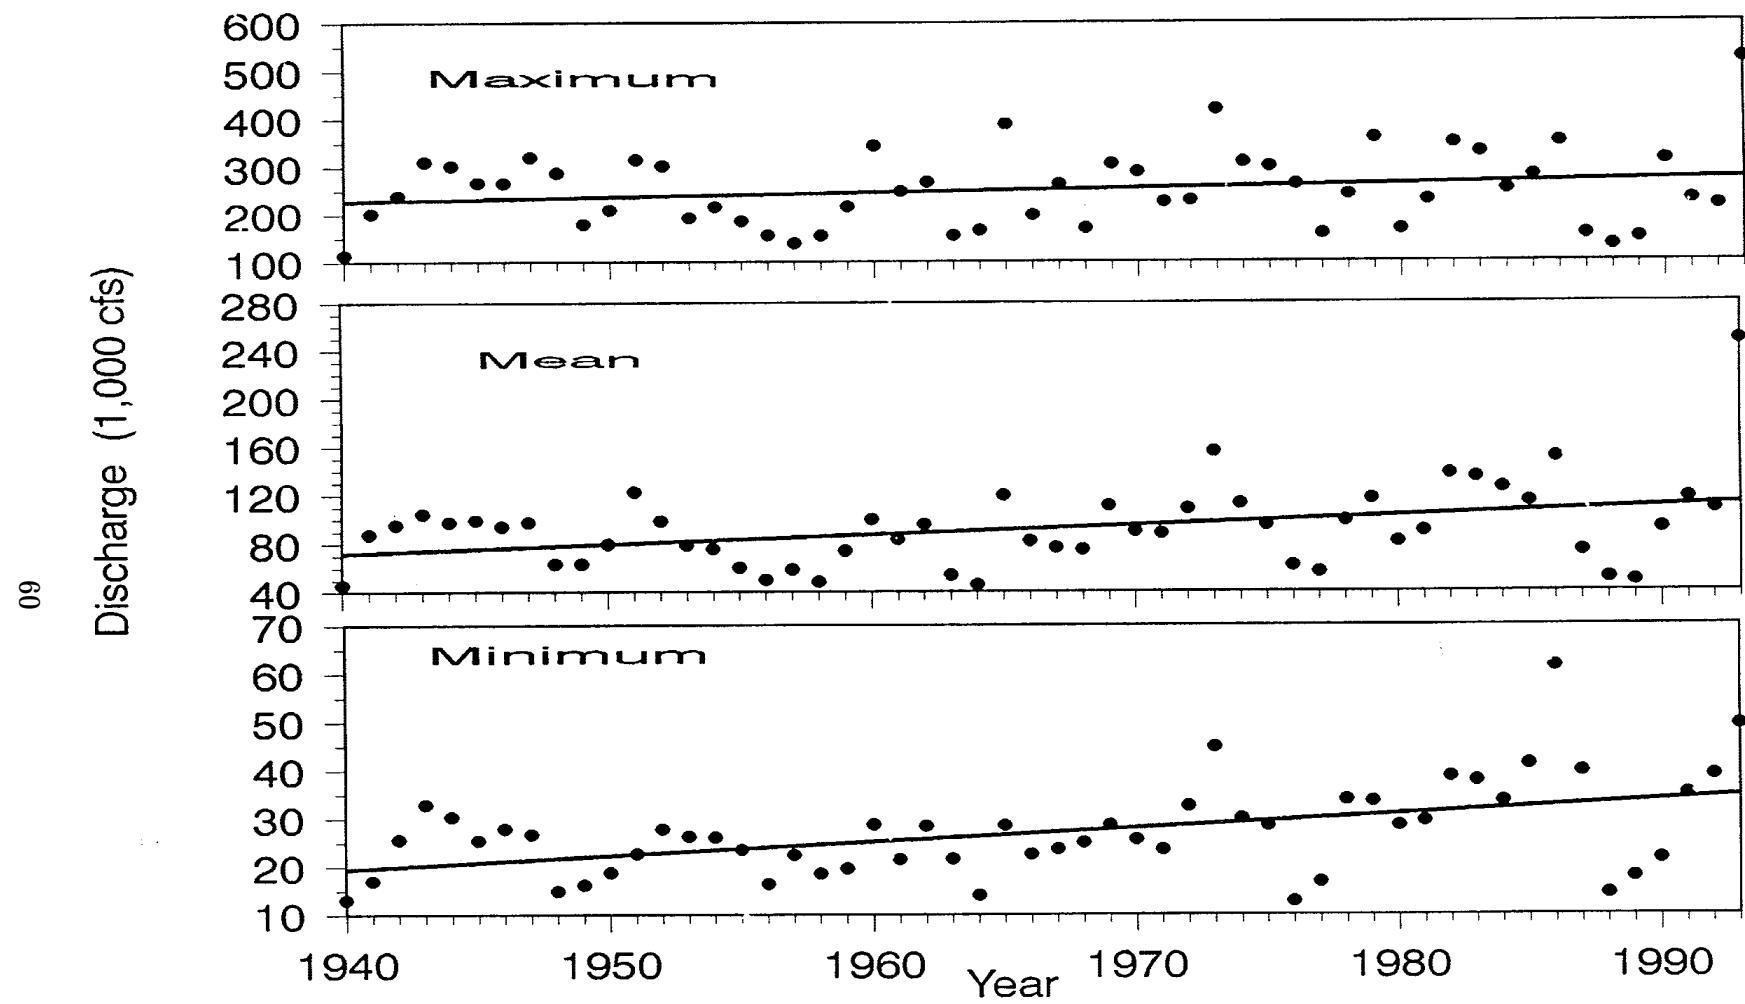

Figure 3. Minimum, mean, and maximum yearly discharges for Upper Mississippi River System Pool 25 from 1940 to 1993, inclusive

cfs = cubic feet per second

19

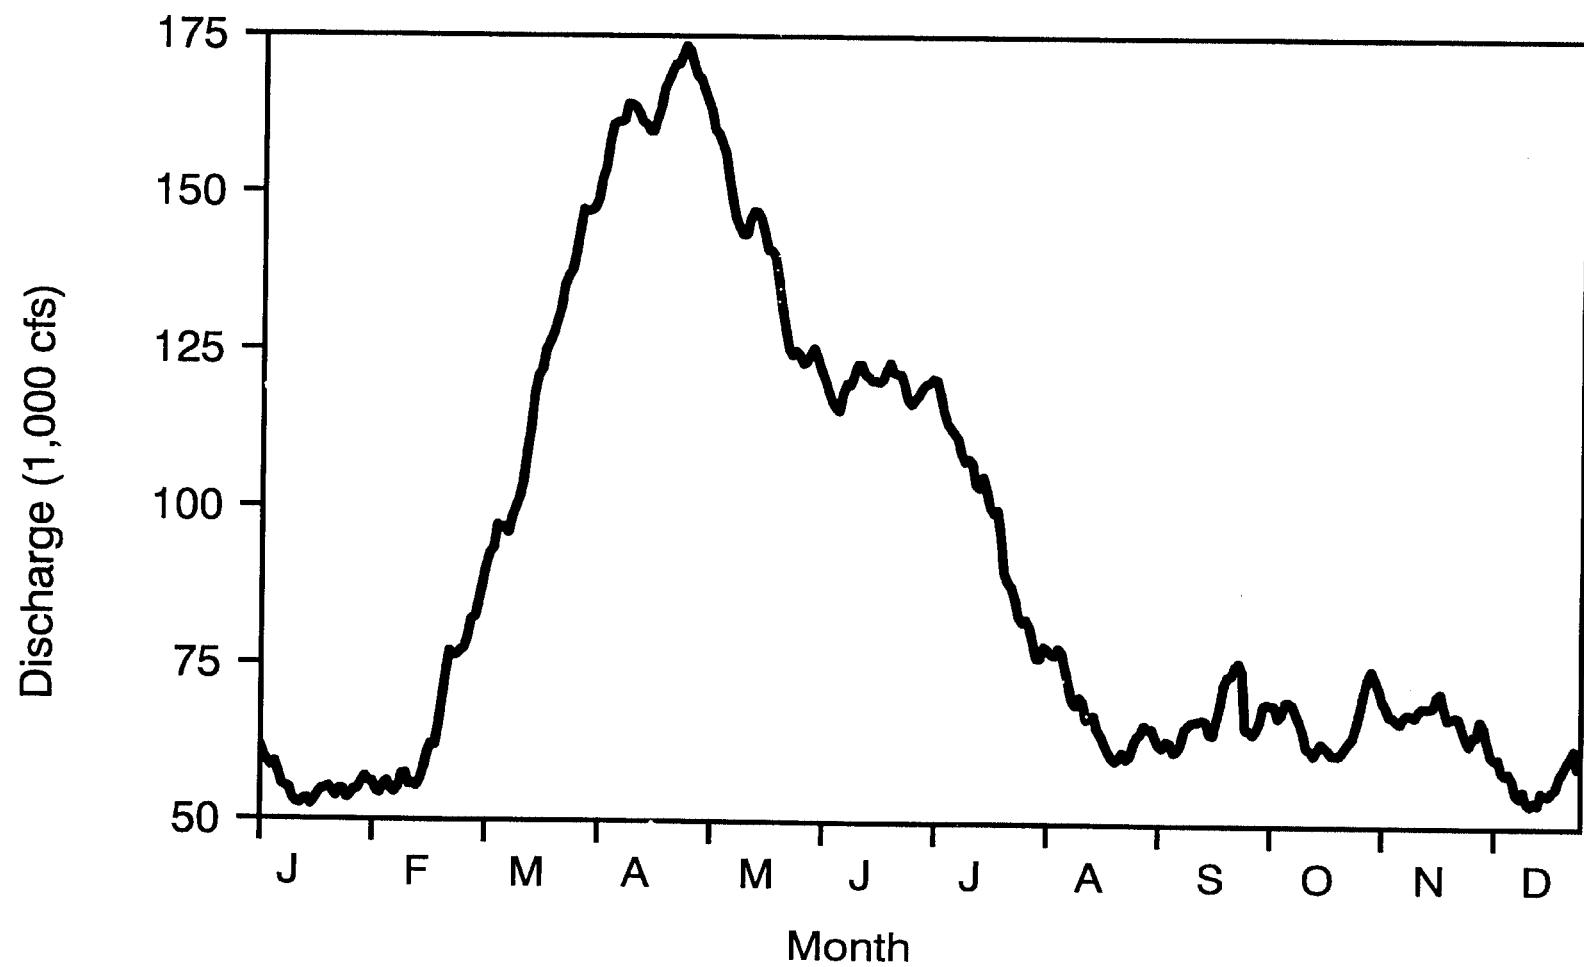

Figure 4. Mean daily discharge for Upper Mississippi River System Pool 25 from 1940 to 1993, inclusive

cfs = cubic feet per second

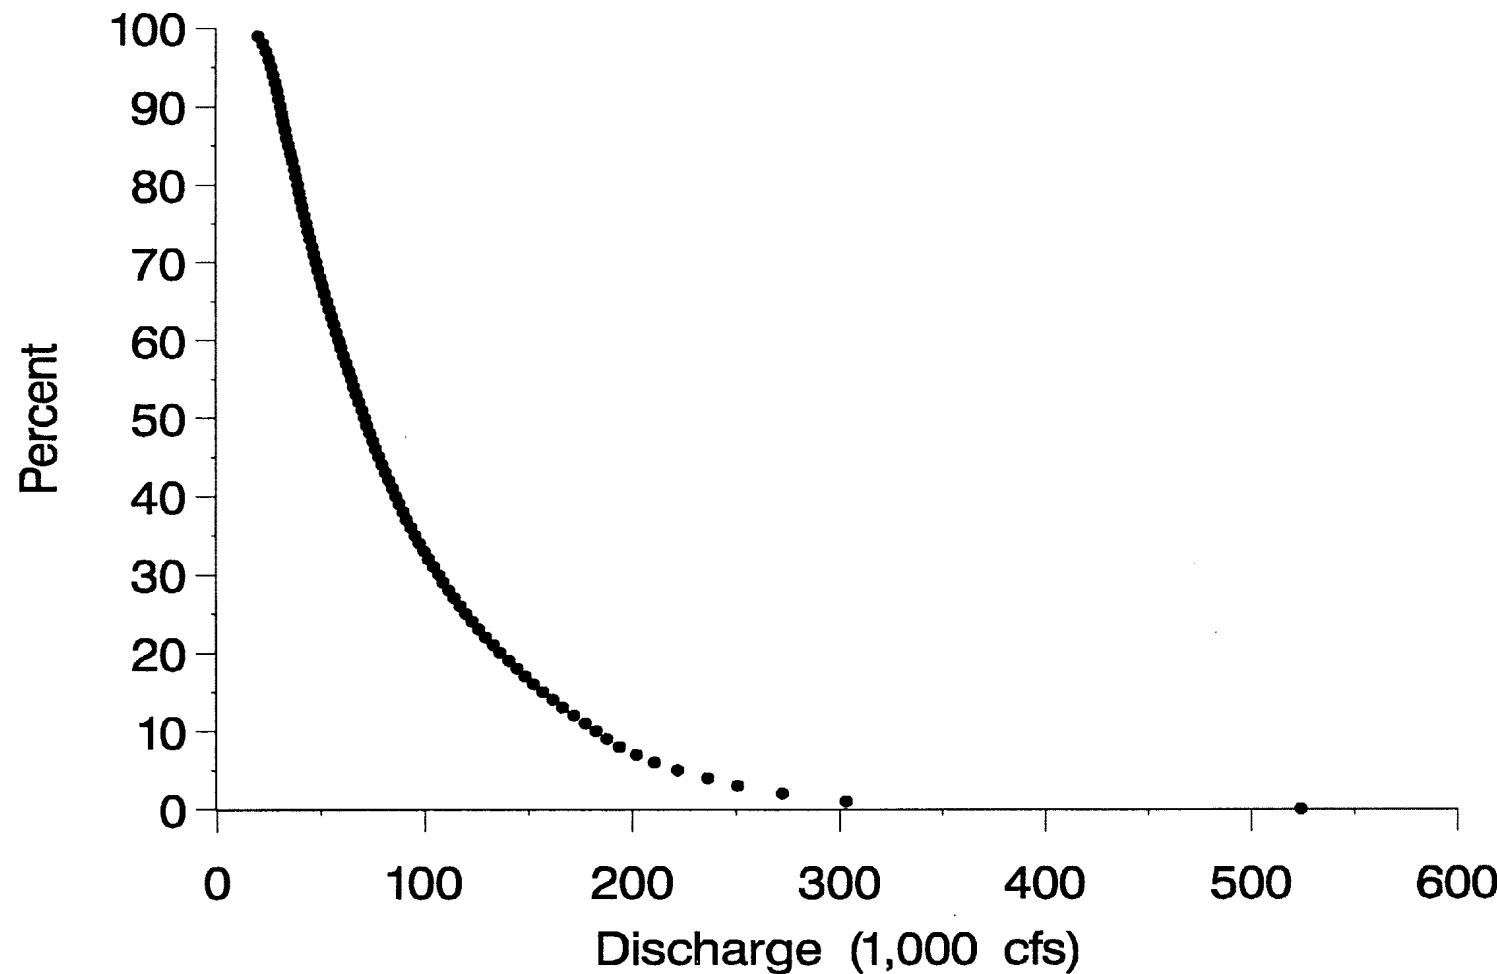

Figure 5. Discharge exceedence curve for the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected from 1939 to 1993. The 50% exceedence value is 71,000 cubic feet per second (cfs).

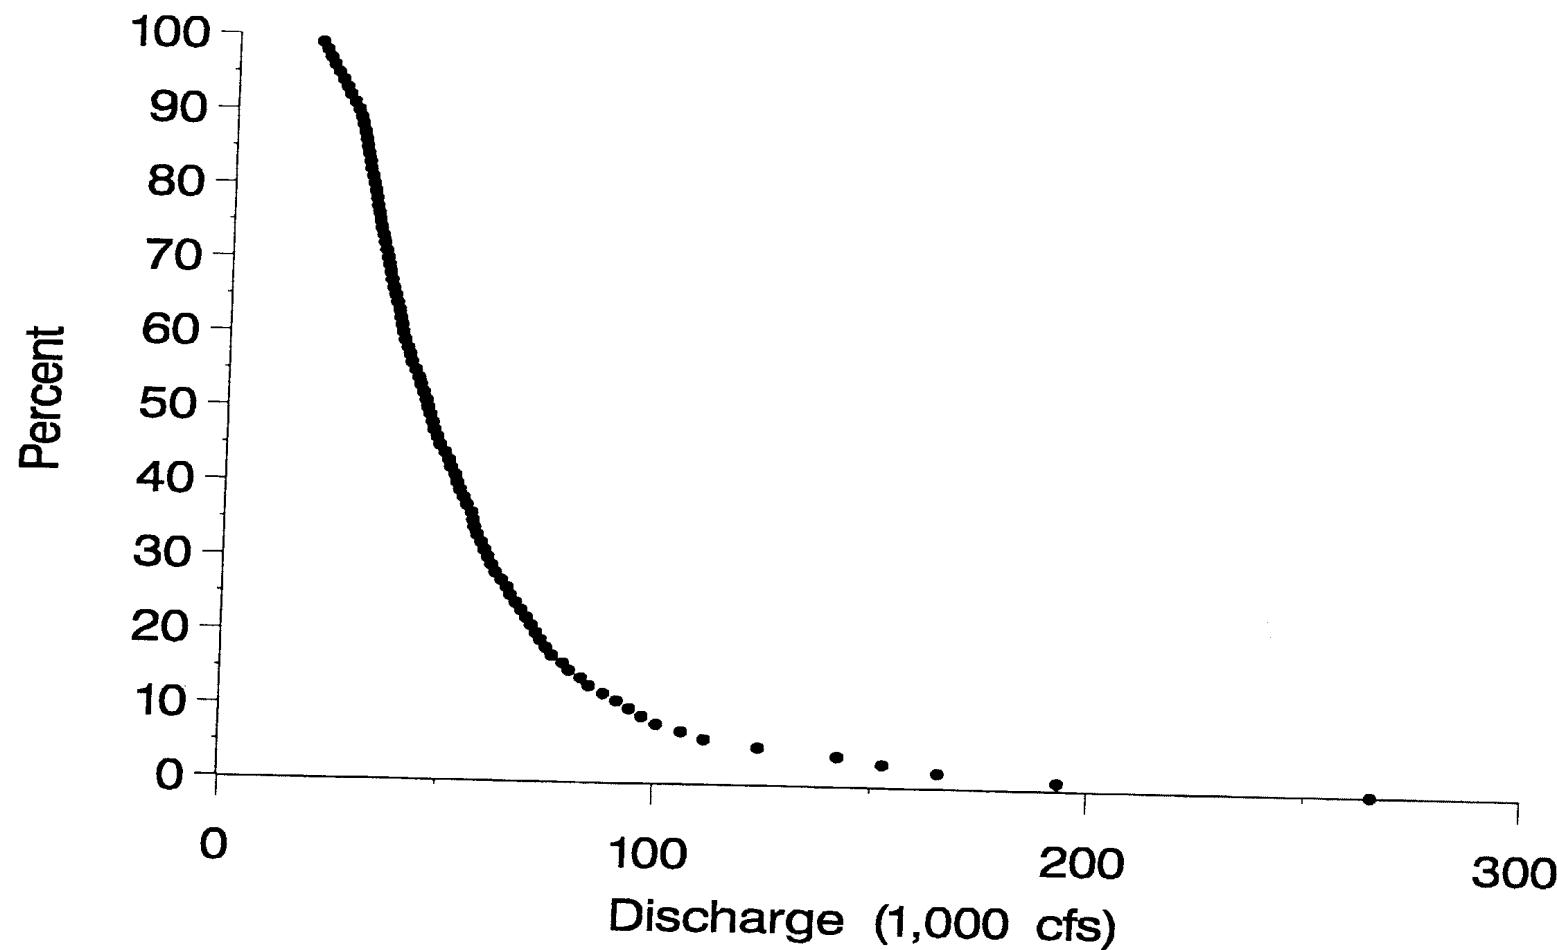

Figure 6. Discharge exceedence curve for the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected during January from 1939 to 1993. The 50% exceedence is 46,000 cubic feet per second (cfs).

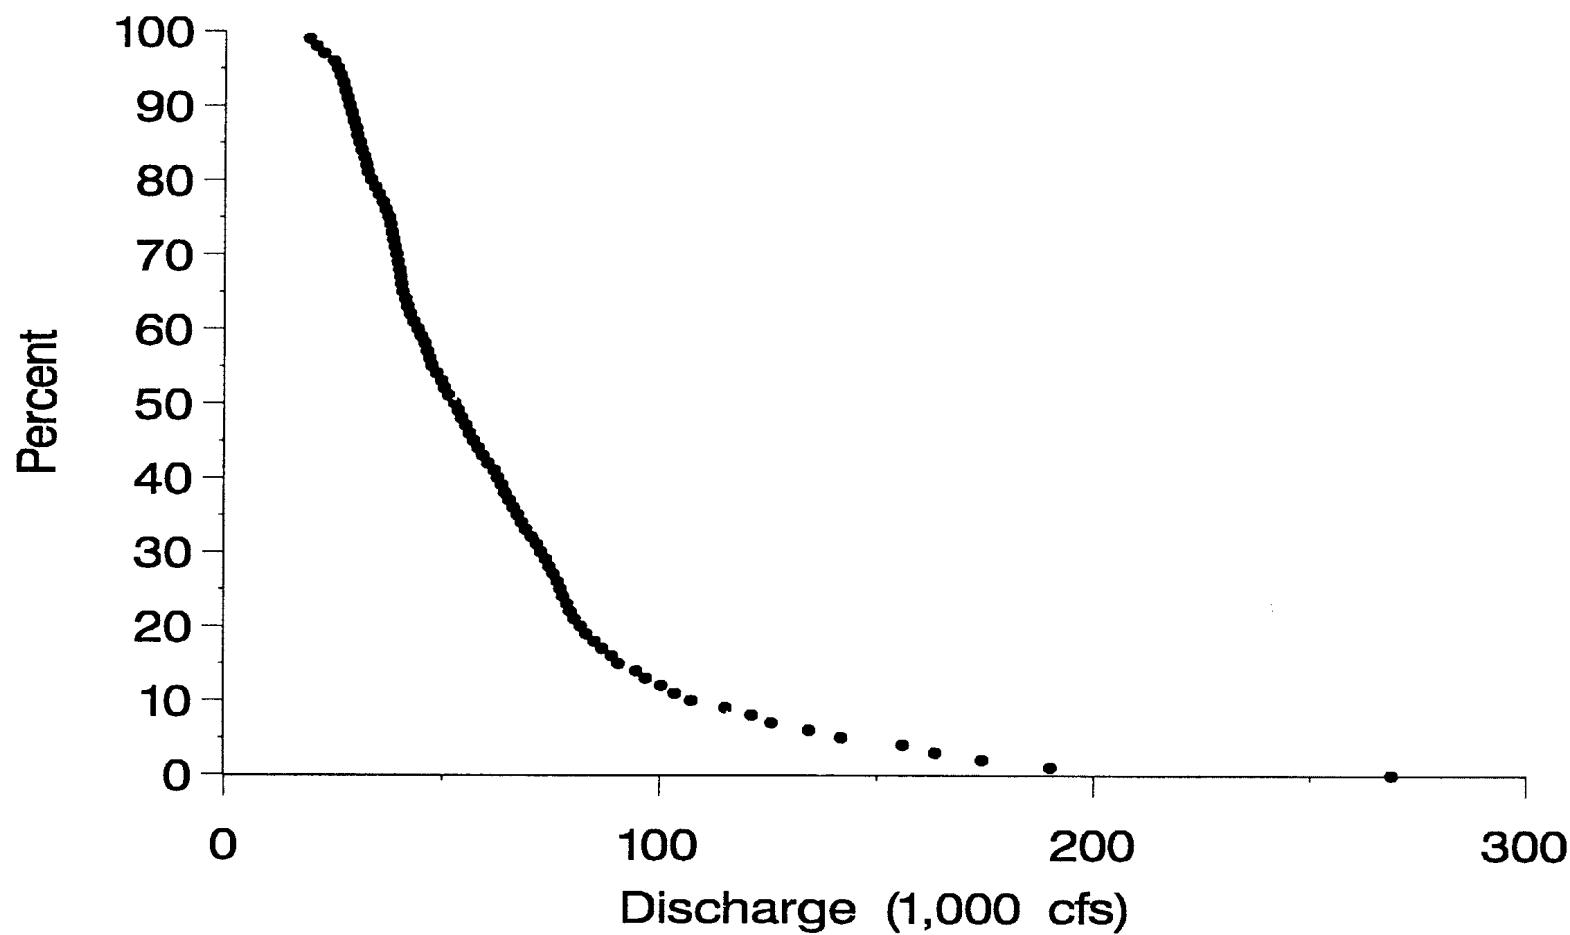

Figure 7. Discharge exceedence curve for the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected during February from 1939 to 1993. The 50% exceedence value is 53,000 cubic feet per second (cfs).

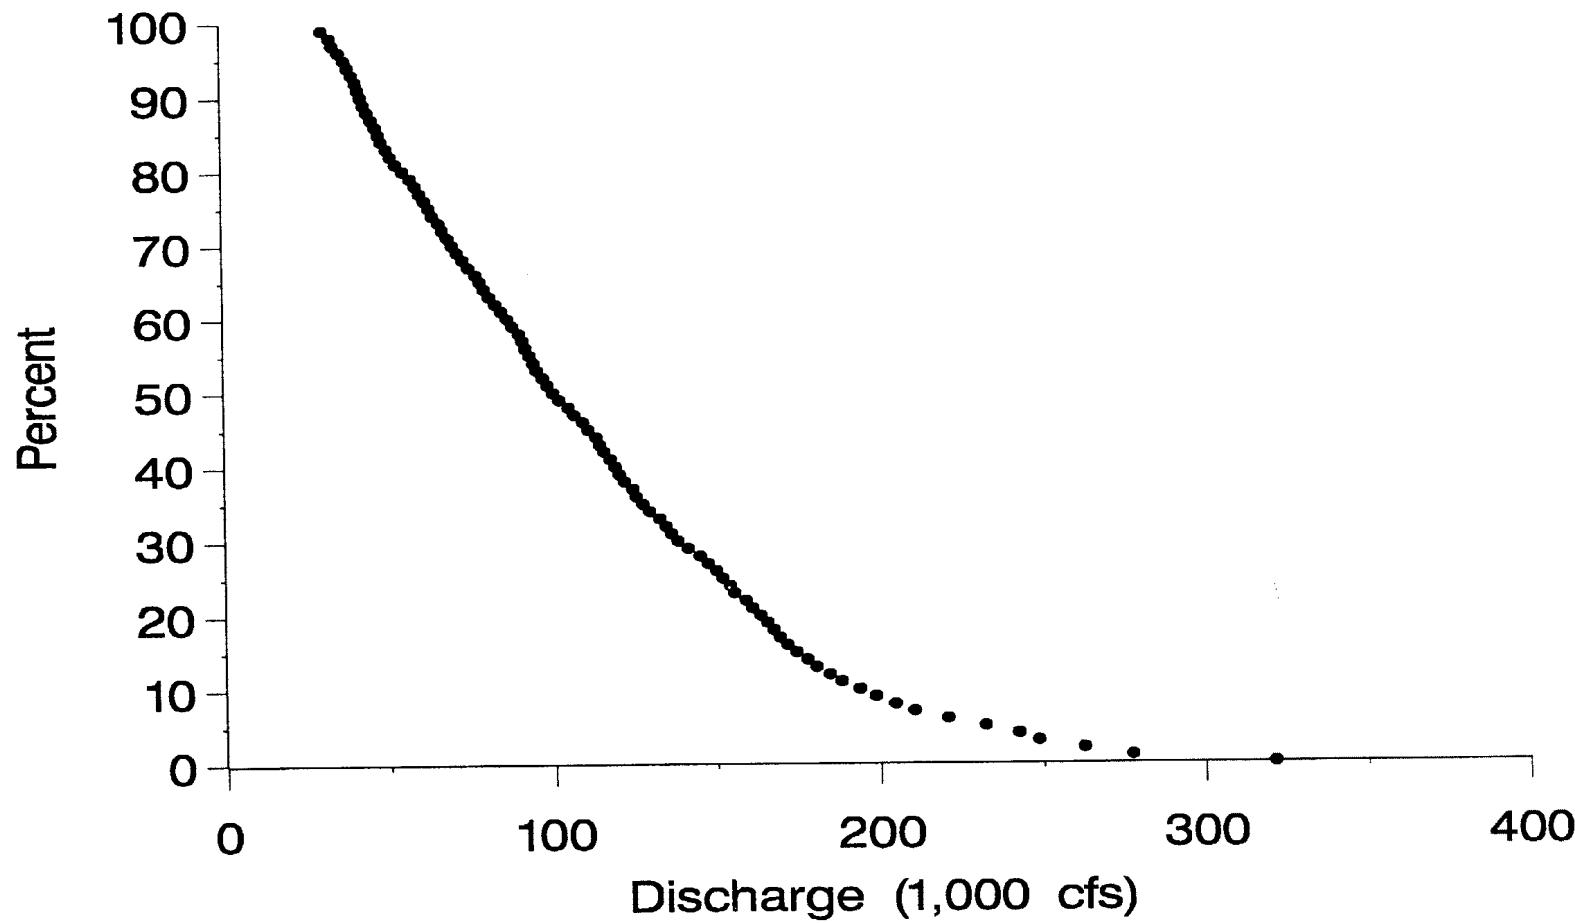

Figure 8. Discharge exceedence curve for the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected during March from 1939 to 1993. The 50% exceedence value is 100,000 cubic feet per second (cfs).

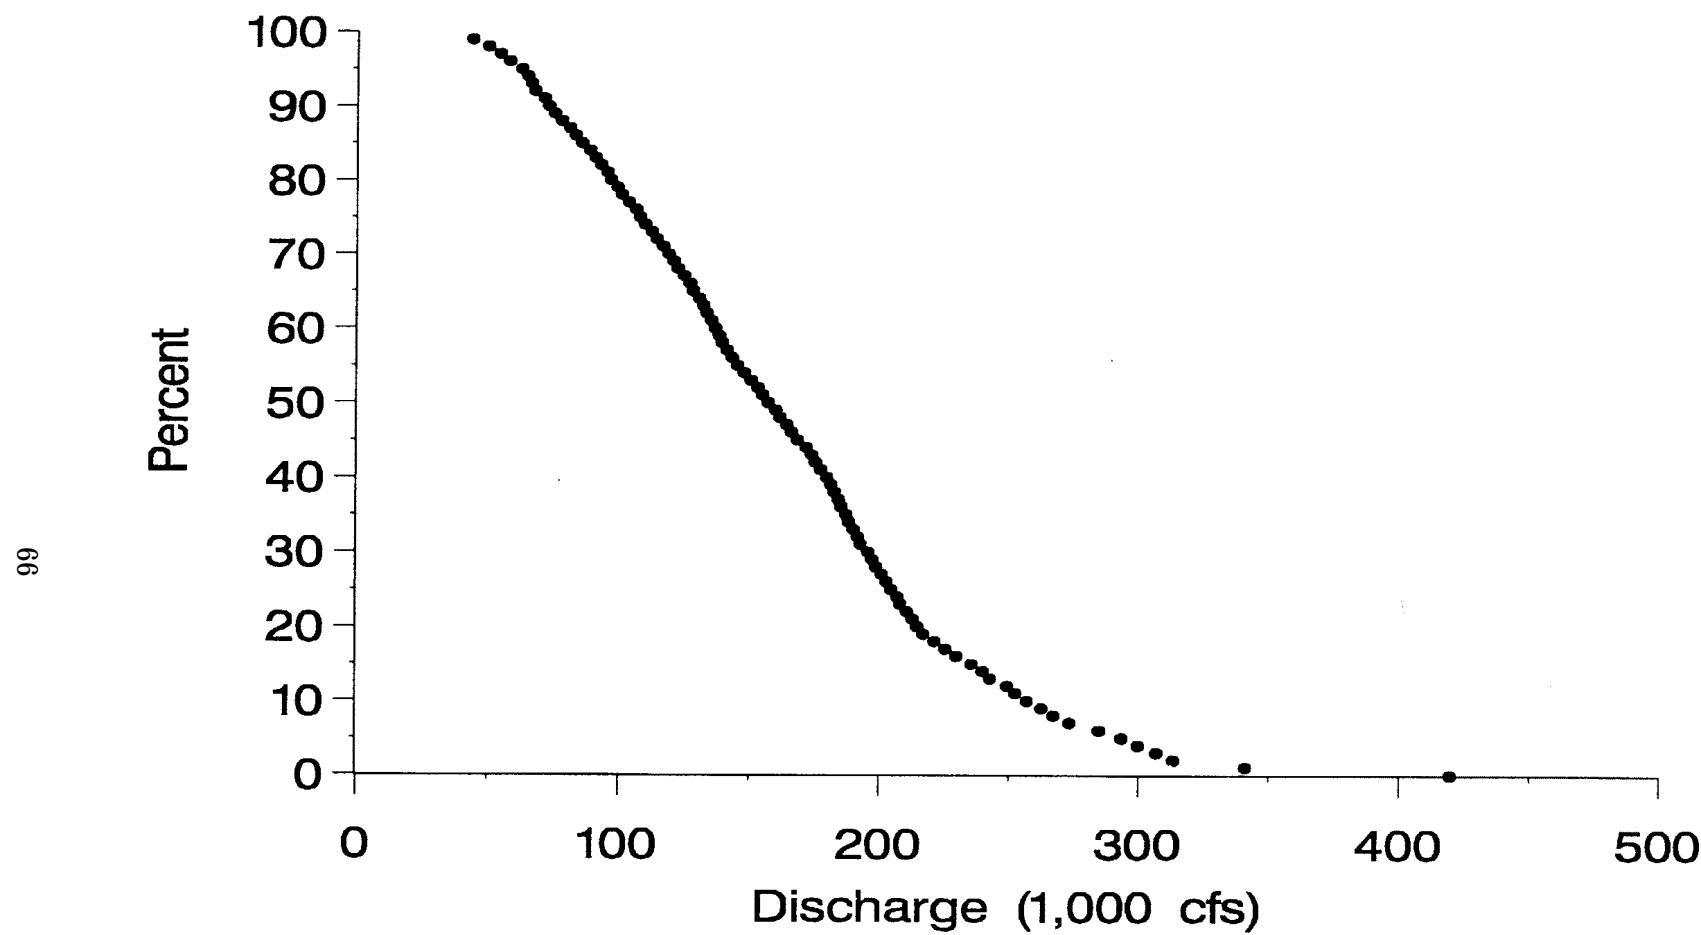

Figure 9. Discharge exceedence curve for the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected during April from 1939 to 1993. The 50% exceedence value is 157,000 cubic feet per second (cfs).

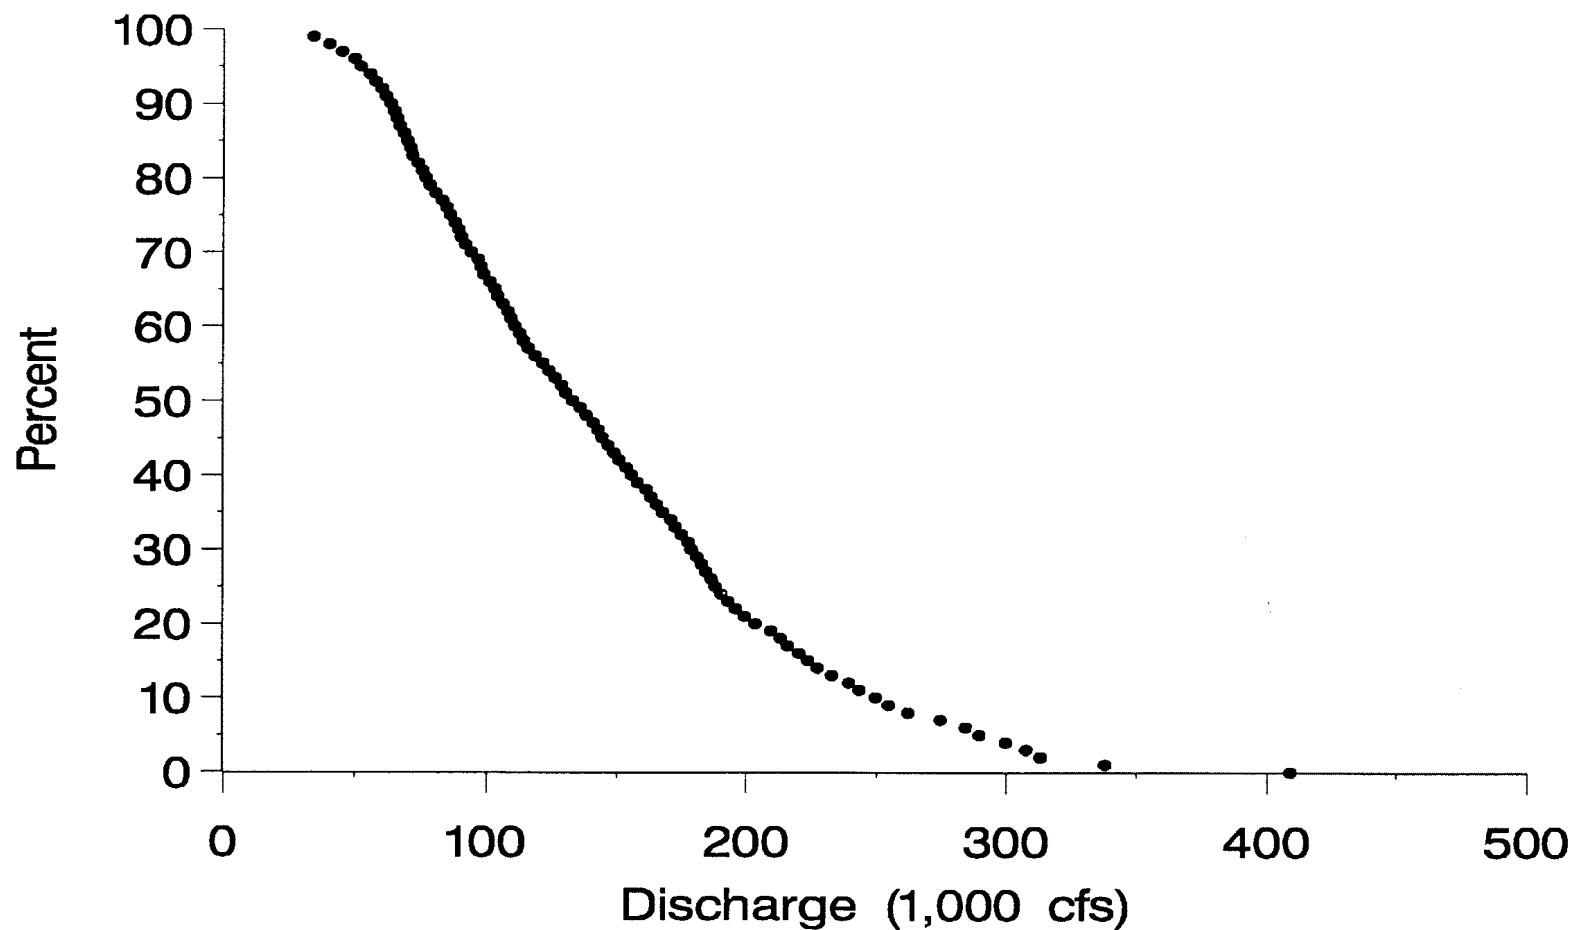

Figure 10. Discharge exceedence curve for the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected during May from 1939 to 1993. The 50% exceedence value is 133,000 cubic feet per second (cfs).

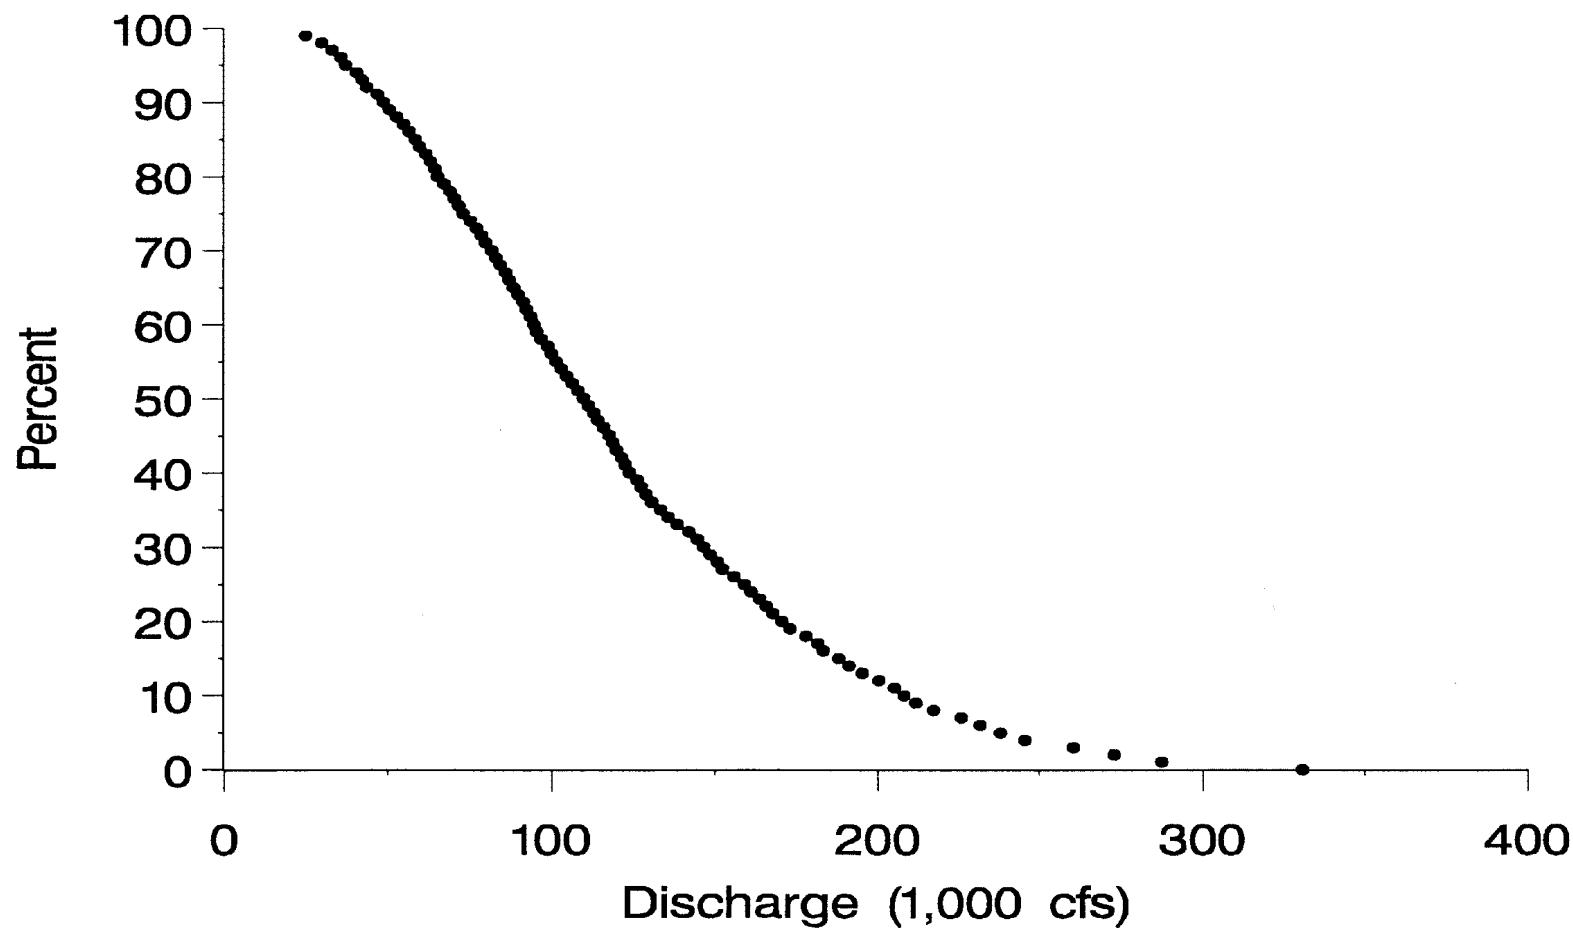

Figure 11. Discharge exceedence curve for the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected during June from 1939 to 1993. The 50% exceedence value is 109,000 cubic feet per second (cfs).

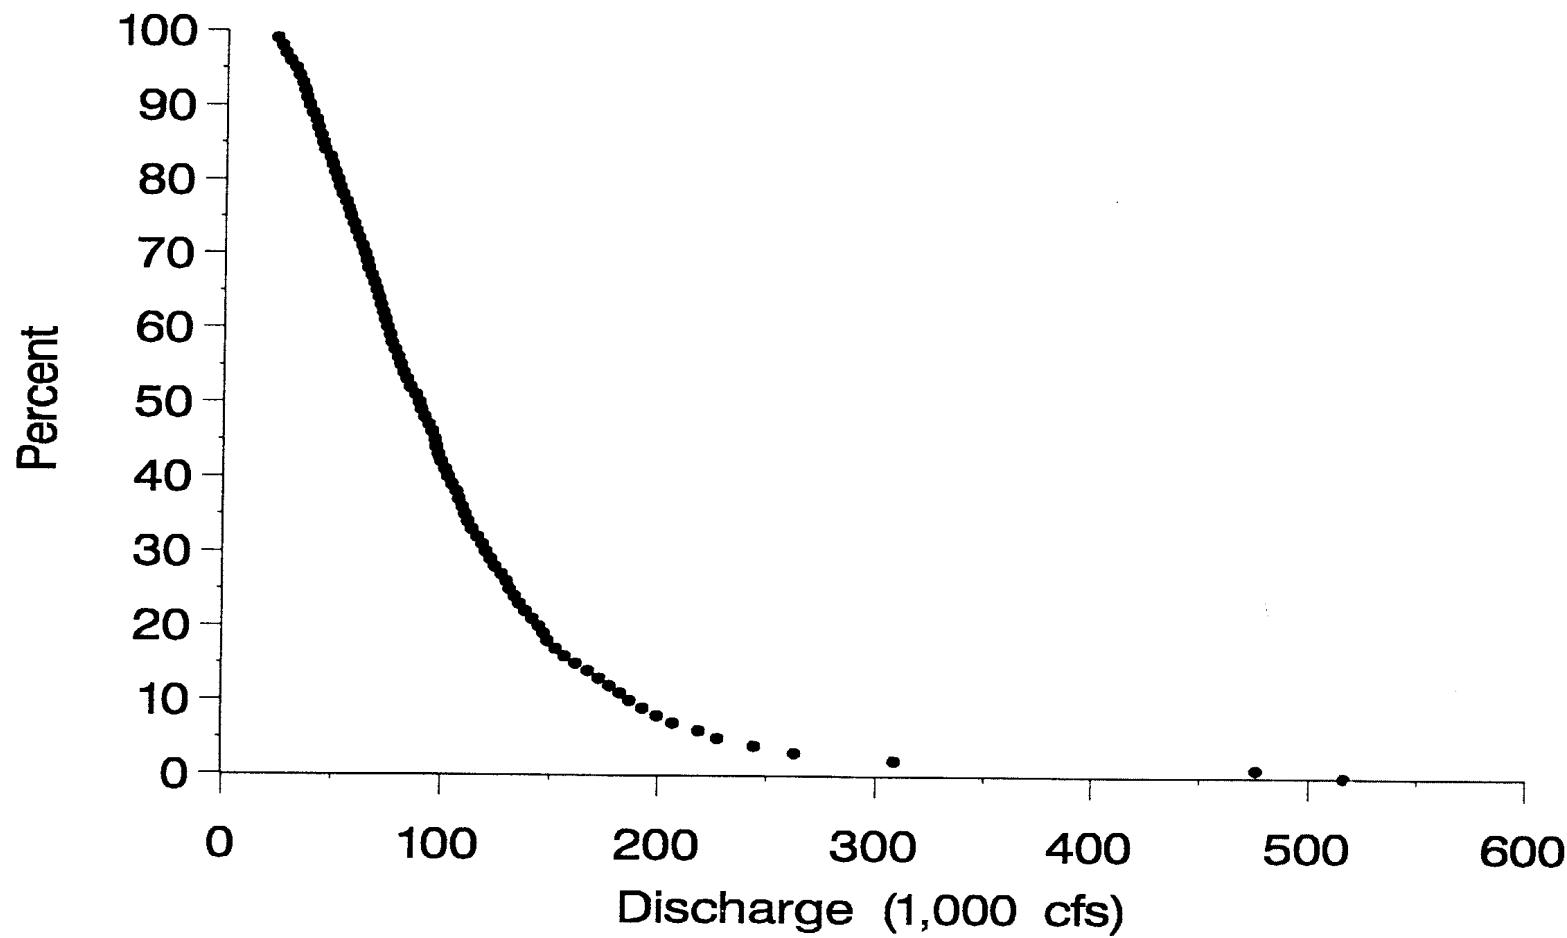

Figure 12. Discharge exceedence curve for the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected during July from 1939 to 1993. The 50% exceedence value is 89,000 cubic feet per second (cfs).

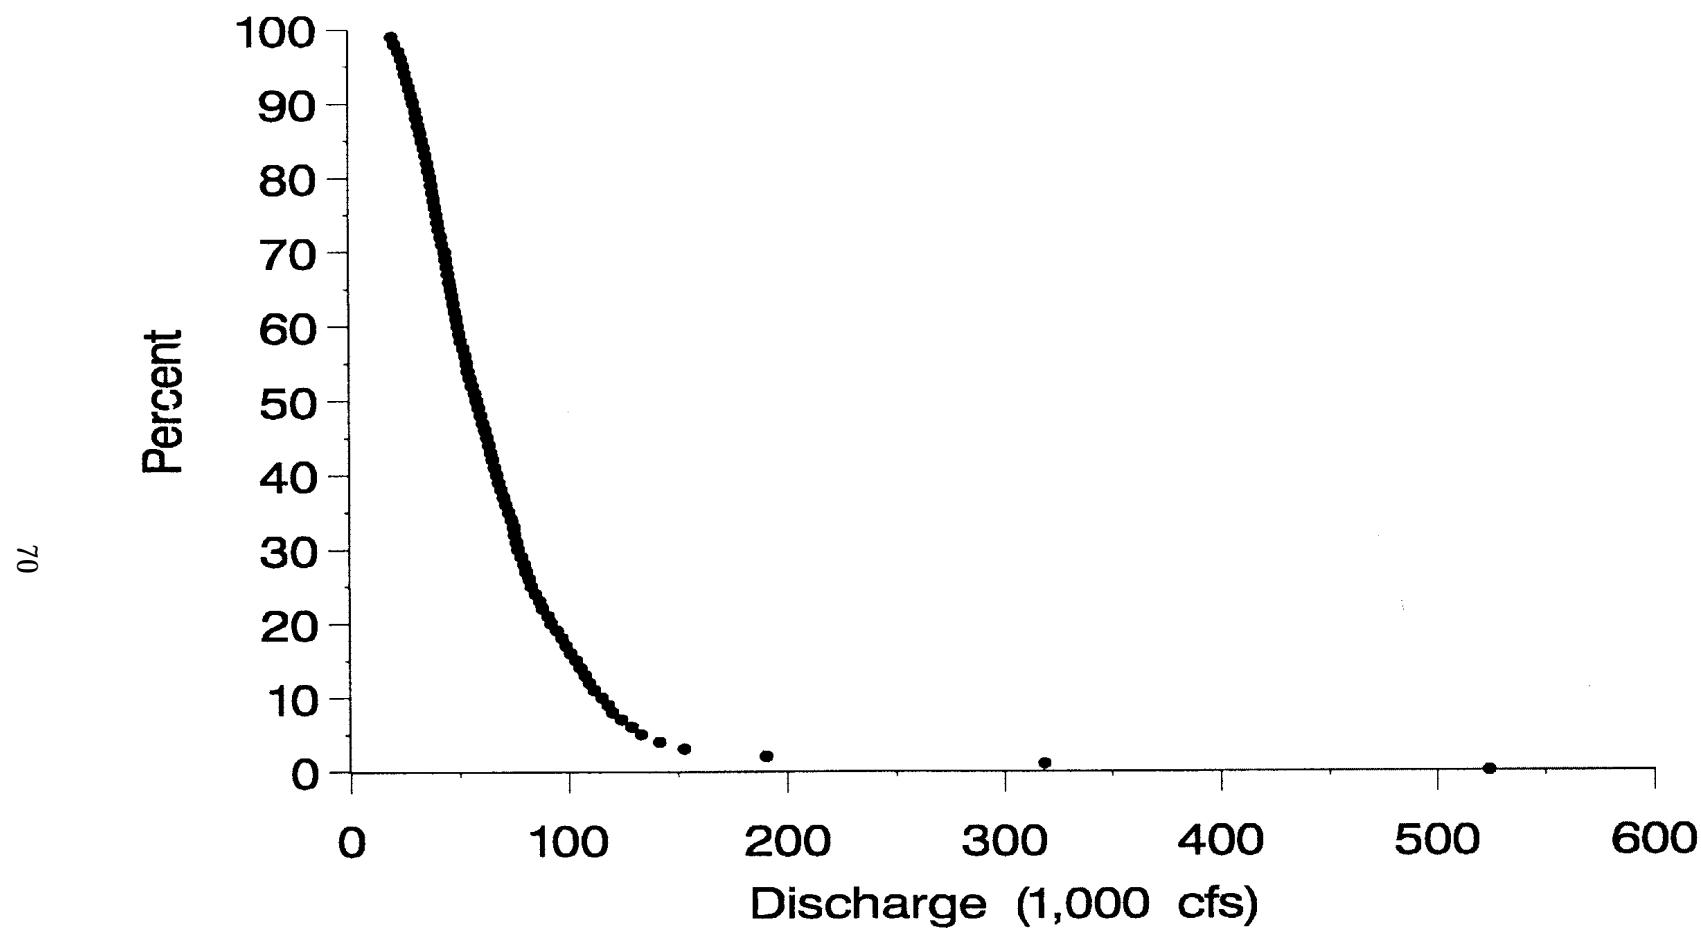

Figure 13. Discharge exceedence curve for the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected during August from 1939 to 1993. The 50% exceedence value is 58,000 cubic feet per second (cfs).

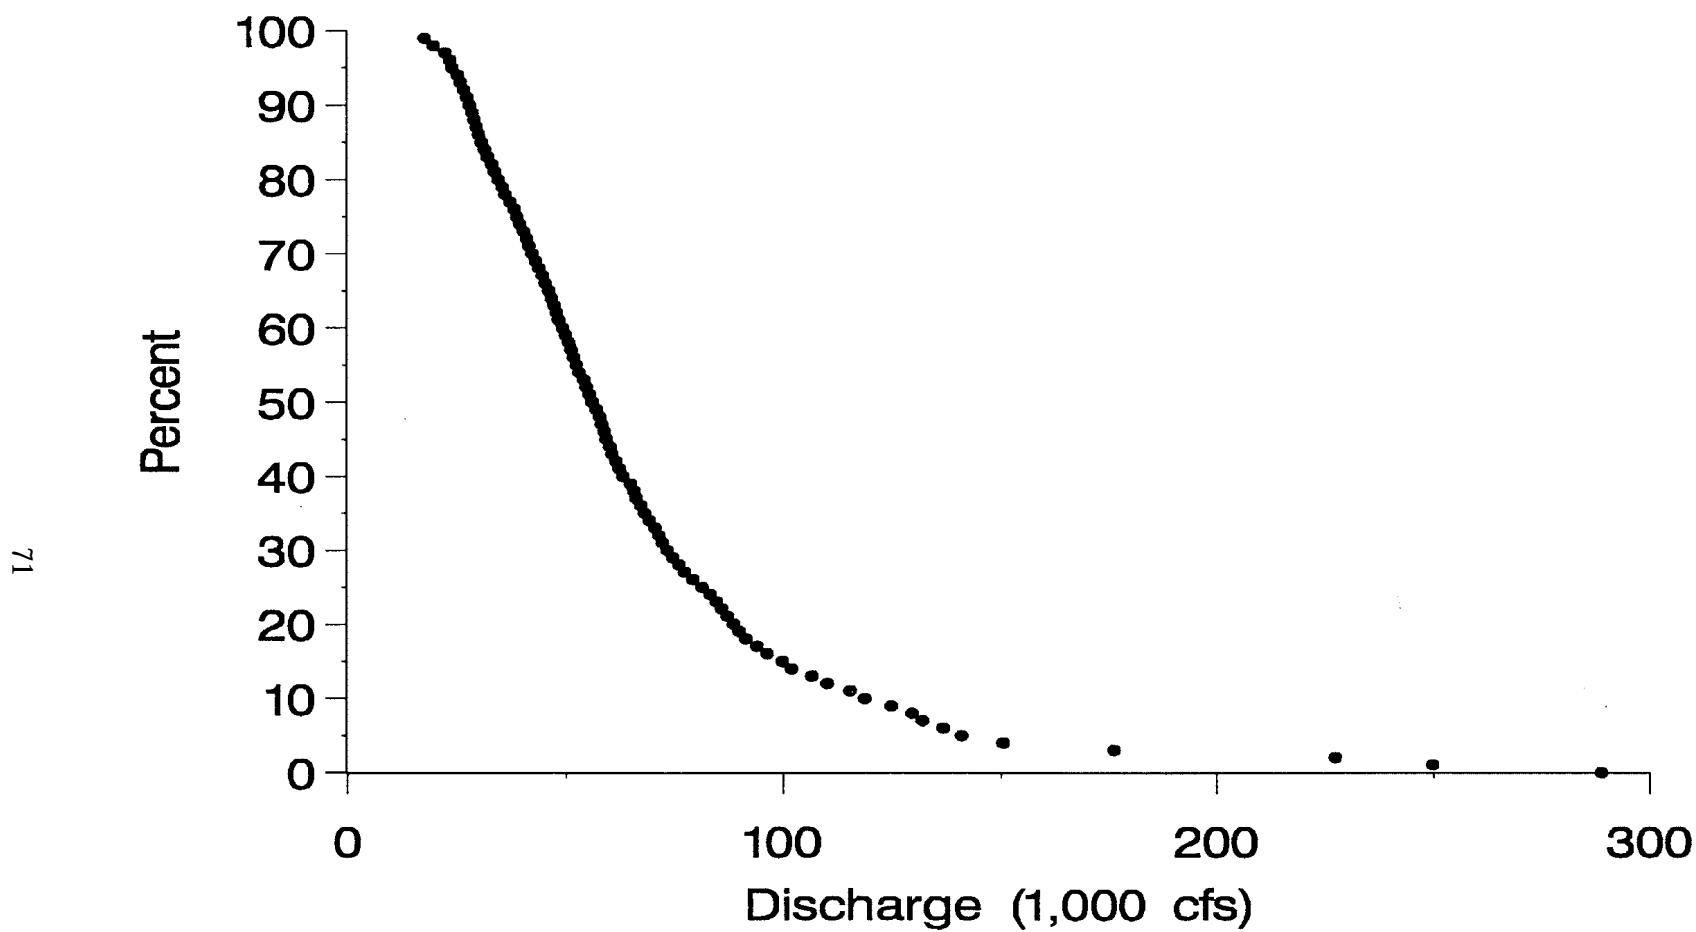

Figure 14. Discharge exceedence curve for the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected during September from 1939 to 1993. The 50% exceedence value is 56,000 cubic feet per second (cfs).

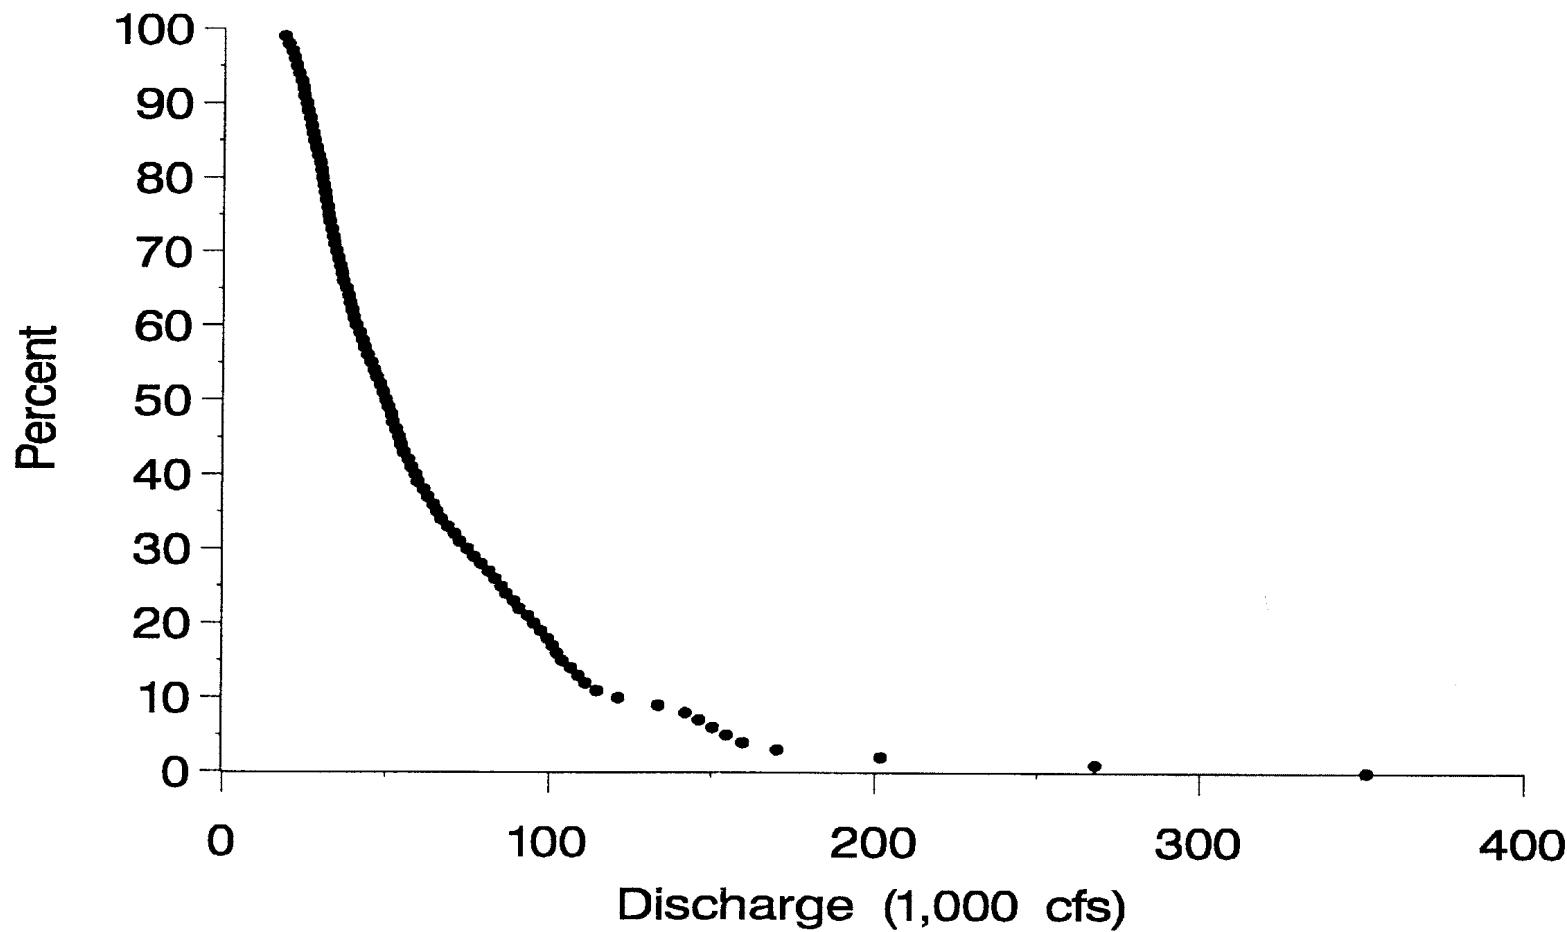

Figure 15. Discharge exceedence curve for the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected during October from 1939 to 1993. The 50% exceedence value is 49,000 cubic feet per second (cfs).

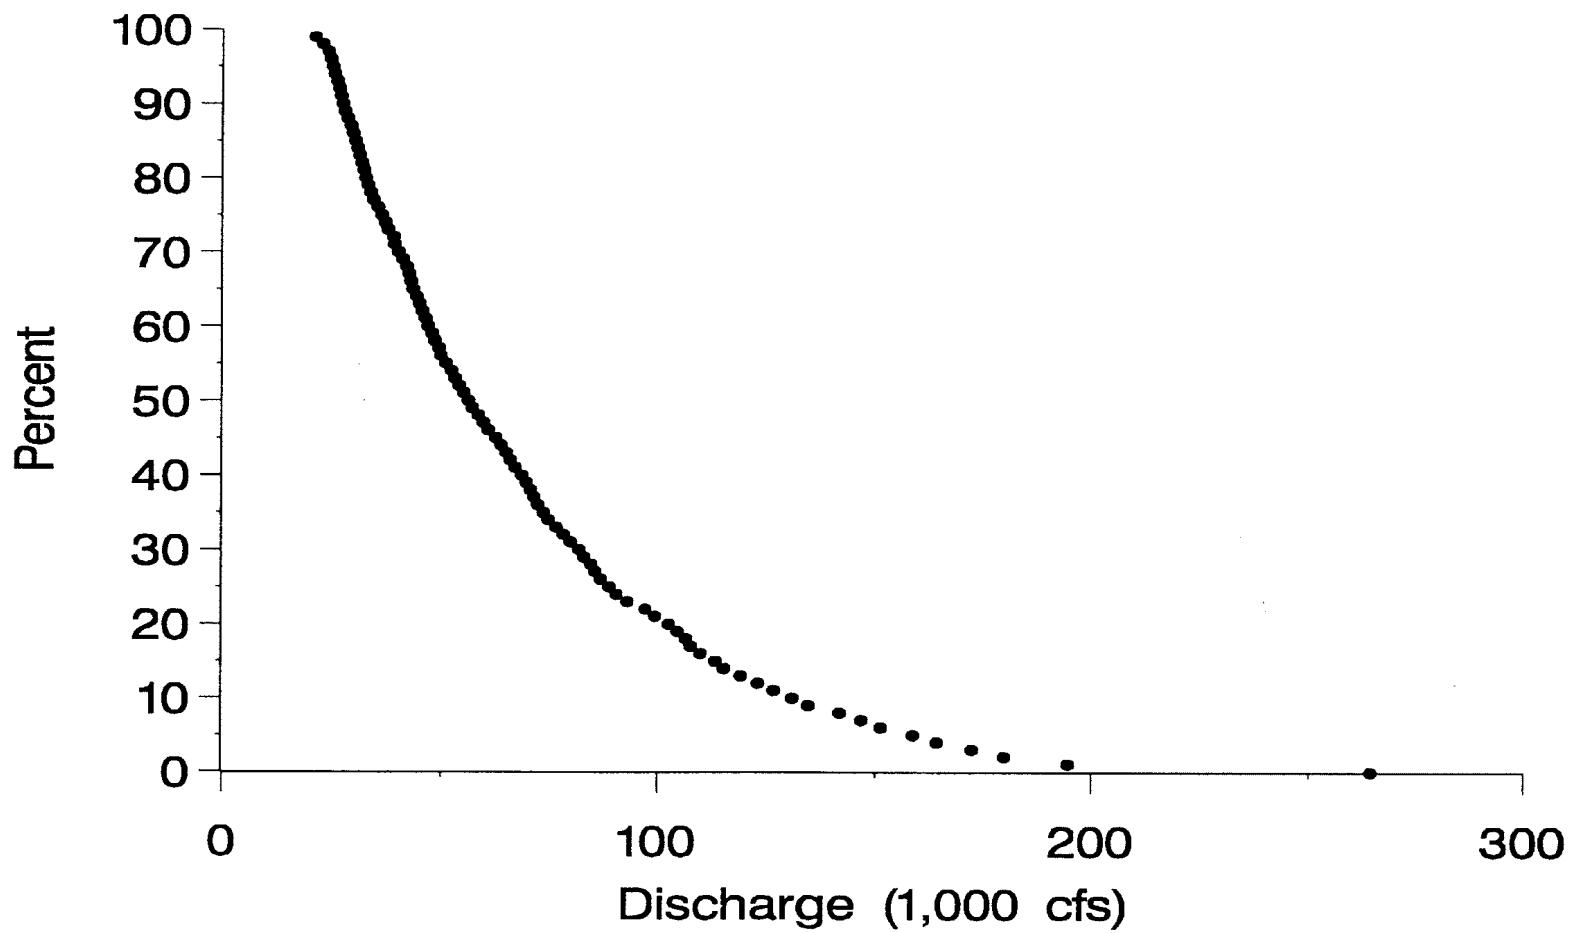

Figure 16. Discharge exceedence curve for the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected during November from 1939 to 1993. The 50% exceedence value is 56,000 cubic feet per second (cfs).

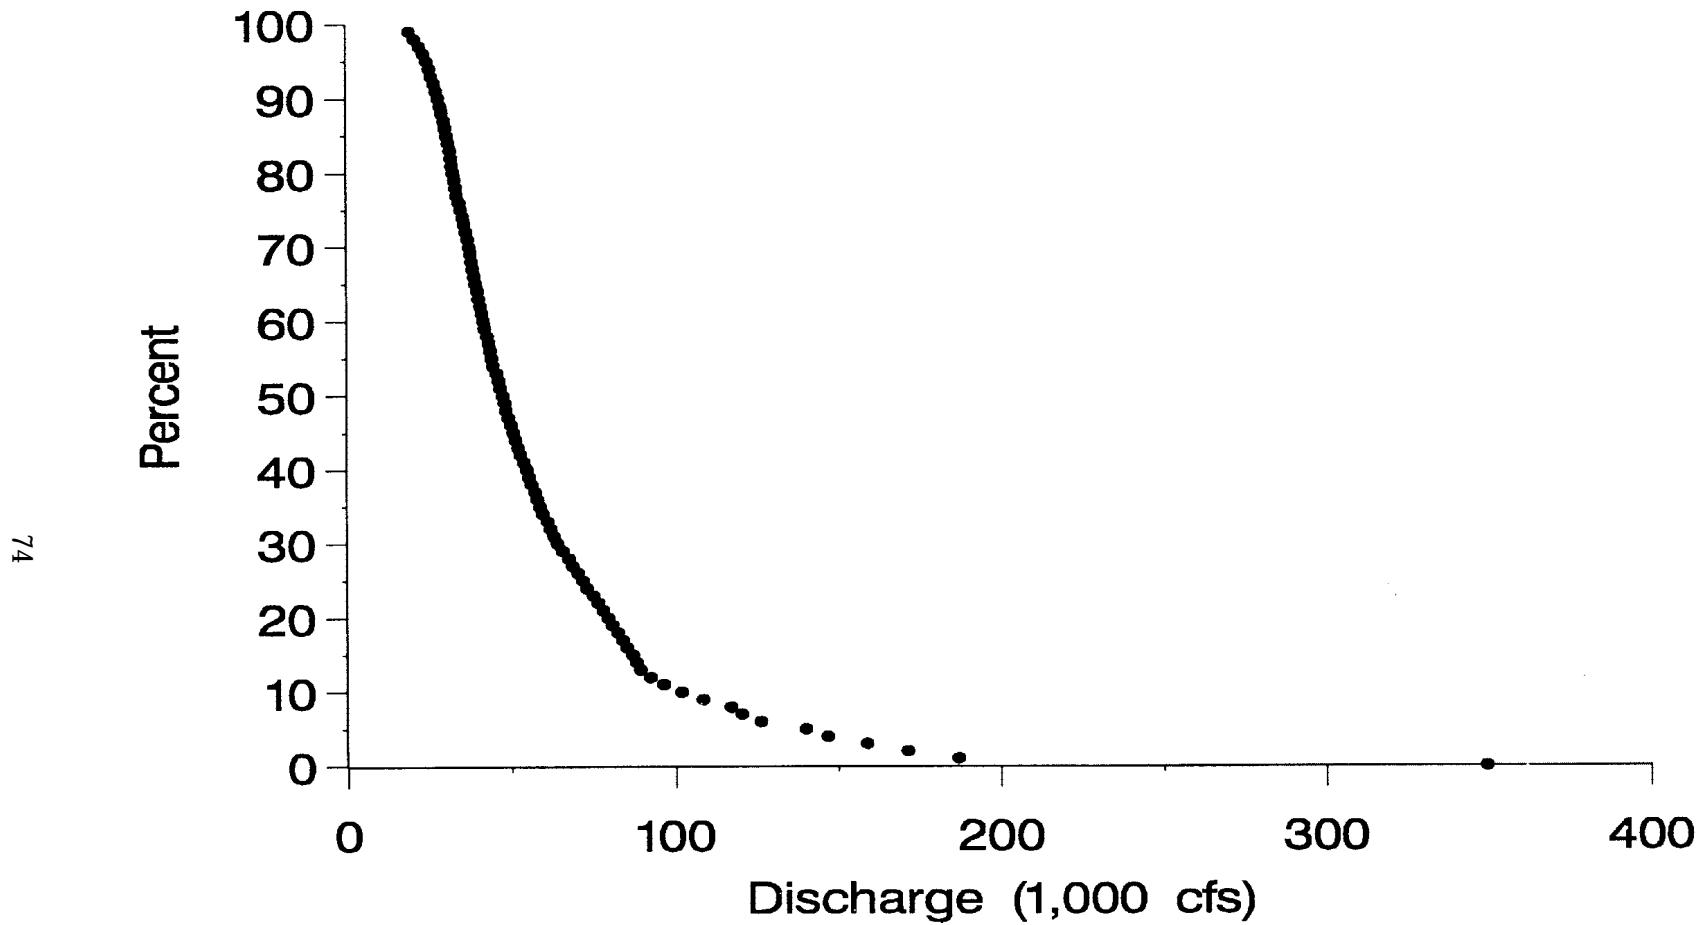

Figure 17. Discharge exceedence curve for the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected during December from 1939 to 1993. The 50% exceedence value is 47,000 cubic feet per second (cfs).

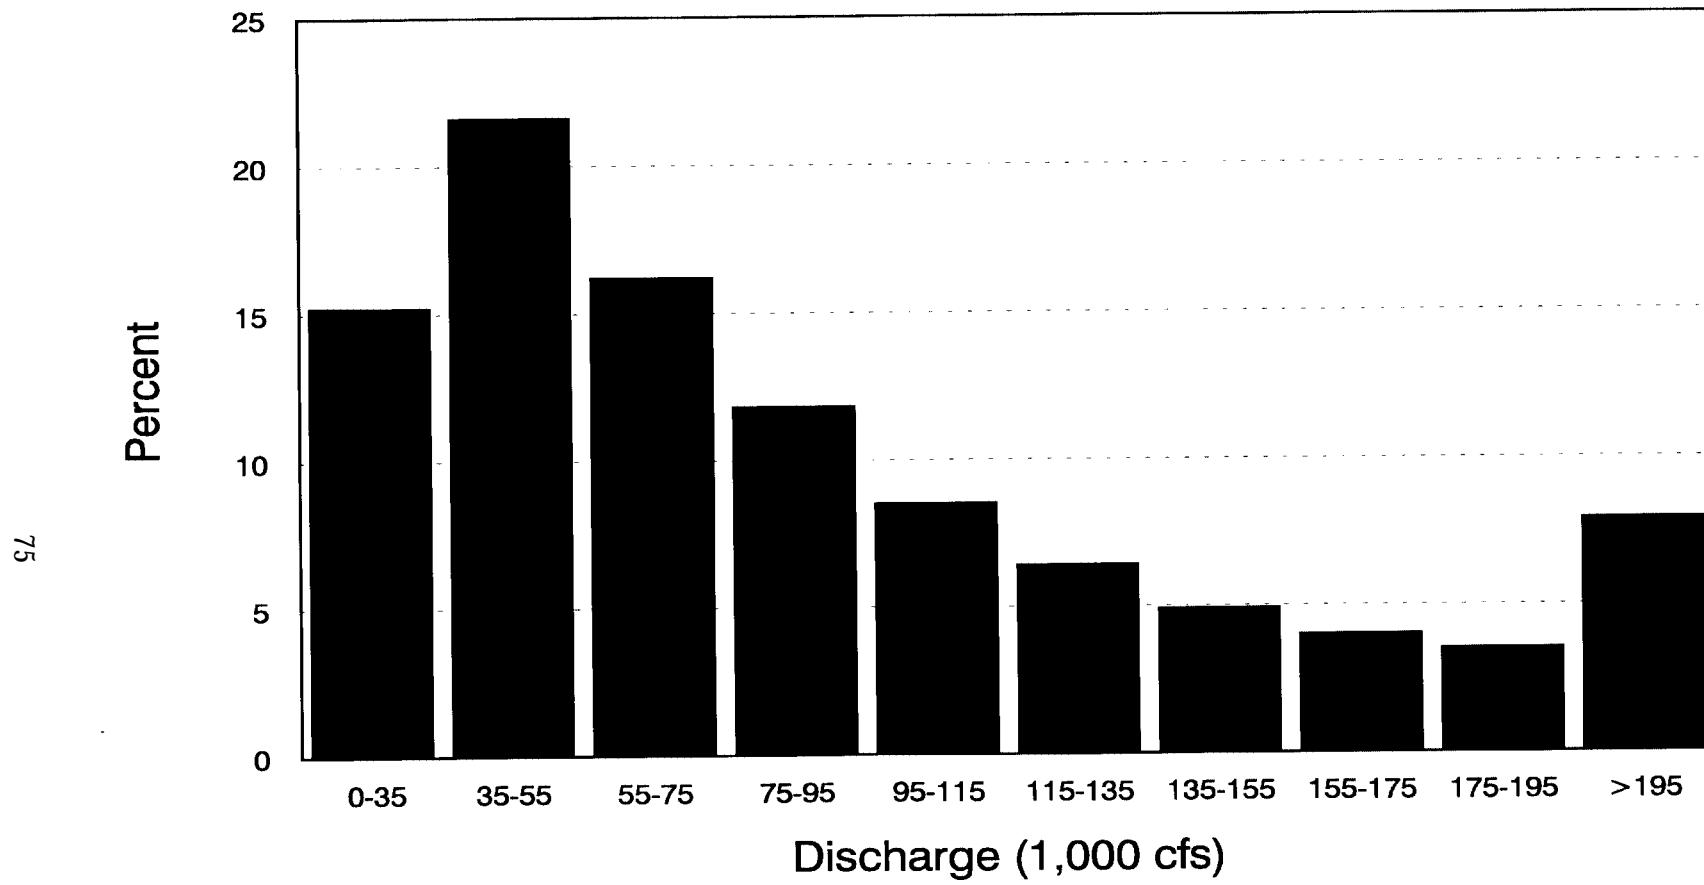

Figure 18. Percentage of time discharges were within certain ranges in the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected from 1939 to 1993

cfs = cubic feet per second

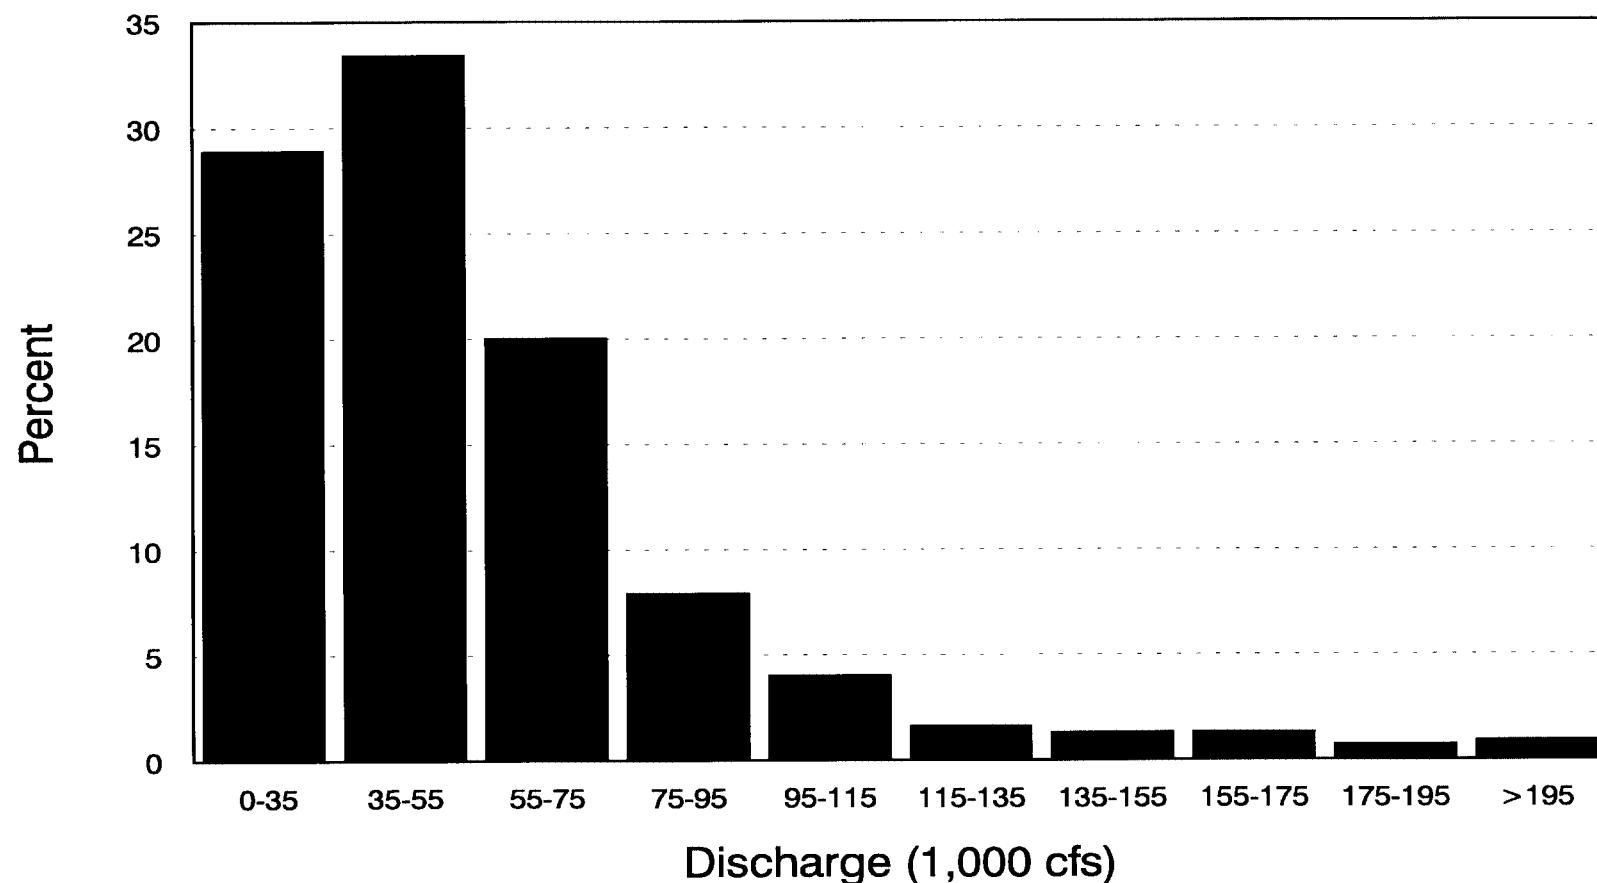

Figure 19. Percentage of time discharges were within certain ranges in the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected during January from 1939 to 1993

cfs = cubic feet per second

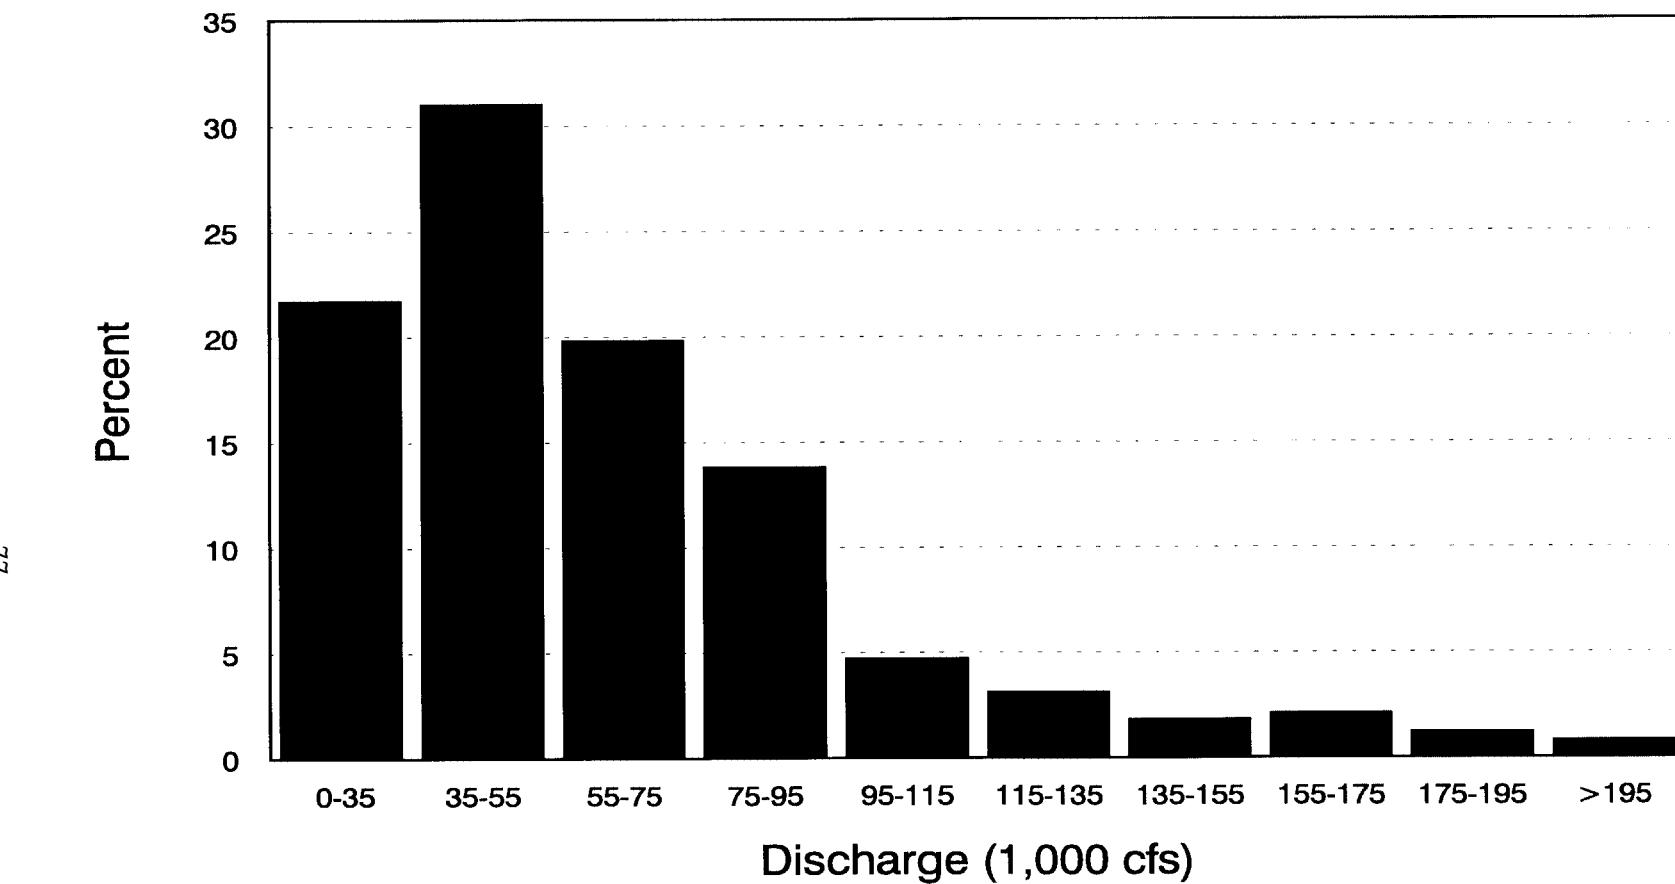

Figure 20. Percentage of time discharges were within certain ranges in the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected during February from 1939 to 1993

cfs = cubic feet per second

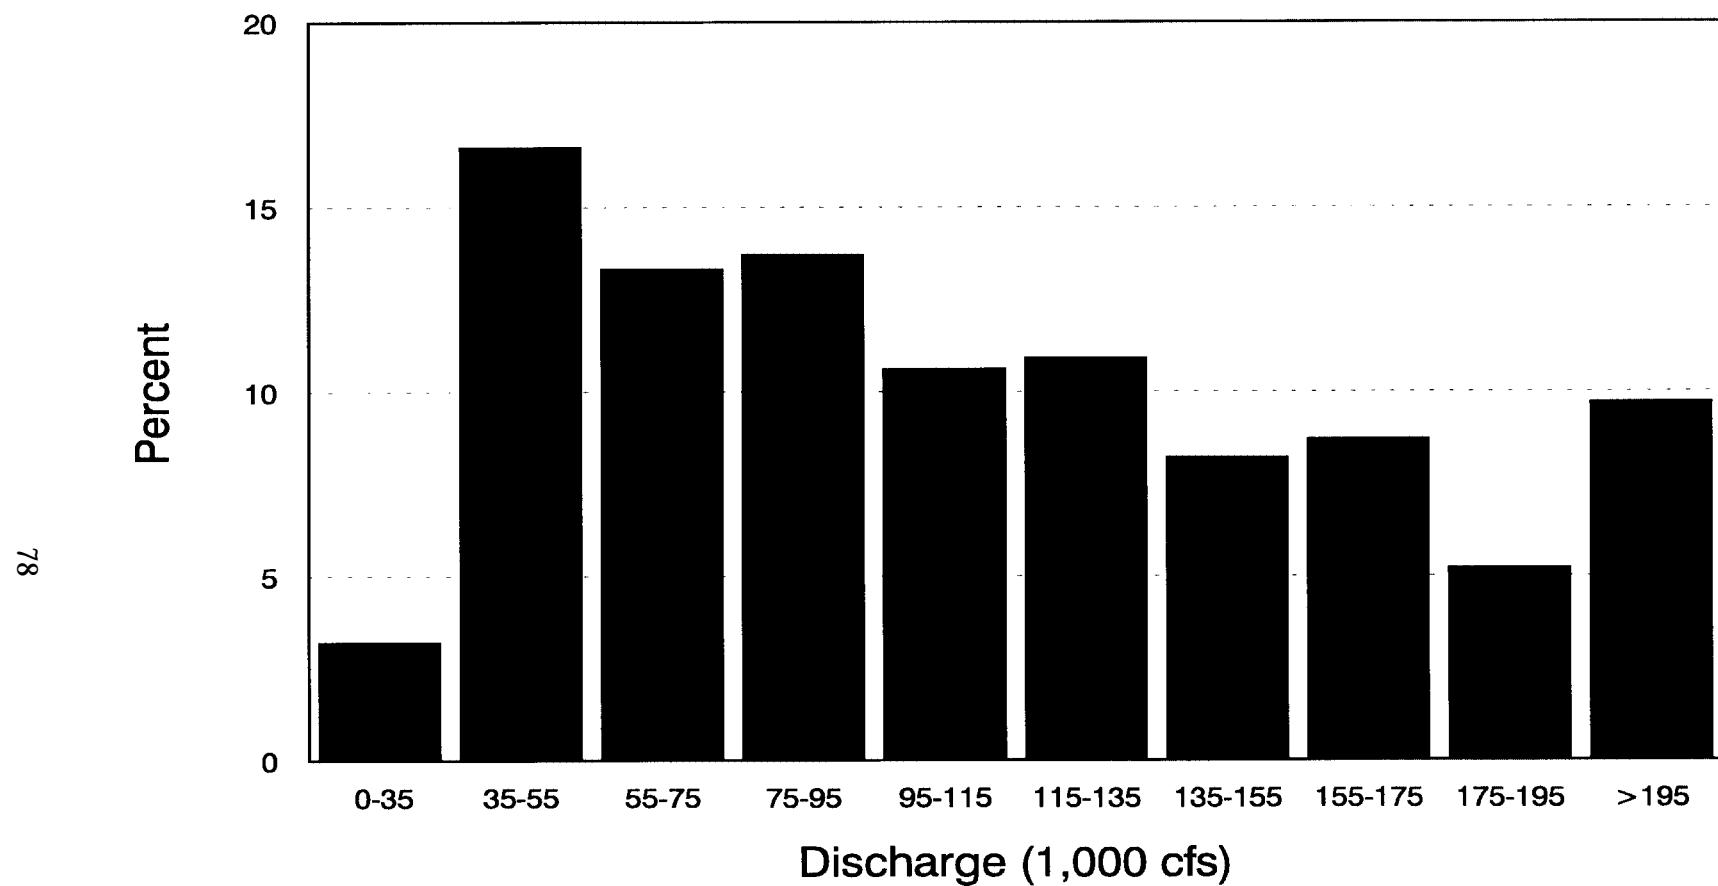

Figure 21. Percentage of time discharges were within certain ranges in the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected during March from 1939 to 1993

cfs = cubic feet per second

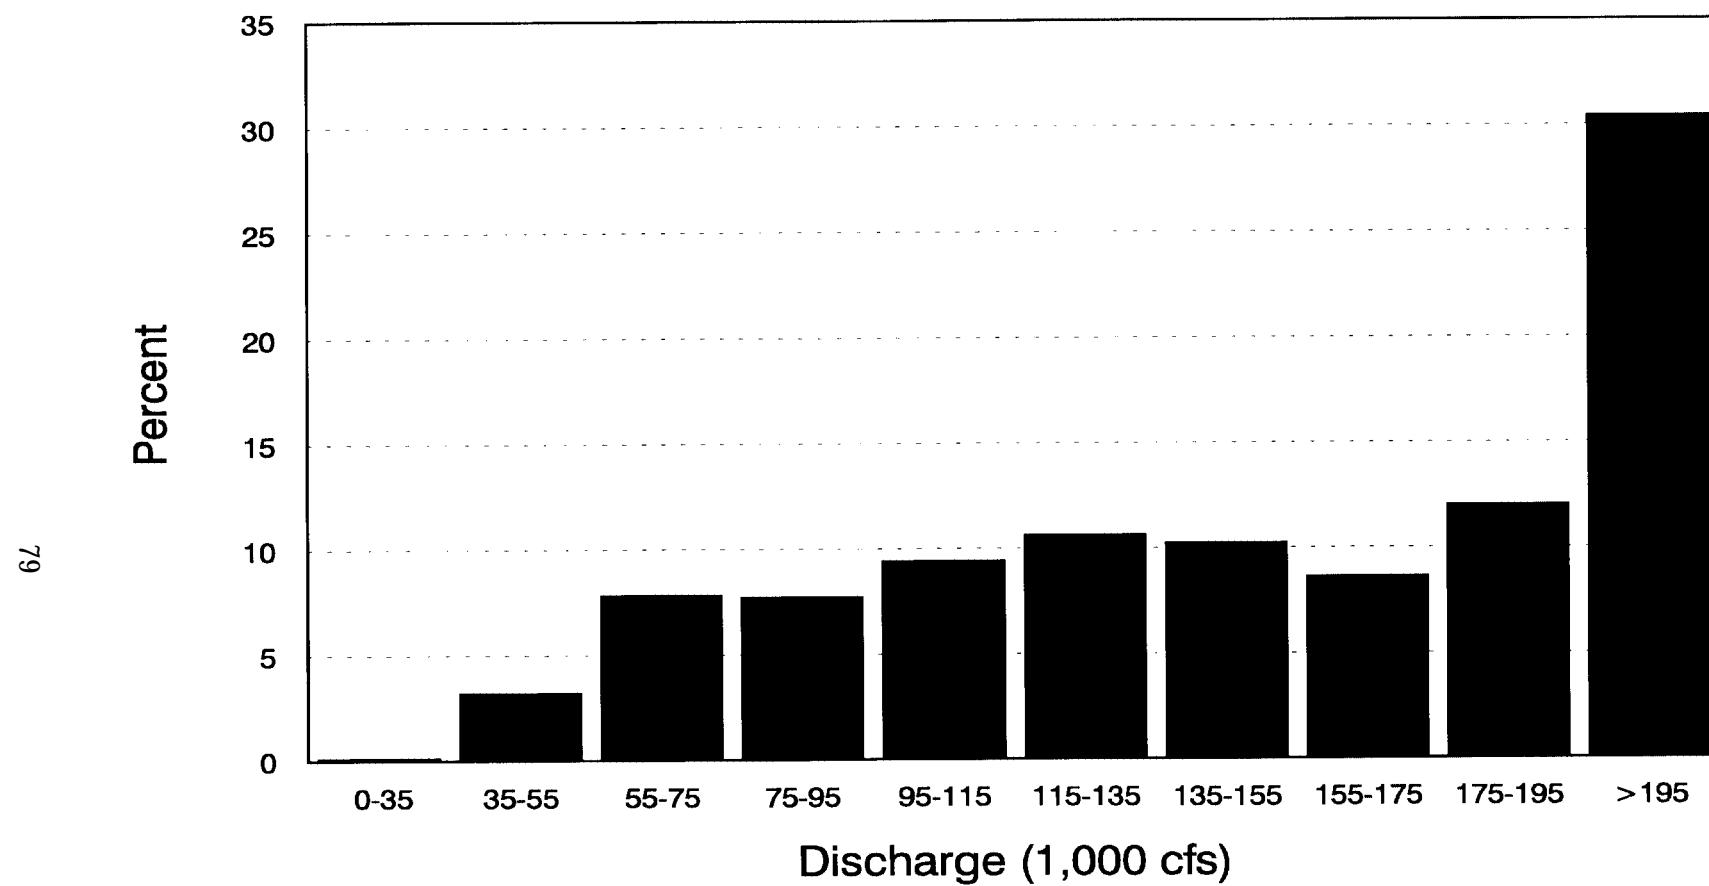

Figure 22. Percentage of time discharges were within certain ranges in the tailwater (river mile 241.2) of Upper Mississippi River System Pool 25 based on estimates of data collected during April from 1939 to 1993

cfs = cubic feet per second

13. ABSTRACT (Maximum 200 words) Analysis of water level elevations and discharges was performed for Pool 25 on the Upper Mississippi River as part of a study to increase ecological benefits of the operation of Lock and Dam 25. This dam was placed in operation in May 1939. Since that time, the operating plan for managing water levels has undergone several changes. Discharges for Pool 25 were estimated using data from the closest gaging stations, with corrections accounting for changes in watershed area. Discharge estimates since 1939 were used to compute exceedence frequencies on a weekly, monthly, and yearly basis. They were also used to calculate the percentage of time discharges were within specified ranges for the three time scales. Water level measurements at five in-pool stations were used to calculate the percentage of time water levels were above specific elevations for the same three time scales. Only data for the period between 1952 and 1993 were used for this part of the analysis because different water level management plans were in use before 1952. The results of this work, along with a companion study, show the expected frequencies when alternative water level plans may be utilized and the amount of habitat that would be affected by alternative plans.

The Long Term Resource Monitoring Program (LTRMP) for the Upper Mississippi River System was authorized under the Water Resources Development Act of 1986 as an element of the Environmental Management Program. The mission of the LTRMP is to provide river managers with information for maintaining the Upper Mississippi River System as a sustainable large river ecosystem given its multiple-use character. The LTRMP is a cooperative effort by the National Biological Service, the U.S. Army Corps of Engineers, and the States of Illinois, Iowa, Minnesota, Missouri, and Wisconsin.
