Abstract

Thompson, Michael T.; DeBlander, Larry T.; Blackard, Jock A. 2005. **Wyoming's Forests, 2002.** Resour. Bull. RMRS-RB-6. Fort Collins, CO: U.S. Department of Agriculture, Forest Service, Rocky Mountain Research Station. 148 p.

This report presents a summary of the most recent inventory information for Wyoming's forest lands. The report includes descriptive highlights and tables of area, number of trees, biomass, volume, growth, mortality, removals, and net change. Most of the tables are organized by forest type, species, diameter class, or owner group. The report also describes inventory design, inventory terminology, and data reliability.

Results show that about 18 percent, or 11.4 million acres, of the total land area of Wyoming is forest land. Fifty-three percent of the forest land is administered by the USDA Forest Service. About 33 percent of the forest land in Wyoming is in reserved status. Lodgepole pine and spruce-fir forest types combined account for 40 percent of total forest land. Lodgepole pine totals 1.2 billion trees or 27 percent of all live trees on forest land. Gross annual growth of all trees on forest land totaled 331 million cubic feet. Annual mortality of all trees on forest land totaled 172 million cubic feet.

The Author

Michael T. Thompson is a Forester and a member of the Analysis Team with the Interior West Forest Inventory and Analysis Program at the Rocky Mountain Research Station in Ogden, UT. He holds a B.S. degree in forestry from North Carolina State University.

Larry T. DeBlander is a Forester and a member of the Analysis Team with the Interior West Forest Inventory and Analysis Program at the Rocky Mountain Research Station in Ogden, UT. He holds a B.S. degree in forestry from Pennsylvania State University.

Jock A. Blackard is a Forester and a member of the Techniques Team with the Interior West Forest Inventory and Analysis Program at the Rocky Mountain Research Station in Ogden, UT. He holds a PhD. degree in Forest Science with emphasis on Geographic Information Systems from Colorado State University.

Acknowledgments

The Rocky Mountain Research Station gratefully acknowledges the cooperation and assistance of the Rocky Mountain and Intermountain Regions, Forest Service, U.S. Department of Agriculture; the Wyoming State Forester and other Wyoming State Land Department personnel; the Bureaus of Land Management and Indian Affairs, and the National Park Service, U.S. Department of the Interior. The authors extend a special note of thanks to private landowners who provided information and access to field sample plots.

Cover: Predicted forest area in Wyoming. See figure 2.

Highlights

Area

- The total land area of Wyoming is almost 63 million acres. Over 18 percent, or 11.4 million acres, is forest land.
- Fifty-three percent of the forest land is administered by the USDA Forest Service, and 17 percent is private, which includes Indian Trust land. Eleven percent is administered by the USDI Bureau of Land Management, 15 percent is controlled by National Parks, and the remaining 4 percent is in other public ownerships.
- About 33 percent of the forest land in Wyoming is in reserved status.
- Lodgepole pine and spruce-fir forest types combined occupy more than 4.5 million acres, or 40 percent, of total forest land.

Biomass and Volume

- The total biomass in live trees in Wyoming forests is estimated to be over 349 million tons.
- Total volume of wood in live trees in Wyoming is estimated to be almost 20 billion cubic feet.

Growth and Mortality

- Gross annual growth of all trees on forest land in Wyoming totaled almost 331 million cubic feet.
- Mortality reduced gross growth by 52 percent to over 158 million cubic feet of net annual growth.

Introduction

This report presents a summary of the most recent inventory data available for Wyoming's forest lands. The purpose of this report is to summarize how much forest exists, where it exists, who owns it, how it may be changing, and how trees are growing compared to those that are dying in the State of Wyoming. Species composition, stand structure, and age of the forests are presented. State-wide population estimates of numbers of trees, inventory volume, inventory biomass, and various categories of these estimates are also presented. Estimates of tree growth, mortality, and removals are discussed in relation to forest health and timber supply assessments. Two sections address the forest resources in Yellowstone National Park and in areas designated as roadless. The information is presented in text, map products, and graphics.

The data reported here are results of inventories conducted by the USDA Forest Service, Interior West Forest Inventory and Analysis (IW-FIA) Program of the Rocky Mountain Research Station, as part of their national FIA activities. Forest Inventory and Analysis (FIA) is a national program that conducts strategic-level inventories for large-scale planning and monitoring. The IW-FIA is one of five regional FIA programs, and conducts inventories in eight States in the Interior West.

The plot design, sampling intensity, and grid layout used in the most recent inventory of Wyoming are nationally consistent, probability based, and sample all ownerships. The design of the field plot, where field crews take the measurements that generate the estimates in this report, is referred to as the mapped-plot design and is explained in the "Methods" section. The sampling protocol used in the Wyoming inventory, which was conducted between 1998 and 2003, differed from protocol used in earlier inventories. Caution should be used in comparing numbers in this report with forest statistics previously reported for Wyoming (Green and Conner 1989). Reserved lands and National Forest System lands were not inventoried by FIA in the 1989 inventory; they were inventoried by National Forest Systems. Additionally, definitions and classifications have been refined over time as FIA moves forward as a national program that samples consistently across regional boundaries.

This information can be used in many ways, such as assessing the sustainability of ecosystem management practices, supporting planning and decisionmaking activities undertaken by public and private enterprises, and evaluating habitat conditions. Key program customers include State and National Forest policy lawmakers, State foresters, forest industry consultants, environmental organizations, Forest Service officials, researchers, journalists, and interested private citizens.

It is beyond the scope of a State-level assessment to do a detailed analysis of small domains or address all pertinent natural resources issues. However, there are a variety of ways that a user can obtain more detailed analysis and data for Wyoming. Since the National Forest System controls over 50 percent of the forest area in Wyoming, with six different National Forests spanning two regions, additional information is available. A set of tables, similar to the set in this report, can be generated for each National Forest and supplied to an interested user. Eventually, a brochure will be published that

provides a detailed summary of forest conditions for each National Forest in Wyoming. A detailed analysis of Wyoming's forest products industry has been published by Morgan and others, 2005. A Web-based data compilation and analysis engine—the Forest Inventory and Analysis Database—is available to the public and allows users to access data and results in a consistent manner for Wyoming and any other State in the country. A highly trained, professional IW-FIA staff, located in Ogden, Utah, is also available to answer questions, provide data, collaborate with the public, and do special analysis upon request.

Wyoming's forest inventory is a broad-scale survey that provides statistically reliable estimates of forest conditions including forest area, inventory volume, growth, and mortality for large geographic areas. Users are cautioned about making assumptions for small geographic areas using FIA inventory statistics.

Land classification categories are individually defined in the "Terminology" section of this report. However, an overview of the classification relationships may provide a better understanding of how these groups are subdivided. Land area is divided into forest and nonforest land (fig. 1). Forest land is subdivided into reserved and nonreserved status and then subdivided into timberland and woodland. Nonreserved forest land is considered available for harvesting activity where wood volume is available to be used for timber products. Reserved forest land is withdrawn from management of timber products through statute or administrative designation.

Timberland includes forests of tree species traditionally used in the forest products industry, such as ponderosa pine and Douglas-fir. Woodland includes tree species such as pinyon, juniper, and oak that are not traditionally used for industrial wood products and typically have a multistem growth form. A map illustrating the spatial distribution of timberland, woodland, and nonforest land in Wyoming is found in figure 2. Each inventory location was classified as timberland or woodland depending on which category of species made up the majority of the stocking. Nonforest land includes rangelands, agriculture, urban lands, and water, and may have a small amount of tree cover.

This report and the included tables were developed based on historical demand and on recent requests from users including private landowners, agency and university researchers, forest industry officials and consultants, National Forest System managers, State and local planning staffs, and regional and national policymakers. The 1998 through 2003 inventory was made possible through a major cooperative effort between Federal and State agencies. Substantial cooperation in terms of logistical assistance was received from many other public and private landowners.

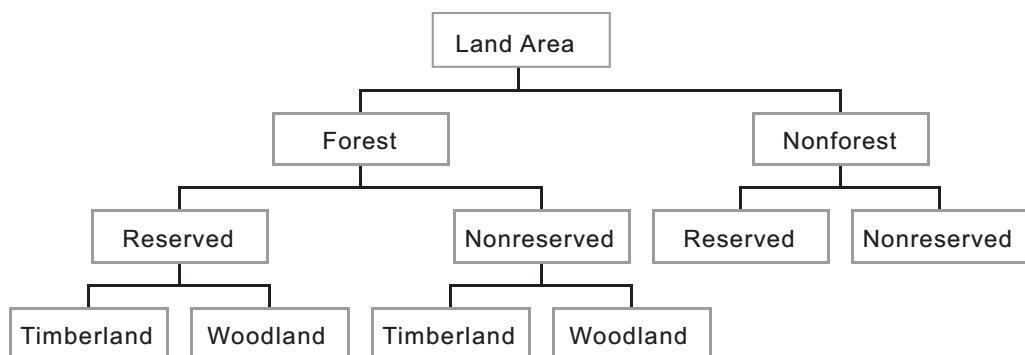

Figure 1—Land classification for FIA reporting, Wyoming, 2002.

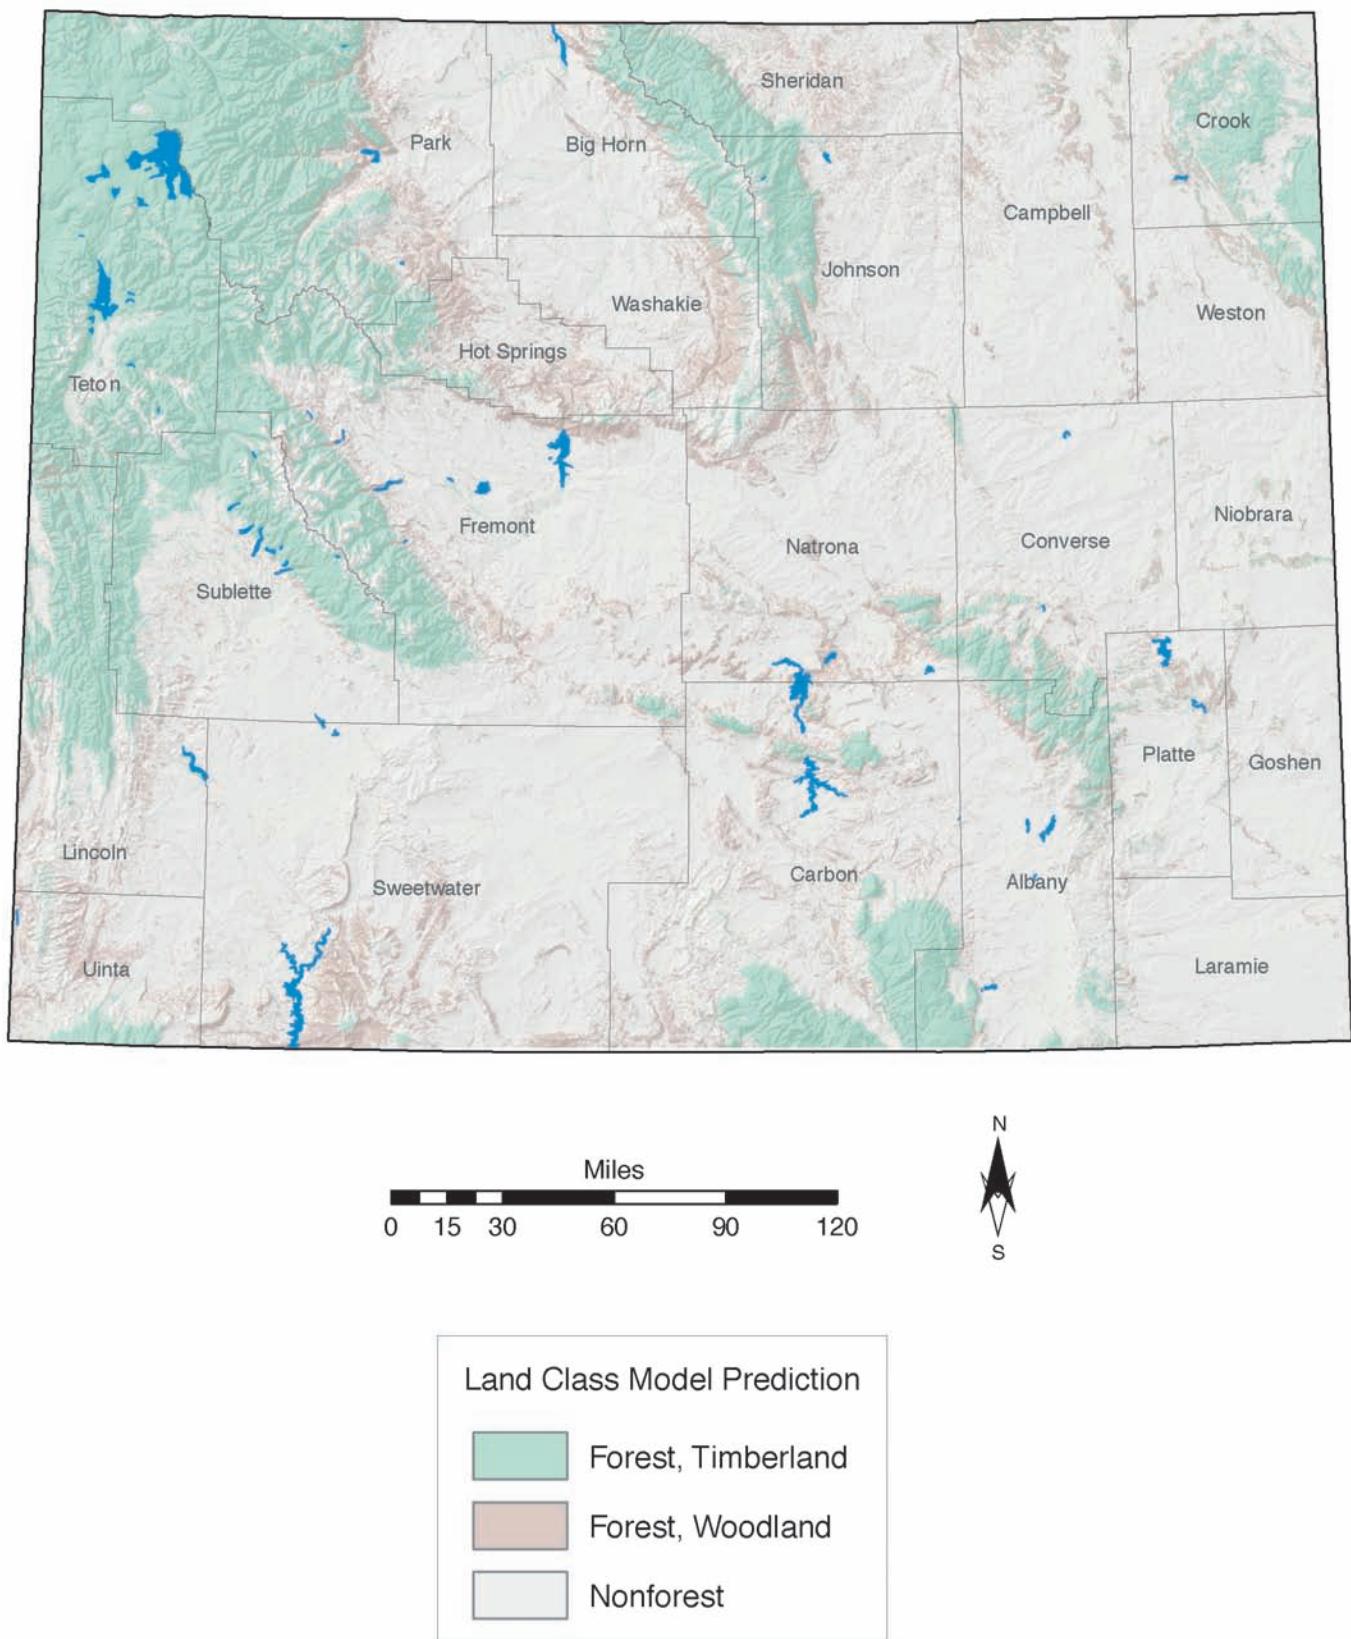

Figure 2—Area of total land by forest-land class, Wyoming, 2002.

Methods

The data in this report represent estimates for all forest land, including all owners and land status. The FIA inventory procedure for estimates in this report consists of two phases. Phase 1 refers to a grid of sample points systematically located across all lands on remote sensing imagery. Phase 2 refers to a systematic random sample of field plots established across the landscape, sampling all ownerships and status. Field crews visit Phase 2 field plots and take detailed measurements that generate inventory estimates such as forest cover type, forest inventory volume, forest growth, and forest mortality. Each Phase 2 plot is located on a grid across the State and represents approximately 6,200 acres.

The current periodic inventory of Wyoming forests began in July 1998 and was completed in August 2003. A periodic inventory measures all of the Phase 2 plots in the State over a period of time, and usually takes several years to complete. Subsequent inventories occurred on an average of about 10 years.

The Phase 1 classification in Wyoming used Landsat Thematic Mapper (TM) satellite imagery obtained from the National Land Cover Data (NLCD) database. The spatial resolution of the imagery was 30 meters and was mapped in the Albers Conic Equal Area projection, NAD 83. The Phase 1 sample was a collection of points located on a 1,000-meter-square grid overlaid on the Wyoming TM image. The State was subdivided into a number of stratified sample areas. Within each sample area, Phase 1 points were raster-classified into three land status strata (timberland, woodland, and nonforest). The area of timberland, woodland, and nonforest land was determined for each sample area by incorporating the Phase 1 and Phase 2 observations into a design that used double sampling with stratification (Cochran 1963).

The area estimator for timberland in each sample area in Wyoming is defined as:

$$\hat{A}_g = A_{Tg} \sum_{h=1}^H \frac{n'_{hg}}{n'_g} \frac{\sum_{i=1}^{n_{hg}} y_{ihg}}{n_{hg}}$$

where:

\hat{A}_g = total timberland area (acres) for sampling area g

A_{Tg} = total land area (acres) in sampling area g

H = number of strata

n'_{hg} = number of Phase 1 points in stratum h in sampling area g

n'_g = total number of Phase 1 points in sampling area g

y_{ihg} = condition proportion on plot i in stratum h in sampling area g

n_{hg} = number of plots in stratum h in sampling area g

The field plot used in Phase 2 is the mapped-plot design (USDA Forest Service, 1999), which consists of four fixed-radius subplots. Each $1/24$ -acre circular subplot samples trees 5.0 inches in diameter. A $1/300$ -acre circular microplot located within the subplot samples seedlings and saplings (trees up to 4.9 inches in diameter). The sampling protocols are essentially those presented in Scott and Bechtold (1995). One of the variables recorded for each plot is the proportion of plot area in each condition class. A condition class is defined as the combination of variables that identify different stand characteristics. In Wyoming, five attributes were used to determine if different conditions existed: land status (forest-nonforest), forest type, stand size, stand origin, and stand density. When the field crew determined a distinct difference in stand conditions on a

subplot, the boundaries between conditions were mapped and trees were assigned to the appropriate condition class. All attributes measured on each location were assigned to their respective condition class. Of the 9,956 Phase 2 plots in Wyoming, 1,981 plots sampled forest land.

The FIA inventories provide a probability-based sample of forest resources across all ownerships that can be used for planning and analyses at local, State, regional, and national levels. The sample is designed to meet national standards for precision in State and regional estimates of forest attributes.

A measure of the variability of inventory statistics is provided by standard errors, listed in table 2, for estimates of area, volume, growth, and mortality on forest land for the entire State. These data indicate a sampling error of ± 1.30 percent for the estimate of total forest land, 2.32 percent for total net volume of live trees, and 9.74 percent for net annual growth of all live trees. As the totals are broken down by forest type, species, tree diameter, or other subdivisions, the sampling error increases. A 95 percent confidence interval can be computed for any estimate by multiplying the estimate's percent standard error (SE) by 1.96, multiplying that product times the estimate, and then adding and subtracting that product from the estimate to get the bounds. The 95 percent confidence interval for total forest land area in Wyoming is between 11.1 and 11.7 million acres. Similarly, the estimate of total forest land volume ranges between 18.9 and 20.7 billion cubic feet.

Users may compute statistical confidence for subdivisions of the reported data using the formula below. Because sampling error increases as the area or volume considered decreases, users should aggregate data categories as much as possible. Sampling errors obtained from this method are only approximations of reliability because homogeneity of variances is assumed. The formula is:

$$S\tilde{E}_g = \frac{SE_t \sqrt{\hat{Y}_t}}{\sqrt{\hat{Y}_g}}$$

where:

$S\tilde{E}_g$ = approximate percent standard error of \hat{Y}_g

SE_t = percent standard error of \hat{Y}_t

\hat{Y} = table variable of interest

g = table cell or group of cells of interest

t = totals from tables 2 or 3

Overview of Tables

Area of forest land, number of trees, wood volume and biomass, growth, mortality, and removals are the primary categories for which statistics are summarized and presented in the tables. There are five groups of tables. Tables 1 through 27 are for all forest land, both reserved and nonreserved. Tables 28 through 43 are for nonreserved forest land—forest land not withdrawn from tree utilization through statute or administrative designation. Tables 44 through 81 are for nonreserved timberland, that is nonreserved forest land that is 10 percent stocked and where timber species—those species traditionally used for industrial wood products—comprise more than half of the total stocking on the site. Tables 82 through 89 are for nonreserved woodland, meaning forest land where timber species make up less than half of the total stocking. The last group of tables, 90 through 111, is a set of tables comparable to similar sets presented by other

FIA groups across the nation and used in the Resources Planning Act Assessment to represent lands traditionally referred to as productive timberland. These “Core” tables are primarily for nonreserved timberland that has a minimum productivity of 20 cubic feet per acre per year.

Map Products

This report contains a number of map-based figures that were generated using ArcGIS software. Some of the maps used modeling techniques to produce the coverage. For example, figure 8 illustrates a map displaying coverage of the major forest types in Wyoming. The modeled coverage in this map was generated by the Cubist procedure (Quinlan 1993) — a rule-based predictive model that estimates forest attributes. The forest type classification at each forested sample location was used to train the model in relation to the various predictor variables extracted from over 50 data layers. Approximately half of these data layers were 2002 Moderate-resolution Imaging Spectroradiometer (MODIS) scenes and the other half were ancillary GIS data layers. By using MODIS imagery and the Cubist modeling procedure, the resulting maps can be produced in a timely and attractive manner that contains a statistical measure of accuracy. Adding map layers such as shaded relief or digital elevation models enables the reader to compare the relationship of topographic features to forest type.

All map-based products that appear in this report have estimates of reliability, and have undergone an evaluation process to assess accuracy and identify potential for misinterpretation. This process may be referred to as predictive performance, which consist of visual and statistical evaluations.

Low estimates of accuracy and low correlation coefficients can be attributed to differences in scale, date inconsistencies, and problems with certain site-specific information. These map-based products should be used with caution especially when evaluating relatively small geographic areas (predictor layers were based on a 250-meter pixel for these models). Invariably, users of these products will attempt to draw conclusions for small domains. Not all FIA response variables yield the same prediction performance when using the same model.

Highlights of Inventory Results For Total Forest Land

Area

The State of Wyoming encompasses over 62 million acres of land area (table 1). The forested areas of Wyoming located in the western and central portions of the State are part of two provinces referred to as the Southern Rocky Mountain Steppe and Middle Rocky Mountain Steppe (Bailey 1978). The Rocky Mountains are rugged glaciated mountains as high as 14,000 feet with local relief between 3,000 feet and 7,000 feet. Most of the forest land in Wyoming is concentrated in the northwest region of the State (fig. 2). An isolated area of forest land exists in the northeast area of the State where ponderosa pine forests have found an ecological niche in the higher elevations of the plains and foothills of the Black Hills. This province is referred to as the Black Hills Coniferous Forest Province (Bailey 1978).

Approximately 18 percent of the land area, or about 11 million acres, is classified as forest land (fig. 3). Fifty-three percent of the forest land is administered by the USDA Forest Service, and 17 percent is privately-owned, which includes Indian Trust land (fig. 4). Fifteen percent is administered by the National Park Service, 11 percent is administered by the USDI Bureau of Land Management (BLM), and the remaining 4 percent is owned by State, county, and miscellaneous Federal agencies. About one-third

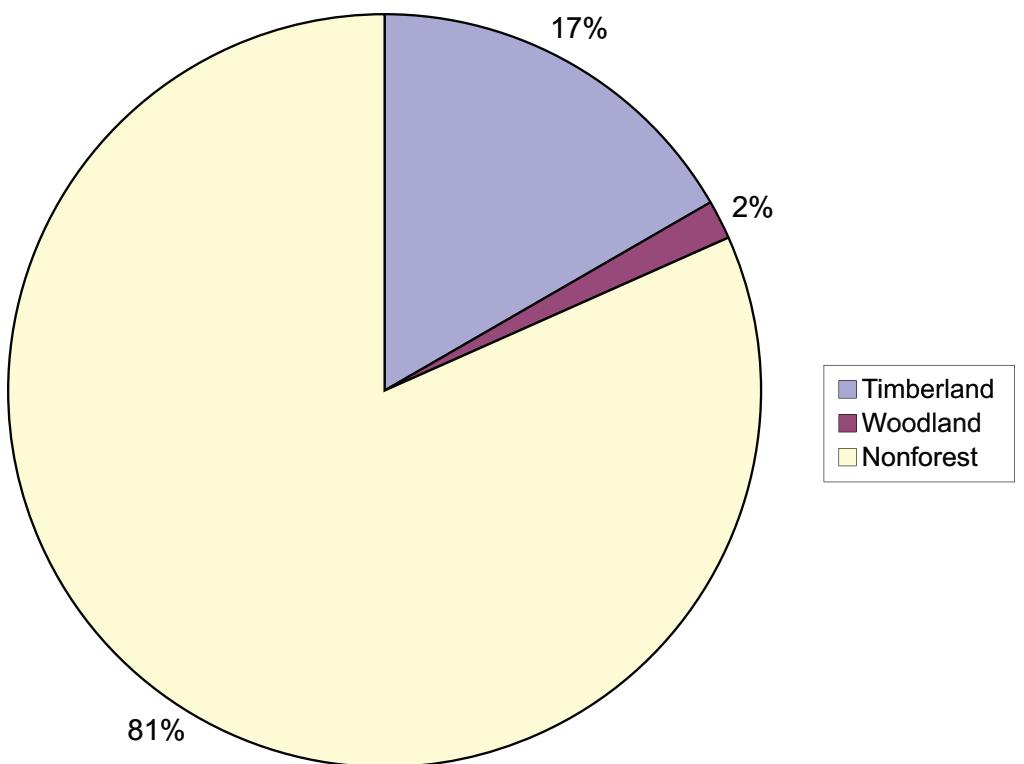

Figure 3—Land area by land class, Wyoming, 2002.

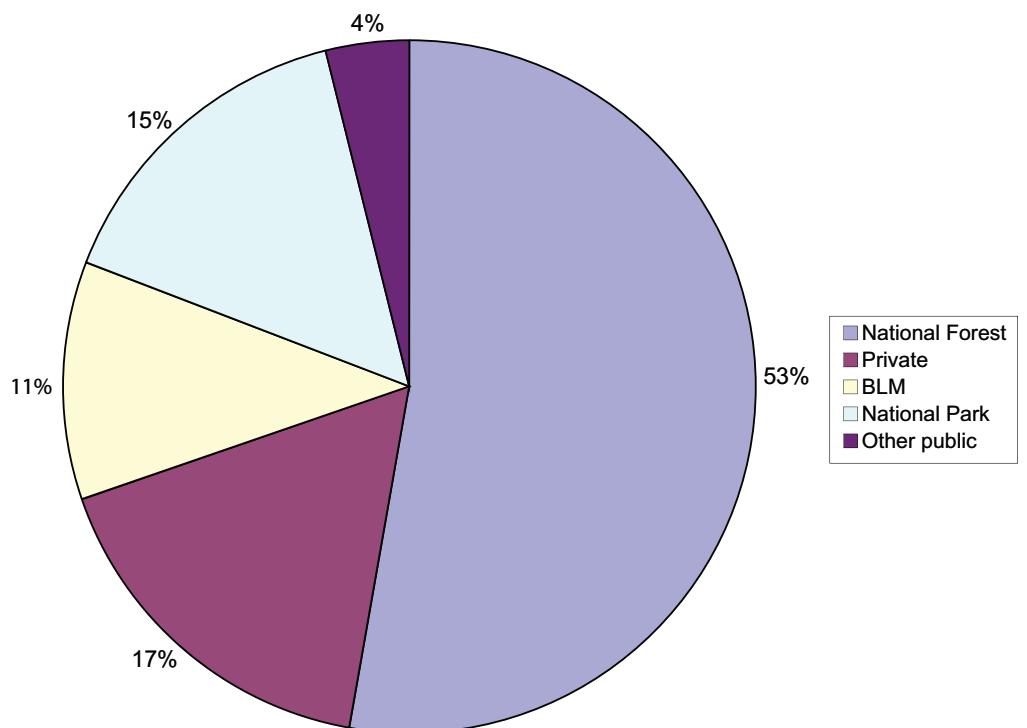

Figure 4—Area of forest land by owner group, Wyoming, 2002.

of the total forest area is in a reserved status. Figure 5 spatially illustrates the location of the major owner groups on forest land in Wyoming.

The area variables discussed below describe the structure and composition of Wyoming's forests. Some of the variables were originally developed to describe forests in terms of growing-stock and timber production and have been adapted for use in describing all trees on all forest land.

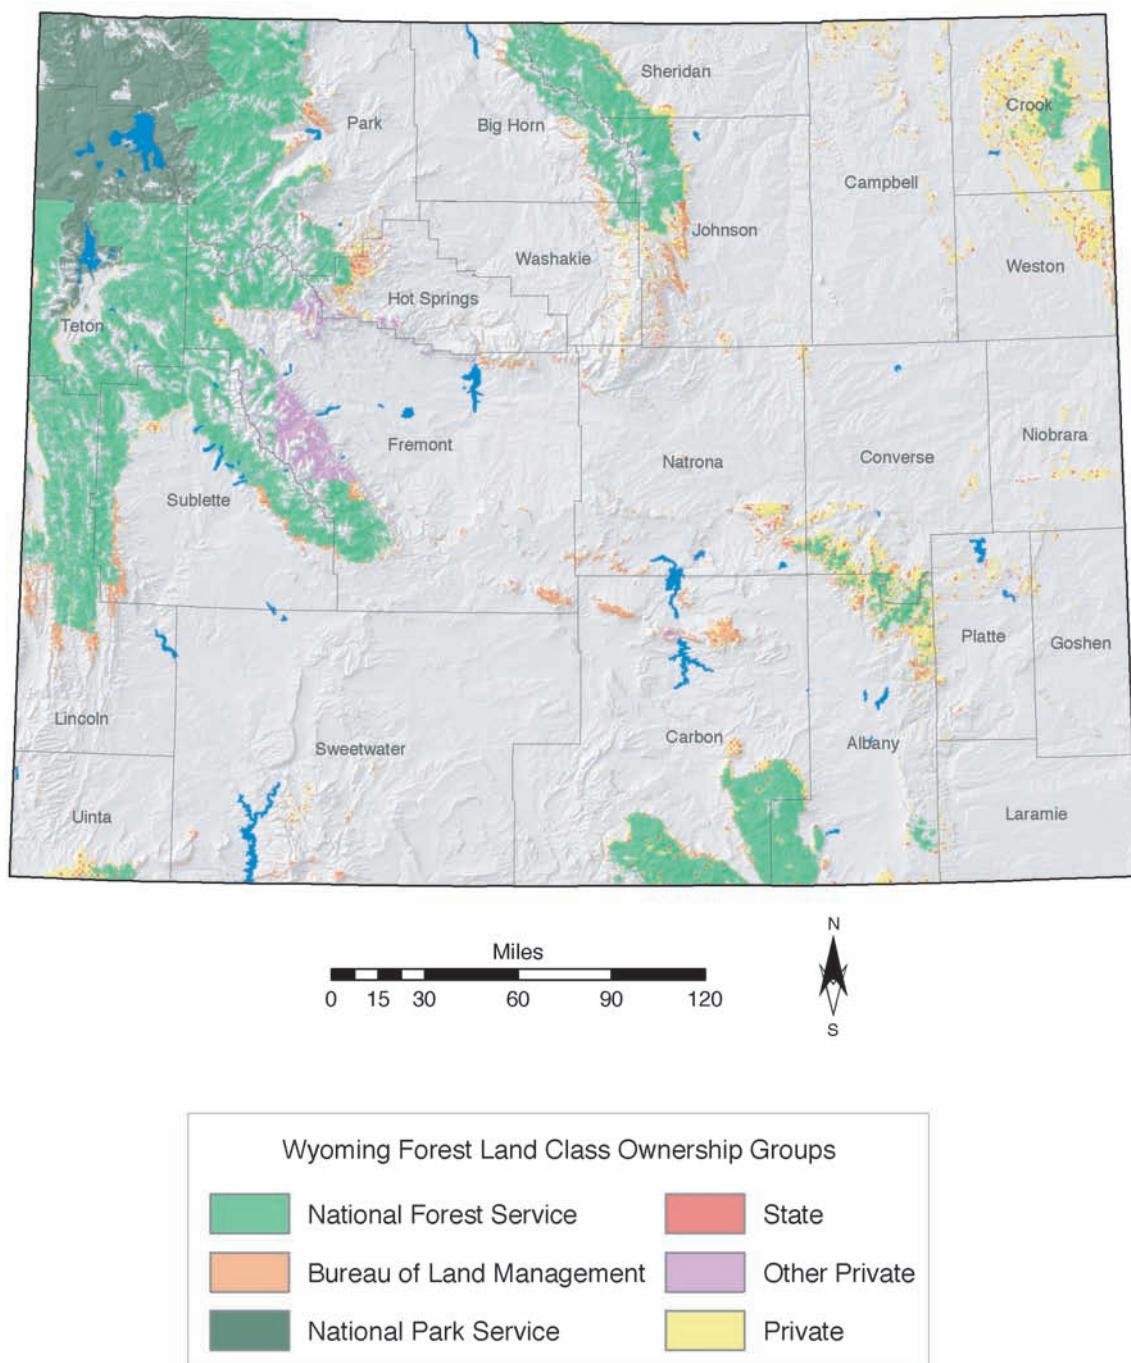

Figure 5—Area of forest land by owner group, Wyoming, 2002.

Forest type—Forest type refers to the predominant tree species in a stand based on tree stocking, and is considered an indicator of forest diversity. The lodgepole pine type is the most abundant forest type in Wyoming, covering over 2.6 million acres, or 23 percent of forest land (table 3). Second in abundance, the spruce-fir type covers 1.8 million acres or 16 percent of the State's forest land. Third, ponderosa pine totals 1.1 million acres and accounts for 9 percent of forest area. Douglas-fir and Engelmann spruce each make up 8 percent of the area; juniper, 8 percent; aspen, 6 percent; whitebark pine 5 percent, and limber pine 4 percent. Nonstocked forest land accounts for 10 percent of total forest land. Nonstocked forest land includes sparsely stocked woodland, recently cut and burned areas, and other areas that fall below a 10-percent stocking threshold of live trees. Figures 6 and 7 illustrate the distribution of forest type on timberland and woodland. Lodgepole pine predominates on timberland, whereas juniper is the most abundant forest type on woodland.

Figure 8 is a map displaying the major forest types and forest type groups overlayed with a shaded relief map layer in Wyoming. This display illustrates the very evident and somewhat predictable nature of vegetation zones in relation to mountainous topographic features. Vegetational zonation in the Southern Rocky Mountain Steppe is controlled by a combination of elevation, latitude, direction of prevailing winds, and slope exposure. The uppermost (alpine) zone is characterized by alpine tundra and the absence of trees. Directly below is the subalpine zone dominated by Engelmann spruce and subalpine fir.

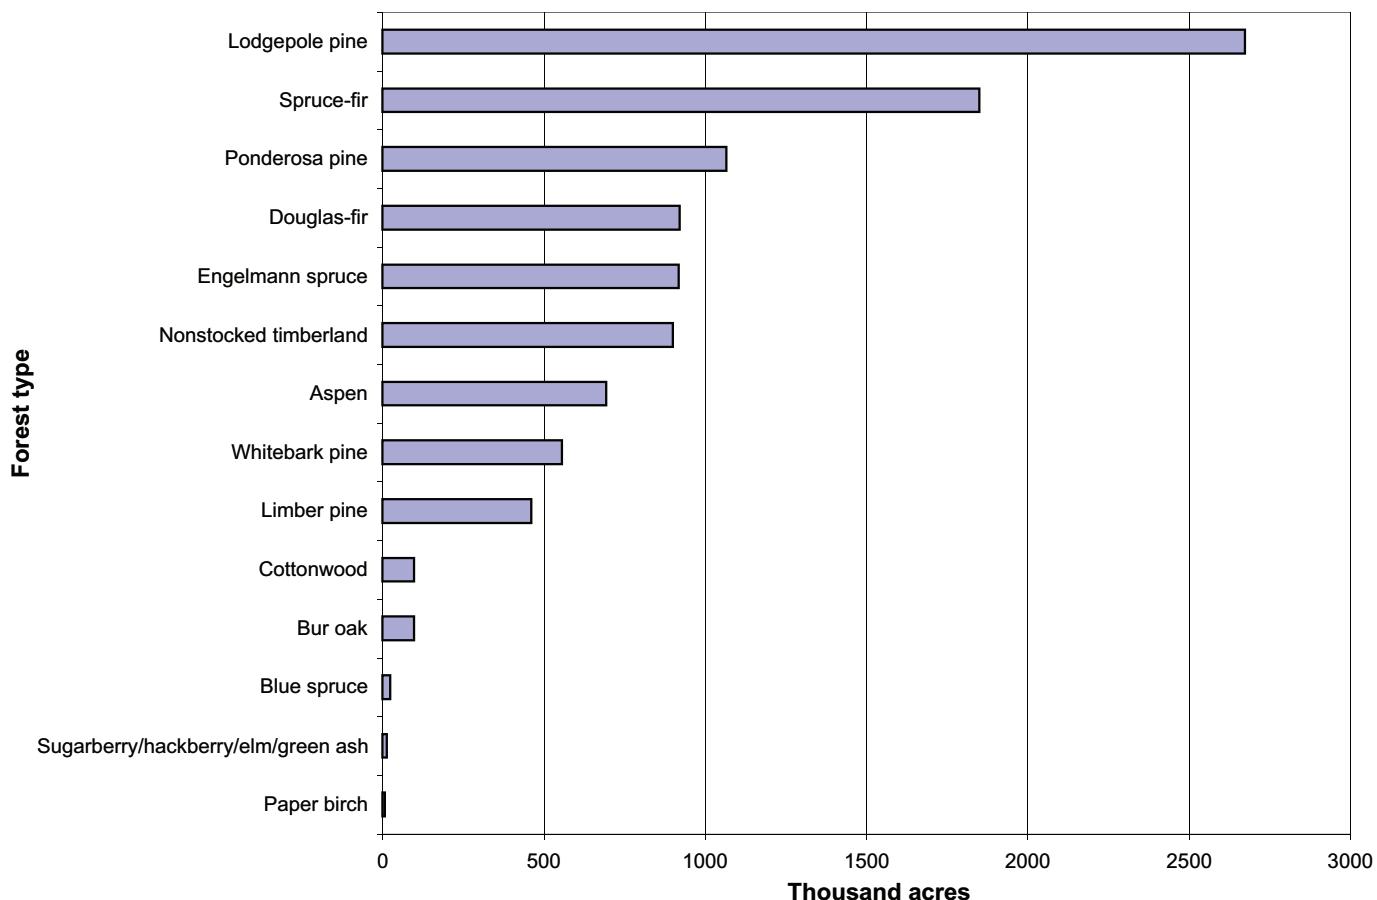

Figure 6—Area of timberland by forest type, Wyoming, 2002.

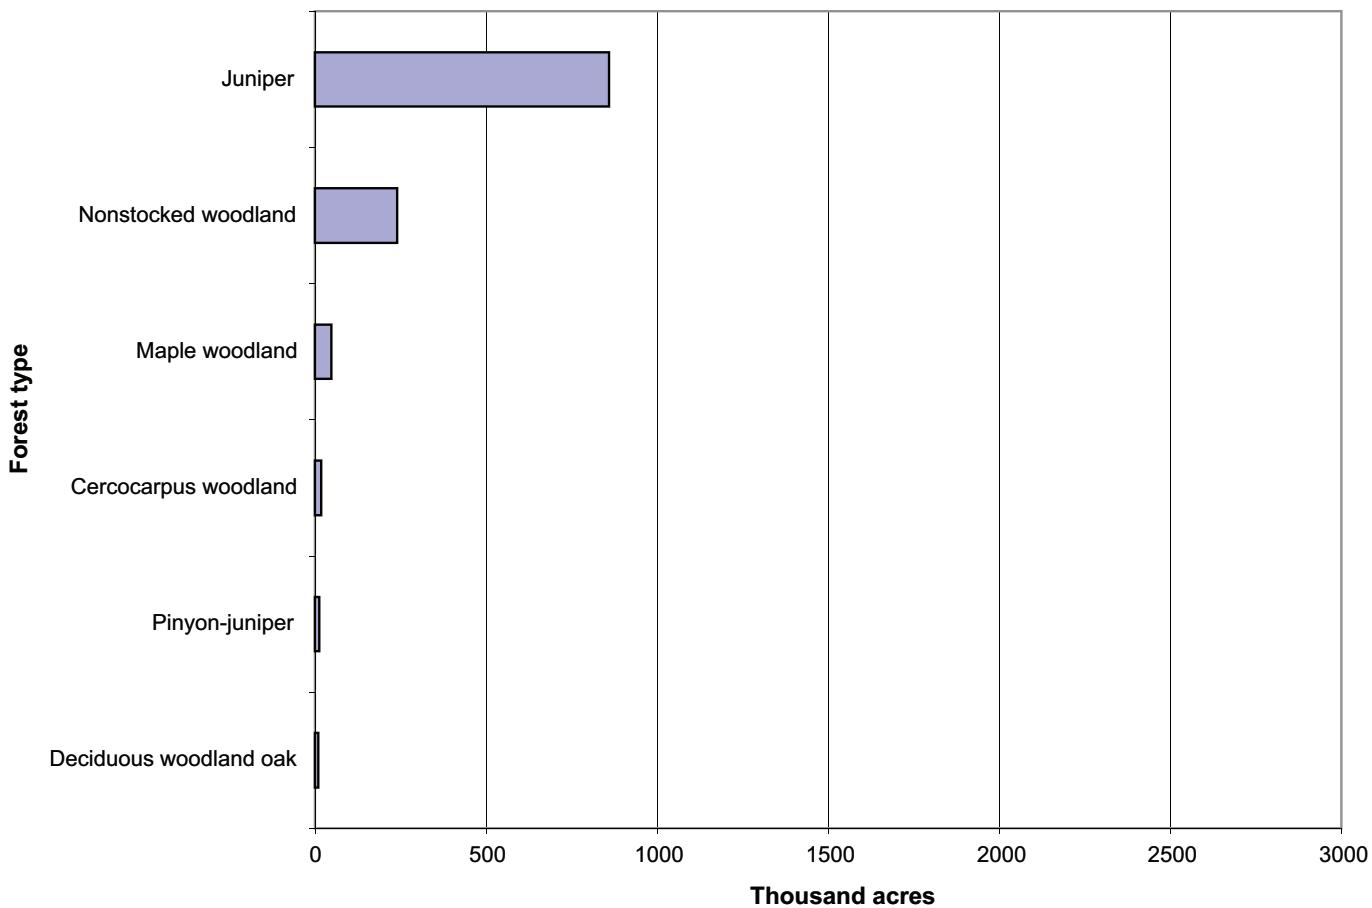

Figure 7—Area of woodland by forest type, Wyoming, 2002.

Below this area lies the montane zone, characterized by ponderosa pine and Douglas-fir, depending on aspect. Ponderosa pine favors drier, exposed slopes, whereas Douglas-fir prefers the higher, moist, sheltered areas. Below the montane zone is the foothill zone where mountain-mahogany and several species of oak are present. Lodgepole pine is heavily concentrated in the northwest region where Yellowstone National Park is located. This area is part of the Middle Rocky Mountain province characterized by basins and ranges. The spruce-fir types indicate an elliptical pattern surrounding the harsh, exposed environment of the alpine zone. Douglas-fir follows the east-facing coves at the higher elevations. Ponderosa pine is heavily concentrated in the northeast region where the Black Hills National Forest is located.

Stand size—Stand size is a classification of forest land based on the predominant diameter class of live trees presently forming the majority of live tree stocking (tables 4 through 7). The names of two of the four stand-size classes (sawtimber and poletimber) are often misinterpreted by readers of FIA reports. Sawtimber and poletimber refer only to a tree-size category and do not imply a commercial species classification. Both timberland and woodland tree species can fall into the sawtimber and poletimber stand-size class. Figure 9 illustrates area of forest land by stand-size class. The majority of stands (56 percent) are comprised of large-diameter trees (sawtimber stand-size class). Eighteen percent of forest stands are composed of small trees (sapling/seedling stand-size class), such as newly regenerated areas following harvesting activity or fire. The distribution of forest land by stand-size class varies significantly between timberland

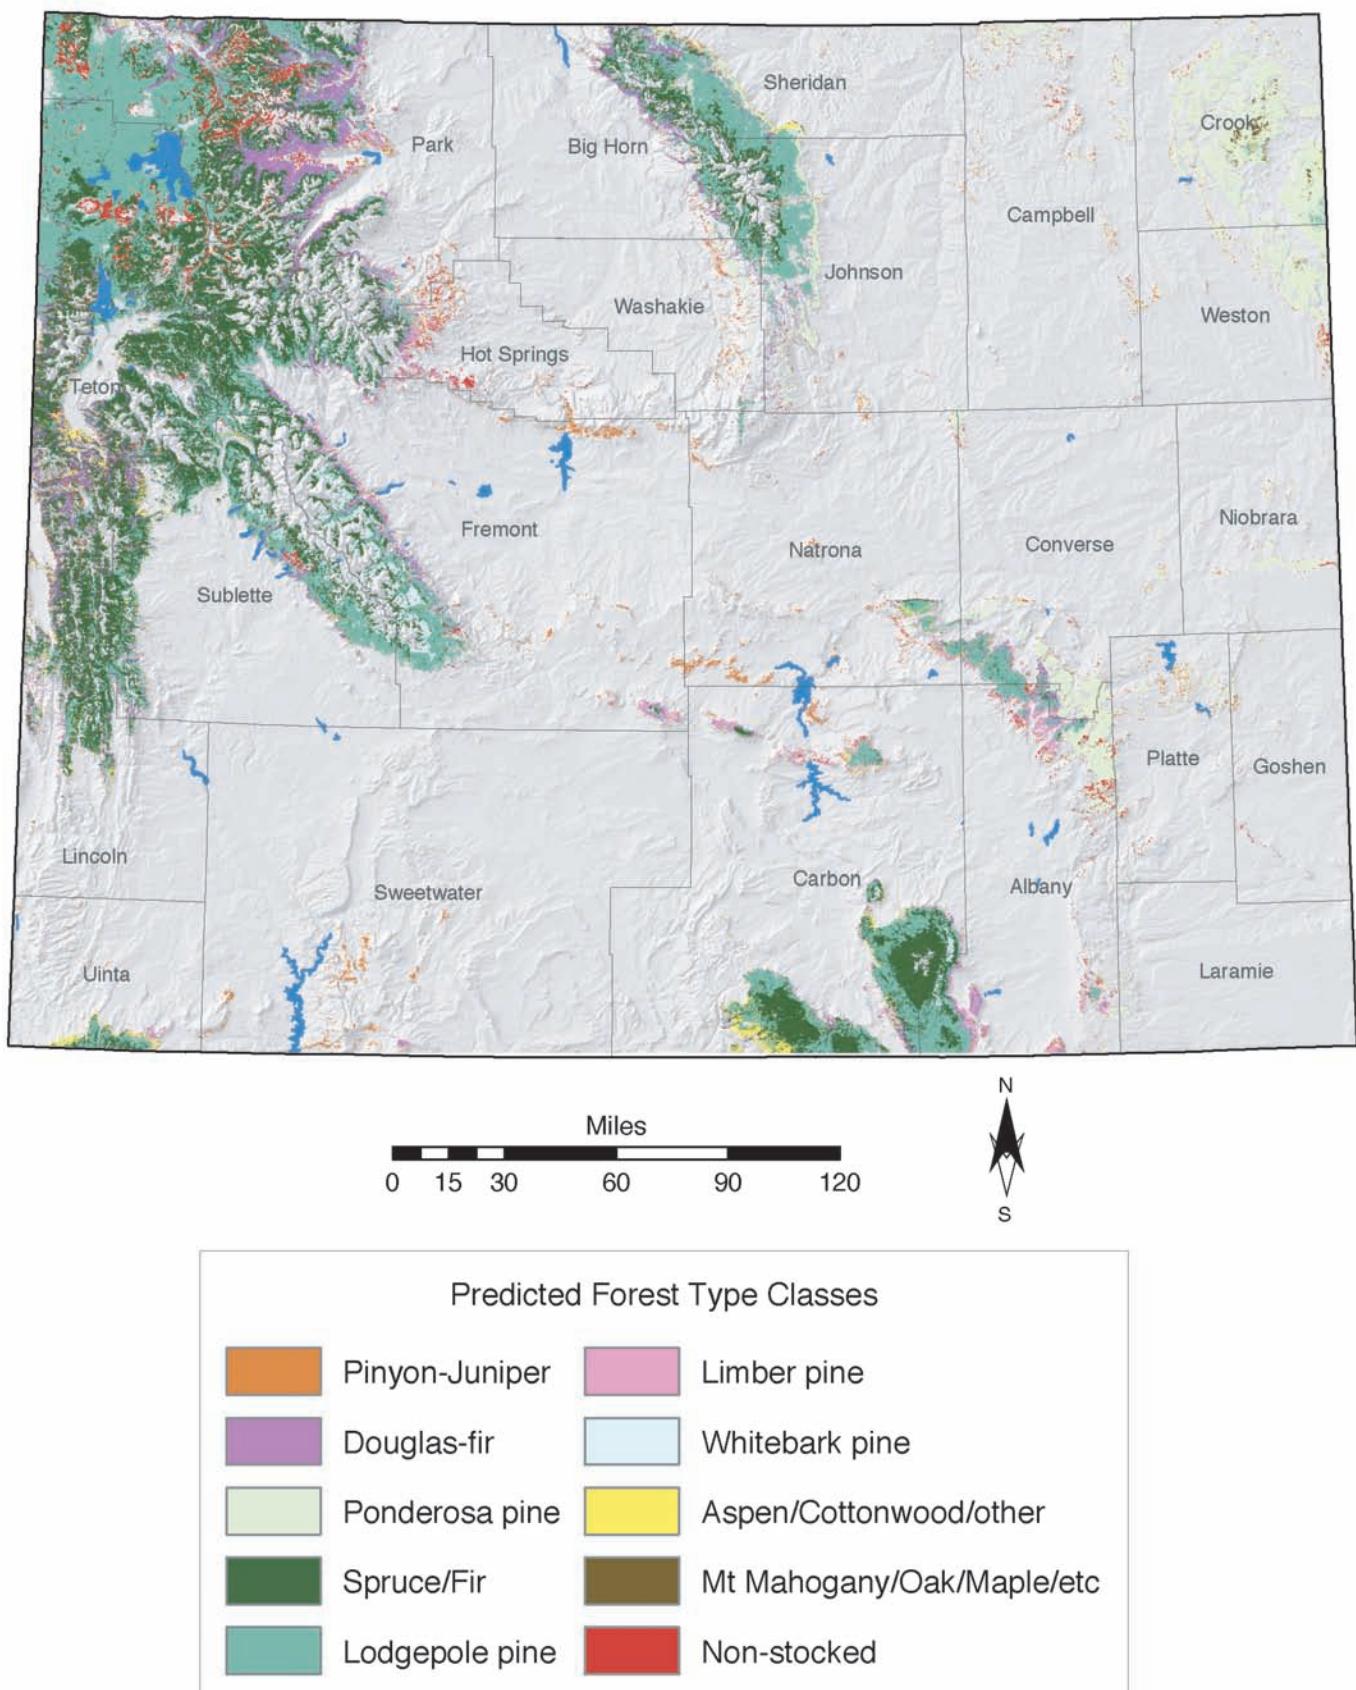

Figure 8—Area of forest land by forest type, Wyoming, 2002.

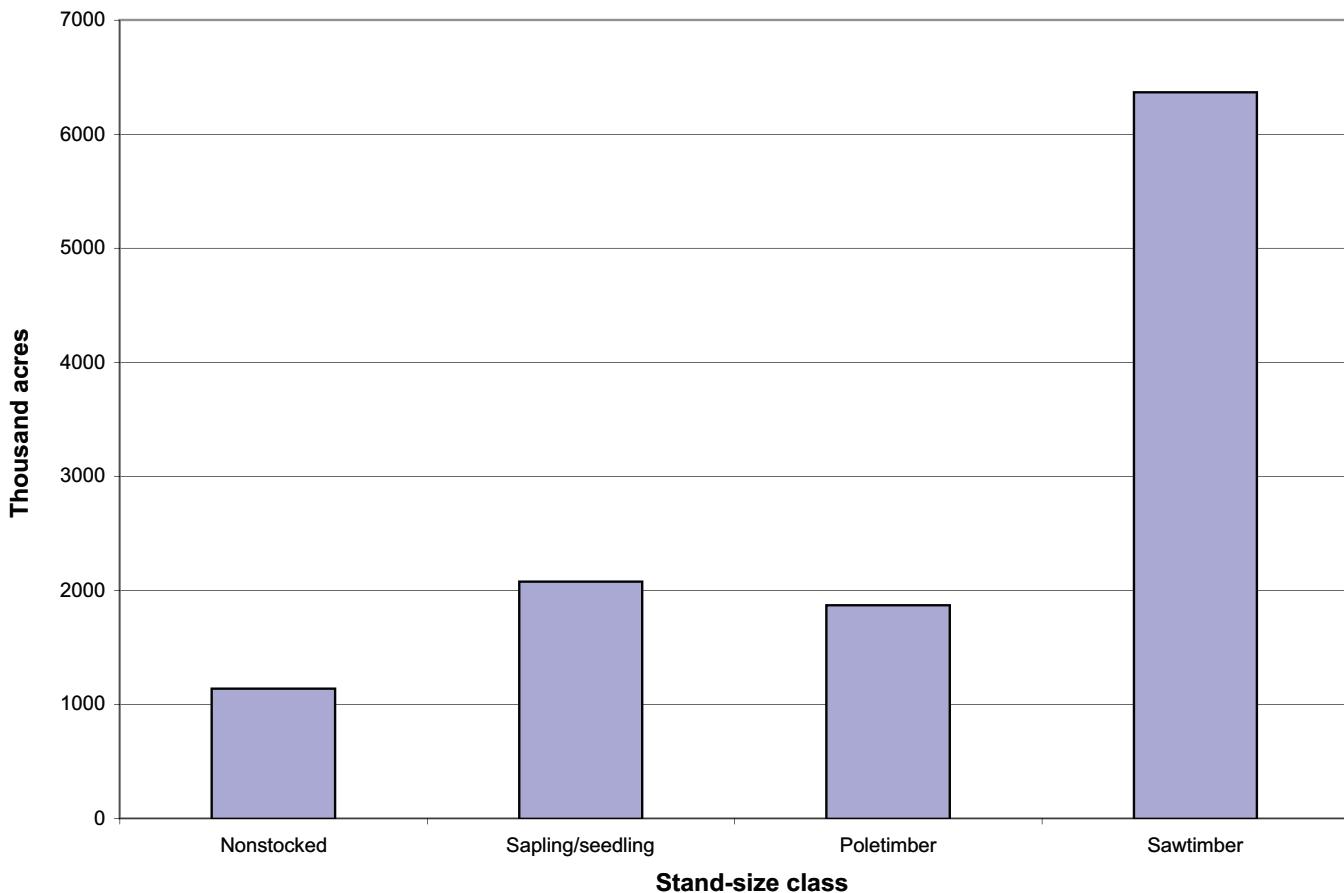

Figure 9—Area of forest land by stand-size class, Wyoming, 2002.

and woodland (fig. 10). The proportion of sawtimber and nonstocked stand-size classes is higher on land classified as woodland as opposed to timberland.

Stand age—Figure 11 illustrates area of forest land by stand-age class. Like stand size, age is an indicator of forest structure, but difficult to quantify in stands comprised of trees of many different ages. Therefore, interpretation of stand-age statistics should be used with caution especially when making certain assumptions such as old-growth conditions. Stand age is a computed variable using only those ages of trees within the computed stand-size class and weighted by trees per acre. If a computed stand-size class is nonstocked, the age class is defined as unclassified. Ninety-one percent of all forest stands in Wyoming are estimated to be less than 200 years old and less than 1 percent is over 300 years old. Figure 12 illustrates how stand-age class distribution differs between timberland and woodland. Figure 13 spatially depicts stand age distribution on forest land in Wyoming. Note the prevalence of stands in the youngest age class in the northwest region of the State. Many of these stands are young lodgepole pine forests that regenerated after the large-scale fires that occurred in 1988.

Basal area class—Basal area (BA) is the cross-sectional area of a tree stem associated with a diameter measured at a specified point on the stem, expressed in square feet. Basal area of a forest stand is the sum of the basal areas of all individual live trees in the

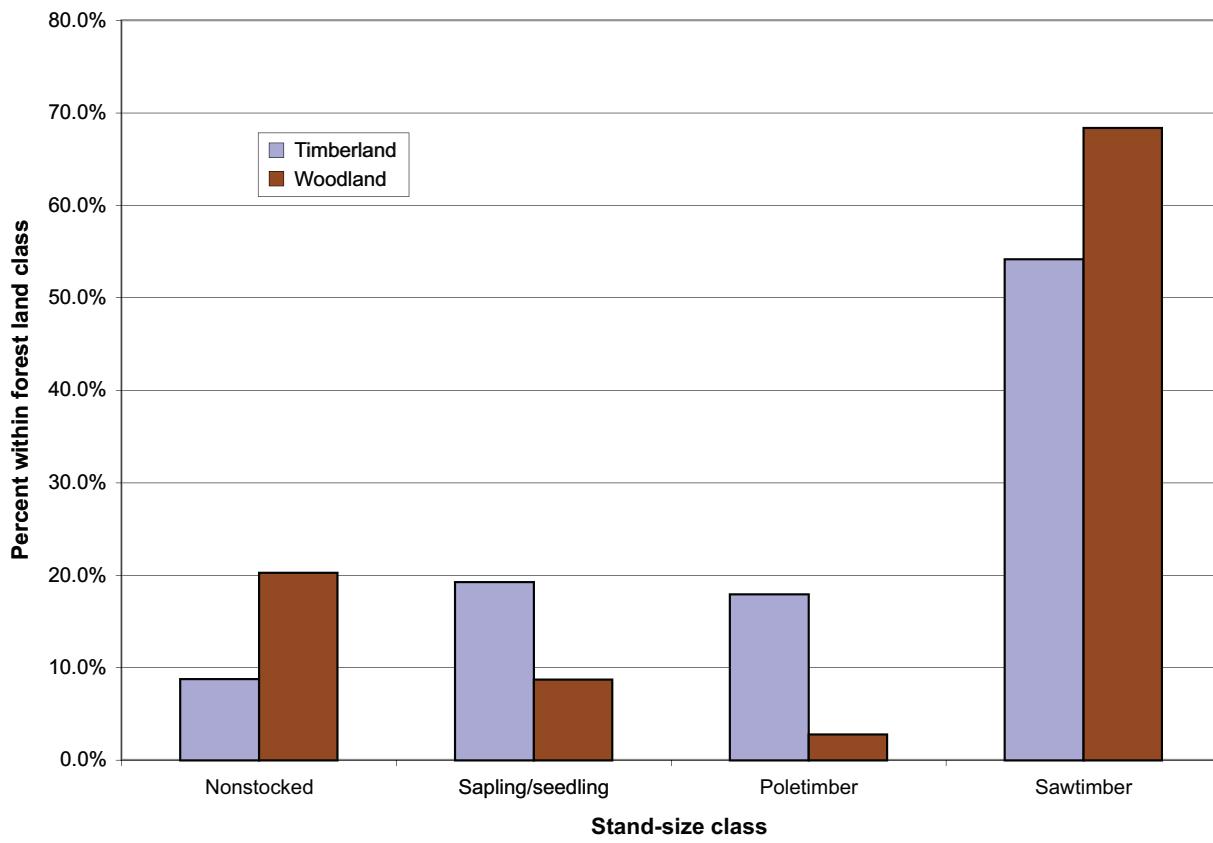

Figure 10—Distribution of forest area by stand-size class and forest land class, Wyoming, 2002.

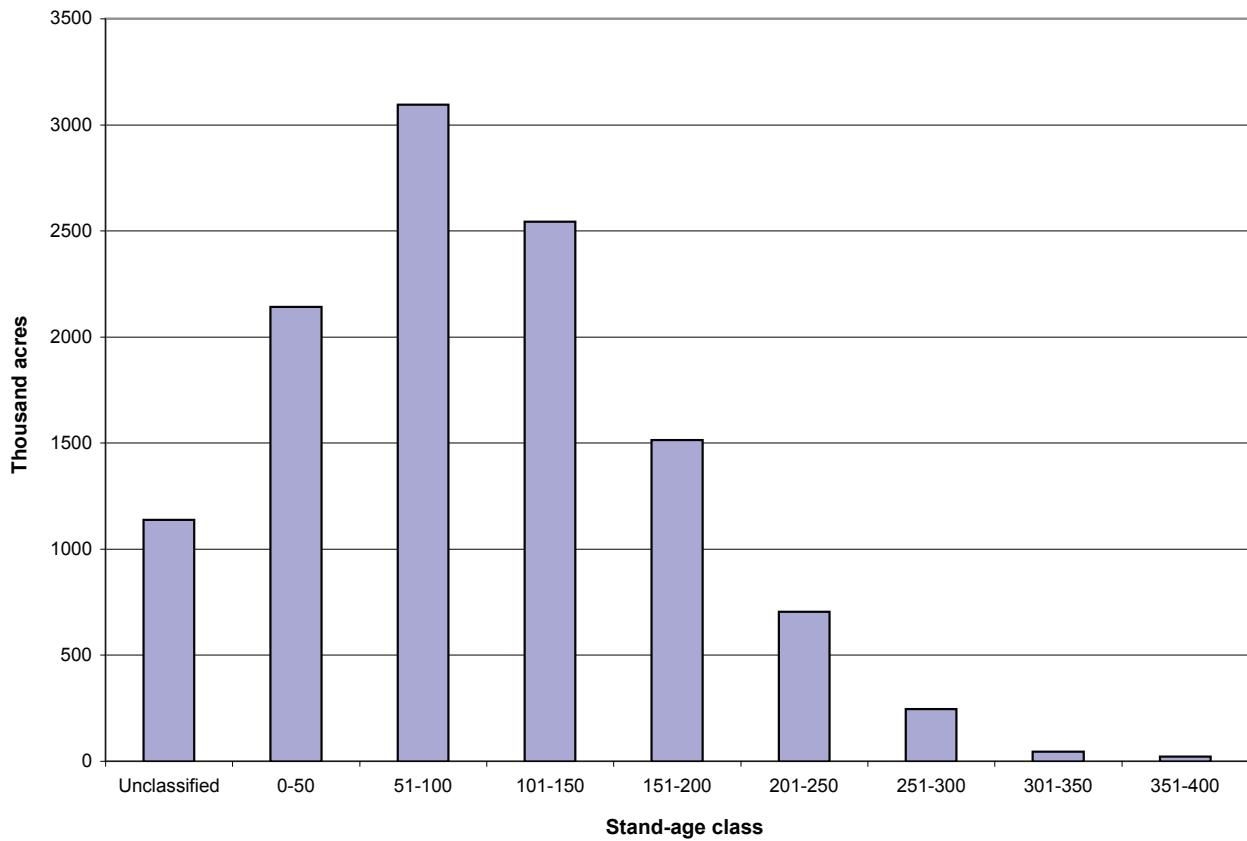

Figure 11—Area of forest land by stand-age class, Wyoming, 2002.

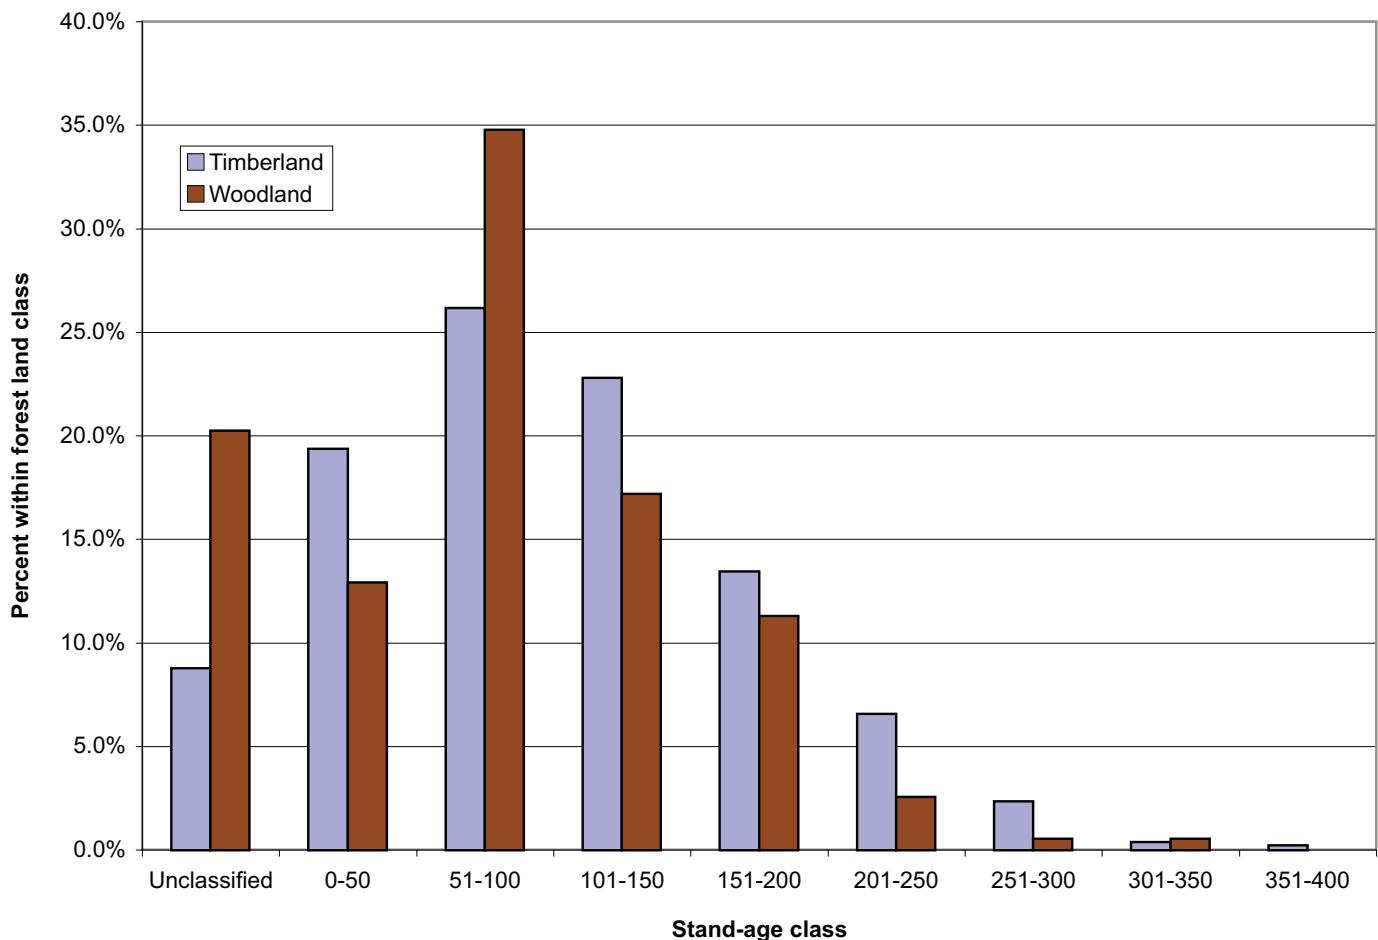

Figure 12—Distribution of forest area by stand-age class and forest land class, Wyoming, 2002.

stand and is often used to measure site occupancy. Figure 14 illustrates area of forest land by basal-area class, and indicates that more than half (52 percent) of forest land in Wyoming is in stands with basal areas of live trees greater than 75 square feet per acre. Mean basal area of live trees averages 91 square feet per acre on all forest land. Mean basal area of live trees on timberland is 93 square feet per acre on timberland and 67 square feet per acre on woodland. Stands with a high level of basal area are often in a state of competition where the trees are stressed and highly susceptible to invasion by disease and insects. Eventually, many trees die and accumulations of standing dead and down material create a fuel source for fires.

Stand density index—Stand density index (SDI), as developed by Reineke (1933), is a relative measure of stand density that quantifies the relationship between trees per acre, stand basal area, average stand diameter, and stocking of a forested stand. Western silviculturists often use SDI as one measure of stand structure to meet diverse objectives such as ecological restoration and wildlife habitat. Originally developed for even-aged stands, SDI can also be applied to unevenaged stands (Long and Daniel 1990; Shaw 2000). SDI is usually presented as a percentage of a maximum SDI for each forest type (USDA Forest Service 1991). SDI was computed for each condition that sampled forest land using maximums shown in table 12, and the results were grouped into six classes. A comparison between the distribution of forest area on timberland and woodland by SDI class is illustrated in figure 15. A site is considered to be fully occupied at 35

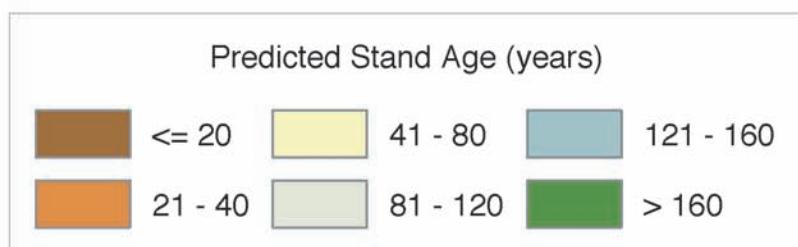

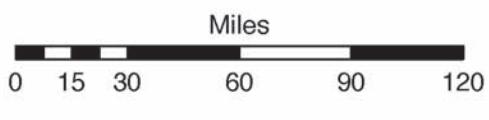

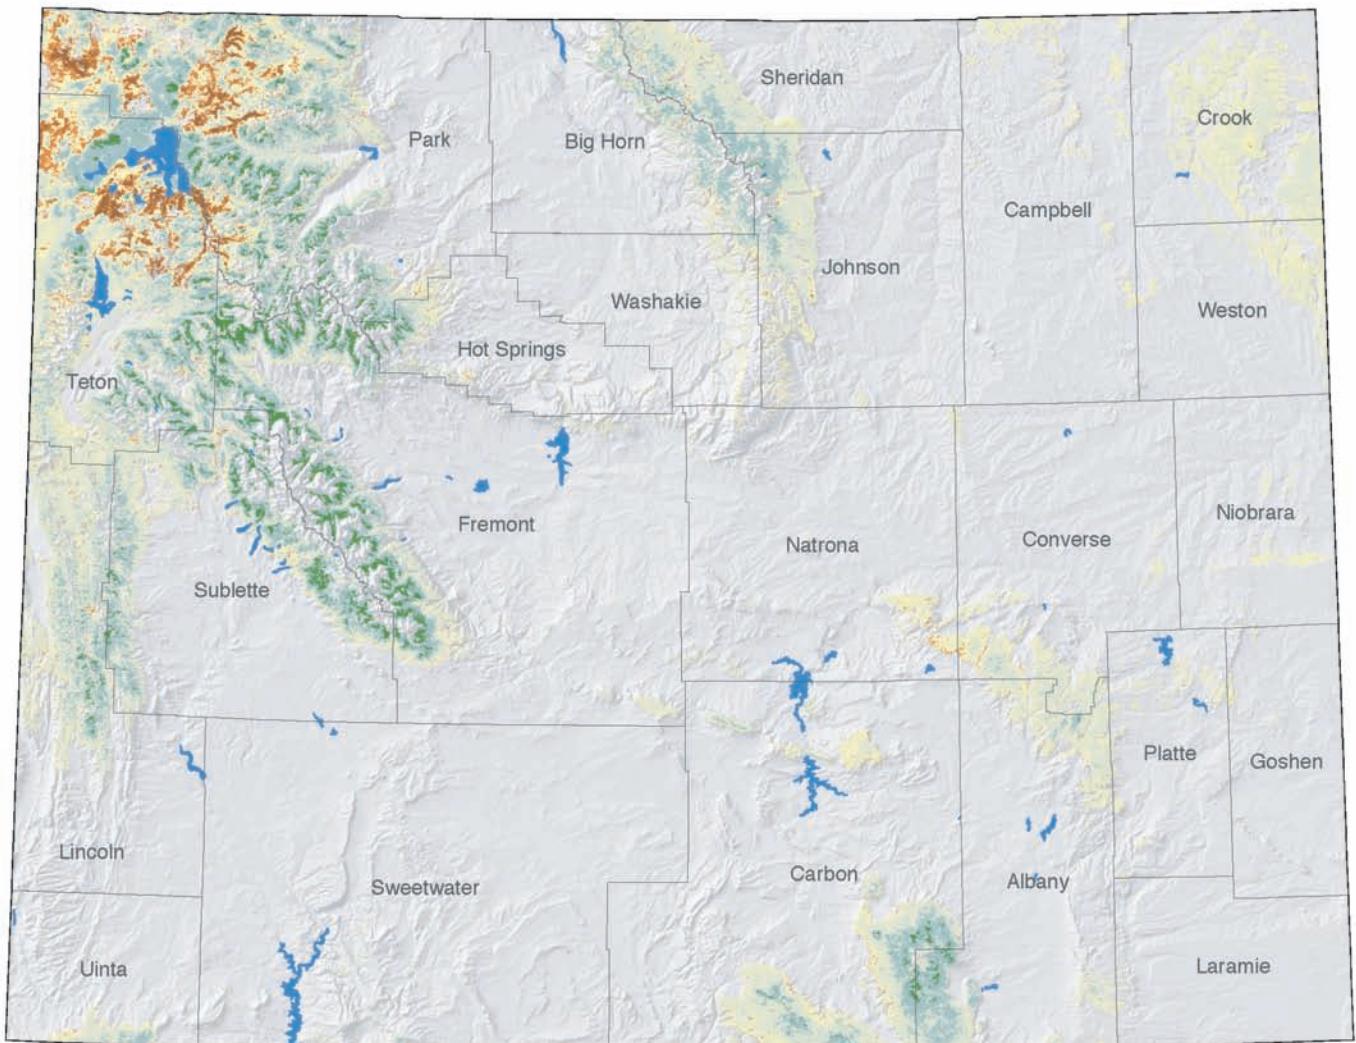

Figure 13—Area of forest land by stand-age class, Wyoming, 2002.

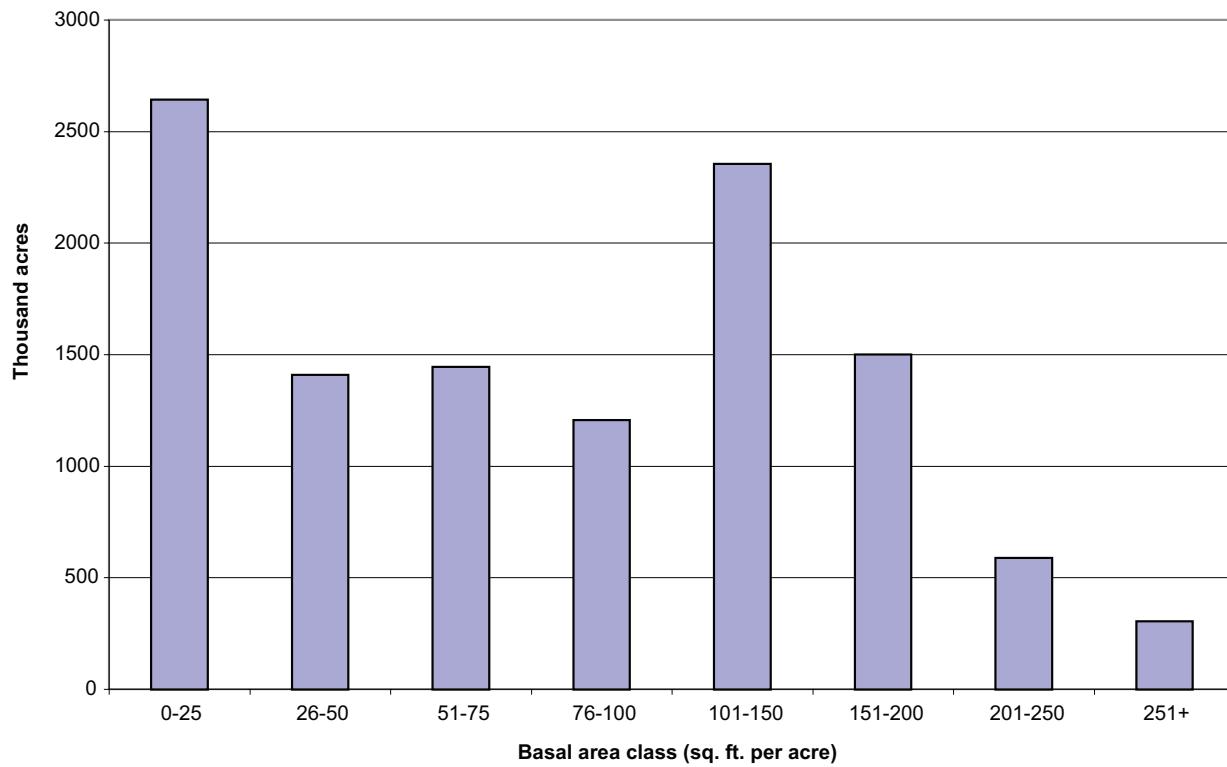

Figure 14—Area of forest land by basal-area class, Wyoming, 2002.

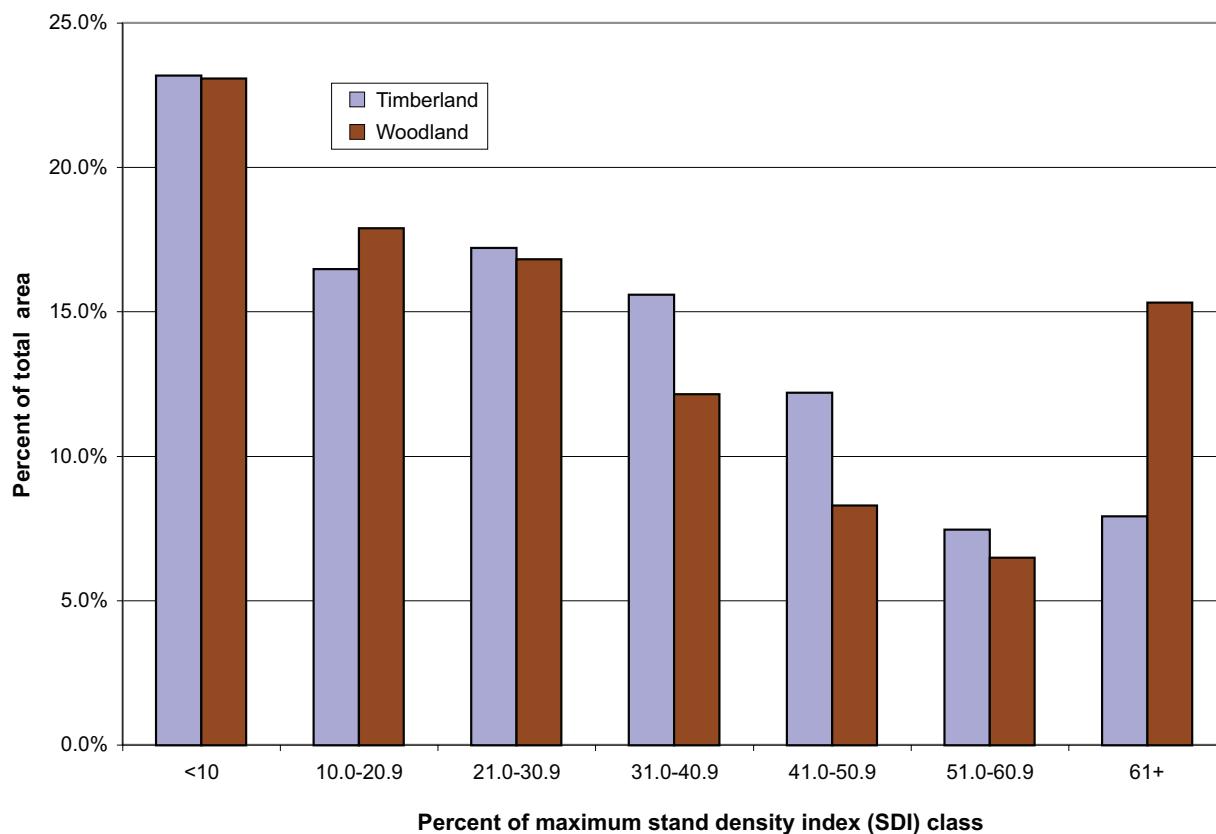

Figure 15—Distribution of forest area by percent of maximum stand density (SDI) class and forest-land class, Wyoming, 2002.

percent of SDI maximum, which marks the onset of competition-related stresses and slowed growth rates. The IW-FIA survey estimates that 35 percent of all forest stands in Wyoming are at or above 35 percent of SDI maximum.

Number of Trees

The number and distribution of individual tree species is another indicator of forest diversity. Softwood species are predominate, with lodgepole pine being the single most abundant species on forest land in Wyoming. Lodgepole pine totals 1.2 billion trees, or 27 percent of all live trees on forest land. Second in abundance is subalpine fir, which accounts for 25 percent of all live trees on forest land, and Engelmann spruce is third at 11 percent.

Lodgepole pine also predominates on forest land that is classified as timberland, followed by subalpine fir and Engelmann spruce. Together, these three species account for two-thirds of all live trees on timberland (fig. 16). The number of live trees on forest land that is classified as woodland totals 232 million trees. Rocky Mountain juniper is the single most abundant species occurring on woodland in Wyoming and accounts for 45 percent of the woodland total (fig. 17). Second in abundance is Utah juniper, which totals 72 million trees or 31 percent of the woodland total. Other species recorded on woodland include Rocky Mountain maple, curleaf mountain-mahogany, and ponderosa pine.

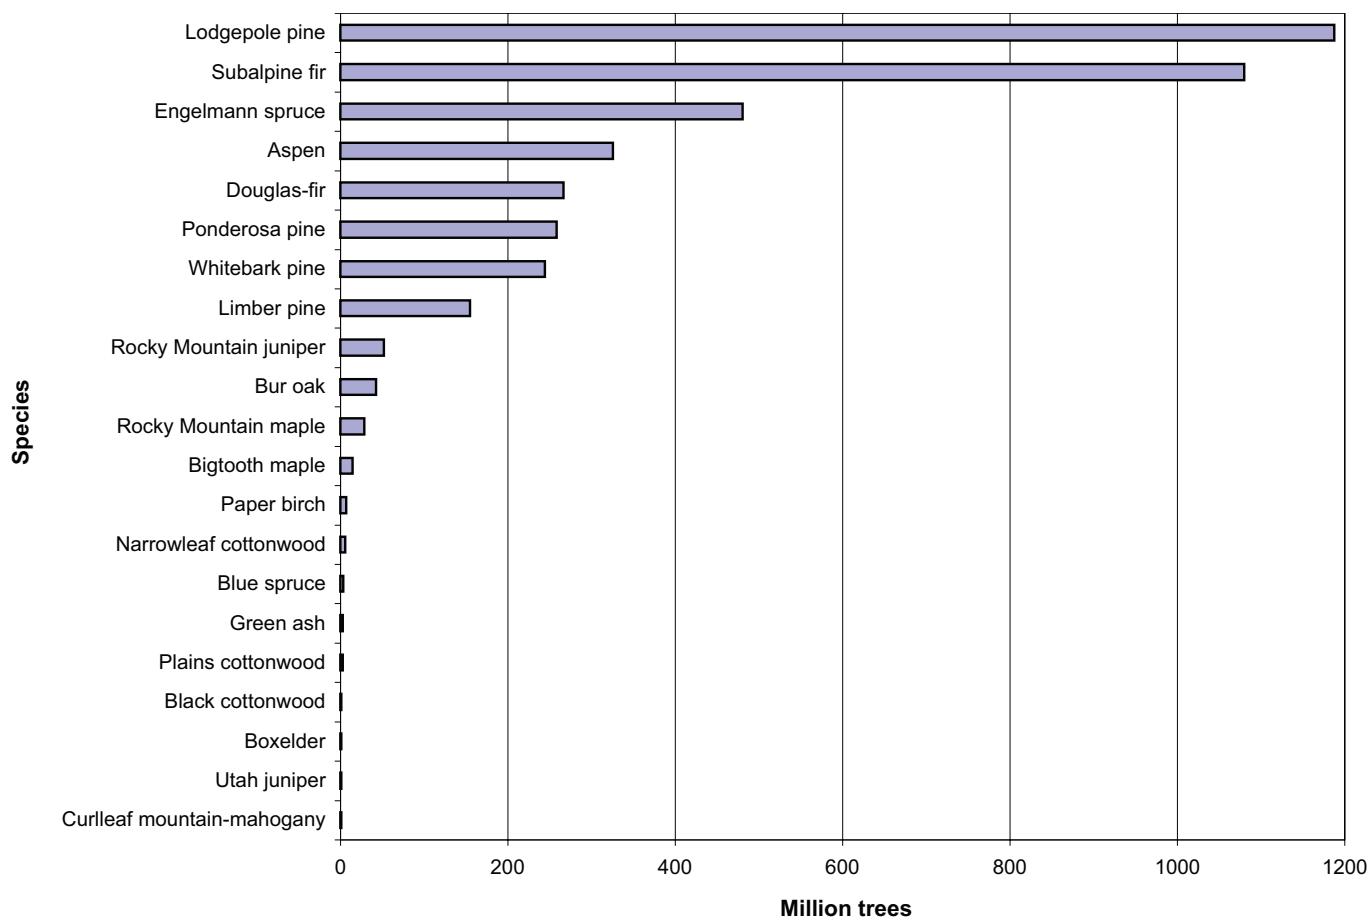

Figure 16—Number of live trees by species on timberland, Wyoming, 2002.

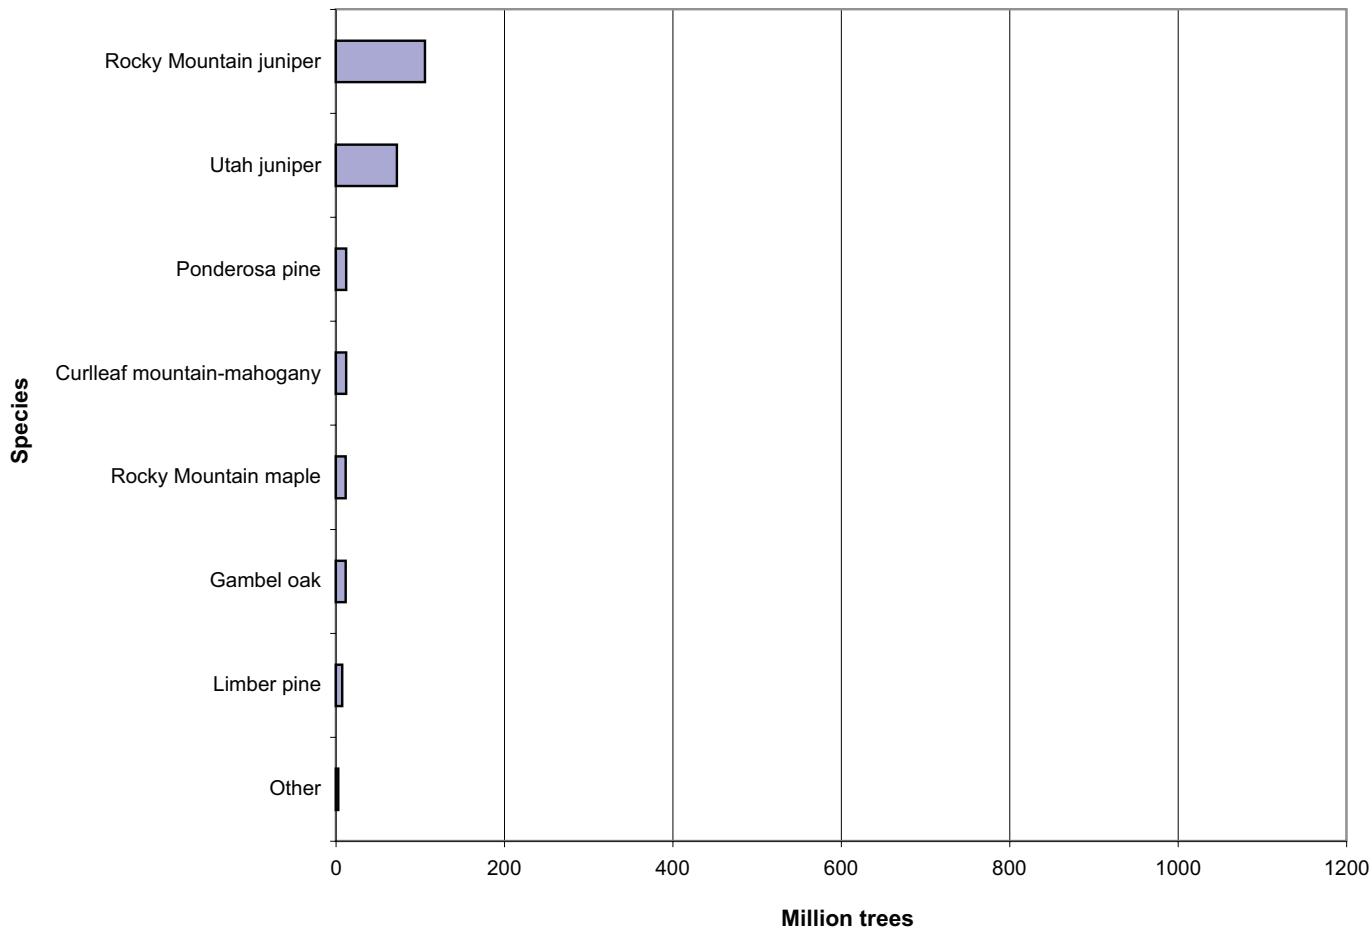

Figure 17—Number of live trees by species on woodland, Wyoming, 2002.

Figure 18 illustrates the distribution of numbers of live trees on timberland and woodland by diameter class (includes d.b.h. and d.r.c.). Sixty-one percent of all live trees on forest land are less than 5 inches in diameter. Less than one percent of all live trees are larger than 22 inches in diameter.

Dead trees, often referred to as snags, are a significant component of forest ecosystems, contributing to habitat for many species of wildlife and soil nutrients. Snags also play an important role in fire-related analysis because of their contribution to fuel sources. The most recent inventory of Wyoming forests recorded slightly less than 1 billion standing dead trees, and 45 percent were greater than 5.0 inches in diameter. Lodgepole pine accounted for the majority (39 percent) of standing dead trees in Wyoming and subalpine fir was second in abundance (21 percent). The mean number of standing dead trees 5.0 inches in diameter and larger averages 38 trees per acre on forest land, 42 on timberland, and 9 on woodland. These averages represent total forest land area and do not account for the uneven distribution of standing dead trees caused by fire, disease, and insect outbreaks. For example, there are significant numbers of standing dead trees in Yellowstone National Park as a result of the large scale fires that occurred in 1988. The average number of standing dead trees 5.0 inches in diameter and larger on National Park land in Wyoming is nearly 89 trees per acre.

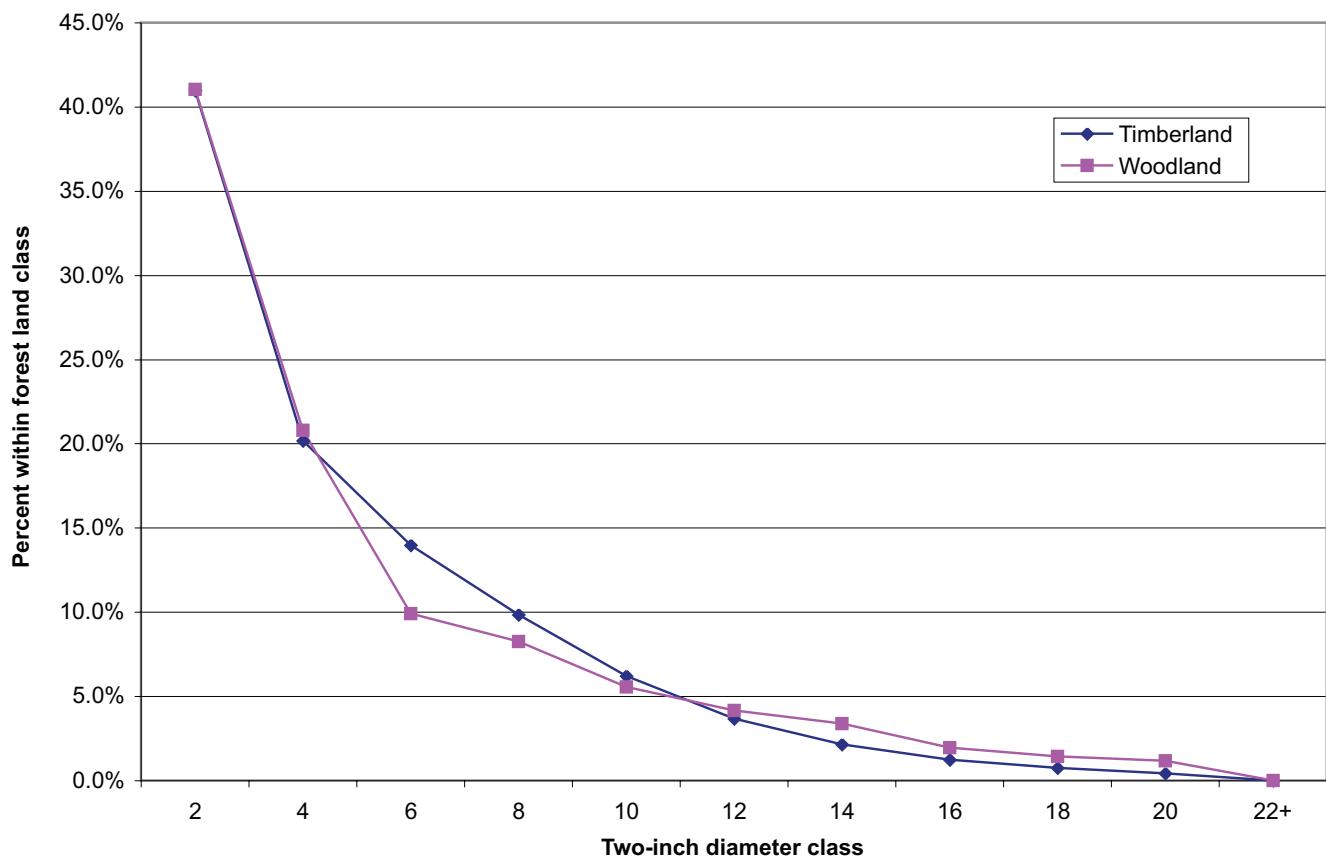

Figure 18—Distribution of live trees by forest land class and two-inch diameter class, Wyoming, 2002.

Biomass and Volume

The total oven-dry biomass of all live trees in Wyoming is 350 million tons. Biomass includes boles, bark, and branches of all live trees. Biomass on timberland totals 345 million tons (fig. 19) and 5 million tons on woodland (fig. 20). Lodgepole pine accounts for 30 percent (105 million tons) of the biomass total in the State. Figure 21 spatially displays oven-dry biomass of live trees in Wyoming.

Net volume of wood in live trees 5.0 inches in diameter and larger in Wyoming totals 19.8 billion cubic feet. Softwoods account for 96 percent of this total volume. Lodgepole pine, Engelmann spruce, and subalpine fir collectively account for 70 percent of the total softwood volume in the State. Aspen accounts for the majority (73 percent) of the hardwood volume total, and plains cottonwood accounts for 15 percent.

Growth and Mortality

Forest growth, for FIA reporting purposes, is an estimate that provides additional information about trends in the population estimate of inventory volume. As time passes, the total volume of live trees in a region or State increases, decreases, or remains the same. These changes can be explained, in part, by examining the dynamics of live tree growth, tree mortality, and trees removed by harvesting practices. Forest growth is a complex estimate for broad-scale inventories. It is not always easy to measure, it is very sensitive to changes in sampling procedures over time, and can be defined in several different ways.

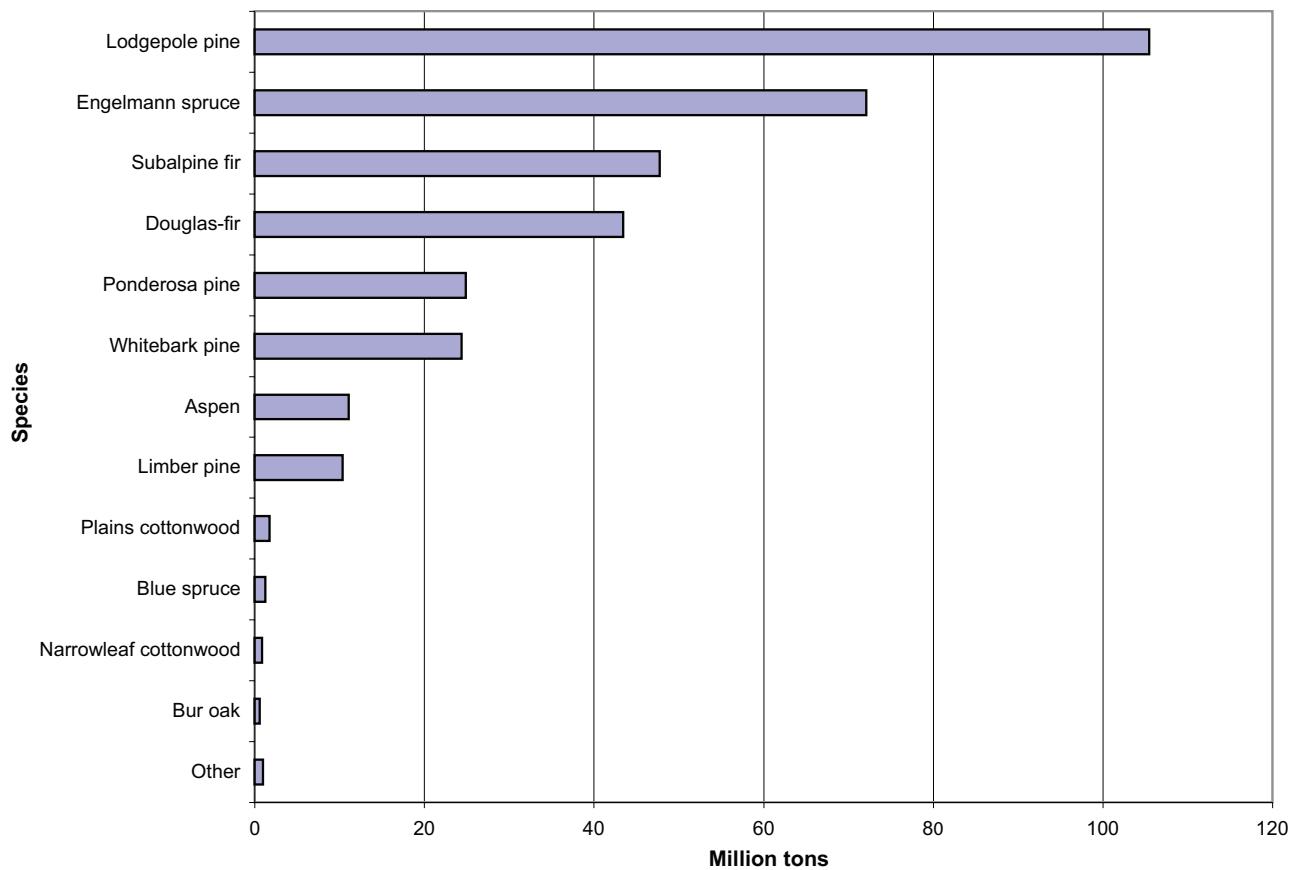

Figure 19—Oven-dry weight of biomass of all live trees by species on timberland, Wyoming, 2002.

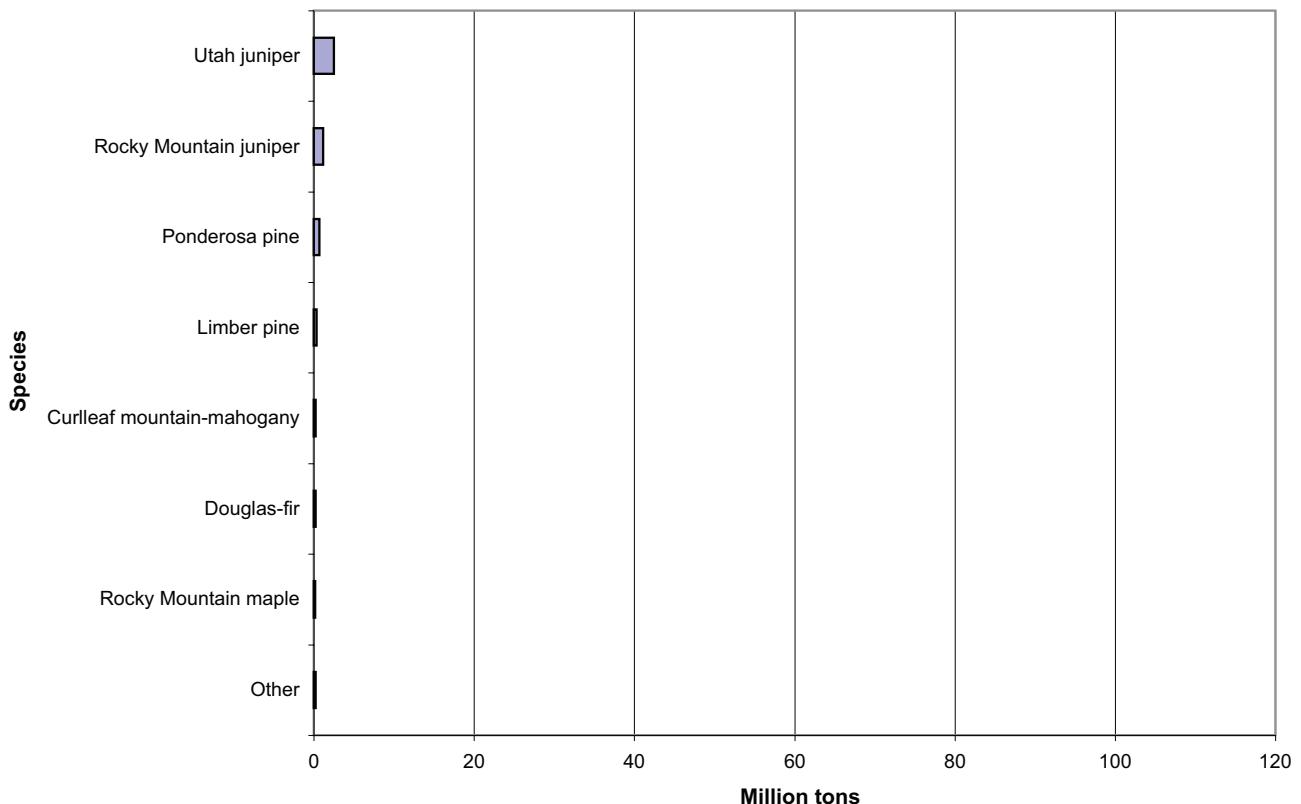

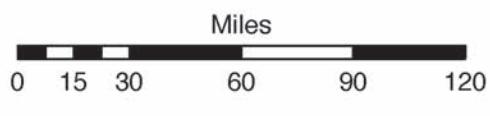

Figure 20—Oven-dry weight of biomass of all live trees by species on woodland, Wyoming, 2002.

Predicted Biomass (oven-dry weight, total tree, tons per acre)

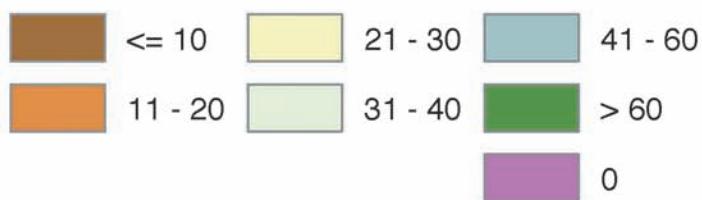

Figure 21—Oven-dry weight of all live tree biomass on forest land, Wyoming, 2002.

For these and related reasons, it is necessary to divide forest growth into component parts to arrive at consistent definitions. All estimates of growth and mortality are for trees 5.0 inches and larger in diameter at the year of inventory. Live tree growth is determined from increment core measurements and is expressed as an annual average over a 10-year period. Survivor growth is the average annual change in volume for trees that are alive in the current inventory and were estimated to be equal to or greater than 5.0 inches in diameter 1 year prior to the current inventory. Ingrowth is the current volume of trees that are alive in the current inventory and were estimated to be below 5.0 inches in diameter 1 year prior to the current inventory. Mortality is the average annual net volume of trees that have died in the 5 years prior to the year of inventory. Removal volume is the average annual net volume of trees that were removed from the inventory as the result of harvesting activity. The estimate of Wyoming's removal volume was obtained from a separate study and is explained in the "Nonreserved Timberland" section. Gross annual growth is the sum of survivor growth, ingrowth, and mortality. Net annual growth is gross annual growth minus annual mortality.

Gross annual growth of all trees on forest land in Wyoming totaled 331 million cubic feet. Gross growth of all trees averaged 327 million cubic feet on timberland and 4 million cubic feet on woodland (figs. 22 and 23). Annual mortality of all trees on forest land in Wyoming averaged 172 million cubic feet. Annual mortality of all trees averaged 171 million cubic feet on timberland and less than 2 million cubic feet on woodland.

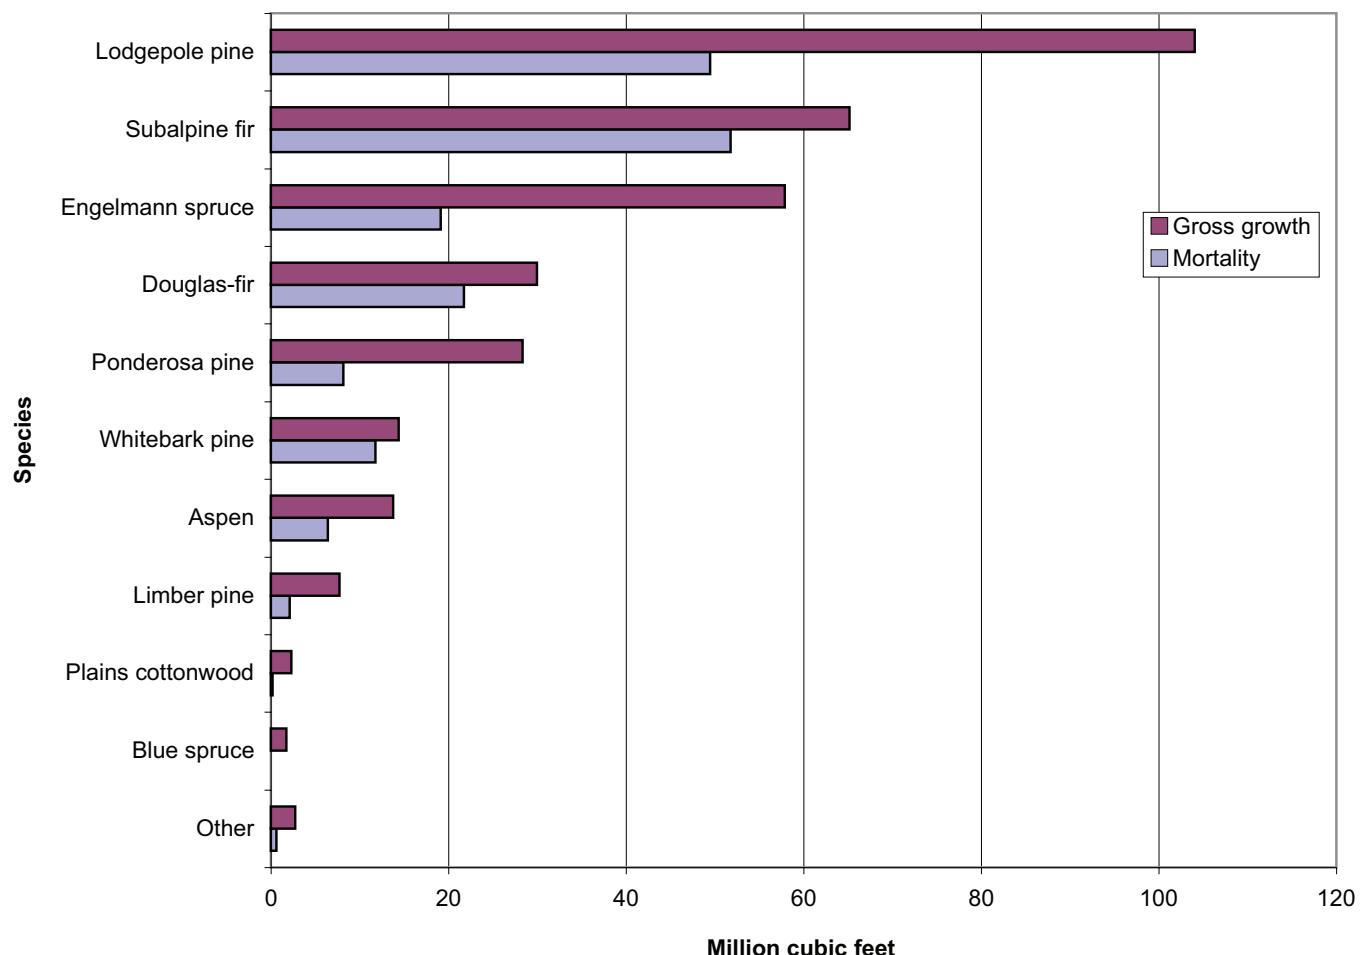

Figure 22—Gross annual growth and annual mortality of all trees by species on timberland, Wyoming, 2002.

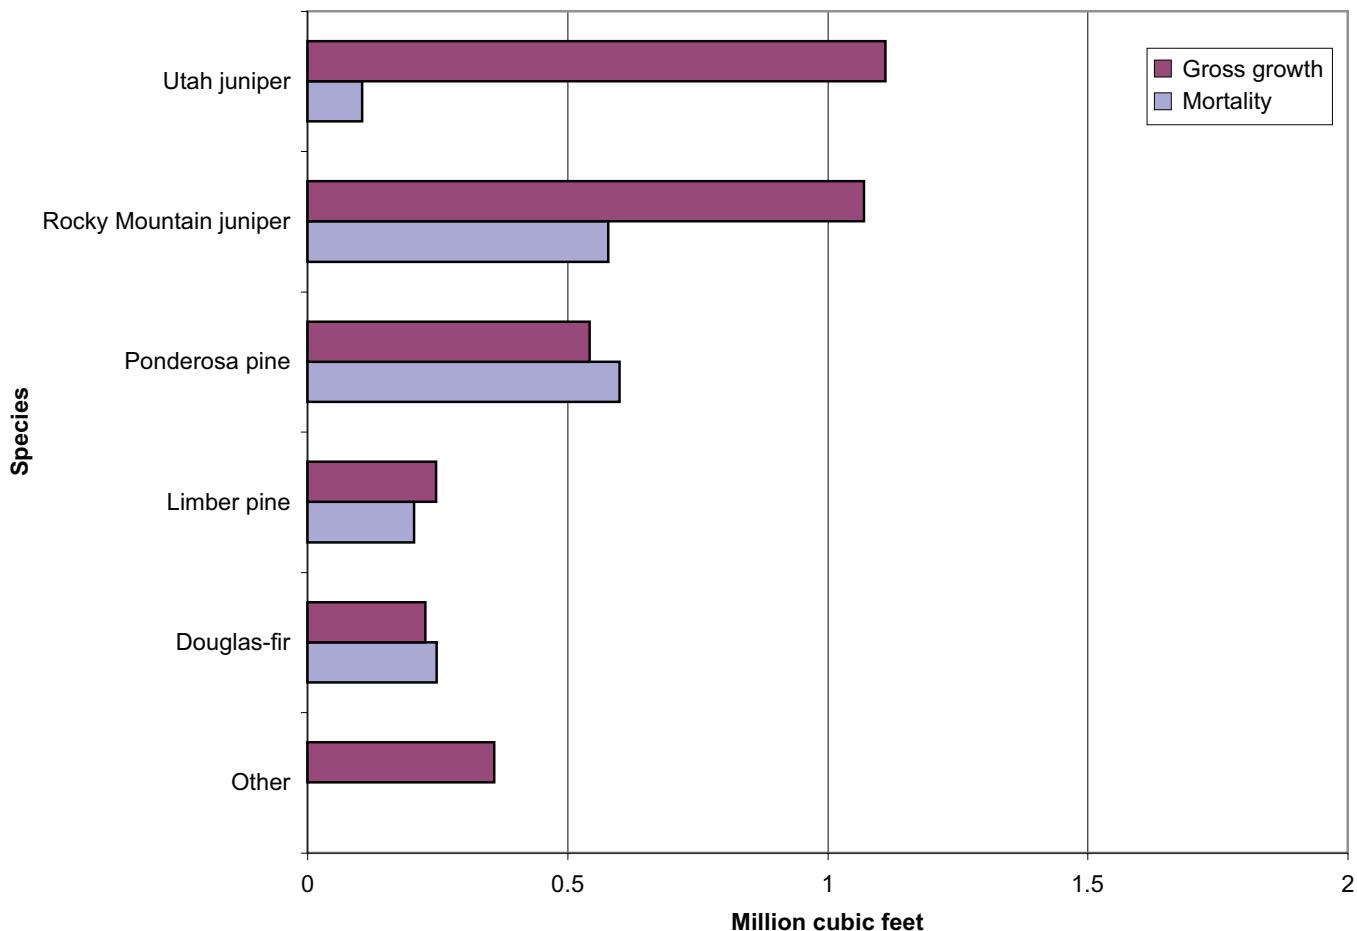

Figure 23—Gross annual growth and annual mortality of trees by species on woodland, Wyoming, 2002.

The relationship between mortality and gross growth can be used to assess overall forest health. High levels of mortality relative to gross growth often indicate deteriorating stand conditions due to stagnation, fire, disease, insects, weather, or a combination of factors. This relationship is usually expressed as a percentage of annual mortality that is deducted from the annual gross growth estimate. Across all forest land, annual mortality reduced gross growth by 52 percent. The amount that annual mortality reduced gross annual growth varied significantly by species (figs. 22 and 23). Of those species occurring on timberland, annual mortality of whitebark pine reduced gross annual growth by 82 percent followed by subalpine fir at 79 percent. Of those species occurring on woodland, annual mortality of ponderosa pine and Douglas-fir reduced gross annual growth by 110 percent.

Highlights of Inventory Results for Nonreserved Timberland

Area and Volume

Wood products are important to local and regional economies, and the majority of these products are obtained from the harvesting activities that occurred on nonreserved timberland. Nonreserved forest land is not withdrawn from management for production of wood products through statute or administrative designation, and the timberland

classification generally refers to forest land comprised of tree species suitable for timber products. Nonreserved timberland in Wyoming totals 57 percent (6.5 million acres) of the total forest area. National Forest lands account for 62 percent (4.0 million acres) of nonreserved timberland; nonindustrial private lands account for 23 percent, and land controlled by other public owners account for the remaining 15 percent of nonreserved timberland in the State.

The total volume of growing stock on nonreserved timberland is over 11.5 billion cubic feet, with 78 percent occurring on National Forest land. Lodgepole pine comprises the greatest percentage (29 percent) of growing-stock volume on nonreserved timberland. The volume of sawtimber on nonreserved timberland totals 37.3 billion board feet (Scribner rule), with 80 percent occurring on National Forest land. Engelmann spruce comprises the greatest percentage (26 percent, or 9.6 billion board feet) of sawtimber volume on nonreserved timberland. Second in abundance, lodgepole pine comprises 23 percent (8.5 billion board feet) of the sawtimber total.

The evaluation of growing-stock volume on a per-acre basis minimizes the effect of differences in the amount of area by ownership class. Across all ownerships, the average net volume per acre on nonreserved timberland is 1,780 cubic feet, and 2,251 cubic feet per acre on National Forest Systems land. In contrast, net volume per acre on other public and nonindustrial private land averages 999 and 1,044 cubic feet, respectively (fig. 24). Sawtimber volume on National Forest land averages 7,442 board feet per acre compared to 2,681 and 3,220 board feet per acre on other public and nonindustrial private land, respectively (fig. 25). Figure 26 spatially illustrates net cubic foot volume per acre of growing-stock trees on forest land in Wyoming.

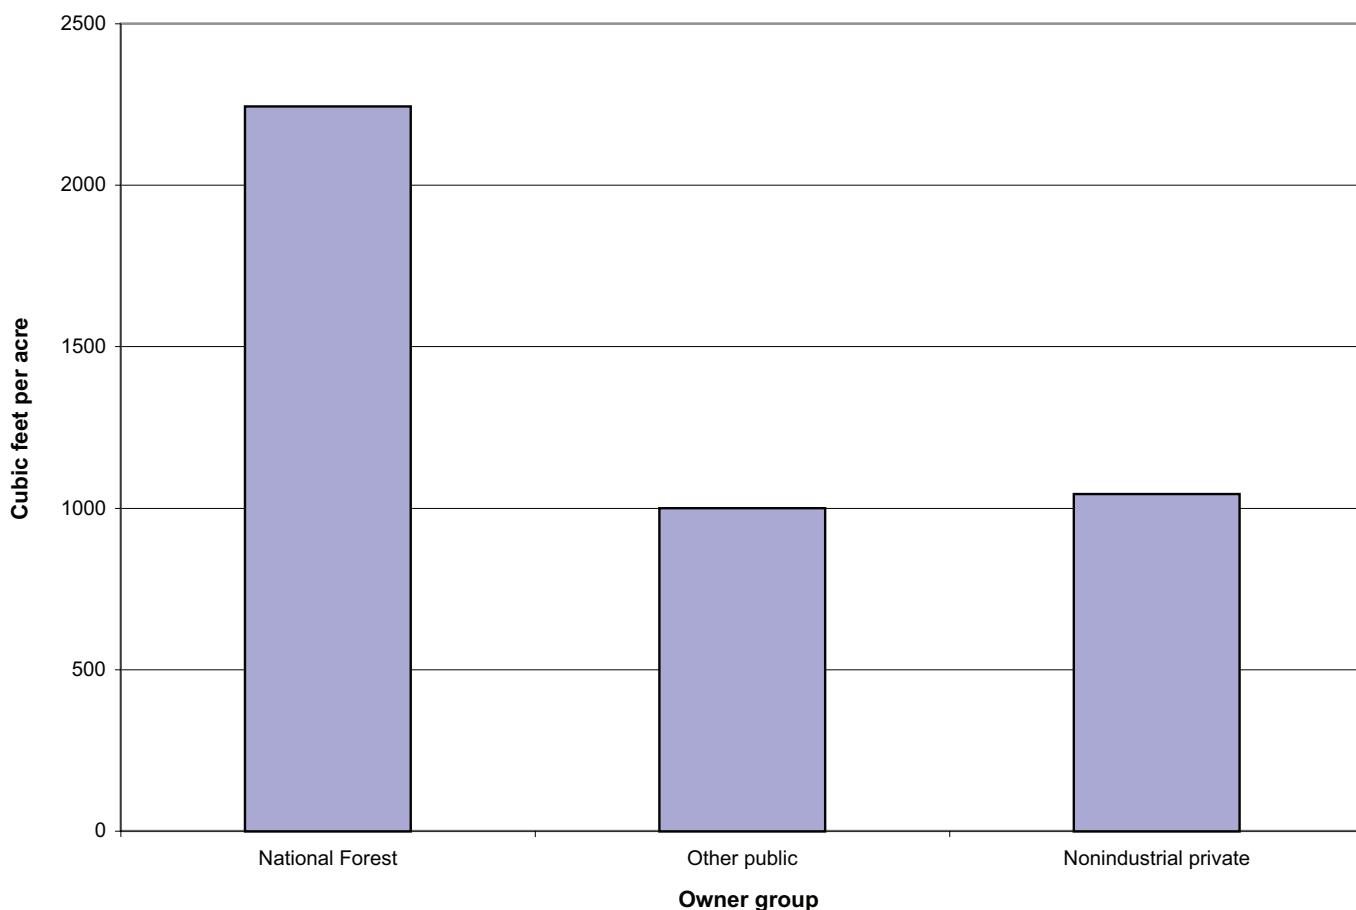

Figure 24—Average net growing-stock volume per acre by owner group on nonreserved timberland, Wyoming, 2002.

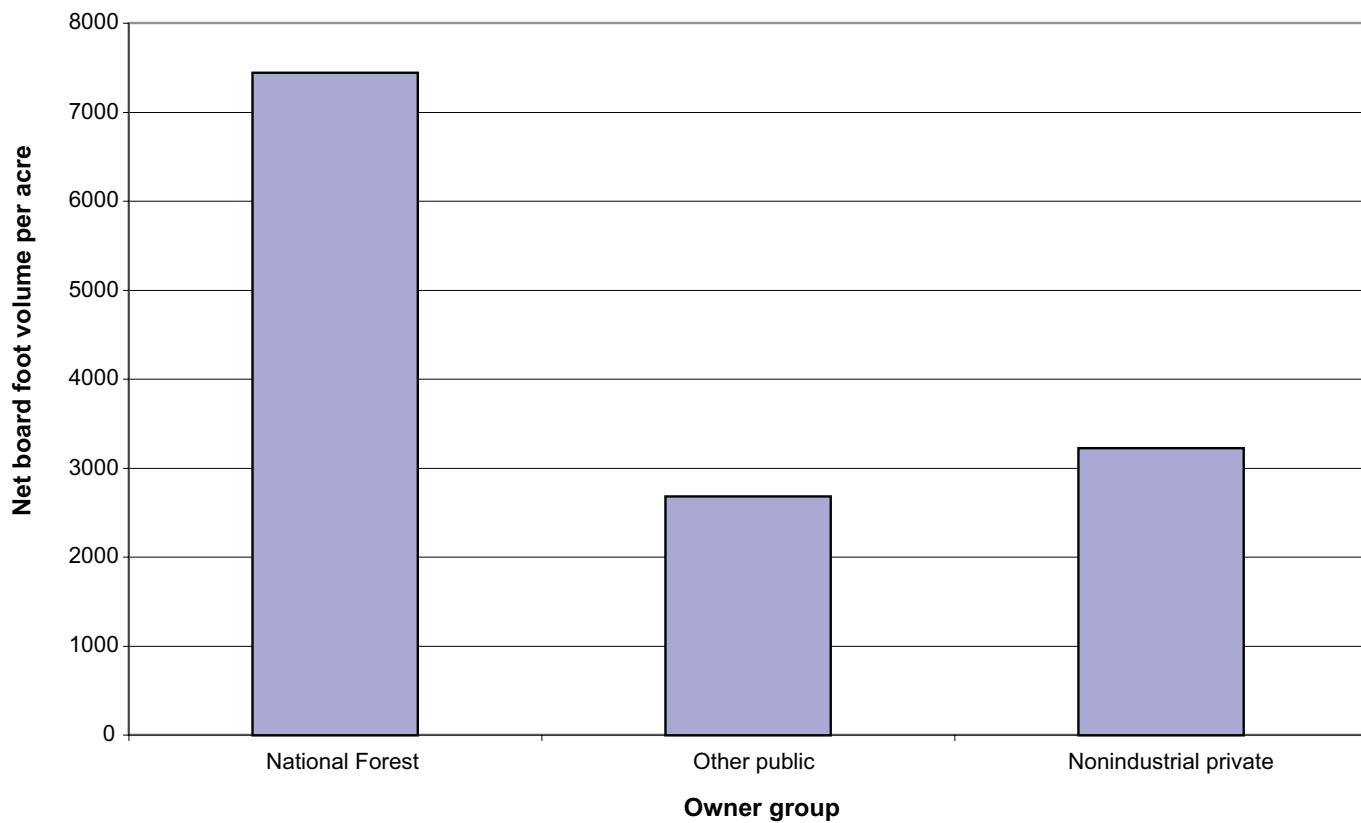

Figure 25—Average net sawtimber volume per acre by owner group on nonreserved timberland, Wyoming, 2002.

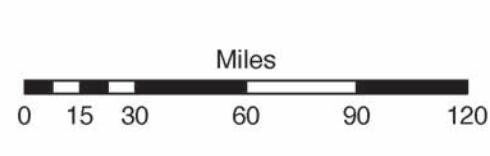

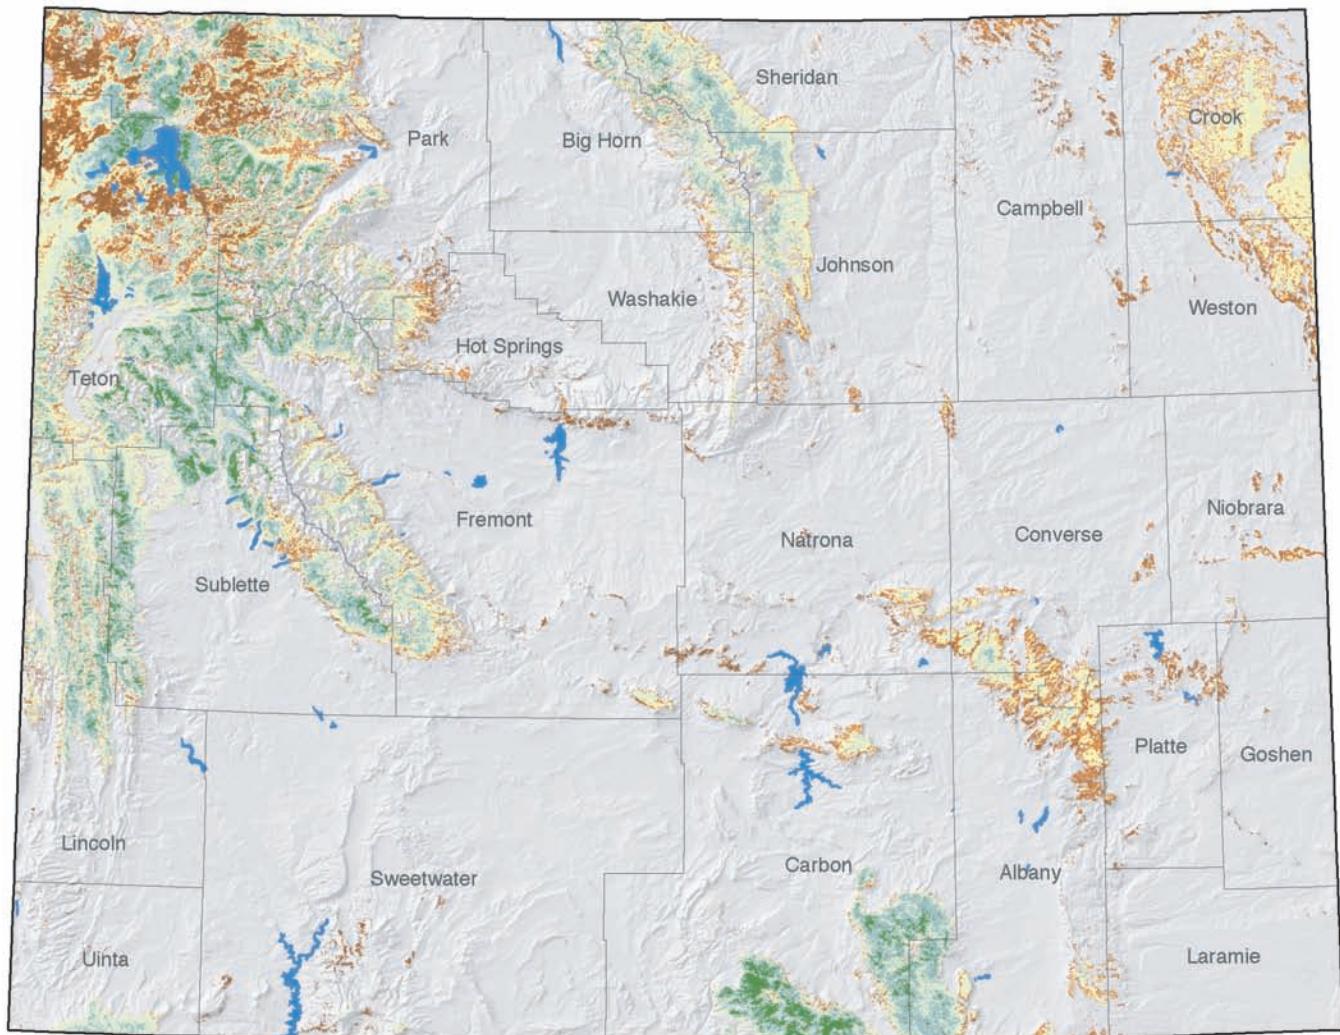

Removals for Timber Products

The net volume of growing-stock trees removed from the inventory by harvesting, cultural operations, land clearing, and changes in land use, is known as removals. This section deals with removals for timber products. These removals include both the volume processed in mills and the volume harvested or killed but not used. Removals, as reported here, are based on data from 1 year (2000). More details about Wyoming's primary forest products industry can be found in Morgan and others (2005). Tables 79 through 81 show harvest and removals by product, species, and ownership group in cubic feet for growing stock removals as well as board feet—Scribner and International—for sawtimber removals.

About 15.4 million cubic feet of wood, exclusive of land clearing volume and changes in land use, were removed from growing stock on Wyoming's nonreserved timberland in 2000. Ninety-four percent of the volume was used for wood products, less than 1 percent was used for industrial fuelwood, and 6 percent was left in the woods as logging residues. Sawlogs were the largest component of removals from growing stock, followed by posts, poles, and pilings.

National Forests supplied 19 percent of the volume removed from growing stock, other public landowners, including the Bureau of Land Management and the State of Wyoming, provided about 7 percent, and private landowners supplied the majority (74 percent) (fig. 27).

Removals of sawtimber-size trees, or sawtimber removals, included 66.7 million board feet (Scribner log rule) or 74.7 million board feet expressed in International $\frac{1}{4}$ -inch log

Predicted Volume (net total stem cubic feet per acre)

Figure 26—Net cubic foot volume of growing-stock trees on forest land, Wyoming, 2002.

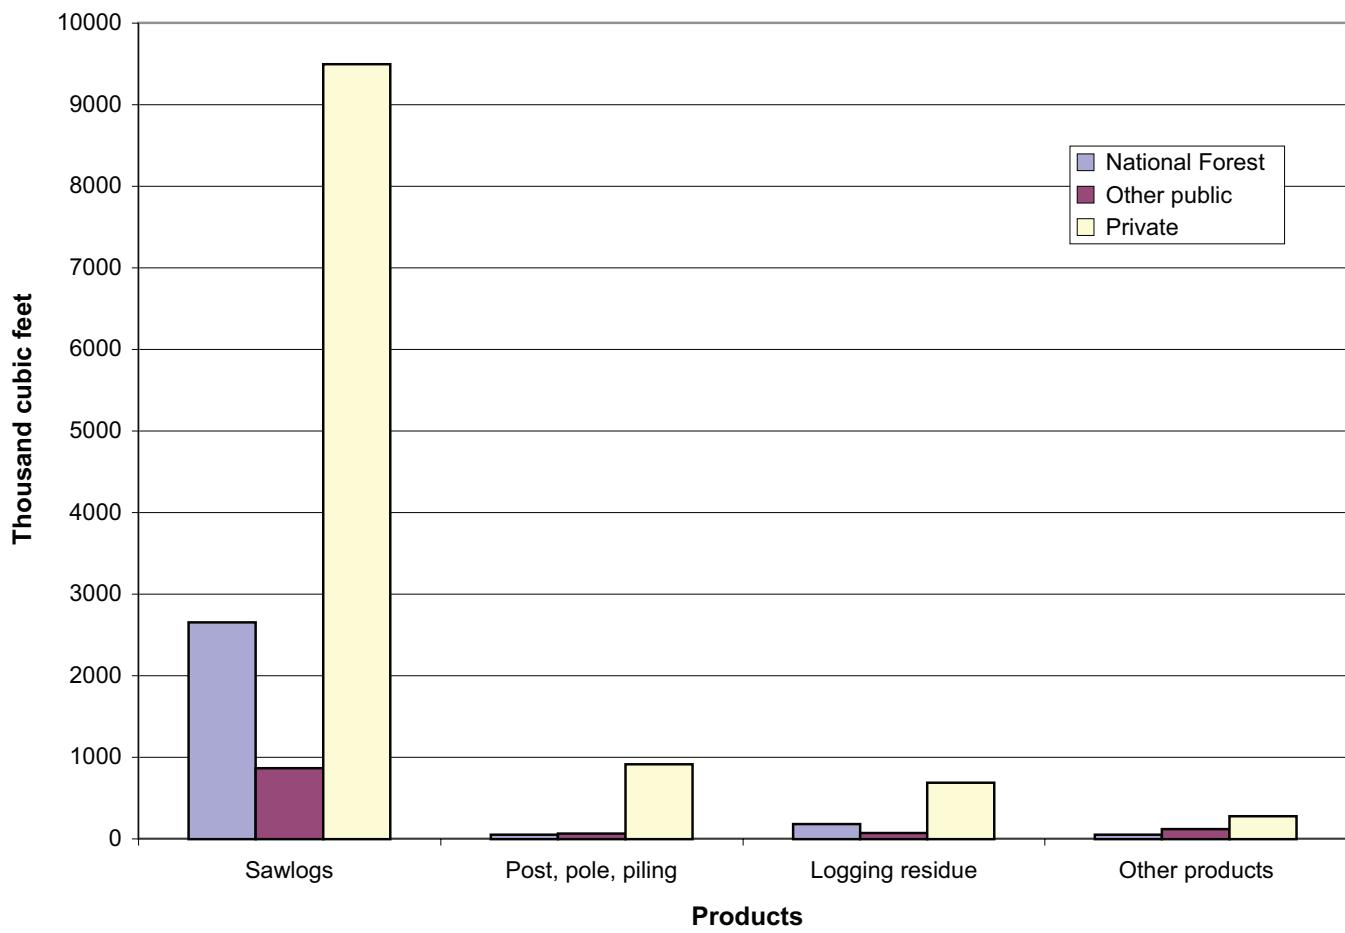

Figure 27—Volume removed from growing-stock inventory, by product and owner group on nonreserved timberland, Wyoming, 2002.

rule. Logs harvested to produce lumber (sawlogs) dominated products harvested from sawtimber, accounting for 95 percent of removals. Logging residues accounted for 1.5 percent of sawtimber removals.

Ponderosa pine was the dominant species harvested, accounting for 62 percent of growing stock removals and 67 percent of sawtimber removals. Lodgepole pine accounted for 25 percent of growing stock removals and 21 percent of sawtimber removals. Douglas-fir, spruces, and true firs accounted for nearly all of the volume of the remaining removals.

Components of Change

Net annual growth is defined as gross annual growth volume minus average annual mortality volume. Net change is defined as net annual growth volume minus the average annual volume removed due to harvesting activity (removals). Positive net change usually indicates an increasing inventory over time whereas negative net change indicates a declining inventory. Figure 28 illustrates the relationship of net growth of growing stock to annual removals for select species groups on nonreserved timberland. Note that the net growth estimate is an annual average based on 10 years for gross annual growth and 5 years for annual mortality, whereas the removals data were collected over a 1-year period. All of the listed species groups indicate that the estimated average an-

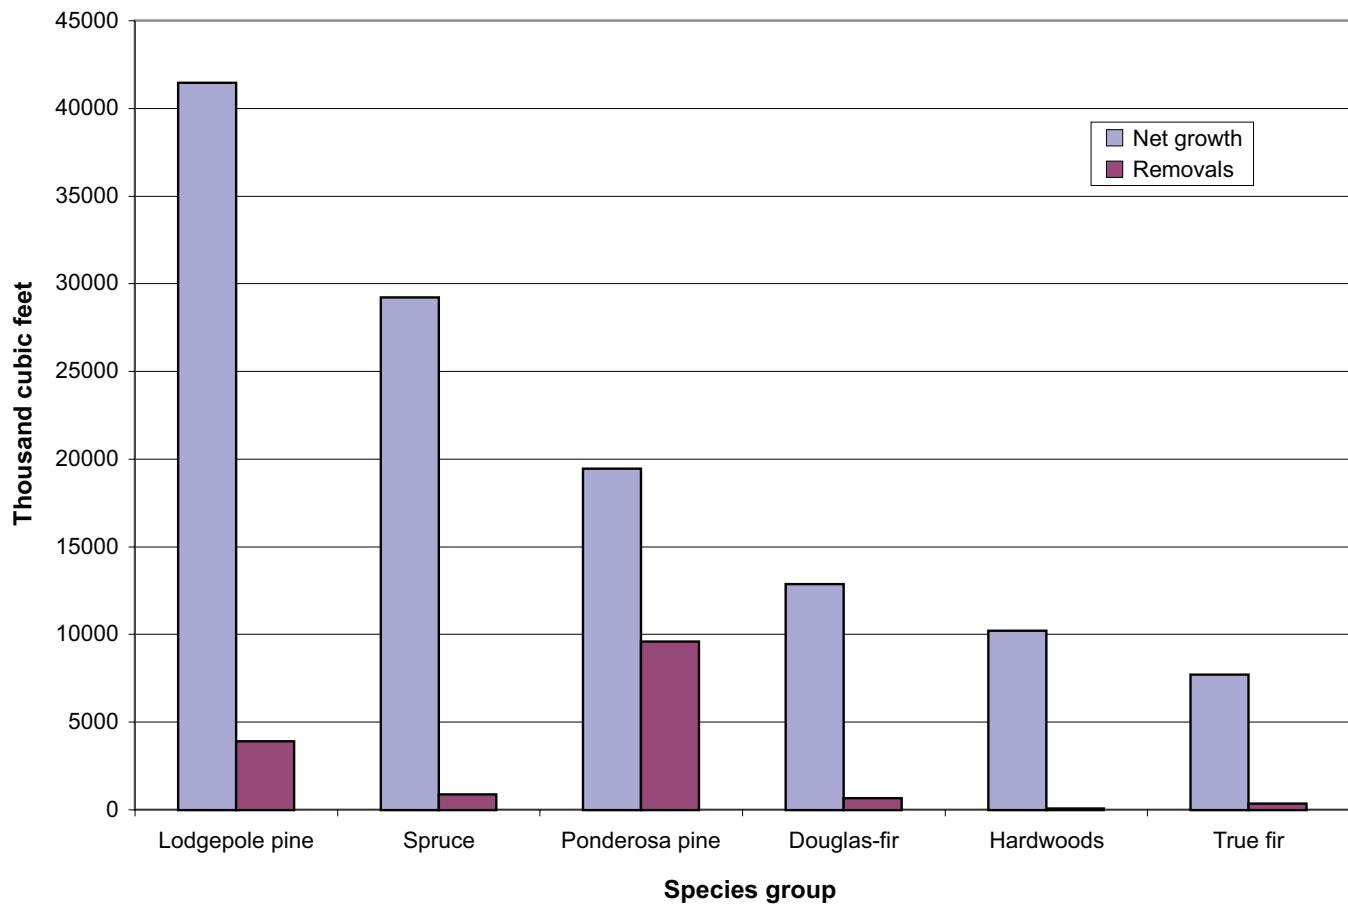

Figure 28—Net annual growth of growing stock compared to removals by species group on nonreserved timberland, Wyoming, 2002.

nual net growth exceeded the amount of wood volume removed for 1 year (fig. 28). When all of the listed species are combined, net growth of growing stock exceeded the growing stock removal estimate by a ratio of 8 to 1. The narrowest margin of growth to removals was indicated by ponderosa pine, where net growth exceeded removals by a margin of 2 to 1.

Wyoming, along with Idaho and Montana, is part of the Northern Rockies. The Northern Rockies is regarded as containing the largest resource for supplying timber products to the wood-using industry in the Interior West. Timber processing capacity is the volume of timber that could be used by existing timber processors if demand for products is firm and sufficient raw material is available. Timber processing capacity for the Northern Rockies has steadily declined over the past 2 decades, largely because of their dependence on National Forest timber. Historically, Federally owned timberland in Wyoming supplied the majority of growing-stock removals for the State. Now, National Forests only supply 19 percent of the growing-stock removals, yet they control 63 percent of the nonreserved timberland in Wyoming. The restricted timber availability on Wyoming's National Forests is the result of numerous constraints, such as appeals and litigation of timber sales, threatened and endangered species protection, and impacts of past harvesting practices on other natural resources, such as water quality and wildlife. The current relationship of growing-stock net growth to growing-stock removals on Wyoming's nonreserved timberland suggests an adequate supply of inventory volume that will increase for the foreseeable future.

Highlights of Inventory Results for Reserved Forest Land

Reserved lands are withdrawn from management for production of wood products through statute or administrative designation. Unlike nonreserved timberland, reserved forest land is usually set aside legislatively for preservation purposes, such as Yellowstone National Park. Reserved forest land totals 3.8 million acres in Wyoming. Nearly all of reserved forest land is classified as timberland. Fifty-two percent of reserved forest land is administered by National Forests and 46 percent is administered by National Parks (fig. 29).

Lodgepole pine is the predominant forest type on reserved forest land (1.4 million acres) (fig. 30). Next in abundance is the spruce-fir type (20 percent), followed by Engelmann spruce at 14 percent of reserved forest land. Whitebark pine accounts for 10 percent of reserved forest land and nonstocked timberland accounts for 9 percent.

Lodgepole pine is the predominant species in terms of biomass and volume on reserved forest land (fig. 31). Oven-dry weight of lodgepole pine biomass is 36 percent (47 million tons) of the reserved biomass total. Second in abundance is Engelmann spruce at 28 percent (37 million tons) of the total. Subalpine fir and whitebark pine account for 13 and 12 percent, respectively.

Two noteworthy differences between reserved forest land and nonreserved forest land occur in the stand age profiles and gross growth/mortality relationships. Reserved forest land is more heavily comprised with older forest stands than nonreserved forest land (fig. 32). Over 33 percent of reserved forest land resides in stands greater than 150 years of age compared to only 16 percent of nonreserved forest land. The annual estimate of gross growth exceeds the annual estimate of mortality on reserved land by 32 percent (fig. 33). In contrast, gross growth exceeds mortality by 143 percent on

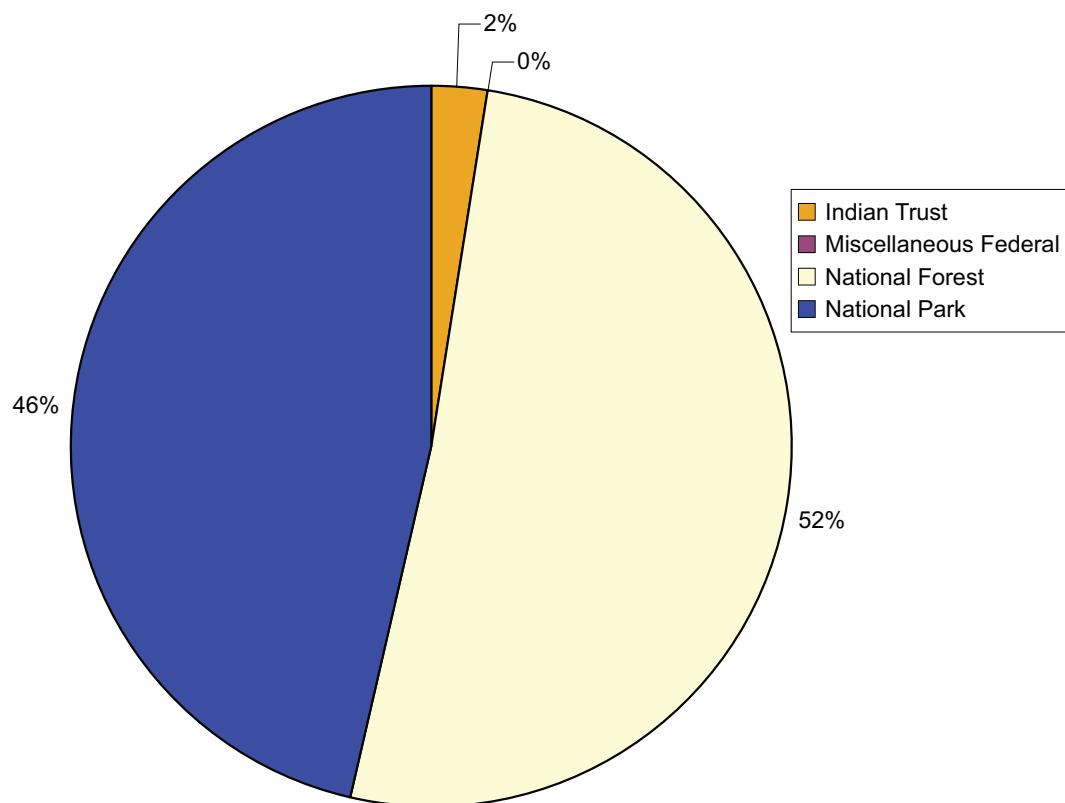

Figure 29—Area of reserved forest land by owner group, Wyoming, 2002.

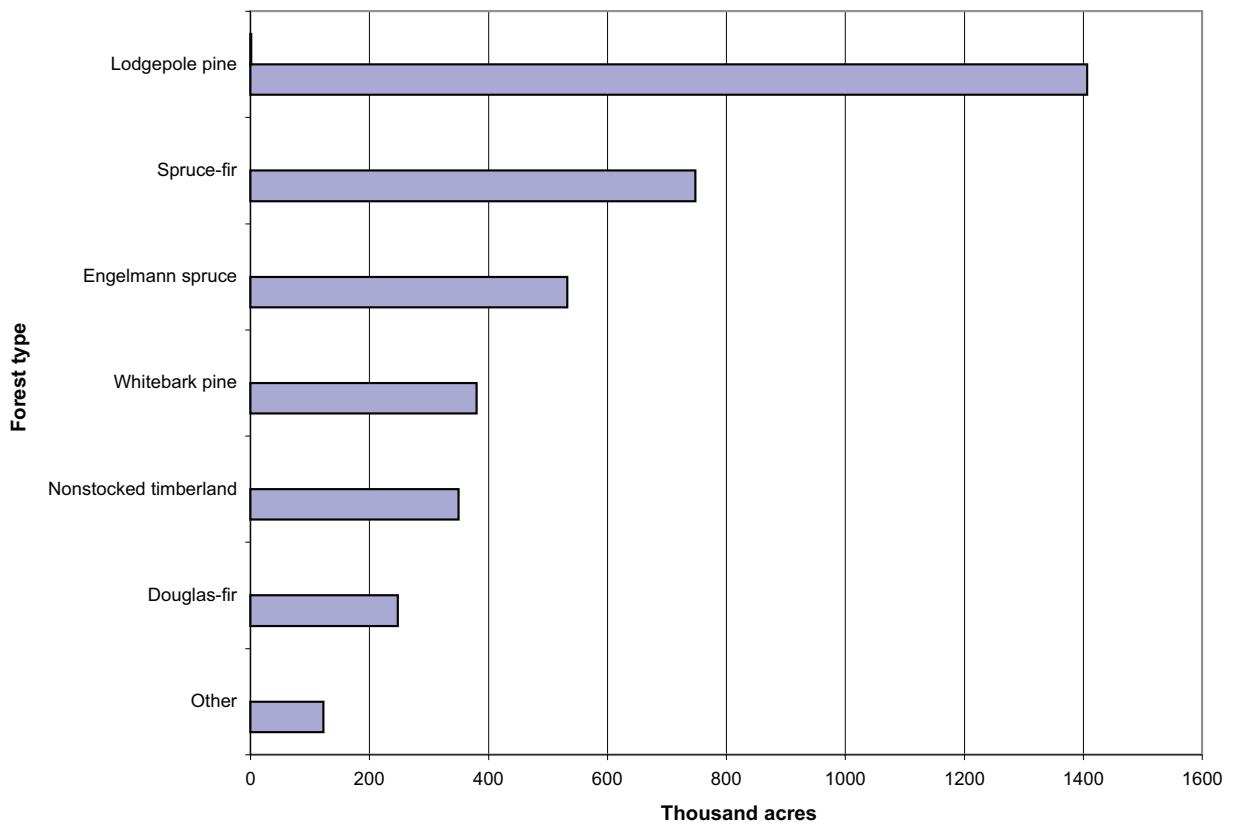

Figure 30—Area of reserved forest land by forest type, Wyoming, 2002.

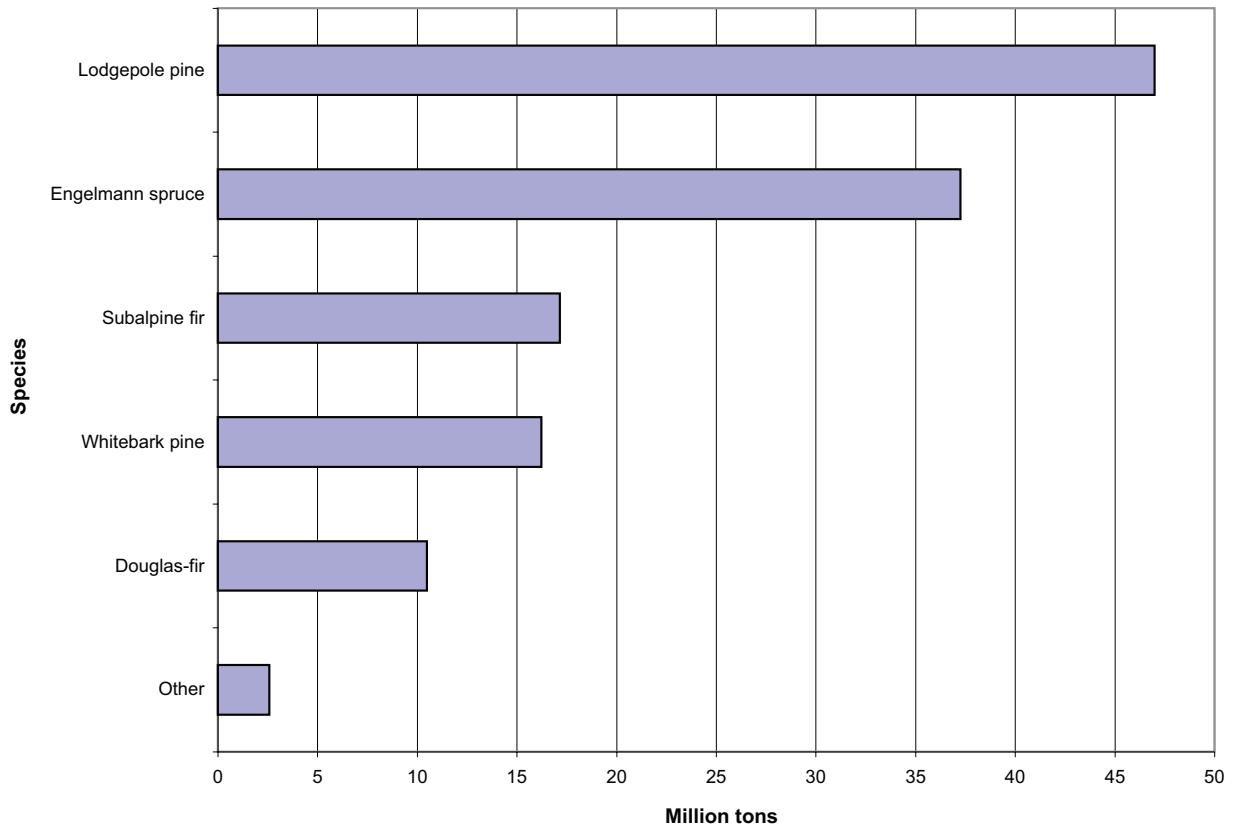

Figure 31—Oven-dry weight of biomass of all live trees by species on reserved forest land, Wyoming, 2002.

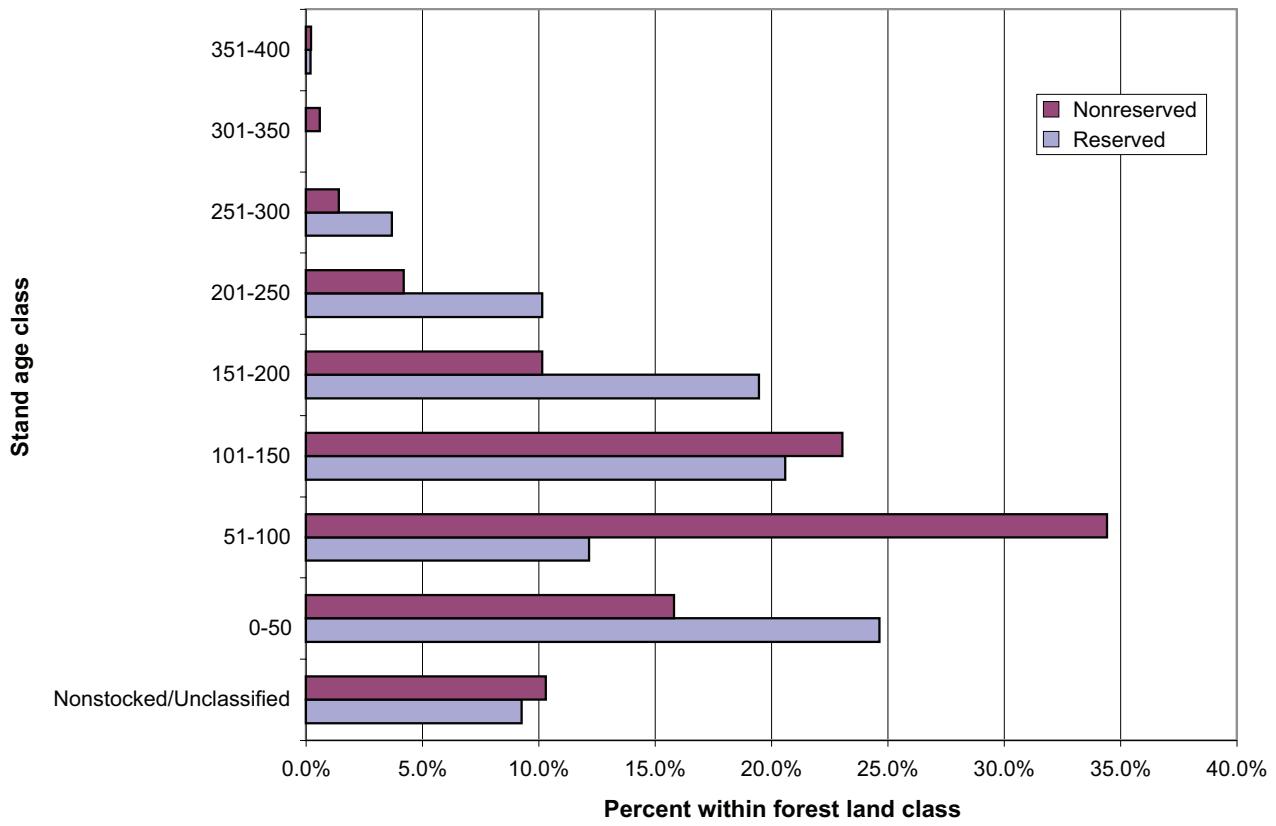

Figure 32—Distribution of reserved and nonreserved forest land by stand-age class, Wyoming, 2002.

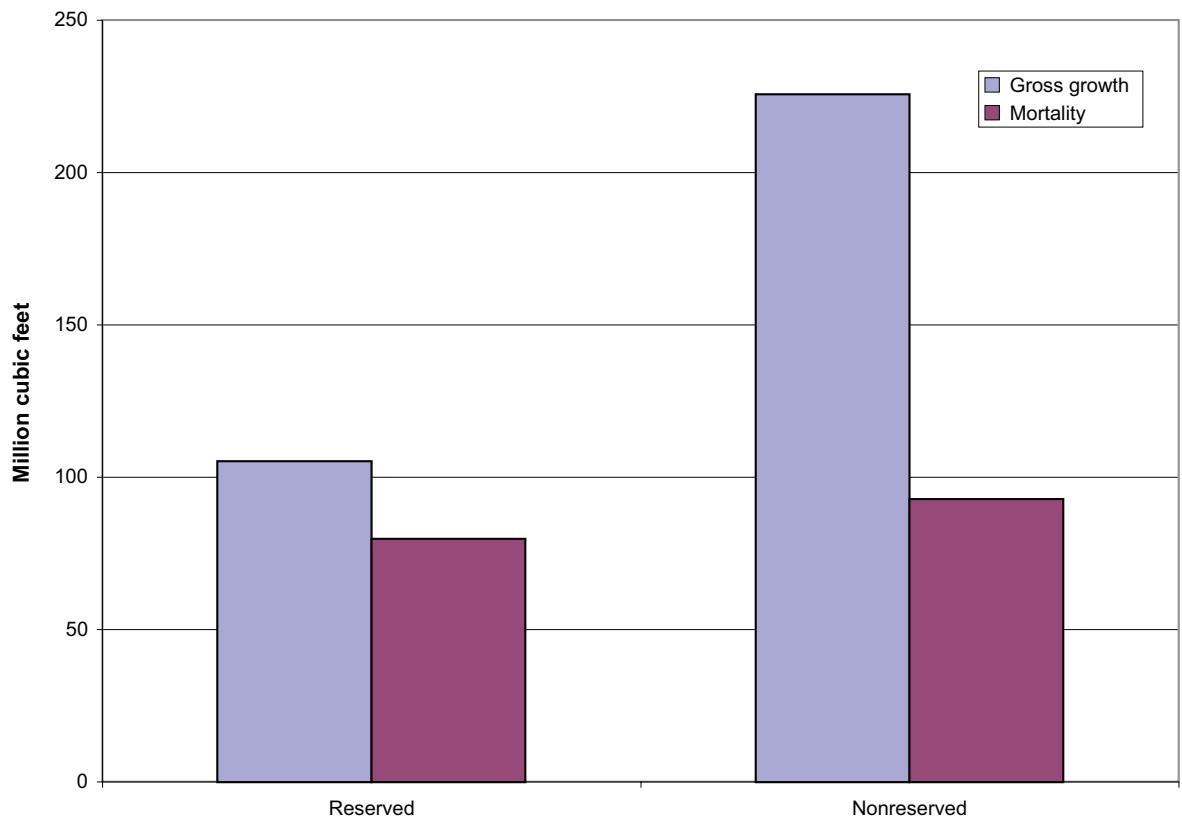

Figure 33—Gross growth and mortality of all live trees by reserved and nonreserved forest land, Wyoming, 2002.

nonreserved forest land. These inventory comparisons indicate that, overall, reserved forest land is comprised of older, slow-growing forest stands with elevated levels of mortality compared to nonreserved forest land. However, significant differences in stand structure exist within the forests classified as reserved. The following chapter on Yellowstone National Park's forests, which are a component of reserved forest land, illustrate some of these differences.

Yellowstone National Park

In 1872, President Ulysses S. Grant signed a law declaring that the area known as Yellowstone would forever be "dedicated and set apart as a public park or pleasure ground for the benefit and enjoyment of the people." This was the first reservation of wild lands for recreational purposes under the direct management of the Federal government. This country's first national park was considered unique by early explorers for its natural beauty, unique geothermal features (such as Old Faithful geyser), and abundant wildlife. This section describes inventory results for the area of Yellowstone National Park within the State of Wyoming.

The FIA's estimate of total land area of Yellowstone National Park in Wyoming is 1.9 million acres, of which 1.6 million acres (84 percent) is forest land. Figure 34 illustrates the area and distribution of forest and nonforest land in Yellowstone National Park in Wyoming. Nearly all of the forest land in Yellowstone is classified as timberland (fig. 35). Juniper, the only recorded woodland forest type, comprises less than 1 percent of Yellowstone's total forest area. Lodgepole pine is the most predominant forest type in Yellowstone, covering nearly 60 percent (1 million acres) of Yellowstone's forest land (fig. 36). Spruce-fir is the second most abundant forest type with 258 thousand acres (16 percent). Nonstocked timberland accounts for 11 percent of Yellowstone's forest area. Over 36 percent of the forest area is classified as a sapling/seedling stand-size class (fig. 37). The majority (35 percent) of forest stands are estimated to be between 0 and 51 years of age (fig. 38).

Figure 39 displays the distribution of number of live trees on Yellowstone's forest land by species. Lodgepole pine makes up the largest percentage (58 percent) of number of trees; second in abundance is subalpine fir (22 percent), and Engelmann spruce comprises 9 percent of the total. Of particular interest is the status of whitebark pine in Yellowstone National Park. Whitebark pine seeds are a critically important fall food source for the grizzly bear, and whitebark pine is susceptible to significant mortality from white pine blister rust, a nonnative fungus that was introduced to North America from Europe. The current estimate of whitebark pine in Yellowstone is 32 million trees, or 6 percent of total live trees. Figure 40 displays plot locations where at least one whitebark pine 1.0 inch in diameter or larger was measured, and whether or not there was at least one tree present in the overstory.

In the summer of 1988, the driest period in Yellowstone's history, large-scale fires burned over one-third of the park. The fires created a unique forest ecosystem that has been extensively studied over the years to evaluate how forests and wildlife recover from severe disturbance. The most significant outcome is a skewed age-class distribution toward the younger stands that regenerated following the fires (fig. 38). In the 2002 inventory of Wyoming, field crews recorded evidence of fire and the year in which it occurred. The inventory estimate of forest area in Yellowstone National Park, Wyoming, that burned in 1988 is 803,000 acres. Sixty-four percent of this burned area is currently classified as a lodgepole pine forest type, and another 19 percent is nonstocked. Spruce-fir types account for 7 percent of the burned area and the remaining 10 percent is comprised of aspen, Douglas-fir, Engelmann spruce, whitebark pine, and limber pine types. Over 58 percent of the burned area is classified as a sapling/seedling stand-size class, 18 percent

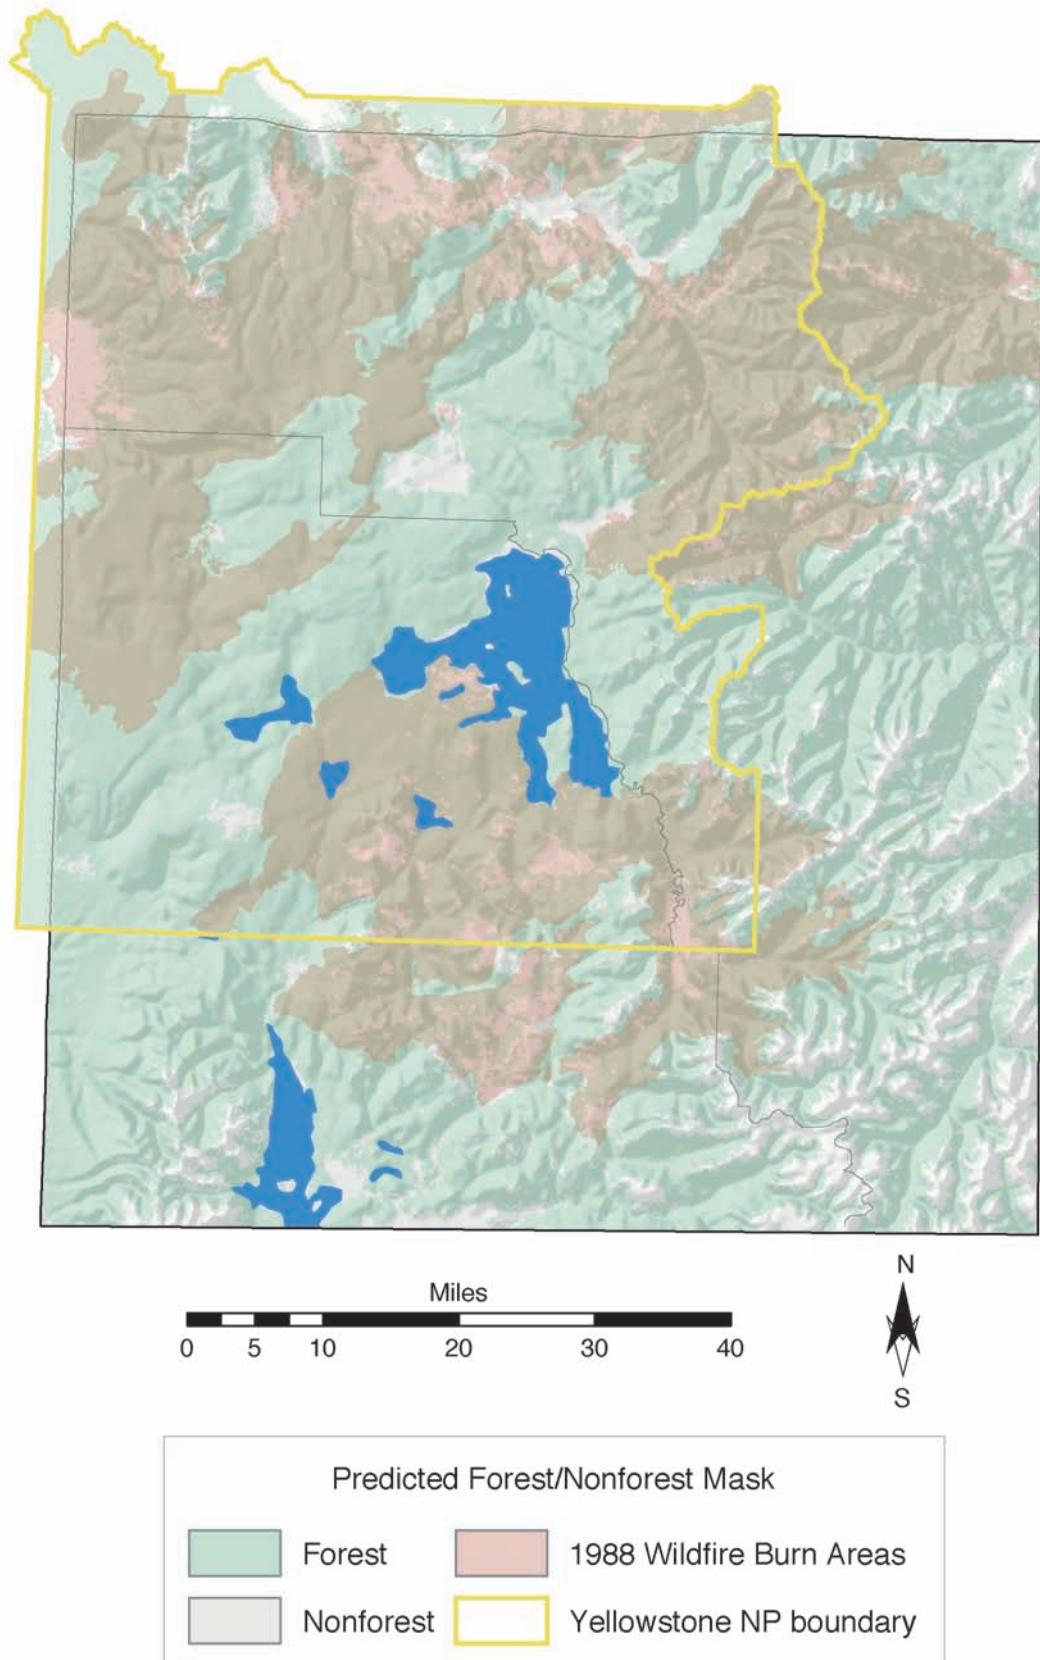

Figure 34—Area of forest and nonforest land overlayed with the areas burned in the 1988 wildfire in Yellowstone National Park, Wyoming, 2002.

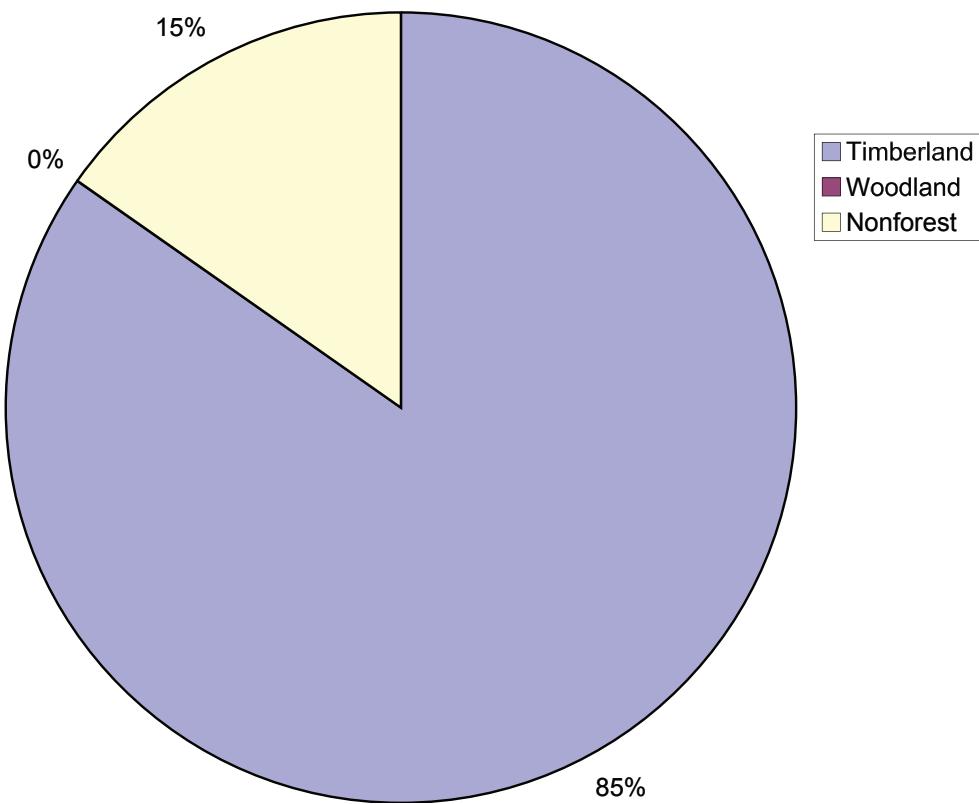

Figure 35—Land area by land class in Yellowstone National Park, Wyoming, 2002.

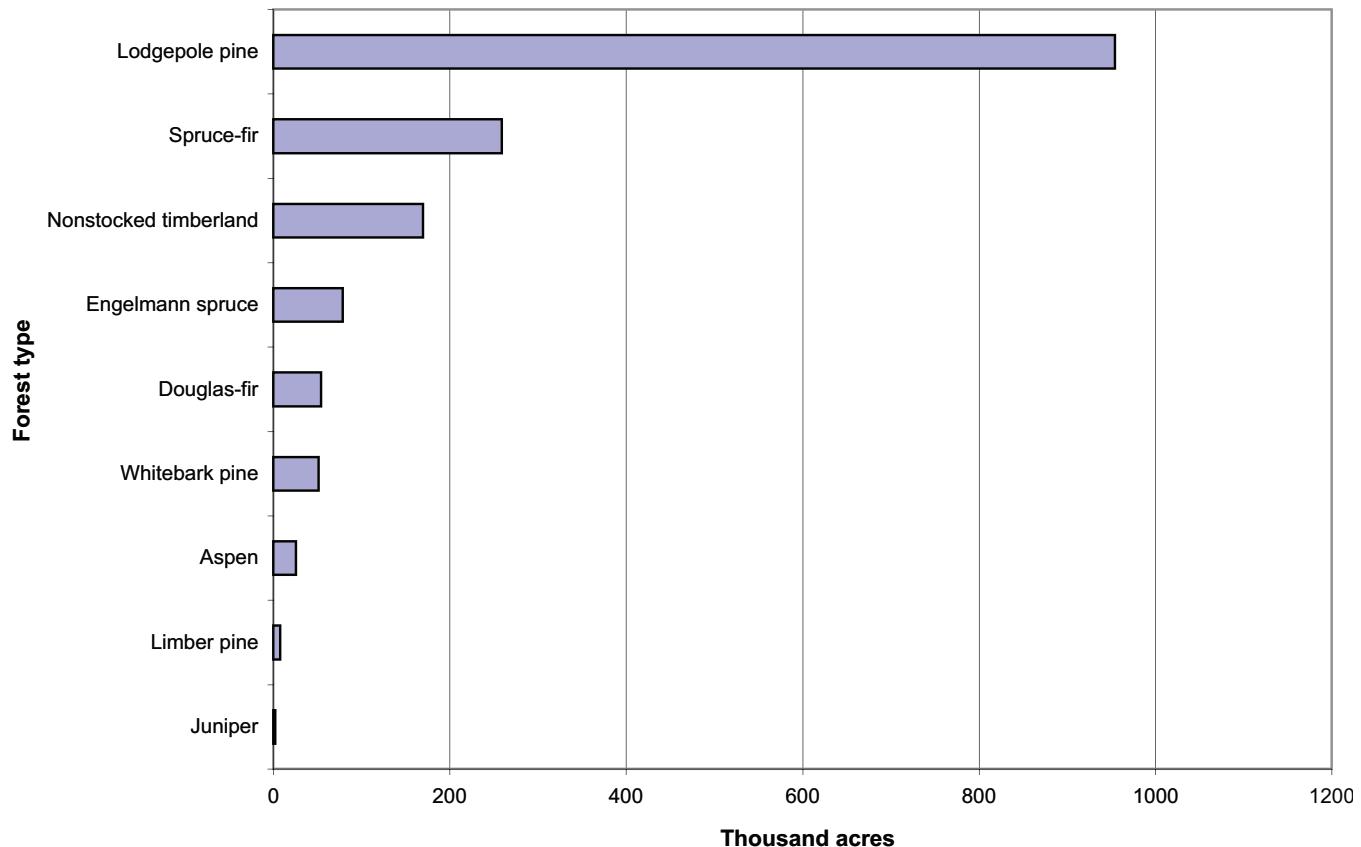

Figure 36—Area of forest land by forest type in Yellowstone National Park, Wyoming, 2002.

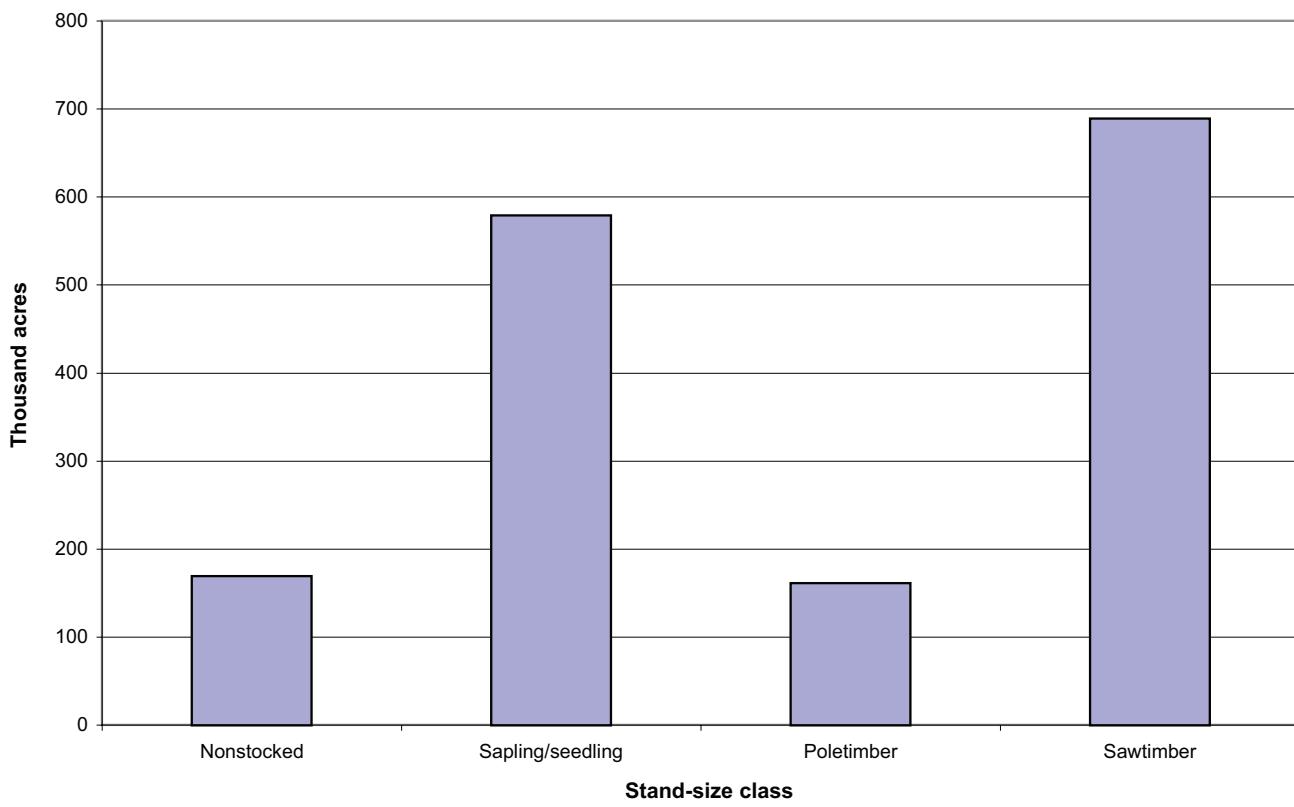

Figure 37—Area of forest land by stand-size class in Yellowstone National Park, Wyoming, 2002.

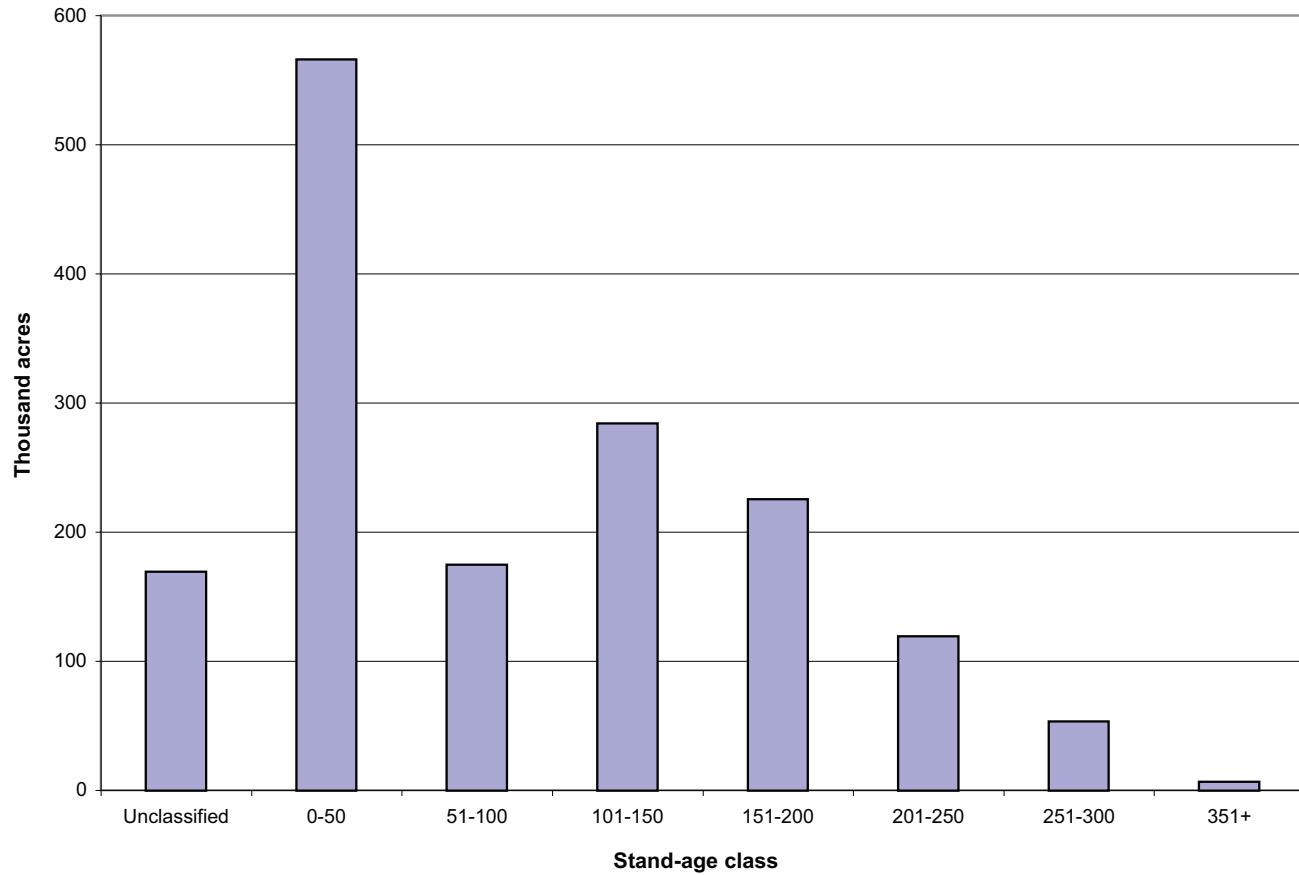

Figure 38—Area of forest land by stand-age class in Yellowstone National Park, Wyoming, 2002.

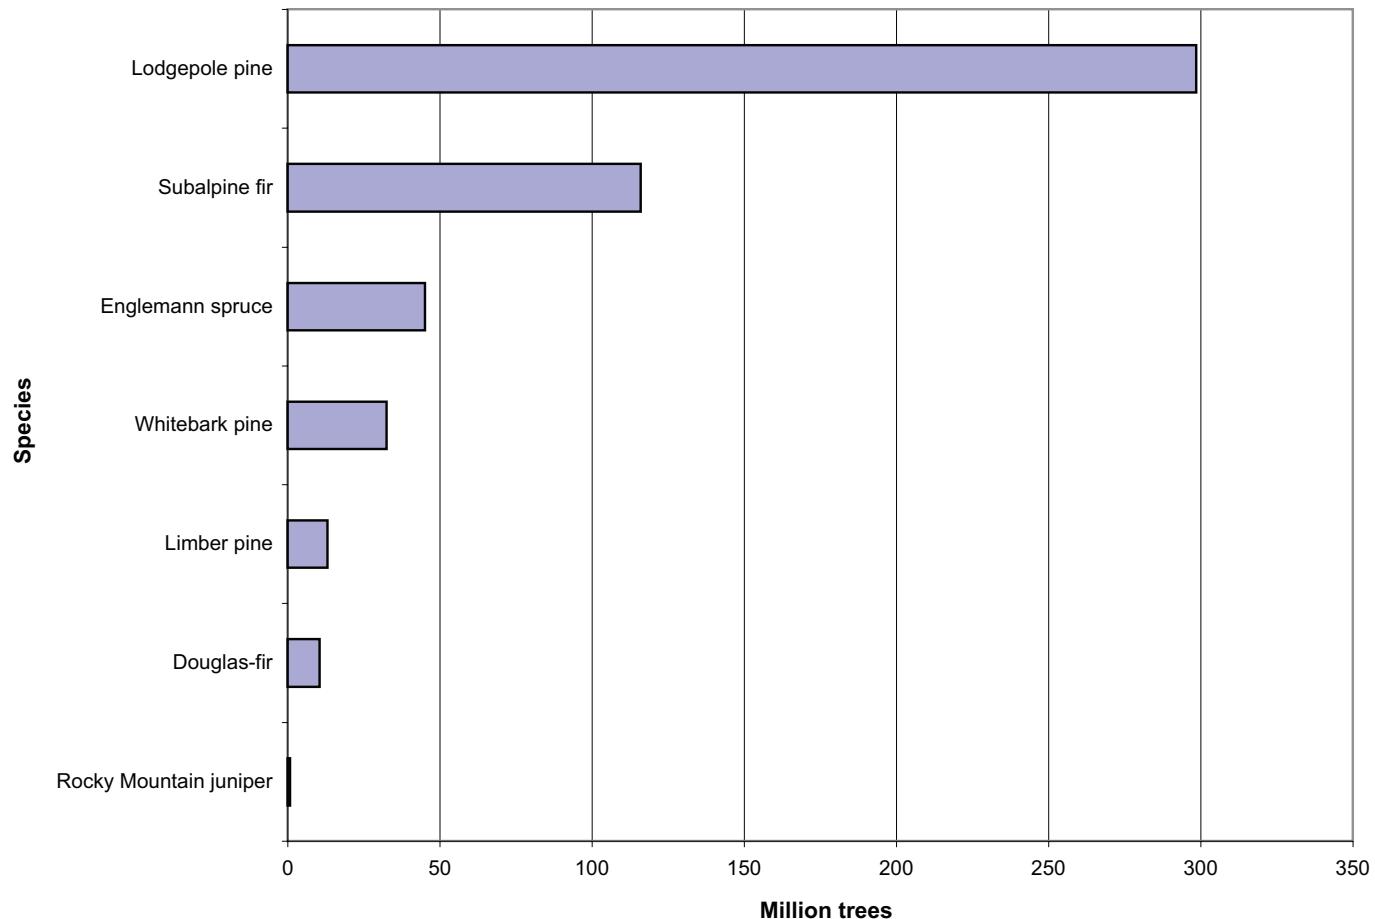

Figure 39—Number of live trees on forest land by species in Yellowstone National Park, Wyoming, 2002.

are sawtimber stands, and 5 percent are poletimber stands. These inventory statistics support what many other studies have concluded: despite the extensive fire-related mortality of large-diameter trees, especially lodgepole pine, most of these stands appear to be adequately stocked with saplings and seedlings that will eventually develop into healthy, mature stands.

Roadless Areas

Roadless areas are lands designated by Federal law that generally limits, with some exceptions, timber harvest and road construction on National Forests and Grasslands across the country. Figure 41 displays those areas currently designated as roadless in Wyoming. The FIA's estimate of roadless areas in Wyoming is 3.1 million acres, and 71 percent (2.2 million acres) is classified as forest land. The lodgepole pine and spruce/fir forest types together comprise 43 percent of roadless area forest land (fig. 42). Douglas-fir accounts for 17 percent and aspen accounts for 10 percent of roadless area forest land. By stand-age class, sawtimber stands comprise 60 percent of forest land, poletimber stands 22 percent, sapling seedling stands 14 percent, and nonstocked stands comprise 4 percent of forest land in roadless areas (fig. 43). By stand-age class, most (56 percent) of the forest area is concentrated in stands between 50 and 151 years old (fig. 44). Less than 15 percent of forest area is in stands 1 to 50 years old and 25 percent is in stands greater than 150 years old.

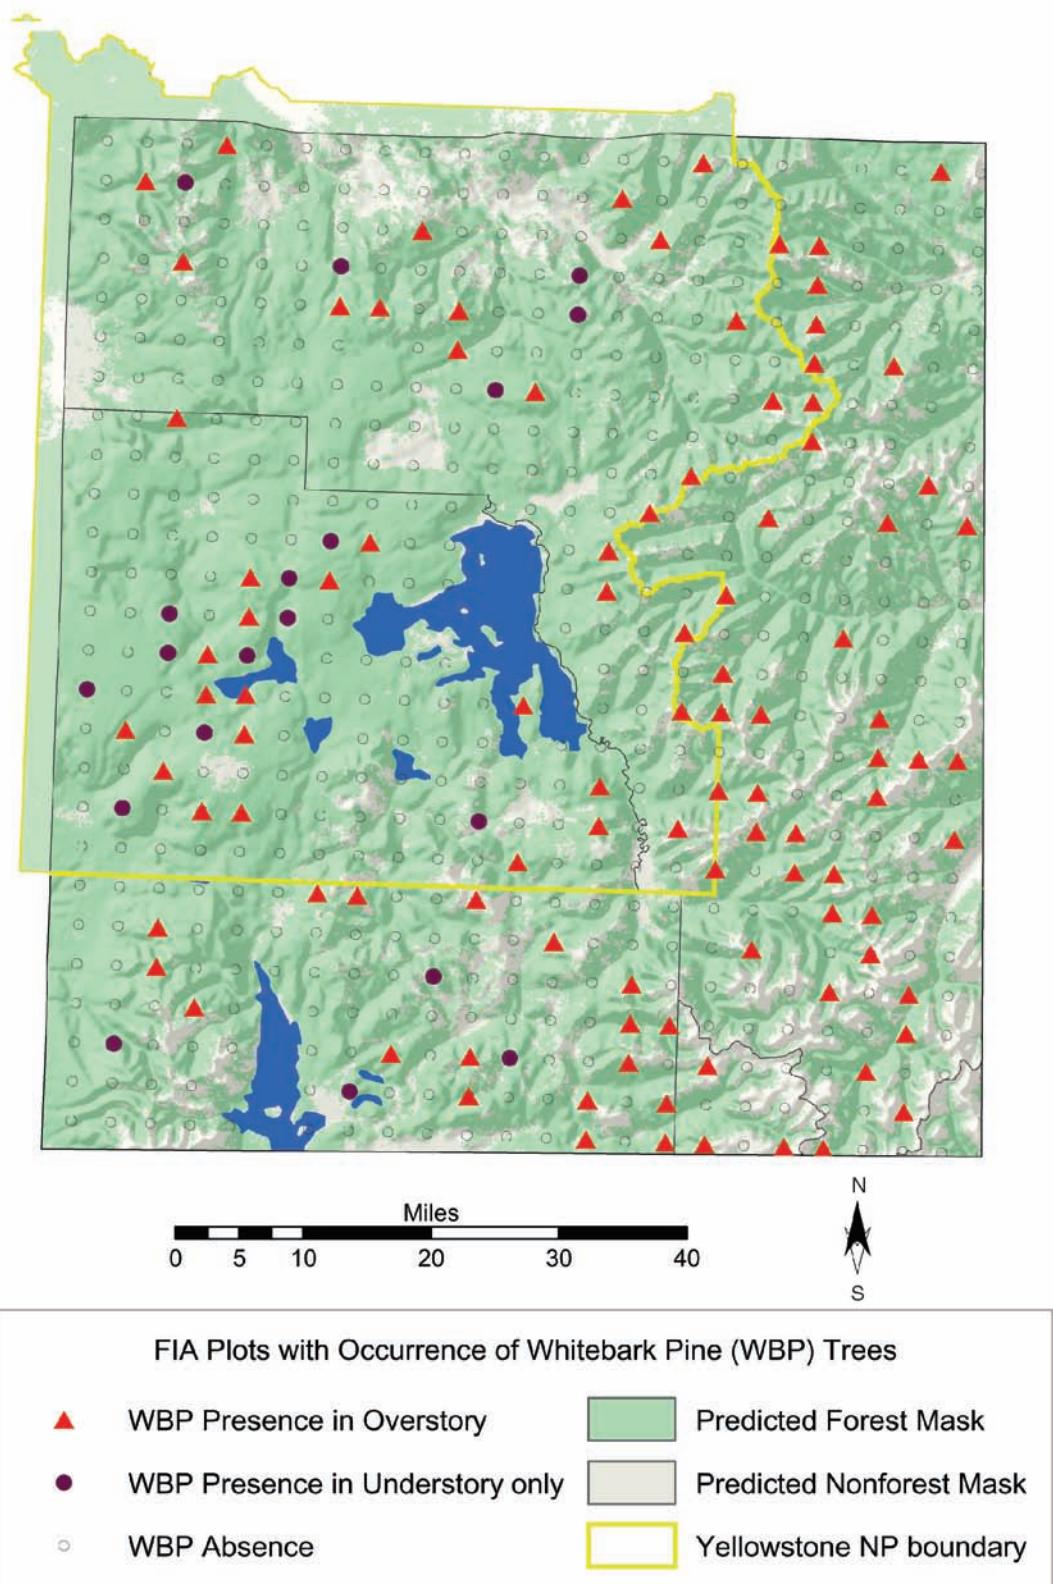

Figure 40—FIA plot locations where at least one live whitebark pine 1.0 inch d.b.h. or larger was measured in Yellowstone National Park, Wyoming, 2002.

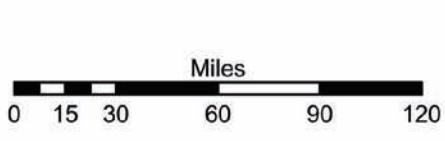

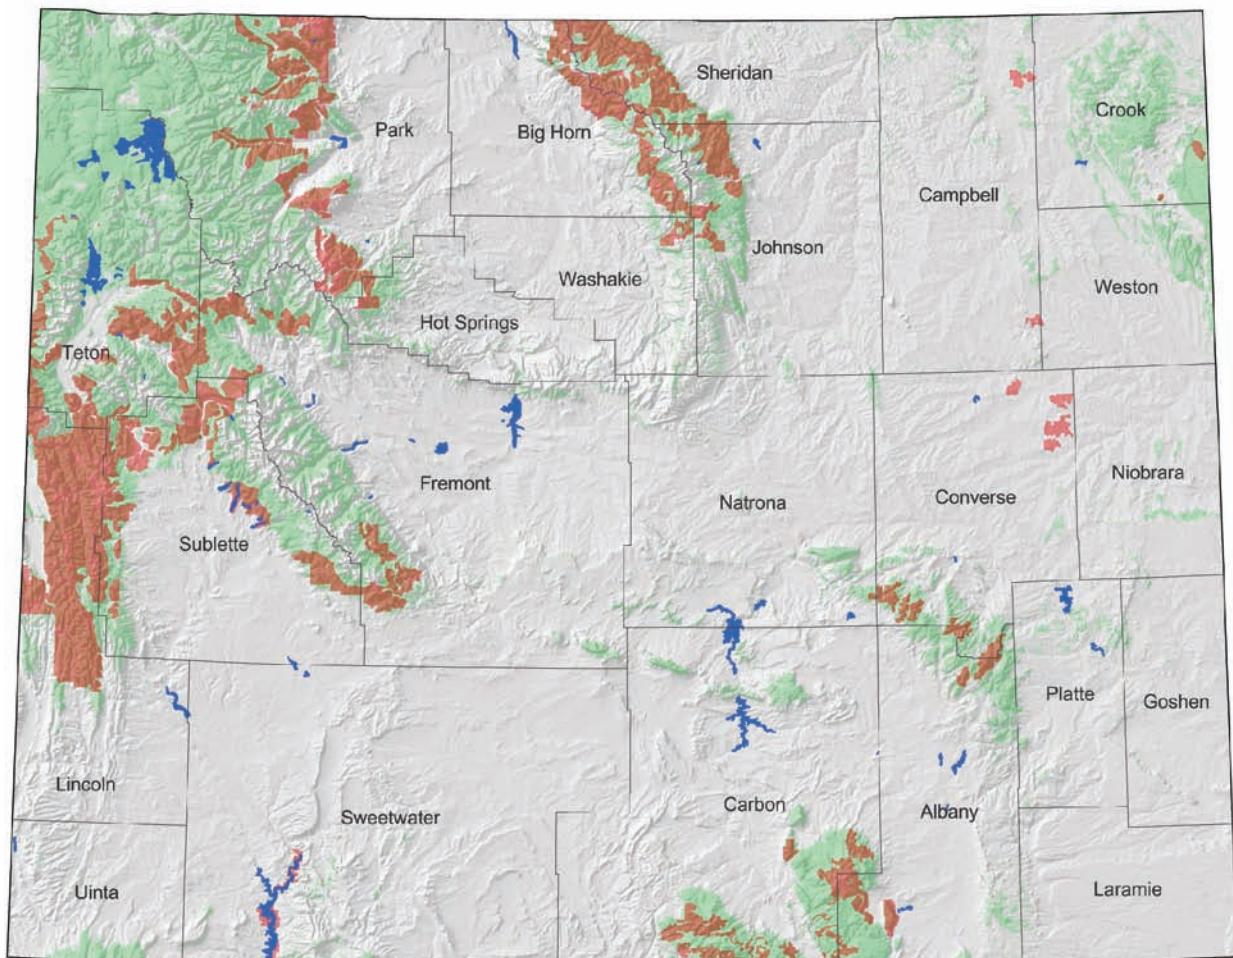

Figure 41—Roadless areas on forest land, Wyoming, 2002.

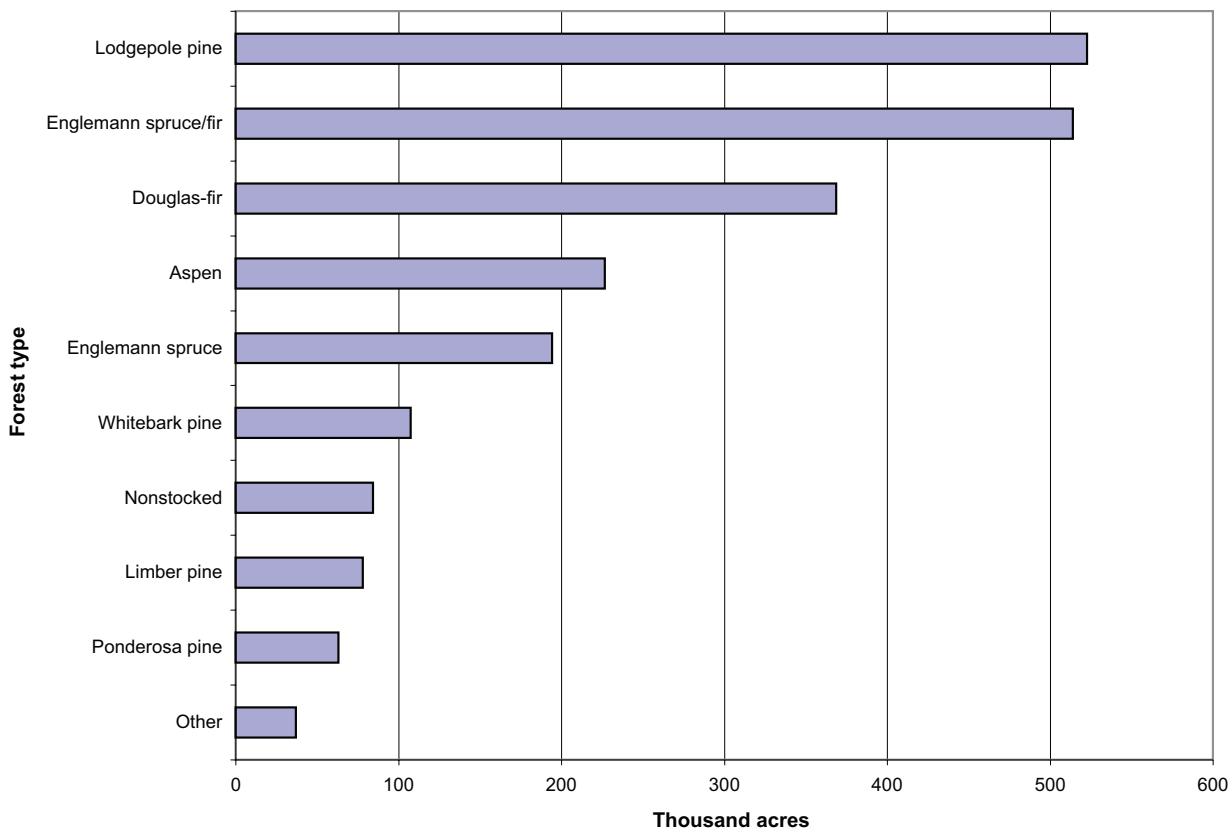

Figure 42—Area of forest land by forest type in roadless areas, Wyoming, 2002.

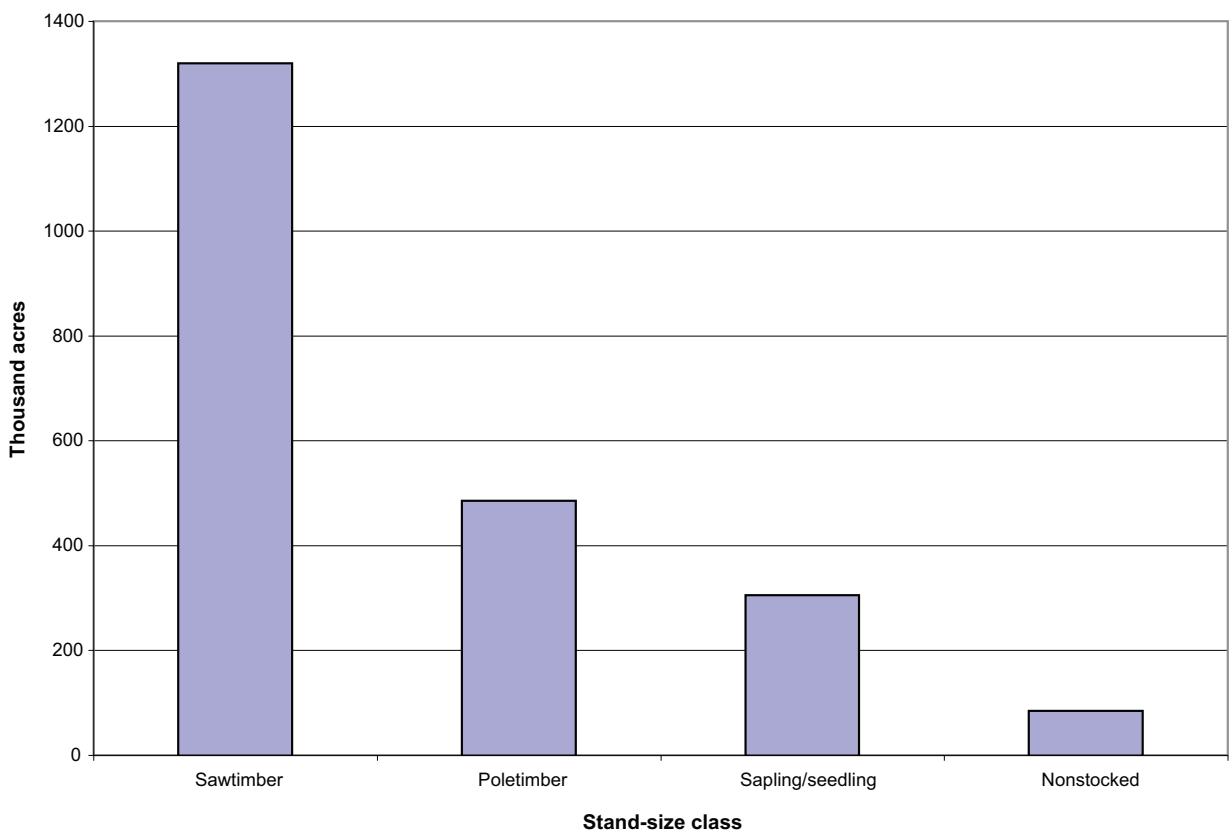

Figure 43—Area of forest land by stand-size class in roadless areas, Wyoming, 2002.

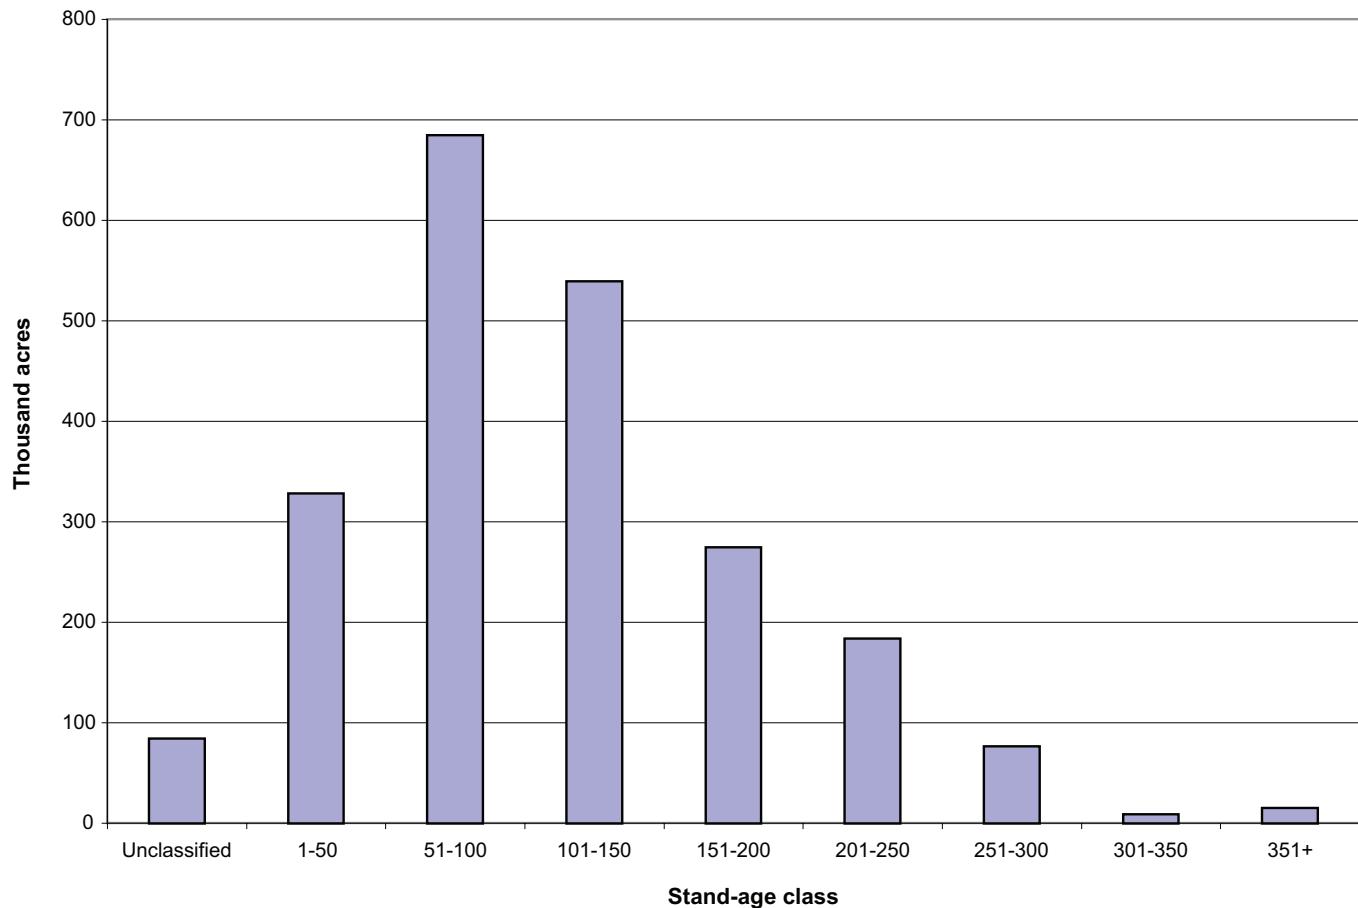

Figure 44—Area of forest land by stand-age class in roadless areas, Wyoming, 2002.

The inventory estimate of live trees on forest land in roadless areas in Wyoming is 892 million trees. Subalpine fir is estimated to make up the highest percentage (32 percent) of number of trees. In continuing order of abundance is lodgepole pine (29 percent); Engelmann spruce (11 percent); Douglas-fir (9 percent); aspen (6 percent); whitebark pine (5 percent); limber pine (3 percent); and ponderosa pine (1 percent) (fig. 45).

The inventory estimate of gross annual growth of all live trees on forest land on roadless areas totals 74.2 million cubic feet and annual mortality totals 35.6 million cubic feet. Annual mortality reduced gross growth by 48 percent. Figure 46 illustrates gross annual growth and annual mortality on roadless areas for the eight most abundant species. The relationships between gross growth and mortality indicate certain species are experiencing elevated levels of mortality and subsequent lower net growth. Annual mortality reduced gross growth 86 percent for subalpine fir and 80 percent for Douglas-fir. In contrast, annual mortality only reduced gross growth by 7 percent for ponderosa pine.

In terms of overall stand structure and composition, roadless areas in Wyoming bear a strong resemblance to reserved land. Elevated levels of mortality compared to gross growth are common to both roadless and reserved forests. The most unique aspect of roadless areas is the amount of area that is located in the subalpine zone of the Southern Rocky Mountain Steppe. This is evidenced by the significant areas occupied by Engelmann spruce, subalpine fir, and Douglas-fir.

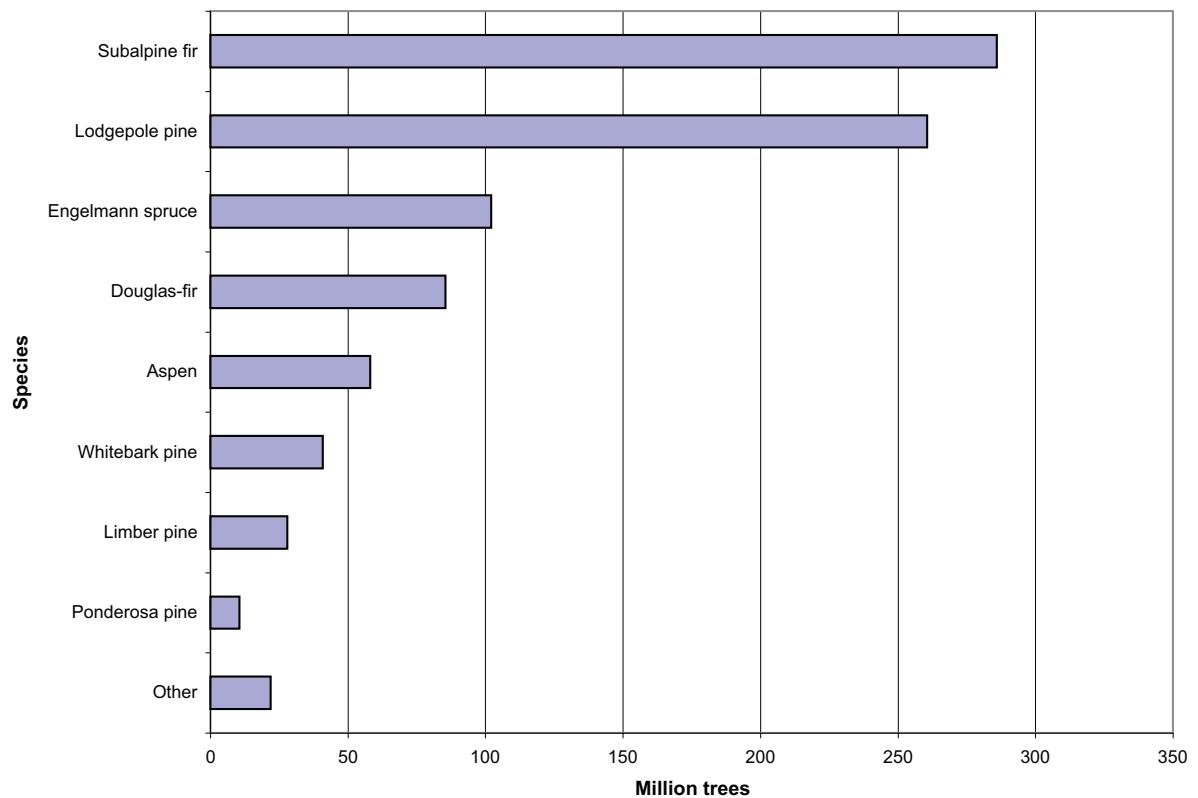

Figure 45—Number of live trees on forest land by species in roadless areas, Wyoming, 2002.

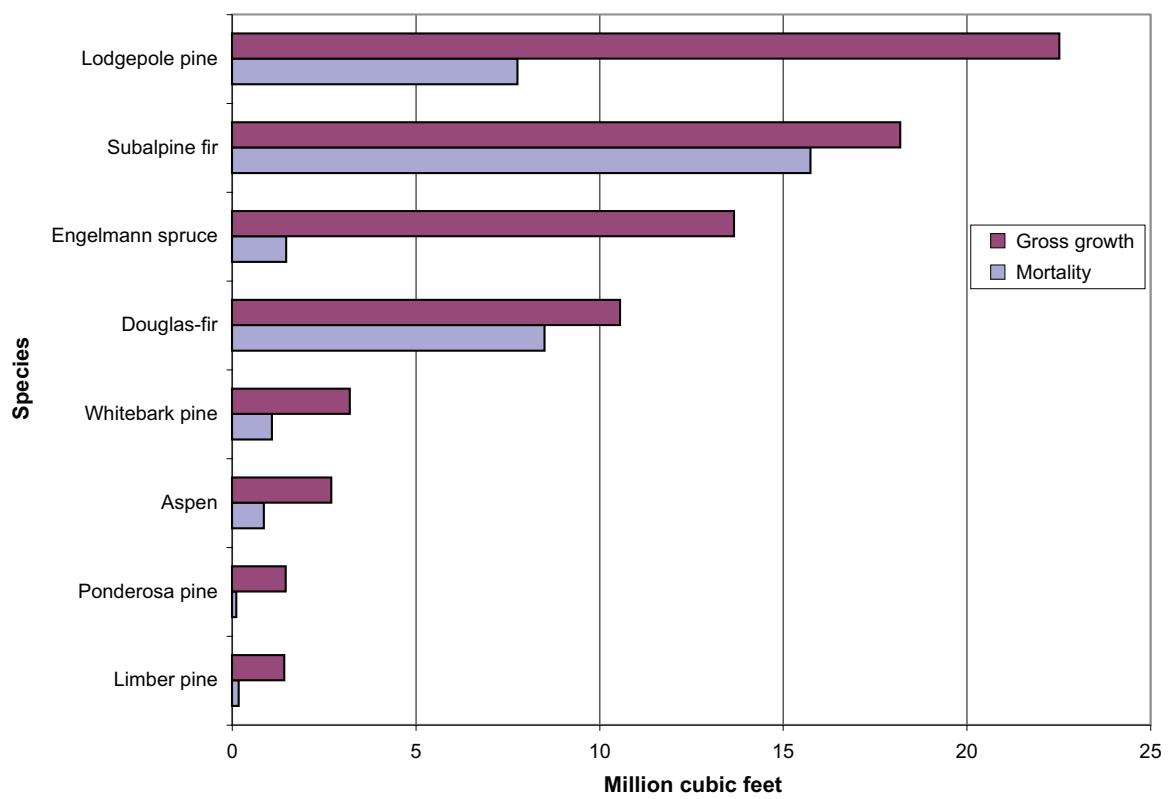

Figure 46—Gross annual growth and annual mortality of live trees by eight most abundant species in roadless areas, Wyoming, 2002.

Summary and Conclusions

At first glance, one might assume that Wyoming's forests are rather homogenous with a predominance of softwood species occurring in mostly mountainous terrain. However, as indicated by the 2002 inventory findings, significant State-wide variability does exist in certain estimates related to species composition and stand structure. Several of the map products underscore these differences. Major differences in species composition and stand structure occur between timberland and woodland. These differences are largely attributable to moisture regimes—woodland typically occurs on very xeric sites whereas timberland progresses from drier sites at lower elevations to the moist, cool environments at the very highest elevations. Reserved forest land is characterized by older, slow-growing forest stands with higher levels of mortality than nonreserved forest land.

Barring significant legislative action, nonreserved timberland will most likely continue to produce timber products at a level well below its potential. The management of Federally owned timberland is far more complicated than it was decades ago because of the diverse demand that today's public puts on natural resources. Every acre of National Forest timberland that is under consideration for a timber sale is subject to intense scrutiny, and any relevant environmental impact must be addressed.

Besides environmental-related restrictions, there are additional restrictions on the timber resource on nonreserved timberland. Figure 47 displays the results of a four-step screening process applied to the total area of nonreserved timberland in Wyoming. The

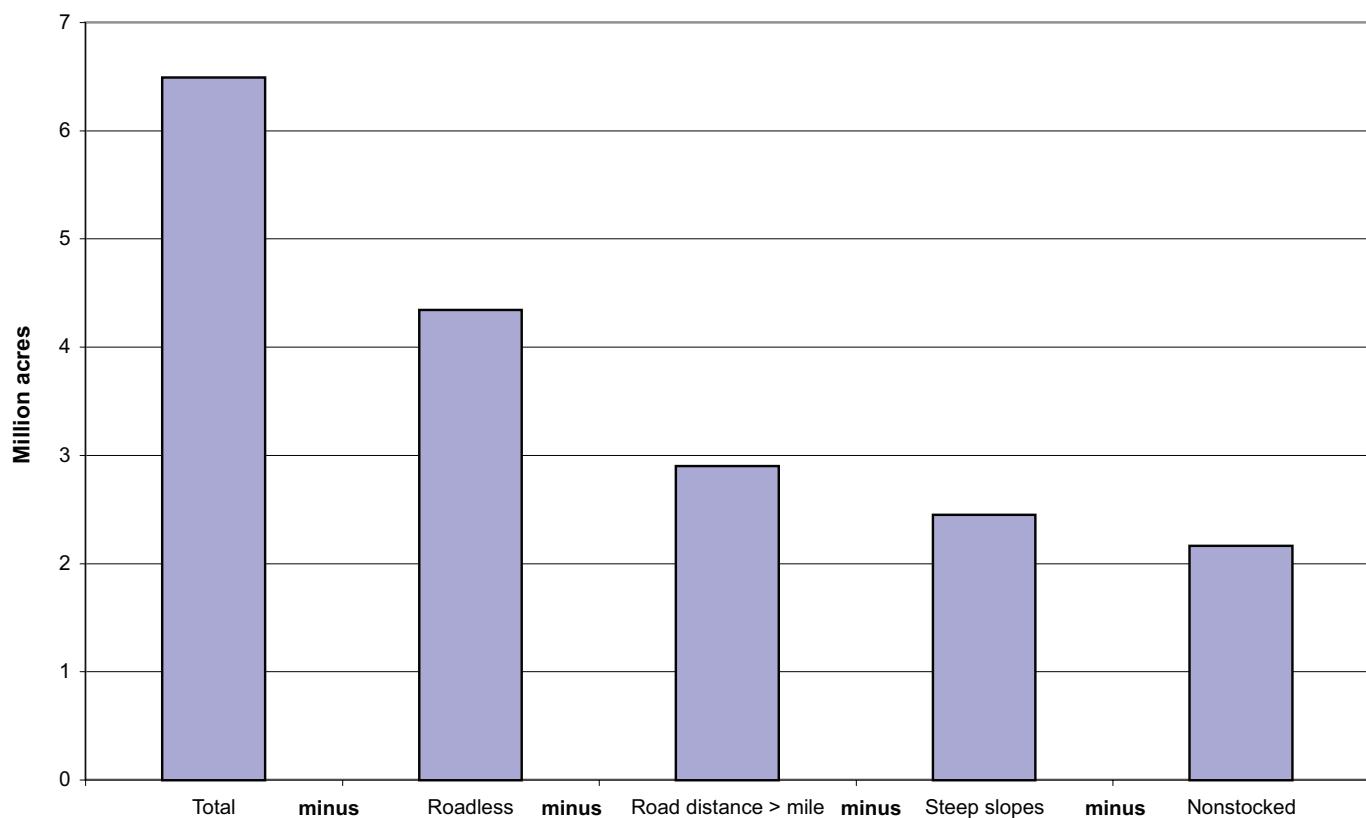

Figure 47—Area of nonreserved timberland discounted for four attributes that may limit timber harvesting, Wyoming, 2002.

purpose of the display is to demonstrate how certain variables collected on FIA plots can be used for arriving at a more realistic estimate of nonreserved timberland area that might be available for timber harvesting. The four screening criteria are (1) roadless areas within nonreserved timberland, (2) areas greater than one mile from a maintained road, (3) slopes greater than 40 percent, and (4) nonstocked conditions. The assumption is that these four criteria present, to a certain degree, a deterrent to logging. After the 6.5 million acres of nonreserved timberland have been deducted using the four criteria, less than 2.2 million acres (34 percent) remain.

Millions of visitors come to enjoy Wyoming's National Parks every year. Yellowstone National Park is internationally famous, and is widely regarded as one of the most unique ecosystems in the world. When the large-scale fires struck in 1988, there was understandable concern about the impacts on the Park's ecosystem. Although unprecedented in the 125-year history of the Park, the scientists reviewing the effects of the 1988 fires reminded the public that fires of such scale burned elsewhere in similar ecosystems during this century, and earlier in the landscape's history. Much of the severely burned forest area naturally regenerated to extremely dense, young lodgepole pine stands. However, lodgepole pine is regarded as a fire-maintained subclimax species, and fire is critical for perpetuating the lodgepole pine ecosystem. The 2002 inventory statistics, especially the stand-age profile, support the conclusion that most of the Park's landscape will evolve into what Yellowstone National Park resembled over 100 years ago.

The information in this report points to several opportunities for further analysis, investigation, and studies. There are significant differences in the stand-age distribution between reserved and nonreserved forest land. Analysis of where these old stands are located, what their species composition is, and evaluating their sustainability could help to address some of the old growth issues. The relationship between gross growth and mortality should be examined in more detail with emphasis on how the relationship differs on each of the National Forests. Gross growth and mortality are often used to explain why the live-tree inventory is increasing or decreasing, and can also indicate a state of forest health. Supply-related studies that examine how much of the live inventory is available for harvest, where this available inventory is located geographically, and what opportunities exist for harvesting this material would be of interest to the forest products industry. The per-acre analysis of growing-stock volume and sawtimber volume indicates that National Forest lands support significantly higher levels of live inventory compared to other ownership groups in Wyoming. The large-scale fires that occurred in 1988 in Yellowstone National Park provided unique opportunities for evaluating how ecosystems respond to fire. The inventory data collected in Yellowstone between 1998 and 2003 could be used for a broad-scale assessment of current stand conditions for those plots that showed evidence of fire-related disturbance in 1988.

Standard Forest Inventory and Analysis Terminology

Note: For a more complete glossary, please go to: http://www.fs.fed.us/rm/ogden/state_report/state_reports.html

Basal area (BA)—The cross-sectional area of a tree stem/bole (trunk) at the point where diameter is measured, inclusive of bark; BA is expressed in square feet. For timber species the calculation is based on diameter at breast height (d.b.h.); for woodland species it is based on diameter at root collar (d.r.c.).

Biomass—The quantity of wood fiber, for trees 1.0 inch in diameter and larger, expressed in terms of oven-dry weight. Includes aboveground portions of trees: bole/stem (trunk), bark, and branches. Biomass estimates can be computed for live and/or dead trees.

Bole—A trunk or main stem of a tree; seedlings and saplings are specified as having stems rather than boles. Woodland trees are also referenced as having stems.

Condition—Generally defined as an area of relatively uniform ground cover, such as homogeneous vegetative cover, meeting minimum size requirements.

Cubic-foot volume (merchantable)—See “Volume.”

Diameter at breast height (d.b.h.)—For timber species: the diameter of a tree bole/stem (trunk) measured at breast height (4.5 feet above ground); measured outside the bark. The point of diameter measurement may vary for abnormally formed trees.

Diameter at root collar (d.r.c.)—For woodland trees: the diameter of a tree stem(s) measured at root collar or at the point nearest the ground line (whichever is higher) that represents the basal area of the tree; measured outside the bark. For multi-stemmed woodland trees, d.r.c. is calculated from an equation that incorporates the individual stem diameter measurements. The point of diameter measurement may vary for woodland trees with stems that are abnormally formed. With the exception of seedlings, woodland stems qualifying for measurement must be at least 1.0 inch in diameter or larger and at least 1.0 foot in length.

Diameter class—A grouping of tree diameters (d.b.h. or d.r.c.) into classes of a specified range. For some diameter classes, the number referenced (for example, 4, 6, 8 inches) is designated as the midpoint of an individual class range. For example, if 2-inch classes are specified (the range for an individual class) and even numbers are referenced, the 6-inch class would include trees 5.0 to 6.9 inches in diameter.

Field/plot location—A reference to the sample site or plot—an area containing the field location center (LC) and all sample points. The mapped-plot design field location consists of four subplots and four microplots distributed over approximately 2.5 acres.

- **Subplot**—A 1/24-acre fixed-radius area (24-foot horizontal radius) used to sample trees 5.0-inches d.b.h./d.r.c. and larger and understory vegetation.
- **Microplot**—A 1/300-acre fixed-radius plot (6.8-foot radius), located at the center of each subplot, and used to inventory seedlings and saplings.

Fixed-radius plot—A circular sample plot of a specified horizontal radius: 1/300 acre = 6.8-foot radius (microplot); 1/24 acre = 24.0-foot radius (subplot).

Forest industry lands—See “Private lands.”

Forest land—Land that is at least 10 percent stocked with live tally tree species (timber or woodland species), including land that formerly had such stocking and that may be regenerated naturally or artificially. The minimum area for classification of forest land is 1 acre and 120 feet wide. Unimproved roads, trails, streams, and openings in forest areas are classified as forest land if they are less than 120 feet wide or 1 acre in size. For field use, sufficient tree crown cover (5 percent cover of tally tree species) or the presence of sufficient reproduction (40 tally tree species seedlings/saplings per acre) is used to represent 10 percent forest land stocking.

- **Timberland**—A subset of forest land, where the designated forest type is derived from timber species.
- **Woodland**—A subset of forest land, where the designated forest type is derived from woodland species.
- **Nonstocked forest land**—Formerly stocked forest land that currently has less than 10 percent stocking but has the potential to again become 10 percent stocked. Examples include recently harvested, burned, or windthrow-damaged areas.

Forest type (historic IW-FIA method)—A classification of forest land based on and named for the tree species presently forming a plurality of live-tree stocking. Stocking is an expression of the extent to which growing space is effectively utilized by live trees. Some exceptions to the single predominant species concept used for classifying forest type apply to sites where (1) hardwoods and softwoods occur together in a stand, or (2) when Engelmann spruce and subalpine fir occur together in a stand, and in combination they compose the predominant live-tree stocking. When hardwoods (for example, maple, oak, or aspen trees) and softwoods (for example, Douglas-fir or ponderosa pine trees) occur together within a stand, forest type is determined as follows: First, the stocking percents of all softwoods are summed as a group, and then again for hardwoods, in order to determine which of the two overall groups has the most live-tree stocking. Next, the individual tree species from the group with the majority of stocking is selected as the forest type. When Engelmann spruce and subalpine fir (or corkbark fir) occur together in a stand, and in combination they constitute the predominant live-tree stocking, forest type is computed using the following criteria: First, all stocking percents are adjusted from an absolute base to a relative base, where the sum of all percents are equal to 100 percent maximum. Next, a stand is classified as an Engelmann spruce type if Engelmann spruce individually is greater than or equal to 20 percent relative stocking, and subalpine fir is less than 20 percent relative stocking. For all other stands where subalpine fir and Engelmann spruce together have plurality, the stand is classified as the spruce-fir type.

Growing stock—A term often used in cubic foot volume tables to describe which trees are included in the net volume, annual growth, and annual mortality estimates. Includes growing-stock trees 5.0 inches d.b.h. and greater (excludes woodland species).

Growing-stock tree—See “Tree class – Sound tree.”

Growth—

- **Gross annual growth**—The average annual increase in the volume of live trees (less deductions for cull volume).
- **Net annual growth**—Gross annual growth minus average annual mortality volume.

Hardwood trees—Trees that are usually broad leaved and deciduous (leaves that fall off or shed at specific seasons).

Indian Trust lands—See “Private lands.”

Industrial wood—See “Logging residue/products.”

Large trees (Sawtimber trees)—See “Tree-size class.”

Logging residue/products—

- **Industrial wood**—All commercial roundwood products, excluding fuelwood.
- **Logging residue**—The unused portions within the merchantable sections of sound (growing-stock) trees cut or killed during logging operations.
- **Primary wood-processing plants**—An industrial plant that processes roundwood products, such as sawlogs, pulpwood bolts, or veneer logs.
- **Pulpwood**—Roundwood, whole-tree chips, or wood residues that are used for the production of wood pulp.
- **Roundwood**—Logs, bolts, or other round sections cut from trees.

Mapped-plot design—A sampling technique that identifies (maps) and separately classifies distinct “conditions” on the field location sample area. Each condition must meet minimum size requirements. At the most basic level, condition class delineations include forest land, nonforest land, and water. Forest land conditions can be further subdivided into separate condition classes if there are distinct variations in forest type, stand-size, stand origin, and stand density, given that each distinct area meets minimum size requirements.

Medium trees (Poletimber trees)—See “Tree-size class.”

Microplot—See “Field/plot location.”

Mortality tree—A standing or downed dead tree, 1.0 inch d.b.h./d.r.c. and larger, that was alive within the past 5 years.

National Forest System (NFS) lands—See “Public lands.”

National Park System (NPS) lands—See “Public lands.”

Net annual growth—See “Growth.”

Nonforest land—For the FIA mapped-plot design baseline inventory, nonforest land includes three main categories: (1) nontree land, (2) nonsampled tree land, and (3) other tree land.

- **Nontree land**—This is land that (1) has never supported tree cover/stocking sufficient for classification as forest land (for example, barren, alpine tundra), or (2) was formerly tree land, but has been converted to a nontree land status (for example, cropland, improved pasture). Other examples of nontree land are improved roads of any width, graded or otherwise regularly maintained for long-term use, and rights-of-way of all powerlines, pipelines, other transmission lines, and operating railroads. If intermingled in forest areas, unimproved roads and nonforest strips must be at least 120 feet wide and 1 acre in size to qualify as nontree land. This category also includes formerly stocked woodland areas if they are currently nonstocked due to a treatment (such as chaining, other land clearing). These areas are treated to eliminate woodland trees for the purpose of enhancing or providing for nonwood commodities or uses (such as increasing herbage production).
- **Nonsampled tree land**—This is land that currently meets the cover or stocking requirements for forest land, but human activity on the site will preclude the natural succession of the stand (areas that might be included in this category are golf courses, cemeteries, picnic grounds, orchards, Christmas tree plantations, and home yards with mowed lawns).
- **Other tree land**—Land that is 10 percent stocked with trees defined as “other tree species” (nontally tree species) but has less than 10 percent stocking or 5 percent cover in tally tree species. Examples would include land stocked with tree species such as paloverde, tamarisk, or Russian olive. See “Other tree species.”

Nonindustrial private lands—See “Private lands.”

Nonreserved forest land—Forest land not withdrawn from management for production of wood products through statute or administrative designation.

Nonstocked forest land—See “Forest land.”

Other private lands—See “Private lands.”

Other public lands—See “Public lands.”

Other tree species (nontally species)—All species classified as trees (Little 1979) that have not at this time been designated nationally by FIA as tally tree species. For the purposes of classifying forest land, only tally tree species are used to determine if minimal stocking requirements have been met. Other tree species include turbinella oak, Russian olive, acacia, etc. See “Nonforest land – Other tree land.”

Poletimber-size trees (Medium trees)—See “Tree-size class.”

Poletimber stands (Medium tree stands)—See “Stand-size class.”

Primary wood-processing plants—See “Logging residue/products.”

Private lands—

- **Forest industry**—Land owned by a company or an individual(s) operating a primary wood-processing plant.
- **Indian Trust**—American Indian lands held in fee, or trust, by the Federal Government, but administered for tribal groups or as individual trust allotments.
- **Nonindustrial private**—All private ownerships except forest industry.
- **Other private**—Privately owned lands other than forest industry or Indian Trust.

Productivity—Developed for timber species, the potential yield capability of a stand calculated as a function of site index (expressed in terms of cubic-foot growth per acre per year at age of culmination of MAI). Productivity values for forest land provide an indication of biological potential. Timberland stands are classified by the potential net annual growth attainable in fully stocked natural stands. Woodland stands are given a default value of 10 cubic feet per acre per year. For FIA reporting, **Productivity Class** is a variable that groups stand productivity values into categories of a specified range. Productivity is sometimes referred to as “Yield” or “Mean annual increment (MAI).”

Public lands—

- **Miscellaneous Federal**—Public lands administered by Federal agencies other than the Forest Service, U.S. Department of Agriculture, or the Bureau of Land Management, U.S. Department of the Interior.
- **National Forest System (NFS)**—Public lands administered by the Forest Service, U.S. Department of Agriculture, such as National Forests, National Grasslands, and some National Recreation Areas.
- **National Park**—Public lands administered by the Park Service, U.S. Department of the Interior, such as National Parks, National Monuments, National Historic Sites (such as National Memorials and National Battlefields), and some National Recreation Areas.
- **Other public**—Public lands administered by agencies other than the Forest Service, U.S. Department of Agriculture. Includes lands administered by other Federal, State, county, and local government agencies, including lands leased by these agencies for more than 50 years.

Pulpwood—See “Logging residue/products.”

Removals—The net volume of growing stock removed from the inventory by harvesting or other cultural operations (such as timber-stand improvement), by land clearing, or

by changes in land use (such as a shift to wilderness).

Reserved land—Land withdrawn from management for production of wood products through statute or administrative designation. Examples include Wilderness areas and National Parks and Monuments.

Sapling and seedling stands—See “Stand-size class.”

Saplings—See “Tree-size class.”

Sawlog portion (timber species)—That part of the bole of sawtimber-size trees between a 1-foot stump and the sawlog top.

Sawtimber—A term often used in board-foot-volume tables to describe which trees are included in net volume, annual growth, and annual mortality estimates. Includes growing-stock trees 9.0 inches d.b.h. and greater for softwoods, and 11.0 inches d.b.h. and greater for hardwoods.

Sawtimber-size trees (Large trees)—See “Tree-size class.”

Sawtimber stands (Large tree stands)—See “Stand-size class.”

Seedlings—See “Tree-size class.”

Site index—A measure of forest productivity for a timberland tree/stand. Expressed in terms of the expected height (in feet) of site trees at an index age of 50 (or 80 for aspen and cottonwood). Calculated from height-to-age equations.

Site productivity—See “Productivity.”

Site tree—A timber species tree used to provide an index of site quality. Timber species selected for site index calculations must meet specified criteria with regards to age, diameter, crown class, and damage (for example, no broken or dead top damage).

Snag—A standing dead tree. See “Tree class – Hard dead tree and Soft dead tree.”

Softwood trees—Coniferous trees that are usually evergreen (retain leaves year-round), and having needlelike or scalelike leaves.

Stand—A community of trees that can be distinguished from adjacent communities due to similarities and uniformity in tree and site characteristics, such as age-class distribution, species composition, spatial arrangement, structure, and so forth.

Stand density—A relative measure that quantifies the relationship between trees per acre, stand basal area, average stand diameter, and stocking of a forested stand. **Stand density index (SDI)**, a widely used measure developed by Reineke (1933), is an index that expresses relative stand density based on a comparison of measured stand values with some standard condition. For FIA reporting, the SDI for a site is usually presented as a percentage of the maximum SDI for the forest type. Site SDI values are sometimes grouped into SDI classes of a specified percentage range. Maximum SDI values vary by species and region.

Standard error—An expression that denotes the precision of an estimate, obtained by statistical sampling methods.

Stand-size class—A classification of forest land based on the predominant diameter size of live trees presently forming the majority of live-tree stocking. Classes are defined as follows:

- **Sawtimber stand (Large-tree stand)**—A stand at least 10 percent stocked with live trees, in which half or more of the total stocking is from live trees 5.0 inches or larger in diameter, and with sawtimber (large tree) stocking equal to or greater

than poletimber (medium tree) stocking.

- **Poletimber stand (Medium-tree stand)**—A stand at least 10 percent stocked with live trees, in which half or more of the total stocking is from live trees 5.0 inches or larger in diameter, and with poletimber (medium tree) stocking exceeding sawtimber (large tree) stocking.
- **Sapling/seedling stand**—A stand at least 10 percent stocked with live trees, in which half or more of the total stocking is from live trees less than 5.0 inches in diameter.
- **Nonstocked stand**—A formerly stocked stand that currently has less than 10 percent stocking, but has the potential to again become 10 percent stocked. For example, recently harvested, burned, or windthrow-damaged areas.

Stocking—An expression of the extent to which growing space is effectively utilized by live trees.

Stocking condition (class)—A classification of forest land used to provide an indication of the extent to which a site is being utilized by live trees (including live cull trees).

- **Overstocked**—Sites at least 100 percent stocked.
- **Fully stocked**—Sites that are 60 to percent stocked.
- **Medium to fully stocked**—Sites that are 35 to 60 percent stocked.
- **Poorly stocked**—Sites that are 10 to 35 percent stocked.
- **Nonstocked**—Sites with a stocking value less than 10.

Subplot—See “Field/plot location.”

Tally trees—Tree species that have been selected to be included in the field inventory/sample because they occur in a tree growth form throughout much of their range (Little 1979). Tally tree species are categorized as “timber” or “woodland” trees. Tally trees are evaluated for a variety of items (such as crown class, crown ratio, damage, rotten/missing material, form defect) and measurements (such as diameter, height) are taken on each tally tree. This information is used to obtain estimates of volume, growth, and mortality for the sample location. Tally tree data can also be used to obtain estimates for other site variables, such as site quality and health.

Timber species—Tree species traditionally used for industrial wood products. These include all species of conifers, except pinyon and juniper. Hardwoods included are aspen, box elder, cottonwood, and paper birch. Timber species are measured for diameter at breast height.

Timberland—See “Forest land.”

Tree class—A classification system based on a tree’s physical characteristics.

- Live trees are classified for Tree Class as follows:
 - **Sound tree (Growing-stock tree)**—A live timber species, 5.0 inches d.b.h. or larger, with less than two-thirds (67 percent) of the merchantable volume cull, and containing at least one solid 8-foot section, reasonably free of form defect, on the merchantable portion of the tree. A live timber species sapling (1.0 to 4.9 inches d.b.h.) is also included in this category if it is expected to become a sound live tree, 5.0 inches d.b.h. or larger, with good form and vigor.
 - **Rough tree**—A live timber species, 5.0 inches d.b.h. and larger, with two-

thirds (67 percent) or more of the merchantable volume cull, and more than half of this cull is due to sound dead wood volume loss, or severe form-defect volume loss (such as severe sweep, crook, forks). Also, a live timber species sapling (1.0 to 4.9 inches d.b.h.) that is not expected to become a sound (growing-stock) tree due to defect, or a timber species (5.0 inches d.b.h. and larger) that does not now, or prospectively, have at least one solid 8-foot section, reasonably free of form defect, on the merchantable portion.

- **Rotten tree**—A live timber species, 5.0 inches d.b.h. and larger, with two-thirds (67 percent) or more of the merchantable volume cull, and more than half of this cull is due to rotten and/or missing material.
- **Live woodland tree**—A live tree of any woodland species.
- Dead trees (timber or woodland species) are classified for Tree Class as follows:
 - **Hard dead tree (Salvable dead tree)**—A standing dead tally tree, 1.0 inch d.b.h./d.r.c. or larger, that has a minimum of one-third of the original merchantable volume sound (less than two-thirds rotten and/or missing material). Also, a down-dead tally tree, 1.0 inch d.b.h./d.r.c. or larger, with a minimum of one-third of the original merchantable volume sound and intact. See “Downed tree” and “Standing tree.”
 - **Soft dead tree (Nonsalvable dead tree)**—A standing dead tree, 1.0 inch d.b.h./d.r.c. or larger, that has less than one-third of the original merchantable volume sound (more than two-thirds rotten/missing material). Also, a down-dead tree, 1.0 inch d.b.h./d.r.c. or larger, with less than one-third of the original merchantable bole sound and intact. See “Downed tree” and “Standing tree.”

Tree-size class—A classification of trees based on d.b.h. for timber species and d.r.c. for woodland species. For woodland trees, with the exception of seedlings, stems qualifying for measurement must be at least 1.0 inch in diameter or larger and at least 1.0 foot in length:

- **Seedling**—An established tree smaller than 1.0 inch d.b.h. for timber species or 1.0 inch d.r.c. for woodland trees, and at least 4 inches tall for softwoods and 12.0 inches tall for hardwoods.
- **Sapling**—A timber species 1.0 to 4.9 inches d.b.h.; also, a single-stemmed woodland tree 1.0 to 4.9 inches d.r.c., or a multistemmed woodland tree with a cumulative d.r.c. of 1.0 to 4.9 inches.
- **Poletimber-size tree or medium tree**—A timber species at least 5.0 inches d.b.h., but smaller than 9.0 inches d.b.h. for a softwood, and smaller than 11.0 inches d.b.h. for a hardwood. A woodland tree 5.0 to 8.9 inches d.r.c. (single stem measurement or computed multistem measurement) is also included in this category.
- **Sawtimber-size tree or large tree**—A timber species that is at least 9.0 inches d.b.h. for a softwood, and at least 11.0 inches d.b.h. for a hardwood. A woodland tree 9.0 inches d.r.c. and larger (single stem measurement or computed multistem measurement) is also included in this category.

Volume for Timber Species—

- **Annual mortality volume**—The net volume contained in timber species (standing or down) that have died over a 1-year period. This estimate is based on a

5-year average. Mortality volume for timber species can be calculated in terms of cubic feet or board feet. See “Mortality tree.”

- **Board-foot volume**—A board-foot is a unit of measure indicating the amount of wood contained in an unfinished board 1-foot wide, 1-foot long, and 1-inch thick. Board-foot volume is computed for the sawlog portion of a sawtimber-size tree; the sawlog portion includes the part of the bole on sawtimber-size tree from a 1-foot stump to a minimum sawlog top of 7 inches diameter outside bark (d.o.b.) for softwoods, or 9 inches d.o.b. for hardwoods. **Net board-foot volume** is calculated as the gross board-foot volume in the sawlog portion of a sawtimber-size tree, less deductions for cull (limited to rotten/missing material and form defect cull deductions, referred to as the **board-foot merchantability factor**). Board-foot volume estimates are computed in both Scribner and International $\frac{1}{4}$ -inch rule, and can be calculated for live and/or dead (standing or down) trees.
- **Cubic-foot volume (merchantable)**—A cubic foot is a unit of measure indicating the amount of wood contained in a cube 1 by 1 by 1 foot. Cubic-foot volume is computed for the merchantable portion of a timber species tree; the merchantable portion includes that part of a bole from a 1-foot stump to a minimum 4-inch top, d.o.b. **Net cubic-foot volume** is calculated as the gross cubic-foot volume in the merchantable portion of a tree, less deductions for cull (limited to rotten/missing cull deductions, referred to as the **cubic-foot merchantability factor**). Merchantable cubic-foot volume estimates can be calculated for live and/or dead (standing or down) trees.

Volume for Woodland Trees—

- **Annual mortality volume**—The net volume contained in woodland trees (standing or down) that have died over a 1-year period. This estimate is based on a 5-year average. Mortality volume for woodland trees is calculated in cubic feet. See “Mortality tree.”
- **Cubic-foot volume**—A cubic-foot is a unit of measure indicating the amount of wood contained in a cube 1 by 1 by 1 foot. Woodland cubic-foot volume is computed for trees 5.0 inches and larger in diameter.
 - **Dead volume**—For dead woodland trees, this volume is equal to gross cubic-foot volume. For live woodland trees, dead volume is calculated as gross cubic-foot volume times the field crew estimate of percent sound dead volume loss. Cull deductions are limited to the merchantable portion of a tree.
 - **Net volume**—The gross cubic-foot volume of live woodland trees, less deductions for rotten and missing material. This estimate includes volume for dead material on live trees. Cull deductions are limited to the merchantable portion of a tree.

Water—In terms of Ground Cover Classification, water includes streams, sloughs, estuaries, and canals more than 30 feet in width; and, lakes, reservoirs, and ponds more than 1 acre in size. Ephemeral and intermittent streams are classified as land. Water is further classified as “census water” or “noncensus” water as follows:

- **Census water**—Rivers, streams, sloughs, estuaries, and canals, more than 200 feet wide and 4.5 acres and larger in size; only portions of rivers and streams meeting the definition criteria are considered census water. Other census water includes lakes, reservoirs, and ponds more than 4.5 acres and larger in size. Portions of braided streams meeting the census water definition criteria and more than 50 percent water at normal high-water level are also considered census water.

- **Noncensus water**—Portions of rivers, streams, sloughs, estuaries, and canals that are 30 to 200 feet wide and at least 1 acre in size; and lakes, reservoirs, and ponds 1 to 4.5 acres in size. Portions of rivers and streams not meeting the criteria for census water, but at least 30 feet wide and 1 acre in size, are considered noncensus water. Portions of braided streams not meeting the criteria for census water, but at least 30 feet in width and 1 acre in size, and more than 50 percent water at normal high-water level are also considered noncensus water.

Wilderness—An area of undeveloped land currently included in the Wilderness System, managed to preserve its natural conditions and retain its primeval character and influence.

Woodland—See “Forest land.”

Woodland species—Tree species that are not usually converted into industrial wood products. Common uses of woodland trees are fuelwood, fenceposts, and Christmas trees. These species include pinyon, juniper (except western juniper), mesquite, locust, mountain-mahogany, Rocky Mountain maple, bigtooth maple, desert ironwood, and most oaks (chinkapin oak is classified as a timber species). Because woodland trees are extremely variable in form, diameter is measured at the root collar.

Appendix A: Common Name, Scientific Name, and Timberland (T) or Woodland (W) Designation for Trees

Tree Species

- Aspen (*Populus tremuloides*) T
- Bigtooth maple (*Acer grandidentatum*) W
- Black cottonwood (*Populus balsamifera*) T
- Blue spruce (*Picea pungens*) T
- Boxelder (*Acer negundo*) T
- Bur oak (*Quercus macrocarpa*) T
- Common or twoneedle pinyon (*Pinus edulis*) T
- Curlleaf mountain-mahogany (*Cercocarpus ledifolius*) W
- Chinkapin oak (*Quercus muehlenbergii*) W
- Douglas-fir (*Pseudotsuga menziesii*) T
- Engelmann spruce (*Picea engelmannii*) T
- Gambel oak (*Quercus gambelii*) W
- Green ash (*Fraxinus pennsylvanica*) T
- Limber pine (*Pinus flexilis*) T
- Lodgepole pine (*Pinus contorta*) T
- Narrowleaf cottonwood (*Populus angustifolia*) T
- Paper birch (*Betula papyrifera*) T
- Plains cottonwood (*Populus deltoides*) T
- Ponderosa pine (*Pinus ponderosa*) T
- Rocky Mountain juniper (*Juniperus scopulorum*) W
- Rocky Mountain maple (*Acer glabrum*) W
- Subalpine fir (*Abies lasiocarpa*) T
- Utah juniper (*Juniperus osteosperma*) W

Appendix B: Volume and Biomass Equation Sources

Volume

Chojnacky (1985) was used for pinyon pine, Rocky Mountain juniper, and curlleaf mountain-mahogany maple volume estimation.

Chojnacky (1992) was used for oak volume estimation.

Edminster and others (1980) was used for western Wyoming ponderosa pine volume estimation.

Edminster and others (1982) was used for aspen volume estimation.

Kemp (1958) was used for cottonwood volume estimation.

Myers (1964) was used for eastern Wyoming ponderosa pine volume estimation.

Myers and Edminster (1972) was used for Douglas-fir, subalpine fir, and Engelmann spruce volume estimation.

Myers (1964) was used for lodgepole pine and limber volume estimation.

Biomass

Chojnacky (1984) was used for mountain mahogany biomass estimation.

Chojnacky (1992). was used for oak and maple biomass estimation.

Chojnacky and Moisen (1993) was used for pinyon and juniper biomass estimation.

Van Hooser and Chojnacky (1983) was used for all timber species biomass estimation.

Forest Inventory and Analysis Tables

Total Forest Land

Table 1--Total area by ownership class and land class, Wyoming, 2002

Ownership class	Land class						Total Acres	
	Nonreserved		Reserved		Noncensus Water

All types	240,969	34,398	34,624	309,990

The Rocky Mountain Research Station develops scientific information and technology to improve management, protection, and use of the forests and rangelands. Research is designed to meet the needs of National Forest managers, Federal and State agencies, public and private organizations, academic institutions, industry, and individuals.

Studies accelerate solutions to problems involving ecosystems, range, forests, water, recreation, fire, resource inventory, land reclamation, community sustainability, forest engineering technology, multiple use economics, wildlife and fish habitat, and forest insects and diseases. Studies are conducted cooperatively, and applications may be found worldwide.

Research Locations

Flagstaff, Arizona

Reno, Nevada

Fort Collins, Colorado*

Albuquerque, New Mexico

Boise, Idaho

Rapid City, South Dakota

Moscow, Idaho

Logan, Utah

Bozeman, Montana

Ogden, Utah

Missoula, Montana

Provo, Utah

2150 Centre Avenue, Building A, Fort Collins, CO 80526

The U.S. Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, age, disability, and where applicable, sex, marital status, familial status, parental status, religion, sexual orientation, genetic information, political beliefs, reprisal, or because all or part of an individual's income is derived from any public assistance program. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact USDA's TARGET Center at (202) 720-2600 (voice and TDD).

To file a complaint of discrimination, write to USDA, Director, Office of Civil Rights, 1400 Independence Avenue, S.W., Washington, DC 20250-9410, or call (800) 795-3272 (voice) or (202) 720-6382 (TDD). USDA is an equal opportunity provider and employer.
