1) The comparison population represents females in New York State exclusive of New York City, 1993-1997.

2) Rates are crude rates (i.e., they are not age adjusted).

3) Distribution of observed cases in the hypothetical study population is fixed (i.e. these numbers were "observed").

4) The expected number of cases is calculated by applying the proportions from the comparison population to the total number of cases in the study population (i.e., for breast, 0.287x513); no adjustment for age or calendar time is being made.

5) Assuming equal overall rates results in fixing the person years at risk in the study population (i.e., the denominator of the rate is fixed at 108,560).
