Definitions of clustered seismicity

Aftershock Sequence

Large initial earthquake

smaller subsequent earthquakes

Doublets or Multiplets

Earthquake(s) are similar in size.
Max $\Delta M = 0.4$, max $\Delta t = 2$ days.
(Lay and Kanamori, 1980; Wesnousky et al., 1986; Xu and Schwartz, 1993.)

Foreshock Sequence

small initial earthquake

larger subsequent earthquake

Do these distinctions indicate different physics?

Objectives

Earthquake Statistics

- Test predictions of the single mode triggering model
- Test challenges to the single mode triggering model

Single Mode Triggering Model

One earthquake triggers slip at the hypocenter of n future earthquakes, where n is proportional to the initial earthquake's area $\propto 10^M$

The triggered earthquakes grow to random magnitudes from the Gutenberg-Richter distribution ($N=10^{a-bM}$)

The triggered earthquakes may be smaller, the same size, or larger than the trigger

Single Mode Triggering Predictions

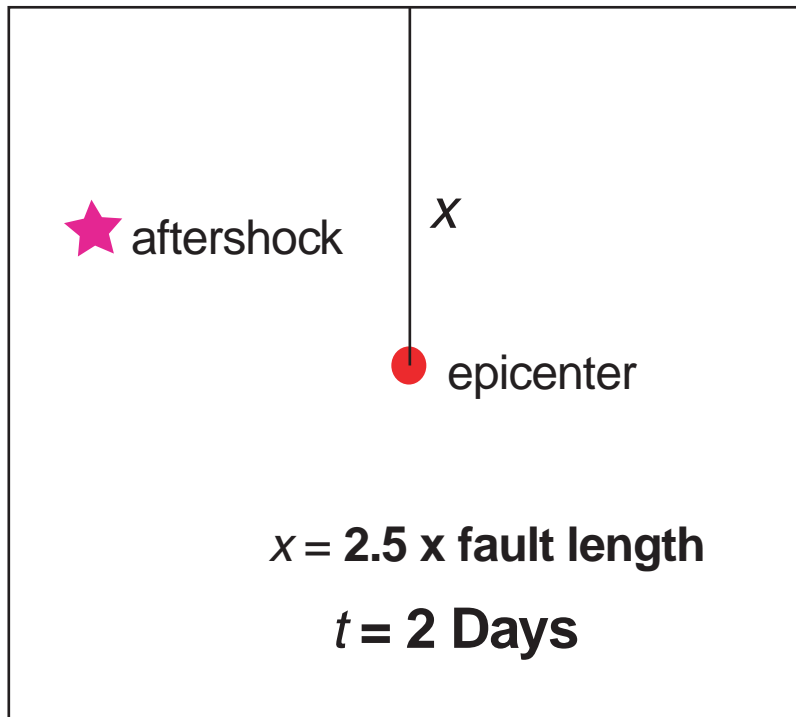

Number of earthquakes triggered by $M_1 \propto 10^{bM_1}$

$$P(M_2) \propto 10^{-bM_2}$$

$$P(M_1 \text{ triggering } M_2) \propto 10^{b(M_1 - M_2)}$$

1. Regional aftershock and doublet rates should vary linearly with each other
2. Regional aftershock and foreshock rates should vary linearly with each other
3. $N(M_2 \text{ aftershocks}) \propto 10^{b(M_1 - M_2)}$
4. Larger foreshock \rightarrow more triggered earthquakes \rightarrow larger mainshock more probable

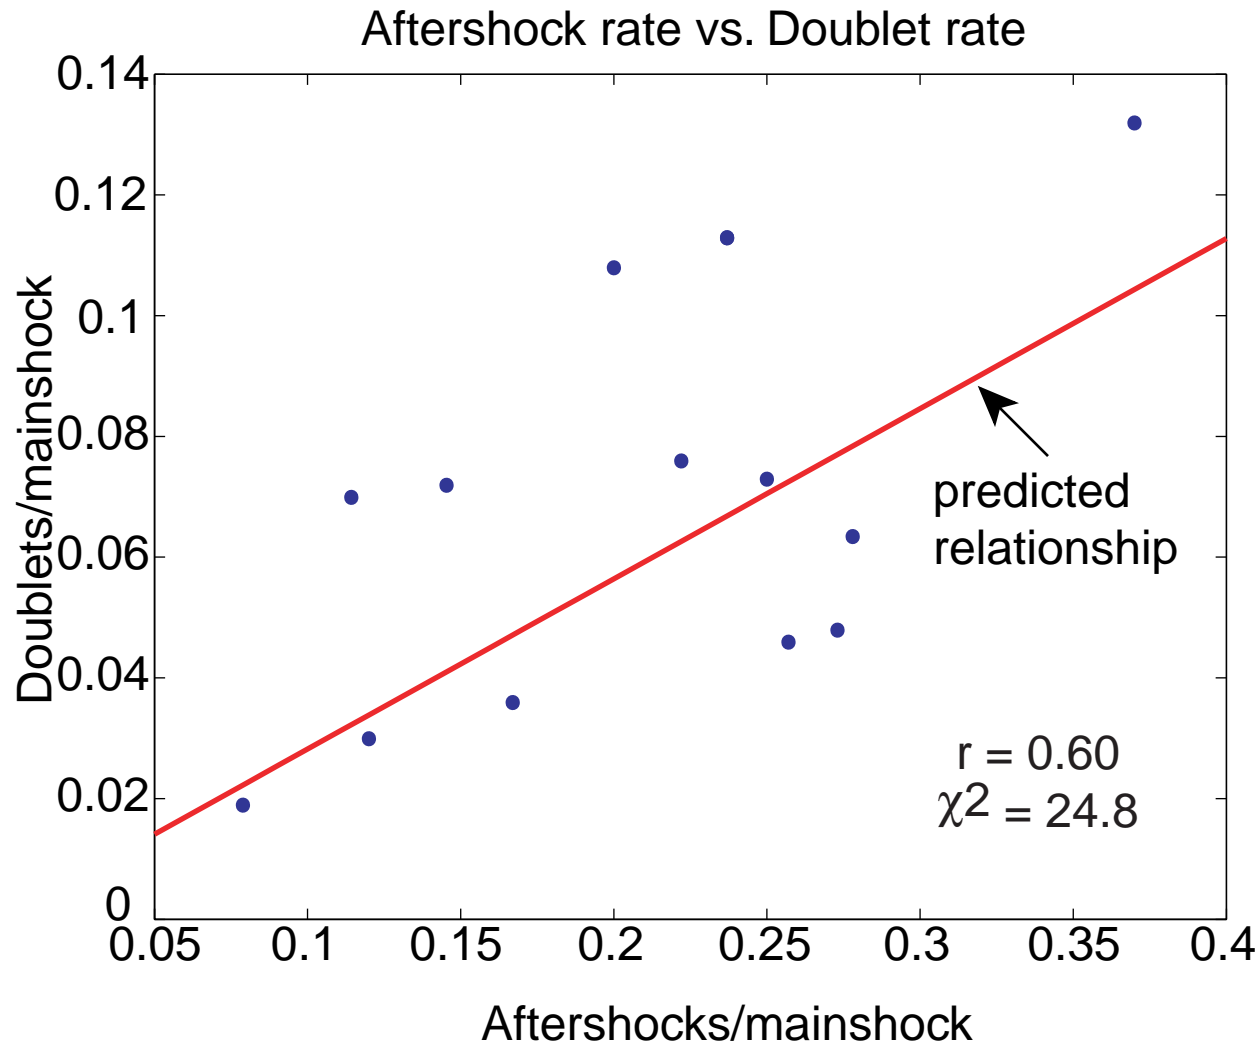

Testing the predictions: counting clustered earthquakes

	event type	min M_1	min M_2	$M_1 - M_2$ (ΔM)
Catalog CMT & NEIC 1975-2002	doublet	6.4	6.0	$-0.4 \leq \Delta M \leq 0.4$
	aftershock	6.6	5.6	$0.4 \leq \Delta M \leq 1.0$
	foreshock	5.6	5.7	$\Delta M < 0.0$

Single Mode Triggering Prediction #1

Regional aftershock and doublet rates vary linearly with each other ✓

Data points are from:

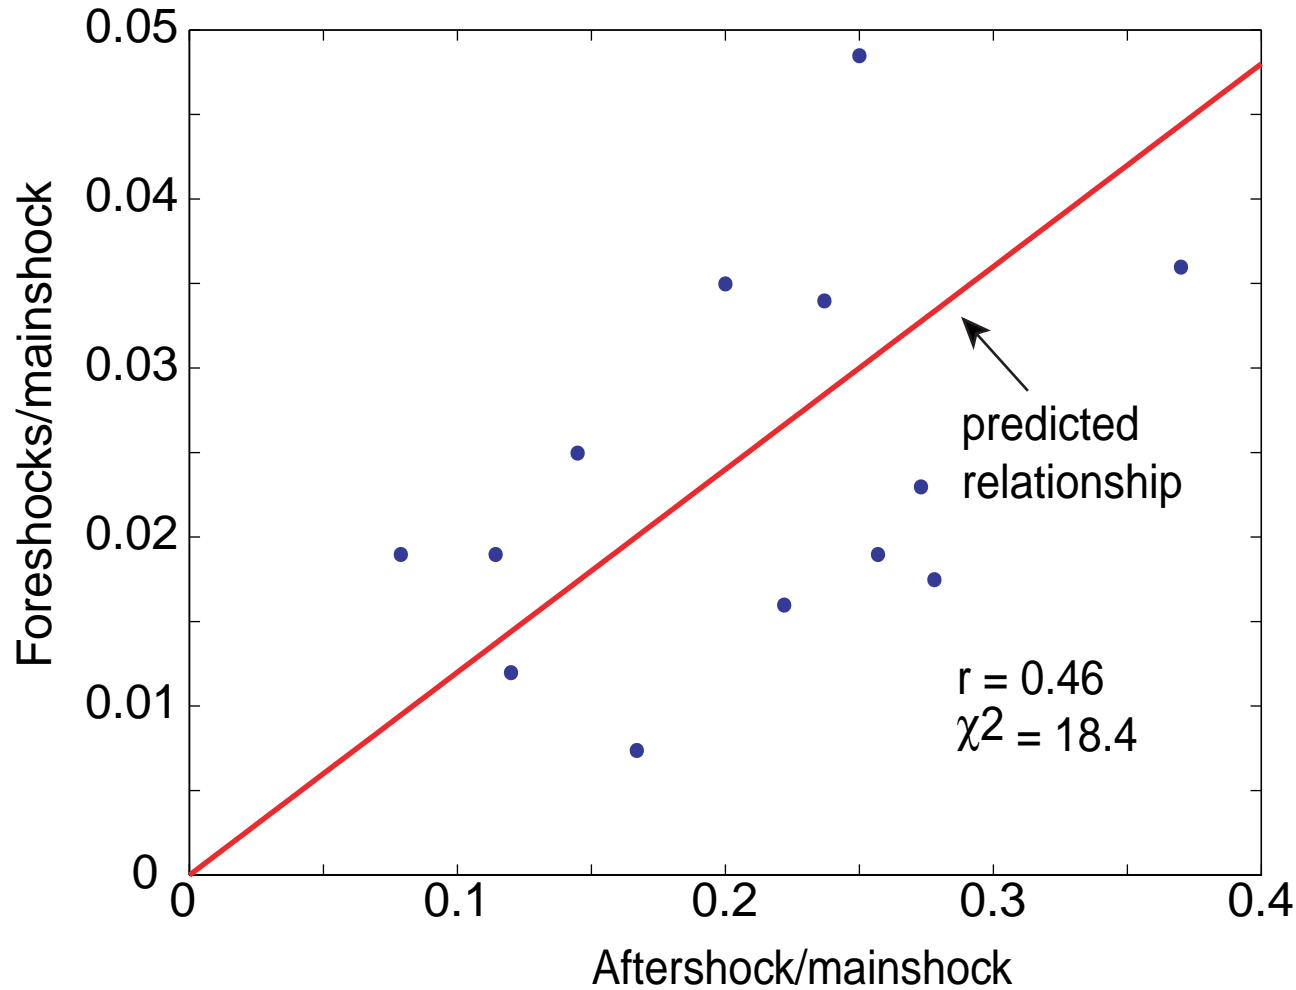

The Kuriles
The Solomon Islands
New Hebrides
The Philippines
The Aleutians
New Zealand
Sumatra
West Coast, N. America
Japan
Southern America
Mid-ocean Ridges
Tibet
Italy

$t = 2$ days $x = 2.5$ x fault length

Single mode triggering prediction #2

Aftershock and foreshock rates vary with each other ✓

Aftershock Rate vs. Foreshock Rate

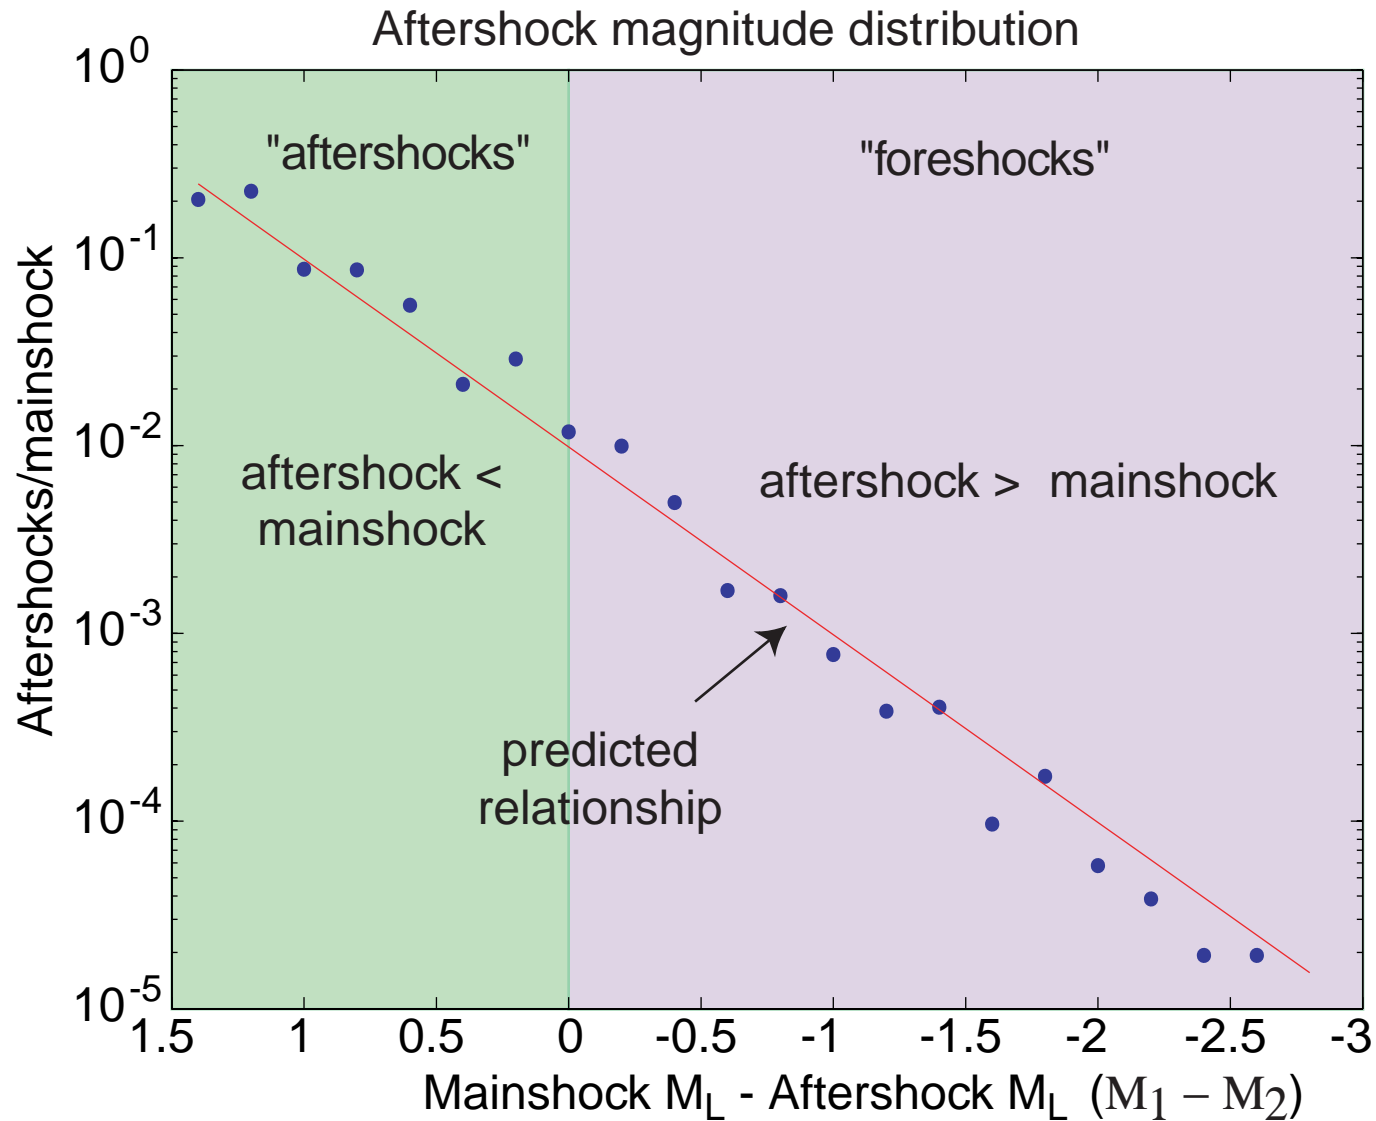

Data points

- The Kuriles
- The Solomon Islands
- New Hebrides
- The Phillipines
- The Aleutians
- New Zealand
- Sumatra
- West Coast, N. America
- Japan
- Southern America
- Mid-ocean Ridges
- Tibet
- Italy

$t = 2$ days $x = 2.5$ x fault length

Single mode triggering prediction #3

$$N(M_2 \text{ aftershocks}) \propto 10^{b(M_1 - M_2)} \quad \checkmark$$

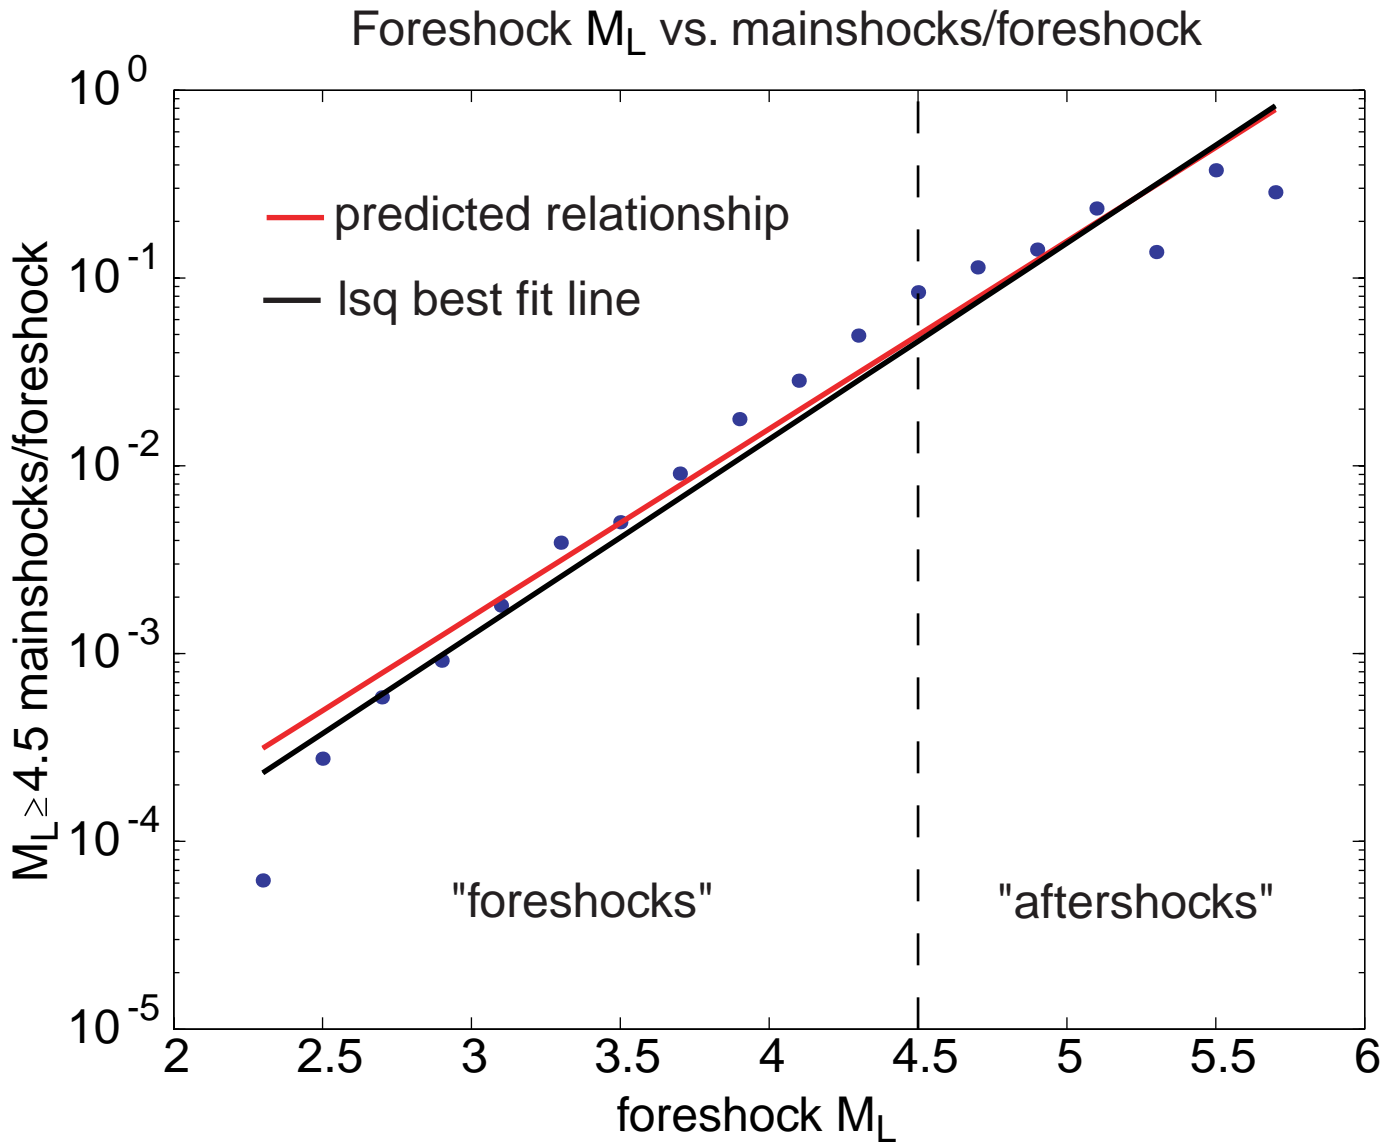

California earthquakes, 1975-2001, $M \geq 2.2$ (101,680 eqs)

$t = 2$ days $x = 2 \times$ fault length

Single mode triggering prediction #4

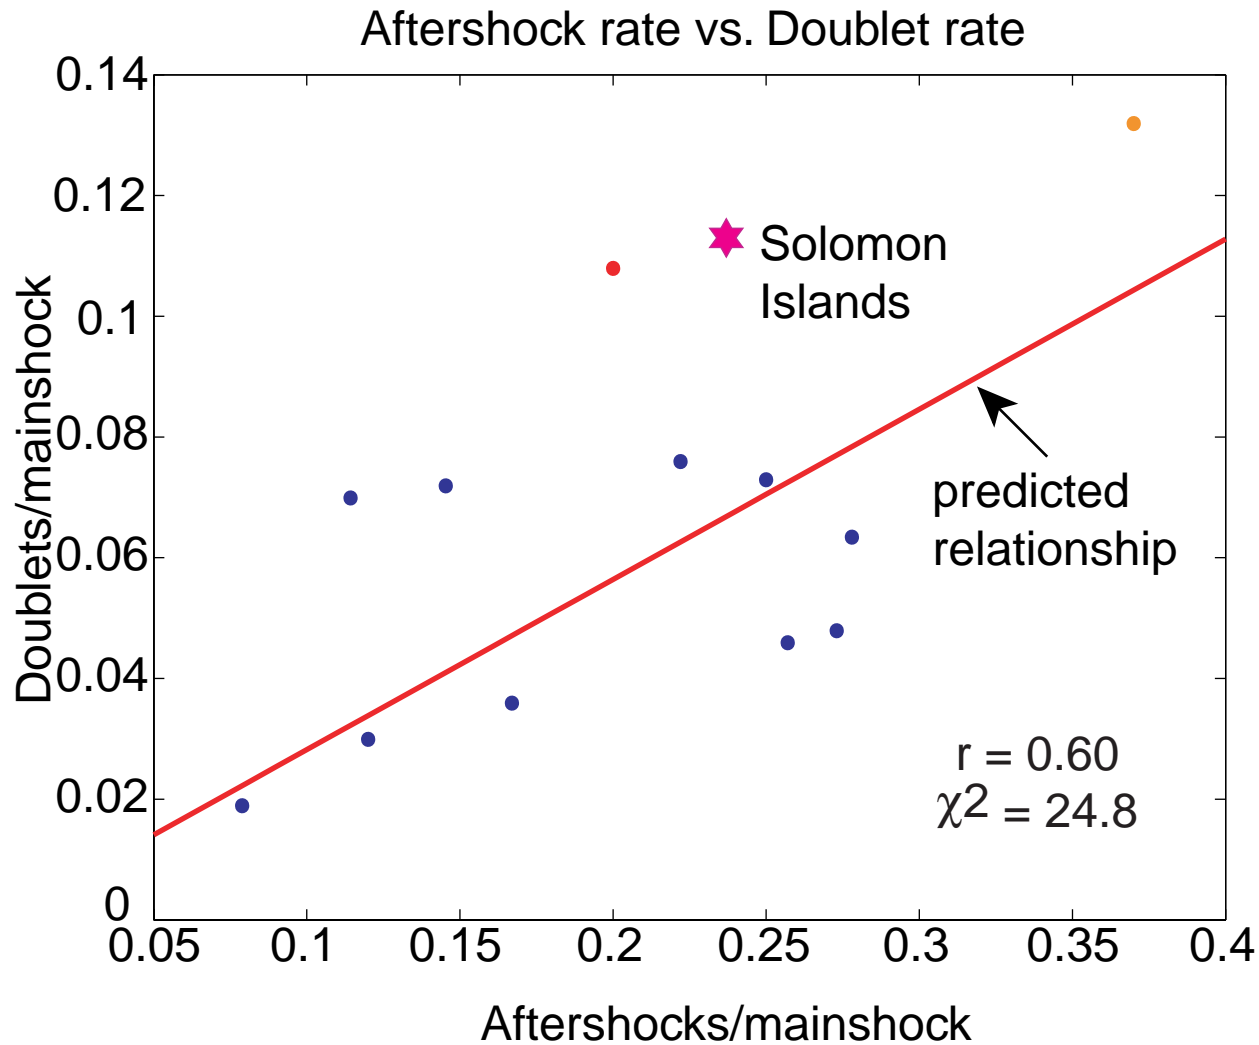

Larger individual foreshocks are more likely to trigger a large mainshock ✓

$t = 2$ days $x = 2 \times$ fault length

Model Challenge #1

The Solomon Islands have too many doublets

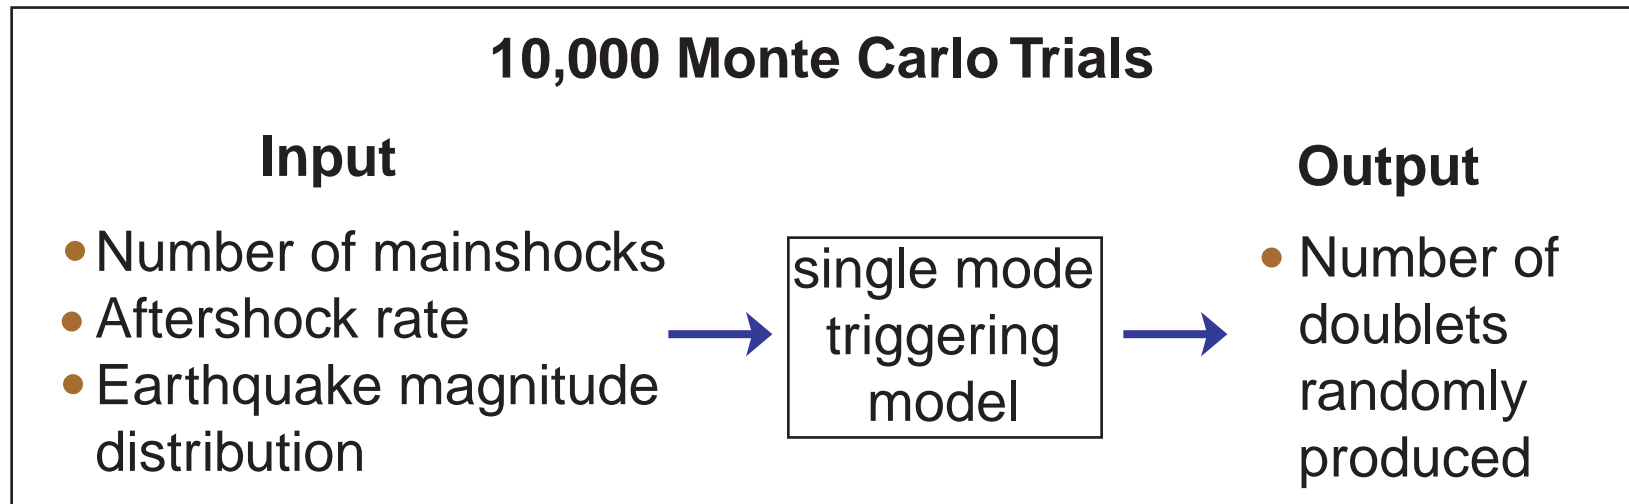

Data points are from:

- The Kuriles
- The Solomon Islands
- New Hebrides
- The Philippines
- The Aleutians
- New Zealand
- Sumatra
- West Coast, N. America
- Japan
- Southern America
- Mid-ocean Ridges
- Tibet
- Italy

Test: Does the doublet rate in the Solomon Islands disprove Single Mode Triggering?

doublet magnitude	no. observed in Solomons	% time expected from random fluctuation
$M \geq 6$	6	38%
$M \geq 7$	4	18%

Observed doublet rates in the Solomons are consistent with single mode triggering

Model Challenge #2

Triggering cannot work small \longrightarrow large

Implications of Challenge #2

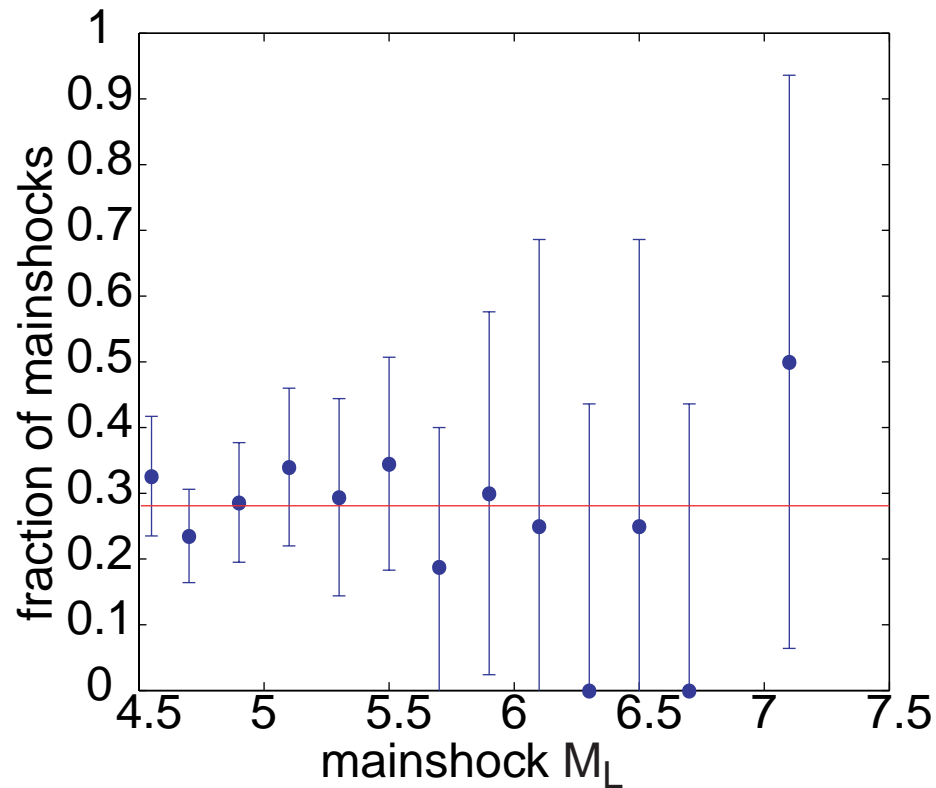

Foreshocks occur because of stressing by the nucleation phase of the mainshock

Predictions of Challenge #2

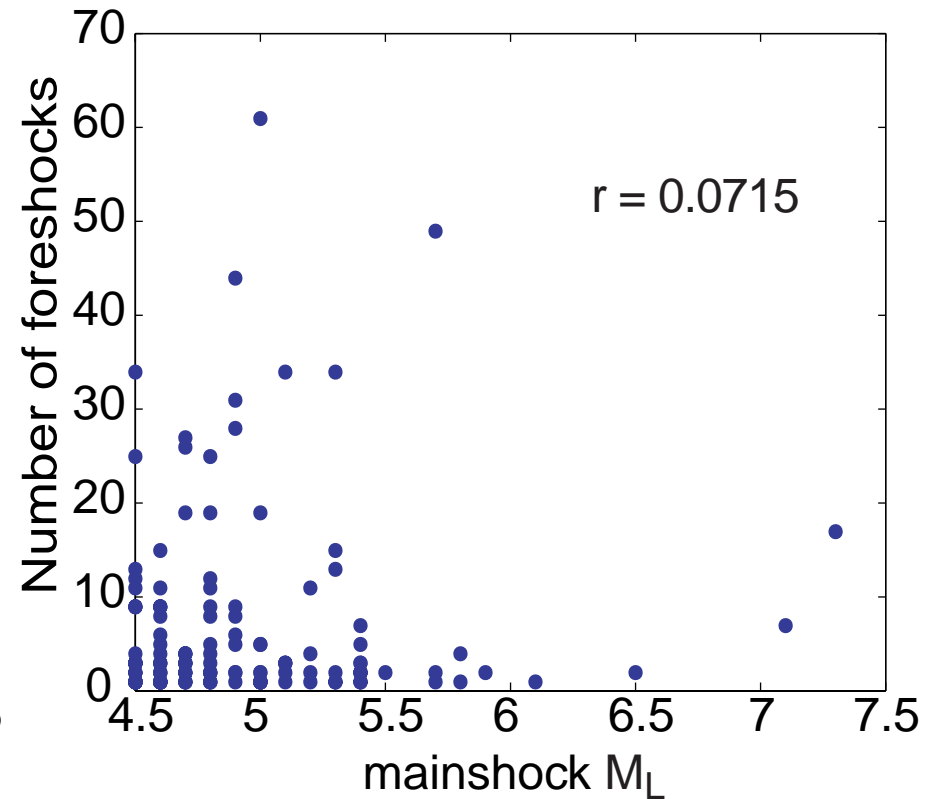

- Nucleation phase size should scale with mainshock magnitude
- Mainshock magnitude should influence foreshock occurrence

Test: Does mainshock size influence foreshocks?

Fraction of California mainshocks with largest foreshock $2.2 \leq M_L \leq 4.5$

Mainshock M_L vs. number of foreshocks $2.2 \leq M_L \leq 4.5$

Conclusions

- Aftershock, doublet, and foreshock rates vary linearly with each other
- The magnitudes of triggered earthquakes may be reproduced by choosing random values from the Gutenberg-Richter distribution
- Foreshock size influences mainshock occurrence
- Mainshock size does not influence foreshocks

Aftershocks, foreshocks, and doublets all result from a single physical triggering process
