Associate Commissioner
The National Center for Education Statistics (NCES) is the primary federal entity for collecting, analyzing, and reporting data related to education in the United States and other nations. It fulfills a congressional mandate to collect, collate, analyze, and report full and complete statistics on the condition of education in the United States; conduct and publish reports and specialized analyses of the meaning and significance of such statistics; assist state and local education agencies in improving their statistical systems; and review and report on education activities in foreign countries.

NCES activities are designed to address high priority education data needs; provide consistent, reliable, complete, and accurate indicators of education status and trends; and report timely, useful, and high quality data to the U.S. Department of Education, the Congress, the states, other education policymakers, practitioners, data users, and the general public.
We strive to make our products available in a variety of formats and in language that is appropriate to a variety of audiences. You, as our customer, are the best judge of our success in communicating information effectively. If you have any comments or suggestions about this or any other NCES product or report, we would like to hear from you. Please direct your comments to:

## Foreword

In addition to official NCES publications, NCES staff and individuals commissioned by NCES produce preliminary research reports that include analyses of survey results, and presentations of technical, methodological, and statistical evaluation issues.

The Working Paper Series was initiated to promote the sharing of the valuable work experience and knowledge reflected in these preliminary reports. These reports are viewed as works in progress, and have not undergone a rigorous review for consistency with NCES Statistical Standards prior to inclusion in the Working Paper Series.

# NAEP Quality Assurance Checks of the 2002 Reading Assessment Results for Delaware 

## EXECUTIVE SUMMARY

In March 2003, the National Center for Education Statistics (NCES) asked the Human Resources Research Organization (HumRRO) to participate in a special study of the 2002 reading assessment results for Delaware. Standard review of test results had revealed that compared with other states, Delaware (DE) was an outlier from the mainstream, both in the change in exclusion rates between 1998 and 2002, and in the $4^{\text {th }}$ grade reading gains between 1998 and 2002, particularly for the Delaware Hispanic population. NCES authorized several teams to investigate various aspects of the assessment. HumRRO was asked to focus on seven specific technical questions, and follow any additional data analysis leads that emerged. Below is a summary of findings for each question.

Question 1: Was there a problem with the sampling of Delaware students?
We found no problems with the sampling of Delaware students. We investigated the sampling process in two ways. First, an expert sampling statistician reviewed the 2002 sampling for Delaware and concluded that there were no problems; inclusion of all Delaware schools led to increased accuracy and did not in and of itself increase or decrease score estimates. Second, the weighted count of students from the NAEP sample was closely comparable to enrollment counts from the Delaware Department of Education.

Question 2: Was there a problem with the weighting [case weights] of the Delaware data?
We detected no problem with the case weights of the Delaware data. Delaware is one of the few states where every school is sampled and in 2002 nearly all of the students in the targeted grades were tested. Consequently, the sampling weight assigned to each school should be 1.0 , and they were exactly that on the 2002 data file. In addition, student weights should all be the same except for minor differences due to reassignment of the weights for students who were absent. The 2002 student weights were found to be entirely consistent with this expectation.

Question 3: Was there a problem with the design for assigning test booklets to students (BIB spiral)?

No problem with the BIB (balanced incomplete block) spiral was detected. Booklets and items were distributed appropriately across the state, as well as within each school. The distribution of booklets in Delaware schools closely matched the distribution in other states.

Question 4: Was there a problem with the scoring (hand scoring or scanning) of the Delaware data?

We found no problem in the scoring of Delaware data. Open-ended responses from Delaware students were mixed in with responses from other states in the scoring process; there was no differential treatment. Similar treatment was also found for the scanning and scoring of responses to the multiple-choice questions. Delaware students did not have unusual gains on any open-ended or multiple-choice item, which might have indicated a problem with the scoring of that item.

However, Delaware students did show slightly larger gains between 1998 and 2002 on the open-ended items relative to the rest of the nation. This difference might be due to a greater emphasis on writing, both in the instruction process and in the state's own assessment, and may account for some of the gain seen by Delaware.

Question 5: Was there an error in the scaling and equating for Delaware?
No scaling or equating problems were identified in Delaware. Several analyses examined patterns of item performance and scale scores for Delaware and the rest of the nation. The relationship between scores on the individual items to scale score estimates was the same for Delaware as for other states.

Question 6: Was there a problem with the coding of any data in Delaware?
We found no coding problems. Race/ethnicity codes used for reporting were reviewed because of large gains by Hispanics. Agreement between race/ethnicity data supplied by students and by schools was sufficient to rule out coding errors, overall and for each school.

Question 7: Was there a breach in test security in Delaware?
No indications of test security breaches were identified. Gains on individual items and on blocks of items associated with a common passage were consistent with gains on these items and blocks for the nation as a whole. Individual schools did not show unusual gains on individual items, blocks of items, or overall.

Additional Exploration: Were any other problems detected that would suggest interpreting the 1998-2002 results with caution?

Prior to calculating the gains between 1998 and 2002, the 1998 results were recomputed (1) using an alternate sample of students who were provided accommodations similar to those provided in 2002 and (2) defining race categories from codes supplied by schools rather than students. Consequences of these changes in the 1998 data were:

- Grade 4 sample size for Hispanics decreased from 198 to 101.
- The exclusion rate for Grade 4 Hispanics dropped from 6 percent to just 3 percent.
- Grade 8 sample size for Hispanic students decreased from 78 to 64 .
- For Grade 8, the exclusion rate for Hispanics dropped from 12 percent to 0 percent.

The "2002 gains" were based upon these recomputed 1998 scores. Gains between 2002 scores and recomputed 1998 scores had large standard errors and therefore wide confidence bands:

- The 95 percent confidence band for Grade 4 Hispanic gain is +13 to +59 points.
- The 95 percent confidence band for Grade 8 Hispanic gain is -14 to +18 points.

CONCLUSION: Based on an extensive analysis of the 2002 Delaware reading assessment data and on data from the 1998 assessment used as the basis for computing gains in 2002, we did not find any technical/analytic problems in data sampling or analysis that affected the 2002 results for Delaware.

We did note that recomputed 1998 score estimates for $4^{\text {th }}$ and $8^{\text {th }}$ grade Hispanic students were based on small sample sizes, large standard errors, and low exclusion rates. Consequently, the score gains between 2002 and recomputed 1998 had wide confidence bands. We recommend that the Delaware Hispanic gains for Grade 4 and Grade 8 from 1998 to 2002 be flagged, with explanatory text, to indicate that the amount of gain should be interpreted with caution.

# NAEP Quality Assurance Checks of the 2002 Reading Assessment Results for Delaware 

## CHAPTER 1: INTRODUCTION

In March 2003, the National Center for Education Statistics (NCES) asked the Human Resources Research Organization (HumRRO) to participate in a special study of the 2002 reading assessment results for Delaware. Standard review of test results had revealed that compared with other states, Delaware was an outlier from the mainstream, both in the increase in exclusions between 1998 and 2002, and in the $4^{\text {th }}$ grade reading gains between 1998 and 2002, particularly for the Delaware Hispanic population. NCES authorized several teams to investigate various aspects of the assessment. Preliminary data presented to HumRRO suggested that the gains are particularly noticeable for Grade 4 and most extreme for the Grade 4 Hispanic students. Table 1.1 presents updated results computed after the 2002 data had received its final edits. Using updated data, these results defined the issue that HumRRO was asked to address.

Table 1.1. Score Gains for NAEP Reading 1998-2002
Score gains for NAEP Reading 1998-2002
(Computed by HumRRO)

| Grade 4 |  |  | Delaware |  |  |
| :--- | :---: | :---: | :--- | :---: | :---: |
| Year | All States/ |  |  |  |  |
|  | All Students | All Students | White | Black | Hispanic |
| 1998 Mean $^{\text {a }}$ | 215 | 212 | 220 | 199 | 193 |
| 1998 Mean-R |  | 213 | 207 | 218 | 189 |
| 2002 Mean | 219 | 224 | 233 | 209 | 212 |
| Gain $^{\text {c }}$ |  | 6 | 17 | 15 | 20 |

Grade 8

|  | All States/ | Delaware |  |  |  |
| :--- | :---: | :---: | :--- | :---: | :---: |
|  | All Students | All Students | White | Black | Hispanic |
| 1998 Mean $^{\text {a }}$ | 262 | 256 | 263 | 238 | 246 |
| 1998 Mean-R | 261 | 254 | 263 | 234 | 248 |
| 2002 Mean | 264 | 268 | 275 | 252 | 250 |
| Gain $^{\text {c }}$ |  | 3 | 14 | 12 | 18 |

${ }^{\text {a }} 1998$ Mean is computed for students who were not provided with accommodations and whose race/ethnicity was based on student-reported data.
${ }^{\mathrm{b}} 1998$ Mean-R is computed for students who were provided with accommodations and whose race/ethnicity was based on school-reported data.
${ }^{\text {c }}$ Gain is 2002 Mean minus 1998 Mean-R.
SOURCE: U.S. Department of Education, Institute of Education Sciences, National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1998 and 2002 Reading Assessments.

Table 1.1 presents two sets of data for 1998. That year included two separate subsamples for a study of the impact of testing with accommodations. Original reports for the 1998 assessment were based on a subsample in which students were not allowed accommodations, consistent with practices in earlier assessments. At the same time, approximately half of the
students were tested under test administration rules that allowed accommodations. Since the 2002 assessment did allow accommodations, it is the 1998 accommodated sample that is most appropriate for comparisons to 2002 achievement; therefore, results for 1998 were recomputed (denoted "Mean-R" in Table 1.1) based on the subsample for which accommodations were allowed in 1998. Furthermore, the 2002 mean is based on information about the race/ethnicity supplied by the schools rather than each student's response to background questionnaire items. The 1998 mean was initially based on student response information. The recomputed 1998 Mean-R reflected this change to school-based race/ethnicity determination.

Several observations that help frame the issue of the Delaware gain can be made from the table. First, the table reveals that recomputing 1998 scores did change the results. For example, comparison of the "1998 Mean" row to the recomputed "1998 Mean-R" row indicates that the difference for the nation as a whole is small (i.e., Grade 4 decreased by two points from 215 to 213; Grade 8 decreased by one point from 262 to 261). On the other hand, the difference between the 1998 Mean and the 1998 Mean-R is larger for Delaware, particularly for Grade 4, with a 17-point difference for Hispanics (from 193 to 176). Thus, had Hispanic gains between 1998 and 2002 been computed on the original 1998 scores, the gain would still be large ( 212 minus 193, or 19 points), but not as large as the 36 -point gain ( 212 minus 176) being reported.

For Grade 8, the atypical result appears to be that Delaware Hispanics did not gain like the rest of Delaware. In addition, the difference between the 1998 Mean and the 1998 Mean-R was in the opposite direction from the differences in the rest of the table.

The definition of the potential problem posed to HumRRO had two parts:

- the difference between Delaware as a whole and the rest of the nation and,
- within Delaware, the difference between Hispanics and the other race/ethnicity categories.

In addition, the data in Table 1.1 suggest that the recomputation of scores for 1998 behaved differently for Delaware than the rest of the nation, again particularly for Hispanics. Therefore, questions about Delaware gains concern both the 2002 and 1998 assessments.

## HumRRO Analysis Goals

Because of the size of the Delaware gains, NCES commissioned four teams to investigate four aspects of the assessment:

- Delaware context
- Technical issues
- Exclusions
- Options for reporting

HumRRO was assigned seven specific technical questions and was asked to follow any additional data analysis leads that emerged.

- Question 1: Was there a problem with the sampling of Delaware students?
- Question 2: Was there a problem with the weighting [case weights] of the Delaware data?
- Question 3: Was there a problem with the design for assigning test booklets to students (BIB spiral)?
- Question 4: Was there a problem with the scoring (hand scoring or scanning) of the Delaware data?
- Question 5: Was scaling and equating performed correctly in Delaware?
- Question 6: Was there a problem with the coding of any data in Delaware?
- Question 7: Was there a breach in test security in Delaware?

One chapter is devoted to each of these issues. This paper is intended to be accessible to a nontechnical audience. Therefore, although some technical details are critical to the full explanation of our findings, numerous visual aids are included to help clarify the results.

## Methodology

The bulk of this effort involved independent analyses of data provided by NCES, Educational Testing Service (ETS), Westat, and Pearson Educational Measurement. In some cases, efforts were made to reproduce results exactly. In other instances, targeted analyses investigated related issues to produce confirmatory/divergent evidence. Some of the analyses address more than one of the above questions. Most of the analyses were focused on Delaware Grade 4 but some parallel analyses were also conducted for Grade 8.

## Foreshadowing the results

Unfortunately, HumRRO did not have all of the details of the two 1998 sampling conditions for 1998 until substantial analyses had been completed. As it turned out, the split sampling in 1998 was one of the keys for understanding Delaware gains, especially for Hispanics. On the other hand, the 1998 split sample does not appear to be the whole story, and our in-depth analysis of 2002 technical issues provides some confirmatory evidence about the Delaware gains in general.

This page intentionally left blank.

## CHAPTER 2: SAMPLING

## Question 1: Was there a problem with the sampling of Delaware students?

Because Delaware is a relatively small state, all schools were included in NAEP assessment in 1998 and 2002. However, the sampling of students within schools differed across the two assessment periods. In 1998, students were sampled, with target numbers within each school set for either one or two test administration sessions (i.e., 32 students or 64 students), depending on the size of the school. In 2002, all students were eligible for testing.

Two types of questions emerge, theoretical and actual. Theoretical questions concern sampling theory and the extent to which sampling, per se, could systematically increase or decrease achievement level estimates. For example, did the fact that all Delaware schools participated in the 2002 assessment provide any statistical advantage over other states where only a sample of schools participated? Similarly, did the fact that all Delaware students were targeted for testing in 2002 provide any statistical advantage over sampling of Delaware students in 1998 ? (For a more complete explanation of sampling theory, see Appendix A.)

The second question concerns the actual characteristics of the tested population. This question is complicated by the split sample for 1998. In addition, when 1998 scores were recomputed, there was one other change that most directly affects the score distribution estimates for the different race/ethnicity categories. For 2002, results are based on the information about race/ethnicity supplied by the schools rather than each student's responses to background questionnaire items. Original 1998 results were based on student response information. Recomputed 1998 score distributions included this change to school-based race/ethnicity determination.

## Theoretical Sampling Issues for Delaware Schools and Students in 2002

Dr. Chuck Cowan of Analytic Focus provided us an overview of theoretical issues pertaining to sampling procedures and described any differences that might be associated with testing in all schools rather than just a sample. Dr. Cowan has extensive experience, both at NCES and at the Bureau of the Census, working on thorny sampling issues and is also a consultant to the Department of Defense on sampling issues associated with the recent renorming of the Armed Services Vocational Aptitude Battery. Dr. Cowan's response, reproduced in Appendix A, indicates that testing more students in more schools would increase the overall accuracy of score estimates but would not affect estimates of average scores in any consistent way. On the other hand, it is well known that samples that are too small may provide inconsistent or unstable results, of particular concern for subgroups.

## Grade 4 Analyses

## Examination of the Data - Accounting for Students

HumRRO also compared estimated counts of Delaware Grade 4 students generated from the NAEP Grade 42002 Reading data file against the Delaware Department of Education
population statistics for Grade 5 in September 2002. ${ }^{1}$ These Grade 5 students would have been in Grade 4 during the 2002 testing window. The Delaware Department of Education reports 9,089 students began Grade 5 this year. The NAEP 2002 reading assessment sample includes 4,185 Delaware students. Slightly more than half of the students in Delaware participated in other assessments or special studies (e.g., mathematics). Thus, one cannot simply compare the number of students in the reading assessment to the state counts. Instead, a weighted count was computed, where each student tested also represented some (slightly more than one) of the other students who participated in a different assessment. The resulting count was 8,283 . Note that NAEP does not attempt to represent students who cannot be assessed. In Delaware, 9 percent of the students selected were excluded because they could not be assessed. Thus, the appropriate comparison count was 91 percent of the 9,089 , or 8,271 . Given transfers in and out of the state after NAEP testing and a few students who may have been retained in grade, the NAEP estimate is very close to the counts reported by Delaware. Consequently, it is reasonable to conclude that NAEP did account for essentially all of Delaware's Grade 4 students in the 2002 Reading assessment.

A school-by-school accounting for $4^{\text {th }}$ grade students was conducted in which student counts from the NAEP data file (linked with school name information provided by ETS) were matched to school population counts from the Delaware Web site. This analysis provided confirmatory evidence that a census test of $4^{\text {th }}$ grade students was conducted.

## Examination of the Data - Accounting for Students by Subsample

By design, the 1998 NAEP Reading assessment divided all sampled students equally into two distinct samples. For historical reasons, these samples are labeled S2 and S3. (An earlier study also had a sample, labeled S1, for which a more limited inclusion policy was used. The impact of the difference in inclusion policy was found to be minimal, so this condition was dropped from the 1998 study.) Within each of the two 1998 samples, students were subdivided into three samples on the basis of information about their status with respect to disabilities (SD) and limited English proficiency (LEP) and whether they were administered the test. As a result, students are identified according to the schema in Table 2.1.

[^0]SOURCE: U.S. Department of Education, Institute of Education Sciences, National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1998 and 2002 Reading Assessments.

Table 2.1 shows the two samples - one for which accommodations were not allowed (S2) and one for which they were (S3). Within each of those samples are three subsamples of

[^1]students: (A) students who were neither SD nor LEP and consequently took the assessment in a regular session, (B) students who were either SD or LEP and could be assessed without accommodations or with the accommodations offered as dictated by their main sample designation, and (C) SD and LEP students who could not be assessed because they required accommodations not available in their main sampling condition. The S2 and S3 subsamples were determined at the school level, that is, schools were either in the S2 sample or the S3 sample, and so the accommodation policy was the same for all students within any school.

State scores for 1998 were originally reported using students from the cells labeled A2, A3, and B2 (see Table 2.2). To make comparisons to 2002 state data, 1998 data were recomputed using students from cells A2, A3, and B3 (see Table 2.3). Thus, the B2 students tested with no accommodations allowed were replaced by the B3 students who were tested with allowed accommodations, as needed. The set of students that include A2, A3, and B2 is labeled reporting sample R2. The set of students that include A2, A3, and B3 is labeled reporting sample R3.

The following tables illustrate the effects of the accommodation policy on samples for Delaware and all states other than Delaware. (The percentages indicate percentage within the column.) The sample size data in Table 2.4 reveal that in states other than Delaware the policy did not shift the proportions between SD/LEP students who were assessed and SD/LEP students who were not assessed (i.e., excluded). On the other hand, for the S 3 sample compared to the S 2 for Delaware, the SD/LEP assessed rose from 9 percent to 14 percent, while the SD/LEP excluded students dropped from 8 percent to 1 percent. The ratio of SD/LEP students assessed to
those excluded in Delaware is 14 to 1 , contrasting markedly not only with non-Delaware states, but also to the Delaware S2 sample.

Having only 1 percent of the Delaware S3 sample excluded seems more consistent with a policy of testing all SD/LEP students unless they are in the severely disabled population, which tends to be $1-2$ percent of the general population. Certainly, this change in exclusion rate raises a question about the test exclusion practices implemented in Delaware's S3 schools versus S2 schools. It also raises a concern about comparing Delaware's exclusion rates in 2002 to those in 1998, because two distinct sets of rates appear to have been operating in 1998.

Table 2.5 examines sample sizes for Hispanics. Because NCES has shifted to defining race by school report as a more accurate indicator, only school-reported race is included. Similar to the above tables, the proportion of SD/LEP and excluded Hispanic students are roughly equal for the S2 and S3 samples for states other than Delaware but are markedly different within Delaware. Following the pattern of the state as a whole, few Hispanic students in the S3 sample were excluded. Furthermore, the proportion of non-SD/LEP students was lower in the S 3 sample than in the S 2 sample. The table also shows that the actual Hispanic sample sizes are small.

Table 2.6 includes some test administration information about the SD/LEP assessed Hispanic students. For both Delaware and non-Delaware states, the data indicate that only about 18 percent of the SD/LEP tested students actually received accommodations, that is, the shift from the S 2 to the S 3 sample is operative for a relatively small number of students. In Delaware's S3 sample, only five students took the Reading assessment with an accommodation.

[^2]Clearly, there is a concern here about the meaning of the sampling change when it involves so few students. On the other hand, perhaps the change has little or no meaning for estimating Delaware scores. The following tables examine test performance data.

## Examination of the Data - Sampling and Score Means

The impact of the changes in testing accommodations and ethnic determination for Delaware Hispanics is evidenced in Table 2.7. The effects of the change in racial/ethnic
determination on average scores are inconsistent. On the other hand, allowing accommodations appears to reduce scores whichever way race is determined. Using school-reported race, there is a 26-point difference between the accommodated (S3) and non-accommodated (S2) samples. Since the purported Delaware Hispanic gain for 1998 to 2002 is 36 scale points, a large part of that gain may be related to the accommodation testing conditions in Delaware.

Table 2.7. Grade 41998 Delaware Hispanic Scale Scores Computed Under Four Conditions

| Accommodations <br> (Original Score, R2 Sample) | 176 <br> allowed | 184 <br> $(\mathrm{n}=184)$ |

SOURCE: U.S. Department of Education, Institute of Education Sciences, National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1998 and 2002 Reading Assessments.

Table 2.8 shows unweighted performance means in order to more directly examine the students who actually took the test. Two different mean scores are presented-one based on the R2 sample (the A2, A3, and B2 students, labeled Original) and one based on the R3 sample (the A2, A3, and B3 students, labeled Recomputed). For states other than Delaware, mean plausible values changed based on the sample change, but only by 1 scale-score point. On the other hand, larger changes are apparent for Delaware, particularly for SD/LEP assessed students. The shift in testing with accommodations had a much larger impact in Delaware than in the rest of the nation as a whole. In fact, the shift in accommodation policy (which again was operative for only 5 Hispanic students), appears to reduce the SD/LEP portion of the Hispanic sample mean by 43 scale points. If this change is coupled with the large change in Hispanic exclusion rates for the S3 sample, the data suggest that the exclusion rule applied to the Delaware S2 sample was not applied to the Delaware S3 sample. It appears as if students who would have been excluded in the S2 sample were tested in the S3 sample. As a result, the means for tested SD/LEP dropped noticeably. Obviously, this would have an impact on the apparent gains for Hispanic students between 1998 and 2002.

For verification of the plausible value results, test performance was also examined using student raw item response data (see Table 2.9). Since students take test forms of different lengths and with different mixes of multiple-choice and open-ended items, maximum possible points are not constant across students. Therefore, raw score performance was calculated as the proportion of total possible points that a student earned, where total points varied by test form. Again, the difference between testing with accommodations allowed versus without accommodations allowed was small in states other than Delaware. In Delaware the difference is more apparent.

## Grade 8 Analyses

Tables 2.10 and 2.11 present comparable information for Grade 8 students. These tables show that, similar to Grade 4, exclusion rates in Delaware appear inconsistent for the S3 sample of the Delaware students overall and for Hispanic students. For Delaware Grade 8 Hispanics, a large change is also seen in the proportion of students in the non-SD/LEP group-from 57 percent to 88 percent. Like Grade 4, it is apparent that the actual number of tested Hispanic
students in Delaware is small. None of the Grade 8 Hispanic students were excluded from testing.

Table 2.12 shows that, as with Grade 4, only about 79 percent of the SD/LEP Hispanic students in states other than Delaware took the assessment with accommodations. However, there were only 3 SD/LEP Hispanics in Grade 8 in the Delaware S3 sample, and none of them used an accommodation. Clearly, one is dealing with very small numbers when considering the effects of the accommodation policy on Delaware Hispanics.

## Delaware Sampling Conclusions

There were no problems found with the sampling of Delaware students. This was investigated in two ways. First, an expert sampling statistician reviewed the 2002 sampling for Delaware and concluded that there were no problems; inclusion of all Delaware schools led to increased accuracy and did not in and of itself increase or decrease score estimates. Second, the weighted count of students from the NAEP sample was closely comparable to enrollment counts from the Delaware Department of Education.

On the other hand, close inspection of Delaware data by subsample, race/ethnicity, and SD/LEP category revealed some apparent inconsistency. One might speculate that there was a shift in exclusion policy between the S2 and S3 sample but that is only speculation. On the other hand, there were small sample sizes in the Hispanic categories. Recognizing the small sample sizes for Hispanics, Table 2.16 repeats the means and gains for Delaware Hispanics for Grades 4 and 8 , this time with standard error and confidence interval data. The lower and upper confidence bounds represent a 95 -percent confidence level, that is, one can state with 95 -percent certainty that the true gain fell within this range. The confidence interval for the Grade 4 Reading gain, for example, ranges from 13 to 59 - a very wide range. Note that the Grade 4 confidence interval does not extend down to zero; therefore, one can conclude with confidence that there was, indeed, an increase in performance between the two years. This is consistent with NCES analyses that show a statistically significant gain for Delaware Hispanics. ${ }^{2}$ Thus, the data suggest that Delaware Grade 4 Hispanics did gain, but they also indicate that the confidence interval is very wide due to small sample sizes and large standard error.

SOURCE: U.S. Department of Education, Institute of Education Sciences, National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1998 and 2002 Reading Assessments.

Standard errors for the means and gains, plus the 95-percent confidence interval for the gains, are reported for Delaware as a whole in Table 2.17. As expected, because of the larger sample sizes standard errors of the gains for all Delaware students are smaller (less than 2) and the confidence intervals are narrower than for the Hispanic analyses presented in Table 2.16. Table 2.17 reveals that the 95 -percent confidence bands are above 0 for both Grade 4 and Grade 8, indicating that Delaware student performance did improve in 2002, relative to 1998. Indeed, for each grade the lower bound of the confidence interval is above 10 .

## CHAPTER 3: WEIGHTING

## Question 2: Was there a problem with the weighting [case weights] of the Delaware data?

We detected no problem with the case weights of the Delaware data. Delaware is one of the few states where every school is sampled, and nearly all of the students in the targeted grades were tested in 2002. Consequently, the sampling weight assigned to each school should be 1.0. This was, in fact, the case for the 2002 data file.

Further, the student weights should all be the same except for minor reassignment of the weights assigned to students who were absent and not tested. The review of the 2002 student weights found them to be entirely consistent with what is known about the sampling design and results.

Finally, as reported in Chapter 2, we compared the weighted counts from the NAEP reading data file to Delaware Department of Education population statistics. Given transfers in and out of the state after NAEP testing and a few students who may have been retained in grade, the NAEP estimate is close to the counts reported by Delaware. Consequently, one can conclude that NAEP did account for all of Delaware's Grade 4 students in the 2002 Reading assessment.

## Delaware Weighting Conclusions

No problems were found with the weighting of Delaware data. As expected, the census testing of all schools and all students within those schools in 2002 yielded appropriate weights.

This page intentionally left blank.

## CHAPTER 4: BIB SPIRAL

## Question 3: Was there a problem with the design for assigning test booklets to students (BIB spiral)?

No problem with the BIB (balanced incomplete block) spiral was detected. Grade 4 testing used 32 books and Grade 8 testing used 37 books. The distribution of Grade 4 books and items was even across the state. About 3 percent of participating students received each of the 32 books. Each item was administered to approximately 950 to 1,000 students. Books were evenly distributed within schools to the extent possible (i.e., with 32 books it was not possible to have exactly equal use of books within schools other than size 32,64 , etc.).

Delaware Grade 8 test book distribution also is consistent with distribution across the nation as a whole. Across all states, 18.25 percent of Grade 8 students received one particular test book (out of 37 test books). ${ }^{3}$ In Delaware, 18.23 percent of $8^{\text {th }}$ graders received that version. Items, on the other hand, were distributed about equally, as expected. Because the predominant use of one book occurs across the nation, this, by itself, should not explain the large Delaware gain.

Tables 4.1 and 4.2 present the distribution of books within Delaware for Grades 4 and 8, respectively. For each test book, the percentage of students within the state who were assigned that book is indicated. In addition, a school-by-school analysis yielded the minimum percentage of students within a school assigned to a given book. A minimum percentage of zero is expected in schools testing fewer than 32 students because at least one book could not be assigned. The maximum percentage of students within a school assigned to each book is also provided. Had any of these percentages been high, that finding would have been a red flag for potential BIB spiraling problems; no unusual percentages were found.

## Delaware BIB Spiraling Conclusions

No problems with the distribution of test books were found, either within any school or across schools in the state. The distribution of books in Delaware schools closely matched the distribution in other states.

## CHAPTER 5: SCORING

## Question 4: Was there a problem with the scoring (hand scoring or scanning) of the Delaware data?

According to Pearson, all responses to any single open-ended item are scored at the same time in the same scoring location with student responses from different states randomly distributed during the scoring process. Therefore, systematic bias in scoring that would cause Delaware scores to be too high seems unlikely. However, HumRRO produced a variety of scatterplot diagrams relating item performance for Delaware in comparison with the rest of the nation. These plots should show a reasonably tight, elliptically-slanted pattern indicative of a strong correlation between item performance (and its inverse, item difficulty) in Delaware and the rest of the nation. Items or sets of items that do not fall in the diagonal pattern may signal unexpected scoring problems, coding problems, breaches of security, or exposure problems.

Figures 5.1 through 5.4, on the following pages, show the relationship between item performance in Delaware and the rest of the nation for Grade 4 Reading for all students and by race/ethnicity. Multiple-choice item performance is simply the p-value, or the proportion of students who answered the item correctly. To put open-ended performance on an analogous 0 -to- 1 scale, item mean performance was divided by total possible points. Items are labeled by block; the blocks correspond to different reading passages.

Figure 5.1 shows tightly clustered items, as expected, and reveals no apparent pattern to the arrangement of the letters by passage in these plots. The pattern is less tightly clustered for Hispanic students (Figure 5.2), as would be expected because of the smaller sample size. The cluster appears more tightly packed for Blacks (Figure 5.3) and even tighter for Whites (Figure 5.4), which, again, is consistent with larger sample sizes.

Figures 5.5 through 5.8 are analogous plots for Grade 8. Again, Figure 5.5, showing all students, is tightly clustered, with no apparent pattern to blocks of items. None of the separate plots of each racial/ethnic category (Figures 5.6,5.7, and 5.8) reveals anything unexpected.

Next, changes in item performance from 1998 to 2002 for Delaware versus non-Delaware states were plotted for a more sensitive view of potential breaches in security. For example, unexpected gains associated with particular item passages could signal teaching to that particular passage. As expected, the plots are more scattered and indicate that Delaware tends to have large gains, but the changes do not appear to be associated with particular blocks of items. Figures 5.9 though 5.12 present the data for all students and each ethnicity category for Grade 4. Figures 5.13 through 5.16 present the data for Grade 8 .

HumRRO received information from NCES that Delaware's state test was patterned after NAEP and included both multiple-choice and open-ended items. HumRRO's experience in two other states that also use both types of items prompted speculation that Delaware students may receive special instruction to facilitate their performance on the open-ended items. Therefore, all the plots presented below were repeated, this time with the items labeled by "M" for multiplechoice or "O" for open-ended. This exploration proved to be informative.

Figures 5.17 though 5.20 show Grade 4 relationships between item performance for Delaware compared to the rest of the nation. Looking closely at Figure 5.17, the Os (encircled separately from the Ms) do appear to perform differently. First, the ellipse enclosing the openended items is lower and to the left of the ellipse for the multiple-choice items, indicating that the (adjusted) mean performance for the open-ended items is lower than the p-values for the multiple-choice items. This difference may or may not be very important since the lower bound for average performance for multiple-choice items is about .25 because of the potential for answering a multiple-choice item correctly by guessing.

On the other hand, the open-ended items appear to be on the top side on the overall pattern, suggesting that Delaware students did a little better on the open-ended items than on the multiple-choice items, in comparison to non-Delaware students. Looking at the center of each ellipse as a way of portraying average performance also shows that Delaware students were performing higher than non-Delaware students on both open-ended and multiple-choice items. Figures 5.18, 5.19, and 5.20 show that the same is true for Hispanic, Black, and White students.

Figures 5.21 through 5.24 show multiple-choice and open-ended performance for Grade 8. The difference between multiple-choice and open-ended items seen in Grade 4 is not apparent in Grade 8.

Finally, we turn to changes in item performance labeled by type of item, presented in Figures 5.25 through 5.28 for Grade 4, and Figures 5.29 through 5.32 for Grade 8. Figure 5.25, the first of these figures, reveals an important finding. It shows that while the nation gained only on multiple-choice items, Delaware improved on both open-ended and multiple-choice items. Therefore, an important part of the difference in score gains between Delaware and the rest of the nation is due to Delaware's gains for open-ended items relative to the rest of the states.

For Grade 8 (see Figure 5.29), the separation of open-ended and multiple-choice item gains is not as dramatic as for Grade 4. However, it does appear that both Grade 8 and Grade 4 improved on multiple-choice items in both Delaware and the rest of the nation, although Delaware appears to have improved a little more. For the open-ended items, Delaware Grade 8 students improved on more of the items then the rest of the nation.

## Delaware Scoring Conclusions

We found no problem in the scoring of Delaware data. Open-ended responses from Delaware students were mixed in with responses from other states in the scoring process; there was no differential treatment. Similar treatment also was found for the scanning and scoring of responses to the multiple-choice questions. Delaware students did not have unusual gains on any open-ended or multiple-choice items or passages, which might have indicated a problem with the scoring or coding, or a breach of security or exposure for any item or passage.

However, Delaware students did show slightly larger gains between 1998 and 2002 on the open-ended items relative to the rest of the nation. The improvements in open-ended items contribute to the overall gains seen by Delaware. This difference might be due to a greater emphasis on writing, which might affect success in answering open-ended items - an emphasis caused by teacher responses to the design of the state's own assessment. State contextual issues, such as state assessment configuration, are more thoroughly reviewed by one of the other investigation teams.

## CHAPTER 6: SCALING AND EQUATING

## Question 5: Was scaling and equating performed correctly in Delaware?

Student scale score estimates are rooted in a sophisticated combination of item response theory (IRT) and sampling theory. IRT item parameters are used in the estimation of state score distributions and in the estimation of student plausible score values. Item parameters define the relationship between the item and the ability trait being measured. Because of the difference in results of open-ended items between Delaware and the rest of the states, one concern is whether the relationship between items and estimated ability is different for Delaware. Several analyses were conducted to look at patterns of item performance and scale scores for Delaware and the rest of the nation. In the end, a single summary figure provided a reasonable view of whether scaling and equating as applied to Delaware students was equivalent to other states.

Figure 6.1 plots the relationship between raw scores and IRT ability estimates for Grade 4 reading in 2002. Since students take different forms of the test with different numbers of possible points, HumRRO calculated raw scores for each student as the number of points earned divided by the student's possible number of points. Thus, raw scores were computed as a proportion of points earned. To avoid multiple analyses, each student's average plausible value was used as the ability estimate. The average plausible values were rounded to the nearest .20 . Then, for each possible average plausible value that was represented by at least 5 students, average proportion of points earned was computed. Average proportion of points earned was computed separately for Delaware and non-Delaware states that participated in 1998. The resulting plot is essentially an IRT "test characteristic curve" captured from the data. Figure 6.1 shows non-Delaware states that participated in 1998 as a series of 0s. Only where Delaware differs does the symbol " 1 " appear. The curve for Delaware is essentially the same as the curves for the other states, indicating that IRT scaling and equating results must be as applicable to Delaware as to the rest of the nation. The parallel plot for Grade 8 is presented in Figure 6.2.

For another check on Delaware score means, HumRRO obtained 2001 state test data for each school in Delaware from the American Institutes for Research (AIR). HumRRO matched these data, by school, to school means that we calculated using unweighted plausible values for NAEP. Delaware's state reading test includes Grades 3, 5, and 8. Therefore, NAEP Grade 4 data were matched with state data for both Grades 3 and 5 (see Figures 6.3 and 6.4). Figure 6.5 presents the Grade 8 match. In each case, a positive relationship between NAEP scores and Delaware state test scores is highlighted by the ovals drawn on the figures. The plots add to the evidence that there were no technical errors in the processing of NAEP data for 2002.

Finally, because results for Hispanics indicated particularly large gains in the $4^{\text {th }}$ grade, HumRRO independently replicated computation of 1998 and 2002 mean scores for Hispanics from plausible values and sampling weights provided in the NAEP data files. After ascertaining the appropriate data to use (e.g. school-provided race was augmented by student-reported race when school-provided race was missing), HumRRO was able to exactly reproduce the mean scores for Delaware Hispanics for 2002 produced by ETS.

## Delaware Scaling and Equating Conclusions

No scaling or equating problems were identified in Delaware. We performed several analyses that examined patterns of item performance and scale scores for Delaware and the rest of the nation. As reported in the previous chapter, the relationship between scores on the individual items and scale score estimates was the same for Delaware as for other states. As shown by data presented in this chapter, Delaware results demonstrate the same relationship between scale scores and overall item mean performance as do test results for the rest of the nation. Finally, NAEP means, by school, were consistent with school means on Delaware's state test.

## CHAPTER 7: CODING

## Question 6: Was there a problem with the coding of any data in Delaware?

The key question here is: Were background information and student responses to the questions coded correctly in the data files used for analyses? This is a particularly relevant question in light of the problem with the coding of Title 1 status in Delaware that was identified previously. The focus in this chapter was detection of gross coding errors, such as reversing codes for two demographic groups. HumRRO checked electronic filing procedures for consistency with other states and with known values, such as the proportion of students in different racial and ethnic categories.

Test results for Hispanics indicated particularly large gains in the $4^{\text {th }}$ grade. This led to a specific investigation into whether the students who were coded as Hispanic were really Hispanic.

Background. Race/ethnicity results for 2002 are based on demographic information supplied by the schools, rather than on student responses to background questions. For $4^{\text {th }}$ graders this was a particularly good idea given research conducted by the American Institutes for Research (AIR) showing that Grade 4 students have difficulty understanding the race/ethnicity questions. On the other hand, the schools, districts, and states supplied information electronically, through a system known as "e-filing." There had previously been a problem in Delaware with the e-filing of Title 1 information. ${ }^{4}$ Thus, it was reasonable to ask whether the race/ethnicity information for Delaware students was correct.

Method. For the state as a whole, the distribution of race/ethnicity based on the school-report variable (SRACE) matched information from other sources reasonably well. This result did not completely answer the question, however, as it was possible that codes for two similar-sized groups might have been switched for individual schools or for the state as a whole. For the $4^{\text {th }}$ grade cohort, roughly 57 percent were White, 33 percent were Black, 7 percent were Hispanic and 3 percent were Asian as reported by the schools. Switching the codes for Hispanics and Asians at some schools would lead to inaccurate score estimates for both groups.

Table 7.1 presents the relationship between student-reported race and school-reported race. Based on previous information, the pattern of relationships is as expected. Students in Grade 4 tend to over-report themselves as being Hispanic. Table 7.2 shows the relationship for Grade 8 and the expectation that Grade 8 students understand the questions, making their reports more consistent with school data.

While these data show that students and schools are not in perfect agreement, they also show that there is enough agreement to use the student data to verify whether racial/ethnic coding from the schools had (or had not) inadvertently mixed up the coding scheme. For example, if schoolcoded information was correctly translated into the NAEP database, then each school should show agreement rates similar to those in Tables 7.1 and 7.2.

For each school, HumRRO looked at each racial/ethnic category reported by the school. The frequency with which students placed themselves in a category was compared to the frequency with which students in the school-based grouping reported themselves in each category. Every instance where another category was more frequently selected for any of the school report groups was flagged. In all, 71 schools had non-discrepant results and 15 schools were flagged as having potentially discrepant results, in all cases for only one racial category. Table 7.3 summarizes discrepancies found for these 15 cases. In 12 cases, a single student who was the only student in a school category caused the discrepancy and who reported a different category, that is, two of the other three cases did involve students coded by the school as Hispanic. In all, the number of discrepancies was very small and each discrepancy involved only one or two students.

For $8^{\text {th }}$ grade students, race/ethnicity code agreement at the school level was higher than for $4^{\text {th }}$ grade students. As shown in Table 7.4, there were only seven schools for which there was a school race category in which students selected some other category more frequently. Again, all instances involved only a very small number of students and, in this case, all of the differences involved the American Indian category for which sample sizes were too small to support reporting.

## Delaware Coding Conclusions

No coding problems were found. Racial/ethnic codes used for reporting were reviewed because of large gains for one category of students. Agreement between race/ethnicity data supplied by students and by schools was sufficient to rule out coding errors, overall and for each school.

## CHAPTER 8: TEST SECURITY

## Question 7: Was there a breach in test security in Delaware?

Chapter 5 has already presented comparisons between Delaware and the rest of the nation for item-level performance and shown no patterns that suggest statewide breach of security. In this chapter, we investigated the question by looking for schools whose 2002 data were inconsistent with their 1998 data. To test this, we created scatter-plot diagrams of school-level gains on item points versus gains on scale scores. The plots provide two ways (via scale score and raw scores) for identifying schools with particularly high gains. For any suspect school, the gains on each item were examined, looking for unusual gains on items associated with a common reading passage.

The matching of schools across years was somewhat surprising, particularly for Grade 4. Although all Delaware schools were tested in both 1998 and 2002, 65 Grade 4 schools were tested in 1998 and 86 in 2002, a net increase of 21 schools. Fifty-nine of these schools were positively matched using NCES school codes, but several other 1998 schools may not have been matched, due to changes in their codes. Because of the differences, HumRRO conducted an accounting of the 1998 schools. Delaware reported 87 schools in 1998, 22 more than the 65 in the 1998 NAEP sample. A by-name list of these schools revealed them to be special schools, the majority of which were "Intensive Learning Centers," which would not be sampled by NAEP. Gains for the 59 matched Grade 4 schools appear in Figure 8.1.

To help identify "unusual" schools, a parallel scatter plot was constructed for the 805 schools outside of Delaware that participated in 1998 as well as in 2002. The range of gains and losses for Delaware (Figure 8.1) and non-Delaware schools (Figure 8.2) is similar. Gains as high as 30 and 40 scale score points were not uncommon among the non-Delaware schools. Of course, item exposure could exist in any of these Delaware or non-Delaware schools. The data show that Delaware gains are within the range of gains for the rest of the nation.

The item-level changes for the two schools highlighted (bold and underlined) in Figure 8.1 were also examined closely. The top right school showed some high gains (greater than .3) for items in two passages. The lower, center school, was examined because it was well outside of the pattern of the other schools. This school showed both large gains and large losses on various items throughout the test. The item-level gain data for the remaining schools were also scanned, but did not reveal any suspect patterns (i.e., gains on a passage that were high and/or discrepant from the rest of the item-level gains of the school).

SOURCE: U.S. Department of Education, Institute of Education Sciences, National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1998 and 2002 Reading Assessments.

Figures 8.3 and 8.4 repeat the by-school gain analysis for Grade 8 schools. Of the 28 Grade 8 schools tested in 1998 and the 35 tested in 2002, 25 schools were matched. The pattern is more scattered, and the highest gains are not as large as those for Grade 4. On the other hand, the gains for Delaware schools all fall within the range of the gains for the rest of the nation.

The one school (bold and underlined in Figure 8.3) with a loss in scale score and a gain in raw score showed, in general, losses and small gains on most items, but had large gains (. 39 to .55) on about a half dozen items clustered in two or three passages. However, none of the passages showed gains on a majority of items in the passage. While there were passages that contained two or three items with large gains, those passages also had items with small gains and losses in performance.

## Delaware Security Conclusions

No indications of test security breaches were identified. Gains on individual items and on blocks of items associated with a common passage were consistent with gains on these items and blocks for the nation as a whole. For the few individual schools that did not show unusual gain patterns overall, there was no consistent pattern to item-level gains.

## CHAPTER 9: CONCLUSIONS

HumRRO investigated the seven specific questions that were identified by NCES. Our findings supported the sampling, weighting, BIB spiral, scoring, scaling and equating, and test security conclusions drawn by NAEP Alliance contractors. However, we detected one related problem that would justify caution in interpretation of the 2002 estimates of Hispanic gains.

Prior to calculation of the gains between 2002 and 1998, the 1998 results were recomputed with two changes:

- Contractors used an alternate sample of students, who were provided accommodations similar to those provided in 2002, in making the recomputation.
- Contractors defined race categories from codes supplied by schools rather than by students. Consequences of these changes affected the sample size, mean, standard error of the mean, and exclusion rate.

Among Delaware fourth graders, the recomputation lowered the 1998 Hispanic mean from 193 to 176. Sample size for Hispanics decreased from 198 to 101. The standard error of the Hispanic mean increased from 4 to 12 scale points. The 1998 exclusion rate for Hispanics dropped from 6 percent to 3 percent. Among Delaware eighth graders, the recomputation raised the 1998 Hispanic mean from 246 to 248. Sample size for Hispanics decreased from 78 to 64. The standard error of the Hispanic mean decreased slightly from 9 to 8 scale points. The 1998 exclusion rate for Hispanics dropped from 12 percent to 0 percent.

We recommend that the Delaware Hispanic gains from 1998 to 2002 be flagged in some way to indicate that the amount of gain may be distorted by small sample size, high standard errors, and large changes in exclusion rates.

In summary, based on an extensive analysis of 2002 Delaware reading assessment data and on data from the 1998 assessment used as the basis for computing gains in 2002, we did not find any methodological or technical procedural problems that could have affected the 2002 results for Delaware. We did note that revised 1998 score estimates for $4^{\text {th }}$ grade Hispanic students had large standard errors. We recommend that estimated gains for $4^{\text {th }}$ grade Hispanic students computed from these revised estimates be flagged with appropriate explanatory text.

## APPENDIX A: OUTSIDE REVIEW OF NAEP SAMPLING PROCEDURES

Chapter 2 indicates that Delaware is unique in two respects regarding the selection of students for NAEP. First, all eligible schools are included for both 1998 and 2002, making Delaware different from the remaining states for which schools are sampled. In addition, the same contrast between full census and sampling occurred within Delaware with regard to the selection of students within schools. In 1998, students were sampled. In 2002, all students were tested. The effects of this difference in selection methodology-sampling a given population or attempting to test all of that same population-are addressed below.

## Samples versus Censuses

Consider whether a sample yields a different result from a census. If sampling is considered part of a continuum up to and including a census as a 100 percent sample, then there is no reason to believe that a sample would yield a result in any way different than a census. If the operations conducted to collect the information are exactly the same, regardless of the size of the sample (up to and including 100 percent) then the values obtained from individual respondents would be the same regardless of how large the sample is.

The only issue that remains is how the results from the sample are projected to the population. The simplest case is a census: each response represents only itself and no other response from the population being studied. The responses are simply aggregated and averaged.

The next simplest case is a simple random sample. Suppose that only half of the students in an area are surveyed to measure educational progress. Each student in the sample represents one other student in the population who was not contacted. However, the process is the same in terms of using the information from the survey. The answers are aggregated and averaged. The average from the sample represents the best estimate of the average in the population. There is no reason to believe that this process would yield a value different from the population value being estimated, except by chance. And in this process, we are equally likely to be slightly high or slightly low in estimating the average educational progress for the group. Typically, the larger the sample, the smaller the chance (or error) variance in population values.

We can make these scenarios increasingly complex. But for each level of complexity added, the process of projection from the sample to the population is essentially the same. We add the results from the sample and average them. If some groups in the population have greater proportional representation than others in the population, we weight the results together so that contributions to the overall average are in proportion to their proper weight in the population.

Are there ways in which sample results might differ from census results? Yes - it is possible for sample results to differ from census results for reasons that are not statistical. Attempting to contact all of the population can be a relatively expensive undertaking. If the researcher is not cautious in how expenditures are made, the quality of data in a census may deteriorate relative to the data that could come from a sample. For a fixed budget, if more resources are channeled into frenetically contacting schools and students and fewer resources are available to collect the data, then the quality of the data may suffer in the census. If a proper balance is maintained in contacting schools and students and the collection of data from these
sources, then there is no reason to believe that the results would differ whether 50 percent, 80 percent, or 100 percent of the students are interviewed.

Sample and census results may differ for one other reason, related to the previous discussion. Those people who are most difficult to find and contact are sometimes different in their characteristics from the balance of the population. For example, students with the worst attendance records will be the students most difficult to contact. These students are also likely to be the ones to show the least progress when measuring educational attainment. If the survey only contacts students on one day and no attempts are made to follow up students who were absent, then an upward bias might result in the survey. A strong follow-up program would alleviate this problem, as the resources expended for the follow-up in the sample would be similar to the types of resources necessary to complete a census. There would be a proportional representation of students who are likely to complete school and those likely to drop out.

The same argument can be made at the local education agency (LEA) and school level. A census of these would naturally make every effort to include every LEA in a state, or every school in an LEA. If a sample is selected, the same efforts need to be made to include the sampled LEAs or the sampled schools. With a properly designed sample, LEAs or schools that would decline to be in the census would be proportionally represented in the sample. Put another way, if 10 percent of the schools in a census of schools would decline to participate, we would expect that on average 10 percent of the schools selected for the sample would decline to participate. If the same resources are put into converting refusals in the sample or the census, there is no reason to believe that the census would be any better or any worse than the sample.

## Summary

There is no reason to believe that using a sample in any way produces a result that would be different from the result that would be obtained by conducting a census. The only difference between the sample estimate and the result from the census is that there is some uncertainty associated with the sample estimate and how close it may be to the true value being estimated. With a sufficiently large sample, proper design, and the same efforts at execution, this variance from the true value will be negligible and not material to any decision-making process using the survey results. Conversely, if sample sizes are too small, error variance may increase so much that the data are not useable.

## Listing of NCES Working Papers to Date

Working papers can be downloaded as PDF files from the NCES Electronic Catalog (http://nces.ed.gov/pubsearch/). You can also contact Sheilah Jupiter at (202) 502-7363 (sheilah.jupiter@ed.gov) if you are interested in any of the following papers.
