Number 213 • April 30, 1992

<u>Advance</u> Data

From Vital and Health Statistics of the National Center for Health Statistics

National Ambulatory Medical Care Survey: 1990 Summary

by Susan M. Schappert, M.A., Division of Health Care Statistics

During the 12-month period from January 1990 through December 1990, an estimated 704.6 million visits were made to nonfederally employed, office-based physicians in the United States, or about 2.9 visits per person. This rate is not statistically different from office visit rates observed since 1975 (1,2).

This report presents data highlights from the 1990 National Ambulatory Medical Care Survey (NAMCS), a national probability sample survey conducted by the Division of Health Care Statistics of the National Center for Health Statistics, Centers for Disease Control. The data summarized here should be considered provisional because final editing may result in minor changes in the estimates. Statistics are presented on patient, physician, and visit characteristics.

Because the estimates presented in this report are based on a sample rather than on the entire universe of office visits, they are subject to sampling variability. The technical notes found at the end of this report give a brief overview of the sample design used in the 1990 NAMCS, an explanation of sampling errors, and guidelines for judging the precision of the estimates.

The Patient Record is used by physicians participating in the NAMCS to record information about their patients' office visits. This form is reproduced in figure 1 and is intended to serve as a reference for readers as they review the survey findings presented in this document.

The physician sample for the NAMCS was selected with the cooperation of the American Medical Association and the American Osteopathic Association. Their contribution to this effort is gratefully acknowledged.

Data highlights

Patient characteristics

Office visits by patient's age, sex, and race are shown in table 1. Females made about 60.6 percent of all office visits during 1990, and accounted for a higher percentage of visits than males in all age categories except the youngest (under 15 years). Females also had significantly higher visit rates than males did in each age category with the exception of the youngest group (under 15 years) and the two oldest groups (65–74 years and 75 years and over).

Visit rates tended to increase with age after the age of 24. Persons aged 65–74 years and 75 years and over had the highest visit rates of all age categories; rates for these two groups did not differ significantly from each other. The pattern, however, was found to be slightly different for males and females. Among males, rates increased with each age group after the age of 44, with males aged 75 years and over having the highest rate of 5.4 visits per person.

Females, despite a general trend toward increasing visit rates with age after the age of 24, showed no statistical difference in the rates for females aged 25-44 years compared with those aged 45-64 years, or in the rates for females aged 65-74 years compared with those aged 75 years and over.

White persons made approximately 84.8 percent of all

Figure 1. Patient record

office visits during 1990, with black persons and Asian/Pacific Islanders accounting for about 8.8 percent and 3.0 percent, respectively. These percentages were not statistically different from those reported in 1989. While visit rates were found to be significantly higher for white persons than for black persons overall, these differences were noted only among the younger age groups (less than 15 years, 15-24 years, and 25-44 years). No significant differences were found between the white population and the black population in the 45-64 years, 65-74 years, and 75 years and over age groups. Visit rates by age, sex, and race were not statistically different from rates observed in the 1989 NAMCS.

Physician characteristics

Table 2 shows the distribution of office visits according to physician specialty for the 13 most visited specialties. The largest share of visits (29.8 percent) was made to physicians specializing in general and

family practice (GFP); this percentage is not significantly different from the percentage of GFP visits in 1989. Provisional data concerning other physician specialties for 1990 indicates slight increases in the proportion of visits made to internists, psychiatrists, and ophthalmologists compared with 1989 figures, as well as slight decreases in the proportion of visits made to pediatricians, dermatologists, and general surgeons. However, 1990 visit rates to each of the 13 specialties

were not found to differ significantly from 1989 visit rates (3).

Visit characteristics

Referral status and prior-visit status

Only 5.5 percent of office visits in 1990 were made as the result of a referral from another physician. The

overwhelming majority of office visits (83.8 percent) were made by patients who had seen the physician on a previous occasion, and more than half (61.2 percent) of all visits were made by persons who were returning to the physician for care of a previously treated problem (table 3). Only 16.2 percent of visits were made by new patients. These percentages are not significantly different from those reported in 1989.

Expected source of payment

Expected sources of payment were most often commercial insurance (36.1 percent of visits) and "self-pay" (30.4 percent of visits) (figure 2). (The self-pay category includes the patient's contribution towards "co-payments" and "deductibles.") The percentage of visits at which commercial insurance was expected as a source of payment was up slightly from the 1989 level, while the percentage of self-pay visits showed a slight decrease. Medicare was an expected payment source at 19.8 percent of visits overall, up slightly from the 1989 level, but was an expected source of payment at 80.0 percent of visits by persons aged 65 years and over. "HMO/pre-paid plan" was mentioned at 14.5 percent of visits, not significantly different from the 1989 level. It should be noted that physicians were asked to check all of the applicable payment categories for this survey item, with the result that multiple payment sources could be coded for each visit.

Reason for visit

Item 9 of the Patient Record asks the physician to record the patient's (or patient surrogate's) "complaint(s), symptom(s), or other reason(s) for this visit in the patient's own words." Up to three reasons for visit are classified and coded from the survey according to A Reason for Visit Classification for Ambulatory Care" (RVC) (4). The principal reason for visit is the problem, complaint, or reason listed in item 9a.

The RVC is divided into the eight modules or groups of reasons displayed in table 4. More than half of all visits were made for reasons classified as symptoms (56.8 percent). Respiratory symptoms accounted for 11.3 percent of all visits while musculoskeletal symptoms accounted for 10.3 percent.

The twenty most frequently mentioned principal reasons for visit, representing 39.5 percent of all visits, are shown in table 5. General medical examination was the most Table 2. Figure 2. Office visits by expected source of payment: United States, 1990

frequently mentioned reason for visit overall (4.3 percent of the total), while cough was the most frequently mentioned reason having to do with illness or injury (3.7 percent). The top twenty reasons for 1990 were also listed as the twenty most frequently mentioned reasons for 1989, although in slightly different order.

Diagnostic and screening services

Table 6 displays statistics on diagnostic or screening services ordered or provided by the physician during the office visit. All diagnostic and screening categories included on the 1990 survey were also found on the 1989 survey. However, this list is changed periodically to reflect the changing needs of data users, recommendations of advisors, and anticipated future health data needs. The most frequently mentioned diagnostic service was blood pressure check, recorded at 38.5 percent of visits. This percentage was significantly higher than the 34.5 percent of visits with a check of blood pressure in 1989. Also, blood pressure checks were ordered or provided at a higher percentage of female visits (42.9 percent) than male visits (31.8 percent) in 1990, as was also the case in 1989.

Other frequently mentioned diagnostic or screening services included "other" blood test (13.3 percent of visits), urinalysis (12.8 percent), and pelvic exam (performed at 12.0 percent of female office visits). With the exception of blood pressure check, none of the diagnostic or screening categories showed significant changes from 1989 levels.

Principal diagnosis

Item 10 of the Patient Record asks the physician to record the principal diagnosis or problem associated with the patient's most important reason for the current visit as well as any other significant current diagnoses. Up to three diagnoses are coded and classified according to the *International* Table 4. Number and percent distribution of office visits by patient's principal reason for visit: United States, 1990

¹Based on "A Reason for Visit Classification for Ambulatory Care" (RVC), Vital Health Stat 2(78) 1979.

Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) (5).

Table 7 displays office visits by principal diagnosis using the major disease categories specified by the ICD-9-CM. The supplementary classification, used for diagnoses that are not classifiable to injury or illness (for example, general medical examination, routine prenatal examination, and health supervision of an infant or child), accounted for 14.8 percent of all office visits. Diseases of the respiratory system (14.2 percent) and diseases of the nervous system and sense organs (11.4 percent) were also prominent on the list. Table 8 displays the 20 most frequently reported principal diagnoses for 1990, categorized at the three-digit coding level of the ICD-9-CM, and accounting for 36.2 percent of all office visits made during the year. Of these 20, 19 also appeared on the list of the 20 most frequent diagnoses for 1989.

The most common diagnosis rendered by physicians at office visits in 1990 was essential hypertension, occurring at 3.9 percent of all visits. Essential hypertension has been the most frequently reported morbidityrelated diagnosis in every survey year since the NAMCS began in 1973. (Morbidity-related diagnoses are those classifiable to illness or injury. Nonmorbidity related diagnoses include routine prenatal examination, health supervision of an infant or child, and general medical examination, among others.)

Therapeutic services

Table 9 presents data summarized from items 13, 14, and 15 of the Patient Record which pertain to therapeutic services ordered or provided by the physician at the office visit.

Medication therapy was the most commonly mentioned therapeutic service, reported at 60.3 percent of office visits in 1990. Physicians were instructed to record all new or continued medications ordered or provided at the visit, including prescription and nonprescription preparations, and immunizing and desensitizing agents. As used in the NAMCS, the term "drug" is interchangeable with the term "medication," and the term "prescribing" is used broadly to mean ordering or providing any medication, whether prescription or over-thecounter. Additional drug data are presented in tables 10, 11, and 12, and are discussed in the next section.

Counseling/advice (defined to include formal and informal counseling, advice, and patient education) was offered at about 37.2 percent of office visits, and weight reduction was the most frequently specified category Table 6. Number and percent distribution of office visits by selected diagnostic service and sex: United States, 1990

Supplementary classification	104,418	14.8
All other diagnoses ²	10,722	1.5
Unknown/blank ³	15,139	2.1

¹Based on the International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM).

²Includes diseases of the blood and blood-forming organs (280–289); complications of pregnancy, childbirth, and the pueperium (630–676); congenital anomalies (740–759); and certain conditions originating in the perinatal period (760–799).
³Includes blank diagnoses, uncodable diagnoses, and illegible diagnoses.

(6.3 percent of visits). More common counseling topics, such as medical, social, and family counseling, were included in the "other" category (28.2 percent of visits). More detailed data on counseling and advice have been collected in the 1991 NAMCS.

Approximately 19.7 percent of visits included a mention of nonmedication therapy ordered or provided by the physician, with the most commonly listed category being psychotherapy (3.8 percent of visits). Ambulatory surgery was ordered or provided at about 2.0 percent of visits, not significantly different from the 1989 level. More detailed data on ambulatory surgery, collected in the 1991 NAMCS, will be forthcoming later this year.

Medication therapy

As noted above, 60.3 percent or about 424.6 million office visits included a new or continuing medication ordered or provided by the physician during 1990. Visits with one or more drug mentions are termed "drug visits" in the NAMCS. As many as five medications, or drug mentions, could be coded per drug visit, resulting in a total of 759.4 million drug mentions during 1990. This yields an average of about 1.1 drug mentions per office visit, or 1.8 drug mentions per drug visit.

Table 10 displays data on number of drug visits and drug mentions by physician specialty. Cardiovascular disease specialists and internists had the highest percentage of drug visits, at 78.5 percent and 74.5 percent, respectively.

Drug mentions are displayed by therapeutic class in table 11. This classification is based on the therapeutic categories used in the National Drug Code Directory (6). It should be noted that some drugs have more than one therapeutic application. In cases of this type, each drug was assigned to the category for which it is most frequently prescribed. Antimicrobial drugs accounted for 16.5 percent of all drug mentions, while cardiovascular-renal drugs (14.4 percent), respiratory tract drugs (11.4 percent), and pain relief drugs (10.2 percent) were also frequently mentioned.

Table 12 shows the 20 most frequently used generic substances for 1990. In this table, drug products containing more than one ingredient (combination products) are included in the data for each ingredient. For example, acetaminophen with codeine is included in both the count for acetaminophen and the count for codeine. Amoxicillin was the generic ingredient most frequently used in drugs ordered or provided by the physician at office visits in 1990, occurring in 4.9 percent of drug mentions.

Fifteen of the 20 most used generic ingredients for 1990 were also on the list of the top 20 for 1989. Albuterol and pseudoephedrine, new on the list for 1990, showed substantial gains of roughly 2.5 million mentions and 3.4 million mentions, respectively, over 1989 levels.

The NAMCS drug data base permits classification by a wide range of variables, including specific product name, generic class, entry form Table 8. Number and percent distribution of office visits by the 20 principal diagnoses most frequently rendered by physicians: United States, 1990

Other	75,338	10.7

¹Total may exceed total number of visits because more than one category may be reported per visit.

²Modications include prescription drugs, over-the-counter preparations, immunizing agents, desensitizing agents, etc. ³Drug visits are visits at which one or more medication is ordered or supplied by the physician. chosen by the physician (that is, brand name, generic name, or the desired therapeutic effect), prescription status (that is, whether the product is prescription or nonprescription), federally controlled substance status, composition status (that is, single or multiple ingredient product), and therapeutic category. A report describing the method and instruments used to collect and process drug information for the NAMCS is available (7).

Disposition of visit

Nearly two-thirds (66.0 percent) of all office visits included a scheduled follow-up visit or telephone call, while another 22.6 percent included instructions to return if needed. Only about 1.0 percent of visits resulted in a hospital admission. Table 13 displays data on office visit disposition.

Duration of visit

Table 14 presents data on the duration of office visits. Duration of visit refers to the amount of time spent in face-to-face contact between the physician and the patient. This time is estimated and recorded by the physician and does not include time spent waiting to see the physician, time spent receiving care from someone other than the physician without the presence of the physician, or time spent by the physician in reviewing patient records and/or test results. In cases where the patient received care from a member of the physician's staff but did not actually see the physician during the visit, duration was recorded as "zero" minutes.

About 69.3 percent of office visits had a duration of 15 minutes or less in 1990. The mean duration time for all visits was 16.7 minutes, significantly higher than the 15.9 minutes reported for 1989.

Additional reports which utilize 1990 NAMCS data are forthcoming in the Advance Data From Vital and Health Statistics series. In addition, survey data will be available on computer tape from the National Table 10. Number and percent distribution of drug visits and drug mentions by physician specialty: United States, 1990

Physician specialty	Number of drug visits ¹ in thousands	Percent distribution	Number of drug mentions in thousands	Percent distribution	Percent drug visits ²

Technical notes

Source of data and sample design

The information presented in this report is based on data collected by means of the National Ambulatory Medical Care Survey (NAMCS) from January 1990 through December 1990. The target universe of NAMCS includes office visits made in the United States by ambulatory patients to nonfederally employed physicians who are principally engaged in office practice, but not in the specialties of anesthesiology, pathology, or radiology. Telephone contacts and nonoffice visits are excluded.

A multistage probability sample design is used in NAMCS, involving samples of primary sampling units (PSU's), physician practices within PSU's, and patient visits within physician practices. For 1990, a sample of 3,063 nonfederal, officebased physicians was selected from master files maintained by the American Medical Association and American Osteopathic Association. The physician response rate for the 1990 NAMCS was 74 percent. Sample physicians were asked to complete Patient Records (see figure 1) for a systematic random sample of office visits occurring during a randomly assigned 1-week reporting period. Responding physicians completed 43,469 patient records.

Characteristics of the physician's practice, such as primary specialty and type of practice, were obtained from the physicians during an induction interview. The U.S. Bureau of the Census, Housing Surveys Branch, was responsible for the survey's data collection. Processing operations and medical coding were performed by the National Center for Health Statistics, Hospital Discharge and Ambulatory Care Survey Section, Research Triangle Park, North Carolina.

Sampling errors

The standard error is primarily a measure of the sampling variability

Table I. Provisional relative standard errorsfor estimated number of office visits:National Ambulatory Medical Care Survey,1990

Estimated number of office visits in thousands	Relative standard error in percent	
200	49.4	
400	35.0	
547	30.0	
600	28.7	
800	24.9	
1,000	22.4	
2,000	16.1	
5,000	10.6	
10,000	8.0	
13,000	7.3	
20,000	6.4	
50,000	5.1	
100,000	4.6	
600,000	4.1	

Example of use of table: An aggregate estimate of 10 million visits has a relative standard error of 8.0 percent or a standard error of 800,000 visits (8.0 percent of 10 million).

Table II. Provisional relative standard errors for estimated number of drug mentions: National Ambulatory Medical Care Survey, 1990

Estimated number of drug mentions in thousands	Relative standard error in percent		
200	63.4		
400	45.0		
500	40.3		
600	36.9		
800	32.0		
912	30.0		
1,000	28.7		
2,000	20.6		
5,000	13.6		
10,000	10.3		
20,000	8.1		
50,000	6.5		
100,000	5.8		
600,000	5.2		

Example of use of table: An aggregate estimate of 10 million drug mentions has a relative standard error of 10.3 percent or a standard error of 1.03 million visits (10.3 percent of 10 million).

that occurs by chance when only a sample, rather than an entire universe, is surveyed. The relative standard error of an estimate is obtained by dividing the standard error by the estimate itself; the result is then expressed as a percent of the estimate. Table I shows provisional relative standard errors for estimated numbers of office visits in 1990, and table II presents provisional relative standard errors for estimated numbers of drug mentions. Provisional standard errors for estimated percents of visits are shown in table III.

Alternatively, relative standard errors for aggregate estimates may be calculated using the following general formula, where x is the aggregate of interest in thousands, and A and B are the appropriate coefficients from table IV.

$$RSE(x) = \sqrt{A + \frac{B}{X}} \cdot 100.0$$

Similarly, relative standard errors for percents may be calculated using the following general formula, where p is the percent of interest and x is the denominator of the percent in thousands, using the appropriate coefficient from table IV.

RSE
$$(p) = \sqrt{\frac{B \cdot (1-p)}{p \cdot x}} \cdot 100.0$$

 Table III. Provisional standard errors for percents of estimated numbers of office visits:

 National Ambulatory Medical Care Survey, 1990

Base of percent visits in thousands	Estimated percent					
	1 or 99	5 or 95	10 or 90	20 or 80	30 or 70	50
	Standard error in percentage points					
200	4.9	10.7	14.8	19.7	22.6	24.6
500	3.1	6.8	9.3	12.5	14.3	15.6
1,000	2.2	4.8	6.6	8.8	10.1	11.0
2,000	1.6	3.4	4.7	6.2	7.1	7.8
5,000	1.0	2.2	3.0	3.9	4.5	4.9
10,000	0.7	1.5	2.1	2.8	3.2	3.5
13,000	0.6	1.3	1.8	2.4	2.8	3.1
20,000	0.5	1.1	1.5	2.0	2.3	2.5
50,000	0.3	0.7	0.9	1.3	1.4	1.6
100,000	0.2	0.5	0.7	0.9	1.0	1.1
600,000	0.1	0.2	0.3	0.4	0.4	0.5

Example of use of table: An estimate of 30 percent based on an aggregate estimate of 13 million visits has a standard error of 2.8 percent or a relative standard error of 9.3 percent (2.8 percent divided by 30 percent).

Table IV. Provisional coefficients appropriate for determining relative standard errors by type of estimate and physician groups: National Ambulatory Medical Care Survey, 1990

	Coe	Coefficient

Adjustments for nonresponse

Estimates from NAMCS data were adjusted to account for sample physicians who were in scope but did not participate in the study. This adjustment was calculated to minimize the impact of response on final estimates by imputing to nonresponding physicians data from visits to similar physicians. For this purpose, physicians were judged similar if they had the same specialty designation and practiced in the same PSU.

Test of significance and rounding

In this report, the determination of statistical inference is based on the t-test. The Bonferroni inequality was used to establish the critical value for statistically significant differences (0.05 level of confidence). Terms relating to differences such as "greater than" or "less than" indicate that the difference is statistically significant. A lack of comment regarding the difference between any two estimates does not mean that the difference was tested and found to be not significant.

In the tables, estimates of office visits have been rounded to the nearest thousand. Consequently, estimates will not always add to totals. Rates and percents were calculated from original unrounded figures and do not necessarily agree with percents calculated from rounded data.

Definition of terms

Ambulatory patient – An ambulatory patient is an individual seeking personal health services who is not currently admitted to any health care institution on the premises.

Physician – A physician is a duly licensed doctor of medicine (M.D.) or doctor of osteopathy (D.O.) who is currently in office-based practice and who spends some time caring for ambulatory patients. Excluded from the NAMCS are physicians who are hospital based; who specialize in anesthesiology, pathology, or radiology; who are federally employed; who treat only institutionalized patients; or who are employed full time by an institution and spend no time seeing ambulatory patients.

Office – Offices are the premises physicians identify as locations for their ambulatory practice. These customarily include consultation, examination, or treatment spaces that the patients associate with the particular physician.

Visit — A visit is a direct personal exchange between an ambulatory patient and a physician (or a staff member working under the physician's supervision) for the purpose of seeking care and rendering personal health services.

Drug mention – A drug mention is the physician's entry of a pharmaceutical agent – by any route of administration – for prevention, diagnosis, or treatment. Generic as well as brand-name drugs are included, as are nonprescription and prescription drugs. Along with all new drugs, the physician also records continued medications if the patient was specifically instructed during the visit to continue the medication.

Drug visit - A drug visit is a visit in which medication was prescribed or provided by the physician.
