Joanne Townsend, R.N., B.A. (Hons) Post Grad Cert HSR	Urogynaecology Nurse Specialist University Hospitals of Leicester, Leicester, UK

Appendix E. Data Abstraction Forms

Prevalence and incidence of urinary incontinence in the community and long-term care settings

Abstraction Form

(Complete for each study**)**

Number of the study in the database (PubMed ID, Cochrane accession number, ISBN)_____
First author_____
Year of publication_____
Purpose/aim of study _____

Design of the study (check one)
☐ prospective cohort
☐ retrospective cohort
☐ cross-sectional
☐ descriptive study
☐ case-control
☐ case-series
☐ randomized controlled clinical trial
☐ not randomized clinical interventions
☐ ecologic

Adjustment for confounding factors: _____

Population variables (independent variables)
Data source for population variables (define) _____
Survey_____
Administrative data base_____
Population based_____
Clinic based_____
Other_____

Settings
Community (general population)_____
Long term care settings_____
Nursing home_____
Long term care hospital_____

Location
Residence _____
Country _____
Region (State, Province, Census region)_____
Urban_____
Rural_____

Time
Year of the publication_____
Year to collect the data (Range)_____

Subjects
Race
African Continental Ancestry Group, %_____
Asian Continental Ancestry Group, %_____
European Continental Ancestry Group, %_____

Ethnicity
Caucasians, %_____
African Americans, %_____
Arabs, %_____
Asian Americans, %_____
Hispanic Americans, %_____

Gender_____
Males, %_____
Females, %_____

Age: _____
Mean age, years_____ Standard deviation_____
Age intervals:_____

Health status
Sample size:_____
Inclusion criteria:_____
Exclusion criteria:_____

Incontinence variables
Methods to assess incontinence:
Self report_____
Medical diagnosis_____
Medical procedure_____

Data source to measure incontinence: _____
Time of followup from the diagnosed incontinence in months_____

Urinary Incontinence (Incidence, Prevalence)
Define _____
Symptoms_____
Signs_____
Acuity_____
Severity_____
Length_____
Bothersomeness_____

Type of Incontinence (Incidence. Prevalence)
Define_____
Symptoms_____
Signs_____
Acuity_____
Severity_____
Frequency_____
Length_____
Bothersomeness_____

Subject Age, Gender, Race, Ethnicity	Prevalence (%) of Incontinence	Prevalence (%) of Incontinence	Prevalence (%) of Incontinence
Race	Definition overall and by type	Severity of urinary incontinence	Bothersomeness
African Continental Ancestry Group			
Asian Continental Ancestry Group			
European Continental Ancestry Group			
Ethnicity			
Caucasians			
African Americans			
Arabs			
Asian Americans			
Hispanic Americans			
Gender

Intervention	Control	Outcomes Definition	Outcome Level in Active Group	Outcome Level in Control Group	Rate in Active Group	Rate in Control Group	Relative Risk, 95% CI
		Urinary Incontinence					
		Fecal Incontinence					
		Combined Incontinence					

Quality of the studies:

Intention to treat:
☐ Yes ☐ No ☐ not stated but all subjected included in analysis

Masking of treatment status:
Double blind _____
Single blind _____
Open label _____

Randomization regime_____
Adequate: computer-generated random numbers or random numbers tables
Inadequate: alternation, case record numbers, birth dates, or days of the week

Adequacy of randomization_____
Baseline data not reported_____
Baseline data confirmed the adequacy of randomization_____

Allocation concealment _____
Not reported_____
Adequate_____
Not adequate_____
Adequate approaches to concealment of allocation:
Centralized or pharmacy-controlled randomization
Serially-numbered identical containers
On-site computer based system with a randomization sequence that is not readable until allocation
Inferior approaches to concealment of allocation:
Use of alternation
Case record numbers
Birth dates or days of the week
Open random numbers lists
Serially numbered envelopes (even sealed opaque envelopes can be subject to manipulation)

Justification for sample size_____

Level of evidence of the individual study (check one)

Interventions:
☐ I Well-designed randomized controlled trial
☐ II-1A Well-designed controlled trial with pseudo-randomization
☐ I-1B Well-designed controlled trial without randomization

Observational studies
☐ I-2A Well-designed cohort (prospective) study with concurrent controls

Appendix F. Evidence Tables

Contents

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community

F1-a. Incidence of urinary incontinence in adults

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject Age, Gender, Race, Ethnicity, Residency	Incidence (new cases/year * 100,000 age standardized adult population, males and females) of UI, Overall: by Type, Severity, and Impact on Life
Townsend, 2007[1] Prospective cohort Adjusted by: Age, BMI, Weight, Race Parity, Smoking, Oral contraceptive use, Menopausal status, Hormone use, Hysterectomy, Diabetes, Physical activity, Diuretic use Level of evidence: II-2A	Female nurses selected using data from the Nurses Health Study II which is updated biennially. Response rate: Approximately 88% Data source: Self-reported mailed questionnaires. Incontinence was defined as, "Leaked or lost control of urine in the last 12 months."	Age: 37-54 (Mean: 46.1) Gender: Female Race: Not reported Ethnicity: Not reported Residency: USA	Incident incontinence: (2 years) 13.60%
Altman, 2006[2] Prospective, observational cohort study with 10-year followup Adjusted for maternal age and parity Level of evidence: 11-2A	304 primiparous women who had a vaginal delivery over a 10-week period in 1995 and completed a bladder function questionnaire Excluded: Elective or acute cesarean delivery; inadequate knowledge of Swedish language; dual pregnancy <u>UI Measurement</u>: Survey using self-administered questionnaire • Do you experience sudden desires to void urine that are difficult to hold back? • Do you experience involuntary loss of urine at physical activities? UI Severity Definition • Mild SUI defined as <1/week Moderate-severe SUI defined as UI >1/week or daily	Swedish women with mean age at index delivery 29.9 ± 4.1 years	Adjusted for age and parity, odds ratios for SUI compared with index delivery: • 6 months: RR 2.2, 95% CI: 0.9-5.8 • 9 months: RR 1.8, 95% CI: 1.6-5.4 • 5 years: RR 4.1, 95% CI: 3.1-9.2 • 10 years: RR 3.9, 95% CI: 1.1-8.2 Adjusted by maternal age and parity, the RR of moderate-severe SUI after first delivery was 5.8, 95% CI 1.2-33.7 Mean incidence rates 10-year period before and after index delivery, respectively: # of cases per 1,000 person years • Mild SUI: 5 vs. 30 • Moderate-severe SUI: 2 vs. 10
Edwards, 2006[3] Prospective cohort study Level of analysis: II-2A	361/460 patients (78.5% response rate) consecutively admitted with ischemic stroke hospitalized between 1999-2000 Inclusion criteria: community residence, absence of serious	Adults ages 22-90 years with a mean age 65,5 (SD 15.2), USA (Missouri) Age: • Continent: 64.6 (SD 15.2) (n=301)	• UI group was older (P <.001) • UI more common in women than men (P <.003) • Individuals continent at 6 month followup were functioning significantly better than incontinent stroke survivors; more independent in basic self-care, functional communication, and cognition as measured by FIM (P

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1-a. Incidence of urinary incontinence in adults (continued)

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject Age, Gender, Race, Ethnicity, Residency	Incidence (new cases/year * 100,000 age standardized adult population, males and females) of UI, Overall: by Type, Severity, and Impact on Life
	cognitive or language deficits, no pre-stroke UI, and met ICD-9 criteria for ischemic stroke Telephone interview 6 months post-stroke UI Measurement: Classified as incontinent if FIM bladder management item ≤5 (e.g., experience loss of bladder control at least 1x/month)	• Incontinent: 70.1 (SD (14.8) (n=59) Gender: • 160 (47%) male; 137 (46%) continent and 23 (40%) incontinent • 201 (53%) female; 165 (54%) continent and 35 (60%) incontinent Race: • 181 (50%) white • 79 (50%) African-American	<.0001) • Individuals continent at 6 months had greater independent in ADLs measured by the FAM (P <.0001) SF-12 scores • Continent vs. Incontinent o Physical health: 45.6 (SD 6.7) vs. 42.0 (SD 5.4) (P = .18) o Mental health: 43.9 (SD 7.8) vs. (37.1 (SD 6.9) (P = .0001)
Engh, 2006[4] Case-control Not adjusted Level of evidence: II-2A	835/1,022 women (81.7% response rate) ages 40-52 years who underwent uterine surgery with ovaries preserved between 1997-2002 Excluded: preoperative urinary symptoms; 6 or more vaginal deliveries, followup time <2 years, uterine size >9 weeks or uterine weight >120g, previous UI surgery and/or concomitant prolapse surgery Types of surgery, n • Total hysterectomy (abdominal/laproscopic) n=198/116 • Subtotal hysterectomy (abdominal/laproscopic) n=163/86 • Total hysterectomy (vaginal/laproscopic assisted vaginal) n=265/7 Control group: women undergoing endometrial destruction (ablation, balloon treatment) n=187 Questionnaire	Women with mean age 44.9 years, Sweden	De novo UI by type of surgery at least 2 years postop: • Total abdominal/laproscopic hysterectomy o 236 (75.2%) no symptoms o 43 (13.7%) SUI o 10 (3.2%) UUI • Subtotal abdominal/laproscopic hysterectomy o 186 (74.7%) no symptoms o 36 (14.5%) SUI o 12 (4.8%) UUI • Total vaginal/laproscopically assisted o 210 (77.2%) no symptoms o 39 (14.3%) SUI o 11 (4.0%) UUI • Endometrial destruction (control) o 138 (73.8%) no symptoms o 26 (13.9%) SUI o 7 (3.7%) UUI • No significant differences noted between groups

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1-a. Incidence of urinary incontinence in adults (continued)

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject Age, Gender, Race, Ethnicity, Residency	Incidence (new cases/year * 100,000 age standardized adult population, males and females) of UI, Overall: by Type, Severity, and Impact on Life
Glazener, 2006[5] Cross-sectional Adjusted Level of evidence:	3,405/4,537 (75.1% response rate) of women responding they had singleton births delivered over 1 year between 1994-1995 (3489/4555 responded to survey) Excluded: Twin pregnancies Conducted in 3 countries Mailed survey UI Measurement: A positive response to one or more of the following questions: • At present, do you ever lose any urine when you don't mean to? • In the last month, how often has this happened on average? • Do you wear a pad for this?	Women mean age 26.7 years (SD 5.3), Scotland, New Zealand, and England	UI onset during index pregnancy: 3% (n=101) UI onset after 3 months index pregnancy: 15% (n=503)
McGrother, 2006[6] Prospective cohort study with 1-year followup Adjusted for age and ADL; separate models adjusted for general and specific morbidities and parity Level of evidence: 11-2A	12,570/19,241 (65.3% response rate) community-dwelling women drawn from 108 general practices (71% of all practices) Mailed questionnaire at baseline and 1 year UI Measurement: SUI: leakage upon laughing, coughing, or exercise ≥monthly Included OAB but could not differentiate those with OAB with urge incontinence from those with OAB without urge incontinence	Women aged ≥40 years (range 40-98), UK Median age: 58 and 56 years	Incident rate at 1-year: 3.6% SUI
van Brummen, 2006[7] Prospective cohort study No adjustment for confounding factors Level of evidence: II-2A Note: van Brummen, 2006[8] had similar sample but recruited from fewer	Consecutive recruitment of nulliparous pregnant women with single, low-risk pregnancy between 12 and 18 weeks gestation recruited from 10 midwifery practices from January 2002 to July 2003 Exclusion criteria: previous urogynaecological surgery, urogynaecological malformations,	Women with a mean age of 30.4 (SF 0.19); Netherlands	Bothersome SUI:: • 53 (15.4%) at 36 weeks • 36 (10.5%) at 1 year after childbirth Moderately or greatly bothersome UUI: • 58 (16.9%) at 36 weeks • 51 (14.8%) at 1 year after childbirth

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1-a. Incidence of urinary incontinence in adults (continued)

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject Age, Gender, Race, Ethnicity, Residency	Incidence (new cases/year * 100,000 age standardized adult population, males and females) of UI, Overall: by Type, Severity, and Impact on Life
midwifery practices over same time period	diabetes mellitus, or neurological disorders; good knowledge of Dutch language; pregnancy within 1 year after index pregnancy 344/954 of those invited and not pregnant with 1 year postpartum (37.1% response rate) 344/904 of those eligible (38.1% response rate) Self-report questionnaire at 12, 24, and 36 weeks gestation, and 3 and 12 months after delivery UI Measurement: Using questions from the UDI, • SUI was defined as: Do you experience urine leakage related to physical activity, coughing, or sneezing? • UUI: Do you experience urine leakage related to the feeling of urgency? Defined symptom bother using item levels and total scores from UDI Baseline continence status unknown		
Wehrberger, 2006[9] Prospective cohort study with mean duration of follow-up of 6.5 years Adjusted for confounding factors Level of evidence: II-2A	441/925 women (47.7% response rate) who completed a free examination in 1998 or 1999 Mailed questionnaire UI Measurement: BFLUTS: Have you leaked any urine at all during past 4 weeks?	Women ages 20-84 years; Austrian	Study described as incidence but unclear how they calculated numbers (see prevalence table) Cumulative incidence of any UI over 6.5 years: • 3.9% annually • 25.6% By age and frequency, cumulative incidence over 6.5 years (n, n with UI, cumulative incidence, annual incidence??, frequency ≥1 time/week, cumulative, annual): • 20-39 years: 8/54 (14.8%, 2.3%), frequency = 2 (3.7%, 0.6%) • 40-49 years: 18/70, 25.7%, 4.0%; frequency = 10 (14.2%, 2.2%) • 50-59 years: 22/92, 23.6%, 3.6%, frequency = 10, 10.8%, 1.7%)

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1-a. Incidence of urinary incontinence in adults (continued)

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject Age, Gender, Race, Ethnicity, Residency	Incidence (new cases/year * 100,000 age standardized adult population, males and females) of UI, Overall: by Type, Severity, and Impact on Life
			• 60-69 years, 11/46, 23.9%, 3.7%; frequency = 7, 15.2%, 2.3% • 70+ years: 18/38, 47.3%, 7.3%, frequency = 13, 24.2%, 5.3% • Total = 77/300, 25.6%, 3.9%; frequency = 42, 13.9%, 2.1% Frequency of UI: • ≤1 time/week: 44% • 2-3 times/week: 28% • 1 time/day: 15% • More often: 13% UI severity: • Enough to make underwear/pads damp: 72% • Enough to make underwear/pads wet: 20% • Enough to wet outer clothes: 5% • Urine runs down legs onto floor: 3% Impact of UI: • 14% not at all • 40% a little • 29% moderate • 17% significant UI type: • 34% SUI • 13% UUI • 53% MUI
Andersson,2004[10] Population based study II-3	3/2000, Life and Health questionnaire sent to 70,000 residents randomly selected. In Orebro, pop of 274,000, one of the five counties that participated in above study, a special section on UI was given to a sample of 15,360 residents Questionnaire mailed to home comprising 12 questions on UI as a supplement to a large public health survey on health and general living Sample of 15,360 residents aged 18-79yrs of Orebro, Sweden;	7680 females 7680 males age categories 18-34 53.9% 35-49 60.3 50-64 69.6 65-79 72.2 Swedish population	Only prevalence rates given – see other table

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1-a. Incidence of urinary incontinence in adults (continued)

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject Age, Gender, Race, Ethnicity, Residency	Incidence (new cases/year * 100,000 age standardized adult population, males and females) of UI, Overall: by Type, Severity, and Impact on Life
	Response rate was 64.5% Used defs from ICS Stats on wts and calibration and found results were the same		
Bogner, 2004[11] Population based longitudinal survey II-2B	Used ECA (Epi Catchment Area) program sample to select from 3,481 community dwelling adults who were initially living in East Baltimore in 1981. 1,920 were contacted (73% of original cohort). Study sample included 822 persons ≥50 years, who completed info on UI. After exclusions for missing data, the final sample was 747. Age ≥65 over sampled GHQ used and self report on UI. UI = "Have you ever had any difficulty in controlling your water, losing your urine or having trouble getting to the bathroom on time?" If any uncontrolled urine loss was reported within the 12mos before the interview, persons were classified as having UI.	Mean age: 67.2 64% were women 72.3% White – mean age 68.2+/- 11 27.7% AA – mean age 64.5 +/-10 White AA diabetes 14.3 16.9 heart trouble 27.4 26.6 arthritis 51.1 56.5 stroke 8.2 7.3 cancer 14.4 6.3 MME 27.6+-2.6 25.6+-3.6 ADL impaired 1.9% 3.9% (AA and Whites ≥50years at followup interview 1993-1996)	
Corcos, 2004[12] Prospective cohort No control mentioned	Population ≥35 years, stratified by census of metro area and by gender. 7,487 persons were sample base. 53.7% response rate. 3249 interviews were final sample. Investigators developed standardized questionnaire to ascertain OAB and SUI and impact on QoL. Computer assisted telephone interviews conducted in 2 steps: an initial questionnaire to evaluate presence of OAB followed by detailed questionnaire to complete assessment.	48.2% men; mean age=52 51.8% women; mean age=50.9 82.4% younger than 65 and 17.6% older Montreal, Toronto, Vancouver and Edmonton, Canada	
Dallosso,2004[13] Prospective longitudinal study	Part of the Leicestershire MRC Incontinence Study. This study focused on women living in the community in UK	Baseline data compared to those who provided FFQ data –	Incidence rate over 1 yr of f/u was 8.3% Highest in perimenopausal group (40-49) and in the very elderly (80+)

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1-a. Incidence of urinary incontinence in adults (continued)

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject Age, Gender, Race, Ethnicity, Residency	Incidence (new cases/year * 100,000 age standardized adult population, males and females) of UI, Overall: by Type, Severity, and Impact on Life
II=2B	age ≥40. Of a random sample of 20,244 women drawn, 12,565 returned the questionnaire (65% response rate). FFQ sent to 10,852 of above sample, 1st Postal questionnaire mailed Oct 1998 and completed by 7,046 women(response rate 65%). 2nd postal questionnaire mailed Oct 1999 and completed by 6,424 women (91% response rate). Excluded women living in residential or nursing homes and those of South Asian origin who make up 5.3% of Leicestershire pop > 40years. Used ICS definitions	Median age 57 vs. 61 Rating of health poorer in baseline after adjusting for age (OR: 1.66; 95% CI 1.51-1.82) More long term health problems in baseline (OR 1.14; 95% CI, 1.05-1.25) No difference in reporting SUI (OR: 1.02; CI 95%, .92-1.13)	Incidence at 1 year followup Total N / SUI cases % 40-49 1,242 9.3 50-59 1,272 7.2 60-69 1,108 7.6 70-79 756 8.3 80+ 214 12.6
Dallosso, 2003[14] Longitudinal, Prospective cohort II – 2B	7,046 women at baseline with follow up collected from 6,426 1 year later, age ≥40 living at home, part of the Leicestershire MRC Incontinence Study on prevalence and incidence including men and women begun 10/98 with followup in 10/99 Postal survey with usual definitions of SI. OAB defined by ICS and for this study as one or both of the sxs urge leakage and urgency. Subgroups of OAB and SI Excluded nursing home or residential pts and SI at baseline was excluded from analysis of onset of S.(19,239 eligible women; 65.3% returned N= 12,565, 6,426 in this study)	Age 40-49 - 26% 50-59 27.4% 60-69 23.3% 70-79 17.1% >80 6.2% BMI Acceptable 48.4% Underwt 7% Overwt 31.4% Obese 13.3% Smoking Never 54.3 Exsmoker 30.3 Current 15.2 United Kingdom	Prevalence of OAB increased with age but no marked change with SI 1 yr f/u there were 492 new cases of OAB and 421 cases of SI giving incidence rates of 9.2% and 8.3% respectively *Being overwt or obese were both sig associated with an increased risk of SUI (OR: 1.42; 95% CI, 1.09-1.84 and OR 1.91; 95% CI, 1.38-2.63) respectivelly*
Deliveliotis, 2004[15] Prospective cohort II-2A	283 of 441 pts enrolled; 105/142pts tx with RRP for prostate cancer, 98/151pts tx with TURP for BPH, 80/148 healthy men as control completed surveys Used AUA Sx Index, UCLA Prostate	Greek men Mean ages 67.4 range 55-75 group 1 70.3 range 58-74 group 2 72.4 range 62-82 control	RRP / TURP Pretx post p pretx post p Urinary function 85.1 80.2 .121 71.2 87.3 .005 Urinary Bother 85.1 70.6 .021 65.1 80.2 .003

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1-a. Incidence of urinary incontinence in adults (continued)

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject Age, Gender, Race, Ethnicity, Residency	Incidence (new cases/year * 100,000 age standardized adult population, males and females) of UI, Overall: by Type, Severity, and Impact on Life
	Cancer Index; Rand 36-Item Health Survey and BMSFI translated into Greek Patient outcomes 2 years post tx compared to pretx status at 2 weeks prior to tx Investigators felt poor returns due to length of questionnaires and the number of them	HRQOL post tx RRP TURP Control Physical functioning 81.5 78.1 82.3	AUA SI 11.1 8.6 .812 24.2 8.2 .001 UI every day 2% 9% .002 12% 2.78% .002 RRP had trend towards worse urinary function 2yrs after surgery but diff not significant. Urinary bother deteriorated. UI in control group was 5.78%
Grodstein, 2004[16] Prospective cohort II-2A Confounded for stroke and physical limitations and results were the same in both analysis	Nurse Health Study from 1996-2000 females, Cohort of 39,436 women 50-75 years Questionnaire mailed in 1996 to 39,436 post menopausal women who had no leaking of urine and were followed for 4 years Incident cases of occasion UI defined as leaking 1-3 times/month; frequent ≥1/week Excluded premenopausal women or users of estrogen creams, or reported leaking in 1996	Mean age; 61 for current HRT use; 64 for never used. BMI for never used HRT was 27, current use BMI = 47, past BMI = 47. Smokers @45% all. HRT use: Never Current Past Cauc 98 97 98 AfrA 1 1 1 Hisp 0 1 0 Asian 1 1 1 Hysterectomy 16 47 40	5,060 incident cases of occasional UI and 2,495 incident cases of frequent UI Average incidence rate of 3.2% per year and 1.6% per year respectively
Hagglund, 2004[17] 4 year followup cohort study II-2A	145 incontinent and 193 continent women 22-50 years in 2000 follow up, who participated in 1995 study on prevalence. Response rate 73% 248/338 Among the 248 responders as followup, 118 reported UI and 130 reported being continent. Changes in type of UI measured using DIS “do you have problem with involuntary loss of urine?”	Sweden	At 4 year followup in 2000 118 women were found to be incontinent. Of these, 95/118 had remained incontinent. 130 women were continent. Of these women, 112/130 had remained continent. Incidence rate from 1996-2000 was 17% (23/135) with a mean annual incidence rate of 4% Persistence of UI – this group consisted of 95 women. 28% reported UI daily, 34% reported UI weekly, 16% reported monthly and 22% reported seldom.

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1-a. Incidence of urinary incontinence in adults (continued)

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject Age, Gender, Race, Ethnicity, Residency	Incidence (new cases/year * 100,000 age standardized adult population, males and females) of UI, Overall: by Type, Severity, and Impact on Life
Haltbakk, 2004[18] Prospective cohort no control mentioned historical control	480 Norwegian men at St. Olavs Hospital, Trondheim Norway. Tentative dx of BPH made on 612 patients and from this pool, sample analyzed was 480 (78%). ICS LUTS questionnaire (ICS-BPH) between 1997-2000. IPSS, SPI and SISI used also. UI defined as any involuntary leakage of urine.	Mean age of patients was 67 years, SD 10.6 years; median 69 years range 39-91 years 15% mild sxs 54% moderate sxs 31% severe sxs mean age in incontinent group was 68 years	
Holroyd-Leduc, 2004[19] Population based Prospective cohort Confounders – sex, age, sex, race, smoking, alcohol, BMI, sensory impairment, comorbid disease, depression, cognitive function and baseline dependency. II-2A	6,506 of 7,447 subjects ≥70 in the Asset and Health Dynamics Among the Oldest Old study who had complete info on continence status at baseline. 3 groups- 5,872 nursing home, 5,521 ADL decline and 5,509 IADL decline as outcomes Subjects interviewed in 1993 and 1995 Blacks, Hispanics and Florida residents were over sampled Overall response rate was 80% UI measured "next question might not be easy to talk about, but it is very impt for research on health and aging, during the last 12 mos, have you lost any amount of urine beyond your control?"	Mean age =/- SD = 77 (range 69-103) 63% female 86% white Median number of baseline comorbid medical conditions was 2 10% received help ≥1 ADLs; 23% were receiving help in ≥1 IADLS at baseline Patients with UI had more comorbidities (p=.001), higher rate of visual impairment (35% vs. 22.4% p <.001) and hearing impairment (39.7% vs. 30.5% p<.001) More functionally impaired at baseline Community dwelling in US	
Hunskaar, 2004[20] Cross national study, Prospective No control group	Postal survey mailed to 29,500 households in 4 countries – France, Germany, UK and Spain age >/= 18yrs 58.1% response rate. Women with UI included in analysis = 5,976 (35% of study pop) Definitions used by ICS; sxs in last 30 days and in last 7 days	Mean age France – 44.8 Germany – 59 UK – 45 Spain – 64 All – 58	

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1-a. Incidence of urinary incontinence in adults (continued)

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject Age, Gender, Race, Ethnicity, Residency	Incidence (new cases/year * 100,000 age standardized adult population, males and females) of UI, Overall: by Type, Severity, and Impact on Life
Jackson, 2004[21] Cross sectional analysis, longitudinal study II-2A	1,584 white and black women 70-79 years at 2 clinical sites in Pittsburg and Memphis. 1,558 answered the questions Limited enrollment to those who reported no difficulty walking quarter mile, climbing 10 steps or performing ADLs Questionnaires – in the past 12 mos, have you leaked even a small amt of urine? How often have you leaked?	Smoking Alcohol Depression Diabetes BMI Parity Hysterectomy Oral estrogen use COPD Stroke Arthritis Age Race	
Jackson, 2004[22] population based Prospective cohort; also randomly selected from HMO diabetes registry II-2A	1,017 post menopausal US women a 55-75 years enrolled in HMO and followed for 2 years (1998-2002) inclusion criteria were no natural menstrual cycle in past 12 months (oral estrogen or vaginal estrogen users were excluded), resided in Washington state. Exclusion factors were residential nursing care, restriction to wheel chair, dementia or severe psych disorder, indwelling catheter or intermittent urinary catheter, end stage renal disease requiring dialysis, active malignancy other than skin cancer and chronic antibiotic use. Acute cystitis in past 90 days exclusionary. Postvoid residual bladder volume measured using portable ultrasound device. 12 month f/u done by 87% and 24mo f/u by 81%. Primary study outcome was sx cystitis	Risk factor (%) Crude HR (95% CI) Complete sample 1,017 Age (years) 55-59-32% 1.0 60-69- 42% 1.3 (0.8–2.2) 70-75- 26% 1.6 (0.9–2.9) Ethnicity White- 87% 1.0 Other-12 % 0.6 (0.3–1.2) General health score from SF-36 76-100(51%) 1.0 51-75(37%) 2.0 (1.2-3.3) 0-50 (12%) 2.6 (1.3-4.8) Smoking history Never (55%) 1.0 Former (39%) 0.9 (0.5-1.4) Current (6%) 0.1 (0.02-0.8) Diabetes at baseline No (79%) 1.0 Yes (21%) 1.9 (1.1-3.1) Diabetes treatment type Not diabetic (79%) 1.0 Diet/pill (17%) 1.2 (0.7-2.0) Insulin (4%) 4.7 (2.2-10.3) Accidental leakage of urine	Incidence of UTI was .07 per person per year. Independent predictors of infection included insulin treated diabetes (hazard ratio [HR]=3.4;95%confidence interval [CI]: 1.7 to 7.0) and a lifetime history of urinary tract infection(HR for six or more infections = 6.9; 95% CI: 3.5 to 13.6). Borderline associations included a history of vaginal estrogen cream use in the last month (HR = 1.8; 95% CI: 1.0 to 3.4), a history of kidney stones (HR=1.9; 95% CI: 1.0 to 3.7), and asymptomatic bacteriuria at baseline (HR= 1.8; 95% CI: 0.9 to 3.5).

Hojberg, 1999[39] Cross-sectional Adjusted by: Age, parity, BMI, smoking, previous abortions, lower abdominal or urological surgery Level of evidence: III	Subjects were selected from all women attending routine antenatal care from January 1993 to April 1996 at the Department of Obstetrics and Gynecology, Aarhus University Hospital. The subjects were asked to fill out a questionnaire at 16 weeks of gestation. Response rate: 91% (n=7,795) Data source: Self-administered questionnaires. Urinary incontinence was defined as, "Involuntary loss of urine within the last year." Stress incontinence was defined as, "Involuntary loss of urine during physical exertion." Urge incontinence was defined as, "involuntary loss of urine associated with a strong desire to void." Mixed incontinence was defined as, "A combination of stress and urge incontinence."	Age: 15-24: 17.3% (n=1,347) 25-29: 41.7% (n=3,253) 30-34: 30.3% (n=2,365) 35+: 10.6% (n=830) Gender: Female Race: Not reported Ethnicity: Not reported Residency: Denmark	Prevalence: Overall: 8,900/100,000 (8.9%) By Type: Stress incontinence: 5,000/100,000 (5%) Urge incontinence: 700/100,000 (0.7%) Mixed incontinence: 2,400/100,000 (2.4%) By Severity: 3,000 / 100,000 (3%) (Reported stress or mixed UI at least once a week)

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1-a. Incidence of urinary incontinence in adults (continued)

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject Age, Gender, Race, Ethnicity, Residency	Incidence (new cases/year * 100,000 age standardized adult population, males and females) of UI, Overall: by Type, Severity, and Impact on Life
Sgadari, 1997[40]	Subjects were selected using data from a cross-national database. The interRAI data-base of nursing home assessments was used, containing information on the countries of Denmark, France, Iceland, Italy, Japan, Sweden, and the USA. The data within the interRAI are population-based for the USA, Denmark, and Iceland. The data from the remaining countries are "likely to be representative, but not as broadly-based." Response rate: Not reported. Data comes from a pre-existing data set. (n=279,191) Data source: Nursing home MDS/Resident Assessment Instrument (RAI). MDS items measuring UI have "been proved to be valid." A resident was considered incontinent when they had, "any uncontrolled leakage of urine, regardless of amount, that occurred two or more times a week."	Age: Denmark: <75: 15.1% 75-84: 34.8% 85+: 50.1% France: <75: 25.2% 75-84: 30.5% 85+: 44.3% Iceland: <75: 11.2% 75-84: 37.3% 85+: 51.5% Italy: <75: 18.2% 75-84: 42.4% 85+: 39.3% Japan: <75: 18.6% 75-84: 46.3% 85+: 35.2% Sweden: <75: 18.3% 75-84: 38.1% 85+: 43.5% USA: <75: 18.9% 75-84: 33.9% 85+: 47.2% Gender: Male and female Denmark: Male: 23.8% Female: 76.2% France: Male: 30.1% Female: 69.9% Iceland: Male: 32.9% Female: 67.1%	Prevalence of urinary incontinence: By country: Denmark: 52,200 / 100,000 (52.2%) France: 65,200 / 100,000 (65.2%) Iceland: 56,500 / 100,000 (56.5%) Italy: 54,400 / 100,000 (54.4%) Japan: 42,900 / 100,000 (42.9%) Sweden: 61,600 / 100,000 (61.6%) USA: 46,400 / 100,000 (46.4%)

	eligibility criteria for the study. Inclusion criteria: primiparity, vaginal route for delivery, age, gestational age ≥37 weeks, and accessibility by telephone. Exclusion criteria: history of urinary incontinence before or during pregnancy, delivery by cesarean section, known diabetes or neurologic disease, and non- English speaking. Definition: Urinary incontinence was defined as the presence of urine loss of any amount that had occurred on at least 2 occasions.			
Sherburn, 2001[57] Cross-sectional and Longitudinal phases III	Subject selection: **2** parts: (1) a cross-sectional phase involving a population-based sample of 1,897 Australian-born women who participated in the baseline interview; (2) a 7-year follow-up phase, assessing a 373 women (premenopausal at 1 year follow-up) from the cross-sectional study. Eligibility for longitudinal study: menstruation in previous 3 months, an intact uterus, at least one ovary, and not currently taking oral contraceptives or HRT. Response rate: of original cohort, 779 met these criteria and 438 (56%) agreed to be interviewed in the first year of the longitudinal study.	Women 45-55 years. Australia	Multivariate analysis found that urinary incontinence patients were significantly more likely than those without incontinence to have higher body mass index (odds ratio [OR] 1.50, 95% confidence interval [CI] 1.15, 1.95), have had gynecologic surgery (OR 2.17, 95% CI 1.42, 3.32), report urinary tract infections (OR 4.75, 95% CI 2.28, 9.90), diarrhea or constipation (OR 1.95, 95% CI 1.27, 3.00), and have had three or more children (OR 1.47, 95% CI 1.06, 2.05).	During the 7-year follow-up phase, overall incidence was 35%. Women who experienced a hysterectomy during the follow-up period had a higher incidence.

Van Kessel, 2001[58] Retrospective Observational II-2 Adjustment for factors including mode of delivery, age in years, and duration of enrollment	Subject selection: The study was conducted at a managed care organization with over 500,000 enrollees. All women who had given birth between 1982 and 1986 and who were continuously enrolled until 1998 were identified with the patient computerized data file. From this cohort, a random sample of women with SUI was selected. 43,288 mother-baby pairs were identified within the computerized database. A random, case-controlled sample of 85 cases and 88 controls was identified	Women 22.6-52.9 years USA	After adjustment factors, the risk for SUI associated with duration of second stage of labor was 1.10 (95% CI 0.90-1.28; *P* = .5) There was no significant difference in mode of delivery between cases and controls with one exception; 10.7% of the cases underwent forceps delivery compared with only 1.1% of controls (odds ratio, 10.4; 95% confidence interval, 1.17-93.4; *P* = .04)	
Larrieu, 2004[59] Cross-sectional III	Data from the Three-City (3C) study; a collaborative research program from a cohort of 9,294 community-dwellers ≥65 years. Subjects living at home were randomly sampled from electoral rolls. Included 8,966 subjects after excluding 328 subjects with missing BMI.	Men and Women ≥65 years 3566 men (39.8%); Mean age: 74.2 y (SD=5.6, not different according to sex) France	BMI	The univariate analysis showed quite frequent incontinence (20.4%) with prevalence significantly higher in the severely obese (39% *vs.* ~ 20% in other categories of BMI, P<0.0001).
Viktrup, 1992[60] Observational II-2	305 primiparas interviewed repeatedly about stress incontinence before and during pregnancy and after delivery over 6 month period. Definition: ICS	Women 17-41years Denmark	Pregnancy	SUI Before pregnancy: 4% During pregnancy: 32% After pregnancy: 7%
Van Kuijk, 2001[61] Observational (cohort) II-2	Subject selection: All patients with first-time, unilateral hemispheric stroke admitted from August 1994 to August 1997 for a post-acute inpatient rehabilitation	Men and Women Age: Men: Mean, 62+-11.5; Range, 32-83yrs Women:		Incidence rates: Overall: 29/1000 Women: 17/1000 Men: 39/1000

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1-b. Risk factors for unrinary incontinence in adults (continued)

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject Age, Gender, Race, Ethnicity, Residency	Levels of Risk Factors	Incidence of Urinary Incontinence, Overall; by Type, Severity, and Impact on Life
	program. Exclusion criteria: non-ischemic stroke, history of previous stroke, evidence of brainstem lesions or bilateral signs on examination, diabetes mellitus, use of anticholinergic medication, history of urinary incontinence, previous urologic surgery, indwelling or intermittent catheterization not regarded as incontinent because of stroke. Definition: Urinary incontinence as any form of involuntary urinary loss. Only urinary incontinence ≤6 months post stroke, considered to be from stroke.	Mean, 62+ - 12.7 years; Range, 30 - 83 years Netherlands		The incidence rate of urinary incontinence was 29/1,000 persons per month (95% confidence interval [CI], 18-48/1,000 persons monthly).
Schmidbauer, 2001[62] Cross-sectional III	Subject selection: Analysis of ~2,500 participants in a health screening project in the area of Vienna, using Bristol LUTS incontinence questionnaire and (a) medical history; (b) a physical investigation; (c) socio-demographic parameters (smoking, eating and drinking habits), and (d) urine and blood study including 14 parameters. The parameters collected during this health investigation were correlated to the presence of urinary incontinence to identify potential risk factors for urinary incontinence. Definition: UI was defined as any involuntary loss of urine within the past four weeks.	Age: Men (49.7+-13.6 years), Women (48.6+-13 years) Austria	Parity showed a strong correlation to UI. 26.3% reported episodes of urinary incontinence in the past 4 weeks. Other factors, age (r = 0.22), BMI (r = 0.20), urgency (r = 0.16), feeling of incomplete bladder emptying (r = 0.21), previous uro-gynecological surgery and fasting blood glucose correlated significantly to UI., 5% of men were incontinent, age (r = 0.12), urgency (r = 0.16), nocturia (r = 0.16), feeling of incomplete emptying (r = 0.16), reduced uroflow (r = 0.18) and previous	In women with no childbirth 16.5% reported on UI, this percentage increased to 29.9% (one child), 29.6% (two children), 33.3% (three children), and 57.7% (four or more children).

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)

			prostatectomy (r = 0.11) correlated to the presence of UI. Smoking habits and education level revealed no association in either sex.	
Hu, 2004[63] Observational II-2	**Subject selection:** women at Group Health Cooperative of Puget Sound (GHC), a staff-model health maintenance organization with approximately 450,000 members in western Washington State. Study subjects with a recent diagnosis of acute UTI. Women were then randomly selected from GHC enrollment files to serve as control subjects, matched to cases by date of birth (within 2 years).	Women aged 55-75 years USA	Acute UTI	Case subjects more likely than controls to report episodes of incontinence >x/month (age-adjusted OR, 1.74; 95% CI, 1.44-2.10) and incontinence with typical quantities greater than a few drops (age-adjusted OR, 1.71; 95% CI, 1.38-2.11). Infrequent incontinence and incontinence of only a few drops were not associated with increased odds of UTI.
Bradley, 2005[64] Cross-sectional Adjusted by: Age, BMI, Parity, Smoking, Alcohol use, Coffee, Exercise, Education, Prior surgery, Angina, Hypothyroidism, Hypertension, Asthma, Pelvic floor symptoms Level of evidence: III	Women with intact uterus enrolled in the Women's Health Initiative Hormone Therapy trial. Response rate: 88% (n=297) Data source: Self-reported written validated questionnaire Incontinence as, "Urinary leaking at least once in the last 3 months."	Age: Mean: 68.2 (SD: 5.6) Gender: Female Race: Not reported Ethnicity: Not reported Residency: Midwest, USA	Risk factor Age Body mass index	UI / OR Difficulty emptying bladder / 3.3 (0.9, 12.2) Feeling of incomplete bladder emptying / 3.4 (1.3, 9.2) Weak urinary stream / 6.4 (2.0, 20.0) Intermittent urinary stream / 4.0 (1.6, 10.4) Vaginal or perineal splinting to defecate / 2.2 (1.0, 4.8) Feeling of incomplete bowel movements / 2.7 (1.2, 5.9) Urgency / 1.8 (0.8, 4.0) Urge urinary / 2.2

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1-b. Risk factors for unrinary incontinence in adults (continued)

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject Age, Gender, Race, Ethnicity, Residency	Levels of Risk Factors	Incidence of Urinary Incontinence, Overall; by Type, Severity, and Impact on Life	
				leaking	(1.0, 4.8)
				Intermittent urinary stream	0.8 (0.3, 1.9)
			Exercise (>weekly)	Urinary urgency	0.6 (0.4, 1.0)
				Fecal urgency	0.3 (0.2, 0.8)
			Coffee drinking	Difficulty emptying bladder	8.6 (1.4, 55.0)
				Weak urinary stream	5.3 (1.5, 19.0)
			Smoking	Pelvic heaviness	5.4 (1.0, 30.0)
				Fecal urgency	2.9 (0.7, 11.7)
O'Donnell, 2005[65] Observational II-2	Subject selection: In 2001, a 13 item questionnaire was mailed to a representative sample of 29,500 community-dwelling women to determine the prevalence, type and treatment behavior of women with UI. Within 2 months of the initial survey a more detailed self-completion questionnaire was mailed to a randomly selected sub-sample of 2,953 women identified as having UI from the initial survey. Follow-up included questions on general health status, quality of life and help-seeking behavior, characteristics of UI, and women's attitudes to health care in general and UI specifically. Response rate: 58% in the initial and 535 in the second. Definition: UI was defined as any	Women ≥18 years with UI France, Germany, Spain and the UK.	UI and women's attitudes were found to be associated with help-seeking after adjusting for age, UI duration and frequency, and 'bother' of UI; factors traditionally associated with help-seeking. After adjustment for these factors, willingness to take long-term medication and having spoken to others about UI were found to be strong predictors of help-seeking in all four countries.	Initial survey: SUI France: 30% Germany: 40% Spain: 39% UK: 41% Total: 37% UUI France: 27% Germany: 16% Spain: 20% UK: 16% Total: 20% MUI France: 34% Germany: 37% Spain: 26% UK: 34% Total: 33% Followup survey: SUI France: 37% Germany: 46%

impairment, comorbid disease, depression, cognitive function and baseline dependency. II-2A	were over sampled Overall response rate was 80% UI measured "next question might not be easy to talk about, but it is very important for research on health & aging, during the last 12 months, have you lost any amount of urine beyond your control?"	IADLS at baseline Patients with UI had more comorbidities (p=.001), higher rate of visual impairment (35% vs. 22.4% p <.001) and hearing impairment (39.7% vs. 30.5% p<.001)	IADL	
Hunskaar, 2004[20] Cross national study, Prospective No control group	Postal survey mailed to 29,500 households in 4 countries – France, Germany, UK and Spain age ≥18 years 58.1% response rate women with UI included in analysis was 5976 (35% of study population) Definitions used by ICS; symptoms in last 30 days and in last 7 days	Mean age France – 44.8 Germany – 59 UK – 45 Spain – 64 All – 58	Age Ethnic background	No new cases reported Only prevalence reported by country
Jackson, 2004[22] Population based Prospective cohort; also randomly selected from HMO diabetes registry II-2A	1,017 post menopausal U.S. women ages 55-75 enrolled in HMO and followed for 2 years (1998-2002) inclusion criteria were no natural menstrual cycle in past 12 months. Exclusion: oral estrogen or vaginal estrogen, residential nursing care, restriction to wheel chair, dementia or severe psych disorder, indwelling catheter or intermittent urinary catheter, end stage renal disease requiring dialysis, active malignancy other than skin cancer, chronic antibiotic use, acute cystitis in past 90 days. Post void residual bladder volume measured using portable ultrasound device 12 month followup done by 87% and 24 month followup by 81% Primary study outcome was sx cystitis	Frequency of Exposures at Enrollment and Univariate Risk of Symptomatic Urinary Tract Infection Characteristic (%) Hazard ratio Washington State, USA	Smoking Alcohol Depression Diabetes BMI Parity Hysterectomy Oral estrogen use COPD Stroke Arthritis Age Race Urinary tract infection Vaginal estrogen use Race and arthritis were associated with SI and Urge. Current oral estrogen use and arthritis were associated with 1.5 to 2 fold higher odds of SI and Urge	Incidence of UTI was .07 per person per year. Independent predictors of infection included insulin treated diabetes (hazard ratio [HR]=3.4;95%confidence interval [CI]: 1.7 to 7.0) and a lifetime history of urinary tract infection(HR for six or more infections = 6.9; 95% CI: 3.5 to 13.6). Borderline associations included a history of vaginal estrogen cream use in the last month (HR = 1.8; 95% CI: 1.0 to 3.4), a history of kidney stones (HR=1.9; 95% CI: 1.0 to 3.7), and asymptomatic bacteriuria at baseline (HR = 1.8; 95% CI: 0.9 to 3.5). 27% white reported weekly UI vs. 14% black (95% Confidence Interval) Complete sample† 1017 (100) Age (years)

	decreased social ability or having hygienic problem with incontinence. Questionnaires returned by 82% in study group, 76% in background group			
Ozerdogan, 2004 [29] Cross sectional study, Prospective II-2A	625 women living in Turkey ages 20 and over 4 different cities of Turkey. Questionnaire and I-QOL; Rare – UI less than once a month Reg – UI more than twice per month Serious – continuous use of sanitary protection. SI and urge defined as usual definitions	Age distribution 20-29 – 26.4% 30-39 – 22.6 40-49 – 18.7 50-59 – 13.4 60-69 – 11/7 ≥70 – 7.2 illiteracy rate 9.4% 1 out of 4 resided in rural area 1 in 5 gave birth at least 4 or more times and most were vaginal deliveries (25%)	Age BMI Smokers Diabetes	UI was associated with advancing age (p <001) UI rate increased from 9.69% in 20-29 to 40% in >70 years. Hysterectomy was a risk factor for MI and Urge (p<.001) BMI (OR 12.75, 95% 6.68-24.6) Diabetes (OR 3.55, 95%, 1.44-8.73 Neuro (OR 3.8, 95%, 1.69-8.58 RUTIs (OR 4.73, 95%, 2.52-8.88) 50% BMI >25, 25% smokers, recurrent UTIs 19%, Diabetes 6.6%, COPD 7.5% Neuro disorders 11.2%
Schytt, 2004[30] Prospective, longitudinal cohort II-2A	Swedish women after childbirth at 593 clinics in Sweden. 5,550 women booked appointments during recruitment time, 4,500 eligible, 3,191 consented, and 3,061 completed 1st questionnaire, 2,762 completed 2nd, and 2,563 completed 3rd. Total 2,450 completed all three. Study sample was 2,390 women after exclusion factors also. Selected data from a National Swedish survey investigating physical and psychological assessment of childbirth May and Sept 1999 and January 2000 antepartal visits Three questionnaires 1st at baseline, 2nd mailed 6-8 weeks after the birth and 3rd 1 year after birth. Women were asked to recall any symptoms of UI during the pregnancy and post. Excluded miscarriages, non-Swedish speaking, and women from nonparticipating clinics, delivery of twins	Average gestation answering 1st quest – 16 weeks, 2nd – 10 weeks post, 3rd – 1 year and 2 weeks. Average age at recruitment – 29.5 years Primiparas – 44% Multiparas – 56% 79.2% had vaginal delivery 13.4% had C-section	Age Parity Education Mode of delivery Smoking	Strongest predictor for SI at 1 year in primiparas as well as multi, was UI during pregnancy and PP. Other predictors were obesity and constipation during pregnancy and after birth. Within the vaginal delivery group, the most important predictors were UI during the third trimester (RR 2.4; CI 95% 2-2.8) and 4-8 weeks PP (RR 2.9, I 95% 2.5-3.3), multiparity (RR 1.3, CI 95% 1.1-1.5), obesity, (RR 1.5 95% 1.1-1.9) and constipation during the third trimester (RR 1.4 (5% CI 1.2-1.6)

Arya, 2001[56] Prospective Observational II-2	Subject selection: 315 consecutive primiparous women delivering by forceps (n = 90), vacuum (n = 75), or spontaneously (n = 150). Follow-up for UI was done at 2 weeks, 3 months, and 1 year after delivery. The labor room logs were screened every morning by a research nurse to identify patients who met the eligibility criteria for the study. Inclusion criteria: primiparity, vaginal route for delivery, age, gestational age ≥37 weeks, and accessibility by telephone. Exclusion criteria: history of urinary incontinence before or during pregnancy, delivery by cesarean section, known diabetes or neurologic disease, and non- English speaking. Definition: Urinary incontinence was defined as the presence of urine loss of any amount that had occurred on at least 2 occasions.	Women ≥18 years USA		

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1-b. Risk factors for unrinary incontinence in adults (continued)

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject Age, Gender, Race, Ethnicity, Residency	Levels of Risk Factors	Incidence of Urinary Incontinence, Overall: by Type, Severity, and Impact on Life
Sherburn, 2001[57] Cross-sectional and Longitudinal phases III	Subject selection: 2 parts: (1) a cross-sectional phase involving a population-based sample of 1,897 Australian-born women who participated in the baseline interview; (2) a 7-year follow-up phase, assessing a 373 women (premenopausal at 1 year follow-up) from the cross-sectional study. Eligibility for longitudinal study: menstruation in previous 3 months, an intact uterus, at least one ovary, and not currently taking oral contraceptives or HRT. Response rate: of original cohort, 779 met these criteria and 438 (56%) agreed to be interviewed in the first year of the longitudinal study.	Women 45–55 years. Australia	Multivariate analysis found that urinary incontinence patients were significantly more likely than those without incontinence to have higher body mass index (odds ratio [OR] 1.50, 95% confidence interval [CI] 1.15, 1.95), have had gynecologic surgery (OR 2.17, 95% CI 1.42, 3.32), report urinary tract infections (OR 4.75, 95% CI 2.28, 9.90), diarrhea or constipation (OR 1.95, 95% CI 1.27, 3.00), and have had three or more children (OR 1.47, 95% CI 1.06, 2.05).	During the 7-year followup phase, overall incidence was 35%. Women who experienced a hysterectomy during the followup period had a higher incidence.
Van Kessel, 2001[58] Retrospective Observational II-2 Adjustment for factors including mode of delivery, age in years, and duration of enrollment	Subject selection: The study was conducted at a managed care organization with over 500,000 enrollees. All women who had given birth between 1982 and 1986 and who were continuously enrolled until 1998 were identified with the patient computerized data file. From this cohort, a random sample of women with SUI was selected. 43,288 mother-baby pairs were identified within the computerized database. A random, case-controlled sample of 85 cases and 88 controls was identified	Women 22.6-52.9 years USA	After adjustment factors, the risk for SUI associated with duration of second stage of labor was 1.10 (95% CI 0.90-1.28; p = .5) There was no significant difference in mode of delivery between cases and controls with one exception; 10.7% of the cases underwent forceps delivery compared with only 1.1% of controls (odds ratio, 10.4; 95% CI, 1.17-93.4; p = .04)	

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)

Larrieu, 2004[59] Cross-sectional III	Data from the Three-City (3C) study; a collaborative research program from a cohort of 9,294 community-dwellers ≥65 years. Subjects living at home were randomly sampled from electoral rolls. Included 8,966 subjects after excluding 328 subjects with missing BMI.	Men and Women ≥65 years 3566 men (39.8%); Mean age: 74.2 y (SD=5.6, not different according to sex) France	BMI	The univariate analysis showed quite frequent incontinence (20.4%) with prevalence significantly higher in the severely obese (39% *vs.* ~ 20% in other categories of BMI, P<0.0001).
Viktrup, 1992[60] Observational II-2	305 primiparas interviewed repeatedly about stress incontinence before and during pregnancy and after delivery over 6 month period. Definition: ICS	Women 17-41years Denmark	Pregnancy	SUI Before pregnancy: 4% During pregnancy: 32% After pregnancy: 7%
Van Kuijk, 2001[61] Observational (cohort) II-2	Subject selection: All patients with first-time, unilateral hemispheric stroke admitted from August 1994 to August 1997 for a post-acute inpatient rehabilitation program. Exclusion criteria: non-ischemic stroke, history of previous stroke, evidence of brainstem lesions or bilateral signs on examination, diabetes mellitus, use of anticholinergic medication, history of urinary incontinence, previous urologic surgery, indwelling or intermittent catheterization not regarded as incontinent because of stroke. Definition: Urinary incontinence as any form of involuntary urinary loss. Only urinary incontinence ≤6 months post stroke, considered to be from stroke.	Men and Women Age: Men: Mean, 62+-11.5; Range, 32-83 years Women: Mean, 62+-12.7 years; Range, 30-83 years Netherlands		Incidence rates: Overall: 29/1000 Women: 17/1000 Men: 39/1000 The incidence rate of urinary incontinence was 29/1,000 persons per month (95% confidence interval [CI], 18-48/1,000 persons monthly).
Schmidbauer, 2001[62] Cross-sectional III	Subject selection: Analysis of ~2,500 participants in a health screening project in the area of Vienna, using Bristol LUTS incontinence questionnaire and (a) medical history; (b) a physical investigation; (c) socio-demographic parameters (smoking, eating and drinking habits), and (d) urine and blood study including 14 parameters. The	Age: Men (49.7+-13.6yrs), Women(48.6+-13yrs) Austria	Parity showed a strong correlation to UI. 26.3% reported episodes of urinary incontinence in the past 4 weeks. Other factors, age (r = 0.22), BMI (r = 0.20), urgency	In women with no childbirth 16.5% reported on UI, this percentage increased to 29.9% (one child), 29.6% (two children), 33.3% (three children), and 57.7% (four or more children).

F1-b. Risk factors for unrinary incontinence in adults (continued)

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject Age, Gender, Race, Ethnicity, Residency	Levels of Risk Factors	Incidence of Urinary Incontinence, Overall: by Type, Severity, and Impact on Life
	parameters collected during this health investigation were correlated to the presence of urinary incontinence to identify potential risk factors for urinary incontinence. Definition: UI was defined as any involuntary loss of urine within the past four weeks.		(r = 0.16), feeling of incomplete bladder emptying (r = 0.21), previous uro-gynecological surgery and fasting blood glucose correlated significantly to UI., 5% of men were incontinent, age (r = 0.12), urgency (r = 0.16), nocturia (r = 0.16), feeling of incomplete emptying (r = 0.16), reduced uroflow (r = 0.18) and previous prostatectomy (r = 0.11) correlated to the presence of UI. Smoking habits and education level revealed no association in either sex.	
Hu, 2004[63] Observational II-2	Subject selection: women at Group Health Cooperative of Puget Sound (GHC), a staff-model health maintenance organization with approximately 450,000 members in western Washington State. Study subjects with a recent diagnosis of acute UTI. Women were then randomly selected from GHC enrollment files to serve as control subjects, matched to cases by date of birth (within 2 years).	Women aged 55-75 years USA	Acute UTI	Case subjects more likely than controls to report episodes of incontinence >x/month (age-adjusted OR, 1.74; 95% CI, 1.44-2.10) and incontinence with typical quantities greater than a few drops (age-adjusted OR, 1.71; 95% CI, 1.38-2.11). Infrequent incontinence and incontinence of only a few drops were not associated with increased odds of UTI.
O'Donnell, 2005[65] Observational II-2	Subject selection: In 2001, a 13 item questionnaire was mailed to a representative sample of 29,500 community-dwelling women to	Women ≥18 years with UI France, Germany, Spain and the UK.	UI and women's attitudes were found to be associated with help-seeking after	Initial survey: SUI France: 30% Germany: 40%

	determine the prevalence, type and treatment behavior of women with UI. Within 2 months of the initial survey a more detailed self-completion questionnaire was mailed to a randomly selected sub-sample of 2,953 women identified as having UI from the initial survey. Follow-up included questions on general health status, quality of life and help-seeking behavior, characteristics of UI, and women's attitudes to health care in general and UI specifically. Response rate: 58% in the initial and 535 in the second. Definition: UI was defined as any leakage or involuntary loss of urine, conforming to the standards recommended by the ICS. For the purpose of this study this definition was restricted to an incidence during the last 30 days.		adjusting for age, UI duration and frequency, and 'bother' of UI; factors traditionally associated with help-seeking. After adjustment for these factors, willingness to take long-term medication and having spoken to others about UI were found to be strong predictors of help-seeking in all four countries.	Spain: 39% UK: 41% Total: 37% UUI France: 27% Germany: 16% Spain: 20% UK: 16% Total: 20% MUI France: 34% Germany: 37% Spain: 26% UK: 34% Total: 33% Followup survey: SUI France: 37% Germany: 46% Spain: 44% UK: 44% Total: 43% UUI France: 9% Germany: 9% Spain: 14% UK: 10% Total: 10% MUI France: 50% Germany: 42% Spain: 34% UK: 42% Total: 42%

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) of UI, Overall: by Type, Severity, and Impact on Life
	the past 12 months, have you leaked or lost control of even a small amount of urine with an activity like coughing, lifting, or exercise (stress incontinence) and "with an urge or pressure to urinate and could not get to the toilet fast enough? " (urge incontinence) Primary outcome: weekly or more frequent UI Bothersome UI and impact of UI: asked to rate degree of worry created by urine leakage and affect of urine leakage on day-to-day activities (categorized by not at all, only a little, versus somewhat, very much, or greatly		normal women (18.2%, P <.01) • Impact on daily activities Is greater among diabetic (12.6%) and prediabetic (14.0%) vs. normal women (4.9%, P <.001)
Danforth, 2006[68] Cross-sectional Adjusted for BMI, Type II Diabetes, hysterectomy, parity, oral contraceptive use, cigarette smoking Level of evidence: II-A	83,355 women who provided information on UI and parity out of 101,294 women who were sampled (82.3% response rate) Nurses Health Study II Mailed survey UI Measurement: During the last 12 months, how often have you leaked or lost control of your urine? (never, <1 time/month, 1x/month, 2-3 x/month, 1 time/week, almost every day) If you lose urine, how much usually leaks? (a few drops, enough to wet underwear, enough to wet outer clothing, enough to wet floor) Created two cases: 1) occasional urine loss (leaking 1-3 times/month 2) frequent urine loss (leaking at least weekly) Severe UI=enough to wet underwear	Women, mean age 44.8 years, USA	Leaked urine in past 12 months: (%) (n's available) • 57% never or <1 time/month • 17% 1-3 times/month • 26% 1 time/week By race (%) • Never or <1 time/month o 56% White o 64% Black o 55% Hispanic o 14% Asian o 17% other or missing • 1-3 times per month o 18% White o 15% Black o 19% Hispanic o 14% Asian o 17% other/missing • 1time/week o 26% White o 22% Black o 26% Hispanic

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1-c. Prevalence of UI in adults in the community (continued)

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) of UI, Overall: by Type, Severity, and Impact on Life
			o 18% Asian o 25% Other/missing Quantity of urine leaked: • 41% a few drops • 53% enough to wet underwear • 6% enough to wet outer clothing/floor Quantity of urine leaked by race/ethnicity: • A few drops o 41% White o 35% Black o 36% Hispanic o 49% Asian o 40% Other/missing • Enough to wet underwear o 53% White o 62% Black o 58% Hispanic o 4% Asian o 6% Other/Missing • Enough to wet outer clothing/floor o 6% White o 4% Black o 6% Hispanic o 4% Asian o 6% Other/missing After adjustment for confounding factors (see table on supplemental evidence table for risk factors): • Significant trend of increasing prevalence with increasing age Women ages 50-54 years had 1.81 times the odds of severe UI compared to women <40 (95% CU 1.66-1.97). After adjustment, Black (OR 0.49, 95% CI: .40-.60) and Asian-American women (OR: .57, CI: .46-.72) were at reduced odds of severe incontinence compared to white women; Hispanic and White women did not differ in UI prevalence

	difficulty controlling urination? Have you ever had any accidental loss of urine, even a small amount?" A negative response was followed by rephrasing the question, "Have you ever wet yourself?" Those who acknowledged any incontinence were asked several questions about onset, course, when it occurred, under what circumstances, and the frequency and volume of urine loss.	USA	
Chen Gin-Den, 2003[123] Level of evidence: II-2	Subject selection: 1,581 women sampled (2.92% of registered female residents aged 20 years and older), Response rate: 1,253 (79.1%) women were successfully interviewed by using the Bristol Female Urinary Tract Symptoms Questionnaire and the Questionnaire of Impact index regarding the impact on quality of life. Definition: Urinary incontinence as involuntary urine leakage occurring during physical activities that cause stress or an increase in the intra-abdominal pressure and was considered by the participant to be a hygienic or social problem. Severity of UI was classified as: Grade 1 is defined as mild leakage with moderate stress, no protection is needed. Grade 2 is moderate leakage with moderate stress, and protection is needed with excessive activity. Grade 3 is severe leakage with mild stress, and constant protection is required except at rest. Grade 4 is incontinence at rest, and in need of constant protection. Urge incontinence was defined as involuntary urinary loss preceded by the urge to void or uncontrollable voiding with little or no warning. Overactive bladder was defined as having symptoms of frequency and urgency, or nocturia, with or without urge incontinence. Women who had both stress and urge incontinence were defined as having mixed incontinence.	Age: Mean= 43.2yrs Taiwan	Prevalence Stress UI:18% Urge UI:18.6% Mixed UI:17.1% Women who were elderly, menopausal, had vaginal deliveries, higher BMIs, parities >2, symptoms of uterovaginal prolapse, a history of diabetes or hypertension were significantly predisposed to an overactive bladder. In multivariate models, previous gynecologic surgery (OR, 2.0; 95% CI, 1.1, 3.7), parity >2 (OR, 2.0; 95% CI, 1.1, 3.8), a history of diabetes (OR, 3.3; 95% CI, 1.5, 7.6), and symptoms of uterovaginal prolapse (OR, 32.9; 95% CI, 12.5, 87.1) are the potential risk factors for Stress UI. Overactive bladder is only associated with symptoms of uterovaginal prolapse (OR, 21.3; 95% CI, 7.8, 58.2). Overall, the women suffering from these three types of urinary incontinence reported that they worried about smelling of urine (65.4%), wetting their clothes (68.2%), pad or towel leakage (45.8%), and exposure of pads or towels (43.0%). At least one third of the women believed that urinary incontinence limited their daily activities, including family life (31.8%), social activities (32.7%), outings for pleasure (50.5%), and changed their interests or hobbies (48.6%). Approximately 19% of the women with urinary incontinence reported an impact of this symptom on their sexual life. The reasons for the restriction of social activities were due to worrying about

Peters, 2003[139] Cross sectional II-2	An age–sex–practice stratified random sample of 1420 patients registered with four general practices in South Bristol was selected. Forty-four patients were excluded because of illness, death or removals out of the area not yet amended on practice records.. Response rates for the four practices varied at 56%, 62%, 68% and 71%, respectively. The majority of respondents were married (54%) and one-third was widowed (33%). A minority were single, cohabiting or were divorced. Just over a third of people were living alone (38%) and nearly half had access to a car (48%). The majority of respondents were living in their own home (63%), with the next largest group (24%) living in local authority rented housing.	White: 99% A total of 915 responses were received (402 males and 513 females), of whom 496 (54%) were in the 65–74 years age range, and 419 (46%) were 75 years or older. UK	Prevalence UI: 39%
Rortveit, 2003[140] Observational(Cohort) II-2	Subject selection: The EPINCONT study, is part of the Nord-Trøndelag health Study 2 (HUNT 2), which was conducted in a county of Norway between 1995 and 1997. All women older than 20 years of age (a total of 47,313 women) received a mailed invitation to visit a screening station. The source population for the EPINCONT study consisted of the 34,755 community-dwelling women who attended the screening. Women were asked to complete a questionnaire at home, and 27,936 women (80 percent) answered questions related to incontinence. Definition If a woman answered yes to an entry question about any involuntary loss of urine, she was asked about the frequency of leakage (less than once a month, once or more per month, once or more per week, or every day, every night, or both), the amount of leakage each time (drops, small amounts, or large amounts), the circumstance of leakage (which could include coughing, sneezing, laughing, and lifting heavy items), whether leakage was accompanied by a sudden and strong urge to urinate, and to what extent she considered leakage a problem (no problem, a small nuisance, some bother, much bother, or a major problem).	Women Age Range: 20-64yrs Norway	Prevalence Any incontinence: 20.7% Moderate /Severe incontinence: 8.7% SUI:12.2% UUI:1.8% MUI:5.9%

Dallosso, 2003[14] longitudinal, Prospective cohort II – 2B	United Kingdom women age ≥40 living at home Part of the Leicestershire MRC Incontinence Study on prevalence and incidence including men and women. This study was women only. 19,239 eligible women; 65.3% returned N= 12,565. 6,424 responded to f/u questionnaire 7,046 women baseline with follow up collected from 6,426 1 yr later = began 10/98 with f/u in 10/99 Postal survey with usual definitions of SI. OAB defined by ICS and for this study as one or both of the sxs urge leakage and urgency. Subgroups of OAB and SI Excluded nursing home or residential pts and SI at baseline was excluded from analysis of onset of SI	Age: 40-49 - 26% 50-59 27.4% 60-69 23.3% 70-79 17.1% >80 6.2% BMI Acceptable 48.4% Underwt 7% Overwt 31.4% Obese 13.3% Smoking Never 54.3 Exsmoker 30.3 Current 15.2	Prevalence of UI at baseline: Stress:17.3% OAB: 16.3% Prevalence of OAB increased with age but no marked change in SI..3% reported SI at baseline.
Stewart, 2003[141] Observational (Case-control) II-2	Subject selection: National telephone survey using a clinically validated interview and a follow-up nested study comparing overactive bladder cases to sex- and age-matched controls. A total of 17,231 households were contacted (includes 2,427 households where eligible members met criteria for region-sex-age-specific strata in which the sampling quota was filled) between November 2000 and January 2001. Response rate: 68% (11,740/17,231) Eligible: 5,539 (47%) Definition: OAB without urge incontinence was defined by a feeling of urgency ≥4 times in the past 4 weeks and either >8 micturitions/day or the use ≥1 of the following coping strategies: restricting fluid intake, locating bathrooms in a new place, limiting travel, or defensive voiding. OAB with urge incontinence included the criteria for OAB without urge incontinence plus ≥3 episodes of urinary leakage in the past 4 weeks that was typical (i.e., frequency of episodes) and was not exclusively due to stress incontinence.	Men and women >18years USA	Prevalence Overall OAB: 16.5% OAB with UUI: 6.1% OAB without UUI: 10.4% Women OAB: 16.9% OAB with UUI: 9.3% OAB without UUI: 7.6% Men OAB: 16.0% OAB with UUI: 2.6% OAB without UUI: 13.4%

F1-c. Prevalence of UI in adults in the community (continued)

Author Sample	Subject Selection, Response Rate, Data Source, Measurement Methods (survey, screening, case finding, definition)	Subject age, gender, race, ethnicity, residency	Prevalence (%) of urinary incontinence, overall and by type, severity, and impact on life
Talcott, 2003[142] Prospective Observational (Cohort) II-2	Subject selection: Recruited patients who consulted physicians at participating sites for advice on primary therapy of pathologically-confirmed, untreated early (nonmetastatic) PC at the Massachusetts General Hospital, the Dana-Farber Cancer Institute, and affiliated clinics of the Joint Center for Radiation Therapy. Baseline questionnaires from 613 eligible patients were returned within 7 days of initiating treatment, a requirement to ensure that the reported baseline symptoms were free from the effects of therapy. 91 enrolled patients (14.9%) dropped out or died of unrelated causes (4 patients) before first follow-up questionnaire at 3 months after treatment, leaving 522 participating patients. Of the remaining patients, 27 patients (11%) had not yet been followed for 24 months, 66 patients (12.5%) dropped out before completing the 24-month questionnaires, and 429 patients (76.6%) continued through 24 months. Definition: The urinary incontinence index assessed the degree of urinary control and the frequency and magnitude of leakage in men who had less than "complete control." Five items assessed urinary obstruction and irritation: hesitancy, frequency of urination during the day, nocturia (urination at night), dysuria, and urgency.	Men 46-82 years Boston, MA USA	Prevalence UI after radical prostatectomy Baseline: 4.9% 3 months: 34.9% 12 months: 23.9% 24 months: 23.4%
Bogner, 2002[143] Cross-sectional Adjusted for age, gender, ethnicity, chronic health conditions, education, ADL status Level of evidence: II-3A	Epidemiologic Catchment Area (ECA) Program, a survey of psychiatric disorders in the general population between 1980 and 1984 at 1 of the 5 university-based sites in US (East Baltimore); data obtained from follow-up interviews which occurred in 1993 to 1996, with most in 1994 Randomly selected blocks based on expected number of households, with a random sample of households, and a randomly selected member within a household Over sampled older people by interviewing all persons in a household aged 65 and older Structured interview in respondent's home by trained lay interviewers	Age range 50-96 years with mean age 67.2 (SD 10.8); Baltimore, MD, USA 502 women (64%) 279 men ((36%) 540 whites (69%) 207 African-Americans (27%) 26 American Indians, Hispanics, or Asians (4%)	20% (n=158) reported UI in past year • 127 women (25.3%) • 30 men (10.8%) 18% (n=29) reported condition-specific functional loss related to UI; 14 people reported 1 limitation, 7 reported 2 limitations, 5 reported 3 limitations, and 3 reported 4 limitations; not specified by gender Adjusting for age, gender, ethnicity, and education, persons with UI were more likely to have psychological distress as measured by the General Health Questionnaire than person without UI (OR 1.56, 95% CI: 1.00-2.43) However, there was no significant difference between those with UI and those without in

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)

Stenberg, 1999[180] Cross-sectional Adjusted by: "Socio-demographic factors," obstetrical and gynecological history, somatic diseases, previous surgery, previous fractures, current medications, and estrogen treatment Level of evidence: III	Subjects were selected from all women born in a county in Sweden between December 1921 and January 1923 (71 year old group) as well as born between December 1911 and January 1913 (81 year old group). Names and addresses were obtained from the population register. Response rate: 87% (Of those aged 71) (n=1,084) 62% (Of those aged 81) (n=611) Data source: Mailed, self-reported questionnaire. Definition of incontinence used in study not reported, but the article claims that the "questionnaire covered all urinary incontinence problems." Symptoms were classified as, "none, trivial, moderate, severe, or unbearable."	Subject age: 71 years of age and 81 years of age Gender: Female Race: Not reported Ethnicity: Not reported Residency: Uppsala County, Sweden	Prevalence: Overall: 71-year-old group: 46,000 / 100,000 (46%) 81-year-old group: 45,000 / 100,000 (45%) Mixed incontinence: 71-year-old group: 20,000 / 100,000 (20%) 81-year-old group: 20,000 / 100,000 (20%) Urge and stress UI prevalence not reported. UI of considerate severity: (Symptoms were deemed considerate when the respondent marked, "moderate, severe, or unbearable" on their response sheet) 71-year-old group: 48,000 / 100,000 (48% of those women experiencing urinary incontinence deemed their UI considerately severe. General population prevalence not reported. "N" not reported either.) 81-year-old group: 59,000 / 100,000 (59% of those women experiencing urinary incontinence deemed their UI considerately severe. General population prevalence not reported. "N" not reported either.)
Swithinbank, 1999[181] Cross-sectional Adjustment factors not reported. Level of evidence: III	Women ≥19 years registered at a general practice were selected and mailed a questionnaire. The practice was chosen because it had near average social and demographic patterns for the city. Response rate: 80% Data source: Validated, self-completed questionnaire. Incontinence defined using the Bristol Female Lower Urinary Tract Symptoms questionnaire (BFLUTS), asking about symptom occurrence during the previous month with a five point likert scale; the 2nd part asks about the degree to which the symptom causes a problem, on a 4-point scale. This definition of UI, was not reported in the article.	Age: 52 (Mean), 19-97 (Range) Gender: Female Race: Not reported Ethnicity: Not reported Residency: a major British city(Not identified in article).	Prevalence: Overall: 69,000/100,000 (69%) By Type: Stress incontinence: 60,000/100,000 (60%) Urge incontinence: 46,000/100,000 (46%) Impact on life: Incontinence having a social or hygienic impact (as per ICS definition of incontinence): 30,000 / 100,000 (30%) Of those women reporting incontinence, 61% reported that it was "problematic." (61,000/100,000) Overall, 40% of women surveyed reported that they experienced incontinence that was "problematic." (40,000/100,000)
Jitapunkul, 1998[182] Cross-sectional Adjusted by: Age, Gender	Selected from all elderly persons living in the Klong Tuey slum in Thailand. Response rate: 72.6% (n=114) Data source: At home interviews	Age 60+ (Mean: 69.3) Gender: Male and female (Male: 33%, Female	Prevalence: Overall: 16.2% Male: 10.8% Female: 18.9 By type, Stress: Overall: 2.84 Male: 0.43 Female: 4.03

Brandeis, 1997[186] Cross-sectional Adjusted by: Age Gender Race Anti-depressant use Impaired mobility ADL's Specific diseases (fecal impaction, CHF, UTI, diabetes, pedal edema, delirium, dementia) Level of evidence: III	Subjects were selected from a representative sample of Medicaid-certified American nursing homes, drawn from ten states. A random sample of residents was selected from each of the 270 nursing homes studied. Response rate: 92.6% (n=2,014) Data source: Standardized forms called the Minimum Data Set (MDS). Registered nurses were trained on data collection using that form. Data was collected from chart review, interview with nursing home staff, and observation of residents. Incontinence was defined as, "at least two episodes per week of involuntary urine loss within the past two weeks."	Age: Residents 60 years of age or older Mean: 84.3 (SD: 8.7) Gender: Male (24.5%) and female (75.5%) Race: White: 81.9% Black: 12.7% Other not reported Ethnicity: Not reported Residency: Nursing home residents in ten states in the USA	Prevalence of urinary incontinence: Overall: 49,000 / 100,000 (49%) Men: 45,100 / 100,000 (45.1%) Women: 78,400 / 100,000 (78.4%) Type, severity, and impact of incontinence not reported.
Brieger, 1997[187] Cross-sectional Adjusted by: Age Height Weight BMI Place of birth Parity	Subjects were randomly selected from telephone directories in the regions of Hong Kong Island, Kowloon, and the New Territories. Response rate: 43% Data source: Telephone survey with a previously validated and tested questionnaire. Incontinence was defined as "involuntary loss of urine which is socially or hygienically unacceptable."	Age: Mean: 45 (SD: 15) Gender: Female Race: Not reported Ethnicity: Chinese Residency: Hong Kong, China	Prevalence: Overall: 13,000 / 100,000 (13%) By Type: Stress Incontinence: 10,000 / 100,000 (10%) Urge Incontinence: 700 / 100,000 (0.7%)

Malmsten, 1997[188] Cross-sectional Adjusted by: Age Marital status Foreign extraction Place of residence Urinary tract infections Level of evidence: III	Subjects were randomly selected from the total population of men 45 and older living in Goteborg, Sweden in 1992. The subjects were selected from the population register, and were selected by year of birth. Several cohorts were obtained at 5-year intervals. A sample was taken from those born in: 1947, 1942, 1937, 1932, 1927, 1922, 1917, and 1912. All men born in 1907 or earlier were included to obtain a more comprehensive sample of older men. Response rate: 74% (n=7,763) Data source: Self-reported, mailed questionnaire Urinary incontinence was defined according to the International Continence Society and was confirmed by a 48-hour pad test and voiding lists.	Age: ≥45 years Mean: 63.1 (SD: 19.0) Gender: Male Race: Not reported Ethnicity: Not reported Residency: Goteborg, Sweden	Age (years) Prevalence % 45 3.6 50 4.1 55 3.3 60 5.1 65 6.1 70 7.3 75 9.6 80 19.7 85-89 21.8 90+ 28.2 Total 9.2 Overall: 9,200 / 100,000 (9.2%) By severity (Of incontinent men): Daily leakage: 64,100 / 100,000 (64.1%) 2-3 times/week: 12,600 / 100,000 (12.6%) Once weekly: 8,200 / 100,000 (8.2%) Once monthly: 15,100 / 100,000 (15.1%) By impact on life: Men who considered their UI to “Limit their social life:” 31,000 / 100,000 (31%)
Mozes, 1997[189] Adjusted by: Age Origin Education Economic status Urinary symptoms Co-morbidities (Heart disease, diabetes, respiratory disease, hypertension, joint disease, peptic disease, renal disease, cancer) Level of evidence: III	Subjects were randomly selected from all Israeli cities and settlements over 5,000. Areas were stratified by region and population size. Within selected cities, the sampling unit was according to dwelling. Within dwellings, individuals were recruited using quotas for socioeconomic status and age. Response rate: 93.3% (n=896) Data source: Personal interviews in homes of respondents with a validated questionnaire. This study looked at “urinary symptoms.” The only question dealing specifically with incontinence was, “Do you experience involuntary urination while coughing or laughing?” Stress incontinence was the only type of incontinence measured.	Age: 45-75 years old Gender: Male Race: (Listed as “origin” in report) Asia-Africa: 43.2% Europe-America: 47.7% Israel: 9.1% Ethnicity: Not reported Residency: Israeli cities and settlements	Prevalence: Stress Incontinence: 2,100 / 100,000 (2.1%) By Severity: (Of any urinary symptoms, which include: weak stream, frequency, hesitancy, dribbling, dysuria, incomplete emptying, nocturia, stress incontinence, urinary retention) Bothersome: Mild: 86,500 / 100,000 (86.5%) Moderate: 8,900 / 100,000 (8.9%) Severe: 4,600 / 100,000 (4.6%)

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)

F1d. Prevalence and incidence of fecal incontinence in adults

Author, Year, Design, Adjustment for Confounding Factors	Subject Selection, Data Source, Methods to Measure Incontinence (survey, screening, case finding), Definition of incontinence)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) or Incidence of Fecal Incontinence, Overall: by Type, Severity, and Impact on Life
Uustal Fornell, 1996 [208] Comparative case control	51 Females with rupture of anal sphincter during vaginal delivery. 31 Females without rupture of anal sphincter during vaginal delivery, rupture groups were subdivided into incomplete sphincter rupture and complete sphincter rupture for some analyses. **Methods:** Questionnaires at 6 months after delivery. **Definition:** 6 point scale, 6= complete continence, 1 = total incontinence, incontinence of gas, liquid stool, solid stool, soiling, no operational definitions were given.	**Age:** With Rupture, Median= 27 years, Range=20-38 years, Without rupture, Median=26 years, Range=20-35 years **Gender:** Female **Residency:** Sweden	Incontinence of Liquid Stool 16% of the 51 with a rupture 13% of the 31 without a rupture Liquid Stool on the 6 Point Scale Unable to determine median severity score for no rupture group Median severity for incomplete rupture group = 5 Median severity of liquid stool incontinence for complete rupture group = 4.5 Solid Stool = 0% per test (These results above are presented by box plots)
Pescatori, 1990 [209] Prospective, observational **Adjustment For:** No determination of whether patients had fecal incontinence pre-operatively was reported.	207 patients who underwent restorative proctocolectomy and ideo-anal reservoir between March 1980 and May 1989 who were in the Italian registry, 156 patients where studied. **Definition:** Disordered continence, occasional soiling of mucus or feces, permanent soiling of mucus or feces, total minor leak, total major leak. None of these were operationally defined; "totals" appear to be mucus and feces	**Age:** <45 years (n=123) >45 years (n=33) **Residence:** Italy	Fecal Soiling: Soiling in those <45 years old=6% of 123 Soiling in those >45 years old=15% of 33 Bivariate analysis of risk, n = stool frequency. Pouchitis 70 patients with fecal soiling, of those with <5 stools/day = 4%, n = 4 of 108 70 patients with fecal soiling, of those with >5 stools/day = 17% (n = 8) Pouchitis: 22% (4/18) patients who had pouchitis had fecal soiling while 6% of those without pouchitis (8/138) had fecal soiling. No significant difference in any risk.
Belmonte-Montes, 2000 [210] Prospective, descriptive, observational **Adjustment For:** Females with a history of anal sphincter damage, diabetes, neurological disease, needing a C section, or history of	98 primiparous females of obstetrics out-patient clinic of medical specialties, Center of Mexican army and air force between May of 1996-1999. **Methods:** Interview, clinical exam, and endo-anal ultrasound that were done 4-6 weeks before and 6 weeks after delivery. **Definition:** Incontinence of gas, mucus, liquid and solid stool, frequency ≥1 x 1 week, ≥2 x 1 month,	**Age:** Average = 22.4 years SD = 3.56, range = 16-34 **Gender:** all Female **Residency:** Mexico	Fecal Incontinence 21 had some fecal incontinence after delivery but gas and mucus leaks are mixed in here so not included. "Major" fecal incontinence later defined as "accidental bowel movements" was in 5 women. **Risks:** 14 women with a sphincter defect on ultrasound had fecal incontinence but 7 did not. Results state there was a strong association between sphincter defect on ultrasound and incontinence. P <.0001 but no "r" or other statistic is reported.

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1d. Prevalence and incidence of fecal incontinence in adults (continued)

Author, Year, Design, Adjustment for Confounding Factors	Subject Selection, Data Source, Methods to Measure Incontinence (survey, screening, case finding), Definition of incontinence)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) or Incidence of Fecal Incontinence, Overall: by Type, Severity, and Impact on Life
previous anarectal or vaginal surgery were excluded.	1 x 1 month		
Ho, 1995[211] Cross section Listed as not eligible	602 consecutive patients who had a curative resection for colorectal cancer ≥12 months prior to survey. **Methods:** mailed questionnaire. **Definition:** used grading classification, grade 3 = occasional liquid soiling, 4 = frequent liquid or mild soiling, 5 = incontinence of solids.	**Age**: x = 64.5 years, SEM = .7 **Gender:** F = 41.3%, M = 58.7% **Residency**: Singapore	No overall % was reported. After R hemicolectomy: Grade 3 = 16.4% of 55 patients After L hemicolectomy: Grade = 9.6%, Grade 5 = 1.9% of 53 patients Sigmoid colectomy: Grade 3 = %.4%, Grade 5 = 3.6% of 56 patients Low anterior resection: Grade 3 = 19.9%, Grade 4 = 5%, Grade 5 + 4.3% of 143 patients
O'Keefe, 1995[212] Cross sectional **Adjustment For:** data were adjusted to age and gender specific proportions in 1980, US census	Random sample of 704 Olmsted County residents ≥ 65 years old 530 responded, 478 completed section containing fecal incontinence information **Method of Measurement-** mailed survey. **Definition: f**ecal incontinence as leakage of stool once per week or more or use of a pad to prevent soiling. The second part of the definition doesn't require leaking, only an intent to prevent it.	**Age:** x = 75 years, range = 65-98 **Gender:** 49% female **Residency:** Olmsted County, MN	Fecal incontinence Overall + 8.2% (5.5, 10.8), 95% CI Men = 8.1 % (4.3, 11.8) Female = 7.9 (4.4, 11.4) Impact on life Functional status and health of those with fecal incontinence did not differ from those with any of the GI condition and did not appear to be significantly different from controls (no p values given). Other Findings: 16% of those with diarrhea had fecal incontinence, 12% of those with IBS had fecal incontinence, no denominators were reported
Hinds, 1990[213] Point prevalence	Every 4th person on mailing list of National MS Society of Allegheny County, 78 persons in Allegheny hospital work force non MS controls. **Methods:** mailed questionnaire, 1 follow up mailed questionnaire to MS patients with fecal incontinence **Definition:** Involuntary passage of stool at least once during preceding 3 months	**Age:** 280/with MS 339 responded, 78 non MS, age MS = 48 years (19-77), non MS = 42 years (22-64) **Gender:** Female = 77% of MS, Female = 78% non MS **Residency:** Allegheny County PA	Prevalence of Fecal Incontinence Overall MS = 51% Mild MS = 25% Non MS = 4% 50/147 MS patients responded to follow up: Fecal incontinence occurred most often when stools were semi-formed as liquid (no data reported) Fecal incontinence frequency: daily = 2%, 1 to several times a week = 22%, ≤1/week - 7.33 months = 23%, once every 3 months = 50%
Kok, 1992[202] Survey, point prevalence	1049 questionnaires were mailed to women ≥60 years in Amstelveen, Netherlands; a random sample of 30 women born each year was selected **Methods:** Mailed survey	**Age:** 60-84 years **Gender:** Female **Residency:** Amstelveen,	Fecal Incontinence; <85 = 4.2% of 625, ≥85 = 16.9% Urinary Incontinence; daily = 14% (n = 96) 60-85 years, fecal incontinence = 8 (8.5%) of those with urinary incontinence, fecal incontinence = 11 (2.9%) of those without urinary incontinence

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1d. Prevalence and incidence of fecal incontinence in adults (continued)

Author, Year, Design, Adjustment for Confounding Factors	Subject Selection, Data Source, Methods to Measure Incontinence (survey, screening, case finding), Definition of incontinence)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) or Incidence of Fecal Incontinence, Overall: by Type, Severity, and Impact on Life
	Definition: Occasional involuntary loss of feces	Netherlands	≥85 years, fecal incontinence = 9 (21.4%) of those with urinary incontinence, fecal incontinence = 15 (12.2% of those w/o urinary incontinence.
Talley, 1992[214] Survey, point prevalence **Adjustment For:** age and sex adjusted using 1980 US white population	Age and sex stratified random sample of non-institutionalized residents in Olmsted Country MN aged 65-93 years. **Methods:** mail questionnaire **Definition:** Stool leakage; clinical significant incontinence was defined as once a week or more, or if wearing a pad is needed	**Age:** not reported **Gender:** not reported **Race and Ethnicity:** all white **Residency:** Olmsted County, MN	Fecal Incontinence; Once/week = 3.7% (1.6-5.9) 1/ week and needs to wear a pad = 7% (4.1-9.9) wear a pad for fecal incontinence- 6.1% (3.3-8.8) **Of the 7%** : Fecal Incontinence and constipation w/o obstructive features = 4% Fecal incontinence and constipation with obstructive features = 17% Fecal Incontinence and diarrhea = 42% Fecal Incontinence without constipation or diarrhea = 42% Age Adjusted Women: Fecal Incontinence >once/week = 3.1 (.39-5.9) Fecal Incontinence and pad = 6.7% (2.9-10.6) Age Adjusted Men: Fecal Incontinence >once/week = 4.5% (1.3-7.7) Fecal Incontinence and pad = 4.6% (1.4-7.8)
Hojberg, 2000[215] Cross sectional	All women getting routine antenatal cure at Aarhus University Hospital from January 1993-April 1996. 7,557 completed questionnaire **Methods:** Questionnaire **Definition:** fecal incontinence as involuntary loss of flatus, liquid, or solid stool in the past year.	**Age:** 15-24 years = 1302 (17%), 25-29 = 3162 (42%), 30-34 = 2292 (30%), 735 = 801 (11%) **Gender:** all female **Residency:** Denmark	Fecal Incontinence: Liquid Stool = 2.3% Solid Stool = .06% Note- Multiple logistic regression was done for flatus incontinence only
Faltin, 2001[216] Cross sectional	All women who attended the maternity outpatient clinics at Geneva University Hospital in Switzerland from August 1st to September 30th, 1996. 1,228 responded **Methods:** Structured questionnaire **Definition:** fecal incontinence as involuntary loss of solid or loose stools or flatus occurring ≥once/month, asked to report type of incontinence: flatus and/or liquid and/or solid stool	**Age:** not reported for whole sample **Gender:** All female **Residency:** Switzerland	Fecal Incontinence M = 38 had solid or loose stools: 38/99 who had any anal incontinence = 38%, 38/1228 = 3% Note: 8% of the 1228 respondents had any anal incontinence
Kirk, 1997 [217]Cross sectional **Adjustment For:** stratified sampling by	171, patients with spinal cord injury ≥1 year duration. **Source:** discharge list from acute rehabilitation, inpatient facility and an	**Age:** x = 39.5 years, SD = 14.5, range= 18-81 years **Gender:** 75% male, n =	Incontinence 30% had incontinence in the past month 65% had incontinence in the past year (only a bar graph reported findings, no exact percentage was given)

F1d. Prevalence and incidence of fecal incontinence in adults (continued)

Author, Year, Design, Adjustment for Confounding Factors	Subject Selection, Data Source, Methods to Measure Incontinence (survey, screening, case finding), Definition of incontinence)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) or Incidence of Fecal Incontinence, Overall: by Type, Severity, and Impact on Life
	Methods: Interview and physical exam **Definition:** No definition of fecal incontinence was reported, "early" fecal incontinence- present within 1 month after surgery and spontaneously resolved, "late" fecal incontinence- occurred after 1 month after surgery and required some type of corrective procedure	Range 18-44 years **Gender:** 93 males **Residency:** Italy	restored within 3 months in 12/15 patients. Note: there is no report of pre-operative continence status
Wagenius, 2003[231] Retrospective case-control **Adjustment:** Case and controls matched for age parity, vaginal delivery birth weight, and year of birth	218 women with a history of obstetric anal sphincter rupture and repair between 1994-1999, 436 women with no rupture **Methods: m**ail questionnaire **Definition:** no definition reported	**Age:** Median(range) = for total n (534) = 29(18-42) years, cases n = 186 = 30(18-40) years, controls m = 348 = 29(18-42) years **Gender:** All female **Residency:** Sweden	Urinary Incontinence Cases = 24 (13%), Controls = 33 (9%) Not significant OR(ci) = 1.41(.81-2.47) Fecal incontinence of liquid stools Cases = 39 (21%), Controls = 26 (7%) p < .0001, 3.29 (1.93-5.6) Fecal incontinence of solid stool Cases = 8 (4%), Controls = 8 (2%) Not Significant = 1.91 (.71-5.170)
Quander, 2005[232] Cross sectional	Chicago Health and Aging Project = 6,099, 1993-1997 time period. **Methods:** In-home interview. **Definition:** Interview question and answer = "In the past few months, have you ever lost control of your bowels when you didn't want to?"	**Age:** 65-74 years = 59%, 75-84 years = 30%, >85 years = 11% **Gender:** 61% female **Subject Race and Ethnicity:** 62% Black, N = 6 American Indian, N = 9 Pacific Islander, N = 41 Hispanic **Residency:** United States	Fecal Incontinence in 585 (9.6%) Multivariate analysis (logistic regression) adjusting for age, sex, and race, fecal incontinence = 1.7 times greater in diabetics vs. non-diabetics (ci = 1.4, 2.1) and 2.8 times greater in stroke vs. non-stroke residents (ci = 2.2, 3.5) Medication use adjusted for sex, age, race, history of diabetes and stroke in multivariate analysis. Antidepressants, 21% using, 1.9(1.2, 3.0) Antipsychotics, 33% using, 3.9(2.5, 6.2) Narcotics, 17% using, 1.7(1.2, 2.5) Hypnotics, 26% using, 3.1(1.8, 4.8) Antiparkinson, 33% using, 4.3(2.5, 3 Anticonvulsant, 22% using, 1.9(1.9, 3.2) Income and Education and Fecal Incontinence Prevalence Fecal incontinence income < $10,000 = 14.3%, $10,000-$20,000 = 8.6%, > $20,000 = 6.8%, x^2 = 65.5 p <.0001 Fecal incontinence in people with 0-8 years education = 12.9%, 9-12 years education = 8.8%, >13 years education = 8.7%, x^2 = 19 p <.0002 "No significant difference in prevalence of fecal incontinence in men vs. women once adjusted for age". "In prevalence of fecal incontinence with age was greater among blacks

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1d. Prevalence and incidence of fecal incontinence in adults (continued)

Author, Year, Design, Adjustment for Confounding Factors	Subject Selection, Data Source, Methods to Measure Incontinence (survey, screening, case finding), Definition of incontinence)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) or Incidence of Fecal Incontinence, Overall: by Type, Severity, and Impact on Life
			than whites (p = .0006)". Among those 85 years and older, fecal Incontinence in white females = ~17%, white Males = 19%, black females = 24%, black Males = 16%. Fecal incontinence in stroke patients = 21.5%, No stroke = 8.3% p < .0001, diabetics = 13.2%, Non-diabetics = 8.8%.
Schweitzer, 2005[233] Retrospective, descriptive	128 women who had surgery for pelvic organ prolapse. **Source:** 3 hospitals **Methods:** postal questionnaire **Definition:** no definition reported; findings report urinary incontinence after surgery	**Subject Age:** N = 112 women ≥80 years, responded (88%), x(range) = 83(80-92) years **Gender:** Female **Residency:** Netherlands	Urinary Incontinence Strenuous urinary incontinence = 14% (12/87) Urge urinary incontinence = 10% Mixed urinary incontinence = 31% No urinary incontinence = 40% Unknown = 5% Note: 36% n = 46 patients had "incontinence" before surgery
Sangalli, 2000[234] Retrospective, descriptive, and cohort	448 women who had a partial (30) or complete (40) tear during delivery between January 1982 and December 1983, 178 responders; 129 had 3rd degree tear, 49 had 4th degree tear **Methods:** Telephone interview >10 years after delivery **Definition:** fecal incontinence response was recorded only if the women perceived the incontinence as bothersome	**Age:** x = 27.7 years in 1982/83, in 1995 age = x = 40.7 years, range = 32-54 years **Gender:** Female **Residency:** Switzerland	Fecal Incontinence Of the 129 with 3 degree tears, 6.2% (n = 8) had fecal incontinence of liquid stools and 0.8% (n = 1) had fecal incontinence of solid stools Of the 48 with the 4 degree tears, 10.2% (n = 5) had fecal incontinence of liquid stools and 6.1% (n = 3) had fecal incontinence of solid stools All were non-significant
Siproudhis, 2005[235] Cross sectional	10,000 people ≥15 years received a household survey in May-June 2003, N = 7,196 responded, 2,915 had anorectal problems **Methods:** mail questionnaire. **Definition: (**question and answer) "During the past 12 months have you ever experienced an uncontrolled anal leakage of stool?" Quality of life = 10cm visual analog scale for professional life, social life, sexual/partner life, family life	**Subject Age:** mean age(SD) = 45.8(23.1) years, 2,388 <35 years, 2,332 >54 years 1,440 ≥65 years (20%) **Gender:** 3,455 males **Residency:** France	Fecal incontinence = 513/2,915 (17%), 513/7,196 (7.1%) Usual stool consistency in those with fecal incontinence. Loose = 18%, Hard = 20%, Very hard = 5%, Normal = 15% (findings reported in graph only) Stool consistency of people with fecal incontinence differed from those without any anorectal problems, p <.01 Usual stool consistency in those with no problems Loose = 7%, Hard = 3%, Normal = 50% Frequency of Fecal Leakage ≥1/day = 11 (2.2%) 1/day to 1/week = 25 (4.8%), 1/week to 1/month = 41 (8%), <1/month = 420 (82%), not applicable = 15 (2.9%) Quality of life for "incontinence" includes gas and stool leakage so unable to determine effect of fecal incontinence on quality of life.
Buchanan, 2002[236]	N= 79, 418 admission MDS forms of Nursing Home residents with Parkinsons's disease from June 23,	**Age:** x = 79.7 years, SD = 9.0 **Gender:** 48.4% male	Prevalence of fecal incontinence = 48% Prevalence of urinary incontinence = 39% Frequent urinary incontinence = 16.8%,

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1d. Prevalence and incidence of fecal incontinence in adults (continued)

Author, Year, Design, Adjustment for Confounding Factors	Subject Selection, Data Source, Methods to Measure Incontinence (survey, screening, case finding), Definition of incontinence)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) or Incidence of Fecal Incontinence, Overall: by Type, Severity, and Impact on Life
	1998 - September 12, 2000 **Methods:** MDS data **Definition:** MDS items for bladder and bowel incontinence	**Subject Race:** white = 89.4%, black = 5.1%, Asian = 1.4%, American Indian = 4%	Occasional urinary incontinence = 9.8% Frequent fecal incontinence = 8.6% Occasional fecal incontinence = 6.5%
Stenzelius, 2007[237] Cross sectional	N = 248, age $\geq$ 75 years **Methods:** Postal questionnaire to people who reported they had fecal incontinence in past 3 months on a different (previous) questionnaire. **Definition:** No definition reported	**Subject Age:** x = 82, SD = 5.19 **Gender:** Female = 142, Male = 106 **Residency:** Sweden	Fecal Incontinence. Fecal Incontinence in 56.4% of respondents. Daily/weekly fecal incontinence: Women = 18.6% Men = 4.9% (p = .01) Overall = 12.8% non-significant Large or medium amount of fecal incontinence: Women = 18.2 Men = 6%, p = .01 Overall = 43.6% non-significant Fecal incontinence did not have significant impact on quality of life.
Sullivan, 1992[238] Cross sectional	N = 109 runners who ran an average of 18 miles per week in a runners club; inclusion criteria was running 3 times per week. **Methods:** Questionnaire. **Definition:** none.	**Age:** 39 $\pm$ 13 Male, 34 $\pm$ 9 Female **Gender:** Male = 78, Female = 31 **Residency:** Canada	Fecal Incontinence in 12% (n = 13) 10 males, 3 females during or after running
Otegbayo, 2006[239] Cross Sectional	Consecutive patients with stroke selected over 18 months (N = 54), controls = normal, volunteers or in-patients (N = 46) without fecal incontinence. **Methods:** Interview or chart.	**Age:** Stroke patients = 58.7 (10.6) control = 52(10.9) **Gender:** Stroke male = 46.3%, control male = 69.6% **Residency:** Africa	Prevalence of Fecal Incontinence Stroke = 5.6% Control = 0% P = .10 No difference in % fecal incontinence by type of stroke (ischemic vs. hemorrhagic, p = .20) or right vs. left side of brain with stroke p = .51
Ween, 1996[240] Cross Sectional	Consecutive admissions of stroke patients to Braintree Hospital in 1993; N = 423 **Methods:** Chart review **Definition:** Report of incontinence by nurses on flow sheet in chart	**Age:** 73 $\pm$ 12 **Gender:** 55% female	Prevalence of incontinence 41% were incontinent at admission Only bivariate analyses were reported primarily x^2 Urinary incontinence was associated with stroke p < .0003 Fecal incontinence was associated with urinary incontinence p < .0001 (80%) and dysphagia p < .0001 (81%) Fecal incontinence was associated with functional impairment as measured by an AFIM score, p < .0001 of those with an AFIM score = >80, 1% had fecal incontinence If AFIM score 60-80, 17% had fecal incontinence If AFIM score 40-60, 66% had fecal incontinence If AFIM score <40, 94% had fecal incontinence

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1d. Prevalence and incidence of fecal incontinence in adults (continued)

Author, Year, Design, Adjustment for Confounding Factors	Subject Selection, Data Source, Methods to Measure Incontinence (survey, screening, case finding), Definition of incontinence)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) or Incidence of Fecal Incontinence, Overall: by Type, Severity, and Impact on Life
			Urinary incontinence on admission was associated with UTI p < .001 18% 50% of residents admitted with incontinence remained incontinent on discharge
Bharucha, 2005[241] Cross-Sectional **Adjustment For:** Results were adjusted by age and the 2000 US white female population on the US census	2800 of 5300 women (53%) responded to survey; sample included NH residents women were ≥ 20 years old **Methods:** Questionnaire to age stratified random sample of women in a Rochester epidemiology project **Definition:** QA: "In the past 12 months have you experienced accidental leakage of solid or liquid stool? Fecal Incontinence severity score was calculated (max score = 13) using a summative scale: an MD assigned a severity score to self-reported fecal incontinence symptoms, no question was reported for any fecal incontinence history Quality of Life: 15 domains with 4 levels 0 = none, 1 = mild, 2 = moderate, 3 = severe Quality of Life: QAs were not tested for validity or reliability	**Gender:** All female **Subject Race:** White **Residency:** Olmsted County, MN	Prevalence of Incontinence Age adjusted fecal incontinence prevalence in last year = 12.1% (I = 11.0 - 13.1) Prevalence of any fecal incontinence history = 14% (I = 12.8 - 15.1) Fecal incontinence frequency m = 503 < 1 per month 55%, adjusted prevalence 6.7(5.8 - 7.5) 1 per month 24%, adjusted prevalence 2.9(2.3-3.4) 1 per week 12%, adjusted prevalence 1.4(1.0-1.8) Several times a week 9%, .9(.6-1.2) Daily 2%, adjusted prevalence .2(.1-.3) Amount m = 502 Small (stain underwear only) 60%, 7.3(6.5-8.2) Moderate (need to change underwear but not clothing) 33%, 3.8(3.2-4.4) Large (change outer clothing) 7%, 0.8(0.5-1.1) 23% of respondents reported fecal incontinence had moderate or severe impact on quality of life in > 1 domain; there was no significant difference in impact of fecal incontinence on specific quality of life domains.
Johannsson, 2002[242]	556 consecutive patients who had Milligan-Morgan hemorochoidectomy at 4 clinics in Sweden between 1987-1995; 40 died, 9 lost to follow up so 507 received questionnaires - ok **Methods:** Questionnaire mailed **Definition:** Anal incontinence	**Age:** x = 51 years, range = 20-82 **Gender:** Male = 231 (55%), Female = 187 (45%) **Residency:** Sweden	Prevalence of Fecal Incontinence overall 56 were incontinent of liquid feces 11 were incontinent of solid feces 72 were incontinent of gas Note: pre-operative incontinence was not reported 25 patients who leaked liquid stool related it to the surgery 6 who leaked solid stool related it to surgery
Karasick, 1997[243] Retrospective cross sectional	Cases of 354 consecutive female patients who had fluoroscopically guided defecograpy between March 1986 and March 1996 **Methods:** Chart review for fecal incontinence telephone interview for OB history and surgery	**Age:** X(SD) = 57.7(16.3) years **Gender:** All female **Residency:** United States	Prevalence of Fecal Incontinence 40% m = 108 No multivariate analysis of risks only correlations

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1d. Prevalence and incidence of fecal incontinence in adults (continued)

Author, Year, Design, Adjustment for Confounding Factors	Subject Selection, Data Source, Methods to Measure Incontinence (survey, screening, case finding), Definition of incontinence)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) or Incidence of Fecal Incontinence, Overall: by Type, Severity, and Impact on Life
	Definition: Fecal Incontinence = widened anal canal (> 2 cm) with barium leakage at rest		
Cavaliere, 1995[244] Retrospective chart review **Adjustment For:** Follow up was 50 months	Records from Cleveland Clinic and Mayo clinic, 178 patients undergoing protocsigmoidscopy and manual colorectal anastomsis for rectal cancer 1981-1990 study n = 68 **Methods:** Questionnaire **Definition:** Not reported Residents ≥ 65 years in 241 nursing homes or hospitals; (N = 6,079) number of acutely ill = 627	**Age:** not reported **Gender:** not reported **Residency:** not reported	Incidence of Fecal Incontinence 57% m = 18 had fecal incontinence Note: Whether patients had fecal incontinence before surgery was not reported Prevalence of Incontinence Urinary incontinence = 27%
Peet, 1995[245] Cross Sectional	**Methods:** "Census" probably means "observation" **Definition:** none reported	**Age:** x = 82.7 years, SD = 7.8 years **Residency:** Leicester, UK	Fecal Incontinence = 1.8% Urinary incontinence and fecal incontinence = 34.3% Note: I did not include those with a urinary catheter as having urinary incontinence Residents > 65 years in 241 nursing homes or hospitals
Fialkow, 2003[246] **Adjustment For:** Exclusions	University of Washington Medical Center - Roosevelt Urology and Urogynecology Clinic; All new adult community patients to clinic between 6/13/2000 and 7/1/2002 were sent a questionnaire; ages 18-90 years **Methods:** questionnaire, N = 7732 **Definition:** Wexner scale of fecal incontinence severity I-QOL for urinary incontinence QoL 3 day voiding diary for urinary incontinence Urinary incontinence severity was measured by questions on questionnaire on 5 point Likert scale 1 = mild, 5 = severe SF12 measured functional status	**Age:** x = 55.9, SD = 14.3 **Gender:** all female **Subject Race:** 80% white **Residency:** United States	Prevalence of Incontinence Fecal incontinence n = 18 Urinary incontinence m = 342 Double incontinence m = 65 mean (SD) Wexner Score for fecal incontinence = 12.33 (4.7) Urinary incontinence severity score = 3.1(1.3) in those with UI I-QOL total score; urinary incontinence = 62.9, double incontinence = 46.4, p = < .001 I-QOL avoid/limit score; urinary incontinence = 59.9, double incontinence = 43.8, p = < .001 I-QOL psychosocial; urinary incontinence = 71.6, double incontinence = 53.2, p = < .001 I-QOL embarrassment; urinary incontinence = 50.4, double incontinence = 37.9, p = < .001 SF-12 PCS12 (physical); fecal incontinence = 45.5, urinary incontinence = 42.4, double incontinence = 38.6, p = .027 SF12 MCS12 (mental); fecal incontinence = 46.9, urinary incontinence = 50.4, double incontinence = 46.4, p = .032
Bek, 1992[247]	152 women who had a complete obstetric tear of anal sphincter at 1 hospital and 121 responded, 56 had another vaginal delivery so study	**Age:** not reported **Residency:** Denmark	Prevalence of Incontinence Fecal incontinence after tear N = 3 but fecal incontinence was only transient Fecal incontinence after next delivery m = 9

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1d. Prevalence and incidence of fecal incontinence in adults (continued)

Author, Year, Design, Adjustment for Confounding Factors	Subject Selection, Data Source, Methods to Measure Incontinence (survey, screening, case finding), Definition of incontinence)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) or Incidence of Fecal Incontinence, Overall: by Type, Severity, and Impact on Life
	sample equals these - 56 **Methods:** questionnaire by mail **Definition:** anal incontinence included flatus but separated fecal soiling results for incidence but not for repression analysis, those results are not included Note: incontinence before sphincter tear was not reported		
Goode, 2005[248] Cross Sectional	Medicare lists of 5 counties (3 rural, 2 urban) of west central Alabama; N = 1,000 community living people **Methods:** interview using a structured questionnaire **Definition:** Fecal incontinence = affirmative response to QA: "In the past year, have you had any loss of control of your bowels, even a small amount that stained the underwear?" Mild fecal incontinence = < 1 x 1 month Urinary incontinence definition was not reported	**Subject Race:** Stratified as 25% black female, 25% black male, 25% white female, 25% white male **Residency:** Alabama, U.S.	Prevalence of fecal incontinence Overall fecal incontinence = 12% 12.4% = male 11.6% = female 11.2% = white male 13.5% = African American male 14% = white female 9.2% = African American female no significant difference 77.6% of women with fecal incontinence and urinary incontinence vs. 48% without fecal incontinence p = .001 50% of men with fecal incontinence had urinary incontinence vs. 34.9% without fecal incontinence p = .02 Moderate /severe fecal incontinence in m = 5.8% and in F = 4.6% p = .40 and no difference by race p = .57 In Women Chronic diarrhea OR = 4.55(2.03-10.20) Urinary incontinence OR = 2.65(1.34-5.25) Hysterectomy and oopharectomy 1.93(1.06-3.54) Poor self perceived health status 1.88(1.01-3.5) Comorbidity scale OR = 1.29(1.07-1.55) In Men Chronic diarrhea OR = 6.08(2.29-16.16) swelling in feet and legs OR = 3.49(1.8-6.76) TIA 3.11(1.3-7.41) Depression score > 5 OR = 2.83(1.27-6.28) Lives alone OR = 2.38(1.23-4.62) Prostate disease OR = 2.29(1.04-5.02) Poor self perceived health 2.18(1.13-4.20)

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1d. Prevalence and incidence of fecal incontinence in adults (continued)

Author, Year, Design, Adjustment for Confounding Factors	Subject Selection, Data Source, Methods to Measure Incontinence (survey, screening, case finding), Definition of incontinence)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) or Incidence of Fecal Incontinence, Overall: by Type, Severity, and Impact on Life
Bergmark, 2002[249] Cross Sectional	332 women registered at 7 departments of gynecologiocal - oncology having early cervical cancer between November 1996 and May 1997; N = 256 responses (77%) **Methods:** Questionnaire **Definition:** 6 category response distress about symptom was reported only Distress about fecal leakage by women treated with surgery alone: much = 2% (2/93); moderate = 3% (3/93) Distress after treatment with radical radiation alone: much = 10% (2/20); moderate = 15% (3/20)	**Age:** x(SD)age = 51(.77) **Gender:** all female **Residency:** Sweden	Impact of incontinence on life. Women treated with surgery and external radiotherapy reported fecal leakage (distress). Much distress = 14% (11/78) Moderate distress = 19% (15/78)
Guren, 2005[250] Cross Sectional	Patients in Norwegian Rectal Cancer Registry who had anterior resection for rectal cancer between 11/03 and 12/01; N = 319 respondents 80% **Methods:** Mail questionnaire	**Age:** Median = 73, Range = 39-94 years **Gender:** Male = 179, Female = 140 **Residency:** Norway	Prevalence of Fecal Incontinence Incontinence of loose stools Anastomsis level $\leq$ 3 cm Never = 12 < 1 per week = 7 1-6 per week = 8 Every day = 3 Anastomosis level 4.6 cm Never = 51 < 1 per week = 30 1-6 per week = 23 Every day = 4 Anastomosis level 7-8 cm Never = 28 < 1 per week = 15 1-6 per week = 3 p = .07 Incontinence of solid stool Anastomosis level $\leq$ 3 cm Never = 19 < 1 per week = 7 1-6 per week = 2 Every day = 2 Anastomosis level 4.6 cm

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1d. Prevalence and incidence of fecal incontinence in adults (continued)

Author, Year, Design, Adjustment for Confounding Factors	Subject Selection, Data Source, Methods to Measure Incontinence (survey, screening, case finding), Definition of incontinence)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) or Incidence of Fecal Incontinence, Overall: by Type, Severity, and Impact on Life
			Never = 87 < 1 per week = 14 1-6 per week = 9 Every day = 3 Anastomosis level 7.8 cm Every day = 0 p = .01
Gunther, 2003[251] Comparative, cohort, retrospective	All patients seen in clinic who under-went operation for familial adeno-matous polyposis between 1971 and 2000; N = 151 candidates data available for 59 patients **Methods:** Telephone interview **Definition:** Jorge-Wexner least-worst score (0-4 scale) and Jostarndt score (0-6 scale) 2 surgeries compared: IRA (ileorectal anastomosis) N = 22: IPAA (ideal pouch anal anastomosis) N = 37 Note: No risks or quality of life could be reported because they used total Wexner and Jostarndt scores which include incontinence of gas	**Age:** IRA x age = 53 years; IPAA = 45 years **Gender:** IRA: Male = 11, Female = 11; IPAA: Male = 22, Female = 15 **Residency:** Germany	Incidence of Fecal Incontinence Wexner Score for incontinence for liquid stool IRA = .11, IPAA = .73 Wexner Scores for Incontinence of Solid Stool IRA = 0, IPAA = .38 Jostarndt score for incontinence of liquid stool IRA = 5.84, IPAA = 5.05 Jostarndt score for incontinence of solid stool IRA = 6, IPAA = 5.68
Adolfsson, 1998[252] Cohort, comparison **Adjustment For:** Analysis adjusted for age as a 3 category variable	CA (prostate cancer) group: men aged 50-80 years diagnosed in 1992 with prostate cancer with prostate cancer in Stockhold region in CA and population. Control Group: men in population registry in Stockholm randomly selected in a stratified fashion to have an age distribution similar to CA patients; mailings N = 431 men with CA, N = 435 men without CA Respondents: 342 men with CA (79%) and 314 controls (72%) **Methods:** Mail questionnaire **Definition:** Not defined specifically, 1 question of questionnaire	**Gender:** All male **Residency:** Sweden	Prevalence of Incontinence Fecal leakage in men with prostate cancer: 8% (27/321); control men 4% (13/292) Urinary leakage in men with prostate cancer: 30% (93/313); control men: 14% (42/291) Relative risk for fecal leakage: men with prostate cancer = 2.2(1.2-2.4); control men = 1.0 Note: multiple variable analysis was not performed

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1d. Prevalence and incidence of fecal incontinence in adults (continued)

Author, Year, Design, Adjustment for Confounding Factors	Subject Selection, Data Source, Methods to Measure Incontinence (survey, screening, case finding), Definition of incontinence)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) or Incidence of Fecal Incontinence, Overall: by Type, Severity, and Impact on Life
Ellerkmann, 2001[253] Descriptive	237 consecutive patients with symptomatic pelvic organ prolapse who were examined within a 24 month period **Methods:** Questionnaire at clinic **Definition:** Likert scale was used for incontinence severity, 0 = none, 3 = severely	**Age:** x = 57.2 years, range 23-93 years **Gender:** all female	Prevalence of Incontinence Urinary incontinence = 73% of whom 13% had stress urinary incontinence; 5% urge urinary incontinence, 76% double urinary incontinence Fecal incontinence = 31% 46 women with fecal incontinence (63%) said fecal incontinence interfered with normal activities
Garcia-Aguilar, 1996[254] Cross Sectional	864 patients with open (N = 521) vs. closed (N = 343) sphincterotomy were surveyed and 63.5% (N = 549) responded of whom 62/2% had open technique **Methods:** Questionnaire **Definition:** soiling of underclothing and accidental bowel movement Note: pre-op fecal incontinence rates were not reported	**Age:** x = 44 years, open = 44 years, closed = 44.7 years **Gender:** of all patients females = 57% **Residency:** United States	Incidence of Fecal Incontinence in "open" surgery: soiling of underclothing occurred in 26.7% vs. 16.1% of closed surgery ($p < .05$) Accidental bowel movement occurred in 11.8% of open surgery patients vs. 3.1% of closed ($p < .05$)
Amdur, 1990[255] Retrospective	225 patients treated by external beam irradiation at the University of Florida between 1964 and 1982 for localized adenocarcinoma of the prostate **Methods:** Chart review **Definition:** moderate = requiring a minor surgical procedure or significant medical management and/or producing minor disability severe = resulting in major surgical procedure or causing significant disability	**Age:** no demographic information given **Gender:** All male	Incidence of fecal incontinence Moderate fecal incontinence = 5 patients Severe fecal incontinence = 2 patients Note: baseline prevalence of fecal incontinence was not reported
Sobhgol, 2007[256] Cross Sectional	N = 319 women at 2 clinics aged 15-49 years, married, non-pregnant, non-breast feeding **Methods:** Questionnaire by interview in clinic **Definition:** Not defined	**Age:** 15-49 years x(SD) = 33.8(8.3) **Gender:** All female **Residency:** Iran	Prevalence of Fecal Incontinence Fecal incontinence in women with dyspareunia (pain after intercourse) = 3/179 = 1.7% Fecal incontinence in women without dyspareunia = 1/145 (0.7%)
Drossman, 1993[257] Cross Sectional	Purchased mailing list of consumer households in 48 US states; stratified probability random sample of 8250 households quotas of sampling were	**Age:** x(SD) = 49(15.1) years **Gender:** 51% female **Subject Race:**	Prevalence of Fecal Incontinence Fecal soiling = 7.1%

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1d. Prevalence and incidence of fecal incontinence in adults (continued)

Author, Year, Design, Adjustment for Confounding Factors	Subject Selection, Data Source, Methods to Measure Incontinence (survey, screening, case finding), Definition of incontinence)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) or Incidence of Fecal Incontinence, Overall: by Type, Severity, and Impact on Life
	according to age, gender, income, household density and size was selected; 5430 respondents (66%) **Methods:** Mail survey **Definition:** Results reported as fecal soiling and gross incontinence	Database lease represents white households **Residency:** United States	
Nicholls, 1990[258] Cohort	205 patients operated on during 1977 to 1987 for ulcerative colitis, familial adenomataus polyps or functional bowel disease; 3 pouches were constructed: S, J, W **Methods:** Patient chart **Definition:** Not reported	**Age:** 33.5(12-16), x(SD) years **Gender:** 116 males, 89 females **Residency:** London, England	Incidence of Fecal Incontinence Fecal leakage occurred in 2/174 Note: preoperative fecal incontinence was not reported
Crook, 1996[259] Cross Sectional	202 prostate CA patients treated consecutively from 3/87-2/93 who had a minimum of 1 year follow up N = 192 95% response **Methods:** Mail questionnaire **Definition:** Fecal incontinence and urinary incontinence were not defined	**Age:** x = 70 years, range = 49-87 years **Gender:** All male **Residency:** Canada	Prevalence of Fecal Incontinence Prevalence of "Bowel incontinence" 13-23 months after treatment = 8% 24-35 months after treatment = 8% 36-47 months after treatment = 8% 48-59 months after treatment = 9% Prevalence of Urinary incontinence daily 13-23 months after treatment = 14% 24-35 months after treatment = 19% 36-47 months after treatment = 18% 48-59 months after treatment = 16% $\geq$ 60 months 25% Prevalence of Urinary incontinence $\geq$ 1 Tbl 13-23 months = 9% 24-35 months = 7% 36-47 months = 8% 48-59 months = 8% $\geq$60 months 10%
Schwartz, 2002[260] Cross sectional, comparative Time between end of treatment and interview was x = 286 days; range = 0-965 days.	Part of a case-control study o occupational risk factors and prostate cancer; letters were sent to 501 men in a population based cancer registry. (79.4%) 398 cancer patients and 181 controls were interviewed. Those with radical prostatectomy (RP) were compared to those with radiation treatment (RT).	**Age:** **Gender:** All male **Residency:** Wayne County, MI	CA group Age 50-59 RP = 39/130 (30%) RT = 13/115 (11.3% Controls = 47/181 (26%) Age 60-69 RP = 80/130 (61.5%) RT = 46/115 (40%) Controls = 89/181 (19.2%)

F1d. Prevalence and incidence of fecal incontinence in adults (continued)

Author, Year, Design, Adjustment for Confounding Factors	Subject Selection, Data Source, Methods to Measure Incontinence (survey, screening, case finding), Definition of incontinence)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) or Incidence of Fecal Incontinence, Overall: by Type, Severity, and Impact on Life
Henningsohn, 2002[281] Cross sectional	Patients who had urinary bladder cancer treated with radical radio therapy before 1995 (N = 58); patients with radical cystectomy and urostomy (N = 251; and people randomly selected from general population (N = 310) as controls. **Methods:** Questionnaire **Definition:** Fecal incontinence as fecal leakage at least every month.	**Age and Gender:** age of radio therapy group (mean ± standard error of mean) at follow up Male = 78.1 ± 0.8, Female = 80.5 ± 1.2 Cystectomy: Male = 73.6 + 0.5 Female = 76 + 0.7 Controls: Male = 75.6 ± 0.4 Female = 76.8 ± 0.6	"Fecal leakage at least every month" Radiotherapy group prevalence = 8/48 (17%) Cystectomy group = 16/169 (10%) Controls = 4/256 (2%)
Sakakibara, 2001[282]	115 consecutive patients with Parkinson's disease seen at neurology clinic controls were 391 locals undergoing an annual health survey **Methods:** Questionnaire **Definition:** "Do you leak feces?"	**Age:** controls = 30-69 years, Parkinson patients age = 35-69 years **Gender:** controls = 271 males and 120 females, Parkinson patients gender = 52 men and 63 females **Residency:** Japan	Prevalence of Incontinence Parkinson Patients Fecal incontinence prevalence = ~6% in females and ~10% in males Stress urinary incontinence = ~38% in females and ~2% in males Urge urinary incontinence = ~26% in females and 30% in males Controls Prevalence of fecal incontinence = 0% in females and 4% in males Stress urinary incontinence = 30% in females and 2% in males Urge urinary incontinence = 6% in females and ~5% in males Note: findings are in bar graphs without values
Eason, 2002[283] Cross sectional	Pregnant women who gave birth in 5 hospitals in 1995-1996 in Quebec Women were part of another study about perineal massage. **Methods:** Mail questionnaire 3 months after delivery, 1,198 received a questionnaire.	Sample size = 949 women	Incidence of Incontinence Fecal incontinence occurred in 3.1% overall Fecal incontinence occurred at least once daily in 0.3% Fecal incontinence was present in 1.8% who had a C section and 2.9% of those with vaginal delivery Note: multivariate analysis for fecal incontinence was not done due to small number affected
Teunissen, 2004[119] Cross sectional	Patients >60 years old in 9 general practices from Jan. 1999-Aug. 2001 **Methods:** Questionnaire **Definition:** Urinary incontinence = involuntary loss of urine twice or more per month Fecal Incontinence = involuntary loss of feces twice or more per month Double Incontinence = Urinary incontinence + fecal incontinence twice or more per month.	**Age**: ≥60 years or over **Gender:** Female = 3,159 Male = 5,748 **Residency:** Netherlands	Prevalence of Incontinence Fecal incontinence of solid stool = 36% Liquid stool = 19% Mucoid stool = 45% Overall fecal incontinence = 6% Solid Stool Fecal Incontinence Men = 30% N = 41 Women = 42% N = 52 Liquid Stool Fecal Incontinence Men = 10% N = 13 Women = 29% N = 37

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1d. Prevalence and incidence of fecal incontinence in adults (continued)

Author, Year, Design, Adjustment for Confounding Factors	Subject Selection, Data Source, Methods to Measure Incontinence (survey, screening, case finding), Definition of incontinence)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) or Incidence of Fecal Incontinence, Overall: by Type, Severity, and Impact on Life
			Mucoid Fecal Incontinence Men = 60% N = 80 Women = 29% N = 37 Overall Urinary Incontinence = 19% Overall Double Incontinence = 3%
Chen, 2003[284]	Taiwanese women in a community in August 1999-March 2001, sample size = 1,247 **Methods:** Door to door survey and interview **Definition:** Fecal incontinence = flatus incontinence and anal incontinence	**Age:** mean = 43.2 years, SD = 15.1 **Gender:** All female **Subject Race:** All Asian Subject **Residency:** Taiwan	Prevalence of fecal incontinence = 2.8% Prevalence of flatus = 8.6% Impact on life = 8.6% had fecal incontinence considered troublesome to their daily lives (N = 30 of 35) Note: risk factors were only reported for anal incontinence
Goldberg, 2003[285] Cross sectional	Mothers of multiples attending the National Organization of Twins Clubs in 2001, Sample size = 733 **Methods:** Survey **Definition:** Fecal incontinence or flatal incontinence	**Age:** median = 37, range = 22-75 years **Subject Race:** 94% white 2.3% African American 0.6% Asian American, 1% Hispanic **Residency:** United States	Fecal Incontinence in women with a C-section only = 5.8% Fecal incontinence in previous vaginal delivery = 11% In multivariate analysis, age was the only significant correlate; fecal incontinence increased by a factor of 2 per 10 years, p = .0001 Overall fecal incontinence = 10% Fecal incontinence of liquid stool only = 5.9% Fecal incontinence of solid and liquid stool = 1.6%
Chiarelli, 2003[286] Cross sectional	586 women who had an instrumental delivery and/or delivered an infant 4000g or more at teaching hospitals, 913 women were approached **Methods:** Survey **Definition:** Fecal incontinence (solid and/or liquid stool) at 12 months post partum	**Age:** 15-44 years **Gender:** All female **Residency:** Australia	Fecal Incontinence Prevalence = 6.9% 2.6% had solid stool fecal incontinence and 4.9% had liquid stool fecal incontinence Risks for fecal incontinence at 12 months postpartum Urinary incontinence at 12 months post partum OR = 6.03 CI = 2.37-15.33 Constipation OR = 2.46 (1.11-5.46) Joint hypermobility OR = 2.75 (1.05-7.19)
Fenner, 2003[287] Cross sectional, retrospective	Primiparous women who delivered vaginally at a University Medical Center from 1/1/97 to 3/30/00; 2,941 were mailed and 943 completed the urinary questionnaire and 831 completed the bowel questionnaire **Methods:** Mail questionnaire about	**Age:** mean = 27.34 years **Gender:** All female **Residency:** United States	Incidence of urinary incontinence overall 0.42% had a worse major problem of urinary incontinence bladder control 5.41% had a worse occasional inconvenience of urinary incontinence bladder control 21.74% had worse minor inconvenience 16.2% had urge urinary incontinence alone 14.6% had mixed stress and urge urinary incontinence

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)
F1d. Prevalence and incidence of fecal incontinence in adults (continued)

Author, Year, Design, Adjustment for Confounding Factors	Subject Selection, Data Source, Methods to Measure Incontinence (survey, screening, case finding), Definition of incontinence)	Subject Age, Gender, Race, Ethnicity, Residency	Prevalence (%) or Incidence of Fecal Incontinence, Overall: by Type, Severity, and Impact on Life
	urinary incontinence and fecal incontinence; charts were reviewed for anal sphincter tears Definition: Questions about urinary incontinence "I wet myself", "I may have an accident:, "I may leak urine in them" Note: I did not include results about fecal incontinence because there was no definition of fecal incontinence like for Urinary incontinence; findings were too vague describing "bowel function" or "bowel control"		
Korman, 2004[288]	150 consecutive patients who underwent radical retro-pubic (RRP) or radical perineal prostatectomy (RPP) and 75 age-matched controls who were biopsied; response rate was 89% N = 201 **Methods:** Questionnaire- the bowel function domain of the Expanded Prostate Cancer Index composite Definition: uncontrolled leakage of stool or feces	**Age:** Age (years) and range RPP group = 61 (42-44) RRP group = 63 (32-35) Controls = 61 (35-39) **Residency:** United States	Prevalence of Fecal Incontinence RPP group = 5.4% (4/75) RRP group = 6.4% (4/63) Controls = 4.8% (3/61) No significant difference
Delaney, 2003[289] Cohort	1,895 patients who had ileal pouch anal anastomosis (IPAA) and were followed for > 6 months **Methods:** Questionnaire **Note:** This study did not report fecal incontinence per se, they report never incontinence and seepage at night.	**Age:** <45 years = 1,410/ and 766 male 46-55 years = 289/ and 174 male 56-65 years = 154/ and 100 male >65 years = 42/ and 31 male	Bowel movement/night (1 year) <45 = 1.4 46-55 = 1.8 56-65 = 2.1 >65 = 1.9 Total = 1.5 P <0.001 Multivariable = 0.001 Never Incontinent (1 year) <45 = 78 46-55 = 68 56-65 = 54 >65 = 44 Total = 73 P <0.001 Multivariable ≤0.001 (3 year)

Chiai, 1995[296] Cross section of consecutive patients with clinically significant MS attending national hospital in London, UK for management of bladder dysfunction. Age: 28-73 (average 47 years) N = 77 61% female (n = 47)	**Method of Measurement:** data about fecal incontinence was obtained using a questionnaire. **Definition of Incontinence:** Current fecal incontinence as involuntary passage of stool at least once in preceding 3 months. Previous fecal incontinence as involuntary passage of stool at least once more than 3 months previously.	Prevalence of fecal incontinence. Current fecal incontinence only; n = 12. Previous fecal incontinence only; n = 12. Constipation and current fecal incontinence; n = 4. Constipation and previous fecal incontinence; n = 11. Normal bowel function; n = 25. Constipation only; n = 13. Note: all have "bladder dysfunction" also but this wasn't defined.

Table F1. Incidence, risk factors, and prevalence for urinary and fecal incontinence in adults in long term care setting and in the community (continued)

F1f. Risk factors of fecal incontinence in adults

Author Sample	Subject Selection, Data Source, Methods to Measure Incontinence (survey, screening, case finding), Definition of Incontinence. Definition of Risk Factors.	Level of Risk Factors	Prevalence (%) or Incidence of Fecal Incontinence, Overall: by Type, Severity, and Impact on Life
Abramowitz, 2000[297] Prospective, descriptive, observational study in France. N = 259 100% female No age given	Consecutive females 6 weeks before and 8 weeks after delivery. **Exclusion criteria:** No history of ano-rectal disease. Neurologic disease, or diabetes **Method of Measurement:** Questionnaire **Definition of incontinence:** fecal incontinence = incontinence of flatus and liquid or solid stools	Sphincter defects by endoanal ultrasound	Incidence of Incontinence of Liquid Stools After Delivery Primiparous = 0.9% Secundiparous = 1.7% Multiparous = 2.1% Total incontinence of liquid stools = 1.4% Sphincter defects by endoanal ultrasound Various conditions of childbirth but although risk factors were assessed, they were for "anal incontinence" and not just leakage of stools
Zetterstrom, 1999[298] Cohort study in Sweden. 100% female. Age: X (SD) = 30 (4.1) years	Of 345 primiparous women, 278 responded to questions about fecal incontinence, 38 had sphincter tears, 240 had non-sphincter tears. Questionnaires 1 day, 5 months, and 9 months after delivery.	Maternal age. Continuous duration of labor >12 hours (yes/no), 2nd stage of labor >1 hour (yes/no), use of oxytocin (yes/no), fundal pressure to assist delivery (yes/no), instrumental vaginal delivery (yes/no), sphincter tear (yes/no), lithotomy position (yes/no) Fecal incontinence at 5 months risk factors per multivariate analysis. Maternal age 2.7(1.2, 6.0). 2nd stage of labor >1 hour 2.2(1.1, 4.2) Instrumental delivery 3.1(1.3, 7.4), Sphincter tear 3.0(1.3, 6.7) Factor in Univariate Analysis. Maternal age at 5 months 3.4(1.6, 7.1), at 9 months 3.1(1.5, 6.6). Labor > 12 hours at 5 months 2.6(1.4, 5.1). 2nd stage labor > 1hour at 5 months 2.7(1.4, 5.0) Use of oxytocin at 5 months 2.1(1.02, 4.2). Fundal pressure 2.3 at 5 months(1.3, 4.4) Instrumental delivery at 5 months	Prevalence of Fecal Incontinence Before Pregnancy Fecal incontinence = 2(1%) total 1(3%) those with a sphincter tear 18(8%) those with no sphincter tears No fecal incontinence = 92%, fecal incontinence < once per week = 1%, fecal incontinence > once per week = 0 Prevalence of Fecal Incontinence at 5 months after delivery Fecal incontinence = 5(2%) total 1(3%) in those with tear 4(2%) in no sphincter tear No fecal incontinence = 73%, fecal incontinence < once per week = 1%, fecal incontinence > once per week = 0.5% Prevalence of Fecal

		3–8 children	1	0.7–1.4

Table F18. Risk factors for urinary incontinence in child-bearing women (pregnancy, post-partum, and up to 1 year post-delivery) (continued)

Author, Sample	Age	Risk Factors	Odds Ratio (95%CI)	
		Previous mode of delivery*		
		Vaginal (at least once)	1	
		Cesarean section (exclusive)	0.9	0.6–1.2
		Pregravida BMI		
		Underweight (<18.5)	1.4	0.6–3.2
		Normal (18.5–24.9)	1	
		Overweight (25–29.9)	1.1	0.8–1.4
		Obesity >30)	1.3	1.0–1.6
		Current pregnancy		
		Constipation*		
		Third trimester	1.3	1.1–1.6
		4–8weeks postpartum	1.3	1.0–1.6
		1 year after birth	1.1	0.8–1.4
		Urinary incontinence (overall)		
		Third trimester	2.9	2.4–3.5
		4–8weeks postpartum	3.1	2.4–3.9
		Mode of delivery		
		Vaginal	1	
		Vacuum extraction or forceps	1.5	1.0–2.3
		Elective cesarean Section	0.5	0.3–0.9
		Emergency cesarean section	0.5	0.3–1.0
		Presentation (vaginal delivery)		
		Vertex	1	
		Occiput posterior	1.1	0.7–1.9
		Breech	0	
		Other	0	
		Infant birth weight (g)		
		<2500	1.8	1.0–3.2
		2500–3499	1	
		3500–4499	1.5	1.2–1.9
		>4500	1.3	0.8–2.0
		Infant head circumference (cm)		
		<33	1	
		34	1	0.7–1.6
		35	1.4	0.9–2.0
		36	1.3	0.9–1.9
		>37	1.1	0.7–1.6
		Spontaneous perineal rupture		
		No perineal rupture	1	
		First- and second degree	1.4	1.2–1.7

Table F18. Risk factors for urinary incontinence in child-bearing women (pregnancy, post-partum, and up to 1 year post-delivery) (continued)

Author, Sample	Age	Risk Factors	Odds Ratio (95%CI)	
		Third- and fourth degree	1.5	0.7–3.2
		Episiotomy*	0.9	0.6–1.5
		Smoking*		
		Prior to pregnancy	1.2	1.0–1.5
		Early pregnancy	1.3	0.9–1.7
		2months after birth	1.2	0.9–1.6
		1 year after birth	1.2	1.0–1.5
		All women		
		Age (years) >35	1.5	1.0–2.1
		Parity: Multiparas	1.4	1.1–1.8
		Pregravida BMI: Obesity	1.5	1.0–2.2
		Constipation		
		4–8weeks after childbirth	1.4	1.1–1.9
		Urinary incontinence (overall leakage of urine) 4–8weeks After childbirth	5.7	4.3–7.6
		Mode of delivery		
		Vaginal	1	
		Vacuum extraction or forceps	1.1	0.7–1.8
		Cesarean section	0.5	0.3–0.9
		Spontaneous perineal rupture		
		No perineal rupture	1	
		First-and second degree	1.2	1.0–1.6
		Third-and fourth degree	1	0.4–2.5
Chaliha, 1999[326]	549 primiparae with vaginal and cesarean deliveries	Urge

Evidence Tables — Clinical Interventions to Reduce Risk of Incidence and Progression of Urinary Incontinence in Adults

Table F58. Effects of implementation of evidence based guidelines on urinary incontinence in residents of nursing homes

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Ryden, 2000[452] Quasi-experimental RCT to examine the effect of scientifically based protocols implemented by advanced practice gerontological nurses for incontinence in nursing home residents Duration: 6 months	Consecutive cohorts of newly admitted residents in 3 licensed proprietary nursing homes certified for Medicare, located in the suburban area comparable by occupancy rates, staff-to-resident ratios, staff turnover, resident acuity, and percentage of residents whose medical care was monitored by external nurse practitioners employed by physician group practices or managed care groups with 201-262 beds. Loss of followup: 86 treatment residents (2.4% withdrew, 18.0% were discharged, and 27.5% died) and 111 comparison group residents (2.0% withdrew, 9.2% were discharged, and 16.3% died).	1. Implementation of evidence-based protocol by advanced practice gerontological nurses: in-service staff education and direct resident care. 2. Usual care by nursing home staff.	Urinary incontinence recorded by nursing home staff in Incontinence monitoring schedule: observations every 2 hours, 24 hours a day for 3 days; percentage of wetness 5; average number of times wet per day for the 3-day period.	No intention to treat. Open label. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. No justification for sample size.
Schnelle, 1995[453] Multicenter non controlled intervention to examine computerized total quality management model for implementation of incontinence system in nursing homes. Duration: 6 months.	9 nursing homes, members of state long-term care association location within 1.5 hours driving distance from one another, agree to train staff. Exclusion criteria: not representative staffing rates and resident mix compared to nursing homes in the area.	Gradual implementation of computerized quality management model based on the federal guidelines for medical assessment and individualized prompted voiding protocols of incontinence.	% of wet residents collected using random hour wet check procedure by independent research assistants with nursing home experience	No intention to treat. Not randomized. Implementation of quality management model with before-after comparisons. No justification for sample size.

Table F59. Comparative effectiveness of implementation of evidence-based guidelines on urinary incontinence in residents of nursing homes

Author Sample	Active Treatment	Control Treatment	Outcome	Number of Cases After Active Treatment	Number of Cases After Control Treatment	Rate (%) After Active Treatment	Rate (%) After Control Treatment	Relative Risk (95% CI)	Number Needed to Treat (95% CI)	Number of attributable Events/1,000 Treated (95% CI)
Ryden, 2000[452] N = 319 71% female	Implementation of evidence-based protocol by advanced practice gerontological nurses: in-service staff education and direct resident care.	Usual care by nursing home staff	% of times wet recorded by nurse	35	40	21.0	26.0	0.8 (0.5; 1.2)		
			% of residents with Improvement in incontinence recorded by nurse	78	66	47.0	43.0	1.1 (0.9; 1.4)		
			Incontinence prevalence reported by a nurse	106	108	63.9	70.6	0.9 (0.8; 1.1)		
Schnelle, 1995[453] N = 85	After gradual implementation of computerized quality management model for medical assessment and individualized prompted voiding protocols of incontinence	Before gradual implementation of computerized quality management model for medical assessment and individualized prompted voiding protocols of incontinence	% of wet residents	14	26	17.0	31.0	0.5 (0.3; 1.0)	7 (5; 77)	140 (216; 13)A

Table F60. Effects of conservative management programs on urinary incontinence in females, residents of nursing homes

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Hu, 1990[454] RCT to examine the effects of behavioral training therapy on incontinent elderly in nursing homes. Duration: 3 months, followup: 22 weeks.	133 incontinent elderly females in seven nursing homes, ages 65 or over, incontinent during the daytime, and able to recognize their own name. Exclusion criteria: not reported. Loss of followup: 7%.	1. Behavioral therapy program for 3 months implemented by project-trained NRAs. With hourly wet checks, prompted and assisted toileting, positive reinforcement, bladder training to hold urine until the next hourly check. 2. Usual care.	Reported by nurses participants' wet episodes and patient requests for toileting.	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data did not confirm adequacy of randomization. Sample size justified
Hu, 1989[455] RCT to examine the effects of behavior therapy program for urinary incontinence on women residents of nursing homes. Duration: 3 months.	143 women with confirmed stress incontinence in seven nursing homes with ability to recognize her own name. Exclusion criteria: hospitalization, insufficient number of wet episodes per day (an average 0.18). Loss of followup: 6.9%	1. 13-week behavior therapy program for urinary incontinence which included hourly checking and prompting of individuals to toilet, praising for successful toileting, and social reinforcement (additional personal service). Assisted toileting between scheduled voiding. The program was implemented 14 hours/day, 7 days/week for 3 months. 2. Control group received usual incontinence-related care.	The change in urinary stress incontinence measured by the RN as wet checks/total checks/day (14 times/day).	No intention to treat. Open label. Randomization schedule not reported. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.
Ouslander, 2001[456] RCT to examine the effects of oral estrogen/progestin on incontinence in female nursing home residents. Duration 6 months	32 incontinent female residents (average age 88) from 5 nursing homes. Incontinence was diagnosed by nursing home staff and research staff using checks for wetness as involuntary loss of urine at least daily. Exclusion criteria: Medicare reimbursement (indicating a potential short stay and/or medical instability), terminal illness, cognitive impairment; history of breast or cervical cancer; wet <1/day on research staff checks; enteral feeding ; poor cooperation with screening procedures ; severe physical immobility, requiring a lift or 3-person transfer. Loss of follow up: 34%	1.Oral estrogen (0.625mg) combined with progesterone (2.5mg) and regular toileting assistance (prompted voiding) by trained research aides during 3-day data-collection periods 2. Placebo and regular toileting assistance (prompted voiding) by trained research aides during 3-day data-collection periods	The frequency of urinary incontinence as wetness rate = the percentage of checks at which research staff found residents to be wet during three 8-hour days of prompted voiding. The appropriate toileting rate was calculated by dividing the number of continent voids by the total number of voids.	No Intention to treat. Open label. Central randomization with table of random numbers. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F60. Effects of conservative management programs on urinary incontinence in females, residents of nursing homes 9continued0

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
			Cough tests for stress incontinence as positive (simultaneous leakage with cough), negative with estimated bladder volumes of at least 100ml (determined by voided volume plus residual bladder volume by ultrasound), negative, or unable to perform (some subjects would not cough on command).	

Table F61. Comparative effectiveness of conservative management programs on urinary incontinence in females, residents of nursing homes (events)

Author	Active Treatment	Control Treatment	Outcome	Number of Cases After Active Treatment	Number of Cases After Control Treatment	Rate (%) After Active Treatment	Rate (%) After Control Treatment	Relative Risk (95% CI)	Number Needed to Treat (95% CI)	Number of attributable Events/1,000 Treated (95% CI)

Author	Active Treatment	Control Treatment	Outcome	Mean ± STD After Active Treatment	Mean ± STD After Control Treatment	Mean Difference (95% CI)	% Change from Baseline (95% CI)
Hu, 1989[455]	Behavioral therapy program for 3 months implemented by the project-trained registered nurses	Usual care	Urinary wet episodes/day reported by nursing home staff	1.7 ± 1.8	1.9 ± 1.3	-0.2 (-0.5; 0.2)	-9.0 (-26.3; 8.3)
	13-week behavior therapy program for urinary incontinence	Usual incontinence-related care	Number of incontinence episodes/day	2.2 ± 1.3	2.1 ± 1.1	0.1 (-0.2; 0.5)	6.0 (-9.9; 21.9)
Ouslander, 2001[456] N = 32	Oral estrogen (0.625 mg) combined with progesterone (2.5 mg) and regular toileting assistance (prompted voiding) by trained research aides during 3-day data-collection periods	Placebo and regular toileting assistance (prompted voiding) by trained research aides during 3-day data-collection periods	Appropriate toileting rate,% of continent voids by the total number of voids	37 ± 31	31 ± 29	0.20 (-0.50; 0.90)	0.20 (0.36; -0.50)

Table F63. Effects of conservative management programs on urinary incontinence in residents of nursing homes

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Schnelle, 1989[457] RCT to examine the effects of prompted voiding treatment of urinary incontinence in nursing home patients. Duration: 5-10 days.	126 incontinent patients from proprietary nursing homes (bed size 90-150), not affiliated with universities with correct discriminatory responses to instructions to point to shown subjects (pencil or glass). Exclusion criteria: continence, transfer to hospital during run-in period. Loss of followup: 60% during the run-in period, 2.4% after randomization.	1. Prompted voiding treatment: check for incontinence, asking for needed toileting assistance, prompted voiding, and socially reinforced for appropriate toileting. 2 .Usual care.	Urinary incontinence measured by nurse as wet checks/total checks and daily percent of appropriate toileting equal number of times the patient voided in any toilet receptacle/total number of appropriate and incontinent voiding.	No intention to treat. Open label. Randomization and allocation concealment unclear. Baseline data not reported. Sample size not justified.
Ouslander, 2005[458] Crossover RCT to examine the effects of functional incidental training on incontinence in nursing homes. Duration: 8 weeks.	107 patients in nursing homes, (resided in the facility at least 30 days and not initially admitted for short-term care; able to state their name, or in the presence of aphasia, capable of reliably pointing to two objects; required assistance by two or fewer people for transfer from bed to chair; with life expectancy of at least 6 months; not receiving active physical therapy; and ages 60 and older. Exclusion criteria: continence, severe behavioral changes, terminally ill. Loss of followup: 60%.	1. Functional incidental training: prompted voiding combined with individualized, functionally oriented endurance and strength-training exercises offered 4 times/day, 5 days/week. 2. Usual care.	Urinary and fecal incontinence measured as wet checks/total checks of the participants every 2 hours. Appropriate toileting rate: number of voids or bowel movements that were continent divided by the total number of voids or bowel movements.	No intention to treat. Open label. Computer-generated random numbers. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.
Schnelle, 2002[459] RCT to examine the effects of integrated incontinence care and exercise on urinary incontinence in nursing home residents. Duration: 8 months.	256 incontinent residents in 4 nursing homes. Exclusion criteria: post-acute skilled care units, terminally ill. Loss of followup: 26%.	1. Integrated incontinence care and exercise every 2 hours 5 days a week including fluid prompting, prompted toileting, and regular wet checks, arm raise and arm curl exercises. 2. Usual care.	Fecal and urinary incontinence frequency as % of hourly wet checks and the appropriate toileting ratio calculated by dividing the number of times a resident used a toilet or toilet substitute by the total number of voids.	No intention to treat. Single blind. Computerized randomization. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F63. Effects of conservative management programs on urinary incontinence in residents of nursing homes (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Jirovec, 2001[460] RCT to examine the effects of individualized scheduled toileting program on incontinent, memory-impaired elders being cared for at home. Duration: 6 months.	118 caregivers for incontinent, memory-impaired elders. Exclusion criteria: fecal continence. Loss of followup: 16.9% during implementation and 37% during 6 months period.	1. Individualized scheduled toileting procedure of every 2 hours and fluid intake ~six 8-oz glasses /day provided by trained caregivers. 2. Usual care.	Incontinence calculated as the percentage of time the patient was incontinent by dividing the incontinent episodes by the total number of voiding episodes, both continent and incontinent.	No Intention to treat, Open label. Randomization using the table of random numbers. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size not justified.
Colling, 1992[461] Quasi-experimental RCT to examine the effects of individualized form of habit training for urinary incontinence among elderly nursing homes residents. Duration: 12-week intervention and 12 week followup.	113 elderly subjects, 65 years and older with >3 episodes of clinical and urodynamic urinary incontinence/week for the last 12 weeks, cognitively and/or physically impaired, residents of 4 non-profit urban nursing homes with bed size 120-342. Exclusion criteria: toilet with assistance of more than1 staff member, fecal impaction, rectal or pelvic mass, prostate diseases, severe prolapse, atrophic vaginitis, neurological diseases, post-residual volume >200ml. Loss of followup: 21%	1. Individualized form of habit training for urinary incontinence administered by trained staff: toileting within 30 minutes prior to the mean time of voids within 1 hour block of time. Verbal encouragement to nursing staff to comply with the program. 2. Usual care.	Episodes of urinary incontinence/day measured by nursing staff. Wet checks were done hourly for one 24-hour period at 3-week intervals. Continuous electronic monitoring of voids for precise voiding schedule for each subject.	No intention to treat. Open label. Randomization at unit level. Allocation concealment unclear. Baseline data differed by the proportion of males and length of stay. Sample size justified.

Table F64. Comparative effectiveness of conservative management programs on urinary incontinence in residents of nursing homes (severity measures)

Author Sample	Active Treatment	Control Treatment	Outcome	Mean ± STD After Active Treatment	Mean ± STD After Control Treatment	Mean Difference (95% CI)	% Change from Control (95% CI)
Colling, 1992[461] N = 113 66% female	Individualized form of habit training for urinary incontinence administered by trained staff: toileting within 30 minutes prior to the mean time of voids within 1 hour block of time. Verbal encouragement to nursing staff to comply with the program.	Usual care	Incontinent volume of urine loss, ml	500.0 ± 450.0	600.0 ± 400.0	-0.2 (-0.6; 0.1)	0.0 (-0.1; 0.0)
Schnelle, 2002[459] N = 190 84% female	Integrated incontinence care and exercise every 2 hours 5 days a week including fluid prompting, prompted toileting, and regular wet checks, arm raise and arm curl exercises	Usual care	Urinary incontinence frequency, % of wet checks	23.0 ± 21.0	35.0 ± 21.0	**-0.6 (-0.9; -0.3)**	-1.6 (-2.5; -0.8)
Schnelle, 1989[457] N = 126 75% female	Prompted voiding treatment: check for incontinence, asking for needed toileting assistance, prompted voiding, and socially reinforced for appropriate toileting	Usual care	Percent appropriate toileting	59.4 ± 26.7	16.8 ± 22.0	**1.7 (1.3; 2.2)**	10.4 (7.9; 12.8)
			Percent wet checks/total checks, %	17.8 ± 13.0	34.5 ± 16.8	**-1.1 (-1.5; -0.7)**	-3.2 (-4.3; -2.1)
Colling, 1992[461] N = 113 66% female	Individualized form of habit training for urinary incontinence administered by trained staff: toileting within 30 minutes prior to the mean time of voids within 1 hour block of time. Verbal encouragement to nursing staff to comply with the program.	Usual care	Urinary incontinence episodes/day (wet checks)	3.9 ± 1.0	4.8 ± 1.0	**-0.9 (-1.3; -0.5)**	-18.8 (-26.9; -10.6)
Ouslander, 2005[458] N = 107 10% female	Functional Incidental training: prompted voiding combined with individualized, functionally oriented endurance and strength-training exercises offered 4 times/day, 5 days/week	Usual care	Change after the treatments in wet checks/total checks,%			-17 (-83.9; 49.9)	
			Wet checks/total checks, %	25.0 ± 50.0	50.0 ± 28.0	**-0.6 (-1.0; -0.2)**	-1.2 (-2.0; -0.5)

Author Sample	Active Treatment	Control Treatment	Outcome	Mean ± STD After Active Treatment	Mean ± STD After Control Treatment	Mean Difference (95% CI)	% Change from Control (95% CI)
Jirovec, 2001[460] N = 118 30 % female	Individualized scheduled toileting procedure of every 2 hours and fluid intake ~six 8-oz glasses/day provided by trained caregivers.	Usual Care	% of urinary incontinent episodes/total voids	37.0 ± 28.0	49.0 ± 36.0	-0.4 (-0.7; 0.0)	-0.8 (-1.5; 0.0)

Bold- significant differences in outcomes at 95%confidence level

Table F65. Effects of conservative management programs on urinary incontinence in patients admitted for rehabilitation following acute unilateral hemispheric stroke

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Wikander, 1998[462] RCT to examine the effects of rehabilitation governed by functional independence measure on urinary incontinence in patients with acute hemispheric stroke Duration: Length of stay in the ward (~90 days)	34 incontinent stroke patients admitted for rehabilitation following acute unilateral hemispheric stroke. Exclusion criteria: not reported. Lost of followup: none	1. Specially designed education for ward staff based on the Functional Independence Measure Scale and for patients to manage incontinence independently. 2. Conventional method inhibiting abnormal muscle tone by handling and guiding the stroke patient in specific ways to relearn normal movements, which makes the patient dependent on ward staff for a longer period of time.	Urinary incontinence and the need for assistance because of urinary incontinence assessed by the staff with FIM-G (7-point scale, 7 - independent - 1- totally dependent	Intention to treat not stated but all patients were included in the analysis. Open label. Allocation concealment not adequate, patients were randomly allocated to one of two different wards depending on the availability of beds on the day of admission. Baseline data confirmed adequacy of randomization. No justification for sample size.

Table F66. Comparative effectiveness of conservative management programs on urinary incontinence in patients admitted for rehabilitation following acute unilateral hemispheric stroke

Author Sample	Outcome	Active Treatment	Control Treatment	Number of Case After Active Treatment	Number of Cases After Control Treatment	Rate (%) After Active Treatment	Rate (%) After Control Treatment	Relative Risk (95% CI)	Number Needed to Treat (95% CI)	Number of attributable Events/1,000 Treated (95% CI)
Wikander, 1998[462] N = 34 56% female	Number cured at discharge	Specially designed rehabilitation program to increase patient independent management of UI	Conventional rehabilitation program (patient dependent on ward staff for a longer period of time).	20	3	95.2	23.1	**4.1 (1.5; 11.2)**	1 (0; 8)	722 (121; 2,350)E

Clinical Interventions on Urinary Incontinence in Adults in the Community

Table F67. Effects of implementation of evidence based guidelines on urinary incontinence in adults

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Chadha, 2000[463] RCT to examine the effects of national guidelines and local protocols in improving hospital care for women with UI. Duration: 12 months	449 women with urinary incontinence from gynecology units in four district general hospitals across Scotland. Exclusion criteria: not reported. Loss of followup: 7.6%	National evidence based guidelines adapted locally to protocols, which were disseminated at specific local educational meetings and implemented by placing a copy of the appropriate protocol in women's hospital case notes prior to consultation.	Self reported perception of urinary incontinence based on questions routinely asked by clinicians.	No intention to treat. Randomization stratified by hospital size and location. 2 x 2 balanced incomplete block controlled before and after study. Baseline data confirmed adequacy of randomization. Sample size justified for process of care outcomes.

Table F68. Comparative effectiveness of evidence based guidelines on urinary incontinence in adults, self reported severity and impact of urinary incontinence

Author Sample	Active Treatment	Control Treatment	Outcome	Mean ± STD After Active Treatment	Mean ± STD After Control Treatment	Mean Difference (95% CI)	% Change from Control (95% CI)
Chadha, 2000[463] N = 449 100% female	National evidence based guidelines adapted locally to protocols, which were disseminated at specific local educational meetings and implemented by placing a copy of the appropriate protocol in women's hospital case notes prior to consultation.	Pre-guidelines levels	Self -reported perception of urinary incontinence, scores	15.5 ± 20.3	13.9 ± 20.7	0.1 (-0.1; 0.2)	0.6 (-0.4; 1.5)

Table F69. Effects of conservative management programs on urinary incontinence in community-dwelling adults

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Williams, 2005[464] RCT to examine the effects of continence service provided by specially trained nurses delivering evidence-based interventions using predetermined care pathways in adults. Duration: 6 months	3,746 men and women ages 40 years and over living in private households reporting incontinence several times per month or more, or several times a year and reported significant impact of symptoms on quality of life. Exclusion criteria: pregnancy, urinary fistula, pelvic malignancy, treatment for urinary symptoms. Loss of followup: 37% refused followup at 3 months, 22% refused followup at 6 months.	1. Continence service that included advice on diet and fluids; bladder training; pelvic floor awareness and lifestyle advice. 2. Existing primary care including GP and continence advisory services in the area.	Self-reported in validated questionnaire improvement or cure in one or more symptoms of total incontinence, urgency, frequency and nocturia.	Intention to treat. Open label. Randomization by household, at a ratio of 4:1 in favor of the continence nurse practitioner. Allocation concealment and randomization adequate. Sample size justified.
Borrie, 2002[465] RCT to examine the effects of combined lifestyle and behavioral interventions led by nurses in the management of urinary incontinence. Duration: 6 months	421 subjects 26 years of age or older with self reported urinary incontinence at least once per week, resided in the community, and communicated in English. Exclusion criteria: pregnancy, residency of long-term care institutions, dementia. Loss of followup: 10.1%	1. Lifestyle modification sessions every 4 weeks led by trained "nurse continence advisers" with a physician with expertise in continence management. 2. Usual care	Self reported urinary incontinent events (measured using bladder diaries) and pad use (measured using the questionnaire) per 24 hours	Intention to treat. Open label. Computer generated randomization with random permuted blocks, block size of 4. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. No justification for sample size.
Dowd, 2000[466] RCT to examine the effects of cognitive strategies combined with educational programs in urinary incontinence. Duration: 6 weeks	40 subjects >40 years of age, independent in self-care, with history of incontinence and/or frequency for at least 6 months, able to read and write English, and having hearing adequate for listening to an audiotape. Exclusion criteria: presence of urinary tract infections or severe neurological disorders. Loss of followup: not reported	1. Education about bladder health, recorded incontinence and frequency episodes in a voiding diary, and listening to the audiotape daily. 2. Education about bladder health and recorded incontinence and frequency episodes in the voiding diary	Comfort measured with the Urinary Incontinence and Frequency Comfort Questionnaire (UIFCQ) - 23 positive and negative items ranging from strongly agree to strongly disagree scored from 1 to 6 - higher comfort. The number of incontinent episodes and frequency of toileting recorded in a voiding diary with scores 8-96 incontinent episodes and 50-125 frequency episodes per week.	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F69. Effects of conservative management programs on urinary incontinence in community-dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Moore, 2003[467] RCT to examine the effects of nurse continence advisors and urogynaecologists in conservative management of urinary incontinence. Duration: 12 weeks	145 consecutive patients with stress and/or urge incontinence with idiopathic detrusor instability, sensory urgency, and mild or moderate leakage (urine loss in 1-hour pad test 2-9.9ml/hour or 10-50ml/hour). Exclusion criteria: previous pelvic radiotherapy, proven recurrent bacterial cystitis, prolapse beyond the introitus, uterine enlargement or incomplete bladder emptying (postvoid residual >100ml). Loss of followup: 22%	1. 2 nurse continence advisors/patient and consulting urogynecologist for 25-35 minutes/week provided bladder training, gradual increase in fluid intake, individual deferment techniques, pelvic floor muscle exercise and examination, transvaginal electrostimulation. 2. Outpatient regimen with 15-20 minute consultation with referral to physiotherapist and bladder training.	1-hour pad test, frequency volume charts, a 20-point incontinence score, and two quality of life tests (Incontinence Impact Questionnaire and Urogenital Distress Inventory). Objective cure as dry on 1-hour pad test. Subjective cure as >50% benefit on pad test but the patient felt cured and ready for discharge	Intention to treat. Open label. Computer-generated randomization stratified with respect to mild and moderate leakage with permuted blocks of 20. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
McFall, 2000[468,469] RCT to examine the effects of community-based intervention on self-management of urinary incontinence in elderly women Duration: 3 months	145 women ages 65 or older with self reported urinary incontinence ≥ 3 months, residing in Oklahoma. Exclusion criteria: Severe prolapse of uterus, hematuria, diverticulum, fistula, unresolved urinary tract infection, two or more urinary tract infections within 3 months, urinary obstruction, overflow incontinence, a postvoid residual volume of urine (PVR) >100ml, and blood glucose >300 mg/dl on two or more visits in a 3 month period, functional disability, severe hearing or vision problems, low literacy, and cognitive impairment. Loss of followup: 8.3%	1. Community-based intervention with 5 biweekly sessions of education and skill-building, for bladder training, managing the urge to urinate, and performing pelvic muscle exercises. Group support by registered nurses; occupational therapist, and public health educator. 2. Usual care	Self reported episodes of incontinence and frequency of voluntary micturition (voiding) per week.	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. No justification for sample size.

Table F70. Comparative effectiveness of conservative management programs on urinary incontinence in adults (events)

Table F75. Effects of dietary and other lifestyle interventions on risk and progression of urinary incontinence in adults

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Subak, 2005[470] RCT to examine the effect of weight loss on urinary incontinence in overweight and obese women. Duration: 3 months	48 women 18 to 80 years old with body mass index between 25 and 45 kg/m2, urinary incontinence for at least 3 months and at least 4 incontinent episodes/week, the stable dose of other incontinence therapy . Exclusion criteria: pregnancy, urinary tract infection, significant medical condition, pelvic cancer, neurological condition possibly associated with incontinence, interstitial cystitis or potential inability to complete the study. Lost of followup: 4 women; 1 withdrew from the study, 1 dropped due to medical condition, 2 had missing primary outcome data.	Weight reduction intervention: 3-month standard low calorie liquid diet (800kcals/day or less), increased physical activity to 60 minutes/day, training by a nutritionist, exercise physiologist or behavioral therapist 1. Immediate intervention group 2. Delayed for 3 month intervention	A 7-day voiding diary to report frequency of voids and incontinent episodes classified by clinical type (urge, stress, other). Urodynamic outcomes.	Intention to treat. Single blind (investigators assessing outcomes and statistical analysts). Randomization was stratified by type of incontinence, with randomly permuted blocks of 4. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Dowd, 1996[471] RCT to examine the effects of hydration on the number of urinary incontinence episodes. Duration: 5 weeks	58 women 50 years old and older with incontinence more than 6 months, independent in self-care, English speakers with >20 scores on Mini-Mental State. Exclusion criteria: not provided. Lost of followup: Not reported, 32 women maintained diaries and included in the analysis.	1. Increase fluid intake by 500cc 2. Maintain fluid intake at baseline level 3. Decrease by 300cc	Self reported episodes of urinary incontinence per week	No intention to treat. Open label. Allocation concealment unclear. Baseline data not provided but some differences at baseline reported. No justification of the sample size.
Swithinbank,2005[472] Cross-over RCT to examine the effect of caffeine restriction and fluid manipulation in the treatment of patients with urodynamic stress incontinence. Duration: 4 weeks	69 women with urodynamically proven stress incontinence naive to surgery. Exclusion criteria: Urinary tract infection, hepatic, cardiac or renal disease and diabetes mellitus, use of antidepressants, anticholinergics or diuretics. Lost of followup: 9 women.	1. Increased decaffeinated fluids to 3 liters daily (20 cups) or decreased decaffeinated fluids to 750ml (5 cups) daily 2. Caffeine restriction and increased fluid intake to 2, 2,673ml /day 3. Caffeine restriction and decreased fluid intake to 872ml/day	Detailed urinary diaries that included information concerning episodes of urgency and leakage. A 24-hour pad test.	No intention to treat. Open label. Allocation concealment unclear. Baseline data not provided. Sample size justified.
Tomlinson, 1999[473] Quasi-experimental RCT to examine the effect of behavioral management for continence on involuntary urine loss in older, rural women living at home. Duration: 4 weeks	94 women living in own home with self reported urinary incontinence at least 2/week. Exclusion criteria: Urinary tract infection, bladder cancer, retention of urine, need for a caregiver. Loss of followup: 41 women completed the reported self-monitoring phase.	1. Nurse managed behavioral management for continence: caffeine intake 1-2 cups/day, fluid intake 1,800-2,400ml/day before 6:00 P.M., voiding schedule every 4 hours, bowel management. 2. Recommendation on behavioral changes without special training or monitoring.	Self reported number of episodes and severity of urine incontinence. Pad test to measure grams of lost urine.	No intention to treat. Open label. The article reported outcomes before/after active treatment (one phase of RCT) excluding 44% of randomized women. Baseline data provided for active group only. No justification for sample size.

Table F75. Effects of dietary and other lifestyle interventions on risk and progression of urinary incontinence in adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Manonai, 2006[474] Cross-over RCT to examine the effect of a soy-rich diet on urogenital symptoms in peri- and postmenopausal women. Duration: Two 12-week diet periods and two 4-week washout periods.	42 healthy perimenopausal and postmenopausal women between 45-70 years old reported at least one type of urinary incontinence. Exclusion criteria: Presence or history of sex hormone dependent malignancies, liver or renal disorders, and pathology of urogenital tract. Loss of followup: 5 women withdrew from the study because of their inability to comply with this study and 1 was lost to pelvic examination followup.	1. Self-selected diet with low-fat and low cholesterol foods and soy protein 25g in various forms of soy foods containing more than 50mg/day of isoflavones 2. Self-selected diet with low fat and low cholesterol foods	Self reported presence of stress and urge urinary incontinence, urgency and frequency of urination (defined by the International Continence Society) scores of symptoms from none (0), mild (1), moderate (2), and severe (3).	No intention to treat. Single blind (physician and cytopathologist). Allocation concealment unclear. Baseline data provided with no analysis for incontinence rate. Sample size not justified.
Brown, 2006[475] Placebo controlled multi center RCT to examine the effects of intensive lifestyle intervention or metformin on prevalence of urinary incontinence among overweight pre-diabetic women. Duration: 2.9 years	2,191 women in the Diabetes Prevention Program RCT older than 25 years, body mass index ≥24kg/m^2, a fasting plasma glucose level 95-125mg/dl, and a 2-hour post-challenge glucose level 140-199mg/dl. Exclusion criteria: Taking medications that could affect glucose tolerance or serious medical illness. Loss of followup: 234 (11%) women with missing urinary incontinence data were excluded from the analysis.	1. Intensive lifestyle therapy to lose and maintain at least 7% of initial body weight through a low fat diet and to engage in moderate intensity physical activity for at least 150 minutes/week. 2. Metformin 850mg twice daily 3. Placebo twice daily.	Self reported incontinence symptoms by frequency and type using a validated questionnaire	Intention to treat. Double-blind. Randomization was stratified by clinical center. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified for the primary outcome-diabetes prevention.
Bryant , 2002[476] RCT to examine the effects of caffeine restriction on urinary incontinence symptoms Duration: 4 weeks	95 consecutive adult patients with urinary symptoms with routine intake of caffeine >100mg every 24 hours. Exclusion criteria: Cognitive impairment, pregnancy, urinary tract infection. Lost of followup: 21%, 14 subjects failed to return for followup, 4 had anxiety or family problems, 2 were treated, 1 had intercurrent illness.	1. Education to reduce caffeine intake to <100mg/day plus bladder training. 2. Bladder training: increasing intervals between voiding; increasing fluid intake to 2 L/day; urinary deferment techniques; ceasing “just in case” voiding	Self reported frequency, urgency and leakage episodes.	No intention to treat. Open label. Allocation concealment unclear. Baseline data confirmed the adequacy of randomization. Sample size not justified.

Table F76. Effects of weight reduction on improvement in urinary continence in females

Table F80. Effects of behavioral interventions on female urinary incontinence related to pregnancy and birth

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Chiarelli, 2002[477] RCT to examine the effectiveness of physiotherapist delivered intervention to prevent urinary incontinence among women three months after giving birth. Duration: 3 months	720 women 48 hours after forceps or ventouse deliveries or their babies with a birth weight of 4,000g or more. Lost of followup: 6%	1. Training in pelvic floor exercises and incorporated strategies to improve adherence. 2. Usual postpartum care	Self reported in bladder diary and during phone survey "occasionally," "often," or "always" incontinence symptoms: -leaked even small amounts of urine when coughing, sneezing, laughing, or lifting -gone to the toilet urgently for fear of leak -leaked even small amounts before using the toilet -leaked even small amounts on way to the toilet or immediately as needed	Intention to treat. Single blind (physiotherapist). Allocation concealment adequate. Results adjusted to baseline differences. Sample size justified.
Reilly, 2003[478] RCT to examine the effects of supervised pelvic floor exercises antenatally on incidence of postpartum stress incontinence in at-risk primigravidae women. Duration: 5 months	268 primigravidae women in antenatal clinic at ~20 weeks of gestation with bladder neck mobility, on standardized valsalva, of 5mm or more linear movement. Exclusion criteria: Urge incontinence. Loss of followup: 101 due to unwilling to travel to the hospital dislike of perineometry and ultrasound.	1. Supervised by physiotherapist pelvic floor exercises 1/month before delivery: 3 repetitions of 8 contractions each held for 6 seconds to 2 minutes, rest repeated 2/day. At 34 weeks of gestation the number of contractions per repetition was increased to 12. 2. Verbal advice on pelvic floor exercises from their midwives antenatally	Self reported postpartum stress incontinence. Volume of leakage using one-hour International Continence Society pad test. Pelvic floor muscle strength by perineometry	Intention to treat. Single blind (observers to assess outcomes) Simple randomization with pseudo-random numbers generated by computer. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F80. Effects of behavioral interventions on female urinary incontinence related to pregnancy and birth (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Sampselle,1998[479] RCT to examine the effect of pelvic muscle exercise on postpartum symptoms of stress urinary incontinence in primigravidas during pregnancy and postpartum. Duration: 12 months	72 primigravidas at 20 weeks of gestation, 18 years or older with negative history of genitourinary pathology, permanent residents in the area, able to read and understand English. Loss of followup: 8 not willing to participate, 6 moved from the area, 5 conceived the second child during 12 months after the first birth, 7 provided incomplete incontinence information.	1. Standardized instruction in pelvic muscle exercise 2. Routine care with no systematic pelvic muscle exercise instruction	Self reported stress urinary incontinence scores by severity from 0 - no leakage to 3 - soaking. Pelvic muscle strength measured with a new speculum—maximum voluntary contraction force of pelvic muscle	Intention to treat. Single blind (observers to assess outcomes). Simple randomization generated by computer. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.
Chiarelli, 2004[480] followup to Chiarelli, 2002[477] RCT to examine the effects of physiotherapist-delivered promotion of pelvic floor exercise frequency on continence status for women at 12 months postpartum Duration: 12 months	720 women 48 hours after forceps or ventouse deliveries or their babies with a birth weight of 4,000g or more. Loss of followup: 13.2% in intervention and 14.3% in the control groups.	1. Training in pelvic floor exercises and incorporated strategies to improve adherence. 2. Usual postpartum care	Self reported in bladder diary and during phone survey “occasionally,” “often,” or “always” incontinence symptoms: -leaked even small amounts of urine when coughing, sneezing, laughing, or lifting -gone to the toilet urgently for fear of leak -leaked even small amounts before using the toilet -leaked even small amounts on way to the toilet or immediately as needed.	Intention to treat. Single blind (physiotherapist). Allocation concealment adequate. Results adjusted to baseline differences. Sample size justified.
Meyer, 2001[481] RCT to examine the effect of pelvic floor education after vaginal delivery on pelvic floor characteristics in nulliparous women. Duration: 10 months	107 white nulliparous women Exclusion criteria: Pregnancy complications (twin gestation, diabetes, or preterm labor, hemorrhage from low-lying placenta), women with beginning labor, history of urinary infections. Loss of followup- not reported.	1. 12 sessions of pelvic floor exercises with 20 minutes of biofeedback and 15 minutes of electrostimulation with an electrode placed in the lower third of the vagina. 2. No training	Self reported urinary incontinence using questionnaire, perineosonography, urethral pressure profiles, and intravaginal and intra-anal pressure recordings during pelvic floor contraction.	Intention to treat not stated. Open label. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F80. Effects of behavioral interventions on female urinary incontinence related to pregnancy and birth (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Labrecque, 2000[482] RCT to examine the effects of perineal massage performed during pregnancy on perineal symptoms after delivery. Duration of followup: 3 months	Pregnant women with (n = 493) and without (n = 1,034) a previous vaginal birth. Exclusion criteria: High risk of cesarean delivery, including previous cesarean delivery for cephalopelvic disproportion; multiple gestation; placenta previa; severe fetal growth restriction; breech presentation; preeclampsia; nonparticipating physicians; outbreak of genital herpes during the current pregnancy, inability to speak French or English, inability to understand the instructions, and already doing the massage. Loss of followup: 0.3%	1. Self administered perineal massage daily from the 34th or 35th week of pregnancy until delivery introducing 1 or 2 fingers 3 to 4cm deep into the vagina and applying and maintaining pressure. 2. Usual obstetric care.	Self reported urinary and incontinence as ever lost urine involuntarily (accidentally), when coughing, sneezing, laughing, or running. Response choices: never, less than once per week, 1 to 6 times a week, once a day, and more than once a day.	Intention to treat. Single-blind. Central randomization balanced in blocks of 4 or 6 stratified by history of previous vaginal birth, specialty of the attending physician and hospital. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Glazener, 2001[483] RCT to examine the effect of nurse assessment with reinforcement of pelvic floor muscle training exercises and bladder training among women with persistent postnatal incontinence. Duration: 12 months	747 women with urinary incontinence (defined as any involuntary loss of urine) 3 months postnatally, living within a 50km radius and who delivered in these units during a 12 month recruitment period. Exclusion criteria: mothers of stillborn or died neonates. Loss of followup: 25% in active and 35% in the control group.	1. Assessment by nurses of urinary incontinence with conservative advice on pelvic floor exercises (of 8-10 sessions each day of fast and slow contractions with the aim of 80-100 contractions daily) at five, seven, and nine months after delivery supplemented with bladder training if appropriate at seven and nine months. 2. The control group did not receive any visits from research nurses but received peripartum preparation, which sometimes included pelvic floor exercises, and could seek medical advice	Self reported persistence of any urinary incontinence; severe incontinence - at least once a week; type of incontinence, stress - during cough, laugh, sneeze, run, jump, or play sport; urge - feel an urgent desire to pass water and are unable to reach the toilet in time; mixed—combination of stress and urge.	Intention to treat. Single blind. Computer generated randomization stratified by parity (4 versus fewer), method of delivery (caesarean versus other), and frequency of incontinence (at least once a week versus less). Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F80. Effects of behavioral interventions on female urinary incontinence related to pregnancy and birth (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Glazener, 2005[484] Glazener, 2001[483] RCT to examine the effect of nurse assessment with reinforcement of pelvic floor muscle training exercises and bladder training among women with persistent postnatal incontinence	747 women with urinary incontinence (defined as any involuntary loss of urine) 3 months postnatally, living within a 50km radius and who delivered in these units during a 12 month recruitment period. Exclusion criteria: Mothers of stillborn or died neonates. Loss of followup: 29% in active and 31% in the control group.	1. Assessment by nurses of urinary incontinence with conservative advice on pelvic floor exercises (of 8-10 sessions each day of fast and slow contractions with the aim of 80-100 contractions daily) at five, seven, and nine months after delivery supplemented with bladder training if appropriate at seven and nine months. 2. The control group did not receive any visits from research nurses but received peripartum preparation, which sometimes included pelvic floor exercises, and could seek medical advice	Self-reported 6 years after intervention persistence of any urinary incontinence; severe incontinence - at least once a week; type of incontinence—stress during cough, laugh, sneeze, run, jump, or play sport; urge—feel an urgent desire to pass water and are unable to reach the toilet in time; mixed—combination of stress and urge.	Intention to treat. Single blind. Computer generated randomization stratified by parity (4 versus fewer), method of delivery (caesarean versus other), and frequency of incontinence (at least once a week versus less). Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Adherence to the intervention was the same in active and control group 6 years at followup. Sample size justified.
Sleep,1987[485] RCT to examine the effects of pelvic floor exercise on urinary incontinence in postnatal care. Duration: 3 months postpartum.	1,800 women 24 hours after vaginal delivery. Exclusion criteria: Mothers of stillborn or ill babies. Loss of followup: 10.6%	1. Standard care: initial instruction on pelvic floor exercise and advice to repeat as often as possible. 2. Intensive exercise care: initial instruction on pelvic floor exercise, extra session of exercise daily, visits and phone calls by community midwives, reminders, feedback to self measure squeeze pressure, and voiding diary.	Self reported urinary incontinence and frequency of wet episodes/day	Intention to treat. Open label. Randomization schedule not reported. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.
Mørkved , 2003[486] RCT to examine the effects of intensive pelvic floor muscle training during pregnancy on prevention of UI. Duration of intervention: 12	301 healthy nulliparous women ≥18 years, with a single live fetus at routine ultrasound scan. Exclusion criteria: pregnancy complications, high risk for preterm labor, pain during pelvic floor muscle contractions, ongoing urinary tract infection, diseases that could interfere with participation, residency too far from	1. Training in intensive pelvic floor muscle and general exercises with physiotherapist for 60 minutes/week. Exercise at home twice a day in a preferred position for 12 weeks (between weeks 20 and 36 of pregnancy). Near maximal contractions of 6–8 seconds for 3-4 fast	Self-reported symptoms of urinary incontinence: involuntary leakage >1/week during the last month. Pelvic floor muscle strength (vaginal squeeze pressure [cm/H2O]) measured by a vaginal balloon connected to a pressure transducer	Intention to treat. Single-blind. Randomization in blocks of 32 maximum. Allocation concealment not adequate. Baseline data confirmed the

Table F85. Effects of behavioral interventions on risk and progression of incontinence in community dwelling females

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Diokno, 2004[487] Duplicate: Sampselle, 2005[488] RCT to examine the effects of behavioral modification program on incidence of urinary incontinence in older women. Duration: 1 year.	359 postmenopausal, continent women (0-5 days of incontinent episodes in the previous year) 55 years and older. At baseline 2 groups reported identical 39% absolute continence and zero UI days. 61% of participants reported 1 to 5 UI episodes in year. Exclusion criteria: neurologic diseases, mini-mental scores <24, positive paper towel cough test, grade 4 uterine prolapse. Loss of followup: 9% in the control and 14% in active groups did not return communication, relocated or experienced changes in personal health or the health of a family member.	1. 2 hour classroom presentation on behavioral modification program: pelvic floor muscle training, bladder training, and individualized test of knowledge, adherence, and skills to reinforce the technique as needed. 2. Usual care	Self reported in the standardized Medical Epidemiologic and Social Aspects of Aging (MESA) questionnaire absolute continence: urinary incontinence episodes no more than 5 days in the last 12 months. Voiding frequency and intervoid interval reported in 3-day voiding diary. Displacement and pressure digital scores from test for pelvic floor muscle strength.	Intention to treat not stated. Single blind (nurse examiner). Randomizations in blocks of 16 women to provide balanced recruitment between groups. Allocation concealment adequate. Results adjusted to baseline differences. Sample size not justified.
Dumoulin, 2004[489] RCT to compare the effectiveness of multimodal supervised physiotherapy programs among women with persistent postnatal stress urinary incontinence. Duration: 2 months	64 premenopausal women younger than 45 years presenting symptoms of stress urinary incontinence at least once per week 3 months or more after their last delivery. Exclusion criteria: Current pregnancy, urinary incontinence before pregnancy, previous surgery for stress incontinence, moderate to severe urogenital prolapse, involuntary detrusor contraction on cystometry neurologic or psychiatric disease, or a major medical condition, taking medication that could interfere with their evaluation or treatment, inability to understand French or English instructions. Loss of followup: 2, plus 2 did not attend the final examination and were excluded from the analysis.	1. Pelvic floor rehabilitation: 15 minute electrical stimulation of the pelvic floor muscle; then 25 minute pelvic floor muscle exercise program with biofeedback, which included strengthening and motor relearning exercises and a home exercise 5 days/week. 2. Pelvic floor rehabilitation plus abdominal training: in addition to PFE 30 minutes of deep abdominal muscle training consisting of isolation, reeducation, and functional retraining of the transversus abdominis 3. Relaxation massage for the back and extremities by physiotherapist. They were asked not to exercise their pelvic floor muscles at home.	1. 20 minute pad test with standardized bladder volume. 2. Perceived symptoms and burden of incontinence using a Visual Analog Scale Urogenital Distress Inventory (19-items); Incontinence Impact Questionnaire (26 items) focusing on daily living, social interaction, sex life, and self-perception. 3. Pelvic floor maximum strength and rapidity of contraction using static pelvic floor muscle dynamometer	Intention to treat not stated. Single blind. Stratified randomization by the results from pad test using a balanced block randomization schedule generated from a table of random numbers. Allocation concealment adequate Baseline data confirmed adequacy of randomization. Sample size justified.

Table F85. Effects of behavioral interventions on risk and progression of incontinence in community dwelling females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Goode, 2003[490] RCT to examine whether pelvic floor electrical stimulation increases efficacy of behavioral training for community-dwelling women with stress incontinence Duration: 8 weeks	200 ambulatory, nondemented, community-dwelling women ages 40 to 78 years with urinary incontinence (at least 2 stress incontinence episodes per week on the 2-week baseline bladder diary) confirmed during urodynamic testing. Exclusion criteria: Continual leakage, postvoid residual urine volume >150ml, severe uterine prolapse, congestive heart failure, hemoglobin A_{1C} ≥9, or impaired mental status (Mini-Mental State Examination score <24). Loss of followup: 18.2% in the behavioral group, 11.9% in the pelvic floor electrical stimulation group, and 37.3% in the self-help booklet.	1. Behavioral training (biofeedback-assisted pelvic floor muscle training, home exercises, bladder control strategies, and self-monitoring with bladder diaries). Anorectal biofeedback (~20 minutes) with 3-balloon probe to measure sphincter pressure and rectal pressure. Pelvic floor muscle exercises:15 repetitions of 2- to 4-second contractions with equal periods of relaxation/day. Bladder diary to use "stress strategies" for prevention of urine leakage 2. Behavioral training plus pelvic floor electrical stimulation 15 minutes/day 3. Control: self-administered behavioral training administered with a self-help booklet with suggestions for isolating the pelvic floor muscles, progressive home exercise, self monitoring, and bladder control strategies.	Self reported % reduction in the number of incontinent episodes documented in bladder diaries. Leakage in stress test and bladder capacity during urodynamic examination.	Intention to treat. Open label. Computer-generated stratified by types and severity of incontinence and race randomization with block size of 6. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F85. Effects of behavioral interventions on risk and progression of incontinence in community dwelling females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Wyman, 1998[491] RCT to examine the efficacy of bladder training, pelvic muscle exercise with biofeedback-assisted instruction, and combination therapy, on urinary incontinence in women. Duration: 12-week intervention program, 3 month followup	204 community-dwelling women age 45 years and older diagnosed with genuine stress incontinence, (urine loss at least once per week), with urodynamic evidence of genuine stress incontinence, and mentally intact (Mini-Mental State Examination Score >23). Exclusion criteria: Reversible causes of urinary incontinence, uncontrolled metabolic conditions, residual urine volume after voiding >100ml, urinary tract infection, genitourinary fistula or indwelling catheterization, and inability to correctly perform a pelvic muscle contraction on digital examination. Loss of followup: 6% withdrew either immediately after randomization or during the intervention visits, 8% failed to keep their followup appointment or to mail in completed instruments at the 3-month followup.	Structured 12-week program of patient education, self-monitoring of voiding behavior with daily treatment logs, compliance assessment, and positive reinforcement administered by trained registered nurses. 1. Bladder training with schedule voiding interval from 30-60 minutes (baseline diary) to increase by 30 minutes each week. 2. The pelvic muscle exercise with 5 fast (3 second) contractions and 10 sustained (10 second) contractions with 10-second relaxation periods between contractions twice a day. Sustained contractions were increased by 10 contractions/week so that by the third week a total of 10 fast and 40 sustained contractions were performed daily (total = 50 contractions). Visual and verbal biofeedback to observe pelvic and abdominal muscle pressure during fast, sustained, and preventive contractions recorded with vaginal balloon device and displayed on a strip-chart recorder. 3. Combination therapy of bladder training and pelvic muscle exercise.	Self-reported in a standardized diary the number of weekly incontinent episodes. Patient perception of improvement and treatment satisfaction. Pad weight test.	No intention to treat. Open label. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F85. Effects of behavioral interventions on risk and progression of incontinence in community dwelling females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Theofrastous, 2002[492] RCT to examine the efficacy of bladder training and pelvic muscle exercise with biofeedback-assisted instruction on urinary incontinence in women. Duration: 12-week intervention program, 3 month followup	137 community-dwelling women age 45 years and older diagnosed with genuine stress incontinence, (urine loss at least once per week), with urodynamic evidence of genuine stress incontinence, and mentally intact (Mini-Mental State Examination Score >23). Exclusion criteria: Reversible causes of urinary incontinence, uncontrolled metabolic conditions, residual urine volume after voiding >100ml, urinary tract infection, genitourinary fistula or indwelling catheterization, and inability to correctly perform a pelvic muscle contraction on digital examination. Loss of followup: 6% withdrew either immediately after randomization or during the intervention visits, 8% failed to keep their followup appointment or to mail in completed instruments at the 3- month followup.	1. Pelvic floor muscle training: 4 office biofeedback sessions and home exercise with two sets of 5 quick and 10 sustained contractions with 10-second rest periods increased to 5 quick and 20 sustained contractions 2/day for a total of 50 contractions per day. Reinforcement with home audiocassette tapes, 4 weekly 30-minute biofeedback sessions, and regular contact with the research nurses. 2. Bladder training: initial voiding interval of 30 or 60 minutes increased each week depending on the subject's tolerance of the schedule to 22.5 hours.	Self reported urinary incontinence episodes/week using diaries and vaginal pressure measurements by using balloon manometry.	No intention to treat. Open label. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F85. Effects of behavioral interventions on risk and progression of incontinence in community dwelling females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Alewijnse,2003[493] RCT to examine the effectiveness of pelvic muscle floor exercise therapy supplemented with a health education program urinary incontinence among women. Duration: 14-22 weeks of intervention and 1 year followup.	129 community-dwelling women over 17 years old with urinary incontinence, able ability to complete questionnaires in Dutch language. Exclusion criteria: Continence, neurological conditions, venereal disease, viral infections, using medication that may impact incontinence, pregnancy or 3 months after delivery, after surgical treatment for incontinence, and women with physical impairments. Severe prolapse, vaginal atrophy, and urinary tract infection were not exclusion criteria. Loss of followup: 20% for different reasons, one died.	1. Bladder training with voiding frequency of ~7 voidings/day and pelvic floor muscle exercise: 10 slow twitch contractions (10-30 seconds) and 10 fast twitch contractions (2-3 seconds), 5 times/day, each contraction being followed by relaxation; correct toileting and drinking behavior (1,500-2,000ml/day); techniques to prevent leakage. Combination of PFME with Health education therapy. 2. Reminder intervention: information and reminders of PFME therapy and adherence behavior 3. Reminder and self-help guide with individualized information on coping with urinary incontinence, tips to increase adherence behavior, and relapse prevention strategies to support the self-management process. 4. Reminder, self-help guide and counseling intervention: addition of counseling by physiotherapists, structural oral feedback, and reinforcement to promote adherence behavior.	Self reported weekly frequency of wet episodes and change in frequency of wet episode.	Intention to treat. Open label. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.
Aukee, 2004[494] RCT to examine the effectiveness of pelvic floor training with home biofeedback device among women with tress urinary incontinence Duration: 12 weeks intervention, 1 year followup.	35 women 21-70 years old with urodynamically confirmed stress incontinent (maximal urethral closure pressure >20cm/H2O and cough leak point pressure >90cm/H2O). Exclusion criteria: Previous incontinence operations, genital prolapse, inability to understand instructions for home training, pregnancy, severe diseases such as malignancies in the abdominal region, multiple sclerosis and diabetes mellitus requiring insulin. Loss of followup: 1 woman at 1 year.	1. Home program with given verbal and written instructions for home practice and advise to practice for 20 minutes/day, 5 times/week. 2. Pelvic floor training by physiotherapist 5 times/12 weeks: 3-5 second contractions with 10 second intervals in supine and standing position with home biofeedback using a personal EMG-assisted biofeedback device.	Review of hospital records to identify gynecologic surgery during 1 year of followup. Pelvic floor muscle activity while supine (*m*V).	Intention to treat. Open label. Randomization was performed by a random numbers table, in blocks of four. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F85. Effects of behavioral interventions on risk and progression of incontinence in community dwelling females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Bergman, 1987[495] RCT to examine the effects of bladder training on urinary incontinence in women after surgery for stress urinary incontinence. Duration of followup: 3 months	89 women with a clinically and urodynamically proved diagnosis of genuine stress urinary incontinence after surgery for incontinence (40 revised Pereyra procedure and 49 Burch retropubic urethropexy). Exclusion criteria: Not reported. Loss of followup: None	1. "Bladder training" scheduled clamping and unclamping of the suprapubic Bonnano catheter throughout postoperative period. 2. "Nonbladder training" continuous bladder drainage with suprapubic Bonnano catheter throughout postoperative period.	Length of postoperative bladder catheterization	No intention to treat. Open label. Randomization using a randomization list. Allocation concealment unclear. Baseline data not reported. Sample size not justified.
Wang, 2004[496] RCT to examine the efficacy of pelvic floor muscle training, biofeedback-assisted PFMT , and electrical stimulation in the management of overactive bladder. Duration: 12 weeks.	120 women age 16-75 years, symptoms of overactive bladder for more than 6 months, frequency of voiding eight times or more per day, and urge incontinence one time or more per day. Exclusion criteria: pregnancy, deafness, neurologic disorders, diabetes mellitus, pacemaker or intrauterine device use, genital prolapse greater than Stage II of the International Continence Society grading system, residual urine >100ml, and urinary tract infection. Loss of followup: 14.2%	1. Pelvic floor muscle training with submaximal to maximal PFM contractions for 6 seconds 5 times and 10 fast contractions per session at least 3 times/day. 2. Biofeedback-assisted pelvic floor muscle training with an intravaginal electromyogram probe to contract or relax PFMs following the visual EMG signals. 3. Electrical stimulation in the management of overactive bladder with intravaginal electrode at the physiotherapy unit.	Self-reported urge urinary incontinence. The strength of the PFMs using palpation by way of the vagina according to the “PERFECT” scheme to assess the power (P), endurance (E), number of repetitions (R), and number of fast (1-second) contractions (F). The power is graded from 0-5, according to the Oxford grading system. PFM strength - vaginal pressure using a balloon probe connected to a pressure transducer.	No intention to treat. Single blind. Central computer-generated randomization in blocks of 6. Allocation concealment adequate. Baseline data did not confirm adequacy of randomization. Sample size justified.
Bo, 2005[497] Followup RCT to examine the effects of intensive exercise on stress urinary incontinence. Duration of followup: 6 months and 15 years	52 women with urodynamic stress urinary incontinence participated in the original RCT. Exclusion criteria: Response rate 90.4% Loss of followup: 9.6%	1. Intensive pelvic floor exercise with 8-12 maximum contractions for 6-8 seconds 3 series/day under the supervision of physical therapist for 6 months. 2. Home exercise groups	Self reported urinary incontinence and severity of lower urinary tract symptoms by the severity index and the International Consultation of Incontinence Questionnaire Urinary Incontinence Short Form	Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F85. Effects of behavioral interventions on risk and progression of incontinence in community dwelling females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Elser, 1999[498] RCT to examine the effects of pelvic floor muscle training, bladder training, or both, on urodynamic parameters in women with urinary incontinence. Duration: 12 weeks	204 women 45 years or older, ambulatory, mentally intact with urodynamic genuine stress incontinence or detrusor instability, with or without stress incontinence, experiencing 1–100 episodes of incontinence per week as recorded on the qualifying 7-day urinary diary, capable of performing a pelvic floor muscle contraction as assessed by digital exam. Exclusion criteria: Reversible cause of incontinence, uncontrolled metabolic conditions (e.g., diabetes mellitus), postvoid residual of >100ml, persistent urinary tract infection, urinary tract fistula, or indwelling catheterization. Loss of followup: 11.3%	Patient education, self-monitoring with treatment logs, compliance assessment, and positive reinforcement techniques administered by trained research nurses. 1. Pelvic floor muscle training with10 fast (3 second) contractions and 40 sustained (10 second) contractions with 10 second rest periods between contractions performed daily (total 50 contractions) in two or more exercise sets. Visual and verbal biofeedback via a strip-chart recorder of vaginal and abdominal pressures measured by vaginal balloons. 2. Bladder training. 3. Pelvic floor muscle training combined with bladder training.	Multi-channel urodynamics outcomes: first sensation to void, maximum cystometric capacity, the difference between MCC and FSV (MCC − FSV), functional urethral length, maximum urethral closure pressure, urethral closure pressure, maximum Kegel urethral closure pressure, Kegel urethral closure pressure, pressure transmission ratio, maximum pressure transmission ratio, and straining urethral axis.	No intention to treat Open label. Stratified by severity of urinary incontinence, urodynamic diagnosis, and treatment site randomization. Allocation concealment not reported. Baseline data did not confirm adequacy of randomization. Sample size justified.

Table F85. Effects of behavioral interventions on risk and progression of incontinence in community dwelling females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Tibaek, 2005[499] RCT to examine the effect of pelvic floor muscle training in women with urinary incontinence after ischemic stroke. Duration: 12 weeks	26 women 40 and 85 years old with acute ischemic stroke verified by CAT scan lasting >24 hours; stroke symptoms in at least 1 month; normal cognitive function (mini-mental state examination >25); urinary incontinence related to stroke; independent walking abilities indoors >100 meters with/without aids; independence in toilet visits. Exclusion criteria: Urinary tract infection; symptom of vaginal prolapse; chronic respiratory diseases; psychiatric diseases; other neurological diseases; does not speak Danish. Loss of followup: 8%	1. Intensive pelvic floor muscle training 1-2 times/day by specialized physiotherapist: group information on incontinence and instruction in self-palpation of PFM, motivation and instruction in home exercises with close to maximum contraction (6 second contraction/6 second rest) and endurance PFM exercise with 30% of maximum contraction as long as possible (maximum 30 second contraction/30 second rest). Group treatment: isolate PFM contraction (6 second contraction/6 second rest); strength exercises (3 second contraction/3 second rest, and 6 second contraction/6 second rest); endurance exercises (maximum 30 second contractions/30 second rest). 2. Usual care	Self reported in voiding diary time and frequency of voiding, the number of incontinence episodes, and the number of used pads.	No Intention to treat. Single blind. Randomization with a table of random numbers. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.
Subak, 2002[500] RCT to examine the effects of low-intensity behavioral therapy program on urinary incontinence in older women Duration of followup: 6 weeks	Women 55 years and older with self reported urinary incontinence, members of health maintenance organization, living independently in the community and functionally capable of independent toileting. Exclusion criteria: Uncontrolled diabetes mellitus, urinary tract infection, history of urinary obstruction, overflow, functional incontinence, urinary tract anomalies. Loss of followup: 19.1%	1. 6 weekly 20-minute group instructional sessions on bladder training by nurse educators and followed individualized voiding schedules. 2. Usual care	The number of incontinent episodes per week recorded in a 7-day urinary diary.	No Intention to treat. Single blind. Computer based randomization. Allocation concealment unclear. Baseline confirmed adequacy of randomization. Sample size justified.

Table F85. Effects of behavioral interventions on risk and progression of incontinence in community dwelling females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Goode, 2002[501] Placebo-controlled RCT to examine the effect of biofeedback-assisted behavioral training on urinary incontinence in older women. Duration: 8 weeks	105 ambulatory, non demented, community-dwelling women 55 and older with self-reported urge incontinence at least twice per week for >3 months with urodynamic evidence of bladder dysfunction. Exclusion criteria: Continual leakage, postvoid residual urine volume greater than 200ml, uterine prolapse past the introitus, narrow-angle glaucoma, unstable angina pectoralis, congestive heart failure, history of malignant arrhythmias, or impaired mental status. Loss of followup: 46.7%	1. Four sessions (over 8 weeks) of biofeedback-assisted behavioral training by nurse practitioners. 2. Placebo control condition, usual care	Self reported urinary incontinence and urodynamic outcomes.	No Intention to treat. Single blind. Randomization and allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size not justified.
Lagro-Janssen, 1992[502] RCT to examine the effects of pelvic floor exercises on stress incontinence and bladder training on urge incontinence. Duration: 3 months	110 women with self-reported urinary incontinence confirmed with urodynamic as stress or urge. Exclusion criteria: Not reported. Loss of followup: 3.6%	1. Pelvic floor exercises alone (stress) or bladder training (urge) or its combination (mixed) 2. Usual care	Self reported urinary incontinence	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Fantl, 1991[503] RCT to examine the effects of bladder training on urinary incontinence in older women. Duration: 6 weeks.	131 noninstitutionalized women 55 years and older with clinical and urodynamic urinary incontinence >1 leakage/week; mentally intact (Mini-Mental State Examination score >23), capable of independent toileting. Exclusion criteria: Uncontrolled diabetes, urinary tract infection, urinary obstruction, reversible cause of incontinence, permanent catheterization. Loss of followup:6.1%	1. Bladder training using 6 weekly visits included patient education; voiding schedule to have micturition from every 30-60 minutes to every 2.5-3 hours; and positive reinforcement. 2. Usual care	Self reported number of urinary incontinence episodes/week and urodynamic outcomes using standard urinary diary.	No intention to treat. Open label Randomization stratified by urodynamic incontinence. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F85. Effects of behavioral interventions on risk and progression of incontinence in community dwelling females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Dougherty, 2002[504] RCT to examine the effects of behavioral management for continence on urinary incontinence in older rural women in their homes. Duration: 6 months and followup 2 years.	218 women 55 years and older, who lived in a private residence in rural area; with involuntary urine loss >2/week of 1g/24 hours or more; without urinary tract infection. Exclusion criteria: Bladder cancer or kidney disease, indwelling urinary catheter, residual urine >100cc, needed caregiver. Loss of followup:18%	1. Behavioral management for continence: -Self-monitoring and bladder training to reduce caffeinated beverages to <2 cups/glasses, 1,500 <daily fluid intake <4000cc, no fluid consumption after 6 p.m., daytime voiding interval <4 hours, and treatment of constipation. -Pelvic muscle exercise with biofeedback: 15 repetitions per day increased by 15 repetitions every 3 weeks to 45 contractions/day) three times a week for 12 weeks. 2. Control group	Severity of urine loss was evaluated by pad test. Self reported episodes of urine loss, micturition frequency, voiding interval.	Intention to treat. Open label minimization. Randomization with minimization to balance by severity, age, bacteriuria ethnicity, and caregiver. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size not justified.
Burgio, 2002[505] RCT to examine the effects of biofeedback as a part of complex behavioral training program for urge incontinence in community-dwelling older women. Duration: 8 weeks	222 ambulatory, nondemented, community-dwelling women ages 55 to 92 years with urge incontinence or mixed incontinence >2 times/week for at least 3 months, and with urodynamic evidence of bladder dysfunction (detrusor instability during filling or provocation or maximal cystometric capacity of ≤400ml). Exclusion criteria: Continual leakage, postvoid residual urine volume >150ml, severe uterine prolapse past the vaginal introitus, decompensated congestive heart failure, or impaired mental status (Mini-Mental State Examination score <24). Loss of followup: 5.7%	1. Biofeedback-assisted behavioral training implemented by nurse practitioners. Abdominal pressure and sphincter responses were measured with 3-baloon probe inserted in rectum. Pelvic floor muscle exercise with 10 second contractions/10 second relaxation for 45 minutes/day. 2. 4 visits of behavioral training without biofeedback (verbal feedback based on vaginal palpation). Pelvic floor muscle exercise with 10 second contractions/10 second relaxation for 45 minutes/day. 3. Self-administered behavioral treatment using a self-help booklet to advise pelvic floor exercise and bladder control.	Self reported number of incontinence episodes documented in bladder diaries	Intention-to-treat. Open label. Randomization stratified by race, type, and severity of incontinence. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F85. Effects of behavioral interventions on risk and progression of incontinence in community dwelling females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Wyman, 1997[506] RCT to examine the effects of bladder training on quality of life in older women with urinary incontinence. Duration: 6 weeks.	131 women 55 years and older, ambulatory, mentally intact, independent residents in the community with urodynamic stress urinary incontinence >1 episode/week. Exclusion criteria: Metabolic decompensation, urinary tract infection, outlet obstruction, fistula, reversible cause of urinary incontinence, permanent indwelling catheter. Loss of followup: 6%	1. Bladder training: patient education, progressive scheduled voiding regimen, positive reinforcement. 2. Usual care	Self reported quality of life measures (Incontinence Impact Questionnaire (IIQ) with 26 items and 4 point scale from 0 - not at all to 3 - greatly.	No Intention to treat, Open label. Randomization stratified by type of incontinence. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size not justified.
Yoon, 2003[507] RCT to examine the effectiveness of bladder training versus pelvic muscle exercises in the treatment of urinary incontinence in women. Duration: 8 weeks	50 parous women 35–55 years old a with urine loss of 1.0g or more on a 30 minute pad test and 14 voids or more during a period of 48 hours before the preliminary evaluation. Exclusion criteria: Urinary tract infection tested by urinalysis and urine culture, previous experience of surgery for urinary incontinence, HRT and other medication for urinary incontinence. Loss of followup: 8%	1. Bladder training with increased interval between voluntary voids. 2 Pelvic muscle exercise (30 contractions for 15 to 20 minutes/day) with immediate and simultaneous visual feedback of pelvic muscles during a 20 minute weekly biofeedback session with electromyography. 3. Usual care	Self reported voids and incontinence scores (5-Likert scale) and urodynamic outcomes	No intention to treat. Single blind. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified
Janssen, 2001[508] RCT to examine the effects of individual and group physiotherapy for urinary incontinence in women. Duration: 3 months, followup 12 months.	530 women of all ages (mean 47.8 years) with stress, urge, or mixed incontinence. Exclusion criteria: Neurological cause of incontinence, a tumor or infection in the pelvis, severe vaginal prolapse. Loss of followup: 22%	1. Individual pelvic floor exercises 5 times/day and bladder training with delay voiding, training with 11 30-minute sessions. 2. Group pelvic floor exercises 5 times/day and bladder training with delay voiding, training with 9 2-our sessions.	Objective changes in the severity of urinary incontinence, frequency of urine loss, and frequency of nocturnal urine loss.	Intention to treat. Single blind. Stratified by type, severity and duration of incontinence frequency sampling randomization. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F85. Effects of behavioral interventions on risk and progression of incontinence in community dwelling females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Nygaard, 1996[509] RCT to examine the effects of pelvic floor muscle exercises in combination with specially designed audiotape on stress, urge, and mixed urinary incontinence in women. Duration: 3 months	71 women non pregnant women >21 years old with urinary incontinence. Exclusion criteria: Genital prolapse past the vaginal introitus, parturition within the preceding 6 months, and deafness. Loss of followup: 23%.	1. Pelvic floor muscle exercises with 2 5-minute daily sessions, beginning with contractions for 4-8 seconds in combination with specially designed audiotape with 270 minutes of music and verbal instructions of technique tips, reminders, and exercise cues. 2. Pelvic floor muscle exercises with 2 5-minute daily sessions, beginning with contractions for 4-8 seconds.	Self reported number of incontinent episodes, documented with a 3-day voiding diary	Intention to treat. Single blind. Randomization with random numbers table, in blocks of 4. Allocation concealment not reported. Baseline data not reported. Outcomes reported by type of incontinence, randomization ignored. Sample size justified.
McClurg, 2006[510] RCT to examine the effects of pelvic floor training and advice , electromyography biofeedback, and neuromuscular electrical stimulation on urinary incontinence in patients with multiple sclerosis. Duration of treatment: 9 weeks. Duration of follow up: 24 weeks	30 women >18 years with multiple sclerosis stabilized for the previous 3 months. Expanded Disability Status Scale score <7.5 with at least one of the following: any involuntary leakage of urine, voiding frequency >8/24 hours, nocturia, and/ or reported voiding dysfunction such as hesitancy, straining, poor stream, and incomplete emptying demonstrated by uro-flowmetry. Exclusion criteria: MS relapse necessitating hospitalization 3 months prior to or during the study, symptomatic prolapse, presence of urinary tract infection, current or recent diagnosis of a serious medical condition (other than MS), severe cognitive impairment, contraindications to neuromuscular electrical stimulation. Loss of follow up: 6.7%	1. Pelvic Floor Training and Advice: education with booklet about normal bladder control, lifestyle interventions (weight reduction, relieving constipation, cessation of smoking, caffeine reduction, fluid management, clothing, reducing emotional stress), bladder training, pelvic floor exercise with individualized contractions/relaxation duration based on assessment of power endurance. 2. Pelvic Floor Training and Advice and EMG Biofeedback . 3. Pelvic Floor Training and Advice with EMG Biofeedback and neuromuscular electrical stimulation. Stimulation at clinic (weekly) initially for 5 min 30 minutes .using pulse rate 40Hz, pulse width 250msec,with 5sec on and10 sec off or 10 Hz, 450msec, 10sec on and 3sec off, at maximum-tolerated intensity	3-day voiding diary; 24 hr pad-test; Uroflowmetry; Pelvic Floor Muscle Assessment; Incontinence Impact Questionnaire (IIQ); Urogenital Distress Inventory (UDI); King's Health Questionnaire (KHQ), and the Multiple Sclerosis Quality of Life-54 Instrument (MSQoL-54).	Intention to treat. Open label. Computer generated randomization list. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size not justified

Table F86. Effects of behavioral interventions on risk and progression of stress urinary incontinence in females

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Laycock, 2001[511] RCT to examine the effects of vaginal cones, pressure biofeedback, and pelvic floor exercises on stress urinary incontinence in females. Duration: 3 months.	101 women 20-64 years old with symptoms of stress urinary incontinence. Exclusion criteria: Moderate or severe urge urinary incontinence, moderate or severe genital prolapse, pregnancy or plans to become pregnant, use of medications that can affect the lower urinary tract, HRT for <3 months, neurological diseases. Loss of followup: 32.7%	1. Pelvic floor exercise with maximum contraction for 1 second and rest for 4 seconds, 10 minutes/day combined with home pressure biofeedback using intra-vaginal perineometer. 2. Vaginal cones for 10 minutes/day with individually adjusted size and increasing weight. 3. Pelvic floor exercise for 10 minutes/day.	Pad use/day, wet episodes/day, Pelvic floor muscles contractility	No intention to treat. Open label. Permuted block randomization in ratio 2:2:1. Allocation concealment not reported. Baseline data not reported. Sample size not justified.
Bo, 2000[512] RCT to examine the effects of pelvic floor muscle exercise on female genuine stress incontinence. Duration: 6 months.	59 women with clinically and urodynamically proven genuine stress incontinence .4grams of leakage measured by the pad test. Exclusion criteria: Urinary incontinence other than GSI, involuntary detrusor contractions exceeding 10cm/H2O on cystometry, residual urine .50ml, maximal uroflow, 15ml/second, previous surgery for GSI, neurological or psychiatric disease, ongoing urinary tract infections, other diseases that could interfere with participation, use of concomitant treatments during the trial, and inability to understand instructions given in Norwegian. Loss of followup: 6.7%.	1. Pelvic floor muscle exercise with 8-12 maximum contractions in 3 series/day and 45 minutes/week group sessions. 2. Untreated control group	Self reported urinary incontinence using 7 point satisfaction scale. Norwegian version of the Quality of Life Scale (QoLS-N) and the Bristol Female Lower Urinary Tract Symptoms (B-FLUTS) questionnaire.	No Intention to treat. Open label. Computer generated randomization stratified by degree of leakage. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified

Table F86. Effects of behavioral interventions on risk and progression of stress urinary incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Bo,1999[513] RCT to examine the effects of pelvic floor exercises, electrical stimulation, vaginal cones, and no treatment on females genuine stress incontinence. Duration: 6 months	107 women with clinically and urodynamically proved genuine stress incontinence >4g of leakage measured by pad test with standardized bladder volume. Exclusion criteria: urinary incontinence other than genuine stress incontinence, involuntary detrusor contractions >10cm/H2O on cystometry, abnormal bladder function (residual urine >50ml and maximal uroflow <15ml/second), previous surgery for genuine stress incontinence, neurological or psychiatric disease, ongoing urinary tract infections, other diseases that could interfere with participation, use of concomitant treatments during the trial, and inability to understand instructions given in Norwegian. Loss of followup: 12.3%	1. Pelvic floor exercise with 8-12 contractions 3 times/day and in groups with skilled physical therapists 1/week. 2. The electrical stimulation using vaginal intermittent stimulation with the MS 106 Twin at 50Hz 30 minutes/day. 3. The vaginal cones of 20, 40, and 70g for 20 minutes/day. 4. The untreated control group offered the use of a continence guard.	Muscle strength measured by vaginal squeeze pressure 1/month. Pad test with standardized bladder volume. 24 hour pad test. Self reported symptoms of severity. Leakage index. Patients indicated on a 5 point scale (5 always, 4 often, 3 sometimes, 2 seldom, 1 never) the frequency of urinary leakage during sneezing, coughing, laughing, walking, walking downhill, running, jumping, and lifting. The mean was calculated as an index of leakage frequency before and after treatment. Objective cure as <2g leakage on the pad test with standardized bladder volume. Subjective cure as (number of women stating that the condition was “unproblematic” after the treatment).	Intention to treat. Single blind. Computer generated random numbers stratified by baseline leakage. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F86. Effects of behavioral interventions on risk and progression of stress urinary incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Cammu,1998[514] RCT to examine the effects of pelvic floor exercises and vaginal weight cones in the treatment on female genuine stress incontinence. Duration: 12 weeks	60 ambulatory and fit white women with urodynamic urinary stress incontinence, and vaginal capacity permitting the use of a vaginal probe-EMG biofeedback-or cones post-partum period, and had neither a genital prolapse nor any other associated pathology that warranted surgery. Furthermore, these women had no detrusor instability, no outflow obstruction, and no intrinsic urethral sphincter deficiency. Loss of followup: Not reported	1. Weekly session of pelvic floor exercises vaginal probe-EMG biofeedback using perineometer 2. Vaginal weight cones (20, 32, 45, 57, and 70g) for 15 minutes, twice daily.	Self reported urinary incontinence using visual analog scale. Pad test	Intention to treat. Open label. Computerized randomization with random numbers tables. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified
Miller, 1998[515] RCT to examine the effects of intentionally contracting the pelvic floor muscles before and during a cough on mild and moderate female stress urinary incontinence. Duration: 1 week	27 women with self reported stress urinary incontinence and demonstrable urine loss during a deep cough with leakage occurring at least weekly and up to 5 times/day. Exclusion criteria: History of systemic neuromuscular disease, previous bladder surgery, active urinary tract infection, leakage that was delayed after coughing and categorized as detrusor instability, leakage that saturated a paper towel and/or pooled on the floor when coughing in the standing posture, inability to demonstrate any voluntary contraction of the pelvic floor muscles despite detailed instruction during the pelvic exam, and significant coexistent pelvic organ prolapse below the hymenal ring. Loss of followup: Not reported	1. Immediate intervention group taught intentionally contracting the pelvic floor muscles before and during a cough (Knack) 2. Wait-listed control group	Self report 6-day urination diary, digital test for pelvic muscle strength and self reported symptoms (possible score range: 0-21).	Intention to treat not stated. Single-blind randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.

Table F86. Effects of behavioral interventions on risk and progression of stress urinary incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Aksac, 2003[516] RCT to examine the effects of pelvic floor muscle exercises or biofeedback on female urinary stress incontinence. Duration: 2 months	50 postmenopausal women with female urinary stress incontinence taking HRT. Exclusion criteria: Not reported. Loss of followup: Not reported.	1. Pelvic floor muscle exercise (contractions for 10 seconds and relaxation for 20 seconds, 10 times/session, 3 sessions/day) via digital palpation at home 2. Pelvic floor muscle exercise (contractions for 10 seconds and relaxation for 20 seconds) via biofeedback (vaginal probe in EMG pressure mode) 3 times/ week. 3. Usual care, hormone replacement therapy	Pad test, perineometry outcomes, digital palpation based Pelvic floor muscle strength, incontinence frequency: 1=urine loss 1/day, 2=urine loss >1/week, 3=urine loss <1/week, 4=urine loss 1/month). Visual analog scale based social activity index: 0=cannot undertake any social activity, 10=does not have any problem.	Intention to treat not stated. Randomization with choosing closed letters (patients had to pick up closed letters). Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.
Burns, 1993[517] RCT to examine the effects of biofeedback and pelvic muscle exercise treatment on stress incontinence in older community-dwelling women. Duration: 6 months	135 community-dwelling women older than 55 years with sphincteric incompetence, >3 urine losses/week, urodynamic incontinence, >23 scores in Mini-Mental State exam. Exclusion criteria: glycosuira, pyuria, residual urine >50cc, Peak urine flow <15cc/second Loss of followup: 7%	1. Biofeedback using vaginal EMG probe, contraction for 10 seconds and relaxations for 10 seconds 10 times in each weekly session. 2. Pelvic muscle exercise with 4 sets of 20 increasing by 10/set until maximum 200 sets/day. 3. Usual care.	Self reported urinary incontinent episodes, improvement in incontinence. Urodynamic outcomes.	No Intention to treat. Single-blind. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified
Sherman, 1997[518] RCT to examine the effects of pelvic muscle exercises with urethral biofeedback on exercise-induced urinary incontinence in females soldiers. Duration: 8 weeks.	39 female active duty soldiers with exercise-induced urinary incontinence (stress or mixed). Exclusion criteria: not reported. Loss of followup: not reported.	1. Pelvic muscle exercises with contractions for 10 seconds and relaxation for 10 seconds 5 times/session, 20 minutes twice/day with urethral biofeedback using vaginal EMG probe. 2. Pelvic muscle exercises with contractions for 10 seconds and relaxation for 10 seconds 5 times/session 20 minutes twice/day alone.	Self reported urinary incontinence symptoms. Urodynamic outcomes.	Intention to treat not stated. Open label. Randomization stratified by diagnosis of physical stress incontinence or mixed urge/stress incontinence. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified

Table F86. Effects of behavioral interventions on risk and progression of stress urinary incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Burns,1990[519] RCT to examine the effects of pelvic floor exercises or biofeedback on female stress urinary incontinence. Duration: 8 weeks	128 women with stress or mixed urinary incontinence >3/week with Mini-Mental scores >23. Exclusion criteria: urinary tract infection. Loss of followup: not reported.	1. Kegel pelvic floor exercises 4 times/day. 2. Biofeedback with vaginal EMG probe and visual control. 3. Usual care.	Self reported urinary symptoms. Electromyographic outcomes	No Intention to treat not stated. Single blind. Randomization with permuted blocks of 10. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Wells, 1991[520] RCT to examine the effects of pelvic muscle exercise or pharmacologic treatment of stress urinary incontinence in community-living elderly women. Duration: 6 months	157 community-living women, ages 55 to 90 years. Exclusion criteria: nursing home residency Loss of followup: 34% in active and 15% in control group.	1. Pelvic muscle exercises with contractions for 10 seconds and relaxation for 10 seconds, 90-160 times/day. 2. Phenylpropanolamine hydrochloride in a dose of 50mg /day, increasing to 50mg 2 times/ day.	Subjective improvement, self recorded frequency of wetting.	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified
Aukee, 2002[521] RCT to examine the effects of electromyography-assisted biofeedback training and pelvic floor muscle training on female stress urinary incontinence. Duration: 12 weeks.	30 women with urodynamically tested stress incontinence ages 31 to 69 years without previous incontinence operations and an abdominal leak point pressure >90. Exclusion criteria: Genital protrusion beyond the vaginal hymen, an inability to understand instructions for home training, pregnancy, and any severe disease such as malignancy in the abdominal region, multiple sclerosis, and insulin-dependent diabetes. Loss of followup: 6.7%	1. Pelvic floor muscle exercise after verbal and written instructions for home practice of 20 minutes/day 5 times/week and individual EMG-assisted biofeedback device with vaginal probe and verbal control. 2. Pelvic floor muscle exercise after verbal and written instructions for home practice of 20 minutes/day 5 times/week.	24 hour pad test, leakage index of 13 types of physical exertions that trigger urinary leakage in women with stress incontinence.	Intention-to-treat. Open label. Randomization with random numbers table with permuted blocks of four. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F86. Effects of behavioral interventions on risk and progression of stress urinary incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Berghmans, 1996[522] RCT to examine the effects of biofeedback and pelvic floor muscle exercise on female genuine stress incontinence. Duration: 12 weeks.	40 women 18-70 years with mild or moderate stress incontinence (grade 1). Exclusion criteria: Use of medicine to counteract functional disabilities of the lower urinary tract, pronounced lesions of the pudendus nerve during clinical neurophysiological examination, positive sediment of urine culture, non-compliance in the diagnostic phase, neurogenic bladder function disability caused by surgery of urological and or gynecological nature, period of 6 weeks after a delivery, other forms of treatment to cure stress incontinence, stress incontinence grade 3 or 4, psychological disorders, irritable vagina, pacemaker, hip prosthesis, pathology such as spina bifida, spinal cord lesion. Loss of followup: none	1. Pelvic floor muscle exercise 12 treatment sessions, 3 times/week with contractions 3 -30 seconds 10-30 times beginning with 4 sets of 10 (5 quick and *5* sustained) and increased by 10 per set until 30 times/set. Biofeedback with EMG vaginal probe and visual control. 2. Pelvic floor muscle exercise 12 treatment sessions, 3 times/week with contractions 3-30 seconds 10-30 times beginning with 4 sets of 10 (5 quick and *5* sustained) and increased by 10 per set until 30 times/set.	Involuntary urine loss, measured with 48 hours pad test. Self completed urinary symptoms questionnaire as 10-point scale and maximum of 50 points for more serious problem: 1. At what level of bladder pressure involuntary loss of urine starts 2. Degree of wet caused by involuntary loss of urine 3. Frequency of involuntary loss of urine 4. Level of limitation of social activities because of incontinence *5.* Emotional state related to involuntary loss of urine	Intention to treat Single blind. Computer generated randomization stratified by seriousness of incontinence (grade 1 and 2) and by referral (general practitioner or urologist) with permuted blocks of 4. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.
Liebergall-Wischnitzer ,2005[523] RCT to examine the effects of circular muscle exercises on female urinary stress incontinence. Duration: 12 weeks.	59 women, mainly hospital employees with stress or mixed urinary incontinence with urine loss >1gin pad test. Exclusion criteria: Pregnancy, severe cardiac or respiratory diseases, pelvic surgery within 6 months, grade 3 and 4 cystocele, previous pelvic radiation, active mucosal lesion in vagina or perineum. Loss of followup: 13.3%	1. Paula method of circular muscle training 15-45 minutes/day with training sessions of 45 minutes/week. 2. Pelvic floor muscle exercise 15 minutes with 30 minute lesson session/week.	Self reported incontinence, quality of life (I-QOL), 1-hour pad test, and pelvic floor muscle strength (assessed by perineometer and digital examination).	No intention to treat. Single blind. Computer generated randomization with block of 4 stratified by age. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F86. Effects of behavioral interventions on risk and progression of stress urinary incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Sung, 2000[524] RCT to examine the effects of pelvic floor muscle exercises on female genuine stress incontinence. Duration: 6 weeks	90 married women with urinary incontinence. Exclusion criteria: not reported. Loss of followup: not reported.	1. Functional electrical stimulation-biofeedback for 20 minutes/session with frequency 35Hz-50Hz and contractions of 32 seconds, 2 sessions/week 2. Intensive pelvic floor muscle exercises 3. Control usual care	Jackson's Bristol female urinary symptom questionnaire with scores from 1 (not a problem) to 5 - very serious problem). Objective changes of pelvic muscle contraction force measured by perineometer.	Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.
Lagro-Janssen , 1991[525] RCT to examine the effects of pelvic floor exercise on urinary incontinence in women. Duration: 3 months	66 women ages 20-65 years with genuine stress incontinence. Exclusion criteria: Previously undergone an operation for incontinence; if they suffered from underlying neurological causes for incontinence, from diabetes mellitus or from urinary tract infection; or if there was a temporary cause for their incontinence (for example, pregnancy or bed rest). Loss of followup: none.	1. Instructions in pelvic floor exercises 5- 10 sessions of 10 pelvic muscle contractions for 6 seconds each day. 2. No therapy	Self reported urinary incontinence and impact of incontinence on life.	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Kim, 2001[526] RCT to examine the effects of continence efficacy intervention program on stress urinary incontinence in Japanese women. Duration: 3 months.	48 women 20-75 years old with stress or mixed urinary incontinence. Exclusion criteria: Drug or surgery treatment for incontinence. Loss of followup: 15.2%	1. Continence efficacy intervention program: common pelvic floor muscle education, audiovisual tape, calendar, counseling, schedule guideline, assessing self-care methods. 2. Conventional care.	Self reported urinary continence and improvement in symptoms of urinary incontinence graded from 0 to 100.	No Intention to treat. Open label. Randomization by the order of coming to the clinic. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F86. Effects of behavioral interventions on risk and progression of stress urinary incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Arvonen, 2001[527] RCT to examine the effects of pelvic floor muscle training with and without vaginal balls on females stress urinary incontinence. Duration: 4 months	37 women ages 25-65 with stress urinary incontinence, understanding of spoken Swedish. Exclusion criteria: Pregnancy, cysto/rectocele, prolapse, urinary tract infection, altered vaginal tissue, and medication affecting the functioning of the urinary tract or kidneys. Loss of followup: 7%	1. Pelvic floor muscle training program with contractions/relaxations for 5 seconds 10 times twice a day. 2. Pelvic floor muscle training program with contractions/relaxations for 20/20 seconds 10 times twice a day using weighted vaginal balls 50-100g.	Pad-test with a standardized bladder volume. The strength of the pelvic floor musculature assessed by vaginal palpation graded from 0=no contraction to 5=very strong pressure with a strong lift for 6±7 seconds.	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Borello-France, 2006[528] RCT to examine the effects of exercise position during pelvic-floor muscle exercises on females stress urinary incontinence. Duration:12-weeks	44 women 38 to 70 years old, ambulatory, with symptoms of stress urinary incontinence >1/week. Exclusion criteria: Pregnancy, symptoms of urgency or urge urinary incontinence, prior treatments for stress urinary incontinence (collagen injection, medications affecting bladder tone, pessary, or surgery), practicing pelvic-floor muscle exercises, pacemaker, use of intrauterine device, medical history of pelvic cancer, severe endometriosis, neurologic or metabolic disorders likely to impair bladder or sphincter function. Loss of followup: 18%	1. Pelvic floor muscle exercises with EMG biofeedback in the supine position only using maximum 30-60 repetitions of 3-12 second contractions twice daily. 2. Pelvic floor muscle exercises with EMG biofeedback in both supine and upright positions,1 set (3- and 12-second contractions) in each position with maximum 20 repetitions (2 sets of 10) of the 3-12 second contractions twice daily.	1-week bladder diary, 1 hour pad test, urodynamic outcomes, quality-of-life (Incontinence Impact Questionnaire ranges from 0-400 with poorer perceived quality of life).	Intention-to-treat. Open label. Block randomization schedule with a random-number table. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F86. Effects of behavioral interventions on risk and progression of stress urinary incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Mørkved, 2002[529] RCT to examine the effects of individual pelvic floor muscle training with and without biofeedback in women with urodynamic stress incontinence. Duration of treatment and followup: 6 months	103 women with symptoms of stress incontinence and >2g leakage measured by a pad test with standardized bladder volume. Exclusion criteria: involuntary detrusor contractions on cystometry, abnormal bladder function (residual urine >50ml), previous surgery for stress incontinence, neurologic or psychiatric disease, urinary tract infection, other diseases that could interfere with participation, pregnancy, use of concomitant treatments during the trial period, and inability to understand instructions in Norwegian. Loss of follow up: 8.7%	1. Pelvic floor muscle training with 3 sets of 10 contractions 3 times/day, individually supervised by a physical therapist. At home, 3 sets of 10 high intensity (close to maximum) contractions per day with a biofeedback apparatus 2. Pelvic floor muscle training with 3 sets of 10 contractions 3 times/day, individually supervised by a physical therapist. At home, 3 sets of 10 high intensity (close to maximum) contractions per day without biofeedback	Pad test with standardized bladder volume with 300ml of saline. Women wore pre-weighed pads and jumped with legs in subsequent adduction and abduction (jumping jacks/star jumps: 20 repetitions) and coughed three times. Objective cure ≤2g of leakage. Self-report of severity using 5-point scale (unproblematic, minor problem, moderate problem, problematic, very problematic). Subjective cure - reporting the leakage to be unproblematic after treatment. The leakage index in 5-point scale (1-never, 5-always) containing 13 types of physical activities known to trigger urinary leakage. The social activity index with nine social settings and 10cm visual analogue scale (0 - impossible to participate, 10 - no problem to participate).	Intention to treat. Single blind. Centralized but no computerized randomization stratified by results of a pad test with standardized bladder volume (20g or less and more than 20g of leakage). Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F87. Effects of behavioral interventions on urinary continence in females (events) (tables sorted by rate of urinary continence after active treatment, from highest to lowest)

Author Sample	Active Treatment	Control Treatment	Definition of Cure	Number of Cases After Active Treatment	Number of Cases After Control Treatment	Rate (%) After Active Treatment	Rate (%) After Control Treatment	Relative Risk (95% CI)	Number Needed to Treat (95% CI)	Number of attributable Events/1,000 Treated (95% CI)
Aksac, 2003[516] N = 50	Pelvic floor muscle exercise (contractions for 10 seconds and relaxation for 20 seconds) via biofeedback (vaginal probe in EMG pressure mode) 3 times/week	Usual care	Cure from stress urinary incontinence in pad test	16	0	80.0	0	**17.3 (1.1; 261.7)**		799 (0; 261)E
	Pelvic floor muscle exercise (contractions for 10 sec and relaxation for 20 sec, 10 times/session, 3 sessions/day) via digital palpation at home		Cure from stress urinary incontinence in pad test	15	0	75.0	0	**16.2 (1.1; 246.5)**		749 (0; 246)E

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Wille,2003[530] RCT to examine the effects of pelvic muscle exercises, electrical stimulation and biofeedback on urinary incontinence after radical retropubic prostatectomy. Duration: 3 months Duration of followup: 12 months	139 patients who underwent radical retropubic prostatectomy Exclusion criteria: Patient unwillingness to make 2 visits 3 and 12 months Postoperatively. Loss of followup: 7.9%	1. Instructions about postoperative pelvic muscle exercises. 2. Instructions about postoperative, electrical stimulation (ES) for 15 minutes twice daily with frequency 27Hz, biphasic pulse shape with 1-second bursts, a 5-second pulse width and 2-second pulse trains. Intensity was controlled by each patient from 10% to 100%. 3. Instructions about postoperative, electrical stimulation (ES) for 15 minutes twice daily and biofeedback (BFB) 15 minutes twice daily with stimulation time of 5 seconds, and contracting and relaxing time of 5 and 15 seconds. Treatment was started immediately after catheter removal and performed for 3 months.	Self reported urinary incontinence with symptom inventory. 20-minute pad test Subjective continence - no or 1 pad used daily. Objective continence-urine loss of less than 1gm.	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Yokoyama, 2004[531] RCT to examine the effects extracorporeal magnetic innervation and functional electrical stimulation on urinary incontinence after retropubic radical prostatectomy. Duration: 1-2 months Duration of followup: 6 months	36 patients with urinary incontinence after retropubic radical prostatectomy. Exclusion criteria: <100g pad weight after the 24-hour pad test 1 day after removing the catheter, use of anticholinergic drugs. Loss of followup: none	1. Extracorporeal magnetic innervation (ExMI) using neocontrol system was used with 20 minute treatment sessions, 2/week for 2 months. The frequency of the pulse field was 10Hz for 10 minutes, followed by a second treatment at 50Hz for 10 minutes. 2. Functional electrical stimulation (FES) using anal electrode and pulses of 20Hz square waves at a 300μs pulse duration were used for 15 minutes twice daily for 1 month. 3. Control group: pelvic floor muscle exercises.	Self reported bladder diaries, 24-hour pad weight testing	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F90. Behavioral interventions on risk and progression of stress urinary incontinence in males with prostate diseases (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Filocamo,2005[532] RCT to examine the effects of early pelvic floor muscle training on urinary incontinence after radical retropubic prostatectomy. Duration of followup: 12 months	300 consecutive patients who had undergone standard radical retropubic prostatectomy for clinical stage T1 or T2 prostate cancer. Exclusion criteria: Prior bladder or prostate surgery, prior urinary or fecal incontinence, neurogenic dysfunction of the lower urinary tract, and a preoperative history of overactive bladder. Loss of followup: 1%	1. Early pelvic floor rehabilitation program after removal of the catheter with verbal explanations, palpation, and visualization of Kegel exercises: 3 sets of 10 contractions for 5 seconds and 10 seconds of muscular relaxation under digital anal control. 2. No formal training in pelvic floor rehabilitation after catheter removal.	Self reported urinary incontinence using International Continence Society (ICS)-male questionnaire. 1 hour and 24 hour pad test	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Moore, 1999[533] RCT to examine the effects of intensive pelvic muscle exercises and electrical stimulation on urinary incontinence after radical prostatectomy. Duration: 12 weeks. Duration of followup: 8 months	63 patients >4 weeks after radical prostatectomy, with urinary incontinence (>2g of urine loss on pad test), within 12 hours drive of study center, not seeking other treatments, able to speak and read English and comply with the study protocol. Exclusion criteria: Demand pacemaker, previous pelvic floor stimulation, active rectal lesions or infections, known detrusor instability. Loss of followup: 7.9%	1. Intensive pelvic muscle exercises conducted by a physiotherapist for 30 minutes 2/week: maximal contractions for 5 seconds, slow release and 10 seconds of muscular relaxation. 2. Intensive pelvic muscle exercises conducted by a physiotherapist for 30 minutes 2/week: maximal contractions for 5 seconds, slow release and 10 seconds of muscular relaxation; plus electrical stimulation : 50Hz, biphasic pulse shape with 1 second bursts, 1 second width, and 1 second pulse trains. 3. Standard treatment with verbal and written instructions about postoperative pelvic muscle exercises from urologist and from the nurses at the pre-admission clinic.	Urine symptom inventory. Continence: a loss of <2g of urine. Socially acceptable continence: loss of <10g of urine. 24-hour pad test	No intention to treat. Open label. Computer generated randomization with random numbers list. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Mathewson-Chapman, 1997[534] RCT to examine the effects of pelvic muscle exercises with biofeedback on urinary incontinence after radical prostatectomy for localized prostate cancer. Duration: 12 weeks	53 patients after radical prostatectomy for localized prostate cancer. Exclusion criteria: not reported Loss of followup: none	1. Education booklet and instruction for pelvic muscle exercises with biofeedback: maximal contractions for 10 seconds, slow release, and 10 seconds of muscular relaxation, 3 times/week. 2. Standard care with no pelvic muscle exercises. All patients were recommended to limit coffee, tea, chocolate, alcohol, and over counter medication for bladder control.	Self reported in three-day bladder diaries length of time urine loss was experienced; 2) episodes and frequency of urine loss; and 3) ounces of urine lost and number of pads used.	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F90. Behavioral interventions on risk and progression of stress urinary incontinence in males with prostate diseases (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Floratos, 2002[535] RCT to examine the effects of electromyographic biofeedback with verbal instructions as learning tools of pelvic muscle exercises on urinary incontinence after radical prostatectomy. Duration: 12 weeks. Duration of followup: 6 months	42 consecutive patients with urinary incontinence after radical retropubic prostatectomy for localized prostate cancer, able to participate in a learning program, in good general condition and willingness to participate in the study. Exclusion criteria: Significant perioperative complications (ureteric or rectal injury, urine leakage from anastomosis, thrombo-embolism), history of preoperative incontinence and pelvic or lower urinary tract operations, psychiatric history. Loss of followup: 2.4%	1. Electromyographic biofeedback as learning tools for pelvic muscle exercises immediately after catheter removal: submaximal contractions 3-5 seconds, relaxation for 6-10 seconds, 80-100 times/day and 15 sessions of 2-channel electromyographic biofeedback (three times weekly, 30 minutes each). 2. Verbal feedback as learning tools for pelvic muscle exercises immediately after catheter removal: submaximal contractions 3-5 seconds, relaxation for 6-10 seconds, 80-100 times/day.	Self reported in 3-day bladder diaries. Continence: a loss of <1g of urine. 1 hour pad test	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Van Kampen, 2000[536] RCT to examine the effects of pelvic floor re-education for patients with urinary incontinence after radical prostatectomy. Duration of followup: 1 year	102 consecutive incontinent patients who had had radical retropubic prostatectomy for clinically localized prostate cancer, incontinent on day 15 after surgery after removal of the catheter, and who could comply with the ambulatory treatment schedule. Exclusion criteria: Continence Loss of followup: 3.9%	1. Pelvic floor re-education program with active pelvic floor muscle exercises and biofeedback for as long as they were incontinent.. 2. .Placebo electrotherapy (a false interferential current) via four skin electrodes, two placed on the abdomen and two on the adductor muscles of the thighs	Self reported urinary incontinence with a visual analogue scale (0=completely dry, 10=completely incontinent). 1 hour and 24 hour pad tests.	Intention-to-treat. Single blind. Computer generated randomization with random permuted blocks. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Bales,2000[537] RCT to examine the effects of preoperative biofeedback training on urinary continence in men undergoing radical prostatectomy. Duration: 2-4 weeks. Duration of followup: 6 months	100 men with Stages T1c-T2c prostate cancer who were to undergo radical retropubic prostatectomy. Exclusion criteria: Preoperative radiotherapy or neoadjuvant hormonal blockade, transurethral resection of the prostate, pre-existing neurologic disease. Loss of followup: 3%	1. Graded pelvic muscle exercise training with biofeedback 2-4 weeks before surgery 4 times/day until surgery and to resume exercises when the urethral catheter was removed following surgery. Surface electrodes were used to assess muscle strength and contractions of 5-10 seconds, and 10-15 repetitions were performed. 2. Control group: Pelvic muscle exercises without biofeedback.	Self reported urinary continence: one pad or less/day, either because of minimal urine leakage or for security if no leakage was present,	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.

Table F90. Behavioral interventions on risk and progression of stress urinary incontinence in males with prostate diseases (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Porru, 2001[538] RCT to examine the effects of pelvic floor muscle exercises on urinary incontinence in patients after transurethral prostatectomy. Duration: 4 weeks	63 consecutive patients with bladder outflow obstruction and diagnosis of symptomatic benign prostatic hyperplasia after transurethral prostatectomy. Exclusion criteria: Age over 80 years old, history of urethral or pelvic surgery, neurogenic bladder, or prostatic carcinoma. Loss of followup: Not reported	1. Verbal instruction, feedback on contractions of pelvic floor muscles, and verbal reinforcement of appropriate responses to teach selective contractions of anal sphincter muscles and relaxation of abdominal muscles for 45 times/day, divided into 3 sessions of 15 exercises each. 2 Standard care without instruction on pelvic floor muscle exercises.	Self reported urinary incontinence using The American Urological Association Symptom Score	Intention to treat not stated. Single blind. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.
Franke, 2000[539] RCT to examine the effects of biofeedback and pelvic floor exercises 6 weeks after radical prostatectomy on urinary incontinence. Duration: 6 months	30 patients who underwent radical retropubic prostatectomy. Exclusion criteria: Previous transurethral prostatic resection, neurological condition affecting the urinary tract, residual urine greater than 50ml. or a urinary tract infection. Loss of followup: Not reported	1. Pelvic floor muscle exercises at home of 20 contractions 3 times/day, with 45 minute perineal patch, electromyography biofeedback behavioral therapy session and timed voiding schedule to decrease urgency and urge incontinence. 2. Standard care without instruction on pelvic floor muscle exercises.	Self reported urinary incontinence and voiding diary and 48-hour pad test	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Parekh,2003[540] RCT to examine the effects of physical therapy and pelvic floor exercises before and after radical prostatectomy on urinary incontinence. Duration: 3 months Duration of followup: 6 months	38 consecutive patients scheduled to undergo radical prostatectomy. Exclusion criteria: Prior bowel or bladder incontinence. Loss of followup: Not reported	1. Physical therapy for a pelvic floor exercise program with 2 treatment sessions before surgery and every 3 weeks for 3 months after the catheter removal. A home exercise program was followed for 6 months or longer by patients requiring further physical therapy guidance. 2. Standard care without instruction on pelvic floor muscle exercises.	Self reported urinary incontinence and number of pads used daily. Continence - 0 or 1 precautionary pad	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.

Table F90. Behavioral interventions on risk and progression of stress urinary incontinence in males with prostate diseases (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Dorey, 2004[541] RCT to examine the effects of pelvic floor muscle exercises and manometric biofeedback for post-micturition dribble in men with erectile dysfunction. Duration of followup: 3 months	55 men with erectile dysfunction. Exclusion criteria: Urological congenital abnormalities, neurological deficits, and previous urological surgery. Loss of followup: 9.1%	1. Pelvic floor muscle exercises including a strong post-void "squeeze out" pelvic floor muscle contraction, biofeedback, and suggestions for lifestyle changes. 2. Advice on lifestyle changes	24 hours, pad test, anal manometric outcomes.	No intention to treat. Single blind. Random number system of odd or even tickets not adequate. Allocation concealment not adequate. Sample size not justified.
Burgio, 2006[542] RCT to examine the effects of preoperative biofeedback assisted behavioral training on urinary incontinence after radical prostatectomy. Duration of follow up: 6 months	125 continent men 53 to 68 years old who elected radical prostatectomy for prostate cancer. Exclusion criteria: >2 episodes of urinary incontinence in the previous 6 months, documented incontinence in the bladder diary, prior prostatectomy, impaired mental status (score less than 20 on the Mini-Mental State Examination), <1 week before scheduled surgery. Loss of follow up: 18.4%	1. Single preoperative session of biofeedback assisted behavioral training plus daily home exercise daily until the surgery and after catheter removal: 45 pelvic floor muscle exercises in various positions, divided into 3 sessions of 15 exercises to contract sphincter muscles (2 -10-second contraction, 2-10 seconds of relaxation with immediate visual feedback of rectal pressure and external anal sphincter contractions using 3 small balloons). 2. Usual care control condition, consisting of simple postoperative instructions to interrupt the urinary stream.	Self reported incontinence duration from bladder diaries, incontinence severity (the proportion with severe/continual leakage), Incontinence Impact Questionnaire, psychological distress (Hopkins Symptom Checklist) pad use, and health related quality of life (Medical Outcomes Study Short Form Health Survey). Self reported continence -3 consecutive 1-day diaries with no leakage or a 7-day diary with no leakage.	Intention to treat. Single blind. Randomization with computer generated random numbers and block size of 4 stratified by age (<65 vs. ≥65 years) and tumor differentiation (Gleason score ≤5 vs. > 5). Allocation concealment not adequate. Baseline data confirmed the adequacy of randomization. Sample size justified.

Table F91. Effects of behavioral interventions on urinary continence in males (events) (table sorted by rate of continence in the active group, from highest to lowest)

Author Sample	Active Treatment	Control Treatment	Definition of Continence	Number of Cases After Active Treatment	Number of Cases After Control Treatment	Rate (%) After Active Treatment	Rate (%) After Control Treatment	Relative Risk (95% CI)	Number Needed to Treat (95% CI)	Number of attributable Events/1,000 Treated 95% CI)
Filocamo, 2005[532] N = 300	Early pelvic floor rehabilitation program after removal of the catheter with verbal explanations, palpation, and visualization of Kegel exercises: 3 sets of 10 contractions for 5 seconds and 10 seconds of muscular relaxation under digital anal control.	No formal training in pelvic floor rehabilitation after catheter removal	Self reported urinary continence	148	132	98.7	88.0	**1.1 (1.1; 1.2)**	9 (6; 21)	107 (47; 170)E
Mathewson-Chapman, 1997[534] N = 53	Education booklet and instruction for pelvic muscle exercises with biofeedback: maximal contractions for 10 seconds, slow release and 10 seconds of muscular relaxation, 3 times/week.	Standard care with no pelvic muscle exercises. All patients were recommended to limit coffee, tea, chocolate, alcohol, and over counter medication for bladder control.	Self reported urinary continence	26	24	96.3	100.0	1.0 (0.9; 1.1)

Table F93. Behavioral clinical interventions on urinary incontinence in adults

Study	Participants	Clinical Interventions	Outcome	Quality Issues
O'Brien, 1991[309] RCT to examine the effects of pelvic floor exercises and bladder retraining supervised by non-specialist nurse on urinary incontinence in adults with regular urinary incontinence. Duration: 3 months	561 adults ages 35 years and older with regular urinary incontinence (two or more leaks in any one month). Exclusion criteria: Urinary tract infection. Loss of followup: not reported	1. Four sessions of pelvic floor exercises and bladder retraining supervised by non-specialist nurse. 2. Usual care	Self reported urinary incontinence and changes in incontinence.	No Intention to treat. Single blind. Computer based randomization. Allocation concealment unclear. Baseline data not reported. Sample size justified.
McDowell, 1999[543] Cross-over RCT to examine the effects of behavioral therapies of urinary incontinence in homebound older adults. Duration: 8 weeks.	105 adults 60 years and older, homebound (Health Care Financing Administration, cognitively intact (Folstein Mini-Mental State Examination score >24), with urinary incontinence (>2 urinary accidents/week for at least 3 months), who understand and speak English. Exclusion criteria: Folstein MMSE scores <24, severe pelvic prolapse, terminal illness, post-void residual >100ml unable to toilet independently, no caregiver willing and able to assist with toileting, <2 urinary accidents per week, unable to provide satisfactory self-report bladder diary data after three attempts. Loss of followup: 19%	1. Biofeedback-assisted pelvic floor muscle training by NPs skilled in behavioral therapies for urinary incontinence. Behavioral therapy: 8 weekly sessions at homes with biofeedback-assisted pelvic floor muscle exercises, urge and stress strategies, and bladder retraining. Biofeedback with surface electromyography for immediate visual and/or auditory feedback of pelvic floor and abdominal muscle activity. PFM exercises 3/day, 10-15 exercises at each session to contract and relax muscles for 10 seconds. 2. Usual care with attention control (visits by the NP every 1-2 weeks to provide social interaction).	Self reported episodes of urinary incontinence/day and changes in severity of urinary incontinence (mild: <5 accidents/week; moderate: 5-10 accidents/week; severe: >10 accidents/week).	No intention to treat. Single blind. Computer-generated stratified by cognitive ability, toileting skills, and severity of urinary incontinence randomization with permuted blocks. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F93. Behavioral clinical interventions on urinary incontinence in adults (continued)

Study	Participants	Clinical Interventions	Outcome	Quality Issues
Engberg, 2002[544, part of McDowell, 1999{McDowell, 1999 #10200}] Cross-over RCT to examine the effects of prompted voiding in cognitively impaired homebound older adults. Duration: 8 weeks	19 adults 60 years and older with urinary incontinence >2 episodes/week for >3 months who met Center for Medicare and Medicaid Services criteria for being homebound, residents in 2 large Medicare-approved home health agencies in a large metropolitan area who understand and speak English. Exclusion criteria: Terminal illness; postvoid residual volume >100ml; caregiver was unable or unwilling to provide toileting assistance, complete bladder diaries, or implement the PV protocol. Loss of followup: 19%	1. Prompted voiding by caregivers to approach subjects hourly for perceived wet/dry status vs. objective wet checks, feedback and praising for correct response, toilet by request, positive feedback for appropriate toileting. 2. Usual care with attention control (visits by the NP every 1-2 weeks to provide social interaction).	Incontinent episodes reported by subjects' caregivers in 2-week bladder diary.	Intention to treat. Single blind. Computer-generated stratified by cognitive ability, toileting skills, and severity of urinary incontinence randomization. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size not justified but power reported.
Paterson, 1997[545] RCT to examine the effects of pelvic floor exercises and urethral milking as treatments for post-micturition dribble in males. Duration: 12 weeks.	49 men 36-83 years old who had not undergone surgery on the bladder, urethra, or prostate gland but with history of post-micturition dribble. Exclusion criteria: not reported. Loss of followup: 12.2%	1. Pelvic muscle exercise with 1 second contractions (~5) to increase length and strengths of contractions as much as possible. 2. Urethral milking after appropriate education. 3. Counseling including drinking pattern, aperient use, toileting habits, dietary advice, and relaxation therapy.	Objectively measure pad weight gain.	No intention to treat. Single blind. Randomization with random numbers table and balanced block design. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F100. Electrical stimulation on risk and progression of urinary incontinence in adults

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Electrical stimulation of pelvic floor muscles				
But, 2003[546] Placebo controlled RCT to examine the effects of functional magnetic stimulation in the treatment of women with urinary incontinence. Duration: 2 months	55 women with urinary incontinence older than 18 years, not pregnant, and not physically or mentally disabled. Exclusion criteria: Implanted electronic equipment (pacemakers), urolithiasis, bladder infection, tumor, recent urethral or continence surgery, use of anticholinergic drugs, beta-blocking agents, and diuretics. Loss of followup: 7.7%	1. Functional magnetic stimulation with Pulsegen device, which produced a pulsating magnetic field of B = 10 microT intensity and a frequency of 10Hz. 2. Placebo treatment with sham not active device.	Pad test use and pad weight. Self reported nocturia. PFM contractions measured with perineometer after performing five maximal consecutive PFM contractions, with an interval of 30 seconds between every two contractions.. The power of the PFM contractions was measured as the percentage of the maximum (100% = 45mm/Hg); the time of the PFM contractions was measured in seconds.	No intention to treat. Double-blind. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Spruijt, 2003[547] RCT to examine the effects of intravaginal electrical stimulation of the pelvic floor for urinary incontinence in elderly women. Duration: 8 weeks	51 women ≥65 years of age, with symptoms of stress, urge or mixed urinary incontinence of >3 months' duration, and with urinary leakage >10cc /24hours. Exclusion criteria: Persistent urinary tract infection (positive urine culture after antibiotic treatment), recurrent urinary tract infection (within 4 weeks after treatment), bladder pathology or dysfunction because of fistula, tumor, pelvic irradiation, neurological or other chronic conditions (diabetes mellitus, Parkinson's disease), genital , pacemaker, and insufficient mental condition. Loss of followup: 3.9%	1. Intravaginal electrical stimulation of the pelvic floor using stimulator generated biphasic current pulses with duration of 1ms and a frequency of 50Hz (stress urinary incontinence) or 20Hz (urge urinary incontinence). 2. Kegel exercise program with verbal instructions on how to exercise at home.	Urinary leakage during a pad test, pelvic muscle strength measured by a perineometer, detrusor instability. Self reported change in urinary symptoms based on the PRAFAB score.	No intention to treat. Open label. Blocked randomization (Pocock). Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Yamanishi, 2000[548] Placebo controlled RCT to examine effects of electrical stimulation for urinary incontinence due to detrusor overactivity. Duration: 4 weeks	68 patients with urinary incontinence due to detrusor overactivity urodynamically defined as involuntary detrusor contractions of more than 15cm/H2O during the filling phase. Exclusion criteria: Use of anticholinergics or tricyclic depressants, pelvic floor exercise, bladder training, or pelvic surgery before entry into the study. Loss of followup: 11.8%	1. Electrical stimulation 15 minutes twice daily for 4 weeks (vaginal electrode in women and an anal or surface electrode in men to provide alternating pulses of 10Hz square waves of 1-ms pulse duration and a maximum output current of 60mA). 2. Sham inactive device	Self reported urinary incontinence in frequency/volume chart and urodynamic outcomes. Degree of urgency scored as 0-none, 1-slight, 2-moderate, and 3-very much.	No intention to treat. Double-blind. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Yamanishi, 2000[549] RCT to examine effects of functional magnetic stimulation and functional electrical stimulation on the inhibition of detrusor overactivity. Duration: acute	32 patients with urinary incontinence due to detrusor overactivity defined urodynamically as involuntary detrusor contractions of more than 15cm/H2O during the filling phase. Exclusion criteria: Not reported Loss of followup: No followup	1. Functional magnetic stimulation applied continuously at 10Hz 2. Functional electrical stimulation applied continuously at 10Hz with vaginal electrode in women and a surface electrode on the dorsal part of the penis in men.	Urodynamic outcomes before and after stimulation.	No intention to treat. Open label. Randomization not reported. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.
Lappin, 2003[550] Crossover, placebo controlled RCT to examine effects of pulsed electromagnetic fields on bladder control in patients with multiple sclerosis. Duration: 10 weeks, 2 weeks washout period.	145 patients 18-65 years old with clinically definite multiple sclerosis and light spasticity (>2 in 6 point scale) and bladder control problems. Exclusion criteria: Changes in medication last 2 months, pregnancy, pacemaker, chronic diseases. Loss of followup: 19%	1. Daily simulation with low frequency pulsed electromagnetic fields 2. Sham inactive device	The MS Quality of Life Inventory (MSQLI) was used to assess changes in bladder control form 0-none to 10-severe	No intention to treat. Double-blind. Central computer generated randomization. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F100. Electrical stimulation on risk and progression of urinary incontinence in adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Amaro, 2006[551] RCT to examine the effects of intravaginal electrical stimulation in treating mixed urinary incontinence. Duration: 7 weeks, Followup: 1 month	40 women with predominant urge urinary incontinence. Exclusion criteria: Use of anticholinergic and tricyclic antidepressants, pelvic floor exercise, bladder training, vaginal prolapse >II grade, urinary infection, metal implants, neurological diseases. Loss of followup: none	1. Effective and sham intravaginal electrical stimulation with 3 20-minute sessions/week using Dualpex Uro 996 frequency of 4Hz. 2. Sham intravaginal electrical stimulation.	Self reported Improvement in urge incontinence	Double blind. Randomization and allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.
Berghmans, 2002[552] RCT to examine effects of physiotherapy in women with proven bladder overactivity. Duration: 9 weeks	98 patients older than 18 years with proven bladder overactivity defined as Detrusor Activity Index (DAI) ≥0.50, able to understand Dutch. Exclusion criteria: Mechanical intravesical obstruction, urinary calculus, urinary tract infection, colpitis, pacemaker, pregnancy, physiotherapy within 3 months, uncontrolled diabetes mellitus. Loss of followup: 8%.	1. Pelvic floor exercises with contractions for >20 seconds controlled by physiotherapist palpation with relaxation period of 10 seconds. Bladder training to inhibit the sensation of urgency and to postpone voiding, voiding schedule with an interval >2 hours, positive reinforcement of patient motivation by the physical therapist. 2. Office- and home-based functional electrostimulation maximum 100mA frequency 4 - 10Hz. 3. Office-based functional electrostimulation, pelvic floor exercise, and bladder training. 4. No treatment. All treated subjects received 9 sessions, 1/week	Detrusor Activity Index - combined cystometry outcomes (number of contractions/hour, mean duration of a contraction and mean amplitude of a contraction) and voiding diary (mean volume drunk/hour, mean number of micturitions/hour and mean volume voided per micturition. The DAI represents a score between 0 and 1, where '0' represents no activity of the bladder during the filling phase and '1' represents severe overactivity of the bladder.	Intention to treat. Single blind. Randomization using blocks of 4. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F100. Electrical stimulation on risk and progression of urinary incontinence in adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Pages,2001[553] RCT to examine the effects of intensive group physical therapy program with individual biofeedback training for female patients with urinary stress incontinence. Duration: 4 weeks	51 women, referred by gynecologists for nonoperative treatment of genuine stress incontinence of mild-to-moderate severity. Exclusion criteria: Not reported. Loss of followup: 21%	1. Specific physical therapy program. Group therapy 5 times/week and home pelvic floor exercise with 50 contractions for 10 minutes 2times/day. Recommendation of weight loss and aerobic sports. 2. Biofeedback training daily 90 minutes in groups and individually for 15 minutes, 5 times/week. Intra vaginal pressure sensor and visual biofeedback in computer monitor.	Nocturnal urinary frequency and subjective improvement of incontinence, standardized exams of digital contraction strength, speculum tests, and manometric outcomes.	No intention to treat. Open label. Randomization and allocation concealment unclear. Baseline data not reported. Sample size not justified.
Sand, 1995[554] Placebo-controlled RCT to examine the effects of transvaginal electrical stimulation in treating genuine stress incontinence. Duration: 15-weeks	52 community dwelling women with urodynamically proven genuine stress incontinence, who would comply with visits, not use/seek other treatment for incontinence. Exclusion criteria: Detrusor instability, pregnancy, pacemaker, prior pelvic floor stimulation, pelvic implanted devices, active vaginal lesions or infections, urinary tract infection, hypermenorrhea or menorrhaghia, urinary retention (>100ml), pelvic surgery in past 6 months, atrophic vaginitis, genital prolapse to introitus, pelvic irradiation, intrinsic sphincteric deficiency. Loss of followup: 15%	1. Active pelvic floor stimulator with gradually adjusted 60-80mA from 5 seconds on/1 second off for 15 minutes to 5 seconds on/5 seconds off for 30 minutes. 2. Sham inactive device.	Self reported urinary stress incontinence and voiding in diaries, urodynamic outcomes, pad test, and pelvic muscle strength.	Intention to treat. Double-blind. Computer-generated random numbers with blocks at a 2:1 rate favoring active over placebo devices. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F100. Electrical stimulation on risk and progression of urinary incontinence in adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Indrekvam, 2001[555] Prospective cohort study to examine the effectiveness of home-managed electrical stimulation on urinary incontinence in females. Duration: 2 years	3,198 women treated with home-managed electrical stimulation in Norway from 1992-1994. Exclusion criteria: Pregnancy, use of a pacemaker, malignancy. Loss of followup: 1.2%; 15 women did not start treatment because of severe illness or because they had died, and 24 did not complete the treatment because of pregnancy or cancer.	Home-managed electrical stimulation with vaginal/anal stimulators (20–50Hz) for 6–8 hours/day for at least 3 months before evaluation of the effect. Before-after comparison. The stimulators Vitacon Norway AS for long-term stimulation (20–50 Hz) delivered below the sensory threshold. Devices were used for 6–8 hours/day for at least 3 months before evaluation of the effect. Max stimulation (10– 20 Hz) used a high-intensity stimulus. The companies recommended application of not more than 20 min (the machine switches off automatically) daily or at least twice weekly. Patients were advised to increase the stimulation intensity continuously using a control knob to as high as possible, but below the level of pain. The stimulator should be used at least 10–20 times before evaluation of the effect.	Self reported frequency of incontinence episodes and amount of leakage before and after treatment, number of voidings during the day and night, and number of protective pads used (4 item ordinal scale).	Intention to treat. Not random sampling adjustment for age, duration of incontinence, diagnosis (urge/stress component), previous surgery for urinary incontinence, urodynamic investigation, type of stimulator, frequency, amount of leakage, physicians' work, patients' practical problems and discomfort with treatment.
Amaro, 2006[551] RCT to examine the effects of intravaginal electrical stimulation in mixed urinary incontinence. Duration: 7weeks, Followup: 4 weeks.	40 women symptoms of predominant urge incontinence not taking anticholinergics or tricyclic antidepressants. Exclusion criteria: Use of pelvic floor exercises or bladder training, vaginal prolapse >grade II, retention complaint or obstruction diagnosis during UDS, urinary infection, changes in cutaneous sensitivity, metal implants, and neurological diseases. Loss of followup: Not reported	1. Effective intravaginal electrical stimulation using frequency of 4 Hz with 3 20-minute sessions/week 2. Sham intravaginal electrical stimulation using frequency of 4Hz with 3 20-minute sessions/week	Self reported urge urinary incontinence.	Intention to treat not stated. Double-blind. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F100. Electrical stimulation on risk and progression of urinary incontinence in adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Smith, 1996[556] RCT to examine the effects of intravaginal electrical stimulation on genuine stress urinary incontinence and detrusor instability in women. Duration: 4 months	57 women with urinary incontinence. Exclusion criteria: Type 3 stress urinary incontinence, pregnancy, urinary retention, vaginal prolapse, cardiac pacemaker, mixed incontinence with no major and minor components. Loss of followup: 1.8%	18 women with stress urinary incontinence: 1. Electrical stimulation using frequency 12.5Hz.-50Hz and amplitude 5-10mA-80mA for 15 to 60 minutes 2/day 2. Kegel exercise 38 women with detrusor instability: 1. Anticholinergic therapy with Propantheline bromide in dose of 7.5 to 45mg 2-3 times/day 2. Electrical stimulation using frequency 12.5Hz.-50Hz and amplitude 5-25mA for 15-60 minutes 2/day.	Self reported cure from urinary incontinence and no longer requiring pads. Reduction in episodes of urinary incontinence by >50 and 10 or fewer voids per 24 hours	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Brubaker, 1997[557] RCT to examine the effects of transvaginal electrical stimulation for treatment of urinary incontinence in women. Duration: 8 weeks, Followup: 2 weeks	121 women >25 years of age with either urinary incontinence due to detrusor instability or genuine stress incontinence, or both (mixed incontinence) diagnosed with filling urethrocystometry. Exclusion criteria: Urinary incontinence other than genuine stress incontinence, detrusor instability, or mixed incontinence; leakage episodes <3/week, inadequate genitourinary estrogen (minimum 3 months HRT), inadequate cognitive ability (investigator judgment), urinary tract infection, anatomic defect that precluded use of device, postvoid residual >100ml, implanted electric device, genitourinary surgery, drug treatment for urinary incontinence, anticipated geographic relocation during study. Loss of followup: 18%.	1. The transvaginal electric stimulation for 20 minutes 2 times/day using frequency of 20Hz, a 2-second-4-second work-rest cycle with a range of stimulation intensities, from 0-100mA 2. Sham inactive device	Multichannel urodynamic testing, quality-of-life scale, and urinary diaries	No intention to treat. Double-blind. Computer generated randomization stratified by incontinence type. Allocation concealment unclear but centralized data manager blinded for treatment status analyzed the data. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F100. Electrical stimulation on risk and progression of urinary incontinence in adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Amaro, 2005[558] RCT to examine the effect of intravaginal electrical stimulation on pelvic floor muscle strength in women with mixed urinary incontinence. Duration: 1 month	40 women with mixed urinary incontinence and predominant urge incontinence. Exclusion criteria: Anticholinergic and tricyclic antidepressant medications, pelvic floor exercise, bladder training, vaginal prolapse more than II grade, urinary tract infection, metal implants, and neurological diseases.	1. Intravaginal electrical stimulation with 3 20-minute sessions/week using 4Hz frequency. 2. Sham stimulation with inactive device	Objective evaluation of perineal muscle by perineometry, vaginal weight test, and urodynamic outcomes	No intention to treat. Double-blind. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.
But, 2005[559] RCT to examine effects of functional magnetic stimulation for treating women with mixed urinary incontinence. Duration: 2 months	39 women with mixed urinary incontinence and predominant urge incontinence. Exclusion criteria: Not reported. Loss of followup: Not reported	1. Functional magnetic stimulation applied continuously at 18.5Hz day and night 2. Sham inactive device	Urodynamic diagnosis of detrusor overactivity and patient subjective assessment of mixed urinary incontinence.	No intention to treat. Double blind. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.
Bo, 1997[560] Crossover RCT to examine the effect of voluntary pelvic floor muscle contraction and vaginal electrical stimulation on urethral pressure in women with genuine stress incontinence. Duration: 1 day experiment.	12 women with genuine stress incontinence participated in pelvic floor exercise program with 8-12 contractions. Exclusion criteria: Not reported Loss of followup: Not applicable	3 voluntary PFM contractions and 2 electrical stimulators 1. Conmax 50Hz – pulse width 0.75ms, 0-90mA 2. Medicon 50Hz - pulse width 0.5ms, 0-100mA	Urethral and bladder pressures	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data is not reported. Sample size not justified.

Table F100. Electrical stimulation on risk and progression of urinary incontinence in adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Luber, 1997[561] RCT to examine the effects of functional electrical stimulation for stress incontinence in women. Duration: 3 months	57 women with stress urinary incontinence who could adequately retain the vaginal probe and cooperate with the study protocol. Exclusion criteria: Significant pelvic prolapse and detrusor instability, postvoid residual urine >100cc, extra urethral incontinence, history of vaginal intraepithelial neoplasia, urinary tract infection, a fixed, immobile urethra, and urodynamic evidence consistent with intrinsic sphincteric deficiency. Loss of followup: 18.5%	1. Functional electrical stimulation with 15-minute treatment session/day using pulse-width of 2msec scheduled for 2 seconds with 4 seconds rest, frequency of 50Hz, and power 10-100mA. 2. Sham stimulation with inactive device.	Self reported improvement or cure from stress urinary incontinence and urodynamic outcomes. Objective cure: negative stress test on repeat urodynamics. Objective failure: positive stress test on repeat studies.	Double-blind. Randomization using the table of random numbers. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Emmons, 2005[562] RCT to examine the effects of acupuncture on overactive bladder in women. Duration: 4 weeks	85 women older than 18 years, with symptoms of overactive bladder with urge incontinence,>8 voids per day, subjective urgency to void, and urge-associated incontinence at least twice during a 3-day period of time. Exclusion criteria: Pregnancy, taking medications for overactive bladder or receiving acupuncture treatments for any condition, unable to ambulate or unable to complete a 3-day voiding diary, and hematuria or untreated urinary tract infection. Loss of followup: 13%	1. Acupuncture treatment expected to improve bladder symptoms 2. Placebo acupuncture treatment designed to promote relaxation	Number of incontinent episodes over 3 days, voiding frequency and urgency, cystometric bladder capacity, maximum voided volume, and the urinary distress inventory and incontinence impact questionnaire symptom scores.	No intention to treat. Single-blind. Computer-generated randomization with random numbers table. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F100. Electrical stimulation on risk and progression of urinary incontinence in adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Yamanishi, 1997[563] CT to examine the effects of electrical pelvic stimulation in stress incontinence. Duration: 4 weeks	35 patients with stress incontinence. Exclusion criteria: Persistent urinary infection, uterine or rectal prolapse and cystocele, severe cardiac or cerebrovascular disorders including on-demand heart pacemakers, hepatic disorders and renal dysfunction. Anticholinergics, calcium antagonists, alpha or beta agonists or antagonists, or tricyclic depressants were discontinued medications for 1 week. Loss of followup: 5.7%	1. Electrical pelvic stimulation with 50Hz. square waves of 1msec. pulse duration and vaginal electrode in women and an anal electrode in men for 15 minutes 2 or 3 times daily 2. Sham electrical pelvic stimulation with inactive device	Frequency/volume chart, results of 1-hour pad test and urodynamic parameters. Subjective data (patient impressions) ranked as very good, good, fair, or not good. Daily frequency of pad changes was scored as 0-no change, 1-once, 2-twice and 3-3 times or more. Degree of disturbance in daily activities was scored as 0-not disturbed, 1-slightly disturbed, 2-moderately disturbed and 3-very disturbed. Cured-no incontinence on the frequency/volume chart and leakage of <1.0gm in the pad test. Improved-frequency of incontinence decreased by >50% or if the pad test showed a decrease in leakage by >50%, Unchanged or aggravated-frequency of incontinence or amount of leakage in pad test was unchanged or aggravated	No Intention-to-treat. Double-blind (doctors and patients). Randomization and allocation concealment not reported. Unclear who assigned patients to the treatment groups. Baseline data confirmed no differences among groups. Sample size not justified.

Table F100. Electrical stimulation on risk and progression of urinary incontinence in adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Barroso, 2004[564] Placebo controlled RCT to examine the effects of transvaginal electrical stimulation on urinary incontinence. Duration: 12 weeks. Duration of followup: 6 months	36 women (24 patients and 12 controls) with stress, urge, or mixed urinary incontinence. Exclusion criteria: Prolapse or first degree urogenital prolapse, intrinsic sphincter deficiency, cardiac pacemaker; pregnancy, postmenopausal climacteric with symptoms and signs of urogenital atrophy (they could be included after 3 months of treatment with hormone-replacement therapy); urinary tract infection, genitourinary surgery during the previous 6 months; previous electrical stimulation of the pelvic floor; use medication chronically (e.g., antidepressants, diuretics and others) known to possibly change voiding function, reflex urinary incontinence (clear presence of neurological lesions); paradoxical urinary incontinence (presence of intravesical obstructive factor); urinary incontinence caused by overflow, characterized by the presence of a large urinary residual volume; urge incontinence treated with medication during the last 3 months. Loss of followup: Not reported	1. Transvaginal electrical stimulation at home twice a day (20-minute sessions) with frequency of 20 (urge) or 50Hz (stress UI), a pulse width of 300ms, with asymmetrical biphasic pulses, an adjustable current intensity (0-100mA), a 1 s rise time, sustained for 5 seconds and resting for 5 seconds. 2. Placebo (identical equipment but with no electrical current)	Self reported urinary incontinence in voiding diary. Urodynamic outcomes	No intention to treat. Double-blind. Randomization before the study by drawing lots. Allocation concealment not reported. Baseline data did not confirm adequacy of randomization. Sample size justified.
Neurostimulation				
Scheepens,2002[565] Crossover RCT to examine the effects of bilateral sacral neuromodulation. Duration: 4 days	33 patients with chronic voiding dysfunction (urge incontinence with or without urodynamic instabilities), complete urinary retention and incomplete voiding with residual of >100ml. Exclusion criteria: Stress incontinence, untreated urinary tract infection, stone disease, psychiatric disturbance, pregnancy, neurogenic voiding disorders (including diabetes mellitus, spinal cord injury, multiple sclerosis), Reiter's syndrome, pelvic pain syndrome, cerebrovascular accident less than 6 months ago, anatomical obstructive voiding disorders, malignancy of the urinary tract, severe (grade III/IV) pelvic prolapse, cystocele, urethrocele, enterocele, proven interstitial cystitis or evident functional neurological asymmetry. Loss of followup: none	1. Bilateral sacral stimulation with external stimulation device to deliver alternating pulses left and right programmed individually at amplitude just above sensory threshold. Patients were instructed to adjust the stimulation amplitude if necessary. 2. Unilateral sacral stimulation with external stimulation device in a side with the best response using the lowest amplitude	Standardized voiding diaries were used to record voiding, catheterization and leaking episodes	No intention to treat, but all subjects were analyzed. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F100. Electrical stimulation on risk and progression of urinary incontinence in adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Schmidt, 1999[566] RCT to examine the effects of sacral nerve stimulation for treatment of refractory urinary urge incontinence. Duration: 5 months	98 patients older than 16 years refractory to standard medical therapy, with 100ml bladder capacity and normal upper urinary tract, able to complete study documentation and return for followup evaluation. Exclusion criteria: Neurological conditions (multiple sclerosis, diabetes with peripheral nerve involvement, spinal cord injury, stroke), stress urinary incontinence, primary pelvic pain Loss of followup: 22%	1. Implantation of multiprogrammable neurostimulator subcutaneously in lower quadrant of the abdomen with lead positioned to target sacral nerve and anchored in place. 2. Standard medical therapy	Voiding diary results and pad test.	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Weil, 2000[567] RCT to examine effects of sacral root neuromodulation refractory urinary urge incontinence. Duration: 6 months.	44 patients >16 years with refractory urge incontinence, normal urinary tract function, muscular and sensory responsiveness, detrusor storage capacity >100ml and no sphincter anomaly. Exclusion criteria: Stress urinary incontinence, multiple sclerosis, Reiter's syndrome, uncontrolled diabetes, pregnancy, spinal cord injury or cerebrovascular accident, active degenerative disc diseases, bleeding complications, urinary tract infection. Loss of followup: 4.5%	1. Sacral root neuromodulation with an implantable impulse generator 2. Prior conservative management: medications, or pelvic floor exercise	Self reported urge urinary incontinence, voiding diaries, quality of life questionnaires, urodynamic testing	No intention to treat. Open label. Computer generated randomization, 1:1 ratio. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size not justified.
Karademir, 2005[568] RCT to examine the effects of Stoller afferent neurostimulation with and without a low-dose anticholinergic (oxybutynin hydrochloride) in patients with detrusor overactivity. Duration: 8 weeks	43 patients with symptoms of detrusor overactivity confirmed urodynamically. Exclusion criteria: Urinary tract obstruction, urinary retention, neurologic or metabolic disorder, other treatments for urinary incontinence. Loss of followup: Not reported	1. Stoller afferent neurostimulation with frequency 20Hz and amplitude 0.5-10mA 2. Stoller afferent neurostimulation with frequency 20Hz and amplitude 0.5-10mA combined with 5mg of oral oxybutynin hydrochloride	Self reported quality of life and voiding diaries	Intention to treat not stated. Randomization and allocation concealment not reported. Baseline data reported for age only. Sample size not justified.

Table F100. Electrical stimulation on risk and progression of urinary incontinence in adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Bower,1998[569] RCT to examine the effects of surface neuromodulation on cystometric pressure and volume parameters in women with detrusor instability or sensory urgency. Duration: unclear	48 women with proved detrusor instability or sensory urgency. Exclusion criteria: Urinary tract infection, pregnancy, cardiac pacemaker, impaired cognition, neurogenic bladder dysfunction or cystocele beyond the introitus. Loss of followup: Not reported	1. Active transcutaneous electrical nerve stimulation with 10Hz. frequency and 200 microsecond pulse width (sacral placement). 2. Active transcutaneous electrical nerve stimulation with 150Hz. frequency and 200 microsecond pulse with (suprapubic placement) 3. Sham transcutaneous electrical nerve stimulation with sacral or suprapubic placement.	Urodynamic outcomes.	No intention to treat. Double blind. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.
Fujishiro, 2000[570] RCT to examine the effects of magnetic stimulation of the sacral roots for the treatment of stress incontinence. Duration: 1 week	62 women, 37 to 79 years old with stress incontinence, >1 episodes of urinary leakage recorded in a 3-day voiding diary, and 2gm or more urine loss on a 1-hour pad test. Exclusion criteria: Urinary infection, interstitial cystitis and large uterine myoma, and other treatments for stress incontinence, including pelvic floor exercises, medical treatment and electrical stimulation. Loss of followup: Not reported	1. Magnetic stimulation of sacral roots with 15Hz. frequency, 50% intensity output for 5 seconds per minute for 30 minutes. 2. Sham stimulation with inactive device	Self reported number of voids daily, mean urine volume per void, and number of leaks for 3 days	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Fujishiro ,2002[571] RCT to examine the effects of magnetic stimulation of the sacral roots for treating urinary frequency and urge incontinence. Duration 1 week	37 women 43 to 75 years old with the complaint of urinary frequency and/or urge incontinence, >8 voids daily and/or >1 episode of urge incontinence on a 3-day voiding diary, and mean of less than 250ml. urine volume per void on a 3-day voiding diary. Exclusion criteria: neurological disorders suggesting neurogenic bladder dysfunction, apparent episode of stress incontinence, urinary infection, interstitial cystitis or large uterine myoma , other treatments for urinary frequency or urge incontinence, including pelvic floor exercises, medical treatment or electrical stimulation. Loss of followup: not reported	1. Magnetic stimulation of sacral roots with 15Hz. frequency , 50% intensity output for 5 seconds per minute for 30 minutes. 2. Sham stimulation with inactive device	Self reported number of voids daily, mean urine volume per void, and number of leaks for 3 days.	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F100. Electrical stimulation on risk and progression of urinary incontinence in adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Walsh, 2001[572] RCT to examine the effects of non-invasive third sacral nerve (S3) stimulation on bladder activity during filling cystometry. Duration: Acute experiment	146 patients with urge incontinence refractory to an average of three previous treatments, encompassing bladder retraining, anticholinergic medication, or bladder/urethral dilatation. Exclusion criteria: Not reported. Loss of followup: Not applicable	1. Antidromic transcutaneous sacral neurostimulation during the second fill of standard urodynamic filling cystometry with 10Hz frequency, a pulse width of 200msec in continuous mode at the maximum tolerable level. 2.Control group underwent a second fill of standard urodynamic filling cystometry without neurostimulation	Cystometric filling volumes and corresponding detrusor pressures at first desire to void, strong desire to void, sensation of urgency, and maximum cystometric capacity	Intention to treat nor stated. Open label. Randomization in age- and gender-matched control and study groups. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Borawski, 2007[573] RCT to examine the effects of percutaneous needle electrode technique or a surgical first stage lead placement on implantation of a pulse generator in older urge incontinent women. Duration: 2 weeks	30 women >55 years with refractory urge incontinence after failure of medical, behavioral, and pelvic floor reeducation management. Exclusion criteria: Not reported. Loss of followup: 6.6%	1. Electrical stimulation with percutaneous needle electrode (22-G spinal needle) placement 2. Electrical stimulation with surgical first stage lead placement	Self reported urinary incontinence in bladder diary, daily pad count, and a 24-hour pad weight test. Successful test stimulation period for implantation of the impulse generator->50% improvement in daily incontinence episodes or 24-hour pad weight.	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data did not confirm adequacy of randomization. Sample size justified.

Table F110. Effects of devices on risk and progression of incontinence in females

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Nygaard, 1995[576] Crossover RCT to examine the effects of Hodge pessary with support, a super tampon on urinary incontinence during exercise. Duration: three exercise sessions.	20 female exercisers ages 33-73 with urinary incontinence during exercise and positive coughing test. Exclusion criteria: Prolapse of the uterus, stenotic vagina, or pelvic mass. Loss of followup:10%	1. 40-minute standardized aerobics session wearing a Hodge pessary with support 2. 40-minute standardized aerobics sessions wearing a super tampon 3. 40-minute standardized aerobics sessions with no mechanical device	Urine loss as change in the weight of the pad during exercising. Continence-pad weight gain <4g	No intention to treat. Open label. Block randomization. Allocation concealment not reported. Baseline data not reported. Sample size not justified.
Thyssen, 2001[577] Crossover RCT to examine the effects of disposable intravaginal device on stress incontinence in women. Duration: 5 weeks	94 women with the predominant symptom of stress incontinence, 39 were recruited in Denmark, 28 in England, and 27 in Australia. Exclusion criteria: Major uterovaginal prolapse. Loss of followup: 34%	1. Conveen Continence Guard, CCG made of hydrophilic polyurethane and requires soaking in water before being placed on a handle like applicator for insertion. 2. Contrelle Continence Tampon, CCT, coloplastis made of hydrophobic polyurethane and supplied ready-assembled within an applicator, allowing insertion directly into the vagina with no manual contact.	24 hour pad test, uroflowmetry, postvoid residual urine volume and a voiding diary	No Intention to treat. Open label. Block randomization. Allocation concealment not reported. Baseline data not reported. Sample size not justified.
Seo, 2004[578] RCT to examine the effects of vaginal cone with conventional FES-biofeedback therapy for female urinary incontinence. Duration: 6 weeks.	120 patients, who required a non-surgical treatment for urinary incontinence. Exclusion criteria: not reported. Loss of followup: not reported.	1. Pelvic floor exercise (5 second contraction and 10 second relaxation, 3-5 times for >5 minutes/day) and functional electrical stimulation biofeedback (35Hz-50Hz for 24 seconds); 2 training sessions /week. 2. Vaginal cone, 150g dumbbell-shaped made of fine ceramic material.	Self reported urinary incontinence. Urodynamic outcomes.	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.

Table F110. Effects of devices on risk and progression of incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Robinson, 2003[579] RCT to examine the effects of new urethral device or the reliance insert on female urinary incontinence. Duration of followup: 4 months	24 women 30-75 years old with mixed or stress urinary incontinence >2 episodes/week >2g urine loss on baseline pad weight test, with sound mental condition, willing to use >3 devices/week. Exclusion criteria: overflow incontinence or neurogenic bladder, type III incontinence, kidney inflammatory diseases, urinary tract infection, use of anticoagulants or incontinence medications, allergy to antibiotics, diabetes mellitus type II, pregnancy, urethral mucosal abnormalities, prosthetic heart valve, HRT last 3 months, collagen injections or other urethral bulking agents last 3 months, detrusor contraction >20cm/H20. Loss of followup: 33.3 %	1. Urethral device (NEAT) – sterile urethral insert with disposable applicator packaged with device. 2. Reliance insert sterile balloon type device	Success was defined as a 50% or greater reduction in urine loss using the formula 100 [(pad weight without device -pad weight with device)/pad weight with device]. Pure stress incontinence-urine loss with no detrusor contractions >15cm/H20 in any point before cystometric bladder capacity achieved. Mixed urinary incontinence- urine loss with detrusor contractions at 16-20cm/H20 in any point before cystometric bladder capacity achieved.	No Intention to treat. Single blind. randomization and allocation concealment not reported . Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F110. Effects of devices on risk and progression of incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Bo,1999[513] RCT to examine the effects of pelvic floor exercises, electrical stimulation, vaginal cones, and no treatment on females' genuine stress incontinence. Duration: 6 months	107 women with clinically and urodynamically proved genuine stress incontinence >4g of leakage measured by pad test with standardized bladder volume. Exclusion criteria: Urinary incontinence other than genuine stress incontinence, involuntary detrusor contractions >10cm/H2O on cystometry, abnormal bladder function (residual urine >0ml and maximal uroflow <15 ml/s), previous surgery for genuine stress incontinence, neurological or psychiatric disease, ongoing urinary tract infections, other diseases that could interfere with participation, use of concomitant treatments during the trial, and inability to understand instructions given in Norwegian. Loss of followup: 12.3%	1. Pelvic floor exercise with 8-12 contractions 3 times/day in groups with skilled physical therapists 1/week. 2. Electrical stimulation using vaginal intermittent stimulation with MS 106 Twin at 50Hz 30 minutes/day. 3. Vaginal cones of 20, 40, and 70g for 20 minutes/day. 4. Untreated control group offered use of a continence guard	Muscle strength measured by vaginal squeeze pressure 1/month. Pad test with standardized bladder volume. 24 hour pad test. Self reported symptoms of severity. Leakage index. Patients indicated on a 5 point scale (5 always, 4 often, 3 sometimes, 2 seldom, 1 never) the frequency of urinary leakage during sneezing, coughing, laughing, walking, walking downhill, running, jumping, and lifting. The mean was calculated as an index of leakage frequency before and after treatment. Objective cure as <2g leakage on the pad test with standardized bladder volume. Subjective cure as (number of women stating that the condition was "unproblematic" after treatment).	Intention to treat. Single blind. Computer generated random numbers stratified by baseline leakage. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified

Table F110. Effects of devices on risk and progression of incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Nielsen, 1993[580] Cross-sectional RCT to examine effects of urethral plug on female genuine urinary stress incontinence. Duration: 2 weeks	40 women with genuine urinary stress incontinence. Exclusion criteria: not reported Loss of followup: 55%	1. Urethral plug as oval metal plate, a soft stalk, and 1 sphere along the stalk with fixed distances between the metal plate and the spheres. Inside the stalk is a removable semi-rigid guide pin to ease insertion. 2. Urethral plug as oval metal plate, a soft stalk, and 2 spheres along the stalk with fixed distances between the metal plate and the spheres. Inside the stalk is a removable semi-rigid guide pin to ease insertion.	Self reported urinary incontinence. Pad weighting test.	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Chancellor, 1999[581] RCT to examine effects of sphincteric stent or external sphincterotomy on urinary incontinence in spinal cord injured men. Duration of followup: 24 months	57 men with spinal cord injury and electromyographic and manometric evidence of external detrusor-sphincter dyssynergia during involuntary detrusor contractions. Exclusion criteria: Concomitant documented bladder neck or prostatic obstruction Loss of followup: 42.5%	1. UroLume sphincteric stent (2, 2.5,or 3cm) prosthesis inserted using a 22F cystoscopic insertion tool with distal end of the prosthesis extended at least 5mm into the bulbous urethra and well beyond the distal aspect of the external sphincter. 2. Conventional external sphincterotomy.	Urodynamic outcomes. Self reported changes in urinary incontinence.	No Intention to treat. Open label. Randomization and allocation concealment not reported**.** Baseline data confirmed adequacy of randomization. Sample size not justified
Moore, 2004[582] Cross-over RCT to examine effects of penile compression devices on male urinary incontinence. Acute test.	12 men, 6 months after radical prostatectomy with stress urinary incontinence requiring continuous incontinence pad protection, normal perineal and penile sensation, intact penile skin, and the ability to read and speak English. Exclusion criteria: Neurologic or cognitive impairment (Mini-Mental State Examination score <27), neurologic disorders that could affect sensation or peripheral circulation, sufficient manual dexterity to manage the penile compression device, previous radiotherapy, symptoms of overactive bladder.	Penile Compression Devices: 1. C3 penile compression device with 2 styrofoam arms with a raised bottom arm applies pressure on the urethra. 2. Cunningham clamp 3. U-tex male adjustable tension nylon band with a urethral occlusion pad and nylon strap adjustable for comfort and continence.	4 hour pad test weight gain of 2g or more in one pad was considered urinary incontinence	Intention to treat not stated. Open label. Computer-generated randomization with random number table. Allocation concealment not adequate. Sample size justified.

Table F116. Effects of bulking agents and transurethral radiofrequency energy collagen micro-remodeling on urinary incontinence in females

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Corcos, 2005[583] Noninferiority RCT to examine effects of collagen injection or surgery on female stress urinary incontinence. Duration of followup: 12 months	133 women older than 30 years with stress urinary incontinence lasted for >6 months. Exclusion criteria: Contraindications to surgery or collagen injections (allergic reaction), associated conditions (e.g., severe medical disease or indication for hysterectomy) or pelvic prolapse (vault, cystocele, rectocele), neurogenic bladder or interstitial cystitis or a history of pelvic radiation or previous treatment by collagen injection. Loss of followup: 3.7%	1. Intraurethral collagen submucosal injection 4 injections at 1-month intervals 2. Surgery (needle bladder neck suspensions, Burch, and slings). The choice of technique was left to the surgeon.	Success as dry 24 hour pad test (<2.5g). Symptoms of incontinence, general QOL, disease-specific QOL	Intention to treat. Centralized randomization stratified by center with randomly distributed blocks 4 and 6 in size. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Bano, 2005[584] RCT to examine effects of porcine dermal implant (Permacol) and silicone injection (Macroplastique) on urodynamic stress incontinence in females. Duration of followup: 6 months	50 women with urodynamically proven stress incontinence. Exclusion criteria: not reported. Loss of followup: 2%	1. Peri or transurethral porcine dermal implant injection (Permacol) 2. Transurethral silicone injection (Macroplastique)	International Continence Society (ICS) standard 1 hour pad test. Self reported incontinence using Stamey scoring system and Kings College Hospital Quality of Health Questionnaire (KCQ)	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Schulz, 2004[585] RCT to examine effects of periurethral and transurethral injections of bulking agents on stress urinary incontinence in females. Duration of followup: 12 months	40 women ages 18-80 years old, with genuine stress incontinence for >12 months, or mixed incontinence with a minor and controlled urge component, who failed 3 months conservative treatments. Exclusion criteria: Other treatments for incontinence, urinary tract infection, bladder capacity <250ml or postvoid residual volume >100ml, neurogenic bladder, grade 3 cystoele, uterine prolapse or rectocele, radiation of urethra, pregnancy, life expectancy <15 months. Loss of followup: 15%	1. Periurethral route of injection of bulking agent-dextran copolymer 2. Transurethral route of injection of bulking agent-dextran copolymer	Urinary continence as 100% improvement in self reported symptoms, no leakage episodes and negative pad test	Intention to treat. Open label. Computer generated block randomization scheme. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F116. Effects of bulking agents and transurethral radiofrequency energy collagen micro-remodeling on urinary incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Lightner, 2001[586] RCT to examine effects of bulking agents on stress urinary incontinence due to intrinsic sphincter deficiency in women. Duration of followup: 12 months	355 women diagnosed with stress urinary incontinence due to intrinsic sphincter deficiency, abdominal leak point pressure of less than 90cm/H2O, who failed prior surgical and medical treatment. Exclusion criteria: Prior injections of any urethral bulking agents, positive intradermal test injections of bovine collagen and beta-glucan Loss of followup: 38%	1. Injection of bulking agent 1.0ml durasphere maximum 5 times with a minimum 7 day interval. 2. Injection of bulking agent bovine collagen maximum 5 times with a minimum 7 day interval.	Self reported urinary incontinence with grade 0 (dry) to grade 3 (continuous) urinary leakage	No Intention to treat. Double blind. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.
Appell, 2006[587] Placebo controlled RCT to examine effects of transurethral radiofrequency energy collagen micro-remodeling on female stress urinary incontinence. Duration of followup: 12 months	173 women with stress urinary incontinence, bladder outlet hypermobility, and leak point pressure >60cm/H2O. Exclusion criteria: Evidence of detrusor overactivity on cystometrogram, post-void residual bladder volumes >50cc, significant pelvic organ prolapse (POP-QStage IV) on physical examination, history of dry or wet overactive bladder, previous surgical or bulking agent therapy, abnormal urinalyses, positive urine cultures, and positive pregnancy test. Loss of followup: 18%	1. Transurethral radiofrequency energy collagen micro-remodeling 2. Sham treatment probes lacked needle electrodes and sham treatment of radiofrequency generator	Self reported improvement in urinary incontinence as 25% reduction in both incontinence episode frequency and stress pad weight. Impact on subject quality of life as incidence of >10 point improvement on the Incontinence Quality of Life (I-QOL) score. A baseline I-QOL score of 0-30 points - “severe SUI,” 31- 60 points - ‘‘moderate SUI,” and 61-90 points – “mild SUI.”	No intention to treat. Single blind. Computer generated randomization with ratio 2:1. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F116. Effects of bulking agents and transurethral radiofrequency energy collagen micro-remodeling on urinary incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Lee, 2001[588] Placebo controlled RCT to examine effects of periurethral autologous fat injection on female stress urinary incontinence. Duration of followup: 24 months	68 women with stress urinary incontinence determined by history, urinary leakage via the urethra with cough provocation. Exclusion criteria: Detrusor instability on multichannel urodynamic, co-interventions, including hormone replacement, weight reduction, or Kegel exercises, other diagnoses causing incontinence, including bladder instability. Loss of followup:19%	1. Periurethral injections of autologous fat (30cc of fat from the anterior abdominal wall or buttock through a single 2-3mm) with 3 maximum injections depending on outcomes measures. 2. Placebo (saline).	Cure from urinary incontinence as no leakage on the 1 hour pad test, no leakage seen from the urethra with coughing and a continence questionnaire score of 0. Improvement was defined as a decrease in the continence questionnaire score of 5 points or greater.	No Intention to treat. Double blind. Computerized randomization with random number tables. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.
Strasser, 2007[589] RCT to examine the effects of ultrasonography-guided injections of autologous cells or endoscopic injections of collagen on stress urinary incontinence. Duration of follow up: 12 months	63 females 36-84 years old with intrinsic sphincter insufficiency or stress urinary incontinence with only mild hypermobility of the urethra and the urinary bladder; good state of health who failed pelvic floor muscle exercises. Exclusion criteria: urge incontinence and pronounced hypermobility of the urethra. Loss of follow up -none	1. Transurethral ultrasonography-guided injections of autologous myoblasts and fibroblasts; regular training of the rhabdosphincter for 12 weeks and trans vaginal electrical stimulation for 4 weeks. 2. Conventional endoscopic injections of collagen; regular training of the rhabdosphincter for 12 weeks and trans vaginal electrical stimulation for 4 weeks	24-hour voiding diary with incontinence score (range 0–6): 0 representing continence; 6 representing complete incontinence. 24-hour pad test. Quality of life questionnaire with possible scores from 22 (severely restricted quality of life) to 110 (no restrictions on quality of life).	Intention to treat. Single blind. Computer-generated randomization list with permuted blocks and ratio of 2:1. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F119. Effects of obstetric interventions on incidence and progression of urinary incontinence in females

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Dannecke, 2005[590] Followup RCT to examine the effects of restrictive use of mediolateral episiotomy vs. routine episiotomy. Duration: 18 months	146 primiparous women with an uncomplicated singleton pregnancy >34 weeks of gestation intending a vaginal delivery. Exclusion criteria: Previous surgery at the pelvic floor and neurological disorder. Loss of followup: 45% in restrictive policy group, 32% in liberal policy group.	1. Restrictive episiotomy - avoidance of episiotomy (for fetal indications only) 2. Liberal – in addition to fetal indications use episiotomy when a tear is judged to be imminent	Self reported presence of urinary and fecal incontinence with standardized questionnaire. Anorectal manometry and urodynamic outcomes. Pelvic floor muscle strength with vaginal palpation. Effort to contract the elevator; graded with the Oxford Score (4-strongest).	Intention-to-treat. Open label. Simple random sampling. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Sartore, 2004[591] Non randomized CT to examine the effect of mediolateral episiotomy on puerperal pelvic floor strength and dysfunction. Duration: 3 months after vaginal delivery	519 consecutive primiparous women with singleton pregnancies and spontaneous vaginal delivery with fetal head in occiput anterior position, residents of Trieste. Exclusion criteria: Not delivered in lithotomy position, cesarean delivery, third and fourth-degree perineal lacerations, preterm, breech, and operative delivery, anal and urinary incontinence that pre-existed vaginal delivery, and history of vaginal or anal surgery.	1. Mediolateral episiotomy 2. No episiotomy	Stress urinary incontinence - observation of involuntary loss of urine synchronous with coughing (+stress test) with comfortably full bladder. Self reported urge incontinence - loss of urine associated with strong desire to void. Self reported anal incontinence - loss of flatus, liquid, or solid stool. Pelvic floor muscle strength scored 0-5. Vaginal manometry abnormal perineometric values <12cm H20. Urine stream interruption test abnormal any urine stream interruption test scores >5seconds.	No intention to treat. Open label. Groups were comparable at baseline except neonatal weight. Crude odds ratios reported.

Table F119. Effects of obstetric interventions on incidence and progression of urinary incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Hannah, 2002[592] Term Breech Trial, RCT to examine the effects of planned cesarean section on incontinence 3 months postpartum. Duration: 3 months	1,159 women with singleton live fetus in a frank or complete breech presentation at term (37 weeks' gestation). Exclusion criteria: Fetopelvic disproportion, fetus weight >4000g, hyperextension of the fetal head, lethal anomaly or a condition that might cause a mechanical problem at delivery, and contraindication to labor or vaginal delivery. Loss of followup: 16.5%	1. Planned vaginal birth group, management was expectant until spontaneous labor began, unless an indication to induce labor (e.g., post term pregnancy) 2. Planned cesarean delivery (egg, footling breech presentation) scheduled for 38 or more weeks' gestation. If the woman was in labor at the time of randomization, the caesarean section was undertaken as soon as possible. Immediately before caesarean section, the fetal presentation was reassessed and if cephalic, a vaginal birth was planned.	Self reported stress urinary incontinence and fecal or flatus incontinence within the previous 7 days. Perception of incontinence: no problem at all, a little problem, or a big problem.	Intention to treat. Open label. Centralized randomization stratified by parity with block sizes of two. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.
Hannah, 2004[593] Followup to Term Breech Trial, RCT to examine the effects of planned cesarean section on incontinence 2 years postpartum. Duration: 2 years	917 of 1,159 women with singleton live fetus in a frank or complete breech presentation at term (37 weeks' gestation). Exclusion criteria: Fetopelvic disproportion, fetus weight >4000g, hyperextension of the fetal head, lethal anomaly or a condition that might cause a mechanical problem at delivery, and contraindication to labor or vaginal delivery. Loss of followup: 20.9% in planned Cesarean groups and 19.6% in vaginal birth group.	1. Planned vaginal birth group, management was expectant until spontaneous labor began, unless an indication to induce labor (e.g., post term pregnancy) 2. Planned cesarean delivery (egg, footling breech presentation) scheduled for 38 or more weeks' gestation. If the woman was in labor at the time of randomization, the caesarean section was undertaken as soon as possible. Immediately before caesarean section, the fetal presentation was reassessed and if cephalic, a vaginal birth was planned.	Self-reported stress urinary incontinence and fecal or flatus incontinence within the previous 3 to 6 months. Perception of incontinence: no problem at all, a little problem, or a big problem.	Intention to treat. Open label. Centralized randomization stratified by parity with block sizes of two. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F119. Effects of obstetric interventions on incidence and progression of urinary incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Klein, 2005[594] Multi center RCT to examine the urinary and sexual consequences of vaginal delivery compared with Caesarean section. Duration: 3 months postpartum	1,044 women participated in RCT. Exclusion criteria: not reported. Loss of followup: 4.3%, from 135 women delivered by Caesarean section, only 25 were randomized to this group. Cross treatment occurred due to the decision made by attending physician.	1. Caesarean section 2. Vaginal delivery	Self reported non specified and stress urinary incontinence 3 months postpartum. Severe incontinence-wearing a pad.	No intention to treat. The article presented cohort analysis; subjects were grouped by received treatment, not by randomization status. Open label. Randomization not reported. No justification for sample size.
Sleep, 1987[595] Followup RCT to examine policies of restricted versus liberal episiotomy during spontaneous vaginal delivery on urinary incontinence. Duration: 3 years postpartum.	1,000 women with live singleton fetus of at least 37 completed weeks' gestational age presenting cephalically and spontaneous normal vaginal delivery. Exclusion criteria: 15 participants from the original trial (8-not fluent in English; 2 refused to complete 3 month questionnaire; 3 had given the baby up for adoption; 1 baby had been taken into care; and 1 baby had died in the neonatal period). Loss of followup: 33% of contacted participants did not respond to the survey 3 years postpartum.	Two management policies aimed to minimize perineal trauma during spontaneous vaginal delivery: 1. “Try to avoid episiotomy" : restrict episiotomy to fetal indications (fetal bradycardia, tachycardia, or meconium stained liquor) 2. "Try to prevent a tear" - use episiotomy more liberally to prevent tears.	Self reported presence of total, stress, and urge urinary incontinence. Frequency of incontinency episodes.	No intention to treat. Randomization procedure is not described. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified for the original RCT.
Johanson, 1999[596] Followup RCT to examine effects of delivery by forceps or vacuum extractor on maternal and child outcomes. Duration: 5 years postpartum.	607 women requiring assisted vaginal delivery. Exclusion criteria: 47% of participants from the original RCT were not contacted for unclear reasons. Loss of followup: 26.2% non responders to the survey 5 years postpartum.	1. Delivery with vacuum extractor 2. Forceps delivery.	Self reported fecal and urinary incontinence 5 years postpartum	No intention to treat. Open label. Randomization procedure is not described. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F119. Effects of obstetric interventions on incidence and progression of urinary incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Garcia, 2005[597] RCT to examine effects of surgical techniques for the primary repair of obstetric anal sphincter lacerations. Duration: 4 months postpartum	51 women with complete third- or fourth-degree anal sphincter laceration who underwent primary repair at the time of vaginal delivery. Exclusion criteria: not reported Loss of followup: 35.6%	1. End-to-end technique to repair obstetric anal sphincter lacerations: 4 separate sutures of polyglycolic acid to reapproximate the sphincter ends directly. 2. Overlapping repair of obstetric anal sphincter lacerations used 3 sutures of 2-0 PDS to reapproximate the sphincter ends in an overlapping fashion.	Self reported urinary and anal incontinence graded with the Fecal Incontinence Score (FIS) from 18 - total incontinence >2/week, scores 1-3 incontinence of flatus only. Anal incontinence was defined as a fecal incontinence score of >0.	No Intention to treat. Single blind. Computer-generated randomization table. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F122. Effects of hysterectomy on incidence and progression of urinary incontinence in females

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Gimbel, 2003[598] RCT to examine effects of total abdominal hysterectomy and subtotal abdominal hysterectomy performed for benign uterine diseases. Duration: 1 year	319 women going to have a hysterectomy for benign diseases of the uterus able to read and write Danish. Exclusion criteria: Laparoscopic or vaginal hysterectomy, dysplasia of cervix, prolapse of uterus, former operation for a urological diseases, former or present malignancy, diabetes, neurological diseases, alcoholism, poor mental function. Loss of followup: 13.2% excluded from the intention to treat analysis	1. Total abdominal hysterectomy 2. Subtotal abdominal hysterectomy	Self reported urinary incontinence defined as 'always' or 'often' using the validated, self administered, postal questionnaire	Intention to treat. Open label, statistician was blinded. Restricted, computer-generated block randomization (1:1) stratified by clinical centers and clinical groups. Within each stratum, random permuted block sizes of 2, 4 and 6 occurred. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Thakar, 2002[599] RCT to examine effects of total abdominal hysterectomy and subtotal abdominal hysterectomy performed for benign uterine diseases. Duration: 1 year	279 women referred for hysterectomy because of benign disease; most of the women were premenopausal. Exclusion criteria: Age >60 years, suspected cancer, body weight that exceeded 100kg, previous pelvic surgery, known endometriosis, abnormal cervical smears, symptomatic uterine prolapse, and symptomatic urinary incontinence for which the patient might seek expert medical advice. Loss of followup: 16% in total and 12% in subtotal abdominal hysterectomy groups.	1. Subtotal hysterectomy 2. Total hysterectomy	Self reported urinary incontinence using standardized Questionnaire. Stress incontinence scores from 0-none to 4-always. Twin-channel subtracted cystometrography and uroflowmetry outcomes.	No intention to treat for cystometry outcomes. Double blind. Randomization with computer-generated numbers. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F122. Effects of hysterectomy on incidence and progression of urinary incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Lalos, 1986,[600] RCT to examine effects of subtotal or total hysterectomy on urinary symptoms. Duration of followup: 6 weeks.	22 women admitted to the hospital for hysterectomy. Exclusion criteria: pathological findings of the cervix. Loss of followup: not reported	1. Subtotal hysterectomy 2. Total hysterectomy	Urodynamic outcomes	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data not analyzed for comparability. Sample size not justified.
Kaya, 2004[601] RCT to examine effects of extrafascial and intrafascial total abdominal hysterectomy on urinary urge incontinence. Duration of followup: 12 months	90 women undergoing total abdominal hysterectomy. Exclusion criteria: gynecologic malignancy, stress incontinence, inflammatory bladder disorders, other gynecological surgery. Loss of followup: 11.1%	1. Extrafascial total abdominal hysterectomy 2. Intrafascial total abdominal hysterectomy	Surgical morbidity and presence of urge incontinence defined as urodynamically established detrusor overactivity at the end of 12 months	No intention to treat. Open label. Randomization with random numbers tables. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.
Learman, 2003[602] RCT to examine effects of total versus supracervical abdominal hysterectomy on clinical outcomes during 2 years of followup. Duration: 2 years.	135 premenopausal women over 30 years who had abdominal hysterectomy for symptomatic uterine leiomyomata, abnormal uterine bleeding refractory to hormonal treatment, or both, follicle stimulating hormone <30mIU/ml, and endometrial biopsy within 6 months was negative for hyperplasia or carcinoma. Exclusion criteria: Age >50 years at screening, positive results of pregnancy test, desire for future childbearing, known or suspected genital tract carcinoma, cervical dysplasia or carcinoma-in-situ, complex or atypical endometrial hyperplasia, candidate for vaginal hysterectomy (as determined by their gynecologist), and unlikely to remain geographically accessible for 4 years. Loss of followup: 4% assigned to total and 10% assigned to supracervical abdominal hysterectomy.	1. Total abdominal hysterectomy (removal of both the corpus uteri and cervix uteri) 2. Subtotal supracervical hysterectomy	Self reported urinary incontinence using questionnaires with checklists and Likert scales	Intention to treat. Open label. Stratified by clinical center computer-generated Randomization with permuted blocks 4, 6, and 8. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Long, 2005[603] RCT to examine the effects of vesicourethral function following laparoscopic	94 women with various indications for hysterectomy but no indication of uterine myomas. Exclusion criteria: incomplete records, combined procedures (colposuspension or tension-free vaginal tape procedure). Loss of follow up: 10.5%	1. Laparoscopic hysterectomy without vaginal cuff suspension. Patients with severe SUI underwent concomitant anti-incontinence procedures	Q-tip test, introital ultrasonography, and personal interviews using the Bristol Female Lower Urinary Tract	No Intention to treat. Open label. Computer-generated numbers. Allocation concealment

Table F122. Effects of hysterectomy on incidence and progression of urinary incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
hysterectomy with and without vaginal cuff suspension on urinary incontinence. Duration of follow up: 6 months		2. Laparoscopic hysterectomy with vaginal cuff suspension: the use of absorbable polyglactin sutures through the cardinal-uterosacral ligament complex, anchoring bilaterally to 3cm near the angle of vaginal cuff. Patients with severe SUI underwent concomitant anti-incontinence procedures	Symptoms Questionnaire. Stress urinary incontinence – urine leakage during stress urethral pressure profilometry. Intrinsic sphincter deficiency - maximum urethral closure pressure <20cm/H2O at maximum cystometric capacity. Sever stress incontinence - urine leakage during the pad test >10g. The anatomic position and dynamic mobility of the bladder neck by introital ultrasonography and Q-tip test with patients in the semi-supine position.	unclear. Baseline data confirmed adequacy of randomization. Sample size justified

Table F125. Effects of vaginal tapes and sling procedures on risk and progression of incontinence in females

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Schraffordt Koops, 2006[604] Prospective cohort study to examine effects of tension-free vaginal tape in women with a history of surgery for urinary incontinence and/or prolapse. Duration: 2-36 months.	809 women with indication for TVT who had a history of previous incontinence or prolapse surgery were recruited from the Netherlands TVT database, 28 teaching and 13 local hospitals, patients of 54 gynecologists and urologists who performed tension-free vaginal tape. Exclusion criteria: Recurrent and difficult to-treat urinary tract infections, predominant symptoms of urge urinary incontinence (defined as urge incontinence being more prevailing than the stress incontinence), detrusor overactivity at cystometry, post voiding bladder retention (>150ml), bladder capacity <200ml, or a physical/mental impairment that would make participation impossible. Loss of followup: 1.8%	Tension-free vaginal tape (Gynecare, Ethicon Inc, Sommerville, NJ) was performed with Ulmsten's method.	Stress urinary incontinence as a positive response to the question "Do you experience urinary leakage during physical activity, coughing or sneezing?" Incontinence Impact Questionnaire (IIQ-7) and Urogenital Distress Inventory (UDI-6) ranked with 4-step scale from ''not at all'' to ''greatly'' impaired. The total score was transformed to a scale from 0 as continent to 100	Clinic based not random sampling. Adjustment was not reported. Sample size not justified.
Rafii, 2004[605] Case-control study to examine effects of tension-free vaginal tape alone or in conjunction with vaginal procedures on stress or mixed urinary incontinence in women. Duration of followup: 24 months	186 females with urodynamically confirmed stress urinary incontinence undergoing TVT. Exclusion criteria: not reported. Loss of followup: none	1. Tension-free vaginal tape with Ulmsten's method alone 2. Tension-free vaginal tape with Ulmsten's method and concomitant vaginal hysterectomy. 3. Tension-free vaginal tape with Ulmsten's method and pelvic floor reconstruction.	Postoperative voiding diaries, standing stress-test results, and patient satisfaction. Objectively cured - no stress incontinence (clinical stress provocation test and urodynamic examinations) and no urinary retention (residual urine volume >150ml or more). Subjective Cured - improvement and failure rates based on the Contilife 28-item questionnaire.	Clinic based not random sample. Adjustment was not reported. Sample size not justified.

Table F125. Effects of vaginal tapes and sling procedures on risk and progression of incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Rechberger, 2003[606] RCT to examine effects of monofilament and multifilament tapes positioned without tension at the midurethra on urinary incontinence. Duration of followup: 13.5 months	100 patients with stress urinary incontinence confirmed by a urodynamic profile including cystometry and urethral pressure profile. Exclusion criteria: Intrinsic sphincter deficiency, other gynecologic disease, such as uterine myoma, ovarian cyst or severe uterine or vaginal prolapse. Loss of followup: not reported.	1. Monofilament tape inserted at the midurethra using the tension-free vaginal tape delivery instrument 2. Multifilament tape using the intravaginal slingplasty delivery instrument	Urinary continence – no stress urinary incontinence symptoms; negative cough tests in the supine and standing positions; no need of hygienic pads. "improvement"- negative cough test but patients still experienced stress urinary leakage (much less frequent than previously) and the pads were occasionally wet.	Intention to treat not stated. Single blind. Simple computer generated randomization. Allocation concealment not reported. Baseline data not reported. Sample size not justified.
Wadie, 2005[607] RCT to examine effects of fascial sling or polypropylene tape stress urinary incontinence. Duration of followup: 6 months	53 female patients older than 21 years with stress urinary incontinence as leading symptom, life expectancy >1 year, normal upper tract, and normal manual dexterity. Exclusion criteria: Bladder or urethral pathology, as well as those with cystocele greater than grade 2, pelvic or vaginal surgery within 6 months, predominant urge incontinence, active urinary tract infection as evidenced by positive urine culture. Loss of followup: not reported.	1. Fascial sling with free ends of flap fixed by a 1-zero polyglactin suture and the sling is fixed to the underlying periurethral fascia using 4-zero polyglactin sutures at the 6 and 12 o'clock positions 2. Tension-free vaginal polypropylene tape	Urinary continence (cure) as complete dryness with no usage of pads, anti-incontinence surgery response score of 0 and negative stress test, Failure – visible leakage on stress test and a total score of 6.	Intention to treat not stated. Open label. Randomization with simple random numbers table. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.
Lightner, 2001[586] RCT to examine effects of bulking agents on stress urinary incontinence due to intrinsic sphincter deficiency in women. Duration of followup:12 months	355 women diagnosed with stress urinary incontinence due to intrinsic sphincter deficiency, abdominal leak point pressure of less than 90cm/H2O, who failed prior surgical and medical treatment. Exclusion criteria: Prior injections of any urethral bulking agents, positive intradermal test injections of bovine collagen and beta-glucan. Loss of followup: 38%	Injection of bulking agent 1.0ml Durasphere maximum 5 times with a minimum 7 day interval. Injection of bulking agent bovine collagen maximum 5 times with a minimum 7 day interval.	Self reported urinary incontinence with grade 0 (dry) to grade 3 (continuous urinary leakage)	No Intention to treat. Double-blind. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.

Table F125. Effects of vaginal tapes and sling procedures on risk and progression of incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Adamiak, 2002[608] RCT to examine effects of tension-free vaginal tape using local or spinal anesthesia on female stress urinary incontinence Duration of followup: 6 months	103 women with objectively confirmed stress urinary incontinence. Exclusion criteria: mixed urinary incontinence Loss of followup: 2.9%	1. Tension-free vaginal tape with local analgesia (injection of 0.5-0.75% lidocaine hydrochloride in subcutaneous tissue). 2.Tension-free vaginal tape with spinal analgesia (0.5% bupivacaine hydrochloride administered at L_3–L_4 or L_4–L_5 interspace)	Self reported urinary incontinence symptoms with three grades using Ingelman-Sundberg scale	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Ward, 2002[609] RCT to examine effects of tension-free vaginal tape or colposuspension on female stress incontinence. Duration of followup: 6 months	344 women with urodynamic stress incontinence. Exclusion criteria: Detrusor overactivity, vaginal prolapse requiring treatment, previous surgery for prolapse or incontinence, a major degree of voiding dysfunction (voiding pressure >50cm H20, maximum flow <15ml/s, and residual urine volume >100ml), neurological disease, and allergy to local anesthetic. Loss of followup: 3.5%	1. Tension-free vaginal tape procedure performed as described by Ulmsten, under local anesthesia and sedation. 2. Colposuspension was performed according to standard technique.	Self reported urinary incontinence using SF-36, the Bristol female lower urinary tract symptoms questionnaire, the EQ-5D health questionnaire. One week urinary diary, one hour perineal pad test, and cystometry outcome. objective cure of stress incontinence based on a negative stress test on urodynamic testing, combined with a negative one hour pad test (<1g change in weight).	Intention to treat. Open label. Computer generated randomization with permuted blocks of four and six. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.
Valpas, 2004[610] Double publication: Valpas 2003[611] RCT to examine effects of tension-free vaginal tape or laparoscopic mesh colposuspension on female stress urinary	128 women with urodynamic stress incontinence, unequivocal indication for operation according to the clinic's standards, urodynamically confirmed stress incontinence (stabile bladder in cystometry), positive stress test result (300ml of saline in the bladder, maximum repetitive coughs in a supine position. Exclusion criteria: Age older than 70 years, previous incontinence surgery, more than 3 episodes of urinary tract infection within the last 2 years, coincident other gynecological surgery, body mass index more than 32 kg/m(2), urethral closure pressure less than 20cm/H2O, and residual volume more than 100ml in preoperative	1. Tension-free vaginal tape under local anesthesia with polypropylene mesh tape placed under the midurethra. 2. Laparoscopic mesh colposuspension under general anesthesia (Hannah and Chin)	Urinary continence as negative stress test and negative 48-hour pad test (weight gain of pads was less than 8g in 48 hours). Urinary Incontinence Severity Score 0, 1, or 2 (no, slight, or marked impairment of quality of life,	No Intention to treat. Open label. Computer-generated randomization separately for each center. Allocation concealment not reported. Baseline data confirmed adequacy of randomization.

Table F125. Effects of vaginal tapes and sling procedures on risk and progression of incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
incontinence. Duration of followup: 12 months	urodynamic evaluation Loss of followup: 5.4%		respectively) 0 - no inconvenience at all, 20 - maximal inconvenience. Urge Score: >7 indicates increased risk of motor urge incontinence. King's College Health Questionnaire with 21 questions in 8 domains, with separate scales, to measure the severity of urinary symptoms. Scores in the domains range from 0 to 100, a higher score indicating greater quality of life impairment.	Sample size justified.
deTayrac, 2004[612] RCT to examine effects of tension-free vaginal tape or transobturator suburethral tape on female stress urinary incontinence. Duration of followup: 12 months	61 women with urodynamically proved genuine stress incontinence Exclusion criteria: Predominant urge incontinence, urodynamic detrusor instability, prolapse. Loss of followup: not reported	1. Tension-free vaginal tape. 2. Transobturator suburethral tape	Self reported symptoms of urinary incontinence in visual analog scale ranging from 0 to 10 (0 – no symptoms to 10 - maximum severity) ‘‘objectively cured’’ - negative stress test, ‘‘objectively improved’’ - improvement of SUI but positive stress test	Intention to treat not stated. Computer-generated random allocations in a ratio of 1:1 in balanced blocks of 10. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified
Andonian, 2005[613] RCT to examine effects of suprapubic arch sling or tension-free vaginal tape on female stress urinary	84 women with urodynamic stress incontinence with or without pelvic organ prolapse, stable bladder function and good flow rates without clinically significant post-void residual, who failed anti-incontinence surgeries or bulking agent treatments. Exclusion criteria: Mixed urinary incontinence with abnormal capacity, compliance and uninhibited contractions, obstructive, unstable bladder functions, or	1. Suprapubic arch sling 2. Tension-free vaginal tape by Ulmsten. Anterior and posterior colporrhaphy, and vaginal hysterectomy were performed simultaneously in symptomatic women with pelvic organ	Objective cure as 1-hour pad test of ≤2g Incontinence Impact Questionnaire score: <50 - good quality of life , 50-70 - moderate QoL, and >70 – poor quality of	No intention to treat. Single blind. Randomization with random numbers table. Allocation concealment not adequate. Baseline data confirmed

Table F125. Effects of vaginal tapes and sling procedures on risk and progression of incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
incontinence. Duration of followup: 12 months	neurogenic bladders, and urinary tract infection. Loss of followup: 1.2%	prolapse	life	adequacy of randomization. Sample size justified.
Lim, 2005[614] RCT to examine effects of three types of suburethral slings on female urodynamic stress incontinence. Duration of followup: 12 months	195 consenting patients with urodynamic stress incontinence that failed conservative management for symptomatic stress incontinence, or required prophylactic incontinence surgery during prolapse repair for occult stress incontinence (no subjective stress leakage but urodynamic incontinence). Exclusion criteria: Past history of urogenital malignancy, fistula or pelvic radiotherapy. Loss of followup: 6.7%	1. Suburethral slingplasty with tension-free vaginal tape macroporous monofilament threads, inserted using 'bottom to top' (caudocranial) approach. 2. Suburethral slingplasty with intravaginal sling multifilament threads with much smaller pore sizes, inserted using 'bottom to top' (caudocranial) approach. 3. Suburethral slingplasty with suprapubic arc sling macroporous monofilament threads, with an absorbable tensioning suture that is designed to aid tape tension adjustment inserted with a 'top to bottom' (craniocaudal) approach.	Urodynamic stress incontinence as positive cough leak with 300ml of water either in supine or erect position. intrinsic sphincter deficiency as maximum urethral closure pressure <20cm water. Improvement in urinary incontinence as >50% reduction in frequency of occurrence compared to preoperative state.	No Intention to treat. Single blind. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified
Lord, 2006[615] RCT to examine effects of tension-free vaginal tape and suprapubic urethral support sling on female stress incontinence. Duration of followup: 6 weeks	313 women with clinical diagnosis of stress urinary incontinence and a recommendation of minimally invasive sling surgery to treat their symptoms with possible previous incontinence and/or other pelvic surgery including combined treatment with other pelvic operations, e.g., vaginal hysterectomy and repair. Exclusion criteria: Age <18 years, pregnancy, major voiding dysfunction specified as an abnormal flow (i.e. maximum urinary flow rate <10ml/s) or residual urinary volume of ≥150ml. Loss of followup: 4.3%	1. Tension-free vaginal tape 2. Suprapubic urethral support sling	Subjective cure from stress urinary incontinence as no use of protection, improvement in symptoms and a scale of improvement (1-100). The objective definition of cure as observed absence of urinary leakage in stress cough test while supine and with a comfortably full bladder.	Intention to treat. Double blind. Central computer generated random numbers stratified based on previous surgery and experience of surgeon with permuted blocks of four, six and eight. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size justified

Table F125. Effects of vaginal tapes and sling procedures on risk and progression of incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Meschia, 2006[616] RCT to examine effects of tension-free vaginal tape or intravaginal slingplasty on female stress urinary incontinence. Duration of followup: 2 years	190 women with primary urodynamic stress incontinence and urethral hypermobility. Exclusion criteria: Previous anti-incontinence surgery, vaginal prolapse requiring treatment, coexisting pelvic pathology, known bleeding diathesis or current anticoagulant therapy, detrusor overactivity, and urethral hypomobility (difference in Q-tip % 20 degrees from horizontal with straining). Loss of followup: 15.37%	1. Tension-free vaginal tape under local or epidural anesthesia. 2. Intravaginal slingplasty under local or epidural anesthesia.	Objective cure as no leakage of urine in stress cough test, with at least 300ml of saline solution in the bladder and as a pad weight gain <1g during the 1-hour test. Subjective cure as no urine loss during ‘‘stress’’ and failure as any reported leakage of urine during exertion.	No Intention to treat. Open label. Centralized computer-generated random list. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified
Arunkalaivanan, 2003[617] RCT to examine effects of porcine dermal sling or tension-free vaginal tape on female stress incontinence. Duration of followup: 12 months	142 women with urodynamic genuine stress incontinence. Exclusion criteria: Detrusor instability. Loss of followup: none.	1. Porcine dermal sling (pelvicol implant) by Barrington 2. Tension-free vaginal tape by Ulmsten	Cure as no leakage in stress cough test, patient self reported urinary continence “dry,” improvement in quality of life scores >90%	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
David-Montefiore, 2006[618] RCT to examine effects of retropubic and transobturator suburethral sling procedure on female urinary stress incontinence. Duration of followup: 24 months	88 women undergoing sub-urethral sling procedure for stress urinary incontinence. Exclusion criteria: not reported Loss of followup: none	1. Retropubic suburethral sling procedure using I-STOP® device macroporous (>75-micron pore size) non-elastic monofilament polypropylene mesh 2. Transobturator suburethral sling procedure using I-STOP® device macroporous (>75-micron pore size) non-elastic monofilament polypropylene mesh	Self reported urinary continence (dry) and improvement in symptoms.	No Intention to treat. Open label. Computer-generated randomization Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F125. Effects of vaginal tapes and sling procedures on risk and progression of incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Dietz, 2005[619] RCT to examine effects of suburethral slings on female urinary incontinence. Duration of followup: 23 months	195 women with urinary incontinence. Exclusion criteria: missing data Loss of followup: 6.7%	Two-dimensional (2D) and three-dimensional (3D) pelvic floor ultrasound with a 7-4MHz volume transducer. 1. Tensionless vaginal tape 2. Intravaginal sling 3. Suprapubic arc sling	Self reported urinary continence (cured or improved). Free flowmetry outcomes.	No Intention to treat. Single blind. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization Sample size justified.
Maher, 2005[620] RCT to examine effects of pubovaginal sling or transurethral macroplastique on female stress urinary incontinence and intrinsic sphincter deficiency. Duration of followup:1 year and 5 years	45 women with stress urinary incontinence and intrinsic sphincter deficiency diagnosed by maximum urethral closure pressure <20cm/H2O who failed to respond to conservative treatments. Exclusion criteria: Required prolapse surgery, previous sling procedure, contraindications for general anesthesia. Loss of followup: 4.4%	1. Pubovaginal 11-12cm sling by McGuire positioned suburethrally at the proximal urethra 2. Transurethral macroplastique	Self reported urinary incontinence using validated questionnaires [Short Urinary Distress Inventory (SUDI) and Incontinence Impact Questionnaire (IIQ). 1-hour pad test. Objective success was defined as no urinary leakage due to stress urinary incontinence on repeat urodynamic studies	Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization Sample size justified.
Abdel-Fattah, 2004[621] RCT to examine effects of Pelvicol pubovaginal sling or tension-free vaginal tape on females urodynamic stress incontinence Duration of followup: 3 years	142 women with pure stress urinary incontinence Exclusion criteria: not reported Loss of followup: 4.2%	1. Pelvicol pubovaginal sling 2. Tension-free vaginal tape	Self reported urinary continence (dry) and improvement in urinary incontinence symptoms. Pad use.	No intention to treat. Open label. Randomization using random numbers table. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F125. Effects of vaginal tapes and sling procedures on risk and progression of incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Darai, 2007[622] RCT to examine effects of suburethral sling procedure on female urinary stress incontinence Duration of followup: 10 months	88 women older than 18 years undergoing suburethral sling procedure for urodynamic stress urinary incontinence (some had mixed incontinence). Exclusion criteria: Previous history of radio- or chemotherapy, use of anticoagulants or antipsychotic medications, and pregnancy. Loss of followup: none	1. Suburethral sling procedure with retropubic routes by Ulmsten 2. Suburethral sling procedure with transobturator routes by Delorme	Objective cure from stress urinary incontinence: no stress incontinence by clinical and urodynamic and during stress provocation test, and no urinary retention or a residual urine volume of <150ml. Objective improvement - no incontinence in stress provocation test. Self reported quality of life using Urinary Distress Impact Questionnaire [UDI]), and the social and emotional impact of SUI (Incontinence Impact Questionnaire [IIQ]).	Intention to treat not stated. Open label. Computer-generated randomization code. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.
Choe, 2000[623] RCT to examine effects of transvaginal antimicrobial mesh and anterior vaginal wall slings on females stress urinary incontinence Duration of followup: 6 months	40 women with stress urinary incontinence and vaginal prolapse. Exclusion criteria: not reported. Loss of followup: none	1. Transvaginal antimicrobial mesh synthetic mesh 2. Anterior vaginal wall slings	Subjective cure from stress urinary no involuntary loss of urine during physical activities incontinence objective cure-negative stress test and no leakage in urodynamic exam. Self reported urinary incontinence using standardized Medical Epidemiologic and Social Aspects of Aging Questionnaire, and validated visual analog scale.	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F125. Effects of vaginal tapes and sling procedures on risk and progression of incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Kuo, 2001[624] RCT to examine effects of pubovaginal sling procedure using rectus fascia or polypropylene mesh on female stress urinary incontinence. Duration of followup: 6 months	50 women with various types of stress urinary incontinence. Exclusion criteria: Stress incontinence with a large cystocele or uterine prolapse. Loss of followup: none.	1.Pubovaginal sling procedure using rectus fascia 2. Pubovaginal sling procedure using polypropylene mesh Sling was placed at the level of the bladder neck and tied with sufficient tension to prevent urinary leakage without obstructing the bladder outlet.	Video urodynamics. Type 2 stress incontinence : abdominal leak point pressure >90cm. H20 or significant urethral hypermobility. Type 3 stress incontinence: abdominal leak point pressure <60cm H20. Mixed type 2 to 3 stress incontinence abdominal leak point pressure. 60 and 90cm H20.	Intention to treat not stated. Open label. Randomization with random numbers table. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Cholhan, 2004[625] RCT to examine effects of conventional suburethral sling or modified sling on female genuine stress urinary incontinence. Duration of followup :3 months	48 women with genuine stress urinary incontinence diagnosed with demonstrated loss of urine with increased abdominal pressure (cough, Valsalva) in the absence of detrusor contractions on multichannel urodynamic. Exclusion criteria: not reported. Loss of followup: none	1. Conventional suburethral sling 2. Modified sling placed at the mid-urethra without tension	Multichannel urodynamic outcomes. Self reported urinary incontinence.	No intention to treat. Open label. Randomization with permuted blocks of 10. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Hilton, 1989[626] RCT to examine effects of suburethral sling or Stamey endoscopic bladder neck suspension on female genuine stress incontinence. Duration of followup:3 months and 2 years.	20 women with urodynamically proven genuine stress incontinence with or without other urinary symptoms and previous treatments. Exclusion criteria: not reported. Loss of followup: not reported.	1. Suburethral sling 2. Stamey endoscopic bladder neck suspension	Self reported urinary incontinence and urodynamic and profilometry outcomes.	No intention to treat. Open label. Randomization with random number list. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F125. Effects of vaginal tapes and sling procedures on risk and progression of incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Tseng, 2005[627] RCT to examine effects of suprapubic arc sling procedure or tension-free vaginal taping on female stress incontinence. Duration of followup: 2 years	62 women with genuine stress incontinence (GSI) alone or combined with pelvic prolapse less than International Continence Society (ICS) stage II treated with anterior colporrhaphy with or without posterior colporrhaphy and with vaginal total hysterectomy with or without sacrospinous ligament fixation for pelvic prolapse greater than ICS stage II. Exclusion criteria: Previous anti-incontinence surgery, pelvic prolapse >stage II Loss of followup: none	1. Suprapubic arc sling procedure 2. Tension-free vaginal taping by Ulmsten	Objective cure as pad weight 1g or less. Improvement as decreased >50% in urine loss. Urodynamic outcomes including free flowmetry urethral pressure profilometry, filling (provocative) and voiding cystometry, and a 1-hour pad test.	Intention to treat not stated. Double blind (patients and examiners). Computer-generated randomization code. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.
Barbalias, 1997[628] RCT to examine effects of Goretex pubovaginal sling or typical indigenous material graft made of rectal fascia on female stress urinary incontinence. Duration of followup: 30 months	48 consecutive women with type III incontinence. Exclusion criteria: not reported. Loss of followup: none	1. Vesicourethral suspension by allogenic Goretex sling 2. Vesicourethral suspension by indigenous rectus abdominis fascia sling	Cure as complete freedom from urinary stress incontinence. Urodynamic outcomes.	Intention to treat not stated. Computer generated random codes. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Laurikainen, 2007[629] RCT to examine effects of retropubic tension-free vaginal tape procedure or transobturator tension-free vaginal tape procedure on female urinary stress incontinence. Duration of followup: 2 months	273 women with history of stress urinary incontinence, indication for surgical treatment of stress incontinence, positive cough stress test, detrusor Instability Score 7 or less. Exclusion criteria: Previous incontinence surgery, postvoid residual urine volume >100ml, lower urinary tract anomaly, current urinary tract infection or >3 urinary tract infection episodes within the past year, urogenital prolapse of more than second degree, body mass index >35kg/m2, previous radiation therapy of the pelvis, active malignancy, anticoagulant therapy, hemophilia, neurogenic disease which can be associated with bladder disorders, use of antiholinergic medication or duloxetine, patient immobilization. Loss of followup: 3.7%	1. Retropubic tension-free vaginal polypropylene tape procedure by Ulmsten 2. Transobturator tension-free vaginal polypropylene tape procedure by de Leval	Objective cure as a negative stress test. Self reported symptoms using Urinary Incontinence Severity Score, Detrusor Instability Score, a visual analog scale (VAS 0-100), Incontinence Impact Questionnaire–Short Form, and Urogenital Distress Inventory–Short Form (UDI-6).	No intention to treat. Open label. Central computer-generated randomization in a ratio of 1:1 in balanced blocks of 4. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F125. Effects of vaginal tapes and sling procedures on risk and progression of incontinence in females (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Ward, 200 [630] RCT to examine the effects of tension-free vaginal tape or colposuspension on stress urinary incontinence. Duration of follow up: 2 years	344 women with urodynamic stress incontinence unresponsive to pelvic floor muscle exercise, who had completed their family. Exclusion criteria: vaginal prolapse requiring treatment, previous surgery for incontinence or prolapse, neurologic disease, known bleeding diathesis or current anticoagulant therapy, allergy to local anesthetic, detrusor over-activity, and voiding difficulty (maximum flow <15ml/sec or voiding pressure >50cm/H2O or residual volume >100ml). Loss of follow up: 15.7%	1. Tension Free Tape procedure using the Gynecare TVT device by Ulmsten 2. Colposuspension using either two or three sutures to support paravaginal fascia from the ileopectineal ligament on each side.	Objective cure of stress incontinence as negative 1-hour pad test (<1g change in weight). Subjective cure using Short Form-36 health status questionnaire, the Bristol Female Lower Urinary Tract Symptoms questionnaire. The responses were combined and transformed to generate eight health dimensions; with a potential score of 0 to 100 - higher scores indicate better perceived health.	Intention to treat. Open label. Randomization was computer generated using randomly varying block sizes of 4 and 6. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F126. Effects of vaginal tapes and sling procedures on urinary continence in women (events) (table is sorted by rate of urinary continence after active treatment, from highest to lowest)

Author Sample	Active Treatment	Control Treatment	Definition of Continence	Number of Cases After Active Treatment	Number of Cases After Control Treatment	Rate (%) After Active Treatment	Rate (%) After Control Treatment	Relative Risk (95% CI)	Number Needed to Treat (95% CI)	Number of attributable Events/1,000 Treated 95% CI)
Rafi, 2004[605]* N = 186	Tension-free vaginal tape with Ulmsten's method and concomitant vaginal hysterectomy	Tension-free vaginal tape with Ulmsten's method and pelvic floor reconstruction	Objective assessment: cured at 24 months	39	43	97.5	93.1	1.0 (1.0; 1.1)		
Lord, 2006[615] N = 313	Tension-free vaginal tape	Suprapubic urethral support sling	Stress incontinence: objective cure	150	155	97.3	97.4	1.0 (1.0; 1.0)		
Kuo, 2001[624] N = 50	Pubovaginal sling procedure using rectus fascia	Pubovaginal sling procedure using polypropylene mesh	Urinary continence: cured	23	26	95.8	100.0	1.0 (0.9; 1.1)		
Choe, 2000[623] N = 40	Transvaginal antimicrobial mesh synthetic mesh	Anterior vaginal wall slings	Objective cure from stress urinary incontinence	19	14	95.0	70.0	1.4 (1.0; 1.8)	4 (2; 1,046)	250 (1; 588)E
Adamiak, 2002[608] N = 103	Tension-free vaginal tape with local analgesia (injection of 0.5–0.75% lidocaine hydrochloride in subcutaneous tissue).	Tension-free vaginal tape with spinal analgesia (0.5% bupivacaine hydrochloride administered at L3–L4 or L4–L5 interspace)	Urinary continence (complete cure)	61	34	93.8	97.1	1.0 (0.9; 1.1)		
Rafii, 2004[605] N = 186	Tension-free vaginal tape with Ulmsten's method alone	Tension-free vaginal tape with Ulmsten's method and pelvic floor reconstruction	Objective assessment: cured at 24 months	93	43	93.0	93.1	1.0 (0.9; 1.1)

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
Colombo, 1996 [633] RCT to examine effects of cystopexy alone versus cystopexy with posterior pubourethral ligaments placation on prevention of urinary incontinence in women with genitourinary prolapse. Duration of followup: 6 months, 1 and 2 years	107 continent women admitted for surgical correction of severe urethrocystocele grade 2 or greater, a negative stress test with repositioning, and a positive cotton swab test. Exclusion criteria: urethrocystocele <grade 2, positive stress test with repositioning (potential stress incontinence), maximum urethral closure pressure less than 30cm/H2O, uninhibited detrusor contraction of any size during bladder filling, and previous retropubic anti-incontinence surgery. Loss of followup: 3.7%, one patient (cystopexy alone) died on day 2 of a hemorrhagic complication due to a chronic hepatic dysfunction	1. Cystopexy alone 2. Cystopexy with posterior pubourethral ligaments plication	Urinary incontinence as occurrence both subjectively (patient's history) and objectively (positive stress test). Stress incontinence at any time after surgery. Urethral Functional Length and Maximum Urethral Closure Pressure	No intention to treat. Open label. Computer-generated randomization. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size not justified.
Brubaker, 2006[634] RCT to examine the effect of standardized Burch colposuspension in addition to abdominal sacrocolpopexy for the treatment of pelvic-organ prolapse on postoperative stress urinary incontinence in women without preoperative symptoms of stress incontinence. Duration of followup: 3 months after surgery	322 women who did not report symptoms of stress incontinence and who chose to undergo sacrocolpopexy to treat prolapse. 22 women had prior surgery for incontinence, 60 women at baseline had stress incontinence and 89 had urge incontinence. Exclusion criteria: unable to undergo the Burch colposuspension on the basis of the assessment of the mobility of the urethrovesical junction. Loss of followup: none	1. Sacrocolpopexy with Burch colposuspensions. 2. Sacrocolpopexy alone	Self reported stress incontinence and urge incontinence. Maximum cystometric capacity	Intention to treat. Single blind. Computer-generated, stratified by surgeon and intention to perform paravaginal repair randomization in blocks of various sizes. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F131. Surgical interventions on risk and progression of incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
Bump, 1996 [635] RCT to examine the effect of needle colposuspension or bladder neck endopelvic fascia plication as part of vaginal reconstructive surgery on urinary symptoms. Duration of followup: 6 weeks and 6 months	32 women with bladder neck hypermobility and stage III or IV pelvic organ prolapse. Exclusion criteria: not reported. Loss of followup: 12.5%	1. Needle colposuspension. 2. Bladder neck endopelvic fascia plication as part of vaginal reconstructive surgery	Stress incontinence diagnosed based on self reported symptoms and positive stress test or abnormal urethral pressure profilometry or a positive direct visualization test immediately after catheters were removed in total absence of detrusor instability during urethrocystometry.	No intention to treat. Open label. Randomization with block size 4 or 6 chosen randomly. Allocation concealment unclear. Baseline data not provided but states the same in groups. Sample size justified.
Meshcia, 2004 [631] RCT to examine the effect of tension-free vaginal tape or plication of the endopelvic fascia in women with severe genital prolapse. Duration: 6 months after surgery	50 patients with ≥ stage II anterior defect and a positive stress test result with prolapse reduction. Exclusion criteria: age >75 years, obesity (body mass index, >30kg/ml), diabetes mellitus, previous pelvic and anti-incontinence surgery, symptoms of SUI, cotton swab test <30 degrees, and uninhibited detrusor contraction of any size during bladder filling. Loss of followup: none	Vaginal hysterectomy, McCall culdoplasty, and cystocele repair for pelvic floor defects and 1. Tension-free vaginal tape 2. Plication of the endopelvic fascia	Self reported stress urinary incontinence, stress test, cotton swab test, and urodynamic outcomes.	Intention to treat not stated but all patients were analyzed. Open label. Computer-generated random list. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Colombo, 1997,[636] RCT to examine effects of posterior pubourethral ligament plication or Pereyra suspension in patients with severe genitourinary prolapse and coexisting clinical or potential stress incontinence. Duration: 6 months	109 patients with urethrocystocele of ≥grade 2 and a positive stress test result with prolapse reduction. Exclusion criteria: urethrocystocele <2, negative stress test results with repositioning, maximum urethral closure pressure <30cm/H_20, occurrence of uninhibited detrusor contraction of any size during bladder filling, or previous retropubic anti-incontinence surgery. Loss of followup: none	Cystopexy and 1. Posterior pubourethral ligament placation. 2. Pereyra suspension	Self reported and clinical stress incontinence - positive stress test result with repositioning	Intention to treat not stated but all patients were analyzed. Open label. Computer-generated random list. Allocation concealment unclear. Baseline data differ by incontinence score, no adjustment reported. Sample size not justified.

Table F131. Surgical interventions on risk and progression of incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
Jarvis, 2005 [575] RCT to examine the effect of perioperative physiotherapy in women undergoing corrective surgery for pelvic organ prolapse and/or incontinence Duration: 12 weeks	60 women undergoing corrective surgery for pelvic organ prolapse and/or incontinence, able to follow verbal and written instructions in English. Exclusion criteria: neuromuscular disorders or other significant medical problems, pelvic floor muscle intervention, tension-free vaginal tape. Loss of followup: 6.6%	Incontinence and/or prolapse surgeries and 1. Preoperative physiotherapy 2. No preoperative physiotherapy	Paper towel test, urinary symptom specific health and quality of life questionnaire, frequency/volume chart and pelvic floor muscle manometry. Urinary symptoms (frequency, nocturia, urgency, urge, stress incontinence, coital incontinence, nocturnal enuresis, frequent urinary tract infections, bladder pain and difficulty passing urine) were estimated with self-reported scores, max score of 33 indicates high negative impact.	Intention-to treat. Single-blind. Computer-generated randomization with balanced blocks of 20. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Roovers, 2004 [637] RCT to examine effects of vaginal hysterectomy and abdominal sacro-colpopexy on urogenital function in women undergoing surgical correction of uterine prolapse stages II-IV. Duration: one year.	82 women undergoing surgical correction of uterine prolapse stages II-IV. Exclusion criteria: the presence of adnexal mass, history of two or more abdominal pelvic surgical procedures, BMI>35kg/ml, inflammatory bowel or pelvic diseases, fecal incontinence. Loss of followup: 4.9%	1. Vaginal hysterectomy (combined with anterior and/or posterior colporraphy). 2. Abdominal sacro-colpopexy (with preservation of the uterus) on urogenital function	Urogenital distress inventory (UDI) to measure discomfort of urinary incontinence symptoms Domain scores of the UDI (from 0 = lowest to 100 = highest discomfort)	Intention-to treat. Single-blind. Computer-generated randomization. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Surgical treatments to treat female stress urinary incontinence				
Sand, 2000[638] RCT to examine effects of modified Burch procedure	36 women with stress incontinence, low-pressure urethra, and urethral hypermobility (straining cotton swab angle >30 degrees), maximum urethral closure pressure of ≤20cm/H_2O in the sitting position, who failed previous	1. Burch procedures with 4 2-0 polytetrafluoroethylene sutures and tension placed on the periurethral sutures (modified	Objective cure of stress incontinence as no leakage of urine at maximum	Intention to treat not stated. Open label. Randomization and allocation

Table F131. Surgical interventions on risk and progression of incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
or suburethral sling on females stress incontinence complicated by a low-pressure urethra. Duration of followup: 3 months	surgery and medications. Exclusion criteria: significant anterior pelvic support defects. Loss of followup: none	Tanagho method). 2. Suburethral sling with continuous polytetraflouroethylene strip from rectus fascia into retropubic space and beneath urethra at urethrovesical junction level	cystometric capacity during coughing or Valsalva maneuvers in sitting or standing position. Subjective cure as no loss of urine during any activity that increases intra-abdominal pressure.	concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.
Demirci, 2001 [639] RCT to examine effects of pubovaginal sling or Burch colposuspension operations on females with type I/type II genuine stress urinary incontinence. Duration of followup: 1 year	46 women with type I/type II genuine stress urinary incontinence. Exclusion criteria: preoperative detrusor instability, recurrent genuine stress urinary incontinence, severe pelvic prolapse, Valsalva leak point pressure >90 cm/H20. Loss of followup: 26%	1. Burch colposuspension (Tanagho); 9 patients had abdominal hysterectomy with or without bilateral salpingo-oopherectomy. 2. McGuire's free-rectus fascial sling from inferior leaf of rectus fascia (5 to 6cm in length, 2cm center diameter and 1.5cm at either end; 8 patients had abdominal hysterectomy with or without bilateral salpingo-oopherectomy.	Self reported urinary continence (dry) urodynamic outcomes.	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Culligan, 2003 [640] RCT to examine effects of modified Burch procedure or sling procedure on female stress incontinence with a low-pressure urethra. Duration of followup: 72.6 months	36 women with urodynamic stress incontinence, low-pressure urethra, urethral hypermobility. Exclusion criteria: significant anterior or apical pelvic floor support defects. Loss of followup: 18%	1. Burch colposuspension (Tanagho). 2. Suburethral sling (Horbach) with polytetrafluororthylene strip from rectum fascia beneath urethra under minimal tension.	Objective cure of the stress incontinence as negative stress test and negative pad-weight test. Subjective cure of stress incontinence, no incontinence episodes on a 1-week voiding diary and voiding function studies	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.
Bai, 2005[641] RCT to examine effects of Burch colposuspension, pubovaginal sling, and tension-free	92 women with Grade 1 or 2 stress urinary incontinence. Exclusion criteria: detrusor overactivity, urinary tract infection, intrinsic sphincter deficiency, pelvic organ prolapse >stage II. Loss of followup: not reported.	1. Burch colposuspension. 2. Pubovaginal sling using autologous rectus muscle fascia. 3. Tension-free vaginal tape	Self reported urinary continence.	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
vaginal tape on female stress urinary incontinence. Duration of followup: 12 months				data confirmed adequacy of randomization. Sample size not. Justified.
Liapis, 2002[642] RCT to examine effects of tension-free vaginal tape or Burch colposuspension on female genuine stress incontinence. Duration of followup: 12-24 months	72 women with genuine stress incontinence. Exclusion criteria: prolapse >1degree, previous surgical treatment of stress urinary incontinence, and detrusor instability. Loss of followup: not reported	1. Laparoscopic Burch colposuspension. 2. Tension-free vaginal tape procedure	Objective cure as pad weight difference <1g, and improvement as a reduction of urine loss to less than 50% of urine loss prior to the operation - measured with 1 hour pad test	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not. justified
Paraiso, 2004[643] RCT to examine effects of laparoscopic Burch colposuspension or tension-free vaginal tape procedure on female stress urinary incontinence. Duration of followup: 12 months. The trial was stopped early due to slow recruitment and lack of funding, prior to statistical analysis	72 females candidates for surgical correction of primary urodynamic stress incontinence , with abdominal leak-point pressures greater >60cm/H2O (or a positive cough stress test if the patient did not leak with the catheters in place); urethral hypermobility defined as maximal straining cotton-tipped swab angle >30°; and ability to undergo general anesthesia and laparoscopy. Exclusion criteria: previous anti-incontinence surgery; detrusor overactivity on urodynamic studies defined by a rise in the true detrusor pressure not due to bladder compliance of >15cm/H2O; anterior vaginal wall prolapse to or beyond the hymen. Loss of followup: 8.3%	1. Burch colposuspension (Tanagho). 2. Tension-free vaginal tape procedure. Concomitant procedures were performed in both groups.	Objective cure as no urinary leakage during urodynamic studies. Self reported urinary symptoms using Urogenital Distress Inventory with score range of 0 to 300, higher scores indicating greater distress. Incontinence Impact Questionnaire with score range of 0 to 400, higher scores indicating greater adverse impact on quality of life.	Intention-to-treat Single blind. Computer-generated randomization. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F131. Surgical interventions on risk and progression of incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
Ustun, 2003[644] RCT to examine effects of laparoscopic Burch colposuspension or tension-free vaginal tape procedure on female genuine stress incontinence. Duration of followup: 18 months	46 women with genuine stress incontinence. Exclusion criteria: not reported. Loss of followup: not reported.	1. Laparoscopic Burch colposuspension. 2. Tension-free vaginal tape procedure	Urodynamic outcomes. Objective cure as no urinary leakage in urodynamic exam. Subjective cure as no pad use and no urinary leakage in urodynamic exam	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified
El-Barky, 2005[645] RCT to examine effects of Burch colposuspension or tension-free vaginal tape procedure on female genuine stress incontinence. Duration of followup: 6 months	50 women with genuine stress incontinence Exclusion criteria: high grade cystocele, previous surgical failure for stress incontinence, uninhibited detrusor contraction during bladder filling on urodynamic study, incompetent internal sphincters. Loss of followup: not reported	1. Burch colposuspension. 2. Tension-free vaginal tape procedure	Self reported stress urinary incontinence	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified
Wang, 2003[646] RCT to examine effects of modified Burch colposuspension tension-free vaginal taping on female genuine stress incontinence. Duration of followup: 1 year	116 women with genuine stress incontinence. Exclusion criteria: pelvic prolapse, bladder outlet obstruction defined as presence of maximal flow rate of noninvasive uroflowmetry <2ml/second in repeated free uroflow studies combined with detrusor pressure at maximal flow >20cm/H2O or postvoid residual urine >100ml; previous anti-incontinence surgery. Loss of followup: 16.3%	1. Modified Burch colposuspension. 2. Tension-free vaginal taping	Objective cure as no demonstrable involuntary urine loss during any provocative maneuver in multi-channel urodynamic tests in the absence of detrusor instability or pad weight 2g or less. Objective improvement as decrease in urine loss during pad test by >50% from	No intention to treat. Open label. Computer-generated randomization. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified

Table F131. Surgical interventions on risk and progression of incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
			baseline. Subjective cure as no loss of urine during physical exercise. Subjective improvement as reduction by >50% in amount of preoperative leakage episode	
Colombo, 1996[647] RCT to examine effects of Burch colposuspension or abdominal paravaginal defect repair on female stress urinary incontinence. Duration of followup: 6 months	36 women with stress urinary incontinence. Exclusion criteria: urethral sphincter weakness (maximum urethral closure pressure <20cm/H20), detrusor instability (occurrence of uninhibited detrusor contraction of any size during bladder filling), and previous failed abdominal anti-incontinence procedures. Loss of followup: none.	1. Burch colposuspension with placement of 2 couples of permanent polybutylate-coated polyester sutures. 2. Abdominal paravaginal defect repair with 5-7 pairs of permanent braided silicone-coated polyester suture.	Cure as no incontinence episodes by history and no urine loss at stress test Profilometry outcomes.	Intention to treat not stated. Open label Computer-generated randomization table. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified
Gilja, 1998[648] RCT to examine effects of Raz, Burch and transvaginal Burch procedures on females stress urinary incontinence. Duration of followup: 3 years.	146 women operated on for stress urinary incontinence. Exclusion criteria: prior gynecological or urological operation for urinary incontinence and a clear neuropathic condition. Loss of followup: 28%.	1. Transvaginal Burch procedure. 2. Burch retropubic urethropexy. 3. Modified bladder neck suspension by Raz	Subjective cure from stress urinary incontinence as no leakage episodes and symptoms. Objective cure as no urine loss in urodynamic exam.	No Intention to treat. Open label. Randomization with random numbers table. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Berglund, 1996[649] RCT to examine effects of retropubic urethrocystopexy or pubococcygeal repair on females stress urinary	45 women with stress urinary incontinence. Exclusion criteria: age>65 years, previous surgery for stress urinary incontinence, other gynecological diseases necessitating immediate surgical treatment, severe somatic diseases, e.g. diabetes mellitus, neurological diseases, heart failure, chronic kidney disease and psychiatric disorders. Loss of followup: not reported	1. Retropubic urethrocystopexy. 2. Pubococcygeal repair	Subjective cure as self reported urinary continence. Objective cure as negative 1hour pad test.	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not

Table F131. Surgical interventions on risk and progression of incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
incontinence. Duration of followup: 12 months				justified.
Lalos, 1993[650] RCT to examine effects of retropubic urethrocystopexy or pubococcygeal repair on females stress urinary incontinence. Duration of followup: 1 year	45 women with stress incontinence. Exclusion criteria: age>65 years, previous surgery for stress urinary incontinence. Loss of followup: 20%	1. Retropubic urethrocystopexy. 2. Pubococcygeal repair	Subjective cure as self reported urinary continence. Objective cure as negative 1hour pad test.	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.
Osman, 2003 [651] RCT to examine effects of anticholinergic treatment or surgery on female urinary incontinence. Duration of followup: 6 months	75 women with mixed urinary incontinence and negative cystometrogram for detrusor overactivity for >6 months. Exclusion criteria: other treatment for incontinence for ≥3 months, non-sterile urine culture; cystometrogram positive for motor detrusor overactivity and detrusor pressure rise of >5cm/H2O); obstructed uroflow; previous surgery for incontinence; carcinoma *in situ* and interstitial cystitis. Loss of followup: 9.3%	1. Burch retropubic suspension (if Valsalva leak-point pressure >90cm/H20) with simple elevation of vaginal wall and periurethral fascia to 1/2way between original position of bladder neck and Cooper ligament Pubovaginal sling (if Valsalva leak-point pressure <90cm/H20) with minimal tension by McGuire. 2. Oxybutynin hydrochloride 5mg 3 times/day	Self reported symptoms of urinary incontinence and urodynamic test	No intention to treat. Open label. Block randomization. Allocation concealment not reported. Baseline data not reported. Sample size not justified.
Costantini, 2007[652] RCT to examine effects of sacropexy combined with a Burch colposuspension on urinary incontinence in females with advanced prolapse. Duration of followup: 40 months	66 consecutive continent patients with advanced prolapse with negative stress test before and after prolapse reduction. Exclusion criteria: history of symptoms of urinary incontinence, positive symptoms questionnaire, and leakage during urodynamics tests. Loss of followup: not reported	1. Sacropexy combined with a Burch colposuspension. 2. Colposacropexy, no prophylactic colposuspension	Incidence of ex novo urinary incontinence measured with Ingelman Sunderberg scale for incontinence, Urogenital Distress Inventory. Urodynamic outcomes.	No Intention to treat. Open label. Randomized block design. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F131. Surgical interventions on risk and progression of incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
Persson, 2002[653] RCT to examine effects of laparoscopic colposuspension or tension-free vaginal tape on female stress urinary incontinence. Duration of followup: 1 year	79 consecutive women presenting for evaluation of stress urinary incontinence symptoms urethral closing pressure ≥20cm/H2O, urethral functional length ≥25mm, hypermobility of the bladder neck (>45 degrees of down rotation at valsalva maneuver), and >5ml leaking on pad test. Exclusion criteria: predominant urge incontinence, previous surgery for stress urinary incontinence, incontinence after previous vaginal repair, >2 grad uterovaginal prolapse, not having completed childbirth, need of gynecologic surgery, contraindication to incontinence surgery, increased risk for complications during general anesthesia or laparoscopic surgery, i.e. those with cardiovascular disease, known or suspected intra-abdominal adhesions, or abdominal obesity. Loss of followup: 13.9%	1. Laparoscopic colposuspension. 2. Tension-free vaginal tape by Ulmsten	Objective cure as no leaking at postoperative pad-test, improvement as less than one third of the preoperative leakage	No Intention to treat. Open label. Randomization with self selected envelopes assigned to two treatments. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Fatthy, 2001[654] RCT to examine effects of laparoscopic or open Burch colposuspension on female genuine stress incontinence. Duration of followup: 18 months	74 women with genuine stress incontinence. Exclusion criteria: urinary tract infection, detrusor instability, under-active detrusor, intrinsic sphincter deficiency (Valsalva leak point pressure <90cm/H20), limited vaginal mobility, stages III and IV of vaginal prolapse, contraindications to surgery. Loss of followup: 1.4%	1. Laparoscopic Burch colposuspension with polypropylene suture. 2. Open Burch colposuspension with polypropylene suture	Cure as no self reported urine loss, negative stress test and no leakage in urodynamic exam. Urodynamic outcomes.	No Intention to treat. Open label. Randomization with random numbers tables and permuted blocks. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size not justified.
Kitchener, 2006[655] RCT to examine effects of open or laparoscopic colposuspension on female stress urinary incontinence. Duration of followup: 24 months	291 women with urodynamic stress urinary incontinence requiring colposuspension who failed previous anterior colporrhaphy. Exclusion criteria: comprised detrusor overactivity, previous retropubic surgery, severe obesity. Loss of followup: 7.9%	1. Open abdominal retropubic colposuspension. 2. Laparoscopic colposuspension	Objective cure as negative 1-hour pad test (<1g/hour). Subjective cure as response of 'perfectly happy/pleased' to question 33 of the Bristol questionnaire (If you had to spend the rest of your life with your urinary symptoms as they	Intention to treat Open label. Central computer generated randomization with random permuted block sizes 2 and 4 with a dispersed block throughout the string, stratified by centre, age >50 years and previous bladder neck surgery. Allocation

Table F131. Surgical interventions on risk and progression of incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
			are now, how would you feel?). Quality of life using UK version of Short Form-36 (SF-36), the Bristol Female Lower Urinary Tract Symptom questionnaire, Symptom Severity and Symptom Impact Index and the EQ-5D.	concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified
Cheon,2003[656] RCT to examine effects of laparoscopic and open colposuspension in women with genuine stress incontinence. Duration of followup: 12 months	90 women with urodynamically proven genuine stress incontinence. Exclusion criteria: intrinsic sphincter deficiency, reduced vaginal capacity or fibrosis, previous anti-continence surgery or intrinsic sphincter deficiency (resting maximum urethral closure pressure <20cm/H2O or Valsalva leak point pressure <60cm/H2O). Loss of followup: not reported.	1. Laparoscopic colposuspension. 2. Burch open colposuspension	Objective cure as dry during severe cough on urodynamic testing. Self reported improvement in urinary incontinence symptoms.	No Intention to treat. Open label. Computer generated random number table. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Su, 1997[657] RCT to examine effects of laparoscopic or open colposuspensions on female genuine stress incontinence. Duration of followup: 12 months	92 patients with urodynamically proven genuine stress incontinence. Exclusion criteria: reduced vaginal capacity or fibrosis, uterine prolapse or cystocele>1 Grade, detrusor instability, under-active detrusor or outflow obstruction, previous anti-incontinent surgery or hysterectomy. Loss of followup: none	1. Laparoscopic colposuspension. 2. Open Burch colposuspension	Urodynamic outcomes. Objective cure as no leakage during urodynamic exam.	Intention to treat not stated. Open label. Randomization with computer generated random numbers table. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
German, 1994[658] RCT to examine effects of modified needle suspension procedure or	50 women with proven genuine stress incontinence. Exclusion criteria: not reported. Loss of followup: not reported.	1. Modified needle suspension procedure. 2. Vagina/obturator shelf procedure	Self reported urinary continence and de novo urge incontinence.	Intention to treat not stated. Open label. Randomization and allocation concealment not

Table F131. Surgical interventions on risk and progression of incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
vagina/obturator shelf procedure on female genuine stress incontinence. Duration of followup: 2 years				reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Zullo ,2002[659] RCT to examine effects of transperitoneal laparoscopic urethropexy on female genuine stress incontinence Duration of followup: 12 months	60 women with mild or moderate genuine stress incontinence. Exclusion criteria: sphincteric dysfunction (urethral pressure <20cm/H20 and Valsalva leak point pressure<60cm/H20), severe stress urinary incontinence. Prolapse >2 grade, previous pelvic or incontinence surgery, severe abdomino-pelvic infection, extensive abdominal adhesions, detrusor instability, other gynecological diseases, BMI>30kg/ml. Loss of followup: 6.7%	1. Transperitoneal laparoscopic retropubic urethropexy using nonabsorbable sutures. 2. Transperitoneal laparoscopic retropubic urethropexy using polypropylene mesh fixed with tacks or staples	Objective cure as no leakage during cough and Valsalva maneuver in standing position with bladder filled to maximum cystometric capacity during multichannel urodynamic exam. Subjective cure as self reported continence in Visual analog Scale (0=dry sensation, 10=severe leakage).	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.
Colombo, 2000[660] RCT to examine effects of Burch colposuspension or the anterior colporrhaphy in women with both stress urinary incontinence and advanced anterior vaginal wall prolapse. Duration of followup: 14 years	71 women undergoing surgery for primary genuine stress incontinence and concurrent grade 2 or 3 cystocele (descending at or outside the vaginal introitus) and positive cotton swab test. Exclusion criteria: detrusor instability, previous anti-incontinence or prolapse surgery (retropubic or vaginal), concomitant pelvic diseases requiring laparotomy, medical conditions with a high risk of abdominal surgery. Loss of followup: 4.2%	1. Burch colposuspension with abdominal hysterectomy. 2. Anterior colporrhaphy with vaginal hysterectomy	Subjective cure as no incontinence episodes. Objective cure as negative stress test result.	No Intention to treat. Open label. Computer generated random numbers table. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Quadri, 1999[661] RCT to examine effects of Burch colposuspension or Marshall-	30 women with stress urinary incontinence and low pressure (maximum urethral closure pressure of ≤20cm/H_2O throughout its entire length) and hypermobility of the urethra (difference of >30 degrees between results of the cotton swab test performed in the supine position at	1. Burch colposuspension. 2. Marshall-Marchetti-Krantz urethropexies with videourethroscopic control	Subjective cure as no incontinence episodes. Objective cure as negative stress test	Intention to treat not stated. Open label. Computer-generated random numbers. Allocation

Table F131. Surgical interventions on risk and progression of incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
Marchetti-Krantz urethropexy with videourethroscopic control on stress urinary incontinence in females with low pressure and hypermobility of the urethra. Duration of followup: 12 months	rest and during stress and as a straining angle of >30 degrees from the horizontal). Loss of followup: none		result.	concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Colombo, 1994[662] RCT to examine effects of Burch colposuspension or modified Marshall-Marchetti-Krantz urethropexy on female genuine stress urinary incontinence. Duration of followup: 2-7 years, median 3 years.	80 women with moderate or severe genuine stress urinary incontinence. Exclusion criteria: urethral sphincter weakness (maximum urethral closure pressure <30cm/H_2O), detrusor instability (occurrence of uninhibited detrusor contraction of any size during bladder filling), prolapse of genitourinary tract ≥ 2º, urethral diverticula, urogenital fistulas, and previous failed abdominal anti-incontinence procedures. Loss of followup: none.	1. Burch colposuspension. 2. Modified Marshall-Marchetti-Krantz urethropexy	Subjective cure as no incontinence episodes by history. Objective cure as no urine loss at stress test. Subjective improvement as clinical score of incontinence decreased from 8 to ≤4 or from 4 to ≤2.	No Intention to treat. Open label. Computer-generated random assignment. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.
Bergman, 1995[663] RCT to examine effects of Kelly plication, modified Pereyra needle suspension, or Burch urethropexy on female stress urinary incontinence. Duration of followup: 5 years	127 consecutive women with stress urinary incontinence. Exclusion criteria: failure of previous anti-incontinence procedures, gynecologic disease necessitating hysterectomy, other gynecologic operations, or other indications for laparotomy. Loss of followup: 26.7%	1. Anterior colporrhaphy with Kelly plication. 2. Modified Pereyra needle urethropexy using inclusions of the pubourethral ligaments and endopelvic fascia at the level of the proximal urethra and bladder neck. 3. Burch urethropexy included the basic principles of the Tanagho modification: (1) minimal dissection within 2cm of the urethrovesical junction and urethra, (2) placement of sutures	Subjective cure as absence of complaint of persistent incontinence. Objective cure as no evidence of loss of urine on cough profile during urodynamic evaluation at maximum cystometric capacity.	No Intention to treat. Open label. Randomization with computer generated random numbers table. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified

Table F131. Surgical interventions on risk and progression of incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
		through full thickness of shiny white paravaginal fascia, (3) use of two sutures on each side, one opposite to the urethrovesical junction and another at the level of the midurethra, (4) removal of adipose tissue lateral to the sutures to stimulate fibrosis, and (5) facilitating typing of sutures to the Cooper ligament with intravaginal fingers elevating the anterior vaginal wall.		
Kammerer-Doak , 1999[664] RCT to examine effects of Burch retropubic urethropexy or modified anterior colporrhaphy on female genuine stress urinary incontinence. Duration of followup: 1 year	35 women with stress incontinence with grading of prolapse (grades 0–4). Exclusion criteria: incontinence of neurological origin, detrusor instability, history of previous radical pelvic surgery, pelvic radiation, intrinsic sphincteric deficiency (low abdominal leak point and maximal urethral closure pressures <65 and <20cm/H20) and history of interstitial cystitis or urethral syndrome. Loss of followup: 5.7%	1. Burch retropubic urethropexy by Tanagho. 2. Modified anterior colporrhaphy	Objective cure as absence of urine loss during cough and valsalva maneuver in the supine and standing positions, with the bladder filled to maximal cystometric capacity. Multichannel urodynamic outcomes. 20-minute pad test, and subjective grading of incontinence severity with questionnaires (0 =none, 4 = more than one daily), number of incontinent episodes (0 = none, 6 = with every cough, sneeze, or laugh) and self assessment score (1 =dry, 10 = severe leakage), and overall quality of life according to the Incontinence Impact Questionnaire	No Intention to treat. Double blind. Computer-generated randomization table. Allocation concealment not reported. Baseline data confirmed adequacy of randomization except age and post menopausal status. Sample size not justified

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
Bergman, 1989[665] RCT to examine effects of anterior colporrhaphy, revised Pereyra procedure, or Burch retropubic urethropexy on female genuine stress incontinence. Duration of followup: 1 year.	127 consecutive patients with urodynamic genuine stress incontinence. Exclusion criteria: other gynecological diseases necessitating hysterectomy, previous anti incontinence surgery, other indications for laparotomy. Loss of followup: 5.5%	1. Anterior colporrhaphy with Kelly placation. 2. Modified Pereyra needle urethropexy using inclusions of the pubourethral ligaments and endopelvic fascia at the level of the proximal urethra and bladder neck. 3. Burch urethropexy included the basic principles of the Tanagho modification: (1) minimal dissection within 2cm of urethrovesical junction and urethra, (2) placement of sutures through full thickness of shiny white paravaginal fascia, (3) use of two sutures on each side, one opposite to the urethrovesical junction and another at the level of the midurethra, (4) removal of adipose tissue lateral to sutures to stimulate fibrosis, and (5) facilitating typing of sutures to the Cooper ligament with intravaginal fingers elevating the anterior vaginal wall	Subjective cure as absence of complaint of persistent incontinence. Objective cure as no evidence of loss of urine on cough profile during urodynamic evaluation at maximum cystometric capacity	No Intention to treat. Open label. Randomization with computer generated random numbers table. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Persson, 2000[666] RCT to examine effects of laparoscopic Burch colposuspension using one double-bite or two single-bite sutures on each side of the urethra on female stress urinary incontinence. Duration of followup: 1 year	161 women with primary stress urinary incontinence, with normal urethral closing pressure and hypermobility of the bladder neck. Exclusion criteria: urge incontinence, stress incontinence due to low urethral closing pressure (< 20cm/H2O) , uterovaginal descent > grade 1 cystocele, incontinence after previous vaginal repair, recurrent incontinence, at increased risk for general anesthesia (i.e.), significant respiratory or cardiac disease, former complications attributable to general anesthesia, age >70 years old) and surgical complications (BMI>35kg/m2), known or suspected intra-abdominal adhesions, history of complications with laparoscopic surgery. Loss of followup: 2.5%	1. Laparoscopic Burch colposuspension using one double-bite of polytetrafluoroethylene sutures placed on each side of the urethra under transperitoneal video laparoscopy. 2. Laparoscopic Burch colposuspension using two single-bite sutures of polytetrafluoroethylene sutures placed on each side of the urethra under transperitoneal video laparoscopy	Objective cure as negative pad test. Improvement as maximal one third of preoperative leaking volume on pad test. Failure as > one third of preoperative leaking volume on pad test. Subjective cure rate as no reported leakage.	No intention to treat. Open label. Randomization 1:1 with random numbers table. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified

Table F131. Surgical interventions on risk and progression of incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
Zullo, 2001[667] RCT to examine effects of 2 transperitoneal laparoscopic Burch procedures on female genuine stress incontinence. Duration of followup: 1 year	60 women with mild or moderate genuine stress incontinence. Exclusion criteria: severe genuine stress incontinence (loss of urine with minimal physical activity), prolapse >2º, previous pelvic or anti-incontinence surgery, history of severe abdomino-pelvic infections or known extensive abdomino-pelvic adhesions, detrusor instability and/or intrinsic sphincter dysfunction, presence of other gynecologic pathologies (e.g., fibroids, ovarian cysts), BMI>30kg/ml. Loss of followup: 11.7%	1. Transperitoneal laparoscopic Burch procedure using nonabsorbable sutures. 2. Transperitoneal laparoscopic Burch procedure using Prolene mesh fixed with tacks or staples	The subjective self reported urine loss on a visual analog scale graded from 0 (dry sensation) to 10 (severe leakage). Subjective failure as a postoperative visual analog scale value equal to or higher than that obtained before surgery. The objective cure failure as involuntary loss of urine during cough and Valsalva maneuver in the standing position with the bladder filled to maximal cystometric capacity during clinical observation or abnormal urodynamic tests.	No Intention to treat. Single blind. Computer-generated randomization list. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified
Ankardal, 2005[668] RCT to examine effects of open Burch colpo-suspension using sutures with laparoscopic colpo-suspension using sutures and laparoscopic colpo-suspension using mesh and staples on female stress UI. Duration of followup: 1 year	Women with genuine stress urinary incontinence or mixed incontinence with a predominantly stress component. Exclusion criteria: recurrent incontinence, detrusor instability diagnosed during filling cystometry, other gynaecologic surgery, e.g. hysterectomy or anterior colporaphia. Loss of followup: 1.4%	1. Open Burch colposuspension using sutures. 2. Laparoscopic colposuspension using sutures. 3. Laparoscopic colposuspension using mesh and staples	48-hour frequency-volume chart, a 48-hour pad test and a standardized stress test. Cure was defined as a urinary leakage <8g/24 hours. Stress test cure was defined as urinary leakage <5g. The patients' degree of overall satisfaction regarding the result of the operation was also estimated using a VAS scale (0 = lowest degree of	No intention to treat. Open label. Randomization with block ratio 2:1:2. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified

Table F131. Surgical interventions on risk and progression of incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
			satisfaction and 100 = maximum satisfaction).	
Ankardal, 2004[669] RCT to examine effects of open Burch colposuspension using sutures or laparoscopic colposuspension using mesh and staples on female stress urinary incontinence Duration of followup: 1 year	240 women with genuine stress urinary incontinence or mixed incontinence with a predominant stress component. Exclusion criteria: recurrent incontinence, need of additional gynecological surgery, extremely large 24 hours urinary volumes. Loss of followup: 2.1%	1. Open Burch colposuspension using sutures. 2. Laparoscopic transperitoneal colposuspension using polypropylene mesh and staples	Objective and subjective cure rates from 48-hour frequency-volume chart, a 48-hour pad test and a subjective assessment of the woman's incontinence and quality of life(Visual analog scale graded with maximum score of 100 for maximum bother)	No intention to treat. Open label. Central randomization with random numbers table. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified
Ross, 1996[670] RCT to examine effects of laparoscopic Burch procedure with mesh and staples or suture technique on female genuine stress incontinence. Duration of followup: 1 year	69 previously untreated women with genuine stress incontinence and hyper mobile urethrovesical junction. Exclusion criteria: previous incontinence surgery, detrusor instability, inferred intrinsic sphincter dysfunction. Loss of followup: for cure rate not reported. Urodynamic outcomes reported in 30%.	1. Laparoscopic Burch procedure with sutures for bladder neck elevation. 2. Laparoscopic Burch procedure with mesh and staples for bladder neck elevation	Objective cure as negative stress test.	No intention to treat. Open label. Randomization with random numbers table. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.
Klarskov, 1986[671] RCT to examine effects of pelvic floor training program or surgery on female genuine urinary stress incontinence. Duration of followup: 4 months	50 consecutive female patients with genuine urinary stress incontinence Exclusion criteria: previous surgery or pelvic floor training, significant urge incontinence, need of other gynecological surgery (prolapse, hysterectomy), mental impairment. Loss of followup: not reported. 14 patients did not have urodynamic exam.	1. Pelvic floor training program 5 times/week guided by trained physiotherapists. 2. Surgery: Burch colposuspension for anterior suspension defect. Vaginal repair for posterior bladder descent.	Self reported urinary incontinence and cystometric outcomes.	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified

Table F131. Surgical interventions on risk and progression of incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
Albo, 2007[672] RCT of "The Stress Incontinence Surgical Treatment Efficacy Trial" to examine effects of pubovaginal sling, using autologous rectus fascia, or Burch colposuspension on female stress incontinence. Duration of followup: 24 months	655 women with predominant stress urinary incontinence for at least 3 months, positive standardized urinary stress test and urethral hyper mobility. Exclusion criteria: not reported. Loss of followup: 21%	1. Burch colposuspensions. 2. Pubovaginal sling, using autologous rectus fascia. Key elements of the two surgical procedures were standardized among all participating surgeons (the use of preoperative antibiotics, skin-incision length, number and type of Burch sutures, fascial-sling length and width, and cystoscopic evaluation of the bladder).	Overall success as no self-reported symptoms of urinary incontinence, an increase <15g in pad weight during a 24-hour pad test, no incontinence episodes recorded in a 3-day diary, a negative urinary stress test (no leakage noted on examination during cough and Valsalva maneuvers at a standardized bladder volume of 300ml), and no retreatment for urinary incontinence. Incidence if urge incontinence 6 weeks after surgery. Patient satisfaction assessed with the question; ("How satisfied or dissatisfied are you with the result of bladder surgery related to urine leakage?"). 5 response options: from "completely satisfied" to "completely dissatisfied."	No Intention to treat. Open label. Central randomization using permuted-block randomization schedule with stratification according to clinical site. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified
Carey, 2006[673] RCT to examine the effects of laparoscopic	200 women with urodynamic stress incontinence who failed conservative therapy. Exclusion criteria: previous retropubic continence surgery, maximum urethral closure pressure <20cm/H2O;	1. Laparoscopic Burch colposuspension 2. Open Burch colposuspension by Tanagho with 2 polyester	Cure as absence of USI at 6 months following surgery. Self reported quality	Intention-to-treat. Single blind. Computer generated randomization lists

Table F131. Surgical interventions on risk and progression of incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes (Incidence)	Quality Issues
Burch colposuspension and open Burch colposuspension on urinary stress incontinence. Duration of follow up: 6 months	medically unsuitable for laparoscopic or open surgery; major degrees of coexisting pelvic organ prolapse, requiring surgery other than a simple rectocele repair. Loss of follow up: 12.5%	sutures in each side and third suture if a cystocele was present	of life using. The Short Form-36 (SF-36) with lower scores for better general, physical, and mental health; the Short Urinary Distress Inventory (SUDI) and Short Incontinence Impact Questionnaire (SIIQ)	with a block size of 6, stratified for each centre and for women undergoing concomitant rectocele repair for symptomatic rectocele. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F136. Effects of radiotherapy on urinary incontinence in adults with adenocarcinoma of the rectum

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Peeters, 2005,[674] RCT to examine effects of preoperative short-term radiotherapy in patients treated with total mesorectal excision. Duration of followup: 5 years	1,861 patients with histologically confirmed adenocarcinoma of the rectum with inferior margin of the tumor had <15cm from the anal verge and below the level of S1 and S2. Exclusion criteria: distant metastases, fixed tumors, locally treated (transanal resected) tumors. Loss of followup: 32%, 597responded to questionnaire.	1. Radiotherapy with total dose of 25Gy administered in 5 fractions over 5 to 7 days before total mesorectal excision. 2. Total mesorectal excision	Self reported urinary and fecal incontinence with 4-point scale from “no, never” to “sometimes” (<1/week), “often” (>1/ week but not every day), and “yes, always” (every day) for time-dependent symptoms and from “no, not at all” to “a little,” “pretty much,” and “very seriously” for time-independent symptoms.	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F138. Clinical interventions to reduce risk and progression of urinary incontinence in males with urologic diseases

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Little, 2003[676] Followup RCT to examine effects of radiotherapy for prostate cancer on urinary incontinence and bowel function. Duration of followup: 3 years	301 patients 3 with histologically confirmed adenocarcinoma of the prostate and no metastatic disease treated with a four-field box technique to a dose of 46Gy. Exclusion criteria: not reported. Response rate 70%.	1. Radiation with a four-field box technique to a dose of 70Gy arm. 2. Radiation with three-dimensional conformal techniques to generate a six-field boost plan of a total dose of 78Gy	Self reported bladder, bowel and sexual function (Fowler)	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Srougi ,2005[677] RCT to examine effects of bladder neck mucosal eversion during retropubic radical prostatectomy on urinary incontinence Duration of followup: 6 months	100 patients with stage T1c–T2c prostate cancer. Exclusion criteria: previous TURP, suprapubic prostatectomy or local radiotherapy; a history of neurological diseases; surgical pathology specimens that showed positive margins at bladder neck. Loss of followup: 5%	1. Retropubic radical prostatectomy and vesico-urethral anastomosis with bladder neck mucosal eversion. 2. Retropubic radical prostatectomy and vesico-urethral anastomosis without bladder neck mucosal eversion	Self reported urinary incontinence (more than one pad/day)	Intention to treat. Double blind. Computer generated randomization. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Wasson, 1995[678] RCT to examine effects of transurethral resection of the prostate or watchful waiting in men with moderate symptoms of benign prostatic hyperplasia. Duration of followup: 3 years	556 men over the age of 54 years with symptoms of benign prostatic hyperplasia. Exclusion criteria: < 55 years old, previous prostate surgery or radiation treatment, unable to walk, active urinary tract infection not responding to treatment, diagnosed prostate or bladder cancer, residual urinary volume after voiding >350ml, serious medical conditions including uncontrolled diabetes, neurogenic bladder, cirrhosis, active alcoholism, bleeding diathesis, psychosis, and late-stage cardiac or respiratory disease, creatinine concentration >3.0mg/deciliter (265 µmol per liter) Loss of followup: 7.4%	1. Transurethral resection of prostate. 2. Watchful waiting	Urinary symptoms were scored on a scale ranging from 0 to 27 points with the use of a nine-question interview. Persistent incontinence requiring the use of a pad, penile clamp, or condom	Intention-to-treat Open label. Stratified randomization by participating hospital and the severity of disease. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F138. Clinical interventions to reduce risk and progression of urinary incontinence in males with urologic diseases (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Van Cangh, 1998[679] RCT to examine effects of postoperative radiotherapy for locally advanced disease on urinary incontinence. Duration of followup: 3 years 24 months	100 patients with N0M0 prostate cancer treated with radical prostatectomy for locally advanced disease (positive surgical margin, capsular perforation and/or seminal vesicle infiltration). Exclusion criteria: not reported. Loss of followup: none	1. 60Gy. external radiotherapy with 18MV photon beams between 12 and 16 weeks after radical prostatectomy. 2. Radical prostatectomy alone	A validated modified pad weighing test by the International Continence Society: grade 0 - dry-< 1gm. with no pads, grade 1 –"minimal" between 1 and 9gm with 1 to 4 pads, grade 2 –"moderate" 10 - 50gm. with 1 to 4 pads (soaked) and grade 3 "severe"- >50gm. with >4 pads	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Srougi ,2001[680] RCT to examine effects of bladder neck preservation and resection radical retropubic Prostatectomy. Duration of followup: 6 months	70 patients with clinical stage T1 or T2 prostate cancer who were scheduled for radical prostatectomy and 2 patients with T3a with small prostatic nodules that may have been invading the prostatic capsule but with no established periprostatic tumor extension. Exclusion criteria: transurethral prostate resection, neurogenic dysfunction of the lower urinary tract. Loss of followup: 1.4%	1. Radical retropubic prostatectomy with bladder neck preservation according to the technique described by Malizia. 2. Radical retropubic prostatectomy with bladder neck resection according to that of Walsh, .	Self reported urinary continence (1 or no protective pad daily)	No Intention to treat. Double blind. Randomization by the toss of coin. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Ghaly, 2003[681] RCT to examine effects of supplemental beam radiation on prostate brachytherapy-related urinary incontinence. Duration of followup: 12 months	Trial 1: 106 low-risk patients, with Gleason Grade 2–6, prostate-specific antigen (PSA) 4–10ng/ml, Trial 2: 108 intermediate-risk patients, with Gleason Grade 7 or higher or PSA of 10—20ng/ml Exclusion criteria: not reported. Loss of followup: not reported.	Trial 1: 1. I-125 (144Gy, TG-43) I-125 source strength ranged from 0.4 to 0.89mCi (median .55mCi). 2. Pd-103 (125Gy, NIST-99) and Pd-103 source strength ranged from 1.6 to 2.0mCi (median 2.0mCi). Trial 2: 1. Pd-103, delivering 90Gy (with 44Gy external beam irradiation delivered with a four-field arrangement, designed to cover the prostate and seminal vesicles with a 2cm margin (reduced to 1.0cm posteriorly). 2. Pd-103, delivering 115Gy 20Gy external beam irradiation delivered with a four-field arrangement, designed to cover the prostate and seminal vesicles with a 2cm margin (reduced to 1.0cm posteriorly).	Self reported urinary incontinence using standard American Urologic Association (AUA) Grade 1: Occasional use of incontinence pads (<1/week), Grade 2: Intermittent use of incontinence pads (<1/day), Grade 3: Regular use of incontinence pad or self-catheterization, Grade 4: Permanent catheter or surgical intervention	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F138. Clinical interventions to reduce risk and progression of urinary incontinence in males with urologic diseases (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Imamoglu, 2005[682] RCT to examine effects of macroplastique injection with artificial urinary sphincter implantation on postprostatectomy incontinence. Duration of followup: 48-60 months	45 patients with urinary incontinence for >6 months after radical retropubic prostatectomy, transvesical prostatectomy, and transurethral prostatectomy. Exclusion criteria: radiotherapy for prostate carcinoma, minimum bladder capacity of 150cc, detrusor instability or hyperreflexia. Loss of followup: not reported.	1. Artificial urethral sphincter implantation. 2. Macroplastique injection (polydimethylslioxane elastomer implants as the solute component and hydrogel as the carrier) of 5–7.5cc above or around the striated sphincter region of the urethra submucosally.	Minimal incontinence was defined as total number of pads, total weight of pads. Continent (“dry”)- no need to use pads; ‘‘socially continent’’ - <1pad; ‘incontinent’’- >1pad/day	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Deliveliotis, 2005 [683] RCT to examine effects of applying local steroids to the neurovascular bundles of the prostate after bilateral nerve-sparing radical retropubic prostatectomy. Duration of followup: 12 months	60 potent men <60 years old undergoing bilateral nerve-sparing radical retropubic prostatectomy for clinically localized prostate cancer Exclusion criteria: allergy to steroids, assistance to obtain erections. Loss of followup: not reported.	1. 10ml of betamethasone cream 0.1% was applied locally to both neurovascular bundles. 2. Usual neurovascular bundles with no corticoid cream.	Urinary continence - wearing no pads or one pad that remained dry.	Intention to teat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Parsons , 2004[684] Placebo controlled RCT to examine effects of postoperative methylprednisolone on urinary incontinence after nerve-sparing radical retropubic prostatectomy. Duration: 6 days Duration of followup: 12 months	70 potent men ≤ 60 years old, undergoing bilateral nerve-sparing radical retropubic prostatectomy for clinically localized adenocarcinoma of the prostate. Exclusion criteria: no sexual partner, prior history of an allergic reaction to steroids, prior steroid use, or active use of sildenafil citrate for the treatment of erectile dysfunction. Loss of followup: 11.4%.	1. Methylprednisolone beginning on postoperative day 1: 24mg intravenously on postoperative day 1, 20mg orally on day 2, 16mg orally on day 3, 12mg orally on day 4, 8mg orally on day 5, and 4mg/orally on day 6. 2. Placebo.	Urinary continence as participant-reported wearing no pads or a single pad that remained dry.	No Intention to treat. Double blind. Central randomization. Allocation concealment unclear Baseline data did not confirm adequacy of randomization. Sample size justified

Table F138. Clinical interventions to reduce risk and progression of urinary incontinence in males with urologic diseases (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Akakura, 1999[685] RCT to examine effects of radical prostatectomy versus radiotherapy with the combination of endocrine therapy on urinary incontinence. Duration of followup: 58.5 months	100 patients 75 years old or younger with a performance status of 0 or 1 and adenocarcinoma of the prostate by needle core biopsy before treatment. Exclusion criteria: obvious enlargement of pelvic lymph nodes by computed tomography or magnetic resonance imaging. Loss of followup: 5%.	1. Radical prostatectomy with pelvic lymph node dissection with 300mg of diethylstilbestrol diphosphate/day 8 weeks before surgery or radiation, and continued thereafter. 2. External beam radiation by linear accelerator with 40 to 50Gy to the whole pelvis and a 20Gy boost to the prostatic area and with 300mg of diethylstilbestrol diphosphate/day 8 weeks before surgery or radiation, and continued thereafter	Urinary incontinence using quality-of-life questionnaire of EORTC.	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data did not confirm adequacy of randomization. Sample size not justified.
Fransson, 2001[686] RCT to examine effects of radiotherapy for localized prostate carcinoma. Duration of followup: 30-40 months	166 patients with localized prostate carcinoma cytologically or histologically verified as T1a-T2, G1-G2, pN0, and M0. Exclusion criteria: expected survival <10 years. Loss of followup: 35%.	1. Radiotherapy with a total dose of 4.8Gy (range, 62.3–70.0Gy) given for 5 days a week, 2Gy per fraction. 2. Active surveillance	Self reported urinary and fecal incontinence using validated symptom specific self-assessment questionnaire, QUFW94 with values between 0 and 10; 0 - “no problem/very good function” and 10 - “many problems/very bad function.”	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Gupta, 2002[687] RCT to examine effects of transurethral vesection of the prostate or vapor resection of prostate on urinary incontinence. Duration of followup: 1 year	100 patients with benign prostatic hyperplasia and prostate size >40cc. Exclusion criteria: finasteride preoperatively, histopathologic adenocarcinoma of the prostate. Loss of followup: not reported	1. Transurethral vesection of the prostate with the thick vapor resection loop using electrosurgical generator with settings of 120 to 150W and 50 to 70W for cutting and coagulating. 2. Transurethral resection of the prostate with standard wire loop using electrosurgical generator with settings of 70 to 80W and 40 to 50W for cutting and coagulating	Self reported urinary incontinence using International Prostate Symptom Score. Urodynamic outcomes.	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Gallucci ,1998[688] RCT to examine effects of transurethral electrovaporization of the prostate on urinary incontinence. Duration of followup: 12 months	150 patients with symptoms due to obstructive benign prostatic hypertrophy, urodynamically obstructed. Exclusion criteria: complete urinary retention, bladder calculi, neurogenic bladder, prostate weight>70g, bladder cancer, prostate cancer, mental illness. Loss of followup: none	1. Transurethral electrovaporization of the prostate. 2. Transurethral resection of the prostate	I-PSS score. Urodynamic outcomes	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F138. Clinical interventions to reduce risk and progression of urinary incontinence in males with urologic diseases (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Wilson, 2006[689] RCT to examine effects of holmium laser enucleation of the prostate or transurethral resection of the prostate for treatment of men with bladder outflow obstruction secondary to benign prostatic hyperplasia. Duration of followup: 24 months	61 men with bladder outflow obstruction secondary to benign prostatic hyperplasia and prostate size 40-200g, maximum urinary flow rate of 15 ml/second or less, American Urological Association symptom score of ≥8, post-void residual assessment of less than 400ml, and urodynamic Schaffer grade 2 or greater. Exclusion criteria: prostatic carcinoma, catheterization, history of previous urethral or prostatic surgery. Loss of followup: 21.3%	1. Holmium laser enucleation of the prostate with maximum power set at 100W for each case. 2. Transurethral resection of the prostate with a tungsten cutting wire at 160W cutting and 80W coagulating current	Urinary incontinence using American Urological Association symptom score. Maximum urinary flow rates	No Intention to treat. Open label. Balanced blocked randomization schedule (block of six patients). Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Steineck , 2002[690] RCT to examine the effects of radical prostatectomy or watchful waiting of incontinence in patients with localized cancer. Duration of follow up: 12 months after surgery and 14 months after randomization	376 men <75 years with life expectancy >10 years (as judged by the attending physician) from the Scandinavian Prostatic Cancer Group Study # 4, with localized prostate cancer (T0d, T1, or T2 and grade 1 or 2 according to the criteria of the World Health Organization Against Cancer). Exclusion criteria: previously diagnosed cancer, concurrent disorder considered to increase the risk of operative mortality, or inability to comply with treatment and follow-up. Loss of follow up: 13.3%	1. Radical prostatectomy 2. Watchful waiting with no advice for initial radical therapy was given	Self reported urinary incontinence using the Spielberger's Trait Measure from the State–Trait Anxiety Inventory	Intention-to-treat. Open label. Randomization not described in this paper. Allocation concealment not clear. Baseline data did not confirm the adequacy of randomization. Adjustment for age, time from randomization to completion of the questionnaire, date of responding to the questionnaire, and educational level did not effect the relative risks

Table F139. Effects of clinical intervention on urinary continence in males (events) (sorted by rate of urinary continence after active treatment, from highest to lowest)

Table F143. Effects of hormone replacement therapy on risk and progression of urinary incontinence in women

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Goldstein, 2005[691] Placebo-controlled RCT to examine the efficacy and safety of raloxifene for osteoporosis prevention in postmenopausal women. Duration: 36 months	619 women age 40 - 60 years, postmenopausal (naturally or surgically), with a hysterectomy no more than 15 years before beginning study, serum estradiol ≤73pmol/l (≤ 20pg/ml) and follicle-stimulating hormone ≥40 IU/l. Exclusion criteria : history of breast carcinoma or estrogen-dependent tumors, cancer within the last 5 years (except excised skin cancers), estrogen therapy (other than vaginal estrogens), progestin, androgen, calcitonin, or systemic corticosteroids within the previous 6 months, a history of thromboembolic disorders or diabetes mellitus or other endocrine disorders requiring therapy (except thyroid hormone replacement), or serious postmenopausal symptoms. Loss of followup 4.5%; Discontinuation - adverse events (17.6%), personal reasons (11.0%). The percentage of women missing at least 20% of study medication was similar across the groups (10% to 14%; *P* = 0.71)	1. Raloxifene HCl 60mg/day. 2. Raloxifene HCl 150mg/day. 3. Conjugated equine estrogen 0.625mg/day 4. Placebo supplement of 400/600mg/day elemental calcium	Self-reported new or worsening urinary incontinence rated as "mild," "moderate," or "severe."	Intention to treat. Double-blind. Randomized block design (block size = 4); baseline data confirmed adequate randomization. No justification of sample size. Incontinence - secondary outcome.
Vardy, 2003[692] Placebo-controlled RCT to examine urogenital effects of raloxifene, tamoxifen, conjugated equine estrogen, and placebo in healthy postmenopausal women Duration: 5 month	100 healthy white postmenopausal women > 1 year from last menstrual period, age 45 - 70 years, with normal mammogram within 6 months of the study and free from any serious acute or chronic medical disorder. Exclusion criteria: previous hysterectomy or reconstructive pelvic surgery, intake of estrogen, calcitonin, fluoride steroid, or diuretic therapy within 6 months, contraindication to hormone replacement therapy or either SERM	1. 0.625mg/day conjugated equine estrogen 2. 20mgday tamoxifen 3. 60mg/day raloxifene 4. Placebo	Weekly symptom diaries to report urinary urgency, frequency, and incontinence ranked as “new,” “worsened,” “improved,” or “remained the same.” Pelvic organ prolapse quantitation. Urethral axis deflection by cotton swab.	Intention to treat not stated. Double-blind. Allocation concealment unclear. Subjects had Incontinence at baseline (32.7%) with unknown distribution in the groups. No justification for sample size.
Warming, 2003[693] Placebo-controlled RCT To examine the adverse events after 12 month treatment with levormeloxifene and followup of 12	234 generally healthy women, age 45 - 65 years, at least 1 year postmenopausal and with an intact uterus. Exclusion criteria: known or suspected acute or chronic disease, or taking medication known to interfere with the results of the study. Completed 12 months treatment 77% Withdrawn at the end of 12 months 0.7% Included in followup 78% Withdrawn during followup (adverse event) 0.3% Completed 12-month followup 77%	1. Levormeloxi-fene at 1.25 ,5, 10, or 20mg/per day, 2. Continuous combined HRT (17β-oestradiol 1 mg and norethisterone acetate 0.5mg per	Self-reported urinary incontinence (including worsening of a previously existing condition). Utero-vaginal prolapse detected by transvaginal ultrasonography	Intention to treat not stated. Double-blind. Allocation Concealment unclear. No justification for sample size. Outcomes reported independent of the

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
months without treatment.		day). 3. Placebo: calcium supplement 500/mg/day		dose of levormeloxifene.
Steinauer, 2005[694] Placebo-controlled RCT The Heart Estrogen/progestin Replacement Study to examine HRT for the prevention of heart disease events in women with established heart disease Duration: 4.2 years	1,208 postmenopausal women age <80 years, with coronary heart disease and an intact uterus who reported no loss of urine in the previous 7 days at baseline Loss of followup: 1 participant taking hormone therapy discontinued due to adverse reactions, 58 died, and 5 failed to return, and 11 were lost to followup for other reasons. Placebo group: 60 died, 5 failed to return, and 12 were lost to followup for other reasons. The compliance rates were 80% in the placebo group and 68% in the hormone groups	1. Conjugated estrogen (0.625mg) and medroxy progesterone acetate (2.5mg) in 1 pill 2. Identical looking placebo	Self-reported urinary incontinence (including worsening of a previously existing condition). Stress incontinence : unintentionally leaking some urine with coughing, sneezing, straining, laughing, or lifting Urge incontinence: unintentionally leaking some urine before getting to the bathroom. Weekly incontinence >1 episodes in the previous week	Intention to treat. Double-blind. Randomization in each of 20 clinical centers using randomly permuted blocks of 4. Groups of continent women were comparable at baseline. No justification for sample size Incontinence - secondary outcome.
Hendrix, 2005[695] Placebo-controlled RCT. Women's Health Initiative Study to examine effects of HRT in preventing coronary heart disease and hip fractures in postmenopausal women. Duration: 1 year	25,597 women age 50 to 79 years, postmenopausal, and likely to reside in the study area for 3 years with adherence rate of 80% or greater during 4-week placebo run-in. Exclusion criteria: breast cancer, other invasive cancer in the last 10 years, venous thromboembolism, hypertriglyceridemia, medical condition likely to result in death within 3 years, or unwillingness to be randomized to placebo, severe menopausal symptoms. Loss of followup: in 1st group 0.2% deceased and 0.1% lost to followup, [9.7]% and 6.6% in placebo stopped taking study pills for various reasons. Adherence 74% and 81% in the placebo group at 1 year. 2nd active group: 0.4% deceased, 8.4% and 8.0% in placebo stopped taking study pills for various reasons. Adherence: 77.4% and 81.4% in placebo at 1 year.	1. 0.625mg/day conjugated equine estrogen plus 2. 5mg/day of medroxyprogesterone acetate 2. 0.625mg/day conjugated equine estrogen 3. Placebo estrogen plus progestin 4. Placebo estrogen alone	Self-reported incident at 1 year. Prevalent incontinence: ever leaking any amount of urine. Stress incontinence: leaking of urine during a cough, laugh, sneeze, lift, stand up or exercise. Urge incontinence – leaking of urine before getting to the toilet. Mixed incontinence – a combination of stress and urge	Intention to treat Double-blind. Central randomization at a 1:1 ratio. The study pill bottles had unique bar codes and computer-based selection to enable double-blinded dispensing. Incontinence - secondary outcome. Baseline data confirmed adequacy of randomization.

Table F143. Effects of hormone replacement therapy on risk and progression of urinary incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
			symptoms. Continence – no leaking urine once during the past year or no longer leaking urine. Changes in self-reported frequency, amount (barely noticeable, soaked underpants, soaked through to outer clothing), limitations in daily activities (never to very often), and bother/disturbance (not at all to very disturbing) as better, same, or worse	
Vestergaard, 2003[696] RCT of The Danish Osteoporosis Prevention Study (DOPS) to examine effects of HRT for primary prevention of osteoporotic fractures in healthy recently postmenopausal women. Duration: 5 years.	1,006 women age (45-58 years) from a random sample of 47,720 with intact uterus and 3-24 months past last menstrual bleeding or experiencing perimenopausal symptoms (including irregular menstruations), the latter combined with elevated serum follicular stimulating hormone (FSH), and hysterectomised women age 45-52 years with elevated FSH. Exclusion criteria: (1) Metabolic bone disease, including osteoporosis defined as nontraumatic vertebral fractures on X-ray. (2) Current oestrogen use or oestrogen use within the past 3 months. (3) Current or past treatment with glucocorticoids <6 months. (4) Current or past malignancy. (5) Newly diagnosed or uncontrolled chronic disease. (6) Alcohol or drug addiction	1. Sequential oestrogen and progestogen (28 day cycle: 2mg oestradiol for the first 12 days, 2mg oestradiol and 1mg norethisterone acetate for the next 10 days followed by 1mg oestradiol for 6 days, in women with intact uterus 2. Continuous oestradiol 2mg/day in hysterectomised women 3. No HRT	Self reported presence of incontinence. Symptom scores were recorded on a modified Greene scale (range 0-4 with 0 equaling no symptoms, and 4 maximal symptoms).	Intention to treat. Open label. Group 1 and 2 were block-randomized in groups of ten by the envelope method. Baseline data providing difference between treatment regimens not analyzed. No justification for sample size. Outcomes reported in two groups: HRT vs. No HRT.

Table F143. Effects of hormone replacement therapy on risk and progression of urinary incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Goldstein, 2002[697] Placebo-controlled RCT to examine different doses of levormeloxifene for the treatment of postmenopausal osteoporosis and prevention of vertebral compression fractures in elderly women. Planned duration: 3 years, stopped after 10 months	2,924 generally healthy women age ≥65 years, with diagnosed osteoporosis. Exclusion criteria: known or suspected hormone-dependent or other cancers, previous myocardial infarctions, deep venous thrombosis, corticosteroid treatment, or endometrial thickness >8mm, as gauged by transvaginal ultrasound scanning. Loss of followup: 9.6% before the trial was discontinued because of adverse events and other reasons that included noncompliance	1. 0.5 or 1.25mg of levormeloxifene 2. Placebo: Daily dietary supplement of 800/1000mg calcium and 400IU vitamin D	Self reported new urinary incontinence, micturition frequency, and the frequency of urinary incontinence as an adverse event	Intention to treat not stated. Double-blind. No justification for the sample size. Allocation concealment unclear. Only a subset of the data was ever validated; no summary statistics were calculated for demographic data. No justification for sample size.
Kok, 1999[698] Randomized non controlled clinical trial to examine effects of HRT for endometrial protection in healthy postmenopausal women. Duration: 6 months	102 healthy postmenopausal nonhysterectomized women amenorrhoeic for at least 12 months with postmenopausal status confirmed by elevated serum FSH (>35 IU/l) and LH (>10 IU/l) levels and decreased oestradiol (<120pmol/l) levels. Loss of followup: 7% stopped HRT due to irregular bleeding episodes, lack of medication compliance and lack of improvement of climacterial complaints other than urinary complaints	2mg 17 beta-estradiol continuously combined with one of four doses (2.5, 5, 10, or 15mg) of dydrogesterone. No placebo group: before-after comparison in one active group	Diurnal micturition – number of reported voids during the day, frequency as more than seven times a day. Nocturnal micturition - number of times one has to get up to void at night and nocturia, a condition with more than two voids a night	Intention to treat not stated. Double-blind. Randomization with permuted blocks Allocation concealment unclear. Nonparametric tests for randomization bias. Baseline data confirmed the adequacy of randomization. No justification for sample size.
Long, 2006[699] RCT to examine effects of oral and vaginal estrogen therapy on the lower urinary tract in postmenopausal	57 hysterectomised, postmenopausal women with serum FSH level of >40 IU/l and an E_2 level of <20pg/ml. Exclusion criteria: vasoactive medication, prior breast or endometrial cancer, diabetes, anemia (Hg <10g/dl), urinary tract infection, use of HRT in the previous 12 months, and non visible periurethral vessels during ultrasonographic assessment. 16 patients interrupting ET were excluded from the analysis	1. Oral 0.625mg of conjugated equine estrogen per tablet 2. Topical 0.625mg conjugated equine estrogen per 1g vaginal cream	The Bristol Female Lower Urinary Tract Symptoms Questionnaires and standardized urinary diary to report episodes of total, urge, and stress	No Intention to treat. Two investigators were blind to each other's results. Allocation concealment unclear. No

Table F143. Effects of hormone replacement therapy on risk and progression of urinary incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
women with prior hysterectomy Duration: 3 months			urinary incontinence and episodes of stress urinary incontinence/week	justification for the sample size. No comparison provided between groups, before/after treatments only.
Jackson, 2002[700] Placebo-controlled RCT to examine effects of HRT in improvement of quantity or quality, of pelvic collagen in postmenopausal women. Duration: 6 months	67 postmenopausal women with urodynamic diagnosis of genuine stress incontinence without symptomatic prolapse. 55 consented to vaginal biopsy and were randomized. Loss of followup: 3 dropped the trial due to personal reasons, vaginal discharge, and advice from general practitioner. 3 preferred not to undergo a second biopsy. 49 women included in the analysis	1. Oestradiol valerate 2mg/day. 2. Placebo	Clinical improvement in urinary incontinence diagnosed with urodynamic tests	No Intention to treat. Double-blind. Randomization (computer generated simple random sampling) by hospital pharmacy. Allocation concealment unclear. Sample size justified for the primary outcome-% of total collagen. No baseline comparison reported.
Fantl, 1996[701] Placebo-controlled RCT to examine efficacy of cyclic postmenopausal hormone replacement in treating urinary incontinence in hypo estrogenic women. Duration: 3 months	83 hypo estrogenic women 45 years or older, who reported involuntary loss of urine at least once a week. Exclusion criteria: institutionalization, permanent catheterization, impaired mental status, functional disability limiting use of the toilet (alone or assisted), neuropathic or uncontrolled metabolic conditions, chronic urinary tract infection, reversible causes of urinary incontinence, or major contraindications for the use of estrogen therapy. Loss of followup: none	1. Conjugated equine estrogens (0.625mg) and medroxy-progesterone (10mg) cyclically. 2. Placebo	Number of incontinent episodes/week recorded in standardized urinary diary. Amount of fluid loss (measured by a standardized pad test) and the number of voluntary diurnal and nocturnal micturition per week obtained with the same diary technique.	Intention to treat not stated. Double-blind. Blocked randomization stratified by baseline severity of urinary incontinence was performed at each site with sets of sequenced, sealed, opaque envelopes, each containing the bottle number to be given to an individual patient. Sample size not justified.

Table F143. Effects of hormone replacement therapy on risk and progression of urinary incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Jackson,1999[702] Placebo-controlled RCT to examine effect of hormone replacement therapy on post-menopausal urinary stress incontinence Duration: 6 months	67 post-menopausal women with genuine stress incontinence confirmed with urodynamic evaluation, not taking hormone replacement therapy. Exclusion criteria: history of cancer of the endometrium, liver, or breast; endometrium more than 4mm thick. Loss of followup: 5 women did not complete the trial; one woman underwent surgical treatment	1. Oestradiol valerate 2mg daily. 2. Placebo	Urinary diary to report subjective incontinence symptoms, frequency, and severity. Standard perineal pad test, and urodynamic evaluation to measure functional capacity, detrusor pressure, voiding flow, post-micturition residual, and volume at first desire to micturate	Intention to treat not stated. Double-blind. Randomization by hospital pharmacy with computer generated blocks (5 oestradiol and 5 placebos). Baseline data confirmed the adequacy of randomization. Sample size justified.
Ishiko, 2001[703] RCT to examine effects of combination pelvic floor muscle exercise and estriol on postmenopausal stress incontinence. Duration: 2 years	73 women with postmenopausal stress incontinence. Exclusion criteria: urge or mixed incontinence. Loss of followup: 6 women withdrew for personal reasons, one due to adverse effects	1. Combination of estriol (1 mg/day) and pelvic floor muscle exercise 2. Pelvic floor muscle exercise alone	Standardized questionnaire to report severity of stress incontinence scored ranked mild (10-17), moderate (18-23), and severe (24-26) incontinence. Continent rate in groups	No Intention to treat. Open label. Allocation concealment unclear. Baseline data confirmed the adequacy of randomization. No justification for sample size.
Rufford, 2003[704] Placebo-controlled RCT to examine the effect of systemic estrogen on the 'urge syndrome' in postmenopausal women. Duration: 6 months	40 postmenopausal women (>1 year at menopause) with the 'urge syndrome'; with estradiol <150pmol/l in women after hysterectomy with no contraindication for estrogen therapy. Exclusion criteria: medication treatment of urge syndrome, diuretics, HRT, history of diabetes, endometrial thickness >4mm urinary tract infection, pelvic masses and urogenital prolapse. Loss of followup: 11 women decided not to participate	1. 25mg 17 beta-estradiol implant subcutaneous tissue. 2. Placebo implant	Urodynamic outcome; frequency volume chart with self reported incontinence symptoms	No intention to treat. Double blind. Allocation concealment adequate. Baseline data confirmed the adequacy of randomization. Sample size justified.

Table F143. Effects of hormone replacement therapy on risk and progression of urinary incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Ahlstrom, 1990[705] Placebo-controlled crossover RCT to examine effects of estrogen with alpha-adreno-receptor agonist compared to estrogen alone on incontinence in postmenopausal women. Duration: 6 weeks	29 postmenopausal women with slight to severe stress urinary incontinence and estrogen deficiency symptoms confirmed during urodynamic exam. Exclusion criteria: use of hypotensives, neuroleptics, sedatives, antihistamines, ephedrine, HRT, bacteriuria, history of breast cancer. Loss of followup: none, one woman was excluded from the analysis due to failure in medication	1. Estriol 4mg/day and 50mg phenyl-propanolamine twice daily. 2. Estriol 4mg/day and placebo	Urodynamic outcomes : mean maximum urethral pressure, mean maximum urethral closure, mean functional urethral length, and abdominal pressure transmission ratio to the urethra	No intention to treat. Double blind. Allocation concealment unclear. Baseline data not provided but reported as balanced. Sample size not justified.
Cardozo, 1993[706] Placebo-controlled multicenter RCT to examine effects of oestriol in treatment of postmenopausal sensory and motor urge incontinence. Duration: 3 months	64 postmenopausal women with symptoms of sensory and motor urge incontinence, at least 1 year without menstruation, FSH>40UI/l and oestradiol <220pmol/l. Exclusion criteria: voiding difficulties, incontinence before menopause, pelvic anatomical defect requiring surgery, neurological disease, medications to treat incontinence. Loss of followup: 27%	3mg oral oestriol/day. Placebo	Self reported incontinence episodes/day. Urodynamic outcomes.	No intention to treat. Double-blind. Central stratified by incontinence randomization. Allocation concealment adequate. Baseline data confirmed the adequacy of randomization. Sample size justified.
Kinn, 1988[707] Cross-over RCT to examine effects of oral estriol, phenylpropanolamine, and its combination on stress urinary incontinence in postmenopausal women Duration: 4 weeks/treatment	36 women 1 or more years after post-menopause with stress incontinence verified with urodynamic examination. Exclusion criteria: use of hormones, alpha-agonists and alpha-antagonists, urinary tract infection. Loss of followup: 16.6%	1. Oral estriol (Triovex, 2mg x 1) + Placebo. 2. Phenylpro-panolamine (Kontexin, 50mg x 2) + Placebo. 3. Combination of oral estriol and phenylpropano-lamine	Micturition schedule recorded in the diary. Urodynamic outcomes.	Intention to treat. Single blind (subjects). Randomization and allocation concealment not reported. Baseline data not reported but stated the same in the treatment groups. Sample size not justified.
Wilson, 1987[708] Placebo-controlled RCT to examine	36 postmenopausal women with stress incontinence confirmed with urodynamic examination. Exclusion criteria: outflow obstruction, use of HRT, urinary tract infection.	1. Cyclical treatment with piperazine	7-day bladder charts, urethral pressure profiles (UPP)	No intention to treat. Double-blind. Randomization with

Table F143. Effects of hormone replacement therapy on risk and progression of urinary incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
effect of oestrogens in treatment of genuine stress incontinence in postmenopausal women Duration: 3 months	Loss of followup: 6%.	oestrone sulphate 2. Placebo		standard statistical tables with random numbers. Allocation concealment not reported. Baseline data not reported but stated the same in the treatment groups. Sample size not justified.
Waetjen, 2004[709] RCT to examine effects of treatment with raloxifene on urinary incontinence in postmenopausal women. Duration: 3 years.	Multiple Outcomes of Raloxifene trial included women age ≤80 years, >2 years past menopause, who met the World Health Organization criteria for osteoporosis. Exclusion criteria: use of estrogen, progestins, or androgens within 6 months of enrollment, known or suspected cancer, abnormal uterine bleeding, history of thromboembolic disease, and secondary causes of osteoporosis. Loss of followup: 21%	Daily supplements of 400 to 600IU of cholecalciferol and 500mg of calcium raloxifene 60mg/day or raloxifene 120mg/day Placebo	Severity of incontinence using the validated Sandvik 4-level index: mild, moderate, severe, and very severe. "Worsened" – severity score was higher 3 years after baseline, "no change" when there was no change from baseline, and "improved" if the severity score decreased. The effect of incontinence on daily activities in 0 (none) to 10(most of the time). The effect of incontinence on feeling with scale from 0 (not at all) to-10 (extremely disturbing)	No intention to treat Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.
Grady, 2001[710] RCT to examine the effects of postmenopausal hormone therapy on severity of	2,763 postmenopausal women < 80 years with coronary disease and intact uteri- from the Heart and Estrogen/Progestin Replacement Study. The outcomes are reported for 1,525 women who reported at least one episode of incontinence/week at baseline. Exclusion criteria: average compliance with treatment <80% by pill count Loss of follow up: 21% and 16% in active and placebo groups	1. 0.625mg/day of conjugated estrogens plus 2.5 mg of medroxyprogester one acetate in one	Self reported severity of incontinence as -improved (decrease of at least 2 episodes/week),	No Intention to treat. Double blind. Randomization using randomly permuted blocks of size 4 stratified by

Table F143. Effects of hormone replacement therapy on risk and progression of urinary incontinence in women (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
urinary incontinence. Duration of follow up: 4.1 years	respectively (excluded from analysis because of bad compliance).	tablet 2.Placebo	-unchanged (change of at most 1 episode/week), -worsened (increase of at least 2 episodes/week)	site. Allocation concealment adequate (reported previously). Sample size justified

Table F144. Effects local estrogen therapy on progression of urinary incontinence in women

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Von Holst, 2000[711] Placebo controlled RCT with initial screening phase (phase I), a 3-month placebo-controlled phase (phase II) and a 3-month open followup phase (phase III) to examine the efficacy and tolerability of a continuously applied 7-day-Estradiol patch in the treatment of hysterectomised women with postmenopausal complaints compared with placebo Duration: 6 months	186 hysterectomised women age 40-65 years, with postmenopausal complaints, normal gynecological history and examination, serum estradiol < 30pg/ml and follicle stimulating hormone > 30IU/ml. Exclusion criteria: use of sex hormones taken orally within the last 28 days; locally-applied sex hormones within the last 21 days or injectable sex hormones within the last 6 months. Loss of followup: one patient did not receive any study medication and 12 patients (5 in active and 7 in placebo group) were excluded from the intention-to-treat analysis of the placebo-controlled phase due to lack of availability of efficacy data	1. 7-day-Estradiol patch (1.5mg estradiol/week or 50mg estradiol/24 hours). All patients received active drug therapy (7-days). Estradiol patch) for a further 3 months (three cycles). 2. Placebo once-weekly	The sum of scores for self-reported incontinence symptoms that occurred since the previous visit. The severity of these symptoms was assessed on a four-point scale (0; no symptoms, 1; mild symptoms; 2; moderate symptoms, 3; severe and heavy symptoms).	Intention to treat. Double-blind. Randomization with 1:1 ratio. Allocation concealment unclear. Baseline data confirmed the adequacy of randomization (no data presented). No justification for sample size.
Waetjen, 2005[712] Placebo-controlled RCT to examine effect of ultra low-dose transdermal estradiol (E2) on incontinence in postmenopausal women Duration: 2 years	417 postmenopausal women age 60-80 years, with a uterus and at least 5 years after menopause, with normal bone mineral density for age (*z* score not below –2.0 at the lumbar spine). Exclusion criteria: use of estrogen or progestin within 3 months of randomization or having unexplained uterine bleeding, endometrial hyperplasia or an endometrium 5mm or more in double-wall thickness, abnormal mammogram, breast cancer, a history of metabolic bone disease, cancer, coronary disease, cerebrovascular disease, uncontrolled hypertension, uncontrolled thyroid disease, liver disease, fasting triglycerides >300mg/dl, or fasting glucose >180mg/dl. Loss of followup: 10%. 83% of the women in active group and 77% in the placebo group continued to use their assigned patch; 84% in both groups used at least 75% of their patches	1. 14mg of transdermal E2 per day. 2. Placebo.	Self-reported stress Incontinence: leakage “while coughing, sneezing, straining, laughing, or lifting”; and urge incontinence: “an urge to urinate and could not get to the toilet fast enough.” Changes in frequency of incontinence from baseline to 4 months and 2 years as	Intention to treat. Double-blind. Computer-generated randomization stratified by clinical center in blocks of 4. Treatment numbers were printed on labels adhered to identical-looking study medications. Allocation concealment

Table F144. Effects local estrogen therapy on progression of urinary incontinence in womenwomen (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
			"worsened": episodes increased by 2 or more per week; "unchanged": frequency changed by no more than 1 episode per week; "improved": incontinence episodes per week decreased by 2 or more	adequate. Baseline data confirmed the adequacy of randomization. Sample size justified.
Holtedahl, 1998[713] RCT to examine effects of conservative treatment for urinary incontinence Duration: 6 months for controlled trial	95 women, 50-74 years of age with regular incontinence (>2 leakage episodes per month) diagnosed during gynecological examinations, with positive pad test, or self reported in 48 hour chart. Exclusion criteria: Cardiac pacemaker, dementia, medical conditions that would prevent following the protocol. Loss of followup: 3 patients were found protocol deviant and excluded from the analysis.	1. Local estrogen in vagitories or jelly plus physiotherapy and electrostimulation 2. Delayed treatment	1. Change in severity of incontinence from start of treatment (index range 0-8). 2. Change in impact from start of treatment (index range 0-4). 3. Quantitative measures in relation to micturition. 4. Criteria based classification; cured, improved, unchanged, worse	No intention to treat. Randomization by phone from the university department. Allocation concealment unclear. Open label. Baseline data confirmed adequacy of randomization. Sample size justified.
Dessole, 2004 [714] Placebo-controlled RCT to examine the efficacy and safety of intravaginal estriol administration on urinary incontinence, urogenital atrophy, and recurrent urinary tract infections in postmenopausal women.	88 postmenopausal women with incontinence confirmed by the direct visualization of loss of urine from the urethra during the standard stress test and by urodynamic investigation. Exclusion criteria: estrogen treatment, anatomical lesions of the urogenital tract, detrusor over activity and abnormal maximal cystometric capacity; presence of severe systemic disorders, thromboembolic diseases, biliary lithiasis, previous breast or uterine cancer, abnormal uterine bleeding, and body mass index of ≥25kg/ml. Loss of followup: 11 women, 4 due to discomfort and 3 due to local adverse reactions	1. Intravaginal estriol ovules: 1 ovule/day (1mg) for 2 weeks and then 2 ovules/week for 6 months. 2. Placebo: vaginal suppositories	Self-reported urinary incontinence complaints as none, mild, moderate, or severe. Cured: change from "mild," "moderate," "severe" to "none." Improved – change from "moderate" to "mild" or from "severe" to "moderate/mild." Urodynamic outcomes: mean	Intention to treat. Double-blind. Randomization was obtained using sets of sequenced, sealed, opaque envelopes, each containing the bottle number to be given to each participant. Allocation concealment adequate. Baseline data confirmed

Table F144. Effects local estrogen therapy on progression of urinary incontinence in womenwomen (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Duration: 6 months			maximum urethral pressure, mean maximum urethral closure, mean functional urethral length, and abdominal pressure transmission ratio to the urethra. Urethrocystometry outcomes.	adequacy of randomization. Sample size justified.
Zullo, 2005[632] RCT to examine the efficacy of tension-free vaginal tape procedure and topical estrogen therapy on overactive bladder symptoms in menopausal women. Duration: 6 months	59 women with confirmed urodynamic stress incontinence, at least 1 year at menopause status, with serum estradiol <150pmol/l after hysterectomy, without contraindications to local estrogen therapy or to vaginal surgery. Exclusion criteria: urogenital prolapse above grade 1, detrusor over activity, intrinsic urethral sphincter deficiency, previous urogynecologic surgery, endometrial thickness more than 4mm, previous estrogen therapy within the past 6 months, unexplained uterine bleeding, or history of diabetes mellitus or insipidus, congestive cardiac failure, diuretic therapy, or neoplasms. Loss of followup: 3 eligible patients (5%) refused to participate	1. Tension-free vaginal tape procedure plus postoperative vaginal estrogen: 1 estriol ovule/day (1mg) for 1 month, then 2 ovules a week for the 5 months. 2. Tension-free vaginal tape procedure alone	Self-reported urinary symptoms using standardized questions (International Continence Society definition). Urodynamic outcomes.	No intention to treat. Single blind (physicians who performed all examinations and urodynamic assessment). Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.
Mikkelsen, 1995[715] Placebo-controlled RCT to examine effects of low-dose vaginal treatment with oestradiol before vaginal operation. Duration: 3 years	47 postmenopausal women (>1 year after menopause) scheduled for vaginal repair operation for genital descensus, 7 patients with urinary stress incontinence. Exclusion criteria: previous breast and uterine malignancies and other hormone dependent neoplasm, genital bleeding, acute thrombophlebitis. Loss of followup: 3 patients preferred conservative treatment, one died, 43 patients included in the analysis.	1. Vagifem (25mg/day oestradiol) administered as vaginal pessaries 3 weeks prior to surgery. 2. Placebo administered daily as vaginal pessaries 3 weeks prior to surgery.	Self perceived satisfaction with the treatment results, presented as cured rate.	No intention to treat. Double blind. Allocation concealment unclear. Baseline data not presented. Sample size not justified.
Akhila, 2006[716] RCT to examine the clinical efficacy of oral hormone	116 menopausal women with self-reported post-menopausal symptoms. Exclusion criteria: contraindications for hormone replacement therapy Loss of followup: 28 women excluded from the analysis.	1. Conjugated equine oral estrogen 0.625mg/day.	Self reported urinary symptoms of incontinence	No intention to treat. Open label. Allocation concealment

Table F144. Effects local estrogen therapy on progression of urinary incontinence in womenwomen (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
therapy, percutaneous gel, and transdermal patch in incontinent menopausal women. Duration: 1 year		2. Estradiol gel percutaneous 1.25g/day. 3. Transdermal patch with 50mg/day estradiol		unclear. Baseline data confirmed the adequacy of randomization. Sample size not justified.
Lose, 2000[717] RCT to examine the efficacy of an oestradiol-releasing vaginal ring and oestriol pessaries on lower urinary tract symptoms in postmenopausal women. Duration: 24 weeks	251 women reporting at least one bothersome lower urinary tract symptom after spontaneous or surgical post menopause. Exclusion criteria: known or suspected oestrogen-dependent neoplasia or malignancy, vaginal bleeding, clinically significant liver diseases, acute or intermittent porphyria, uterovaginal prolapse II-III, sex hormone treatment within 6 months, vaginal irritation or atrophy or ulceration. Loss of followup: none	1. Oestradiol-releasing ring, 7.5mg oestradiol. 2. Oestriol pessaries 0.5mg every second day.	Subjective scores of urgency, frequency, nocturia, dysuria, stress incontinence and urge incontinence.	Intention to treat. Open label. Central randomization. Allocation concealment unclear. Baseline data confirmed the adequacy of randomization. Sample size justified.
Chompootaweep 1998, [718] RCT to examine Effects of combined contraceptive intravaginal pill and standard conjugated estrogen cream on urogenital symptoms in postmenopausal Thai women. Duration: 8 weeks	40 postmenopausal women with urogenital symptoms related to estrogen deficiency. Exclusion criteria: thromboembolic disorders, severe liver diseases, estrogen-dependent tumors, high blood pressure (diastolic >140mm/Hg). Loss of followup: none.	1. Combined contraceptive intravaginal 1 pill/week at bedtime with 250mg levonorgestrel +30mg ethinyl estradiol. 2. Intravaginal conjugated estrogen cream (1g=0.625mg conjugated equine estrogens) at bedtime, 3/week in week 1, 2/week in week 2, and then 1/week for the 6 weeks	Self reported urinary urgency	Intention to treat not stated. Open label. Randomization procedure not reported. Allocation concealment unclear. Baseline data confirmed the adequacy of randomization. Sample size not justified.

Table F144. Effects local estrogen therapy on progression of urinary incontinence in womenwomen (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Blom,1995,[719] Crossover RCT to examine effects of a transdermal estradiol delivery system, alone and in combination with naproxen, in elderly women with confirmed urge incontinence. Duration: 8 weeks, 2 week washout period.	19 ambulant elderly women (52 years and older) with confirmed urge incontinence. Exclusion criteria: history of breast and endometrial cancer, thromboembolic disorders, severe hypertension, cardiac failure, diabetes mellitus, peptic ulceration. Loss of followup: 15.8%	1. Estradiol transdermal therapeutic system (0.05mg estradiol/day). 2. Estradiol transdermal therapeutic system (0.05mg estradiol/day) combined with naproxen 250mg tablets twice daily. 3. Placebo matching estradiol transdermal therapeutic system	Bladder-diary charts with frequency of urination, nocturia, and episodes of incontinence. Cystometric outcomes	No intention to treat. Single-blind. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.

Evidence Tables—Clinical Interventions to Reduce Risk of Incidence and Progression of Fecal Incontinence in Adults

Table F151. Clinical interventions on fecal incontinence in long-term care settings

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Effects of conservative management of fecal incontinence in the residents of nursing homes				
Schnelle, 1989[457] RCT to examine the effects of prompted voiding treatment of urinary incontinence in nursing home patients Duration: 5-10 days	126 incontinent patients from proprietary nursing homes (bed size 90-150), not affiliated with universities with correct discriminatory responses to the instructions to point shown subjects (pencil or glass). Exclusion criteria: continence, transfer to hospital during run-in period Loss of followup: 60% during the run-in period, 2.4% after randomization.	1. Prompted voiding treatment: check for incontinence, asking for needed toileting assistance, prompted voiding, and socially reinforced for appropriate toileting. 2. Usual care.	Urinary incontinence measured by nurse as wet checks/total checks and daily percent of appropriate toileting equal the number of times the patient voided in any toilet receptacle/total number of appropriate and incontinent voiding.	No intention to treat. Open label. Randomization and allocation concealment unclear. Baseline data not reported. Sample size not justified.
Ouslander, 2005[458] Crossover RCT to examine the effects of functional incidental training on incontinence in nursing homes. Duration 8 weeks	107 patients in the nursing homes, (resided in the facility at least 30 days and not initially admitted for short term care; able to state their name, or in the presence of aphasia, capable of reliably pointing to two objects; required assistance by two or fewer people for transfer from bed to chair; with life expectancy of at least 6 months; not receiving active physical therapy; and ages 60 and older. Exclusion criteria: continence, severe behavioral changes, terminally ill. Loss of followup: 60%	1. Functional Incidental Training: prompted voiding combined with individualized, functionally oriented endurance and strength-training exercises offered 4 times per day, 5 days per week 2. Usual care.	Urinary and fecal incontinence measured as wet checks/total checks of the participant's every 2 hours. Appropriate toileting rate: number of voids or bowel movements that were continent divided by the total number of voids or bowel movements. Change after the treatments in wet stool checks/total checks 0±22%, p<0.001	No intention to treat. Open label. Computer-generated random numbers. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.
Schnelle, 200[459] RCT to examine the effects of integrated incontinence care and exercise on urinary exercise in nursing home residents. Duration 8 months	256 incontinent residents in 4 nursing homes Exclusion criteria: post–acute skilled care units, terminally ill. Loss of followup: 26%	1. Integrated incontinence care and exercise every 2 hours 5 days a week including fluid prompting, prompted toileting, and regular wet checks, arm raise and arm curl exercises. 2. Usual care.	Fecal and urinary incontinence frequency as % of hourly wet checks and the appropriate toileting ratio calculated by dividing the number of times a resident used a toilet or toilet substitute by the total number of voids.	No intention to treat. Single blind. Computerized randomization. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size not justified.

Table F151. Clinical interventions on fecal incontinence in long-term care settings (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Effects of pharmacological intervention on progression of fecal incontinence in residents of long term care units				
Chassagne, 2000[720] RCT to examine the effects of treatment of constipation in elderly patients with fecal incontinence. Duration: 2 months	206 patients older than 65 years, residents of long-term care units, with daily fecal incontinence associated with chronic rectal emptying impairments such as fecal impaction. Exclusion criteria: severe diarrhea, non compliance (missing treatment of followup for >48 hours), refusal to participate. Loss of followup: 30.8%	1.Single osmotic laxative -30g lactulose 2. Osmotic agent 30g lactulose with a rectal stimulant (glycerine suppository) and weekly tap-water enemas	Episodes of fecal incontinence reported by patients and caregivers and associated details of soiled laundry	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Effects of individualized evidence-based conservative management on fecal incontinence in patients after stroke				
Harari, 2004[721] RCT to examine the effect of evidence based treatment program on fecal incontinence in patients after stroke. Duration of followup: 12 months	146 stroke patients with constipation (<2 bowel movements per week or >2 of the following on more than 1 in 4 occasions: straining, hard stools, feeling of incomplete evacuation), rectal outlet delay (need for self-digitation or feeling of anal blockage or prolonged defecation >10 minutes), and fecal incontinence (any degree of bowel leakage). Exclusion criteria: acute diarrhea or colonic disease other than diverticular disease. Loss of followup: 28%	1. RN assessment (history and rectal examination). 2. Patient care provider education with instructions on regular toilet habits, pelvic floor and sphincter-strengthening exercises, suppository insertion, and laxative and loperamide dose titration. 3. Evidence based treatment recommendations to patient's general practitioner 4. Regular care	Self-reported fecal incontinence and bowel movements measured by postal prospective 7-day stool diary. Visual analogue scores for severity rating, quality of life (bowel-related and SF-12).	Intention to treat. Open label. External computer generated randomization. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Effects of dietary interventions on progression of fecal incontinence in adults				
Bliss, 2001[722] Placebo-controlled RCT to examine the effects of fiber supplements in community-living adults who were incontinent loose or liquid stools. Duration 31 days	42 adult volunteers with incontinent loose or liquid stools at least weekly. Exclusion criteria: rectal prolapse, colon cancer, or a rectal fistula Lost of followup: 3 withdrew during the baseline period, 1 subject underwent a hysterectomy; 1 subject required treatment for diverticulitis, and 1 subject had a relapse of clinical depression with suicidal thoughts.	1. Usual diet supplemented with 25g of Metamucil, 7.1g of psyllium/day 2. Usual diet supplemented with 25g of gum arabic/day 3. Usual diet supplemented with 0.25g of pectin/d as a placebo	Self-reported fecal incontinence: involuntary passage of stool from the rectum. Stool composites	No intention to treat. Single blind. Allocation concealment unclear. Baseline data reported for age, BMI, and diet. Sample size not justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Effects of conservative management programs on postnatal fecal incontinence in females				
Glazener, 2001[483] RCT to examine the effect of nurse assessment with reinforcement of pelvic floor muscle training exercises and bladder training among women with persistent postnatal incontinence Duration: 12 months	747 women with urinary incontinence (defined as any involuntary loss of urine) three months postnatally, living within a 50 km radius and who delivered in these units during a 12 month recruitment period. Exclusion criteria: mothers of stillborn or dead neonates. Loss of followup: 25% in active and 35% in the control group.	1. Assessment by nurses of fecal incontinence with conservative advice on pelvic floor exercises (8-10 sessions each day of fast and slow contractions with the aim of 80-100 contractions daily) at five, seven, and nine months after delivery supplemented with bladder training if appropriate at seven and nine months. 2. The control group did not receive any visits from research nurses but received peripartum preparation, which sometimes included pelvic floor exercises, and could seek medical advice.	Self-reported Presence of fecal incontinence: ever lost control of wind or bowel motions from back passage between visits to the toilet	Intention to treat. Single blind. Computer generated randomization stratified by parity (4 versus fewer), method of delivery (caesarean versus other), and frequency of incontinence (at least once a week versus less). Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.
Glazener, 2005[484] Glazener, 2001[483] 6 years followup RCT, 2005 to examine the effect of nurse assessment with reinforcement of pelvic floor muscle training exercises and bladder training among women with persistent postnatal incontinence	747 women with urinary incontinence (defined as any involuntary loss of urine) three months postnatally, living within a 50km radius and who delivered in these units during a 12 month recruitment period. Exclusion criteria: mothers of stillborn or dead neonates. Loss of followup: 29% in active and 31% in the control group.	1. Assessment by nurses of fecal incontinence with conservative advice on pelvic floor exercises (of 8-10 sessions each day of fast and slow contractions with the aim of 80-100 contractions daily) at five, seven, and nine months after delivery supplemented with bladder training if appropriate at seven and nine months. 2. The control group did not receive any visits from research nurses but received peripartum preparation, which sometimes included pelvic floor exercises, and could seek medical advice	Self-reported 6 years after intervention presence of fecal incontinence: ever lost control of wind or bowel motions from back passage between visits to the toilet. Reported use of pelvic floor muscle training.	Intention to treat. Single blind. Computer generated randomization stratified by parity (4 versus fewer), method of delivery (caesarean versus other), and frequency of incontinence (at least once a week versus less). Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Adherence to the intervention was the same in active and control group 6 years at followup. Sample size justified.
Effects of behavioral interventions on incidence and progression of fecal incontinence in females				
Labrecque, 2000[482] RCT to examine the effects of perineal massage performed during	Pregnant women with (n = 493) and without (n = 1,034) previous vaginal birth. Exclusion criteria: high risk of cesarean delivery, including previous cesarean delivery for cephalopelvic disproportion; multiple gestation; placenta previa; severe fetal growth	1. Self administered perineal massage daily from the 34th or 35th week of pregnancy until delivery introducing 1 or 2 fingers 3 to 4 cm deep into the vagina and applying and	Self-reported fecal incontinence as: never, less than once per week, 1 to 6 times a week, once a day, and more than once a	Intention to treat. Single-blind. Central randomization balanced in blocks of 4 or 6 stratified by history of previous vaginal birth, specialty of the attending physician and

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
pregnancy on perineal symptoms after delivery Duration of followup: 3 months	restriction; breech presentation; preeclampsia; nonparticipating physicians; outbreak of genital herpes during the current pregnancy, inability to speak French or English, inability to understand the instructions, and already doing the massage. Loss of followup: 0.3%	maintaining pressure 2. Usual obstetric care	day.	hospital. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified
Fynes, 1999[723] RCT to examine the effects of augmented biofeedback with sensory biofeedback alone on fecal incontinence and anorectal manometry after obstetric trauma. Duration: 12 weeks	40 females with impaired fecal continence after obstetric anal sphincter injury. Exclusion criteria: not reported Loss of followup: 1 woman	1. Sensory biofeedback training with a vaginal perineometer and standard Kegel pelvic floor exercise. 2. Augmented biofeedback training of pelvic floor with audiovisual feedback and electric stimulation of slow and fast twitch fibers.	Fecal continence questionnaire and anorectal manometry outcomes: mean maximum resting pressure, mean maximum squeeze pressure, squeeze increment, vector symmetry index.	No intention to treat. Single blind. Computer generated randomization. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.
Ilnyckyj, 2005[724] RCT to examine the effects of biofeedback on fecal incontinence in women. Duration: 2 months	23 women over 18 years age with regular and frequent idiopathic fecal incontinence defined as soiling with formed or liquid stool and/or fecal staining or smearing of undergarments for 6 months or more, at least once weekly. Exclusion criteria: complicated diabetes, less than 6 months after postvaginal or Caesarean birth, irritable bowel syndrome, inability to attend weekly sessions for 2 months, and conversational insufficient English. Loss of followup: 22%.	1. Education and explanation and instruction in pelvic floor muscle strengthening exercises with max possible squeeze duration for 5 repetitions spaced by a 20 second pause, 6 times/day. 2. Education and visual and verbal biofeedback therapy using a radial catheter with a latex balloon	Self-reported success in bowel control: at least one weekly episode of any degree of incontinence (frank soiling, liquid seepage, staining or smearing) before the trial and no incontinence whatsoever after the trial.	No Intention to treat. Open label. Randomization and allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.
Effects of behavioral interventions on fecal incontinence in adults from the community				
Byrne, 2002[725] RCT to examine the effects of biofeedback in patients with neuropathic fecal incontinence. Duration: unclear	118 patients with neuropathic fecal incontinence. Exclusion criteria not reported Loss of followup: 14.2%	1. Pelvic floor exercises and biofeedback 2. Usual care	Direct questioning of objectives quality-of-life measure on a scale of 0 to 10 reported pre and post treatment. Saint Mark and Pescatori scores of quantitative incontinence were calculated.	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Byrne, 2005[726] Nonrandomized controlled CT to examine the effects of telephone-assisted biofeedback treatment for patients living in rural and remote areas with the standard face-to-face protocol for patients with fecal incontinence. Duration: 6 months	239 consecutive patients with fecal incontinence diagnosed by a colorectal surgeon with anal manometry and transanal ultrasound, with no improvement after usual conservative treatment including standard dietary advice, use of fiber supplements, constipating medications, and enemas. Inclusion criteria for telephone-assisted protocol: difficulties attending the clinic regularly, residence in remote areas, spoken English, and access to a telephone. Exclusion criteria: a complete external sphincter defect, a non functioning stoma, inflammatory bowel disease, acute perianal inflammation, a potentially reversible cause of incontinence (such as diarrhea), or untreated full-thickness rectal prolapse. Loss of followup: 44%	1. Initial face-to-face assessment and treatment with transanal manometry and ultrasound biofeedback, followed by three treatments conducted via telephone and a final face-to-face assessment. 2. Standard treatment with 5 face-to-face treatment sessions with manometry and ultrasound	St. Mark's Hospital fecal incontinence score (full continence 0; complete incontinence 13). Pescatori fecal incontinence score (full continence 0; complete incontinence 6). Anal manometry and external sphincter isometric and isotonic fatigue times. Treatment success: the patient's self-assessed continence ranking (from a Visual Analog Scale), and a composite grading scored by independent colorectal surgeons.	Intention to treat. Single blind. Nonrandomized trial. Baseline data were comparable. Sample size not justified.
Solomon, 2003[727] RCT to examine the effects of pelvic floor exercises with biofeedback using anal manometry or transanal ultrasound, and pelvic floor exercises with feedback from digital examination alone. Duration: 4 months	120 patients with mild to moderate fecal incontinence Loss of followup: 15%	1. Biofeedback with anal manometry 2. Biofeedback with transanal ultrasound 3 .Pelvic floor exercises with feedback from digital examination alone. 4. 45 minute sections of sphincter exercises with biofeedback (instrumental or digital examination).	St Mark Hospital Fecal incontinence score (0-13), Pescatori fecal incontinence score (0-6), self-reported fecal continence, physiologic sphincter strength, and compliance	No intention to treat. Single blind. Randomization with a chart of random numbers. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Pager, 2002[728] Solomon, 2003[727] Followup evaluation in the participants of the RCT. Duration of followup: 42 months	83 patients from 120 participants of the RCT with mild to moderate fecal incontinence. Loss of followup: 31%	1. Pelvic floor exercises with feedback from digital examination alone every day or 2-3 times/week. 2. 45 minute sections of sphincter exercises with biofeedback (instrumental or digital examination).	St Mark Hospital Fecal incontinence score (0-13), Pescatori fecal incontinence score (0-6), self-reported fecal continence, physiologic sphincter strength, and compliance	The authors reported followup outcomes from the RCT in subjects who continued treatments. Baseline data confirmed no differences between subjects.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Norton, 2003[729] RCT to examine the effects of biofeedback in patients with fecal incontinence. Duration: 3 months. Duration of followup: 1 year.	171 patients with fecal incontinence. Exclusion criteria: previous course of biofeedback or exercises for fecal incontinence, age less than 18 years, major neurologic disease significant cognitive impairment, active inflammatory bowel disease, unable to consider informed consent issues adequately with insufficient written English skills to complete the questionnaires. Loss of followup: 29%	1. Standard care with 9 40–60-minute sessions to advise on diet, fluids intake, bowel training. 2. Standard care with 9 40–60-minute advice sessions on diet, fluids intake, bowel training plus instruction on sphincter exercises with at least 50 maximal voluntary sustained sphincter contractions and 50 fast-twitch contractions per day. 3. Hospital-based computer-assisted sphincter pressure biofeedback. 4. Hospital biofeedback plus the use of a home electromyelogram biofeedback device once daily for 20 minutes.	Self-reported symptoms of fecal incontinence, fecal continence score, patient's rating of effectiveness of treatment rated as "worse," "same," "improved," or "cured," and rating of that change on an ordinal scale of -5 to +5. Quality of life (disease specific). Anal manometry outcomes.	Intention to treat. Single blind. Randomization with random numbers generated by Excel function. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Jorge, 1994[730] RCT to examine the effects of pelvic floor exercise program on fecal incontinence in patients after ileoanal reservoir procedure. Duration: 5 weeks.	26 patients with ulcerative colitis after total colectomy with double-stapled ileoanal reservoir. Exclusion criteria: one stage double-stapled ileoanal reservoir without temporary ileostomy. Loss of followup: none	1. Pelvic floor exercise program with 10 second contractions for 5 minutes 5 times/day before surgery 2. Regular care before surgery	Self-reported fecal incontinence score from 0 to 20. Anal manometry outcomes	No Intention to treat. Open label. Randomization and allocation concealment not adequate. Baseline data not reported. Sample size not justified.
Miner, 1990[731] Crossover RCT to examine the effects of biofeedback training on fecal incontinence. Duration: 4 weeks Duration: of followup 1 year.	25 consecutive patients with fecal incontinence. Most patients had idiopathic fecal incontinence associated with abnormal perineal descent and many also had features of the irritable bowel syndrome	1. Pelvic floor exercise with active sensory retraining (3 20-minute sessions) to perceive small rectal volumes of air into the rectal balloon. 2. Pelvic floor exercise retraining with no instruction on how to improve performance.	Self-reported fecal incontinence: -Do you believe your continence has improved? -Do you now have more warning before an imminent incontinent episode? -Has your life-style changed? -Are you able to go out more? -Can you travel farther	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed the adequacy of randomization. Sample size not justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
			from the toilet? Anal manometry outcomes.	
Effects of electrical stimulation on fecal incontinence in adults				
Norton, 2006[732] RCT to examine the effects of anal electric stimulation in the absence of any adjunctive exercises or advice on fecal incontinence Duration: 8 weeks	90 patients with fecal incontinence. Exclusion criteria: age under 18 years old; pregnancy; vaginal delivery <6 weeks ago; history of pelvic malignancy; active inflammatory bowel disease; active perianal sepsis or painful hemorrhoids or fissure, previous experience of using an electric stimulator to treat urinary or fecal incontinence. Loss of followup: 22.2%	1. Active anal stimulation at 35Hz/ for 40 minutes a day. 2. Sham anal stimulation at 1Hz.	1 week bowel diary, symptom questionnaire, manometry, and self-reported patients' evaluation of outcome	Intention-to-treat. Single blind. Computer generated randomization with random numbers. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Leroi, 2005[733] Crossover RCT to examine the effects of sacral nerve stimulation on fecal incontinence. Duration: 1 month	34 patients with fecal incontinence to solid or liquid stools or urgency episodes causing patients to remain at home to avoid incontinence accidents, with >1/week incontinence episodes for at least 3 months, with demonstrable unilateral bulbo(clitorido)-cavernosus reflex, and who failed other conservative treatments Exclusion criteria: not reported. Loss of followup: 21%	After permanent implantation of percutaneously placed lead turned ON for 1-3 months, subjects were randomized to: 1. Active sacral nerve continuous stimulation with pulse width of 210 microseconds, frequency 14 pulses/second, and amplitude adapted to the patient's perception of perineal and anal sphincter muscle contraction. The stimulator was left on during defecation and urinary voiding. 2. Sham sacral nerve stimulation with lead turned off.	Self-reported in patient diary number of weekly fecal incontinence and urgency episodes, and mean delay for postponing defecation and manometric outcomes.	No intention to treat. Double-blind. Randomization with a random number table. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.
Chang, 2003[734] RCT to examine the effects of electrical stimulation therapy in constipated patients with impaired rectal sensation. Duration: 10-14 days	22 patients with functional constipation as defined by Rome II criteria and impaired rectal sensation (rectal desire threshold volume ≥90ml) on an anorectal manometry, not responsive to conventional therapy such as dietary modification or laxatives for at least 6 months. Exclusion criteria: diabetes mellitus, hypothyroidism, psychiatric disturbances, drug abuse, organic diseases that could lead to constipation. Loss of followup: none	1. External electrical stimulation therapy using an anal plug with pulse generator in the anal canal once a day for 20 minutes over 10–12 sessions with pulse width of 360–960 μs, a frequency of 2–110Hz, and an amplitude of 30–35V. 2. Biofeedback therapy using the EMG system. The visual feedback observing changes in pressure activity on a monitor	Self-reported bowel frequency and habit, degree of straining, sensation of incomplete evacuation, and anal obstruction using visual analogue scale. Anorectal manometry outcomes	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
		screen during rise in rectal pressure synchronized with anal relaxation for 60–90 minutes over 10–14 sessions.		
Healy, 2006[735] RCT to examine the effects of chronic low-frequency endo-anal electrical stimulation on fecal incontinence. Duration 3 months	58 patients with fecal incontinence female with a mean age of 55 years (range 40–78). Exclusion criteria: significant anal sphincter disruption that needed early surgical repair. Loss of follow up: 17%	1.Endo-anal pudendal nerve stimulation daily at home with a portable home unit programmed for frequencies of 3, 10, 20, 30, 40 and 10 Hz and with a current train of 4 s on and 4 s off. 2. Endo-anal electrical stimulation under physiotherapeutic supervision: 1-weekly treatment of two 15-min cycles of alternate stimulation followed by a patient contraction with EMG biofeedback unit. The first 15-min cycle used 10 Hz followed by a further 15-min cycle of 40 Hz. The second treatment used electrical stimulation alone using the same frequencies 2 times/weekly without biofeedback	Self reported quality-of-life questionnaire (RAND 36-item general health survey)	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data not compared. Sample size not justified
Effects of electrical stimulation on postpartum fecal incontinence				
Mahony, 2004[736] RCT to compare intra-anal electromyographic biofeedback alone with intra-anal biofeedback with electrical stimulation of the anal sphincter in treatment of postpartum fecal incontinence. Duration: 12 weeks	60 women with fecal continence 12 weeks after obstetric injury. Exclusion criteria: history of diabetes mellitus, inflammatory bowel disease, irritable bowel disease, previous anorectal surgery, or malignancy. Loss of followup: 6 women did not complete the study and were excluded from the analysis.	Standard Kegel exercises daily: 1. Standard intra-anal electromyographic biofeedback training of the pelvic floor 2. Intra-anal electromyographic biofeedback with electrical stimulation of the anal sphincter weekly for 12 weeks by physiotherapists	The structured bowel function questionnaire to report presence of fecal urgency, flatal incontinence, fecal soiling, frank fecal incontinence, and any impact on daily lifestyle scored from 0 (complete continence) to 20 (complete incontinence). Median resting pressure. Median squeeze pressure using anorectal manometry	No Intention to treat. Single blind (investigators) Randomization with computer generated allocations in a ratio of 1:1 in sealed opaque envelopes. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Effects of perineal massage in the second stage of labor on fecal incontinence				
Stamp, 2001[574] RCT to examine effects of perineal massage in the second stage of labor on urinary and fecal incontinence. Duration: 3 months	1340 women at 36 weeks' gestation expecting normal birth of a singleton progressed in labor to full dilatation of the cervix or 8cm or more if nulliparous or 5cm or more if multiparous. Exclusion criteria: caesarean section and instrumental birth Loss of follow up:30%	1. Massage and stretching of the perineum during the second stage of labor with a water soluble lubricant 2. Usual Care	Self reported using postal survey urinary and fecal incontinence 3 months after postpartum	Intention to treat. Open label. Stratified by parity status. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Effects of pharmacological agents on incidence and progression of fecal incontinence in adults				
Ho, 2005[737] RCT to examine the effects of lateral sphincterotomy and tailored sphincterotomy on anal incontinence in patients with chronic anal fissure. Duration of followup: 4 months	132 patients with chronic anal fissure and symptoms of sharp pain on defecation for more than 6 weeks and/or anal bleeding, together with exposure of internal anal sphincter muscle fibers at the base of the fissure, and the presence of a sentinel pile and/or hypertrophied anal papilla. Exclusion criteria: previous anal sphincter surgery, pre-existing fecal incontinence, concomitant hemorrhoids who required, inflammatory bowel disease, use of nitrates or calcium channel blockers for hypertension or cardiac conditions. Loss of followup: none	1. 'Chemical sphincterotomy' with oral nifedipine 20mg twice a day for 6 weeks. 2. Lateral sphincterotomy: internal anal sphincter muscle was identified and the muscle proximal to dentate line was lifted with a small pair of artery forceps. The level of internal anal sphincter division was defined accurately before division using diathermy.	Self-reported fecal incontinence, Wexner incontinence scores. Anal manomtery outcomes	Intention to treat not stated. Open label. Randomization with random numbers table. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization Sample size justified.
De Nardi,2006[738] RCT to examine the effects of "chemical sphincterotomies" for chronic anal fissure. Duration of followup: 12 months	30 consecutive patients with chronic posterior anal fissure defined as symptoms lasting for >3 months and the presence of typical features, such as skin tag, indurations of the edges of the fissure, hypertrophic proximal papilla, and exposure of fibers of internal anal sphincter. Exclusion criteria: acute fissure, low resting tone at digital examination, inflammatory bowel disease, incontinence, previous anal surgery, and treatment with oral or transdermal nitrate. Loss of followup: none	1. 0.2 percent glycerine trinitrate ointment applied three times daily at the anal margin for eight weeks 2. 20 units Botulinum toxin A injection into the internal anal sphincter on each side of the anterior midline	Self-reported fecal incontinence with Wexner incontinence score questionnaire	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.
Ron, 2001[739] RCT to examine the effects of botulinum toxin type-A (Botox)	25 patients older than 18 years with history of constipation and symptoms of outlet obstruction for >1 year, nonrelaxing puborectalis muscle on both modalities, who were unable to expel a rectal balloon and who	1 Local injection of Botox—10 units to each side of the puborectalis 2. Local injection of Botox—20 units to the posterior aspect of	Self-reported fecal incontinence	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
injection to the puborectalis muscle in patients with anismus. Duration of followup: 52 weeks	failed laxatives and enema therapy. Exclusion criteria: concomitant fecal incontinence, pregnancy. Loss of followup: 4%	this muscle.		justified.
Mentes, 2003 [740] RCT to examine effects of lateral internal sphincterotomy and injection of botulinum toxin for the treatment of idiopathic anal fissures. Duration of follow up: 1 year	111 patients with sever chronic anal fissure with the horizontal fibers of the internal anal sphincter visible in its base. Exclusion criteria: concurrent fistula, significant haemorrhoidal diseases, inflammatory bowel disease, anal incontinence, slow transit time constipation, diabetes, alcoholism, drug abuse, ano-receptive intercourse, previous anorectal surgery. Lost of followup: none.	1. 20 to 30 units (~ 0.3U/kg) of type A botulinum toxin (Botox) injection into the internal anal sphincter. The injection was repeated 2 months later if complete healing was not achieved. 2. Lateral internal anal sphincterotomy.	Self-reported incidence of anal incontinence using scoring system by Miller (0-18, 18-complete incontinence)	Intention to treat not stated. Single blind. Randomization with random number table. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Iswariah, 2005[741] RCT to examine effects of lateral internal sphincterotomy and injection of botulinum toxin for treatment of idiopathic anal fissures. Duration of followup: 25 weeks	38 adult patients older than 18 years with chronic idiopathic fissure in and who had failed conservative treatment. Exclusion criteria: prior sphincterotomy or anal dilatation, fissure associated with inflammatory bowel disease, performance of concomitant anal procedure, fecal incontinence, pregnancy or breast-feeding. Loss of followup: 13.6%	1. Botox, 20 units injected on either side of the fissure into the internal anal sphincter. 2. Sphincterotomy by open or closed technique in the left lateral position using Park's anal retractor	Self reported modified Wexner Fecal Continence scoring system	No Intention to treat. Open label. Randomization suing random numbers tables. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.
Brisinda, 1999[742] RCT to examine effects of botulinum toxin and topical nitroglycerin ointment for treatment of chronic anal fissure. Duration of followup: 2 months, 15 months	50 adults with symptomatic chronic posterior anal fissures. Exclusion criteria: acute fissure, or fissure associated with other conditions (inflammatory bowel diseases, HIV infection, hemorrhoids, fistula in ano, anal abscesses, or anal or perianal cancer), previous surgical procedures in the anal canal. Lost of followup: none	1. 20 units of botulinum toxin injected into the internal anal sphincter on each side of the anterior midline 2. 0.2 percent nitroglycerin ointment applied twice daily	Anal manometry outcomes	Intention to treat not stated. Single blind. Computer-generated random numbers tables. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Siproudhis, 2003[743] Placebo-controlled RCT to examine effects of single injection of botulinum toxin in the internal anal sphincter of patients with chronic anal fissure. Duration of followup: 12 weeks.	44 patients 18-75 years old with chronic anal fissure >1 month, mean value of post-defecation anal pain >30mm on a 100mm visual analogue scale 1 week before inclusion. Exclusion criteria: anal sepsis, inflammatory bowel disease, cancer, trauma, anal stenosis, previous surgery, functional pelvic disorders, use of non steroidal anti-inflammatory and analgesic drugs. Loss of followup: 4.5%.	1. Single injection of botulinum toxin in the internal anal sphincter, 100 units of Dysport toxin, 250.units/ml. Daily laxatives and suppositories. 2. Single injection of isotonic saline. Daily laxatives and suppositories	Self-reported incidence of anal incontinence	No Intention to treat. Double-blind. Stratified by center randomization with permuted block =4. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Hallgren,1994[744] Crossover placebo controlled RCT to examine the effects of Loperamide on fecal continence after restorative proctocolectomy. Duration: 7 days	30 patients operated for ulcerative colitis with endoanal mucosectomy and a hand sewn ileal pouch-anal anastomosis or with abdominal proctocolectomy and stapling of the pouch to the top of the anal canal. Exclusion criteria: not reported. Loss of followup: 6.6%	1. Loperamide hydrochloride (Imodium) 2mg 2 capsules 3 times/day for 7 days 2. Placebo with the same frequency.	Self-reported fecal continence. Anal manometry outcomes	No Intention to treat. Double blind. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Sun, 1997[745] Placebo controlled crossover RCT to examine the effects of loperamide oxide on anorectal function in patients with chronic diarrhea. Duration: 4 weeks with 1 week run-in and wash out	11 patients with chronic diarrhea, fecal incontinence >1 time/month, and severe urgency >3 times/week. Exclusion criteria: positive microbiologic analysis for feces, fat, and blood, large-volume diarrhea >500ml/day, anal seepage, use of anti diarrhea medication. Loss of followup: none	1. Loperamide oxide 4mg twice daily 2. Placebo	Self-reported fecal incontinence as leakage of several ml of fluid, enough to require cloth change. Self-reported fecal urgency as acute desire to defecate which would result in incontinence if not relieved within 30 seconds. Visual analog scale from 0 (absent) to 100 (extreme). Anal manometry outcomes	Intention to treat. Double blind. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.
Kneebone, 2004[746] Placebo-controlled RCT to examine the effects of oral	338 males receiving definitive radiotherapy for prostate cancer with prescribed dose >60Gy and the superior limit of the treatment fields situated below the level of the greater sciatic	1. 3g of oral sucralfate suspension twice daily starting 1 day before RT and continuing every day for 8 weeks	Self-reported patients' symptoms of fecal incontinence using the Radiation Therapy	No Intention to treat. Double-blind. Central computer generated randomization a one-to-one stratified allocation

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
sucralfate to prevent fecal incontinence in prostate cancer patients treated with radiotherapy. Duration: 8 weeks Duration of followup: 2 years	notch to ensure that significant portions of small bowel were not irradiated. Exclusion criteria: active gastro-intestinal conditions including acute diverticulitis, Crohn's disease, or ulcerative colitis, prior colostomy for any reason, significant renal impairment (serum creatinine >0.3 mmol/l). Loss of followup: 11.8%	2. Identical placebo twice daily	Oncology Group Grade 2 or more criteria. Flexible sigmoidoscopy outcomes	within blocks of 8. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Carapeti, 2000[747] Placebo controlled crossover RCT to examine the effects of topical phenylephrine in the treatment of faecal incontinence due to internal sphincter dysfunction. Duration: 4 weeks, washout 1 week	36 patients with fecal incontinence for solid or liquid stool and ultrasonographically structurally normal anal sphincter muscles. Exclusion criteria: pregnancy, ischemic heart disease, hypertension, aortic aneurysm, treatment with monoamine oxidase inhibitors or tricyclic antidepressants, underlying treatable causes for incontinence such as inflammatory bowel disease or surgically repairable external sphincter. Loss of followup: not reported	1. Topical 10% phenylephrine 0.5 ml applied topically to the anus twice daily for 4 weeks. 2. Identical placebo gel 0.5 ml applied topically to the anus twice daily for 4 weeks.	Self-reported fecal incontinence score modified from the Wexner scale: 24-worst incontinence; 0-no incontinence scored to analyze the frequency of incontinence for solid or liquid stool or gas, alteration in lifestyle, need to wear a pad, urgency and use of constipating drugs.	No Intention to treat. Double-blind. Central randomization with computer-generated random numbers. .Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.
Carapeti, 2000 [748] Placebo controlled crossover RCT to examine the effects of topical phenylephrine gel on fecal incontinence in patients with an ileoanal reservoir pouch. Duration: 4 weeks	12 patients with fecal incontinence, noninflamed pouch for previous ulcerative colitis of normal size and ultrasonographically structurally normal anal sphincter muscles. Exclusion criteria: pregnancy, ischemic heart diseases, hypertension, aortic aneurism, treatment with monoamine oxidase inhibitors or tricyclic antidepressants. Loss of followup: none	1. Alpha1-adrenergic agonist phenylephrine, topical 10% 0.5ml application 2 times/day 2. Placebo gel	Self-reported fecal incontinence symptoms (0-no symptoms to 280) and scores using validated Wexner scale from 0-continence to 24 – complete incontinence. Anorectal manometry outcomes.	Intention to treat not stated. Double-blind. Computer generated random numbers. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Nessim, 1999[749] RCT to examine the effects of medical bowel confinement and regular diet on fecal incontinence after anorectal	54 patients 23-87 years old after anorectal reconstructive surgery including 32 after sphincteroplasty for fecal incontinence. Exclusion criteria: age younger than 18 years, immunosupression, prior pelvic irradiation, active proctitis, inflammatory bowel disease Loss of followup: none	1. Medical bowel confinement: clear liquid diet with loperamide 4mg 3 times/day and codeine phosphate 30mg 4 times/day for 3 days. 2. Regular diet beginning the day of surgery	Self-reported fecal incontinence scores from 1 to 20 in 32 patients treated with sphincteroplasty for fecal incontinence	No Intention to treat. Single blind. Computer generated randomization. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
reconstructive surgery. Duration of followup: 13 months				
Tankova, 2002[750] RCT to examine the effects of topical mononitrate hydrogel for the treatment of anal fissure. Duration: 3 weeks. Duration of followup: 3 months	19 patients with symptomatic chronic anal fissures lasting for >2 months. Exclusion criteria: Anal fissures associated with other conditions (Crohn's disease, human immunodeficiency virus infection, fistula in ano, anal abscess, anal cancer) and previous surgical procedures. Loss of followup: none	1. Rectal administration of hydrogel containing 0.2% isosorbide-5-mononitrate 2 times/day 2. Placebo gel.	Self-reported fecal incontinence. Anal manometry outcomes	Intention to treat not stated. Masking not reported but the authors stated that active gel and placebo look the same. Randomization and allocation concealment not reported. Baseline data confirmed the adequacy of randomization. Sample size not justified.
Effects of surgical interventions on fecal incontinence related to obstetric trauma in females				
Fernando, 2006[751] RCT to examine the effects of primary overlap versus end-to-end repair of the external anal sphincter after acute obstetric trauma. Duration: 12 months	64 women with third-degree (3b = greater than 50% external anal sphincter thickness, 3c = internal sphincter injury) or fourth-degree (including anorectal epithelium) perineal tears Exclusion criteria: 3a tear (<50% thickness of the external anal sphincter torn) or a previous 3rd or 4th degree perineal tear. Loss of followup: 19%, 2 women had left the area and could not be contacted, and 10 declined to complete further questionnaires.	1. End-to-end technique to repair obstetric anal sphincter: torn ends of the external anal sphincter were approximated and repaired with 2-3 mattress sutures using 3-0 PDS sutures. 2. Overlap technique to repair obstetric anal sphincter: the outer surface of the sphincter was mobilized from the surrounding tissue, the first row of sutures was inserted ~1.5 cm from one side of the torn edge of external anal sphincter and overlapped within 0.5 cm of the other edge of the torn external anal sphincter.	Self-reported fecal incontinence, urgency, flatus incontinence, and improvement of anal incontinence symptoms scored with Wexner scale from; 24 – complete incontinence to 0 - complete continence. Questionnaires were sent at 6 weeks, and 3, 6, and 12 months after the repair	Intention to treat. Single-blind (subjects). Customized computer randomization using minimization protocol. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Garcia, 2005[597] RCT to examine the effects of surgical techniques for the primary repair of obstetric anal sphincter lacerations. Duration: 4 months postpartum	51 women with complete third or fourth degree anal sphincter laceration and who underwent primary repair at the time of vaginal delivery. Exclusion criteria: not reported Loss of followup: 35.6%	1. End-to-end technique to repair obstetric anal sphincter lacerations: 4 separate sutures of polyglycolic acid to reapproximate the sphincter ends directly. 2. Overlapping repair of obstetric anal sphincter lacerations used 3 sutures of 2-0 PDS to reapproximate the	Self-reported urinary and anal incontinence graded with the Fecal Incontinence Score (FIS) from 18 - total incontinence >2/week, scores 1-3 incontinence of flatus only. Anal incontinence was	No Intention to treat. Single blind. Computer-generated randomization table. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
		sphincter ends in an overlapping fashion.	defined as a fecal incontinence score of >0	
Williams, 2006[752] RCT to compare two surgical techniques and two types of suture material for anal sphincter repair after obstetric injury. Duration: 3 months	150 women with an anal sphincter injury sustained during childbirth. Exclusion criteria not reported. Loss of followup: 20% at 3 months.	1. End–end repair of the torn anal sphincter with braided polyglactin (Vicryl retains 50% of its strengths at 3weeks, minimal tissue reaction). 2. Overlap repair of the torn anal sphincter with braided polyglactin (Vicryl retains 50% of its strengths at 3 weeks, minimal tissue reaction). 3. End–end repair of the torn anal sphincter with PDS (a monofilament suture with minimal absorption until 90 days, no chronic suture sinuses) 4. Overlap repair of the torn anal sphincter with PDS (amonofilament suture with minimal absorption until 90 days, no chronic suture sinuses).	Self-reported fecal incontinence using St Mark's bowel symptom questionnaire and scoring. Anorectal function using endoanal ultrasound. Anal manometry and pudendal nerve terminal latency tests.	No Intention to treat. Single blind. Randomization sequence was generated using a table of random numbers in varied blocks of 4-8. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.
Tjandra, 2003[753] RCT to examine the effects of two surgical techniques (direct end-to-end vs. overlapping) of delayed repair of a localized anterior defect of external anal sphincter after an obstetric trauma. Duration of followup: 18 months	23 women with localized anterior defect of external anal sphincter after an obstetric trauma, normal pudendal nerve terminal motor latency. Exclusion criteria: prolonged pudental nerve terminal motor latency. Loss of followup: none.	1. Direct end-to-end repair using 2-0 PDS sutures 2. Overlapping sphincter repair with fibro muscular ends using 2-0 PDS sutures	Self-reported fecal continence using the Cleveland Clinic Continence Score (0-20); 0 - perfect continence. Endoanal ultrasound, anorectal manometry, and neurophysiologic exam outcomes.	Intention to treat not stated. Single blind. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Fitzpatrick, 2000[754] RCT to examine the effects of primary anal	112 primiparous women who sustained a third-degree tear defined as any recognized disruption of the external anal sphincter (partial or complete).	1. Primary anal sphincter overlap: the sphincter ends in an overlapping fashion. 2. Approximation repair: the torn	Self-reported fecal incontinence using detailed bowel function questionnaire scored	All subjects included in the analysis. Intention to treat was not stated. Open label. Allocation concealment

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
sphincter overlap or approximation repair of third-degree obstetric tears on postpartum incontinence. Duration: 3 months postpartum	Exclusion criteria: not reported. Loss of followup: 0%	sphincter ends were grasped by means of an Allis forceps and approximated end to end without tension	with a modified Wexner score. anal manometry and anal endosonography outcomes	unclear. Baseline data confirmed adequacy of randomization. Sample size justified.
Effects of clinical interventions to prevent fecal incontinence after obstetric trauma				
Dannecke, 2005[590] Followup RCT to examine the effects of restrictive use of mediolateral episiotomy vs. routine episiotomy. Duration: 18 months	146 primiparous women with an uncomplicated singleton pregnancy >34 weeks of gestation intending a vaginal delivery. Exclusion criteria: previous surgery at the pelvic floor and neurological disorder. Loss of followup: 45% in restrictive policy group, 32% in liberal policy group	1. Restrictive episiotomy - avoidance of episiotomy (for fetal indications only). 2. Liberal – in addition to fetal indications use episiotomy when a tear is judged to be imminent	Self-reported presence of urinary and fecal incontinence with standardized questionnaire. Anorectal manometry and urodynamic outcomes. Pelvic floor muscle strength with a vaginal palpation. The effort to contract the levator ani was graded with the Oxford Score (4 - strongest).	Intention-to-treat. Open label. Simple random sampling. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Sartore, 2004[591] Nonrandomized CT to examine the effect of mediolateral episiotomy on puerperal pelvic floor strength and dysfunction. Duration: 3 months after vaginal delivery	519 consecutive primiparous women with singleton pregnancies and spontaneous vaginal delivery with the fetal head in occiput anterior position, residents of Trieste. Exclusion criteria: Not delivered in the lithotomy position, cesarean delivery, third and fourth-degree perineal lacerations, preterm, breech, and operative delivery, anal and urinary incontinence that pre-existed vaginal delivery, and history of vaginal or anal surgery.	1. Mediolateral episiotomy. 2. No episiotomy	Stress urinary incontinence - observation of involuntary loss of urine synchronous with coughing (+ stress test) with comfortably full bladder. Self-reported urge incontinence - loss of urine associated with strong desire to void. Self-reported anal incontinence – loss of flatus, liquid, or solid stool. Pelvic floor muscle strength scored from 0 to 5. Vaginal manometry:	No intention to treat. Open label. Groups were comparable at baseline except neonatal weight. Crude odds ratios reported.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
			abnormal perineometric values <12 cm of water. Urine stream interruption test: abnormal any urine stream interruption test scores >5 seconds.	
Hannah, 2002[592] Term Breech Trial, RCT to examine the effects of planned cesarean section on incontinence 3 months postpartum. Duration: 3 months	1,159 women with singleton live fetus in a frank or complete breech presentation at term (37 weeks' gestation). Exclusion criteria: Fetopelvic disproportion, fetus weight >4000g, hyperextension of the fetal head, lethal anomaly or a condition that might cause a mechanical problem at delivery, and contraindication to labor or vaginal delivery. Loss of followup: 16.5%	1. Planned vaginal birth group, management was expectant until spontaneous labor began, unless an indication to induce labor (e.g., post term pregnancy) 2. Planned cesarean delivery (e.g., footling breech presentation) scheduled for 38 or more weeks' gestation. If the woman was in labor at the time of randomization, the caesarean section was undertaken as soon as possible. Immediately before caesarean section, the fetal presentation was reassessed and if cephalic, a vaginal birth was planned.	Self-reported stress urinary incontinence and fecal or flatus incontinence within the previous 7 days. Perception of incontinence: no problem at all, a little problem, or a big problem.	Intention to treat. Open label. Centralized randomization stratified by parity with block sizes of two. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.
Hannah, 2004[593] Followup the Term Breech Trial, RCT to examine the effects of planned cesarean section on incontinence 2 years postpartum. Duration: 2 years	917 of 1,159 women with singleton live fetus in a frank or complete breech presentation at term (37 weeks' gestation). Exclusion criteria: Fetopelvic disproportion, fetus weight >4,000g, hyperextension of the fetal head, lethal anomaly or a condition that might cause a mechanical problem at delivery, and contraindication to labor or vaginal delivery. Loss of followup: 20.9% in planned Cesarean groups and 19.6% in vaginal birth group.	1. Planned vaginal birth group, management was expectant until spontaneous labor began, unless an indication to induce labor (e.g., post term pregnancy) 2. Planned cesarean delivery (e.g., footling breech presentation) scheduled for 38 or more weeks' gestation. If the woman was in labor at the time of randomization, the caesarean section was undertaken as soon as possible. Immediately before caesarean section, the fetal presentation was reassessed and if cephalic, a vaginal birth was planned.	Self-reported stress urinary incontinence and fecal or flatus incontinence within the previous over the previous 3 to 6 months. Perception of incontinence: no problem at all, a little problem, or a big problem.	Intention to treat. Open label. Centralized randomization stratified by parity with block sizes of two. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Fitzpatrick, 2002[755] RCT to examine the effects of delayed vs. immediate pushing in second stage of labor with epidural analgesia on postpartum faecal continence. Duration: 3 months	178 primiparae in either spontaneous or induced labor with a singleton fetus, cephalic presentation between 37 and 42 weeks of gestation with effective epidural analgesia in situ. Exclusion criteria: diabetes, irritable bowel syndrome or other bowel or neurological disorder Loss of followup: none	1. Immediate pushing 2. 60-minute delay, prior to the commencement of active pushing. If delivery was not imminent after 60 minutes pushing, a decision was made regarding the need for instrumental or caesarean delivery.	Self-reported FI using bowel function questionnaire With modified continence score from 0 - complete continence, to 20 – complete incontinence. Anal manometry outcomes. Anal ultrasound to evaluate potential structural damage to the anal sphincters.	All patients were analyzed, Intention to treat not stated. Single blind. Computer-generated randomization, ratio of 1:1 in blocks of 10. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Johanson, 1999[596] Followup RCT to examine the effects of delivery by forceps or vacuum extractor on maternal and child outcomes. Duration: 5 years postpartum.	607 women requiring assisted vaginal delivery. Exclusion criteria: 47% of participants form the original RCT were not contacted for unclear reasons. Loss of followup: 26.2% non responders to the survey 5 years postpartum.	1. Delivery with vacuum extractor. 2. Forceps delivery.	Self-reported fecal and urinary incontinence 5 years postpartum	No intention to treat. Open label. Randomization procedure is not described. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.
Fitzpatrick, 2003[756] RCT to examine the effects of forceps or vacuum assisted vaginal delivery on anal sphincter function in standard-ized management of labor. Duration: 12 weeks	130 primiparous women in either spontaneous or induced labor with a singleton fetus, cephalic presentation, between 37 and 42 weeks of gestation and required instrumental assistance with delivery. Exclusion criteria: diabetes, irritable bowel syndrome or other bowel or neurological disorders Loss of followup: 16 failed vacuum-forceps	1. Vacuum assisted delivery 2. Low-cavity, non-rotational forceps assisted delivery	Self-reported fecal continence scored from 0 - complete contin-ence, to 20 - complete incontinence. Fecal urgency - unable to defer defecation for >5 minutes. Anal manometry outcomes. Endoanal ultrasound outcomes.	Intention to treat. Open label. Computer-generated randomization, ratio of 1:1 in balanced blocks of 10. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.
Sultan, 1999[757] RCT to examine the effect of forceps and vacuum delivery on anal sphincter trauma 5 years postpartum. Duration: 5 years postpartum	44 from 313 contacted participants in Keele University Multicenter Assisted Delivery Trial (607 women were randomized in the original trial) Exclusion criteria: unclear why only 313 from 607 participants were contacted for a survey; 44 only agree to have anal endosonography and manometry 5 years postpartum.	1. Delivery with vacuum extractor 2. Forceps delivery.	Anal endosonography outcomes. Anal manometry outcomes.	Intention to treat. Single blind. Randomization procedure is not described. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Effects of surgical interventions to reduce fecal incontinence in females				
Faltin, 2005[758] RCT to examine whether diagnosis of sphincter tears followed by immediate surgical repair reduces the occurrence of incontinence. Duration: 3 months and 1 year	752 nulliparous women older than 18 years with no scheduled cesarean delivery with second-degree perineal tear (spontaneous or after episiotomy). Exclusion criteria: anal sphincter ruptures (third- or fourth-degree perineal tear, International Classification of Diseases, 10th Revision), Cesarean delivery, intact perineum or minimal perineal tear ruptures (first-degree perineal tear). Loss of followup: 0.8%	1. Clinical and ultrasound examination of the anal sphincter immediately after vaginal delivery 2. Clinical examination alone	Self-reported fecal incontinence, need to wear a pad, and lifestyle alterations caused by fecal incontinence using the Wexner scale grading (0-absent; 4- daily).	Intention-to treat. Single blind. Computer-generated randomization in blocks (4, 6, and 8) arranged in random order. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Deen, 1994[759] RCT to examine the effects of abdominal resection rectopexy or perineal rectosigmoidectomy and pelvic floor repair in elderly female patients with full-thickness rectal prolapse and faecal incontinence. Duration of followup: 17 months	20 elderly female patients with full-thickness rectal prolapse and fecal incontinence. Exclusion criteria: not reported. Loss of followup: none	1. Abdominal resection rectopexy and pelvic floor repair. 2. Perineal rectosigmoidectomy and pelvic floor repair.	Self-reported fecal incontinence graded from A (fully continent) to D. anal manometry outcomes.	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed the adequacy of randomization. Sample size not justified.
Sayfan, 1990[760] Non randomized controlled CT to examine the effects of sutured posterior abdominal rectopexy with sigmoidectomy or Marlex rectopexy on fecal incontinence in patients with rectal prolapse. Duration of followup: 2 weeks	29 women with full-thickness rectal prolapse. Exclusion criteria: not reported. Loss of followup: none.	1. Marlex mesh posterior rectopexy alone. 2. Sigmoidectomy combined with a sutured posterior rectopexy	Self-reported fecal incontinence, anal manomtery outcomes and rectal emptying during proctography.	Intention to treat not stated. Open label. Not randomization. Baseline data not reported. Sample size not justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Yoshioka, 1999[761] RCT to examine the effects of total pelvic floor repair with gluteus maximus transposition for women with post obstetric fecal incontinence. Duration of followup: 18 months	24 women with post obstetric neuropathic fecal incontinence. Exclusion criteria: comorbidity (diabetes), endosonographic sphincter defect, previous anal surgery. Loss of followup: not reported	1. Gluteus maximus transposition (without electrical stimulation). 2. Total pelvic floor postanal repair with anterior levatoroplasty	20 point clinical incontinence score. -failing to achieve full continence -fecal urgency secondary outcome measures: -post-operative complications -adverse functional effects -physiological outcomes	Intention-to-treat. Open label. Permuted block randomization. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Deen, 1993[762] RCT to examine total pelvic floor repair with anterior levatorplasty and sphincter plication alone and postanal repair alone. Duration: 6 months	36 women 28-75 years with neuropathic fecal incontinence confirmed by manometry with >4 incontinent episodes/month. Exclusion criteria: isolated anal sphincter defect, diabetes mellitus. Loss of followup:53%	1. Total pelvic floor repair 2. Anterior levatorplasty and sphincter plication alone 3. Postanal repair alone 4. Control: 18 females undergoing herniorrhaphy and cholecystectomy	Self-reported fecal continence. Manometric and radiologic outcomes.	No Intention to treat. Open label. Computer generated random tables. Allocation concealment not reported. Baseline data not reported. Sample size not justified.
Davis, 2004[763] RCT to examine the effects of adjuvant biofeedback following anal sphincter repair on fecal incontinence. Duration of biofeedback: 6 weeks Duration of followup: 3 months and 1 year	38 females with fecal incontinence who failed other conservative treatments, with persistent leakage of liquid or solid stool over at least the previous 12 months, with external anal sphincter defect identifiable on endoanal ultrasound. Exclusion criteria: Coexistent rectocele, full thickness rectal prolapse, congenital abnormalities, non-obstetric trauma to the sphincter complex, inflammatory bowel disease or significant, women under the age of 18 years, planning pregnancy or who suspected pregnancy. Loss of followup: 5.3%	1. Anterior overlapping sphincter repair using interrupted non-absorbable sutures and levatorplasty using absorbable sutures. 2. Anterior overlapping sphincter repair plus visual or auditory biofeedback with dual-balloon pressure system during pelvic floor exercise 2 times/day. Three types of exercises: 'maximal' -maximal squeeze for as long as possible up to 10 seconds; 'submaximal' - halfway squeeze held for up to 5 seconds; or series of repetitive fast squeeze and relax contractions.	Self-reported fecal incontinence symptoms with 3-point scale of 'improved,' 'remained the same,' or 'got worse,' change in continence score ranging from 0 to 20 (0 - no incontinence to 20 - complete incontinence), and anorectal outcomes.	Intention to treat. Single blind. Randomization with computer generated list of random numbers. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Deen, 1995[764] RCT to examine the effects of	33 women with neuropathic fecal incontinence with a history of prolonged or difficult vaginal delivery, >6 fecal accidents/month, using pad	1. Adjuvant internal anal sphincter plication in pelvic floor repair	Self-reported fecal incontinence scores from 1 - satisfactory to	Intention to treat not stated. Open label. Randomization with random number tables.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
adjuvant internal anal sphincter plication in women with neuropathic fecal incontinence. Duration of followup: 1 year.	for fecal incontinence. Exclusion criteria: external sphincter defect, diabetes mellitus, rectal prolapse. Loss of followup: none	2. Pelvic floor repair alone	7 – poor. Anorectal manometry outcomes	Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.
Davis, 2004[763] RCT to examine the effects of adjuvant biofeedback following sphincter surgery. Duration of followup: 12 months	47 consecutive female patients with defect of external anal sphincter identifiable on endoanal ultrasound and fecal incontinence who failed to control symptoms of persistent leakage of liquid or solid stool over at least the previous 12 months. Exclusion criteria: coexistent rectocele, full thickness rectal prolapse, congenital abnormalities, non-obstetric trauma to the sphincter complex, inflammatory bowel disease or significant neuropathy, women under the age of 18 years, planning pregnancy or who suspected pregnancy. Loss of followup:18%	1. Direct sphincter repair and levatorplasty with pelvic floor muscle exercise training with maximal or submaximal squeeze for 10 seconds 10 times day in different positions. Biofeedback therapy 3 months after surgery using dual-balloon pressure system with color led visual or auditory signals of sphincter pressure as feedback. 2. Direct sphincter repair and levatorplasty	Self-reported fecal continence using fecal incontinence scale with continence score (0 - no incontinence to 20 - complete incontinence). Endoanal ultrasonography outcomes.	No Intention to treat. Open label. Randomization with computer generated list of random numbers. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Van Tets, 1998[765] RCT to examine the effects of postanal and total pelvic floor repair for female neurogenic incontinence. Duration of followup: 12 weeks	Type D incontinence (no control of solid stool by Parks and Browning). Exclusion criteria: sphincter defects. Loss of follow up: not reported	1. Postanal repair with levator ani and plicated of the external anal sphincter. 2. Total pelvic floor repair with a combination of postanal repair, anterior levatorptasty, and anterior sphincter plication	Self-reported fecal incontinence	Intention to treat not stated. Open label. Randomization by drawing lots. Allocation concealment not reported. Baseline data confirmed the adequacy of randomization. Sample size not justified.
Thakar, 2002[599] RCT to examine the effects of total abdominal hysterectomy and subtotal abdominal hysterectomy performed for benign uterine diseases. Duration: 1 year	279 women referred for hysterectomy because of benign disease; most of the women were premenopausal. Exclusion criteria: age >60 years, suspected cancer, a body weight that exceeded 100kg, previous pelvic surgery, known endometriosis, abnormal cervical smears, symptomatic uterine prolapse, and symptomatic urinary incontinence for which the patient might seek expert medical advice. Loss of followup: 16% in total and 12% in subtotal abdominal hysterectomy groups.	1. Subtotal hysterectomy 2. Total hysterectomy	Self-reported urinary incontinence using standardized Questionnaire. Stress incontinence scored from 0 - none to 4 - always. Twin-channel subtracted cystometrography and uroflowmetry outcomes.	No intention to treat for cystometry outcomes. Double blind. Randomization with computer-generated numbers. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Effects of surgical interventions to reduce fecal incontinence in males				
Peeters, 2006[766] RCT to examine the effects of three-dimensional conformal radiotherapy for prostate cancer. Duration of followup: 44 months	641 patients with localized adenocarcinoma of the prostate. Exclusion criteria: not reported Loss of followup: 0.6%.	1. Three-dimensional conformal radiotherapy 68Gy 2. Three-dimensional conformal radiotherapy 78Gy	Fecal incontinence as use of incontinence pads for rectal loss of blood, mucus, or stools (requiring the use of pads more than twice a week) reported using Radiation Therapy Oncology Group/European Organization for the Research and Treatment of Cancer questionnaire.	No Intention to treat. Open label. Randomization stratified by hospital, hormonal therapy, age, and four treatment groups. Allocation concealment not reported. Baseline data did not confirm adequacy of randomization. Sample size not justified
Fransson, 2001[686] RCT to examine the effects of radiotherapy for localized prostate carcinoma. Duration of followup: 30-40 months	166 patients with localized prostate carcinoma cytologically or histologically verified as T1a-T2, G1-G2, pN0, and M0. Exclusion criteria: expected survival <10 years. Loss of followup: 35%.	1. Radiotherapy with a total dose of 4.8Gy (range, 62.3–70.0Gy) given for 5 days a week, 2 grays (Gy) per fraction. 2. Active surveillance	Self-reported urinary and fecal incontinence using validated symptom specific self assessment questionnaire, QUFW94 with values between 0 and 10; 0 - “no problem/very good function” and 10 - “many problems/very bad function.”	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Little, 2003[676] Followup RCT to examine the effects of radiotherapy for prostate cancer on urinary incontinence and bowel function. Duration of followup: 3 years	301 patients: 3 with histologically confirmed adenocarcinoma of the prostate and no metastatic disease treated with a four-field box technique to a dose of 46Gy. Exclusion criteria: not reported Response rate 70%.	1. Radiation with a four-field box technique to a dose of 70Gy arm 2. Radiation with three-dimensional conformal techniques to generate a six-field boost plan of a total dose of 78Gy	Self-reported bladder, bowel and sexual function (Fowler)	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Effects of bowel management in patients with spinal cord injury and symptoms of neurogenic bowel dysfunction				
Christensen, 2006[767] RCT to examine the effects of	87 patients 18 years or older after spinal cord injury at any level at least 3 months after injury and at least one of the following symptoms of neurogenic bowel dysfunction: 1) spending	1. Transanal irrigation with integrated system of coated rectal balloon catheter, control unit including a manual pump,	Cleveland Clinic constipation scoring system (0-30, 30 = severe symptoms). St	Intention to treat. Open label. Computer-generated block-randomized across centers. Allocation concealment not

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
transanal irrigation on fecal incontinence in patients with spinal cord injuries. Duration: 10 weeks	>30 minutes attempting to defecate each day or every second day, 2) episodes of fecal incontinence >1 per month, 3) symptoms reflecting autonomic dysreflexia before or during defecation, and 4) abdominal discomfort before or during defecation. Exclusion criteria: coexisting major unsolved physical problems due to the injury, performance of transanal irrigation on a regular basis, evidence of bowel obstruction or inflammatory bowel disease, history of cerebral palsy or cerebral apoplexy, multiple sclerosis, diabetic polyneuropathy, previous abdominal or perineal surgery (excluding minor surgery such as appendectomy or hemorrhoidectomy), pregnancy or lactation, evidence of spinal shock, mental instability, treatment with more than 5mg/day prednisolone, and implant for sacral nerve stimulation. Loss of followup: 6.8%	and a water container with the volume increased to 1,500ml or reduced gradually to 250ml. 2. Conservative bowel management with scheduled bowel care at least every 2 days, modulated diet, fluids, and regular physical activity and use of laxatives or constipating medicine.	Mark's fecal incontinence grading system (0-24, 24 = severe symptoms) Neurogenic Bowel Dysfunction Score (0-no symptoms, 47 = severe symptoms). The modified American Society of Colorectal Surgeon fecal incontinence scores (0-4, 4 = high quality of life)	adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Effects of surgical interventions on fecal incontinences in adults with hemorrhoid disease				
Hetzer, 2002[768] RCT to examine the effects of stapled hemorrhoidectomy and excision hemorrhoidectomy on fecal incontinence. Duration of followup: 12 months	40 patients with second- and third-degree hemorrhoid disease. Exclusion criteria: not reported Loss of followup: none	1. Stapled hemorrhoidectomy (Longo technique) with circular anal dilatator introduced to reduce the prolapse of the anoderm and parts of the anal mucous membrane. 2. Excision hemorrhoidectomy (Ferguson technique).	Self-reported fecal incontinence	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Konsten, 2000[769] RCT to examine the effects of anal dilation and hemorrhoidectomy for haemorrhoidal disease on fecal incontinence. Duration of followup: 1 year.	138 patients with second-degree and third-degree hemorrhoids. Exclusion criteria : not reported Loss of followup: 14%, 14 patients died.	1. Hemorrhoidectomy with no retractor (Miller method). 2. Hemorrhoidectomy with forced anal dilation and after treatment for 6 months (original Lord's procedure. 3. Hemorrhoidectomy with forced anal dilation.	Self-reported fecal incontinence	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Jayne, 2002[770] RCT to examine the effects of open diathermy haemorrhoidectomy and a new technique of haemorrhoidectomy using the Ligasure device suited to day-case surgery on fecal incontinence. Duration of followup: 3 months	40 patients with grade III or IV hemorrhoids. Exclusion criteria: use of regular anticoagulants, immunosuppressant or analgesics, American Society of Anesthesiologists grade III and IV risk, pregnancy, and the inability to give written informed consent. Loss of followup: none	1. Ligasure haemorrhoidectomy applying repeated diathermy forceps across the hemorrhoid with associated skin tag. Completion of coagulation was signaled by the feedback sensors, and haemorrhoidal tissue was excised along the line of coagulum. 2. Open diathermy haemorrhoidectomy	Self-reported fecal incontinence.	No Intention to treat. Single blind. Randomization with a random numbers table. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Galizia, 2000[771] RCT to examine the effects of adding a lateral internal sphincterotomy to haemorrhoidectomy Duration of followup: 24 months	48 consecutive patients with severe prolapsed piles suitable for surgical haemorrhoidectomy. Exclusion criteria: younger than 30 years or over 50 years, associated anorectal diseases such as anal scars, fissures, fistulas in ano, proctitis, or thrombosed hemorrhoids. Loss of followup: none.	1. Complete excision of three hemorrhoids (Milligan-Morgan technique) and lateral internal sphincterotomy up to the dentate line, in left haemorrhoidectomy wound. 2. Complete excision of three hemorrhoids (Milligan-Morgan technique)	Self-reported fecal incontinence. Anal manometry outcomes.	No Intention to treat. Open label. Randomization using random number table. Allocation concealment not adequate. Baseline data not reported. Sample size not justified.
Lawes, 2004[772] Followup RCT to examine the effects of Ligasure haemorrhoidectomy on fecal incontinence in patients with prolapsing hemorrhoids. Duration of followup: 12months	34 patients with prolapsing hemorrhoids. Exclusion criteria: not reported Loss of followup: 11.7%.	1. Ligasure haemorrhoidectomy with controlled quantity of bipolar diathermy current to tissue ensuring the complete coagulation of blood vessels 2. Standard diathermy haemorrhoidectomy	Self-reported fecal incontinence using validated continence scoring system, the Continence Grading Scale	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.
Filingeri, 2004[773] RCT to examine the effects of submucosal hemorrhoidectomy with radiofrequency	102 patients with fourth-degree hemorrhoids. Exclusion criteria: presence of previous proctologic surgery or associated proctologic diseases, pregnancy, scores III or IV on the ASA score of the American Society of Anesthesiologists. Loss of followup: 7.8%	1. Submucosal hemorrhoidectomy with radiofrequency bistoury. 2. Conventional Parks' hemorrhoidectomy	Self-reported fecal continence	No Intention to treat. Double blind. Randomization using random number table. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization Sample size not

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
bistoury or conventional Parks' haemorrhoidectomy on fecal incontinence. Duration of followup: 6 months				justified.
Johannsson, 2006[774] RCT to examine the effects of open (Milligan-Morgan) and closed (Ferguson) haemorrhoidec-tomy on fecal incontinence. Duration of followup: 1 year	225 patients older than 18 years attended the clinic for haemorrhoidectomy. Exclusion criteria: history of anal incontinence. Loss of followup: 6.2%	1. Open (Milligan-Morgan) haemorrhoidectomy 2. Closed (Ferguson) haemorrhoidectomy with wounds sutures without tension	Self-reported anal incontinence using validated questions and an Miller incontinence scores	No Intention to treat. Open label. Randomization stratified by the center. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Khan, 2001[775] RCT to examine the effects of closed excisional hemorrhoidectomy and the Harmonic Scalpel technique on fecal incontinence. Duration of followup: 6 weeks	30 patients with Grade 2 and 3 symptomatic hemorrhoids. Exclusion criteria: not reported Loss of followup: not reported	1. Excisional Hemorrhoidectomy with the ultrasonically activated scalpel (Harmonic Scalpel). 2. Closed excisional hemorrhoidectomy assisted by electrocautery	Self-reported fecal incontinence, and quality of life using the Short Form-36 survey	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified
van Tets, 1997[776] RCT to examine effects of the Parks' anal retractor on anal sphincter function during closed hemorrhoidectomy Duration of followup: 12 weeks	40 patients with symptomatic third-degree hemorrhoids with normal continence. Exclusion criteria: not reported. Loss of followup: none.	1. Closed hemorrhoidectomy performed intra-anally using the Parks' anal retractor 2. Closed hemorrhoidectomy performed perineally without the use of a retractor	Anal manometry outcomes.	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Ho, 2000[777] RCT to examine effects of stapled or conventional open diathermy hemorrhoidectomy on fecal incontinence in adults. Duration of followup: 3 months	119 consecutive patients with prolapsed irreducible hemorrhoids. Exclusion criteria: previous perianal surgery, acute thrombosis of internal hemorrhoids, bleeding disorders. Loss of followup: not reported	1.Conventional open diathermy hemorrhoidectomy. 2.Stapled hemorrhoidectomy	Self-reported fecal incontinence and quality of life outcomes. Anal manometry outcomes. Endoanal ultrasound outcomes.	Intention to treat not stated. Single blind. Randomization by drawing sealed envelopes. Allocation concealment not adequate. Baseline data confirmed the adequacy of randomization. Sample size not justified.
Effects of the clinical interventions in patients with rectal diseases to reduce risk of fecal incontinence				
Schouten, 1991[778] RCT to examine the effects of fistulectomy in patients with anorectal abscess. Duration of followup: 42 months	70 patients with anorectal abscess. Exclusion criteria: recurrent abscess. Loss of followup: 5.7%	1. Incision, drainage and fistulectomy with primary partial internal sphincterotomy. 2. Incision and drainage alone with secondary partial internal sphincterectomy	Self-reported anal continence	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.
Singer, 2005[779] RCT to examine the effects of Tisseel-VH fibrin sealant in combination with intra-adhesive cefoxitin, surgical closure of primary opening, or both modifications on fecal incontinence in patients with chronic fistula-ano. Duration of followup: 12 months	Patients with fistula-in-ano for at least 3 months. Exclusion criteria: not reported. Loss of followup: none	1. Tisseel-VH fibrin sealant intra-adhesive cefoxitin 100mg. 2. Tisseel-VH fibrin sealant surgical closure of primary opening. 3. Tisseel-VH fibrin sealant intra-adhesive cefoxitin 100mg surgical closure of primary opening	Self-reported fecal incontinence.	No Intention to treat. Open label. Randomization with random numbers table. Allocation concealment adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Libertiny, 2002[780] RCT to examine the effects of glyceryl trinitrate or lateral	70 patients with chronic anal fissure for >2 months, with the presence of ulcerated induration, and the presence of internal sphincter fibers at the base of the fissure, who failed to respond to treatment with stool	1. Glyceryl trinitrate application 0.2% paste to perianal area 3 times/day for 8 weeks. 2. Lateral sphincterotomy	Self-reported fecal incontinence.	Not intention to treat. Open label. Randomization by selection of sealed postcards. Allocation concealment not reported. Baseline data not

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
sphincterotomy on fecal incontinence in patients with chronic anal fissure. Duration of followup: 24 months	softeners and topical ointments. Exclusion criteria: acute fissures, postpartum stage, incontinence, previous history of anorectal surgery Loss of followup: not reported			reported. Sample size justified
Mishra, 2005[781] RCT to examine the effects of glyceryl trinitrate or lateral sphincter-otomy on FI in patients with for chronic anal fissure. Duration of followup: 6 weeks	40 consecutive patients with primary idiopathic chronic anal fissure with symptoms (pain, bleeding) lasting for more than 6 weeks, fibers of internal anal sphincter visible at the floor of the fissure, sentinel pile, and induration of the edges. Exclusion criteria: secondary fissures, systemic diseases (diabetes mellitus, jaundice, collagen diseases), pregnancy, or those being treated with nitrates. Loss of followup: not reported	1. Glyceryl trinitrate application 0.2% paste to perianal area 3 times/day 2. Lateral sphincterotomy	Self-reported fecal incontinence	No intention to treat. Open label. Randomization using randomized block design (balance by age, sex, and weight). Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified
Oettle, 1997[782] RCT to examine the effects of glyceryl trinitrate or lateral sphincter-otomy on FI in patients with chronic anal fissure. Duration of followup: 22 months	24 consecutive patients with chronic anal fissure. Exclusion criteria: Crohn's disease, tuberculosis, AIDS, anal abscess or fistula. Loss of followup: 0%	1. Glyceryl trinitrate application 0.2% paste to perianal area 3 times/day. 2. Lateral sphincterotomy	Self-reported fecal incontinence	Intention to treat. Open label. Randomization with random number tables (odd-even). Allocation concealment not reported. Baseline data not reported. Sample size justified
Richard, 2000[783] RCT to examine the effects of topical nitroglycerin or internal sphincterotomy on fecal incontinence in patients with chronic anal fissure. Duration of followup: 6 months	90 patients with symptomatic chronic anal fissures (fibrosis at the base of fissure, visible internal sphincter, hypertrophied anal papilla proximal to fissure, sentinel pile distal to fissure). Exclusion criteria: refusals of Internal sphincterotomy, healing of fissure before surgery, fissure was not observed at surgery, sepsis, Crohn's disease, AIDS, practicing anal intercourse, contraindication to nitrates. Loss of followup: 8.8%	1. Application of 0.25% nitroglycerin twice per day to perianal area 3 times/day 2. Internal sphincterotomy	Self-reported fecal incontinence using Continence Index by Jorge and Wexner.	No Intention to treat. Open label. Central computer generated randomization with permuted blocks of 2, 4, and 6 stratified by center. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Evans, 2001[784] RCT to examine the effects of glyceryl trinitrate or lateral sphincterotomy on fecal incontinence in patients with chronic anal fissure. Duration 8 weeks. Duration of followup:12 months	65 patients with symptoms of chronic anal fissure (symptoms >2 weeks). Exclusion criteria: inflammatory bowel disease, AIDS, previous fecal incontinence, sphincter injury or surgery, medical conditions that contraindicated general anesthesia, use of nitrates. Loss of followup:7.7 %	1. Glyceryl trinitrate application 0.2% paste to perianal area 3 times/day for 8 weeks. 2. Lateral sphincterotomy	Self-reported minor fecal incontinence.	No intention to treat. Open label. Central randomization. Allocation concealment not adequate. Baseline data not reported. Sample size justified
Zimmerman, 2003[785] RCT to examine the effects of two different types of anal retractors on fecal continence after fistula repair. Duration of followup: 12 weeks	30 patients with perianal fistula. Exclusion criteria: fistulotomy. Loss of followup: none.	1. Parks retractor during fistula repair. 2. Scott retractor during fistula repair	Self-reported fecal continence using Rockwood fecal continence Severity Index. Anal manometry outcomes.	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization Sample size not justified.
Ho, 2005[786] RCT to examine the effects of dermal island flap anoplasty on fecal incontinence in patients with trans-sphincteric fistula-in-ano. Duration of followup: 16 weeks	20 patients with fistula-in-ano confirmed by endoanal ultrasound. Exclusion criteria: not reported. Loss of followup: none.	1. Dermal island flap anoplasty with cutaneous advancement flap into the rectum 2. Conventional treatment: lay open fistulotomy or seton insertion	Self-reported fecal incontinence scores.	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization Sample size not justified.
Clinical interventions in patients with rectal cancer				
Peeters, 2005[674] RCT to examine the effects of preoperative short-term radiotherapy in patients treated with total	1,861 patients with histologically confirmed adenocarcinoma of the rectum with inferior margin of the tumor had <15 cm from the anal verge and below the level of S1 and S2. Exclusion criteria: distant metastases, fixed tumors, locally treated (transanal resected) tumors	1. Radiotherapy with total dose of 25Gy administered in 5 fractions over 5 to 7 days before total mesorectal excision. 2. Total mesorectal excision	Self-reported urinary and fecal incontinence with 4-point scale from “no, never” to “sometimes” (<1/week), “often” (>1/ week but not every	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
mesorectal excision. Duration of followup: 5 years	Loss of followup: 32%, 597responded to questionnaire.		day), and "yes, always" (every day) for time-dependent symptoms and from "no, not at all" to "a little," "pretty much," and "very seriously" for time-independent symptoms.	
Dahlberg, 1998[787] Followup RCT to examine effects of preoperative high-dose radiotherapy on long-term bowel function in patients with rectal cancer. Duration of followup: 5 years	400 patients younger than 80 years with respectable rectal cancer participated in nationwide Swedish Rectal Cancer Trial. 171 patients survived after a minimum of five year responded to the questionnaire. Exclusion criteria: postoperative stomas and dementia. Loss of followup: 57% from the initial trial, 16% among survivors.	1. Preoperative high-dose radiotherapy with 25Gy given in 5 fractions for 5-7 days followed by anterior resection of rectal cancer. 2. Anterior resection of rectal cancer alone	Self-reported defecation frequency, emptying difficulties, urgency, and incontinence	No Intention to treat. Open label. Randomization and allocation concealment not reported in this article. Baseline data confirmed adequacy of randomization. Sample size justified.
Pollack, 2006[675] RCT to examine the effects of rectal cancer surgery with or without preoperative radiotherapy on incontinence. Duration of follow up:15 years	1,406 patients with biopsy-proven adenocarcinoma of the rectum, resectable for cure by an abdominal procedure who participated in the Stockholm I and II trials. 252 alive 15 years after surgery surveyed Exclusion criteria: distant metastases, locally advanced cancer or previous irradiation to the pelvis, local excision; mental or physical condition that did not allow to participate in the survey. Loss of follow up: 90% (139 patients available for follow-up and willing to participate).	1.Abdominal rectal resection with preoperative radiotherapy in a dose of 25 (5 × 5) Gy using a two field technique (The Stockholm I trial) or four-field box technique (The Stockholm I trial II). 2. Abdominal rectal resection without preoperative radiotherapy	Self reported fecal and urinary incontinence using the European Organization for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire (QLQ)	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data did not confirm adequacy of randomization. Sample size not justified From the original publication: Balanced central randomization lists with a block size of six - 596 were randomized to radiotherapy
Allgayer, 2005[788] Controlled CT to examine the effects of pelvic floor exercise/ biofeedback training combined with irradiation on fecal incontinence after surgery for colorectal cancer. Duration of	90 patients with colorectal cancer, lower anterior resection as the standard surgical procedure; a UICC II/III tumor stage; macroscopically and histologically tumor-free resection margins; normal laboratory tests including carcinoembryonic antigen (CEA) and a normal abdominal ultrasound/CT on admission. Exclusion criteria: impaired general health conditions (Karnofsky index <80), age >75 years, a second malignancy or other relevant adverse clinical conditions such as advanced	1. Intensive daily pelvic floor exercise under the supervision of therapist (30-40 minutes) for 3 weeks in routine rehabilitation programs with biofeedback intra-anal electromyogram electrode device. Postoperative irradiation (total dose 50.4 ± 2.0 Gy) applied in split doses (1.8Gy, 5 /week). 2. Intensive daily pelvic floor exercise under the supervision	Self-reported severity of fecal incontinence using Modified Cleveland Incontinence Score (MCIS) questionnaire 16-point scale: <6.0 total incontinence with complete inability to retain solid stools; 7.0- 12.0- partial incontinence with	No intention to treat. Open label. Not randomized with significant differences at baseline. No adjustment reported.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
followup: 3 weeks and one year.	heart failure (NYHA III/IV), pulmonary diseases, metabolic diseases, poorly controlled diabetes (Hba1c > 7.7%), neurologic diseases and/or language barriers. Loss of followup: 34.7%	of therapist (30-40 minutes) for 3 weeks in routine rehabilitation programs With biofeedback intra-anal electromyogram electrode device.	incontinence for liquid stools; and >14.0 almost normal continence. The major criteria included stool frequency (number of daily evacuations), stool consistence, urgency (time to reach a toilet in minutes, seconds or immediately), discrimination between air, liquid and/or solid stool, spoiling to underwear and concomitant antidiarrheal medication and/or bulk-forming agents. Each item graded from 0 to 3 by the patient and by a trained nurse/ physician and subsequently controlled by an independent observer.	
Lundby, 2005[789] 15933797 RCT to examine the effects of adjuvant postoperative radiotherapy for rectal cancer on fecal incontinence. Duration of follow up: 15-20 years	494 patients with Dukes B or C rectal carcinoma who were surveyed 15-20 years after surgery. Exclusion criteria: not reported Loss of follow up:81%	1.Postoperative radiotherapy after anterior resection. 2.Anterior resection alone	Self-reported fecal incontinence.	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed the adequacy of randomization. Sample size not justified.
Effects of the surgical interventions on fecal incontinence in patients with rectal prolapse				
Luukkonen, 1992[790] RCT to examine effects of	30 consecutive patients with a full-thickness circumferential rectal prolapse. Exclusion criteria: not reported. Loss of followup: 3.3%	1. Posterior sutured abdominal rectopexy combined with sigmoidectomy complete rectal prolapse and end-to-end	Self-reported anal continence graded from 0 to 3: normal (grade 0), incontinent	No intention to treat. Open label. Randomization with random numbers tables. Allocation concealment not

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
abdominal rectopexy and sigmoid resection with polyglycolic acid mesh rectopexy without sigmoidectomy for complete rectal prolapse. Duration of followup: 6 months		anastomosis made with a circular stapler. 2.Polyglycolic acid mesh rectopexy without sigmoidectomy for complete rectal prolapse anterior rectal wall free	for flatus (grade 1), incontinent for liquid stool (grade 2), incontinent for solid stool (grade 3). Anal manometry outcomes	adequate. Baseline data not reported. Sample size not justified.
Racalbuto, 2004[791] RCT to examine the effects of haemorrhoidal stapler prolapsectomy or Milligan-Morgan hemorrhoidectomy on fecal incontinence. Duration of followup: 48 months	100 patients with 3rd and 4th degree hemorrhoids. Exclusion criteria: thrombosed hemorrhoids, partial prolapse (only one nodule), perianal fistulas, presence of chronic associated fissures. Loss of followup: not reported	1. Stapled prolapsectomy using longo circular stapler. 2. Traditional Milligan-Morgan Hemorrhoidectomy with exeresis of the haemorrhoidal piles upon low ligature of each vascular pedicle	Self-reported fecal incontinence using Continence Grading Scale with Wexner scores. Anal manomtery outcomes.	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.
Novell, 1994[792] RCT to examine the effects of Ivalon sponge versus sutured rectopexy for full-thickness rectal prolapse. Duration of followup: 47 months	63 patients with full thickness rectal prolapse and coexistent fecal incontinence. Exclusion criteria: not reported. Loss of followup: 12 died from causes unrelated to surgery - 19%	1. Ivalon sponge with sutured rectangle of sponge placed along the length of the sacrum. 2. Sutured rectopexy with sutured rectangle of sponge or sutures alone placed along the length of the sacrum	Self reported fecal incontinence as fecal soiling or using a pad	No intention to treat. Open label. Randomization with random numbers tables. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Solomon, 2002[793] RCT to examine effects of laparoscopic and open abdominal rectopexy in patients with full thickness rectal	40 patients with full thickness rectal prolapse with or without fecal incontinence. Exclusion criteria: concomitant gynecological procedures, previous rectopexy, large irreducible prolapse. Loss of followup: 2.5%	1. Laparoscopic rectopexy 2. Open abdominal rectopexy	Self-reported fecal incontinence scores with visual analog scale	No intention to treat. Single blind. Randomization not reported. Allocation concealment unclear. Baseline data confirmed adequacy of randomization. Sample size justified

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
prolapse. Duration of followup: 24 months				
Galili, 1997[794] RCT to examine the effects of polyglycolic acid and polypropylene mesh for rectopexy in the treatment of rectal prolapse. Duration of followup: 3.6 years	37 consecutive patients with complete rectal prolapse. Exclusion criteria: not reported. Loss of followup: none	1. Posterior abdominal rectopexy with non-absorbable mesh (Polypropylene, Prolene, Ethicon Ltd). 2. Posterior abdominal rectopexy with absorbable mesh (Polyglycolic acid, Dexon, Davis & Geck)	Self-reported impact on quality of life in scale from 0 to 10. Social activity as 0 - inability to leave home; 1- unrestricted social life. Fecal incontinence as 0 -complete incontinence, 0.5 - incontinence for loose stool only, 1 - complete continence.	Intention-to-treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.
Boccasanta, 2006[795] RCT to examine the effects of Altemeier's procedure with levatorplasty with handwritten and stapled anastomosis in patients with full thickness rectal prolapse and fecal incontinence. Duration of followup: 28 months	40 patients (55 females; mean age, 70.9 ± 11.3 years) with full thickness rectal prolapse, rectal procidentia >5cm; fecal incontinence with score >10. Exclusion criteria: associated colorectal diseases including cancer, rectal procidentia <5cm; fecal incontinence score <10; absolute contraindications to surgery; mental disorders; inflammatory bowel disease; polyps. Loss of followup: none	1. Altemeier's procedure with levatorplasty, monopolar electrocautery and hand sewn anastomosis. 2. Altemeier's procedure with levatorplasty using harmonic scalpel and circular stapler	Self-reported fecal continence using a validated scoring system (Wexner score, ranging from 0 - full continence to 20 – complete incontinence). Anal manometry and electromyogram outcomes.	Intention to treat not stated. Single blind. Computer-generated randomization list, with block size 4-6. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
Boccasanta, 1998[796] RCT to examine the effects of laparoscopic rectopexy and open technique in the treatment of complete rectal prolapse.	21 patients with complete full thickness rectal prolapse with variable degree of fecal incontinence aged between 22-76 years. Exclusion criteria: not reported. Loss of followup: none.	1. Laparoscopic stapled Well's rectopexy, perineal physiotherapy, external electric stimulation, and perineal biofeedback. 2. Well's rectopexy by the open technique without division of lateral rectal ligaments, perineal physiotherapy, external electric stimulation, and perineal	Self-reported fecal incontinence scores from 0 - complete continence to 6 - complete incontinence. Dynamic defecography, anorectal manometry, and anal electromyography	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

Duration of followup: 25.7 - 29.5 months.		biofeedback	outcomes.	
Effects of the surgical interventions on anal sphincter to prevent incidence and progression of fecal incontinence in adults				
Wiley, 2004[797] RCT to examine the effects of open and closed internal sphincterotomy on fecal incontinence in patients with chronic anal fissure. Duration of followup: 52 weeks	79 patients with chronic idiopathic fissure-in-ano (defined as fissure-in-ano with >6 weeks symptom duration) in whom conservative treatment had failed, suitable for lateral sphincterotomy. Exclusion criteria: previous sphincterotomy or anal dilation, fissure associated with inflammatory bowel disease, suspicion of malignant fissure or ulcer, concomitant procedure (*i.e.*, hemorrhoidectomy) to be performed at the time of sphincterotomy (excision of skin tags was permitted), and anesthetic requirements, which included spinal or caudal blockade. Loss of followup: 3.7%	1. Closed lateral internal sphincterotomy (Hoffman and Goligher) using a short stab incision and blind division of the internal sphincter guided by the surgeon finger. 2. Open lateral sphincterotomy (Parks) *via* a 1cm radial incision with division of the internal sphincter under direct vision.	Self-reported fecal incontinence with standardized questionnaires (modified Wexner score): score range of 0 to 20, 0 - complete or normal continence	No intention to treat. Open label. Central randomization. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization Sample size justified.
Parellada, 2004[798] RCT to examine the effects of lateral internal sphincterotomy with local 0.2% isosorbide dinitrate on fecal incontinence in patients with chronic anal fissure. Duration of followup: 24 months	63 patients with chronic anal fissure (anal pain at defecation for at least 2 months) on proctologic examination with observation of sphincter fibers at the base of the fissure independent of the presence of the sentinel pile or hypertrophic papilla who failed conservative treatments with a high-fiber diet, bulking agents, and warm sit baths. Exclusion criteria: not reported. Loss of followup: 14%	1. Surgical: open lateral internal spincterotomy and mucose closure with chromic catgut. 2. Chemical: local 0.2% isosorbide dinitrate - pea-size quantity applied manually at the entrance of the anus, 3 times/day immediately after a warm sit bath, for 6 weeks.	Self-reported fecal incontinence. Anal manometry outcomes.	No intention to treat. Open label. Randomization with random numbers: odd for the treatment group and even for the control group. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.
Wong, 2002[799] Not randomized not controlled multicenter trial to examine the effects of Acticon trade mark artificial bowel sphincter for fecal incontinence.	112 patients older than 18 year, with a fecal incontinence for >6 months and score of 88 or greater (scale, 1-120), who failed surgical treatment, with life expectancy >2 years. Exclusion criteria: adverse comorbities, fecal incontinence scores <88, Crohn's disease, irritable bowel syndrome as only cause of fecal incontinence, active pelvic sepsis, pregnancy, history of pelvic radiation, anal	Implantation of Acticon trade mark artificial bowel sphincter - solid silicone elastomer device.	Self-reported fecal incontinence using Fecal Incontinence Scoring System (FISS), from 0 - complete continence to 120 - complete incontinence.	Not randomized not controlled trial. The authors reported outcomes before and after the treatment.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Duration of followup: 12 months	receptive intercourse. Loss of followup: 2.6%			
Arroyo , 2005[800] RCT to examine the effects of close lateral internal sphincterotomy and botulinum toxin sphincterotomy for chronic anal fissure. Duration of followup: 2 months and 1- 3 years	80 patients with chronic anal fissure (presence of fibrous induration or exposed internal sphincter fibers) after at least 6 weeks of conservative treatments. Exclusion criteria: associated anal diseases (stenosis, abscess, fistula, hemorrhoids), comorbidities (inflammatory bowel disease, AIDS, tuberculosis, sexually transmitted diseases), anticoagulants, and pregnancy. Loss of followup: none	1. Close lateral internal sphincterotomy 2. Chemical sphincterotomy with 25 units botulinum toxin injected into the internal sphincter	Self-reported fecal incontinence using the Cleveland Clinic Scoring System (0 - perfect continence to 20 - complete incontinence)	Intention to treat not stated. Computer generated randomization. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.
Zbar, 2003[801] RCT to examine the effects of conventional cutting vs. internal anal sphincter-preserving seton for high trans-sphincteric fistula. Duration of followup: 12-13 months	34 patients with cryptogenic high trans-sphincteric fistulas. Exclusion criteria: not reported. Loss of followup: none.	1. Modified cutting seton, which repaired the internal anal sphincter muscle and re-routed the seton through the intersphincteric space. 2. Conventional cutting seton	Self-reported fecal continence using Pescatori's continence Scale. Anal manometry outcomes.	Intention to treat not stated. Open label. Randomization with random numbers. Allocation concealment not reported. Baseline data confirmed the adequacy of randomization. Sample size not justified.
Osterberg, 2004[802] RCT to examine the effects of levatorplasty and anal plug electrostimulation of the pelvic floor in idiopathic faecal incontinence. Duration of followup: 12 months	70 patients with disabling fecal incontinence of idiopathic (neurogenic) origin, persistent after dietary advice and a standardized treatment with bulking agents attempted for at least 2 months. Exclusion criteria: endosonographic anal sphincter defect, rectal prolapse or intra-anal intussusception, previous anorectal surgery other than haemorrhoidectomy. Loss of followup: 15.7%	1. Anterior levatorplasty with mobilization of external sphincter. 2. Anal (and vaginal in women) plug electrostimulation of the pelvic floor with stimulation frequency was 25Hz and the duration 1.5 seconds, with a pulse-train interval of 3 seconds.	Self-reported anal incontinence, pad use, stool frequency using standard bowel questionnaire to calculate Miller's incontinence score (0 - total continence to 18 - maximum incontinence). Anorectal manometry outcomes.	No intention to treat. Open label. Permuted block (4) randomization stratified by baseline squeeze and resting pressure. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Tjandra, 2004[803] RCT to examine the effects of injectable silicone biomaterial, PTP to augment the internal anal sphincter. Duration of followup: 3 months	82 patients (64 females; median age, 66 years) with severe fecal incontinence and a low anal resting pressure caused by internal anal sphincter dysfunction, who failed treatment with bulking or constipating agents and pelvic floor physiotherapy. Exclusion criteria: pregnancy, active perianal sepsis, unresected anorectal cancer, and immunosuppression. Loss of followup: 14.6% at 3 months	1. PTP injection into intersphincteric space and internal anal sphincter with guidance by endoanal ultrasound using 25 gauge hypodermic needles inserted to provide guidance to the position of intersphincteric space and the depth of insertion. 2. PTP injection into intersphincteric space and internal anal sphincter without guidance by endoanal ultrasound	Self-reported fecal Wexner continence score (0 - perfect continence; 20 - complete incontinence), visual analog scale (10 being best) for global quality of life, fecal incontinence quality of life scales.	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
O'Brien, 2004[804] RCT to examine the effects of an artificial bowel sphincter (Acticon Neosphincter) on fecal continence in severely incontinent adults. Duration of followup: 6 months	14 patients with severe fecal incontinence (the Cleveland Clinic Scoring System >15), mentally able to consent. Exclusion criteria: history of previous sphincter repair, chronic inflammation in perianal region, use of immunosuppressive drugs, inflammatory bowel disease, high anesthetic risk. Loss of followup: none	1. Placement of the artificial bowel sphincter activated at 6 weeks after surgery. 2. Usual supportive care: physiotherapy, pelvic floor exercise, dietary advice.	Self-reported fecal Incontinence score using the Cleveland Clinic Scoring System (0 - perfect continence to 20 - complete incontinence). American Medical Systems quality of life questionnaire specialized on fecal incontinence	Intention to treat not stated. Open label. Computer generated random numbers. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.
Muscle Transfer Procedures on FI				
Effects of the surgical interventions (diversion) on fecal incontinence in adults with cancer				
Seow-Choen, 1995[805] RCT to examine the effects of ultra-low anterior resection with a J colonic pouch and straight coloanal anastomosis in patients with rectal cancer. Duration of followup after closure of ileostomy: 12 months	40 patients with low rectal cancer and median distance from the lower edge of the tumor to the anal verge of 5cm. Exclusion criteria not reported. Loss of followup: 5%	1. Ultra-low anterior resection with total mesorectal excision and 8cm J colonic pouch-anal anastomosis (median distance of anastomosis from the anal verge 3cm). 2. Ultra-low anterior resection with total mesorectal excision and straight coloanal anastomosis (median distance of anastomosis from the anal verge 3.25cm).	Self-reported bowel urgency, fecal incontinence, pad use for fecal incontinence.	No Intention to treat. Open label. Randomization scheme not reported. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Ho, 2001[806] RCT to examine the effects of colonic J-pouch and straight coloanal anastomosis after ultra-low anterior resection of rectal cancer. Duration of followup: 2 years	40 patients with adenocarcinoma of the mid and lower rectum. Exclusion criteria: extensive local disease, which would preclude ultra-low anterior resection. Loss of followup: 17%	1. Standardized ultra-low anterior resection with straight coloanal anastomosis, the descending colon was anastomosed to the anorectal stump. 2. Standardized ultra-low anterior resection with J pouch anastomosis by folding the descending colon to the form of a `J', 6cm in length	Self-reported fecal incontinence using validated Wexner scale from 0 - continence to 24 - complete incontinence. Anal manometry outcomes.	No Intention to treat. Single blind. Randomization with random number table. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size not justified.
Soliani,1992[807] RCT to examine the effects of Conseal Colostomy Plug, a new device for the regulation of continence in patients with colostomies. Duration 2 weeks	57 patients with left terminal colostomies at least 6 months after neoplastic or inflammatory diseases, trained for self-irrigation. Exclusion criteria: stomal pathology, short transit intestinal syndrome, not self independent, unreliable for correct colostomy handling. Loss of followup: none	1. Conseal Colostomy Plug fit with a two-piece Conseal system. 2. Conseal Colostomy Plug fit with a one-piece Conseal system	Self-reported fecal incontinence as modification in continence time	No Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Hallbook, 1996[808] RCT to examine the effects of a low anterior resection with either straight or colonic J pouch anastomosis in patients with rectal cancer. Duration of followup after closure of ileostomy: 1 year	100 patients with rectal adenocarcinoma, lower margin not more than 12cm from the anal verge with possible curative sphincter-saving resection. Exclusion criteria: not reported. Loss of followup: 3%	1. Low anterior resection with total mesorectal excision with straight anastomosis 6 to 8cm in length. 2. Low anterior resection with total mesorectal excision colonic J pouch anastomosis 6 to 8cm in length.	Anastomotic leakage: abscess on CT scan or ultrasound; discharge of pus either per anum or through a fistula; and necessity of laparotomy or a transanal drainage procedure. Self-reported bowel function using questionnaire: Frequency of bowel movements per night. Degree of urgency: Ability to defer defecation for 30 minutes: always, often, sometimes, never. Composite score of grade and frequency of	No intention to treat. Single blind. Computer generated permuted block (4) randomization stratified for center and gender. Allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
			fecal incontinence (Miller scale). Ability to evacuate the bowel in <15 minutes: always, often, sometimes, never. Sensation of incomplete evacuation: never, sometimes, often, always. Impact on overall well-being: not at all, a little, quite a bit, very much.	
Ho, 2002[809] RCT to examine the effects of J-pouch and coloplasty pouch for low rectal cancer. Duration of followup: 1 year.	88 patients with mid- and low rectal adenocarcinoma. Exclusion criteria: extensive local disease, which would preclude ultralow anterior resection. Lost of followup: 23%, 7 deaths from chest infection and residual cancer	1. Standardized total mesorectal excision with at least 2cm of distal tumor clearance. J-pouch was constructed from descending colon 6cm in length using an Autosuture ILA 75 linear cutting stapler. 2. Standardized total mesorectal excision with at least 2cm of distal tumor clearance. Coloplasty pouch was anastomosed to stapled anorectal stump.	Self-reported fecal continence score with validated Fecal Incontinence Quality of Life Scale, anorectal manometry, and endoanal ultrasound.	Intention to treat. Randomization with a computer-generated code. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.
Machado, 2005[810] RCT to examine the effects of colonic J-pouch or a side-to-end anastomosis after low anterior resection for rectal cancer. Duration of followup: 2 years	71 patients with rectal cancer. Exclusion criteria: not reported. Loss of followup: none.	1. Low anterior resection and total mesorectal excision with a colonic J-pouch anastomosis. 2. Low anterior resection and total mesorectal excision with a colonic J-pouch or a side-to-end anastomosis.	Self-reported fecal incontinence using with scores from 0 to 18 (total incontinence). Bowel rank scores: number of bowel movements, incontinence scores, ability to defer defecation for 30 minutes and empty bowel for 15 minutes. Anorectal manometry outcomes	Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Laurent, 2005[811] RCT to examine the effects of staples or hand	37 patients with rectal adenocarcinoma requiring total mesorectal excision. Exclusion criteria: distant metastases. Loss of followup: 2.7%	1. Total mesorectal excision and hand sewn colonic J-pouch-anal anastomosis (6cm) 2. Total mesorectal excision and	Self-reported continence to gas, liquids, and solid stools Cleveland Clinic	No Intention to treat. Open label. Randomization in the operating room using computerized random number

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
sewn colonic J-pouch-anal anastomosis for rectal cancer. Duration of followup: 2 years		stapled colonic J-pouch-anal anastomosis (6cm) using PI-30 stapling instrument	Fecal Incontinence Score Scale	tables. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Lazorthes, 1997[812] RCT to examine the effects of small and large colonic J-pouch following coloanal anastomosis on fecal incontinence in patients with rectal carcinoma. Duration of followup: 12, and 24 months after colostomy closure.	59 consecutive patients with rectal cancers 4 to 8cm from the anal verge. Exclusion criteria: inadequate bowel length, thickened mesentery. Loss of followup: 34%	1. Complete rectal excision with coloanal anastomosis 6cm J-pouch group 2. Complete rectal excision with coloanal anastomosis 10cm J-pouch group	Self-reported bowel urgency and fecal continence	No Intention to treat. Open label. Randomization and allocation concealment not adequate. Baseline data confirmed adequacy of randomization. Sample size justified.
McKee, 1992[813] RCT to examine the effects of abdominal rectopexy with and without sigmoidectomy in rectal prolapse. Duration of followup: 20 months	18 patients with full thickness prolapse of the rectum. Exclusion criteria: not reported. Loss of followup: not reported	1. Abdominal rectopexy without sigmoidectomy 2. Abdominal rectopexy with sigmoidectomy of redundant sigmoid colon and end-to-end anastomosis of colon and rectum made in pelvic brim	Fecal incontinence using saline solution infusion test	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.
Furst, 2003[814] RCT to examine the effects of Colonic J-pouch and coloplasty in patients with resected distal rectal cancer. Duration of followup after closure of ileostomy: 6 months	40 patients with distal rectal cancer (<12cm from the anal verge) after low rectal resection and coloanal anastomosis. Exclusion criteria: preoperative incontinence, inflammatory bowel diseases, adenocarcinoma of proximal rectum (>12cm above the anocutaneous line). Loss of followup: 25%	1. 5cm colonic J-pouch constructed with a linear stapler 2. 8cm coloplasty pouch sutures horizontally with minimal extension effect.	Self-reported stool frequency. Anorectal manometry outcomes.	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Hasegawa, 2000[815] RCT to examine the effects of fecal diversion after sphincter repair on fecal incontinence. Duration of followup: 13 months	27 patients with fecal incontinence requiring sphincter repair due to localized sphincter damage. Exclusion criteria: not reported. Loss of followup: none	1. Fecal diversion with defunctioning stoma (closed at 4 months after surgery) for sphincter repair with standard overlapping technique 2. Sphincter repair with standard overlapping technique with no stoma	Self-reported fecal Incontinence score using the Cleveland Clinic Scoring System (0 - perfect continence to 20 - complete incontinence). Incontinence episodes as never; rarely if<1/month; sometime if <1/week; usually if >1/week; always if>1/day. Anal manometry outcomes.	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.
Sailer, 2002[816] RCT to examine the effects of straight and pouch coloanal reconstruction. Duration of followup: 3 months, 1 year	64 patients undergo low anterior rectal resection for primary cancer of the lower and middle third of the rectum. Exclusion criteria: manifest or latent fecal incontinence. Loss of followup: 39%, 11 patients died.	1. Total mesorectal excision and straight anastomosis with descending colon anastomosed in end-to-end fashion to the anal canal. 2. Total mesorectal excision and coloanal J pouch anastomosis by folding the descending colon to the form of a `J', 5 ± 6cm in length.	Self-reported fecal incontinence using Gastrointestinal Quality of Life Index (0-4 scale for 36 items with total 144 scores for nest outcome) European Organization for Research and Treatment of Cancer (EORTC) QLQ-C30) (0-100 scores for the best outcome) and disease-specific (EORTC QLQ-CR38) scales: 0-36 (perfect continence)	Intention-to treat. Open label. Randomization with computer-generated random clusters. Allocation concealment adequate. Sample size justified.
Ho, 2002[817] RCT to examine the effects of colonic J-pouch and straight coloanal anastomosis after ultra-low anterior resection of rectal cancer. Duration of followup: 1 year	12 patients with mean age 61.5 years with adenocarcinoma of the mid and lower rectum. Exclusion criteria: not reported. Loss of followup: none	1. Standardized ultra-low anterior resection with straight coloanal anastomosis, the descending colon was anastomosed to the anorectal stump. 2. Standardized ultra-low anterior resection with J pouch anastomosis by folding the descending colon to the form of a `J', 6cm in length	Self-reported fecal incontinence using bowel questionnaire Anal manometry outcomes. Scintigraphy with technetium TC 99m tin-colloid liquid test meal/I-131 microcapsule	No Intention to treat. Single blind. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
Furst, 2002[818] RCT to examine the effects of short colonic J-pouch and straight coloanal anastomosis for low rectal cancer. Duration of followup: 6 months.	74 consecutive patients (55 males) with rectal cancer in the lower and middle third of the rectum (<12cm above anocutaneuous line), local curative resection with preservation of sphincter, normal baseline continence. Exclusion criteria: inflammatory bowel disease, adenocarcinoma of proximal rectum (>12cm above anocutaneuous line). Loss of followup:16%, 6 deaths	1. The standardized total mesorectal excision with preaortal lymph node dissection, autonomic nerve preservation, and short (5cm) colonic J-pouch anastomosis. 2. The standardized total mesorectal excision with preaortal lymph node dissection, autonomic nerve preservation, and straight coloanal anastomosis.	Self report fecal incontinence using standardized questionnaire (European Organization for Research and Treatment of Cancer, EORTC-QLQ-C30). Anorectal manometry outcomes	No Intention to treat. Single blind. Randomization by independent person. Allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Jiang 2005[819] RCT to examine the effects of side-to-end or colonic J-pouch group on fecal incontinence in patients with rectal cancer. Duration of follow up: 2 years	56 consecutive patients with middle-to-low rectal cancer eligible for local curative resection with possible sphincter preservation, and normal continence preoperatively, Exclusion criteria: emergency admission. Loss of follow up: 14.3%	1.Side-to-end anastomosis after low anterior resection. 2.Colonic J-pouch reconstruction after low anterior resection	Self-reported fecal incontinence. Anal manometry outcomes. Continence was recorded as Grade 1 (perfect continence), Grade 2 (incontinence of flatus), Grade 3 (occasional minor soiling), Grade 4 (frequent major soiling), and Grade 5 (total incontinence).	No intention to treat. Randomization using random number table. Allocation concealment not reported. Baseline data confirmed the adequacy of randomization. Sample size not justified.
Surgical interventions in patients with chronic ulcerative colitis				
Reilly, 1997[820] RCT to examine the effects of staples or hand sewn techniques for excision of anal mucosa during ileas pouch-anal anastomosis. Duration of followup: 6 months after closure of the temporary stoma.	41 patients with chronic ulcerative colitis. Exclusion criteria: not reported. Loss of followup: 22%	1. Abdominal colectomy excising anal transition zone and hand sewing the pouch to the anal canal (Ileal Pouch-Anal Anastomosis). 2. Abdominal colectomy preserving anal transition zone and double stapling the pouch to the anal canal (Ileal Pouch-Anal Anastomosis)	Quality of life scores: 1 -severely restricted performance to 5 - improved performance. Anorectal manometry, scintigraphic outcomes and pudendal nerve terminal motor latency	Intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Johnston, 1996[821] RCT to examine the effects of	60 patients with ulcerative colitis. Exclusion criteria: not reported. Loss of followup: 5%	1-2. Duplicated (J) pelvic ileal reservoirs in restorative proctocolectomy constructed	Self-reported faecal leakage, anal soreness, the ability to	No Intention to treat. Single blind. Randomization and allocation concealment not

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
duplicated and quadruplicated pelvic ileal reservoirs in restorative proctocolectomy for ulcerative colitis. Duration of followup after operation or closure of the defunctioning ileostomy: 1 year		with either 30 or 40cm of ileum 3-4.Quadruplicated (W) reservoir pelvic ileal reservoirs in restorative proctocolectomy, constructed with either 30 or 40cm of ileum	defer defecation. Anorectal manometry outcomes.	reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Selvaggi, 2000[822] RCT to examine the effects of J-pouch and W-pouch configurations for ulcerative colitis. Duration of followup after ileostomy closure: 1 year	24 patients with ileal pouch-anal anastomosis for ulcerative colitis. Exclusion criteria: not reported. Loss of followup: none	1. Ileal pouch-anal anastomosis including total colectomy, total rectal excision, and two-limb J reservoir. 2. Ileal pouch-anal anastomosis including total colectomy, total rectal excision, and four-limb W reservoir	Self-reported bowel function and fecal incontinence scores with Wexner scale from 0-continence to 24 - complete incontinence. Anorectal manometry outcomes.	Intention to treat not stated. Single blind. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Oresland,1988[823] RCT to examine the effects of balloon dilatation of the pouch and sphincter biofeedback training in patients with an ileo-pouch anal anastomosis. Duration: 8 weeks Duration of followup after closure of ileostomy: 1 year	40 patients with ulcerative proctocolitis 4 weeks after ileo-pouch anal anastomosis with J pouch extended to pelvis and sutured to pectinate line. Exclusion criteria: not reported. Loss of followup: 5%.	1. Anal balloon dilatation with step-wise increasing pressure (5-80cm H20), distention ~ 60 seconds for 50-60 minutes. 2. Sphincter training with visual feedback for 50-60 minutes/day.	Resting anal pressure, self-reported number of bowel evacuations.	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size not justified.
Hahnloser, 2007[824] Retrospective analysis to analyze	1,885 patients with preoperative diagnosis of chronic ulcerative colitis operated with Ileal pouch-anal anastomosis – 1,824 J pouch, 44	1. Stage: abdominal colectomy, construction of ileal reservoir -J, S, or W pouch. Completion by	Self-reported fecal incontinence during the day and night as never,	Time-to-event and cumulative probability of remaining free from specific outcomes was

F151a. Effects of clinical interventions on fecal incontinence in community dwelling adults (continued)

Study	Participants	Clinical Interventions	Outcomes	Quality Issues
the effects of Ileal pouch-anal anastomosis for ulcerative colitis on fecal incontinence. Duration of followup: 11 years.	S pouch, and 17 W pouch. A diverting ileostomy was performed in 98·4% of patients (30% one-stage procedure). Loss of followup: response rates to the questionnaires by 1, 5, 10, 15, and 20 years were 80, 72, 73, 64, and 54%.	excision of anal transition zone and hand sewing the pouch to the dentate line area, or by preserving anal transition zone and double -stapling the pouch to the dentate line. 2. Stage: closure of the diverting stoma accomplished 2-3 months later.	occasional (1-2 episodes/ week), or frequent (>2 episodes per week).	estimated using the method of Kaplan and Meier, and survival curves were compared with the log rank test. No adjustment reported.
Diversion in patients with rectal prolapse				
McKee, 1992[813] RCT to examine the effects of abdominal rectopexy with and without sigmoidectomy in rectal prolapse. Duration of followup: 20 months	18 patients with full thickness prolapse of the rectum. Exclusion criteria: not reported. Loss of followup: not reported	1. Abdominal rectopexy without sigmoidectomy. 2. Abdominal rectopexy with sigmoidectomy of redundant sigmoid colon and end-to-end anastomosis of colon and rectum made in pelvic brim	Fecal incontinence using saline solution infusion test	No intention to treat. Open label. Randomization and allocation concealment not reported. Baseline data not reported. Sample size not justified.
Diversion in patients with sphincter damage				
Hasegawa, 2000[815] RCT to examine the effects of fecal diversion after sphincter repair on fecal incontinence. Duration of followup: 13 months	27 patients with fecal incontinence requiring sphincter repair due to localized sphincter damage. Exclusion criteria: not reported. Loss of followup: none	1. Fecal diversion with defunctioning stoma (closed at 4 months after surgery) for sphincter repair with standard overlapping technique. 2. Sphincter repair with standard overlapping technique with no stoma	Self-reported fecal Incontinence score using the Cleveland Clinic Scoring System (0 - perfect continence to 20 - complete incontinence). Incontinence episodes as never; rarely if<1/month; sometime if <1/week; usually if >1/week; always if>1/day. Anal manometry outcomes.	Intention to treat not stated. Open label. Randomization and allocation concealment not reported. Baseline data confirmed adequacy of randomization. Sample size justified.

Table F152. Comparative effectiveness of conservative management of fecal incontinence in residents of nursing homes (severity measures)

Author Sample	Active Treatment	Control Treatment	Outcome	Mean ± STD After Active Treatment	Mean ± STD After Control Treatment	Mean Difference, (95%CI)	% Difference from Control (95%CI)
Schnelle, 2002[459] N = 190 84% female	Integrated incontinence care and exercise every 2 hours 5 days a week including fluid prompting, prompted toileting, and regular wet checks, arm raise and arm curl exercises	Usual care	Fecal incontinence frequency, % of wet checks	3.0 ± 8.0	7.0 ±10.0	**-0.44 (-0.73;-0.15)**	-6.3 (-0.4;-2.2)
Schnelle, 1989[457] N = 126 75% female	Prompted voiding treatment: check for incontinence, asking for needed toileting assistance, prompted voiding, and socially reinforced for appropriate toileting	Usual care	Percent wet checks/total checks	17.8 ± 13.0	34.5 ± 16.8	**-1.1 (-1.5; -0.7)**	-3.2 (-4.3; -2.1)
			Percent appropriate toileting	59.4 ± 26.7	16.8 ± 22.0	**1.7 (1.3; 2.2)**	10.4 (7.9; 12.8)
Ouslander, 2005[458] N = 107 10% female	Functional Incidental Training: prompted voiding combined with individualized, functionally oriented endurance and strength-training exercises offered 4 times per day, 5 days per week	Usual care	Wet checks/total checks	25.0 ± 50.0	50.0 ± 28.0	**-0.6 (-1.0; -0.2)**	-1.2 (-2.0; -0.5)
			Wet stool checks/total checks	0.0 ± 44.7	1.0 ± 22.0	0.0 (-0.4; 0.4)	-2.9 (40.8; 35.0)
			Change after treatments in wet checks/ total checks			17.0 (-83.9; 49.9)	
			Change after treatments in wet stool checks/total checks			0.0 (-46.0; 446.0)

Table F209 Evidence tables of diagnostic values of the tests to identify UI and FI in adults .

Author, Year, Study Design Level of Evidence Settings	Purpose/Aim of Study	Population: Subject Age, Gender, Race, Ethnicity, Residency	Urodynamic Criteria of UI Definition of Incontinence,
De Muylder, 1992[826] Prospective Observational II-2 Community	To evaluate diagnostic value of careful history taking compared to urodynamic evaluation in the diagnosis of female patients with micturition disorders	408 women with symptoms of UI, 18-78 years old; 202 postmenopausal	ICS. A UD diagnosis of detrusor instability was made if urethrocystometry demonstrated a rise in true detrusor pressure of 15cm water or more. A diagnosis of detrusor instability was also made if a true detrusor rise of more than 5cm water was associated with urethral relaxation and incontinence. Genuine stress incontinence was diagnosed when UI occurred in the absence of a detrusor contraction associated with a rise in intra-abdominal pressure.
Cundiff, 1997[827] Retrospective Observational II-2 Community	To characterize historic and clinical parameters in incontinent women to determine the predictive value for urodynamic diagnoses	535 Women Mean age: 55.7 Range:21-95 SD:13.5 USA	Occurrence of UI coincident with coughing, sneezing, lifting, and walking was recorded as symptoms of stress urinary incontinence. UI occurring with symptoms of urgency was documented as urge urinary incontinence. ICS
Holtedahl, 2000[828] RCT I Community	To test the usefulness of urodynamic examination in female urinary incontinence	698 Women Age range: 50-74 Norway	ICS. Leakage was objectively demonstrated in at least one of three ways: visible leakage on coughing during the gynecological examination; a positive 48 hour pad test; or recording of “wet” on a 48 hour frequency/volume chart. UD diagnoses were based on both symptoms and signs: USI when there was a positive stress test with pad weight increase and/or negative maximal urethral closure pressure on coughing; UUI when there was leakage together with motor urgency in the form of detrusor contractions associated with strong desire to void during the filling phase (definite urge), or when there were signs of sensory urgency (such as a subjective maximal capacity <400ml and/or >7 voids/24 hours as shown in the frequency/volume chart brought along by each woman) associated with a history of involuntary leakage together with a strong desire to void (presumed urge); Mixed incontinence if criteria of stress as well as urge were fulfilled. A maximal urethral closing pressure of <25cm/H2O when the patient was resting was interpreted as a sign of urethral insufficiency, although there is no precise cut-off for this condition.
Yalcin, 2004[829] RCT I Community	To assess the accuracy with which a clinical diagnostic algorithm for SUI based on symptoms and signs without including urodynamics predicted the observation of	1,455 women Mean age: 51.3 Range: 28-81.7 SD: 11.2 USA	Subjects must have reported a predominant symptom of SUI with a weekly incontinent episode frequency ≥4 in the Phase 2 study and an incontinent episode frequency of ≥7 in 2 Phase 3 studies, in which an episode was defined as easily noticeable urine leakage that wet a pad or clothing and occurred with

Table F209 Evidence tables of diagnostic values of the tests to identify UI and FI in adults (clinical history vs. multi channel urodynamics) (continued)

Author, Year, Study Design Level of Evidence Settings	Purpose/Aim of Study	Population: Subject Age, Gender, Race, Ethnicity, Residency	Urodynamic Criteria of UI Definition of Incontinence,
	urodynamic SUI and the condition of SUI		physical stress such as coughing, sneezing or exercising. ICS
Diokno, 1987[830] Prospective Observational II-2 Community	To characterize urinary incontinence observed in elderly women and to assess the importance of various parameters used to evaluate urinary incontinence	200 women Mean: 68.5 Range age: 55-90 SD:8.6 USA	A clinical diagnosis of SUI was made when patient described loss of urine while straining, coughing, bending over, and/or provided objective evidence of stress loss during the physical exam. The loss of urine was clinically considered UUI when it followed an immediate toilet need and nocturia of three or more times was reported. ICS
Diokno, 1990[831] RCTI Community	To determine the value of various tests used to evaluate UI	456 women Age range:60-86 USA	SUI when urine loss was associated with physical exertion. UUI when urine loss was preceded by an urge to void. A UD diagnosis of incompetent urethral sphincter was made when 1 of the 3 findings was observed: Positive stress test, positive urine loss on stress cystography, positive findings on dynamic urethral profilometry. A diagnosis of competent urethral sphincter made if none of the criteria was satisfied,
Fitzgerald, 2002[832] CT II-1 Community	To determine whether scores on two validated urinary incontinence symptom scales predicted eventual urodynamic diagnoses.	293 women Mean age: 57 Range: 15-87 USA	ICS
Ishiko, 2000[833] CT II-1 Community	Purpose was to determine whether the urinary incontinence (UI) score is significantly useful in evaluating the clinical status of UI	198 women Mean age: 59.1 Range: 27-73 SD: 12.2 Japan	Gaudenz questionnaire partially modified to make it more suitable for a Japanese population was used in this study. It consisted of 15 questions. The answers to each question were assigned a certain number of points, and depending on the answer, included in the stress-score s-s or urge-score u-s. The total s-s and u-s points were added up separately, and a diagnosis was made based on the zones into which each of the scores fell. ICS
Korda, 1987[834] CT II-1 Community	To evaluate the diagnostic potential of careful history taking	566 women Mean age: 49 Australia	ICS
Kujansuu, 1982[835] Prospective Observational II-2	To evaluate the diagnostic accuracy of a scored urological questionnaire in the differential diagnosis of female urinary incontinence	121 women	

Table F209 Evidence tables of diagnostic values of the tests to identify UI and FI in adults (clinical history vs. multi channel urodynamics) (continued)

Author, Year, Study Design Level of Evidence Settings	Purpose/Aim of Study	Population: Subject Age, Gender, Race, Ethnicity, Residency	Urodynamic Criteria of UI Definition of Incontinence,
Lagro-janssen, 1991[836] CT II-1 Community	To assess the diagnostic potential of the patient's medical history in distinguishing between genuine USI, detrusor instability and mixed incontinence in primary care.	103 women Age range: 20-65 Netherlands	Incontinence was defined as the involuntary loss of urine twice or more times a month. SUI is the loss of urine during coughing and /or sneezing. UUI is the involuntary loss of urine associated with a strong desire to void. ICS
Niecestro, 1992[837] Prospective Observational II-2 Community	To evaluate the ability of stresscath to detect bladder neck incompetence in patients referred for urodynamics	66 women USA	
Ouslander, 1987[838](Prospect ive Observational II-2 Community	To compare the clinical presentation of incontinence to diagnoses based on urological and urodynamic evaluation	135 women Age >65years USA	ICS
Ramsay, 1993[839] Retrospective Observational II-2 Community	To define the symptomatology of those patients with detrusor instability, and those with genuine stress incontinence, looking particularly at the severity of urinary incontinence; and to devise a model to more accurately predict the diagnosis from the history alone.	200 women Mean age: 50.3 SD: 11.15 UK	Assessment of the severity made by asking 4 questions: 1. The frequency of urinary leakage (from 0 = never, 1 = <1/monthly, to 6 = ≥6/day) 2. The severity of urinary leakage was assessed by degree of protection required (ranging from 0 = none, 1 = minimal to 5 = continuous sanitary protection) 3. The number of pads used per day 4. The social restriction their incontinence caused (this was graded 0 = none, 1 = restricted, and 2 = housebound)
Sand, 1988[840] CT II-1 Community	To assess the value of history in assessing in establishing the etiology of UI.	218 women Mean age: 51.8 Range: 18-80 USA	ICS
Sandvik, 1995[841] CT II-1 Community	To validate simple diagnostic questions concerning female urinary incontinence, for the subsequent implementation in an epidemiological survey.	785 women Norway	A positive answer to the following question was presumed to be an indication of SUI: “Do you lose urine during sudden physical exertion, lifting, coughing or sneezing?’ UUI was presumed to be indicated by a positive answer to the question: “Do you experience such a strong and sudden urge to void that you leak before reaching the toilet?” A positive answer to both questions was registered as mixed incontinence. ICS
Sunshine[842]	Clinical correlation of urodynamic testing in patients with UI	109	

Table F209 Evidence tables of diagnostic values of the tests to identify UI and FI in adults (clinical history vs. multi channel urodynamics) (continued)

Author, Year, Study Design Level of Evidence Settings	Purpose/Aim of Study	Population: Subject Age, Gender, Race, Ethnicity, Residency	Urodynamic Criteria of UI Definition of Incontinence,
Cantor, 1980[843] Prospective Observational II-2		214 women	
Weidner, 2001[844] Prospective Observational II-2 Community	To determine the predictive value of the symptom of stress urinary incontinence and to evaluate the ability of other factors suggested by a published Agency for Health Care Policy and Research guideline for the discrimination of patients unlikely to require urodynamic testing before surgical management	950 women Mean age: 55.8 SD: 13.3 USA	The diagnosis of genuine SUI was made if the subject had the symptom of stress incontinence and had observable leakage produced by stress without concurrently demonstrable detrusor activity during urethrocystometry or urethral profilometry or had a positive result of a direct visualization test immediately after the catheters were removed in the total absence of detrusor instability during previous urethrocystometry. The diagnosis of detrusor instability was made if the subject had a detrusor contraction in association with urgency and leakage. The diagnosis of intrinsic sphincteric deficiency was made on the basis of combined historical, physical, urodynamic, and endoscopic parameters. 16. ICS
Bergman, 1990[845] Prospective Observational II-2 Community	To evaluate prospectively the reliability of the history in the evaluation of female UI	154 women Mean age: 48.7 France	Genuine SUI was urodynamically diagnosed when there was visible loss of urine during coughing with pressure equalization between bladder and urethra and in the absence of bladder contraction. ICS
Le Coutour, 1990[846] Prospective Observational II-2 Community	To assess the diagnostic value of history and UD investigation in female urinary incontinence	113 women Mean age: 50 Sweden	
Petros, 1992[847] Retrospective Observational II-2 Community	To test the proposition that the history of urge UI was accurate, by direct observation of events occurring during a provocative hand washing test.	Age range: 35-71	ICS
van Waalwijk van Doorn, 1997[848] Prospective Observational II-2 Community	To investigate the usefulness of ambulatory UD to quantify detrusor activity, and develop a parameter to quantify the grade of detrusor over-activity.	228 women Mean age:44.4 Range: 9-75 Netherlands	ICS

Table F209 Evidence tables of diagnostic values of the tests to identify UI and FI in adults (clinical history vs. multi channel urodynamics) (continued)

Author, Year, Study Design Level of Evidence Settings	Purpose/Aim of Study	Population: Subject Age, Gender, Race, Ethnicity, Residency	Urodynamic Criteria of UI Definition of Incontinence,
Ficazzola, 1998[849] Prospective/Observational II-2 Community	To determine the incidence of intrinsic sphincter deficiency and bladder dysfunction, and the contribution of each to incontinence.	60 men Mean age: 64.8 Range: 48-73 USA	Detrusor instability was defined as any involuntary bladder contraction of 15 cm. water, according to the International Continence Society, or involuntary contraction of any magnitude associated with urge. ICS
Ding, 1997[850] Prospective/Observational II-2	To study the usefulness of lower urinary tract symptoms and postvoid residual urine volume in the diagnosis of voiding dysfunction in elderly men	126 men	
Porru, 1994[851] Prospective/Observational II-2 Community	To evaluate bladder behavior in patients with DI correlated incontinence and micturition disorders by performing both a conventional UD investigation and extramural ambulatory monitoring during normal daily activity.	46 Men and women Mean age: 48.4 Range: 22-80 Italy	ICS
Digesu, 2003[852] CT I	To determine whether the urodynamic diagnosis is useful in the management of women with symptoms of an overactive bladder (OAB).	4,500 women Mean age: 55.4 Range: 22-73 UK	Genuine stress incontinence was classified as mild, moderate, and severe if leakage of urine occurred following five, three or one coughs, respectively. Detrusor instability was diagnosed when detrusor contractions were seen in the presence of urgency or urinary leakage while attempting to inhibit micturition. ICS
Clarke, 1997[853]	To characterize historic and clinical parameters in incontinent women to determine the predictive value for urodynamic diagnoses	1,000 women Mean age: 53 Australia	
Kong, 1990[854] Retrospective/Observational II-2		269 women Mean age: 77 Range: 59-94 UK

Men	None

Table F211. Questionnaires with rigorous validity, reliability and responsiveness highly recommended by the Symptom and Quality of Life Committee of the International Consultation on Incontinence[855]

International Consultation on Incontinence Questionnaire[856]

Consists of four questions and numeric scales:

1. How often do you leak urine? (0-5); never - all the time
2. How much urine do you usually leak? (0-6); none - large amount
3. Overall, how much does leaking urine interfere with your everyday life? (0-10); not at all - a great deal
4. When does urine leak? Multiple choices.

ICIQ score is the sum of questions 1-3.

Bristol Female Lower Urinary Tract Symptoms Questionnaire-short form[857]

BFLUTS questionnaire symptom items: numbers, labels, and response categories

Question	Symptom	Response Categories
1 +P	Frequency (times daily)	1-6, 7-8, 9-10, 11-12, 13+
2 +P	Nocturia	0, 1, 2, 3, 4+
3 +P	Urgency	Never, occasionally, sometimes, most of the time, all of the time
4 +P	Urge incontinence	Never, occasionally, sometimes, most of the time, all of the time
5 +P	Bladder pain	Never, occasionally, sometimes, most of the time, all of the time
6 +P	Frequency incontinence	Never, ≤1/week, 2-3/week, 1/day, several times a day
7 +P	Stress incontinence	Never, occasionally, sometimes, most of the time, all of the time
8 +P	Unpredictable miscellaneous incontinence	Never, occasionally, sometimes, most of the time, all of the time
9	Volume of leakage	No leakage, drops/pants damp, dribble/pants wet, floods: soaking through to outer clothing, floods: running down
12 +P	Hesitancy	Never, occasionally, sometimes, most of the time, all of the time
13 +P	Strain to start	Never, occasionally, sometimes, most of the time, all of the time
14 +P	Intermittency	Never, occasionally, sometimes, most of the time, all of the time
15 +P	Nocturnal incontinence	Never, occasionally, sometimes, most of the time, all of the time
16 +P	Reduced stream	Not reduced, reduced a little, quite reduced, reduced a great deal, no stream
17	Acute retention	No, yes once, yes twice, yes more than twice
18 +P	Burning	Never, occasionally, sometimes, most of the time, all of the time
19 +P	Incomplete emptying	Never, occasionally, sometimes, most of the time, all of the time
20	Stopping flow	Yes easily, yes with difficulty, no cannot stop the flowing
25 +P	Frequency (hours between voiding)	Every 4 hours or more, every 3 hours, every 2 hours, hourly
Sexual functioning		
21 +P	Pain due to dry vagina	Not at all, a little, somewhat, a lot
22 +P	Sex life spoiled	Not at all, a little, somewhat, a lot
23 +P	Pain during intercourse	Not at all, a little, somewhat, a lot
24 +P	Leakage during intercourse	Not at all, a little, somewhat, a lot
Quality of life		
10a	Change underclothes/wear protection	No, change underclothes, panty liners/mini pads, maxi/super sanitary towels, nappies/incontinence products
10b	Number of changes	No change, 1, 2-3, 4-5, more than 5 times
11	Change outer clothing	Never, occasionally, sometimes, most of the time, all of the time
26 +P	Cut down fluid	Never, occasionally, sometimes, most of the time, all of the time
27 +P	Affect daily tasks	Never, occasionally, sometimes, most of the time, all of the time
28 +P	Avoidance of situations where no toilet	Never, occasionally, sometimes, most of the time, all of the time
29 +P	Interfere with physical activity	Never, occasionally, sometimes, most of the time, all of the time
30 +P	Interfere with social life	Never, occasionally, sometimes, most of the time, all of the time
31	Overall interference with life	Never, occasionally, sometimes, most of the time, all of the time
32	How long symptoms bothered	<1 year, 1-2 years, 2-3 years, more than 3 years
33	Spend rest of life with no change	Perfectly happy, pleased, mostly satisfied, mixed feelings, mostly dissatisfied, very unhappy, desperate

+P indicates a linked question on the degree of the problem caused.

Table F211. Questionnaires with rigorous validity, reliability and responsiveness highly recommended by the Symptom and Quality of Life Committee of the International Consultation on Incontinence (continued)

Confidential BFLUTS-SF Questionnaire

We would like to find out about your urinary symptoms and we are very grateful that you can help us by filling in this questionnaire. Please answer each question, thinking about the symptoms you have experienced in the last month. You will see that some questions ask how often you have a symptom:
Occasionally = less than one third of the time
Sometimes = between one and two thirds of the time
Most of the time = more than two thirds of the time
Please put a tick in one box for each question ✔ □

F1 During the night, how many times do you have to get up to urinate, on average?
- None - 0
- 1 - 1
- 2 - 2
- 3 - 3
- 4 or more - 4

F2 Do you have to rush to the toilet to urinate?
- Never - 0
- Occasionally - 1
- Sometimes - 2
- Most of the time - 3
- All of the time - 4

F3 Do you have pain in your bladder?
- Never - 0
- Occasionally - 1
- Sometimes - 2
- Most of the time - 3
- All of the time - 4

F4 How often do you pass urine during the day?
- Every 4 hours or more - 0
- Every 3 hours - 1
- Every 2 hours - 2
- Hourly - 3

BFLUTS-FS: sum scores F1-F4 - -

V1 Is there a delay before you can start to urinate?
- Never - 0
- Occasionally - 1
- Sometimes - 2
- Most of the time - 3
- All of the time - 4

V2 Do you have to strain to urinate?
- Never - 0
- Occasionally - 1
- Sometimes - 2
- Most of the time - 3
- All of the time - 4

V3 Do you stop and start more than once while you urinate?
- Never - 0
- Occasionally - 1
- Sometimes - 2
- Most of the time - 3
- All of the time - 4

BFLUTS-VS: sum scores V1-V3 - -

I1 Does urine leak before you can get to the toilet?
- Never - 0
- Occasionally - 1
- Sometimes - 2
- Most of the time - 3
- All of the time - 4

Table F211. Questionnaires with rigorous validity, reliability and responsiveness highly recommended by the Symptom and Quality of Life Committee of the International Consultation on Incontinence (continued)

I2 How often do you leak urine?
- Never - 0
- Once or less per week - 1
- 2-3 times per week - 2
- Once per day - 3
- Several times per day - 4

I3 Does urine leak when you are physically active, exert yourself, cough, or sneeze?
- Never - 0
- Occasionally - 1
- Sometimes - 2
- Most of the time - 3
- All of the time - 4

I4 Do you ever leak for no obvious reason and without feeling that you want to go?
- Never - 0
- Occasionally - 1
- Sometimes - 2
- Most of the time - 3
- All of the time - 4

I5 Do you leak urine when you are asleep?
- Never - 0
- Occasionally - 1
- Sometimes - 2
- Most of the time - 3
- All of the time - 4

BFLUTS-IS: sum scores 11-15 - -

S1 To what extent do you feel that your sex life has been spoiled by your urinary symptoms?
- Not at all - 0
- A little - 1
- Somewhat - 2
- A lot - 3

S2 Do you leak urine when you have sexual intercourse?
- Not at all - 0
- A little - 1
- Somewhat - 2
- A lot - 3

BFLUTS-sex: sum scores S1 & S2 - -

QoL1 Do you need to change your outer clothing during the day because of urine leakage?
- Never - 0
- Occasionally - 1
- Sometimes - 2
- Most of the time - 3
- All of the time - 4

QoL2 Do you cut down on the amount of fluid you drink so that your urinary symptoms improve, and you can do the things that you want to do?
- Never - 0
- Occasionally - 1
- Sometimes - 2
- Most of the time - 3
- All of the time - 4

QoL3 To what extent have your urinary symptoms affected your ability to perform daily tasks (eg, cleaning, DIY, lifting objects)?
- Not at all - 0
- A little - 1
- Somewhat - 2
- A lot - 3

QoL4 Do you avoid places and situations where you know a toilet is not nearby (eg, shopping, traveling, theater, church)?
- Never - 0
- Occasionally - 1
- Sometimes - 2
- Most of the time - 3
- All of the time - 4

A little - 1
Somewhat - 2
A lot - 3
BFLUTS-QoL: Sum scores QoL1-QoL5 - -

Stress and Urge Incontinence and Quality of Life Questionnaire (SUIQQ)[858]

The Stress Incontinence Index consists of 9 questions on activities that cause leakage (when the woman coughs, sneezes, laughs, walks up or down stairs, rises from the bed, lifts heavy objects and during physical activity, sports and intercourse).
- Frequency of stress incontinence episodes: never, 1-4 times a month, 1-6 times a week, once a day, and more than once daily)
- Amount of leakage: nothing, drops/moist underwear, dripping/wet underwear, running/passes through all clothes, and running down the legs or down to the floor).

The Urge Incontinence Index consists of two questions: how often and to what extent urge incontinence is experienced.
The Quality of Life Index: (1) the number of incontinence diapers used (none, 1-3 per week, 4-6 per week, 1-4 per day, and more than 4 per day), (2) how often activities are avoided due to fear of leakage (never, seldom, sometimes, often, always), (3) how often places or situations are avoided due to fear of leakage (never, seldom, sometimes, often, always), and (4) how leakage influences holidays, family life, social life and sleep during the night. These last four questions are marked 'yes', 'no' or 'not relevant'. Except for the first stress incontinence item, therefore, all items are expressed in a scale of five categories, with scores of 0-4. The nine questions from the first stress item have possible choices 'yes', 'no' and 'not relevant'. The sum score from the nine stress incontinence questions are recalculated into five categories (0, 1-3, 4-5, 6-7 and 8-9) to give this item the same relative weight as the others.

The International Continence Society male questionnaire, short form[859]

We would like to find out about your urinary symptoms and we are very grateful that you can help us by filling in this questionnaire. Please answer each question, thinking about the symptoms you have experienced in the last month.
You will see that some questions ask how often you have a symptom:
Occasionally - less than one-third of the time
Sometimes - between one and two-thirds of the time
Most of the time - more than two-thirds of the time
Is there a delay before you can start to urinate?
Do you have to strain to continue urinating?
Would you say that the strength of your urinary stream is. . .
normal
occasionally reduced
sometimes reduced
reduced most of the time
reduced all of the time
Do you stop and start more than once while you urinate?
How often do you feel that your bladder has not emptied properly after you have urinated?
ICS male VS: sum scores V1–V5
Do you have to rush to the toilet to urinate?
Does urine leak before you can get to the toilet?
Does urine leak when you cough or sneeze?
Do you ever leak for no obvious reason and without feeling that you want to go?
Do you leak urine when you are asleep?
How often have you had a slight wetting of your pants a few minutes after you had finished urinating and had dressed yourself?

The International Continence Society male questionnaire, short form[859]

1 1P	Frequency (times daily)	1-6, 7-8, 9-10, 11-12 1 131
2 1P	Nocturia	0, 1, 2, 3 1 41
3 1P	Urgency	Never, occasionally, sometimes, most of time, all of time
4 1P	Urge incontinence	Never, occasionally, sometimes, most of time, all of time
5 1P	Bladder pain	Never, occasionally, sometimes, most of time, all of time
6 1P	Stress incontinence	Never, occasionally, sometimes, most of time, all of time
7 1P	Unpredictable miscellaneous incontinence	Never, occasionally, sometimes, most of time, all of time
8 1P	Hesitancy	Never, occasionally, sometimes, most of time, all of time
9 1P	Starting strain	Never, occasionally, sometimes, most of time, all of time
10 1P	Continuing strain	Never, occasionally, sometimes, most of time, all of time
11 1P	Urination seated	Standing, seated
12 1P	Decreased stream (words)	Normal, decreased, never, occasionally, sometimes, most of time, all of time
13	Weak stream always	Yes, no
14	Decreased stream (picture)	4 Distances
15 1P	Intermittency	Never, occasionally, sometimes, most of time, all of time
16 1P	Dysuria	Never, occasionally, sometimes, most of time, all of time
17 1P	Incomplete emptying	Never, occasionally, sometimes, most of time, all of time
18 1P	Terminal dribbling	Never, occasionally, sometimes, most of time, all of time
19 1P	Post-void dribbling	Never, occasionally, sometimes, most of time, all of time
20 1P	Nocturnal incontinence	Never, occasionally, sometimes, most of time, all of time
22 1P	Repeat urination	Never, occasionally, sometimes, most of time, all of time
23	Acute retention	No, 1, 2, more than 2
28 1P	Frequency (hrs. between voidings)	4, 3, 2 hours., hourly

Possible responses for the following questions:
- Occasionally - less than one third of the time
- Sometimes - between one and two thirds of the time
- Most of the time - more than two thirds of the time

-Is there a delay before you can start to urinate?
- Do you have to strain to continue urinating?
- Would you say that the strength of your urinary stream is
  - normal
  - occasionally reduced
  - sometimes reduced
  - reduced most of the time
  - reduced all of the time.

-Do you stop and start more than once while you urinate?
-How often do you feel that your bladder has not emptied properly after you have urinated?
-Do you have to rush to the toilet to urinate?
-Does urine leak before you can get to the toilet?
-Does urine leak when you cough or sneeze?
-Do you ever leak for no obvious reason and without feeling that you want to go?
-Do you leak urine when you are asleep?
-How often have you had a slight wetting of your pants a few minutes after you had finished urinating and had dressed yourself?

Overactive bladder symptom and health-related quality of life questionnaire[860]

This questionnaire asks about how much you have been bothered by selected bladder symptoms during the past 4 weeks. Please circle the number that best describes the extent to which you were bothered by each symptom during the past 4 weeks. There are no right or wrong answers. Please be sure to answer every question using possible responses: not at all, a little bit, somewhat, quite a bit, a great deal, a very great deal

During the past 4 weeks, how bothered were you by:
1. Frequent urination during the daytime hours
2. An uncomfortable urge to urinate
3. A sudden urge to urinate with little or no warning
4. Accidental loss of small amounts of urine
5. Nighttime urination
6. Waking up at night because you had to urinate
7. An uncontrollable urge to urinate
8. Urine loss associated with a strong desire to urinate

During the past 4 weeks, how often have your bladder symptoms: none of the time, a little of the time, some of the time, a good bit of the time, most of the time, all of the time
9. Made you carefully plan your commute?
10. Caused you to feel drowsy or sleepy during the day?
11. Caused you to plan 'escape routes' to restrooms in public places?
12. Caused you distress?
13. Frustrated you?
14. Made you feel like there is something wrong with you?
15. Interfered with your ability to get a good night's rest?
16. Caused you to decrease your physical activities (exercising, sports, etc.)?
17. Prevented you from feeling rested upon waking in the morning?
18. Frustrated your family and friends?
19. Caused you anxiety or worry?
20. Caused you to stay home more often than you would prefer?
21. Caused you to adjust your travel plans so that you are always near a restroom?
22. Made you avoid activities away from restrooms (i.e., walks, running, hiking)?
23. Made you frustrated or annoyed about the amount of time you spend in the restroom?
24. Awakened you during sleep?
25. Made you worry about odor or hygiene?
26. Made you uncomfortable while traveling with others because of needing to stop for a restroom?
27. Affected your relationships with family and friends?
28. Caused you to decrease participating in social gatherings, such as parties or visits with family or friends?
29. Caused you embarrassment?
30. Interfered with getting the amount of sleep you needed?
31. Caused you to have problems with your partner or spouse?
32. Caused you to plan activities more carefully?
33. Caused you to locate the closest restroom as soon as you arrive at a place you have never been?

Table F211. Questionnaires with rigorous validity, reliability and responsiveness highly recommended by the Symptom and Quality of Life Committee of the International Consultation on Incontinence (continued)

Urogenital Distress Inventory[861]

Please indicate which symptoms you are now experiencing, and how bothersome they are for you. Be sure to answer all items.

Do you experience frequent urination? If yes, how much does it bother you? not at all; slightly; moderately; greatly
Do you experience a strong feeling of urgency to empty your bladder?
Do you experience urine leakage related to the feeling of urgency?
Do you experience urine leakage related to physical activity, coughing or sneezing?
Do you experience general urine leakage not related to urgency or activity?
Do you experience small amounts of urine leakage (that is, drops)?
Do you experience large amounts of urine leakage?
Do you experience nighttime urination?
Do you experience bedwetting?
Do you experience difficulty emptying your bladder?
Do you experience a feeling of incomplete bladder emptying?
Do you experience lower abdominal pressure?
Do you experience pain when urinating?
Do you experience pain in the lower abdominal or genital area?
Do you experience heaviness or dullness in the pelvic area?
Do you experience a feeling of bulging or protrusion in the vaginal area?
Do you experience bulging or protrusion you can see in the vaginal area?
Do you experience pelvic discomfort when standing or physically exerting yourself?
Do you have to push on the vaginal walls to have a bowel movement?
Other symptoms

Incontinence impact questionnaire

Some women find that accidental urine loss and/or prolapse may affect their activities, relationships, and feelings. The questions below refer to areas in your life which may have been influenced or changed by your problem. For each question, check the response that best describes how much your activities, relationships, and feelings are being affected by urine leakage and/or prolapse. Responses: not at all; slightly; moderately; greatly

Has urine leakage and/or prolapse affected your:
Ability to do household chores (cooking, housecleaning, laundry)
Ability to do usual maintenance or repair work done in home or yard
Shopping activities
Hobbies and pastime activities
Physical recreational activities such as walking, swimming, or other exercise
Entertainment activities such as going to a movie or concert
Ability to travel by car or bus for distances less than 20 minutes away from home
Ability to travel by car or bus for distances greater than 20 minutes away from home
Going to places if you are not sure about available restrooms
Going on vacation
Church or temple attendance
Volunteer activities
Employment (work) outside the home
Having friends visit you in your home
Participating in social activities outside your home
Relationship with friends
Relationship with family excluding husband/companion
Ability to have sexual relations
Way you dress
Emotional health
Physical health
Sleep
Does fear of odor restrict your activities?
Does fear of embarrassment restrict your activities?

In addition, does your problem cause you to experience any of the following feelings?
Nervousness or anxiety
Fear
Frustration
Anger
Depression
Embarrassment

Table F211. Questionnaires with rigorous validity, reliability and responsiveness highly recommended by the Symptom and Quality of Life Committee of the International Consultation on Incontinence (continued)

Incontinence Severity Index[863]

How often do you experience urinary leakage?
- Less than once a month
- One or several times a month
- Every day and/or night

How much urine do you lose each time?
- Drops
- Small splashes
- More

The severity index is created by multiplying the results of questions 1 and 2:
- 1-2 = slight
- 3-4 = moderate
- 6-8- = severe

In the three-level severity index, responses to the second question are first aggregated into drops (1) and more (2), and then multiplied with the frequency, resulting in the following index values (1–8):
- 1–2 = slight
- 3–4 = moderate
- 6–8 = severe

The four-level severity index is based on the following index values (1–12):
- 1–2 = slight
- 3–6 = moderate
- 8–9 = severe
- 12 = very severe

International Continence Society male, lower urinary tract symptoms primarily[865]

During the day, how many times do you urinate, on average?
- 1 to 6 times
- 7 to 8 times
- 9 to 10 times
- 11 to 12 times
- 13 or more times

How much of a problem is this for you?
- Not a problem
- A bit of a problem
- Quite a problem
- A serious problem

During the night, how many times do you have to get up to urinate, on average?
- None
- One
- Two
- Three
- Four or more

How much of a problem is this for you?

Would you say that the strength of your urinary stream is....
- Normal
- Occasionally reduced
- Sometimes reduced
- Reduced most of the time
- Reduced all of the time

How much of a problem is this for you?

Please ring the number that corresponds with the strength of your urinary stream over the past month.

How often do you pass urine during the day?
- Hourly
- Every 2 hours
- Every 3 hours
- Every 4 hours or more

How much of a problem is this for you?

Table F211. Questionnaires with rigorous validity, reliability and responsiveness highly recommended by the Symptom and Quality of Life Committee of the International Consultation on Incontinence (continued)

Incontinence Quality of Life (in persons with UI) questionnaire[867]

I worry about not being able to get to the toilet on time.
I worry about coughing and sneezing.
I have to be careful about standing up after sitting down.
I worry where the toilets are in new places.
I feel depressed.
I don't feel free to leave my home for long periods of time.
I feel frustrated because my UI prevents me from doing what I want.
I worry about others smelling urine on me.
Incontinence is always on my mind.
It's important for me to make frequent trips to the toilet.
Because of my incontinence, it is important to plan every detail in advance.
I worry about my incontinence getting worse as I grow older.
I have a hard time getting a good night's sleep.
I worry about being embarrassed or humiliated be cause of my incontinence.
My incontinence makes me feel like I'm not a healthy person.
My UI makes me feel helpless.
I get less enjoyment out of life because of my UI.
I worry about wetting myself.
I feel like I have no control over my bladder.
I have to watch what I drink.
My UI limits my choice of clothing.
I worry about having sex.

All items use the following response scale:

1 = Extremely
2 = Quite a bit
3 = Moderately
4 = A little
5 = Not at all

Subscale structure:

Avoidance and limiting behavior: items 1, 2, 3, 4, 10, 11, 13, and 20
Psychosocial impacts: items 5, 6, 7, 9, 15, 16, 17, 21, and 22
Social embarrassment: items 8, 12, 14, 18, and 19

Incontinence Classification System[868]

Domain	Nature of the Questions
Social interactions	Relationships with friends Relationships with spouse/companions Difficulty establishing new relationships
Personal strain	Interference with the ability to perform usual daily tasks Ability to engage in physical recreation Ability to engage in non strenuous recreation Nervousness or anxiety related to incontinence
Global health and quality of life	Effect on overall health Effect on overall level of energy Feelings of being less useful Overall quality of life Impact on quality of life if there was no incontinence
Satisfaction	Overall satisfaction with life
Financial	Effect on financial situation
Sexuality	Interference with sexual activity

Table F211. Questionnaires with rigorous validity, reliability and responsiveness highly recommended by the Symptom and Quality of Life Committee of the International Consultation on Incontinence (continued)

King's Health Questionnaire[869]

How would you describe your health at present? very good; good; fair; poor; very poor
How much do you think your bladder problem affects your life? not at all; a little; moderately; a lot

What are your bladder problems and how much do they affect you?
- Frequency: (going to the toilet very often)
- Nocturia: (getting up at night to pass urine)
- Urgency: (a strong and difficult to control desire to pass urine)
- Urge Incontinence: (urinary leakage associated with a strong desire to pass urine)
- Stress Incontinence: (urinary leakage with physical activity e.g. coughing, sneezing or running)
- Nocturnal Enuresis: (wetting the bed at night)
- Intercourse Incontinence: (urinary leakage with sexual intercourse)
- Frequent waterworks infections
- Bladder pain
- Difficulty passing urine

Below are some daily activities that can be affected by bladder problems. How much does your bladder problem affect you?
- a. To what extent does your bladder problem affect your household tasks (e.g. cleaning, shopping)
- b. Does your bladder problem affect your job or your normal activities outside the home

Physical Limitations (Tick the box that applies to you)
- a. Does your bladder problem affect your physical activities (e.g. going for a walk, run, sport, gym etc.)?
- b. Does your bladder problem limit your ability to travel?

Social Limitations
- a. Does your bladder problem affect your social life?
- b. Does your bladder problem affect your ability to see/visit friends?

Personal Relationships
- a. Does your bladder problem affect your relationship with your partner?
- b. Does your bladder problem affect your sex life?
- c. Does your bladder problem affect your family life?

Emotions
- a. Does your bladder problem make you feel depressed?
- b. Does your bladder problem make you feel anxious or nervous?
- c. Does your bladder problem make you feel bad about yourself?

Sleep/ Energy
- a. Does your bladder problem affect your sleep?
- b. Do you feel worn out/tired?

Do you do any of the following? If so how much?
- a. Wear pads to keep dry?
- b. Be careful how much fluid you drink?
- c. Change you underclothes when they get wet?
- d. Worry in case you smell?
- e. Get embarrassed because of your bladder problem?

Incontinence Impact Questionnaire-7[862]

Some people find that accidental urine loss may affect their activities, relationships, and feelings. The questions below refer to areas in your life that may have been influenced or changed by your problem. For each question, circle the response that best describes how much your activities, relationships, and feelings are being affected by urine leakage.

Has urine leakage affected your: not at all=1; slightly=1; moderately=2; greatly=3
- Ability to do household chores (cooking, housecleaning, laundry)?
- Physical recreation such as walking, swimming, or other exercise?
- Entertainment activities (movies, concerts, etc.)?
- Ability to travel by car or bus more than 30 minutes from home?
- Participation in social activities outside your home?
- Emotional health (nervousness, depression, etc.)?
- Feeling frustrated?

Items 1 and 2 = physical activity
Items 3 and 4 = travel
Item 5 = social/relationships
Items 6 and 7 = emotional health

Table F211. Questionnaires with rigorous validity, reliability and responsiveness highly recommended by the Symptom and Quality of Life Committee of the International Consultation on Incontinence (continued)

Scoring. Item responses are assigned values of 0 for "not at all," 1 for "slightly," 2 for "moderately," and 3 for "greatly." The average score of items responded to is calculated. The average, which ranges from 0 to 3, is multiplied by 33 1/3 to put scores on a scale of 0 to 100.

UI Severity Score (UISS)[871 872]

The UISS questionnaire consists of 10 questions designed to quantify the amount of leakage, the degree to which UI affects aspects of a woman's daily life, and need to use pads. The responses are scored from 0 to 2, yielding a total score between 0 and 20. The lower scores reflect better quality of life. Marking the most appropriate alternative: not at all=0; sometimes=1; often=2.

1. Do you experience urine leakage not related to effort or position (for example lying down)?
2. Do you experience urine leakage related to minor physical activity (e.g. walking or rising)?
3. Do you experience urine leakage related to sudden, strong physical activity or even coughing or sneezing?
4. Has urine leakage disturbed your daily chores (shopping, cooking, housecleaning etc.)?
5. Has urine leakage disturbed your employment (client service, work performance etc)?
6. Are you afraid that others will notice your problem (fear of your odour or wetness etc.)?
7. Do you have to restrict or give up social activities (such as visiting friends, physical activity, theatre, church etc.)?
8. Do your incontinence symptoms disturb your sex life?
9. Does incontinence cause irritation of your external genital organs?
10. How often must you use a protective nappy or pad?

CONTILIFE- Urinary Incontinence-Specific Measure of Quality of Life[873]

The following questions are about your health over the last 4 weeks. Choose the answer which best describes what you feel or have felt over the last 4 weeks giving only one answer per line. If certain activities do not apply (e.g. embarrassment when using public transport because you do not use public transport), put a tick in the "not applicable" box. Please answer this questionnaire on your own, without help. To answer, tick the box which applies to you: not at all; a little; moderately; a lot; extremely

DAILY ACTIVITIES

Over the last 4 weeks, how much have your urinary problems bothered you:

1. When you were away from your home?
2. When you were driving or being a passenger?
3. When going up or down stairs?
4. When shopping?
5. When queuing (bus stop, cinema, supermarket)?

Over the last 4 weeks, because of your urinary problems: none; a few; some; many; very many

6. Have you had to take frequent breaks during your work or daily activities?

Over the last 4 weeks, because of your urinary problems, how often: never; rarely; sometimes; often; all the time

7. Have you woken up having wet yourself?

EFFORT

Over the last 4 weeks, how much have your urinary problems bothered you: not at all; a little; moderately; a lot; extremely

8. When lifting or carrying heavy objects?
9. When doing sport (running, dancing, keep-fit)?
10. When blowing your nose, sneezing or coughing?
11. After a fit of laughter?

SELF IMAGE

Over the last 4 weeks, because of your urinary problems, how often: never; rarely; sometimes; often; all the time

12. Have you felt less attractive?
13. Were you afraid of giving off unwanted odors?
14. Were you afraid that other people might become aware of your problems?
15. Were you afraid of leaving stains at other people's homes or at work?
16. Did you have to change your clothes?

Over the last 4 weeks, in spite of your urinary problems, how often: never; rarely; sometimes; often; all the time

17. Have you felt at ease with yourself?

Over the last 4 weeks, because of your urinary problems: I never wear pads; not at all; a little; moderately; a lot; extremely

18. Have you been bothered by having to wear pads?

Table F211. Questionnaires with rigorous validity, reliability and responsiveness highly recommended by the Symptom and Quality of Life Committee of the International Consultation on Incontinence (continued)

EMOTIONAL CONSEQUENCES

Over the last 4 weeks, because of your urinary problems, how often: never; rarely; sometimes; often; all the time

19. Have you felt discouraged?
20. Have you lost patience?
21. Have you been worried that you might have a urinary “accident”?
22. Have you felt that you are losing self-control?
23. Have you felt obsessed by your urinary problems?
24. Did you need to think about taking pads with you before going out?

SEXUALITY

Over the last 4 weeks, because of your urinary problems, how much: not at all; a little; moderately; a lot; extremely

25. Have you felt anxious at the thought of having sexual intercourse?
26. Have you changed your sexual practices?
27. Have you been afraid of having urine leaks during sexual intercourse?

OVERALL QUALITY OF LIFE

28. Taking your urinary problems into account, how would you currently assess your quality of life? From Poor to Excellent (5 scores)

Table F212. Association between sample size of studies and diagnostic values of tests

Questionnaires and Scales	Intercept	Slope	R2, %
Sensitivity, %	75.1	0.01	2.4
Specificity, %	68.9	0.02	1.1
Positive predictive likelihood	12.4	-0.02	4.1
Clinical history for stress UI			
Sensitivity	93.6	-0.02	19.5
Specificity	57.8	0.00	0.3

Positive predictive likelihood	1.0	0.00	52.2
Positive likelihood ratio	7.8	0.03	2.3

Table F213. Scales that provided the largest positive likelihood ratio to detect UI

Author, positive likelihood ratio	Questions
Sandvik, 1995[841] LR+ 14	A positive answer to the following question was presumed to be an indication of stress incontinence: "Do you lose urine during sudden physical exertion, lifting, coughing or sneezing?' Urge incontinence was presumed to be indicated by a positive answer to the question: "Do you experience such a strong and sudden urge to void that you leak before reaching the toilet?" A positive answer to both questions was registered as mixed incontinence.
Kirschner-Hermanns, 1998[874] LR+ 15	How long can you usually hold urine once you feel an urge to urinate? More than 5 minutes 1 to 5 minutes Less than 1 minute, or I have an urge but I can't hold it I have no urge or warning Do you ever lose urine when you laugh, cough, sneeze or bend over? Is the only time that you lose urine when you laugh, cough, sneeze or bend over? When you are awake, can you usually go for half an hour without leaking urine? When you lose urine, how much usually leaks? A few drops Enough to wet your underwear Enough to wet your outer clothes, or enough to wet the floor
Diokno, 1999[875] LR+ 62	The Medical, Epidemiologic and Social Aspects of Aging Urinary Incontinence Questionnaire Please check the appropriate box 1. Over the past 12 months, have you had urine loss beyond your control? [ ] Yes [ ] No 2. How long ago did your urine loss start? years, months, days 3. When does the urine loss usually occur: [ ] Daytime only [ ] Nighttime only [ ] Both daytime and nighttime Questions for Urge Incontinence symptoms: Please check the appropriate box: [ ] Often (3); [ ] Sometimes (2); [ ] Rarely (1); [ ] Never (0) 1. Some people receive very little warning and suddenly find that they are losing, or about to lose, urine beyond their control. How often does this happen to you? 2. If you can't find a toilet or find that the toilet is occupied, and you have an urge to urinate, how often do you end up losing urine and wetting yourself? PREDICTING TYPE II STRESS INCONTINENCE Please check the appropriate box: [ ] Often (3); [ ] Sometimes (2); [ ] Rarely (1); [ ] Never (0) 3. Do you lose urine when you suddenly have the feeling that your bladder is very full? 4. Does washing your hands cause you to lose urine? 5. Does cold weather cause you to lose urine? 6. Does drinking cold beverages cause you to lose urine? Total urge score: Urge score ratio: Questions for Stress Incontinence symptoms: 1. Does coughing gently cause you to lose urine? 2. Does coughing hard cause you to lose urine? 3. Does sneezing cause you to lose urine? 4. Does lifting things cause you to lose urine? 5. Does bending over cause you to lose urine? 6. Does laughing cause you to lose urine? 7. Does walking briskly or jogging cause you to lose urine? 8. Does straining, if you are constipated, cause you to lose urine? 9. Does getting up from a sitting to standing position cause you to lose urine? Total stress score: Stress score ratio:
Moore, 1996[876] LR+ 17.8	Screening Measure (2 parts) Ask: "In the last year, have you ever lost your urine gotten wet? If yes, then ask: "Have you lost urine on at least 6 separate days?

Table F217. Recommended questionnaires for symptoms and quality of life impact of anal incontinence (adapted from the Symptom and Quality of Life Committee of the International Consultation on Incontinence)[855]

Grade	Questionnaire
Grade A (highly recommended): validity, reliability and responsiveness established with rigor	None
Grade B (recommended): validity and reliability established with rigor or validity, reliability and responsiveness indicated	Fecal Incontinence QOL Scale[917]
	Manchester Health Questionnaire[918]
	Birmingham Bowel and Urinary Symptoms Questionnaire[919]

Table F218 . Questionnaires with rigorous validity, reliability, and responsiveness highly recommended by the Symptom and Quality of Life Committee of the International Consultation on Incontinence for anal incontinence[855]

Fecal Incontinence QOL Scale[917]

In general, would you say your health is: excellent; very good; good; fair; poor

For each item, please indicate how much of the time the issue is a concern for you due to accidental bowel leakage. (If it is a concern for you for reasons other than accidental bowel leakage, then check the box under Not Apply, (N/A).) Most of the time; Some of the time; A little of the time; None of the time

Q1. Due to accidental bowel leakage

a. I am afraid to go out
b. I avoid visiting friends
c I avoid staying overnight away from home
d. It is difficult for me to get out and do things like going to a movie or to church
e. I cut down on how much I eat before I go out
f. Whenever I am away from home, I try to stay near a restroom as much as possible
g. It is important to plan my schedule (daily activities) around my bowel pattern
h. I avoid traveling
i. I worry about not being able to get to the toilet in time
j. I feel I have no control over my bowels
k. I can't hold my bowel movement long enough to get to the bathroom
1. I leak stool without even knowing it
m. I try to prevent bowel accidents by staying very near a bathroom

Q2: Due to accidental bowel leakage, indicate the extent to which you AGREE or DISAGREE with each of the following items. (If it is a concern for you for reasons other than accidental bowel leakage then check the box under Not Apply, N/A). Strongly agree; Somewhat agree; Somewhat disagree; Strongly disagree

Q3. Due to accidental bowel leakage:

a. I feel ashamed
b. I can not do many of things I want to do
c. I worry about bowel accidents
d. I feel depressed
e. I worry about others smelling stool on me
f. I feel like I am not a healthy person
g. I enjoy life less
h. I have sex less often than I would like to
i. I feel different from other people
j. The possibility of bowel accidents is always on my mind
k. I am afraid to have sex
1. I avoid traveling by plane or train
m. I avoid going out to eat
n. Whenever I go someplace new, I specifically locate where the bathrooms are

Q4: During the past month, have you felt so sad, discouraged, hopeless, or had so many problems that you wondered if anything was worthwhile? Extremely so - to the point that I have just about given up; Very much so; Quite a bit; Some - enough to bother me; A little bit; Not at all

Table F218 . Questionnaires with rigorous validity, reliability, and responsiveness highly recommended by the Symptom and Quality of Life Committee of the International Consultation on Incontinence for anal incontinence (continued)

Manchester Health Questionnaire[918]

1. How do you describe you health at the present? Very good; Good; Fair; Poor; Very poor
2. How much you think your bowel problem affects your life? Not at all; A little bit; Moderately; Quite a bit; Extremely

We would like to know what your bowel problems are and how much they affect you.
Responses: Never; Occasionally; Sometimes; Most of the time; All of the time

3. How often do you have a strong desire to move your bowels which makes you rush to the toilet?
4. How often your bowels leak when coughing or sneezing?
5. How often your bowels leak when walking?
6. Do your bowels leak during the rest of the day or at night?
7. Do you have difficulties wiping clean after you have opened your bowels?
8. Do you have difficulties controlling wind?
9. Is the leakage from your bowels loose?
10. Is the leakage from your bowels solid?
11. How often do you move your bowels every day?
12. Do your bowels leak during or after sexual intercourse?

How much does the bowel problem you described in the previous page affect you?
Role limitation

13. Does your bowel problem affect you doing your jobs within the home?
14. Does your bowel problem affect your job or your normal daily activities outside the home?

Physical limitations

15. Does your bowel problem affect your ability to travel?
16. Does your bowel problem affect your physical activities (going for a walk, running, sport, gym, etc.?
17. Does your bowel problem limit your social life?
18. Does your bowel problem limit your ability to see and visit friends?

Personal relationships

19. Does you bowel problem affect your relationship with your partner?
20. Does you bowel problem affect your sex life?
21. Does you bowel problem affect your family life?

Emotions

22. Does you bowel problem make you feel depressed?
23. Does you bowel problem make you feel anxious or nervous?
24. Does your bowel problem make you feel bad about yourself?

Sleep/energy

25. Does your bowel problem affect your sleep?
26. Does your bowel problem make you feel worn out and tired?

Do you do any of following ? If so how much?

27. Wear pads to keep clean?
28. Be careful how much food you eat?
29. Change your underclothes because they get dirty?
30. Worry in case you smell?
31. Get embarrassed because of you bowel problem?

Table F218 . Questionnaires with rigorous validity, reliability, and responsiveness highly recommended by the Symptom and Quality of Life Committee of the International Consultation on Incontinence for anal incontinence (continued)

Modified Manchester Health Questionnaire

SECTION A Responses: Never, Occasionally, Sometimes, Most of the time, All of the time

A1. How often do you have a strong desire to move your bowels that makes you rush to the toilet?
A2. How often in the past month have you experienced any amount of accidental bowel leakage that consisted of solid stool?
B1. Do you lose any solid stool when coughing or sneezing?
B2. Do you lose any solid stool when walking?
B3. Besides coughing, sneezing, and walking, do you lose any solid stool during the rest of the day or night?
A3. How often in the past month have you experienced any amount of accidental bowel leakage that consisted of liquid stool?
B4. When you leak stool, how often is it liquid or watery?
B5. Do you lose any liquid stool when coughing or sneezing?
B6. Do you lose any liquid stool when walking?
B7. Besides coughing, sneezing, and walking, do you lose any liquid stool during the rest of the day or night?
A4. How often in the past month have you experienced any amount of accidental bowel leakage that consisted of mucus?
A5. How often in the past month have you experienced any amount of accidental bowel leakage that consisted of gas?
B8. Do you lose any gas when coughing or sneezing?
B9. Do you lose any gas when walking?

SECTION C: If the answers to A1, A2, A3, A4, and A5 are all “Never,” skip this section.

C1. How much do you think your bowel problem affects your life?
C2. How often do you move your bowels each day?
C3. Do you have difficulty wiping clean after you have moved your bowels?
C4. What percent of your bowel movements are hard or little balls?
C5. What percent of your bowel movements are loose or watery?

Role limitations

C6. Do you have a problem with your bowels that affects doing jobs within the home?
C6a. If so, how often does it affect you?
C7. Do you have a problem with your bowels that affects your job, or your normal daily activities outside the home?
C7a. If so, how often does it affect you?

Physical/social limitations

C8. Do you have a problem with your bowels that affects your ability to travel?
C8a. If so, how often does it affect you?
C9. Do you have a problem with your bowels that affects your physical activities (such as going for a walk, running, sport, gym, etc.)?
C9a. If so, how often does it affect you?
C10. Do you have a problem with your bowels that limits your social life?
C10a. If so, how often, does it affect you?
C11. Do you have a problem with your bowels that limits your ability to see and visit friends?
C11a. If so, how often does it affect you?

Personal relationships

C12. Do you have a problem with your bowels that affects your relationship with your partner?
C12a. If yes, how often does it affect your relationship?
C13. Do you have a problem with your bowels that affects your family life?
C13a. If so, how often does it affect your family life?

Emotions

C14. Do you have a problem with your bowels that makes you feel depressed?
C14a. If yes, how often does it affect you?

Table F218 . Questionnaires with rigorous validity, reliability, and responsiveness highly recommended by the Symptom and Quality of Life Committee of the International Consultation on Incontinence for anal incontinence (continued)

C15. Do you have a problem with your bowels that makes you feel anxious or nervous?
C15a. If yes, how often does it affect you?
C16. Do you have a problem with your bowels that makes you feel bad about yourself?
C16a. If yes, how often does it affect you?
Sleep/energy
C17. Do you have a problem with your bowels that affects your sleep?
C17a. If so, how often does it affect your sleep?
C18. Do you have a problem with your bowels that makes you feel worn out and tired?
C18a. If yes, how often does it affect you?
Sexual Activity
For general audience, skip questions C19a to C19b.
C19. Have you resumed sexual activity since delivery?
C19a. If “Yes,” when did you resume sexual activity? __ __ weeks after delivery
C19b. If “No,” why have you not resumed sexual activity?
C20. Do you have a problem with your bowels that affects your sex life?
C20a. If so, how often does it affect your sex life?
C21. Do you lose any gas during or after sexual activity?
C22. Do you lose any stool during or after sexual activity?
C23. Do you lose any urine during or after sexual activity?
Lifestyle Adaptation
C24. Do you wear pads to keep clean because of a problem with your bowels?
C24a. If yes, how often do you wear pads?
C25. Are you careful about how much food you eat because of a problem with your bowels?
C25a. If yes, how often are you careful about how much food you eat?
C26. Do you change your underclothes because they get dirty due to a problem with your bowels?
C26a. If yes, how often do you change your underclothes for this reason?
C27. Do you worry about odor because of a problem with your bowels?
C27a. If yes, how often do you worry about it?
C28. Do you get embarrassed because of a problem with your bowels?
C28a. If yes, how often do you get embarrassed?
Medical
C29. Did you bring any of your bowel symptoms to the attention of your clinician?
C30. Have you received treatment for your bowel symptoms?
C30a. If “Yes,” please specify:

Table F218 . Questionnaires with rigorous validity, reliability, and responsiveness highly recommended by the Symptom and Quality of Life Committee of the International Consultation on Incontinence for anal incontinence (continued)

Birmingham Bowel and Urinary Symptoms Questionnaire[919]

1. How often do you open your bowels?
2. What form are your motions usually?
3. Can you hold onto your motions for more than five minutes?
4. Do you ever have to rush to the toilet to open your bowels?
5. Does stool leak before you can get to the toilet?
6. Do you leak stool for no obvious reason and without feeling that you want to go to the toilet?
7. Do you have to strain to open your bowels?
8. How long do you spend on the toilet, on average, for each bowel action?
9. Do you feel that you cannot completely empty your bowels?
10. Do you use a finger or pressure to help open your bowels?
11. Do you use a finger in your vagina to help open your bowels?
12. Do you have the urge to open your bowels but are unable to pass a motion?
13. Do you find it painful to have your bowels open?
15. Do you use laxatives?
16. During the day, how many times do you urinate, on average?
17. During the night, how many times do you have to get up to urinate, on average?
18. Do you have to rush to the toilet to urinate?
19. Do you have difficulty completely emptying your bladder?
20. Does urine leak before you can get to the toilet?
21. Does urine leak when you are active, exert yourself, cough, or sneeze?
22. Does urine leak for no obvious reason and without feeling that you want to go to the toilet?
