### NATIONAL TOXICOLOGY PROGRAM

The National Toxicology Program (NTP), established in 1978, develops and evaluates scientific information about potentially toxic and hazardous chemicals. This knowledge can be used for protecting the health of the American people and for the primary prevention of disease. By bringing together the relevant programs, staff, and resources from the U.S. Public Health Service, DHHS, the National Toxicology Program has centralized and strengthened activities relating to toxicology research, testing and test development/validation efforts, and the dissemination of toxicological information to the public and scientific communities and to the research and regulatory agencies.

The NTP is made up of four charter DHHS agencies: the National Cancer Institute (NCI), National Institutes of Health; the National Institute of Environmental Health Sciences (NIEHS), National Institutes of Health; the National Center for Toxicological Research (NCTR), Food and Drug Administration; and the National Institute for Occupational Safety and Health (NIOSH), Centers for Disease Control. In July 1981, the Carcinogenesis Bioassay Testing Program, NCI, was transferred to the NIEHS.

### NTP TECHNICAL REPORT ON THE

# TOXICOLOGY AND CARCINOGENESIS STUDIES OF 3-CHLORO-2-METHYLPROPENE

(Technical grade containing 5% dimethylvinyl chloride)

(CAS NO. 563-47-3)

### NOTE TO THE READER

These studies are designed and conducted to characterize and evaluate the toxicologic potential, including carcinogenic activity, of selected chemicals in laboratory animals (usually two species, rats and mice). Chemicals selected for testing in the NTP Carcinogenesis Program are chosen primarily on the bases of human exposure, level of production, and chemical structure. Selection per se is not an indicator of a chemical's carcinogenic potential. Negative results, in which the test animals do not have a greater incidence of cancer than control animals, do not necessarily mean that a test chemical is not a carcinogen, inasmuch as the experiments are conducted under a limited set of conditions. Positive results demonstrate that a test chemical is carcinogenic for animals under the conditions of the test and indicate that exposure to the chemical has the potential for hazard to humans. The determination of the risk to humans from chemicals found to be carcinogenic in animals requires a wider analysis which extends beyond the purview of this study.

Five categories of interpretative conclusions were adopted for use in June 1983 in the Technical Reports series to specifically emphasize consistency and the concept of actual evidence of carcinogenicity. For each definitive study result (male rats, female rats, male mice, female mice), one of the following quintet will be selected to describe the findings. These categories refer to the strength of the experimental evidence and not to either potency or mechanism.

- Clear Evidence of Carcinogenicity is demonstrated by studies that are interpreted as showing a chemically related increased incidence of malignant neoplasms, studies that exhibit a substantially increased incidence of benign neoplasms, or studies that exhibit an increased incidence of a combination of malignant and benign neoplasms where each increases with dose.
- Some Evidence of Carcinogenicity is demonstrated by studies that are interpreted as showing a chemically related increased incidence of benign neoplasms, studies that exhibit marginal increases in neoplasms of several organs/tissues, or studies that exhibit a slight increase in uncommon malignant or benign neoplasms.
- Equivocal Evidence of Carcinogenicity is demonstrated by studies that are interpreted as showing a chemically related marginal increase of neoplasms.
- No Evidence of Carcinogenicity is demonstrated by studies that are interpreted as showing no chemically related increases in malignant or benign neoplasms.
- Inadequate Study of Carcinogenicity demonstrates that because of major qualitative or quantitative limitations, the studies cannot be interpreted as valid for showing either the presence or absence of a carcinogenic effect.

Additionally, the following concepts (as patterned from the International Agency for Research on Cancer Monographs) have been adopted by the NTP to give further clarification of these issues:

The term *chemical carcinogenesis* generally means the induction by chemicals of neoplasms not usually observed, the earlier induction by chemicals of neoplasms that are commonly observed, or the induction by chemicals of more neoplasms than are generally found. Different mechanisms may be involved in these situations. Etymologically, the term *carcinogenesis* means induction of cancer, that is, of malignant neoplasms; however, the commonly accepted meaning is the induction of various types of neoplasms or of a combination of malignant and benign neoplasms. In the Technical Reports, the words *tumor* and *neoplasm* are used interchangeably.

This study was initiated by the National Cancer Institute's Carcinogenesis Bioassay Program, now part of the National Institute of Environmental Health Sciences, National Toxicology Program. The studies described in this Technical Report have been conducted in compliance with NTP chemical health and safety requirements and must meet or exceed all applicable Federal, state, and local health and safety regulations. All NTP toxicology and carcinogenesis studies are subjected to a data audit before being presented for peer review.

Although every effort is made to prepare the Technical Reports as accurately as possible, mistakes may occur. Readers are requested to identify any mistakes so that corrective action may be taken. Further, anyone who is aware of related ongoing or published studies not mentioned in this report is encouraged to make this information known to the NTP. Comments and questions about the National Toxicology Program Technical Reports on Toxicology and Carcinogenesis Studies should be directed to Dr. J.E. Huff, National Toxicology Program, P.O. Box 12233, Research Triangle Park, NC 27709 (919-541-3780).

These NTP Technical Reports are available for sale from the National Technical Information Service, U.S. Department of Commerce, 5285 Port Royal Road, Springfield, VA 22161 (703-487-4650). Single copies of this Technical Report are available without charge (and while supplies last) from the NTP Public Information Office, National Toxicology Program, P.O. Box 12233, Research Triangle Park, NC 27709.

#### **3-CHLORO-2-METHYLPROPENE**

#### CAS No. 563-47-3

#### C<sub>4</sub>H<sub>7</sub>Cl Molecular weight: 90.55

#### Synonyms:

2-Methallyl chloride Methyl allyl chloride β-methallyl chloride y-chloroisobutylene Isobutenyl chloride 3-Chloro-2-methyl-1-propene 2-Methyl-2-propenyl chloride

#### ABSTRACT

Toxicology and carcinogenesis studies of technical-grade 3-chloro-2-methylpropene (containing 5% dimethylvinyl chloride), a widely used insecticide and chemical intermediate, were performed on F344/N rats and B6C3F<sub>1</sub> mice. In the 13-week studies, 50%-100% mortality occurred in groups of male and female rats receiving 400 mg/kg, male rats receiving 300 mg/kg, and male and female mice receiving 500-1,250 mg/kg. Inflammation and necrosis of the liver were seen in rats and mice, and necrosis of cortical tubules of the kidney was seen in mice. Based on these observations, groups of 50 male and 50 female rats were administered 3-chloro-2-methylpropene in corn oil by gavage at doses of 0, 75, or 150 mg/kg body weight, 5 days per week for 103 weeks, and groups of 50 male and 50 female mice received 3-chloro-2-methylpropene at 0, 100, or 200 mg/kg on the same schedule.

In the 2-year studies, the mean body weight of high dose male rats was consistently 10%-15% lower than that of the vehicle control group, and late in the study there was a marginal reduction in survival of high dose male rats. Mean body weights and survival in low dose male rats and in both dosed groups of female rats were comparable to those of their vehicle control groups. Mean body weights of high dose male mice and of both dosed groups of female mice were slightly (5%-9%) lower than those of the vehicle controls, whereas survival in both male and female mice was not affected by 3-chloro-2-methylpropene administration.

Dose-related increases in the incidence of forestomach inflammation were observed in male and female mice (male: vehicle control, 0/49; low dose, 9/49; high dose, 7/49; female: vehicle control, 2/50; low dose, 3/48; high dose, 9/44). Increased incidences of forestomach basal cell hyperplasia were observed in rats and mice of each sex. 3-Chloro-2-methylpropene induced forestomach squamous cell papillomas and squamous cell carcinomas in rats and mice as shown in the table. Invasion or metastasis of the squamous cell carcinomas to other organs was observed in two low dose male, three high dose male, and one high dose female mice.

Renal tubular cell adenocarcinomas (1/49), renal transitional cell carcinomas (1/49), and transitional cell papillomas (1/46) of the urinary bladder were observed in high dose male rats, and renal tubular cell adenomas (1/50) and renal tubular cell adenocarcinomas (1/50) were seen in low dose male rats. These urinary tract neoplasms were not observed in vehicle controls.

The incidences of inflammation of the nasal cavity and of nephropathy/nephrosis were greater in the two dosed groups than in the vehicle control groups of rats and mice of each sex.

#### INCIDENCES OF FORESTOMACH LESIONS IN RATS AND MICE IN THE TWO-YEAR GAVAGE STUDIES OF 3-CHLORO-2-METHYLPROPENE

Negative trends or lower incidences of pheochromocytomas of the adrenal gland and C-cell adenomas or carcinomas (combined) of the thyroid gland were observed in dosed male rats. Negative trends were observed in the incidences of hepatocellular adenomas or carcinomas (combined) in dosed male mice and of hemangiomas or hemangiosarcomas (combined) in dosed female mice.

3-Chloro-2-methylpropene was weakly mutagenic in Salmonella typhimurium strain TA1537 with 10% rat liver S9; results in strain TA100 with 10% Syrian hamster liver S9 or with 10% or 30% rat liver S9 were judged equivocal. Mutagenicity tests with S. typhimurium strains TA1535 and TA98 were negative with or without metabolic activation. 3-Chloro-2-methylpropene was mutagenic in the mouse lymphoma L5178Y/TK<sup>+/-</sup> forward mutation assay without exogenous metabolic activation. Cytogenetics tests with cultured Chinese hamster ovary cells were positive for induction of chromosomal aberrations and sister-chromatid exchanges (SCE's) in the absence of rat liver S9. With metabolic activation, SCE levels remained significantly elevated, but the number of chromosomal aberrations was reduced.

An audit of the experimental data was conducted for these 2-year carcinogenesis studies on 3-chloro-2-methylpropene. No data discrepancies were found that influenced the final interpretations.

Under the conditions of these 2-year gavage studies, there was *clear evidence of carcinogenicity*<sup>\*</sup> for 3chloro-2-methylpropene as shown by the increased incidences of squamous cell neoplasms in the forestomach of male and female F344/N rats and of male and female  $B6C3F_1$  mice.

<sup>\*</sup>Categories of evidence of carcinogenicity are defined in the Note to the Reader on page 2. The public discussion regarding the interpretative conclusions is summarized on page 14.

#### CONTRIBUTORS

The NTP Technical Report on the Toxicology and Carcinogenesis Studies of 3-Chloro-2-methylpropene is based on the 13-week studies that began in September 1978 and ended in December 1978 and the 2-year studies that began in August 1980 and ended in August 1982 at Litton Bionetics, Inc.

### PEER REVIEW PANEL

The members of the Peer Review Panel who evaluated the draft Technical Report on 3-chloro-2methylpropene on November 2, 1984, are listed below. Panel members serve as independent scientists, not as representatives of any institution, company, or governmental agency. In this capacity, Panel members have five major responsibilities: (a) to ascertain that all relevant literature data have been adequately cited and interpreted, (b) to determine if the design and conditions of the NTP studies were appropriate, (c) to ensure that the Technical Report presents the experimental results and conclusions fully and clearly, (d) to judge the significance of the experimental results by scientific criteria, and (e) to assess the evaluation of the evidence of carcinogenicity and other observed toxic responses.

### SUMMARY OF PEER REVIEW COMMENTS ON THE TOXICOLOGY AND CARCINOGENESIS STUDIES OF 3-CHLORO-2-METHYLPROPENE

On November 2, 1984, the draft Technical Report on the toxicology and carcinogenesis studies of 3chloro-2-methylpropene received peer review by the National Toxicology Program Board of Scientific Counselors' Technical Reports Review Subcommittee and associated Panel of Experts. The review meeting was held in the Conference Center, Building 101, South Campus, National Institute of Environmental Health Sciences, Research Triangle Park, North Carolina.

Dr. P. Chan, NTP, began the discussion with a summary of the study design, results and proposed conclusions (clear evidence of carcinogenicity in rats and mice of each sex). Dr. Slaga, a principal reviewer, agreed with the conclusions. As a second principal reviewer, Dr. Jones agreed with the conclusions, but he felt that the forestomach neoplasms might be more accurately described as "squamous cell papillomas or carcinomas (combined)." He asked what effects the contaminant dimethylvinyl chloride (up to 5% of the 3-chloro-2-methylpropene) may have had on the stomach lesions, since preliminary findings from the NTP indicated that it is a carcinogen for the forestomach. Dr. Jones also asked whether there might be a correlation between the poor survival of high dose male rats and the negative tumor trends, especially for thyroid gland C-cell adenomas and carcinomas.

As a third principal reviewer, Dr. Friess did not agree with the composite conclusion for both sexes of both species. Because of the lack of dose response for squamous cell papillomas in rats and no significant increases in carcinomas alone in rats and female mice, he thought the category should be some evidence of carcinogenicity. He agreed with the category of clear evidence of carcinogenicity for male mice. Dr. Kociba concurred. Dr. Friess questioned whether the estimated maximum tolerated doses (EMTD's) had been achieved, except for the doses for male rats. Dr. Swenberg said that the issue of whether an EMTD was reached becomes an important point only with a negative study. Dr. Hook asked that more discussion of how doses were selected be in the report. [See page 56.] Dr. Friess asked for further discussion in the text on (1) the potential contributions of dimethylvinyl chloride to the carcinogenic process in the forestomach and (2) the finding of renal tubular cell adenomas and carcinomas, albeit at low incidences, in male rats, and whether this may be an effect related to lowmolecular-weight chlorinated hydrocarbons in male rats. Dr. Chan commented that the 3-chloro-2methylpropene (containing about 5% dimethylvinyl chloride) was the material commercially available and the formulation to which humans are exposed. Dr. B. Schwetz, NTP, reported that completed NTP 2-year gavage studies with dimethylvinyl chloride in rats and mice showed a spectrum of neoplastic responses not seen in this study, including those of the nasal passage, oral cavities, and esophagus. Dr. Kociba and Dr. Swenberg asked that either the presence of the dimethylvinyl chloride be given in the title of the report or the designation "technical grade" be inserted. Dr. Hook added that the composition should be given more prominence in the abstract.

Considerable discussion ensued as to (1) whether there was some evidence of carcinogenicity or clear evidence of carcinogenicity in rats and female mice and (2) whether the species and sexes should be separated in the conclusions. Dr. J. Huff, NTP, explained that the clear evidence of carcinogenicity category allowed for a substantial increase in benign neoplasms and, further, that the affected organ in each of those four experiments was the same. Hence, the single category seemed appropriate. Dr. Friess said he could agree to the conclusions as explained. Dr. Swenberg and Dr. Slaga agreed that the single categorization for all made the most scientific sense, since there were only small differences between benign and malignant neoplasms of the forestomach, since these are known to progress, and since all groups had the same lesions.

Dr. Jones moved that the Technical Report on the toxicology and carcinogenesis studies of 3-chloro-2methylpropene be accepted with the conclusion as stated, with some additional discussion on certain mentioned items and with the addition of "technical grade" to the title of the report and to the Abstract to indicate the presence of 5% dimethylvinyl chloride. Mr. Beliczky seconded the motion, and the report was approved by nine affirmative votes. There was one negative vote (Dr. Kociba).

### I. INTRODUCTION

#### **3-CHLORO-2-METHYLPROPENE**

#### CAS No. 563-47-3

C<sub>4</sub>H<sub>7</sub>Cl Molecular weight: 90.55

Synonyms:

### 2-Methallyl chloride Methyl allyl chloride β-methallyl chloride y-chloroisobutylene

3-Chloro-2-methylpropene is a colorless, volatile liquid with a pungent odor. It has a specific gravity of 0.92 at 15° C, a boiling point of 71°-72°C, a vapor pressure of 101.7 mm Hg at 20°C, and a refractive index of 1.4318 at 15° C. 3-Chloro-2-methylpropene is insoluble in water but is soluble in chloroform, acetone, alcohol, ether, and benzene. It is flammable with a flash point of  $-12^{\circ}$  C (closed cup). Its explosive limit in air is 2.3%-9.3% (Merck Index, 1983; Hawley, 1977). 3-Chloro-2-methylpropene is relatively stable at room temperature but is unstable at high temperature. It reacts vigorously with oxidizing materials and during decomposition emits toxic fumes of chlorine and hydrochloric acid (Sax, 1979).

3-Chloro-2-methylpropene is produced by substitutive chlorination of isobutylene (Melnikov, 1971). The annual production of 3-chloro-2methylpropene in the United States is 12-24 million pounds; less than 500 pounds was imported in 1984 (I.M. Kipnis, personal communication to NTP, January 1985).

3-Chloro-2-methylpropene is used as an intermediate for the production of plastics, pharmaceuticals, and other organic chemicals and as an insecticide and fumigant for grains, tobacco, and soil (Merck Index, 1983; Hawley, 1977). According to the manufacturer, approximately 97.5% of the 3-chloro-2-methylpropene produced in the United States is used as a site-limited intermediate in the synthesis of agricultural chemicals, 1.8% as a textile additive, 0.6% as a perfume additive, and 0.2% for other purposes. The Isobutenyl chloride 3-Chloro-2-methyl-1-propene 2-Methyl-2-propenyl chloride

material is not registered for use as a pesticide in the United States; it may be used for that purpose in other countries (I.M. Kipnis, personal communication to NTP, January 1985).

3-Chloro-2-methylpropene at concentrations as high as 400  $\mu$ g/m<sup>3</sup> has been detected in the ambient air near Curtis Bay in Maryland (Pellizzari, 1982). Residual 3-chloro-2-methylpropene has also been detected in maize fumigated with the chemical (Taylor, 1975).

3-Chloro-2-methylpropene is toxic when inhaled, applied to the skin, or ingested and irritates the eyes and respiratory tract. The  $LC_{50}$ values of 3-chloro-2-methylpropene are 34,000 mg/m<sup>3</sup> for 30 minutes or 2,000 mg/m<sup>3</sup> for 24 hours for rats and 91,000 mg/m<sup>3</sup> for 10 minutes for mice (Sax, 1979). Inhalation studies in mice showed that 3-chloro-2-methylpropene caused respiratory failure and induced pulmonary tissue damage (Silverman and Abreu, 1938).

Investigations of the genetic toxicity of allylic chloride compounds (Neudecker et al., 1980; Eder et al., 1980, 1982) showed 3-chloro-2methylpropene to be weakly mutagenic to Salmonella typhimurium strain TA100 without exogenous metabolic activation. Like the majority of allyl chlorides, this chemical is considered to be a direct-acting alkylating agent whose mutagenic potential is destroyed by activation. In contrast, the NTP-sponsored tests showed weak mutagenic activity in S. typhimurium strain TA1537 only in the presence of S9 from Aroclor 1254-induced male Sprague-Dawley rat livers;

activity was considered equivocal in strain TA100 with S9 from Aroclor 1254-induced male Syrian hamster and Sprague-Dawley rat livers (Appendix L. Table L1). 3-Chloro-2-methylpropene was also mutagenic in the L5178Y/TK<sup>+/-</sup> mouse lymphoma assay in the absence of S9 (Table L2); it was not tested in the presence of S9. The chemical induced sister-chromatid exchanges (SCE's) and chromosomal aberrations in cultured Chinese hamster ovary cells without metabolic activiation. With Aroclor-1254-induced male Sprague-Dawley rat liver S9, SCE's remained significantly elevated. However, exogenous metabolic activation greatly reduced the strength of the mutagenic response as measured by chromosomal aberrations (Table L3 and L4). In addition, 3-chloro-2-methylpropene

induced unscheduled DNA synthesis in HeLa cells (Schiffmann et al., 1983). No information was found in the literature on the pharmacokinetics, reproductive toxicity, or carcinogenicity of 3-chloro-2-methylpropene.

Workers may be exposed to 3-chloro-2-methylpropene while using it as a gaseous insecticide or as an intermediate in organic synthesis. The U.S. Environmental Protection Agency nominated 3-chloro-2-methylpropene for carcinogenicity testing because of its presence in ambient air and its structural relationship to vinyl chloride, a recognized animal and human carcinogen. The gavage route of administration was chosen because the chemical is volatile and flammable.

### PROCUREMENT AND CHARACTERIZATION OF 3-CHLORO-2-METHYLPROPENE

3-Chloro-2-methylpropene (manufactured by FMC Corporation) was obtained in two different lots (Table 1). Purity, identity, and stability analyses were conducted at Midwest Research Institute. Both lots of chemical were identified as 3-chloro-2-methylpropene by spectroscopy. Infrared, ultraviolet/visible, and nuclear magnetic resonance spectra were all consistent with the literature spectra and the structure of 3chloro-2-methylpropene (Appendix G).

Cumulative data on lot no. 110967 indicated a purity of approximately 93%. The results of elemental analysis agreed with theoretical values. Titration of acidic components indicated the presence of 34 ppm hydrochloric acid. Gas chromatography analysis by two systems showed the study material to be approximately 93% pure and to contain two major impurities with areas of 3% and 6% relative to the major component. The retention time of the 6% relative impurity was consistent with that of dimethylvinyl chloride. The nuclear magnetic resonance spectrum contained five peaks attributed to impurities. Two of these could be assigned to dimethylvinyl chloride; integration ratios indicated a concentration of 5% for the dimethylvinyl chloride. Therefore it was concluded that lot no. 11067 of the study material contained approximately 5% dimethylvinyl chloride as an impurity.

Lot no. P091781 was determined to have a purity of greater than 95% based on the following data. Results of elemental analysis were consistent with theoretical values. Titration of acidic components indicated the presence of 159 ppm hydrochloric acid. Gas chromatographic analysis by two systems showed the study material to be greater than 95% pure and to contain a 3.6% impurity that was identified as dimethylvinyl chloride.

The bulk chemical was stable when stored for 2 weeks at  $-20^{\circ}$  to  $60^{\circ}$  C (Appendix G). The study laboratory stored several portions at  $-20^{\circ}$  C as reference samples, and the remainder was stored at room temperature. Results of periodic reanalysis of the study and reference samples at the study laboratory by infrared spectroscopy and gas chromatography indicated that no notable deterioration of the study chemical occurred over the course of the studies.

### PREPARATION AND CHARACTERIZATION OF DOSE MIXTURES

3-Chloro-2-methylpropene and corn oil were mixed to yield the desired concentrations (Table 2; Appendix H). 3-Chloro-2-methylpropene (2.25% w/v) in corn oil was found to be stable (within the limits of detection) when stored at room temperature for 7 days. In the 2-year studies, mixtures of 3-chloro-2-methylpropene in corn oil were stored at room temperature for no longer than 7 days. Periodic analyses for 3-chloro-2-methylpropene were performed by the study and analytical chemistry laboratories to confirm that correct concentrations were administered to the animals (Appendix I). The analytical method included a methanol extraction followed by gas chromatographic analysis. The analytical results are presented in Appendix J and are summarized in Table 3. Because 53/62 samples analyzed were within  $\pm$  10% of target concentrations, it is estimated that dosing mixtures were formulated within specifications 85% of the time.

(a) The 2.8 mg/ml dose mixture was not used.

### SINGLE-ADMINISTRATION STUDIES

Male and female F344/N rats and B6C3F<sub>1</sub> mice were obtained from Harlan Industries and observed for 2 weeks before the studies began. Groups of five rats of each sex were administered a single dose of 100, 316, 1,000, 3,160, or 10,000 mg/kg 3-chloro-2-methylpropene in corn oil by gavage. Groups of five mice of each sex were administered 31.6, 100, 316, 1,000, or 3,160 mg/kg. The selection of doses was based on available data in the literature. Rats and mice were observed daily and were killed 14 days after the dose was administered. A necropsy was performed on all animals. Details of animal maintenance are given in Table 4.

### FOURTEEN-DAY STUDIES

Male and female F344/N rats and B6C3F1 mice were obtained from Harlan Industries and held for 6 weeks (rats) or 3 or 4 weeks (mice) before the studies began. Groups of five rats of each sex were administered 0, 89, 158, 281, 500, or 750 mg/kg 3-chloro-2-methylpropene in corn oil by gavage for 14 consecutive days. Groups of five mice of each sex were administered 0, 125, 250, 500, 750, 1,250, 1,750, or 2,500 mg/kg on the same schedule. The 125 and 250 mg/kg groups of mice were started (without matched vehicle controls) 7 days after initiation of the studies because of the large number of deaths at 750 mg/kg. Results of the 14-day studies provided information on toxic effects and affected tissues and determined doses to be used in the 13-week studies.

Animals were housed five per cage and received water and feed ad libitum. Details of animal maintenance are presented in Table 4. The rats and mice were observed once per day and were weighed on days 1 and 15. A necropsy was performed on all animals.

### THIRTEEN-WEEK STUDIES

Thirteen-week studies were conducted to evaluate the cumulative toxic effects of repeated administration of 3-chloro-2-methylpropene and to determine the doses to be used in the 2-year studies. Five- to six-week-old male and female F344/N rats and 5- to 6-week-old male and female  $B6C3F_1$  mice were obtained from Harlan Industries and observed for 2 weeks before the studies began. The animals were housed five per cage in polycarbonate cages. Diets consisting of Purina Lab Chow<sup>•</sup> and water (acidified with hydrochloric acid to pH 2.5 for bacterial control) were available ad libitum.

Groups of 10 rats of each sex were administered 0, 50, 100, 200, 300, or 400 mg/kg 3-chloro-2methylpropene in corn oil by gavage, 5 days per week for 13 weeks. Groups of 10 mice of each sex received 0, 125, 250, 500, 750, or 1,250 mg/kg on the same schedule.

Animals were checked two times per day; moribund animals were killed. Clinical examinations were performed and animal weights were recorded once per week. At the end of the 13week studies, survivors were killed. A necropsy was performed on all animals except those excessively autolyzed or cannibalized. Tissues and groups examined and further experimental details are listed in Table 4.

### TWO-YEAR STUDIES

### Study Design

Groups of 50 rats of each sex were administered 0, 75, or 150 mg/kg 3-chloro-2-methylpropene in corn oil by gavage, 5 days per week for 103 weeks. Groups of 50 mice of each sex were administered 0, 100, or 200 mg/kg on the same schedule.

### Source and Specifications of Animals

The male and female F344/N rats and B6C3F<sub>1</sub> (C57BL/6N, female,  $\times$  C3H/HeN MTV<sup>-</sup>, male) mice used in these studies were produced under strict barrier conditions at Charles River Breeding Laboratories (Kingston, NY) under a contract to the Carcinogenesis Program. Breeding stock for the foundation colonies at the production facility originated at the National Institutes of Health Repository. Animals shipped for study were progeny of defined microflora-associated parents that were transferred from isolators to

### TABLE 4. EXPERIMENTAL DESIGN AND MATERIALS AND METHODS IN THE GAVAGE STUDIESOF 3-CHLORO-2-METHYLPROPENE STUDIES (Continued)

barrier-maintained rooms. Animals were shipped to the study laboratory at 5 weeks of age. The animals were quarantined at the study laboratory for 2 or 3 weeks. Thereafter, a complete necropsy was performed on five animals of each sex and species to assess their health status. The rodents were placed on study at 8 weeks of age. The health of the animals was monitored during the course of the study according to the protocols of the NTP Sentinel Animal Program (Appendix K).

A quality control skin grafting program has been in effect since early 1978 to monitor the genetic integrity of the inbred mice used to produce the hybrid  $B6C3F_1$  study animal. In mid-1981, data were obtained that showed incompatibility between the NIH C3H reference colony and the C3H colony from a Program supplier. In August 1981, inbred parental lines of mice were further tested for genetic integrity via isozyme and protein electrophoresis profiles that demonstrate phenotype expressions of known genetic loci.

The C57BL/6 mice were homogeneous at all loci tested. Eighty-five percent of the C3H mice monitored were variant at one to three loci, indicating some heterogeneity in the C3H line from this supplier. Nevertheless, the genome of this line is more homogeneous than that of randomly bred stocks.

Male mice from the C3H colony and female mice from the C57BL/6 colony were used as parents for the hybrid  $B6C3F_1$  mice used in these studies. The influence of the potential genetic nonuniformity in the hybrid mice on these results is not known, but the results of the studies are not affected because concurrent controls were included in each study.

### **Animal Maintenance**

Rats and mice were housed five per cage in polycarbonate cages. Feed and water (acidified with hydrochloric acid to pH 2.5 for bacterial control) were available ad libitum. Details of animal maintenance are summarized in Table 4.

### **Clinical Examinations and Pathology**

All animals were observed two times per day, and clinical signs were recorded once every 4 weeks. Body weights by cage were recorded once per week for the first 13 weeks of the study and once per month thereafter. Mean body weights were calculated for each group. Moribund animals were killed, as were animals that survived to the end of the study. A necropsy was performed on all animals, including those found dead unless they were excessively autolyzed or cannibalized. Thus, the number of animals from which particular organs or tissues were examined microscopically varies and is not necessarily equal to the number of animals that were placed on study in each group.

Examinations for grossly visible lesions were performed on major tissues or organs. Tissues were preserved in 10% neutral buffered formalin, embedded in paraffin, sectioned, and stained with hematoxylin and eosin. Tissues examined microscopically are listed in Table 4.

When the pathology examination was completed, the slides, individual animal data records, and summary tables were sent to an independent quality assurance laboratory. Individual animal records and tables were compared for accuracy, slides and tissue counts were verified, and histotechnique was evaluated. All tumor diagnoses, all target tissues, and all tissues from a randomly selected 10% of the animals were evaluated by a quality assurance pathologist. Slides of all target tissues and those about which the original and quality assurance pathologists disagreed were submitted to the Chairperson of the Pathology Working Group (PWG) for evaluation. Representative coded slides selected by the Chairperson were reviewed by PWG pathologists, who reached a consensus and compared their findings with the original and quality assurance diagnoses. When diagnostic differences were found, the PWG sent the appropriate slides and comments to the original pathologist for review. This procedure has been described, in part, by Maronpot and Boorman (1982) and Boorman et al. (1985). The final diagnoses represent a consensus of contractor pathologists and the NTP Pathology Working Group. For subsequent evaluations, the diagnosed lesions for each tissue type are combined according to the guidelines of McConnell et al. (1985).

Nonneoplastic lesions are not examined routinely by the quality assurance pathologist or PWG. Certain nonneoplastic findings are reviewed by the quality assurance pathologist and PWG if they are considered part of the toxic response to a chemical or if they are deemed of special interest.

### **Statistical Methods**

Data Recording: Data on this experiment were recorded in the Carcinogenesis Bioassay Data System (Linhart et al., 1974). The data elements include descriptive information on the chemicals, animals, experimental design, survival, body weight, and individual pathologic results, as recommended by the International Union Against Cancer (Berenblum, 1969).

Survival Analyses: The probability of survival was estimated by the product-limit procedure of Kaplan and Meier (1958) and is presented in the form of graphs. Animals were censored from the survival analyses at the time they were found dead of other than natural causes or were found to be missing; animals dying from natural causes were not censored. Statistical analyses for a possible dose-related effect on survival used the method of Cox (1972) for testing two groups for equality and Tarone's (1975) life table test for a dose-related trend. When significant survival differences were detected, additional analyses using these procedures were carried out to determine the time point at which significant differences in the survival curves were first detected. All reported P values for the survival analysis are two-sided.

Calculation of Incidence: The incidence of neoplastic or nonneoplastic lesions is given as the ratio of the number of animals bearing such lesions at a specific anatomic site to the number of animals in which that site was examined. In most instances, the denominators include only those animals for which the site was examined histologically. However, when macroscopic examination was required to detect lesions (e.g., skin or mammary tumors) prior to histologic sampling, or when lesions could have appeared at multiple sites (e.g., lymphomas), the denominators consist of the number of animals on which a necropsy was performed.

Analysis of Tumor Incidence: Three statistical methods are used to analyze tumor incidence data. The two that adjust for intercurrent mortality employ the classical method for combining contingency tables developed by Mantel and Haenszel (1959). Tests of significance included pairwise comparisons of high dose and low dose groups with vehicle controls and tests for overall dose-response trends.

For studies in which compound administration has little effect on survival, the results of the three alternative analyses will generally be similar. When differing results are obtained by the three methods, the final interpretation of the data will depend on the extent to which the tumor under consideration is regarded as being the cause of death. All reported P values for tumor analyses are one-sided.

Life Table Analyses--The first method of analysis assumed that all tumors of a given type observed in animals dying before the end of the study were "fatal"; i.e., they either directly or indirectly caused the death of the animal. According to this approach, the proportions of tumorbearing animals in the dosed and vehicle control groups were compared at each point in time at which an animal died with a tumor of interest. The denominators of these proportions were the total number of animals at risk in each group. These results, including the data from animals killed at the end of the study, were then combined by the Mantel-Haenszel method to obtain an overall P value. This method of adjusting for intercurrent mortality is the life table method of

Cox (1972) and of Tarone (1975). The underlying variable considered by this analysis is time to death due to tumor. If the tumor is rapidly lethal, then time to death due to tumor closely approximates time to tumor onset. In this case, the life table test also provides a comparison of the time-specific tumor incidence.

Incidental Tumor Analyses--The second method of analysis assumed that all tumors of a given type observed in animals that died before the end of the study were "incidental"; i.e., they were merely observed at necropsy in animals dying of an unrelated cause. According to this approach, the proportions of tumor-bearing animals in dosed and vehicle control groups were compared in each of five time intervals: weeks 0-52, weeks 53-78, weeks 79-92, week 93 to the week before the terminal-kill period, and the terminal-kill period. The denominators of these proportions were the number of animals actually examined for tumors during the time interval. The individual time interval comparisons were then combined by the previously described method to obtain a single overall result. (See Haseman, 1984, for the computational details of both methods.)

Unadjusted Analyses--Primarily, survival-adjusted methods are used to evaluate tumor incidence. In addition, the results of the Fisher exact test for pairwise comparisons and the Cochran-Armitage linear trend test (Armitage, 1971; Gart et al., 1979) are given in the appendix containing the analyses of primary tumor incidence. These two tests are based on the overall proportion of tumor-bearing animals and do not adjust for survival differences.

Historical Control Data: Although the concurrent control group is always the first and most appropriate control group used for evaluation, there are certain instances in which historical control data can be helpful in the overall assessment of tumor incidence. Consequently, control tumor incidences from the NTP historical control data base (Haseman et al., 1984) are included for those tumors appearing to show compound-related effects.

Rats that received 1,000, 3,160, or 10,000 mg/kg 3-chloro-2-methylpropene died before the end of the studies (Table 5). Final body weights were not recorded. Animals that died on day 1 frequently had darkened livers, spleens, and kidneys; red lungs; and small intestines filled with red fluid. Animals that received 1,000 mg/kg and died on day 2 or 3 frequently had tan livers, darkened lungs and thymus, and gas in the stomach. No compound-related effects were observed at necropsy in animals dosed at 100 or 316 mg/kg.

### FOURTEEN-DAY STUDIES

Rats that received 3-chloro-2-methylpropene at 500 or 750 mg/kg died before the end of the studies (Table 6). Male rats that received 281 mg/kg lost weight. Final mean body weights of all other dosed groups and vehicle control rats were comparable. Animals that died had yellow

intestines, dark stomachs, darkened and pale areas on the liver, and/or dark fluid in the urinary bladder. Based on survival, 400 mg/kg was chosen as the highest dose for the 13-week studies.

### THIRTEEN-WEEK STUDIES

All rats that received 3-chloro-2-methylpropene at 400 mg/kg and 5/10 males and 2/10 females that received 300 mg/kg died before the end of the studies (Table 7). The deaths of 1/10 males that received 100 mg/kg and 2/10 females that received 200 mg/kg were considered to be due to gavage injury. Final mean body weights of male rats that received 200 or 300 mg/kg were depressed 5.0% and 6.6% relative to that of the vehicle controls.

Compound-related clinical signs (primarily rough coats) were observed in 5/10 females that received 300 mg/kg and in 9/10 males and 4/10 females that received 400 mg/kg.

Histologic evidence of chronic murine pneumonia was found in 5/10 male and 6/10 female vehicle controls. Pneumonia virus of mouse (PVM) antibody titers were found in 8/10 vehicle controls, Kilham rat virus titers were found in 2/10 vehicle controls, and Sendai virus titers in 3/10 vehicle controls.

Focal areas of inflammation, which varied from acute to chronic, were observed in the livers of rats that received 300 or 400 mg/kg (Table 8). The areas of necrosis were distributed throughout the liver. In the more acute lesions, the zone of necrosis was surrounded by congestion or neutrophils. If the zone of inflammation was surrounded by a cellular infiltrate, the lesion was designated as necrotizing.

Dose Selection Rationale: Based on survival and the incidence of liver lesions, 3-chloro-2-methylpropene doses selected for rats for the 2-year studies were 0, 75, or 150 mg/kg in corn oil by gavage.

|                 |              | Mea     | Final Weight Relative |            |                                  |  |

 TABLE 7. SURVIVAL AND MEAN BODY WEIGHTS OF RATS IN THE THIRTEEN-WEEK GAVAGE

 STUDIES OF 3-CHLORO-2-METHYLPROPENE

(a) Number surviving/number in group

(b) Mean weight change of the survivors

(c) Death (s) judged to be accidental

(d) Week of death: 10, 11, 11, 12, 12

(e) Week of death: 1, 2, 11, 11, 11, 11, 11, 11, 11, 11

(f) No data are reported due to the 100% mortality in this group.

(g) Week of death: 3, 10

(h) Week of death: 1, 1, 1, 1, 7, 10, 11, 11, 11, 12

#### TABLE 8. NUMBERS OF RATS WITH LIVER LESIONS IN THE THIRTEEN-WEEK GAVAGE STUDIES OF 3-CHLORO-2-METHYLPROPENE (a)

(a) Ten animals examined per group

### **TWO-YEAR STUDIES**

### Body Weights and Clinical Signs

The mean body weights of high dose male rats were lower (by more than 10%) than those of the vehicle controls beginning at week 10 of the studies (Table 9 and Figure 1). The mean body weights of low dose male rats were slightly lower (approximately 5%) than those of the vehicle controls between week 13 and week 76. Mean body weights of high dose female rats were slightly lower (approximately 5%) than those of the vehicle controls after week 32. Mean body weights of low dose female rats were slightly greater than those of the vehicle controls throughout the studies.

## TABLE 9. MEAN BODY WEIGHTS AND SURVIVAL OF RATS IN THE TWO-YEAR GAVAGE STUDIESOF 3-CHLORO-2-METHYLPROPENE

FIGURE 1. GROWTH CURVES FOR RATS ADMINISTERED 3-CHLORO-2-METHYLPROPENE IN CORN OIL BY GAVAGE FOR TWO YEARS

#### Survival

Estimates of the probabilities of survival for male and female rats at the doses used in these studies and for vehicle controls are shown in the Kaplan and Meier curves in Figure 2. No significant differences in survival were observed between any groups of either sex, although late in the study, survival of high dose male rats was slightly reduced (P=0.056) relative to that of the vehicle controls (Table 10).

# Pathology and Statistical Analyses of Results

This section describes the significant or noteworthy changes in the incidences of rats with neoplastic or nonneoplastic lesions in the forestomach, urinary tract, testis, integumentary system, nasal cavity, liver, adrenal gland, and thyroid gland. Histopathologic findings on neoplasms in rats are summarized in Appendix A (Tables A1 and A2); Appendix A (Tables A3 and A4) also gives the survival and tumor status for individual male and female rats. Findings on nonneoplastic lesions are summarized in Appendix C (Tables C1 and C2). Appendix E (Tables E1 and E2) contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Appendix E (footnotes). Historical incidences of tumors in corn oil vehicle control animals are listed in Appendix F.

TABLE 10. SURVIVAL OF RATS IN THE TWO-YEAR GAVAGE STUDIES OF 3-CHLORO-2-METHYL-PROPENE

|   | Vehicle Control | 75 mg/kg | 150 mg/kg |  |
|---|-----------------|----------|-----------|--|
| MALE (a)                                    |                 |          |           |  |
| Animals initially in study                  | 50              | 50       | 50        |  |
| Nonaccidental deaths before termination (b) | 19              | 25       | 32        |  |
| Accidentally killed                         | 1               | 0        | 1         |  |
| Killed at termination                       | 30              | 25       | 17        |  |
| Survival P values (c)                       | 0.053           | 0.419    | 0.056     |  |
| FEMALE (a)                                  |                 |          |           |  |
| Animals initially in study                  | 50              | 50       | 50        |  |
| Nonaccidental deaths before termination (b) | 19              | 15       | 22        |  |
| Accidentally killed                         | 0               | 3        | 2         |  |
| Killed at termination                       | 31              | 32       | 26        |  |
| Survival P values (c)                       | 0.456           | 0.561    | 0.509     |  |
|   |                 |          |           |  |

(a) Terminal-kill period: week 105

(b) Includes animals killed in a moribund condition

(c) The result of the life table trend test is in the vehicle control column, and the results of the life table pairwise comparisons with the vehicle controls are in the dosed columns.

Forestomach: Basal cell hyperplasia was observed at increased incidences in dosed male and female rats (Table 11). Papillomas were observed at significantly increased incidences in high dose male and female rats. Squamous cell carcinomas were observed in 2/48 high dose male rats but not in any other groups. Metastasis was not observed.

Microscopically, the papillomas consisted of arborized finger-like projections from the surface. The projections had a core of fibrovascular tissue contiguous with the submucosa and were covered by hyperkeratotic squamous epithelium. In most instances, the papillomas were pedunculated and the arborized projections arose from a single stalk.

Squamous cell carcinomas were characterized by downward projecting sheets, nests, and anastomosing cords of squamous tumor cells that invaded underlying structures. The invading masses of cells originated at the base of papillomas. Keratinization at the center of a cluster of neoplastic cells resulted in concentrically arranged masses of keratin called "pearls."

### TABLE 11. ANALYSIS OF FORESTOMACH LESIONS IN RATS IN THE TWO-YEAR GAVAGE STUDIES OF 3-CHLORO-2-METHYLPROPENE (a)

|                                      | Vehicle Control                                      | 75 mg/kg    | 150 mg/kg     |

| Incidental Tumor Tests               | P = 0.001  | P = 0.720N  | P = 0.006     |

(a) The statistical analyses used are discussed in Chapter II (Statistical Methods) and Appendix E (footnotes).
(b) Historical incidence of papillomas at study laboratory (mean): 0/147; historical incidence in NTP studies: 5/1,062 (0.5%)

(c) The two animals that had squamous cell carcinomas also had squamous cell papillomas.

(d) Historical incidence of papillomas at study laboratory (mean): 1/150 (0.7%); historical incidence in NTP studies: 5/1,062 (0.5%)

Urinary Tract: The incidences of nephropathy were increased in dosed male and high dose female rats (Table 12). A renal tubular cell adenoma was observed in 1/50 low dose male rats; renal tubular cell adenocarcinomas were observed in 1/50 low dose and 1/49 high dose male rats. A renal transitional cell carcinoma was observed in 1/49 high dose male rats, and a transitional cell papilloma was observed in the urinary bladder of 1/46 high dose male rats.

*Testis*: Interstitial cell tumors in male rats occurred with a significant positive trend, and the incidence in the high dose group was significantly greater than that in the vehicle controls (Table 13).

### TABLE 12. INCIDENCES OF URINARY TRACT LESIONS IN RATS IN THE TWO-YEAR GAVAGE STUDIES OF 3-CHLORO-2-METHYLPROPENE

|  | Vehicle Control                        | 75 mg/kg    | 150 mg/kg         |
|--|--|-------------|-------------------|

### TABLE 13. ANALYSIS OF TESTICULAR TUMORS IN MALE RATS IN THE TWO-YEAR GAVAGE STUDY OF 3-CHLORO-2-METHYLPROPENE

|                             | Vehicle Control | 75 mg/kg     | 150 mg/kg    |  |
|-----------------------------|-----------------|--------------|--------------|--|
| Interstitial Cell Tumor (a) |                 |              |              |  |
| Overall Rates               | 36/50 (72%)     | 43/50 (86%)  | 43/48 (90%)  |  |
| Adjusted Rates              | 97.3%           | 100.0%       | 100.0%       |  |
| Terminal Rates              | 29/30 (97%)     | 25/25 (100%) | 17/17 (100%) |  |
| Life Table Tests            | P<0.001         | P = 0.009    | P<0.001      |  |
| Incidental Tumor Tests      | P=0.003         | P = 0.067    | P = 0.012    |  |

(a) Historical incidence at study laboratory (mean  $\pm$  SD): 92.0%  $\pm$  6.9%; historical incidence in NTP studies: 90.4%  $\pm$  5.7%

Integumentary System: Subcutaneous fibromas in female rats occurred with a significant positive trend; the incidences of fibromas, sarcomas, or fibrosarcomas (combined) in dosed female rats were not significantly greater than that in the vehicle controls (Table 14). Keratoacanthoma in male rats occurred with a significant negative trend (skin: vehicle control, 5/50, 10%; low dose, 0/50; high dose, 0/50; integumentary system: vehicle control, 6/50, 12%; low dose, 0/50; high dose, 0/50; P < 0.02). The incidences in the dosed groups were significantly lower than that in the vehicle controls (P < 0.05).

Nasal Cavity: Suppurative inflammation, acute/ chronic inflammation, or chronic inflammation occurred at increased incidences in high dose male and female rats (male: vehicle control, 0/50; low dose, 0/50; high dose, 26/50, 52%; female: vehicle control, 0/50; low dose, 0/50; high dose, 14/50, 28%).

Liver: Necrosis was observed in dosed male rats but not in any male vehicle controls. Centrilobular necrosis occurred in 1/50 (2%) low dose and 5/48 (10%) high dose male rats, focal necrosis was observed in 2/50 (4%) low dose and 2/48 (4%) high dose male rats, and midzonal necrosis was observed in 1/48 (2%) high dose male rats. The incidences of hepatocellular necrosis in high dose and vehicle control female rats were similar.

 TABLE 14. ANALYSIS OF SUBCUTANEOUS TISSUE TUMORS IN FEMALE RATS IN THE TWO-YEAR

 GAVAGE STUDY OF 3-CHLORO-2-METHYLPROPENE

|                                       | Vehicle Control | 75 mg/kg  | 150 mg/kg  |
|---------------------------------------|-----------------|-----------|------------|
| Fibroma                               |                 |           |            |
| Overall Rates                         | 0/50 (0%)       | 2/50 (4%) | 4/50 (8%)  |
| Adjusted Rates                        | 0.0%            | 6.3%      | 13.7%      |
| Terminal Rates                        | 0/31 (0%)       | 2/32 (6%) | 2/26 (8%)  |
| Life Table Tests                      | P = 0.024       | P = 0.245 | P = 0.047  |
| Incidental Tumor Tests                | P=0.030         | P = 0.245 | P = 0.060  |
| Fibroma, Sarcoma, or Fibrosarcoma (a) |                 |           |            |
| Overall Rates                         | 1/50 (2%)       | 3/50 (6%) | 5/50 (10%) |
| Adjusted Rates                        | 3.2%            | 9.4%      | 16.1%      |
| Terminal Rates                        | 1/31 (3%)       | 3/32 (9%) | 2/26 (8%)  |
| Life Table Tests                      | P = 0.046       | P = 0.316 | P = 0.077  |
| Incidental Tumor Tests                | P = 0.056       | P = 0.316 | P=0.093    |

(a) Historical incidence of fibroma or fibrosarcoma at study laboratory (mean  $\pm$  SD): 2.7%  $\pm$  1.2%; historical incidence in NTP studies: 1.8%  $\pm$  1.5%

Adrenal Gland: Neoplasms of the adrenal medulla (pheochromocytomas and/or malignant pheochromocytomas [combined]) in male rats occurred with a significant negative trend, and the incidences in the high dose group were significantly lower than those in the vehicle controls (Table 15). The incidences of pheochromocytomas in dosed female rats were not significantly different from that in the vehicle controls (vehicle control, 4/50, 8 %; low dose, 1/50, 2%; high dose, 4/50, 8%). Thyroid Gland: The incidence of C-cell adenomas or carcinomas (combined) in high dose male rats was significantly lower than that in the vehicle controls (Table 16). C-cell adenomas in female rats occurred with a significant negative trend, and the incidences in the dosed groups were significantly lower than that in the vehicle controls; however, the incidences of of C-cell adenomas or carcinomas (combined) in dosed female rats were not significantly different from that in the vehicle controls.

# TABLE 16. ANALYSIS OF THYROID GLAND TUMORS IN RATS IN THE TWO-YEAR GAVAGE STUDIESOF 3-CHLORO-2-METHYLPROPENE

#### SINGLE-ADMINISTRATION STUDIES

All mice that received 3-chloro-2-methylpropene at 3,160 mg/kg died before the end of the studies (Table 17). Final body weights were not recorded. Yellow gelatinous intestines and pale

livers, spleens, and kidneys were found in mice that died before the end of the studies. No compound-related lesions were observed in animals that survived to the end of the studies.

| Dose<br>(mg/kg) | Initial Mean Body Weight<br>(grams) | Survival |  |
|-----------------|-------------------------------------|----------|--|
| MALE            |                                     |          |  |
| 31.6            | 18                                  | 5/5      |  |

# TABLE 17. SURVIVAL AND INITIAL MEAN BODY WEIGHTS OF MICE IN THESINGLE-ADMINISTRATION GAVAGE STUDIES OF 3-CHLORO-2-METHYLPROPENE (a)

(a) The steep survival curves preclude accurate  $LD_{\rm 50}$  calculations.

(b) Day of death: 2, 2, 2, 2, 5-14 (c) Day of death: 2, 2, 2, 2, 3

#### FOURTEEN-DAY STUDIES

All the mice that received 3-chloro-2-methylpropene at 750, 1,250, 1,750, or 2,500 mg/kg died on day 1 (Table 18). The death of 1/5 female mice that received 3-chloro-2-methylpropene at 250 mg/kg was considered unrelated to the chemical. Male and female vehicle control animals lost weight during the studies. Animals that died during the studies had bright red or orange lungs, pale livers, or soft intestines. No gross lesions were observed at necropsy at the end of the studies, except for a pale liver in one male in the 125 mg/kg group.

### TABLE 18. SURVIVAL AND MEAN BODY WEIGHTS OF MICE IN THE FOURTEEN-DAY GAVAGE STUDIES OF 3-CHLORO-2-METHYLPROPENE

(a) Number surviving/number in group. All compound-related deaths occurred on day 1.

(b) Mean body weight change of the survivors

(c) No data are reported due to the 100% mortality in this group.

(d) Deaths judged accidental

#### THIRTEEN-WEEK STUDIES

All mice that received 3-chloro-2-methylpropene at 750 or 1,250 mg/kg and 9/10 males and 5/10 females in the 500 mg/kg groups died before the end of the studies (Table 19). The deaths of 1/10 males in the 500 mg/kg group and of mice in the other groups were considered to have been due to gavage injury.

Compound-related degenerative lesions were observed in the kidney and liver (Table 20). The kidney lesions consisted of degeneration and necrosis of cortical tubules, with accumulations of cellular debris in damaged tubules. Kidney lesions varied in severity within affected dose groups. The incidence and severity were greater in males than in females. Liver lesions consisted of coagulative necrosis and/or cytoplasmic vacuolization of hepatocytes. Liver and kidney lesions often occurred in the same mice; more severe liver lesions were often associated with the more severe kidney lesions. Some animals, however, had neither lesion. Mice in all groups had lung lesions consisting of interstitial inflammation, sometimes with hyperplasia of bronchiolar epithelium and epithelialization of alveolar linings. The lesions were compatible with a viral infection. Mice in these studies had antibody titers for Sendai virus, PVM, or mouse hepatitis virus (MHV).

Dose Selection Rationale: Because of the liver lesions observed at 250 mg/kg, doses selected for mice for the 2-year studies were 0, 100, or 200 mg/kg 3-chloro-2-methylpropene in corn oil by gavage.

### TABLE 20. NUMBERS OF MICE WITH LIVER AND KIDNEY LESIONS IN THE THIRTEEN-WEEKGAVAGE STUDIES OF 3-CHLORO-2-METHYLPROPENE (a)

(a) Nine animals examined in vehicle control groups; 10 animals examined in all dosed groups.

#### **TWO-YEAR STUDIES**

#### Body Weights and Clinical Signs

Mean body weights of high dose male mice and low dose and high dose female mice were lower (by less than 10%) than those of the vehicle controls throughout most of the studies (Table 21 and Figure 3). No compound-related clinical signs were observed.

# TABLE 21. MEAN BODY WEIGHTS AND SURVIVAL OF MICE IN THE TWO-YEAR GAVAGE STUDIESOF 3-CHLORO-2-METHYLPROPENE

FIGURE 3. GROWTH CURVES FOR MICE ADMINISTERED 3-CHLORO-2-METHYLPROPENE IN CORN OIL BY GAVAGE FOR TWO YEARS

#### Survival

Estimates of the probabilities of survival for male and female mice administered 3-chloro-2methylpropene at the doses used in these studies and for vehicle controls are shown in the Kaplan and Meier curves in Figure 4. The survival of the male vehicle control group was significantly lower than that of the low dose group (Table 22). In one of the cages of the high dose female mice, four pregnant mice were discovered and were promptly removed from the study.

# Pathology and Statistical Analyses of Results

This section describes the significant or noteworthy changes in the incidences of mice with neoplastic or nonneoplastic lesions in the forestomach, nasal cavity, thyroid gland, kidney, circulatory system, and liver. Histopathologic findings on neoplasms in mice are summarized in Appendix B (Tables B1 and B2); Appendix B (Tables B3 and B4) also gives the survival and tumor status for individual male and female mice. Findings on nonneoplastic lesions are summarized in Appendix D (Tables D1 and D2). Appendix E (Tables E3 and E4) contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Appendix E (footnotes). Historical incidences of tumors in corn oil vehicle control animals are listed in Appendix F.

|   | Vehicle Control | 100 mg/kg | 200 mg/kg |  |
|---|-----------------|-----------|-----------|--|

TABLE 22. SURVIVAL OF MICE IN THE TWO-YEAR GAVAGE STUDIES OF 3-CHLORO-2-METHYL-PROPENE

(a) Terminal-kill period: week 105

(b) Includes animals killed in a moribund condition

(c) The result of the life table trend test is in the vehicle control column, and the results of the life table pairwise comparisons with the vehicle controls are in the dosed columns.

(d) Four pregnant mice in one cage were removed.

#### FIGURE 4. KAPLAN-MEIER SURVIVAL CURVES FOR MICE ADMINISTERED 3-CHLORO-2-METHYLPROPENE IN CORN OIL BY GAVAGE FOR TWO YEARS

Forestomach: Incidences of inflammation of the forestomach were increased in dosed male and dosed female mice (male: vehicle control, 0/49; low dose, 9/49, 18%; high dose, 7/49, 14%; female: vehicle control, 2/50, 4%; low dose, 3/48, 6%; high dose, 9/44, 20%). Incidences of epithelial hyperplasia were increased in dosed male and dosed female mice (Table 23). Squamous cell papillomas in male and female mice, squamous cell carcinomas in male mice, and squamous cell papillomas or carcinomas (combined) in male and female mice occurred with significant positive trends. The incidences of papillomas in dosed male and dosed female mice, carcinomas in dosed male mice, and papillomas or carcinomas (combined) in dosed male and dosed female mice were significantly greater than those in the vehicle controls. Evidence of metastasis or invasion of other organs was observed in two low dose and three high dose male mice and in one high dose female mouse. The microscopic characteristics of squamous cell neoplasms of mice were similar to those described in rats.

Nasal Cavity: Acute inflammation of the nasal cavity was observed at increased (P < 0.05) incidences in high dose male and female mice (male: vehicle control, 0/50; low dose, 0/50; high dose, 6/50, 12%; female: vehicle control, 0/50; low dose, 0/48; high dose, 5/44, 11%). The acute inflammation of the nasal cavity was similar histopathologically to that observed in rats. Thyroid Gland: The incidences of follicular cysts in low dose and high dose female mice were greater than that in the vehicle controls (vehicle control, 5/44, 11%; low dose, 17/47, 36%; high dose, 8/38, 21%). Incidences of follicular cell neoplasms were not increased in dosed female mice.

*Kidney*: The incidence of nephrosis was increased in high dose male mice (male: vehicle control, 9/50, 18%; low dose, 10/50, 20%; high dose, 17/50, 34%; female: vehicle control, 2/50, 4%; low dose, 4/48, 8%; high dose, 5/44, 11%).

Circulatory System: Hemangiomas and hemangiomas or hemangiosarcomas (combined) in female mice occurred with significant negative trends (Table 24). The incidence of hemangiomas or hemangiosarcomas (combined) in the high dose female group was not significantly different from that in the vehicle controls. The following incidences of hemangiomas or hemangiosarcomas (combined) were observed in male mice: vehicle control, 2/50 (4%); low dose, 2/50 (4%); high dose, 3/50 (6%).

*Liver*: Hepatocellular carcinomas and hepatocellular adenomas or carcinomas (combined) in male mice occurred with a significant negative trend, and the incidences in the dosed groups were significantly lower than that in the vehicle controls (Table 25). In female mice, the following incidences of hepatocellular adenomas or carcinomas (combined) were observed: vehicle control, 4/50 (8%); low dose, 3/48 (6%); high dose, 1/44 (2%).

### **IV. DISCUSSION AND CONCLUSIONS**

The discovery that vinyl chloride is carcinogenic in humans (Creech and Johnson, 1974) and animals (Maltoni, 1977) has focused attention on the potential mutagenicity and carcinogenicity of the structurally analogous aliphatic and olefinic halogenated hydrocarbons (NIEHS, 1977). Many halogenated aliphatic and olefinic hydrocarbons have since been shown to be carcinogens (Soderman, 1982). The present studies assessed the toxicity and carcinogenicity of another member of the olefinic halogenated hydrocarbon series: 3-chloro-2-methylpropene.

The toxicity and carcinogenicity of 3-chloro-2methylpropene in F344/N rats and B6C3F<sub>1</sub> mice were evaluated in a series of short-term and 2year studies. In the single-administration studies, rats received 100-10,000 mg/kg 3-chloro-2methylpropene by gavage and mice received 31.6-3,160 mg/kg. In the 14-day studies, rats received 89-750 mg/kg and mice, 125-2,500 mg/kg by gavage on 14 consecutive days; vehicle control groups received corn oil on the same schedule. Rats in the 13-week gavage studies received 50-400 mg/kg and mice, 125-1,250 mg/kg; vehicle controls were administered corn oil.

In the 13-week studies, 50%-100% mortality occurred in groups of male and female rats receiving 400 mg/kg, male rats receiving 300 mg/kg, and male and female mice receiving 500, 750, or 1,250 mg/kg. Inflammation and necrosis of the liver occurred in both rats and mice administered 3-chloro-2-methylpropene for 13 weeks. Necrosis of cortical tubules of the kidneys was also observed in mice. Pathologic changes in the forestomach of dosed rats and mice were not found. Based on the histopathologic findings and the survival of the study animals in the 13-week studies, doses of 75 and 150 mg/kg for rats and 100 and 200 mg/kg for mice were selected for the 2-year studies.

Male rats receiving 150 mg/kg in the 2-year studies had reduced survival late in the study and lower mean body weights; body weight and survival were not affected in female rats or in male and female mice (see Tables 9, 10, 21, and 22; Figures 1-4).

Rats and mice administered 3-chloro-2-methylpropene by gavage in the 2-year studies had significantly increased incidences of forestomach neoplastic lesions (Table 26). For rats, these lesions were observed at 150 mg/kg. Both dosed groups of rats developed basal cell hyperplasia of the forestomach. Only a few cases of inflammation were observed. Male and female mice administered 100 or 200 mg/kg developed forestomach inflammation and forestomach epithelial hyperplasia and had significantly increased incidences of squamous cell papillomas and carcinomas of the forestomach accompanied by metastasis. The tumor data indicated that the doses of 3-chloro-2-methylpropene selected for the studies in rats and mice were appropriate for each species, even though body weight and survival were not affected in the female rats or in the male and female mice in the studies.

The forestomach of the rat and mouse is sometimes affected by chemical carcinogens, particularly when the chemical is administered by oral intubation. The squamous-lined forestomach (nonglandular stomach) is the proximal two-thirds of the stomach, immediately adjacent to the esophagus, and is sharply demarcated from the distal glandular stomach. The glandular portion of the rodent stomach is rarely a site of carcinogenesis in untreated animals or those given chemical carcinogens. The presence of mucus and/or a difference in local pH may play a role in protecting the glandular stomach from carcinogens. In the induction of malignant neoplasms in rodent forestomach by diglycidyl resorcinol ether, the earliest changes were basal cell hyperplasia. The hyperplasia progressed to papilloma and subsequently to carcinoma (NTP, 1986a). In the present studies, the pathogenesis of the forestomach neoplasm appeared to follow a similar pattern, from basal cell hyperplasia through papilloma to carcinoma.

In addition to these forestomach effects, lesions of the urinary bladder, kidney, testis, and liver were observed in dosed male rats. Although the incidence in vehicle controls was high, the incidence of nephropathy was increased in the dosed male rats (vehicle control, 35/50, 70%; low dose, 44/50, 88%; high dose, 47/49, 96%), and the

### TABLE 26. NUMBERS OF RATS AND MICE WITH FORESTOMACH LESIONS IN THE TWO-YEARGAVAGE STUDIES OF 3-CHLORO-2-METHYLPROPENE

(a) Incidence significantly (P < 0.01) greater than that in the vehicle controls

(b) Incidence significantly (P < 0.05) greater than that in the vehicle controls

incidence of nephrosis was increased in male mice (vehicle control, 9/50, 18%; low dose, 10/50, 20%; high dose, 17/50, 34%). A urinary bladder transitional cell papilloma, a renal transitional cell carcinoma, and a renal tubular cell adenocarcinoma occurred in high dose male rats, and renal tubular cell adenocarcinomas or adenomas were observed in two low dose male rats: neoplasms of the urinary system were not seen in the vehicle controls. Neoplasms of the urinary bladder have not been reported previously in male F344/N rats administered corn oil by gavage in NTP studies (Appendix F, Table F7). The NTP historical incidence of renal tubular cell neoplasms in male F344/N corn oil vehicle control rats is 4/1,091 (0.4%) and that for renal transitional cell neoplasms, 1/1,091 (0.1%) (Table F6). Thus, the renal lesions might have been compound related.

Increased incidences of testicular interstitial cell tumors in male rats were dose related. This neoplasm is commonly found in aging F344/N male rats, and the incidence of testicular interstitial cell tumors in the male rats dosed with 3-chloro2-methylpropene was within the range of historical incidence (Table F7); the development of these neoplasms was probably not chemically related. Liver necrosis, seen in rats and mice in the 13-week studies, was observed only in a few dosed male rats in the 2-year studies.

Negative trends or lower incidences were observed in dosed male rats for adrenal pheochromocytomas, C-cell adenomas or carcinomas (combined) of the thyroid gland, and keratoacanthomas of the skin. Negative trends were observed also in the incidences of liver tumors in dosed male mice and of hemangiomas or hemangiosarcomas (combined) in dosed female mice. The biologic significance of these findings is not clear. The marginally lower incidence of C-cell adenomas or carcinomas (combined) of the thyroid gland in the dosed male rats may be due to the low survival rate.

Increases were observed in the incidences of inflammation of the nasal cavity in high dose male and female rats and mice and in the incidences of follicular cysts of the thyroid gland in dosed female mice. The effects on the nasal cavity may be related to the dimethylvinyl chloride (1-chloro-2-methylpropene). Commercial 3-chloro-2-methylpropene normally contains about 5% dimethylvinyl chloride. This component is difficult to remove by distillation (Deichmann and Gerarde, 1969). The two lots of 3chloro-2-methylpropene used in the present studies contained about 5% and 4% dimethylvinyl chloride, respectively. Thus, the male and female rats administered 75 or 150 mg/kg per day of 3-chloro-2-methylpropene received about 3 or 6 mg/kg per day of dimethylvinyl chloride, and male and female mice administered 100 or 200 mg/kg per day of 3-chloro-2-methylpropene received about 4 or 8 mg/kg per day of dimethylvinyl chloride.

Dimethylvinyl chloride caused neoplasms in F344/N rats and  $B6C3F_1$  mice (NTP, 1986b). Administered to rats at 100 or 200 mg/kg in corn oil by gavage, it induced carcinomas of the nasal cavity in male and female rats; metastasis to the brain was also observed. Squamous cell papillomas or carcinomas were found in the oral cavity, esophagus, and forestomach of dosed male and female rats. Mice administered dimethylvinyl chloride by gavage at 100 or 200 mg/kg had increased incidences of squamous cell carcinomas of the forestomach with metastasis to the lungs.

In the present studies of 3-chloro-2-methylpropene, neoplasms of the oral and nasopharyngeal areas were not observed in rats or mice; however, the high dose rats and mice developed inflammation of the nasal cavity (Tables C1, C2, D1, and D2). This inflammation may possibly be related to the effects of low doses of dimethylvinyl chloride. The presence of dimethylvinyl chloride in 3-chloro-2-methylpropene may have contributed to the development of forestomach neoplasms in rats and mice in the present studies. Future studies could help to delineate the effects of low doses of dimethylvinyl chloride on forestomach carcinogenesis in rats and mice.

In general, studies suggest that chlorine substitution enhances the mutagenic and carcinogenic potential of propene and that monomethylation increases the alkylating potential, mutagenicity, and probably the carcinogenicity of allylic chlorides (Neudecker et al., 1980). Propene

(propylene;  $CH_2 = CH - CH_3$ ) administered by inhalation was not carcinogenic in rats and mice (NTP, 1985) and was not mutagenic in Escherichia coli (Sandmeyer, 1981), whereas the structurally related 1-chloropropene (CHCl=CH- $CH_3$ ) and allyl chloride ( $CH_2 = CH - CH_2Cl$ ) administered orally induced forestomach tumors in mice (Van Duuren et al., 1979; NCI, 1978) and were mutagenic in Salmonella (McCoy et al., 1978; Eder et al., 1980; Neudecker et al., 1980). The mutagenicity of allyl chloride was enhanced by monomethylation: that is, the mutagenic potential of allyl chloride in Salmonella TA100 was less than that of 3-chloro-2-methylpropene (I); 3-chloro-1-butene (II) and 1-chloro-2-butene (III) were more potent mutagens than 3-chloro-2-methylpropene (Neudecker et al., 1980). Bimethylated allyl chlorides were slightly less mutagenic than were monomethylated allylic chlorides, and the mutagenic potencies of all of these compounds correlated well with their alkylating activities.

$$CH_{3}$$

$$| \\ CH_{3}$$

$$| \\ III. CH_{2} = CH - CH_{2}C|$$

Halogenated alkenes are thought to undergo epoxidation reactions that are catalyzed by the cytochrome P-450 dependent polysubstrate mono-oxygenase system. The resultant epoxides may react with tissue macromolecules, leading to toxicity, mutagenicity, and/or carcinogenicity (Bonse and Henschler, 1976; Anders, 1982; MacDonald, 1983). Halogenated hydrocarbons with more than two carbon atoms, such as allyl chloride, have also been postulated to be activated via the epoxidation pathway (Van Duuren, 1977).

The NTP found that 3-chloro-2-methylpropene required liver S9 to induce reverse mutation in Salmonella strains TA100 and TA1537 (Appendix L, Table L1). However, Neudecker et al. (1980) and Eder et al. (1982) reported that 3-chloro-2-methylpropene was a direct-acting mutagen in strain TA100 and that rat liver S9 greatly reduced its mutagenic effect. Results of the NTP mouse lymphoma tests (Table L2) and cytogenetic investigations (Tables L3 and L4) also suggest that 3-chloro-2-methylpropene is a direct-acting mutagen. The discrepancy between the findings of Neudecker et al. (1980) and Eder et al. (1982) and those of the NTPsponsored tests in Salmonella may be due to differences in purity of the compound and in protocols. Taken as a whole, however, mutagenicity testing of 3-chloro-2-methylpropene indicates that it is a direct-acting mutagen in both bacterial and mammalian cells. This finding is consistent with the observation that the administration of 3-chloro-2-methylpropene by gavage to rats and mice induced neoplasms in the forestomach, the site of application.

**Conclusion:** Under the conditions of these 2year gavage studies, there was *clear evidence of carcinogenicity*<sup>\*</sup> for 3-chloro-2-methylpropene as shown by the increased incidences of squamous cell neoplasms in the forestomach of male and female F344/N rats and male and female  $B6C3F_1$ mice.

<sup>\*</sup>Categories of evidence of carcinogenicity are defined in the Note to the Reader on page 2. The public discussion regarding the interpretative conclusions is summarized on page 14.

#### TABLE A2. SUMMARY OF THE INCIDENCE OF NEOPLASMS IN FEMALE RATS IN THE TWO-YEAR GAVAGE STUDY OF 3-CHLORO-2-METHYLPROPENE (Continued)

\* NUMBER OF ANIMALS RECEIVING COMPLETE NECROPSY EXAMINATION; ALL GROSS LESIONS INCLUDING MASSES EXAMINED MICROSCOPICALLY. \*\* PRIMARY TUMORS: ALL TUMORS EXCEPT SECONDARY TUMORS

# NUMBER OF ANIMALS EXAMINED MICROSCOPICALLY AT THIS SITE

## SECONDARY TUMORS: METASTATIC TUMORS OR TUMORS INVASIVE INTO AN ADJACENT ORGAN † THE PWG DIAGNOSED THIS TUMOR AS A FIBROSARCOMA.

## TABLE A4. INDIVIDUAL ANIMAL TUMOR PATHOLOGY OF FEMALE RATS IN THE TWO-YEAR GAVAGE STUDY OF 3-CHLORO-2-METHYLPROPENE: HIGH DOSE

 + : Tissue Examined Microscopically

 - : Required Tissue Not Examined Microscopically

 X : Tumor Incidence

 N : Necropsy, No Autolysis, No Microscopic Examination

 S : Animal Missexed

 : No Tissue Information Submitted

 C : Necropsy, No Histology Due To Protocol

 A : Autolysis

 M : Animal Missing

 B : No Necropsy Performed

#### TABLE B4. INDIVIDUAL ANIMAL TUMOR PATHOLOGY OF FEMALE MICE IN THE TWO-YEAR GAVAGE STUDY OF 3-CHLORO-2-METHYLPROPENE: HIGH DOSE

 + : Tissue Examined Microscopically

 - : Required Tissue Not Examined Microscopically

 X : Tumor Incidence

 N : Necrops, No Autolysis, No Microscopic Examination

 S : Animal Missered

 : No Tissue Information Submitted

 C : Necropsy, No Histology Due To Protocol

 A : Autolysus

 M : Animal Missing

 B : No Necropsy Performed

#### TABLE E1. ANALYSIS OF PRIMARY TUMORS IN MALE RATS IN THE TWO-YEAR GAVAGE STUDY **OF 3-CHLORO-2-METHYLPROPENE (Continued)**

(a) Number of tumor-bearing animals/number of animals examined at the site

(b) Kaplan-Meier estimated tumor incidence at the end of the study after adjusting for intercurrent mortality

(c) Observed tumor incidence at terminal kill

(d) Beneath the control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence. A negative trend or lower incidence is indicated by (N). (e) Two animals also had squamous cell carcinomas.

#### TABLE E2. ANALYSIS OF PRIMARY TUMORS IN FEMALE RATS IN THE TWO-YEAR GAVAGE STUDY OF 3-CHLORO-2-METHYLPROPENE (Continued)

(a) Number of tumor-bearing animals/number of animals examined at the site(b) Kaplan-Meier estimated tumor incidence at the end of the study after adjusting for intercurrent mortality

(c) Observed tumor incidence at terminal kill

(d) Beneath the control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence. A negative trend or lower incidence is indicated by (N).

### TABLE E3. ANALYSIS OF PRIMARY TUMORS IN MALE MICE IN THE TWO-YEAR GAVAGE STUDY OF 3-CHLORO-2-METHYLPROPENE (Continued)

#### TABLE E3. ANALYSIS OF PRIMARY TUMORS IN MALE MICE IN THE TWO-YEAR GAVAGE STUDYOF 3-CHLORO-2-METHYLPROPENE (Continued)

(a) Number of tumor-bearing animals/number of animals examined at the site

(b) Kaplan-Meier estimated tumor incidence at the end of the study after adjusting for intercurrent mortality

<sup>(</sup>c) Observed tumor incidence at terminal kill

<sup>(</sup>d) Beneath the control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence. A negative trend or lower incidence is indicated by (N).

## TABLE E4. ANALYSIS OF PRIMARY TUMORS IN FEMALE MICE IN THE TWO-YEAR GAVAGE STUDY OF 3-CHLORO-2-METHYLEPROPENE (Continued)

(a) Number of tumor-bearing animals/number of animals examined at the site

(b) Kaplan-Meier estimated tumor incidence at the end of the study after adjusting for intercurrent mortality

(c) Observed tumor incidence at terminal kill

(d) Beneath the control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence. A negative trend or lower incidence is indicated by (N).

3-Chloro-2-methylpropene, NTP TR 300 144

|          |                         |   |                                    |

### APPENDIX G. CHEMICAL CHARACTERIZATION

Note: Under these conditions, dimethylvinyl chloride, an isomer of 3-chloro-2methylpropene, had a retention time of 1.1 minute. Peak no. 3 could be dimethylvinyl chloride, but this was not confirmed by addition of dimethylvinyl chloride to the sample.

7. Conclusions: The results of the elemental analysis agree with the theoretical values. Gas chromatography with one system indicated 31 impurities, one with an area 3% that of the major peak; the combined areas of the other 30 impurities totaled less than 0.3% that of the major peak. A second system indicated 26 impurities; the two largest impurities had areas 6% and 3% that of the major peak. Titration for acidic components indicated  $34 \pm 5$  ppm acidity (assumed to be HCl). The infrared spectrum was consistent with the structure. The nuclear magnetic resonance spectrum was basically consistent with the structure but indicated five peaks attributed to impurities. The chemical shifts of two of these were consistent with the shifts observed for dimethylvinyl chloride. By this assignment, the integration ratios indicated a concentration of 5% dimethylvinyl chloride. The retention time of the 6% impurity observed in one gas chromatographic system was consistent with that of dimethylvinyl choride, but this assignment was not confirmed by addition of dimethylvinyl chloride to the samples used for gas chromatography or nuclear magnetic resonance spectroscopy.

6. Chromatographic analysis: Gas chromatography

Instrument: Varian 3700 Detector: Flame ionization Inlet temperature: 200° C Detector temperature: 250° C Carrier gas: Nitrogen, 70 ml/min

a. System 1

Column: 10% Carbowax 20M-TPA on 80/100 Chromosorb W (AW) Oven temperature program: 50° C for 5 min then 50°-200° C at 10° C/min Samples injected: Neat liquid (4 µl) and 1% (v/v) and 0.5% (v/v) solutions of 3chloro-2-methylpropene in o-dichlorobenzene to quantitate impurities and check linearity of detector response

**Results:** Major peak and 10 impurities with individual areas greater than 0.01% that of the major peak area. Three impurities eluting before the major peak and seven eluting after the major peak had a combined area 6.65% that of the major peak area. Peak no. 3 was identified by spiking as dimethylvinyl chloride. Quantitation against standards indicated a concentration of  $3.6\% \pm 0.5\%$  (v/v) dimethylvinyl chloride in the sample.

| major 2  | 2.8                     | 1.0                                      | 100                             |
| 3        | 4.2                     | 1.5                                      | 0.01                            |
| 4        | 6.6-6.9                 | 2.4-2.5                                  | 0.41                            |
| 5        | 16.1                    | 5.7                                      | 0.26                            |

7. Conclusions: The sample was identified as 3-chloro-2-methylpropene by spectroscopy. Less than 0.01% water was found in the sample. Gas chromatography with one system indicated impurities totaling 6.65% that of the major peak, and with a second system, impurities totaling 1.11% that of the major peak. The largest peak in the first system (5.1%) was identified by spiking as dimethylvinyl chloride and quantitated against standards at  $3.6\% \pm 0.5\%$  (v/v) in the sample. This impurity was not observed in the second system and is believed to have coeluted with the major peak, accounting for the lower relative total area of impurities in that system.

### **APPENDIX G. CHEMICAL CHARACTERIZATION**

# II. Chemical Stability Study of Lot No. 110967 Performed by the Analytical Chemistry Laboratory

- **A. Sample storage:** Samples of 3-chloro-2-methylpropene were stored for 2 weeks at 20°, 5°, 25°, and 60° C.
- B. Analytical method: Gas chromatography

Instrument: Bendix 2500 Detector: Flame ionization Column: 20% SP 2100/0.1% Carbowax 1500 on 100/120 mesh Supelcoport, 4 mm × 1.8 m, glass Carrier gas: Nitrogen, 40 ml/min Retention time: 2.7 min Temperatures Inlet: 100° C Detector: 285° C Oven: 30° C, isothermal

C. Results: One impurity was detected in all samples at the detection sensitivity used for this study. The retention time was 1.4 minute, and the peak area was constant at 0.41%  $\pm$  0.002% relative to the major component.

| Storage Temperature<br>(degrees centigrade) | Area of Major Peak<br>Relative to – 20° Sample (percent) |  |
|---|--|--|
| - 20  | 100 ± 4  |  |
| 5   | $102 \pm 4$  |  |
| 25  | $102 \pm 4$  |  |
| 60  | $100 \pm 4$  |  |
|   |  |  |

**D.** Conclusion: 3-Chloro-2-methylpropene is stable as the bulk chemical when stored for 2 weeks at temperatures of up to 60° C.

#### III. Chemical Stability Study of Lot No. 1 10967 Performed by the Study Laboratory

A. Storage conditions: 4°C

#### B. Analytical methods for purity and identity

1. Purity: Gas-liquid chromatography

Instrument: Hewlett Packard 5880 with 7672A Liquid Sampler Column: 1.8 m × 2 mm ID, silanized glass, 20% SP 2100/0.1% Carbowax 1500 on 100/120 mesh Supelcoport Detector: Flame ionization Detector temperature: 270° C Inlet temperature: 200° C Oven temperature program: 50° C for 5 min, 50°-200° at 10° C/min, 200° for 5 min Carrier gas: Nitrogen, 40 ml/min Sample size: 3 µl neat liquid, followed by 1% and 0.5% 3-chloro-2-methylpropene in o-dichlorobenzene to quantitate major peak and check for detector overloading

2. Identity: Infrared spectroscopy

Instrument: Perkin Elmer Model 283B, 398, or 457 Cell: Neat liquid

- 2. Infrared: All bulk and reference spectra were essentially identical.
- **D.** Conclusion: No notable degradation occurred during the studies.

3-Chloro-2-methylpropene, NTP TR 300 170

### APPENDIX H

## **PREPARATION AND CHARACTERIZATION**

### OF DOSE MIXTURES

## **APPENDIX H. PREPARATION AND CHARACTERIZATION**

#### Studies Conducted at the Analytical Chemistry Laboratory

- I. Sample preparation and storage: Solutions of 3-chloro-2-methylpropene in corn oil (2.25% w/v; 22.5 mg/ml) were prepared in duplicate for storage of 0, 5, 6, or 7 days, respectively. A typical sample was prepared as follows: 2 ml of corn oil was transferred into an 8.5-ml septum vial, and the vial was sealed (Microsep F-138 gas chromatography septa with Teflon® film facing from Canton BioMedical Products, Inc.; aluminum crimp seals from Wheaton Scientific Co., Inc.) and weighed. Approximately 45 mg of 3-chloro-2-methylpropene then was injected via microliter syringe, and the vial was reweighed. The sample was agitated on a vortex mixer for 30 seconds and then stored at room temperature (25° C) in the dark for the appropriate time period.
- II. Sample extraction and analysis: At the end of each storage time period, the appropriate samples were extracted with 2 ml of absolute methanol that was injected into the vials with a 2-ml syringe. The two-phase mixtures were thoroughly agitated on the vortex mixer for 1 minute and placed in an ultrasonic vibratory bath for 1 minute. Aliquots for analysis were removed directly from the upper (methanol) layer of each sample by microliter syringe and analyzed by the gas chromatographic system described below.

#### Instrument: Bendix 2500

Column:  $1.8 \text{ m} \times 2 \text{ mm}$  ID, silanized glass, 20% SP 2100/0.1% Carbowax 1500 on 100/120 mesh Supelcoport Detection: Flame ionization

#### Temperatures

Inlet: 100°C Oven: 30°C, isothermal Detector: 285°C Carrier gas: Nitrogen, 40 ml/min Retention time: 2.7 min

#### **III.** Results

| <u>Storage Time (days)</u> | Average Percent<br>Chemical Found in<br><u>Chemical/Vehicle Mixture</u> (a) |  |  |
|----------------------------|---|--|--|
| 1                          | (b) $2.27 \pm 0.20$   |  |  |
| 5                          | $1.97 \pm 0.17$   |  |  |
| 6                          | $2.04 \pm 0.18$   |  |  |
| 7                          | $1.97 \pm 0.17$   |  |  |

(a) Corrected for a spike recovery of  $70.8\% \pm 4.3\%$ 

(b) The original concentration of 3-chloro-2-methylpropene in corn oil at time of sample preparation was 2.27% with a variation among samples of 0.02%.

**IV. Conclusion:** 3-Chloro-2-methylpropene mixed with corn oil at the 2.25% concentration is stable, within the error limits of this study, when stored in the dark at room temperature (25° C) for 7 days, with an average loss of 0.27% after 5, 6, and 7 days of storage.

### **APPENDIX I**

## METHODS OF ANALYSIS OF DOSE MIXTURES

#### Analysis Performed at Analytical Chemistry Laboratory

- I. Preparation of standard spiked corn oil: Two standard solutions of 3-chloro-2-methylpropene were prepared independently in methanol. The solutions were diluted with methanol to make four additional standards. Aliquots (20 ml) of the six standard solutions were pipetted into individual 35-ml septum vials containing 2 g of undosed corn oil to make spiked corn oil standards bracketing the specified dose range of the referee sample. One 35-ml septum vial containing 2 g of undosed corn oil was treated with 20 ml of methanol for use as a blank. After the vials with Teflon®-lined septa were sealed, the spiked corn oils and the corn oil blank were used in the analysis procedure described below.
- II. Preparation of referee sample: Three portions (approximately 2 g each) of the referee sample were transferred to individual tared 35-ml septum vials and weighed to the nearest 0.001 g. Methanol (20 ml) was pipetted into each vial; the vials then were sealed, and the samples were analyzed immediately by the procedure below.
- III. Analysis procedure: Vials containing the samples, standards, and the blank were agitated for 10 seconds on a vortex mixer and then shaken at maximum stroke for 20 minutes on a wristaction shaker. After the extraction mixtures were centrifuged for 3 minutes, a 5-ml aliquot of the methanol layer from each vial was diluted to 10 ml with methanol. The solutions were mixed; then the 3-chloro-2-methylpropene content was determined by the gas chromatographic systems described below.

Instrument: Varian 3700 Gas chromatograph with Autosampler and Varian CDS 111-C integrator Detection: Flame ionization Detector temperature: 250°C Inlet temperature: 200°C Carrier gas: Nitrogen, 30 ml/min Volume of solution injected: 3-5 µl

A. System 1

Column: 1% SP 1000 on 100/120 Supelcoport, 1.8 m × 4 mm ID, glass, silanized
Oven temperature program: 60° or 70° C, isothermal
Internal standard: None or anisole
Retention times

3-chloro-2-methylpropene at 60° C: 6.2 min
Internal standard at 60° C: 4.2 min

**Results:** The total amount of 3-chloro-2-methylpropene in the referee corn oil samples was computed from the linear regression equation obtained from the standard data by relating the peak area of each spiked corn oil sample to the amount of chemical in the respective spiked corn oil sample.

#### B. System 2

Column: 1% SP 2100/0.1% Carbowax 1500 on 100/120 Supelcoport, 1.8 m × 4 mm ID, glass, silanized Oven temperature program: 38°C, isothermal Internal standard: 1,2-dichloroethylene Retention times 3-chloro-2-methylpropene: 4.0 min Internal standard: 2.3 min

IV. Quality Assurance Measures: The referee corn oil sample was analyzed in triplicate, and the undosed corn oil sample was analyzed once. Individually spiked portions of undosed corn oil (six concentrations bracketing the specified dose range of the referee sample) were prepared from two independently weighed standards and were used for obtaining standard data. Triplicate injections of each standard and sample were made into the gas chromatograph in a randomized order.

(a) Results of triplicate analysis

### APPENDIX K

### SENTINEL ANIMAL PROGRAM

#### I. Methods

Rodents used in the Carcinogenesis Program of the National Toxicology Program are produced in optimally clean facilities to eliminate potential pathogens that may affect study results. The Sentinel Animal Program is part of the periodic monitoring of animal health that occurs during the toxicologic evaluation of chemical compounds. Under this program, the disease state of the rodents is monitored via viral serology on sera from extra (sentinel) animals in the test rooms. These animals are untreated, and these animals and the study animals are both subject to identical environmental conditions. The sentinel animals come from the same production source and weanling groups as the animals used for the studies of chemical compounds.

Fifteen  $B6C3F_1$  mice and 15 F344/N rats of each sex are selected at the time of randomization and allocation of the animals to the various study groups. Five animals of each designated sentinel group are killed at 6, 12, and 18 months on study. Data from animals surviving 24 months are collected from 5/50 randomly selected vehicle controls of each sex and species. The blood from each animal is collected and clotted, and the serum is separated. The serum is cooled on ice and shipped to Microbiological Associates' Comprehensive Animal Diagnostic Service for determination of the viral antibody titers. The following tests are performed:

|      | Hemagglutination<br><u>Inhibition</u>   | Complement<br><u>Fixation</u>   | <u>ELISA</u>                   |
|------|---|---|--------------------------------|

# TABLE K1. MURINE VIRUS ANTIBODY DETERMINATIONS FOR RATS AND MICE IN THE TWO-YEAR GAVAGE STUDIES OF 3-CHLORO-2-METHYLPROPENE (a)

(a) Blood samples were taken from sentinel animals at approximately 6, 12, and 18 months after the start of dosing and from the vehicle control animals just before they were killed; samples were sent to Microbiological Associates, Inc. (Bethesda, MD) for the Animal Disease Screening Program.

#### TABLE L1. MUTAGENICITY OF 3-CHLORO-2-METHYLPROPENE IN SALMONELLA TYPHIMURIUM

(a) The S9 fractions were prepared from the livers of Aroclor 1254-induced male Sprague-Dawley rats and male Syrian hamsters. Cells and study compound or solvent (water) were incubated for 20 minutes at 37° C in the presence of either S9 or buffer. After the addition of soft agar, the contents of each tube was poured onto minimal medium, and the plates were incubated at 37° C for 48 hours (Haworth et al., 1983). The experiment was performed twice, each in triplicate; because the re-sults were similar, data from only one experiment are shown.

# TABLE L2. MUTAGENICITY OF 3-CHLORO-2-METHYLPROPENE IN L5178Y/TK\*/~ MOUSE LYMPHOMACELLS IN THE ABSENCE OF S9

(a) Experiments were performed twice, and all doses were tested in triplicate except the solvent control that was tested in quadruplicate. Because the results were similar, data from only one experiment are shown. The protocol was basically that of Clive et al. (1979). Cells ( $6 \times 10^5$ /ml) were treated for 4 hours at 37° C in medium, washed, resuspended in medium, and incubated for 48 hours at 37° C. After expression,  $3 \times 10^6$  cells were plated in medium supplemented with trifluorothymidine for selection of cells that were mutant at the thymidine kinase (TK) locus, and 600 cells were plated in nonselective medium to determine the percentage of viable cells.

(a) SCE = sister-chromatid exchange

(b) In the absence of S9, Chinese hamster ovary cells were incubated with study compound or solvent at 37° C; 2 hours after initiation of treatment, 10  $\mu$ M BrdU was added, and incubation was continued for an additional 22-24 hours. Cells were washed, fresh medium containing BrdU (10  $\mu$ M) and colcemid (0.1  $\mu$ g/ml) was added, and incubation was continued for 2-3 hours (Galloway et al., 1985).

(c) In the presence of S9, Chinese hamster ovary cells were incubated with study compound or solvent for 2 hours at 37° C. Then cells were washed, and medium containing 10 µM BrdU was added. Cells were incubated for a further 26 hours, with colcemid (0.1 µg/ml) present for the final 2-3 hours. S9 was from the livers of Aroclor 1254-induced male Sprague-Dawley rats (Galloway et al., 1985).

(d) Cells were collected by mitotic shake-off, treated for 3 minutes with potassium chloride (75 mM), washed twice with fixative, and dropped onto slides and air-dried (Galloway et al., 1985).

#### TABLE M4. CONTAMINANT LEVELS IN NIH 07 RAT AND MOUSE RATION

.

#### TABLE M4. CONTAMINANT LEVELS IN NIH 07 RAT AND MOUSE RATION (Continued)

(a) All values were less than the detection limit, given in the table as the mean.

(c) Source of contamination: Alfalfa, grains, and fish meal

(f) Excludes one very high value of 1,100 obtained in batch produced on 12/16/80

(i) All values were corrected for percent recovery.

- in batches produced on 1/26/81, 2/23/81, and 4/27/81.
- (k) Mean, standard deviation, and range include the very high values given in footnote j.
- (1) BHC = hexachlorocyclohexane or benzene hexachloride

under the range.

<sup>(</sup>b) Detection limit reduced from 10 ppb to 5 ppb after 7/81

<sup>(</sup>d) Source of contamination: Soy oil and fish meal

<sup>(</sup>e) Two batches contained less than 0.5 ppm.

<sup>(</sup>g) Includes the high value listed in footnote f(h) All values were less than 3 MPN/g. MPN = most probable number.

<sup>(</sup>j) Mean, standard deviation, and range exclude three very high values in the range of 115-273.2 ppb

<sup>(</sup>m) One observation was above the detection limit. The value and the date it was obtained are listed

<sup>(</sup>n) Eleven batches contained more than 0.05 ppm.

3-Chloro-2-methylpropene, NTP TR 300 194

### APPENDIX N

### DATA AUDIT SUMMARY

The data from the 2-year toxicology and carcinogenesis studies of 3-chloro-2-methylpropene in F344/N rats and  $B6C3F_1$  mice were audited for accuracy, completeness, and procedures consistent with Good Laboratory Practice regulations by personnel from ImmuQuest Laboratory, Inc., from August 20 to September 7, 1984, at the NTP Repository, Rockville, Maryland. The studies were begun at Litton Bionetics, Inc., Kensington, Maryland, before the NTP required full compliance with Good Laboratory Practice procedures in October 1981. The members of the audit team were: P. Errico, C. Reese, K. Witkin, L. Brennecke, and D. Haynes. The full audit report is on file at the National Toxicology Program, NIEHS.

The records were reviewed for body weights, clinical observations, correlation between gross and microscopic observations, animal identification, and wet tissue examinations from a randomly selected 10% of the animals in each group. All the chemistry, environmental, and mortality records were examined. Slide and block matches were performed on all high dose and vehicle control animals.

The inlife data included the study protocol, animal shipment receipts, method of randomization of animals, method of animal identification, condition of the animals during and at the end of the quarantine period, dosing records (animal weights, volume administered, date of mix used, dose volume calculation), clinical observations, mortality, and environmental conditions. Sera collection and viral data were recorded at regular intervals during the 2-year period. The data were found to have been appropriately and completely recorded.

The pathology records from a randomly selected 10% of the rats and mice were reviewed. Most of the animals were identifiable by the method indicated (toe clips, ear punch/tab). One rat and three mice were unidentifiable because of missing ear tag or missing ears. Some tissues/organs were missing from the wet tissue bags. A number of tissues for which gross observations had been notated were apparently not examined microscopically. Most of these grossly described masses were recorded for the nontarget organs. However, grossly observed masses in the forestomach not examined microscopically were found in one high dose male rat, one low dose male mouse, two high dose male mice, one low dose female mouse, and three high dose female mice. No errors were noted in slide/block match, data entry, or disposition code for the tissues that were trimmed and examined microscopically. The untrimmed masses in the forestomach were examined histologically, and the final Technical Report reflects the revised diagnoses. No additional gross lesions were observed in the forestomachs of vehicle control rats and mice.

In conclusion, no discrepancies that might have affected the final interpretations of the 2-year studies of 3-chloro-2-methylpropene were noted. The data examined in the audit are considered adequate to meet the objectives of the study.
