#### NATIONAL TOXICOLOGY PROGRAM

The National Toxicology Program (NTP), established in 1978, develops and evaluates scientific information about potentially toxic and hazardous chemicals. This knowledge can be used for protecting the health of the American people and for the primary prevention of disease. By bringing together the relevant programs, staff, and resources from the U.S. Public Health Service, DHHS, the National Toxicology Program has centralized and strengthened activities relating to toxicology research, testing and test development/validation efforts, and the dissemination of toxicological information to the public and scientific communities and to the research and regulatory agencies.

The NTP is made up of four charter DHHS agencies: the National Cancer Institute (NCI), National Institutes of Health; the National Institute of Environmental Health Sciences (NIEHS), National Institutes of Health; the National Center for Toxicological Research (NCTR), Food and Drug Administration; and the National Institute for Occupational Safety and Health (NIOSH), Centers for Disease Control. In July 1981, the Carcinogenesis Bioassay Testing Program, NCI, was transferred to the NIEHS.

#### NOTE TO THE READER

This study was performed under the direction of the National Institute of Environmental Health Sciences as a function of the National Toxicology Program. The studies described in this Technical Report have been conducted in compliance with NTP chemical health and safety requirements and must meet or exceed all applicable Federal, state, and local health and safety regulations. Animal care and use were in accordance with the U.S. Public Health Service Policy on Humane Care and Use of Animals. All NTP toxicology and carcinogenesis studies are subjected to a data audit before being presented for public peer review.

Although every effort is made to prepare the Technical Reports as accurately as possible, mistakes may occur. Readers are requested to identify any mistakes so that corrective action may be taken. Further, anyone who is aware of related ongoing or published studies not mentioned in this report is encouraged to make this information known to the NTP. Comments and questions about the National Toxicology Program Technical Reports on Toxicology and Carcinogenesis Studies should be directed to Dr. J.E. Huff, National Toxicology Program, P.O. Box 12233, Research Triangle Park, NC 27709 (919-541-3780).

These NTP Technical Reports are available for sale from the National Technical Information Service, U.S. Department of Commerce, 5285 Port Royal Road, Springfield, VA 22161 (703-487-4650). Single copies of this Technical Report are available without charge (and while supplies last) from the NTP Public Information Office, National Toxicology Program, P.O. Box 12233, Research Triangle Park, NC 27709.

#### **BROMODICHLOROMETHANE**

CAS No. 75-27-4

CHBrCl<sub>2</sub>

Molecular weight 163.83

Synonym: Dichlorobromomethane

#### **ABSTRACT**

Bromodichloromethane (99% pure), one of several trihalomethanes commonly formed after chlorination of water, was selected for study because no carcinogenicity data were available for this compound and because chloroform, a related trihalomethane, had been found to cause tumors in rodents. The general population might be exposed to bromodichloromethane in drinking water supplies, in swimming pools, and in a variety of food substances.

Single-administration, 14-day, 13-week, and 2-year studies were conducted in F344/N rats and B6C3F<sub>1</sub> mice. The chemical was administered by gavage in corn oil because human exposure is primarily oral. Additional studies were performed to evaluate the potential for genetic damage in bacteria and mammalian cells.

Results of the Short-Term Studies: In the single-administration studies, the chemical was administered at doses of 150-2,500 mg/kg per day. All rats and female mice at 1,250 and 2,500 mg/kg and all male mice at 600, 1,250, and 2,500 mg/kg died; 2/5 male rats, 1/5 female rats, and 2/5 female mice at 600 mg/kg died; all animals at lower dose levels survived.

In the 14-day studies, rats received doses of 38-600 mg/kg, and mice received doses of 19-300 mg/kg per day. One female rat at 38 mg/kg and one female rat at 600 mg/kg died. Weight loss or decreased weight gain was seen at 300 and 600 mg/kg in male and female rats. All male mice at 150 and 300 mg/kg died, and one female mouse at 300 mg/kg died; no weight effects were observed in surviving mice. Dose-related necropsy findings included reddened renal medullae in male rats at 600 mg/kg and in male mice at 150 and 300 mg/kg. Clinical signs seen in high dose groups after dosing were hyperactivity in rats and lethargy in mice.

In the 13-week studies, male and female rats received doses of 19-300 mg/kg per day, male mice received doses of 6.25-100 mg/kg per day, and female mice received doses of 25-400 mg/kg per day. Five of 10 male rats and 2/10 female rats at 300 mg/kg died. None of the mice died. Final body weights of male and female rats at 150 and 300 mg/kg were lower than those of vehicle controls (45%-88% of vehicle control weights); final body weights of male mice at 100 mg/kg and female mice at 400 mg/kg were 92% and 94% of those of the vehicle controls. Centrilobular degeneration in the liver and degeneration and necrosis of the kidney were seen in male rats at 300 mg/kg; centrilobular degeneration was seen in female rats at 300 mg/kg; degeneration and necrosis of the kidney were seen in male mice at 100 mg/kg, and centrilobular degeneration of the liver was seen in female mice at 200 and 400 mg/kg.

Experimental Design of the Two-Year Studies: The 2-year toxicology and carcinogenesis studies of bromodichloromethane were conducted by administering the chemical in corn oil by gavage, 5 days per week for 102 weeks, to groups of 50 male and female rats at doses of 0, 50, or 100 mg/kg per day; to groups of 50 male mice at doses of 0, 25, or 50 mg/kg per day; and to groups of 50 female mice at doses of 0, 75, or 150 mg/kg per day. The study in male rats was restarted because at 10.5 months into the original study, a temperature elevation killed 45/50 vehicle control male rats.

Survival and Body Weight in the Two-Year Studies: Final survival of dosed rats was comparable to that of vehicle controls (male: vehicle control, 28/50; low dose, 36/50; high dose, 28/50; female: 34/50; 27/50; 41/50). Mean body weights of high dose male and female rats were decreased during the last 1.5 years of the study; final mean body weights of high dose male and female rats were 88% and 79% of vehicle control mean weights. Final mean body weights of low dose male and female rats were comparable to those of the vehicle controls.

Final survival of dosed male mice was comparable to that of the vehicle controls (34/50; 32/50; 42/50). At week 84, survival of female mice was greater than 50% in all dose groups. After week 84, survival of dosed and vehicle control female mice was reduced (final survival: 26/50; 13/50; 15/50), and this decreased survival was associated with ovarian abscesses (8/50; 19/47; 18/49). The final mean body weight of high dose male mice was 95% that of the vehicle controls; the final mean body weight of low dose male mice was comparable to that of the vehicle controls. Mean body weights of high dose female mice were decreased during the last 1.5 years of the study; the final mean body weight was 75% that of vehicle controls. The final mean body weight of low dose female mice was 91% that of vehicle controls.

Nonneoplastic Effects in the Two-Year Studies: Compound-related nonneoplastic lesions included cytomegaly and tubular cell hyperplasia of the kidney and necrosis and fatty metamorphosis of the liver in male rats; eosinophilic cytoplasmic change, clear cell change, focal cellular change, and fatty metamorphosis of the liver and tubular cell hyperplasia of the kidney in female rats; fatty metamorphosis of the liver, renal cytomegaly, and follicular cell hyperplasia of the thyroid gland in male mice; and follicular cell hyperplasia of the thyroid gland in female mice.

Neoplastic Effects in the Two-Year Studies: Bromodichloromethane caused compound-related increases in the incidences of neoplasms of the large intestine and kidney in male and female rats, the kidney in male mice, and the liver in female mice, as shown in the facing table. The neoplasms of the large intestine and kidney are uncommon tumors in F344/N rats and B6C3F<sub>1</sub> mice.

Administration of bromodichloromethane was also associated with a decrease in tumors of the adrenal glands in male rats, the pituitary and mammary glands in female rats, and the pituitary gland in female mice.

Genetic Toxicology: Bromodichloromethane was not mutagenic in Salmonella typhimurium strains TA98, TA100, TA1535, or TA1537 when tested by the preincubation protocol at concentrations of up to 1,000 µg/plate with or without metabolic activation. The compound was not mutagenic in the mouse lymphoma L5178Y/TK<sup>+/-</sup> assay in the absence of S9 but did induce forward mutations in this system in the presence of metabolic activation from rat liver S9. Cytogenetic tests with Chinese hamster ovary cells demonstrated no induction of chromosomal aberrations or sister chromatid exchanges following treatment with bromodichloromethane in either the presence or absence of metabolic activation.

#### COMPOUND-RELATED INCREASED INCIDENCES OF NEOPLASMS IN RATS AND MICE IN THE TWO-YEAR GAVAGE STUDIES OF BROMODICHLOROMETHANE

ATS			
Male	Vehicle Control	50 mg/kg	100 mg/kg
Large intestine			
Adenomatous polyp	0/50	3/50	33/50
Adenocarcinoma	0/50	11/50	38/50
Kidney

Liver			
Hepatocellular adenoma	1/50	13/48	23/50
Hepatocellular carcinoma	2/50	5/48	10/50

Data Audit: An audit of the experimental data was conducted for the 2-year toxicology and carcinogenesis studies of bromodichloromethane. No discrepancies were found that influenced the final interpretation of the results of these studies.

Conclusions: Under the conditions of these 2-year gavage studies, there was clear evidence of carcinogenic activity\* for male and female F344/N rats and B6C3F<sub>1</sub> mice as shown by increased incidences of tubular cell adenomas and adenocarcinomas in the kidney and adenocarcinomas and adenomatous polyps in the large intestine in male and female rats, increased incidences of tubular cell adenomas and adenocarcinomas in the kidney of male mice, and increased incidences of hepatocellular adenomas and carcinomas in female mice.

<sup>\*</sup>Explanation of Levels of Evidence of Carcinogenic Activity is on page 7.
A summary of the Peer Review comments and the public discussion on this Technical Report appears on page 11.

## SUMMARY OF THE TWO-YEAR GAVAGE AND GENETIC TOXICOLOGY STUDIES OF BROMODICHLOROMETHANE

Male F344/N Rats	Female F344/N Rats	Male B6C3F <sub>1</sub> Mice	Female B6C3F <sub>1</sub> Mice

Neoplastic effects Renal tubular cell adenomas and adenocarcinomas, and adenomatous polyps and adenocarcinomas of the large intestine	Renal tubular cell adenomas and adenocarcinomas, and adenomatous polyps and adenocarcinomas of the large intestine	Renal tubular adenomas and adenocarcinomas	Hepatocellular adenomas and carcinomas
Level of evidence of carcino		C1	GI
Clear evidence	Clear evidence	Clear evidence	Clear evidence

Genetic toxicology
Not mutagenic in S. typhimurium strains TA98, TA100, TA1535, or TA1537; not mutagenic in mouse L5178Y lymphoma cells; did not induce chromosomal aberrations or sister chromatid exchanges in Chinese hamster ovary cells

#### EXPLANATION OF LEVELS OF EVIDENCE OF CARCINOGENIC ACTIVITY

These studies are designed and conducted to characterize and evaluate the toxicologic potential, including carcinogenic activity, of selected chemicals in laboratory animals (usually two species, rats and mice). Chemicals selected for NTP toxicology and carcinogenesis studies are chosen primarily on the bases of human exposure, level of production, and chemical structure. Selection per se is not an indicator of a chemical's carcinogenic potential.

Negative results, in which the study animals do not have a greater incidence of neoplasia than control animals, do not necessarily mean that a chemical is not a carcinogen, inasmuch as the experiments are conducted under a limited set of conditions. Positive results demonstrate that a chemical is carcinogenic for laboratory animals under the conditions of the study and indicate that exposure to the chemical has the potential for hazard to humans.

The National Toxicology Program describes the results of individual experiments on a chemical agent and notes the strength of the evidence for conclusions regarding each study. Other organizations, such as the International Agency for Research on Cancer, assign a strength of evidence for conclusions based on an examination of all available evidence including: animal studies such as those conducted by the NTP, epidemiologic studies, and estimates of exposure. Thus, the actual determination of risk to humans from chemicals found to be carcinogenic in laboratory animals requires a wider analysis that extends beyond the purview of these studies.

Five categories of evidence of carcinogenic activity are used in the Technical Report series to summarize the strength of the evidence observed in each experiment: two categories for positive results ("Clear Evidence" and "Some Evidence"); one category for uncertain findings ("Equivocal Evidence"); one category for no observable effects ("No Evidence"); and one category for experiments that because of major flaws cannot be evaluated ("Inadequate Study"). These categories of interpretative conclusions were first adopted in June 1983 and then revised in March 1986 for use in the Technical Reports series to incorporate more specifically the concept of actual weight of evidence of carcinogenic activity. For each separate experiment (male rats, female rats, male mice, female mice), one of the following quintet is selected to describe the findings. These categories refer to the strength of the experimental evidence and not to either potency or mechanism.

- Clear Evidence of Carcinogenic Activity is demonstrated by studies that are interpreted as showing a dose-related (i) increase of malignant neoplasms, (ii) increase of a combination of malignant and benign neoplasms, or (iii) marked increase of benign neoplasms if there is an indication from this or other studies of the ability of such tumors to progress to malignancy.
- Some Evidence of Carcinogenic Activity is demonstrated by studies that are interpreted as showing a chemically related increased incidence of neoplasms (malignant, benign, or combined) in which the strength of the response is less than that required for clear evidence.
- Equivocal Evidence of Carcinogenic Activity is demonstrated by studies that are interpreted as showing a marginal increase of neoplasms that may be chemically related.
- No Evidence of Carcinogenic Activity is demonstrated by studies that are interpreted as showing no chemically related increases in malignant or benign neoplasms.
- Inadequate Study of Carcinogenic Activity is demonstrated by studies that because of major qualitative or quantitative limitations cannot be interpreted as valid for showing either the presence or absence of carcinogenic activity.

When a conclusion statement for a particular experiment is selected, consideration must be given to key factors that would extend the actual boundary of an individual category of evidence. This should allow for incorporation of scientific experience and current understanding of long-term carcinogenesis studies in laboratory animals, especially for those evaluations that may be on the borderline between two adjacent levels. These considerations should include:

- The adequacy of the experimental design and conduct;
- Occurrence of common versus uncommon neoplasia;
- Progression (or lack thereof) from benign to malignant neoplasia as well as from preneoplastic lesions;
- Some benign neoplasms have the capacity to regress but others (of the same morphologic type) progress. At present, it is impossible to identify the difference. Therefore, where progression is known to be a possibility, the most prudent course is to assume that benign neoplasms of those types have the potential to become malignant;
- Combining benign and malignant tumor incidences known or thought to represent stages of progression in the same organ or tissue;
- Latency in tumor induction;
- Multiplicity in site-specific neoplasia;
- Metastases;
- Supporting information from proliferative lesions (hyperplasia) in the same site of neoplasia or in other experiments (same lesion in another sex or species);
- The presence or absence of dose relationships;
- The statistical significance of the observed tumor increase;
- The concurrent control tumor incidence as well as the historical control rate and variability for a specific neoplasm;
- Survival-adjusted analyses and false positive or false negative concerns;
- Structure-activity correlations; and
- In some cases, genetic toxicology.

These considerations together with the definitions as written should be used as composite guidelines for selecting one of the five categories. Additionally, the following concepts (as patterned from the International Agency for Research on Cancer Monographs) have been adopted by the NTP to give further clarification of these issues:

The term chemical carcinogenesis generally means the induction by chemicals of neoplasms not usually observed, the induction by chemicals of more neoplasms than are generally found, or the earlier induction by chemicals of neoplasms that are commonly observed. Different mechanisms may be involved in these situations. Etymologically, the term carcinogenesis means induction of cancer, that is, of malignant neoplasms; however, the commonly accepted meaning is the induction of various types of neoplasms or of a combination of malignant and benign neoplasms. In the Technical Reports, the words tumor and neoplasm are used interchangeably.

#### PEER REVIEW PANEL

The members of the Peer Review Panel who evaluated the draft Technical Report on bromodichloromethane on August 19, 1986, are listed below. Panel members serve as independent scientists, not as representatives of any institution, company, or governmental agency. In this capacity, Panel members have five major responsibilities: (a) to ascertain that all relevant literature data have been adequately cited and interpreted, (b) to determine if the design and conditions of the NTP studies were appropriate, (c) to ensure that the Technical Report presents the experimental results and conclusions fully and clearly, (d) to judge the significance of the experimental results by scientific criteria, and (e) to assess the evaluation of the evidence of carcinogenicity and other observed toxic responses.

# SUMMARY OF PEER REVIEW COMMENTS ON THE TOXICOLOGY AND CARCINOGENESIS STUDIES OF BROMODICHLOROMETHANE

On August 19, 1986, the draft Technical Report on the toxicology and carcinogenesis studies of bromodichloromethane received peer review by the National Toxicology Program Board of Scientific Counselors' Technical Reports Review Subcommittee and associated Panel of Experts. The review meeting was held at the National Institute of Environmental Health Sciences, Research Triangle Park, North Carolina.

Dr. J. Dunnick, NTP, introduced the studies by reviewing the experimental design, results, and proposed conclusions (clear evidence of carcinogenic activity for male and female rats and male and female mice).

Dr. Capen, a principal reviewer, agreed with the conclusions as written. He questioned the rationale for giving female mice threefold higher doses than male mice. Dr. Dunnick reported that the dose levels used derived from marked differences in mortality in short-term studies.

As a second principal reviewer, Dr. Chinchilli agreed with the conclusions. He said the experimental design appeared adequate but asked that more information on the randomization scheme be included in the report.

As a third principal reviewer, Dr. Perera also agreed with the conclusions. She said that the rationale for using corn oil gavage should be expanded because drinking water and microencapsulation were the exposure routes in studies by other investigators. Dr. Dunnick replied that the NCI/NTP studies with other trihalomethanes, chloroform, and chlorodibromomethane, were by corn oil gavage so the same route was chosen to allow more direct comparison of the results.

Other discussion centered on whether formal statistical analyses should be carried out for nonneoplastic lesions and whether results on these lesions, when deemed to be statistically and biologically significant, should be included in the abstract of the report. In particular, there was discussion as to whether the renal lesions in rats were similar to those observed in male rats exposed to other hydrocarbons. Dr. Popp stated it would be worthwhile to compare these lesions in the current studies with renal lesions induced by other halogenated hydrocarbons. Dr. Scala suggested that the findings with the trihalomethanes be summarized.

Dr. Capen moved that the Technical Report on bromodichloromethane be accepted with the conclusions as written for male and female rats and mice, clear evidence of carcinogenic activity. Dr. Perera seconded the motion, and it was approved unanimously with 10 affirmative votes.

#### **CONTRIBUTORS**

The NTP Technical Report on the Toxicology and Carcinogenesis Studies of Bromodichloromethane is based on 13-week studies that began in August 1979 and ended in November 1979 and on 2-year studies that began in June 1981 for male rats, July 1980 for female rats, and June 1980 for male and female mice and ended in June 1983 for male rats, July 1982 for female rats, and June 1982 for male and female mice at EG&G Mason Research Institute.

Molecular weight 163.83

Synonym: Dichlorobromomethane

#### Formation and Regulation

Bromodichloromethane, a clear, colorless liquid with a density of 1.980 g/ml at 20° C, is one of several trihalomethanes formed when organic substances in water react with chlorine or bromine (Hoehn et al., 1978; Rook, 1980; Stevens et al., 1976; NAS, 1980a). The U.S. Environmental Protection Agency has established a maximum contamination level of 0.1 mg/liter for total trihalomethanes in community water systems serving more than 10,000 persons (USEPA, 1979, 1983a,b). The presence of trihalomethanes in drinking water is believed to pose a risk to humans because chloroform, another trihalomethane found in drinking water, was determined to be a carcinogen in rats and mice (NCI, 1976a; Eschenbrenner and Miller, 1945; Roe et al., 1979; IARC, 1979). The organic precursors of tribalomethanes are more frequently found in surface water than in ground water (USEPA, 1979). Trihalomethanes are widespread in the environment, not only in water supplies but also in swimming pools (Beech et al., 1980), soft drinks (Abdel-Rahman, 1982), baby bottles (Lahl et al., 1982), fish samples (Hiatt, 1983), and dump sites (Silkworth et al., 1984). The content of trihalomethanes in water increases with chlorination (Rook, 1974; Bellar et al., 1974; Brass et al., 1977; Symons et al., 1975). The mean concentration of bromodichloromethane in chlorinated water supplies in the United States is 0.017 mg/liter (range, 0-0.125 mg/liter) (USEPA, 1979). Assuming that the average daily water consumption for an adult male weighing 70 kg is 2 liters per day, intake of bromodichloromethane could reach a

maximum daily consumption of 4.0 µg/kg per day (Balster and Borzelleca, 1982).

Bunn et al. (1975) have proposed the following model for the formation of trihalomethanes by the chlorination of organic material in surface water (where X = Cl, Br and/or I and R = organic material):

#### Toxicity in Animals

The following oral LD<sub>50</sub> values have been reported for bromodichloromethane: 450 mg/kg, male ICR mice; 900 mg/kg, female ICR mice; 916 mg/kg, male Sprague Dawley rats; 450 mg/kg, male CD-1 mice; 900 mg/kg, female CD-1 mice; and 969 mg/kg, female Sprague Dawley rats (Bowman et al., 1978; Borzelleca, 1983; Chu et al., 1982a). Clinical signs associated with bromodichloromethane administration at LD50 or higher doses included piloerection, sedation, flaccid muscle tone, ataxia, prostration, and enlargement and congestion of the liver and kidneys. Bromodichloromethane administered in corn oil by gavage for 14 consecutive days to 10 male CD-1 mice at 148 mg/kg per day caused liver and kidney damage; no effect on body

weight gain was seen (Condie et al., 1983). Microscopic evaluation showed focal inflammation of the liver and intratubular mineralization and epithelial hyperplasia of the kidney. Kidney function was judged to be impaired because uptake of p-aminohippurate in renal cortical slices was decreased. No dose-related changes were seen in blood urea nitrogen and serum creatinine levels; serum glutamic-pyruvic transaminase activity (SGPT) was elevated. Acetone pretreatment (15 mmol/kg) has been shown to potentiate the hepatotoxicity of bromodichloromethane administered as a single oral dose in corn oil (1.0 ml/kg) to Sprague Dawley rats (Hewitt et al., 1983).

Munson et al. (1982) conducted a 14-day study in male and female CD-1 mice in which bromodichloromethane was administered by gavage in a solution of 10% emulphor at levels of 50-250 mg/kg per day. At the highest dose, liver weight, serum glutamic-oxaloacetic transaminase and SGPT activities, and blood urea nitrogen levels increased; body weight gain, serum glucose levels, and spleen weight decreased. Four days before being killed, a separate group of mice was immunized with sheep erythrocytes. The mice were killed, and spleen cell suspensions were prepared and assayed for antibodyforming cells; at 250 mg/kg, antibody-forming cells were decreased, suggesting impairment of the immune system. Histopathologic evaluation of tissues was not reported.

Bromodichloromethane administered to male and female Sprague Dawley rats for 90 days in drinking water at levels up to 2,500 ppm (resulting in doses of approximately 100 mg/kg body weight and 135 mg/kg body weight) produced mild toxicity in the liver and decreased body weight gain (Chu et al., 1982a,b). The vacuolar changes observed in the liver, interpreted as fatty infiltration, were reversed after a 90-day recovery period.

Bromodichloromethane was given to pregnant Sprague Dawley rats by gavage in corn oil on days 6-15 of gestation at doses of 0, 50, 100, or 200 mg/kg per day (Ruddick et al., 1983). At the highest doses, maternal body weight gain was decreased, but no teratogenic effects were observed. A mixture of trihalomethanes and other

organic substances concentrated from water was given by gavage in dimethyl sulfoxide to pregnant CD-1 mice at 51, 170, or 510 mg/kg per day on days 7-14 of gestation; no indication of fetal toxicity was observed (Kavlock et al., 1979). By weight, the mixture contained 69% chloroform, 16% bromodichloromethane, 10% chlorodibromomethane, and 4% bromoform.

#### Studies of Chronic Toxicity

Bromodichloromethane or chloroform was administered in drinking water to male and female Wistar rats for up to 180 weeks (Tumasonis et al., 1985). During the first 72 weeks of the study, bromodichloromethane was administered at concentrations of 0 or 1.2 ml (2.4 g) per liter of drinking water; at week 72, the concentration was halved because of a gradual increase in water intake. The dose of bromodichloromethane is estimated at 150 mg/kg per day in female rats and 200 mg/kg per day in male rats. Chloroform was administered at 0 or 2 ml (3 g) per liter drinking water (the concentration was halved after week 72). The liver and grossly observable lesions were examined. An increased incidence of hepatic neoplastic nodules was found in female rats (but not in male rats) when bromodichloromethane or chloroform was administered throughout the lifespan of the rat. The incidence of neoplastic nodules after bromodichloromethane administration was as follows: male rats--control, 5/22; dosed, 6/47; female rats--0/18; 17/53.

Bromodichloromethane was administered as a microencapsulated preparation in feed to Wistar rats at concentrations of 0, 140, 550, or 2,200 ppm (w/w) bromodichloromethane for 24 months. Histologic findings included cholangio-fibrosis and/or fibrosis in the liver of males and females in the 2,200-ppm dose group at 6, 12, 18, and 24 months. Tumors of the liver were observed in dosed rats but not in control rats (M. Tobe, National Institute of Hygienic Sciences, Tokyo, Japan, personal communication to J. Dunnick, NTP, 1985).

#### Metabolism and Distribution

Bromodichloromethane was administered in corn oil by gavage to male Sprague Dawley rats

at 100 mg/kg (16 µCi/kg) and to male B6C3F1 mice at 150 mg/kg (32 µCi/kg) (Mink et al., 1986). Urine and expired gas were monitored for radioactivity: tissue distribution was determined. Eight hours after administration of bromodichloromethane, the percentage of radioactivity recovered as expired carbon dioxide was 14% in rats and 81% in mice; the percentage of unmetabolized compound in expired air was 41% in rats and 7% in mice. The percentage of recovered label at 8 hours in expired air, urine, and tissues was 63% for rats and 93% for mice. Radioactivity was found in the liver, kidney, and stomach. (Distribution to the colon and rectum and the dose per milligram of tissue were not reported.) These studies indicate that mice metabolize bromodichloromethane at a faster rate than do rats. Similar studies with chloroform. chlorodibromomethane, and bromoform indicated that mice also metabolize these trihalomethanes at a faster rate than do rats (Mink et al., 1986).

In another series of experiments, bromodichloromethane, chloroform, chlorodibromomethane, bromoform, and iodoform were administered intraperitoneally in corn oil to male Sprague Dawley rats at 1 mmol/kg body weight; blood samples were collected from the tail vein and the amount of total carbon monoxide was measured. The highest blood carbon monoxide levels were observed after iodoform and bromoform administration; chlorodibromomethane, bromodichloromethane, and chloroform were metabolized at slower rates (Anders et al., 1978).

In vitro studies with rat microsomal preparations demonstrate that trihalomethanes can be metabolized to carbon monoxide by hepatic microsomal mixed function oxidases. The authors hypothesize that the trihalomethanes, like chloroform, are metabolized to a phosgene-like intermediate, although this intermediate has not been isolated for bromoform, chlorodibromomethane, or bromodichloromethane (Stevens and Anders, 1979; Ahmed et al., 1977).

#### Genetic Toxicology

Bromodichloromethane at doses of 25-250 µl was mutagenic in *Salmonella typhimurium* strains TA100 and TA1535 with and without metabolic

activation when exposure to the chemical occurred for a 7-10 hour period within the sealed environment of a desiccator (Simmon et al., 1977; Simmon, 1978; Simmon and Tardiff, 1978; Simmon and Kauhanen, 1978). Simmon et al. (1977) also reported a mutagenic effect in Escherichia coli strain WP2 exposed to bromodichloromethane in a desiccator by using this same treatment protocol with and without metabolic activation. However, in tests by these same investigators, bromodichloromethane was not mutagenic after exposure at up to 5,000 µg/ml in the standard Salmonella/microsome plate incorporation assay of Ames et al. (1975) with strains TA100, TA1535, TA1537, TA1538, or TA98 with or without metabolic activation. The chemical also was not mutagenic when tested by the NTP at doses up to 1.000 ug/plate in a 30-minute preincubation protocol with strains TA100, TA1535, TA1537, or TA98 with or without metabolic activation from Aroclor 1254-induced male Sprague Dawley rat and Syrian hamster liver S9 (Mortelmans et al., 1986; Appendix E, Table E1).

Bromodichloromethane did not induce mitotic recombination in the presence or absence of S9 in studies with Saccharomyces cerevisiae strain D3 treated in suspension (Simmon and Kauhanen, 1978). However, recent studies by Nestmann and Lee (1985) revealed weak effects in S. cerevisiae strains D7 and XV185-14C after exposure to bromodichloromethane in the absence of exogenous metabolic activation. The authors defined these responses as "weak" because the increase in the frequency of mitotic crossing-over did not exceed twice that of the controls, and the incidence of such events was not clearly related to the dose of bromodichloromethane.

Bromodichloromethane, when tested by the NTP in the L5178Y mouse lymphoma cell assay, induced forward mutations at the TK locus in the presence of S9 from the liver of Aroclor 1254-induced male F344 rats. Bromodichloromethane was not mutagenic to mouse lymphoma cells in the absence of exogenous metabolic activation; the number of mutants increased with increasing dose, but no single value for mutation frequency was significant at the P<0.05 level (Table E2).

In NTP-sponsored in vitro cytogenetics tests with Chinese hamster ovary cells, bromodichloromethane at doses of up to 5,000 ug/ml did not significantly increase the frequency of chromosomal aberrations or sister chromatid exchanges (SCEs) in either the presence or absence of S9 from Aroclor 1254-induced male Sprague Dawley rat liver; however, results of the second of two trials for induction of SCEs in the presence of S9 activation were considered questionable (Tables E3 and E4). Morimoto and Koizumi (1983) reported that bromodichloromethane produced a significant increase in the frequency of SCEs in both cultured human peripheral blood lymphocytes treated in vitro and in mouse bone marrow cells treated in vivo. The in vitro tests with human lymphocytes demonstrated doserelated increases in SCEs after a 72-hour exposure, with the highest dose (0.01 M, or approximately 1,640 µg/ml) producing a 60% increase in SCEs per cell over the solvent controls. In the in vivo studies, oral administration of bromodichloromethane in olive oil at doses of 25, 50, or 100 mg/kg per day for 4 days increased the frequency of SCEs in bone marrow cells of male ICR mice from less than six SCEs per cell in the vehicle controls to just over seven SCEs per cell in the 50 mg/kg group (P<0.05) and to just under eight SCEs per cell in the 100 mg/kg group (P<0.01). No increase in SCEs was observed in the 25 mg/kg group. Doses above 100 mg/kg per day killed all of the animals.

Three other trihalomethanes tested by Morimoto and Koizumi (1983) (chloroform, chlorodibromomethane, and bromoform) also induced SCEs in cultured human lymphocytes and mouse bone marrow cells in vivo. The relative mutagenic potential of all four trihalomethanes, as measured by their ability to induce SCEs, was directly proportional to the number of bromine atoms contained in the compound. Although Simmon et al. (1977) also obtained positive results with these same trihalomethanes in S.

typhimurium after exposure in a desiccator, the magnitude of the effect was not related to the number of bromine atoms. In Salmonella, the greatest response was produced by chlorodibromomethane and the weakest response by bromoform.

#### Epidemiologic Studies

Epidemiologic studies have investigated the association between the effects of drinking chlorinated water containing various organic contaminants, including the trihalomethanes. These studies have looked at the risks for cancer of the urinary bladder, colon, and rectum (Cantor et al., 1978, 1985; Cantor, 1982, 1983; Lawrence et al., 1984; Cragle et al., 1985). Although some of these studies have suggested an association between these cancers and trihalomethane consumption, others have not. Reviews of epidemiologic studies (IARC, 1979, 1982; NAS, 1980a,b; Crump and Guess, 1982; Craun, 1985) indicate that final interpretation concerning the causal association must await completion of ongoing studies.

#### Study Rationale

Bromodichloromethane was studied because a related trihalomethane, chloroform (trichloromethane), had been found to be a carcinogen in rodents and because no data were available on the carcinogenicity of the other trihalomethanes at the time these studies were started. In addition to bromodichloromethane, tribromomethane (bromoform) and chlorodibromomethane were studied by the NTP in 2-year gavage studies in F344/N rats and B6C3F<sub>1</sub> mice. The oral route of administration was chosen for the present studies because human exposure is primarily oral. In the NCI/NTP studies, the trihalomethanes were administered in corn oil by gavage because these compounds are not soluble in water at the concentrations used.

# PROCUREMENT AND CHARACTERIZATION OF BROMODICHLOROMETHANE

Bromodichloromethane was obtained in three lots from PCR Research Chemicals, Inc. (Table 1). Purity and identity analyses were conducted at Midwest Research Institute (MRI) (Kansas City, Missouri). (MRI reports on the analyses performed in support of the bromodichloromethane studies are on file at NIEHS.)

All lots of the study chemical were identified as bromodichloromethane by infrared, ultraviolet/ visible, and nuclear magnetic resonance spectroscopy. Infrared and nuclear magnetic resonance spectra were consistent with the structure and with literature spectra (representative spectra presented in Figures 1 and 2). The ultraviolet/visible spectrum was consistent with the structure of bromodichloromethane; no absorbance was found in the visible region.

Purity for all lots studied was determined by elemental analysis, Karl Fischer water analysis, titration of acidic components with sodium hydroxide, and gas chromatography. Gas chromatographic analysis was performed with flame ionization detection and either a 20% SP-2100/0.1% Carbowax 1500 on 100/120 Supelcoport packed column (system 1) or a 10% Carbowax 20M-TPA on 80/100 Chromosorb W(AW) packed column (system 2). Each batch of study material was purified to remove excess acid to enhance the long-term stability of the bulk material. Batches 01 and 02 of lot no. 1257 were purified by shaking with aqueous sodium carbonate solution, drying with anhydrous magnesium sulfate, and treating with deactivated charcoal. All subsequent batches were purified by column chromatography with deactivated Woelm Basic Alumina. Results of the purity analyses are presented in Table 2.

Stability studies performed by gas chromatography with the same column as that described above for system 2 indicated that bromodichloromethane was stable as a bulk chemical when kept for 2 weeks at temperatures of up to 60° C. Due to the formation of free acid, the bromodichloromethane study material was passed through an alumina column each month before use at the beginning of the 2-year studies. Approximately 60 ml of the bulk chemical was percolated through a 1.5 cm × 15 cm bed of Woelm Basic Alumina in a glass chromatographic column with a Teflon® petcock. The eluate was collected in an amber bottle preflushed with dry nitrogen. After July 1981, bromodichloromethane was passed through an alumina column only if the acid content was determined to be over 500 ppm after bulk reanalysis. During the 13-week and 2-year studies, bromodichloromethane was stored at lower than 0° C. Confirmation of the stability of the bulk chemical during the toxicity and carcinogenic activity studies was obtained by titration for free acid and by gas chromatographic analysis with the same column as that described above for

system 1. No deterioration of the study material was seen over the course of the studies. Identity of the chemical at the study laboratory was confirmed by infrared spectroscopy.

## PREPARATION AND CHARACTERIZATION OF DOSE MIXTURES

The appropriate amounts of bromodichloromethane and corn oil were mixed (w/v) to give the desired concentrations (Table 3). The stability of bromodichloromethane in corn oil (10% concentration) was determined by gas chromatography with system 2 after extraction with methanol containing 0.5506 mg/ml n-amyl alcohol as an internal reference. The chemical in corn oil was found to be stable for at least 7 days at room temperature. During the 13-week studies, bromodichloromethane/corn oil mixtures were stored under a nitrogen atmosphere at 4° C for no longer than 2 weeks. During the 2-year studies, the dose mixtures were stored under an inert atmosphere at  $0^{\circ} \pm 5^{\circ}$  C for no longer than 10 days.

TABLE 3. PREPARATION AND STORAGE OF DOSE MIXTURES IN THE GAVAGE STUDIES OF BROMODICHLOROMETHANE

Single-Administration Studies	Fourteen-Day Studies	Thirteen-Week Studies	Two-Year Studies
Preparation Appropriate amounts of bromodichloromethane diluted with 50 ml corn oil in serum vials	Appropriate amounts of bromodichloromethane diluted with corn oil	Appropriate amounts of bromodichloromethane and corn oil mixed in ground glass-stoppered, graduated cylinders by inversion until visually uniform	Same as 13-wk studies
Maximum Storage Time	2 wk	2 wk	10 d
Storage Conditions 4° C	4°C under nitrogen	4° C under nitrogen	0° ± 5° C, flushed with nitrogen and sealed in amber vials; after 5/14/81, flushed with argon and daily doses put in individual vials

#### II. MATERIALS AND METHODS

Periodic analysis of formulated bromodichloromethane/corn oil dose mixtures was conducted at the study laboratory and the analytical chemistry laboratory by extraction of the dose mixtures with methanol containing 0.2 mg/ml namyl alcohol as an internal standard followed by gas chromatographic analysis of the resultant extract with system 2. Dose mixtures were

analyzed three times during the 13-week studies. The results of the analysis of the first two mixes ranged from 166% to 17% of the target concentration. A problem with the mixing procedure was identified. The results of the third set of dose mixtures submitted for analysis (105%-90% of target) indicated that the revised formulation procedure was adequate (Table 4).

<sup>(</sup>e) Remix

During the 2-year studies, the dose preparations were analyzed at approximately 8-week intervals. The mixtures were formulated within  $\pm 10\%$  of the target concentrations approximately 96% (76/79) of the time throughout the studies (Table 5). Of the three dose formulations determined to be out of specifications, one was

found to be 148% of the target concentration, and the other two were within  $\pm 16\%$  of the target concentration. Referee analyses were periodically performed by the analytical chemistry laboratory. Generally good agreement was found between laboratories (Table 6).

#### SINGLE-ADMINISTRATION STUDIES

Male and female F344/N rats and B6C3F<sub>1</sub> mice were obtained from Charles River Breeding Laboratories and observed for 19 days before the studies began.

Groups of five rats and five mice of each sex were administered a single dose of 150, 300, 600, 1,250, or 2,500 mg/kg bromodichloromethane in corn oil by gavage. Animals were observed once per hour for 3 hours after dosing and then twice per day for 14 days. A necropsy was performed on at least one animal of each sex and dose group. Details of animal maintenance are presented in Table 7.

#### FOURTEEN-DAY STUDIES

Male and female F344/N rats and B6C3F<sub>1</sub> mice were obtained from Charles River Breeding Laboratories and held for 15 days (rats) or 13 days (mice) before the studies began. The rats were approximately 6 weeks old and the mice 7 weeks old when placed on study.

Groups of five rats of each sex were administered 0, 38, 75, 150, 300, or 600 mg/kg bromodichloromethane in corn oil by gavage for 14 consecutive days. Groups of five mice of each sex were administered 0, 19, 38, 75, 150, or 300 mg/kg on the same schedule.

Animals were housed five per cage. Water and feed were available ad libitum. The rats and

mice were observed twice per day and were weighed on days 0 and 14 and at the end of the studies. A necropsy was performed on all animals. Details of animal maintenance are presented in Table 7.

#### THIRTEEN-WEEK STUDIES

Thirteen-week studies were conducted to evaluate the cumulative toxic effects of repeated administration of bromodichloromethane and to determine the doses to be used in the 2-year studies.

Four-week-old male and female F344/N rats and 5- to 7-week old male and female B6C3F<sub>1</sub> mice were obtained from Charles River Breeding Laboratories, observed for 21 days, and then assigned to dose groups so that the average cage weights were approximately equal for all animals of the same sex and species. Rats were approximately 7 weeks old and mice 8-10 weeks old when placed on study.

Groups of 10 rats of each sex were administered 0, 19, 38, 75, 150, or 300 mg/kg bromodichloromethane in corn oil by gavage, 5 days per week for 13 weeks. (The 19 mg/kg group of rats was administered 1.9 mg/kg for the first 3 weeks of the studies.) Groups of 10 male mice were administered 0, 6.25, 12.5, 25, 50, or 100 mg/kg; and groups of female mice were administered 0, 25, 50, 100, 200, or 400 mg/kg on the same schedule.

(a) Rats and mice were exposed to temperatures in excess of 32° C (89.6° F) on 4/24/81-4/25/81. Forty-five vehicle control male rats died; therefore, the male rat study was restarted in a separate room. The restarted study is the one described in this report.

Rats and mice were housed five per cage. Feed and water were available ad libitum. Further experimental details are summarized in Table 7.

Animals were checked twice daily; moribund animals were killed. Individual animal weights were recorded weekly.

At the end of the 13-week studies, survivors were killed. A necropsy was performed on all animals except those excessively autolyzed or cannibalized. Tissues and groups examined are listed in Table 7.

#### TWO-YEAR STUDIES

#### Study Design

Groups of 50 rats of each sex were administered 0, 50, or 100 mg/kg bromodichloromethane in corn oil by gavage, 5 days per week for 102 weeks. Groups of 50 male mice were administered 0, 25, or 50 mg/kg; and groups of 50 female mice were administered 0, 75, or 150 mg/kg on the same schedule. The studies in male rats were restarted because at 10.5 months into the original study, 45/50 vehicle control male rats died after the temperature in the animal room exceeded 32° C.

#### Source and Specifications of Animals

The male and female F344/N rats and B6C3F1 (C57BL/6N, female, × C3H/HeN MTV<sup>-</sup>, male) mice used in these studies were produced under strict barrier conditions at Charles River Breeding Laboratories under a contract to the Carcinogenesis Program. Breeding stock for the foundation colonies at the production facility originated at the National Institutes of Health Repository. Animals shipped for study were progeny of defined microflora-associated parents that were transferred from isolators to barriermaintained rooms. Male rats were shipped to the study laboratory at 5 weeks of age, female rats at 4-5 weeks of age, and mice at 5-6 weeks of age. The animals were quarantined at the study laboratory for 3 weeks. Thereafter, a complete necropsy was performed on five animals of each sex and species to assess their health status. The rodents were placed on study at 8 weeks of age. The health of the animals was monitored during the course of the studies according to the protocols of the NTP Sentinel Animal Program (Appendix F).

A quality control skin grafting program has been in effect since early 1978 to monitor the genetic integrity of the inbred mice used to produce the hybrid B6C3F<sub>1</sub> study animal. In mid-1981, data were obtained that showed incompatibility between the NIH C3H reference colony and the C3H colony from a Program supplier. In August 1981, inbred parental lines of mice were further tested for genetic integrity via isozyme and protein electrophoresis profiles that demonstrate phenotype expressions of known genetic loci.

The C57BL/6 mice were homogeneous at all loci tested. Eighty-five percent of the C3H mice monitored were variant at one to three loci, indicating some heterogeneity in the C3H line from this supplier. Nevertheless, the genome of this line is more homogeneous than that of randomly bred stocks.

Male mice from the C3H colony and female mice from the C57BL/6 colony were used as parents for the hybrid B6C3F<sub>1</sub> mice used in these studies. The influence of the potential genetic nonuniformity in the hybrid mice on these results is not known, but results of the studies are not affected because concurrent controls were included in each study.

#### Animal Maintenance

Animals were housed five per cage. Feed and water were available ad libitum. Neither the cages or racks were rotated during this study. Vehicle control animals were housed on the top two levels of the racks, low dose animals on the middle two levels, and high dose animals on the lower two levels. Further details of animal maintenance are given in Table 7.

#### Clinical Examinations and Pathology

All animals were observed two times per day, and clinical signs were recorded once per week. Body weights by cage were recorded once per week for the first 12 weeks of the study and once per month thereafter. Mean body weights were calculated for each group. Animals found moribund and those surviving to the end of the studies were humanely killed. A necropsy was performed on all animals including those found dead, unless they were excessively autolyzed or cannibalized, missexed, or found missing. Thus, the number of animals from which particular

organs or tissues were examined microscopically varies and is not necessarily equal to the number of animals that were placed on study.

During necropsy, all organs and tissues were examined for grossly visible lesions. Tissues were preserved in 10% neutral buffered formalin, embedded in paraffin, sectioned, and stained with hematoxylin and eosin. Complete histopathologic examinations were performed on all dosed and vehicle control mice and female rats. For male rats, histopathologic examination of tissues was performed according to the "inverse pyramid" design (McConnell, 1983a,b). Complete histopathologic examinations (Table 7) were performed on high dose and vehicle control male rats and on all male rats dying early in the studies, including those in lower dose groups. In addition, histopathologic examinations were performed on all gross lesions and tissues/organs from male rats in the lower dose groups when chemically related neoplastic or nonneoplastic effects were identified in the high dose male rats.

When the pathology evaluation was completed, the slides, paraffin blocks, and residual wet tissues were sent to the NTP Archives for inventory, slide/block match, and wet tissue audit. The slides, individual animal data records, and pathology tables were sent to an independent quality assessment laboratory. The individual animal records and tables were compared for accuracy, slides and tissue counts were verified, and histotechnique was evaluated. All tumor diagnoses, all target tissues, and all tissues from a randomly selected 10% of the animals were evaluated by a quality assessment pathologist. The quality assessment report and slides were submitted to the Pathology Working Group (PWG) Chairperson, who reviewed all target tissues and those about which there was a disagreement between the laboratory and quality assessment pathologists.

Representative slides selected by the Chairperson were reviewed by the PWG, which includes the laboratory pathologist, without knowledge of previously rendered diagnoses. When the consensus diagnosis of the PWG differed from that of the laboratory pathologist, the laboratory pathologist was asked to reconsider the original diagnosis. This procedure has been described, in part, by Maronpot and Boorman (1982) and Boorman et al. (1985). The final diagnoses represent a consensus of contractor pathologists and the NTP Pathology Working Group. For subsequent analysis of pathology data, the diagnosed lesions for each tissue type are combined according to the guidelines of McConnell et al. (1986).

Slides/tissues are generally not evaluated in a blind fashion (i.e., without knowledge of dose group) unless the lesions in question are subtle or unless there is an inconsistent diagnosis of lesions by the laboratory pathologist. Nonneoplastic lesions are not examined routinely by the quality assessment pathologist or PWG unless they are considered part of the toxic effect of the chemical.

#### Statistical Methods

Data Recording: Data on this experiment were recorded in the Carcinogenesis Bioassay Data System (Linhart et al., 1974). The data elements include descriptive information on the chemicals, animals, experimental design, survival, body weight, and individual pathologic results, as recommended by the International Union Against Cancer (Berenblum, 1969).

Survival Analyses: The probability of survival was estimated by the product-limit procedure of Kaplan and Meier (1958) and is presented in the form of graphs. Animals were censored from the survival analyses at the time they were found dead of other than natural causes or were found to be missing; animals dying from natural causes were not censored. Statistical analyses for a possible dose-related effect on survival used the method of Cox (1972) for testing two groups for equality and Tarone's (1975) life table test for a dose-related trend. When significant survival differences were detected, additional analyses using these procedures were carried out to determine the time point at which significant differences in the survival curves were first detected. All reported P values for the survival analysis are two-sided.

Calculation of Incidence: The incidence of neoplastic or nonneoplastic lesions is given as theratio of the number of animals bearing such lesions at a specific anatomic site to the number of animals in which that site was examined. In most instances, the denominators include only those animals for which the site was examined histologically. However, when macroscopic examination was required to detect lesions (e.g., skin or mammary tumors) prior to histologic sampling, or when lesions could have appeared at multiple sites (e.g., lymphomas), the denominators consist of the number of animals on which a necropsy was performed.

Analysis of Tumor Incidence: Three statistical methods are used to analyze tumor incidence data. The two that adjust for intercurrent mortality employ the classical method for combining contingency tables developed by Mantel and Haenszel (1959). Tests of significance included pairwise comparisons of high dose and low dose groups with vehicle controls and tests for overall dose-response trends.

For studies in which compound administration has little effect on survival, the results of the three alternative analyses will generally be similar. When differing results are obtained by the three methods, the final interpretation of the data will depend on the extent to which the tumor under consideration is regarded as being the cause of death. Continuity-corrected tests are used in the analysis of tumor incidence, and reported P values are one-sided.

Life Table Analyses--The first method of analysis assumed that all tumors of a given type observed in animals dying before the end of the studies were "fatal"; i.e., they either directly or indirectly caused the death of the animal. According to this approach, the proportions of tumor-bearing animals in the dosed and vehicle control groups were compared at each point in time at which an animal died with a tumor of interest. The denominators of these proportions were the total number of animals at risk in each group. These results, including the data from animals killed at the end of the studies, were then combined by the Mantel-Haenszel method to obtain an overall P value. This method of adjusting for intercurrent mortality is the life table method of Cox (1972) and of Tarone (1975). The underlying variable considered by this analysis

#### II. MATERIALS AND METHODS

is time to death due to tumor. If the tumor is rapidly lethal, then time to death due to tumor closely approximates time to tumor onset. In this case, the life table test also provides a comparison of the time-specific tumor incidences.

Incidental Tumor Analyses--The second method of analysis assumed that all tumors of a given type observed in animals that died before the end of the studies were "incidental"; i.e., they were merely observed at necropsy in animals dying of an unrelated cause. According to this approach, the proportions of tumor-bearing animals in dosed and vehicle control groups were compared in each of five time intervals: weeks 0-52, weeks 53-78, weeks 79-92, week 93 to the week before the terminal-kill period, and the terminal-kill period. The denominators of these proportions were the number of animals actually examined for tumors during the time interval. The individual time interval comparisons were then combined by the previously described method to obtain a single overall result.

(See Haseman, 1984, for the computational details of both methods.)

Unadjusted Analyses--Primarily, survivaladjusted methods are used to evaluate tumor incidence. In addition, the results of the Fisher exact test for pairwise comparisons and the Cochran-Armitage linear trend test (Armitage, 1971; Gart et al., 1979) are given in the appendixes containing the analyses of primary tumor incidence. These two tests are based on the overall proportion of tumor-bearing animals and do not adjust for survival differences.

Historical Control Data: Although the concurrent control group is always the first and most appropriate control group used for evaluation, there are certain instances in which historical control data can be helpful in the overall assessment of tumor incidence. Consequently, control tumor incidences from the NTP historical control data base (Haseman et al., 1984, 1985) are included for those tumors appearing to show compound-related effects.

#### SINGLE-ADMINISTRATION STUDIES

All rats that received 1,250 or 2,500 mg/kg bromodichloromethane and 2/5 males and 1/5 females that received 600 mg/kg died before the end of the studies (Table 8). Lethargy and labored breathing were observed for rats that received 1,250 or 2,500 mg/kg. At necropsy, the

liver appeared pale in the 1,250 and 2,500 mg/kg groups. No dose-related weight effects were seen in animals surviving to the end of the 14-day observation period. The high dose selected for the 14-day studies was 600 mg/kg because all animals in the single-administration studies that received 1,250 and 2,500 mg/kg died.

<sup>(</sup>k) Day of death: 4,4,4,6,6 (l) Day of death: 3,3,3,4,4

### FOURTEEN-DAY STUDIES

One of five female rats that received 38 mg/kg bromodichloromethane and 1/5 female rats that received 600 mg/kg died before the end of the studies (Table 9). All rats that received 600 mg/kg were hyperactive after they were dosed. Rats that received 600 mg/kg lost weight or gained no weight during the studies. Final mean body weights in the 300 mg/kg groups were 21% lower than those of the vehicle controls for males and 7% lower for females. Renal medullae were reddened in 5/5 male rats in the 600 mg/kg group, 1/5 female vehicle controls, 1/5 female rats in the 38 mg/kg group, and 1/5 female rats in the 600 mg/kg group.

The high dose selected for the 13-week studies was 300 mg/kg because the final mean body weight was lower than the initial mean weight in male rats receiving 600 mg/kg and there was no gain in mean body weight in female rats receiving 600 mg/kg.

### THIRTEEN-WEEK STUDIES

Five of 10 male rats and 2/10 female rats that received 300 mg/kg died before the end of the studies (Table 10). Final mean body weights of male rats that received 150 or 300 mg/kg and of female rats that received 300 mg/kg were 30% or more lower than those of the vehicle controls; the final mean body weight of female rats receiving 150 mg/kg was 12% lower than that of the vehicle controls. No other compound-related clinical signs were reported.

Compound-related lesions were observed in the 300 mg/kg groups but not in the 150 mg/kg groups. In the 300 mg/kg group, compound-related effects were observed in the liver of 4/9 males and in the kidney of 4/9 males. The liver lesion consisted of centrilobular degeneration and was characterized by enlarged vacuolated cells and occasional necrotic cells with pyknotic nuclei and shrunken eosinophilic cytoplasm. In one male rat, excessive mitotic figures were

<sup>(</sup>a) Number surviving/number initially in the group

noted. Mild bile duct hyperplasia was also observed in these animals. The kidney changes in male rats at 300 mg/kg consisted of degeneration of proximal tubular epithelial cells, and 2/9 males had definite foci of coagulative necrosis of the tubular epithelium. Lymphoid atrophy of the thymus, spleen, and lymph nodes was observed in 4/9 high dose males. Mild to moderate atrophy of the seminal vesicles and/or prostate was present in 4/9 high dose males.

Compound-related changes were observed in the liver of 2/9 high dose (300 mg/kg) female rats and consisted of enlarged hepatocytes. Atrophy of the thymus, lymph nodes, and spleen occurred in high dose female rats but was much less than that observed in males. Rats in the high dose groups were emaciated and appeared to consume less feed on dosing days (although actual feed consumption was not measured).

Dose Selection Rationale: Based on deaths at 300 mg/kg, body weight gain depression at 150 and 300 mg/kg in male and female rats, lesions of the liver and kidney in male rats at 300

mg/kg, and lesions in the liver of female rats at 300 mg/kg, bromodichloromethane doses selected for rats for the 2-year studies were 50 and 100 mg/kg administered in corn oil by gavage 5 days per week.

### TWO-YEAR STUDIES

### Body Weights and Clinical Signs

The initial mean body weight of the high dose male rats was 6% lower than that of the vehicle controls (Table 11 and Figure 3). After week 16, the mean body weights of high dose male rats were 10%-17% lower than those of the vehicle controls, and those of high dose female rats were 5%-25% lower. After week 64, the mean body weights of high dose female rats were 17%-25% lower than those of the vehicle controls. Final mean body weights of low and high dose male rats were 106% and 88% that of vehicle controls, and final mean body weights of low and high dose female rats were 98% and 79% that of the vehicle controls. No compound-related clinical signs were observed.

<sup>(</sup>b) Initial mean group body weight  $\pm$  standard error of the mean; subsequent calculations based on those animals surviving to the end of the study.

<sup>(</sup>c) Final mean group body weight ± standard error of the mean

<sup>(</sup>d) Mean body weight change of the survivors of the group ± standard error of the mean

### Survival

Estimates of the probabilities of survival for male and female rats administered bromodichloromethane at the doses used in these studies and for vehicle controls are shown in the Kaplan and Meier curves in Figure 3. There were no significant differences in survival between dosed and vehicle control groups (Table 12).

## Pathology and Statistical Analyses of Results

This section describes the significant or noteworthy changes in the incidences of rats with neoplastic or nonneoplastic lesions of the large intestine, kidney, skin, lung, liver, adrenal gland, anterior pituitary gland, and mammary gland.

Lesions in male rats are summarized in Appendix A. Histopathologic findings on neoplasms are summarized in Table A1. Table A2 gives the survival and tumor status for individual male rats. Table A3 contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Table A3 (footnotes). Historical incidences of tumors in corn oil vehicle control male rats are listed in Table A4. Findings on nonneoplastic lesions are summarized in Table A5.

Lesions in female rats are summarized in Appendix B. Histopathologic findings on neoplasms are summarized in Table B1. Table B2 gives the survival and tumor status for individual female rats. Table B3 contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Table B3 (footnotes). Historical incidences of tumors in corn oil vehicle control female rats are listed in Table B4. Findings on nonneoplastic lesions are summarized in Table B5.

Large Intestine (Colon or Rectum): Adenomatous polyps and adenocarcinomas in male and female rats occurred with significant positive trends (Table 13). The incidences of adenomatous polyps and adenocarcinomas in high dose males and high dose females were significantly greater than those in the vehicle controls. The incidence of adenocarcinomas also

was significantly elevated in low dose males. The adenomatous polyps and adenocarcinomas were generally pedunculated masses several millimeters to a centimeter in diameter, and they occurred in the colon and rectum. Adenomatous polyps consisted of a thickened, folded mucosal epithelium overlying a stalk of mature connective tissue. The epithelium was arranged in papillary (villous) or tubular patterns and did not show differentiation into goblet cells or normal absorptive cells. All the adenocarcinomas were minimally invasive and arose from adenomatous polyps. These lesions were diagnosed as adenocarcinomas when invasion or extension through the muscularis mucosa occurred and/or when the epithelium exhibited marked dysplasia and cellular atypia. Invasion of the submucosa by neoplastic cells was sometimes accompanied by a scirrhous response with marked proliferation of immature connective tissue.

Kidney: Cytomegaly of tubular epithelial cells was observed at increased incidences in dosed male rats (Table 14). Cytomegaly was not diagnosed in female rats. The incidence of nephrosis in high dose female rats was greater than that in the vehicle controls.

Tubular cell adenomas in female rats, tubular cell adenocarcinomas in male and female rats. and tubular cell adenomas or adenocarcinomas (combined) in male and female rats occurred with significant positive trends (Table 14). The incidences of tubular cell adenomas in high dose female rats and tubular cell adenocarcinomas and tubular cell adenomas or adenocarcinomas (combined) in high dose male and high dose female rats were significantly greater than those in the vehicle controls. Tubular cell hyperplasia was seen in three high dose male rats, two of which did not have kidney neoplasms. Tubular cell hyperplasia occurred in one low dose and four high dose female rats, none of which had kidney neoplasms.

Skin: The incidence of squamous cell papillomas or carcinomas (combined) in low dose but not in high dose male rats was significantly greater than that in the vehicle controls (Table 15).

Lung: Alveolar/bronchiolar adenomas or carcinomas (combined) in male rats occurred with a significant positive trend, but the incidences in the dosed groups were not significantly greater than that in the concurrent vehicle controls; the incidence in the high dose group was equal to the highest recorded in vehicle controls at this

laboratory (Table 16; Table A4d). The incidences in the dosed female groups were identical to that in the vehicle control group (vehicle control, 1/50; low dose, 1/50; high dose, 1/50).

Liver: Necrosis was observed at slightly increased incidences in dosed male rats (Table 17). Clear cell change, eosinophilic cytoplasmic change, and focal cellular change were observed at increased incidences in high dose female rats. Fatty metamorphosis was observed at increased incidences in dosed male and female rats.

Necrosis	1	3	1
Neoplastic nodule	1	3	1
Hepatocellular carcinoma	0	0	0

Adrenal Gland: Pheochromocytomas in male rats occurred with a significant negative trend. The incidence in the high dose group was significantly lower than that in the vehicle controls (Table 18).

Anterior Pituitary Gland: Adenomas and adenomas or carcinomas (combined) in female rats occurred with significant negative trends, and the

incidences in the dosed groups were significantly lower than those in the vehicle controls (Table 19).

Mammary Gland: Fibroadenomas in female rats occurred with a significant negative trend; the incidence in high dose female rats was significantly lower than that in the vehicle controls (Table 20).

### SINGLE-ADMINISTRATION STUDIES

All mice that received 1,250 or 2,500 mg/kg bromodichloromethane and 5/5 male mice and 2/5 female mice that received 600 mg/kg died before the end of the studies (Table 21). Male mice that received 600 or 1,250 mg/kg and female mice that received 600, 1,250, or 2,500 mg/kg were lethargic. The liver was pale and the cranial cavity contained blood in animals in the 1,250 or 2,500 mg/kg groups. No dose-related body weight effects were seen in animals that survived to the end of the 14-day observation period. The high dose selected for the 14-day studies was 300 mg/kg because deaths occurred at 600 mg/kg and above in the single-administration studies.

### FOURTEEN-DAY STUDIES

All male mice that received 150 or 300 mg/kg bromodichloromethane and 1/5 female mice that received 300 mg/kg died before the end of the studies (Table 22). The death of the female mouse was a result of an accident. All male mice that received 150 or 300 mg/kg were lethargic and dehydrated and had hunched posture. The final mean body weights of the surviving mice were comparable. The renal medullae were reddened in 4/5 males that received 150 mg/kg, 5/5 males that received 300 mg/kg, and 1/5 females that received 150 mg/kg. The high dose selected for the 13-week study in male mice was 100 mg/kg because all male mice in the 14-day study died at 150 mg/kg and above. The high dose selected for the 13-week study in female mice was 400 mg/kg because no body weight effect or compound-related mortality was seen at 300 mg/kg in the 14-day study.

<sup>(</sup>a) Number surviving/number initially in the group

### THIRTEEN-WEEK STUDIES

All mice survived to the end of the studies (Table 23). The final mean body weight of males that received 100 mg/kg was 9% lower than that of the vehicle controls. The final mean body weight of females that received 200 or 400 mg/kg was 94%-95% that of the vehicle controls. Focal necrosis of the proximal renal tubular epithelium occurred in 6/10 males that received 100 mg/kg. Nephrosis of minimal severity occurred in 2/10 males that received 100 mg/kg. No compound-related lesions were seen in the 50 mg/kg groups. Hepatocytes in the centrilobular area of the liver of 8/10 female mice at 400 mg/kg and 7/10 female mice at 200 mg/kg were enlarged

with vacuolated or foamy cytoplasm characteristic of lipid accumulation. Microgranulomas were present in the liver of 7/10 female mice that received 200 mg/kg. No compound-related lesions were noted in the 100 mg/kg female group. No compound-related clinical signs were noted.

Dose Selection Rationale: Based on weight gain depression and liver and kidney lesions observed at 100 mg/kg, bromodichloromethane doses selected for male mice for the 2-year study were 25 and 50 mg/kg administered in corn oil by gavage. Based on liver lesions and body weight gain depression seen at 200 and 400 mg/kg, but not at 100 mg/kg, doses selected for female mice for the 2-year study were 75 and 150 mg/kg.

<sup>(</sup>b) Initial mean group body weight  $\pm$  standard error of the mean; subsequent calculations based on those animals surviving to the end of the study.

<sup>(</sup>c) Mean body weight change of the survivors of the group ± standard error of the mean

<sup>(</sup>d) Day of death: 4,4,5,8,8

<sup>(</sup>e) No data are reported due to the 100% mortality in this group.

<sup>(</sup>f) Day of death: 3,3,4,4,4

<sup>(</sup>g) Death judged to be accidental

### TWO-YEAR STUDIES

### Body Weights and Clinical Signs

Throughout the studies, the mean body weights of the high dose male mice were never more than 10% lower than those of the vehicle controls (Table 24 and Figure 5). Mean body weights of low dose and vehicle control male mice were comparable. Final mean body weights of low and

high dose male mice were 99% and 95% that of the vehicle controls. Mean body weights of high dose female mice relative to those of the vehicle controls decreased progressively throughout the study, reaching a low of 64% of the vehicle controls' weight at weeks 92 and 96. Final mean body weights of low and high dose female mice were 91% and 75% that of the vehicle controls. No compound-related clinical signs were observed.

<sup>(</sup>b) Initial mean group body weight ± standard error of the mean

<sup>(</sup>c) Final mean group body weight ± standard error of the mean

<sup>(</sup>d) Mean body weight change of the group ± standard error of the mean

FIGURE 5. GROWTH CURVES FOR MICE ADMINISTERED BROMODICHLOROMETHANE IN CORN OIL BY GAVAGE FOR TWO YEARS

#### Survival

Estimates of the probabilities of survival for male and female mice administered bromodichloromethane at the doses used in these studies and for vehicle controls are shown in the Kaplan and Meier curves in Figure 6. Survival of dosed male mice was comparable to that of the vehicle controls (Table 25). The survival of both the low dose group (after week 79) and high dose group (after week 61) of female mice was significantly lower than that of the vehicle controls, and this decreased survival was associated in part with ovarian abscesses (vehicle control, 8/50, 16%; low dose, 19/47, 40%; high dose, 18/49, 38%).

## Pathology and Statistical Analyses of Results

This section describes the significant or noteworthy changes in the incidences of mice with neoplastic or nonneoplastic lesions of the kidney, liver, anterior pituitary gland, thyroid gland, ovary, and testis.

Lesions in male mice are summarized in Appendix C. Histopathologic findings on neoplasms

are summarized in Table C1. Table C2 gives the survival and tumor status for individual male mice. Table C3 contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Table C3 (footnotes). Historical incidences of tumors in corn oil vehicle control male mice are listed in Table C4. Findings on nonneoplastic lesions are summarized in Table C5.

Lesions in female mice are summarized in Appendix D. Histopathologic findings on neoplasms are summarized in Table D1. Table D2 gives the survival and tumor status for individual female mice. Table D3 contains the statistical analyses of those primary tumors that occurred with an incidence of at least 5% in one of the three groups. The statistical analyses used are discussed in Chapter II (Statistical Methods) and Table D3 (footnotes). Historical incidences of tumors in corn oil vehicle control female mice are listed in Table D4. Findings on nonneoplastic lesions are summarized in Table D5.

FIGURE 6. KAPLAN-MEIER SURVIVAL CURVES FOR MICE ADMINISTERED BROMODICHLOROMETHANE IN CORN OIL BY GAVAGE FOR TWO YEARS

Kidney: Most dosed male mice had renal cytomegaly consisting of enlargement of both the cytoplasm and nucleus of isolated renal tubular cells (vehicle control, 0/49; low dose, 41/50; high dose, 47/50). The nuclei of affected cells tended to show chromatin clumping and a prominent nuclear membrane. This change was not seen in females. Renal tubular cell adenomas or adenocarcinomas (combined) in male mice occurred with a significant positive trend; the incidence

in the high dose group was significantly greater than that in the vehicle controls (Table 26). Renal tubular cell neoplasms were not diagnosed in female mice. The adenomas were small, discrete aggregations of basophilic cells arranged in small nests or larger clusters. Tubular cell adenocarcinomas were larger than adenomas and showed increased cellular atypia and occasionally necrosis and/or invasion of the renal capsule.

<sup>(</sup>b) No P value is reported because no tumors were observed in the 25 mg/kg and vehicle control groups.

<sup>(</sup>c) Historical incidence at study laboratory (mean): 2/299 (0.7%); historical incidence in NTP studies: 5/1,490 (0.3%)

Liver: The incidence of fatty metamorphosis was notably increased in dosed male mice (male: vehicle control, 4/49; low dose, 8/50; high dose, 19/50; female: 11/50; 16/48; 15/50).

Hepatocellular adenomas and carcinomas occurred with significant positive trends in female mice, and the incidences in the high dose group were significantly greater than those in the vehicle controls (Table 27). The incidences of adenomas and adenomas or carcinomas (combined) in the low dose group were significantly greater than those in the vehicle controls. The incidences of hepatocellular adenomas or carcinomas (combined) in dosed and vehicle control male mice were comparable (vehicle control, 17/49; low dose, 16/50; high dose, 20/50).

<sup>(</sup>a) Historical incidence at study laboratory (mean  $\pm$  SD): 30/298 (10%  $\pm$  5%); historical incidence in NTP studies: 116/1,489 (8%  $\pm$  6%).

Anterior Pituitary Gland: Adenomas in female mice occurred with a significant negative trend, and the incidence in the high dose group was significantly lower than that in the vehicle controls (Table 28).

Thyroid Gland: The incidences of follicular cell hyperplasia were increased in dosed male and female mice (male: vehicle control, 0/48; low dose, 3/44; high dose, 5/49; female: 6/50; 18/45; 21/48). The incidence of follicular cell adenomas was not increased in dosed mice (male: 2/48; 0/44; 0/49; female: 1/50; 2/45; 1/48).

Ovary: Ovarian abscesses were found in all dosed female groups, and the incidences in the dosed groups were greater than that in the vehicle controls (vehicle control, 8/50; low dose,

19/47; high dose, 18/49). All diagnoses of this lesion were in animals that died before the end of the study. The lesions were large (1-2 cm), thinwalled cysts involving the proximal fallopian tube and ovaries which were filled with polymorphonuclear leukocytes and necrotic debris. The abscesses sometimes ruptured, producing acute peritonitis. They were frequently bilateral and were a leading cause of early death among female mice.

Testis: Focal atrophy of the testis/tubule was observed at increased incidence in high dose male mice (vehicle control, 1/49, low dose, 2/50; high dose, 7/50). This lesion was seen in animals that had underlying disease and was not considered directly related to chemical administration.

Two-Year Studies in Mice
Comparison of Results with Other Carcinogenicity Studies
Genetic Toxicology
Data Audit
Conclusions

### Study Rationale

Bromodichloromethane (99% pure) was one of three trihalomethanes selected for study in F344/N rats and B6C3F<sub>1</sub> mice because chloroform, a related trihalomethane, was found to cause tumors in rodents and no carcinogenicity data were available for these other common water contaminants at the time these studies were started. The chemical was administered by gavage in corn oil. Two other recent carcinogenicity studies of bromodichloromethane allow for a comparison of results after administration by gavage (current NTP studies), drinking water (Tumasonis et al., 1985), and microencapsulation in feed (M. Tobe, National Institute of Hygienic Sciences, Tokyo, Japan, personal communication to J. Dunnick, NTP, 1985).

### Results of Short-Term Studies

Bromodichloromethane was administered by gavage 5 days per week to F344/N rats and B6C3F1 mice in a series of single-administration, 14-day, and 13-week studies to determine the affected sites and to set doses for the 2-year studies. These studies showed that the kidney and liver were the affected organs in rodents. In the 14day studies, male rats at the highest dose (600 mg/kg) and male mice at the two highest doses (150 and 300 mg/kg) had reddened medullae of the kidney. In the 13-week studies, the kidney was again found to be affected in male rats at the highest dose (300 mg/kg) and in male mice at the highest dose (100 mg/kg) but not in female rats or mice. In the 13-week studies, centrilobular degeneration of the liver was seen in male and female rats at 300 mg/kg and in female mice at 200 and 400 mg/kg.

In the 13-week studies, male and female rats received doses of 19-300 mg/kg. Based on deaths at 300 mg/kg, body weight gain depression at 150 and 300 mg/kg in male and female rats, and lesions of the liver and kidney in male rats and of the liver in female rats at 300 mg/kg, doses selected for rats for the 2-year studies were 50 and 100 mg/kg.

In the 13-week studies, male mice received doses of 6.25-100 mg/kg and female mice received doses of 25-400 mg/kg. Body weight gain depression and kidney lesions were observed at 100

mg/kg but not at 50 mg/kg in male mice; in female mice, body weight gain depression and liver lesions were seen at 200 and 400 mg/kg but not at 100 mg/kg. Based on these results, doses selected for the 2-year studies were 25 and 50 mg/kg for male mice and 75 and 150 mg/kg for female mice.

### Two-Year Studies in Rats

Final survival of dosed rats was comparable to that of vehicle controls. Body weights of high dose male and female rats were decreased during the last 1.5 years of the study; final mean body weights of males and females were 88% and 79% those of respective vehicle control mean body weights. Final mean body weights of low dose male and female rats were comparable to those of the vehicle controls.

Dose-related nonneoplastic lesions in male rats included cytomegaly and tubular cell hyperplasia in the kidney and necrosis and fatty metamorphosis of the liver and, in female rats, eosinophilic cytoplasmic change, focal cellular change, and fatty metamorphosis in the liver and tubular cell hyperplasia in the kidney. These results confirm the short-term study findings that showed that bromodichloromethane was toxic for the kidney of male rats and for the liver of female rats. The 13-week study results did not predict the kidney toxicity observed in the female rats or the large intestine tumors seen in male and female rats in the 2-year studies.

Administration of bromodichloromethane to male and female rats induced uncommon neoplasms of the large intestine and kidney (see Tables 13 and 14); the historical control incidence of large intestine tumors is less than 0.2% in males and is 0% in females. The intestinal neoplasms diagnosed as adenomatous polyps are similar morphologically to the polypoid adenomas (in contrast to the hyperplastic polyps) seen in humans (Lane et al., 1978). Similarly, invasion of the polyp stalk and submucosa by neoplastic cells marks the progression from the benign to the malignant stage. There is substantial morphologic and empirical evidence that the development of common colon cancer in humans proceeds through a similar sequence of stages.

The spectrum of kidney disease seen in rats after bromodichloromethane administration differs from that seen after animals are exposed to gasoline vapors, light hydrocarbons (Mehlman et al., 1984), 1,4-dichlorobenzene (NTP, 1987a), or dimethyl methylphosphonate (NTP, 1987b). With these compounds, the kidney neoplasms were seen primarily in the male rat; nonneoplastic lesions of the kidney of male rats in the 2-year studies included an increased severity of nephropathy and an increased incidence of mineralization (calcification), and hyaline droplet formation in the kidney was usually seen in the 13week studies. The kidney neoplasms seen in male and female rats and in male mice administered bromodichloromethane were not accompanied by an increase in nephropathy and mineralization; no hyaline droplet formation in the kidney was seen in the 13-week studies.

Other compounds studied by the NTP which cause kidney lesions include the halogenated hydrocarbons trichloroethylene (NTP, unpublished; NTP, 1987c) and tetrachloroethylene (NTP, 1986). Administration of trichloroethylene by gavage in corn oil or tetrachloroethylene by inhalation caused cytomegaly and karyomegaly of tubular epithelial cells in rats and mice of each sex. Cytomegaly of the kidney was seen only in male rats and male mice given bromodichloromethane by gavage. Whereas renal tubular cell tumors were seen in rats and mice given bromodichloromethane, renal tumors were seen only in rats given the halogenated hydrocarbons.

Miscellaneous lesions noted in rats included increased incidences of skin neoplasms in low dose but not high dose male rats. These lesions were not considered to be clearly compound related.

Decreased incidences of naturally occurring tumors were seen in the adrenal glands of high dose male rats and in the pituitary and mammary glands of female rats; these decreases might be related to decreased body weight in high dose animals.

### Two-Year Studies in Mice

Final survival of dosed male mice was comparable to that of vehicle controls. At week 84,

survival of female mice was greater than 50% in all dosed groups; after week 84, survival in dosed and vehicle control female mice was reduced (final survival: vehicle control, 26/50; low dose, 13/50; high dose, 15/50). This decreased survival was associated with ovarian abscesses (8/50; 19/47; 18/49). These abscesses were not cultured. In the 2-year pentachloronitrobenzene study conducted at this laboratory (June 1981-May 1983), female mice also had ovarian abscesses, and culture of these lesions showed that Klebsiella sp. were the primary pathogens (NTP, 1987d). The mean body weight of high dose male mice was 5%-9% lower than that of vehicle controls throughout the study; the mean body weight of low dose male mice was comparable to that of vehicle controls. Mean body weights of low and high dose female mice were 9% and 25% lower than those of vehicle controls at the end of the study. No compound-related clinical signs were observed.

Dose-related nonneoplastic lesions included renal cytomegaly, fatty metamorphosis of the liver, and follicular cell hyperplasia of the thyroid gland in male mice and follicular cell hyperplasia of the thyroid gland in female mice.

Bromodichloromethane administration caused compound-related neoplasms in the kidney of male mice and in the liver of female mice (see Tables 26 and 27). Decreased incidences of naturally occurring tumors were seen in the pituitary gland of dosed female mice (see Table 28).

Positive serologic titers for Sendai virus, mouse hepatitis virus, and rat coronavirus were seen in the sentinel animals; however, there was no evidence for an active infection in the study animals, and it is unlikely that these viruses had any impact on the interpretation of the studies.

# Comparison of Results with Other Carcinogenicity Studies

Under the conditions of these studies, bromodichloromethane caused the widest spectrum of carcinogenic responses of the trihalomethanes studied in the NCI/NTP program (Table 29) and was associated with the formation of neoplasms of the large intestine and kidney in male and female rats, kidney neoplasms in male mice, and

(c) NTP, 1985

liver neoplasms in female mice (Table 30). Bromodichloromethane is the only trihalomethane studied to date which caused colon/rectum neoplasms in rodents. Like chloroform, this chemical caused liver neoplasms in female mice and kidney neoplasms in male rats. Chlorodibromomethane caused liver neoplasms in female mice but no neoplasms in rats.

In a drinking-water study in Wistar rats, Tumasonis et al. (1985) estimated that approximately 150 mg/kg per day (females) or 200 mg/kg per day (males) of bromodichloromethane was consumed for the lifetime of the animals, and administration of the chemical at these concentrations resulted in an increase in hepatic neoplastic nodules in female rats. The impact of the relative insolubility of bromodichloromethane in water and its volatile properties were not

discussed. In a study in which bromodichloromethane was administered in a microencapsulated form in the diet at concentrations up to 2,200 ppm for 24 months, an increase in liver neoplasms was observed in male and female Wistar rats (M. Tobe, National Institute of Hygienic Sciences, Tokyo, Japan, personal communication to J. Dunnick, NTP, 1985).

A comparison of the carcinogenicity studies of chloroform (doses for male and female Osborne-Mendel rats and B6C3F<sub>1</sub> mice given in Table 29) administered by gavage in corn oil (NCI, 1976a) or in drinking water (Jorgenson et al., 1985) showed that chloroform by either route of administration caused kidney neoplasms in male rats; liver neoplasms in female mice were seen only in the gavage study. The time-weighted-average doses of chloroform in the

Jorgenson study were 0, 19, 38, 81, or 160 mg/kg per day for male rats and 0, 34, 65, 130, or 263 mg/kg per day for female mice.

The results of these different studies suggest that the trihalomethanes are carcinogenic in rodents when given in drinking water, by gavage in corn oil, or in feed. The spectrum of lesions differed somewhat with the chemical, the species, and the experimental design. The male mouse metabolizes bromodichloromethane and the other trihalomethanes at a faster rate than does the male rat (Mink et al., 1986), and this difference may contribute to the species

difference in tumor patterns. The mechanism for tumor formation cannot be determined based on the results of these rodent studies. In these studies, neoplasms were seen at dose levels that are higher than the levels of trihalomethanes ordinarily found in most drinking water supplies (USEPA, 1979; Balster and Borzelleca, 1982).

### Genetic Toxicology

Bromodichloromethane has been demonstrated to be mutagenic in both in vitro and in vivo test systems. Although bromodichloromethane did not induce gene mutations in microbial plate assays with Salmonella, positive results were observed in bacterial tests both in the presence and absence of metabolic activation when chemical exposure was in a desiccator. In this test system, bromoform and chlorodibromomethane were also mutagenic whereas chloroform was not (Simmon et al., 1977).

The seemingly conflicting results among various microbial tests could be because of the volatile nature of this compound and the consequent difficulties in achieving sufficient exposure. This concept is supported by the studies of Nestmann and Lee (1985) in which mitotic crossing-over was seen when Saccharomyces was incubated with bromodichloromethane for 16 hours, whereas a similar assay by Simmon and Kauhanen (1978) did not demonstrate mitotic crossing-over in another yeast strain incubated with bromodichloromethane for 4 hours.

Bromodichloromethane is also mutagenic to mammalian cells. It induced forward mutations at the thymidine kinase locus in cultured mouse lymphoma cells in the presence of S9. Although results from NTP-sponsored cytogenetic tests in Chinese hamster ovary cells were negative, induction of sister chromatid exchanges in cultured human lymphocytes as well as mouse bone marrow cells treated in vivo is reported in the literature (Morimoto and Koizumi, 1983). Again, these somewhat conflicting responses with mammalian cells in culture may simply be

because of a lack of adequate exposure to this volatile chemical or the variable metabolic capacity of the different cell types used in these experiments.

#### Data Audit

The experimental and tabulated data for the NTP Technical Report on bromodichloromethane were examined for accuracy, consistency, completeness, and compliance with Good Laboratory Practice regulations. As summarized in Appendix H, the audit revealed no major problems with the conduct of the studies or with collection and documentation of the experimental data. No discrepancies were found that influenced the final interpretation of the results of these studies.

#### Conclusions

Under the conditions of these 2-year gavage studies, there was clear evidence of carcinogenic activity\* for male and female F344/N rats and B6C3F<sub>1</sub> mice as shown by increased incidences of tubular cell adenomas and adenocarcinomas in the kidney and adenocarcinomas and adenomatous polyps in the large intestine in male and female rats, increased incidences of adenomas and adenocarcinomas in the kidney of male mice, and increased incidences of hepatocellular adenomas and carcinomas in female mice.

<sup>\*</sup>Explanation of Levels of Evidence of Carcinogenic Activity is on page 7.

A summary of the Peer Review comments and the public discussion on this Technical Report appears on page 11.

Cochran-Armitage Trend Test (d)	P = 0.417		
Fisher Exact Test (d)		P = 0.339	P = 0.500

<sup>(</sup>a) Number of tumor-bearing animals/number of animals examined at the site

<sup>(</sup>b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality

<sup>(</sup>c) Observed tumor incidence at terminal kill

<sup>(</sup>d) Beneath the vehicle control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the vehicle controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. A negative trend or lower incidence in a dosed group is indicated by (N).

<sup>(</sup>e) No P value is reported because no tumors were observed in the dosed and vehicle control groups.

<sup>(</sup>f) Only 23 spleens were examined.

<sup>(</sup>g) Incomplete sampling of tissue

### TABLE A4a. HISTORICAL INCIDENCE OF LARGE INTESTINE TUMORS IN MALE F344/N RATS ADMINISTERED CORN OIL BY GAVAGE (a)

#### Historical Incidence at EG&G Mason Research Institute

No colon or rectum tumors have been observed in 250 male vehicle control rats.

Overall Historical Incidence	No. Examined	No. of Tumors	<u>Diagnosis</u>
Colon	1,390	1 1 1	Adenomatous polyp Cystadenoma Adenocarcinoma
TOTAL		(b) 3 (0.2%)	
Rectum	1,390	0	

<sup>(</sup>a) Data as of August 30, 1985, for studies of at least 104 weeks; large intestine includes both colon and rectum.

### TABLE B3. ANALYSIS OF PRIMARY TUMORS IN FEMALE RATS IN THE TWO-YEAR GAVAGE STUDY OF BROMODICHLOROMETHANE (Continued)

(c) Observed tumor incidence at terminal kill

(e) No P value is reported because no tumors were observed in the 50 mg/kg and vehicle control groups.

<sup>(</sup>a) Number of tumor-bearing animals/number of animals examined at the site
(b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality

<sup>(</sup>d) Beneath the vehicle control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the vehicle controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. A negative trend or lower incidence in a dosed group is indicated by (N).

# TABLE B4a. HISTORICAL INCIDENCE OF RENAL TUBULAR CELL TUMORS IN FEMALE F344/N RATS ADMINISTERED CORN OIL BY GAVAGE (a)

### Historical Incidence at EG&G Mason Research Institute

No tubular cell tumors have been observed in 250 vehicle control animals

Overall Historical Incidence	No. Examined	No. of Tumors	Diagnosis
		1 1	Adenoma, NOS Tubular cell adenoma
	1,447	2 (0.1%)	

<sup>(</sup>a) Data as of August 30, 1985, for studies of at least 104 weeks. No more than one tumor has been observed in any vehicle control group.

# TABLE B4b. HISTORICAL INCIDENCE OF LARGE INTESTINE TUMORS IN FEMALE F344/N RATS ADMINISTERED CORN OIL BY GAVAGE (a)

### Historical Incidence at EG&G Mason Research Institute

No large intestine tumors have been observed in 236 corn oil vehicle control animals.

### Overall Historical Incidence

No large intestine tumors have been observed in 1,400 corn oil vehicle control animals.

(a) Data as of August 30, 1985, for studies of at least 104 weeks.

Incidental Tumor Tests (d)	P = 0.213N	P = 0.639	P = 0.233N
Cochran-Armitage Trend Test (d)	P = 0.231N		
Fisher Exact Test (d)		P = 0.651N	P = 0.301 N

<sup>(</sup>a) Number of tumor-bearing animals/number of animals examined at the site

<sup>(</sup>b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality

<sup>(</sup>c) Observed tumor incidence at terminal kill

<sup>(</sup>d) Beneath the vehicle control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the vehicle controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. A negative trend or lower incidence in a dosed group is indicated by (N).

<sup>(</sup>e) No P value is reported because no tumors were observed in the 25 mg/kg and vehicle control groups.

TABLE C4. HISTORICAL INCIDENCE OF RENAL TUBULAR CELL TUMORS IN MALE B6C3F<sub>1</sub> MICE ADMINISTERED CORN OIL BY GAVAGE (a)

	No. Examined	No. of Tumors	<u>Diagnosis</u>
Historical Incidence at EG&G Mason Re	search Institute		
TOTAL	299	(b) 1 (c) 1 2 (0.7%)	Tubular cell adenoma Tubular cell adenocarcinoma
Overall Historical Incidence			
TOTAL	1,490	3 2 5 (0.3%)	Tubular cell adenoma Tubular cell adenocarcinoma

<sup>(</sup>a) Data as of August 30, 1985, for studies of at least 104 weeks. No more than one tumor has been observed in any vehicle control group.

<sup>(</sup>b) Observed in the n-butyl chloride study
(c) Observed in the 1,2-dichloropropane study

Life Table Tests (d)	P = 0.036N	P = 0.459N	P = 0.038N
Incidental Tumor Tests (d)	P = 0.005N	P = 0.158N	P = 0.006N
Cochran-Armitage Trend Test (d)	P<0.001N		
Fisher Exact Test (d)		P = 0.033N	P = 0.001 N

<sup>(</sup>a) Number of tumor-bearing animals/number of animals examined at the site

<sup>(</sup>b) Kaplan-Meier estimated tumor incidences at the end of the study after adjusting for intercurrent mortality

<sup>(</sup>c) Observed tumor incidence at terminal kill

<sup>(</sup>d) Beneath the vehicle control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the vehicle controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. A negative trend or lower incidence in a dosed group is indicated by (N).

<sup>(</sup>a) Study performed at SRI International. The detailed protocol is presented in Haworth et al. (1983). Cells and study compound or solvent (95% ethanol) were incubated in the absence of exogenous metabolic activation (-S9) or with Aroclor 1254induced S9 from male Syrian hamster liver or male Sprague Dawley rat liver. High dose was limited by toxicity or solubility but did not exceed 10 mg/plate; 0  $\mu$ g/plate dose is the solvent control.

(b) Revertants are presented as mean  $\pm$  standard error from three plates.

<sup>(</sup>c) Slight toxicity

<sup>(</sup>d) Positive control; 2-aminoanthracene was used on all strains in the presence of S9. In the absence of metabolic activation, 4nitro-o-phenylenediamine was used with TA98, sodium azide was used with TA100 and TA1535, and 9-aminoacridine was used with TA1537.

<sup>(</sup>a) Study performed at Inveresk Research International. The experimental protocol is presented in detail by Myhr et al. (1985) and follows the basic format of Clive et al. (1979). Indepth explanations and mathematical derivations of assay characteristics are presented by Myhr et al. (1985). The highest dose of study compound is determined by solubility or toxicity and may not exceed 5 mg/ml. All doses are tested in triplicate; the average for the three tests is presented in the table. Cells  $(6 \times 10^5 \, / \text{ml})$  were treated for 4 hours at 37° C in medium, washed, resuspended in medium, and incubated for 48 hours at 37° C. After expression,  $3 \times 10^6 \, \text{cells}$  were plated in medium and soft agar supplemented with trifluorothymidine for selection of cells that were mutant at the thymidine kinase (TK) locus, and 600 cells were plated in nonselective medium and soft agar to determine the cloning efficiency.

<sup>(</sup>b) Mean  $\pm$  standard error of replicate trials for approximately  $3 \times 10^6$  cells each. All data are evaluated statistically for both trend and peak response (P<0.05 for at least one of the three highest dose sets). Both responses must be significantly (P<0.05) positive for a chemical to be considered mutagenic. If only one of these responses is significant, the call is "questionable"; the absence of both trend and peak response results in a "negative" call.

<sup>(</sup>c) Mutant fraction (frequency) is a ratio of the mutant count to the cloning efficiency, divided by 3 (to arrive at MF per  $1 \times 10^6$  cells treated); MF = mutant fraction.

<sup>(</sup>d) Significant positive response; occurs when the relative mutant fraction (average MF of treated culture/average MF of solvent control) is greater than or equal to 1.6.

<sup>(</sup>e) Tests conducted with metabolic activation were performed as described in (a) except that S9 prepared from the liver of Aroclor 1254-induced F344 rats was added at the same time as the study chemical and/or solvent.

## TABLE E3. INDUCTION OF SISTER CHROMATID EXCHANGES IN CHINESE HAMSTER OVARY CELLS BY BROMODICHLOROMETHANE (Continued)

- (a) Study performed at Environmental Health Research and Testing Laboratory. SCE = sister chromatid exchange; BrdU = bromodeoxyuridine. A detailed description of the SCE protocol is presented by Galloway et al. (1985). Briefly, Chinese hamster ovary cells were incubated with study compound or solvent as described in (d) or (e) below and cultured for sufficient time to reach second metaphase division. Cells were then collected by mitotic shake-off, fixed, air-dried, and stained.
- (b) Because some chemicals induce a delay in the cell division cycle, harvest times are occasionally extended to maximize the proportion of second division cells available for analysis.
- (c) SCEs/cell of cultures exposed to study chemical relative to that of cultures exposed to solvent
- (d) In the absence of S9, cells were incubated with study compound or solvent (dimethyl sulfoxide) for 2 hours at 37° C. Then BrdU was added, and incubation was continued for 24 hours. Cells were washed, fresh medium containing BrdU and colcemid was added, and incubation was continued for 2-3 hours.
- (e) In the presence of S9, cells were incubated with study compound or solvent (dimethyl sulfoxide) for 2 hours at 37°C. The cells were then washed, and medium containing BrdU was added. Cells were incubated for a further 26 hours, with colcemid present for the final 2-3 hours. S9 was from the liver of Aroclor 1254-induced male Sprague Dawley rats.

<sup>(</sup>a) Study performed at Environmental Health Research and Testing Laboratory. Abs = aberrations. A detailed presentation of the technique for detecting chromosomal aberrations is found in Galloway et al. (1985). Briefly, Chinese hamster ovary cells were incubated with study compound or solvent as indicated in (b) or (c). Cells were arrested in first metaphase by addition of colcemid and harvested by mitotic shake-off, fixed, and stained in 6% Giemsa.

<sup>(</sup>b) In the absence of S9, cells were incubated with study compound or solvent (dimethyl sulfoxide) for 8-10 hours at 37°C. Cells were then washed, and fresh medium containing colcemid was added for an additional 2-3 hours followed by harvest.

<sup>(</sup>c) In the presence of S9, cells were incubated with study compound or solvent (dimethyl sulfoxide) for 2 hours at 37°C. Cells were then washed, medium was added, and incubation was continued for 8-10 hours. Colcemid was added for the last 2-3 hours of incubation before harvest. S9 was from the liver of Aroclor 1254-induced male Sprague Dawley rats.

## APPENDIX F

## SENTINEL ANIMAL PROGRAM

		PAGE
TABLE F1	MURINE ANTIBODY DETERMINATIONS FOR RATS AND MICE IN THE TWO- YEAR GAVAGE STUDIES OF BROMODICHLOROMETHANE	173

#### I. Methods

Rodents used in the Carcinogenesis Program of the National Toxicology Program are produced in optimally clean facilities to eliminate potential pathogens that may affect study results. The Sentinel Animal Program is part of the periodic monitoring of animal health that occurs during the toxicologic evaluation of chemical compounds. Under this program, the disease state of the rodents is monitored via viral serology on sera from extra (sentinel) animals in the study rooms. These animals are untreated, and these animals and the study animals are both subject to identical environmental conditions. The sentinel animals come from the same production source and weanling groups as the animals used for the studies of chemical compounds.

Fifteen B6C3F<sub>1</sub> mice and 15 F344/N rats of each sex are selected at the time of randomization and allocation of the animals to the various study groups. Five animals of each designated sentinel group are killed at 6, 12, and 18 months on study. Data from animals surviving 24 months are collected from 5/50 randomly selected vehicle control animals of each sex and species. The blood from each animal is collected and clotted, and the serum is separated. The serum is cooled on ice and shipped to Microbiological Associates' Comprehensive Animal Diagnostic Service for determination of the antibody titers. The following tests are performed:

	Hemagglutination <u>Inhibition</u>	Complement <u>Fixation</u>	<u>ELISA</u>
Mice	PVM (pneumonia virus of mice) Reo 3 (reovirus type 3) GDVII (Theiler's encephalomyelitis virus) Poly (polyoma virus) MVM (minute virus of mice) Ectro (infectious ectromelia) Sendai	M.Ad. (mouse adenovirus) LCM (lymphocytic choriomeningitis virus)	MHV (mouse hepatitis virus)
Rats	PVM KRV (Kilham rat virus) H-1 (Toolan's H-1 virus) Sendai	RCV (rat coronavirus)	M. pul. (Mycoplasma pulmonis)

#### II. Results

Results are presented in Table F1.

Telodrin (b)	< 0.01		36
Chlordane (b)	< 0.05		36
Toxaphene (b)	< 0.1		36
Estimated PCBs (b)	< 0.2		36
Ronnel (b)	< 0.01		36
Ethion (b)	< 0.02		36
Trithion (b)	< 0.05		36
Diazinon (b)	< 0.1		36
Methyl parathion (b)	< 0.02		36
Ethyl parathion (b)	< 0.02		36
Malathion (n)	$0.08 \pm 0.05$	< 0.05-0.25	36
Endosulfan I (o)	< 0.01		36
Endosulfan II (o)	< 0.01		36
Endosulfan sulfate (o)	< 0.03		36

#### TABLE G4. CONTAMINANT LEVELS IN NIH 07 RAT AND MOUSE RATION (Continued)

- (a) One observation was above the detection limit. The value obtained is listed under the range.
- (b) All values were less than the detection limit, given in the table as the mean.
- (c) Source of contamination: alfalfa, grains, and fish meal
- (d) Source of contamination: soy oil and fish meal
- (e) Excludes one high value of 150/g obtained in the batch produced on 8/26/82.
- (f) Mean, standard deviation, and range include the high value given in footnote e.
- (g) Mean, standard deviation, and range exclude the high value of 118.4 ppb obtained for the batch produced on 4/27/81.
- (h) All values were corrected for percent recovery.
- (i) Mean, standard deviation, and range include the high value given in footnote g.
- (j) Mean, standard deviation, and range exclude the high value of 117.0 ppb obtained for the batch produced on 4/27/81.
- (k) Mean, standard deviation, and range include the value given in footnote j.
- (1) BHC = hexachlorocyclohexane or benzene hexachloride
- (m) Two observations were above the detection limit. The values and the dates they were obtained are listed under the range.
- (n) Thirteen batches contained more than 0.05 ppm.
- (o) Eighteen batches produced during 5/20/80-11/25/81 were not analyzed for endosulfan I, endosulfan II, and endosulfan sulfate.

## APPENDIX H

# DATA AUDIT SUMMARY

### APPENDIX H. DATA AUDIT SUMMARY

The experimental data, documents, pathology materials, and draft Technical Report for the 2-year toxicology and carcinogenesis studies of bromodichloromethane in rats and mice were audited for accuracy, consistency, completeness, and compliance with Good Laboratory Practice regulations of the Food and Drug Administration (implemented by the NTP beginning on October 1, 1981). The laboratory experiments were conducted for the NTP by EG&G Mason Research Institute, Worcester, Massachusetts, under a subcontract with Tracor Jitco, Inc. Animal dosing with bromodichloromethane began in June 1980 and ended in May 1983. The retrospective audit was conducted at the NTP Archives in February and March 1986 by the following personnel from Program Resources, Inc.: W. Oller, Ph.D. (Principal Investigator); K. Connor; J. Kovach, B.A.; S. Corson, H.T. (ASCP); K. Pace, B.S.; and J.R. Wright, B.S. The following individuals from Veritas Laboratories, Inc., also were involved in the audit: J. Sagartz, D.V.M., A.C.V.P.; and N. MacLachlan, D.V.M., A.C.V.P. F. Voelker, D.V.M., A.C.V.P., Pathology Associates, Inc., performed a 100% examination of the wet tissues for uncut lesions and trimmed, embedded, and sectioned the additional lesions found. S. Eustis, NTP, D.V.M., Ph.D., A.C.V.P., read and diagnosed these additional lesions.

The full report of the audit is on file at the NIEHS. The audit included, as minimum requirements, a review of:

- (1) All records concerning animal receipt, quarantine, randomization, and disposition prior to study start.
- (2) All chemistry records.
- (3) Body weight and clinical observation data for a random 10% sample of the study animals.
- (4) All inlife records concerning environmental conditions, masses, mortality, and animal identification.
- (5) All postmortem records for individual animals concerning identification, disposition codes, condition codes, and correlation between gross observations and microscopic diagnosis.
- (6) Wet tissues from a random 10% sample of the study animals to check for animal identification and the presence of untrimmed lesions.
- (7) Slides and blocks of tissues from all vehicle control and high dose animals to examine for proper match and inventory.
- (8) Tabulated pathology diagnoses for a random 10% of study animals to verify computer data entry.

The audit showed that the data in the Technical Report (including inlife observations and chemistry data) reflect the data at the NTP Archives. Uncut lesions in the wet tissues were found which were due in part to failure to open and examine the large intestines completely. As a result of this finding, all wet tissues were examined for uncut lesions, and these lesions then were sectioned by an NTP pathology support contractor. NTP pathology staff diagnosed these additional lesions. The final tables include the additional lesions found and represent a complete examination of all tissues. This additional pathology did not change the interpretations of the studies but primarily increased the number of tumors found in dosed animals.

In three instances, the animal number in the wet tissue bags did not agree with the number on the bag, but there was no indication that animals had been interchanged. There were six animals (two rats and four mice) whose deaths were listed as natural but might have been attributed to gavage accident.

The audit findings were reviewed by NTP staff. In conclusion, the documents and materials at the NTP Archives support the data and conclusions presented in this Technical Report.

#### NATIONAL TOXICOLOGY PROGRAM TECHNICAL REPORTS PUBLISHED AS OF SEPTEMBER 1987

TR No	. CHEMICAL	TR No.	. CHEMICAL
201	2,3,7,8-Tetrachlorodibenzo-p-dioxin (Dermal)	261	Chlorobenzene
206	Dibromochloropropane	263	1,2-Dichloropropane
207	Cytembena	267	Propylene Oxide
	FD & C Yellow No. 6	269	Telone II
209	2,3,7,8-Tetrachlorodibenzo-p-dioxin (Gavage)	271	HC Blue No. 1
210	1,2-Dibromoethane (Inhalation)		Propylene
212	Di(2-ethylhexyl)adipate		Tris(2-ethylhexyl)phosphate
213	Butylbenzyl Phthalate		2-Chloroethanol
214	Caprolactam		8-Hydroxyquinoline
	Bisphenol A		H.C. Red No. 3
216	11-Aminoundecanoic Acid	282	Chlorodibromomethane
217	Di(2-ethylhexyl)phthalate		Diallylphthalate (Rats)
219	2,6-Dichloro-p-phenylenediamine		C.I. Basic Red 9 Monohydrochloride
220	C.I. Acid Red 14	287	Dimethyl Hydrogen Phosphite
221	Locust Bean Gum		1,3-Butadiene
222	C.I. Disperse Yellow 3		Benzene
223	Eugenol	291	Isophorone
224	Tara Gum	293	HC Blue No. 2
	D & C Red No. 9		Chlorinated Trisodium Phosphate
226	C.I. Solvent Yellow 14	295 296	Chrysotile Asbestos (Rats)
227	Gum Arabic	290	Tetrakis(hydroxymethy)phosphonium Sulfate and Tetrakis(hydroxymethy)phosphonium Chloride
	Vinylidene Chloride	298	
229	Guar Gum	298 299	Dimethyl Morpholinophosphoramidate
230	Agar	300	C.I. Disperse Blue 1 3-Chloro-2-methylpropene
231 232	Stannous Chloride	301	o-Phenylphenol
232	Pentachloroethane	303	4-Vinylcyclohexene
233 234	2-Biphenylamine Hydrochloride	304	Chlorendic Acid
234 235	Allyl Isothiocyanate Zearalenone	305	Chlorinated Paraffins (C <sub>23</sub> , 43% chlorine)
236	D-Mannitol	306	Dichloromethane
236 237	1,1,1,2-Tetrachloroethane	307	Ephedrine Sulfate
238	Ziram	308	Chlorinated Paraffins (C <sub>12</sub> , 60% chlorine)
239	Bis(2-chloro-1-methylethyl)ether	309	Decabromodiphenyl Oxide
240	Propyl Gallate	310	Marine Diesel Fuel and JP-5 Navy Fuel
242	Diallyl Phthalate (Mice)	311	Tetrachloroethylene (Inhalation)
244	Polybrominated Biphenyl Mixture	312	n-Butyl Chloride
245	Melamine	314	Methyl Methacrylate
247	L-Ascorbic Acid	315	Oxytetracycline Hydrochloride
248	4,4'-Methylenedianiline Dihydrochloride	316	1-Chloro-2-methylpropene
249	Amosite Asbestos	317	Chlorpheniramine Maleate
250	Benzyl Acetate	318	Ampicillin Trihydrate
251	Toluene Diisocyanate	319	1,4-Dichlorobenzene
253	Allyl Isovalerate	322	Phenylephrine Hydrochloride
255	1,2-Dichlorobenzene	325	Pentachloronitrobenzene
257	Diglycidyl Resorcinol Ether	327	Xylenes (Mixed)
259	Ethyl Acrylate		

These NTP Technical Reports are available for sale from the National Technical Information Service, U.S. Department of Commerce, 5285 Port Royal Road, Springfield, VA 22161 (703-487-4650). Single copies of this Technical Report are available without charge (and while supplies last) from the NTP Public Information Office, National Toxicology Program, P.O. Box 12233, Research Triangle Park, NC 27709.
