## **INTRODUCTION**

Omalizumab received FDA approval on June 20, 2003 and is the first biotechnology product for the treatment of asthma related to allergies. It is indicated for individuals 12 years of age and older with moderate to severe persistent asthma who have a positive skin test or *in vitro* reactivity to a perennial aeroallergen and whose symptoms are inadequately controlled with inhaled corticosteroids. Safety and efficacy have not been established in other allergic conditions. Omalizumab is manufactured by Genentech and will be jointly marketed with Novartis.

Many patients with asthma are atopic and possess specific IgE antibodies to allergens responsible for driving airway inflammation. Asthma is characterized by the early-phase response and the late-phase response upon exposure to allergen. The early phase response is IgE-mediated whereby IgE binds to FcεR1 receptors located on the surface of effector cells, ultimately leading to the release of stored inflammatory mediators from the effector cell. Although not well defined, it has been postulated that IgE may also be involved in the initiation of the late-phase response.

Omalizumab is a recombinant humanized monoclonal anti-IgE antibody that selectively binds to the Cε3 domain of IgE, which inhibits free IgE from binding to the mast cell FcεR1 receptor thereby preventing activation and subsequent release of cellular mediators.

## **PHARMACOKINETICS/PHARMACODYNAMICS**

The absolute bioavailability after subcutaneous administration is 62%. Peak concentration is reached after 7-8 days. The volume of distribution is  $78 \pm 32$  ml/kg, approximating plasma volume. Omalizumab is cleared by liver reticuloendothelial system and endothelial cells and has a half-life of ~ 26 days.

At recommended doses, serum free IgE is decreased by > 96%. Serum free IgE levels decrease in a dose-dependent fashion within 1 hour of the dose and are maintained between doses. Total serum IgE (omalizumab:IgE complex and free IgE) levels increase. After 16 weeks of treatment, total IgE levels were 5-fold higher than baseline levels. There appears to be no rebound in IgE levels after discontinuation of omalizumab. Total IgE levels do not return to pre-treatment levels for up to 1 year after discontinuation.

## **EFFICACY IN ALLERGIC ASTHMA**

Pediatric trials and trials using IV administration of omalizumab were excluded from this review.

The 2 pivotal trials 008 and 009 utilized an identical protocol (see appendix for details on study design and results).<sup>1,2</sup> Patients had to be symptomatic despite treatment with inhaled corticosteroids (ICS), and had to have positive immediate response to skin prick test to  $\geq 1$  common allergen (mites, cockroach, dog, cat), total serum IgE  $\geq 30 - \leq 700$  IU/mL, and FEV1  $\geq 40\% - \leq 80\%$  predicted. Patients on other asthma controller drugs and current smokers were excluded. The patients' usual ICS was switched to an equivalent dose of beclomethasone (BDP). The trial was divided into 2 phases, a stable steroid phase (weeks 0-16) and a steroid reduction phase (weeks 16-28). During the stable steroid phase, the baseline BDP dose was maintained. During the steroid-reduction phase the dose of BDP was reduced by 25% every 2 weeks for 8 weeks until discontinued or worsening of asthma symptoms. For the last 4 weeks, the lowest effective dose of BDP that did not result in worsening of symptoms was maintained. Worsening of asthma symptoms was defined as: unscheduled physician visit; PEF < 50% of personal best;  $\geq 20\%$  in am PEF on  $\geq 2$  of 3 consecutive days; 50% increase in 24-h albuterol use (> 8puffs/ d) on  $\geq 2$  of 3 consecutive days,  $\geq 2$  of 3 consecutive nights with awakening due to asthma symptoms requiring medication.

September 2003

Updated versions can be found at <http://www.vapbm.org> or <http://vaww.pbm.med.va.gov>

The primary endpoint was the number of exacerbations during the stable steroid phase and the steroid reduction phase. An exacerbation was defined as worsening of asthma requiring treatment with systemic steroids or a doubling of the baseline inhaled steroid dose determined during the run-in period. In both trials, the number of exacerbations per patient was significantly lower in the patients receiving omalizumab compared to placebo (Table 1).

**Table 1. Asthma exacerbations**

	Study phase	Trial 008		Trial 009	
		Omalizumab	Placebo	Omalizumab	Placebo
<b>Exacerbations/patient</b>	Stable steroid phase	0.28*	0.54	0.28*	0.66
<b>% of patients w/ <math>\geq</math> 1 exacerbation</b>	Stable steroid phase	14.6%*	23.3%	12.8%*	30.5%
<b>Exacerbations/patient</b>	Steroid reduction phase	0.39*	0.66	0.66*	0.75
<b>% of patients w/ <math>\geq</math> 1 exacerbation</b>	Steroid reduction phase	21.3%*	32.3%	15.8%*	29.8%

\*Significant versus placebo

Secondary endpoints included the percent reduction in the BDP dose at the end of the steroid-reduction phase, rescue albuterol use, asthma symptom score, peak expiratory flow rate and FEV1. The dose of inhaled steroids was significantly reduced in the group receiving omalizumab compared to placebo (Table 2). It is interesting to note that the placebo group also was able to substantially reduce their ICS dose. The difference from placebo in the mean reduction of rescue albuterol use was 0.5-1.5 puffs/day. There was approximately a 0.5-point difference in total asthma symptom score in favor of omalizumab. There was no appreciable difference in FEV1 or peak flow between omalizumab and placebo.

**Table 2. Inhaled steroid use**

	Trial 008		Trial 009	
	Omalizumab	Placebo	Omalizumab	Placebo
<b>Mean baseline BDP dose (mcg/d)</b>	570	568	769	772.1
<b>Median % reduction of ICS</b>	75%*	50%	75%*	50%
<b>% of patients with <math>\geq</math>50% reduction in ICS dose</b>	72.4%*	54.9%	79%*	55%
<b>% of patients able to d/c ICS</b>	39.6%*	19.1%	43%*	19%

\*Significant versus placebo

The baseline demographics for urgent healthcare use in the previous year was relatively low suggesting that the study population had less severe disease. The mean number of unscheduled outpatient visits per patient in studies 008 and 009 was approximately 0.75 and 1.2 respectively and the mean number of ER visits per patient was approximately 0.2. The percent hospitalized in the previous year for asthma in study 008 was 2% and 4% in the omalizumab and placebo group respectively.<sup>8</sup> In study 009, the percent hospitalized for asthma was 4.1% and 7.5% respectively. Corren et al. presented the event rates/100 patient-years for unscheduled outpatient visits, emergency room treatment and hospitalizations for asthma exacerbation during 1 year of treatment<sup>3</sup>

**Table 3. Event rates/100 patient-years**

	Trial 008		Rate ratio [95% CI]	Trial 009		Rate ratio [95% CI]
	Omalizumab	Placebo		Omalizumab	Placebo	
Unscheduled outpatient visit	18.16	31.83	0.57* [0.35, 0.92]	14.84	32.07	0.46* [0.26, 0.8]
ER treatment	1.18	3.05	0.39 [0.00, 2.75]	1.14	2.92	0.39 [0.00, 2.75]
Hospitalization	0.39	1.31	0.30 [0.00, + inf]	0.38	4.16	0.09* [0.00, 0.56]

\*Significant

Trial 011 used a similar study design and dosing strategy as trials 008 and 009 with the following exceptions: fluticasone was the ICS used, included was an additional 4-week observation period after the steroid reduction phase, patients were considered as having severe asthma, patients taking oral steroids

were included, exacerbation was defined as the need for systemic steroids, and the primary endpoint was a decrease in ICS dose in those taking ICS only.<sup>8</sup>

The median percent decrease in ICS dose was 60% with omalizumab and 50% with placebo and was considered to be significant. Exacerbation rates, asthma symptom scores and spirometry were not significantly different compared to placebo. For the subgroup using both inhaled and oral steroids, the outcomes were not significantly different than that of placebo; however, the number of patients was relatively small. (See appendix for study details)<sup>8</sup>

Trials Q2143g (ALTO) and 1A04 are 2 randomized open-label trials comparing omalizumab to usual asthma care. There were no restrictions on concomitant asthma medications. They were primarily designed as safety trials; however, exacerbation rates, ER visits, urgent office visits, and hospitalizations for asthma were evaluated as secondary endpoints. In both trials, there were significantly less asthma exacerbations in the groups receiving omalizumab. Urgent office or ER visits and hospitalization did not greatly differ between groups in ALTO. In trial 1A04, there were less unscheduled office or ER visits in the omalizumab group; however, a statistical analysis was not done. (See appendix for study details)

#### Extension trials

In a 24-week extension, 483 patients continued randomized treatment from trial 009.<sup>4</sup> The lowest effective dose of BDP was continued and may be adjusted. Additional asthma medications may be used and/or switched if deemed necessary. The number of asthma exacerbations per patient was significantly reduced in the omalizumab group compared to placebo. Twenty-four percent of omalizumab patients had one or more exacerbations compared to 40.6% in the placebo group.

Fifty-seven percent of patients receiving omalizumab were able to decrease their dose of inhaled steroid by 50% or more compared to 32% receiving placebo. Similarly, 34% and 12% of omalizumab and placebo patients respectively were able to discontinue inhaled steroids.

#### **QUALITY OF LIFE TRIALS**

Asthma-related quality of life was also assessed in trials 008 and 009.<sup>5,6</sup> The Juniper Asthma Quality of Life Questionnaire (AQLQ) was used. This validated questionnaire is grouped into 4 domains: activity limitations (11 items), emotions (5 items), symptoms (12 items), and exposure to environmental stimuli (4 items). Each question is answered by the patient on a 7-point scale according to the level of impairment in the preceding 2 weeks. A lower score reflects greater impairment. An increase in domain or total score of  $\geq 0.5$  points is considered clinically meaningful and an increase  $\geq 1.5$  points is considered a large improvement. The AQLQ was assessed at the end of the steroid-stable, steroid-reduction, and extension phases. Total baseline scores in study 008 were 4.0 and 4.2 with omalizumab and placebo respectively and were 4.43 and 4.36 respectively in study 009. The omalizumab-treated patients had a larger increase in the AQLQ score and a greater percentage achieving a  $\geq 0.5$  or  $\geq 1.5$  point increase than did the placebo-treated patients.

**Table 4. AQLQ results**

	Trial 008		Trial 009	
	Omalizumab	Placebo	Omalizumab	Placebo
<b>Steroid stable phase</b>				
Mean change in AQLQ score	0.93*	0.66	0.9*	0.6
% with $\geq 0.5$ point change	64.1%*	51.7%	62%	55%
% with $\geq 1.5$ point change	28.3%*	18.6%	22%*	17%
<b>Steroid reduction phase</b>				
Mean change in AQLQ score	0.97*	0.7	1.02*	0.65
% with $\geq 0.5$ point change	66.4%*	54.8%	68%*	57%
% with $\geq 1.5$ point change	32.8%*	17.8%	30%*	18.5%
<b>Extension trial</b>				
Mean change in AQLQ score	1.19*	0.91	1.15*	0.8
% with $\geq 0.5$ point change	74.6%*	65.5%	68%	70%
% with $\geq 1.5$ point change	42.1%*	27%	32%*	24%

\*Significant versus placebo; Results for study 009 estimated from graph

Evaluation of treatment effectiveness was assessed at the end of 28 weeks by both the patient and the investigators. Asthma control was rated as excellent (complete control), good (marked improvement), moderate (discernible but limited improvement), poor (no appreciable change), or worse. More than half the patients and clinicians considered the asthma control to be excellent or good.

**Table 5. Patient and clinician assessment of asthma control**

	Trial 008		Trial 009	
	Omalizumab	Placebo	Omalizumab	Placebo
Excellent/good (Patient/ clinician)	60.6% / 53.1%	38.1% / 33.3%	68% / 65%	40% / 33%
Moderate (Patient/ clinician)	21.9% / 28.9%	27% / 26.3%	19% / 20%	32% / 34%
Poor/ worse (Patient/ clinician)	17.6% / 18%	34.9% / 40.4%	11% / 12%	28% / 30%

Results for trial 009 estimated from graph

### SEASONAL ALLERGIC RHINITIS

Omalizumab has been evaluated for prophylaxis of symptoms of seasonal allergic rhinitis (SAR) in a large 12-week trial.<sup>7</sup> Patients aged 12-75 years (n=536) with  $\geq 2$  year history of ragweed-induced SAR and a baseline IgE level between 30-700 IU/ml were randomized to receive omalizumab or placebo. Treatment began just prior to ragweed season and continued throughout the pollen season. Patients with IgE levels between 151-700 IU/ml were given, 50mg, 150mg, or 300mg SQ every 3 weeks for a total of 4 doses. For IgE levels between 30-150 IU/ml, the dose was administered every 4 weeks for a total of 3 doses. The primary outcome measure was daily nasal symptom severity score. Compared to placebo, only the 300mg dose significantly resulted in a lower nasal score (0.75 vs. 0.98). Other endpoints included ocular symptom severity and rescue antihistamine use. All 3 doses resulted in improved ocular symptoms. Rescue antihistamine use was slightly lower in the omalizumab 300mg and 150mg groups versus placebo.

### SAFETY AND TOLERABILITY

From a database of 2076 patients, of whom 1687 were exposed for 6 months and 555 were exposed for a year or more, the most frequent adverse events included injection-site reactions (45%), viral infection (23%), upper respiratory tract infection (20%), sinusitis (16%), pharyngitis (11%), or headache (15%).

It is not known whether IgE plays a role in surveillance in cancer prevention. If IgE is blocked there is a theoretical question of whether there is an associated increase in cancer incidence. The incidence of new or recurrent cancer was 0.5% with omalizumab and 0.2% with placebo. When expressed as 1000 patient-years of exposure the event rate was 6.3 and 3.3 respectively. The types of malignancies observed included breast, melanoma, non-melanoma skin, prostate, and parotid. Most patients were observed for less than a year. It is unknown if longer exposure or use in patients higher risk factors for malignancy increases the risk of developing cancer. It should be kept in mind that current smokers were excluded from the trials; therefore, it is unknown if their risk for cancer is further increased. The sponsor is planning long-term trials to determine whether there is a relationship between omalizumab treatment and cancer.

Anaphylaxis occurred in 4 omalizumab patients and in 3 control patients. In one of the omalizumab cases, the event was temporally associated with exposure to levofloxacin. In the 3 cases temporally related to omalizumab, the onset of the reaction began within 2 hours of the first or subsequent dose. Symptoms included urticaria, dyspnea, and throat and/or tongue edema.

Injection site reactions were common in both groups with an incidence of 45% in the omalizumab group and 43% in the placebo. Of these, 12% with omalizumab and 9% with placebo were considered severe. Symptoms included bruising, redness, warmth, burning, stinging, itching, hive formation, pain induration, mass, and inflammation. The reaction usually occurs within one hour of the injection, lasts less than 8 days and generally diminishes with subsequent injections.

No patient developed anti-omalizumab antibodies and there was no evidence of immune complex disease.

Only a small number of patients  $\geq 65$  years old (n=142) received omalizumab. It appears this group may have had a higher incidence of adverse events compared to those  $< 65$  years old. Compared to the control group aged  $\geq 65$ , the incidence of body as a whole, cardiovascular, digestive, musculoskeletal, nervous, and GU/reproductive adverse events were higher.

**DRUG INTERACTIONS**

No formal drug interaction trials have been conducted.

**DOSAGE**

Omalizumab is administered subcutaneously. Dose and dosing frequency is based on serum total IgE level measured before the start of treatment and body weight (Table 6). No more than 150mg is injected at a single site. Doses  $> 150$ mg are to be divided among more than 1 injection site. Dosage adjustments may be made based on changes in body weight. Repeat IgE levels cannot be used to adjust dose as total levels which measure both the omalizumab:IgE complex and free IgE are elevated.

**Table 6. Omalizumab dosing**

Pre-tx serum IgE (IU/mL)	Body weight (kg)				Dosing frequency
	30-60	>60-70	>70-90	>90-150	
30-100	150mg	150mg	150mg	300mg	Q4 weeks
>100-200	300mg	300mg	300mg	225mg	Q2 weeks
>200-300	300mg	225mg	225mg	300mg	
>300-400	225mg	225mg	300mg	Do not dose	
>400-500	300mg	300mg	375mg		
>500-600	300mg	375mg	Do not dose		
>600-700	375mg	Do not dose			

**PREPARATION FOR ADMINISTRATION**

Omalizumab is for single use only and contains no preservatives. The solution should be used for SC administration within 8 hours following reconstitution when stored in the vial at 2-8°C (36-46°F), or within 4 hours of reconstitution when stored at room temperature.

The lyophilized product takes 15-20 minutes to dissolve. The fully reconstituted product will appear clear or slightly opalescent and may have a few small bubbles or foam around the edge of the vial. The reconstituted product is somewhat viscous; in order to obtain the full 1.2 mL dose, ALL OF THE PRODUCT MUST BE WITHDRAWN from the vial before expelling any air or excess solution from the syringe.

A vial delivers 1.2 mL (150 mg) of omalizumab. For a 75 mg dose, draw up 0.6 mL into the syringe and discard the remaining product.

**COST**

The FSS cost for each 150mg vial is \$323.29.

Dose	# of vials/ month	Cost/year
150mg	1	\$3879.49
300mg	2	\$7758.96
450mg (administered as 225mg twice monthly)*	4	\$15, 517.92
600mg (administered as 300mg twice monthly)	4	\$15, 517.92
750mg (administered as 375mg twice monthly)*	6	\$23,276.88

\*For a 75mg dose, withdraw 0.6ml and discard remaining product

## SUMMARY

In the 2 pivotal trials, the omalizumab group had half as many exacerbations, when defined as worsening of asthma requiring treatment with systemic steroids or a doubling of the ICS dose, compared to placebo. The omalizumab treated patients were also able to reduce their baseline dose of ICS by about 1/4 more than the placebo group. Unscheduled outpatient visits were less frequent in the omalizumab treated group than the placebo group; however, hospitalization or ER visits due to asthma were not significantly different between the groups. It should be kept in mind that the pivotal trials enrolled a relatively “less sick” population who were taking, on average, moderate doses of ICS, not taking any other asthma controller drugs including oral steroid maintenance and had few urgent office or ER visits or hospitalizations in the year prior to enrollment.

Patients in trial 011 had more severe asthma than those in the pivotal trials. Unfortunately, asthma exacerbation, defined as need for systemic steroids, was a secondary endpoint. Nevertheless, the exacerbation rates did not differ significantly between groups. The median decrease in ICS dose was about 10% greater in the omalizumab group versus placebo. In contrast, the 2 open label trials did show benefit in a population with more severe disease; however, the open-label nature makes it difficult to draw firm conclusions.

Omalizumab does not have an effect on FEV1 or PEF and a relatively small favorable effect on asthma symptoms scores and rescue albuterol use.

Given the cost of this drug, it is unlikely that it will be used in patients with moderate allergic asthma. Blinded trials evaluating a population of severe asthmatics are needed, particularly in those who are oral steroid dependent.

Other areas where data are needed are in individuals who are  $\geq 65$ y/o, smokers, non-white, and who have COPD with an asthmatic component. Also needed are long-term efficacy and safety data beyond one year of exposure and blinded trials evaluating omalizumab in patients whose asthma and allergy treatments have been optimized.

The safety of omalizumab use in those traveling to endemic parasitic regions is unknown. There is an ongoing study in Brazil evaluating omalizumab in patients who have intestinal helminthic exposure.
