## INTRODUCTION

The passage of the National Environmental Policy Act in 1970 curtailed further development and exploitation of the natural environment without due consideration for the environment's welfare. The Act required an environmental impact statement prior to the development of alteration of the environment.

Oil exploitation and development was underway in 1976 in an area off South Texas in the Gulf of Mexico (Fig. 1). The Bureau of Land Management (BLM) was responsible for the leasing of this offshore area to various oil companies for exploration and development. As part of this responsibility, BLM developed an environmental impact statement for this area and implemented a program to develop precise and relevant baseline information to provide data upon which future management decisions can be made.

To obtain the baseline data and information needed, BLM obtained the services of various universities and federal agencies. The Gulf Fishery Center, National Marine Fisheries Service (NMFS), was responsible to BLM for certain studies concerning the environmental and biological assessment of the lease area. To meet NMFS responsibilities, studies were conducted, or analyses made, on hydrology, plankton, bottom fish, crustaceans, pelagic fish, and recreational fisheries. This paper concerns the recreational fisheries survey conducted in the South Texas coastal area during 1975-76.

Two excellent reviews are available on the effects of oil on the marine ecosystem (Evans and Rice 1974, Rose 1974) but the impact of oil, or of oil exploration and development, on recreational fisheries is not dealt with specifically. Alterations of the environment resulting from oil exploration and development can have both positive and negative effects on recreational fisheries. The ability of fishermen to catch fish can be greatly improved as a result of building permanent structures in the water column in offshore areas (Wickham, Watson, and Ogren 1973). These structures serve to attract and congregate fish in localities that are easily found by the fishermen. Some alterations resulting from oil development, however, can have negative effects on recreational fisheries. Pipelines and storage tanks are often constructed in estuarine areas. These alterations can destroy, or decrease, the productivity of an area or otherwise make the area undesirable for recreational fishing. Crude oil, resulting from oil spills or seepage at varying levels of concentration, is toxic to marine organisms, including the recreational fish species and the organisms upon which they feed (Evans and Rice 1974). The effects of chronic low-level oil pollution on marine organisms is less understood but could have more deleterious effects on the biotic community than do sporadic high levels. Oil spills can seriously damage recreational fishing without causing harm to the fish populations. If, as a result of unsightly spills, the apparent desirability of an area for fishing is reduced, the amount of fishing effort may be correspondingly decreased. Thus, the resource becomes less valuable and the incomes of people, dependent upon income from services provided to recreational fishermen, are decreased.

Important marine recreational fisheries exist along the South Texas coast from Port Aransas to Port Isabel. These fisheries can be classified as: inshore where fishing occurs in bays, marshes, and rivers shoreward of tidal

Figure 1. Area leased for oil exploration and development in South Texas.

inlets; onshore where fishing occurs from jetties, piers, and the beach in shallow waters; and offshore where fishing occurs from boats in water depths of 1.8-182.9 m. This study deals only with the onshore and offshore fisheries.

Some data on recreational fisheries in the South Texas study area (including inshore) are available from: creel censuses taken by Springer and Pirson (1958), and the Texas Parks and Wildlife Department (Heffernan et. al. 1976); research conducted on artificial reefs (Martinez 1963, Stevens 1963, Texas Coastal and Marine Council 1974); national surveys (Clark 1962, Deuel and Clark 1968, U.S. Department of Interior 1972, Deuel 1973); billfish surveys by the NMFS (Rivas 1975, Rivas and Pristas 1975, Nakamura 1976); and from economic surveys (Grubb 1969, Kitchen and James 1970, Texas Game and Fish Commission 1958, 1960). The value of the fisheries in the study area in terms of fishing effort, catches, and dollars to the local economies, has not, however, been determined in much detail. The need for, and use of, information of this type for the Texas coast were documented in detail in a proposal by Ditton and Jarmon (1974).

The objectives of this study were to estimate for the daytime onshore and offshore fisheries from May 1975 through April 1976 (1) seasonal and total fishing effort by recreational fishermen, (2) catch per unit effort for the dominant species caught in each fishery, and (3) the approximate value of these fisheries to the local economy.

#### STUDY AREA

Fishing sites in the study area can be precisely delineated for the onshore fishery (jetty, pier, and beach) but not for the offshore fishery (Fig. 2). For the onshore fishery, the study area extends from and includes the south jetty at Port Aransas to and including the north jetty at Port Isabel on the beach side of the islands. Included are two piers on Mustang Island and one pier on Lower Padre Island. For the offshore fishery, the study area is defined as the area fished by boats that depart and return during the same day through the channels at Port Aransas and Port Isabel. Most of this fishing effort, with the exception of the larger boats, is expended within a 20-mile radius of one of the channels. The larger boats usually fish within a 50-mile radius of one of the channels.

#### SAMPLING METHODS

All sampling was done by three survey technicians through direct observation and personal interview. Each technician on any given workday either counted the number of fishing units (boats or people), or interviewed people to determine the length of time they had been fishing and what they had caught, or both. Two survey technicians were located at Port Aransas and one at Port Isabel.

A stratified random sampling scheme was used to estimate the total amount of fishing effort expended in the study area. Strata, and the number of units in each, were: 2-week periods (26), regions (2), sections (4), types of fishing platforms (6), and times of week (2). Regions and sections are shown in Figure 2. Types of fishing platforms were: head or party boats, inboard boats, outboard boats, jetties, piers, and beaches. Times of week were weekdays (WD), except holidays, and weekend-days (WED) including holidays. Days for sampling

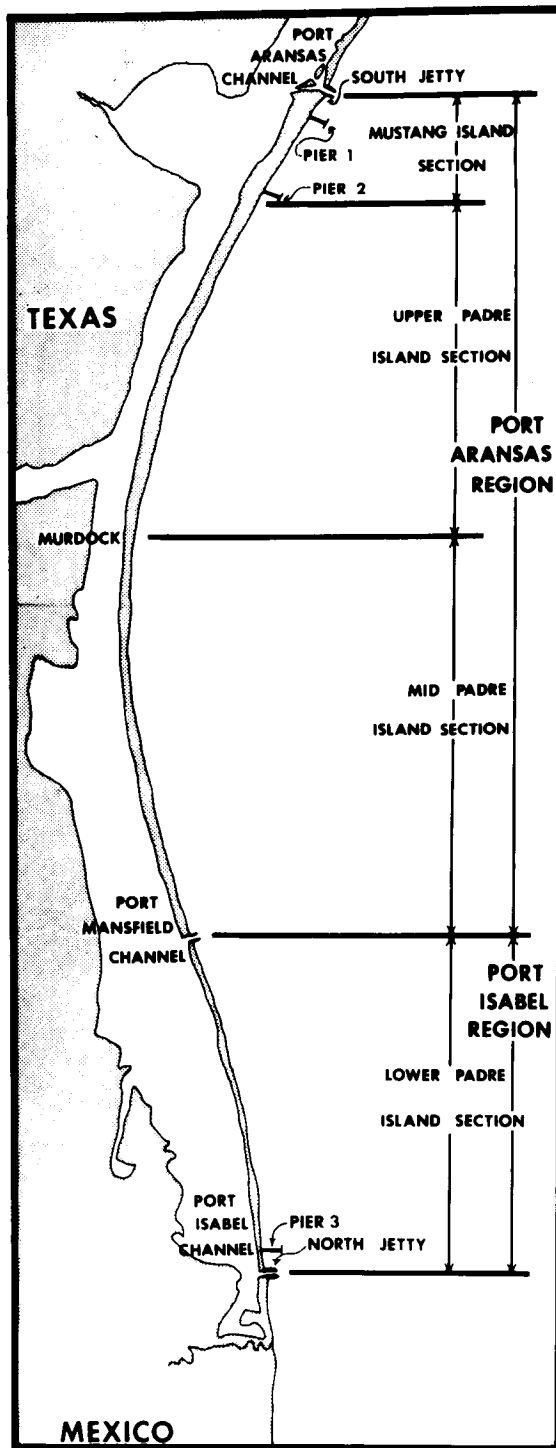

Figure 2. Regions, sections, and fishing platforms in the South Texas study area.

within each stratum complex were selected at random with the only restrictions on randomization being in those situations where two or three jobs were selected on the same day and only one (Port Isabel) or two (Port Aransas) technicians were available to perform these jobs.

Fishing effort (number of boats going or returning from fishing, or number of people fishing) was determined as follows by a single survey technician on a given randomly selected day. Jetty fishermen, and the number of fishing boats, were counted by a technician located at the jetty (Mustang Island or Lower Padre Island section) from 7 a.m. to 7 p.m. Boats were identified, using binoculars, and recorded as they exited or entered each tidal pass and the numbers of people fishing on the jetty were counted at 2-hr intervals. The survey technician had to classify the boat, at the time of sighting, using his best judgment as to whether it was or was not a recreational fishing boat. On other days: the number of beach and pier fishermen were counted in the morning and in the afternoon (Mustang Island or Lower Padre Island section); the number of beach fishermen were counted during the morning and afternoon (Upper Padre or Mid Padre Island section). The time of day the counts were made could not be randomized because 2-4 hr were required to make each count. This cycle was repeated during each 2-week period within each time of week with two exceptions. Occasionally, sampling days were missed because of sickness. The Mid Padre Island section was not surveyed on a regular schedule until late August and was surveyed only half as frequently as the other sections during the latter part of the survey.

Catch-effort data were obtained by asking fishermen or boat captains the number of hours fished and the number of each species caught during the respective time period. For boats, the number of people aboard during the particular trip was also determined. As many interviews as possible were obtained during the allotted times at boat landings and docking sites; care was taken to obtain information about each boat type. Catch-effort data were obtained from beach and pier fishermen during the time that effort counts were made, whereas these data were obtained from boat fishermen usually on days other than those that effort counts were made. All interviews of boat and jetty fishermen represented completed-trip interviews. Those of beach and pier fishermen were mixed (complete- and incomplete-trip interviews).

The basic unit of fishing effort was defined as one person fishing during 1 day. We defined this as a man-day of fishing. We counted boats going or coming from fishing, and people in the act of fishing, during daylight hours only. The following methods were used to convert our effort counts to man-days of fishing. For boats, we assumed that we counted all boats that went fishing on a particular day based on the assumption that all boats entering the Gulf before 7 a.m. returned before 7 p.m. and that all boats that returned after 7 p.m. entered the Gulf after 7 a.m. Based on this assumption, we used the total number of boats exiting or entering the Gulf, whichever was higher. By using our estimates of the total number of boats fishing during a particular day, and determining the average number of people that fished on a particular boat type, we were able to estimate the total number of man-days of fishing on the sampling dates. For jetty, pier, or beach platforms, we averaged our counts of fishermen for a particular day, assumed that the average count represented an instantaneous

count during daylight hours (12), determined the average length of a fishing trip, divided this average into 12, and multiplied this factor by the mean number of fishermen counted on the particular day.

These estimates of the number of man-days fishing on the sampling days were then used to expand over monthly or greater periods of time within the various strata.

#### SEASONAL ASPECTS OF FISHING EFFORT

The greatest daily amount of fishing effort from boat platforms occurred from April through September (Fig. 3 and Tables 1-2). Daily effort from outboard and inboard boats was generally much higher on weekend-days than on weekdays during the warmer months; this difference was not observed for headboats. Seasonal patterns in fishing effort between Port Aransas and Port Isabel appeared similar for outboard and inboard boats but not for headboats. Fishing effort from headboats was drastically reduced during December-February in Port Aransas but not in Port Isabel.

Fishing effort varied through time at the shore platforms (Figs. 4-5) but did not show distinct seasonal patterns. Effort at jetties and piers was much higher during weekend-days than weekdays during the warmer months whereas this difference occurred on the Upper Padre Island Beach throughout the year.

Fishing effort from shore platforms showed much less seasonal change than did effort from boat platforms (Figs. 3-5). Observed differences in effort patterns between boat and shore platforms were probably caused by seasonal differences in weather and fish availability. During the colder months, weather is not suitable for small boat operation much of the time and most pelagic species (king mackerel, Scomberomorus cavalla; Spanish mackerel, S. maculatus; bluefish, Pomatomus saltatrix; etc.) are not available. In contrast, fishing for some species of nearshore fishes is often better during winter than summer and jetties, piers, and beaches provide easy, comfortable, and safe access to fishing.

#### ESTIMATES OF TOTAL EFFORT

Estimates of the mean daily effort, and the total effort, in man-days of fishing for the 12-month period in relation to section and fishing platform are shown in Table 1. The average amount of effort per day was greater on weekend-days than weekdays for each platform and section except headboats and the pier in the lower Padre Island section. The daily intensity of fishing effort on weekend-days was more than twice that on weekdays for outboard and inboard platforms in the Mustang Island and Lower Padre Island sections and the beach platform in Upper and Mid Padre Island sections. Total effort between weekdays and weekend-days varied between platforms and sections. Overall a slightly larger amount (55%) of the total effort was expended during weekdays (329,132 versus 264,226 man-days).

By far the greatest amount of fishing effort occurred in the Mustang Island section of the study area. Percents of the total fishing effort in relation to section were: Mustang Island, 61.6%; Upper Padre, 5.5%; Mid Padre, 1.0%;

Figure 3. Estimated mean daily numbers of fishermen at the Port Aransas and Port Isabel tidal passes by time of week, boat type, and 4-week interval.

\*After expansion for inflation.

Figure 4. Mean instantaneous numbers of people fishing from jetties and piers in relation to section, time of week, and 4-week interval.

Figure 5. Mean instantaneous numbers of people fishing from the beach in relation to section, time of week, and 4-week interval.

and Lower Padre, 21.9%. The amount of effort expended in the Mid Padre section may be seriously underestimated, because counts for computing mean effort were not made in this section during April through mid-August.

Of the two general types of fishing platforms (shore and boat), the shore platforms accounted for 80% of the total effort expended in the study area. Within the Mustang Island and Lower Padre Island sections, the shore platforms accounted for 79% and 80%, respectively, of the total fishing effort.

In the Mustang Island section, the two piers accounted for the most and outboards accounted for the least amount of fishing effort. The estimated total man-days of fishing in relation to platform were: pier, 177,120; beach, 96,671; jetty, 61,669; headboat, 42,532; inboard, 32,231; and outboard, 14,709.

The order of importance of the platforms in the Lower Padre Island section was quite different from that in the Mustang Island section. The estimated total man-days of fishing were: jetty, 54,820; beach, 43,467; inboard, 12,011; headboat, 8,021; outboard, 6,091; and pier, 5,777.

The pier and beach were the most important fishing platforms in terms of man-days of fishing in the entire study area. Percents of the total fishing effort in relation to platform were: pier, 30.8%; beach, 30.1%; jetty, 19.6%; headboat, 8.5%; inboard, 7.4%; and outboard, 3.5%.

#### VALUE OF THE FISHERIES

Conceptual problems involved in defining and estimating the values of recreational fisheries are complex and generally similar to the difficulties encountered in the estimation of the value of outdoor recreation (Gordon, Chapman, and Bjornn 1973). Three types of estimates are frequently used to determine the value of recreational fisheries. These are gross expenditures, net economic values, and capitalized values.

Gross expenditures include the monies spent by anglers in connection with fishing and are categorized into transfer and durable costs. Transfer costs include expenses such as transportation, food, and lodging incurred while traveling to, using, and returning home from, the fishing area. Durable costs are those for fishing equipment such as tackle, boats, and special clothing that can be used over a period of months or years.

Net economic value for marketed goods is generally defined as the difference between total income and total costs. For recreational fisheries it is difficult to establish a "net" value because the "price" or cost to the fishermen is usually minimal and does not reflect the real value placed on the resource. Thus, it is necessary to formulate a basis of comparison between "net" values of marketed goods and services and non-market recreation-associated activities. The principal difference between outdoor recreation and marketed goods and services is the pricing mechanism. To provide a basis for evaluating the "price" or cost of using outdoor recreational resources, Clawson (1959) simulated a market using transfer costs. In sport fisheries where license fees are non-existent or usually a negligible part of total costs, more expenditures are transfer costs except for the resident fishermen. Gordon et al. (1973) used transfer costs as a basis for estimating the net economic value of an Idaho sport fishery resource.

Capitalized values can be determined using the relation  $V = N/i$  where  $V$  = present capitalized value,  $N$  = annual return, as measured by net value (see above), and  $i$  = interest rate.

The above two paragraphs are academic and were included to define the methods, other than the gross expenditure method, available to estimate values of recreational fisheries. We obtained data on the amount of fishing effort in the study area but did not obtain expenditure data. To estimate the value of the fisheries, we used our estimates of effort, and expenditure estimates from the 1970 National Survey of Fishing and Hunting (U.S. Department of Interior 1972). In the 1970 survey, it was estimated that, along the Gulf coast, each man-day of salt-water fishing cost \$11.36 (gross expenditure). This cost was multiplied times the effort estimates shown in Table 1 and the value estimates of the fisheries in the study area are shown in Table 2. We consider some, if not all, of the values in column 3 to be grossly conservative, and have used them as our minimum estimates of the value of the fishery.

We believe our estimates (column 3) of the value of recreational fisheries in the South Texas study area are extremely conservative, because (1) the expenditure value was determined in 1970 and has not been adjusted for inflation, (2) the fishing effort that occurred at night was not estimated, and (3) the non-user fishery values were not estimated. Inflation rate since 1970 has averaged about 8% per year. This means that, if direct expenditures in recreational fisheries have increased at the same rate, then our estimate of \$6.74 million in the study area could be adjusted upward to \$9.90 million (column 4). The amount of fishing effort that occurred at night was not estimated, but we know that considerable effort is expended at night from the jetties, piers, and beaches; if nighttime effort on these platforms was 40% of the daytime effort, then the estimate of the total value would be \$13.1 million (column 5). Non-user values of fishery resources have not been estimated in terms of dollars in any fishery, but the values nevertheless exist. Many citizens who will never fish place value on the fisheries and the fish. In some instances, such as on fishing piers, non-fishermen will actually pay to merely observe fishing activity.

Our estimates of the amount of fishing effort, and the amount of money spent in the study area, are difficult to compare with the most recent data base that completely covers our study area. The 1970 National Survey of Fishing and Hunting provides salt-water recreational fishing effort and expenditure data for the entire U.S. Gulf of Mexico coastline for 1970. The 1970 Survey reported 35.62 million recreational fishing days expended, and \$404.65 million spent, in the U.S. Gulf of Mexico salt-water fishery. This value of \$404.65 million, after adjustment for inflation, becomes \$594.56 million. The 1970 Survey included estuarine as well as onshore and offshore fishing. Based on a study conducted in St. Andrew Bay, Florida (Doyle Sutherland, personal communication), we estimated that 63.8% of the effort recorded in the National Survey occurred in inshore waters. The values in the National Survey were therefore adjusted downward (36.2% of the totals) to 12.9 million man-days and \$215.2 million. For the 12 months in this study, we estimated that 0.59 million man-days of effort were expended and that the fishery was valued at between \$6.7 and \$13.1 million. The area from Port Aransas to Port Isabel includes about 10% of the Gulf coastline and the population in counties adjacent to the study area represents about 10% of the

population of the Gulf coastal counties. Based on the above estimates and assumptions, and not accounting for changes that possibly occurred in the amount of fishing effort during the past 5 years, we estimated that about 5% of the total fishing effort, and 3.1% to 6.1% of the total recreational fishery values in the U.S. Gulf of Mexico (excluding inshore waters) are generated in the study area.

The value of the recreational fishery in 1975-76, based on our estimates, was many times greater than the value of the commercial fishery in 1974 in the study area. The commercial landings of finfish from the study area in 1974 were valued at about \$0.48 million (Caillouet 1976).

#### CATCH PER UNIT EFFORT

A total of 70 species was caught by fishermen and identified by our field personnel during the survey (Table 3 and 4). In addition, at least 13 other species were caught, but identification to species or genus was not obtained for these catches.

There are at least two ways to evaluate the importance of a particular fish species to a recreational fishery. One way is to ask the fisherman what he or she is fishing for and obtain this type of information from a large number of fishermen. When the results are tabulated, one then determines the relative value of each species based on the percents of the fishermen that fish for each species. A second way is to evaluate the catches by fishermen and list the species in order of decreasing catch per unit effort. We used the second method.

Listed in Tables 4 and 5 are the species (or species groups) which comprised the 10 most abundantly caught species from each platform within each section. Only the top five species within each platform and section will be discussed.

In the Mustang Island boat fishery, king mackerel and crevalle jack were among the top five species caught from each boat type. The other species comprising the top five, in relation to boat type, were: outboard - Spanish mackerel, spotted seatrout, and sand seatrout; inboard - Spanish mackerel, red snapper, and dolphin; and headboat - red snapper, sandbar shark, and blacktip shark.

In the Mustang Island shore fishery, sea catfish and Atlantic croaker were among the top five species caught from each platform. The other species comprising the top five in relation to platform were: jetty - sand seatrout, pinfish, and sheepshead; pier - pinfish, Gulf kingfish, and southern kingfish; and beach - Gulf kingfish, southern kingfish, and sand seatrout.

From the beach in the Upper and Mid Padre Island sections, four species (Spanish mackerel, sea catfish, Gulf kingfish, and bluefish) were among the top five caught in both sections. Others among the top five were ladyfish along Upper Padre and sheepshead along Mid Padre.

In the Lower Padre Island section, six species comprised the top five in the outboard and inboard platforms combined. Common to both platforms were crevalle jack, red snapper, king mackerel, and little tunny. Dolphin (outboard)

Table 3. Common and scientific names of species caught and identified in this study

Common Name	Scientific name
Spotted seatrout	<u>Cynoscion nebulosus</u>
Sand seatrout	<u>Cynoscion arenarius</u>
Atlantic croaker	<u>Micropogon undulatus</u>
Spot	<u>Leiostomus xanthurus</u>
Red drum	<u>Sciaenops ocellata</u>
Black drum	<u>Pogonias cromis</u>
Gafftopsail catfish	<u>Bagre marinus</u>
Sea catfish	<u>Arius felis</u>
Gulf flounder	<u>Paralichthys albigutta</u>
Southern flounder	<u>Paralichthys lethostigma</u>
Florida pompano	<u>Trachinotus carolinus</u>
Spanish mackerel	<u>Scomberomorus maculatus</u>
King mackerel	<u>Scomberomorus cavalla</u>
Bluefish	<u>Pomatomus saltatrix</u>
Cobia	<u>Rachycentron canadum</u>
Creville jack	<u>Caranx hippos</u>
Blue runner	<u>Caranx crysos</u>
Dolphin	<u>Coryphaena hippurus</u>
Atlantic spadefish	<u>Chaetodipterus faber</u>
Little tunny	<u>Euthynnus alletteratus</u>
Wahoo	<u>Acanthocybium solanderi</u>
Great barracuda	<u>Sphyrna barracuda</u>
Sandbar shark	<u>Carcharhinus milberti</u>
Red snapper	<u>Lutjanus campechanus</u>
Blacktip shark	<u>Carcharhinus limbatus</u>
Greater amberjack	<u>Seriola dumerili</u>
Bull shark	<u>Carcharhinus leucas</u>
Sheepshead	<u>Archosargus probatocephalus</u>
Scamp	<u>Mycteroperca phenax</u>

Gulf kingfish						.412
Gulf flounder						.019
Black drum						.019

\*One or more species.

and Spanish mackerel (inboard) were also included in the top five species. The top five species caught from headboats were red snapper, little tunny, sandbar shark, grouper, and triggerfish.

The five species caught in highest abundance from the shore platforms in the Lower Padre Island section were: jetty - pinfish, sea catfish, sand seatrout, southern kingfish, and Atlantic croaker; pier - sea catfish, Atlantic threadfin, Atlantic spadefish, king mackerel, and sheepshead; beach - Gulf kingfish, sea catfish, southern kingfish, ladyfish, and king mackerel.

The seasonal abundance, as indicated by catch per unit effort estimates, of the five most abundant species within each platform and section are shown in Tables 6 and 7. These estimates could not be made for the Mid Padre Island section, and for the outboard, headboat, pier, and beach platforms in the Lower Padre Island section, because the data were insufficient.

Catch rates were distinctly seasonal for some of the 18 species shown in Tables 6 and 7. The pelagic species (king mackerel, Spanish mackerel, crevalle jack, little tunny, ladyfish, bluefish, and dolphin) were most abundant during the spring, summer, or fall and were absent during the winter with the exception of bluefish. Each of the sciaenid species (spotted seatrout, sand seatrout, Atlantic croaker, Gulf kingfish, and southern kingfish), and pinfish, sea catfish, sheepshead, and red snapper, were caught during each season but the highest catch per unit effort varied among seasons when platforms and areas were considered. For example, highest catch per unit effort of Atlantic croaker occurred during the autumn at both jetties, during the winter and summer at the Port Aransas piers, and during the summer at the beach on Mustang Island. Both the sandbar and blacktip shark were caught during every season.

#### SUMMARY AND CONCLUSIONS

1. Data were collected and estimates made for the period 28 April 1975 through 24 April 1976.
2. During the above period, the greatest amount of fishing effort from boats occurred from April through September in the Port Aransas to Port Isabel area. In contrast, the amount of effort remained relatively constant throughout the year from the jetty, pier, and beach platforms.
3. The intensity of fishing effort was over twice as great on weekend-days as weekdays.
4. A slightly larger amount (55%) of the total effort was expended during weekdays.
5. Percents of total fishing effort in relation to section were: Mustang Island, 7.6; Upper Padre, 5.5; Mid Padre, 1.0; and Lower Padre, 21.9.
6. The estimated total man-days of fishing in relation to platform in the study area were: pier, 182,897 (30.8%); beach, 178,377 (30.1%); jetty, 116,489 (19.6%); headboat, 50,553 (8.5%); inboard, 44,242 (7.4%); and outboard, 20,800 (3.5%).

Table 6. Listing of the species comprising the five most abundantly caught, and the mean number caught per fisherman hour, in relation to platform and season in the Mustang Island section

Platform and species	Winter	Spring	Summer	Autumn
-----Mean number caught per fishermen hour-----				
Outboard

Atlantic croaker	.019	.068	.008	.190

7. The estimated total number of man-days of fishing during the 12-month period was 593,358.
8. The total value of the recreational fisheries in the study area during the 12-month period was estimated between \$67.4 and \$13.1 million. These values were derived from our estimates of effort, and from gross expenditure values taken from other studies.
9. At least 83 species were caught by recreational fishermen during the survey.
10. The three species caught in greatest abundance in relation to platform in the Mustang Island section were: outboard - king mackerel, Spanish mackerel, and crevalle jack; inboard - king mackerel, crevalle jack, and red snapper; headboat - red snapper, king mackerel, and crevalle jack; jetty - sand seatrout, pinfish, and sheepshead; pier - sea catfish, and southern kingfish. All of these species except three were caught during all seasons. King mackerel, Spanish mackerel, and crevalle jack were not caught during the winter.

### **The Department of the Interior Mission**

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering sound use of our land and water resources; protecting our fish, wildlife, and biological diversity; preserving the environmental and cultural values of our national parks and historical places; and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to ensure that their development is in the best interests of all our people by encouraging stewardship and citizen participation in their care. The Department also has a major responsibility for American Indian reservation communities and for people who live in island territories under U.S. administration.

### **The Minerals Management Service Mission**

As a bureau of the Department of the Interior, the Minerals Management Service's (MMS) primary responsibilities are to manage the mineral resources located on the Nation's Outer Continental Shelf (OCS), collect revenue from the Federal OCS and onshore Federal and Indian lands, and distribute those revenues.

Moreover, in working to meet its responsibilities, the **Offshore Minerals Management Program** administers the OCS competitive leasing program and oversees the safe and environmentally sound exploration and production of our Nation's offshore natural gas, oil and other mineral resources. The MMS **Minerals Revenue Management** meets its responsibilities by ensuring the efficient, timely and accurate collection and disbursement of revenue from mineral leasing and production due to Indian tribes and allottees, States and the U.S. Treasury.

The MMS strives to fulfill its responsibilities through the general guiding principles of: (1) being responsive to the public's concerns and interests by maintaining a dialogue with all potentially affected parties and (2) carrying out its programs with an emphasis on working to enhance the quality of life for all Americans by lending MMS assistance and expertise to economic development and environmental protection.
