WORKSHOP ON IMPLEMENTATION OF
UNIVERSAL LEUKOREDUCTION

+ + + + +

FRIDAY, DECEMBER 10, 1999

+ + + + +

The Workshop was held in the Natcher Auditorium, NIH, Bethesda, Maryland 20892 at 8:30 a.m., Jong-Hoon Lee, M.D., Chair, presiding.

PRESENT:

JONG-HOON LEE, M.D.	Chair
CAPTAIN MARY GUSTAFSON	Speaker
EDWARD SNYDER, M.D.	Speaker
CAROLYN JONES	Speaker
BETSY POINDEXTER	Speaker
LARRY FENNER	Speaker
STEPHANIE NORRELL	Speaker
WILLIAM ANDREW HEATON, M.D.	Speaker
CELSO BIANCO, M.D.	Speaker
JIM MacPHERSON	Speaker
JAY MENITOVE, M.D.	Speaker
DENNIS GOLDFINGER, M.D.	Speaker
JOHN WHITBREAD, PhD	Speaker
HARVEY KLEIN, M.D.	Speaker

ALSO PRESENT:

JUDY CIARALDI
LES HOLNESS, M.D.
JAY EPSTEIN, M.D.

	<u>Page</u>
<u>I. Introduction to Universal Leukoreduction</u>	
Welcome, Captain Mary Gustafson	7
Workshop Goals and Overview, Dr. Lee	9
Leukoreduction, Blood Quality and the Transfusion Recipient - Edward Snyder, M.D.	21
Filter Availability, Carolyn Jones	55
<u>II. The Regulatory Approach</u>	
FDA Expectations: Whole Blood and Cells, Dr. Lee	65
FDA Expectations: Platelets, Betsy Poindexter	87
FDA Expectations, Regulations, Captain Mary Gustafson	105
Compliance, Transition Period, Larry Fenner	115
<u>III. Experience to Date and Proposals on Implementation</u>	
The American National Red Cross Stephanie Norrell	125
Blood Systems, Inc., William Heaton, M.D.	142
New York Blood Center, Celso Bianco, M.D.	163
Community Blood Center, Greater Kansas City Jay Menitove, M.D.	178
Cedars-Sinai Medical Center Blood Bank Dennis Goldfinger, M.D.	187
<u>IV. Open Discussion and Concluding Remarks</u>	
Open Presentations and Discussion	201
Review of Workshop Objectives, Dr. Lee	216
Concluding Remarks, Harvey Klein, M.D.	257

P-R-O-C-E-E-D-I-N-G-S

(8:34 a.m.)

DR. EPSTEIN: I'd like to ask people to find seats, so that we can have a nearly on-time start.

We have a full day ahead.

I'm Jay Epstein, Director of the Office of Blood Research and Review at CBER, and it's my pleasure to welcome you and also to thank you for making the effort to come and work on this important issue.

This is, as you know, a public scientific workshop on implementation of universal leukoreduction, and I'm sure most of you are aware that FDA brought the question whether we should recommend universal leukoreduction to the Blood Products Advisory Committee way back in September of 1998.

More specifically, we asked the Committee for its sense of whether the available scientific data supported the utility of universal leukoreduction, absent any question or consideration of potential benefit to reduced risk of Creutzfeldt Jakob Disease or a new variant of Creutzfeldt Jakob Disease.

The question was pointed in that way, because we were dealing with the fact that there had already been recommendation in the United Kingdom, I think dating from July '98, to phase in universal

1 leukoreduction over a two-year period as a theoretical
2 precaution against new variant KJD, but this was very
3 controversial; and we didn't think that we could have a
4 scientific position on that point.

5 Subsequent to that, both Canada and New
6 Zealand have taken public policies on universal
7 implementation of leukoreduction for non-leukocyte
8 cellular products of blood.

9 The outcome of our discussion at that time
10 was a very strong endorsement of leukoreduction -- The
11 vote was 13 in favor with three abstentions -- on the
12 basis of numerous individual benefits, some better
13 established than others, those best established
14 including prevention of febrile non-leukocytic
15 transfusion reaction, HLA, alloimmunization and
16 reduction in CMV risk.

17 Numerous other benefits were discussed but,
18 as I say, are less well established, including perhaps
19 mitigation of immunomodulatory effects of transfusion,
20 as well as other effects due to the process related to
21 producing cytokines.

22 So I think we come here with already a
23 scientific consensus point of view that there is
24 overall a positive risk/benefit ratio or benefits/risk
25 ratio for universal leukoreduction, but we are still

1 left with a broad spectrum of implementation concerns,
2 many of which are logistic.

3 They deal with defining the proper
4 conditions for carrying out leukoreduction. I think it
5 was clear from the data presented in September '98 that
6 there is better quality of the leukoreduced product if
7 it is done as a controlled pre-storage operation in the
8 blood bank.

9 Also, we reviewed the issues of toxicities
10 that have been associated mainly with bedside
11 filtration and recognize also that there is less
12 variability to the residual leukocytes if this is done
13 in the pre-storage controlled environment.

14 We are also aware that a decision to
15 recommend universal leukofiltration or leukoreduction
16 by other equivalent means translates into an unfunded
17 mandate to the blood industry.

18 We know that there is already voluntary use
19 of leukofiltered products for high risk recipients.
20 This has been medically established and is used
21 throughout the world. However, the recommendation or
22 perhaps eventual regulatory requirement for
23 leukoreduction would create a rather large economic
24 burden.

25 From the FDA point of view this, of course,

1 would not be a reason for us to shy from a
2 recommendation, if we felt that it was necessary for
3 public health and optimal use of blood products.

4 However, we are mindful of that concern, and indeed in
5 the larger context of the Public Health Service, which
6 has within it the HCFA Medicare funding program, there
7 is a lively dialogue ongoing about mechanisms to
8 provide appropriate reimbursement for advancements in
9 blood safety.

10 So whereas that's not a key focus for
11 today, we do understand that there may be opinions and
12 needs expressed in that area, and FDA's response would
13 be to convey these to the parts of the Department of
14 Health and Human Services where response may be needed.

15 So I just also want to take a moment to
16 specifically thank the real organizers of the
17 conference, particularly Jong Lee who heads our Blood
18 and Plasma Branch in the Division of Blood
19 Applications, and again to thank you for your
20 participation and the comments that you will provide to
21 us throughout the day.

22 So let me then turn the podium over to Mary
23 Gustafson, Director of our Division of Blood
24 Applications, who has some prepared opening remarks.
25 Mine, of course, were off the cuff.

1 CAPTAIN GUSTAFSON: Thank you, Dr. Epstein.

2 I, too, want to welcome all of you to this
3 459th CBER sponsored blood related workshop for
4 calendar year 1999. Joe Wilczek just gave me a look
5 that it does have a transcription, and perhaps I should
6 clarify that that was really a joke. It just seems
7 like we've had that many workshops.

8 Because of our heavy workshop schedule, we
9 are most grateful that you have taken time out of this
10 holiday season to come and be with us and to share your
11 thoughts with us on the important issue of
12 implementation of universal leukoreduction.

13 Dr. Epstein gave you the background
14 information of our Blood Products Advisory Committee
15 recommendation from September of 1998, and also the
16 world scenario. So I won't repeat any of that.

17 I do want to stress that we want to have an
18 interactive workshop today. We are -- This is not a
19 workshop where we are going to give you a final draft
20 document and you are just to listen to what we say. We
21 are just in the preliminary stages of putting together
22 some guidances, and we really do want your input at
23 this preliminary stage.

24 I, too, would like to thank Dr. Jong Lee
25 for organizing and the Blood and Plasma Branch staff

1 members who have also been on the organizing committee
2 and have arranged the speakers for today.

3 I especially want to thank the speakers who
4 have agreed to come and share their thoughts and also
5 their experiences in implementing leukoreduction either
6 before the BPAC recommendation or after the BPAC
7 recommendation, and a special thanks to Joe Wilczek who
8 is a member of our Policy and Publications staff, who
9 has been Mr. Workshop for this year. Whether it's been
10 a contracted effort or one that we have put on
11 completely internally, Joe has made sure that
12 everything runs smoothly from soup to nuts in the
13 organization of the workshop.

14 In terms of housekeeping, the workshop is
15 scheduled in four sessions today. We have two breaks,
16 morning and afternoon, and a lunch break.

17 There are restrooms and telephone
18 facilities on this floor. There's a cafeteria here in
19 the Natcher Building. The weatherman is telling us
20 that by Noon today we may have some rain. So you may
21 want to take advantage of the cafeteria. If it's not
22 messy outside, there are numerous wonderful restaurants
23 in Bethesda. There's even a MacDonald's across the
24 street at the Navy base.

25 The room is set up so that we have

1 microphones in each aisle, and once again I do want to
2 stress that we want to hear your ideas, your thoughts,
3 and your comments on what is presented today. We
4 should have ample time in the last session to have a
5 good discussion on what has been presented today.

6 So with this, I'll turn the meeting over to
7 Dr. Jong Lee, who will present the goals of today's
8 workshop and an overview of today's schedule. Thank
9 you.

10 CHAIRMAN LEE: Thank you, Mary.

11 If you absorbed every information presented
12 by Dr. Epstein and Mary Gustafson, I think you're
13 pretty much set for a background and overview. He gave
14 a brief -- as usual, a brief but very comprehensive
15 overview of why we are here and where we are with
16 respect to universal leukoreduction.

17 I'll try to go over in a little bit more
18 detail the background of this topic, and also present a
19 more detailed overview of today and present some
20 workshop goals.

21 I have to thank the committee members who
22 have assisted me and provided invaluable guidance in
23 shaping and designing this workshop: Of course, Mary
24 Gustafson, myself -- that long name is actually just
25 pronounced "John" -- Les Holness who will moderate

1 Session II; Judy Ciaraldi who will moderate Session
2 III; Joe Wilczek who you well know by now; as well as
3 the remainder of the workshop committee, Linda Alms,
4 Karan Blum, Marla Cohen, Gil Conley, Mary Ann Denham,
5 and Janet Ishimoto, Carolyn Penny, Monica Yu and Ken
6 Zemann who has assisted me in critiqueing the workshop
7 design as well as recruiting the speakers.

8 First of all, the definition of universal
9 leukocyte reduction: By universal leukocyte reduction,
10 I think we all agree that we mean leukoreduction as a
11 routine, integral step in blood manufacturing. In
12 other words, this is to be a GmP step for generating
13 whole blood, red blood cells, and platelet units for
14 transfusion.

15 We also mean that leukocyte reduction is to
16 be performed pre-storage and also, of course, we mean
17 that this is to be applied only for blood for
18 transfusion use.

19 How do we get to where we are today? I
20 think there has been an ongoing dialogue for several
21 years. Some of the more recent events: Starting with
22 workshop in March of 1995, the regulations and
23 licensing criteria were discussed, and at that point
24 leukocyte reduction was discussed as a way to produce
25 special products that bear a special labeling.

1 Subsequent to that, two years later, the
2 issue was presented before BPAC where leukocyte
3 reduction was discussed as a special indication in
4 terms of its effectiveness against reducing the
5 incidence of transfusion transmitted CMV.

6 Following that, in September of 1998,
7 universal leukoreduction was first introduced as a
8 public discussion, and discussed whether or not this
9 should be considered as a new GMP issue, and we are
10 gathered here today to discuss the implementation steps
11 as to how best to adopt this, potentially adopt this as
12 a national blood policy. The decision has been made to
13 go forward, but it's not clear exactly how to proceed.

14 In developing public consensus, at BPAC the
15 scientific basis for the risks and benefits of
16 leukocyte reduction were discussed, and the charge to
17 the BPAC was to discuss the scientific basis,
18 irrespective of concerns for CJD or new variant CJD,
19 and also, of course, outside the constraints of cost
20 discussions.

21 Depending upon the outcome of the BPAC, the
22 plan was to proceed -- to potentially proceed to
23 examination of the issue in the context of new variant
24 CJD at the TSC Advisory Committee, and then to follow
25 that up with potential examination of the cost and

1 availability issues at the PHS Advisory Committee.

2 The question presented to the BPAC members,
3 the specific wording, is the following: Is the
4 benefit/risk ratio associated with leukocyte reduction
5 sufficient to justify the universal leukocyte reduction
6 of all non-leukocyte transfusion blood components,
7 irrespective of the theoretical considerations for
8 transfusion transmitted CJD?

9 As Dr. Epstein already mentioned, the BPAC
10 vote was 13 to none in favor of universal leukocyte
11 reduction with three abstentions. The consumer and
12 industry nonvoting representatives agreed with the Yes
13 vote.

14 In analyzing the way in which the BPAC
15 members voted, however, you might look at some of the
16 scientific discussions that were held, and as a summary
17 it was clear that the only FDA approved indication for
18 leukocyte reduction was the febrile non-hemolytic
19 transfusion reaction and the scientific basis for that
20 was adequate and, of course, that's why it led to the
21 approval from the FDA for labeling. However, if you
22 consider this in the context of relative clinical
23 importance to the typical transfusion recipient, not to
24 say that febrile transfusion reactions are not
25 important, but in terms of relative importance it was

1 rather low.

2 Some of the other indications for which
3 there is no specific FDA approval but, nonetheless,
4 commonly accepted and used -- leukocyte reduction being
5 used in such settings -- was to reduce the incidence of
6 CMV and also HTLV or, in other words, reduce the
7 incidence of cell associated viruses, and also reducing
8 the incidence of alloimmunization.

9 From a clinical standpoint, although there
10 was insufficient data for this to rise to the level of
11 FDA approval, data is accruing and potentially it will
12 receive FDA labeling approval in the near future, and
13 there is moderate -- and also these indications in
14 terms of relative clinical importance might be stated
15 as being of moderate importance.

16 Now there are a slew of other controversial
17 indications for which there is little scientific data
18 to conclusively recommend leukocyte reduction, and
19 those include immunomodulation, the storage lesion, the
20 transmission of other infectious diseases, viral
21 reactivation, and possibly the reduction of transfusion
22 related acute lung injury.

23 Now the first two of these at least have
24 received a lot of public attention, and potentially, if
25 proven to be true, it carries the highest level of

1 clinical importance for leukocyte reduction. Again,
2 not to say that any of these indications are not
3 important, but in terms of relative scale I believe the
4 controversial indications are actually ones that are
5 really driving the public consensus toward universal
6 leukocyte reduction.

7 Of course, the potential use against
8 transfusion associated graft versus host disease is not
9 relevant, because we have a more definitive way of
10 preventing that from happening by gamma irradiation.

11 So this was the summary of the data
12 presented to the BPAC members, and this is the basis on
13 which many of the committee members reached their
14 decision -- I should say probably all of them, with
15 three abstentions, and all in favor of Yes.

16 In terms of adverse effects, these were
17 also discussed at the BPAC. In terms of reactions that
18 are specific to a particular filter or even a filter
19 lot, only one was discussed, and that was the red eye
20 reaction. This has since been resolved with stopping
21 the distribution of that particular make of the filter.

22 There are several other potential adverse
23 effects that are more general to leukocyte reduction
24 filters in general, including hypotension, and this is
25 largely associated with bedside leukoreduction rather

1 than pre-storage, as well as cell loss and hemolysis,
2 both of which is easily tolerated and more than
3 acceptable.

4 As for adverse effects of leukocyte
5 reduction itself aside from devices that achieve
6 leukocyte reduction, there were none, and I believe in
7 the absence of significant adverse effects and with the
8 charge not to consider costs, the BPAC voted the way
9 they did, despite not having conclusive evidence that
10 leukocyte reduction is beneficial to all transfusion
11 recipients.

12 So if you expand the BPAC committee vote --
13 and of course, I made this up, and this is not in any
14 way a formal record -- you might sort of lay it out in
15 terms of a scale: 3+ Yes; 2+ Yes; 1+ Yes; going to 3+
16 No.

17 Obviously, people abstaining could not
18 really reach a clear decision and didn't vote either
19 way, but I believe the 13 people that voted yes were
20 probably doing so on a 1+ Yes decision, and this is
21 based on the comments that they provided which
22 explained their rationale. Again, health care costs
23 were not considered at this time.

24 So how has the public dialogue shaped up
25 since 1998 BPAC? Well, BPAC recommended universal

1 leukocyte reduction, irrespective of CJD or new variant
2 CJD, and with a charge to not consider cost issues.

3 Because of the way in which BPAC voted,
4 this issue was not presented before the Transmissible
5 Spongiform Encephalopathy Advisory Committee, and the
6 issue was brought before the PHS Advisory committee in
7 terms of blood availability and costs. However, the
8 committee supported BPAC's recommendations without
9 clear guidance on time frame or how aggressively
10 universal leukocyte reduction should be implemented.

11 So it is the goal of today's workshop to
12 develop public consensus on implementation issues as to
13 how we might best move forward, given the
14 recommendations that have been derived thus far.

15 So in terms of an overview, in Session I we
16 will try to lay the ground work once again, just to
17 familiarize everyone in the audience with the
18 scientific issues and clinical issues associated with
19 universal leukocyte reduction.

20 What does universal leukocyte reduction
21 mean for the transfusion recipient? This topic will be
22 addressed by Dr. Ed Snyder who was also invaluable in
23 shaping the BPAC discussion held in 1998.

24 That discussion will be followed by Carolyn
25 Jones from HIMA, a representative of the filter devices

1 manufacturing industry, to make a statement as to the
2 availability of the filter supply in terms of is it
3 possible to immediately implement universal leukocyte
4 reduction if that is the consensus developed today.

5 In Session II presenters from the FDA will
6 provide some potential regulatory approaches. I will
7 go over some of FDA's current thinking on standards and
8 time frame. Betsy Poindexter from Division of
9 Hematology will also do the same with respect to
10 platelets, and the tricky concepts relating to good
11 manufacturing practice standards, licensing issues and
12 a CBER pilot program will be discussed by Mary
13 Gustafson, and Larry Fenner from the Office of
14 Compliance and Biologic Quality will discuss whether or
15 not the transition period will be laden with compliance
16 issues.

17 In Session III the workshop committee has
18 invited five U.S. centers to discuss their experience
19 and provide proposals on implementation. The committee
20 has decided to focus on domestic centers as
21 implementation issues must be addressed from the
22 standpoint of specific -- issues that are specific to
23 the United States, keeping in mind some of the
24 reimbursement structures, that reimbursement structures
25 differ in other countries that have already implemented

1 universal leukocyte reduction.

2 The five centers invited here today are the
3 American Red Cross, Blood Systems, New York Blood
4 Center, Community Blood Center of Greater Kansas City,
5 and Cedars-Sinai Hospital, as well as America's blood
6 centers.

7 Lastly in Session IV, a discussion of key
8 implementation issues will be held, and the highlights
9 of the discussion and concluding remarks will be
10 provided by Dr. Harvey Klein of the Department of
11 Transfusion Medicine at National Institutes of Health,
12 who, among the people that I polled, none disagreed
13 that he was the logical choice, and also he is also
14 part of the regulated industry as well as being
15 somewhat neutral, being part of the government as well.

16 So in terms of actual workshop goals, the
17 ones I listed here are rather slam dunk goals. The
18 fact that we are here ensures that this will happen.
19 We will discuss the U.S. experience to date on
20 universal leukocyte reduction. We hope to exchange
21 ideas on how to best implement ULR and, I think, more
22 importantly than others, provide a forum in which
23 industry guides industry members and, of course,
24 generate the basis for a future FDA guidance.

25 I'd like to point out one ground rule in

1 discussion in proceeding with today's workshop.
2 Participants may refer to the following aspects of
3 leukocyte reduction as they relate to implementation of
4 universal leukocyte reduction, but they should not be
5 addressed as primary issues.

6 Those are cost issues, as this is not the
7 charge to the FDA or for this workshop, clinical risks
8 and benefits as well as scientific principles, as these
9 have been discussed previously and it's really beyond
10 the scope of this workshop.

11 At this stage, I'd like to go over some
12 more specific goals or I call them key decisions, and
13 I'll simply read them:

14 Key decision 1 -- and I believe these are
15 the more tricky issues to be discussed today: Should
16 FDA recommend specific implementation criteria
17 applicable to all blood establishments or should FDA
18 provide only the framework within which blood
19 establishments adopt an implementation plan specific to
20 each center?

21 Key decision Number 2: Should FDA
22 recommend a simple transition period of 12 months or
23 briefer or should FDA support transition periods that
24 are longer than 12 months, which may allow further
25 maturation of cost, clinical and scientific issues?

1 Key decision Number 3: Should the current
2 FDA guidance on leukocyte reduction be retained for use
3 during the transition period or should the definition
4 and quality control of leukocyte reduction be updated
5 form the current FDA recommendations for implementation
6 during the transition period?

7 Key decision Number 4, and this is getting
8 a little bit tricky: Should blood centers, if eligible
9 to participate in the CBER pilot program for
10 streamlining licensure, be able to obtain the license
11 for leukocyte reduced blood products by the simple
12 self-certification of compliance with existing
13 leukocyte reduction standards or should blood centers,
14 if eligible and interested, continue to be required to
15 submit evidence of compliance with existing leukocyte
16 reduction standards for CBER review in obtaining the
17 license to ship leukocyte reduced blood products across
18 state lines?

19 Lastly, key decision Number 5: If a blood
20 center already licensed for whole blood red cells or
21 platelets may self-certify in supplementing its license
22 to include leukocyte reduction, should it be able to
23 self-certify compliance with the existing 1996 FDA
24 memorandum on leukocyte reduction or should CBER write
25 a new pilot guidance for leukocyte reduction under GGP

1 in order to allow self-certification, although the
2 pilot guidance may not be substantively different in
3 terms of content from the existing 1996 memorandum?

4 So I believe those are five relatively
5 tricky issues that will come up in today's discussion
6 that, hopefully, will shape the discussion toward how
7 to best implement ULR. Once again, I would like to
8 thank the entire workshop committee in making today's
9 workshop possible.

10 At this point, I'd like to introduce Dr. Ed
11 Snyder from Yale. He is a speaker who requires no
12 introduction and who will address the issue of
13 leukocyte reduction, blood quality and the transfusion
14 recipient.

15 DR. SNYDER: Thank you. Sorry for the
16 delay.

17 Good morning. I'd like to first thank the
18 FDA for inviting me to make this presentation. It's a
19 somewhat difficult presentation, since so many in the
20 audience are quite sophisticated in this area.

21 So what I plan to do is to cover in my
22 usual fashion all the material I can in the allotted
23 time, but going over those areas which are fairly
24 common quickly, just to mention them for the sake of
25 completeness, and dwell more on some of the more

1 interesting areas that, I think, we should discuss with
2 leukoreduction.

3 I want it to be clear that some of the
4 comments I'll make as we go through this are my
5 thoughts and how I feel that personally that
6 leukoreduction is clearly a safer and a better product
7 and that the time for implementation for this is now.
8 I'll try to rehash many of the medical and clinical
9 indications for these products.

10 As you can see here, we have a fairly large
11 number of types of white cells that need to be removed,
12 and we remove them for various reasons, as we are
13 aware.

14 Filtration started, again, in 1938 with
15 Fantis in Chicago removing basically clots. We then
16 moved fairly rapidly ahead to microaggregate filtration
17 to remove debris, spurred on by the work of Dr. Swank
18 whose filter is over here, and a variety of other
19 filters.

20 This particular filter, as I've mentioned,
21 has a priming volume of 200 ml. This did not survive
22 very long. These filters were very useful for
23 decreasing the microaggregate debris, and were used in
24 treating respiratory distress syndrome. It turned out
25 that was more likely to be due to infection and

1 hypotension than to microaggregate debris. But these
2 kinds of pictures were very histrionic, and certainly
3 impressed a lot of people with the removal of debris.

4 The field moved on quickly, however, to
5 removing individual white cells, and that became
6 clearer as we developed more understanding of
7 immunomodulation and what was happening with cells,
8 that it wasn't just removal of granulocytes and debris
9 but actually white cell leukocytes, lymphocytes and
10 various types. So the ability to remove them developed
11 with the so called third generation leukoreduction
12 filters.

13 We now have indications for leukoreduction,
14 which are seen here. Some of them are more well
15 accepted than others, and I will go through some of the
16 strategy that -- stratification that was presented at
17 the BPAC meeting a year ago in September.

18 So I think, although there were scientific
19 indications, from my perspective what has spurred the
20 field to move forward very rapidly has been the concern
21 about transmission of new variant CJD, and I think most
22 people would agree that that probably is not related to
23 leukoreduction, but it has been, I think, the political
24 motivating force in various countries around the world
25 and I think, to some degree, the concern about

1 transmission has spurred the industry to move forward
2 for reasons which I think are beneficial for the
3 conditions we're going to talk about, not necessarily
4 for that.

5 This slide I wasn't going to show, but I
6 actually think it's still current. Those of you who go
7 on the AABB Web and look at the sig cites realize that
8 there are thought leaders on that site that actually
9 feel that leukoreduction should not be mandated.

10 There are no single noncontroversial
11 indications. I can't think of a single one -- perhaps
12 CJD, but there are people around the world that would
13 quibble with that as well. So I think we are really
14 looking at not one single indication but a group of
15 indications which, taken together, have the sum of the
16 parts being greater than any individual one and,
17 certainly, putting together as a whole I think that
18 each individual indication has certain weight, but when
19 linked with other ones, gives you an overwhelming
20 indication for leukoreduction.

21 So let's look at the level of consensus.
22 To decrease febrile transfusion reactions: I think
23 pretty much everyone agrees -- many people agree that
24 there is consensus that this will occur. We now know
25 why this is the case. Not only does it remove the

1 cells, but it also removes the cytokines before they
2 are formed by removing the cells.

3 Decrease the incidence of HLA
4 alloimmunization: That's because of removing dendritic
5 cells. To a large degree, that will decrease, although
6 not completely eliminate, the HLA alloimmunization.
7 There are data from that. Everyone says, well, there's
8 no data that leukoreduction is needed. There are data
9 for febrile transfusion reactions. There are data
10 which we'll show very briefly for HLA antibodies from
11 the TRAP study.

12 Decreasing cytokine generation with pre-
13 storage leukoreduction: There are data for that, that
14 if you remove the leukocytes prior to storage, there
15 are fewer cytokines generated.

16 The decreased generation of platelet and
17 granulocyte microparticles: There's also data on that.

18 So this slide just goes back to an abstract
19 that Linda Chambers and her group published in 1989 in
20 Transfusion which basically said that leukoreduction
21 filters really didn't have much of an effect on febrile
22 transfusion reactions. With the unfiltered group and
23 the filtered group, 20 percent reaction, 14 percent in
24 the filtered group, not felt to be statistically
25 significant, that only three patients really had any

1 impact on the overall difference.

2 This was, we now realize, due to the fact
3 that they were looking at beside filtration. They were
4 looking at products that had been stored and cytokines
5 that had already been generated. We thought initially
6 that, if you remove the cells, that the febrile
7 reactions would disappear, when in reality, as has been
8 shown by Nancy Heddle -- and I'll show that in a second
9 -- it's the cytokines that apparently are more of a
10 problem. So that was actually correct.

11 This slide -- By the way, I should have a
12 disclaimer. I do have fee for service contracts with
13 Baxter and Terumo and Pall. I do not own any stock in
14 any of these companies, and I am on advisory boards for
15 Baxter and Pall but, as I say, have no financial
16 interest in the companies.

17 This just is a slide which was taken from
18 Baxter, which was data that we had generated, that if
19 you pre-storage leukoreduced platelets, you do not have
20 the production of, in this case, interleukin 8, where
21 in nonfiltered units you do see production of various
22 degrees of interleukin 8 as an example of other
23 cytokines.

24 The importance of this slide, I think, is
25 that there's biologic variability, and I'll come back

1 to biologic variability when I get to the
2 immunomodulation aspects of things. Not all people are
3 the same, certainly when it comes to these kinds of
4 reaction and generation of these cytokines.

5 This paper by Nancy Heddle, which is in a
6 now classic New England Journal where she took
7 platelets and divided them into the platelet for
8 Supernatant and the platelet rich supernatant and
9 infused them into the same individual separated by a
10 period of time and looked for febrile reactions,
11 randomizing whether the platelet for plasma was first
12 or the cells.

13 There was no reaction in 30 of these paired
14 transfusions. Plasma only reactions occurred in 20.
15 Cell only reactions occurred in six, and plasma in
16 cells to eight. The conclusion was that the cytokines
17 that were secreted into the plasma were more important
18 than were the actual cells in producing the febrile
19 reactions, which fits in with what, I think, current
20 status is, and we are still hearing variations on this
21 theme today. That, I think, is pretty well agreed.

22 This is the also classic Mo Blajchman
23 studies on the New Zealand rabbits where he evaluated
24 leukoreduction prestorage, post-storage and non-leuko
25 depleted, looking at the refractory rate. Again, the

1 highest refractory rates in the non-leuko depleted, the
2 least in prestorage, and the interim in the post-
3 storage leukoreduction for the rabbit model.

4 When he just infused plasma into these
5 animals looking for the same things, -- again you are
6 all familiar with this -- stored plasma had a 61
7 percent refractory rate, and fresh plasma only 16
8 percent. So the data was that there was something in
9 the stored plasma that was having an impact on the rate
10 of reaction.

11 When white cells -- reduced red cells were
12 compared with plasma depleted red cells, the refractory
13 rate dropped in his animals from 29 percent to zero.
14 The implication of this, as we are familiar, is that
15 microparticles were present in the leukoreduced red
16 cells that were getting through the filter.

17 This slide just shows you what kinds of
18 these particles might look like, the fragmentation of
19 the membrane. This is in a granulocyte. It's not
20 related to the neutrophil which would have the Class I
21 and the Class II sites on them, which would be more
22 germane, but this picture -- you actually get a
23 stronger visual impact. So I chose that.

24 A paper by Ramos showed that these cell
25 fragments will go through the filters pre- or post-

1 filtration, but there is an increase in the amount of
2 these fragments over time. The presumption is that you
3 are infusing Class I and Class II antigens. You are
4 also -- There's also antigen presenting cells in the
5 recipient, which can present the antigens to produce
6 antibody against Class I and Class II, resulting in
7 alloimmunization.

8 So the idea would be for quality purposes
9 pre-storage, leukoreduction would appear to be the best
10 way to go, decreasing cytokines, decreasing any --
11 minimizing, rather, cytokine production, minimizing HLA
12 alloimmunization.

13 The TRAP trial concluded that
14 leukoreduction by filtration and UVB irradiation was
15 equally effective in preventing alloantibody mediator
16 fragments. So there are data there.

17 Use of leukoreduced single donor versus
18 leukoreduced random donor was of no added benefit, and
19 the slide is here taken from that article by Schlichter
20 and her co-workers, the control group showing the
21 highest degree of refractoriness, and the three types
22 of reduction, alloimmunization suppression, either UVB
23 or filtered concentrates of filtered apheresis products
24 showed a similar lower level.

25 So I think there are data that

1 leukoreduction is beneficial to decrease the incidence
2 of alloimmunization.

3 What about other levels? Well, decreasing
4 HIV activation post-transfusion was thought to be a
5 really good idea. There was information presented,
6 although not formally, at the AABB meeting that the
7 results of the VATS trial which is sort of a leaking of
8 information, if you will, a leaky VAT, is that the use
9 of leukoreduction did not appear to be any different
10 from the control arm as far as p24 antigen and clinical
11 response.

12 I haven't seen the data. We need to be
13 able to evaluate it, but the rumors, unsubstantiated
14 rumors, are that the HLA -- that leukoreduction did not
15 appear to have a beneficial effect for HIV
16 transmission, prevention of it or decreasing
17 reactivation of HIV.

18 This was based on Dr. Mike Busch's paper
19 where he added white cells to cells in culture and
20 looked at the degree of p24 antigen that was secreted
21 into the Supernatant.

22 CMV transmission, however, is an area where
23 people seem to have a general agreement. Now the key
24 paper again for the millionth time is Dr. Bowden's
25 paper, which comes to basically this line over here for

1 the secondary analysis of patients on Day Zero to Day
2 100 with the intention to treat CMV disease only.

3 There were no people in the seronegative
4 group, in the filtered group six, and six versus zero
5 was significant, less than .05, whereas in the 21 to
6 100 primary analysis zero versus three did not reach
7 significance.

8 This sort of sat around for a long time,
9 but then the industry that was transfusing leukoreduced
10 blood products under cGMPs was not reporting an
11 increase incidence of CMV in the recipients, transplant
12 recipients.

13 I think now there's a general -- Although
14 there has been no additional formal study, there is now
15 a general feeling that under cGMP purposes prestorage
16 leukoreduced blood products are considered to be CMV
17 safe, and many centers around the country are using it.

18 We are using it at Yale, including for our
19 allotransplant patients and, knock on wood, have not
20 seen concerns, as are many other major centers around
21 the country.

22 Not everyone follows this. Many places are
23 using it for all but allotransplant patients, but there
24 seems to be, by dent of the numbers in the field, an
25 affirmation that Bowden's study was probably correct in

1 that CMV safe is a real product that's leuko-depleted
2 under cGMP conditions.

3 There is a high level of consensus that
4 leukoreduction will not prevent post-transfusion graft
5 versus host disease. This is a paper by Okahoshi,
6 which was in Transfusion in 1992, which basically
7 showed an individual who had received platelet
8 concentrates that were leukoreduced but not irradiated,
9 and developed post-transfusion graft versus host
10 disease.

11 Although theoretically you might be able to
12 get the numbers down to prevent graft versus host, I
13 think most prudent physicians and, certainly, most
14 attorneys would agree that it's best to use gamma
15 radiation at the indicated dose with the FDA guidance
16 to prevent graft versus host disease.

17 Whether or not the upcoming psoralen
18 inactivation materials, psoralen or riboflavin or other
19 types, will be able to give you the same effect has yet
20 to be shown formally, but it is possible that there may
21 be other ways of inactivating white cells. But for
22 now, leukoreduction is not considered an indication to
23 prevent graft versus host disease, in my reading of the
24 literature.

25 Again, high level of consensus that use of

1 leukoreduction to prevent transfusion transmitted new
2 variant CJD is not a concern. So I won't spend anymore
3 time on that.

4 Now we come to areas that are of much
5 concern, which are areas where there's low level:
6 Removal of bacteria, tumor growth, immunomodulation,
7 post-op infection, reprofusion injury, and response
8 modifiers.

9 Suffice it to say that removal of bacteria
10 from blood is not an indication which will likely to
11 see the light of label copy. There are data in the
12 literature published by our group as well as others, a
13 lot from the Red Cross, Steve Wagner, that you can
14 remove a large number of bacteria from white cells --
15 from units of blood.

16 Whether the leukoreduction is because the
17 filter is removing the bacteria, the filter is removing
18 bacteria stuck to white cells or the filter are
19 removing bacteria ingested by white cells may all be
20 correct. But there are so many strains, and there were
21 examples of various spiked bacterial experiments where
22 they proliferated -- the bacteria proliferated,
23 regardless of leukoreduction, especially with gram
24 negatives, that it is not likely to occur.

25 Is it likely that leukoreduction will

1 enhance the degree of bacterial safeness, if you will?

2 I think probably that's true, but it will be hard to
3 show that data, but it would be another benefit to be
4 achieved if leukoreduction were implemented on a
5 universal basis. So there's low consensus, but there's
6 good data that it is beneficial, to some degree.

7 Let's skip this, because we're going to get
8 back to that in some detail.

9 Prevention of reprofusion injury -- Well,
10 let me just go to this. Biologic response modifiers:
11 There's good evidence again from our lab and others
12 that some blood filters will remove some response
13 modifiers, such as interleuken 8, rantes, the
14 complement factors, primarily because of electrostatic
15 interactions because of their positively charged
16 molecules being ruled by negatively charged filter.
17 But many of the negatively charged response modifiers
18 such as the interleuken 1 and IL6 and TNF alpha are not
19 removed. It's an electrostatic interaction, and the
20 more of the product that's filtered, the less the
21 efficiency of removal. So it's really not an
22 indication.

23 As far as reprofusion injury is concerned,
24 oxygen derived free radicals are certainly associated
25 with the return to profusion of an ischemic organ. If

1 you cross-clamp the aorta or do an organ transplant,
2 there are receptors that are generated on the
3 epithelial cells and other types of cells.

4 White cells become activated, and various
5 agents are released, including oxygen free radicals,
6 which will cause damage in extant infarct areas. Is
7 that an indication for leukoreduction? Not unless you
8 have a leukoreduction filter in the circulation, which
9 is not practical, obviously.

10 So that you may remove the white cells from
11 transfused products, but the granulocytes are not very
12 viable in these products, to begin with. So there
13 really is not much indication, although there are some
14 very interesting data from the surgical literature
15 showing there may be some benefit to this.

16 In addition, there is a paper by Dr.
17 Massberg in Blood 1998 which shows a vessel which is
18 profused normally, and here's a vessel that was
19 released from an ischemic interaction. What you see
20 lit up here are platelets.

21 The purpose of this paper was to show that
22 reprofusion injury can be due to platelet activation as
23 well. So it's not just -- Even if white cells removal
24 did play a role, platelet activation could cause
25 reprofusion injury, in addition. So this again is not

1 a really -- is not a well accepted, by any means,
2 indication for leukoreduction but might be some benefit
3 that would be derived, were it to be used.

4 So let's go and take a little bit of time
5 and look at the immunomodulation aspect of it. This
6 was again another Dr. Blajchman bleed-the-bunny study
7 where he looked at New Zealand white rabbits.

8 What he evaluated was the effect of
9 syngeneic, allogeneic and leukodepleted allogeneic
10 transfusions on metastases. As you can see here,
11 almost all the rabbits essentially did have metastases,
12 but the median number of metastases was the least for
13 the leukodepleted allogeneic and the syngeneic and
14 statistically significantly differently higher for the
15 higher allogeneic.

16 So the implication was -- and there have
17 been lots of studies which show -- seem to show that
18 leukoreduction prevents metastases, recurrence of
19 metastases or the development of metastases, recurrence
20 of tumor and decreased post-operative infection.

21 One of these studies by Lon Jensen showed a
22 statistically significant drop in the number of
23 abdominal wound sepsis, with unfiltered whole blood
24 being the highest and filtered whole blood being very
25 low, again very small numbers. Some of the other

1 things that were looked at did not reach statistical
2 significance, but this is an example.

3 There are lots and lots of papers. I'm not
4 going to go over them. Some show that there are
5 benefits of leukoreduction in preventing tumor
6 recurrence. Others show that there are not. The
7 question is -- Then we have meta-analyses which say
8 maybe, and that's my final answer.

9 There are people who strongly feel it's
10 helpful. There are people who strongly feel it's not.

11 What I feel the time is right is to take a look at the
12 basic science and what data is there that
13 leukoreduction has any impact at all on this or is this
14 just a bunch of clinical trials that have fun things to
15 know and tell, but really don't give any kind of a
16 cohesive picture.

17 This is one of my favorite slides from
18 Jensen's paper showing that unfiltered whole blood --
19 You had a 17 day length of stay, and only 11 days with
20 filtered whole blood. So you could actually drop the
21 length, median length of stay, almost by 50 percent
22 total bed days here. If you didn't get transfused it
23 was 967. If you did, it was only 537, but there were
24 more patients in this group, to be fair.

25 This again showed total bed days were less

1 in essentially a comparable group of people here. So
2 is filtration that wonderful? Can we decrease length
3 of stay. Are we going to wipe out the blood bank by
4 having to pay for all these filters, but the hospital
5 will benefit by having decreased length of stay and it
6 will have a better bottom line.

7 Well, we're not going to discuss that.
8 We're going to discuss some of the science. There was
9 a paper by Dr. Ghio -- the senior author was Francisco
10 Pupo -- in Blood earlier this year on immunomodulatory
11 effects of transfusion.

12 They wanted to evaluate leukocytes in donor
13 blood having effects of inducing transplant tolerance,
14 accelerating tumor growth, recurrence of tumor growth,
15 and increased risk of bacterial infection. These are
16 the issues that they wanted to address.

17 They weren't sure of the exact mechanism,
18 but felt that it may involve induction of anergy, anti-
19 idiotypic antibody, mediated expression, cytokine
20 expression imbalances, T-cell clonal deletion,
21 regulatory activity, and various soluble factors. This
22 is what they concentrated on, soluble HLA Class I,
23 Class II, and soluble Fas ligand.

24 What they showed is here. This bottom
25 panel is soluble Fas ligand. Soluble Fas ligand, as

1 we'll talk about, is a Type II protein which is
2 secreted and binds to Fas. Fas is a receptor on cells
3 which, when bound to Fas ligand, induces apoptosis and
4 cell death. Okay?

5 So we have soluble Fas ligand secretion
6 here, HLA Class II and HLA Class I, in washed red
7 cells. This is going up -- red cells that are absorbed
8 for five days, red cells absorbed for 30 days,
9 leukodepleted red cells, platelets, FFP, and serum.

10 What you can see it that the largest levels
11 of soluble Fas ligand are in 30 day old red cells and
12 in platelets with very low levels in washed five-day-
13 old red cells, leukoreduced red cells and FFP. That's
14 true also for HLA Class I over here and less so for
15 Class II.

16 So there seems to be 30-day red cell and
17 five-day stored platelets, the highest levels of these
18 modifiers. So as I say, Fas ligand is a Type II
19 membrane protein which is expressed in activated T-
20 cells in granulocytes. The Fas, also known as CD-95,
21 is expressed on tissues and, when they bind, apoptosis
22 will develop, cell death.

23 This binding can result in a cloned
24 deletion of T-cells in the periphery and a down
25 regulation of cytotoxic T-lymphocyte activity, and

1 soluble Fas ligand is at serum and reported to be high
2 in hematologic tumors, all very well and good.

3 Well, this is what apoptosis is all about.

4 The cell begins to undergo apoptosis by pulling -- I
5 will bring this back to leukoreduction, if you bear
6 with me, in a minute or two. This is getting it to
7 some of the basic science, and I want to make sure
8 everyone gets at the same level here, to the best of my
9 ability.

10 The cell begins to pull away, which is an
11 apoptotic cell, and undergoes a series of changes
12 resulting in nuclear blebbing and then cytoplasmic
13 blebbing, and this is not necrosis, but this is a
14 program cell death. The cell then gets destroyed, and
15 it gets eaten up by its neighbors.

16 This is a slide showing the exact -- what
17 the cartoon showed previously, with cytoplasm blebbing
18 and so forth.

19 Now this will occur. This is a slide taken
20 from one of the catalogs from one of the companies that
21 makes these reagents. What you see here are a bunch of
22 receptors, and then you see here a bunch of ligands
23 which are binding, and among these is -- here's Fas,
24 and here's Fas ligand. So this is a T-cell, and here's
25 the Fas receptor.

1 When Fas ligand binds to that Fas
2 receptors, a series of quite complicated metabolic
3 processes occur with CAS phases and DCLX and BCL2, a
4 whole variety of things we're not going to go into, but
5 results in cell death. The cell is told it's time to
6 die.

7 Now you can imagine a scenario where you
8 have cytotoxic T-lymphocytes which are suppressing
9 tumor -- this is quite simplistic, but a potential
10 scenario -- and then you infuse red cells or platelets
11 with soluble Fas ligand, which binds to those Fas
12 receptors on those T-cells and induces apoptosis, thus
13 releasing the tumor from inhibition, and you get growth
14 of tumor.

15 This could be one possible scenario for why
16 some people find that there is an increase in tumor
17 metastases with transfusion, but if you leukoreduce,
18 prestorage leukoreduce and then prevent the Fas ligand
19 from being formed, there won't be that kind of
20 inhibition.

21 Again, this may be very simplistic, but it
22 gives us a way to get into the science of this. Now,
23 obviously, there are multiple receptors, and I want you
24 to especially be aware of this one, DCR-1 and DCR-2
25 which have a transmembrane piece, which are also

1 involved. These are called decoy receptors. We'll
2 talk about that in a moment.

3 So I think you understand how finding Fas
4 ligand production in blood products may have an impact
5 clinically on potential effects with tumor growth.

6 Now what's the evidence that the Fas ligand
7 is actually active? Well, this is a way of looking at
8 degree of apoptosis. Here's a cultured medium, and
9 here's DNA content of about 40.

10 If apoptosis is occurring, it's going to
11 become less. There's going to be a shift to the left
12 in the curve, and this is a positive control. Seventy-
13 five percent of the cells involved which are Jurket
14 cells, which are T cells that have a Fas on the
15 surface. So here's a positive control where you've
16 stimulated the Fas and you have apoptosis occurring,
17 because there's a movement from this area to the
18 hypodiploid side, 75 percent.

19 Red cells stored for 30 days, the
20 Supernatant, gave you an 89 percent degree of apoptosis
21 in these Jurket cells, implying that the Fas ligand
22 present in these 30-day stored red cells were active,
23 because it induced death in 89 percent of these Fas
24 cells. Five-day-old red cells only gave you 11
25 percent. There's a small peak here. Washed red cells,

1 12 percent; leukoreduced two percent; platelets, 31
2 percent in this peak; and fresh frozen plasma about 10
3 percent.

4 So there's evidence that at least in a
5 Jurket cell model you can get apoptosis occurring.
6 Also looking at the MLR response, what this showed is
7 that in cells where you got a normal MLR response,
8 looking at the very top square over here -- by showing
9 the amount of radioactivity present; this is normal. If
10 you then added to this MLR reaction the Supernatant
11 from a 30-day-old red cell, it obliterated it
12 completely, and similarly for platelets.

13 This is a normal reaction. If you added
14 the Supernatant of a five-day-old platelet, in the
15 triangles here, you obliterated it. Whereas, adding
16 FFP and leukoreduced -- plasma from leukoreduced
17 platelets in red cells, you did not get deablation,
18 which would be down over here.

19 So what this is showing is these are active
20 molecules, at least in an in vitro assay. Okay. So
21 that's all well and good.

22 So what this means is that both soluble HLA
23 Class I and Class II can modulate immune function, can
24 bind to their ligands and inhibit or stimulate
25 apoptosis. This could lead to immune tolerance or

1 activation. We'll skip through some of these.

2 The main findings were that there are
3 elevated concentrations of soluble Fas ligand in some
4 blood components, primarily 30-day-old red cells and
5 platelets. The level is proportional to the amount of
6 leukocytes. The levels are proportional to the length
7 of storage. They are functional, and it is believed
8 that these are shed from leukocytes during storage.

9 So prestorage leukoreduction would inhibit
10 this. Well, we still need to link this to something,
11 and I'll show you what that linked to right now.

12 There's a paper by Dr. Pitti and a whole
13 slew of people -- this is my own way of not having to
14 write 75 names; the senior author is Dr. Avi Ashkenazi
15 from Genentech -- entitled "Genomic Amplification of a
16 Decoy Receptor for Fas Ligand in Lung and Colon
17 Cancer."

18 What they found was there was another decoy
19 receptor which they called DCR-3 which did not have a
20 transmembrane piece and was secreted. This material,
21 DCR-3, is a decoy receptor, and that it binds to Fas
22 ligand and inhibits Fas ligand induced apoptosis.

23 They found that DCR-3 was produced in the
24 tissues in half of 35 primary lung and colon tumors
25 they studied. So if you have a tumor which is

1 secreting this DCR-3, this decoy receptor, binding Fas
2 ligand, it could block the apoptotic signal and enhance
3 the cancerogenicity, if you will, of that particular
4 tumor. It could be resistant to apoptosis and,
5 therefore, more likely to enhance tumor growth.

6 This suggests that certain tumors may
7 escape Fas ligand dependent cytotoxic attack by
8 expressing this decoy receptor that blocks the Fas
9 ligand. This could -- It would be one explanation why
10 studies that purport to show colon cancers having --
11 there's an effect in colon cancer metastases of using
12 blood transfusions. Some have results that are
13 positive, and some are negative, because not all tumors
14 are the same.

15 What we consider to be colon cancer and a
16 colon cancer and colon cancer may be different, and we
17 have to get more sophisticated analyses to see if these
18 tumors are producing receptors like DCR-3 plus a lot of
19 others.

20 Therefore, it may be, in a sense, garbage
21 in, garbage out. We're looking at what we think is a
22 uniform group of cells. In reality, they are much more
23 sophisticated. In our own naive way we're thinking,
24 well, you leukoreduce, and that's going to cure cancer.

25 It doesn't work that way, necessarily.

1 These are some of the mechanisms which,
2 hopefully, can be developed through the NHLBI and so
3 forth to study this on a scientific basis, knowing that
4 these response modifiers are produced in blood
5 products.

6 So the answer to is leukoreduction going to
7 prevent tumor growth, is it going to prevent sepsis --
8 the answer is we don't know, but there is a linkage,
9 and there may be some justification for why some
10 studies appear to show a positive result and other
11 studies don't.

12 So it's still a low indication, but I think
13 it's one of the most exciting ones, and ones that will
14 be discussed at a conference that we're going to be
15 having in March, that you're aware of.

16 In addition, there is some work that Dr.
17 Harold Merriman published many years ago looking at
18 other aspects of anergy. Not only does leukoreduction
19 seem to prevent the -- take out the antigen presenting
20 cells, but he showed that if you stored blood over 13
21 days, the secondary signal, the B7 signal, did not
22 appear, and there is some additional data now that just
23 came out in Blood a short while ago showing that blood
24 that's been stored for a period of time does not
25 stimulate alloimmunization but actually may produce

1 energy.

2 So leukoreduction removes a lot of these
3 concerns, but there are certainly aspects of
4 immunomodulation which are far more important. I
5 think, if we're going to get the maximum benefit of
6 leukoreduction, it has to be prestorage, and bedside
7 leukoreduction is not going to address these concerns
8 and, certainly, by the time you start leukoreducing,
9 the cytokines and the response modifiers may already be
10 present. So I think that addresses a quality issue.

11 There is also a paper by Dr. Jon Semple
12 that was in Blood in 1999. Extreme leukoreduction of
13 major HLA complex Class II positive B cells enhances
14 allogeneic platelet immunity. This paper purports to
15 show that, if you leukoreduce excessively, you may
16 actually stimulate alloimmunization rather than
17 decrease it. It decreases to a point, and then after a
18 certain level you start to get an increase in
19 alloimmunization, sort of a paradoxical effect.

20 So there's lots of areas. I don't think
21 we're going to get to the degree of leukoreduction that
22 they're talking about here, but it was just another
23 interesting aspect, that all leukoreduction may not be
24 beneficial, depending on the degree.

25 There are data in the literature that,

1 whether it's leukoreduction by filtration or process
2 leukoreduction, you may get different amounts of
3 leukocyte subsets. There are some people that live and
4 die by these concepts and say that there's far too many
5 granulocytes in the process leukoreduced products.

6 I think, generally, many people feel that,
7 if you leukoreduce to the same degree, that the effects
8 are similar. Some people quibble with this. More data
9 are needed, but these are some of these types of data
10 showing that process leukoreduction does give you a
11 slightly different subset analysis, and the
12 implications of this have not been shown at all, as far
13 as I know, in the literature.

14 There was a paper which -- This was a Xerox
15 which I made a slide of -- showing that the good news
16 is that, if you leukoreduce blood, red cells and
17 platelets, you do not fragment the white cells and
18 release prions that may be present in these products,
19 resulting in the spread of CJD. This came out in the
20 British Journal of Hematology earlier this year.

21 It is an example of people looking for
22 concerns in areas I didn't even think was a concern. I
23 don't think this is a good indication for
24 leukoreduction.

25 Kaplan-Meier plots to look at whether the

1 leukoreduction or not had an impact on leukemic outcome
2 of a patient with leukemia, patients with leukemia --
3 This is their Kaplan Meier relapse resurvival, whether
4 they received filtered blood or leukoreduced blood --
5 Sorry, nonleukoreduced blood or leukoreduced. There
6 was really no difference between the two. So
7 leukoreduction does not appear to have an impact on
8 survival from AML.

9 Are there adverse effects of
10 leukoreduction? Yes. We are well aware of the
11 bradykinin issues and the simulation of bradykinin in
12 some situations by some types of blood filtered media
13 that may have a negative charge, with the potential
14 enhancement of the bradykinin that's formed by the
15 inhibition of angiotensin converting enzyme or
16 kininase-2, and there are data for that.

17 This was a paper by Dr. Shiba in
18 Transfusion '97, which showed a maximum increase in
19 bradykinin and decreasing amounts of ACE due to the
20 addition of ACE inhibitors. The r squared of this is
21 about 36 percent, which means that there is a one-third
22 -- One-third of the change in the y axis is explained
23 by a change in the x axis.

24 That's a very low level, and not everyone
25 agrees on the way bradykinin is measured. There are

1 lots of questions. The point is that this was enough,
2 however, for the FDA to issue a medical alert that
3 bedside leukoreduction can produce hypotension. This
4 was in May of 1999. Rapid onset can produce
5 respiratory distress and shock.

6 It resolves when the transfusion is
7 discontinued, and since '94 80 out 20 million
8 leukoreduction filters have produced this. Is this a
9 major health scourge? I don't know. We're presenting
10 the data, and you can decide on scourges at lunch.

11 The FDA doubts that this is due to ACE
12 inhibitors or negative filter media. However, this is
13 sort of like Y2K. There will be no Y2K problem, but
14 get extra flashlights and just don't be in an elevated
15 building or in a subway when the clock strikes
16 midnight.

17 They recommend watching for a decrease in
18 blood pressure with leukoreduction filtration,
19 flushing, stop the transfusion, and use prestorage or
20 in-lab leukoreduction filtration. So again, this is
21 sort of where the state of the art is for this.

22 There is also questions about whether --
23 this is a paper by Willis -- whether fresh frozen
24 plasma should b leukoreduced. The data are that there
25 are bags which have greater than five times 10^6 white

1 cells in it of fresh frozen plasma, leukocytes and
2 lymphocytes that may survive this. Whether that needs
3 to be leukoreduced also hasn't been fully evaluated at
4 all.

5 This slide actually is from The New England
6 Journal from years ago. I used to think this was a
7 patient. This is the doctor. This is not the patient.

8 The doctor -- This IV pole was on loan.

9 What this means is that this is a cost
10 issue, which I'm not going to get into, other than just
11 to show this slide which will not go away. It
12 continually pops up.

13 So what are my thoughts on universal
14 leukoreduction as we get to the new millennium? That,
15 number one, they are Y2K compatible, although often
16 they stop running for no apparent reason. So maybe
17 they are not. Who knows?

18 They are increasing in popularity. Our
19 hospital administrators -- and this means, may they all
20 live and be well -- are accepting leukoreduction as a
21 standard of care. The Red Cross, America's blood
22 centers, and others are converting generally, and
23 probably will drop the cost as the volume of products
24 increases. This is economics.

25 If this is true, it could decrease length

1 of stay. If all those things that we heard about,
2 decreasing length of stay and decreasing tumors work,
3 it may actually be beneficial. So they actually could
4 end up paying for themselves.

5 This will benefit the hospital, but not the
6 blood bank or the blood transfusion service, which is a
7 cost center. One benefit, if you consider universal
8 leukoreduction as CNV safe, there is some financial
9 savings to be considered in that regard.

10 The switch to universal leukoreduction
11 would decrease inventory problems, so you don't have
12 multiple parallel inventories, which certainly we found
13 to be helpful. My belief is that nonleukoreduced blood
14 products will go the way of fresh whole blood.

15 Our institution was able to convert
16 relative small dollars, which we can talk about at
17 another time, and we did this by going to the medical
18 board, presenting the case, and then the medical -- the
19 transfusion committee first, then the medical board,
20 and now we're solely implementing and trying to do
21 internal reassessment of our budget.

22 So lastly, even if universal leukoreduction
23 is in place, according to the CFR 606.122, instructions
24 to use a filter in the administration equipment, you
25 still will need to use a 170 micron filter. That is

1 still a requirement, and the CFR is unlikely to be
2 changed in this regard. This is just an FYI.

3 So are we ever going to get to Happy Valley
4 where everything is wonderful? I don't know. We have
5 a long way to go, but the data, I think, I tried to
6 summarize for what you knew on leukoreduction and
7 express some of the changes that are occurring in the
8 immunomodulatory and the septic area where I think some
9 really exciting science is going to be generated.

10 So I'll stop there. Thank you very much.

11 (Applause.)

12 CHAIRMAN LEE: Thank you, Dr. Snyder.

13 In the way of questions, unless it's really a
14 burning question, I would ask the audience to actually
15 just jot them down and hold them until we get to the
16 panel discussion. Many of the questions may be
17 answered during the course of people's presentations,
18 and also I think it would make for a tighter conference
19 if you would just simply jot them down and hold them.

20 Our next speaker is Ms. Carolyn Jones from
21 the Health Industry Manufacturers Association, who is
22 really is tasked with a difficult job of representing
23 all of the device manufacturers. I really thank her
24 input in contacting all the individual manufacturers,
25 developing a consensus stance for today's presentation.

1 MS. JONES: As Dr. Lee indicated, I'm here
2 today representing the Health Industry Manufacturers
3 Association. HIMA is a Washington, D.C., based trade
4 association and the largest medical technology
5 association in the world.

6 HIMA represents more than 800 manufacturers
7 of medical devices, diagnostic products and medical
8 information systems. HIMA's members manufacture nearly
9 90 percent of the 62 billion of health care technology
10 products purchased annually in the United States and
11 more than 50 percent of the 147 billion purchased
12 annually around the world.

13 Some of our members manufacture products
14 that contribute to the national effort to improve the
15 safety of the nation's blood supply.

16 I just wanted to take note that today's
17 presentation will also include information from the
18 apheresis manufacturing community. It's not just the
19 filters. We decided that we would sort of like to
20 provide the information on the broad landscape rather
21 than just what the filters can do.

22 I'd like to thank the FDA for inviting me
23 today to present the industry perspective on the
24 ability of the medical device industry to meet the
25 demands that will be imposed by CBER's anticipated move

1 to universal leukoreduction of all cellular blood and
2 blood products intended for transfusion.

3 Leukoreduction is being used increasingly
4 to prevent transfusion reactions, alloimmunization,
5 disease transmission, and to reduce health care
6 complications while on transfusion. Leukoreduction can
7 be accomplished by various methods, including the use
8 of dockable systems, in-line red cell systems, in-line
9 whole blood systems, and by apheresis.

10 Interest in these various methods of
11 leukoreduction has increased as the blood supply has
12 come under increasing scrutiny around the world.
13 Leukoreduction is now mandated in at least nine
14 countries, and a number of other countries are
15 considering mandating it, with implementation processes
16 that have ranged from six months to two years.

17 The shorter implementation times are recent
18 initiatives in countries having more experience with
19 the practice of leukoreduction or in countries that
20 have sort of benefitted from the experiences of others.

21 We would like to note that none of the
22 countries where universal leukoreduction has been
23 mandated or implemented collect the number of units
24 collected here in the United States. The number of
25 units collected range from 100,000 units per year to

1 2.3 million per year.

2 Just to provide some idea of how
3 leukoreduction is growing, one year ago there were an
4 estimated 7 million leukoreduced blood units provided
5 worldwide. Currently, worldwide there are an estimated
6 10 million units provided annually.

7 As Dr. Lee indicated earlier in his
8 presentation, in September 1998 the FDA's Blood
9 Products Advisory Committee voted unanimously for
10 leukoreduction of all cellular blood products. By
11 December 1998 leukoreduction in blood centers was
12 already expanding, such that 10-17 percent of the
13 nation's supply was leukoreduced. Of that, bedside
14 leukoreduction was the dominant method and was
15 performed twice as often as prestorage leukoreduction
16 performed in a blood center.

17 Six months later in July of 1999, the rate
18 of use had climbed another 30 percent, so that some 25
19 percent of the nation's supply was leukoreduced. At
20 this time, 60 percent of the leukoreduction was being
21 done not in a hospital but rather at freestanding blood
22 centers. The rate of leukoreduction continues to grow
23 about five to seven percent per month.

24 In general, bedside leukoreduction in
25 hospitals is declining, but is regionally variable as a

1 factor of blood center policy. We will no doubt hear
2 from the blood collection community present that
3 currently blood centers are voluntarily practicing
4 leukoreduction in a range of 15 percent to some 100
5 percent.

6 Methods for leukoreducing blood components
7 at blood centers are dependent on the center's
8 experience, manufacturing costs, manufacturing
9 operations. These operations vary from center to
10 center, creating user preferences based on ease of use,
11 quality control, and facilities' capabilities.

12 This is particularly true for the type of
13 filter or filter set used by the different centers.
14 The question now becomes what's going to be the time
15 frame for implementation of the requirement for 100
16 percent leukoreduction in the United States?

17 If we assume, based on current trends, that
18 one-half the blood transfused in the U.S. in the year
19 2000 will be leukoreduced, we can attempt to make some
20 estimates or some predictions about utilization.

21 We believe that 50 percent of the red cells
22 transfused will be leukoreduced, and that the trend
23 toward prestorage leukoreduction will continue. Next
24 slide.

25 An even higher percentage of platelets will

1 be leukoreduced in the upcoming year. We estimate
2 about 68 percent. This estimate is even higher for
3 single donor platelets where greater than 95 percent
4 will be leukoreduced. Next slide.

5 Fresh frozen plasma has not had visibility
6 as a blood component requiring leukoreduction. To
7 date, there are no standards defined and, therefore,
8 it's difficult to measure the quantity today and in the
9 future. Next slide.

10 This move toward universal leukoreduction
11 in the United States has not been lost on
12 manufacturers, who have already begun to expand
13 manufacturing capacity. Typically meaningful expansion
14 in capacity requires six to eight months for add-on
15 leukoreduction systems, 12 to eight months for integral
16 collection systems, and six to 12 months for transition
17 to whole blood platelets to leukoreduce single donor
18 platelets collected by apheresis.

19 Most manufacturers began the process of
20 expanding manufacturing and production capacity at or
21 before the 1998 FDA Blood Products Advisory Committee
22 vote for universal leukoreduction.

23 At this juncture, that expanded capacity is
24 today becoming available. Realizing the need through
25 discussions with blood providing organizations,

1 manufacturers have already begun allocating more
2 resources to meet the needs of universal
3 leukoreduction.

4 While supplies are still somewhat limited,
5 due in part to some Y2K hoarding outside of the United
6 States, by February 2000 we expect capacity to meet the
7 current rate of expansion, which is about six percent
8 per month. At six percent compounded growth, the U.S.
9 will double to 50 percent leukoreduction in about one
10 year, and achieve universal leukoreduction by December
11 2001.

12 We believe that manufacturers can
13 confidently support this rate of utilization. What is
14 not included in this equation and what is not a
15 manufacturer's issue is the need for the blood banking
16 community to address facility changes, process
17 implementation and validation, licensure, blood
18 component inventory management, and reimbursement
19 issues that are an integral part of determining the
20 timing of any mandated leukoreduction initiative.

21 From our perspective, these issues must be
22 addressed to ensure that our customers have the
23 resources to accomplish this move. It should be a well
24 coordinated effort and cannot happen overnight.

25 The FDA must consider expedited review of

1 biological license applications submitted by the blood
2 banking community for leukoreduced product approvals in
3 order to facilitate any move to universal
4 leukoreduction. Additionally, consideration must be
5 given to who will pay the increased cost of
6 leukoreduced blood components, given the overall
7 emphasis on health care cost containment.

8 Current reimbursement coding is out of
9 date. It does not adequately address the spectrum of
10 available blood products, leukoreduced or otherwise.

11 Several options for leukoreduction are
12 available to blood centers and hospitals, including the
13 dockable systems and the in-lines and the whole blood
14 systems, as well as apheresis. Each method or process
15 has its own set of advantages and disadvantages, which
16 we will not discuss at this time.

17 The red cells are leukoreduced by
18 filtration only. The filtration options include the
19 in-line, the red cell in-line, red cell dockable
20 filters, again each having their own advantages and
21 disadvantages.

22 We expect a natural utilization mix of 50
23 percent add-on and prestorage systems and 50 percent
24 integral leukoreductions in the collection system. Red
25 cells again can also be obtained by apheresis, and then

1 filtered, providing another option.

2 Single donor platelet leukoreduction is
3 accomplished either as part of an apheresis separation
4 technology or, alternatively, post separation
5 filtration. Whole blood derived platelets are either
6 in-line filtered or a separate filter is connected
7 after pooling.

8 FDA has not established a regulatory
9 standard for leukoreduced plasma. However, in-line and
10 dockable filtration methods, as well as apheresis
11 techniques, are available to accomplish leukoreduction.

12 In light of this, CBER should review the need for
13 standards for leukoreduced plasma.

14 Additional options may be available in the
15 future. As such, HIMA believes that the FDA should not
16 mandate the method or means of leukoreduction. It
17 should be up to the blood providing agency or
18 organization to develop or decide on the type of
19 process that is most appropriate for their institution.

20 By this, we mean dockable systems or the
21 in-line systems, in-line whole blood systems,
22 nonfiltered but verified process controlled apheresis
23 systems should all be available and allowed, as long as
24 the end result is a reliably leukoreduced product.

25 We also feel strongly that CBER should

1 continue to review its regulatory process improvements
2 through the device action plan, and CBER should also
3 work to ensure that expedited review procedures and
4 other focus actions help to speed the adoption of the
5 new leukoreduction technologies.

6 In summary, manufacturers of leukoreduction
7 technologies have positioned themselves to meet the
8 demands of universal leukoreduction. The timing of
9 acceptance and implementation of 100 percent
10 leukoreduction by the medical community and by the
11 blood centers are the drivers of the manufacturers'
12 capacity.

13 A responsible approach to leukoreduction,
14 universal leukoreduction, involves a process like this
15 workshop and industry alignment on the issues and
16 timing. We do need to work together. This meeting is
17 an excellent catalyst, and we are grateful to all
18 participants.

19 We in industry look forward to working with
20 the FDA and the blood banking community to achieve
21 universal leukoreduction. Thank you.

22 (Applause.)

23 CHAIRMAN LEE: Thank you, Ms. Jones.

24 This is a rare situation in which we are
25 approximately five to ten minutes ahead of schedule.

1 So we will go ahead and break early, but if we could
2 reconvene at promptly 10:20 to begin the next session,
3 that will probably be good for the thoroughness of the
4 remaining workshop.

5 (Whereupon, the foregoing matter went off
6 the record at 9:58 a.m. and went back on the record at
7 10:21 a.m.)

8 MR. HOLNESS: Thank you. I'm Leo Holness.

9 I'm a medical officer at the Blood and Plasma Branch
10 of Division of Blood Applications. I'm going to
11 moderate Session II of the workshop, and I'm sure this
12 is the session that you've all been waiting for, the
13 regulatory approach of FDA to the implementation of
14 universal leukoreduction.

15 Our first speaker will be Dr. Jong Lee. As
16 Dr. Epstein mentioned, Jong heads our Blood and Plasma
17 Branch at CBER, and he will speak on the revised
18 guidance for whole blood and red blood cells. Jong.

19 CHAIRMAN LEE: Thank you, Les.

20 During the break, I received a few
21 questions about the possibility of copying some of the
22 what I call the key decisions, so that it will be
23 available to look at while they're conducting
24 discussion.

25 We did not do that, because when the panel

1 session opens, what I plan to do is project each one of
2 those on the screen and have it projected as the
3 discussion unfolds. So we'll probably spend about ten
4 to 12 minutes on each point, barring that we stay on
5 schedule.

6 So with that as a brief remark, as people
7 start to trickle in, I'll begin my next presentation.

8 Just as a comment, although the title as currently
9 printed is "Revised Guidance on Implementation of ULR,
10 FDA Expectations for Revised Guidance of Whole Blood
11 and Red Blood Cells," it's really more of FDA
12 expectations in a general way that are not necessarily
13 restrictive to whole blood and red blood cells but
14 potentially applicable to platelets as well.

15 So you might also think of it as sort of a
16 general FDA expectations as to specific. Also, I have
17 to point out that this is not the FDA expectation. As
18 you might anticipate, there are many versions within
19 the FDA alone, let alone the industry, as to how to
20 proceed, and I'm presenting one version of that which,
21 hopefully, represents sort of the sum of the diverse
22 opinions that are existing within the agency alone.

23 Okay. I think most people have gathered
24 back into their seats, and I hear the doors closing.
25 So I'll begin my presentation.

1 Just to point out, whole blood, blood cells
2 and platelets, which are the key issues, although we've
3 heard references to leukoreduction of plasma, I think
4 we can probably deal with that in the discussion
5 section as to what the FDA should state about
6 leukoreduction of plasma. To me, it's a rather novel
7 thought.

8 I think it must be fairly easy to achieve
9 leukoreduction of plasma, given standard procedures of
10 centrifugation, but perhaps not. Anyway, the focus
11 remains on the cellular components, whole blood, red
12 blood cells, and platelets, and these are discussed --
13 these are reviewed -- The submissions for these
14 products are reviewed in basically two areas within
15 CBER.

16 The whole blood and red blood cells are
17 reviewed within the Blood and Plasma Branch of the
18 Division of Blood Applications and, therefore, I am
19 addressing that topic at this time.

20 The platelet submissions are routed through
21 the Division of Blood Applications, but the actual
22 review is performed by the Division of Hematology in
23 the Laboratory of Cellular Hematology, and Betsy
24 Poindexter from Division of Hematology will be
25 discussing that aspect in a more specific way.

1 So there are two presentations on the whole
2 issue. They may come across as two versions, each from
3 the respective review unit, but please keep in mind
4 that portions of each may be applicable to the other,
5 and these are simply alternatives to evolving FDA
6 thinking whenever you notice discrepancies.

7 We made no effort to come up with a single
8 streamlined view of FDA's expectations, and decided to
9 simply let ideas flow, in keeping with the spirit of
10 today's workshop in developing a public consensus.

11 What I will go over in the next few minutes
12 is I'll once again point out that the impetus for the
13 universal leukocyte reduction is the BPAC vote, but
14 then make some additional observations about the
15 transition to ULR which often relates back to the BPAC
16 vote, and go over some of the key decisions in more
17 detail.

18 In my overview this morning, I presented
19 five key decisions, of which I will try to address
20 three as applicable to the actual revised guidance for
21 cellular products, whole blood and red blood cells, for
22 the purposes of this talk.

23 The key decisions I will be addressing are,
24 as you heard this morning, time frame, the actual
25 implementation plan, and the plan for possibly changing

1 the QC aspect of leukoreduction process.

2 Once again, I'd like to reemphasize that
3 the aspect of leukocyte reduction that is of highest
4 clinical importance is actually the controversial
5 indications, and that's the reason we're having so much
6 trouble determining how to proceed. The most important
7 indications are actually the most controversial and,
8 obviously, this happens a lot in medicine.

9 I have to point out that there is the
10 potential reduction of immune suppression, which hasn't
11 been shown conclusively. There is the potential
12 reduction of the blood storage region, which hasn't
13 been shown conclusively, and there are other potential
14 reduction -- beneficial aspects of leukocyte reduction
15 not listed here.

16 Of perhaps slightly less importance but
17 important nonetheless is the more accepted indications,
18 reduction of leukotropic virus transmission, reduction
19 of HLA alloimmunization, and then the widely accepted
20 indication, the prevention of febrile nonhemolytic
21 transfusion reaction.

22 Based on this, BPAC voted 13 to zero with
23 three abstentions, but once again this vote summarizes
24 lack of strong supportive data. However, based on
25 little risks associated with leukocyte reduction, if

1 any, led to this voting; and also the impact on health
2 care was not considered, and each member of the BPAC
3 committee, when they were explaining their votes,
4 supported a gradual approach to universal leukocyte
5 reduction.

6 I believe this workshop today is the first
7 step toward that gradual. Some of you may think that
8 this is too gradual. Others think that this workshop
9 is necessary to make sure that we don't proceed too
10 hastily.

11 Now to turn to some observations, and this
12 is sort of my attempt at summarizing the sentiment
13 reflected in the BPAC voting and the explanation that
14 each BPAC committee member voiced, as well as all the
15 comments I've heard since then.

16 It seems reasonably clear that, although
17 leukocyte reduction is safe, it remains unclear whether
18 the effect of leukocyte reduction is clinically
19 important for the typical transfusion recipient.

20 Point number two: Although the transition
21 period presents a unique opportunity to conduct
22 controlled clinical trials that may be otherwise
23 difficult for ethical or practical considerations or to
24 develop public consensus opinions, just the potential
25 of having an FDA mandate of universal leukocyte

1 reduction, I think, actually removes some of the
2 potential practical considerations of logistics and
3 costs and so forth in terms of conducting such a large
4 controlled clinical trial which is essential, if we are
5 to move forward in generating that data that is
6 supportive of the more important, currently
7 controversial indications for leukocyte reduction.

8 Without the, quote/unquote, "threat" of
9 such a -- of universal leukocyte reduction being a
10 requirement, such clinical trials are probably not
11 going to happen, but with the anticipation that this is
12 coming in the future, although it's not clear exactly
13 how fast, I think we'll probably foster these trials to
14 happen more likely than if there were no such
15 discussion about them.

16 In fact, some of these trials have begun
17 already, based on the BPAC vote, well before today's
18 workshop.

19 The third observation to keep in mind is
20 that the implementation issues differ, obviously, for
21 different centers, and they depend on center mission,
22 the mission of each blood center, the size, and the
23 operational complexity. Although we would like to
24 think that there can be a single FDA guidance to
25 provide as to exactly how each blood center should roll

1 out or implement universal leukocyte reduction, this
2 appears a daunting task.

3 The fourth observation: Universal
4 leukocyte reduction should be implemented in a way that
5 maximizes clinical benefits while minimizing risks, and
6 those risks include the potential adverse impact on
7 health care deliver. In other words, you might
8 produce the highest quality blood, but if it results in
9 lower quality patient care overall, then we have
10 defeated our public health mission.

11 So although we cannot directly consider
12 costs, we are very mindful of the cost issues, and they
13 are always in the back of our minds.

14 So in terms of what the essence of the
15 forthcoming -- potentially forthcoming revised guidance
16 on leukocyte reduction will address, it has to first
17 answer this key decision: Should FDA recommend a
18 simple transition period of 12 months or briefer or
19 should FDA support transition periods that are longer
20 than 12 months which may allow further maturation of
21 costs, clinical and scientific issues?

22 This is kind of like true/false questions
23 on a test. You have two choices. You pick the longer
24 sentencing, and you're usually right. I highlighted
25 the longer one in red, which indeed reflects at least

1 one version, including my version, of how we should go
2 about deciding on a time frame of implementation.

3 To expand on that a bit further, one
4 proposal is the following: Recommend -- FDA may
5 recommend that each blood center develop an
6 implementation plan, not necessarily the whole
7 implementation but develop a plan in six months. Six
8 months is not too slow or not too fast. It's
9 reasonable for a plan. But then the plan to be fully
10 implemented for all whole blood and red cells at least,
11 and potentially to also platelets -- depends on the
12 consensus that we derive internally, based on your
13 input, of course -- to implement all of this in three
14 years.

15 Now that could be interpreted by many as
16 being overly generous, overly lengthy, but many will
17 argue that this is also quite an aggressive schedule.
18 But the idea is to switch the default decision in the
19 absence of definitive data either for or against ULR
20 from not performing leukocyte reduction for all blood
21 components to doing them in three years unless proven
22 otherwise.

23 So rather than doing something and waiting
24 for -- Rather than waiting for the data to appear
25 before acting, you decide to act by a certain time

1 unless there is data against it. So this sort of
2 represents a switch into thinking about the default
3 mode of operation.

4 For those who think that the three years
5 might be overly conservative, what we could do is hold
6 an interim public discussion, perhaps in the form of a
7 BPAC discussion, at the one-year juncture to determine
8 if universal leukocyte reduction should be implemented
9 sooner -- fully implemented sooner. So that represents
10 one current version of FDA thinking about the
11 implementation time frame.

12 Now all of this is to allow and actually
13 encourage the maturation of scientific data regarding
14 the current controversial indications of leukocyte
15 reduction, either in the form of a consensus
16 development or actually in the form of controlled
17 clinical trials.

18 Many clinical endpoints, if you will, can
19 be addressed, but the more important ones that most
20 workers in the field are currently considering involve
21 whether or not there truly is an immune suppression
22 effect, whether or not truly leukocyte reduction can
23 diminish the blood storage lesion, as well as
24 strengthening the currently occurring data for reducing
25 HLA alloimmunization incidence.

1 One consensus development conference is
2 already planned and is scheduled, and I've seen the
3 "Save the Date" notice of fliers -- I've noticed fliers
4 already being distributed at the outside desk. This is
5 being organized actually by Dr. Snyder and Dr.
6 Blajchman from Yale and McMaster Universities and is
7 entitled "The Clinical and Molecular Basis of
8 Transfusion Induced Immunomodulation" to be held in
9 Washington, D.C. in March 2000.

10 I'm sure there will be lots of interesting
11 presentations at that consensus development conference,
12 as well as any other future conferences that might be
13 additionally held.

14 Additional studies are being planned or are
15 currently underway, and these studies actually do
16 include controlled clinical trials. I'm aware that the
17 Massachusetts General Hospital either has begun or will
18 shortly begin a controlled trial on leukocyte
19 reduction.

20 At this juncture I'd like to just point out
21 one study that represents recent data on microchimerism
22 after blood transfusion that is quite interesting and
23 appears relevant to today's discussion. I don't want
24 to violate the ground rule that I referred to this
25 morning, but I believe it is worth pointing out, at

1 least in one slide.

2 Please excuse the amount of words on this
3 slide, but I didn't want to take up too much number of
4 slides on scientific data. But I think by now some of
5 you might be hungry for actual scientific data. So
6 it's probably reasonable to present this slide.

7 There was a paper published in Blood in May
8 of this year, and the lead author is Dr. Lee,
9 unfortunately not this Dr. Lee but Dr. Lee,
10 nonetheless, with the senior author of Dr. Mike Bush
11 from formerly known as Irwin Memorial Blood Center.

12 The title of the paper reads as "Survival
13 of Donor Leukocyte Subpopulations in Immunocompetent
14 Transfusion Recipients: Frequent Long Term
15 Microchimerism in Severe Trauma Patients."

16 What the study looked at -- They looked at
17 two groups of patients, one set of eight elective
18 surgery patients and a second set of ten trauma
19 patients. The difference between the two groups is the
20 number of blood units that they received.

21 Now all of the blood units that these
22 subjects received -- patients received were not
23 leukoreduced and not irradiated. The elective surgery
24 patients received either one or two units, a mean of
25 1.5 units, and the trauma group patients received at

1 least four and up to 18 units, typically ten units per
2 patient.

3 What Dr. Lee and the rest of the
4 investigators did is to analyze the persistence of
5 donor derived blood cells by a technique called
6 quantitative allele specific PCR, polymerase chain
7 reaction, and they actually targeted male to female
8 transfusions as a way of tracking donor cells. Not
9 that male to female transfusion was an important
10 aspect, but it allowed the tracking of the donor cells
11 in a recipient for long periods of time.

12 When they looked at it using this
13 technique, they were able to show that in the elective
14 surgery patients these cells transiently proliferated
15 from days three to five in most patients, but all cells
16 were completely cleared below the threshold of
17 detection by this technique within two weeks in all
18 patients. However, in the group that was heavily
19 transfused, in the trauma patients, the ones that
20 typically received ten units, the cell survival was
21 documented up to 1.5 years after the transfusion, and
22 it included multilineage cells, CD4 and CD8 as T cell
23 markers, CD15 as the myeloid marker, and CD19 as the B
24 cell marker.

25 They were able to show by additional HLA

1 typing studies and one-way mixed lymphocyte reaction
2 studies that these were actually of single donor
3 source, and they represented donor cell engraftment
4 without clinical transfusion associated graft versus
5 host disease.

6 So that's very intriguing. Obviously, it's
7 a very interesting and important paper, but it should
8 be followed up with additional studies, potentially
9 leading up to controlled clinical trials, to determine
10 what meaning this has clinically for the typical
11 transfusion recipient.

12 So what does it mean? What could it mean
13 for the transfusion induced immunomodulation? It
14 appears that this multi-transfused patients, there is
15 evidence of tolerance to donor cells, evidence of
16 clinical transfusion associated graft versus host
17 disease. Professions used that term, because there
18 weren't anything clinically evident that showed that
19 there were any graft versus host disease going on.

20 Potentially, that represents some degree of
21 immunosuppression. Perhaps this is one mechanism of
22 immunosuppression that's being discussed among
23 recipients of blood.

24 It appears engraftment is more likely with
25 more transfusions. It appears that increased post-

1 operative infections and tumor recurrence that we have
2 seen in some studies could potentially be related to
3 this phenomenon.

4 Does this mean that universal leukocyte
5 reduction should be considered in conjunction with
6 gamma irradiation, since irradiation is the method of
7 choice for eliminating transfusion associated graft
8 versus host disease?

9 Does this mean that we should revisit the
10 irradiation induced storage lesion, along with
11 universal leukocyte reduction, because the current data
12 on the fact that irradiation shortens blood unit shelf
13 life is really based on limited data, and also it does
14 not take into account the fact that leukocytes might
15 mediate whatever effect on storage lesion irradiation
16 had?

17 So I think there is additional
18 considerations that must be -- That, fortunately, will
19 be forthcoming in the next several years.

20 Okay. I hope I haven't violated a ground
21 rule, but that's an interesting tidbit to consider.
22 The way I justified it in the framework of this talk is
23 that I think those are interesting considerations that
24 support a longer phase-in or transition period to allow
25 data maturation with potentially the interim discussion

1 at one year to act more aggressively, if indicated.

2 Moving on to the next question: Should FDA
3 recommend specific implementation criteria applicable
4 to all blood establishments or should FDA provide only
5 the framework within which blood establishments adopt
6 an implementation plan specific to each center?

7 Once again, if you are a good test taker,
8 you highlight the longer sentence, and that's my
9 position here, that we should provide some framework
10 but allow each blood center who know their operation
11 best to develop each specific implementation plan.
12 This is consistent with the comments that have been
13 made previously.

14 So if we were to decide on a time frame of
15 three years to full implementation, in the absence of
16 definitive data either for or against ULR as the
17 default decision, then it would be up to each blood
18 center to develop its own specific implementation plan,
19 subject to FDA verification that they have a plan,
20 perhaps at an inspection and perhaps in FDA comments if
21 the plan is unreasonable.

22 The plan will most likely address the
23 milestones in terms of time, as to where they will be
24 with passing of time during the transition period --
25 for instance, X percent of all blood units manufactured

1 by Y period in time, and whether or not the blood
2 center strategically picks one blood type over the
3 other before proceeding with universal leukocyte
4 reduction, and whether or not the leukocyte reduced
5 blood components should preferentially be triaged to
6 certain patients for certain patient indications.

7 Those are physician decisions that are even
8 beyond the control of the blood center, but actually
9 resides at the level of the hospitals and the treating
10 physicians.

11 The issues regarding additional staff that
12 might be necessary, additional training that might be
13 necessary, additional equipment, laboratory space and
14 inventory control -- these are all complex operational
15 issues that each blood center is best equipped to
16 decide for themselves.

17 Then I will move on to the third question,
18 which reads: Should the current FDA guidance on
19 leukocyte reduction be retained for use during the
20 transition period or should the definition on quality
21 control of leukocyte reduction be updated from the
22 current FDA recommendations for implementation during
23 the transition period?

24 Now here, if you apply your test taking
25 skills, you would be wrong, because I actually favor

1 the shorter sentence, that we simply retain it, just to
2 analyze -- just to separate the variables in time. I
3 don't think we want to attempt too much all at once,
4 but do it one step at a time.

5 This is not to say that our current
6 recommendation is perfect. It certainly could be
7 improved, as I'll illustrate as follows: The current
8 recommendations say that you should sample a minimum of
9 one percent or four units per month, whichever is
10 greater, and the sample may come from the units that
11 have been manufactured in the previous 30 days, and
12 with the requirements that the level of residual
13 leukocytes remain at five times 10^6 cells per unit or
14 below, with a product recovery of at least 85 percent
15 of the red blood cells.

16 If a blood center applies these QC criteria
17 and receives acceptable results, then does it assure a
18 robust leukocyte reduction process? I mean, how robust
19 is it? What do we know about the possibility of
20 unacceptable products slipping through?

21 If we pick a scenario where a blood center
22 manufactures and leukocyte reduces 400 red cells per
23 month, suppose an error in filter priming procedures
24 used by a new staff member results in achieving
25 acceptable final product standards in only 80 percent

1 of the leukocyte reduced units, and that's probably an
2 unacceptable situation where 20 percent of the units
3 that you believe to be leukocyte reduced is actually
4 not and, since you're not testing every one, there's no
5 way to know that.

6 Per FDA recommendations, the blood center
7 performs quality control testing on four units, and the
8 units are all satisfactory. Well, what does that tell
9 you about the fact that everything is okay?

10 I applied this simple formula with the
11 guidance of statisticians within the agency who
12 cautioned that this is applicable only with large N or
13 with large number of products produced, but not
14 applicable when the numbers are small. Be that as it
15 may, I think that still serves to illustrate a point.

16 The probability of obtaining a good unit,
17 given the flaw in process procedures, is 80 percent.
18 Then the chances of obtaining a good unit four times in
19 a row is 41 percent, and that the chance of obtaining
20 at least one bad unit by applying this QC criteria is
21 one minus that or 59 percent.

22 That's not very good in terms of
23 sensitivity, in terms of your ability to pick up the
24 significant deviation that might be creeping up and
25 might persist for months unless you do other QC

1 testing.

2 You could generate a table full of numbers
3 based on similar calculations for other sets of N or
4 total number of units and other criteria, other
5 thresholds that you feel is acceptable. For instance,
6 across the top, 50, 60, 70, on through 99.9 represents
7 the number of good units that your current procedures
8 are producing in terms of leukocyte reduction, and it
9 remains to be debated as to exactly what is acceptable.

10 Obviously, if your procedure is generating
11 80 percent with 20 percent units not meeting criteria,
12 then that requires correction. But perhaps 90 or 95,
13 perhaps 99 -- where is the threshold of acceptance?
14 Ninety-five appears a reasonable number at this point.

15 Along the lefthand column is the total
16 number of units and the total number of QC units that
17 are required per current guideline. When you are
18 making only 100 units, you would still test four. At
19 400 you would test four as a one percent. Then as one
20 percent on up forward -- upwards of 10, 60 and 100
21 units.

22 If you apply similar thinking, I think for
23 you to have 95 percent level of confidence, that at
24 least 95 percent of the products that you manufactured
25 meets the criteria that you think you're manufacturing.

1 You need to be testing 60 units. That's independent
2 of the total number of units that you are
3 manufacturing.

4 In other words, if you make 6 million
5 units, you still only need to test 60, but again, as
6 pointed out by my statistical consultant, this analysis
7 falls apart as the number of units that you test
8 approaches -- number of units that you manufacture
9 approaches the number of units that you actually test.

10 So, in fact, for most small blood centers
11 the QC testing requirement to achieve 95 percent
12 confidence level should be well below 60, but it
13 certainly is larger than four, as is specified
14 currently.

15 Just to point that out but not to actually
16 argue for changing the recommendation, but I think we
17 should probably retain the recommendation but keep this
18 in mind and work toward perhaps making the QC process
19 more robust.

20 So as a summary then, in terms of QC there
21 seems to be some room for improvement, but it appears
22 that there need to be no maximum -- there need to be no
23 need for testing beyond the maximum of 60 units per
24 month. The number 60 is not engraved in stone,
25 obviously. This is just a number that I have derived

1 by briefly thinking about the process.

2 The current method of sampling once a month
3 means that, if some error creeps into your process, you
4 won't know it for a whole month. That doesn't seem
5 desirable. Seems like it should be more frequent than
6 monthly sampling.

7 In terms of the actual residual leukocytes,
8 five times 10^6 cells per unit in the product recovery
9 thresholds still seem reasonable for the moment.

10 So I think what we would like to probably
11 move toward in the future in terms of QC
12 recommendations is to perform in such a way to have 95
13 percent confidence that 95 percent of your process
14 units meet leukoreduction standards. That's a criteria
15 that's not currently specified and, therefore, it is
16 not necessarily being applied at all blood centers.

17 Okay. So the summary of the potential
18 revision to FDA guidance on ULR for whole blood and red
19 blood cells: I think the planning process should
20 probably occur by six months with potential interim
21 discussion at one year, with potentially full
22 implementation in three years, and each center to
23 design its own implementation plan, and retain the
24 current recommendations on process control for now, for
25 sake of separating out complex variables.

1 These general guidelines may be also
2 applied to ULR for platelets, but platelets will be
3 discussed in much more detail by Betsy Poindexter
4 immediately following this presentation.

5 These recommendations -- The purpose of
6 these recommendations is to allow an encourage
7 maturation of leukocyte reduction as a clinical
8 science, and also to absorb and cushion reimbursement
9 concerns, and to potentially avoid -- avoid any
10 potential adverse impact on blood availability,
11 including health care delivery.

12 So, basically, leukocyte reduction clearly
13 by now is no longer a method to manufacture a choice
14 product. It's coming as blood GMP, but the
15 conservative implementation of ULR as blood GMP will
16 probably be the best route, in the absence of
17 definitive data for or against universal leukocyte
18 reduction as the default decision.

19 So this is rather general, and may also be
20 impractical to platelets, but I think I'll reserve my
21 comments to potential revisions of guidance for whole
22 blood and red blood cells to this for now.

23 That concludes my talk.

24 (Applause.)

25 DR. HOLNESS: Thanks, Jong. The next

1 speaker is Betsy Poindexter from the Division of
2 Hematology. Here at CBER Betsy is considered the queen
3 bee of platelets. Betsy will speak on revised guidance
4 on platelets and platelets pheresis.

5 MS. POINDEXTER: It's still morning. Good
6 morning, everyone. I'd like to thank you for giving me
7 the opportunity to make this presentation.

8 The title of my presentation is the
9 expectations of the FDA with regard to whether we need
10 to revise guidance for platelets and platelets
11 pheresis. I will attempt to cover -- and for those of
12 you who may not be as aware of the various types of
13 leukoreduction in a very brief overview describe those,
14 describe the current regulatory process for submitting
15 platelet and platelet pheresis samples to the Center,
16 and the regulatory process for applications that might
17 be involved, the labeling issues that might be involved
18 with the leukoreduced products that are currently
19 licensable and are licensed every day by our Center,
20 the distribution of products that may not meet the
21 current standards for platelets pheresis, particularly
22 because they are single donor platelets meant for a
23 single transfusion dose to a single patient, unlike
24 whole blood derived platelet concentrates where a pool
25 of products is used and the patient might receive four

1 to six units, so the potential as to whether we need to
2 revise the guidance documents that are currently in
3 place, if we do go in the direction of leukoreduction,
4 what its implication will not currently include, to
5 look at some areas that we need to maybe stop and be
6 aware of and to investigate and to listen to what the
7 manufacturers are telling us and what the other blood
8 centers might be telling each other, as well as we at
9 CBER, and then I will discuss my conclusions.

10 Currently, there are many different types
11 of leukoreduction. There are the in-line integral
12 filters that are currently attached to many of the
13 whole blood collection sets, many of which involve
14 filtering either the whole blood unit and producing a
15 leukocyte reduced whole blood unit that can be then
16 processed into red blood cells or platelets, and some
17 of the units also contain an in-line or integral
18 platelet filter so that you spin your whole blood. You
19 then filter your platelet rich plasma into a collection
20 container, add your additive solution, and produce your
21 red cells, spin your platelet product, produce a
22 leukoreduced platelet concentrate and an FFP product.

23 There are also continuous flow in-line
24 filters for some of the apheresis devices. There are
25 filters now that are manufactured that are freestanding

1 with a filter unit and a storage bag for the production
2 of leukoreduced red cell products, and there are now a
3 generation of automated apheresis devices that allow
4 one to collect the platelet pheresis product or
5 multiple platelet pheresis products without the use of
6 a filtration device.

7 Our goal, if we go toward universal
8 leukoreduction, is to have these processes done in a
9 blood center or a laboratory rather than at the bedside
10 or at a transfusion service on a product for which we
11 have little or no control over the processing of the
12 filtered product.

13 I have some cartoons here to describe those
14 filter units that I described. The first is the one
15 that people most frequently see currently, is an in-
16 line filter. That second red blood cell bag is
17 supposed to be attached. The second, the post-
18 processing filter, is one that can be used on a product
19 within the eight-hour room temperature hold or at three
20 to five days post-production.

21 The diagram on the left describes what is
22 currently in the Heamonetics MCS-Plus device. The
23 platelets are collected in that process mode, and each
24 of those batches of platelet pheresis product are then
25 delivered through a filter and delivered into a final

1 storage container.

2 The process on the right is currently
3 available through the Cobe and Baxter systems where the
4 product is natively leukoreduced just by centrifugation
5 process and yields a leukoreduced platelet pheresis
6 product.

7 The filtration of platelets and platelets
8 pheresis involves a variable number of filters. Each
9 of the manufacturers has provided very specific
10 information about the use of their products, and these
11 instructions for use should be specifically used for
12 each of those products in the blood center.

13 This is one of the areas that at least
14 currently we cannot just take one set of processing
15 procedures and say one sizes fits all.

16 In addition to specifically following each
17 of the manufacturers' instructions, studies have shown
18 that you should not use any sort of mechanical force,
19 whether it's manually squeezing the product to be
20 filtered or applying a blood pressure cuff around the
21 unit to increase the flow through the filter. It has
22 been shown that not only does it cause hemolysis in the
23 end unit, but it does not leukoreduce the product.

24 If the QC results indicate that the product
25 is not leukoreduced, then you should not put a

1 leukoreduced labeling on your product, and it should
2 definitely not be leukoreduced a second time. We have
3 not received any data to support secondary filtration
4 through any of the filters that are available.

5 Again, I want to stress following the
6 directions for use for each of the filters that are
7 involved and each manufacturer's variations on filters.

8 They may not be identical.

9 For platelet products, in particular,
10 produced from whole blood and from platelet pheresis
11 procedures that may go on to be filtered at the end of
12 the process, do allow for the rest period that's
13 recommended by the manufacturers.

14 Through many of the centrifugation
15 processes, both from the whole blood products and the
16 apheresis devices, the platelets that are initially in
17 that primary storage container or collection container
18 are slightly jazzed up and are activated to a slight
19 extent, and they need a time period, generally an hour
20 to two hours, to -- I call them happy campers -- to be
21 happy campers, and then be allowed to go through the
22 filtration process.

23 Products that have been allowed to go
24 through this process then can be labeled as
25 leukoreduced products, assuming that your process is in

1 control and that those units that you are testing have
2 met the current guidelines for labeling leukoreduced
3 products.

4 For licensing procedures for licensed --
5 for centers who currently have a license for whole
6 blood derived platelets pheresis, we have not required
7 any additional product submission.

8 What we have asked is that they validate
9 the process within their blood center, that they
10 validate their QC method to make sure that their QC
11 method allows them to count to the levels that are
12 necessary for them to be able to label those products
13 appropriately, to perform the monthly QC that is
14 required by the regs and by the current guidance
15 documents, to investigate all procedures.

16 Don't just write it off and say, well, you
17 know, sometimes filters don't filter or sometimes
18 filters leak. Try to figure out, either through your
19 own investigation or discussions with the
20 manufacturers exactly what might have gone wrong.

21 With the apheresis devices, we'll come to
22 that later. There are other methods for going into
23 this.

24 Make the SOPs that you have available for
25 both your process, your validation and your labeling

1 available for our inspectors upon time of review.

2 For unlicensed products that are kept
3 within the state, the same criteria apply except that
4 we, the Center, will not have seen any of those SOPs
5 perhaps for smaller sites that maintain all of their
6 products within their state.

7 The inspectors would be fully aware of
8 those, and it is not infrequent for us to field phone
9 calls from inspectors on site, wondering whether a
10 particular method, counting methods, have been
11 validated in enough people's hands and written in
12 scientific literature for us to make those
13 determinations as to whether those counts are really
14 accurate or not.

15 For licensed platelet pheresis procedures
16 for leukoreduced products, both for filtered products
17 and for apheresis in process, leukoreduced products, we
18 have required and requested licensed applications for
19 each particular variation on a theme. In addition to
20 the initial four criteria, we do ask that the centers
21 currently submit either the license application forms
22 and rapidly on the heels of that the biologic license
23 application, including an SOP for CBER's review.

24 We do review those SOPs concurrently with
25 your product license applications. In addition, we ask

1 for at least two months' worth of in-house quality
2 control on your leukoreduced products or any other
3 apheresis products that you might be producing on that
4 particular instrument or filtration.

5 We do still require samples to be sent to
6 the Center for our evaluation and comparison to the
7 results that the blood centers might have gotten.

8 It is not infrequent that we have concerns
9 about particularly the volumes that are being put on
10 the platelet pheresis products. We have had volume
11 determinations that have been off by 40 and 80 grams.

12 Now that makes a considerable difference in
13 the total yield of the platelet concentrate or the
14 platelet pheresis products, but where it is
15 particularly of concern is that the volume then that is
16 used to store the final product may not adequately --
17 the plasma volume that's stored may not adequately
18 reflect what is able to go into a particular storage
19 container.

20 Forty and 80 grams usually represents one
21 bag weight or two bag weights and the tearing of the
22 balance, and we made a presentation at AABB this year,
23 but this is a very frequent error.

24 For unlicensed products that -- unlicensed
25 pheresis products that are kept within the state, the

1 same validation process, QC method, monthly quality
2 control, and investigation of all failures of the
3 product to meet the leukoreduced criteria should be
4 met. In addition, the SOPs that are being used by the
5 blood centers should be available for review by
6 inspectors at the time of review.

7 We frequently encounter calls from blood
8 centers saying, well, what is the proper product code
9 for platelets that are leukoreduced or for platelet
10 pheresis products that are leukoreduced. So I have
11 provided those product codes. You can take them back
12 to your center. We do have those on guidance documents
13 that are available through Ken Zieman in the Division
14 of Blood Applications.

15 These are for the whole blood collected
16 products, and these are for the pheresis products. As
17 you may be aware, there are capabilities of producing
18 single, double and, in some cases, triple platelet
19 pheresis products on the apheresis devices, each of
20 which must meet the 3.0×10^{11} platelets and the
21 leukoreduction standard, if that standard is being used
22 for your products.

23 For less than standard content products,
24 those products that have less than three times 10^{11}
25 platelets, we do not allow those products to bear the

1 license number. Our policy has been that those
2 products can be used within your state with the other
3 than standard content label and with a tie tag or a
4 sticker on the bag that indicates what the final
5 concentration of the unit is. As you can tell from the
6 asterisk, these should not bear your license number.

7 We have allowed variations of plus or minus
8 ten percent. So three times 10^{11} or 2.7 times 10^{11} to
9 bear the other than standard content. Concentrations
10 which are less than that may not adequately store in
11 the storage containers that are currently available,
12 and will require further investigation.

13 Disposition of products -- and I've covered
14 a little bit of this already: Platelets containing
15 less than 5.5 times 10^{10} platelets, if you know that in
16 advance, you should put an other than standard content
17 label on that bag.

18 Obviously, we don't count every single
19 whole blood platelet that we produce, but if it's a
20 filtered product and you do have a pre-filtration count
21 and a post-filtration count and you do know that that's
22 less than 5.5 times 10^{10} , you have the option of putting
23 that label on it.

24 For platelet pheresis products containing
25 less than three times 10^{11} , they should be labeled with

1 the less than standard content label. The platelet
2 content should be put on the label. It should be used
3 within the state, and I pretty much covered this in the
4 previous discussion.

5 Jong Lee discussed the current guidance
6 documents and perhaps our need for modifying the
7 documents that are there, based on the information that
8 we might derive from today's discussion. We currently
9 have at least two documents out there, one being the
10 1988 guidance document for the collection of platelets
11 pheresis.

12 It is something that we are considering
13 updating, particularly to include the multiple product
14 collections as well as the leukoreduced product
15 collections, and then we have the recommendations and
16 licensing requirements for leukoreduced blood products
17 from 1996.

18 Based on our discussion here today, and
19 possible disagreement with Jong, maybe we will want to
20 modify that to have more information about process
21 control and statistical analyses of the data that we do
22 collect at the blood centers.

23 In the future, we do plan on updating the
24 platelet pheresis guideline, and perhaps we should
25 consider modifying the draft apheresis red cell

1 guidance document to include leukoreduced red cell
2 products. Currently, that is not addressed in that
3 document.

4 Should we change the current definition of
5 leukoreduction? The current international standards
6 are listed on the left in the orange print, and our
7 current CBER standards are listed in blue --
8 recommendations, CBER recommendations.

9 The Council of Europe suggests that each of
10 the products should contain one times 10^6 white blood
11 cell units per transfusion dose, and there is a slight
12 addendum there for the whole blood platelet products.
13 They state that 90 percent of the units should meet
14 that standard. We require 100.

15 They require a minimum of ten units per
16 month tested for each product type, and they agree on
17 the one count of the one percent of production.

18 Jong had discussed whether we should modify
19 our monthly QC to perhaps be a more frequent event, so
20 that we are able to track more carefully when our
21 process might be falling out of control. I would like
22 to suggest that we might consider a weekly QC process.

23 I know that there are some blood centers,
24 particularly for the platelet pheresis products, that
25 do weekly QC. They will take one double, one triple,

1 and one single product per week and test it for each of
2 the machine variations that they might have on hand.

3 This could potentially reduce the number of
4 massive recalls that might be involved if a process was
5 found to be out of control at the end of the month and
6 reflected whatever products you might have collected
7 during that last 30 to 31 day period.

8 If the process is found to be out of
9 control, we would like to suggest that any products
10 that are still in-house be recounted to assure that
11 they are truly leukoreduced. If they are not, then
12 that labeling should be changed. If the products that
13 have been released are recalled from the hospitals or
14 transfusion services that may still have them on hand,
15 they could be replaced with products that do meet the
16 standard.

17 Obviously, products that have been out
18 there for any length of time -- read after about three
19 to five days -- any redoing of the leukoreduction --
20 the leukocyte counting by any of the methods currently
21 available is probably only going to give you garbage
22 information, because the cells will -- What few cells
23 might still be there are going to start breaking up,
24 and those products are probably a loss. But that's
25 something is definitely up for discussion.

1 What implementing universal leukoreduction
2 will not do at this time: Currently, it will not
3 extend the dating of platelets and platelet pheresis
4 products to seven days. We need to have additional
5 studies performed to determine the effects of
6 leukoreduction and, in some cases, super-leukoreduction
7 on the platelet storage parameters.

8 At this time it won't eliminate the
9 concerns regarding bacterial contamination. Although
10 many studies have been done, and the data are
11 inconclusive, the jury is still out regarding the
12 ability of filters to remove a variety of bacteria or
13 other microorganisms.

14 Currently, it will not allow blood centers
15 to self-certify conformance to a CBER document on
16 leukoreduction, because currently we don't have a
17 document that could be referred to by the blood
18 centers. But this is something that we could consider
19 when a document such as this is available.

20 It will not currently eliminate the need
21 for submission of products to the Center, particularly
22 for the platelet pheresis products, and for new sites
23 that are coming on line for whole blood derived
24 platelet concentrates.

25 Although leukoreduction process in itself

1 might yield a product for which a leukoreduced product
2 label could be borne, the processing itself sometimes
3 doesn't yield quite the product that the blood centers
4 might hope for, primarily due to their not adequately
5 following the instruction manuals of the instrument
6 manufacturers.

7 Okay. So this is sort of my stop, look,
8 and listen. Stop: The purpose of this universal
9 leukoreduction proposal and potentially implementation
10 is to eliminate transfusion service and bedside
11 filtration for which we have no process control.

12 I'd like everyone to consider investigating
13 your process. If your processes are out of control, to
14 seek help, if you don't have help in-house, for finding
15 where you could improve your process, improve your
16 counting method, your sampling method, the numbers of
17 samples that you might be testing; to investigate your
18 long filtration times.

19 At the AABB this year, there were a couple
20 of presentations by physicians who had remarked that
21 long filtration times frequently occur in donors who
22 have sickle trait.

23 If sickle trait is an item that might cause
24 filters to not filter in a proper amount of time and
25 might not actually leukoreduce the product at the end

1 of the filtration process, we may have a concern,
2 particularly during a time when we're trying to enlist
3 minority populations to donate both for HLA typing for
4 bone marrow transplantation and for transfusion
5 products that are particularly matched for their ethnic
6 population.

7 Failures to produce leukocyte reduced
8 products should be investigated, not only through your
9 past performance but also with manufacturers of the
10 filter devices. Many of these manufacturers are more
11 than willing to send people on site and to watch your
12 process and to assist you in making this process work
13 for everyone.

14 Too frequently, the blood centers will call
15 in frustration, and we don't have the filters at CBER.

16 We don't filter red blood cell and platelet pheresis
17 or platelet products. At best, we read a lot and see
18 an awful lot of applications from device manufacturers
19 and from blood centers, but we don't have hands-on
20 experience using these devices.

21 So that all that we can go with is sort of
22 gut feelings about things. Frequently, we tell the
23 blood centers to call the manufacturers of the devices
24 and ask their technical staff for assistance.

25 Listen to the comments from your staff.

1 Don't just write them off as, well, she's always
2 complaining that this filter doesn't work right. Maybe
3 there's something to what that person is saying, and
4 share that information with other blood centers within
5 your region and other people within your processing
6 staff.

7 If the eight o'clock shift doesn't know
8 what the four o'clock shift found out last night, maybe
9 that same problem is going to occur. Again, listen to
10 the -- Ask the manufacturers questions, and listen to
11 their responses and, most of all, read their package
12 inserts and their directions for use.

13 My conclusions: Validate each process to
14 be performed in the blood center. That may sound like
15 a done deal, but there are centers that are out there
16 trying to implement processes that have not been
17 validated.

18 There are some instrument manufacturers who
19 are claiming that they can count the leukoreduced
20 products, and I can tell you that many of these
21 manufacturers have not submitted 510(k) either to CBER
22 or to CDRH for specific clearance for being able to
23 count residual leukocyte loads in either red cells or
24 platelet products.

25 Work with the manufacturers to improve the

1 quality of the process as well as the quality of the
2 products. This benefits everyone, from the
3 manufacturers of the devices to the blood centers and,
4 most of all, to the patients who are going to be
5 receiving these products.

6 Remember that any guidance that might be
7 issued as a result of this workshop will be in draft
8 format, and it will be ready and awaiting your
9 comments, and we know that we will receive them.

10 Thank you very much.

11 (Applause.)

12 DR. HOLNESS: Thanks, Betsy.

13 Our next speaker will be Mary Gustafson.
14 Mary is our Director at Division of Blood Applications,
15 and she will speak on revised regulatory expectations.

16 CAPTAIN GUSTAFSON: Thank you, Dr. Holness,
17 and just putting up my very low tech slides, my
18 overheads.

19 I changed the title of my presentation
20 somewhat from what was listed in the agenda. I think
21 it says revised regulations, and I want to reflect the
22 fact that we don't have revised regulations to present
23 to you today nor have we started working on the section
24 of the regulations that would include the
25 leukoreduction.

1 You may have noticed that we have published
2 some proposed regulations in the past few months, and I
3 can attest to the fact that writing them and getting
4 them through the clearance process is a very laborious,
5 time consuming process. So we are sometime away from
6 updating the actual regulations and the 640 additional
7 standards that would include the leukoreduction.

8 What I will discuss -- I'll put my title
9 up. What I will discuss with you this morning are some
10 of my thoughts on regulatory expectations as they
11 relate to universal leukoreduction.

12 First is the issue of licensure. Licenses
13 are required for blood and blood components when those
14 components are introduced or delivered for introduction
15 into interstate commerce. This includes products that
16 are modified by leukoreduction.

17 As Dr. Lee mentioned earlier, the approved
18 indication that we have to date is for the decreasing
19 febrile nonhemolytic transfusion reactions and,
20 although some of the other indications that were
21 discussed today are under study or under discussion, I
22 do want to stress that we don't expect the
23 implementation of universal leukoreduction to hinge on
24 proving or disproving each and every possible clinical
25 indication.

1 In fact, there's a part of me that's very,
2 very happy that blood and blood components have been
3 licensed for approximately 50 years, because I think it
4 would be very difficult to get them licensed under
5 today's scenario.

6 If an establishment is already licensed for
7 nonleukoreduced blood components, the addition of
8 leukoreduction is a change that is to be reported as a
9 prior approval supplement to your license that requires
10 currently review and approval prior to distribution of
11 the leukoreduced product.

12 What does this mean in terms of regulatory
13 burden for us in reviewing applications, and for you,
14 the industry, in submitting applications, waiting for
15 approval and implementing the change? My answer to
16 that is I really don't know.

17 Unlike the initial licensing of irradiated
18 blood components several years ago in which we had a
19 sudden influx of license applications that took us a
20 couple of years to kind of crawl out from under the
21 heap, the leukoreduced blood components have been
22 licensed for many years.

23 A search of our database reveals that many
24 licensed establishments are already licensed for
25 leukoreduced red blood cells and a somewhat smaller

1 number licensed for leukoreduced platelets. What is
2 not clear by reviewing our database is how many of you
3 will need to add more processing facilities to
4 accommodate universal leukoreduction or update your
5 license applications to reflect more up-to-date
6 technologies.

7 We don't have a handle on all of the
8 technology changes that may be in design or development
9 by the device manufacturers. In addition, it is not
10 known how many new applicants will pursue licensing.

11 My initial impression is that the
12 implementation of universal leukoreduction will not
13 result in a huge influx of applications, since so many
14 establishments are already licensed. However, I tend
15 to be a Pollyanna, and also this could change with the
16 technological changes that come along with implementing
17 a new process and the advances within that process.

18 The recommendation from the Blood Products
19 Advisory Committee was made slightly over one year ago,
20 and many have already ramped up and submitted new or
21 updated license applications. We expect the timeline
22 for implementation to be gradual enough to accommodate
23 spacing of applications.

24 I do want to stress again that any
25 implementation plan and proposed timeline is a straw

1 person for discussion today only. We thought that
2 putting together a straw person plan and timeline would
3 stimulate more discussion than trying to deal with just
4 an abstract concept, without giving you any idea of
5 what may be anticipated.

6 If I could have the next slide. We do have
7 some plans, though, to offer some regulatory relief,
8 and these are plans under our existing action plans.

9 Approximately two years ago, the agency
10 undertook a systematic approach to implementing changes
11 in our blood program. The changes needed were
12 precipitated by oversight investigations, including
13 Congress, the General Accounting Office, the
14 Department's Inspector General, the Institute of
15 Medicine, and others on the outside; and amazingly, we
16 were also able to add some of our own initiatives that
17 we wanted to accomplish.

18 The compilation of actions is termed the
19 Blood Action Plan, which is what is showing here, and
20 we also have a Device Action Plan. The plans clearly
21 address tasks to be performed and prioritizes work.

22 As you may be aware, we are a big
23 bureaucracy. One of the problems in the past in
24 reaching the end zone in any task was individual
25 components priorities. You would work really hard on

1 something that was very important to you, only to find
2 that the next agency component that was to move the
3 task had their priorities which didn't include your
4 priority.

5 The Blood Action Plan provides a framework
6 for agency and, in some cases, Department
7 prioritization of every initiative. The Blood Action
8 Plan has six areas of emphasis with assigned teams that
9 is directed by an umbrella core team.

10 I direct your attention to the third bullet
11 entitled "Reinvention of blood regulation," which I
12 noticed this morning had a typo. It's the one on there
13 that I wanted to talk about, and it's the one with the
14 typo.

15 The team has as one of its tasks the
16 initiation of a pilot program for licensing by self-
17 certification of compliance to a monograph standard.
18 The self-certification licensing scheme is intended to
19 supplement and, in some cases, replace our current
20 licensing mechanism of reviewing an extensive license
21 application submitted by the applicant prior to issuing
22 a biologics license approval.

23 The monograph standard is an FDA guidance
24 document developed under our standard operating
25 procedures for developing guidances under good guidance

1 practices. One such guidance for irradiated blood
2 components published for comment last year, and should
3 be publishing as a final guidance very, very soon so
4 that we can begin the pilot in that area.

5 Another guidance for red blood cell
6 immunization of source plasma donors is nearing
7 completion internally, to be ready to publish as a
8 draft for comment early next year.

9 We have envisioned adding a third pilot to
10 the program to include licensing of leukoreduced
11 components, at least red blood cells. We have begun
12 early, early efforts in writing a document, and your
13 input today on whether this would be a valuable
14 exercise and what elements of the guidance would be
15 helpful.

16 I think, in Dr. Lee's -- maybe it's
17 question number 5, it mentions about the guidance
18 document and the self-certification pilot. I do want
19 to modify that a bit when you see it again. I think
20 the issue would be whether the content of the 1996
21 document should remain the same.

22 Our Associate Director for Policy at the
23 Center level is not here today, which is good, because
24 we pretty well have a mandate that we will put all of
25 these memos that we have into good guidance practices.

1 So I think it mentions using the memo as it
2 is, and we will need to revise and put that into at
3 least the format for good guidance practices, but the
4 true issue is whether we need to make changes in the
5 content of that document in order to have a self-
6 certification pilot initiated.

7 Also, in addition to the licensing for the
8 individual manufacturers of the leukoreduced products,
9 I did want to discuss a bit about device manufacturer
10 issues. I don't have an overhead, but under the Device
11 Action Plan the FDA is committed to meet the statutory
12 timelines for review of device applications.

13 These are 90 days for a 510(k) and 180 days
14 for a premarket approval application. In order to
15 maximize our review process, I cannot emphasize enough
16 the importance of early and frequent contact with FDA
17 during product design, actually inception design,
18 development and the testing phase, in order to ensure
19 that the application that you submit to the FDA will be
20 reviewable within the 90 days and will be reviewable
21 within one review cycle.

22 Okay. In addition to action plan issues
23 and licensure, there are some other regulatory issues
24 that are perhaps more in the future, but I will touch
25 on those a bit.

1 One issue, and it was one that Dr. Snyder
2 mentioned, was what will become of the nonleukoreduced
3 blood components? I believe Dr. Snyder mentioned that
4 they should go the way of fresh whole blood. Another
5 term for that would be basically will they become
6 obsolete or should they be allowed to coexist with
7 leukoreduced components, as is the current situation?

8 FDA regulations include a section entitled
9 21 Code of Federal Regulations 601.5 that outlines the
10 grounds for revoking a biologics license. One of the
11 grounds is that the licensed product is not safe and
12 effective for all of its intended uses or is misbranded
13 with respect to any such use.

14 Does the leukoreduced product offer such
15 clinical advantages that the nonleukoreduced product
16 should be rendered as no longer being safe and
17 effective and, therefore, should the licenses for the
18 nonleukocyte reduced components be revoked?

19 Is this my lucky day or what? Another
20 initiative under the Blood Action Plan, as I mentioned
21 before, is the systematic review and updating of blood
22 regulations. I don't think people like regulations or
23 the regulatory process. Did you all pay him to do
24 this?

25 We have our additional standards for blood

1 components in Part 640 of Title 21 of the Code of
2 Federal Regulations. As we update those standards and
3 add leukoreduction, should we specifically add
4 leukoreduced products as new components or should the
5 processing steps for the current components be updated
6 to include mandatory leukoreduction?

7 In essence, rather than having
8 leukoreduction as a manufacturing option, should
9 leukoreduction become the standard for all blood
10 components? This, by the way, is what's happening in
11 Canada, because they have requested labels for plasma
12 and cryoprecipitate, and basically everything as being
13 leukoreduced.

14 Another future consideration is the issue
15 of labels and labeling. Currently, the container of
16 each leukoreduced component identifies the component as
17 leukoreduced. As we move to universal leukoreduction,
18 will the addition of the verbiage to each container be
19 unnecessary?

20 There's limited room on a blood collection
21 container. The real estate is -- As we design for ISBT
22 128, there's all kinds of discussions on what has to be
23 in there and what doesn't have to be in there. So if
24 everything is going to be leukoreduced, does each
25 container have to say so or should we remove the term

1 from the container label and have the processing steps
2 of leukoreduction be added as statements to the
3 circular of information?

4 These are the types of regulatory questions
5 we are considering. You may think of more, and I
6 invite you to mention those to us today. We invite
7 your comments and ideas as we develop our regulatory
8 strategies for universal leukoreduction.

9 Thank you.

10 DR. HOLNESS: Thanks, Mary, for persevering
11 through those trying conditions.

12 The final speaker for this session will be
13 Larry Fenner. He's with the Division of Case
14 Management, the Office of Compliance and Biologics
15 Quality at CBER. His topic will be compliance and
16 blood quality during the transition period.

17 MR. FENNER: Bear with me while I load my
18 program. We can maybe change some screens during that
19 time. This isn't my laptop, and I don't know what I'm
20 doing. I'm okay.

21 Okay. My topic today is compliance and
22 blood quality during the transition period. I'm going
23 to talk about compliance as it relates to the
24 regulations and guidance documents, the manufacturing
25 processes, enforcement, and also an opportunity to

1 appeal.

2 My first topic is the regulations and the
3 guidance documents. I'll assume that everybody is
4 familiar with the Code of Federal Regulations, but just
5 in case if you aren't, there are some blank pieces of
6 paper in your folders today, and FDA would appreciate
7 it if you would put your name and the name of your
8 institution and the address on them, and pass them to
9 the middle aisles, and we'll gather them and send
10 somebody out from the local district office who will
11 acquaint you with the Code of Federal Regulations.

12 Since the CFR is published subject to the
13 notice and comment rulemaking process, the rules that
14 are in CFR are binding requirements. On the other
15 hand, we have the guidance documents.

16 The purpose of guidance documents is to
17 provide assistance to regulated industry by clarifying
18 statutory and regulatory requirements and compliance
19 expectations or also to provide specific review and
20 enforcement approaches to ensure effective, fair and
21 consistent implementation by FDA.

22 They do this by explaining how industry can
23 comply with the requirements. Some guidance documents
24 provide information about what the agency considers to
25 be important characteristics of preclinical and

1 clinical testing procedures or manufacturing processes,
2 as in the case of the leukocyte reduced products, and
3 scientific protocols.

4 Others explain FDA's view on how to comply
5 with the relevant statutes and regulations and how to
6 avoid enforcement actions.

7 The term guidance documents includes
8 documents that are prepared by either FDA, applicants
9 or sponsors, and also the public that relate to
10 processing, content and evaluation or approval of
11 submissions. They can relate to the design,
12 production, manufacturing and testing of regulated
13 products.

14 They describe the agency's policy and
15 regulatory approach to an issue, and they establish
16 inspection and enforcement policies and procedures.

17 Guidance documents do not normally include
18 documents that relate to internal FDA procedures,
19 agency reports, general information documents provided
20 to consumers, speeches, journal articles and
21 editorials, media interviews, press materials, warning
22 letters or other communications that are directed to an
23 individual person or to a firm.

24 The good guidance practices document
25 established FDA's general policies and procedures for

1 developing and issuing guidance documents. It was
2 published in the Federal Register dated February 27,
3 1997, and the purpose of that document was to ensure
4 that guidance documents are developed with public
5 participation such as this meeting today, they're
6 readily available to the public when they are
7 published, and that they are not applied as binding
8 requirements.

9 All guidance documents include a statement
10 of nonbinding effect that says that the guidance
11 document represents the agency's current thinking on
12 whatever, today leukocyte reduction. It doesn't create
13 or confer any rights on or for or on any person and
14 does not operate to bind FDA or the public, and we
15 always give the opportunity to use an alternative
16 approach, as long as that approach is as good as or
17 better than the one that we recommend.

18 My next topic is good manufacturing
19 practices. The information that I'm going to give you
20 today was taken from the preamble to the GMP
21 regulations in 1978, and FDA in those preamble -- it
22 said that FDA determines what is considered to be cGMP
23 through experience, through inspectional and compliance
24 activities, through review of new applications and
25 other submissions, and also through the consideration

1 of comments from interested persons in response to
2 proposals that we send out for amending the cGMP
3 requirements.

4 For a practice to be considered to be cGMP,
5 the practice must be current in the industry. Congress
6 did not require that a majority or any other percentage
7 of manufacturers already follow the proposed mandated
8 practices, as long as it was current, good
9 manufacturing practice in the industry, meaning that it
10 had been shown to be both feasible and valuable in
11 assuring quality.

12 Now as far as enforcement, the
13 investigators have a number of references that are
14 available to them, and I'm going to talk about two of
15 them today. The first one is the investigations
16 operations manual, commonly known as the IOM.

17 The IOM is a primary source of the guidance
18 regarding agency policy and procedures for field
19 investigators and inspectors, and it directs the
20 conduct of all field inspections.

21 It's available on the Internet at the
22 address here. It's also in your handout. So you don't
23 have to try to scribble it down, because there Internet
24 addresses aren't the easiest thing to try to get real
25 fast.

1 The IOM has very specific instructions
2 concerning the use of guidance documents during
3 inspections. What it says is you shouldn't reference
4 the guidance document directly, but since guidance
5 documents are normally based on GMP or other
6 regulations, if the observation that the investigator
7 makes during the inspection relates to the GMP, then
8 they can put the failure to follow what we're telling
9 you to do on a guidance document in a 483, just as long
10 as it's based on the regulation.

11 So I will use as an example here the SOP
12 regulations from the CFR. It's 21 CFR 606.100(b).
13 That says, if you're doing something, you should have
14 an SOP for it. So theoretically, if you're performing
15 the procedure that's based on a guidance document, you
16 should have an SOP. If you're not doing what you have
17 in that SOP, you can be cited on a 483 for it.

18 The other reference guide that's available
19 to FDA investigators is the compliance policy guides or
20 the CPGs. They provide a convenient and organized
21 system for statements of FDA compliance policy,
22 including statements which can contain regulatory
23 action guidance information.

24 It's also available on the Internet, and
25 the address is in the handouts.

1 CPGs are usually written as a result of a
2 request for an advisory opinion, a petition from
3 outside the agency, or because of a perceived need for
4 policy clarification by FDA personnel. It's not
5 uncommon for a CPG to interpret regulations or
6 guidance, and in some cases the CPGs also instruct
7 investigators to use enforcement discretions.

8 For an example, if we have a regulation
9 that's outdated because of new technology, a CPG may
10 give instructions to an investigator that that
11 particular regulation shouldn't be used as the basis
12 for a 483 citation.

13 Finally, I was asked to talk about an
14 opportunity to appeal. The process for the opportunity
15 to appeal was outlined in the Federal Register of
16 February 27, 1999, for the GPPs.

17 An appeal might be an appropriate action to
18 take if a person believes that the GPPs weren't
19 followed in issuing a guidance document or if a person
20 believes that the guidance document has been used as a
21 binding requirement, like if you were cited directly
22 about a guidance document in a 483.

23 Very specific information is available in
24 that Federal Register notice, and if you wish to go
25 through this process, I suggest that you go to that to

1 get the specifics. But in general, what they tell you
2 to do is your first -- You can go through -- up the
3 chain of command.

4 In other words, if the investigator cites
5 you, you should go to their supervisor, and then up
6 through within the district or you can follow the
7 specific center and office procedures that are
8 available or also you can contact the Office of the
9 Ombudsman, and all the information to contact the
10 Office of the Ombudsman and very specific information
11 concerning these other routes is also available in that
12 Federal Register notice.

13 That's really all I have today. I have to
14 go to another meeting this afternoon. So I won't be
15 around for the question and answer period. So if
16 anybody has any questions, I'll take them now. Good.

17 Thank you very much.

18 (Applause.)

19 DR. HOLNESS: Now it's time for lunch. I
20 think Session III will start at one o'clock.

21 (Whereupon, the foregoing matter went off
22 the record at 11:53 a.m.)

2 (1:03 p.m.)

3 MS. CIARALDI: Will everybody please start
4 to take their seats, and we'll get on with our
5 workshop.

6 I would like to welcome everyone to the
7 second half of today's workshop. Thank you for coming
8 back after lunch.

9 My name is Judy Ciaraldi, and I am a
10 consumer safety officer in the Blood and Plasma Branch
11 of the Division of Blood Applications. I will be
12 moderating this third section.

13 In this session we will be hearing from
14 representatives of the blood bank and blood center
15 community. They will describe their experiences with
16 implementing a universal leukoreduction and offer their
17 proposals and recommendations for implementation.

18 Please hold your questions for each speaker
19 until the panel discussion.

20 Besides introducing our esteemed speakers,
21 part of my job is to make sure that the speakers stay
22 on time. If they go over, I have been authorized to
23 bring out the hook. In keeping with the holiday
24 season, I'll be using this as my hook. I'm going to
25 put it on the floor, as I sit right here; and if people

1 start getting close, I'm just going to place it on the
2 table and kind of wiggle it a little bit, and people
3 will know that they're getting close to their time.

4 Our first speaker will be representing the
5 American Red Cross. Stephanie Norrell has a Bachelor's
6 of Science in nursing from George Mason University.
7 She joined the American Red Cross, Washington, D.C.
8 region in 1986 as a QA coordinator for the nursing
9 department.

10 IN 1996 Ms. Norrell was appointed Senior
11 Director of Manufacturing Operations in the
12 Manufacturing Department of Blood Services, and she is
13 currently the Acting Vice President for Manufacturing.

14 I now present Ms. Norrell, who will talk
15 about American Red Cross's experiences in implementing
16 universal leukoreduction. Ms. Norrell.

17 MS. NORRELL: Good afternoon, and thank you
18 for the introduction. Specifically, thank you to Dr.
19 Lee for inviting us to speak today on the American Red
20 Cross's experience in moving toward leukoreduction.

21 So when we actually made the decision that
22 we were going to move toward leukoreduction, the very
23 first thing we did was really look at what we had to
24 work with when we started out. Basically, this is all
25 we had to work with, a filter from each one of our

1 manufacturers and not much of the support or ancillary
2 things that you need to implement leukoreduction.

3 So what I'm going to go through today,
4 since we were asked to speak specifically on our
5 experience, is really going back all the way to our
6 internal decision making process, the planning process
7 that we have been in and continue to work with, some of
8 the system tracking issues that we're working with,
9 issues, opportunities and challenges, and what our
10 current -- saving the best for last, what our current
11 conversion status is.

12 So taking us back through a little bit of
13 history here, the BPAC recommendation, which was
14 already discussed this morning, came out in September
15 of 1998. At that time, there was no formal
16 recommendation that followed, and in January of 1999 we
17 internally performed a feasibility analysis to look at
18 what our mission was going to be with leukoreduction.

19 We decided at that time that we were ready
20 to move on, and thought it was the right thing to do.
21 In April of '99 we initiated a task force to work the
22 conversion issues.

23 The real instigators for movement in our
24 organization were statements that were made by our COO
25 at the time and by our Chief Medical Officer, Dr. Rich

1 Davey, and I'm just going to read those to you, because
2 they were important mission statements, really, for us
3 to get started.

4 So the COO at the time said that this is a
5 change that will directly improve patient outcomes.
6 The Red Cross would be taking a leadership role in
7 transfusion therapy and reinforcing its commitment to
8 patients, physicians and hospitals.

9 Right after he said that, Dr. Davey said,
10 "As more studies on leukoreduction are conducted, and
11 as benefits become clearer, it is apparent that
12 prestorage leukoreduction is the right thing to do for
13 our patients and for our health care system."

14 We then put together a cross-functional
15 task force, because there were -- almost every
16 department in a region and one of our centers is
17 touched by this conversion. It's a major conversion
18 for us anyway.

19 So the task force in our organization
20 consisted of regional representation from at least five
21 of our regions, subject matter experts. We had our
22 QA/RA department in the task force, chief medical
23 office, staff from the Holland lab, our manufacturing
24 department both from engineering and planning and
25 operations perspectives, and sales and marketing was a

1 joint partner with us during this initiative.

2 So this was the task force, and the task
3 force is still actually in action.

4 The deliverables of the task force were
5 fairly straightforward. We needed to look at our
6 policies and procedures related to leukoreduction. We
7 were at that point in time somewhere in the
8 neighborhood of producing ten percent leukoreduced
9 products, and we were looking at moving or converting
10 the system to 100 percent. So, obviously, we needed to
11 relook at our policies and procedures to make sure that
12 they were in synch with that kind of a conversion plan.

13 We needed to look at our supplies and
14 equipment, a filter mix allocation. What that really
15 refers to is the fact that there are several different
16 filter manufacturers, and we use filters from all of
17 them. Not only do we use filters from the different
18 manufacturers, but we also use different product codes
19 from each one of them.

20 To further complicate it, our regions all
21 at this point in time are using a mix of those filters.

22 So there are some filter allocations and tracking that
23 are important to us.

24 We needed to look at facilities and work
25 flow issues, and produce a timeline for ramp-up. If we

1 made a statement that we were going to convert our
2 system to 100 percent leukoreduced cellular products,
3 we needed to at least have a target that we were aiming
4 for. In fact, we do, and then, of course, keeping in
5 mind the financial impact and so forth. One of
6 the very early things that the task force did was to
7 assess the current industry status and find out if
8 there were things that industry had implemented in
9 terms of equipment or work flow or whatever that we
10 could benefit from in our conversion planning.

11 So we actually evaluated centers in the
12 U.S., as well as in Europe, and actually learned a lot
13 of valuable information, as you'll see later on in the
14 presentation. We were also looking for some best
15 practices as we went through that effort.

16 We also, very importantly, needed to assess
17 our customer requirements. So we had made a decision,
18 but were our customers ready to be there with us?

19 In fact, we did a market survey of about
20 300 hospitals. About 50 percent were Red Cross
21 hospitals, and the other 50 percent were not. They
22 represented small, medium and large hospitals, and what
23 we found out from that survey is that 74 percent of
24 them said they would be ready to convert by the end of
25 2000, if costs were not an issue.

1 We, of course, needed to obtain input from
2 the staff that were going to be most affected by this
3 change. That's the component lab staff, which we did,
4 and identify any other issues that could be potential
5 big hurdles for us to address.

6 We also identified some areas that we
7 needed to research further. Different filter types:
8 We knew of the ones that were immediately available,
9 but we wanted to make sure that what we were looking at
10 was the best possible solutions for our needs. So we
11 actually looked at about 20 filters during this phase
12 here, some of them available in the U.S. and some of
13 them not.

14 We looked at the concept of a sterile dock
15 shop. What that really refers to -- Because we have
16 regions all over the country, what we were looking to
17 potentially do is locate sterile dock shops where units
18 would be collected and then sent to centralized
19 locations where they would have the rest of the
20 manufacturing process done at those locations.

21 Well, we assessed it, and at least at this
22 particular point in time we're not ready to move there.

23
24 Sickle cell trait has already been spoken
25 of today. There are issues when we try to leukoreduce

1 products from donors who have sickle cell trait. We
2 are going to be performing a study, I think, in
3 collaboration with the Army where we're going to be
4 looking at three different filters and looking for
5 which filter works the best, actually, with that type
6 of donor, and looking for other things that we can do
7 to enhance that part of the process.

8 Timing studies: With each one of these
9 filters, they are unique, and so we had to find out
10 which filters we could work with in efficient manners.

11 So with each one of the filters that we use today, we
12 have performed timing studies.

13 What we found as a result of these reviews
14 is that we really did need to make some process
15 enhancements, because we had been leukoreducing so
16 little in our organization that our processes really
17 had not been developed to be efficient when you're
18 doing large scale leukoreduction.

19 So we began in earnest and looking to
20 provide some burden relief in the procedures as they
21 stood. We evaluated work flow and space issues, the
22 different filter limitations. As you know, there are
23 different head heights required when you're doing
24 leukoreduction with the different filter manufacturers.

25 There are different timing with the actual

1 filtration process. So we really needed to understand
2 the filtration limitations.

3 Equipment limitations, we ran into as we
4 did our assessment in the beginning. The component lab
5 staff were having serious problems with repetitive
6 motion injuries with the stripping of the segments and
7 so forth. So we had to assess ways to deal with those
8 types of issues, looking at different ways to deal with
9 the staff going in and out of refrigeration and so
10 forth.

11 We also had to really concentrate on the QC
12 issues, and that's been talked a lot about this
13 morning. In our organization we are doing QC primarily
14 with the manual method, and so you can imagine the
15 impact of going from ten percent to 100 percent using a
16 manual method of QC.

17 So we really had to begin at the beginning,
18 and that was literally visiting each one of our regions
19 and evaluating their facilities and the facility
20 design, and how they would implement leukoreduction.

21 Leukoreduction takes more space. It just
22 does, and so some of our regions have actually been
23 constrained because of space requirements, the
24 inability to add refrigeration space, and so forth.

25 We had to look at them in terms of -- We began to look

1 at them in terms of small, medium and large, what type
2 of filtration they were doing, and any other issues
3 that were relevant to their local area.

4 Based on the information that we had heard
5 from the component lab staff and during our walk-
6 throughs during these work flow assessments, it became
7 very clear that the equipment that has been available
8 to the industry for leukoreduction really isn't
9 appropriate when you go to 100 percent leukoreduction.

10 So we really began to think about having to
11 -- Well, we went out and looked for equipment, even
12 asked some of the filter manufacturers if they would
13 like to come up with some equipment for us, and in the
14 end some of the equipment we are developing ourselves
15 internally.

16 Then again the operational procedure
17 enhancements, which we've talked about.

18 So with the help of computers, we've
19 actually done some modeling. For each type of filter -
20 - this is, for example, an in-line whole blood filter.

21 For each type of filter that we use, sterile dock,
22 etcetera, and for each product that we're making, and
23 for each size of center, small, medium or large, we
24 have a template like this which shows the appropriate
25 work flow or a template for a work flow.

1 So this is something that will be provided
2 to all of the regions in their planning process as they
3 go forward. It actually starts from when the unit
4 comes in, processing. The red arrows cover the red
5 cells process, and the yellow is actually plasma, the
6 path for plasma during this.

7 It takes it all the way to the point where
8 you've completed the leukoreduction process. So this
9 is now complete for all of the different variables that
10 I've talked about.

11 When you begin to think about carts, carts
12 -- you know, it just seems like it should be such a
13 simple thing, but in fact the carts we were using --
14 some of the regions were still using IV poles and so
15 forth. That was okay when we were doing a very limited
16 number of leukoreduced units, but when you go to full
17 force, 100 percent, there is a lot of movement of these
18 units back and forth from the refrigerator.

19 So we began to look t a model of a cart
20 where -- We also found that, for some strange, unknown
21 reason, a lot of people who work in the component lab
22 were short. So with all the various head heights of
23 these filters requirements, it can be very high, and
24 it's hard for these staff to reach and so forth.

25 So we actually are in the process of

1 developing carts with variable head height adjustments
2 and can actually come down low enough for short people
3 like myself. So they actually also hold more units
4 than any of the carts that we have seen available on
5 the market today. So this is a very early prototype,
6 and we're hoping to be able to implement it fairly
7 soon.

8 Another issue that came up with the staff
9 as we were doing our early assessments was -- you know,
10 they have to spend a lot of time in very cold
11 environments, going back and forth into the
12 refrigerator, sometimes doing some of the actual
13 procedural steps in the refrigerator, and they weren't
14 really happy about that.

15 So one of the things that we identified on
16 our European assessment was this reach-in refrigerator
17 concept. There are two models that we're looking at,
18 one that's actually mobile, on wheels, and one that's
19 actually just stays in place once you install it.

20 What that allows you to do is actually
21 batch your work and take advantage of not having to
22 move the product back and forth, in and out of the
23 refrigerator. It is looking in very preliminary pilot
24 data for us as a very efficient new piece of equipment
25 for us. So we are very excited about this.

1 The templates that I talked about, those
2 are being -- will be used by every region to plan their
3 floor space. Some of the regions actually are going to
4 need to have build-outs, because they're just space
5 constrained.

6 There are floor plans in there, etcetera.
7 There is also an additional binder that's going out
8 which has information, for example, about change
9 control, that they need to be working on in parallel
10 during the actual conversion process, because there is
11 a lot surrounding this.

12 There's validation if you're implementing a
13 new filter. There is all the training involved,
14 etcetera, etcetera. So we're providing some templates
15 for change control during the conversion process.

16 It also has some templates for marketing
17 information, and the number of FTEs or staff required,
18 depending on what filter methodology a region is
19 intending to use and so forth.

20 The system tracking is very important to
21 us, because we have a large system, and the real reason
22 that I'm addressing it here today is because it became
23 a critical path for us on our conversion process to
24 track how many of these filters we were going to -- we
25 were forecasting to use, because the filter

1 manufacturers have had some difficulty in keeping up
2 with the conversion rate in this country.

3 So we have literally been almost on a
4 weekly basis tracking filters that are going to be
5 needed across the country for the following week, and
6 working hand in hand with our manufacturer partners.

7 That's been a critical piece, but we do
8 track the weekly system inventory and the forecast for
9 production planning, all of that same information
10 biweekly, and then the monthly production results.
11 We're tracking filter failures and our outdate rate of
12 leukoreduced products, which I have to say is extremely
13 low.

14 The next couple of overheads address some
15 of the issues that our organization is still wrestling
16 with somewhat. So the customer issues that we're
17 continuing to hear are that the increased cost
18 associated with leukoreduced products is a major
19 inhibitor for our customers, and they are continuing to
20 -- Some customers, I should say, are continuing to have
21 some resistance based on cost alone.

22 So we are trying to work with them as best
23 we can. We are working with issues with the
24 appropriate agencies on some of the reimbursement
25 issues, but that's still an issue today for the

1 customers. It is a more expensive product.

2 Consumer demand: That has been a hard
3 thing, really, for us to track, because we can do the
4 best forecasting possible as we're meeting with our
5 hospital customers, but if for some reason a hospital
6 board or whatever decides that it's time for them to
7 convert, their demand can change from one day to the
8 next. That really causes some stress on the
9 availability of filters and so forth.

10 The policy issues that we're still working
11 with as an organization are, just an example of some of
12 them: Whether to leukoreduce autologous units;
13 leukoreduction of plasma is still something that has
14 been discussed this morning and is also being discussed
15 within our organization.

16 We do, of course produce and use SD plasma,
17 and there are reasons why it is important that we
18 should continue to look at the data, because we know
19 that FFP does contain leukocytes.

20 Other issues -- and again, the QC testing.
21 I think almost every speaker has addressed this issue.
22 So I'm not going to go into more detail about that,
23 but it is an issue that needs to be addressed.

24 The increased need for space: Again, some
25 of our regions have actually been constrained in their

1 ability to convert because of their space issues.

2 Ergonomic issues: Strippers were a major
3 issue, and we are, in fact, developing an ergonomically
4 designed stripper to help that situation.

5 Filter inventory stockouts: I don't think
6 we've ever gotten there yet, but it's something that's
7 been at such serious levels that we have really had to
8 track it almost on a daily basis.

9 The filter methodology we're looking at:
10 There are two methodology types, in-line versus sterile
11 dock. As I mentioned before, in our organization we
12 use both methodologies at this point, and we are
13 looking to use the most efficient methodology that's
14 out there.

15 One of the other issues that we're still
16 looking at is random versus single donor platelets, and
17 just the basic cost of implementation. The regions
18 that have size constraints, the amount of capital
19 investment to make this possible is not insignificant.

20 Our inventory management during conversion:
21 What we are finding is those regions that have gotten
22 to around the 40 percent to 50 percent conversion rate
23 have really found it difficult to maintain both
24 leukoreduced inventory and, as we call it, a vanilla
25 red cell inventory. So that's something that we're

1 working through as we go.

2 The recommendations that we -- and
3 proposals that we'd like to make, I think, have already
4 been heard today. So that's kind of comforting to know
5 that everybody is experiencing the same issues.

6 Our thoughts are that we should move
7 quickly with 100 percent prestorage leukoreduction of
8 red cells and platelets. We think that it takes at
9 least a year for organizations to make that conversion,
10 and maybe more.

11 We'd like to hope that there is a way to
12 decrease the QC testing involved with leukoreduction,
13 and also we'd like to think that there's a way to fast
14 track some of the filter reviews and approvals that the
15 FDA is required to do.

16 So saving the best for last, our conversion
17 status so far -- What I'm going to show you now is
18 where we were in April of '98 and where we are or where
19 actually as of October '99.

20 That's kind of hard to see, but where we
21 were in October is 37.6 percent, and that's as a
22 system. You can see here, in September is when the
23 BPAC recommendation came out. We made our decision as
24 an organization, and then the task force work began,
25 and the ramp-up has been fairly significant.

1 So our target is to be converted by this
2 date, and we've mapped it out that, in order to achieve
3 that goal, this is the percent of progress that we're
4 going to need to make on a monthly basis. Here is
5 where we are with respect to that.

6 It's not too far off, and I have very
7 strong reason to believe that, even in November, we're
8 getting much closer to where we need to be to be
9 consistent with reaching that goal.

10 So we're on our way, and I'll be happy to
11 answer any questions during the panel process. Thanks.

12 (Applause.)

13 MS. CIARALDI: Thank you very much, Ms.
14 Norrell.

15 Our next speaker is Dr. Heaton. Dr. Andrew
16 Heaton recently joined the Blood Systems, Incorporated,
17 as their Chief Medical Officer following an affiliation
18 with the blood centers of the Pacific. Dr. Heaton was
19 trained in medicine at the University of Dublin in
20 Ireland, in pathology at the University of Cape Town,
21 and in blood banking at Washington University in St.
22 Louis, Missouri.

23 He has a research interest in component
24 manufacturing, and currently serves as the head of the
25 component group of the BEST Committee of the ISBT. I

1 was going to try to get in touch with him to know if
2 that BEST meant "better" than something or -- I'm sure
3 it's initials. Maybe you can tell us what it is.

4 Dr. Heaton will describe BSI's plans to
5 move to universal leukoreduction. Dr. Heaton.

6 DR. HEATON: Thank you for the opportunity
7 to speak at such an august meeting.

8 BEST stands for Biological Excellence for
9 Safer Transfusion. Could I have the first slide,
10 please.

11 It's my pleasure to report on the planning
12 system that we've utilized at Blood Systems in order to
13 implement universal leukodepletion. Next slide,
14 please.

15 As part of my arrival at Blood Systems,
16 we've established what we call a medical policy
17 committee, which is a group of medical -- general
18 medical physicians and research scientists who get
19 together on a monthly basis to review medical/technical
20 upcoming policy related issues.

21 So we met shortly after the BPAC
22 recommendation and analyzed the medical questions, and
23 we developed an opinion on the indications for
24 leukodepletion.

25 We then proceeded to encourage operations

1 to validate both the sterile dock and the in-line
2 system. We worked with operations to develop a cost
3 versus volume, negotiated a revised process with our
4 manufacturers, and then we made certain critical
5 decisions for our operations.

6 We decided that our operational groups
7 should be free to choose sterile dock versus in-line.
8 We wouldn't mandate which they should use. We also
9 decided that we would maintain bedside filtration
10 filters to balance inventory during the transition
11 process. Finally, we decided on central quality
12 control, using the BMI device. Next slide, please.

13 With that in mind, the key goals of
14 leukodepletion and the accepted ones that we felt were
15 appropriate was the prevention of febrile reactions,
16 avoidance of HLA immunization, avoidance of CMV
17 infection.

18 We believe that the evidence for the
19 reduction of post-operative infection was compelling
20 and, as I'll show you later, we also believe that the
21 quality of the red cells is significantly improved by
22 prestorage leukocyte reduction. Next slide, please.

23 In terms of customer conversion then, we
24 reviewed the attempts or plans to convert the
25 customers, and we decided no mandates, that we wouldn't

1 order any customer that they had to go to
2 leukodepletion.

3 We decided that we would implement a
4 program of IND User, I-N-D, for transfusing MD
5 education, and that we would provide a comprehensive
6 briefing to our blood banks as we went through the
7 transition process.

8 In order to facilitate it, we trained our
9 regional management, both the technical directors and
10 the executive directors of our centers. We
11 restructured the price in order to facilitate the
12 conversion and narrow the gap between leukocyte
13 depleted and standard products.

14 We issued a newsletter. Our trade
15 association, America's Blood Centers, has an excellent
16 newsletter, and we supplied that to our customers, and
17 we began a program of hospital visits with technical
18 staff, physician visits by vendor and support
19 personnel, and then our executive management visited
20 administration.

21 So we visited the customer at three or four
22 different levels. We also supported local seminars,
23 focus groups, and technical advisory committee meetings
24 as well in order to improve the knowledge. Next slide,
25 please.

1 As we talk to the customers, there's
2 generally concurrence that it does avoid febrile
3 transfusion reactions to leukodeplete blood, and that
4 it reduces HLA immunization, and it said most of our
5 customers have increasing acceptance that there's
6 equivalence in CMV reduction.

7 There is some residual concern of viremia
8 versus reactivation, as some CMV donors carry the virus
9 that are antibody negative. There's increasing
10 acceptance of the post-op wound infection reduction
11 indication, and certainly everyone agrees or
12 increasingly they agree that it's convenient, and the
13 consistency of product quality is significantly
14 enhanced.

15 The question that the hospitals came back
16 to us with, though, was is this a change in the
17 standard of practice? Is it mandated? You did mandate
18 things like p24 antigen, but you are not mandating the
19 leukocyte depletion, and is there some significance to
20 that difference? Can you prove cost effectiveness, and
21 will it be acceptable for neonates to utilize
22 leukodepleted blood instead of CMV screened blood?
23 Next slide, please.

24 Well, then we began to look specifically at
25 the different product lines, and the first is leukocyte

1 depleted platelets. The reality is most heme-onc
2 patients may come up for transplant. It's well known
3 now that 22 degree Centigrade platelet results in
4 cytokine production and, therefore, reactions; and
5 most, about 60 percent, of our platelet transfusions
6 were already bedside filtered.

7 Bedside filter platelets were very
8 expensive. So they are easily facilitated the
9 conversion to leukocyte depleted product lines, because
10 the difference in the new product versus t he old was
11 much less when you added in the cost of the bedside
12 filter.

13 Finally, the ease of technology access:
14 The pheresis manufacturers have all produced very
15 efficient leukocyte depletion SDP devices, and these
16 facilitate -- The fact that it was so easily available
17 facilitated a start with platelets. Next slide,
18 please.

19 In 1997 and 1998, single donor platelets
20 represented 66 percent of our total platelet doses.
21 Now from our perspective, the transition from standard
22 platelets to leukocyte depleted, we elected not to
23 validate the leukocyte depleted random donor platelet
24 filter.

25 There were concerns that it was expensive

1 and that it was an additional validation that we didn't
2 have time for. So for us, the switch to leukocyte
3 depletion also means a switch to pheresis platelets.

4 So when we talk here about this conversion,
5 what we're saying is that 66 percent in those previous
6 two years was pheresis platelets, largely leukocyte
7 depleted, and the other third was random donor
8 platelets and, therefore, leukocyte rich. So
9 the priority was a focus on leukocyte depleted
10 platelets, and you can see the LD/SDP as a percent of
11 our total platelet doses. They were 66 percent in the
12 two previous years, and they've gradually climbed to 77
13 percent across this year.

14 We also looked at our QC data, and we did
15 approximately 2,000 QC samples using the BMI device,
16 and only 0.7 percent fell below the 5 million times 10^6
17 standard, which I think is excellent.

18 We noticed -- This is the leukocyte count
19 in the failures -- the average failure was 67 million,
20 and there was a log normal distribution in the profile
21 of the leukocyte failures, which I will come back to
22 when I talk to quality control of leukocyte depletion.

23 Next slide, please.

24 We then -- So the outstanding platelet
25 issues then is that LD/SDP manufacture is far more

1 expensive than RDP manufacture. The switch to
2 leukocyte depletion then pushes two extra costs on the
3 hospital, both the leukodepletion cost and the switch
4 to pheresis.

5 We believe that there is much that could be
6 done to cut the cost of leukocyte depleted manufacture.

7 The critical issue here is that Europe has largely
8 converted to pooled buffy coat platelets for two
9 critical reasons, one of which is that their regulatory
10 authorities are much more sympathetic to pooling and to
11 the use of the sterile dock device to allow pooling.

12 In Europe pheresis is relatively less
13 common than pooled buffy coats, which are very much
14 less expensive than leukocyte depleted single donor
15 platelets. So one issue, we believe, that the FDA
16 should look at is the FDA restrictions on pooling and
17 the FDA restrictions on wet wet docks associated with
18 the use of the sterile connection device. Next slide,
19 please.

20 Switching to red cells, in the past red
21 cells were basically boutique orders. They were
22 special order manufacture, and so for us then the
23 priority was manufacturing flexibility. The customer
24 ordered. The customer didn't order, and we wanted to
25 be able to have maximum flexibility.

1 The effect of that was that a very large
2 percentage of our leukodepletion at the beginning of
3 the year was by sterile dock, because that maximizes
4 your operational flexibility. But as we increased our
5 leukocyte depletion -- and this is our leukocyte
6 depletion, the total red cell charges linked to the
7 filter purchases -- it went from 17 percent to 42
8 percent across the year.

9 The fraction that we prepared by sterile
10 dock came down, because it is quite clumsy to use the
11 sterile dock in a manufacturing environment, and when
12 they're offered the choice, your operating units prefer
13 to use in-line systems, simply because they are easier
14 to use and easier to build into the manufacturing
15 process.

16 QC data was excellent. 0.4 percent
17 exceeded the five times 10^6 . The average leukocyte
18 count of the failures was 21 million, and again there
19 was a log normal distribution, which I will come back
20 to later. Next slide, please.

21 Looking at the year 2000, our presumption
22 is that many of the larger hospital systems will
23 convert with our new contract year. There is no
24 regulatory mandate. So at this point the hospitals
25 don't feel obligated to convert.

1 There is no significant standard of care
2 litigation or other reasons to make the hospitals go
3 forward, and we believe that with continuing leukocyte
4 depletion promotion and giving you the best
5 guesstimate, we think that we will reach about 60
6 percent leukocyte depletion by the end of the year, and
7 we believe that we will end up leukocyte depleting
8 around 24 percent of our red cells by sterile dock,
9 once we reach the fourth quarter of next year. Next
10 slide, please.

11 Switching now then from market issues on to
12 production issues, the sterile connection. The sterile
13 connection is about a \$2.00 premium for the cost of the
14 device and wafer, and from a manufacturing perspective
15 you offset the cost of this through avoidance of bad
16 sticks, lab losses, test losses, and increased
17 outdateding through improvements to your manufacturing
18 flexibility. But you do have additional instrument
19 quality control, and you do have additional process
20 quality control.

21 At the moment, the guidelines don't --
22 There is some guidelines on quality control of the
23 sterile connection device, but they probably could be
24 improved. There is also significant labor to perform
25 the connection filter and relabel.

1 Critical question for us is: There is no
2 definition of prestorage, and we believe that the FDA
3 should identify -- and that this is a most important
4 issue -- a standard for what prestorage means. So our
5 suggestion is less than 72 hours.

6 Secondly, there is also a difference in the
7 way that a regulatory agency treats the licensing of a
8 device, via 510(k), versus a PMA, i.e., an in-line
9 filter system. We believe that it would be helpful if
10 the licensing of these two could be standardized. Next
11 slide, please.

12 Whole blood filtration: Well, it's much
13 more convenient. The containers come pre-labeled.
14 Manufacturing is simple. The plasma is leukoreduced,
15 which is not with the sterile dock device.

16 We believe that an increased hold period
17 might enhance phagocytosis and, therefore, reduce
18 bacterial contamination and, as I will show you, 4
19 degrees Centigrade filtration greatly prolongs the
20 process. So from an operational perspective, your
21 operating units are desperate to filter at room
22 temperature and not filter in the cold.

23 In the regulatory process, the questions, I
24 think, that need to be asked is: Would a minimum hold
25 decrease bacterial growth? Could we prolong the period

1 of hold to increase presumably phagocytosis and
2 subsequent removal?

3 If 22 degrees Centigrade products are
4 comparable to 4 degrees products, we would very much
5 like to be able to hold the whole blood at 22 degrees
6 Centigrade, at least for eight hours, if not overnight,
7 in order to cut our manufacturing costs, and the 24
8 hour hold is standard in the rest of the world.

9 The last question is: Is blood mobile
10 filtration acceptable? Once you collect the unit, can
11 you just mix it up, turn it upside down, break the seal
12 and filter it on the mobiles, because again that would
13 convey very significant operating flexibility. Next
14 slide, please.

15 The advantage then of whole blood is you
16 don't have to centrifuge and filter. You do have a
17 problem with whole blood in that platelets are nearly
18 always slightly activated by phlebotomy, and certainly,
19 consistent leukocyte reduction requires platelet
20 removal.

21 So the penalty that you pay as you switch
22 into in-line whole blood systems is that you don't have
23 any random donor platelets and, therefore, you are
24 forced to convert to single donor platelets with all
25 the associated cost implications of that transition.

1 The effect that has is that we are now
2 desperate to increase our single donor platelet
3 production, because we now have to meet all the needs
4 that used to be met by random donor platelets.

5 That's going to place pressure on the need
6 to increase the number of donations per year and, in
7 addition, our customers are beginning to get anxious
8 over the number of platelet products we're splitting,
9 because the average content of the average pheresis
10 product is coming down as we more aggressively split
11 products.

12 So one of the issues we believe the agency
13 should carefully consider is the effect of leukocyte
14 depletion on the single donor pheresis regulations, the
15 frequency of donation, and the long term implication
16 that it will push or drive multi-component apheresis.
17 Next slide, please.

18 The current reservations that we most
19 frequently hear then are the CMV question on wound
20 infection -- is it really true? Now hospitals push
21 us: Won't you please prove cost effectiveness. They
22 ask why must we switch to single donor platelets; can't
23 we get our random donor platelets that were
24 inexpensive?

25 Lastly -- and this is a new bureaucratic

1 trick -- the hospitals have started saying, well, if
2 it's not a change in the standard of practice, and if
3 the FDA doesn't mandate it, we are defrauding Medicare
4 by supplying a leukocyte depleted product unless the
5 physician writes an order for leukocyte depleted
6 products on every single order he makes.

7 That is a significant issue now for the
8 more aggressively cost oriented hospitals. Next slide,
9 please.

10 Well, moving on to production variables.
11 As you know, I'm very interested in the technology of
12 manufacture, and I'll show you a couple of issues, but
13 many things affect the quality of your leukocyte
14 reduction, the capacity, your temperature, your whole
15 blood versus ASRVC filtration, your filter height,
16 filtration speed which will have some effect in your
17 complement of kinin activation. Next slide, please.

18 Now these are studies that were done in my
19 research lab with the American Red Cross, and I show
20 them to emphasize the very significant difference
21 between filtration at 4 degrees Centigrade versus
22 filtration at 22 degrees Centigrade.

23 On average you get one log better leukocyte
24 reduction. In this system, which was the PALL RC-300
25 filter in-line, none passed the 5 million limit, but

1 there is a significant difference. You can see the
2 implications of the conflict between the production
3 staff, who want room temperature filtration, and the
4 product quality people like me who want 4 degrees
5 Centigrade filtration, because you get a more
6 consistent product. Next slide, please.

7 We also observed that there is an improved
8 -- slight improvement in red cell quality. Post-
9 transfusion recoveries are about three percent better,
10 and all of the groups that have studied leukocyte
11 reduction, as the quality of the leukocyte reduction
12 improved, the degree of improvement in red cell quality
13 was quite significant.

14 You will observe this most dramatically if
15 you look at the hemolysis in the units. It is
16 significantly less in prestorage leukocyte depleted
17 units. Next slide, please.

18 If you look at platelets, we've done a
19 series of studies. In this case, these are paired
20 studies where we did tests and control, and we did the
21 same donor with leukocyte rich platelet products and
22 leukocyte depleted platelet products, leukotrap, buffy
23 coat and pheresis, and you'll see that there is no
24 significant effect on the quality of the platelet as a
25 result of the leukocyte depletion technology.

1 So we felt that there were no manufacturing
2 issues in terms of platelet quality. Next slide,
3 please.

4 Then we began to look at the details of
5 manufacturing and the quality control and the
6 statistical process control needed to back up your
7 leukocyte depletion system. At BCP we are the
8 coordinating center for the VATS study, and we have
9 developed a PCR based method which will allow us to
10 quantitate leukocytes down to the 10^3 level in the
11 containers.

12 In essence, we have primers that are primed
13 with the DQ alpha gene, and we use PCR to grow up the
14 DQ alpha segment in the leukocytes, and we use that to
15 quantitate the level of leukocyte contamination. Next
16 slide, please.

17 In this study there were 11 centers that
18 performed leukocyte depletion. QC was performed on
19 every single unit that was transfused, and you'll
20 notice a few things that drop out that are quite
21 interesting.

22 Basically, all met the current standards,
23 with a few outliers that meet the current
24 specifications. But the in-line systems here where
25 filtration was performed at 4 degrees Centigrade

1 performed more consistently and with less outliers than
2 the whole blood systems that were performed either at
3 22 degrees Centigrade or in a less structured fashion
4 than these three particular laboratories. Next slide,
5 please.

6 So leukocyte residual count is minimized by
7 a hold filtration time significantly shortened by room
8 temperature filtration. The current regs, though, if
9 you read them, imply that you should be cooling your
10 red cells as fast as you can to 4 degrees Centigrade,
11 and yet your production people -- that's the last thing
12 they want to do in order to speed up the filtration
13 process.

14 So we would like the FDA to consider
15 classifying prestorage to 72 hours, increase the 22
16 degrees component hold time to 24 hours, and there are
17 some manufacturers' instructions issues which I will
18 come back to later. Next slide, please.

19 Now when you look at what actually happens
20 -- this is now the VAT study, compiled in a single
21 group, and this is the log residual leukocytes, and
22 you'll observe that on a log normal basis you get a
23 nice bell shaped curve.

24 What you should actually be drawn to are
25 the little blips out here. In practice, it's our

1 belief that the failures in leukocyte depletion
2 probably are a separate subpopulation. Now this is not
3 a continuous distribution, but rather it is a bimodal
4 distribution of one population of normals and a
5 separate population of abnormals.

6 If you apply that statistical model -- next
7 slide, please -- to the sampling frequency that you
8 need, you can identify the size of sample that you will
9 need in order to pick up that subpopulation. This
10 becomes especially important, because in the United
11 Kingdom and the Council of Europe there are
12 requirements that the one percent or four units per
13 month is relatively common standard; but unlike this
14 country, they don't demand 100 percent pass.

15 In fact, there is a 75 percent requirement
16 in the U.K. and a 90 percent requirement in the Council
17 of Europe standard.

18 Now if you apply the bimodal approach to
19 quality control -- next slide, please -- you will see
20 that, in order to have a statistically valid chance, a
21 95 percent chance, of picking of five percent outliers,
22 there is a standard probability curve which allows you
23 to calculate the sample size that you need.

24 Our estimate was that, based on the average
25 counts of the leukocyte depleted failures, a blood

1 center would need to count 40 samples in order to have
2 a 90 percent chance of picking up ten percent failures.

3 So as we look at QC, we believe that the
4 agency should consider the statistical basis on which
5 leukocyte depletion fails, and then develop a
6 statistical model that would apply specifically to that
7 failure profile, rather than applying a one percent or
8 a four per month.

9 Four per month would be inadequate to
10 detect a bimodal failure, but one percent per month is
11 a very large and burdensome requirement that would not
12 necessarily meet the goals of the leukocyte depletion
13 system. Next slide, please.

14 So what we would suggest is a validation
15 sample of 40, followed up by samples of six. The 40
16 will allow you to pick up both the unimodal and the
17 bimodal distribution, and a routine sample size of six
18 per location would give you a very good chance of
19 picking up a unimodal shift.

20 The concern is that, if you push your
21 standards too hard, your beater error, your chance of
22 identifying an error when one doesn't exist goes up
23 very dramatically; and in leukocyte depletion, since
24 the filters perform so well, there is a very high
25 beater error, because it is very easy for a single

1 outlier to extrapolate into a perception of QC failure
2 when, in fact, that does not exist. Next slide,
3 please.

4 So in terms of product issues then,
5 different systems have different performance
6 characteristics. We believe the user should validate
7 against the defined standard. The QC should be
8 adequate to detect deviation, and we believe the system
9 performance must be judged against clinical criteria
10 rather than against statistical criteria.

11 So a recommendation that the manufacturer
12 should supply a reference database of how their system
13 performs so that an operator can compare their
14 performance with that of the reference database.

15 We believe that minimum validation
16 standards should be part of all 510(k) PMA or NDA
17 instructions, and that the one percent or four per
18 month standard requires review. Next slide, please.

19 Moving on to -- Can we go on to the next
20 slide? I'll skip that one.

21 So in conclusion then, we believe that
22 we've had an effective program for implementing
23 leukocyte depletion. We believe that, if we offer the
24 hospitals the choice, that we should be able to
25 relatively easily get to around two-thirds leukocyte

1 depletion, but that in order to exceed that level, we
2 will need some form of additional guidance or mandate
3 or very strong recommendation from the agency.

4 Secondary, we believe that the agency could
5 facilitate our activities by providing amended QC
6 guidelines that are more orientated toward the failure
7 distribution profile of leukocyte depletion systems.

8
9 Lastly, we believe that the agency could
10 help us with costs, if it would amend some of the
11 regulations related to component manufacture,
12 specifically focusing on pooling and the time to
13 leukocyte depletion.

14 Thank you.

15 (Applause.)

16 MS. CIARALDI: Thank you very much, Dr.
17 Heaton. You probably were wondering where my cane was,
18 because we are a few minutes past. All the information
19 has been so interesting that I just left it on the
20 floor.

21 For our next talk, we'll be getting two for
22 t he price of one, essentially. Both Dr. Bianco and
23 Mr. MacPherson will talk. I'm going to introduce them
24 both at the beginning.

25 Dr. Celso Bianco joined the New York Blood

1 Center in 1983 and is currently the vice president for
2 medical affairs at the New York Blood Center. Dr.
3 Bianco is a former assistant professor at New York
4 University School of Medicine and Rockefeller
5 University and a former professor of pathology at the
6 State University of New York in Brooklyn.

7 He is also the President of American Blood
8 Centers. Dr. Bianco will be speaking today on the
9 efforts of ABC's members to implement leukoreduction.

10 Following Dr. Bianco will be Mr. Jim
11 MacPherson, the Executive Director of American Blood
12 Centers. He will present ABC's position on a universal
13 leukoreduction.

14 Mr. MacPherson has held the position of
15 Executive Director since 1986. Previously, he was
16 director of hemopheresis, regulatory affairs and
17 operations research for the American Red Cross in
18 Washington, D.C.

19 Mr. MacPherson holds two Master's degrees,
20 one in cellular physiology from GW University in D.C.
21 and one in pathophysiology from the State University of
22 New York in Buffalo.

23 Dr. Bianco will start the ABC's
24 presentation. Thank you.

25 DR. BIANCO: Well, thank you very much for

1 the opportunity to be here. My presentation -- Our
2 presentation, actually, will be kind of different than
3 what the other presentations were this afternoon. I
4 think that we got enough of the technical aspects of
5 it.

6 What I'm going to try to do is a little bit
7 -- is to talk a little bit about the premises of
8 leukoreduction, to review with you the status of
9 implementation among ABC centers, to talk about some of
10 the implementation issues, and ultimately where do we
11 go from here.

12 Why, I think, is very interesting. We have
13 been trying to justify it in costs and all that, but
14 that has been the history of our life in what we do.
15 The purer, the better. We start with whole blood. We
16 went to packed red blood cells. We started with random
17 donor platelets. We went to apheresis. We started
18 with cryo, went to crude Factor VIII, went to
19 monoclonals.

20 The science also has supported, as was very
21 well discussed today, some of the indications for
22 filters. We have had also many years of experience
23 with bedside filtration -- positive, but very variable,
24 depending on the performance of those filters and on
25 the difficulties that were associated with their use.

1
2 The introduction of apheresis platelets
3 created a rather cost effective system for the
4 introduction of leukoreduced products, because they
5 didn't need filters. They didn't need the labor
6 associated with that leukoreduction.

7 The problems that we have is that we have
8 in recent years, because of the substantial cost
9 associated with leukoreduction -- essentially, a 25
10 percent increase in the cost of manufacture of these
11 components -- that none of the cost/benefit studies
12 that came out so far or that have been discussed are
13 really convincing, and I have the impression that that
14 study about cost/benefits will never be done.

15 Finally, the mythology has moved several
16 countries around the world to introduce leukoreduction,
17 and if it is for folklore, maybe that's something that
18 we should do.

19 Among ABC centers, the numbers that I am
20 going to provide you are based on a survey of ABC
21 member centers. The survey was completed a few days
22 ago, a week ago, and at that time 57 members had
23 responded out of the 72, almost 80 percent. Actually,
24 we had two more responses that came later, and then so
25 I did not incorporate them here.

1 If we talk about single donor platelets,
2 the vast majority of the centers that are included in
3 the survey provide most of their platelets as
4 leukoreduced platelets. There are centers all over the
5 range, but essentially platelets -- single donor
6 platelets are not the issue, essentially, of what we
7 are discussing today.

8 If they were to replace the current use of
9 random donor platelets as some speakers have discussed
10 before, this would be a big issue. The real issues are
11 in red blood cells.

12 Among our member centers, among these 57
13 centers, the majority of the centers leukoreduce less
14 than half of the products that they distribute, and
15 you'll see that the peak of distribution is in centers
16 distributing around 10-25 percent of their red blood
17 cells as leukoreduced products.

18 When we talk about random donor platelets,
19 very few of the centers are distributing -- Actually,
20 only two of these 57 centers were producing random
21 donor platelets that were leukoreduced for distribution
22 to their customers.

23 The plans for implementation that our
24 members have: Very few centers are done. They have --
25 Two of our centers have totally seroconverted --

1 Seroconverted? That's a real Freudian slip. Two of
2 our centers have totally converted their products to
3 leukoreduced products.

4 Another center, a major center, is on
5 January 17th, all the products that they are going to
6 distribute will be leukoreduced products to their
7 hospitals in a major city in the southwest.

8 Forty percent of our centers have made
9 plans for implementation and are gradually executing
10 those plans. However, half of our centers are not at
11 this point considering leukoreduction.

12 As we asked our centers for how they plan
13 to do it, most of them are being very careful in their
14 plans for implementation, but as I mentioned a minute
15 ago, a few of our centers have come with a real
16 specific date for the implementation of leukoreduction.

17 However, most of our members have been in very intense
18 discussion with our hospitals or the hospitals that we
19 serve in terms of how we would do it, what are the
20 issues, and trying to bring the hospitals up to date on
21 all the information that is available for this type of
22 activity.

23 There are many implementation issues. Many
24 of them were discussed in excellent ways. So I'm going
25 to go, more or less, quickly. I'm going to try to

1 compensate for the time that Dr. Heaton stole from us.

2 In terms of indications, I'm very disturbed
3 about some of the discussions about plasma and
4 leukoreduction. We knew for many years that plasma has
5 some red cells.

6 There were some interesting abstracts from
7 Dr. Holland's group at the last AABB meeting, but I
8 don't think that we have, at least at this point,
9 sufficient amount of clinical indications to really go
10 heavy on that sense. I think that we should pay
11 attention to the products for which we really see that
12 the most benefit will come to our patients.

13 In terms of technology, we heard about the
14 two major methods, and that's a difficulty that most of
15 our centers are having in terms of choosing the in-line
16 versus sterile docking.

17 In-line is a very interesting system.
18 However, the losses associated with the number of units
19 that are not utilized because the donors are deferred
20 or tests are positive or problems occurred during the
21 manufacture, because they don't meet the release
22 criteria.

23 Sterile docking is very labor intensive.
24 You need separate filters, and the question of labor
25 and space is also very important.

1 QC: We had a lot of discussion today, and
2 I think that we feel that we are all going on the right
3 track.

4 There are two issues that are very, very
5 important. One of them is the sickle cell trait. Some
6 of the speakers prior to me mentioned that units with
7 the sickle cell trait will not filter adequately.
8 About one in 400 black -- African Americans have this
9 sickle cell -- are homozygous, and about ten percent of
10 African Americans have this sickle cell trait.

11 So that's a substantial issue for the
12 African American community, and we will have to find
13 actually, I hope, ways to deal with these issues in
14 terms of we need to increase the number of minority
15 donors.

16 We are looking for them, and at the same
17 time, we don't want to see a procedure that we
18 introduce being an important obstacle to having these
19 individuals participating of the donation process and
20 actually providing many of the rare units that we are
21 looking for in terms of use or even piece that are less
22 frequent in other ethnic groups.

23 Again, another product that is somewhat
24 threatened by leukoreduction is source leukocytes.
25 Just in research we -- for research, we produce an

1 immense amount of leukocytes to universities and
2 clinical laboratories in New York.

3 There are some companies that manufacture
4 products that are based on source leukocytes. If we go
5 to in-line filtration, source leukocytes disappear, at
6 least if they continue being manufactured as they are
7 being manufactured today.

8 In terms of logistics, we will have to
9 increase personnel. We will have to have bigger cups
10 in our centrifuges. We will need more space. We will
11 need hangars.

12 I like the cart that the Red Cross has.
13 The people that are doing this study with us have
14 suggested that we buy these things that they have in
15 cleaners so that the unit enters in one side, and they
16 go walking around the room to come out on the other
17 side, and we are going to compete with the diaper
18 industry in terms of generating biological waste.

19 Again, a timeline is something that is very
20 important, and we hear the discussions. We have to
21 have time to availability of filters, training,
22 validation.

23 We hope that Captain Gustafson is going to
24 make licensure very easy for us, and maybe -- I really
25 like the idea of utilizing the new approach of the

1 monograph and maybe making the process easier for
2 introduction into several centers, and we have time for
3 that.

4 We discussed extensively the accepted
5 indications, but we have to recognize that these
6 accepted indications really represent about 20 percent
7 of usage of blood currently, of red blood cells and
8 platelets. To extend that to universal leukoreduction,
9 we have many steps to go.

10 I think that we are in synch, and from what
11 we heard today here, everybody -- either some of the
12 people are already there, and other people are a way
13 getting there. However, I think that we have a serious
14 disassociation of our thinking with the thinking of our
15 major customers, the hospitals.

16 The hospitals tell us that costs are
17 unacceptable, that leukoreduction, universal
18 leukoreduction, is unaffordable, that they cannot do it
19 without adequate reimbursement. They tell us you
20 cannot impose leukoreduction, because you do not have
21 an FDA mandate, and this is not a standard of care.

22 They raise questions about the medical
23 benefits beyond the patient groups that we clearly
24 discussed here today, and they also discuss about
25 question of costs/benefits. They don't believe in us

1 when we tell them that in-hospital times and admissions
2 and all that will be shortened and that their costs
3 will go down.

4 Finally, I think that they really resent
5 that they have not been part of this process. We have
6 been evolving our thinking toward leukoreduction as a
7 natural process. We have not been able to bring all
8 those participants of the health care system to come
9 with us.

10 We will try to propose a solution, because
11 that's a real conflict to you. But I have to tell you
12 that a few days ago during Thanksgiving, I went to
13 visit my closest friends to spend Thanksgiving with
14 them in a small town in West Virginia, and I found a
15 sign that really represents the situation where we are.

16 Since we are somewhat confused, I have
17 asked Jim MacPherson to come and present to us the
18 position of members of America's Blood Centers. Thank
19 you.

20 (Applause.)

21 MR. MacPHERSON: Thank you very much. I
22 will try not to duplicate anything, and try to be very
23 brief. I appreciate the opportunity.

24 The position is pretty simple, and that is:
25 When, and as required, the members of America's Blood

1 Centers, which represent about 6.7 million donations or
2 about half the blood supply, they will participate and
3 comply; and as Dr. Bianco said, most of them are
4 already in some kinds of planning stages already.

5 Now we've already heard about the patient
6 outcomes that may offset costs, but these are all
7 inconclusive, and I think -- You know, Jong Lee said,
8 you know, don't talk so much about money; talk about
9 implementation issues. Well, it's all about the money.

10 What we're talking about here is a cost
11 increase to the health care system of in the
12 neighborhood of half a billion dollars. As Everett
13 Dirksen -- or to paraphrase him -- once said, you know,
14 100 million here, 100 million there; pretty soon,
15 you're talking real money.

16 Without the data to support this, this is a
17 very, very hard sell for hospitals. This is the back
18 of an envelope calculation, but it does include a lot
19 of things that have been talked about here, one of the
20 things that Dr. Heaton emphasized, talked about, the
21 loss of random platelets to go into single donor
22 platelets.

23 That's not only a loss in terms of -- or
24 not a loss, but an increase in cost, but it's -- to the
25 blood centers, it's a loss margin that subsidizes the

1 price of red cells. It doesn't cost \$40 to \$50 to
2 produce a unit of platelets. Everyone knows that, but
3 there is a huge margin built into that that subsidizes
4 the price of red cells.

5 When that's gone, that has to come from
6 increased fees for red cells. So when we're talking
7 about passing along the cost of leukoreduction, that's
8 a hidden cost that a lot of people don't directly
9 address.

10 Now the big problem, of course, is
11 reimbursement. If we all got paid for it, we wouldn't
12 care. But we know today, the way the health care
13 system is set up, there is a two to three year delay in
14 adjustments to Medicare and Medicaid payments under the
15 DRG system. Of course, most transfusions take place on
16 in-patients and take place under the DRG system.

17 That's just the way the system is set up.
18 So when you start talking about putting something in
19 place that's going to start costing a half a billion
20 dollars a year, that's a lot of money to pass along to
21 the hospitals in general, especially if they don't know
22 what the offsets are.

23 Second, it also shows up specifically in
24 one budget in the hospitals, and that is the hospital
25 laboratories.

1 Now Medicare and Medicaid, we know, also
2 pays. They're the lead dog here, because they pay for
3 well over half of all transfusions that take place.
4 Now HCFA has the authority to fix this. They don't
5 need Congressional help on this. There are ways that
6 they can do this themselves.

7 There are some simple fixes that would
8 reduce the two to three-year delay down to maybe one
9 year, and those have been proposed to them. There's
10 also carve-outs, if they would be interested in doing
11 that, and as Jay Epstein said this morning, there's
12 some active discussions going on within HCFA to try to
13 figure out how to do this.

14 You solve that problem, and much of it goes
15 away. Now you still haven't proven that you've
16 improved the out-patient outcomes and saved the money,
17 but at least in terms of the hospital blood bank and
18 the blood center, you've paid for what you're doing.

19 So our recommendation is that, when FDA has
20 a recommendation like this -- and in the future, too
21 because most of the new technology that you're looking
22 at that's going to come down the pike is going to be a
23 whole lot more expensive than adding two to three
24 dollars on for tests. That was a big chunk to add,
25 about five percent of the cost, but now you're talking

1 adding 20 to 25 percent cost.

2 We're talking about other technologies in
3 the future in terms of viral inactivation that are
4 going to double or triple the price of blood. So you
5 can't have two to three-year delays when you try to
6 talk about that.

7 So when FDA starts coming out with these
8 kinds of recommendations, we say, hey, you're part of
9 HHS. You ought to talk to the other side, and you
10 ought to coordinate your activities, and there should
11 be some kind of joint approach to assuring that the
12 reimbursement is there when the recommendation comes
13 out.

14 In terms of implementation period, other
15 people have already addressed this. So I won't belabor
16 this issue, but obviously, the reimbursement concern is
17 the big concern for the hospitals and for the blood
18 centers.

19 It's a manually intensive process, as
20 you've seen by everyone. It requires that you hire
21 staff, train staff, put new quality process control
22 procedures in place. You heard this morning there's
23 the problem of the availability of filters, that there
24 may not even be enough filters to go to total universal
25 leukoreduction until the end of 2000.

1 A shortage of platelets, if we had a very
2 short phase-in period, because it's just impractical to
3 replace 4-6 million random platelets with the million
4 or so pheresis platelets that you would need to perform
5 -- platelet pheresis procedures, that there's a huge
6 gear-up for that.

7 So we recommended and are glad to see that
8 FDA is thinking along the same lines of a phase-in
9 period perhaps for three years. Those communities that
10 want to do it now, want to do it tomorrow, want to do
11 it next week, if they are comfortable with that, that's
12 terrific. For everyone else, let them have some time
13 to try to work out some of these logistics as other
14 problems go and to solve some of the problems that
15 we've all seen today.

16 In terms of logistics, all of this again
17 has been talked about before. You need flexibility in
18 this process, and again we're real pleased to see that
19 FDA, between a choice of bad and awful, they're giving
20 us the choice of bad.

21 So we would just as soon like to see as
22 much flexibility as possible in terms of this, and not
23 to be very specific on how it's done, and with their
24 oversight and guidance I'm sure they will make sure
25 that we do it right. But again, leave the details to

1 be worked out between the vendors, the blood centers,
2 and the hospitals. Thank you.

3
4 (Applause.)

5 MS. CIARALDI: Thank you very much, Dr.
6 Bianco and Dr. MacPherson.

7 All right. Our next presenter is Dr.
8 Menitove. Dr. Jay Menitove is the Executive Director
9 and Medical Director of the Community Blood Center of
10 Greater Kansas City.

11 He is also a clinical professor of medicine
12 at the University of Missouri, Kansas City, and at the
13 Kansas University School of Medicine. He is board
14 certified in internal medicine, hematology and blood
15 banking.

16 Currently, he is the Chair of the AABB
17 standards committee and is on the board of directors of
18 America's Blood Centers. Dr. Menitove will talk about
19 community blood centers leukoreduction implementation
20 plan. Dr. Menitove.

21 DR. MENITOVE: Thank you very much, and
22 thank you for inviting me to the presentation workshop.

23 What I'd like to do is to present a summary
24 of our experience in Kansas City. Just to show you
25 where we are, we're in the heart of it all, right in

1 the middle of the country, and are actually a combined
2 program now of the Community Blood Center and also the
3 Kansas Blood Services in Topeka.

4 Our current volumes of collection for this
5 year are about -- Our current collections are about
6 113,000 units per year, and we're producing about 8500
7 single donor platelet preparations, of which most are
8 leukocyte reduced, about 27,000 random donor platelets,
9 37,000 units of fresh frozen plasma, and about 4,000
10 units of cryoprecipitate, just to give you a sense of
11 what we've done.

12 Now similar to some of the data you've seen
13 before, in the beginning of 1998 about ten percent or
14 so of the units -- a little under ten percent of the
15 units leaving the blood center went out as leukocyte
16 reduced.

17 In June of 1998 one of our hospitals
18 decided to go to 100 percent leukocyte reduction, and
19 then subsequent to that, and actually slightly -- a
20 couple of months after the BPAC meeting in September of
21 '98, the usage continued to increase -- that is, the
22 switch to leukocyte reduction increased.

23 Initially, our approach was to use sterile
24 connection devices for making leukocyte reduced red
25 cell components, and that did, in fact, require that we

1 add a third person or an additional person on the third
2 shift.

3 Subsequently, we thought we would be
4 switching to in-line filters, presumably because
5 they're more efficient, and the target, which is really
6 a typo there, in our thoughts was that we would go to
7 about 50 percent sterile connection, about 50 percent
8 in-line leukocyte reduction.

9 By doing that, we would save the cost of
10 the third bag. So we would only have a double bag
11 configuration. In-line would allow us to do
12 leukocyte reduction on second shift, but we would lose
13 the random donor platelets.

14 The components laboratory, on the other
15 hand, felt that the sterile connection facilitated
16 inventory management, and in-line filters -- in terms
17 of looking at the mix when we made decisions about
18 that, decided to go with a single whole blood filter
19 rather than a dual process where there would be multiple
20 filters involved.

21 Predominantly, that decision was made,
22 because the multiple filter system was felt to be
23 cumbersome, would require a change in the
24 centrifugation buckets, and that was felt to be a
25 lesser desirable option.

1 The whole blood being filtered prior to the
2 centrifugation also, we felt, was helpful in terms of
3 just logistical approaches to what we were doing.

4 So as you can see, we started -- and I just
5 want to concentrate on this part of the curve -- saw an
6 increase in leukocyte reduction to approximately about
7 30 percent of production by December of last year. At
8 the same time, we saw the need for random donor
9 platelets decreasing.

10 That was at the same time we decided to
11 start up going with the in-line filter process, and we
12 did that, actually, at higher than the initial target
13 and, I guess, the first month made about two-thirds of
14 our needs in leukocyte reduced red cells using the in-
15 line approach.

16 What we found was that the demand for
17 random donor platelets increased at the same time that
18 we had made the switch. So we backtracked what we did,
19 and actually the curve reversed. So that we're back
20 using mostly sterile connection filtration at this
21 point in time.

22 We've also seen a slight increase in the
23 use of leukocyte reduced units subsequent to that time,
24 about 35 percent. Actually, currently we're a little
25 closer to 40 percent of the units collected as

1 leukocyte reduced units.

2 Some of the issues are: Can we manage our
3 ABO mix in terms of providing enough leukocyte reduced
4 units, and are we able to make enough random donor
5 platelets, again similar to some of the comments you've
6 heard before.

7 At about a 35 percent rate of leukocyte
8 reduction for red cells, our thoughts are what do we do
9 if it increases towards 100 percent. The initial
10 plans are to increase the use of in-line filters. We
11 could do that on the second shift.

12 We wouldn't need additional staff, and
13 again we would have the advantages of reducing the
14 number of bags that are there to a double
15 configuration. However, we feel that the limit of
16 using the in-line approach is 50 percent.

17 We hit the wall at about 50 percent
18 leukocyte reduced red cells, and that's related to our
19 current need for producing random donor platelets. Now
20 if that were to change, then, obviously, where we hit
21 the wall would change, but that's about what we're
22 making today in terms of random donor platelets, plus
23 making some cryoprecipitate and quad preparations for
24 neonates.

25 So we think that's probably what's going to

1 -- where we're going to have to make additional
2 decisions. The options are to increase sterile
3 connections -- that would require us to add an
4 additional staff person with a cost associated with
5 that -- or we could go to 100 percent in-line
6 filtration plus converting all of our platelets, the
7 single donor platelets, which we don't believe will be
8 accepted by the physicians and hospitals, or we could
9 use specific red cell and platelet filters.

10 We have not made any decisions about that.

11 So that's where we stand at the current time. Now
12 just for -- Dr. Lee asked -- allowed me and asked for
13 suggestions for the FDA, and just a few comments.

14 In terms of a conceptual approach, one way
15 of looking at what we've done with blood safety is
16 donor deferral, screening process, inactivation and
17 removal of pathogens.

18 So looking at it in a triad type of way,
19 perhaps one way of looking at leukocyte reduction is
20 the scientific basis, and we've heard comments about
21 that, then an implementation plan. Then,
22 unfortunately, reimbursement does become an issue and
23 cannot be avoided.

24 I believe we should be looking at evidence
25 based decision making, and I like Celso's slide of the

1 two arrows converging on each other. I think this is
2 very difficult, and my own personal belief is that
3 we're in a time of incredible flux, and I have changed
4 my mind on this subject probably more than any other in
5 terms of the value of going to universal leukocyte
6 reduction. But if there is a scientific basis and it
7 is based on evidence, we can then do professional
8 education.

9 I think that, if the data are there, it
10 would be accepted. Then going the next step, to
11 reimbursement education, would be a natural step.

12 In terms of implementation, I've kind of
13 bifurcated this into two options that blood centers can
14 follow. One is to take a responsive stand, and the
15 other is to take a directive one.

16 We have chosen to take a responsive stance.

17 That is that we'll see if the evidence is out there to
18 make a decision. If it is, it allows for educated
19 decision making; and if it's supported scientifically,
20 we believe the trend will move in that direction. So
21 the train will follow the tracks that they ought to
22 follow, presumably.

23 The opposite stance is one of a directive
24 approach where you have standardization presumably to
25 achieve economies of scale, and in all fairness, that's

1 probably where the trend is taking us anyhow. So you
2 can get there faster. But as I said, we prefer to take
3 the responsive one.

4 So what have we found? In our area, we
5 really see a bimodal distribution. What I put on the
6 y axis is the number of hospitals; on the abscissa,
7 the percent that these hospitals are using that are
8 leukocyte reduced.

9 So hospitals -- More than 30 of our 65 --
10 or actually 70 hospitals are accounting for 41 percent
11 of the red cells that are transfused, use somewhere
12 between zero and five percent leukocyte reduced red
13 cells.

14 On the other end of the spectrum are
15 hospitals accounting for -- about 15 or so hospitals,
16 accounting for 31 percent of the red cells that are
17 transfused in our area that are using close to 100
18 percent leukocyte reduction.

19 Then we see a few hospitals that actually
20 account for a large percent of the blood transfuse
21 using somewhere between 15 and 20 percent of the
22 leukocyte reduced red cells.

23 So my sense is that this really is a
24 bipolar distribution, either none or all, and then a
25 few hospitals using about 15 to 20 percent leukocyte

1 reduced red cells, and when asked, the comments that I
2 get are that the red cells that are leukocyte reduced
3 in those hospitals are used by oncology patients and a
4 few of the anesthesiologists are using -- are ordering
5 those leukocyte reduced red cells.

6 Now I can't help but come back to an issue
7 of reimbursement. The health care triad is the
8 quality, access, and cost. In this arena we do have to
9 talk about reimbursement.

10 From a personal point of view, I am not
11 certain that this is the best way to spend a half a
12 billion dollars in a zero sum type of environment.
13 There are clear advantages.

14 If they are supported scientifically, then
15 I think it makes sense, and I think that if it really -
16 - some of the data that we really head are correct, in
17 the long run there may be some reimbursement savings or
18 cost savings to the hospitals. But the reimbursement
19 issue is a very significant one.

20 When I've spoken to pathologists in our
21 area, they particularly wanted me to dwell on this for
22 a moment, because they are facing enormous pressures
23 from their administration.

24 To go along with what others have said, if
25 there's an FDA mandate or if it becomes t he standard

1 of practice, then they will obviously move in that
2 direction. However, in a time of indecision they are
3 going to wait and see what happens, and this is a
4 factor in that decision making process.

5 Thank you very much for your attention.

6 (Applause.)

7 MS. CIARALDI: Thank you, Dr. Menitove.

8 Our last speaker is Dr. Dennis Goldfinger of the Rita
9 and Taft Shriver Division of Transfusion Medicine of
10 Cedars-Sinai Hospital.

11 Dr. Goldfinger is also a clinical professor
12 of pathology and laboratory medicine at UCLA. He
13 attended medical school at the State University of New
14 York in Buffalo and followed it up with studies in
15 clinical pathology at UCSF and a fellowship in
16 transfusion medicine at NIH.

17 Dr. Goldfinger will talk about the
18 experience of his hospital with universal
19 leukoreduction and what has happened since then. Dr.
20 Goldfinger.

21 DR. GOLDFINGER: Thank you, and I'd like to
22 thank the Food and Drug Administration and their staff
23 for inviting me today. I would also like to thank Dr.
24 Menitove for catching us up, so that I've only lost
25 half of my allowable time to give this talk.

1 What I'd like to do today is discuss with
2 you some historical perspectives of Cedars-Sinai and my
3 own involvement in leukocyte reduction, talk about our
4 own experience in attempting to accomplish this goal,
5 and finally to try to tell you how I think you should
6 not attempt to achieve the goal of universal leukocyte
7 reduction.

8 First of all, after 25 years of trying to
9 convince the rest of the world that leukocyte reduction
10 would be a good idea, I can't resist the opportunity to
11 say I told you so. So I'm going to show you four old
12 slides.

13 You can see that these are old, and they
14 were actually made in 1980, just to point out that the
15 same kinds of issues that we discussed then are the
16 very same issues that are the hot topics right now.

17 First of all, a study that we did in the
18 late 1970s looking at the incidence of transfusion
19 reactions, nonhemolytic transfusion reactions. We
20 followed about 10,000 transfusions and found that there
21 was a significant reduction in the incidence of all
22 forms of nonhemolytic transfusion reactions in patients
23 who received, in this case, saline washed red cells.

24 We also talked about infectious
25 complications and recognized that perhaps the removal

1 of leukocytes from blood might reduce the risk of
2 transmitting agents that were carried in peripheral
3 blood leukocytes like cytomegalovirus.

4 Also we talked about alloimmunization to
5 leukocyte and platelet antigens and the impact that
6 that might have on patients who were to receive
7 platelet and granulocyte transfusions.

8 Finally, we recognized that substances that
9 accumulated in blood during storage might be harmful to
10 the recipient. In those days the word cytokine was not
11 known, but as you know, there is concern that these
12 kinds of things do impact on the quality of the
13 transfusions that we give.

14 Now so much for ancient history. I'd like
15 to tell you about our experience in achieving the goal
16 of 100 percent leukocyte reduction. We did this for
17 two years, beginning in 1992.

18 This decision to deliver this was based
19 upon two premises. First of all, that the passenger
20 leukocyte, as Dr. Harvey Klein has referred to these,
21 could not possibly benefit the recipient of a blood
22 transfusion, but might cause harm.

23 Secondly, unlike some others, we believe
24 that febrile nonhemolytic transfusion reactions are not
25 something to be ignored, and that are potentially a

1 serious problem.

2 We did not believe in this approach of
3 waiting until patients had adverse reactions to blood
4 transfusion, to transfusion of ordinary nonleukocyte
5 reduced components, before switching to a leukocyte
6 reduced product or, even worse, using a rule of two or
7 three, waiting until the patient had two or three
8 adverse reactions before giving the better product.

9 This is kind of a preventive therapy, and
10 it kind of can be -- We could use the analogy of a
11 drug, which is something that the FDA, of course, is
12 more used to regulating.

13 If we had a new antibiotic, for example, a
14 new cephalosporin, and this was a highly effective
15 antibiotic but it caused adverse reactions in one to
16 two percent of recipients, and we had another
17 preparation of that same antibiotic. It was just as
18 effective, but it caused no untoward reactions. Which
19 one of these would we choose to give? Certainly, which
20 one would patients want?

21 I think, in a regulated environment, we
22 would not even be able to allow to market the less safe
23 material. This is the same kind of thinking that we
24 applied to leukocyte reduction.

25 This effort -- First of all, we recognized

1 that washed cells were really not happy cells, and that
2 it was impossible to achieve the goal of leukocyte
3 reduction with saline washing. But of course,
4 filtration allows this to occur.

5 This was a multi-focal effort. It required
6 the participation, first of all, of our community blood
7 center, the American Red Cross in southern California,
8 along with the Palm Beach blood bank from which we were
9 getting a significant amount of blood.

10 They would prestorage filter all of the
11 blood that they sent to us. We have a collection
12 facility that collects about a quarter of the blood
13 that we transfuse, and we did prestorage filtration on
14 all of those.

15 We also filtered in our component lab all
16 red cell units that did not come to us already
17 filtered. This represented a small number of units,
18 like directed donor units that came from other centers.

19 Finally, on the nursing units nurses performed bedside
20 filtration on all units of platelets.

21 Some statistics here. First of all, we
22 used only single donor platelets in those days, which
23 is what we use now, and I'll talk to you a little bit
24 more about that in a moment. But all of these units,
25 about 2500 units a year, and they were filtered all at

1 the bedside.

2 We were transfusing in those years about
3 22,000 units of red cells per year, and as you can see,
4 they were all filtered, most of them, prestorage.

5 There are real advantages to going to 100 percent
6 or to universal leukocyte reduction. Now, clearly, the
7 downside is that there is increased cost. On the other
8 hand, inventory management is really a cinch. There's
9 only one kind of component. It's all leukocyte
10 reduced. So that the technologists in the blood bank,
11 the nurses dealing with this, love this approach.

12 In addition, clinical decision making is
13 also made very easy. All patients receive leukocyte
14 reduced components. So that all patients are getting
15 the same thing, and I think in this case all patients
16 were getting the best thing.

17 Now in 1994 we abandoned this project, and
18 we did it because of a need to reduce costs. We've
19 heard -- Many times over the years I've heard that
20 Cedars-Sinai is a so called boutique hospital, and it
21 really doesn't operate in the real world.

22 Well, of course, that's a ridiculous
23 statement. We get paid the same way that every other
24 hospital gets paid, Medicare, private insurance and,
25 more and more, capitated contracts. So there's really

1 no difference in the way we operate and the way
2 everyone else operates. However, in these years --
3 this is 1994 -- we were facing serious cost
4 constraints.

5 In the case of the laboratory we lost 25
6 percent of the individuals who worked in the
7 laboratory, from over 400 people to just around 300
8 people. This was a huge cut. After 20 years of trying
9 to convince unsuccessfully the rest of the world that
10 leukocyte reduction really made sense, we had to kind
11 of throw in the towel here and say that we could no
12 longer justify losing personnel while we're trying to
13 maintain an inventory of only leukocyte reduced
14 components.

15 So we stopped doing it, and we went to
16 doing what most of you all do, and that is leukocyte
17 reducing on demand. Right now we probably transfuse
18 about a quarter of our units of red cells in a
19 leukocyte reduced form.

20 Now finally, I'd like to discuss with you
21 what I believe you should not do in order to achieve
22 this goal, and what you should not do is reverse the
23 accomplishments of 50 years of transfusion medicine
24 progress, things like autologous transfusions, single
25 donor platelets, reducing donor exposure or resisting

1 new developments like safer plasma.

2 I'm dismayed to hear more and more, really,
3 I think, excellent people coming from fine institutions
4 talking about doing this sort of thing. Our journals
5 are filled with articles, typically mathematical
6 models, that suggest that these kinds of technologies
7 are not so called cost effective.

8 Autologous transfusion: This is pre-
9 deposit autologous blood prior to surgery. Clearly,
10 this was a great boon to patients in the early 1980s
11 during the AIDS epidemic, and it's clearly the choice
12 of patients. We do this, and we think it makes sense,
13 but it is a more costly kind of technology.

14 Single donor platelets: This is an
15 unbelievable one, to me, because there is -- How
16 anybody can argue in favor of the use of pooled
17 platelet concentrates is just beyond me.

18 Yet we're hearing from more and more
19 institutions that they think it's a good idea, and it's
20 one of the ways that they're going to justify the use
21 of universal leukocyte reduction, and that is to go
22 back to pooled platelet concentrates.

23 The only reason for doing so would be
24 increased cost. Clearly, if there's any product that
25 should go the way of fresh whole blood, it should be

1 this product, this 30-year-old, outmoded product that,
2 in my opinion, represents a clear and present danger to
3 the American public. We'll come back to this in a
4 second.

5 Now the supposed justification, of course,
6 is that blood is so safe that we need not be concerned.

7 Now most unbelievably, I think, recently we're seeing
8 articles suggesting that we no longer have to protect
9 our children from blood, that programs for neonates
10 that minimize donor exposure can be abandoned, because
11 they're really not cost effective.

12 Now, of course, the patient doesn't seem to
13 have any say in any of this kind of decision making.
14 Well, very often transfusion medicine physicians seem
15 to see their role strictly as gatekeepers, and strictly
16 trying to dissuade clinical colleagues from utilizing
17 more expensive blood components.

18 Yet the role, I think, of a transfusion
19 medicine physician, and for all of us who practice this
20 field and for the Food and Drug Administration, is to
21 be patient advocates. That's really our job, and that
22 means to give patients what is the safest and most
23 effective therapy.

24 Cost is an important issue, but it should
25 not necessarily be our first issue. Patients don't

1 want to go to physicians who are, first of all, cost
2 effective and, secondly, patient advocates.

3 Imagine trying -- If you try to tell a
4 patient -- Take a patient who has had chemotherapy for
5 acute leukemia, for example, and is going to require 15
6 platelet transfusions while recovering from
7 chemotherapy induced bone marrow hypoplasia.

8 That patient can be exposed to 15 donors,
9 in the case of single donor platelets, or perhaps 90
10 donors for pooled platelets, six in a pool. Now if you
11 ask the patient, would you mind if I gave you some
12 blood from 75 different individuals, I don't really
13 have to do it, but I'd like to do it to save some
14 money, what do you think of that -- well, of course, no
15 patient would accept this kind of an approach.

16 Imagine going to the parents of a newborn
17 child and saying, you know, we have a new way of
18 transfusing this little baby; we're going to expose the
19 baby to many units of blood, but blood is pretty safe
20 and it's going to save the hospital a lot of money. Of
21 course, this is an absurd thing, and no patient would
22 ever accept this kind of an approach.

23 So the only way that we can accomplish this
24 is by not telling anybody what we're doing, and I don't
25 think it's right.

1 We've heard from tobacco companies for
2 years, cigarettes do not cause lung cancer, heart
3 disease or emphysema. Nicotine is not addicting. Now
4 what have we heard from the blood banking community?

5 In 1983, just 16 years ago, we heard that
6 blood transfusion does not transmit AIDS, and if it
7 does, the risk is only one in a million, like any hit
8 and kill by a bolt of lightning. Well, in fact, the
9 risk in large cities in those early years was more like
10 one in 100 to one in 1,000.

11 The new watchword seems to be blood is
12 safer than ever, and we see it repeated over and over
13 again. Now I don't know. Is this deceptive
14 advertising or what?

15 Just scanning, for example, a list of
16 topics that were presented at this year's American
17 Association of Blood Banks meeting just a month ago,
18 looking at some of the infectious complications of
19 blood transfusion that were discussed at this meeting,
20 there were discussions about hepatitis B, hepatitis C,
21 HIV and HTLV, because we recognize that we still have
22 not eliminated that risk. It still remains a risk,
23 albeit it smaller.

24 There were discussions about hepatitis G
25 virus, a virus looking for a disease or for something

1 bad to do, but clearly transmitted by blood
2 transfusion, and Creutzfeldt Jakob Disease as a
3 potential risk.

4 There were discussions -- There were
5 abstracts presented on the risk of tick borne
6 infections, human erlichiosis, babesiosis, lyme
7 disease. There were discussions about other parasites
8 like Trypanosoma cruzi, the agent of Chagas Disease,
9 and malaria, clearly agents that we know can be
10 transmitted by blood transfusions.

11 There were discussions about human herpes
12 viruses. We've been concerned about CMV, but what
13 about oncogenic agents like Epstein Barr virus, human
14 herpes virus 8, also known as Kaposi's sarcoma virus?
15 Are these transmitted by blood transfusion? Probably
16 so, and should we be concerned about that? I don't
17 know. I think maybe so.

18 Finally, a whole host of bacteria that can
19 contaminate all of our blood components. So just how
20 safe is it?

21 Well, recently, Philip Morris has come
22 around and said that cigarettes do cause emphysema,
23 heart disease and lung cancer, and that nicotine is
24 addicting. So do you think that maybe it's time for
25 the blood banking community to kind of 'fess up and

1 admit that we produce a product that saves many lives,
2 but it's inherently risky and, therefore, we should do
3 everything we can to improve the safety of the
4 components that we transfuse, and that this should
5 really be mandatory.

6 After all, we did think that blood was
7 safer than it ever had been in 1980, and then came
8 AIDS, and we all got killed. So the bottom line here:

9 Leukocyte reduction does cost a lot more, although as
10 you've heard, there are efforts to try and demonstrate
11 that perhaps there are advantages of leukocyte
12 reduction that will reduce costs, but that remains to
13 be seen.

14 It is definitely achievable. We did it,
15 and I know that it can be done, although I am impressed
16 by some of the difficulties that some of the large
17 institutions have demonstrated that this is not
18 something that can happen overnight for the entire
19 country. But it can be done and, as they say in
20 Washington, it is the right thing to do.

21 Thank you.

22 (Applause.)

23 MS. CIARALDI: Thank you, Dr. Goldfinger.

24 We will now take -- Dr. Lee, can we still
25 have 20 minutes or should I cut it down? Okay. We

1 will now take a 20 minute break. Please return to the
2 auditorium at -- It will be ten after three for the
3 open presentations and the panel discussion. Thank you
4 very much.

5 (Whereupon, the foregoing matter went off
6 the record at 2:50 p.m. and went back on the record at
7 3:08 p.m.)

8 DR. LEE: While everyone is trickling back
9 in, we have had a request to make an open presentation,
10 and the order of the process for the rest of the
11 afternoon would be that the open presenter to make his
12 presentation, which should be about 15 minutes, and
13 then after that we will have the panel up at the table,
14 and then start going over some of the questions.

15 The questions are meant to foster
16 discussion, and other questions can be entertained
17 also.

18 I'm waiting for the quorum. If everyone
19 would please get back in your seats.

20 CAPTAIN GUSTAFSON: I have the honor of
21 moderating the fourth and last session of the workshop.

22 When the staff and the audio-visual department heard
23 that I would be moderating this session, they sent a
24 warning: Keep your hands up, and you will not be
25 harmed. I'm not allowed to have any heavy tablets or

1 touch anything.

2 Anyway, as Jong mentioned, we do have one
3 speaker who asked to give more than just a couple of
4 words at the microphone. Dr. John Whitbread from
5 Cytometrix, International, in New York will present
6 information on process control for the manufacture of
7 leukoreduced blood components.

8 Dr. Whitbread, and upon completion then we
9 will invite the panel up for panel discussion.

10 DR. WHITBREAD: Thank you very much.

11 I would like to just spend a few minutes
12 during this open presentation session to share a few
13 ideas with you on process control of leukocyte reduced
14 components.

15 I think the morning session was very
16 interesting in that there seemed to be a new consensus
17 that seemed to be being generated on using some sort of
18 methodology over and above quality control to help us
19 better understand what the process of leukocyte
20 reduction is doing and, moreover, how we can really
21 monitor the process in a comprehensive, reliable way,
22 essentially to make us good manufacturers for those
23 components.

24 This is a topic which recently was brought
25 up at the BEST committee meeting about a month ago.

1 The discussion -- Most of the discussion at the BEST
2 meeting was really mostly theoretical and getting into
3 the various questions and various models that one might
4 think about, even in terms of trying to design or
5 implement a statistical process control program.

6 What I am going to be talking about today
7 is really more the practical side of it: What is
8 process control? How does it compare, really, to
9 quality control programs? And essentially, at the end
10 of the day, how can we use this to achieve our bottom
11 line of being able to accurately predict what fraction
12 of our manufactured component is liable to be outside
13 the acceptable manufacturing range or just flat out
14 fail QC?

15 To accomplish this, I'd like to break these
16 comments, really, into four points: As I mentioned, to
17 compare and contrast quality control to process
18 control; to talk a little bit about the manufacturing
19 standards one needs to think about in terms of
20 implementing a good process control program; some of
21 the unique technical challenges, and this refers
22 somewhat to the types of models and the types of theory
23 that go into formulating a statistical process control
24 program; and finally, I'd like to finish with some real
25 life experience that we've had with statistical process

1 control.

2 Okay. Why process control? Well, we
3 process control essentially to define manufacturing
4 thresholds, traditionally through types of analysis
5 that take, say, a range of values. That would be QC
6 values for leukocyte components -- establish a mean,
7 and then you could sort of imagine the familiar bell
8 shaped curve that gives us sort of a range of what we
9 expect that manufacturing process to produce, and then
10 we might establish sort of standard deviation or
11 confidence intervals outside from that mean that give
12 us some idea of what might be acceptable and what might
13 not be acceptable.

14 Certainly, traditionally process control
15 has been used in many manufacturing organizations,
16 primarily as, really, a great means of measuring
17 manufacturing efficiency. The pharmaceutical industry,
18 for instance, uses process control, really, for
19 determining and monitoring potency of their
20 manufactured products.

21 Really, many of the manufacturing
22 industries that are out there use some form of process
23 control to get a better measurement of what the process
24 is doing, rather than solely focusing on the product
25 alone.

1 Certainly, as a result -- which has been
2 well documented that the implementation of process
3 control helps minimize wasted product and helps
4 increase manufacturing confidence.

5 Just to quickly go through some of the key
6 differences between product QC and process control:
7 Certainly, from product QC we know that we measure the
8 final product. At the end of the day, what we wind up
9 with is a pass/fail type result. Either we are above
10 or below five times 10^6 , and then what we get also with
11 the product QC is, of course, we don't have a clear
12 idea of what the probability may be for future QC
13 failure.

14 Process control, on the other hand, we're
15 measuring a process. We're measuring the day to day
16 experience of our, in this case, leukocyte reduction
17 process. This essentially gives us a means for
18 measuring a trend and efficiency of the process.

19 What is particularly attractive about
20 process control is that, by doing this type of
21 measuring, doing this type of analysis, it gives us
22 instant feedback about what our probability of failure
23 and success is as we go forward in the manufacturing
24 process.

25 Another key aspect to process control is

1 confidence. We had some talks earlier talking about
2 the sensitivity of QC and process control. Just as
3 sort of a primer to confidence, basically confidence is
4 an indicator based on sample number, frequency and
5 failure rate of the process.

6 These are essentially what is combined
7 together to give us a confidence of whether or not our
8 process is in or out of control. For instance, we did
9 a quick analysis actually right before this meeting,
10 and if we assume a failure rate of about eight percent
11 -- that is, a leukocyte reduction failure of about
12 eight percent, which is probably very conservative.
13 Certainly, the failure rates that have been reported
14 most recently are quite a bit lower than this, but I
15 think eight percent actually serves us well in terms of
16 this illustration.

17 What confidence do we have in detecting a
18 failure, using the current QC approach -- that is, of
19 sampling one percent of the product? What you see here
20 is the relative confidence level here and the monthly
21 sample size that you need to detect a failing unit,
22 assuming an eight percent failure rate.

23 As you can see, with a minimal sampling
24 here of four, our confidence level is really quite low
25 at about 28 percent. Earlier, Dr. Lee had indicated to

1 us that, really, 95 percent -- as well as other
2 speakers, have indicated 95 percent really being a
3 better number to shoot for in terms of trying to
4 establish a good sense that we understand the
5 manufacturing process.

6 For this -- Under these assumptions, you
7 would need to test about 35 samples per month to get a
8 confidence level of 95 percent.

9 Okay. So if we are convinced that process
10 control is the way we want to go, what would we think
11 about in terms of making sort of an idea process
12 control program?

13 Well, ideally we want it to be interactive.

14 I mean, after all, we have -- everybody has different
15 manufacturing needs, although we're conscious of the
16 five times 10^6 . Nevertheless, having a mechanism that
17 allows us to adjust the manufacturing thresholds --
18 say, if one month we want to try to make a product
19 which is quite a bit better than five times 10^6 , for
20 instance -- that allows us to do that.

21 Certainly, we want to be maximally
22 sensitive to failing process, and perhaps most
23 importantly, provide us a real time state of
24 manufacturing.

25 Currently, with the sampling of once a

1 month, this makes it difficult, and perhaps one of the
2 things that we would want to think about in parallel
3 with process control is, if not more samples per month,
4 perhaps more frequently taking whatever number of
5 samples we're going to be taking for that month.

6 That will certainly help establish getting
7 a closer feel for what the real state of manufacturing
8 is today. After all, we're doing process control to
9 help us get a better handle on the manufacturing
10 process. This type of analysis really becomes
11 important.

12 Keeping it simple: It doesn't take long
13 for me to stand up here and start talking about
14 statistics, and you start seeing a lot of glazed eyes.

15 I think that one of the key points to implementation
16 of any type of process control program is going to have
17 to be that it ultimately makes it easy for the user to
18 use.

19 This has got to be something that
20 essentially data can be dropped into and out comes a
21 graphic or out comes a table that gives a real time
22 indication for what that process is doing that week or
23 that day.

24 Certainly, if we looked into the future and
25 kind of think about what we might want out of sort of

1 an idealized process control program, it would be
2 certainly to try and be predictive as much as we can be
3 about the future. What is this type of manufacturing
4 trend likely to produce one month or three months or a
5 year down the line?

6 I think this may be particularly important
7 even for product qualification type analyses, in that
8 we want to try and use this information. Essentially,
9 we're using quality control information. We would
10 essentially use this information and be able to work as
11 much information -- much value out of that information
12 as we can.

13 So, certainly, one of the things we can do
14 with a lot of these current statistical methods is to
15 help us extrapolate what the future might look like,
16 and I think this is certainly something that we can
17 work towards.

18 Some of the difficulties -- I'll go through
19 these quick -- in detecting failing processes, since
20 this starts to border on some of this statistical
21 mumbo-jumbo:

22 Essentially, the current type of
23 distribution that's associated with a leukocyte
24 reduction process may have actually very different
25 types of distributions, and the current methodologies

1 for trying to estimate probability, at least in a
2 statistical sense, very often tend to underestimate the
3 real probability of getting an accurate estimate of how
4 frequently you're going to have a failing process and
5 ultimately a failing product.

6 A sensitivity -- The Shewhart method here
7 is considered more or less a standard within the
8 process control circles, but really is probably the
9 least sensitive compared to other statistical methods
10 which I list up there.

11 Autocorrelation, I'll just pass by. The
12 other key aspect of the leukocyte reduction process
13 that really makes putting together a good statistical
14 program difficult is the very nature of the process
15 itself.

16 When you consider the range of results that
17 you can get with a QC result, you can be down at the
18 level of sensitivity, which for flow cytometry or PCR
19 may be down to 10^3 leukocytes per unit, are ranging up
20 to 5 million and greater. You can appreciate the large
21 amount of variance that you have within that
22 distribution, and trying to use some of these methods
23 to accurately estimate what your probabilities are
24 becomes very difficult.

25 Okay. So what are some of the design

1 characteristics that we would ideally like to put
2 together for a good, comprehensive statistical process
3 control program?

4 Well, certainly, first and foremost, we
5 want a continuous estimate of the probability
6 defective. After all, without this, process control is
7 useless, and we need to have some way to have this
8 estimate presented to us, if possible, on a daily basis
9 that gives us a very clear idea of what to expect for
10 that day and also be able, again, to maximally use the
11 experience that we have with that process.

12 The issues of control versus out of control
13 performance criteria: This is, I think, an important
14 issue that in considering a good statistical process
15 control program we think a little about how we want to
16 define these and, certainly, there are some good
17 statistical arguments, which I won't go into here, as
18 to how we might best define control versus out of
19 control.

20 Similarly, the standards that we define as
21 control and out of control certainly shouldn't occur in
22 a vacuum, and that the standards should be consistent
23 with what medical device manufacturers who have large
24 databases on performance of their products -- that they
25 should be consistent, certainly, within peer.

1 If one blood service or blood center,
2 series of blood centers has a large collective
3 database, that certainly putting together the criteria
4 for control and out of control performance criteria
5 should be sensitive to that experience.

6 Lastly, the sensitivity should always be
7 high, and that the level of confidence remains
8 constant. This is sort of a statistical geek point
9 which I think, again, goes along with the point I made
10 earlier about the variance being very large; and when
11 you're working with that type of data, that it becomes
12 very difficult, particularly as the database grows in
13 size, to keep the sensitivity very high while
14 maintaining the confidence at a standard level of,
15 let's say, 95 percent.

16 So ideally, what might this look like, in
17 sort of a very simple world? Well, we could imagine
18 something like this where, for instance, we have
19 categories here for all units less than certain
20 thresholds.

21 Again, I mentioned earlier about the
22 interactive thresholds. These are numbers that are
23 sort of important to us from a regulatory level, but
24 perhaps as manufacturers we may have other levels that
25 might be important to us as well.

1 A target efficiency, that essentially being
2 the probability of producing all of our units under
3 these given thresholds. Then what we might have as
4 what we call measured efficiency. Basically, where are
5 we this week or this month.

6 Graphically, we could present this as a
7 fairly -- I realize there are a lot of lines on here.
8 It probably looks a little complicated, but essentially
9 this shows a process which is going along here over
10 time, months down here. We have basically production
11 efficiency over here.

12 Levels for all processes being less than
13 five times 10^6 , one times 10^6 and five times 10^5 , and by
14 design this particular process is just to illustrate
15 how this might work.

16 This yellow line, if you follow it along,
17 is showing for the first 100 months or so a process
18 which is always producing units under 5 times 10^6 . What
19 we can see is that after about the 109th month here, it
20 now departs from that probability.

21 What's interesting, and in fact, when you
22 look at real data, real datasets, is that this always
23 seems to bear out. That is that you see sort of a
24 major fluctuation in some of the lower levels prior to
25 getting a defect in your process at your regulatory

1 level or at your highest level.

2 So I think this, again, may be the sort of
3 tool that would be helpful, again as manufacturers, to
4 help us get alerted to when processes may be going out
5 of control.

6 As I mentioned, there's some experience.
7 This is actually from some work that was presented at
8 the most recent AABB meeting and related the
9 experience, actually, in Canada where they used a
10 process control program in 13 blood centers.

11 Essentially, just to quickly go through the
12 results from this study, was they had six of the 13
13 centers which were always in control, three of the
14 centers which were in control and then went out of
15 control, and then there were four centers which were,
16 in terms of the statistical process control, always out
17 of control.

18 This gives you the number of units that
19 were looked at. As you can see, clearly, the failure
20 rate for the ones which were always in control was much
21 better than the ones which were out of control. So,
22 certainly in this scenario, the process control was
23 very beneficial in alerting these centers when
24 processes were going out of control and, clearly, when
25 there was no response to that signal, that in fact they

1 did get failing product.

2 So as I just said, the centers received
3 warning ahead of the product QC failure. This prompted
4 retraining of some of the key operations within
5 centers, and they concluded that the process control is
6 a powerful method to prevent increases in the risk of
7 QC failure.

8 I think this is really an excellent study,
9 and really proof positive of the value of statistical
10 process control when it's applied to a leukocyte
11 reduction process.

12 So to summarize, the current QC sampling
13 plan, at least as it currently exists, really may not
14 detect substantial numbers of products that are
15 essentially -- that may be failing. Again, this can be
16 improved one of two ways, either by more samples or
17 more frequently sampling.

18 I tend to think that, in terms of moving
19 towards a process control program, that a more frequent
20 sampling with perhaps some more modest increase in the
21 number of samples would really work out quite well.

22 The statistical process control provides
23 key manufacturing data, again to make manufacturing
24 decisions. I mean, as manufacturers -- and we want to
25 really have a good feel for what the process is doing

1 on a day to day basis, that this is a mechanism that
2 allows us to make those key manufacturing decisions.

3 Process control will augment QC. We're
4 certainly not advocating here that we get rid of QC
5 completely. I think that there's certainly a value to
6 doing the types of QC that's currently being done, and
7 I think that the process control can really be a nice
8 addition to the current QC program.

9 Certainly, finally, the process control is
10 now a method which evidences accumulating -- Several
11 other studies which were presented at the BEST meeting
12 which related process control experiences using it in
13 the leukocyte reduction process.

14 I think that as time goes on and the
15 studies accumulate that, again, the message will be
16 that much more convincing.

17 Just in closing, I'd like to take a quote
18 from the 1987 FDA guidelines on general principles of
19 process validation. With that, thank you very much for
20 your attention.

21 (Applause.)

22 CAPTAIN GUSTAFSON: Does anyone have any
23 questions for Dr. Whitbread? Okay. If the panel
24 members, the invited speakers, would come to the panel,
25 and Dr. Jong Lee will briefly go through the -- recap

1 the workshop objectives, and then we will open the
2 floor to discuss Dr. Lee's key questions, key elements,
3 whatever, and also any other issues that were raised
4 during the presentations or any other questions that
5 any of you may have.

6 CHAIRMAN LEE: I guess we've lost two
7 members of the panel from the original plan. That
8 creates some additional space at the table, I think.
9 If Dr. Whitbread is interested in joining us, he would
10 be welcome.

11 I'd like to simply go through some of the
12 points that I made earlier this morning, as takeoff
13 points for discussion. That is not to say that
14 discussion should be limited to these questions, but I
15 think what we'll do is have each question up on the
16 slide while we are going on, and try to step through
17 them at approximately at a pace of eight minutes per
18 decision, trying to leave some time for any additional
19 topics that might arise at the end of the day.

20 Once again to remind you that participants,
21 while we are discussing things, may refer to the
22 following aspects, but not to dwell on them as primary
23 topics, and we've gone over this extensively today:
24 Cost, clinical risk and benefits and scientific
25 principles -- we have heard a lot about them. They

1 should be mentioned as they relate to implementation
2 issues.

3 The first point that I made this morning
4 was: Should FDA recommend specific implementation
5 criteria applicable to all blood establishments or
6 should FDA provide only the framework within which
7 blood establishments adopt an implementation plan
8 specific to each center?

9 Key decision number 2: Should FDA
10 recommend a simple transition period of 12 months or
11 briefer or should FDA support transition periods that
12 are longer than 12 months which may allow further
13 maturation of cost, clinical and scientific issues?

14 Decision number 3: Should the current FDA
15 guidance on leukocyte reduction be retained for use
16 during the transition period or should the definition
17 and QC of leukoreduction be updated from the current
18 FDA recommendations for implementation during the
19 transition period?

20 Number 4: Should blood centers, if
21 eligible to participate in the CBER pilot program for
22 streamlining licensure, be able to obtain the license
23 for leukocyte reduced blood products by the simple
24 self-certification process, referring back to the
25 existing leukocyte reduction standards, or should blood

1 centers, if eligible and interested, continue to be
2 required to submit evidence of compliance with existing
3 leukoreduction standards for CBER review in obtaining
4 the license to ship leukocyte reduced blood products
5 across state lines?

6 Lastly, if a blood center already licensed
7 for whole blood, red cells and platelets may self-
8 certify in supplementing its license to include
9 leukocyte reduction, should it be able to self-certify
10 compliance with the existing 1996 FDA memorandum on
11 leukocyte reduction or should CBER write a new pilot
12 guidance for leukocyte reduction under GGP in order to
13 allow self-certification, although the pilot guidance
14 may not be substantively different from the existing
15 1996 memorandum?

16 I guess the last question is really
17 referring to the speed of the GGP process. We all
18 realize that regulations take a long time to formulate,
19 but guidance -- although guidances are much quicker,
20 they, too, take some time in terms of making a
21 statement.

22 So having gone over these, I'll go back to
23 decision number 1 and leave this up throughout the
24 discussion, and then we'll move on to the next decision
25 and so on.

1 The floor is now open for comments,
2 questions, regarding this topic. If there are no
3 particular views, I guess we could do a vote or
4 something, but I don't want to do that.

5 DR. BIANCO: Oh, there are views.

6 CHAIRMAN LEE: Thank you.

7 DR. BIANCO: I think that during the
8 discussion several speakers -- You saw that there are
9 different approaches, different ways to get there. I
10 think that the most successful guidances and
11 regulations that came out of FDA were when they set a
12 goal that everybody should attain but didn't really try
13 to micro manage the institutions to get to that goal.

14 I wish you would continue following this
15 path. I think it is very important that we define what
16 is the goal that is -- what we are going to call a
17 leukoreduced product, and that's the subject of some
18 discussion; and second, obviously, when we are going to
19 get to this point.

20 Here, the framework -- I love frameworks.

21 CHAIRMAN LEE: Are there any opposing
22 views? Just to confirm, I also thank everyone in the
23 audience who has persisted through the day to come to
24 the panel session. I realize the panel discussions
25 necessarily come at the end of the workshops, but in

1 fact are the most important part of them, and I thank
2 you for staying with us.

3 Just to confirm my impression of the
4 opinions of those still in attendance, if I could
5 simply see a raise of hand for those in favor of the
6 former, that specific implementation criteria be
7 reserved to each blood center to formulate on their
8 own.

9 All those that are in favor of the bottom
10 sentence, could I see a raise of hand, please? Looking
11 around, that seems to be the majority.

12 All those in favor of the top? That makes
13 it black and white and explains the lack of comments as
14 an opposition to Dr. Bianco's statement.

15 In that case, we'll move right along. I
16 think this might be more contentious. We've heard
17 opposing views built right into the presentations
18 today. Should FDA recommend a simple transition period
19 of 12 months or briefer or should FDA support
20 transition periods that are longer than 12 months which
21 allow further maturation of costs, clinical and
22 scientific issues?

23 Would anyone like to make some statements
24 about that? Ms. Norrell?

25 MS. NORRELL: Well, Well, based on our

1 experience, it is a complicated conversion process, and
2 there are infrastructure changes that need to happen in
3 many of the facilities. So I don't think it's
4 feasible, really, for many centers to do anything
5 briefer than 12 months unless they were initially set
6 up to do that.

7 If there is some flexibility to be built in
8 even greater than 12 months, but not much more, but
9 we've definitely needed a full 12 month period to go
10 that route.

11 CHAIRMAN LEE: Dr. Snyder.

12 DR. SNYDER: Yes. I think certainly longer
13 than 12 months, but I would like to see an upper limit
14 as well. I think, left to its own devices, the medical
15 -- some parts of the medical community would let it go
16 on ad infinitum. So I'd like to see some by a certain
17 period of time as well, but certainly longer than 12
18 months.

19 CAPTAIN GUSTAFSON: Dr. Snyder, from the
20 presentations today did you get a feel for maybe what
21 might be a maximum time period?

22 DR. SNYDER: I heard three years most
23 frequently, but others may have heard something else.

24 CAPTAIN GUSTAFSON: I mean, you heard three
25 years, but you heard from the presentations like where

1 Red Cross is, where BSI is, where ABC is. Did you get
2 an idea that perhaps three years might be an outlier,
3 that maybe a shorter time is realistic?

4 DR. SNYDER: Well, the impression I got is
5 that the Red Cross and other major blood services,
6 blood suppliers, would certainly be compliant in much
7 closer to 12 months, but I'm concerned about the ten,
8 15 percent of Mom and Pop groups or places that may not
9 be able to comply quite that readily.

10 So I'm sensitive to that, but some people
11 have other administrative opinions about that. But I
12 think most people will be closer to 12 months, but I
13 don't know whether, therefore, you should make it 12
14 for everybody.

15 CHAIRMAN LEE: Yes? Would you please state
16 your name and affiliation and proceed with the question
17 or comment?

18 MS. SAZAMA: Yes. My name is Kathleen
19 Sazama, and I don't know what my affiliation is at the
20 moment.

21 Let me just raise the question that's
22 related to this, and I know you're trying to avoid the
23 clinical and scientific issues, but in fact you can't.

24 The implementation period that permits the collectors
25 to ramp up and actually provide the components is only

1 one part of this equation.

2 I'm troubled still that the right players
3 are not present for a discussion about how the
4 implementation then occurs in the actual delivery
5 system, which is to patients in hospitals.

6 So I think the statement as written is a
7 little simplistic, if I may say that, and shouldn't be
8 decided in the absence of thorough discussion with
9 respect to the impact of this process at the other end.

10 We know lessons have been learned from implementing
11 testing, for example, that did not adequately address
12 how inventory transfers occurred, and harm happened to
13 patients.

14 So I think it's premature to answer this
15 question completely unless you were to modify it to
16 say, you know, how long will it take for the collection
17 side to be prepared to provide these components, and
18 then convene the right group of people to discuss how
19 long then would it take for the receipt of those
20 components and the transition of the policies and
21 practices in hospitals to accommodate the new
22 components, and what is the plan?

23 If you're going to transition, what
24 inventory should be being managed in hospitals in the
25 transition? Is it what the collectors can provide or

1 is it what the collective wisdom of those who care for
2 patients decide is the right thing for patient care?

3 So I just would like to have the record
4 reflect that I believe the question does not adequately
5 address the implications of a decision on this point.

6 CHAIRMAN LEE: Yes, thank you for your
7 comments. Although these questions are formulated by
8 CBER, I'd like for the responses to come as much from
9 the audience as well as from the panel rather than
10 people from the agency responding.

11 Are there any counter-comments or any other
12 comments?

13 MS. NORRELL: I would just like to add one
14 more statement, that another critical part of the
15 decision is whether we'll have enough filters. So we
16 can't really set a date without knowing that we're
17 going to have the materials that we need to be able to
18 implement.

19 So that's an important piece of information
20 that I don't know.

21 DR. GOLDFINGER: If I could respond, I
22 don't see the problem in implementing this at the
23 hospital level. The big problem at the hospital level
24 is simply the cost that's involved.

25 If the blood centers can deliver leukocyte

1 reduced components, then we can transfuse them. The
2 analogy to -- I'm not sure if you were alluding to the
3 problem associated with NAT testing, because the
4 problem with that has been that the suppliers have not
5 been able to deliver the kind of turn-around time that
6 allows us to transfuse only NAT tested blood.

7 I think that is a problem, but I think with
8 leukocyte reduction, if the suppliers could provide it,
9 then we could transfuse it.

10 MS. SAZAMA: I think that that
11 oversimplifies the problem, Dennis, if I may say so,
12 and I ask your indulgence to let me speak again.

13 There are current practices in many
14 hospitals in which bedside filtration is a common
15 practice, for example. In planning a transition, you
16 want to avoid that. There's no need to have
17 duplication of those activities, as just one simplistic
18 idea here.

19 The second is that there is a moment in
20 time when you go from what you had to what you will
21 have. How long is that moment in time, and how much
22 advance planning needs to go into it?

23 Yes, it is true that the budgetary
24 implications are a part of this, but I don't want to
25 lose the fact that there is process and policy and a

1 lot of institutions in which the clinicians believe,
2 rightly or wrongly, that they still are in charge of
3 the therapies to their patients.

4 I don't disagree with your position that we
5 should assist them in doing what is good for patients,
6 but that takes time to lay the foundation, for the
7 medical staff to understand what's going to happen and
8 why, for administration to make the adjustments to what
9 they expect in terms of how their resources are going
10 to be deployed, and then the physical act itself of
11 simply swapping out or using up or whatever it is that
12 we're going to do.

13 I mean, if today our region -- I'll use
14 Philadelphia as an example -- were to say to us,
15 tomorrow you can have all the leukoreduced blood
16 components to transfuse, if that were theoretically
17 possible, there still would be implications inside the
18 walls of the blood bank and the transfusion activities
19 that have to be planned for.

20 So those are the kinds of things that I was
21 interested in addressing. So there are policy,
22 process, and procedure activities in hospitals for
23 which there will be implications. Just like the
24 diversity of opinion we've heard here today, I bet you
25 not everybody agrees with what you said, and not

1 everybody agrees with what I'm saying.

2 It takes time to make those transitions.
3 That's all I'm saying, and a plan for implementation
4 should not simply look at how soon can we have the
5 material to deliver. It's also how soon can we put in
6 place the right process to make sure that delivery
7 happens the way it's intended.

8 DR. GOLDFINGER: I would agree with you,
9 but I thought that -- That's why I think that the
10 three-year approach is a reasonable one. I think that
11 you would be right. If it would be done in less than a
12 year, that might be asking too much.

13 In addition, I think that a couple of the
14 speakers making this mandate to the FDA that they
15 somehow work with HCFA to get better reimbursement is
16 one of the most important things that I heard here
17 today. It's got to be done.

18 It's not possible for one agency just to
19 turn their back on the other and just say that we don't
20 see it, and we really don't want to see it. It's a
21 serious problem that, I think, could be changed,
22 because there's some logic involved here. I mean, this
23 is something that's good for our patients.

24 CHAIRMAN LEE: Could you come to the
25 microphone?

1 MR. DICKSTEIN; I'm sorry to go out of
2 order, but I'd like to answer Ms. Norrell and Dr.
3 Goldfinger's comment. I'm Rob Dickstein from Pall
4 Corporation.

5 Speaking for Pall, we're prepared to meet
6 the filter demand of 100 percent leukocyte reduction by
7 August of 2000, in answer to your question, Stephanie.

8 CHAIRMAN LEE: Thank you.

9 DR. PITTMAN: Yes. I'm Dr. David Pittman.
10 I'm representing the Barnes Jewish Christian group out
11 of St. Louis, Missouri. We transfused about 67,000 red
12 cell units last year, and we certainly support a longer
13 time such as three years to allow the implementation of
14 this.

15 We have hospitals doing all different sorts
16 of leukodepletion, from almost none to almost
17 everything. I especially enjoyed seeing Dr. Lee's
18 written comments regarding the BPAC members' opinion
19 that quotes, "There's insufficient scientific evidence
20 to conclude that the effect of leukocyte reduction is
21 clinically important for the typical transfusion
22 recipient."

23 We believe it's important to have a longer
24 time. We still believe that prospective, randomized,
25 controlled trials are necessary, not only to answer the

1 scientific issue but to aid, as Dr. Goldfinger said,
2 getting HHS or HCFA and FDA together as far as having
3 some type of reimbursement.

4 We see that very important, because we're
5 setting, as all hospitals are, in a fixed
6 reimbursement, and it's hard enough when you're certain
7 that something is scientifically valid to decide if
8 you're going to get this laser or if you're going to
9 get some other technology. But you're asking us to
10 take something where many of us as transfusion
11 professionals still believe there's not adequate
12 scientific evidence to use it in 100 percent of
13 patients, and what are we going to give up?

14 Are we going to have fewer nurses? Are we
15 going to have less SOPs, less adequate QC, fewer OR
16 techs, fewer custodians; because in our system what
17 gets cut in general is personnel, the people that
18 actually take care of patients.

19 We don't think that that's appropriate to
20 institute something like this without given time to
21 prove this.

22 I understand Dr. Snyder's opinion, that
23 though there may not be a single reason that justifies
24 universal leukoreduction, that perhaps the cumulative
25 effect of many less than complete indications might

1 help.

2 As I came in, I noticed a homeless man on
3 Wisconsin Avenue. If you would each take a dollar bill
4 out of your pocket and tear the right third off, I'll
5 collect them and take that to that man; but he still
6 won't be able to buy a hamburger and a cup of coffee.

7 So I kind of -- I understand what Dr.
8 Snyder is saying, but it often doesn't work out, that
9 many small things add up.

10 Many of us are not resisting new
11 developments. We're not doing that at all. We're
12 attempting not to accept the wrong new developments,
13 and the FDA should take that advice.

14 In doing that, you might look, as you told
15 me a year ago that you would put more transfusion
16 professionals, that transfusion medicine is part of
17 their life, day to day, hour to hour and minute to
18 minute, rather than so many researchers,
19 epidemiologists, people that do a little bit of
20 transfusion, on the BPAC. That may benefit you as
21 well.

22 (Applause.)

23 CHAIRMAN LEE: Thanks for your comments.
24 If you could, move to this microphone over here.

25 MR. MURPHY: I'm Scott Murphy from

1 Philadelphia. I'm very sympathetic with the last
2 comments, and we have many customers in Philadelphia
3 who agree with you.

4 I think the other side of the coin of the
5 way this is being structured, waiting for three years,
6 is that a blood center can ramp up to make the products
7 available, but if there's a three-year implementation
8 period, it may encourage hospitals that have a
9 difficulty with this to wait.

10 So that it will be hard for a blood center
11 to ramp up to 100 percent, for example, in a year or a
12 year and a half, if the full implementation of the
13 program won't take place for two or three years.

14 I think what Kathleen was saying is that
15 the hospitals have to be in step with what we're doing,
16 and from many different points of view.

17 CHAIRMAN LEE: Dr. Sayers?

18 DR. SAYERS: Merlin Sayers, Carter Blood
19 Care, Bedford, Texas.

20 There's one other maturation that I suspect
21 is going to take longer than a year for us to fully
22 appreciate, and that has to do with how universal
23 leukoreduction is going to influence our inventories
24 and the management of those inventories. If
25 we look at donor deferral these days, it's tantamount

1 to 5,000 cuts. What we're looking at here are another
2 two cuts which we must not underestimate.

3 One has to do with how many donors will we
4 be deferring through no reason other than filter
5 failure, and then how many donors are we going to be
6 losing for reasons that have already been referred to,
7 namely, the incidence of sickle cell trait in African
8 American donors. That group has already been
9 highlighted as a group of individuals who are very
10 important in their contribution to the national
11 inventory.

12 We certainly are going to need more than 12
13 months to decide how to manage what is going to be an
14 obligatory additional deferral rate superimposed on
15 already compromised national blood supplies.

16 CHAIRMAN LEE: What time -- Could you stay
17 up there just one second longer, Dr. Sayers. Do you
18 have a time frame in mind or just simply longer than 12
19 months?

20 DR. SAYERS: Well, we didn't hear anything
21 about other people's experience with exactly what
22 filter failure rates are, and our own experience with
23 knowing what the loss of individuals with sickle cell
24 trait is, is an experience which is too small for me to
25 rely on to confidently predict how much longer we're

1 going to need, but I strongly suspect it's going to be
2 longer than 12 months.

3 DR. HEATON: I would certainly like to
4 comment from the blood center's perspective. The
5 practical reality of manufacturing is that you can run
6 two inventories up to about 30 or 40 percent, but once
7 you cross 50 percent, you can't run two inventories;
8 because you cannot allow hospitals to order
9 leukodepleted as a boutique product when half of what
10 you're manufacturing is leukodepleted and half isn't.

11 So as a purely practical manufacturing
12 matter, once you cross the 50 percent barrier, you have
13 to mandate universal leukodepletion on your customers.

14 If you link that to your stated goal, that
15 you believe that universal leukodepletion is medically
16 appropriate, I think you're going to need an
17 implementation period probably of around two years,
18 because it takes about six months to get organized. It
19 takes about six months to drive the first piece of your
20 transition, and probably a year to wrap it up. But I
21 can tell you that anyone who gets over 50 percent will
22 be desperate to switch the rest of their production
23 into leukodepletion, simply as a practical matter of
24 meeting the order of the customer who wants
25 leukodepleted.

1 MS. NORRELL: And that has been our
2 experience as well.

3 DR. MENITOVE: Yes, and ours as well. On
4 the other hand, I think we have seen, at least in our
5 area, the hospitals that are willing to switch. They
6 have come forward and have said we're going to 100
7 percent leukocyte reduction. In our area, it's
8 approaching 40 percent of usage.

9 I don't see or hear that the other
10 hospitals are willing at this point to make a
11 commitment. So at least from the area where I'm from,
12 we could persist in this chimeric 50/50 relationship
13 probably for the indefinite future or at least three
14 years.

15 My only thought is, is that period of time
16 long enough, Jong, to do some of those things that you
17 were talking about before in terms of an ethical and
18 time period long enough to put together some studies.

19 On the other hand, I'm not exactly sure
20 what we're looking for. If we're looking for reduction
21 of post-op infections, I think we could get an answer
22 potentially, or at least another answer, to that
23 question. But of some of the other open questions, I'm
24 not sure a study could be designed and implemented and
25 completed in that period of time.

1 CHAIRMAN LEE: Dr. Snyder.

2 DR. SNYDER: You know, not all hospitals
3 are the same. At our institution we have four blood
4 bank directors. I spend all of my time focused on this
5 issue, and I have a certain amount of sway with the
6 institution, small though it may be.

7 So if I push for leukoreduction -- the
8 concept, if you don't know your jewels, know your
9 jeweler -- the administration will rely on what I say,
10 so far, as being a reasonable approach. They think I'm
11 a reasonable person.

12 Many hospitals, the blood bank director is
13 off doing autopsies, surgicals, hardly ever is in the
14 blood bank. To say that they're not willing to
15 leukoreduce and convert isn't because the blood bank
16 director doesn't feel that it's appropriate.

17 He or she just isn't pushing the issue, and
18 the institution will say, well, I'm not going to give
19 you another penny, and he says fine, and he or she goes
20 and finishes the autopsy and lets the blood bank run on
21 its own.

22 So I don't think it's appropriate to say
23 that a couple of centers are really interested in this,
24 but the vast majority of hospitals don't want to, as if
25 they've studied the issue, they've had debates and

1 they've talked about it.

2 It's really, I think, apples and applesauce
3 or apples and alligators, and maybe looking at -- it
4 would be worthwhile to take a survey of academic
5 institutions where there are similar people focused on
6 blood banking all the time and other hospitals where
7 they're not, and seeing what those statistics show.

8 MR. DRESSLER: I'm Kent Dressler with the
9 Park Madison Clinical Labs in New York City, and New
10 York Biologics.

11 I think that I would agree, of course, with
12 the latter part of this statement, that there is a
13 need for longer than 12 month period, but I think that
14 the FDA has to continue to maintain the active role
15 that they took in driving this process through BPAC to
16 get this movement towards the universal leukocyte
17 reduction occurring by supporting actively in ways that
18 they need to figure out how to do, to have the studies
19 that can be done right now to look at cost
20 effectiveness and clinical effectiveness.

21 There is a transition period occurring
22 where there are both products being used, and it is a
23 data acquisition maneuver that could be done now that
24 will disappear as an opportunity once the universal
25 leukocyte reduction has been achieved by whatever

1 process, sterile docking or in-line.

2 So I think that there has to be a continued
3 active involvement on the part of the FDA to get data
4 collected that currently is collectable, and to make
5 that a process that they work out somehow with HCFA so
6 that everybody can be brought into selling this, which
7 is inherently probably a good thing, to the community
8 that ultimately has to pay for it.

9 CHAIRMAN LEE: Thank you. Dr. Holmberg.

10 DR. HOLMBERG: Jerry Holmberg with the
11 Joint Readiness -- or Joint Clinical Readiness Advisory
12 Board with Military.

13 I was one of the -- I think that was my
14 last BPAC that we voted on that. As a former member of
15 BPAC, I strongly encourage the longer than 12 months,
16 primarily for the fact that it gives some time for
17 scientific issues to be resolved and questions to be
18 answered.

19 I also raise the issue of the cost. I
20 agree. I don't think we have everybody sitting at the
21 table today. We talk about HCFA, the reimbursement
22 costs, what's best for the patient, but also what if
23 the patient can't afford it, who picks up the tab on
24 that, the cost centers involved with the
25 leukoreduction.

1 So I think that 12 months -- We need to
2 have longer than 12 months. Also I raise another
3 issue, that you know, three years may be too long.
4 However, I think Captain Gustafson mentioned this
5 earlier in her presentation, about the real estate on
6 the label and the issue with ISBT.

7 We've been down this road before with ISBT
8 and the label, and one of the problems was that nobody
9 set a definitive date. The only date that was
10 definitive was when the Red Cross said they could not
11 do it until this certain date, and that happened to be,
12 I think, December 31st of 2001.

13 I think that there's an ideal opportune
14 time to maybe correlate and orchestrate some of the
15 dates together. One of the things that we can learn
16 from Canada is how do we go through the labeling
17 process as this country goes through a period of time
18 of transitioning to a new labeling process where the
19 product code will be a mechanism that hospitals can
20 capture that reimbursement cost, that I think it might
21 be wise to maybe put on the outside limit when do we
22 think that we will be converting over to the ISBT-128.

23 I also agree with Captain Gustafson as far
24 as the real estate on the label and what do we mean,
25 and Dr. Bianco with his comment about the FFP and do we

1 put leukoreduced fresh frozen plasma.

2 I think it's absolutely ridiculous to have
3 that on the label. However, I strongly would encourage
4 that, if we are going to go to 100 percent universal
5 leukodepletion, that what we do is we put that into the
6 circular of information, that the premise says that we
7 are starting with a leukoreduced product, so that we're
8 not messing up our label.

9 I guess my encouragement to the FDA would
10 be to bring more people to the table to iron out some
11 of these issues as far as the cost, the transition,
12 along with ISBT, and also, most importantly, to give us
13 enough time to be able to answer some of those
14 scientific questions.

15 DR. BIANCO: I want to add a couple of
16 words to what Jerry just very emphatically told us. We
17 may not be able to time everything together, as it
18 appears that we will go to universal leukoreduction.

19 There are technical issues, and there are
20 the donor issues related to them. That is, to
21 leukoreduce red cells seems to be a reasonably
22 straightforward matter, provided that you choose either
23 the in-line or the docking system, with all the other
24 issues that we discussed. But the platelet issue, I
25 think, is very concerning, at least to me.

1 If we made a conversion today to single
2 donor platelets, I don't know how long it's going to
3 take us to ramp up to be there and to have practical
4 means of doing pooled platelets leukoreduced. I don't
5 think we have them. I think that our techs in the
6 components lab today, they would get entangled in the
7 number of wires and tubing that would be there, and we
8 would have deaths in the lab.

9 So probably red cell -- probably, again,
10 when this is written, we will have to say that our goal
11 is that we'll get there, but we may not get there with
12 all things at the same time.

13 CHAIRMAN LEE: Any other comments?

14 MS. NORRELL: I just want to clarify what
15 that last recommendation was. Are you suggesting that
16 we set or that the FDA would set a timeline specific to
17 red cells first, period, and the other would fall in
18 behind?

19 CHAIRMAN LEE: Interesting approach.

20 DR. GOLDFINGER: Well, it's interesting,
21 but you know, probably one of the great advantages of
22 going to an all leukocyte reduced inventory will be the
23 elimination of pooled platelet concentrates, which is a
24 common sense approach that is not coming from academic
25 medical centers but rather I find that the pathologists

1 running a blood bank at a small institution is very
2 happy to make those kinds of changes, especially if
3 they're mandated so that he doesn't have to be looked
4 upon by his administration as doing something that is
5 unnecessarily increasing the cost.

6 I must say, I've always been a great fan of
7 the Red Cross, but I've never really looked upon the
8 Red Cross as the great leader in transfusion medicine,
9 but it's interesting how things have come around;
10 because the Red Cross is pushing this issue
11 tremendously, and I think rightfully so, the efforts
12 toward safer plasma coming again from some blood
13 centers as well as the Red Cross.

14 I think that these are good things for the
15 country.

16 DR. BIANCO: I want to hear Dr. Snyder,
17 about the pooled platelets.

18 DR. HEATON: Well, I would like to comment
19 on our pooled platelets. Dennis, you're referring to a
20 30-year-old product. The reality is that there is in-
21 line filters, leukodepleted platelet, random donor
22 platelets available now, which would meet most of the
23 criteria that you're concerned about, avoidance of
24 cytokines and other cellular products.

25 In addition, in Europe it's standard

1 practice to pool buffy coats and make platelet products
2 out of four pooled buffy coats. Again, it's a very
3 cost effective system. It's one that's worked
4 extremely well in practice, and the only reason it's
5 not available in this country is a very restrictive
6 approach toward the licensure of pooling and a very
7 restrictive approach toward the licensing of the use of
8 a sterile docker.

9 So I think that there is great life in
10 random donor platelets, and I think that we should
11 adjust our regulations to be more sympathetic, to allow
12 the licensure of the very low cost, high quality
13 product.

14 DR. BIANCO: Do you know any center that is
15 licensed for the preparation of buffy coat derived
16 platelets in this country, and how long do you think --
17 and what would we have to do to do that?

18 DR. HEATON: There is none licensed, and
19 the licensing cycle would be at least 24 months.

20 DR. GOLDFINGER: Just one point. You know,
21 my issue on single donor platelets really has nothing
22 to do with leukocyte reduction. It's strictly donor
23 exposure, which to me is such a basic issue.

24 I can't imagine anyone, any patient that
25 you could find that wasn't -- that hadn't lost his

1 faculties that would choose pooled platelets over
2 single donor platelets, especially multiple
3 transfusions, 50 extra exposures. It's just so
4 unbelievable to me to think that anyone would do it,
5 and in fact, nobody in his right mind would do it.

6 It's only if we choose not to ask and to
7 make this the only product available.

8 AUDIENCE PARTICIPANT: But, Dennis, no one
9 would choose a non-leukoreduced blood product.

10 DR. HEATON: I don't think leukocyte
11 reduction -- that's more of a blood banker's thing. I
12 must say, I don't think leukocyte reduction is
13 something that the public would jump on the way they
14 would these multiple exposures. It's not just an extra
15 person. It's like so many more people to whom you have
16 to be exposed.

17 If you're in a hospital setting and you see
18 patients who have to be transfused, they're so
19 frightened. A physician who sticks himself with a
20 patient's blood or a donor room nurse who sticks
21 herself or himself runs down to the employee health or
22 something for some careful monitoring and maybe a shot
23 of gamma globulin. That's one exposure, and it's not
24 50. I guess I don't understand it.

25 CHAIRMAN LEE: Go ahead.

1 AUDIENCE PARTICIPANT: I just wonder, does
2 any of the panel want to comment on whether three years
3 is too long, which was what I was implying or is
4 everybody happy with that?

5 DR. SNYDER: Well, I discussed it with the
6 homeless person out there, and we both agree that two
7 years would be -- I'm concerned about the inventory
8 issue. That's something that was brought up, and I
9 think our Red Cross provides us -- and we've had
10 discussions with them, and I think two years -- If we
11 decided not to go to leukoreduction or if we did and
12 the rest of the state didn't, and had to keep dual
13 inventories, it would be almost an impossible
14 situation.

15 So I think that should be something that
16 really needs to be considered. There are efficiencies
17 on the blood center side as well as on the hospital
18 side that have to be considered.

19 You know, I mean, HCFA -- I believe the
20 basis of this is HCFA believes that we're over-bedded
21 in the United States, and they would like to see X
22 number of hospitals closed. How we do it is up to us,
23 and I don't know how it's going to happen.

24 In Greenwich Hospital, for example, in
25 Connecticut, it's a relatively small hospital with

1 maybe 150 beds. Do you think that the town of
2 Greenwich is not going to want their local hospital to
3 remain open? I mean, they have the money in Greenwich
4 to be able to raise millions of dollars in a very, very
5 short period of time.

6 I think that's the problem we face, that
7 we're looking at a mandate to close hospitals with a
8 group of individuals that don't want to close the
9 hospitals, and we're stuck with advances in technology,
10 and I don't think there are simple solutions to this.

11 So I'm not really sure how the quandary
12 works out, but economics, I think, on the blood center
13 and the hospital side has to be considered in the
14 equation.

15 CHAIRMAN LEE: In the interest of moving
16 forward, if you could keep your comments kind of brief.

17 Go ahead.

18 DR. PITTMAN: It's interesting that Dr.
19 Snyder discussed that with that homeless person,
20 because when I gave him five dollars, it was obvious he
21 was mute.

22 I agree with Dr. Goldfinger. I'm one of
23 the people that has not used random platelets since
24 1992 in my institution for the donor exposure problem.

25 Am I the only one that worries, however, about if we

1 make a flat statement saying that random platelets are
2 no more, that we're going to take so many donors out of
3 our red cell donations unless the regulations are
4 changed, because they will now become platelet pheresis
5 donors who are very faithful and give, you know, as
6 often as they can. I worry about that. I don't know
7 if anybody has studied that.

8 DR. HEATON: Well, that's the issue that I
9 was attempting to address. As we go to universal
10 leukodepletion, as a matter of manufacturing
11 convenience we will want in-line filtration.

12 In-line filtration means no random donor
13 platelets. No random donor platelets means more
14 pheresis. More pheresis cuts into red cells, which
15 means multi-component pheresis, and that then means
16 changes to the way we regulate the pheresis segment of
17 our business in order to maximize production.

18 So there is a technological knock on effect
19 of this type of decision. To respond to Dr. Lee, I
20 think the manufacturers' main concern is that there be
21 a sunset. If it's 22 months or 26 months or 28 months,
22 I really don't care, but I don't think it should be
23 longer than three years, and there should be a sunset.

24 One way of handling that would be to
25 withdraw a licensure of non-leukodepleted products and

1 state the time period of sunset, and three years, I
2 believe, will be quite adequate. We could probably do
3 it in less than that.

4 CHAIRMAN LEE: Dr. Sazama.

5 DR. SAZAMA: Just one other point that has
6 not been mentioned specifically, and that is there are
7 many hospitals, particularly the smaller hospitals,
8 where inventories are not kept on site, and the ability
9 to get single donor platelets in a timely way that
10 benefits patient care is an issue.

11 In fact, even getting the ones that Dennis
12 doesn't care for, which is a pool -- and just a
13 parenthetical comment -- the majority of the platelets
14 that are transfused among the eight hospitals I have
15 previously been associated with are not to support
16 heme-onc patients with multiple transfusions.

17 In fact, they go to people who get one or
18 two dose of a pool of four. So the relative exposure
19 is much less. You have to keep in mind that there are
20 many places where a pool of random is better than no
21 platelets at all.

22 So I think the availability part of this,
23 which was alluded to on the donor side, but is also --
24 you know, as a practical matter, some platelets are
25 better than no platelets, and even though they may not

1 be the exposure that you would prefer for yourself,
2 there are many places where you got to have something,
3 and even the availability of pooled randoms is not that
4 easily acquired.

5 So you start building in time delays where
6 patients are in need of transfusion, and there's
7 nothing for them. I think that cannot be ignored.

8 CHAIRMAN LEE: Thank you. Dr. Klein.

9 DR. KLEIN: Harvey Klein, Clinical Center,
10 NIH.

11 Three years seems like a very long period,
12 to me. I don't see how I could explain to the American
13 public that their mandate through BPAC, if you believe
14 that that is their mandate, came, and it took our
15 organizations three years to implement this. I don't
16 think that that's rationale, if we think this is a
17 better blood component and we're accepting that.

18 I agree that hospitals should be part of
19 this equation, because there certainly are issues that
20 have not been addressed today that are important for
21 hospitals, and they need to be addressed.

22 It also seems to me that, hearing what I've
23 heard today about the major blood collectors in the
24 United States, knowing what I know about the European
25 blood collectors, we can do it well with all due haste,

1 and we can do it sooner.

2 There doesn't seem to be any reason that,
3 if we reevaluate halfway through a period and find
4 that, in fact, my optimistic views have been totally
5 wrong, that we can't say, you know, maybe we should go
6 an additional six months.

7 AUDIENCE PARTICIPANT: Just one question.
8 Why are you rejecting the -- for both red cells and
9 platelets? I mean, the filter is manufactured and, in
10 fact, other countries are using it. I know it produces
11 some technical problems, and it's not easy to work
12 with, but it is not a slam-dunk that you can't make
13 leukoreduced platelets.

14 So I'm just wondering, is it just felt to
15 be impractical, too expensive, too difficult to write
16 the SOPs, all those things?

17 DR. HEATON: Yes, time to license, and it's
18 also quite a tricky filter to use. So you've got to be
19 careful with the manufacturing process. That's quite a
20 demanding filter. Terumo has one, I believe, and Asahi
21 has one as well.

22 CHAIRMAN LEE: I'd just like to make one
23 last comment before we move forward to the next
24 question.

25 The American Hospital Association was

1 actually invited as speakers -- as presenters for this
2 workshop, to which they could not accommodate. If
3 there is any member representation at this time from
4 American Hospital Association, referring back to Dr.
5 Sazama's comments, I would welcome that. But if there
6 are none, we'll go forward.

7 Okay. I think we have gone over that
8 fairly thoroughly. The next issue -- Are people
9 interested in a show of hands or something? Yes? I
10 have to defer this to Captain Gustafson. Should we go
11 through that for each one of these?

12 DR. GUSTAFSON: Well, I think we're kind of
13 running out of time, if we do a vote for every one. I
14 think we have got guidance. I mean, I think we've
15 heard people in terms of that 12 months is not enough
16 time, and I think we have to work from there.

17 CHAIRMAN LEE: Okay. If we have time,
18 maybe we'll come back to that at the end of the day.

19 Moving forward then: Should the current
20 FDA guidance on leukocyte reduction be retained for use
21 during the transition period or should the definition
22 and QC of leukocyte reduction be updated from the
23 current FDA recommendations for implementation during
24 the transition period, which is obviously going to be
25 somewhere between one and three years, as the way it's

1 shaping up right now?

2 Any comments from the panel?

3 DR. HEATON: Definitely. There are several
4 areas of the guideline that I believe need urgent
5 attention, the first of which is we need to define
6 prestorage leukocyte depletion. That is not defined in
7 the guidelines. It's absolutely critical.

8 We have different products with different
9 manufacturers' instructions, with different filtration
10 periods, and we don't have defined -- We don't have a
11 product definition. So I think that's a critical step.

12 The second step is the quality control
13 process, the QC process. The four or one percent was
14 fine for a boutique product where you weren't making
15 much of it, but the reality is you're asking an entire
16 system to switch, and any manufacturer would tell you
17 that they use statistical process control in order to
18 control the quality of their products.

19 The BEST committee of ISBT recently had a
20 whole half-day seminar just on statistical process
21 control as applied to leukocyte QC. I know the FDA has
22 experts on that topic, because it's a very common
23 manufacturing issue. I would seek that the QC segment
24 be amended as well.

25 I believe those are two critical elements

1 that should be changed.

2 CHAIRMAN LEE: Yes, Dr. Menitove?

3 DR. MENITOVE: I think this might be a nice
4 opportunity for the professional associations that we
5 all belong to and the FDA to work together. It may be
6 less cumbersome for the professional associations to
7 come out with some recommendations first that may tide
8 it over until whatever that interval is, at which time
9 then the FDA guidance could come out.

10 DR. HOLMBERG: Jerry Holmberg. I agree
11 with Dr. Heaton. There's just one more parameter that
12 I'd like you to look at in that QC package, and that's
13 the 85 percent red cell recovery.

14 Coming from an institution that freezes a
15 lot of red cells, what do you do when you de-gloss
16 those red cells? Are you going to go from the 80
17 percent to the 85 percent or just how do you handle
18 those other kind of manipulations?

19 DR. HEATON: I would also like to add the
20 comment that I attended yesterday the Donor Suitability
21 Workshop, and linked to this I believe it would be very
22 important to amend the guidelines relative to pheresis,
23 particular red cell pheresis and platelet pheresis.

24 I know that you're reviewing those
25 regulations, but an implication of universal

1 leukodepletion will be much more pheresis, and the
2 implication of more pheresis means multi-component
3 pheresis, and I believe that we need, in parallel with
4 amending the leukodepletion guidelines, to amend the
5 pheresis guidelines to allow multi-component pheresis
6 and indeed more frequent platelet pheresis during the
7 year.

8 CHAIRMAN LEE: Okay. If there are no more
9 comments, I would like to move forward.

10 Issue number 4 -- This is regarding the
11 pilot: Should blood centers, if eligible to
12 participate in the CBER pilot program for streamlining
13 licensure, be able to obtain license for leukocyte
14 reduced blood products by simple certification or not?

15 DR. BIANCO: Yes.

16 DR. HEATON: Yes. Me, too. I would
17 comment. I was talking to Captain Gustafson, I think,
18 some four years ago to discuss what we believe to be a
19 critical issue here, and that is at the moment the FDA
20 treats the change in the manufacturing process as an
21 individual unit change requiring approval and sometimes
22 proof of manufacture.

23 The reality is the manufacturers develop a
24 product. They usually develop a pretty specific SOP,
25 and they go through a very good quality licensing

1 process. I would seek that the FDA should require the
2 manufacturers' detailed manufacturer's instructions, a
3 specific validation protocol, adequate that an end user
4 or a purchaser could acquire that product, perform the
5 validation according to the manufacturer's SOP,
6 determine that their manufacture complied with the
7 manufacturer's reference standard, and proceed without
8 proof of purchase.

9 I think that would reduce the workload on
10 the FDA. It would transfer the responsibility for
11 adequate instructions to the manufacturer, where it
12 should appropriately be, and it should transfer
13 responsibility for effective and appropriate operation
14 to the user of the system, which is also where it
15 should be, and then the RA can inspect and just people
16 against the predefined standards.

17 I think this would be a huge step forward
18 for the blood banking industry.

19 CHAIRMAN LEE: I see. Since the last issue
20 is so closely related to the fourth, I might as well
21 just consider them together.

22 If a blood center already licensed for red
23 cells, whole blood and platelets may self-certify,
24 then should the existing 1996 memorandum on leukocyte
25 reduction be able to serve that purpose or should CBER

1 write a new pilot guidance document to that extent?

2 I think we just heard a comment in direct
3 response to that problem from Dr. Heaton.

4 Any other comments? From the floor, yes?

5 MS. GREGORY: You might know I couldn't
6 pass up this opportunity. Kay Gregory from the
7 American Association of Blood Banks, and also the
8 Coalition for Blood Safety.

9 This idea of self-certification is
10 something that we've been trying to work with FDA for a
11 number of years now, and it seems to me it's time to
12 finally move forward instead of just talking about it.

13 MR. DRESSLER: Kent Dressler. Just one
14 comment. I know it's embedded in the law, but it
15 certainly is something silly about shipping materials
16 across state lines and having anything to do with
17 protecting the public or patients. That really doesn't
18 make any sense in terms of licensure issues.

19 CHAIRMAN LEE: Thank you. Since we seem to
20 have a few minutes still in the panel discussion time,
21 I would simply go back to 2 and actually have a brief
22 show of hands -- I'll try to step through this rapidly.

23 It's clear that it's got to be somewhere
24 between one and three years, is sort of what I hear.
25 So those that persist to the last minute get the most

1 say in shaping FDA's thinking.

2 I'll start at the upper limit. For those
3 who are in favor of three, could I see a brief show of
4 hands, please? For those who are in favor of three
5 years as the maximum upper ceiling of time limit, could
6 I see a show of hands, please?

7 Okay. How about two years?

8 Anything between two years and one year?

9 Thank you very much.

10 I think we are right on schedule, and I
11 would like to thank Dr. Harvey Klein for accepting the
12 difficult charge of being the spokesperson for today's
13 workshop. Dr. Klein will have the last words, at least
14 for this workshop today and, obviously, he needs no
15 introduction.

16 DR. KLEIN: Thank you very much. It's a
17 pleasure to be here.

18 The task that I was given was to summarize
19 this day's workshop, but not necessarily to summarize
20 each speaker's talk, and I don't plan to do so, nor do
21 I even plan to try to summarize all of the data that's
22 been presented. It's really too long, and it's really
23 unnecessary. In fact, since this is being transcribed,
24 I'm sure you'll be able to read it very soon on the
25 'Net.

1 So what I'd like to do is try to
2 encapsulate the nucleus of the discussion of the day,
3 and give some editorial comments along with it. Those
4 will be my own. They won't belong to the FDA, and they
5 certainly don't represent the National Institutes of
6 Health.

7 We've been reminded that leukocyte
8 reduction has been front and center formally for a very
9 long time. There was a workshop already held by the
10 FDA in March of 1995, and the Blood Products Advisory
11 Committee discussed the issue regarding cytomegalovirus
12 in September of '97.

13 Then there was what I think we can only
14 characterize as an overwhelmingly positive response of
15 the advisory committee in September of '98, 13/4, none
16 against and three abstentions. Now one can argue that
17 the advisory committee is constituted of the wrong
18 people or you can argue a variety of things, but if in
19 fact that represents the advice to the FDA, I think it
20 is overwhelming.

21 That is, positive benefit to risk ratio,
22 and based on the available science, and excluding the
23 well meaning, if somewhat overemphasized potential risk
24 of Creutzfeldt Jakob Disease and new variant
25 Creutzfeldt Jakob Disease, the data do not support

1 blood transmission of those agents; and even the murine
2 studies don't suggest that depletion of leukocytes
3 would make the blood supply safer.

4 We're reminded that the FDA's own mandate
5 is safety and efficacy, not cost, but cost may be a
6 safety factor if inappropriate expenditures prevent
7 more appropriate public health interventions. So cost
8 has clearly been on the FDA's radar screen, and it
9 should be. We've heard that over and over and over
10 today. But cost shouldn't be the decisive factor in
11 public health.

12 This meeting wasn't designed to review the
13 science and the indications, except as background, but
14 was designed for implementation issues. We may, in
15 fact, be a little late in this arena, since nine
16 countries are already involved in universal leukocyte
17 reduction, either doing it or are well into the
18 implementation phase.

19 They have taken between nine months and two
20 years to get to that phase. However, the United States
21 has six times as much blood collected each year as the
22 country with the largest amount of blood.

23 So I think we can be excused if universal
24 implementation of leukocyte reduction is not
25 necessarily quick in this country and is not

1 necessarily easy. But we can and we must benefit from
2 the experience of those other countries.

3 Prior to universal leukocyte reduction, we
4 know that the U.S. already is leukocyte reducing about
5 a quarter of its blood, and is going to go to about 50
6 percent, by our estimates, by the year 2000.

7 About six percent per month is what I
8 heard, and about 70 percent of what is done is
9 prestorage, and prestorage needs to be defined.

10 The manufacturers, to no one's surprise --
11 this is going to really be tough -- they've recognized
12 these trends and the international trends, and they've
13 accelerated their production already, both with filters
14 and with apheresis strategies, and they are prepared
15 for universal leukocyte reduction, at least at the six
16 percent per month increment, and I suspect a good deal
17 more, despite Y2K concerns. However, they've reminded
18 us today that they don't take the primary
19 responsibility for licensure review -- that belongs to
20 CBER -- for logistics, for reimbursement, but they're
21 willing to help the industry in all of those areas.

22 They've already asked CBER to consider
23 expedited licensure review and an end result guideline,
24 not a detailed type of process guideline, in their
25 guidance document, and to help with HCFA reimbursement,

1 which again, we've heard, might be a critical issue.

2 We've heard from the two review units of
3 CBER, the Blood and Plasma Branch, Division of Blood
4 Applications, Division of Hematology, the laboratory of
5 cellular hematology. I bet not everyone knew that two
6 different units of the FDA dealt with leukocyte
7 reduction.

8 It was certainly good to hear them both
9 speaking today in public and giving us an opportunity
10 to both hear their views and to criticize them and for
11 them to hear one another.

12 There seems to be, fortunately, a consensus
13 thinking here. First of all, recognition that
14 different centers, hospitals and manufacturers do
15 differ in their mission, in their size, and in their
16 operational complexity.

17 The FDA guidance looks like it will let
18 manufacturers come up with a plan in six months and an
19 implementation in somewhere between two and three years
20 perhaps, and most interestingly, to change the default
21 in human blood collected in the United States from
22 leukocyte containing to leukocyte reduced.

23 I like that term, Jong. I don't know
24 whether that was yours or not, but I think changing the
25 default is perhaps precisely what we want to do. As a

1 physician who, in the early seventies and late sixties
2 prescribed digitalis leaf -- it was a brown substance
3 in a jar that was spooned out to patients -- I don't
4 think that would be acceptable today. It's simply not
5 pure enough, and I think we need to increasingly think
6 of our blood components in the same way.

7 The proposal by the FDA seems reasonable.
8 It's a better product. Many organizations seem to be
9 on target for one to two years. So let's get on with
10 it, with all appropriate speed.

11 Three years seems to be a little long, to
12 me. Three years have been suggested, because they
13 would allow clinical trials for controversial
14 indications. I have several reservations about that.

15 As someone who's done clinical trials for
16 their life's work, I sincerely doubt that they are
17 going to be done or going to be done well or going to
18 be done completely or definitively in a three-year
19 period of time.

20 I think, if some were to be done, they
21 would be of scientific interest, but they won't really
22 affect the public health, because leukocyte reduction
23 is going to be done anyway, and whether some of these
24 controversial indications turnout to be important or
25 not important will become a moot point for public

1 health purposes.

2 There are several other advantages of
3 stretching out this implementation period: certainly,
4 as a cushion for reimbursement, we heard, and concerns
5 about blood availability. But I hope that we can, in
6 fact, move more expeditiously, and the United States
7 system of collection and provision of blood has been
8 able to do so in the past.

9 We had discussions about the standard, five
10 times 10^6 leukocytes per unit, fewer than such, which
11 differs in the U.S. than in Europe, as well as the
12 quality control requirements. Much has already been
13 written about process control and testing.

14 As was already said, half of the BEST
15 committee's meeting this year dealt with that. The FDA
16 ought to look at these issues. They know about process
17 control.

18 Quite a bit has been published, both in
19 this industry and in others, but they should make their
20 requirements the simplest consistent with safety and
21 efficacy, perhaps a 95 percent confidence, that 95
22 percent of the components meet whatever standard is
23 defined.

24 Do we need to revise the current
25 guidelines? Listening to the two units, I guess the

1 answer is yes and no. The leukocyte reduction
2 guidance, relatively new, has to be somehow revised.
3 The platelet pheresis guidance is clearly going to be
4 revised. The answer is probably yes, but the optimal
5 timing for such revisions remains to be seen.

6 We heard about requirements for licensure,
7 and we hope and assume that the FDA will have the
8 resources to process these expeditiously. If the
9 public says something is safe and effective, then the
10 public ought to give the FDA the resources to provide
11 mechanisms for licensure.

12 We appreciate the issues of labeling with
13 the new default, and we appreciate the need for process
14 control, and that all leukocyte reduction will be done
15 in current good manufacturing process fashion,
16 according to regulations, in appropriate laboratories.

17 That probably ends the era of bedside
18 filtration, which in terms of safety and efficacy,
19 that's probably a good thing.

20 There are still major logistical issues.
21 Some deal with cost, single donor platelets, sterile
22 docking, in-line filters, source leukocyte
23 availability, sickle trait blood, loss of units of
24 blood in the filtration process. These are all going
25 to be worked out.

1 There are some helpful, specific
2 recommendations to the agency. Some say they should
3 mandate change. This might help make it a little bit
4 more palatable to the hospitals which are under the
5 financial gun, but perhaps there are other ways of
6 getting a standard of care other than a regulatory
7 agency's mandate.

8 They need to relook at quality control
9 issues and strategies and process control, and they
10 need to help with HCFA in reimbursement, because the
11 issue, after all, is reimbursement. It really isn't
12 cost.

13 I must admit that, looking at the
14 implementation plans of the Red Cross, Blood Systems,
15 Incorporated, and others, I'm impressed at the ability
16 of our heterogeneous system of blood collection and
17 delivery to respond to such a sea change with such
18 rapidity, especially when there's a public mandate.

19 We still have to deal with our customers.
20 I've heard that over and over again today, but our
21 customers aren't just the hospitals, and that's coming
22 from someone who runs a hospital transfusion service.
23 Our customers really are those who receive the units of
24 blood, and we need to bear that in mind.

25 Do our customers see universal leukocyte

1 reduction as a better component? Do we need a mandate?

2 Are there threats of litigation? Who defines this as
3 a new standard of care? How do we deal with the costs?

4 I think those are all issues that remain to be
5 addressed.

6 We heard, I believe, that any guidance
7 that's issued by the FDA will be in a draft format for
8 public comment, and I think that, too, is a good thing.

9
10 We also heard, I believe, that guidances
11 and regulations differ, and that guidance isn't binding
12 unless it's associated with other regulations such as
13 with cGMP. Don't believe it.

14 If there is guidance issued for universal
15 leukocyte reduction, I suspect you'll do it, and I'll
16 do it. Otherwise, that yellow tape may appear across
17 our door. But more importantly, that guidance is
18 important for public health and for public confidence.

19 I found the workshop today incredibly
20 helpful. It's told me where we are, and I think it
21 tells me where we're going. I suspect that universal
22 leukocyte reduction may be done well before the final
23 guidance is published.

24 That, in fact, would be a father in the cap
25 of the stewards of the American blood supply.

1 Thank you.

2 (Applause.)

3 CAPTAIN GUSTAFSON: Thank you, Dr. Klein.
4 That was a wonderful summary. I think you hit all of
5 the salient points, and we're very pleased with that.

6 I would like to thank all of you who stayed
7 until the bitter end. It's too bad that we don't have
8 workshop incentives to give out, out in the lobby.
9 Maybe next time. But we thank you so much.

10 We appreciate your input, and I think we've
11 had a very valuable session.

12 (Whereupon, the foregoing matter went off
13 the record at 4:42 p.m.)
