

PENNSTATE

Cognition and Decision Making in Non-Primate Animals

Victoria Braithwaite

Decisions, decisions....

Which mate?

Where to forage? What to eat? How do I avoid being eaten?

Decisions can be simple - stimulus response
e.g. escape responses

Or, they can be more complex
- integrate different types of information / compare with
remembered events / decide on most appropriate response

Food
storing
birds

What, where, when - episodic memory

Clark's
nutcracker

>

Mexican jay

Fish are an excellent model organism for cognition studies:

General vertebrate plan
but simplified

Despite the simplicity...

- They still generate mental representations such as maps
- They integrate different modes of information e.g. time and place information
- They show hemisphere lateralization
- They exhibit different 'personalities' - risk prone / bold vs. risk averse / timid

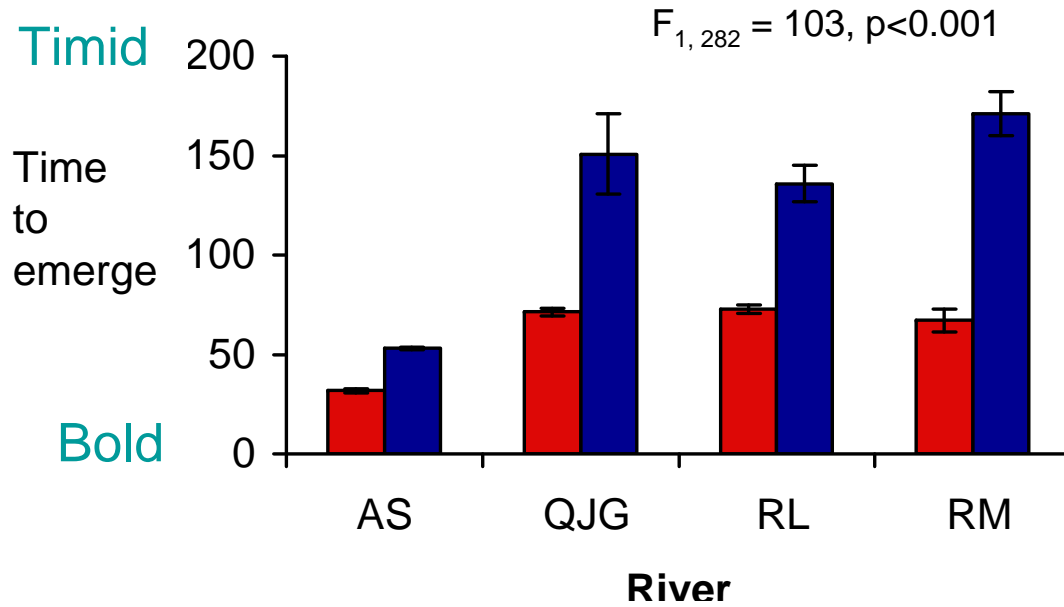

How does living in a dangerous environment affect how animals make decisions?

Panamanian bishop
Brachyrhaphis episcopi

Risk perception

■ high predation / high risk
■ low predation / low risk

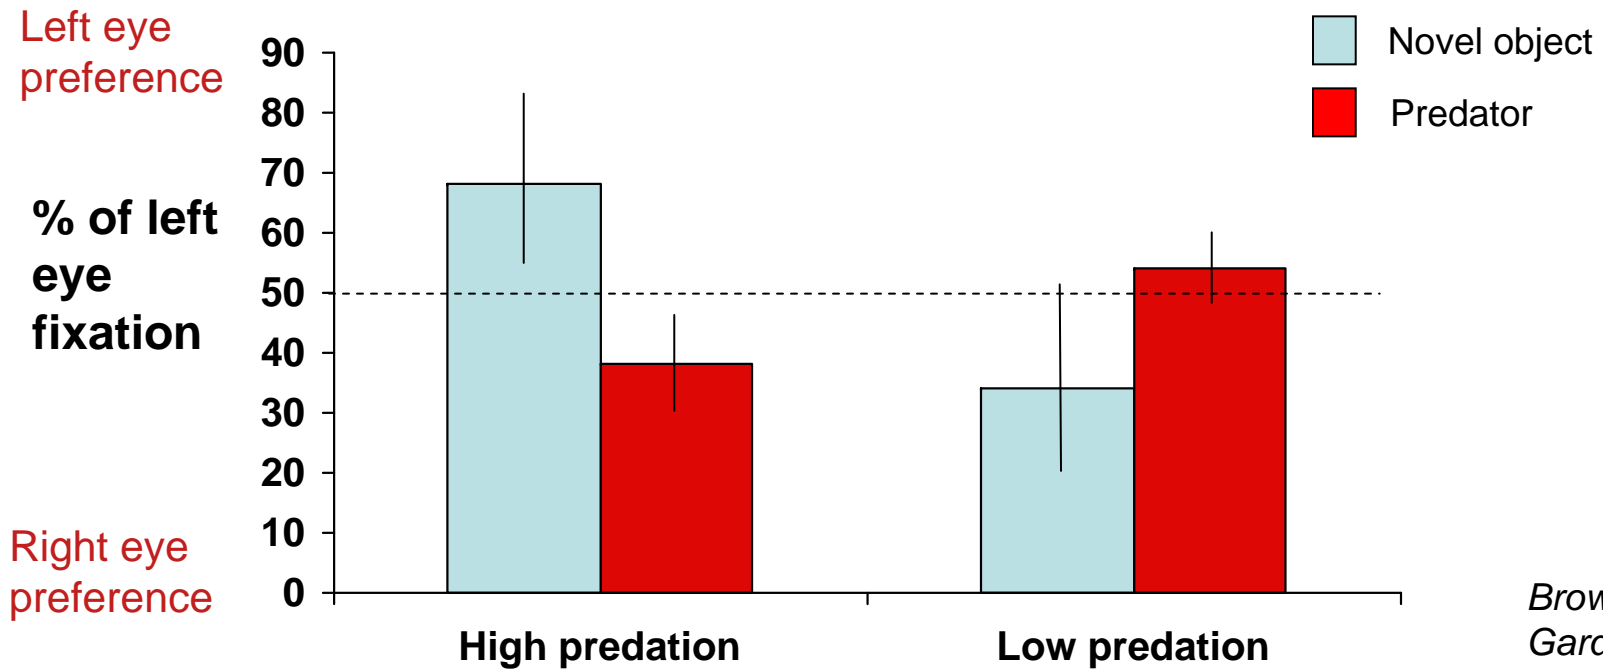

Brown & Braithwaite, 2004

Brown & Braithwaite, 2005

Lateralized visual responses - different use of left and right eyes

Brown,
 Gardner &
 Braithwaite 2004

Finding your way...

*Finding reliable food sources...
Locating shelter when threatened...
Navigating a safe route home...*

How do animals living in stable or unstable environments solve spatial problems?

Ponds
spatially
stable

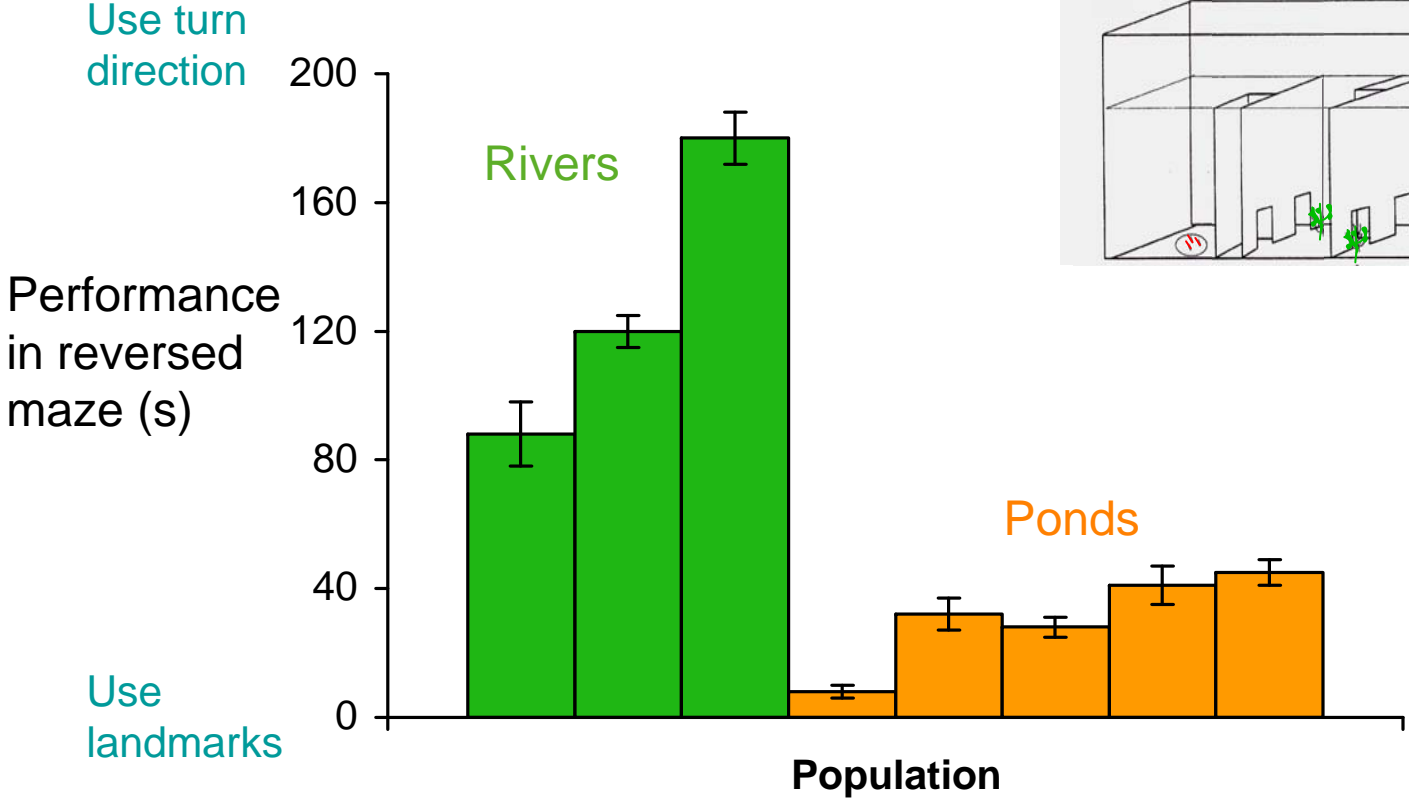

Landmarks

River
spatially
unstable

Do fish from ponds & rivers solve mazes the same way?

Girvan & Braithwaite 1998
 (Girvan & Braithwaite 2001; Odling-Smee & Braithwaite 2003)

2 possible spatial cues: (i) water flow direction or (ii) landmarks

Braithwaite & Girvan 2003

How does coping with a distraction affect decision making?

When fish are experiencing pain their perception of threat changes

% time spent near (<5cm) novel object

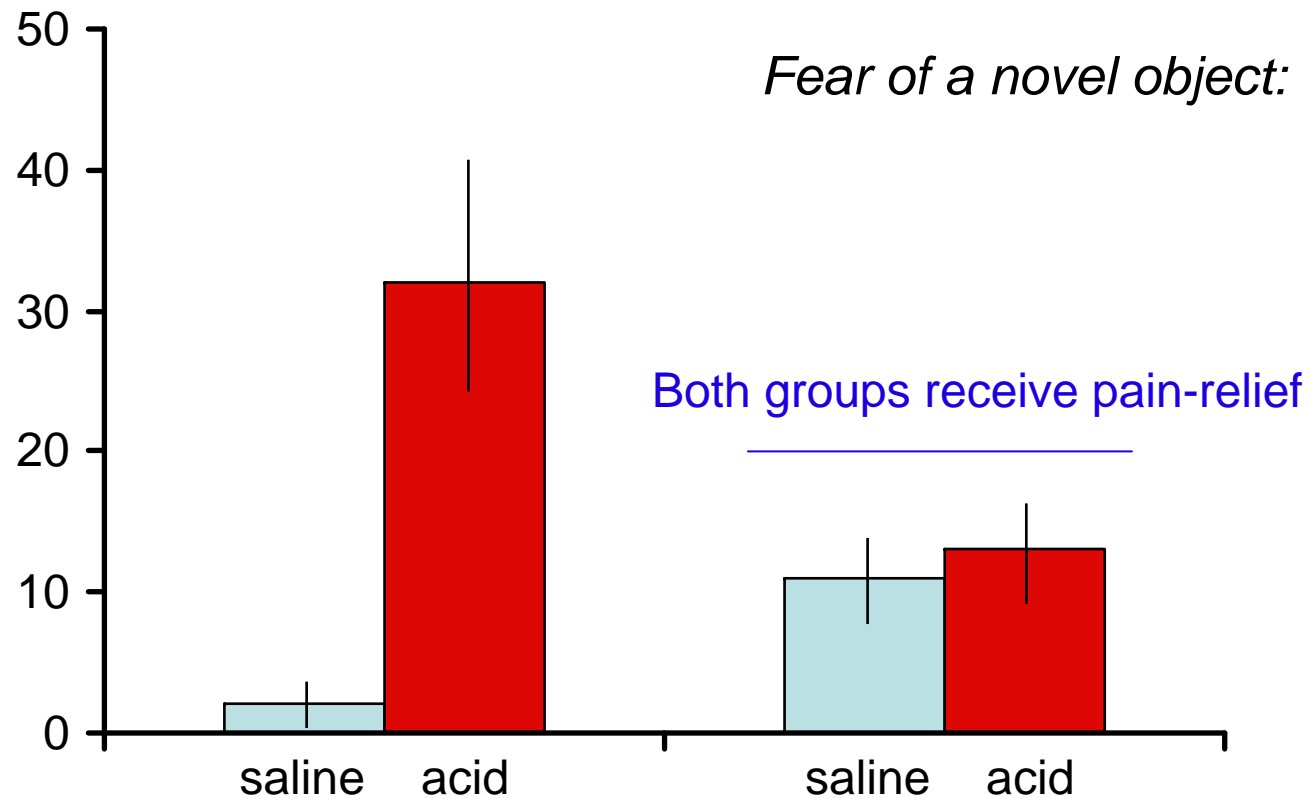

Fear of a novel object:

How does coping with a distraction affect decision making?

When fish are experiencing pain their perception of threat changes

% time spent near (<5cm) novel object

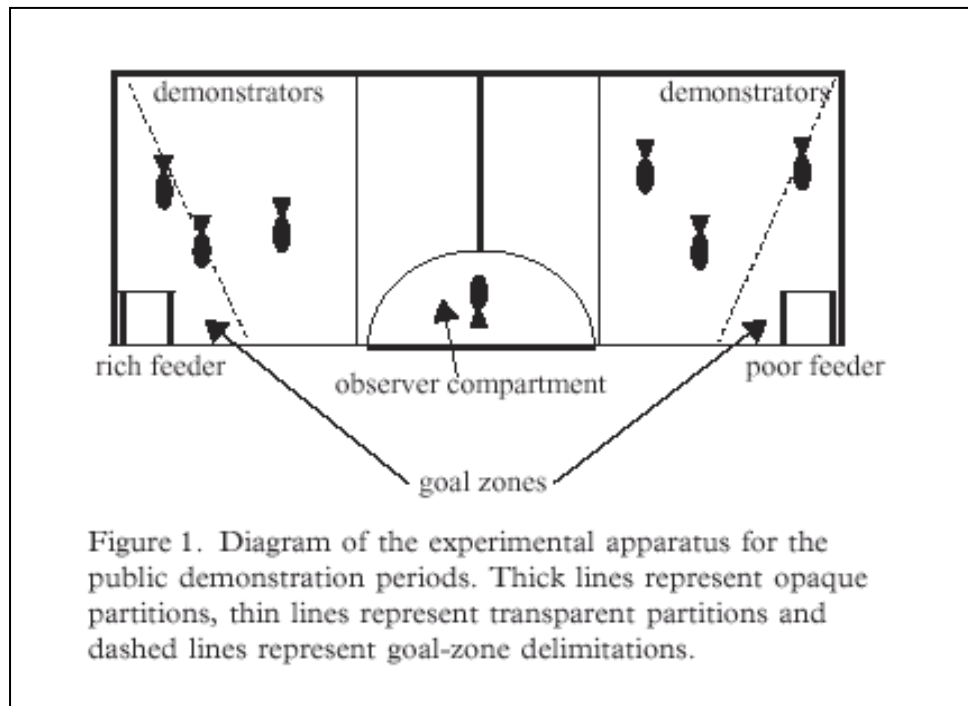

When do animals pay attention to personal information vs. social information / copy others?

QuickTime™ and a TIFF (Uncompressed) decompressor are needed to see this picture.

Risk averse / timid
- learns by watching others

Risk prone / bold
- learns by trial & error

Animal decisions are affected by:

- The environment in which an animal is making decisions
- Mental state & perceived awareness of the animal
- Personality / temperament traits (bold vs timid)

Current Application:

Manipulating rearing environments of captive reared animals to generate appropriate behavioral flexibility prior to release

E.g.

Studies of animal cognition provide a number of opportunities...

Animals are excellent models to understand risk (physical and cognitive)
....Simplicity of their brains and nervous system an advantage...

We could use them probe questions about 'agility' and 'resilience'

Particularly we can make use of animals from natural environments
where real selection pressures shape behavior and create
solutions

Do we see lateralized responses in other senses?

Blind Mexican cave fish
