MORBIDITY AND MORTALITY
WEEKLY REPORT

Salmonellosis Associated with Chicks and Ducklings — Michigan and Missouri, Spring 1999

During the spring of 1999, outbreaks of salmonellosis associated with handling chicks and ducklings occurred in Michigan and Missouri. This report summarizes the epidemiologic information for the outbreaks and provides an overview of legislative efforts to control the distribution of chicks and ducklings. These outbreaks demonstrate that handling chicks and ducklings is a health risk, especially for children, and highlight the need for thorough handwashing after contact with chicks, ducklings, and other young fowl.

Michigan

In May 1999, the Michigan Department of Community Health (MDCH) was notified of an increase in *Salmonella* serotype Infantis infections with closely related pulsed-field gel electrophoresis (PFGE) patterns; 21 case-patients were reported with onset of illness during April 1–July 31, 1999. Ages of infected persons ranged from 8 days to 82 years (mean: 25 years); eight (38%) were aged <10 years. Twelve (57%) were female. Symptoms reported during patient interviews included diarrhea (81%), fever (57%), bloody diarrhea (24%), and vomiting (14%). Three patients were hospitalized. Overall, 17 (82%) patients reported direct and/or indirect contact with young fowl: eight (38%) with chicks, two (10%) with ducklings, one (5%) with pheasant, and six (29%) with multiple species, including chicks and ducklings. Of the young fowl that were traceable, 88% were shipped from a single hatchery.

MDCH conducted a case-control study to identify exposures associated with illness. Nineteen patients were enrolled and were matched by age and place of residence to 37 healthy controls using sequential-digit dialing. During the 5 days before illness onset, 14 (74%) of 19 patients had direct contact with young fowl or resided in a household that raised fowl (chicks, ducklings, goslings, pheasants, and/or turkeys) compared with six (16%) of 37 controls (matched odds ratio [MOR]=20; 95% confidence interval [CI]=3–378). In several households, young birds were kept inside the home. One child kept young birds in his bedroom and another carried chicks inside his jacket.

MDCH, with assistance from the Michigan Department of Agriculture (MDA), visited the implicated hatchery in September 1999. During the spring, the hatchery shipped approximately 100,000 birds per week by mail order directly to customers and to several feed and farm supply retail outlets across the state. Fowl were shipped in lots of 25 to 100 birds, and usually were raised for backyard use (i.e., meat and egg production for

Salmonellosis Associated with Chicks and Ducklings — Continued

the family). *S*. Infantis with the outbreak PFGE pattern was recovered from three of 47 environmental samples and five of 33 bird samples taken at the hatchery. Other *Salmonella* serotypes also were isolated from the environmental samples, including serotypes Montevideo (seven), Chester (one), and Mbandaka (one).

Missouri

In April 1999, the Missouri Department of Health (MDOH) noted a cluster of *Salmonella* serotype Typhimurium infections with an identical PFGE pattern; 40 case-patients were identified with onset of illness during April 4–May 30, 1999. The ages of infected persons ranged from 8 months to 46 years (mean: 13 years); 28 (70%) were age <20 years; 23 (58%) were male. Symptoms reported by the 33 patients interviewed included fever (42%), bloody diarrhea (27%), stomach cramps (27%), and vomiting (21%). Three patients were hospitalized. Overall, 32 (97%) persons reported exposure to young fowl: 18 (56%) were exposed to chicks, 10 (31%) to ducklings, three (9%) to both chicks and ducklings, and one (3%) to a young turkey.

MDOH conducted a case-control study of persons exposed to chicks or ducklings to identify whether specific behaviors were associated with illness. Twenty case-patients were enrolled; 40 controls who had been exposed to chicks and ducklings during the same time were identified through media advertisements and word-of-mouth. During the 4 weeks before onset of patient illness, chicks or ducklings that were identified as ill by the patient or handler were associated with human illness (odd ratio [OR]=21; 95% CI=2–508); handwashing after handling fowl was protective against illness (OR=0.0; 95% CI=0.0–0.2).

Legislative Efforts

During February 2000, CDC contacted 51 state and territorial public health departments to ascertain laws on the sale of baby fowl to noncommercial distributors and private persons; 28 (55%) responded. Ten (36%) states have laws restricting the sale of baby fowl for noncommercial purposes, including the sale of fowl aged <3 weeks (Indiana and Maryland), <4 weeks (Ohio and Pennsylvania), <8 weeks (Massachusetts and Virginia), and <12 weeks (Connecticut). In addition, Connecticut, Ohio, and Virginia require fowl to be sold in groups of greater than five birds. Illinois prohibits the sale of chicks during the Easter season, and Kansas requires persons to have a temporary or permanent license to sell chicks.

Reported by: S Bidol, MPH, MG Stobierski, DVM, B Robinson-Dunn, PhD, J Massey, DrPH, W Hall, MD, M Boulton, MD, State Epidemiologist, Michigan Dept of Community Health. M Warwick, MD, M Borst, S Wiedlocher, Missouri Dept of Health. State Br, Div of Applied Public Health Training, Epidemiology Program Office; Foodborne and Diarrheal Diseases Br, Div of Bacterial and Mycotic Diseases, National Center for Infectious Diseases; and an EIS Officer, CDC.

Editorial Note: Although most of the 1.4 million human salmonellosis cases that occur annually in the United States are caused by foodborne sources (*1*), direct contact with animals, particularly reptiles and occasionally birds, also may be a source of infection (*2–4*). Most reptiles and many birds shed *Salmonella* in their feces. Humans become infected when contaminated food, hands, or other objects are placed in the mouth; therefore, handwashing is critical to prevent *Salmonella* infections following direct or indirect contact with animals. The Missouri outbreak described in this report and previous outbreaks (*3,4*) demonstrate that handling young fowl can be a risk for *Salmonella* infections, particularly in children who receive fowl as gifts during Easter; children have

Salmonellosis Associated with Chicks and Ducklings — Continued

more frequent hand-to-mouth contact and are less likely to practice handwashing after handling fowl. The Michigan outbreak describes the risk for infection associated with the backyard production of fowl.

Prevention efforts, such as sales restrictions and consumer education, may be difficult because selling pet fowl and raising backyard fowl are largely unregulated. Several states responding to the survey reported laws that restrict the sale of chicks, ducklings, and other young fowl. Some of these restrictions are based on previous reports of chick-associated and duckling-associated salmonellosis during Easter (*5*). Enforcement also may be difficult because young fowl can be purchased by mail and Internet orders from out-of-state hatcheries. State-mandated point-of-sale educational material may be effective in educating consumers about the risk for salmonellosis. States may wish to join Michigan and Missouri in issuing a press release during the spring of 2000 to raise public awareness about the risk for *Salmonella* infections posed by young fowl. MDCH, MDA, and MDOH have developed safety instructions to be distributed with young fowl that emphasize the importance of handwashing and supervision of young children interacting with young fowl.

To prevent the transmission of *Salmonella* from chicks, ducklings, and other young fowl to humans, persons should avoid contact with feces and carefully wash their hands with soap and water after handling young fowl or anything that has come in contact with them. Chicks, ducklings, and other young fowl may not be appropriate pets for children and should not be kept in households with infants, children aged <5 years, or immunocompromised persons. During investigations of *Salmonella* infections, especially during spring and Easter, health-care workers and public health personnel should consider contact with young fowl as a potential source and obtain cultures from these animals if they are suspected as the source of infection.

Measles Outbreak — Netherlands, April 1999–January 2000

On June 21, 1999, a cluster of five cases of measles was reported among the 390 students attending a religion-affiliated elementary school in the Netherlands. Persons belonging to this religious denomination routinely do not accept vaccination. Municipal health services (MHSs) investigated and found 160 suspected measles cases among children attending the school. By February 4, 2000, 2961 measles cases, including three measles-related deaths, had been reported by 35 MHSs to the national registry. This report summarizes the investigation of the measles outbreak in the Netherlands,

Measles — Continued

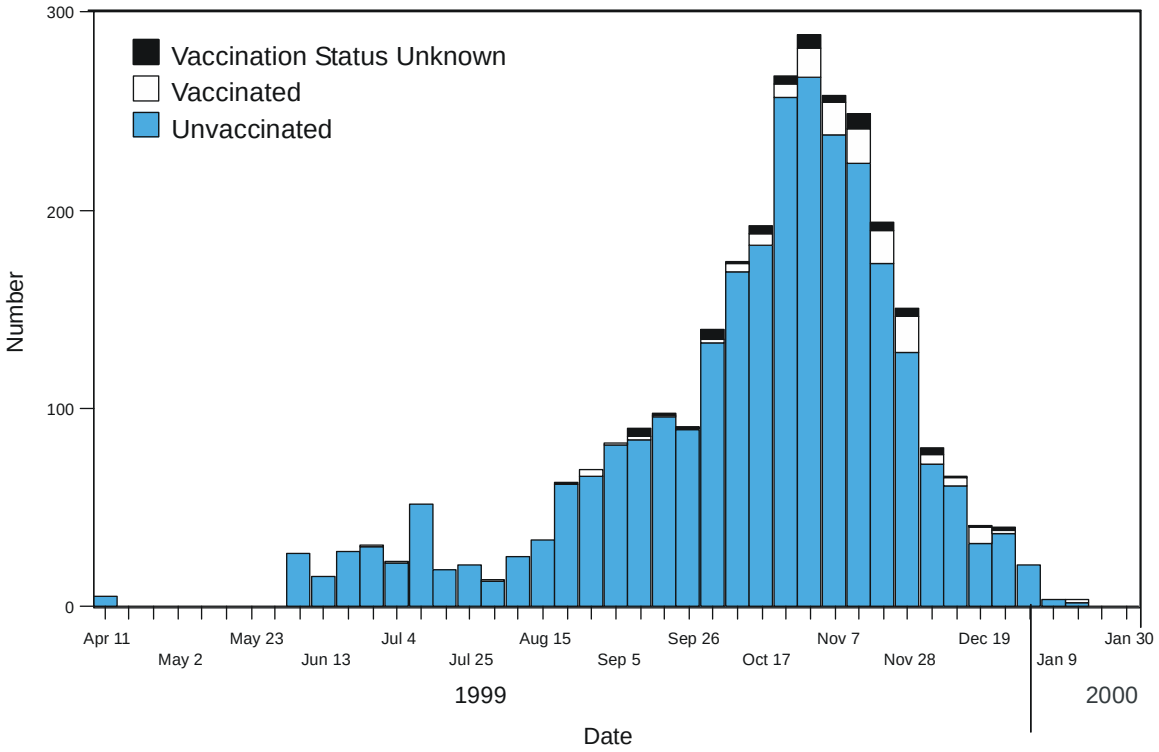
which indicated that measles can be a severe disease among unvaccinated populations in the Netherlands.

Measles is a notifiable disease in the Netherlands, and cases that occurred during this outbreak were reported by physicians to the local MHS as part of routine surveillance. The vaccination status of ill persons was reviewed based on written records kept by reporting physicians and sent to the vaccination registry. In April 1999, the first cluster of measles cases occurred, followed by the reported elementary school outbreak in June. No cases of measles with onset in May were reported, and transmission was low during June and July (Figure 1). When schools reopened in August, the number of cases increased. The outbreak peaked during October–November, then decreased rapidly. As of February 4, the last reported cases had onset during the week of January 16. Since then, the number of reported cases has decreased substantially, suggesting that the outbreak is ending.

From April 15, 1999, to February 4, 2000, 2961 cases of measles were reported in 35 (67%) of the country's 52 MHSs; 2317 (78%) were reported by 10 MHSs. All reporting municipalities have large communities affiliated with the religious group. Of the 105 case-patients tested for measles immunoglobulin type M, 100 (95%) had serologically confirmed measles.

Complications among acute measles case-patients were assessed by telephone follow-up with reporting physicians; 510 (17%) cases had one or more complications and/or hospitalizations (Table 1). Three patients died as the result of measles complications: one child aged 2 years had an underlying cardiac disorder and subsequent cardiac failure, one child aged 3 years developed myocarditis, and one adolescent aged 17 years

FIGURE 1. Reported number of measles cases, by week of disease onset and vaccination status — Netherlands, April 15, 1999–February 4, 2000



Measles — Continued

TABLE 1. Complications from reported cases of measles — Netherlands, April 15, 1999–February 4, 2000

Complication	No.	(%)
Death	3	(0.1)
Hospitalization for encephalitis	5	(0.2)
Hospitalization for other reasons	63	(2.1)
Pneumonia	130	(4.4)
Otitis media	170	(5.7)
Pneumonia and otitis media	26	(0.9)
Other respiratory disorders	56	(1.9)
Other	57	(1.9)
No complications	2451	(82.8)
Total	**2961**	**(100.0)**

developed kidney failure and acute respiratory distress syndrome. Sixty-eight (2.2%) persons were reported hospitalized: 37 (1.2%) for pneumonia, seven (0.2%) for dehydration, five (0.2%) for encephalitis, four (0.1%) for high fever, three (0.1%) for shortness of breath, two (0.1%) for severe otitis media, two (0.1%) for croup, and six (0.2%) for other reasons. Two persons developed measles while hospitalized for other reasons.

Of the 2882 patients whose ages were known, the median age was 6 years (range: 0–52 years): 95 (3%) were aged <1 year; 949 (33%), aged 1–4 years; 1282 (44%), aged 5–9 years; 382 (13%), aged 10–14 years; 87 (3%), aged 15–19 years; and 87 (3%), aged ≥20 years. Information on vaccination status was available for 2907 persons; 2770 (95%) were unvaccinated and 137 (5%) were vaccinated children. Of the 137, 117 (85%) were aged <9 years and all had received one dose of measles, mumps, and rubella vaccine (MMR); in 20 (15%) children the number of doses was unknown. Based on data from the national registry, 2749 persons whose ages were known were unvaccinated: 2317 (84%) persons eligible for vaccination were not vaccinated for religious reasons and 173 (6%) for other reasons (e.g., lack of concern about measles or concern about adverse events); 187 (7%) were not eligible for vaccination: 160 (85%) were aged <14 months (the recommended age for administration of the first dose of measles vaccine), 20 (11%) were born before 1976 (the year measles vaccination was introduced), and seven (4%) had a contraindication for measles vaccination. For the remaining 72 (3%) unvaccinated persons, the reason for not being vaccinated was unknown.

In response to the outbreak in the Netherlands, on July 1, control activities were implemented, including 1) tracing contacts of cases, 2) offering vaccine or immunoglobulin to susceptible contacts, 3) alerting all secondary-care and tertiary-care hospitals about the measles outbreak, 4) requesting general physicians to report all suspected cases, 5) conducting catch-up vaccination sessions at MHSs and mother and child clinics, 6) increasing media attention about undervaccination, and 7) urging parents to complete vaccination of children.

Editorial Note: The three measles-related deaths and 68 hospitalizations that occurred among 2961 cases in the Netherlands indicate that measles can be severe and may result in death even in industrialized countries. Rates of complications reported in this outbreak are comparable with those in the United States and other industrialized countries (*1*).

Measles notification and vaccination began in 1976 in the Netherlands, where measles epidemics have occurred every 5–7 years: 1976, 1983, 1988, 1992–1993, and 1999–2000. Since 1987, two doses of MMR have been recommended at age 14 months and 9 years. Measles vaccination is not mandatory for entry into school in the Netherlands. During 1997–1999, nationwide coverage of children for both doses was reported between 95% and 96% (*2*). However, coverage was not distributed uniformly throughout the country. In 1999, coverage ranged from 53% to 90% in municipalities that had a high percentage of residents who were members of a particular group that refrains from vaccination on religious grounds (*2*). This community in the Netherlands, estimated at 300,000 persons (2% of the overall population) lives as a close social network in a circumscribed geographic area mostly in the provinces of Gelderland, Utrecht, Zuid-Holland, and Zeeland. Approximately half of the 4%–5% of unvaccinated persons in the Netherlands are members of this group. Although the Netherlands has high overall MMR coverage, 36 (7%) of 539 municipalities have one-dose coverage of <90%.

Although measles is more severe in malnourished or immunosuppressed persons, severe disease or death may result in persons with no underlying illness. Measles vaccine is a highly effective method for preventing this disease, and lack of vaccination resulted in this outbreak. Similar to the outbreak of poliomyelitis among religious communities in 1992 (*3,4*), measles spread from the Netherlands to Canada through visiting relatives. The resulting outbreak in Canada was limited to 17 cases within the religious community possibly because stringent control measures were taken (*5*).

Until measles is eradicated worldwide, epidemics will continue to occur periodically in the Netherlands. The World Health Organization (WHO) has established goals to eliminate measles as an indigenous disease from the Region of the Americas by the end of 2000, the European Region by 2007, and the Eastern Mediterranean Region by 2010. To reach these goals, the WHO regional office for Europe has conducted workshops aimed at assisting participating countries to develop an elimination strategy based on the percentage of persons susceptible to measles in their population. In addition to these activities, increased commitment at the regional and national levels is needed to eliminate measles in the European Region (*6*).

Fatal Yellow Fever in a Traveler Returning from Venezuela, 1999

On September 28, 1999, a previously healthy 48-year-old man from California sought care at a local emergency department (ED) and was hospitalized with a 2-day history of fever (102 F [38.9 C]), chills, headache, photophobia, diffuse myalgias, joint pains, nausea, vomiting, constipation, upper abdominal discomfort, and general weakness. On September 26, he had returned from a 10-day trip to Venezuela. On September 29, an infectious disease physician from the ED contacted the Marin County Health Department (MCHD) about the patient's symptoms; MCHD reported his illness to the California Department of Health Services (CDHS) as a suspected case of viral hemorrhagic fever. This report describes the investigation of the case.

On admission to the hospital, physical examination revealed icteric sclerae and tenderness in the upper abdomen. Multiple red papular lesions with excoriations consistent with recent mosquito bites were seen on his lower legs and feet. No hepatosplenomegaly or lymphadenopathy was noted. Laboratory results indicated markedly elevated serum bilirubin (5.9 mg/dL) and liver enzymes (alanine aminotransferase: >5000 U/L; aspartate aminotransferase: >3750 U/L; and alkaline phosphatase: 194 U/L), leukopenia (white cell count: $3.4 \times 10^3/mm^3$ with 82% segmented, 2% bands, and 2% atypical lymphocytes), thrombocytopenia (platelet count: $77{,}000/mm^3$), and evidence of acute renal failure (creatinine: 5.9 mg/dL; potassium: 6.4 mmol/L; and bicarbonate: 16 mmol/L).

A preliminary diagnosis of hemorrhagic fever syndrome was made, and the patient was placed on doxycycline and ceftriaxone. Cultures of blood and urine were negative for bacterial pathogens. Blood smears for malaria were negative. On October 1, the patient developed general seizures and upper respiratory obstruction. He was placed on mechanical ventilation and transferred to the intensive care unit. His condition deteriorated rapidly, with severe coagulopathy and cardiac arrhythmias. He died on October 4.

On October 7, an autopsy of the chest and abdomen was performed at the University of California San Francisco Medical Center. Histopathologic examination of the liver showed extensive necrosis, steatosis, and numerous Councilman bodies compatible with fulminant yellow fever (YF) hepatitis. Evidence of disseminated angioinvasive aspergillosis involving the lungs, heart, kidneys, adrenal glands, small and large bowel, stomach, and disseminated intravascular coagulation also was seen. Specimens of the liver were examined at CDC; YF viral antigens were found by immunohistochemistry (IHC) and YF virus-specific nucleic acids by polymerase chain reaction. Other IHC tests were negative for dengue virus, leptospira, New World arenaviruses, spotted fever group rickettsiae, and hantavirus. The patient's serum was tested by CDHS; no antibody to YF virus (17D) was detected by immunofluorescence in serum drawn September 28, but an IgG titer of 1:128 and an IgM titer of >1:80 were detected in serum drawn October 1.

During September 16–25, the patient had traveled with six companions to rainforests in southern Venezuela (Amazonas State). He experienced multiple mosquito bites during his visit despite using DEET-based repellents. Before his trip, the patient had received tetanus toxoid, typhoid vaccine, hepatitis A vaccine, and malaria prophylaxis, but not YF

Yellow Fever — Continued

vaccine. The six travel companions were contacted by CDHS about their health and vaccination status; none had become ill during or following the trip. Five had received YF vaccine before travel. The unvaccinated traveler's serum was negative for YF virus antibody tested at CDC by enzyme-linked immunosorbent assay.

Reported by: F Schwartz, MD, Marin County Health Dept, San Rafael; F Drach, MD, ME Guroy, MD, San Rafael; J Olson, MD, J Rabban, MD, H Sanchez, MD, Univ of California San Francisco, San Francisco; MS Ascher, MD, CA Glaser, MD, SB Werner, MD, DJ Vugia, MD, Acting State Epidemiologist, California Dept of Health Svcs. Infectious Disease Pathology Activity, Div of Viral and Rickettsial Diseases; Arbovirus Diseases Br, Div of Vector-Borne Infectious Diseases; Surveillance and Epidemiology Br, Div of Quarantine, National Center for Infectious Diseases; and an EIS Officer, CDC.

Editorial Note: This report describes the second case of imported fatal YF in a U.S. resident returning from South America since 1996, and the first such cases since 1924. Neither patient had received YF vaccine before travel. In the case described in this report, viral hemorrhagic fever was suspected and reported to the local health department. Histopathology, IHC studies, nucleic acid testing, and serology all demonstrated that the traveler died of YF complicated by angioinvasive aspergillosis. In 1996, a Tennessee resident returned from a 9-day trip to Brazil with fever, headache, and myalgias (*1*). He died 10 days after onset of symptoms, and YF virus was identified from tissue culture.

YF occurs in at least seven tropical South American countries (Bolivia, Brazil, Colombia, Ecuador, French Guiana, Peru, and Venezuela) and much of sub-Saharan Africa (*2*). The sylvatic cycle involves nonhuman primates and mosquitoes that breed in tree holes (*3*). Persons living or working in proximity to such jungle or forest habitats who are bitten by infected mosquitoes can develop "jungle YF." Another cycle exists between humans and *Aedes aegypti* mosquitoes. *Ae. aegypti* mosquitoes are present in most urban centers of South and Central America, the Caribbean, and parts of the southern United States; persons in these areas are at risk for urban YF infection. YF has not been reported from India or other parts of Asia despite the presence of *Ae. aegypti* (*4*).

World Health Organization (WHO) data suggest that YF transmission is increasing (*4,5*). After adjustments for underreporting, WHO estimates that approximately 200,000 YF cases occur each year, most in sub-Saharan Africa (*4*). Concomitant with increased YF transmission, the number of travelers from the United States to South America and Africa has more than doubled since 1988 (*6*). These travelers may be at risk for YF unless precautions are taken, including receipt of YF vaccine.

YF is one of three diseases (the others are plague and cholera) subject to international quarantine regulations (*7*). CDC is required to notify WHO of all YF cases in the United States within 24 hours. Accordingly, all suspected and confirmed cases should be reported immediately through local and state health departments to CDC's National Center for Infectious Diseases, Division of Quarantine (DQ), telephone (404) 639-8100; acute and convalescent-phase serum should be collected and sent for viral isolation and diagnosis to CDC's National Center for Infectious Diseases, Division of Vector-borne Infectious Diseases, telephone (970) 221-6400. CDC's DQ also is responsible for certifying YF vaccination centers in the United States. Since September 1, 1977, CDC has delegated to state and territorial health departments the responsibility to designate and supervise nonfederal YF vaccination centers within their jurisdictions. The location of certified U.S. YF vaccination centers is available from local and state health departments. If YF vaccine is medically contraindicated, health-care providers should supply

Yellow Fever — Continued

persons with a letter listing reasons for not vaccinating, and persons should carry this with them when traveling. Details of vaccine recommendations and requirements of individual countries are available from the CDC World-Wide Web site, http://www.cdc.gov/travel (*2*).

CDC recommends YF vaccination for travelers to countries reporting YF (*2*). Vaccination also is recommended for travel outside urban areas of countries that officially do not report the disease but are in the YF-enzootic zone. Travelers should also take protective measures to reduce contact with mosquitoes; these include wearing clothes that cover most of the body, staying in well-screened areas, using insect repellent (containing DEET at a concentration of <35% are recommended) on exposed skin and clothing, and sleeping under bed nets treated with permethrin or deltamethrin insecticides.

Satellite Broadcast on Geographic Information System

A satellite broadcast on Geographic Information System (GIS), "GIS in Public Health: Using Mapping and Spatial Analysis Technologies for Health Protection," is scheduled for May 11, 2000, from noon to 2:30 p.m. eastern daylight time. This broadcast, produced jointly by CDC and the Agency for Toxic Substances and Disease Registry, will provide an overview of GIS applications in public health, environmental health, and health-care practice, including research and surveillance using GIS. GIS provides a mechanism for layering health, demographic, environmental, and other data in a geographic format to facilitate analysis and highlight patterns of health-related occurrences. The program is intended to assist participants in identifying ways in which GIS can be useful to their own health professions. It will include demonstrations of GIS technology and show how GIS has helped health professionals understand health issues. Additional information is available on the World-Wide Web at http://www.cdc.gov/phtn/gis/gis.htm, or telephone (404) 639-6338.

U: Unavailable -:no reported cases

*Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of 100,000 or more. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.

†Pneumonia and influenza.

§Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.

¶Total includes unknown ages.

The *Morbidity and Mortality Weekly Report (MMWR)* Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy on Friday of each week, send an e-mail message to *listserv@listserv.cdc.gov*. The body content should read *SUBscribe mmwr-toc*. Electronic copy also is available from CDC's World-Wide Web server at *http://www.cdc.gov/* or from CDC's file transfer protocol server at *ftp.cdc.gov*. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone (202) 512-1800.

Data in the weekly *MMWR* are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the *MMWR* Series, including material to be considered for publication, to: Editor, *MMWR* Series, Mailstop C-08, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333; telephone (888) 232-3228.
