Suitability for Construction Materials: Gravel Source - Maine (2008)

Gravel is used in great quantities in many kinds of construction. Specifications for each purpose vary widely, though gravel as a construction material is defined as particles ranging in size from 4.76 mm (sieve #4) to 76 mm (3 in) in diameter.

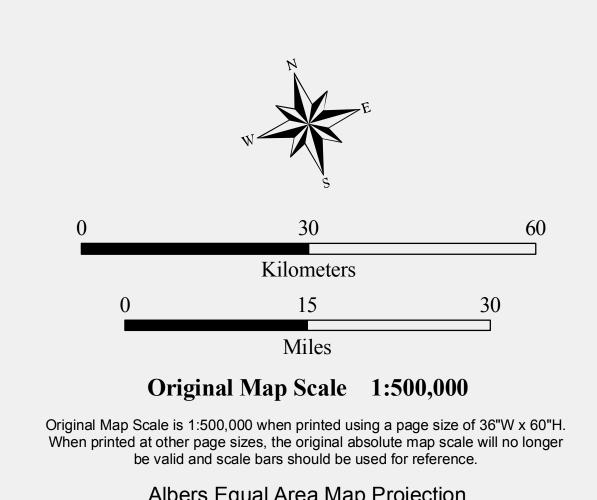

quantity. The suitability of the gravel for specific purposes is not evaluated. Final site evaluation and selection require an onsite inspection to determine the suitability and quality of the materials for the intended purpose. Implementation of these interpretations helps minimize the need for excessive random exploratory investigation by pinpointing potential sites.

Soils are rated and placed into gravel source suitability rating classes per their rating indices. These are poor (rating index = 0), fair (rating index > 0

and < 1.0), or good (rating index = 1.0).

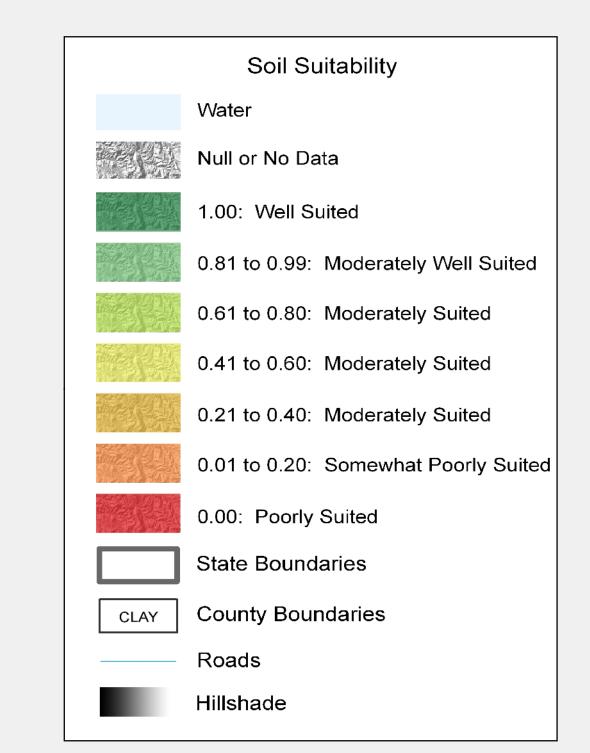

Soil properties used to evaluate the soil as a probable source of gravel are grain size as indicated by the Unified soil classification, the thickness of the gravel layer, and the amount of rock fragments in the soil material. If the lowest layer of the soil contains gravel, the soil is rated as a probable source regardless of thickness.

Soil survey interpretations for construction materials are designed to provide guidance to users in selecting the site of a potential source. Soils may be selected as potential source materials because they are nearby, are the only source available, or meets some or all of the physical or chemical properties required for the intended application. In theory, every soil may be used as source materials, but in reality, only a few soils have the profile characteristics that meet the defined criteria and performance requirements when rated for a specific propose. The use of rating guides can provide the user a means to select potential sites for further evaluation.
