## Series 16: Compilations of Advance Data From Vital and Health Statistics No. 18

Data in this report from health and demographic surveys present statistics by age and other variables on office visits to cardiovascular disease specialists, characteristics of persons dying from heart and cerebrovascular diseases, use of vitamin and mineral supplements, firearm mortality among children and youth, and AIDS knowledge and attitudes. Estimates are based on the civilian noninstitutionalized population of the United States. These reports were originally published in 1989.

# Office Visits to Cardiovascular Disease Specialists, 1985 

by Cheryl Nelson, M.S.P.H., Division of Health Care Statistics

In 1985 an estimated 10.6 million patient visits were made to the offices of physicians specializing in cardiovascular disease. This represented 1.7 percent of all ambulatory visits to all physician specialties. Patients seeking health care services from cardiovascular disease specialists were generally older than patients seeking care from physicians in other specialties. Patients 45 years of age and older represented 87 percent of the ambulatory visits. Patients 65 years of age and older accounted for an estimated 5 million visits and had a visit rate of 186 visits per 1,000 persons (table 1). The mean age of patients visiting cardiovascular disease specialists was 61.7 years (table 2). In other physician specialties, the next highest mean patient age was about 54 years for internal medicine, ophthalmology, and urological surgery.

Table 2. Mean age of visiting patients by physician specialty: United States, 1985

| Physician speciaty | Mean age of visting pationt |
| :---: | :---: |
| All specialties . | 39.6 |
| Cardovascular disease. | 61.7 |
| Ophthalmology | 54.4 |
| Internal medicine | 54.3 |
| Urological surgery. | 54.1 |
| General surgery | 48.5 |
| Neurology. | 45.3 |
| Dermatology | 41.0 |
| General and family practice | 40.2 |
| Orthopedic surgery | 40.0 |
| Psychlatry | 39.1 |
| Otorhinolaryngology | 36.5 |
| Obstatics and gynecology | 32.5 |
| Pediatrics | 5.9 |
| All other specialtios | 46.2 |

This report is based on data from the 1985 National Ambulatory Medical Care Survey (NAMCS). NAMCS, a year-long probability sample survey of the Nation's office-based physicians, was conducted annually from 1973

Table 1. Number, percent distribution, and rate of office visits to cardiovascular disease specialists, by age of patient: United States, 1985

| Age of pattent | Number of visits in thousands | Parcent distribution | Visit rate per <br> 1,000 persons |
| :---: | :---: | :---: | :---: |
| All ages | 10,617 | 100.0 | 45 |

| 65 years and over | 5.015 | 47.2 | 186 |

through 1981 and again in 1985 by the Division of Health Care Statistics of the National Center for Health Statistics. General findings from the 1985 NAMCS have been published (1).

In the office-based setting, visits by white patients outnumbered visits by black patients and by patients of other races in seeking health care services from cardiovascular disease specialists (table 3).

Established patient-physician relationships accounted for 88 percent of the visits, and the majority of those visits ( 78 percent) were from patients with old problems returning to the physician's office (table 4). In 1975-76. established patient-physician relationships accounted for 75 percent of the visits to cardiovascular disease specialists (2).

## Patient's reason for visiting the physician

A symptom was most often given by patients as the major reason for visiting cardiovascular disease specialists (table 5). The general symptom most often recorded as a reason for visit was chest pain (table 6). However, the most often recorded reason for visit was a general medical examination, accounting for about 14 percent of all reasons for visit. Diseases of ti.e circulatory system, such as ischemic heart disease and hypertension, were also among the most common reasons for visiting the cardiovascular disease specialist.

## Physician diagnoses

Cardiovascular disease physicians ordered or provided some type of diagnostic service for the majority of their patients' visits. No diagnostic services were utilized in almost 14 percent of the patient visits (table 7). Except for internal medicine and obstetrics and gynecology, cardiovascular disease specialists used the blood pressure check as a diagnostic tool more often than did physicians in other specialties. In 70 percent of the visits, cardiovascular physicians ordered or provided a blood pressure check. The EKG was another principal diagnostic tool used by cardiovascular disease physicians; in 30 percent of the patient visits, the physicians ordered or provided an EKG. Internists utilized the EKG in 11 percent of their patient visits; they ranked second to cardiovascular disease physicians in EKG utilization.

Sixty-three percent of all visits to cardiovascular disease physicians resulted in diagnoses of diseases of the circulatory system (table 8). Other forms of chronic ischemic heart disease, essential hypertension, cardiac dysrhythmias, angina pectoris, and heart failure represented 48 percent of the most common principal diagnoses made by cardiovascular disease specialists (table 9).

## Medication therapy

The 26 million drugs prescribed or provided by cardiovascular disease physicians account for almost 4 percent of all drugs reported by all specialties. Drugs mentioned in visits to general and family practitioners and internists account for the majority ( 54 percent) of all reported drugs (3). Medication was prescribed or provided by cardiovascular disease specialists in almost 81 percent of the visits (table 10); that was more often than in any other physician specialty. General and family practitioners and internists, respectively, prescribed or provided drugs in 72 and 77 percent of their visits. Cardiovascular disease physicians prescribed or provided two or more medications in 66 percent of their visits; general and family practitioners and internists prescribed or provided two or more medications in only 33 and 45 percent of their visits, respectively. The average number of drugs prescribed or provided by cardiovascular physicians was 2.5 drugs per visit. When drugs were prescribed or ordered by cardiovascular disease physicians, the average number of drugs per drug visit was 3.1.

Forty-six percent of the drugs reported by cardiovascular disease physicians were classified as cardiovascular drugs-specifically, cardiac drugs, vasodilating drugs, and hypotensive drugs (table 11). The cardiac drug Lanoxin accounted for 5 percent of the drugs reported. Digoxin, the principal generic ingredient of Lanoxin, was mentioned at least 2 percent of the time (table 12). Digoxin, as a generic ingredient, accounted for 7 percent of all drug ingredients (table 13).

Counseling was the principal nonmedication therapy utilized by cardiovascular disease specialists (table 14).

[^4]Table 13. Number and percent of the 10 generic ingredients most frequently utilized in the office practice of cardiovascular disease specialists: United States, 1985

| Generc ingradents | Number of mentions in thousands | Percent |

[^5]
## Duration and disposition of visit

The mean duration of all visits to cardiovascular disease specialists was 22 minutes. Seventy-three percent of those visits had a duration of between 11 and 30 minutes (table 15). However, when patient visits are stratified by the patient's prior visit status, the mean duration of visit was 38 minutes for new patients and 20 minutes for established patients.

Some type of "return" disposition was given in 92 percent of visits to cardiovascular disease specialists; eighty percent of visits were given the disposition of "return at a specified time" (table 16).

## Technical notes

## Source of data and sample design

The information presented in this report is based on data collected by means of the National Ambulatory Medical Care Survey (NAMCS) from March 1985 through February 1986. The target universe of NAMCS includes office visits made within the coterminous United States by ambulatory patients to nonfederally employed physicians who are principally engaged
in office practice, but not in the specialties of anesthesiology, pathology, or radiology. Telephone contacts and nonoffice visits are excluded.

A multistage probability sample design is used in NAMCS, involving samples of primary sampling units (PSU's), physician practices within PSU's, and patient visits within physician practices. For 1985 a sample of 5,032 non-Federal, office-based physicians was selected from master files maintained by the American Medical Association and the American Osteopathic Association. The physician
response rate for the 1985 NAMCS was 70 percent; the response rate for cardiovascular disease specialists was 51 percent. Sample physicians were asked to complete patient records (see text figure) for a systematic random sample of office visits occurring during a randomly assigned 1 -week reporting period. Responding physicians completed 71,594 patient records; 1,506 patient records were from cardiovascular disease specialists. Characteristics of the physician's practice, such as primary specialty and type of practice, were obtained during an

Figure. 1985 National Ambulatory Medical Care Survey patient record
induction interview. The National Opinion Research Center, under contract to NCHS, was responsible for the survey's data collection and processing operations.

## Adjustments for nonresponse

## Estimates from NAMCS data

 were adjusted to account for sample physicians who were in scope but did not participate in the study. This adjustment was calculated to minimize the impact of response on final estimates by imputing to nonresponding physicians the practice characteristics of similar responding physicians. For this purpose, physicians were judged similar if they had the same specialty designation and practiced in the same PSU.
## Sampling errors

The standard error is primarily a measure of the sampling variability that occurs by chance when only a sample, rather than an entire universe, is surveyed. The relative standard error of an estimate is obtained by dividing the standard error by the estimate itself; the result is then expressed as a percent of the estimate. These measurements are applied to office visits in tables I and II; in tables III and IV they are applied to drug mentions.

## Rounding

In the tables, estimates of office visits have been rounded to the

Table 1. Relative standard errors of estimated numbers of oftice visits to cardiovascular disease specialists: National Ambulatory Medical Care Survey, 1985.

| Estimated number of office visits in thousands | Relathe standard error in percent |
| :---: | :---: |
| 100* | 55.0 |
| 300* | 32.4 |
| 353 | 30.0 |
| 500 | 25.5 |
| 1,000 | 18.8 |
| 3,000 | 12.5 |
| 5,000. | 10.8 |
| 10,000 | 9.4 |
| 30,000 | 8.3 |

Example of use of table: An aggregate estimate of 4,000,000 visits has a relative standard orror of 11.5 percent, or a standard error of 460,000 visits ( 11.5 percent of $4,000,000$ ).

Table II. Approximate standard errors of percent of estimated numbers of office visits to cardiovascular disease specialists: National Ambulatory Medical Care Survey, 1985

| Estimatod number of office visils in thousands | Estimated percent |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\begin{gathered} 1 \text { or } \\ 99 \end{gathered}$ | $\begin{aligned} & 5 \text { or } \\ & 95 \end{aligned}$ | $\begin{gathered} 10 \text { or } \\ 90 \end{gathered}$ | $\begin{gathered} 20 \text { or } \\ 80 \end{gathered}$ | $\begin{gathered} 30 \text { or } \\ 70 \end{gathered}$ | 50 |
|  | Standard error in percentage points |  |  |  |  |  |
| 200. | 3.8 | 8.4 | 11.6 | 15.4 | 17.6 | 19.3 |
| 300. | 3.1 | 6.8 | 9.4 | 12.6 | 14.4 | 15.7 |
| 500. | 2.4 | 5.3 | 7.3 | 9.7 | 11.2 | 12.2 |
| 1,000 | 1.7 | 3.7 | 5.2 | 6.9 | 7.9 | 8.6 |
| 2,000 | 1.2 | 2.6 | 3.6 | 4.9 | 5.6 | 6.1 |
| 3,000 | 1.0 | 2.2 | 3.0 | 4.0 | 4.6 | 5.0 |
| 5,000 | 0.8 | 1.7 | 23 | 3.1 | 3.5 | 3.8 |
| 10,000. | 0.5 | 1.2 | 1.6 | 2.2 | 25 | 2.7 |
| 20,000. | 0.4 | 0.8 | 1.2 | 1.5 | 1.8 | 1.9 |

Example of use of fable: An estimate of 3 percert based on an aggregate estimate of $10,000,000$ vistrs has a standard error of 0.85 percent, or a ralative standard error of 28 percent ( 0.85 percent +3 percenti).

Table III. Relative standard errors of estimated numbers of drug mentions in the office-based practice of cardiovascular disease specialists: National Ambulatory Medical Care Survey, 1985

$\left.$| Estimated number of <br> drug mentions <br> n ithousands |
| :---: | | Revative standard |
| :---: |
| error in percent | \right\rvert\,

Exumple of use of table. An aggregate estime of 15,000,000 drug mentions has a relative stendard error of 128 percert, or a standard error of $1,800,000$ drug mentions (12.6 percent of $15,000,000$ ).
nearest thousand. Consequently, estimates will not always add to totals. Rates and percents were calculated from original unrounded figures and do not necessarily agree with percents calculated from rounded data.

## Definition of terms

An ambulatory patient is an individual seeking personal health services and is not currently admitted to any health care institution.

A physician is a duly licensed doctor of medicine (M.D.) or doctor of osteopathy (D.O.) who is currently in office-based practice, and who spends some time caring for ambulatory patients. Excluded from NAMCS are physicians who are hospital-based; who specialize in anesthesiology, pathology, or radiology; who are federally employed; who treat only institutionalized patients; who are employed full-time by an institution; and who spend no time seeing patients.

An office is a place that physicians identify as a location for their ambulatory practice; these customarily include consultation, examination, or treatment spaces the patients associate with the pasticular physician. Respon-

Table IV. Approximate standard arrors of percent of estimated numbers of drug mentions by cardiovascular disease specialists: National Ambulatory Medical Care Survey, 1985

| Estimated number of office vatis hi thousands | Estumatod parcent |  |  |  |  |  |

|  | 1 or 99 | $\begin{gathered} 5 \text { or } \\ 95 \end{gathered}$ | $\begin{gathered} 10 \text { or } \\ 90 \end{gathered}$ | $\begin{gathered} 20 \text { or } \\ 80 \end{gathered}$ | $\begin{gathered} 30 \text { or } \\ 70 \end{gathered}$ | 50 |
|  | Standard error in percentaga points |  |  |  |  |  |
| 500. | 3.4 | 7.5 | 10.4 | 13.9 | 15.9 | 17.3 |
| 1,000 | 2.4 | 5.3 | 7.3 | 9.8 | 11.2 | 12.3 |
| 2,000 | 1.7 | 3.8 | 5.2 | 6.9 | 7.9 | 8.7 |
| 3,000 | 1.4 | 3.1 | 4.2 | 5.7 | 6.5 | 7.1 |
| 5,000 | 1.1 | 24 | 3.3 | 4.4 | 5.0 | 5.5 |
| 10,000. | 0.8 | 1.7 | 23 | 3.1 | 3.5 | 3.9 |
| 20,000. | 0.5 | 1.2 | 1.6 | 2.2 | 2.5 | 2.7 |
| 30,000. | 0.4 | 1.0 | 1.3 | 1.8 | 2.0 | 2.2 |
| 50,000. | 0.3 | 0.7 | 1.0 | 1.4 | 1.6 | 1.7 |

Example of use of fable: An estimate of 2 percent based on an aggregate estimate ot $30,000,000$ drug mer ens has a standard error of 0.55 percent, or a relative standerd enor of 27.5 percent ( 0.55 percent +2 percam).
sibility for patient care and professional services rendered in an office resides with the individual physician rather than with an institution.

A visit is a direct personal exchange between an ambulatory patient and a physician or a staff member working under the physician's supervision, for the purpose of seeking care and rendering personal health services.

A drug mention is the physician's entry of a pharmaceutical agent-by
any route of administration-for prevention, diagnosis, or treatment. Generic as well as brand-name drugs are included, as are nonprescription as well as prescription drugs. Along with all new drugs, the physician also records continued medications if the patient was specifically instructed during the visit to continue the medication.

A drug visit is a visit in which medication was prescribed or provided by the physician.

# Characteristics of Persons Dying From AIDS 

Preliminary Data From the 1986 National Mortality Followback Survey<br>by Gloria Kapantais, M.A., and Eve Powell-Griner, Ph.D., Office of Vital and Health Statistics Systems

## Introduction

In the span of one decade, acquired immune deficiency syndrome (AIDS) has become a public health problem of global urgency. Since its identification in 1981, both the absolute number and rate of deaths from AIDS have increased steadily in the United States. For example, between 1983 and 1986, the estimated number of AIDS deaths based on death certificates received by the National Center for Health Statistics (NCHS) through the mortality vital registration system grew from 1,141 to 10,900 , and the estimated AIDS death rate increased from 0.5 to 4.5 per 100.000 population (1). AIDS is one manifestation of infection from the human immunodeficiency virus (HIV). Estimates of numbers of persons in the United States who are infected with HIV range from 1.0 to 1.5 million persons (2).

This report presents data from the 1986 National Mortality Followback Survey (NMFS) on selected characteristics of persons with mention of AIDS (ICD-9 code 279.1) on the death certificate. See the technical notes for
a discussion of the ICD-9 codes. The analysis focuses on three broad subject areas: social and demographic characteristics, health care access and utilization during the last year of life, and measures of disability prior to death.

The 1986 NMFS is a 1-percent stratified random national sample representative of adults aged 25 years or over who died in the United States during 1986. The 1986 NMFS is the fifth of the periodic followback.surveys on decedents conducted by the National Center for Health Statistics. The four earlier surveys, all conducted in the 1960's, were less comprehensive than the 1986 survey (3-9).

The purpose of the mortality followback surveys is to collect information not typically available from death certificates, thus enabling analysts to explore in much greater detail the characteristics of decedents and the circumstances of their death. Data collected during the 1986 NMFS provide detailed information on a nationally representative sample of adult deaths and an opportunity to examine many characteristics of the decedents and their last year of life.

The 1986 NMFS consists of data for 18,733 decedents. Data on social, demographic, economic, and behavioral and health related characteristics of decedents were obtained from a mailed questionnaire or personal interview with the person identified as the informant on the death certificate. The overall response rate for the survey was 89 percent.

The NMFS population included 284 decedents for whom HIV infection was reported on the death certificate as either the underlying cause of death or as a condition contributing to death and 18,449 decedents for whom no HIV infection was reported. Information from the NMFS questionnaire was available for 245 of the HIV decedents and for 16,353 of the other decedents. When weighted to yield national estimates, these deaths represent 9,276 AIDS deaths and $1,977,593$ other deaths. The nonresponse rate for NMFS decedents with HIV mentioned on the death certificate was approximately twice as high as that for decedents dying from other causes. Further description of the cause-of-death classification and weighting procedure used in the 1986

[^6]MMFS can be found in the technical notes.

Only substantive responses to the questionnaire items were included in these tables-blank items, a reply of "don't know" or "N/A," and so forth were not included. In addition, items were not imputed for nonresponse. For these reasons, the total number of responses varies by questionnaire item and is reflected in the totals for the tables in this report. Therefore, the number of deaths in the tables vary because of the exclusion of "no answer" and "multiple answer" deaths from the totals shown.

## Sociodemographic and economic characteristics

Table 1 presents information on the age, sex, and race of persons dying from AIDS and from all other causes. Males accounted for 8,556 (92 percent) of the AIDS deaths, with 4,916 ( 53 percent) occurring among men 25-39 years of age and 2,781 ( 29 percent) among men $40-54$ years of age. Females accounted for only 720 (8 percent) of the AIDS deaths. Black persons accounted for 2,063 (22 percent) of the AIDS deaths, and races other than black for 7,212 deaths

NOTE: Numbers may not add to totals because of rounding Oregon not included in the 1986 NMFS.
(78 percent). There were approximately equal proportions of males and females dying from all other causes of death, and the largest proportion of deaths were to those 55 years of age or more (table 1). Black persons accounted for 11 percent of all other deaths, and persons of races other than black accounted for 89 percent. Because of the small numbers of AIDS deaths in the 1986 NMFS, the remaining tables in this report present data with no sex, age, or race breakdowns.

Table 2 shows selected demographic characteristics of persons who died from AIDS or other causes. Over half ( 53 percent) of the AIDS decedents had some college education compared with 19 percent of other decedents. Fewer than one fourth ( 24 percent) of the AIDS decedents had less than a high school education compared with 52 percent of other decedents.

Even though most of the AIDS decedents were in the younger age groups, a population that is usually employed, only 34 percent of them were employed at the time of their death. In general, persons having AIDS had stopped working for health reasons.

For those who had been employed previously, information was obtained on their longest held occupation (table 2). Unlike those dying from other causes, more than half of the persons who died from AIDS were in managerial and professional specialty occupations ( 39 percent) and technical, sales, or administrative support occupations ( 21 percent). Over half of the AIDS decedents ( 59 percent) lived alone or with a nonrelative during the last year of life compared with onefourth of other decedents (table 2). Over one-third ( 35 percent) of AIDS decedents lived with one relative or more compared with 63 percent of other decedents.

Although persons who died from AIDS generally were in "white collar" occupations, they were likely to have had low levels of family income- 28 percent had 1985 incomes below $\$ 5,000$ (table 3). About 36 percent of the AIDS decedents were in the

| \$5.000-\$24,999. | *888 | -11 | 261,922 | 16 |
| \$25,000 or more . . . | *1,852 | *23 | 725,827 | 45 |

NOTE: Numbers may not add to totals because of rounding. Oregon not included in the 1986 NMFS.
highest income category of $\$ 19,000$ or more. In addition, the AIDS decedents tended to have few assets at death. Thirty-eight percent of AIDS decedents had no assets compared with 20 percent of other decedents, and 28 percent of AIDS decedents had total assets of between \$1 and $\$ 5,000$ compared with 19 percent of other decedents. Assets included home, cash, stocks, bonds, cars,
jewelry, business interests, and so forth. Because only a minority of AIDS decedents had lived with relatives in the year before their death, family income reported in the 1986 NMFS in most cases reflected only the income of the decedent. Often, the AIDS decedents, who tended to be young, were unemployed at the time of death. These factors may account, in part, for their lower income and assets.

## Health care and costs

Selected measures of health care utilization for decedents are shown in table 4. Utilization of various health care services in the last year of life indicates that AIDS decedents tended to be sick for a substantial part of the year prior to death.

Persons who died from AIDS made frequent visits to a physician during the last year of life. Over onethird ( 37 percent) had 25 physician visits or more during the last year of life compared with 18 percent of other decedents. About 5 percent of the persons dying from AIDS had no physician visits during this time compared with 13 percent of persons dying from other causes. Larger proportions of persons who died from AIDS had one or more visits to a psychiatrist or other mental health professional during their last year of life (19 percent) than did persons who died from other causes ( 5 percent).

Of the estimated 9,276 AIDS decedents in the NMFS, 8,010 were reported to have been overnight patients in a hospital in the last year of life. Almost half (49 percent) of the AIDS decedents who were overnight patients spent 1 month or longer in a hospital compared with 29 percent of all other decedents. About 17 percent of the AIDS decedents received home hospice care during the last year of life compared with 9 percent of other decedents. During the 1986 NMFS, questions were also asked about residence in a nursing home during the last year of life, but the number of AIDS decedents residing in a nursing home was too low to yield reliable estimates.

The health care costs for almost one-half ( 45 percent) of the AIDS decedents and one-fourth of other decedents were primarily paid by private insurance or HMO's (table 5). (Another NCHS survey also reported substantial use of private insurance for payment of medical expenses among persons with AIDS (10). Approximately 22 percent of the AIDS decedents, compared with 9 percent of other decedents, l: d Medicaid as their

primary payment source. Thirty-nine percent of the AIDS decedents spent less than $\$ 200$ for their health care, and almost two-thirds spent less than $\$ 2,000$ of personal money for such care (table 6).

## Disability measures

Selected health status characteristics for decedents were also collected during the 1986 NMFS; these characteristics indicate that persons dying from AIDS were likely to suffer from
certain disabilities. Table 7 shows how many persons who died from AIDS or other causes were reported to be disoriented prior to death. Twenty-six percent of the persons dying from AIDS and 13 percent of those dying from other causes were reported as having trouble recognizing family or friends during the last hours or days before death. About 18 percent of AIDS decedents and 11 percent of other decedents were reported to have had trouble remembering the current year in the last hours or days before death. Approximately 26 percent of AIDS decedents and 15 percent of other decedents had difficulty understanding their whereabouts.

A large proportion of decedents were also reported to have received help from others or to have used special equipment in daily activities, such as bathing, eating, walking, dressing, or using the toilet. There were few differences in these disabilities by cause of death. As table 8 shows, 60 percent of persons dying from AIDS were reported as having received assistance in bathing, and 57 percent received help with using the toilet. The least assistance received by AIDS decedents was with eating-40 percent were reported to have received such assistance.

Over half ( 52 percent) of the AIDS decedents were reported receiving help at home during the last year of life with daily activities and 54 percent were reported receiving help at home during the last year with medical care, such as taking medicines, giving pills or injections, or changing bandages (table 9). Similar proportions of persons dying from other causes reported such help. Among those who received help, about 69 percent of the AIDS decedents, compared with 91 percent of other decedents, had a relative provide the care. Thirty-eight percent of the AIDS decedents, compared with 13 percent of the other decedents, received help from a neighbor or friend. About 38 percent of AIDS decedents were helped by visiting homemakers or visiting nurses, as were 32 percent of persons dying from other causes.

## Summary

The 1986 NMFS data indicate that persons dying of AIDS tend to be young, have a high educational attainment, and have high-status occupations. However, although persons who died from AIDS generally were in "white collar" occupations, as a group they were also likely to have had very low levels of family income in 1985
and no assets at the time of death. Employment status at time of death, living arrangements, and age structure of the AIDS deaths appear to be associated with the level of assets and income for these decedents.

Despite their young age, persons dying from AIDS were likely to suffer certain disabilities and to be disoriented prior to their death. A large number of AIDS decedents were
reported to have used special equipment in daily activities such as bathing, eating, walking, dressing, and using the toilet. Large proportions of AIDS decedents were also reported to have received help at home in taking medicines, receiving injections, or obtaining other nursing care. These patterns reflect the prolonged and severe debilitating nature of their illness.

Persons who died from AIDS frequently used physicians' services and spent substantial time in the hospital during the last year of life. A considerable proportion of AIDS decedents were reported to have consulted a psychiatrist or other mental health professional during the last year of life, and to have received home hospice care. The primary source of payment for most AIDS decedents was private insurance or a health maintenance organization. However, Medicaid was the primary source of payment for care among more than one-fifth of the decedents.

## Technical notes

## Sources of data and sample design

The NMFS sample was selected from the Current Mortality Sample (CMS). This is a systematic 10-percent sample of death certificates received each month in the 50 States, the District of Columbia, and the independent registration area of New York City (11). Oregon was not included in the 1986 NMFS because of respondent consent requirements. Thus, these data are representative of deaths in the United States excluding Oregon. Oregon accounts for 1.1 percent of all deaths in the United States: there is little variation in the percent by age among Oregon deaths.

Oversampling by race, age, and selected causes of death was done to permit the study of race differentials in mortality and the characteristics of persons who died at a younger age. All CMS death certificates for decedents with certain characteristics were included in the 1986 NMFS. These included all women in the CMS $25-54$ years of age and all men 35-64 years of age who died from ischemic heart disease, all deaths from asthma, rare cancer deaths, and all deaths of American Indians, Aleuts, or Eskimos. In addition, deaths to persons under

55 years of age were oversampled 3.1 times, and deaths to black people were oversampled 2.9 times. Death certificates in the CMS that were eligible for the 1986 NMFS were sequentially assigned to 1 of 18 sampling strata. The strata formation was based on the decedent's age, sex, race, and cause of death.

For the 1986 NMFS, questionnaires were mailed by the U.S. Bureau of the Census to the next of kin or to the person listed on the death certificate as providing the personal information on the decedent's death certificate about 6 months after the death. A reminder letter was mailed 10 days after the first mailing, followed by a second mailing 1 month after the first mailing. Telephone or personal visits were made by Census interviewers to nonrespondents 1 month after the second mailing.

Eighty-two percent of all the respondents who completed the NMFS questionnaire were close relatives-either the spouses, parents, siblings, or adult children-of the decedents. However, approximately 22 percent of the respondents for AIDS decedents were nonrelatives, compared with 6 percent for non-AIDS decedents. The total
response rate was 89 percent, yielding 16,598 completed questionnaires.

For 1986, acquired immunodeficiency syndrome (AIDS) and human immunodeficiency virus (HIV) infection, when reported on the death certificate, were assigned to the category "deficiency of cell-mediated immunity" (code 279.1), as were other diseases classifiable as deficiency of cell-mediated immunity (12). Because the rules for selecting the underlying cause of death for 1986 give preference to other categories (for example, pneumocystosis), deaths with HIV infection used in this study were those for which deficiency of cellmediated immunity was classified as either an underlying or a nonunderlying cause of death.

Information on age, race, sex, underlying and multiple cause-ofdeath data for each decedent was obtained from final data on the Multiple Cause-of-Death Statistical File compiled by NCHS. Records from the 1986 multiple cause-of-death file were matched to the data from the NMFS informant questionnaire for each decedent in the survey. The overall match rate was 99.9 percent.

Comparisons of number of deaths from the vital statistics registration system and the 1986 NMFS estimates
suggest that the counts of deaths are similar. For example, the NMFSweighted data for 180 deaths to males $25-54$ years of age yields 8,128 estimated deaths with mention of code 279.1 on the certificate, compared with 8,799 for the final vital statistics system file. Although the final weights applied to the NMFS adjust for differential sampling by race, sex, and age, no adjustment was made for cause of death. Hence, NMFS estimates of deaths by cause will not necessarily equal counts obtained from the vital statistics file.

## Estimation procedures

Probability sampling allows the NMFS data to be weighted to produce national estimates for the United States except for Oregon. It also allows approximation of the sampling error.

The NMFS sampling weights are prepared by a poststratified ratio estimation procedure. The sampling weight for each sample decedent is based on a product of the following three component weights.
(1) Probability of selection. The basic weight for each sample decedent is the reciprocal of its probability of sample selection.
(2) Adjustment for nonresponse. In an attempt to reduce nonresponse bias, the NMFS sampling weights are adjusted for nonresponse. This adjustment was implemented within subsets of the sampling strata and was the reciprocal of the response rate within the subset. This adjustment reduces nonresponse bias to the extent that data for a nonrespondent is similar to data for respondents in these adjustment classes. No adjustment was made for the exclusion of Oregon from the survey.
(3) Poststratification by age, sex, and race. Within 28 poststrata defined by decedent age, sex, and race (see table I), the NMFS estimates were ratio adjusted to counts for the number of deaths reported to the National Vital Registration System for the

Table I. Parameters used to approximate the relative standard errors for estimates based on the 1986 National Mortality Followback Survey, by domain of study

United States excluding Oregon. This adjustment makes the sample more representative of the target population by age, sex, and race.

## Sampling errors and rounding of percents

Because the statistics presented in this report are based on a sample, they may differ from figures that would have been obtained if a complete census of all death certificates for decedents aged 25 years or over had been taken, using the same questionnaire, instructions, and procedures. The standard error of an estimate is primarily a measure of the variability that occurs by chance because only a sample of the population, rather than the total population, is surveyed. The standard error also reflects part of the measurement error, but it does not measure any systematic biases in the data. The chances are about 95 out of 100 that an estimate from the sample differs from the value that would be obtained from a complete census by less than twice the standard error.

Preliminary estimates of standard errors for the percents of the estimated number of decedents are presented in table I. The parameters shown in table I were estimated by a balanced-repeated-replication procedure using 20 replicate half samples. This method estimates the standard errors for survey estimates through
observation of variability of estimates based on replicate half samples of the total sample. A description of the development and evaluation of the replication technique for error estimation has been published ( 13,14 ).

## Standard error applications

## Standard error for agrresate

 estimates - The approximate standard error of an estimated number of decedents with a particular characteristic, $x$, is calculated by$$
\operatorname{RSE}(x)=\sqrt{A+(B / x)}
$$

and

$$
\begin{aligned}
& \mathrm{SE}(x)=x \quad \operatorname{RSE}(x) \\
& \text { where } \quad x=\text { estimated number of } \\
& \text { decedents } \\
& A, B=\text { parameters from } \\
& \text { table I } \\
& \operatorname{RSE}(x)=\text { relative standard error } \\
& \text { of } x \text {, and } \\
& S E(x)=\text { standard error of } x \text {. }
\end{aligned}
$$

## Rounding of numbers and percents

Numbers and percents within the tables and text were rounded to the nearest whole number or tenth of a percent. Therefore, the estimates may not add to the totals. In addition. the total estimated number of decedents
varies from one table to another because of the exclusion of decedents with "no answer" responses.

NOTE: Nine other Federal agencies signed interagency agreements with NCHS to co-sponsor the 1986 NMFS. These agencies are the National Heart, Lung, and Blood Institute; the National Institute of Child Health and Human Development; the National Cancer Institute; the National Institute of Aging: the National Institute of Mental Health: the Health Care Financing Administration; the U.S. Department of Veterans Affairs; the Indian Health Service; and the Office of the Secretary for Planning and Evaluation in the Department of Health and Human Services. Special thanks go to Jeffrey Maurer, Richard Klein, and other reviewers for their helpful comments on this report, and to Charles Adams, Tracy Lloyd, Arlene Siller, and George Wolf for programming assistance.

# Use of Vitamin and Mineral Supplements in the United States: Current Users, Types of Products, and Nutrients 

by Abigail J. Moss, Division of Health Interview Statistics, National Center for Health Statistics, and Alan S. Levy, PhD., Insun Kim, Dr. P.H., and Youngmee K. Park, PhD., Food and Drug Administration

## Introduction

There is general agreement among health professionals that a balanced diet provides most persons with those nutrients essential for good health (1). Exceptions include individuals with certain specified diseases and those with special dietary needs, such as infants and pregnant or lactating women $(2,3)$. The use of vitamin and mineral products to supplement the diet, however, continues to be an everyday practice for millions of Americans.

The first National Health and Nutrition Examination Survey conducted between 1971 and 1974 showed that about 23 percent of U.S. adults took supplements daily (4). More recently, estimates from the National Telephone Interview Special Dietary Foods Study conducted by the U.S. Food and Drug Administration's Division of Consumer Studies, Center for Food Safety and Applied Nutrition, indicated that in 1980, excluding pregnant and lactating females who have special supplementation needs, about 4 in 10 adults regularly used one vitamin and mineral product or more (5).

In 1986, the National Center for Health Statistics (NCHS), in collaboration with the U.S. Food and Drug Administration (FDA) and as part of its National Health Interview Survey (NHIS), collected information to produce measures of vitamin and mineral supplement users and the composition and quantities of specific nutrients consumed.

Because the use and composition of vitamin and mineral products fluctuate, one objective of the NCHS study was to update the 1980 FDA estimates and to make it possible to identify trends. In addition, an attempt was made to overcome several limitations of the earlier FDA survey. The FDA survey, for example, did not include young children; and the survey's sample size placed some constraints on the types of analyses that could be undertaken, including deriving nutrient intake level estimates for certain small population domains. NHIS' larger and more representative sample was expected to permit more focused analyses on specific population subgroups than were previously possible.

A second objective for the NCHS survey was to provide relevant esti-
mates that would address a priority objective stated in the Public Health Service (PHS) plans for attaining the 1990 Objectives for the Nation (6). The specific objective addressed was to develop nutrition status monitoring systems that would have the ability to detect nutritional problems in special population groups, as well as to obtain data for decisions about national nutrition policies.

This report presents estimates from the NCHS survey of the percent of adults and young children 2 to 6 years of age residing in the United States who used nonprescription vitamin and mineral supplement products in 1986. These estimates are shown by age, race, and sex, and by age with Hispanic origin, family income, poverty status, education, marital status, geographic region, place of residence, respondent-assessed health status, and weight status. Percent estimates for these variables are shown in tables 1 and 2.

The report also presents estimates of the percent of persons using types of products and nutrients, and the number of individual products taken. Tables 3, 4 , and 5 contain these estimates. Vitamin and mineral product

[^7]estimates are presented in table 6 by the frequency with which they were taken. In tables 7 and 8, the median, 90th, and 95th percentile levels of intake are given for specific nutrients, expressed as a percent of the Recommended Dietary Allowance (RDA) or as a percent of the midrange levels of "Estimated Safe and Adequate Daily Dietary Intakes" (ESADDI) as applicable, and as established by the Food and Nutrition Board (7). Most of the estimates in tables 3 to 8 are shown by age and sex as well. Tables 9 and 10 contain population estimates needed to derive estimated frequencies for the percent estimates presented in tables 1 to 6 .

## Description of data

The data presented in this report are based on information obtained from NCHS' 1986 National Health Interview Survey. For each family interviewed during January and into July of that year, one adult 18 years of age or older and one child from 2 to 6 years of age were randomly selected to receive the vitamin and mineral questionnaire. All estimates shown are based upon these sample person counts and, except for tables 7 and 8, are weighted to produce national estimates.

The questionnaire items used to derive the estimates shown in this report identified which sample persons took any vitamin, mineral, or fluoride products during the 2 -week period preceding the interview and the number of different products taken. Sample persons reporting any use were then asked to get the vitamin and mineral product containers so that the name of the product, the manufacturer's name, and the exact nutrient components and units information could be obtained directly from the labels. Where no container was available, persons were asked to report the name and manufacturer of the product(s) taken.

Other questionnaire items obtained information about the frequency and length of time each vitamin and mineral product was taken and whether it was obtained through a
doctor's prescription. In addition, women of childbearing age were asked whether they were pregnant or breastfeeding a baby during the preceding 2 weeks.

A facsimile of these questionnaire items is provided in Current Estimates From the National Health Intenview Survey, 1986 (8).

The technical notes section of this report contains a brief description of sample size, response rates, terms used, and data collection procedures employed.

## Results

## Profile of vitamin and mineral supplement users

For this report, a vitamin and mineral supplement user is anyone who took at least one nonprescription vitamin, mineral, or fluoride product during a 2 -week reference period before the interview. It should be noted here, however, that pregnant and lactating sample persons are excluded from the estimates derived for tuis report. Persons taking only pre ription vitamin and mineral product: 409 sample persons, or 3 percent of the total sample) are not classified as supplement users because the
intended purpose of this report is to provide estimates that describe the self-prescribed supplement user popu lation.

During 1986, more than one-third of all U.S. adults ( 36 percent) took nonprescription vitamin and mineral supplements (table 1). The percent of adults under 25 years of age who used them was somewhat lower ( 28 percent) than for all other adults (38 percent). Women were more likely to consume these products ( 41 percent) than were men ( 31 percent). Differences in vitamin and mineral product usage between adult men and women were found in all but the youngest age groups (figure 1).

Young children were also major consumers of vitamin and mineral supplement products ( 43 percent). However, use was slightly lower among school age children, from about 47 percent among 3 - and 4 -year-olds to 40 percent among 5 and 6 -year-olds. A difference was also found in the use of vitamin and mineral products among white and black young children. About 46 percent of white children and 30 percent of black children 2-6 years of age were reported to use vitamin and mineral supplements (table 2).

Figure 1. Percent of adults using vitamin and mineral products, by age and sex: United States, 1986

## ggure 2. Percent of adults using vitamin and mineral products, by age, race, and sex: United States, 1986

Among adults, about two-fifths of all white persons in the United States used vitamin and mineral supplements compared with about one-fifth of all black adults. Differences in supplement usage between black and white persons were found for both sexes and among all age groups (figure 2). Within the population of Hispanic origin, about 29 percent of adults used nonprescription vitamin and mineral products. The greatest difference among racial groups was found among the elderly. Of persons aged 65 years and over, about 40 percent of white persons and persons of Hispanic origin and about 14 percent of black persons took vitamin and mineral supplements. Among elderly persons of all other races, over 50 percent reported their use.

As expected, family income and educational level are directly related to the use of vitamin and mineral products. Only about 28 percent of adults with family incomes under $\$ 7,000$ compared with about 45 percent of persons with incomes at or
above $\$ 40,000$ reported their use. Differentials in usage by family income level were most pronounced for children. Specifically, only 23 percent of children aged 2 to 6 years in families earning under $\$ 7,000$ took supplements compared with 50 percent of children in families earning $\$ 40,000$ or more. Similarly, with increasing education, proportionately more persons took vitamin and mineral supplements. Among adults, the estimates ranged from about 25 percent of those not completing high school to 44 percent of those with 1 year of college or more. About 27 percent of young children were given vitamin and mineral supplement products in households where no related adult was a high school graduate, compared with over 50 percent of children in households where at least one related adult had some college education.

Differences in the percent of persons using vitamin and mineral supplements were also found by geographic area. Proportionately more
persons in the West used vitamin and mineral products ( 45 percent) than in other regions of the country. Similarly, a higher proportion of persons living in metropolitan statistical areas (MSA's) reported using vitamin and mineral products than did those living outside these areas ( 38 percent compared with 31 percent).

Of the health status measures shown in this report, persons 18 years of age or older in "good health," that is, those who were not overweight and whose health was assessed as "good," "very good," or "excellent," were more likely to use vitamin and mineral supplements than less healthy persons. For example, 38 percent of persons whose assessed health was excellent or very good reported taking supplements compared with 31 percent of those in fair or poor health. About the same proportion of young children in fair or poor health, however, took vitamin and mineral supplements as did children whose health was rated as excellent or very good (about 45 percent).

## Types of products and nutrients taken

Tables 3 and 4 present data on the kinds of products and nutrients taken. The first type of product classification shown in these and several other tables in this report contains nine distinct vitamin and mineral product categories according to a scheme developed by Stewart (5). For a description of the criteria for these categories, see the technical notes.

The second type of product classification separates products into two types, "broad-spectrum" and "specialized" products, using the scheme developed by Levy and Schucker (9). In this classification, broad-spectrum products are those that contain at least three of the following vitamins: A, B vitamins, C, D , and E . In addition, they may also contain one or more of the following minerals: calcium, phosphorus, iodine, iron, magnesium, copper, zinc, and manganese. All remaining products for this two-category classification are defined as specialized products.

The percents shown in table 3 are for all persons of specified ages in the U.S. population (except those excluded). Percents in table 4 are based on those persons who used at least one nonprescription vitamin and mineral product. For example, as shown in table 3, vitamin $C$ was taken by about one third of all U.S. adults. Among adult vitamin and mineral supplement users, however, 85 percent took vitamin C (table 4). Both percent estimates are included in this report since each describes vitamin and mineral users in a meaningful way.

The following results refer to estimates for the U.S. population as shown in table 3. Single vitamins and vitamin and mineral combination products were the two most common types of products taken by U.S. women (each was taken by 17 percent of adult women). Among men, the two types of products consumed most often were single vitamins and multivitamins (13 percent for each type). About the same proportion of men and women reported taking multivitamins ( 13 percent and 15 percent, respectively).

Regardless of age, women were more likely than men to take single mineral products ( 10 percent compared with 4 percent). The difference in the percent of women and men taking single minerals was greatest for persons aged 45 to 64 years. Within this age group, 15 percent of women compared with 5 percent of men took at least one single mineral product, reflecting in part the greater usage of calcium products among older females.

Multivitamins were by far the most common type of vitamin and mineral product used by young children. In 1986, one-third of all U.S. children 2 to 6 years of age were taking multivitamins. However, unlike adults, few young children were given other types of vitamin and mineral products. For example, only 6 percent of children these ages took single vitamins.

In the second product classification, that is, broad-spectrum versus specialized products, the percent of women who took each type varied according to age. Younger women (under 45 years of age) were more likely to take broad-spectrum products (27 percent compared with the 22 percent who took specialized products). In contrast, women 45 years of age and over were more likely to take specialized products. Among those 45 to 64 years of age, 35 percent took specialized products and 26 percent took broad-spectrum products; for those 65 years old and over, 30 percent took specialized and 24 percent took broad-spectrum products.

Men under 45 years of age also were more likely to use broadspectrum products than specialized products ( 21 percent compared with 15 percent). However, unlike older women, the proportion of men 45 years or older who used each type of product was about the same ( 20 percent for each).

Many more young children consumed broad-spectrum products (including multivitamin products) than consumed specialized products ( 38 percent compared with 8 percent).

What specific nutrients were in the products being consumed most
often by adults and children in this country in 1986 ? More men and women (about 31 percent of adults) consumed vitamin $C$ than any other nutrient. Calcium and iron led the list of minerals taken by women. About one-fourth of all women took calcium; the highest percent was among those women 45 to 64 years of age ( 29 percent). The percent of women in the United States who took iron ranged from about 21 to 25 percent, depending upon their age. Among men, iron was taken more than any other mineral (16 percent).

Because most children were given multivitamins, percent estimates were about the same for each of the specific vitamins listed except for pantothenic acid and biotin, which are not included in many multivitamins. The mineral taken most by young children was iron (about 18 percent).

## Number of products taken and frequency of use

Table 5 contains percent estimates of vitamin and mineral supplement users by the number of individual products taken. For persons taking 1, 2 , and 3 products or more, percents are also shown according to the type(s) of product(s) taken. The product type categories included in this table are the same as those shown in tables 3 and 4.

Among vitamin and mineral supplement users, most adults (60 percent) reported taking only one over-the-counter vitamin and mineral product (table 5). Similarly, among young children taking vitamin and mineral supplements, the vast majority, over 85 percent, used only one product.

The percent of adults who used two vitamin and mineral products or more was higher for persons 45 years of age or older ( 45 percent) than for those under 45 years of age (about 36 percent). Also, proportionately more women than men used more than one vitamin and mineral product ( 45 percent compared with 34 percent). About 5 percent of all adult users, which represents 3.1 million persons, reported using at least 5 vitamin and mineral products.

There were also differences in the res of vitamin and mineral products sen by persons who used only one product compared with persons who used more than one product. Whereas only 16 percent of adults who used one product took a single vitamin product, 86 percent of adults reporting 3 products or more reported taking a single vitamin product. Similarly, single mineral products were taken by only 6 percent of adults using one product compared with 49 percent of all adults taking 3 products or more. Among adults taking only one product, two-thirds of them took a broad-spectrum product.

About the same proportion of adults took multivitamin products, regardless of the total number of products taken (between 38 and 41 percent). Similarly, about the same proportion of young children given one product used a multivitamin as did children given two products ( 80 percent). Over 90 percent of all young children taking one product were given a broad-spectrum product.

Table 6 differs from other tables in this report in that the numbers and percents refer to the estimated number of vitamin amd mineral products reported, not the number of persons taking them. These data are shown by the frequency with which individual types of vitamin and mineral products were taken over a 2 -week period. The time intervals shown are every day, from 2 to 6 days each week, and once a week or less.

Over 70 percent of all vitamin and mineral products used by adults and young children during 1986 were taken every day. The percent of products taken by adults on a daily basis did not vary appreciably among the different product categories.

About 75 percent of all multivitamins consumed by young children were taken every day. The percent of all other vitamin and mineral products taken by children on a daily basis, however, was somewhat lower (about 65 percent).

## Intake levels of nutrients taken

Table 7 shows median, 90th, and 95th percentile average daily nutrient
intake levels (most often represented as percents of the Recommended Dietary Allowances (RDA's)) for 12 vitamins and 7 minerals for men and women by three age groups. The RDA's are "the levels of intake of essential nutrients considered, in the judgment of the Committee on Dietary Allowances of the Food and Nutrition Board on the basis of available scientific knowledge, to be adequate to meet the known nutritional needs of practically all healthy persons" in the United States (7). For those nutrients for which no RDA values are established because of lack of information on which to base allowances, intakes are instead represented as percents of the midrange levels of Estimated Safe and Adequate Daily Dietary Intakes (ESADDI) as established by the Food and Nutrition Board. The nutrients reported as percents of the midrange ESADDI levels are pantothenic acid, biotin, and copper.

Table 8 is similar in content to table 7 except that the estimates are for young children. The individual nutrient estimates shown in both of these tables are based only on those persons taking the specific vitamin or mineral listed. Furthermore, they do not include persons who took any prescribed vitamin and mineral product or whose average daily intake for that nutrient is unknown. These exclusions may have had an effect on the estimates shown.

The estimates shown in tables 7 and 8 were obtained by first ordering numerically the RDA or ESADDI (unweighted) values for all eligible sample persons consuming a particular nutrient. The three RDA or ESADDI values (expressed in percents) that corresponded to the 50th, 90 th, and 95 th percentile positions in the listing were then selected.

Even if two individuals are adjacent by the order of their nutrient intake level, their intake levels still could differ by a relatively large amount. Such large differences would be more frequent at the extremes of intake level. Thus, the intake values shown in these two tables for the 90th and the 95th percentiles in particular
are subject to considerable variability because of sampling.

Standard errors for these estimates are not available at this time because of the complexities involved in generating the figures. Therefore, data in tables 7 and 8 should be considered "provisional" and caution should be exercised in interpreting the findings. Nevertheless, the estimates for many of the nutrients are similar to results obtained from the 1980 FDA survey (5).

The median average daily intake for most of the vitamins listed in table 7 was between 100 and 200 percent of the RDA for both men and women. Among men, the vitamins with the highest median values were vitamin $C$ ( 250 percent RDA) and vitamin $B_{12}$ ( 300 percent RDA). Stated another way, the average amount of vitamin C consumed each day by 50 percent of all men reporting its use was no more than $21 / 2$ times the RDA. For women, vitamin $E$ and vitamin $B_{12}$ had the highest median intake values ( 250 percent RDA for each), followed by thiamin ( 225 percent RDA) and riboflavin (217 percent RDA).

Data in table 7 show that some segment of the vitamin and mineral supplement user population took certain vitamins far in excess of the RDA. For 10 percent of adult male and female users, average daily intake for six vitamins-vitamins E, C, thia$\min$, riboflavin, vitamin $B_{1}$, and vitamin $\mathrm{B}_{12}$-was greater than 15 times the RDA . Average daily intake of thiamin, riboflavin, vitamin $B_{6}$, and vitamin $B_{i z}$ was in excess of 30 times the RDA for 5 percent of these men and women. And 5 percent of women taking vita$\min E$ ingested it at levels in excess of 35 times the RDA. Unfortunately, reasons for taking the vitamins were not determined for the NCHS survey.

All of the median intake values for the minerals listed were less than 200 percent of the RDA's or ESADDI's for both sexes. Although individual mineral intakes fell within a relatively close range, iron had the highest RDA value among 50,90 , and 95 percent of male and female users; it ranged from 1.8 to 5.4 times the RDA for men at these three
percentiles and from 2.8 to 4.5 times the RDA for women.

Among young children, the median intake level for most of the individual nutrients shown in table 8 also was between 100 and 200 percent of the RDA or ESADDI. At the 50th percentile, the highest intake level (286 percent) was for pantothenic acid. Five percent of children consumed about 4 times the RDA or ESADDI of vitamins $A$ and $E$, folic acid, and pantothenic acid, and about 7.5 times the RDA of vitamin $C$.

It is generally recognized that most Americans meet their nutrient needs from foods alone, and that the use of supplements is therefore not necessary $(10,11)$. Although there are no documented reports that daily
vitamin and mineral supplement use at or below the RDA for a particular nutrient is either beneficial or harmful for the general population, the potentially adverse effects of large doses of certain nutrients are well documented (12).

The results presented are consistent with other studies showing that supplements are commonly used by the U.S. population and that intakes of some nutrients by individuals are well in excess of their RDA's. However, these data by themselves cannot be used to evaluate the need for or the safety of vitamin and mineral supplement use by the general population. These data do not include estimates of nutrient intakes from foods and drinking water; hence, total nutrient intakes
cannot be estimated. Also, these data are limited to intakes during the 2 weeks prior to interview. In addition, the biochemical and clinical measures needed to document adverse physiological effects associated with high intakes of nutrients were not included in the survey.

Nationally representative survey data that quantify nutrient intakes from vitamin and mineral supplements are rare and have not been included in past food consumption and nutritional status surveys. Thus, the results from the 1986 NHIS make an important contribution in updating the knowledge of supplement use and in improving the ability to monitor the nutritional status of the U.S. population.

Table 1. Percent of persons using vitamin and mineral products, by sex and age: United States, 1986

| Age | Both sexes | Female | Male |

${ }^{1}$ Partothenks actd, copper, and blotin are reported as percents of the midrange ESADOI level, as estabilshed by the Food and Nutrilion Board, owing to lack of PDA's for those rutrients.
NOTES: Inchudes vitamins and minerals with established RDA (or ESADDI) values.
The median, 90 th, and 85 th percentles are calculated for users of specific nutrients only.
Exckrded are persors who took ary prescription vilamin or mineral product or whose average daily intake for a specific nutrient was unknown.

## Technical notes

## Source and description of data

This report contains data from the 1986 National Health Interview Survey (NHIS). The NHIS is a continuing cross-sectional nationwide survey of the civilian noninstitutionalized population. Each week a probability sample of households in the United States is interviewed by personnel of the U.S. Bureau of the Census. The interview obtains information on the health and other characteristics of each household member living at the time of interview.

During 1986, NHIS interviews were conducted in 23,838 households, resulting in a sample of 62,052 persons. Interviews were not obtained for an additional 860 eligible households primarily because of respondent refusal or failure to find an eligible respondent at home after repeated attempts, producing a noninterview rate of 3.5 percent of all total eligible households.

The questions on the use of vita$\min$ and mineral products were only asked in the NHIS during the 6 -month period from January into July, 1986. The sample consisted of one randomly selected adult 18 years of age or older and, if available, one randomly selected child 2 through 6 years of age, from each interviewed family. With few exceptions, adults responded to the vitamin and mineral questionnaire for themselves. However, any adult family member knowledgeable about the sample child was eligible to respond about the child's use of vita$\min$ and mineral products. The proxy respondent for sample children was usually the mother of the child.

Information about the use of vita$\min$ and mineral products was not obtained for 3.4 percent of this eligible subsample, primarily because of the self-response requirement among adult sample persons. The final interviewed vitamin and mineral sample contained 13,652 persons- 11,775 lults and 1,877 children from 11,879 ouseholds. The overall response rate, combining response rates for the
household questionnaire and vitamin and mineral questionnaire, was 93.1 percent.

The estimates in this report are actually based on responses for 13,435 sample persons. These data do not include 217 women of childbearing age who reported being pregnant or breastfeeding at the time of the interview. They are excluded from the analysis altogether since their use of vitamin and mineral products was not expected to reflect their usual vitamin and mineral use practices given the special nutrient requirements of pregnant and breastfeeding women. Individuals taking only prescription vitamin and mineral products are included in the analysis but are not classified as vitamin and mineral users.

Item nonresponse for the data discussed in this report ranged from 0.1 percent for whether vitamins and/or minerals were used in the past 2 weeks to 7.9 percent for manufacturer and brand name information used to derive the specific nutrient components of the vitamin and mineral products taken.

## Verification of vitamin and mineral products

Several edit checks were performed during data processing for every reported vitamin and mineral product in order to improve the quality of the specific nutrient potency data collected in the 1986 NHIS. All nutrient potency values reported for each product were checked and corrected by comparison with such references as the 1986 edition of the Physicians' Desk Reference (PDR) for prescription and nonprescription drugs, company brochures, and independently obtained product labels; through direct contact with companies; and through comparison with nutrient concentration data of other records for the same product. Of the 8,700 individual products upon which the estimates in this report are based, about 84 percent had one or more of these independent accuracy checks made. For the remaining products, the reference information just described was not available, nor were other
products of the same brand name or type reported. In many of these cases, however, the vitamin and mineral product nutrient data recorded by the interviewers were checked and corrected by inserting nutrient data from similar products. The nutrient values, as recorded on the questionnaire, were used only when a similar product was not identified.

## Sampling errors

Because estimates shown in this report are based on a sample of the population rather than on the entire population, they are subject to sampling error. When an estimate or the numerator or denominator of a percent is small, the sampling error may be relatively high. In addition, the complex sample design of the NHIS has the effect of making the sampling errors larger than they would be had a simple random sample of equal size been used.

Approximate standard errors for the following estimated percents in tables 1,2 , and 3 of this report may be calculated by using th: formula

$$
\operatorname{SE}(p)=p \sqrt{.0000825+16,700 / x}
$$

where $p$ is the estimated percent and $x=p \mathrm{Y} / 100$ with $\mathrm{Y}=$ the population denominator.

Table 1: all persons 18 years of age and over, and any combination of the age groups 18-24, 25-34, 35-44, 45-54, 55-64, 65-74, and 75 years and over.
Table 2: the estimated percents by sex, race, sex and race, and for the age groups 18 and over: 18-44, 45-64, and 65 years of age and over.
Table 3: all estimated percents in this table.
Approximate standard errors for all other percents presented in tables 1 and 2 not previously mentioned and all estimated percents in tables 4 and 5 may be calculated by using the formula

$$
\mathrm{SE}(p)=\frac{\sqrt{16,700(p)(100-p)}}{y}
$$

where $p$ is the estimated percent and $y$, the population denominator.

Approximate standard errors for all estimated percents in table 6 may be calculated by using the formula

$$
\operatorname{SE}(p)=\frac{\sqrt{(37,000) p(100-p)}}{y}
$$

where $p$ is the estimated percent and $y$ is the population denominator, which in this case is the total number of products shown in column 1.

The estimated parameters for calculating the approximate standard errors for the percentile of RDA's and ESADDI's in tables 7 and 8 of this report are in the process of being generated.

The population numbers for the following age groups in table 9 have been adjusted to official U.S. Bureau of the Census figures and their standard errors are assumed to be 0.0: 18 years of age and over, 18-24, 25-34, $35-44,45-54,55-64,65-74$, and 65 years and over.

Similarly, all population figures in table 10 by sex, race, sex and race, and for the age groups 18 years of age and over, $18-44,45-64$, and 65 years of age and over have no sampling error. The approximate SE's for all remaining estimated numbers $(x)$ in tables 9 and 10 can be computed by the formula
$\mathrm{SE}(x)=\sqrt{(.0000825)(x)^{2}+(16,700)(x)}$
The approximate standard error of a difference between percents is given by the formula

$$
\operatorname{SE}\left(x_{1}-x_{2}\right)=\sqrt{\left(\operatorname{SE}\left(x_{1}\right)^{2}+\operatorname{SE}\left(x_{2}\right)^{2}\right.}
$$

where $x_{1}$ and $x_{2}$ are the two percents being compared, $x_{1}-x_{2}$ is the difference between them, and $\operatorname{SE}\left(x_{1}\right)$ and $\operatorname{SE}\left(x_{2}\right)$ are the standard errors of the two percents. In this report, a difference was considered statistically significant at the 5-percent level if the difference $\left(x_{1}-x_{2}\right)$ was at least twice as large as its standard error.

## Age-adjusted rates

This report includes data that have been adjusted by the direct
method to the age distribution of the selected standard population, in this case the 1980 civilian noninstitutionalized population of the United States. Age adjustment by the direct method is accomplished by multiplying the age-specific rate for each age group by the population for the corresponding age group in the standard population. The cross products of the multiplications are summed and divided by the total of the standard population to obtain the age-adjusted rate. Eight age groups were used for the age adjustment in this report: $18-24,25-34$, $35-44,45-54,55-64,65-74,74-84$, and 85 years and over.

## Definition of terms

Nine product classificationsSingle vitamin: product contains only one vitamin.
Multivitamin: product contains no minerals and vitamins $A, D, E, C$, $B_{i}, B_{2}, B_{8}, B_{18}$, folic acid, and niacin.
Other vitamin combination: product contains no minera ${ }^{1}$ s, is not a multivitamin, and contains at least two vitamins.
Single mineral: product contains only one mineral.
Multimineral: product contains no vitamins and the following minerals: calcium, phosphorus, iodine, iron, and magnesium.
Other mineral combination: product contains no vitamins, is not a multimineral, and contains at least two minerals.
Multivitamin and multimineral: product contains vitamins $\mathrm{A}, \mathrm{D}, \mathrm{E}$, $C$, folic acid, $B_{1}, B_{2}, B_{9}, B_{12}$, niacin, calcium, phosphorus, iodine, iron, and magnesium.
Multivitamin plus iron: product is a multivitamin as previously defined except that it includes iron.
Other vitamin mineral combination: product is not one of the types of vitamin and mineral products listed above but contains at least one vitamin and one mineral.

Weight status - The weight status classification shown in this report for adults is derived from the calculation of body mass index (BMI) using the formula of weight/height ${ }^{2}$ where weight is in kilograms and height is in meters. It is an approximate measure of overweight given that body composition varies among persons of the same height and weight (13). Specifically, the BMI cutoff points used to identify overweight persons were determined by NCHS' National Health and Nutrition Examination Survey II (NHANES II) and are as follows: for males, $\mathrm{BMI}=27.8$ or greater and for females, $\mathrm{BMI}=27.3$ or greater.

Respondent-assessed health status-The categories related to respondent-assessed health status result from asking the respondent, "Would you say ____'s health is excellent, very good, good, fair, or poor?" As such, it is based on a respondent's opinion and not directly on any clinical evidence.

NHIS poverty index-Persons are classified as being above or below the poverty line by using the poverty index as originated at the Social Security Administration in 1964 and revised by Federal interagency committees in 1969 and 1980. The poverty index is based solely on money income and does not reflect the fact that many low-income persons receive noncash benefits such as food stamps, Medicaid, and public housing. The index is based on the Department of Agriculture's 1961 economy food plan and reflects the different consumption requirements of families according to their size and composition. The poverty thresholds are updated every year to reflect changes in the Consumer Price Index. Because NHIS data on family income are collected by income categories rather than by specific amounts of money, the NHIS estimates of persons living in poverty will vary slightly from the Current Population Survey estimates.

Race and ethnicity-Estimates for the white and black populations are based on respondents' reported racial identifications. The Hispanic classification is also based on the respondent's description.

More detailed discussions of the sample design, estimating procedures, procedures for estimating standard errors, nonsampling errors, and definitions of other sociodemographic terms used in this report have been published in Vital and Health Statistics, Series 10, Nos. 160 and 164, and in Series 1, No. 18 ( $8,14,15$ ).

A public use data file based on the 1986 Vitamin Mineral Supplement questionnaire was released in December 1988. Information regarding the purchase of the public use tape can be obtained by writing the Division of Health Interview Statistics, National Center for Health Statistics, 3700 East-West Highway, Hyattsville, MD 20782.

NOTE: Publication of this report would not have been possible without the contributions of the following persons. Within The National Center for Health Statistics, Sue Hsiung was responsible for constructing and editing the vitamin mineral data tapes from which these data are derived. George Gerhold and Anthony Thomas developed the computer programs that generated the tables for this report. And Catherine Woteki willingly critiqued several versions of the manuscript. Beth Yetley, with the Food and Drug Administration, gave generously of her time throughout the planning and preparation of this report. To all of these persons, the authors express their thanks.

# AIDS Knowledge and Attitudes for December 1988 

Provisional Data From the National Health Interview Survey<br>Ann M. Hardy, Dr.P.H. and Deborah A. Dawson, Ph.D., Division of Health Interview Statistics

## Introduction

The National Center for Health Statistics (NCHS) has included a special set of supplemental questions on the adult population's knowledge and attitudes about acquired immunodeficiency syndrome (AIDS) in the National Health Interview Survey (NHIS). The first AIDS Knowledge and Attitudes Survey was in the field from August through December 1987. Provisional results of that survey were published on a monthly basis in Advance Data From Vital and Health Statistics (Nos. 146, 148, 150, 151, and 153). A public use data tape containing the information collected in 1987 is available from NCHS. During the first 4 months of 1988, the NHIS AIDS questionnaire was revised to meet current program needs for information about AIDS awareness. The revised AIDS Knowledge and Attitudes Survey entered the field in May 1988. Provisional findings for May through November were published in Advance Data From Vital and Health Statistics, Nos. 160, 161, 163, 164, and 167. This report presents provisional results for December 1988.

The Advance Data reports describing the NHIS AIDS data have been restricted to simple descriptive statistics to fucilitate their timely
release. Thus, these reports do not attempt to explain or interpret differences among population subgroups in AIDS knowledge or to examine relationships among various measures of knowledge, attitudes, and perceived risk. The 1987 and 1988 NHIS AIDS data bases permit more complex analyses than those presented in this series of Adrance Data reports, and such analyses are being undertaken by various groups in the Public Health Service.

The AIDS questionnaires were designed to estimate public knowledge and attitudes about AIDS transmission and prevention of AIDS virus infection. The data were needed as input for the planning and development of AIDS educational campaigns and for monitoring major educational efforts, for example, the series of radio and television public service announcements entitled "America Responds to AIDS" and the brochure "Understanding AIDS," both developed by the Centers for Discase Control.

The 1987 and 1988 AIDS questionnaires were developed by the National Center for Health Statistics and interagency working groups established by the Information, Education and Risk Factor Reduction Subcommittee of the Public Health

Service Executive Task Force on AIDS. The working groups included representatives from the Centers for Disease Control; the National Institutes of Health; the Alcohol. Drug Abuse and Mental Health Administration; and the Health Resources and Services Administration.

The current AIDS questionnaire includes items on sources of AIDS information; self-assessed levels of AIDS knowledge; basic facts about the AIDS wirus and how it is transmitted; blood donation experience: awareness of and experience with the blood test for the AIDS virus; perceived effectiveness of selected preventive measures; self-assessed chances of getting the AIDS virus; personal acquaintance with persons with AIDS or the AIDS virus; and willingness to take part in a proposed national seroprevalence survey. A general risk behavior question, similar to that asked hy the Red Cross of potential blood donors, is included in the 19NS AIDS questionnaire.

This report presents provisional data for December 1988 for most items included in the AIDS questionnaire. Table 1 displays percent distributions of persons 18 years of age and over by response categories according to age, sex, race, and
education. In most cases, the actual questions asked of the respondents are reproduced verbatim in table 1 along with the coded response categories. In a few cases, questions or response categories have been rephrased or combined for clearer or more concise presentation of results. Refusals and other nonresponse categories are excluded from the denominator in the calculation of estimates, but responses of "don't know" are included.

## Selected findings

The following highlights describe various aspects of changes in AIDS knowledge and attitudes as observed in the May-December 1988 data from the NHIS AIDS survey. Any differences cited in the text are statistically significant at the 0.05 level (see table II for approximate standard errors of estimates).

Sources of AIDS information Eighty percent of adults interviewed in

December 1988 reported having seen AIDS public service announcements on television in the past month, and 42 percent reported hearing announcements on the radio. These proportions were slightly lower than the proportions who reported seeing or hearing such announcements between May and July 1988 (84-86 percent saw announcements on television and 48-49 percent heard announcements on the radio). In December, as in previous months in 1988, the proportion of adults who had seen or heard announcements was higher for those with 12 or more years of school than for those with less than 12 years.

In May, 25 percent of adults reported having read brochures in the month before interview; this proportion increased to 52 percent in June and July, coincident with the national mailout of the brochure "Understanding AIDS." From August through December, this figure declined so that by December only 28
percent had recently read brochures. From May to July, the percent of adults who reported ever reading brochures or pamphlets about AIDS increased from 43 to 68 percent. This figure remained between 65 and 67 percent through December.

Self-assessed knowledge-In December 1988, 21 percent of adults reported that they knew a lot about AIDS, 44 percent reported some knowledge. 27 percent claimed to know a little, and 8 percent stated that they knew nothing. The proportion of adults in these various response categories did not change from May through December.

General knowledge -For many of the general AIDS knowledge questions, increases in the percent of adults giving the correct definitive responses were noted after May 1988. As shown in Figure 1, the proportion who thought it definitely true that there is no cure for AIDS at present increased from 81 percent in May to

Figure 1. Provisional estimates of percent of adults who think selected statements about AIDS are definltely true: United States, May, July, September, and December 1988

85 percent in December. Similar increases were noted in the proportion who thought it definitely true that any person with the AIDS virus can pass it on to someone else during sexual intercourse (from 77 to 82 percent), that a pregnant women who has the AIDS virus can give the AIDS virus to her baby (from 74 to 80 percent), that AIDS is an infectious disease caused by a virus (from 58 to 63 percent), and that a person can be infected with the AIDS virus and not have the disease AIDS (from 49 to 56 percent). As in the previous months in 1988, the proportion responding correctly to the various AIDS knowledge questions in December increased with education and was higher for those under 50 years of age than for older adults. When the proportions with the correct definitive response were examined by race, the increase in knowledge after May was more pronounced for black adults than for white adults. For some questions, the magnitude of the
difference between the proportion of black and white adults responding correctly decreased. For other questions, racial differentials were completely eliminated. By December, similar proportions of white adults and black adults responded correctly to more than half of the general knowledge questions including those about the major modes of transmission of the AIDS virus (sexual, parenteral, and perinatal).

Misperceptions about transmission of the AIDS virus-A series of questions in the NHIS AIDS survey addressed misperceptions about transmission of the AIDS virus through casual contact. It had been previously noted that accurate knowledge in this area had increased from 1987 to May 1988. From May to June and July 1988, additional increases in knowledge were noted. After July 1988, however, the proportion with the correct responses began to decrease somewhat, so that by

December 1988, the proportion responding correctly to questions about casual transmission was often no different from that observed in May 1988. As shown in figure 2, the percent of adults who thought it was very unlikely or definitely not possible to transmit AIDS by shaking hands increased from 68 percent in May to 73 percent in July and dropped to 71 percent in September and to 69 percent in December. A similar pattern was noted for most of the other conjectured modes of transmission. In December, as in previous months in 1988, the proportion of adults responding correctly to questions about transmission increased with education. However, the pattern described above of an increase in the proportion responding correctly from May to June and July with a decline in subsequent months was noted at all levels of education.

Blood donation and testing-In December 1988, 41 percent of adults

SOURCE: National Center for Health Statistics, Division of Health Interview Statistics, National Health Interview Survey.
Figure 2. Provisional estimates of percent of adults considering it very unlikely or definitely not possible to transmit the AIDS virus In selected ways: United States, May, July, September, and December 1988
stated that they had ever donated blood. 15 percent had donated since March 1985 when routine screening of donated blood for antibodies to HIV began, and 7 percent had donated in the year preceding interview. For all blood donation questions, the percent donating increased with education, and men were more likely to have donated than women.

Three-quarters of all adults had heard of the AIDS blood test as of December 1988. Slightly fewer ( 67 percent) knew that blood donations are now routincly screened for AIDS virus infection, and less than half (46 percent) thought that the present blood supply was safe for transfusion. These proportions were similar throughout 1988.

Including all blood donors since March 1985, a total of 19 percent of adults in December had had their blood tested for antibodies to the AIDS virus, slightly higher than the 16 percent interviewed in May. This increase in testing between May and December was noted in four specific population subgroups: the $18-29$ years age group (from 23 to 29 percent), white adults (from 16 to 20 percent),
those with more than 12 years of school (from 21 to 26 percent), and men (from 20 to 24 percent). Of those who were tested as of December, most ( 72 percent) had their testing done as part of a blood donation, 16 percent were tested voluntarily, and 12 percent took the test as part of another activity requiring routine testing (such as a physical examination for military induction). These figures were similar to those in earlier months in 1988.

In December, 6 percent of adults reported plans to be tested in the 12 months following the NHIS interview; this figure also remained stable throughout 1988.

Preventive measures-As of December 1988, 84 percent of adults thought that condoms were very or somewhat effective in preventing transmission of the AIDS virus; 82 percent of adults thought that having a monogamous relationship with an individual who is not infected with the AIDS virus was a very effective means of prevention. These proportions did not change from May through December. As in previous months in 1988, over half of all adults in December recognized that the
diaphragm, spermicides, and vasectomy are not effective in preventing AIDS virus transmission. Most of the remainder were uncertain about the effectiveness of these particular methods.

Risk of getting the AIDS virus Overall, 3 percent of adults in December 1988 stated that they belonged to one or more of the groups with behaviors associated with increased risk for aquiring AIDS (such as intravenous drug users and homosexually active men). This proportion remained stable throughout 1988.

In December, only 1 percent of adults felt that they had a high chance of having or getting the AIDS virus; 2 percent felt that their chance of getting the AIDS virus was medium, 18 percent felt that they had a low chance, 76 percent felt that they had no chance of getting AIDS, and 3 percent could not assess their chances of getting AIDS. The proportion in December believing that they have no chance of acquiring AIDS was slightly higher than that reported in May (71 percent).

14 Fased on persons answerng no or don't know to question 54.
${ }^{14}$ Eased on persons not answering yes to question 58.

## Technical notes

The National Health Interview Survey (NHIS) is a continuous, cross-sectional household interview survey. Each week, a probability sample of the civilian noninstitutionalized population is interviewed by personnel of the U.S. Bureau of the Census to obtain information on the health and other characteristics of each member of the household. Supplemental information is collected for all or a sample of household members. The 1988 National Health Interview Survey of AIDS Knowledge and Attitudes was asked of a single randomly chosen adult 18 years of age or over in each family. The estimates in this report are based on completed interviews with 4,118 persons, or about 89 percent of eligible respondents.

Table I contains the estimated population size of each of the demo-
graphic subgroups included in table 1 to allow readers to derive provisional estimates of the number of people in the United States with a given characteristic, for example, the number of men who have had their blood tested for the AIDS virus. The population figures in table I are based on 1987 data from the NHIS; they are not official population estimates. Table II shows approximate standard errors of estimates presented in table 1. Both the estimates in table 1 and the standard errors in table II are provisional. They may differ slightly from estimates made using the final data file because they were calculated using a simplified weighting procedure that does not adjust for all the factors used in weighting the final data file. A final data file covering the entire data collection period for 1988 will be available later in 1989.

# AIDS Knowledge and Attitudes for January-March 1989 

Provisional Data From the National Health Interview Survey

by Deborah A. Dawson, Ph.D., Division of Health Interview Statistics

## Introduction

The National Center for Health Statistics (NCHS) has included a special set of supplemental questions on the adult population's knowledge and attitudes about acquired immunodeficiency syndrome (AIDS) in the National Health Interview Survey (NHIS). The first AIDS Knowledge and Attitudes Survey was in the field from August through December 1987. Provisional results of that survey were published on a monthly basis in Advance Data From Vital and Health Statistics (Nos. 146, 148, 150, 151, and 153). A public use data tape containing the information collected in 1987 is available from NCHS.

During the first 4 months of 1988, the NHIS AIDS questionnaire was revised to meet current program needs for information about AIDS awareness. The revised AIDS Knowledge and Attitudes Survey entered the field in May 1988. Provisional findings for the remainder of 1988 were published periodically (Advance Data From Vital and Health Statistics Nos. 160, 161, $163,164,167$, and 175); in addition, two special reports focusing on minority populations were published from the 1988 data (Advance Data From Vital and Health Statistics Nos. 165 and 166). A public use data tape of the 1988 AIDS Knowledge
and Attitudes Survey will be available at the end of the year. The NHIS AIDS questionnaire used in 1988 will be continued throughout 1989. Reports based on the 1989 data will be issued on a quarterly basis. This report presents provisional data for the period January-March 1989.

The Advance Data reports describing the NHIS AIDS data have been restricted to simple descriptive statistics to facilitate their timely release. Thus, these reports do not attempt to explain or interpret differences among population subgroups or to examine relationships among various measures of knowledge and AIDS-related behavior (e.g., testing). The NHIS AIDS data bases permit more complex analyses than those presented in this series of Advance Data reports, and such analyses are being undertaken by various groups in the Public Health Service.

The AIDS questionnaires were designed to estimate public knowledge about AIDS virus (HIV) transmission and its prevention. The data were needed as input for the planning and development of AIDS educational campaigns and for monitoring major educational efforts, for example, the series of radio and television public service announcements entitled "American Responds to AIDS" and
the brochure "Understanding AIDS," both developed by the Centers for Disease Control.

The NHIS AIDS questionnaires were developed by the National Center for Health Statistics and interagency working groups established by the Information, Education and Risk Factor Reduction Subcommittee of the Public Health Service Executive Task Force on AIDS. The working groups included representatives from the Centers for Disease Control; the National Institutes of Health; the Alcohol, Drug Abuse and Mental Health Administration; and the Health Resources and Services Administration.

The current AIDS questionnaire includes items on sources of AIDS information; self-assessed levels of AIDS knowledge; basic facts about the AIDS virus (HIV) and how it is transmitted; blood donation experience; awareness of and experience with the blood test for HIV; personal acquaintance with persons with AIDS or HIV; and willingness to take part in a proposed national seroprevalence survey. A general risk behavior question, similar to that asked by the Red Cross of potential blood donors, is included in the current AIDS questionnaire.

This report presents provisional data for January-March 1989 for most
itens included in the AIDS questionnaire. Table 1 displays percent disıributions of persons 18 years of age and over by response categories according to age, sex, race, and education. In most cases, the actual questions asked of the respondents are reproduced verbatim in table 1 along with the coded response categories. In a few cases, questions or response categories have been rephrased or combined for clearer or more concise presentation of results. Refusals and other nonresponse categories (generally comprising less than 1 percent of total responses) are excluded from the denominator in the calculation of estimates, but responses of "don't know" are included.

The NHIS AIDS questionnaire uses the phrase "the AIDS virus" rather than "HIV," because it was felt that the general population might not be familiar with the more scientific terminology at the time the survey began. In this report, the two terms will be used synonymously.

## Selected findings

The following highlights describe various aspects of AIDS knowledge and attitudes as observed in the January-March 1989 data from the NHIS AIDS survey. Unless otherwise noted in the text, all measures described remained stable over this 3 -month period. Any differences cited in the text are statistically significant at the .05 level (see table II for provisional standard errors of estimates).

Sources of AIDS information - In the first quarter of 1989 , there were no changes in the proportions of U.S. adults who reported having seen or heard public service announcements (PSAs) about AIDS on television (80 percent) or on the radio ( 44 percent). As was true in 1988, less than one-fourth of those adults who had seen such PSAs stated that the announcements were part of the series entitled "America Responds to AIDS;" almost half did not remember. There was a decline in the percentage of adults who reported having read any brochures or pamphlets about AIDS in the month preceding interview -24 percent in

Junuary-March compared to 28 percent in December. There was a smaller decrease in the proportion of adults who said they had ever read brochures or pamphlets about AIDS, from 65 percent in December to 63 percent in January-March.

Sociodemographic differentials in exposure to media coverage of AIDS generally remained the same in the first quarter of 1989 as throughout 1988. Reported exposure to AIDS messages in print, on television, and on the radio decreased with age and increased with education. Black adults and men were more likely than white adults and women to have heard PSAs on the radio. Black individuals were more likely than white individuals to have read brochures or pamphlets in the month preceding interview but equally likely ever to have done so.

Sixty-three percent of adults with children age $10-17$ years reported having discussed AIDS with these children; 60 percent stated that their children age $10-17$ years had received AIDS education in school. Sixty-one percent of adults said they had discussed AIDS with friends or relatives. These percentages have remained fairly stable for many months.

Self-assessed knowledge-During the period January-March 1989, 24 percent of U.S. adults reported knowing a lot about AIDS, up from 21 percent in December 1988. Fortythree percent reported some knowledge, 25 percent claimed to know a little, and 8 percent said they knew nothing about AIDS. Increases in self-assessed knowledge were of similar magnitude in all categories of age, sex, race, and education.

General knowledge - Despite the rise in the level of self-assessed knowledge, there was little or no change in most objective measures of general knowledge about AIDS and HIV. The one improvement was in the proportion of adults who thought it definitely false that "looking at a person is enough to tell if he or she has the AIDS virus," which increased from 66 to 70 percent. The gains in this aspect of knowledge were particularly large among persons age $18-29$ years (up from 71 to 78 percent
responding correctly), black adults (from 55 to 64 percent), and persons with less than 12 years of school (from 47 to 52 percent).

Awareness of the main modes of HIV transmission remained at the high levels previously observed.
Eighty-three percent of adults thought it definitely true that "any person with the AIDS virus can pass it on to someone else during sexual intercourse," and 80 percent said it was definitely true that "a pregnant woman who has the AIDS virus can give the AIDS virus to her baby." In addition, 94 percent thought it very likely that HIV could be transmitted by sharing needles for drug use. As was the case in 1988, the great majority of adults realized that "ihere is no cure for AIDS at present" (87 percent responding definitely true) and that "AIDS leads to death" (85 percent). Three-quarters ( 75 percent) thought it definitely false that "there is a vaccine available to the public that protects a person from getting the AIDS virus."

Misperceptions about HN trans-mission-The NHIS AIDS survey includes a series of questions addressing misperceptions about HIV transmission by means of various forms of casual contact. Accurate knowledge in this area, as expressed by the proportion of adults who thought it very unlikely or definitely not possible to spread HIV through casual contact, improved throughout 1987 and between May and July 1988. After that, the proportions of adults responding correctly to these questions declined slightly, so that by December 1988, responses were similar to those recorded in May of that year. In January-March 1989, there were improvements in several of these measures (figure 1). The proportion of adults who thought it very unlikely or definitely not possible to become infected with HIV by "living near a hospital or home for AIDS patients" increased from 80 to 83 percent. With respect to "working near someone with the AIDS virus," the increase was from 67 to 71 percent. Other increases were in the proportions of adults who thought it very unlikely or definitely not possible to get HIV by "shaking

Figure 1. Provisional estimates of percent of adults who thought it very unlikely or definitely not possible to become infected with HIV in selected ways: United States, selected months, 1988 and 1989
hands, touching, or kissing on the cheek someone who has the AIDS virus" (up from 69 to 73 percent) and by "attending school with a child who has the AIDS virus" (from 72 to 76 percent). For the other conjectured modes of transmission shown in figure 1, there were no changes in knowledge during the period January-March 1989.

Blood donation and testing-In January-March 1989, 40 percent of adults reported ever having donated blood. This includes 14 percent who donated blood since March 1985, when routine screening for HIV antibodies began, and 6 percent who claimed to have donated blood in the preceding year. Almost three-fourths of adults had heard of the blood test for the AIDS virus (i.e., the test to detect HIV antibodies), and two-thirds thought blood donations are routinely tested. Six percent of adults said that they had received a blood transfusion between 1977, when HIV is thought to have entered the United States, and

1985, when routine screening began. About half ( 48 percent) of all adults thought the present supply of blood is safe for transfusions. All of these estimates are similar to those reported in December 1988.

Likewise, there was no change in the proportion of adults estimated to have had their blood tested for HIV, 19 percent in January-March 1989. This figure is fairly evenly divided between persons who reported having been tested ( 10 percent) and those who did not report testing but had donated blood since automatic screening of donations was initiated (9 percent). The proportion of adults tested decreased sharply with age, from 26 percent of those age $18-29$ years to 9 percent of those 50 years of age and over. Seventy-one percent of the individuals who had been tested for HIV reported being tested as a part of blood donation and 2 percent as part of a blood transfusion. Seventeen percent voluntarily sought testing, and 14 percent were tested as
part of some other activity that requires a routine blood test.

Seven percent of adults reported plans to have their blood tested in the year following interview, about the same as in December. This proportion declined with age, from 11 percent of persons age $18-29$ years to 8 and 2 percent, respectively, of those age $30-49$ years and 50 years and over. Men were almost twice as likely as women to report plans to be tested, 9 versus 5 percent. Of persons who reported plans to be tested, 52 percent said that the test would be sought voluntarily as opposed to performed routinely in connection with some other activity. This is a significant increase over December, when the figure was 43 percent. The increase was especially large for adults age 18-29 years, 60 percent in January-March compared to 43 percent in December.

Preventive measures - There was no change between December 1958 and January-March 1989 in the
perceived effectiveness of various methods of preventing HIV transmission. Eighty-three percent of adults rated "two people who do not have the AIDS virus having sex only with each other" as very effective, and 31 percent thought condom use to be very effective. Fifty-four percent considered condom use somewhat effective in preventing HIV transmission during sexual intercourse. More than half of all adults stated that diaphragms, spermicides, and vasectomy were not at all effective.

Risk of getting HIV - During Jannary-March 1989, 2 percent of
adults reported belonging to one or more of the groups with behaviors associated with increased risk of AIDS (e.g., hemophiliacs, intravenous drug users, and homosexnal men). This proportion has not varied since the question was introduced in May 1988.

Eighty-three percent of U.S. adults felt there was no chance of their already being infected with HIV, i.e, of "having the AIDS virus" Thirteen percent assessed their chances of having HIV as low, 2 percent as medium, and less than 1 percent as high. Seventy-eight percent of adults felt that they had no chance
of becoming infected, i.e., "of getting the AIDS virus." This proportion has risen steadily since 1987. The proportions who stated that their chances of getting HIV were low, medium, and high were 17,2 and less than 1 percent, respectively.

One adult in every 8 ( 12 percent) reported knowing someone with ADDS or HIV. This percentage has doubled since August 1987. Adults age 30-49 years were the most likely to report knowing someone with AIDSHHIV (16 percent), followed by persons 18-29 years ( 11 percent) and those 50 years of age and over ( 8 percent).

[^16]
## Technical notes

The National Health Interview Survey (NHIS) is a continuous, cross-sectional household interview survey. Each week, a probability sample of the civilian noninstitutionalized population is interviewed by personnel of the U.S. Bureau of the Census to obtain information on the health and other characteristics of each member of the household. Information on special health topics is collected for all or a sample of household members. The 1989 National Health Interview Survey of AIDS Knowledge and Attitudes is asked of one randomly chosen adult 18 years of age or over in each family. The estimates in this report are based on completed interviews with 8,735 persons, or about 89 percent of eligible respondents.

Table I contains the estimated population size of each of the demo-
graphic subgroups included in table 1 to allow readers to derive provisional estimates of the number of people in the United States with a given characteristic, for example, the number of men who have had their blood tested for HIV. The population figures in table I are based on 1987 data from the NHIS; they are not official population estimates. Table II shows approximate standard errors of estimates presented in table 1. Both the estimates in table 1 and the standard errors in table II are provisional. They may differ slightly from estimates made using the final data file because they were calculated using a simplified weighting procedure that does not adjust for all the factors used in weighting the final data file. A final data file covering the entire data collection period for 1989 will be available at the end of 1990 .

# Utilization of Controlled Drugs in Office-Based Ambulatory Care: National Ambulatory Medical Care Survey, 1985 

by Hugo Koch, M.H_A., Division of Health Care Statistics, and Dee A. Knapp, Ph.D., University of Maryland at Baltimore

## Introduction

An increasingly important issue in current health care and social policy is the use of medications having significant potential for drug dependence or abuse and their possible diversion into illicit channels. Under Federal law, the Controlled Substances Act of 1970, special regulatory controls have been placed on the manufacture, distribution, and dispensing of these drugs. Each controlled drug is placed in one of five schedules, depending on its potential for abuse, its medical usefulness, and the degree of dependence it can produce.
Schedule I. The drag has a high potential for abuse and no current accepted medical usefulness for treatment in the United States. Examples are heroin and LSD. Schedule I drugs are outside the scope of this report.
Schedule II. The drug has a currently accepted medical use in the United States, but its abuse may lead to severe dependence. Included are certain narcotics (e.g., morphine), short-acting barbiturates, and certain stimulants,
such as the amphetamines and cocaine. Prescriptions for these drugs are nonrefillable. Emergency telephone orders for limited quantities of these drugs are permitted, but the prescriber must provide a written, signed prescription to the pharmacy within 72 hours.
Schedule III. The drug has an accepted medical use in the United States, but its abuse may lead to moderate dependence. Included are opiates in fixed-ingredient combination with such other substances as acetaminophen or aspirin, and certain anorexiants. Prescriptions may be oral or written and may be refilled up to five times within 6 months after the date of issue, if authorized by the prescriber.
Schedule IV. The drug has a currently accepted medical use in the United States, but its abuse may lead to limited dependence. Lncluded are the benzodiazepines (minor tranquilizers), phenobarbital, pentazocine, propoxyphene, and certain anorexiants. The same prescription requirements pertain as with Schedule III drugs.

Schedule V. The drug has a currently accepted medical use in the United States, but its abuse may lead to some dependence. The most important are fixed-ingredient combinations containing nonopioid drugs and limited quantities of opioids. There are no limitations on prescriptions or refills, other than those specified by the prescriber. Depending upon State and local regulation, some Schedule V products are available without a prescription.
This report describes the utilization of controlled drugs (Schedules II, III, IV, V) in officebased ambulatory care. The report relies on findings from the National Ambulatory Medical Care Survey (NAMCS), a sample survey of nonFederal, office-based physicians conducted in the coterminous United States over the 12 -month period March 1985 through February 1986.

The term urilization is limited to the prescribing or providing of a controlled drug by a doctor of medicine or osteopathy in the course of an office visit. It does not embrace ultimate patient compliance with the doctor's instruction.

Because the estimates presented in this report are based on a sample rather than on the entire universe of office visits or drug mentions, the data are subject to sampling variability. The technical notes at the end of the report provide guidelines for judging the precision of the estimates. They also supply a brief description of the sample design and survey methodology and a copy of the chief data collection instrument, the patient record (figure 1).

## General findings

From March 1985 through February 1986, 636.4 million office visits were made to physicians within the NAMCS scope, resulting in an estimated 693.4 million drug entries (mentions). This report centers attention on the estimated 47,192,000 office visits in which one or more controlled drugs were ordered or provided (controlled drug visits) and on the $51,877,000$ mentions of controlled drugs that these visits
produced. The controlled drug mentions were distributed among the schedules as shown in table 1 .

NAMCS findings reveal that, between 1980 and 1985, there was a decrease of roughly 11 percent in the overall number of controlled drug mentions. The smaller groups, Schedules II and V, showed the greatest decreases; mentions in each fell off by about 30 percent. The use of Schedule IV drugs registered a modest decline (7 percent) over the period, in large part the result of a

decrease in the utilization of diazepam. Schedule III drugs were the only controlled drugs to hold their own-indeed, they showed a modest increase ( 5 percent) in utilization during the period.

Table 2 offers a ranked listing of the 20 controlled drugs most frequently prescribed by the officebased practitioner. This group of 20 accounted for about two-thirds of all controlled drug mentions. In table 3, the 51.9 million controlled mentions are classified by the therapeutic effect that each was intended to produce. It is noteworthy that narcotic analgesics dominate the drugs prescribed in schedules II and III; they accounted for an estimated 16.1 million mentions, a substantial 31 percent of all controlled drug mentions.

Another finding that merits attention is the dominance of the benzodiazepines (e.g., alprazolam, diazepam, and lorazepam) among the therapeutic family, anxiolytics, sedatives, and hypnotics, at the expense of other agents, chiefly barbiturates, which have more potential adverse effects, drug interactions, lethality, and abuse or dependence liability. With 18.1 million mentions, the benzodiazepines accounted for the largest single proportion ( 35 percent) of all controlled drug mentions.

## Symptoms and diagnoses associated with controlled drug therapy

The findings in table 2 and 3 indicate an application of controlled drugs in the management of pain, anxiety, cough, insomnia, and diarrhea. Table 4 shows the predominance of pain symptoms, which elicited more than one-half of the controlled drug mentions on the list.

Tables 5 and 6 describe the diagnostic correlates of controlled drug therapy, table 5 by listing the 15 principal diagnoses most frequently treated using controlled medications and table 6 by showing the volume of controlled drug mentions associated with each of the major diagnostic groups.

${ }^{4}$ Chuefly psychogenic pain.

Some points require clarification or emphasis:

- The controlled drugs used in the treatment of obesity were not the Schedule II amphetamines, but rather the Schedule IV stimulants phentermine and diethylproprion.
- Seven diagnostic groups are seen to be above average in the
proportion of their overall drug utilization that resulted from the use of a controlled drug. In rank order, these are:
-Mental disorders.
-Injury and poisoning.
-Symptoms, signs, and ill-defined conditions.
-Diseases of the musculoskeletal system and connective tissue.
-Diseases of the digestive system.
-Neoplasms.
-Endocrine, nutritional, and metabolic diseases and immunity disorders.

## Patient characteristics

Viewed as a proportion of all drug therapy within a given age group, the utilization of controlled substances increases with age until it reaches its maximum proportion in the age group 25-44 years (table 7). It then begins a decline among patients in the remaining years of life.

Median patient age is seen to vary according to the controlled schedule utilized, as follows:

$$
\begin{array}{cc} 
& \text { Median patient } \\
\text { Schedule } & \text { age in years }
\end{array}
$$

| All controlled mentions | 45.2 |
| :---: | :---: |
| Schedule ll drugs | 44.0 |
| Schedule It drugs | 39.6 |
| Schedute IV drugs | 50.8 |
| Schedule V drugs | 31. |

In absolute numbers, controlled drug mentions for female patients outnumbered those for males by a substantial 15 million (table 7). In terms of relative utilization, however, the 1-percent difference that favored all female patients was not statistically significant.

Data on racial and ethnic patient groups did not vary strongly enough from the overall norms of controlled drug therapy to warrant comment (table 8).

## Physician characteristics

Table 9 examines the utilization of controlled drugs in terms of the physicians who prescribe them. The following findings merit attention:

- Osteopathic physicians somewhat exceeded doctors of medicine in their proportionate prescribing of controlled drugs. This is due in part to their relatively greater concern with musculoskeletal pain and thus with the opiate analgesics in Schedule III, but chiefly to their more intensive prescribing of the drugs in Schedule V.
- In terms of absolute numbers of controlled drug mentions, it is noteworthy that primary care physicians accounted for about
two-thirds of the total 51.9 million, with general or family physicians alone accounting for 43 percent.
- In relative terms, however-that is, when the 13 most-visited specialties are examined in terms of their proportionate use of controlled drug therapy-five specialties were found to exceed average utilization. In rank order of intensity of use, these were:

1. Psychiatry
2. Orthopedic surgery
3. Neurology
4. General surgery
5. General or family practice

Between the 1980 and the 1985 NAMCS, three specialties demonstrated the largest variations in their proportionate use of the controlled drugs. These were psychiatry, with an increase from 24 percent in 1980 to 31 percent in 1985; neurology, with an increase from 15 percent in 1980 to 20 percent in 1985; and general surgery, with a decrease from 16 percent in 1980 to 9 percent in 1985.

## Other aspects of controlled drug therapy

Are physicians more cautious in prescribing a controlled drug for a new patient than for a patient whom they already know? The differences in relative utilization presented in table 10 are not large enough to answer this question conclusively.

Table 11 examines the extent to which nondrug treatment techniques were used concomitantly with controlled drug therapy. In a clear majority ( 68 percent) of visits involving the utilization of a controlled drug (controlled drug visits), no nondrug therapy is seen to have been ordered or provided. The most frequent nonpharmacologic treatment in concomitant use was psychotherapy; its use in controlled drug visits was three times as great as its use in all visits.

With its data on disposition instructions at the end of the office visit, table 12 supplies some final insights into the nature of office-based prescribing of controlled drugs. Possibly reflecting a desire to maintain closer-than-usual surveillance of a group of drugs that have their own unique hazards of use, the utilization of some form of followup is seen to be the rule, somewhat exceeding the followup norms found in overall office practice.

## Technical notes

## Source of data and sample design

The information presented in this report is based on data collected by means of the National Ambulatory Medical Care Survey (NAMCS) from March 1985 through February 1986. The target universe of the NAMCS consists of office visits made by ambulatory patients to non-Federal physicians who are principally engaged in office practice within the coterminous United States. The specialties of anesthesiology, pathology, and radiology are excluded from the survey scope, as are any telephone contacts with patients or nonoffice visits.

The NAMCS utilizes a multistage probability sample design that involves a sample of primary sampling units and patient visits within physicians' practices. Physician specialty was used as a stratification variable. For 1985, a sample of 5,032 non-Federal, officebased physicians was selected from master files maintained by the American Medical Association and the American Osteopathic Association. For the 4,104 physicians who proved to be in scope, the response rate was

70 percent. Sampled physicians were asked to complete patient records (figure 1) for a systematic random sample of office visits taking place during a randomly assigned 1-week reporting period. Responding physicians completed a total of 71,594 patient records; they recorded 71,182 drug mentions in item 14, medication therapy, of which 5,692 were the mentions of controlled drugs that provided a base for most of the estimates in this report. Characteristics of the physician's practice, such as primary specialty, were obtained during an induction interview.

## Reliability of estimates

The standard error (SE) is primarily a measure of sampling variability that occurs by chance because only a sample rather than the entire universe of office visits or drug mentions is surveyed. The chances are about 68 in 100 that an estimate from the sample would differ from a complete census by less than the standard error. The chances are about 95 in 100 that the difference would be less than twice the standard error, and about 99 in 100 that it would be less than $21 / 2$ times as large.

The relative standard error (RSE) is that percentage of the estimate represented by the standard error. In this report, an asterisk (*) precedes any estimate with more than a 30 -percent relative standard error.

Relative standard errors for visit numbers may be calculated using the following formula, where $x$ is the visit number in thousands:
$\operatorname{RSE}(x)=$
$\sqrt{0.001493373+\frac{28.258848}{x}} \cdot 100$

$$
\operatorname{SE}(x)=\operatorname{RSE}(x) \cdot x
$$

For example, the RSE of the estimated 47,192,000 controlled drug visits (visits in which one or more controlled drugs were utilized) equals 4.6 percent. The SE therefore equals 2,171,000 visits.

Relative standard errors for numbers of drug mentions may be calculated using the following formula, where $x$ is the number of drug mentions in thousands:
$\operatorname{RSE}(x)=$
$\sqrt{0.001884167+\frac{46.903471}{x}} \cdot 100$
$\operatorname{SE}(x)=\operatorname{RSE}(x) \cdot x$

|  | Data not available |
| :---: | :---: |
|  | Category not applicable |
| - | Quantity zero |
| 0.0 | Quantity more than zero but less than 0.05 |
| Z | Quantity more than zero but less than 500 where numbers are rounded to thousands |
| * | Figure does not meet standards of reliability or precision |
| \# | Figure suppressed to comply with confidentiality | confidentiality

For example, the RSE of the estimated $51,877,000$ controlled drug mentions equals 5.3 percent. The SE therefore equals $2,750,000$ mentions.

Relative standard errors (in percent) for estimates of percents may be calculated using the following formulas, where $p$ is the percent of interest and $x$ is the denominator of the percent in thousands.
I. For percents of visit numbers,

RSE $(p)=$

$$
\frac{\sqrt{28.258848 \cdot(1-p)}}{p \cdot x} \cdot 100
$$

SE ( $p$ ) $=\operatorname{RSE}(p) \cdot p$
For example, psychotherapy was utilized in an estimated 10.6 percent of the 47,192,000 controlled drug visits. The RSE of this 10.6 percent equals 7.1 percent. The SE therefore equals 0.8 percent.
II. For percents of drug mentions,

RSE $(p)=$

$$
\frac{\sqrt{46.903471-(1-p)}}{p \cdot x} \cdot 100
$$

$\operatorname{SE}(p)=\operatorname{RSE}(p) \cdot p$

For example, controlled drug mentions accounted for an estimated 7.5 percent of all the $693,355,000$ drug mentions in the 1985 NAMCS. The RSE of this 7.5 percent equals 2.9 percent. The SE therefore equals 0.2 percent.

## Tests of significance and rounding

In this report, the determination of statistical significance is based on a two-sided $t$-test with a critical value of 1.96 ( 0.05 level of confidence). Terms relating to difference, such as "greater than" or "less than," indicate that the difference is statistically significant. In the tables, estimates of office visits and drug mentions have been rounded to the nearest thousand. Consequently, estimates will not always add to totals.

## Definitions of terms

A visit is a direct personal exchange between an ambulatory patient seeking health care and a physician or staff member working under the physician who provides that care.

A drug mention is the physician's entry of a pharmaceutical agent prescribed or provided-by any route of administration-for prevention, diagnosis, or treatment. Generic names as well as brand names are included, as are nonprescription as well as prescription drugs. Along with all new drugs, the physician also records any continued medication if the patient was specifically instructed during the visit to continue medication.

# Firearm Mortality Among Children and Youth 

by Lois A. Fingerhut, M.A. and Joel C. Keinman, Ph.D., Division of Analysis

## Introduction

In a recent comparison of U.S. childhood mortality with mortality in eight other industrializied countries, it was noted that the United States ranked about midway for natural causes of death but highest or second highest for death rates from injuries and violence (1). In particular, the teenage homicide rate was much higher than in any of the other countries. In 1986 the total homicide rate for males $15-19$ years of age in the United States was 15.1 deaths per 100,000 population. For white males it was 8.6 and for black males 51.5 per $100,000-18$ times higher than the next highest rate of 2.9 for males in Australia. In the United States the homicide rate for females was lower, 4.7, than for males. However, the rate for black females, 12.1, was nearly 4 times higher than the rate for white females, 33, and 8 times higher than the next highest rate of 1.4 for females in Canada (2).

In addition to having the highest overall homicide rate, the United States has an unusually large proportion of homicides attributed to
firearms (3). In this report we eramine the contribution of firearms to childhood mortality from homicide, suicidé, and unintentional injury.

## Data sources and definitions

Mortality data for the 50 States and the District of Columbia are based on data from death certificates provided to NCHS by the States where the death certificates are filed (4). Population data are from the Bureau of the Census (4). Data for eight other countries are based on tabulations provided by the World Health Organization and from individual country reports.

Firearm deaths for 1979-87 are a combination of four categories of deaths classified under the International Classification of Diseases, Ninth Revision (4), as follows:
(1) E965.0-E965.4-homicide deaths that are caused by firearms;
(2) E955.0-E955.4-suicide deaths that are caused by firearms; (3) E922unintentional deaths or accidents that are caused by firearms; and
(4) E985.0-E985.4-deaths caused by
firearms for which the intent was unknown. For 1968-78 the Eighth Revision of the ICD was used to classify deaths. In the eighth revision these causes were coded using three digits rather than four so that firearms conld not be distinguished from explosives. However, in 1986 explosives accounted for only 27 out of 31,701 deaths (all ages) from these causes.

While fourth digit Ninth Revision ICD codes are available to identify the type of firearm that was used, the vast majority of weapon types are coded as "other and unspecified", making it impossible to determine the type of weapon responsible for the death. Based on reports to the Federal Bureau of Investigation, an estimated 44 percent of all "murders" were attributable to handguns and 74 percent of all firearm-related "murders" were caused by handguns (5).

Cause-of-death ranking in this report differs from that used in other publications (4). The major difference is that "motor vehicle accidents" are disaggregated from "accidents and adverse effects" in this report.
U.S. DEPARTMENT OF HEALTH AND HUMAN SERVICES

Public Health Service
Centers for Disease Control
National Center for Health Statistics
Manning Feinleib, M.D., Dr. P.H.s. Director

Figure 1. Percent of all childhood deaths resulting from firearms: United States, 1987

## Results

In 1987, 3,392 children aged 1-19 years died from firearm-related injuries and violence. This represented 11 percent of childhood deaths. The proportion rises rapidly with age from 1.0 percent at ages $1-4$ years to 2.9 percent to 10.9 percent to 17.3 percent among teenagers. The proportion varies considerably by race and sex, especially for the two older groups. For black male teenagers 40.8 percent of the deaths were associated with firearms, compared with 16.2 percent among white males (figure 1).

Within each age group the distribution of firearm deaths by manner of death is different. Homicide and unintentional deaths each account for about half of the 203 firearm deaths among children 1-9 years of age. At 10-14 years of age suicide, homicide, and unintentional deaths each account for about $1 / 3$ of the 484 firearm deaths. Among teenagers, homicide accounts for 48 percent of the deaths, suicide for another 42 percent, and unintentional deaths for 8 percent.

From the other perspective, the proportion of homicide deaths that are
firearm-related rises from 12 percent at 1-4 years of age to 39 percent at ages 5-9 to 65 percent at ages $10-14$ to 71 percent of the 1,838 homicide deaths among teenagers $15-19$ years. Among black males $15-19$ years of
age, 82 percent of homicide deaths are associated with firearms. Similarly, 60 percent of suicide deaths among males $10-14$ years of age and $15-19$ years of age result from firearms.

From 1968 to 1987, little overall change occurred in total firearmrelated mortality in the United States except among teenagers for whom the death rate rose from 10.1 per 100,000 in 1968 to 14.7 in 1987 . Among the youngest children (1-4 years of age) there was a decrease in the overall rate during this period (figure 2).

Within each age group, and especially among those ages 5-19 years, firearm-related death rates are much higher for males than for females. The male/female ratio rises from 2.5 for $5-9$ years to 3.8 for those $10-14$ years of age and to 5.9 for teenagers $15-19$ years of age. Because of the concentration of firearm mortality among teenage males, trends in this group will be considered in more detail (table 1).

Among white males 15-19 years of age, motor vehicle injuries have been the leading cause of death for the past several decades, with death rates 3 times higher than the next leading cause, suicide (figure 3).

Figure 2. Firearm death rates for chidren 1-19 years of age: United States, 1968-87

SOURCE: National Center for Heath Statistics: Data computed by the Division of Analysis from data compiled by the Division of Vital Statistics.

Suicide rates have been increasing since 1968 , more than doubling during the following 19 years. Most of the increase, however, occurred by 1977. Homicide mortality increased sharply from 1968 to 1980 . Since then it has
decreased to the levels of the mid1970's. It now ranks as the third leading cause of death for this age group. Death rates for malignant neoplasms and drowning continue to decline.

Among white male teenagers firearms have been responsible for about $60-65$ percent of all suicides over the period 1968 through 1987. Both the firearm and nonfirearmrelated suicide rates doubled between

Figure 3. Trends in leading causes of death among white males $15-19$ years of age: United States, 1968-87

Figure 4. Firearm- and nonfirearm-related death rates for suicide, homicide, and unintentional injury, white males 15-19 years of age: United States, 1968-87

1968 and 1987 (figure 4). Similarly, firearms have been involved in nearly 70 percent of all homicides since 1968. Trends in firearm and nonfirearm homicide mortality have been parallel since 1968. Both rates increased betweeen 1968 and 1980, then declined. Unintentional firearm injury death rates are now the lowest of the firearm death rates for white male teenagers. In the late 1960 's the rate from this manner of death was similar to those for firearm-related homicides and suicides. The rate for unintentional firearm injuries has been halved since 1968.

Among black males 15-19 years of age, the leading cause of death since 1968 has been homicide, followed by motor vehicle injuries (figure 5). From 1969 to 1978 the homicide rate declined by 39 percent. Over the next 6 years the rate increased 24 percent, then fell by nearly the same amount. From 1984 through 1987 the homicide rate increased by 53 percent to 60.0 deaths per 100,000 , the same high level it had reached in the early 1970's. Death rates for motor vehicle injuries declined steadily from 1968 until 1983. From 1983 through 1987 the rate increased 44 percent to 27.2 , still substantially lower than it was in 1968. Drowning mortality has decreased almost continually. Suicide is now the fourth leading cause of death among black male teenagers, bypassing mortality associated with malignant neoplasms. Since 1968 the suicide rate has more than doubled from 3.8 in 1968 to 8.9 in 1987.

Firearms have been responsible for $75-80$ percent of all black male teenage homicides since 1968. Between 1984 and 1987 the firearmrelated homicide rate increased by 66 percent from 29.6 to 49.2 while the nonfirearm-related homicide rate increased by only 13 percent from 9.6 to 10.8 (figure 6). This recent increase in firearm-related homicides accounts for 95 percent of the increase in the total homicide rate for the 1984-87 period among black males 15-19 years of age. Firearm and nonfirearm suicide trends, on the other hand, have been erratic and the death rates remain relatively low. It is noteworthy however,

Figure 5. Trends In leading causes of death among black males $15-19$ years of age: United States, 1968-87
white males and 575 among black males. In contrast, in Canada there were 6 firearm-related homicides out of a total of 21 and in Japan 2 of 21 homicides among males $15-19$ years of age were firearm-related. In 1985 there were no firearm-related homicides among teenage males in England and Wales (out of 11 total homicides) or in Sweden (out of 2) while in the Federal Republic of Germany 5 out of 16 homicides were firearm-related as were 6 of 1 S in Australia. Only in France did the proportion of homicides from firearms approach the U.S. level but the numbers were far lower ( 12 out of 18). (Data are from individual country reports.) These data are based on deaths from firearms. It is likely that case-fatality rates have declined over the past two decades due to improvements in emergency medical treatment. Thus, the increase in firearm-related mortality among teenagers probably masks an even larger increase in the incidence of firearm-related injuries.
that during the 1980 's firearm-related suicides have accounted for steadily increasing proportions of all black teenage male suicides-from 52 percent in 1982 to 71 percent in 1987. Furthermore, between 1982 and 1987 the firearm-related suicide rate doubled. The death rate for unintentional firearm injuries decreased from 9.2 to 2.9 from 1968 through 1987, with most of the decline occurring between 1972 and 1978. Similar to white males, the rate is the lowest of the firearmrelated death rates.

## Conclusion

Clearly, firearms have played a major role in U.S. childhood mortality. In 1987 there were 3,392 firearmrelated deaths among children 1-19 years of age, 11 percent of all childhood deaths. Comparisons with eight other countries demonstrate that the United States is unique with respect to this problem. In 1986 there were 1,043 firearm-related homicides (out of a total of 1,432 ) among U.S. males aged 15-19 years-447 among

NOTE: Deathe for 196s-78 are based on the Eighth Revision of the Intemational Clessification of Diseases. Deaths for 1979-87 are based on the Ninth Revision of the 'rxemational Classtication of Diseases.

Figure 6. Firearm- and nonfirearm-related death rates for homicide, suicide, and unintentional injury, black males 15-19 years of age: United States, 1968-87

The Public Health Service has targeted violence as a priority concern. Two of the 1990 Health Objectives for the United States include lowering the homicide rate among black males $15-24$ years of age as well as the suicide rate for all persons $15-24$ years of age. There is a separate objective to reduce the number of handguns in private ownership (6). Additionally, the American Medical Association has recognized the need to "treat this public health matter [firearm injuries and deaths] with as much urgency as any dread disease" (7). The data presented in this report underscore these concerns.

# AIDS Knowledge and Attitudes for April-June 1989 

Provisional Data From the National Health Interview Survey

by Ann M. Hardy, Dr.P.H., Division of Health Interview Statistics

## Introduction

The National Center for Health Statistics (NCHS) has included a special set of supplemental questions on the adult population's knowledge and attitudes about acquired . immunodeficiency syndrome (ADDS) in the National Health Interview Survey (NHIS). The first AIDS Knowledge and Attitudes Survey was in the field from August through December 1987. Provisional results of that survey were published on a monthly basis in Advance Data From Vital and Health Statistics (Nos. 146, $148,150,151$, and 153). A public use data tape containing the information collected in 1987 is available from NCHS.

During the first 4 months of 1988, the NHIS AIDS questionnaire was revised to meet changing program needs and the new survey entered the field in May 1988. Provisional findings for 1988 were published periodically (Advance Data From Vital and Health Statistics, Nos. 160, 161, 163, 164, 167, and 175); in addition, two special reports focusing on minority populations were published using the 1988 data (Advance Data From Vital and Health Statistics, Nos. 165 and 166). A public use data tape of the 1988 AIDS Knowledge and Attitudes Survey will be available at the end of this year.

The NHIS AIDS questionnaire used in 1988 is being continued throughout 1989. Reports based on the 1989 data will be issued on a quarterly basis; Advance Data From Vital and Health Statistics No. 176 summarized data from the first quarter of 1989. This report presents provisional data for second quarter (April-June) of 1989.

The Advance Data reports describing the NHIS AIDS data have been restricted to simple descriptive statistics to facilitate their timely release. Thus, these reports do not attempt to explain or interpret differences among population subgroups or to examine relationships among various measures of knowledge and AIDS-related behavior (e.g., testing). The NHIS AIDS data bases permit more complex analyses than those presented in this series of Advance Data reports, and such analyses are being undertaken by various groups in the Public Health Service.

The AIDS questionnaires were designed to estimate public knowledge about AIDS virus (HIV) transmission and its prevention. These data are needed to plan and develop AIDS educational campaigns and to monitor major educational efforts, for example, the series of radio and television public service announcements entitled "America Responds to AIDS" and the
brochure "Understanding AIDS," both developed by the Centers for Disease Control.

The NHIS AIDS questionnaires were developed by the National Center for Health Statistics and interagency working groups established by the Information, Education and Risk Factor Reduction Subcommittee of the Public Health Service Executive Task Force on AIDS. The working groups included representatives from the Centers for Disease Control; the National Institutes of Health; the Alcohol, Drug Abuse and Mental Health Administration; and the Health Resources and Services Administration.

The current AIDS questionnaire includes items on sources of AIDS information; self-assessed levels of AIDS knowledge; basic facts about the AIDS virus (HIV) and how it is transmitted; blood donation experience; awareness of and experience with the blood test for HIV: selfassessed chances of getting HIV; personal acquaintance will persons with AIDS or HIV; and willingness to take part in a proposed national seroprevalence survey. A general risk behavior question, similar to that asked by the Red Cross of potential blood donors, is also included.

This report presents provisional data for April-June 1989 for most

items included in the AIDS question naire. Table 1 displays percent distributions of persons 18 years of age and over by response categories according to age, sex, race, and education. In most cases, the actual questions asked of the respondents are reproduced verbatim in table 1 along with the coded response categories. In a few cases, questions or response categories have been rephrased or combined for clearer or more concise presentation of results. Refusals and other nonresponse categories (generally comprising less than 1 percent of total responses) are excluded from the denominator in the calculation of estimates, but responses of "don't know" are included.

The NHIS AIDS questionnaire uses the phrase "the AIDS virus" rather than "HIV," because it was felt that the general population might not be familiar with the more scientific terminology at the time the survey began. In this report, the two terms are used synonymously.

## Selected findings

The following highlights describe various aspects of AIDS knowledge and attitudes as observed in the April-June 1989 data from the NHIS AIDS survey. Unless otherwise noted in the text, all measures described remained stable over this 3 -month period. Any differences cited in the text are statistically significant at the 0.05 level (see table II for provisional standard errors of estimates).

Sources of AIDS information Eighty percent of adults interviewed in April-June 1989 reported having seen AIDS public service announcements on television in the past month, and 45 percent reported hearing announcements on the radio. These proportions were similar to the proportions who reported seeing or hearing such announcements in the first quarter of 1989. As in previous months, the proportion of adults who had seen or heard announcements was higher for those with 12 or more years of school than for those with less than 12 years. The proportion who reported having read AIDS brochures or pamphlets in the previous month ( 23 percent) and
the proportion who had ever read such material ( 62 percent) remained essentially unchanged between the first quarter and second quarter of 1989.

Sixty-two percent of adults said they had discussed AIDS with a friend or relative in the past. For about one-third of these persons, the discussion had occurred more than one month before interview. Sixty-two percent of parents with children between the ages of 10 and 17 reported having discussed AIDS with them. All of these figures have remained stable for many months. The percent of adults who reported that their children aged 10-17 had received instruction about AIDS in school increased slightly from 60 percent in the first quarter of 1989 to 64 percent in the second quarter. This figure has risen steadily from 35 percent in August 1987 when the AIDS survey began.

Self-assessed knowledge - The distribution of adults by level of selfassessed knowledge about AIDS did not change between the first quarter and second quarter of 1989 with 67 percent of the adult population claiming to know at least something about AIDS and the remaining one-third saying they knew little or nothing. The proportion who claimed little or no knowledge increased with decreasing years of school and was over 50 percent for those with less than a high school education. This proportion was also higher for those over 49 years of age than for those who were younger ( 49 percent compared with 24 percent) and higher for black adults than white adults (41 percent compared with 31 percent).

General knowledge - The responses to questions dealing with general AIDS knowledge remained essentially the same in the second quarter of 1989 as in the first quarter. A large proportion of adults ( 75 percent or more) in all the sociodemographic subgroups examined responded correctly to questions about the three major modes of HIV transmission (sexual, through contaminated needles, and from mother to baby during pregnancy). Awareness was particulary high for transmission
by sharing needles for drug use; 90 percent or more in all subgroups thought it very likely that AIDS could be transmitted this way. The majority of adults ( 85 percent) also recognized that there is no cure at present for AIDS and 93 percent knew that the statement that teens cannot get AIDS was definitely false. Awareness of these two facts was also high (79 percent or more with the correct response) in all demographic subgroups.

For the other questions about AIDS, there was more variability among the demographic subgroups in the proportion with the correct response. In general, those who were more educated and those who were less than 50 years old were more likely to give the correct definitive response. As in the past, the two statements that dealt with the pathophysiology of AIDS had the lowest proportions with the correct definitive response. Only 26 percent of adults definitely knew that AIDS can damage the brain and only 16 percent responded "definitely false" to the statement that AIDS usually leads to heart disease. These two statements also had higher proportions responding "don't know" than any other general knowledge question ( 25 and 36 percent, respectively).

Misperceptions about transmission of the AIDS virus-A series of questions in the NHIS AIDS survey addressed misperceptions about HIV transmission through casual contact. In general, there were no changes between the first and second quarter of 1989 in the proportion of adults who thought it very unlikely or definitely not possible to spread HIV by casual contact. As indicated by responses to these transmission questions, kissing with the exchange of saliva was the most likely to be viewed as an actual mode of transmission. Over half of U.S. adults ( 56 percent) felt this was somewhat or very likely to transmit AIDS. Misperceptions also existed for other potential exposures to saliva (such as being coughed or sneezed on or sharing eating utentsils with an HIV infected person) and for transmission by mosquitoes or other insects; 26-29 percent of persons
thought these methods were at least somewhat likely to spread AIDS. Fewer persons ( 11 percent or less) felt that other, more indirect contacts with infected individuals (such as in school or at work) would be likely modes of transmission. In general, black adults, those 50 years and older, and those with less than 12 years of school were less likely to correctly assess the low or nonexistent risk of transmission by casual contact than white adults, those less than 50 years, and those with at least a high school education.

Blood donation and testing-As in the first quarter of 1989,40 percent of adults interviewed in April-June 1989 reported ever having donated blood, 15 percent had donated since March 1985 when routine screening of donated blood for antibodies to HIV began, and 7 percent had donated in the year preceding interview. Threefourths of adults were aware of the AIDS blood test, 66 percent thought that blood donations are routinely screened, while less than half (48 percent) felt that the present blood supply was safe for transfusions. These figures have remained stable for many months.

Including all blood donors since March 1985, 20 percent of adults in April-June 1989 had had their blood tested for antibodies to HIV. This figure has risen slightly but steadily from 16 percent in May 1988. When the 3 months in the second quarter of 1989 were examined separately, an increase was observed from 19 percent tested for those interviewed in both April and May 1989 to 22 percent
tested for those interviewed in June 1989. Within the demographic subgroups, a slight increase in those tested between the first and second quarter of 1989 occurred among black adults (from 15 percent to 19 percent). While the proportion tested has increased over the last year, there has been no change in the distribution of those tested by circumstance. In April-June 1989, the majority of persons tested ( 69 percent) had their testing done as part of a blood donation, 18 percent were tested voluntarily, and 15 percent took the test as part of another activity requiring routine testing (such as a physical examination for military induction).

In the second quarter of 1989, as in the first quarter, 7 percent of adults indicated that they plan to have the HIV antibody test in the next year. The proportion who planned testing differed by sex and race. Men were more likely than women to indicate plans for testing ( 9 percent compared with 5 percent) and black adults were more likely than white adults to plan testing ( 13 percent compared with 6 percent). The proportion of black persons with future testing plans increased from 9 percent in JanuaryMarch 1989.

Preventive measures-As in the first quarter of 1989 , a high proportion (more than 80 percent) felt that condoms and a monogamous relationship between two uninfected persons were two methods that were at least somewhat effective in preventing

[^18]transmission of the AIDS virus. Even within various demographic subgroups, at least 72 percent of persons recognized the effectiveness of these methods and few (5 percent or less) were unfamiliar with them. Over half of all adults felt that the diaphragm, spermicides, and vasectomy were not effective in preventing AIDS virus transmission. Most of the remainder were uncertain about the effectiveness of these particular methods.

Risk of getting the AIDS virusOverall, 2 percent of adults in AprilJune 1989 stated that they belonged to one or more of the groups with behaviors associated with increased risk for aquiring AIDS (such as intravenous drug users and homosexually active men). This figure is not different from that reported in the first quarter of 1989. Less than 1 percent of adults felt that they had a high chance of having or getting the AIDS virus. Most felt their chances were low or nonexistent for either having or getting HIV infection ( 96 percent and 95 percent, respectively).

As in the first quarter of 1989. 12 percent of adults in the second quarter reported knowing someone with AIDS or HIV infection, including 5 percent who said they knew this person very or fairly well. Black adults were more likely than white adults to know a person with AIDS. This proportion also increased with education and was higher for those $30-49$ years than for those who were either younger or older.

Table 1. Provisional estimates of the percent of persons 18 years of age and over with selected AIDS knowledge and attitudes from the 1988 National Health Interview Survey, by selected characteristics: United States, April-June 1989
[Data are based on household interviews of the cwiltan noninstitutionalized population. The survey design, general qualfications, and information on the reliability of the estimates are given in technical notes]

## Technical notes

The National Health Interview Survey (NHIS) is a continuous, crosssectional household interview survey. Each week, a probability sample of the civilian noninstitutionalized population is interviewed by personnel of the U.S. Bureau of the Census to obtain information on the health and other characteristics of each member of the household. Supplemental information is collected for all or a sample of household members. The 1989 National Health Interview Survey of AIDS Knowledge and Attitudes was asked of a single randomly chosen adult 18 years of age or over in each family. The estimates in this report are based on completed interviews with 10,590 persons, or about 89 percent of eligible respondents.

Table I contains the estimated population size of each of the demographic subgroups included in table 1
to allow readers to derive provisional estimates of the number of people in the United States with a given characteristic, for example, the number of men who have had their blood tested for the AIDS virus. The population figures in table I are based on 1988 data from the NHIS; they are not official population estimates. Table II shows approximate standard errors of estimates presented in table 1. Both the estimates in table 1 and the standard errors in table $\Pi$ are provisional. They may differ slightly from estimates made using the final data file because they were calculated using a simplified weighting procedure that does not adjust for all the factors used in weighting the final data file. A final data file covering the entire data collection period for 1989 will be available at the end of 1990 .

# Characteristics of Persons Dying From Cerebrovascular Diseases 

# Preliminary Data From the 1986 National Mortality Followback Survey 

by Eve Powell-Griner, Ph.D., Office of Vital and Health Statistics Systems

## Introduction

Cerebrovascular diseases have a major impact on mortality and morbidity in the United States, and the identification of the characteristics of persons dying from these chronic diseases is of great interest. This report uses preliminary data from the 1986 National Mortality Followback Survey (NMFS) to compare the characteristics of adult decedents who died from Cerebrovascular diseases (ICD-9 nos. 430-438) with those who died from all other causes. In this report, the terms "cerebrovascular diseases" and "stroke" are used interchangeably for editorial convenience.

Cerebrovascular diseases, the third leading cause of death in the United States, accounted for 7 percent of all deaths in 1986 (1). Although stroke mortality declined during the past several decades, it remains a major contributor to years of potential life lost each year. Stroke resulted in an estimated 246,000 years of potential life lost before age 65 in

1986, representing 1.2 years lost per 1,000 persons under 65 years of age (2).

In addition to causing many deaths, stroke has a major impact on morbidity. An estimated 11.9 persons per 1,000 population reported having cerebrovascular disease in 1986.
Nearly 40 percent of persons with this disease reported that it limited their activities. Cerebrovascular disease resulted in an average of 36 days of restricted activity per person with the condition (3).

Data from the 1986 NMFS provide detailed information on the lifestyle, care in the last year of life, and antecedents of and circumstances surrounding death for a nationally representative sample of adults dying from cerebrovascular diseases and other causes in 1986.

## The data

The 1986 NMFS is a stratified randora sample consisting of 18,733 deaths in 1986 of U.S. residents 25
years of age and over. These deaths constitute approximately 1 percent of all resident deaths in the United States. The next of kin or others familiar with the decedent's lifestyle were asked to provide the following information: use of medical and other care facilities in the decedent's last year of life, sources of medical care payment, impairments in daily activities, medical conditions, health practices and behaviors, social and economic characteristics, and the identity of all health facilities in which the decedent stayed overnight during the last year of life.

The 1986 NMFS includes data on 1,121 persons who died from cerebrovascular diseases and 17,612 who died from other causes. The sample deaths represent an estimated 149,699 deaths from stroke and an estimated $1,837,168$ deaths from all other causes. All estimates in this report are national estimates for deaths in 1986 of adults 25 years of age and over. Brief descriptions of the study and the analytic methods used are in the technical notes.

U.S. DEPARTMENT OF HEALTH AND HUMAN SERVICES

Public Health Service

## Social, demographic, and economic characteristics

## Age, sex, and race

Most people who died from stroke were over the age of 75 (table 1). Only 13 percent of stroke deaths were to persons under 65 years of age, while approximately 69 percent were to persons aged 75 years and over. This contrasts sharply with deaths from all other causes: Approximately 27 percent of other deaths, or about two times the proportion for cerebrovascular deaths, were to persons under 65 years of age. An estimated 48 percent of deaths due to other causes incolved persons 75 years of age and over.

Women accounted for a larger proportion of deaths from stroke than men did: an estimated 89,996 ( 60 percent) for cerebrovascular deaths and 867,124 (47 percent) for deaths from other causes. The differences in age distribution by cause of death noted above apply to both males and females, however.

More than 80 percent of all deaths were to persons of races other than black. An estimated 16,694 (11.2 percent) of the cerebrovascular deaths were to persons who were black, in addition to 211,309 of the deaths from other causes
(11.5 percent). Comparison of the age distribution of deaths by cause of death shows that the distributions for decedents of races other than black are similar to those for all persons combined: that is, larger proportions of cerebrovascular than of other deaths involved older persons. For deaths of black persons, however, the only significant differences in age distribution by cause of death were at ages $25-54$ years and at ages 85 and over. Compared with all other causes of death. a smaller proportion of stroke deaths involved persons aged 25-54, while a larger proportion of stroke deaths involved persons aged 85 and over.

## Marital status

Regardless of cause of death. more than 90 percent of adults dying

Figure 1. Percent distribution of deaths from cerebrovascular diseases and all other causest, by marital status: United States, 1986
in 1986 had been married at some point in their life (figure 1). However, there were differences in current marital status by cause of death. The largest proportion of persons who died from stroke were widowed at the time of death, but the largest proportion of persons who died from other causes were married ( 47 percent and 46 percent, respectively). A somewhat smaller proportion of persons who died from stroke than from other causes had never been married, but there was no significant difference by cause of death in the proportion of decedents who were divorced or separated (table 2).

Regardless of cause of death, female decedents were about three times more likely to be widowed at the time of death than were their male counterparts, and they were only about one-third as likely to be currently married. For persons dying from stroke, there were no significant differences by sex in the proportion of decedents who were divorced, separated, or never married. The proportion of men divorced, separated, or never married at the time of death was slightly larger than that for women for persons dying from all other causes.

Compared with women dying of other causes, female decedents who died of stroke were somewhat less likely to be married at the time of
death, but there were no significant differences in other marital status categories for women. Compared with men who died from other causes, males who died of cerebrovascular diseases were somewhat less likely to have never been married.

## Education

Most adults who died in 1986 were reported to have less than a high school education (table 3). There were no significant differences in level of education by cause of death-with one exception: A slightly larger proportion of persons dying from stroke than of other causes had completed 4 years or more of college.

There were no differences in educational attainment between men and women dying of cerebrovascular diseases. Of persons dying from other causes, men were somewhat less likely ( 62 percent) to have completed high school than were women ( 54 percent). Females who died from other causes were slightly more likely to have finished high school or to have completed 1 to 3 years of college than were men, but they were somewhat less likely to have completed 4 years or more of college.

## Occupation

Information on longest-held occupation was available for approximately 93 percent of male and

Figure 2. Percent distribution of deaths from cerebrovascular diseases and all other causes by longest-held occupation, according to aex: United States, 1986

75 percent of female decedents. For decedents reporting occupation, the largest proportions had worked in technical or sales and in operator occupations (figure 2). Persons who died of stroke were slightly less likely to be in a precision production or military occupation and were slightly more likely to be in a farming, fishery, or forestry occupation. Regardless of cause of death, women who had worked in a paid occupation were somewhat more likely to have been in a technical and sales or in a service occupation than were males. Women were less likely than men to have been in a precision production, operator, farm, or armed forces occupation.

## Living arrangements

Regardless of cause of death, most adults dying in 1986 had lived with relatives during the 1985 calendar year. However, there were differences by cause of death in living arrangements during 1985 (figure 3). Compared with persons dying from other causes, a somewhat larger proportion of persons who died from stroke had resided in an institution in 1985. For females, a smaller propor-
tion dying from stroke than from other causes had lived with one or more relatives. Regardless of cause of death, females were at least twice as likely as males to have resided in an institution during 1985. Females were much less likely than their male counterparts to have lived with relatives. There were no significant differences by cause of death in the living arrangements of male decedents. Compared with women dying from other causes, those dying of stroke were nearly two times as likely to have resided in an institution during 1985. Female decedents dying of stroke were somewhat less likely than other female decedents to have resided with relatives during this same period.

## Income and assets

Most decedents in the NMFS had family incomes of less than $\$ 25,000$ in 1985 (figure 4). There was no significant difference by cause of death in the distribution of decedents' income. Regardless of cause of death, larger proportions of female than of male decedents had family incomes under $\$ 5,000$. There were no other significant differences by sex in income
for decedents dying of stroke. For decedents dying from other causes, a larger proportion of males than of females had 1985 incomes of $\$ 9,000$ or more.

There were no differences by cause of death in assets, but there were differences by sex within each cause group (figure 5). For persons dying of stroke, a larger proportion of male than of female decedents had assets of $\$ 25,000-\$ 49,999$ at death. For those dying from other causes, a larger proportion of male than of female decedents had assets of $\$ 5.000$ or more.

## Health care use and source of payment

Most adults who died in 1986 had seen a physician five times or more in the year prior to death (table 4). Persons dying from stroke were more likely than were persons dying from other causes to have no physician visits or 1-4 visits. There were no differences in the number of physician visits between male and female decedents who died from stroke. For those dying from other causes, female decedents were less likely than male

Figure 3. Percant diatribution of deaths from cerabrovascular diaeasea and all other causes by fing arrangements in 1985, according to sex: United States, 1986

Figure 4. Percent distribution of deaths from cerebrovascular diaeases and all other causes by 1985 famity income, according to sex: United States, 1986

Figure 5. Percent distribution of deathe from cerebrovascular diseases and al other causes by total value of assets at death, according to sex: United States, 1986
decedents to have had fewer than five visits to a physician during the last year of life.

Medicare was reported as the primary source of payment for health care in the last year of life for the largest proportion of decedents, regardless of the cause of death (table 5). Self or family was reported as the primary source of health care payment for a somewhat larger proportion of persons dying from stroke than from other causes. Coverage by a health maintenance organization (HMO) or private insurance was reported more often for those dying from other causes than for those dying of stroke. There were few differences in primary source of payment by cause of death within each of the sex categories. Males who died from stroke were somewhat more likely than those dying from other causes to have had Medicare as their primary source of health care payment, and they were less likely to have had an HMO or private insurance as their primary payment source. Females who died from stroke were somewhat less likely than were other female decedents to have had an HMO or private insurance as their
primary source of health care payment.

Most adults who died in 1986 had spent less than $\$ 2,000$ of their own money for health care in the last year of life, but approximately one-fifth had spent $\$ 5,000$ or more (table 6). There was little difference by cause of death in the amount of the decedents' own money spent for care. Persons dying from stroke were somewhat more likely than other decedents to have spent $\$ 5,000$ or more of their own money for care. Regardless of cause of death, female decedents were somewhat more likely than male decedents to have spent $\$ 5,000$ or more of their own funds for health care.

## Health status and risk factors for cerebrovascular diseases

Assistance in activities of daily living or in home medical care was not received by a majority of persons who died in 1986 (table 7). Of those who received help, larger numbers were assisted by family only than by unrelated persons or by a combination of relatives and nonrelatives. For both sexes combined, there were no
significant differences by cause of death in the proportion who received help in daily activities or medical care. There were few differences by sex in the proportion of those dying from stroke who received help, and there were also few differences berween the sexes in the relationship of the caregiver(s) to the decedent. For persons dying from other causes, males were somewhat less likely than females to receive help in daily activities or home medical care.

In addition to cerebrovascular diseases, many of the decedents had other serious health problems (figure 6). Compared with all other causes of death, a larger proportion oi persons dying from stroke hud high blood pressure. Persons dying from other causes were more likey to have had one or more heart attacks. asthma, or other lung conditions.

There was little differenca by sex in the type of other health problems for persons dying of stroke. However. males dying from cerebrovascular diseases were more than twice as likely as females to have had other lung conditions. There were no significant differences in other health conditions by sex for decedents who

Figure 6. Percent cistribution of deathe from cerebrovascubar diseasea and all other casses, by prosence of setected bealth conditions: United States, 1986
were black, but decedents who were not black showed the same pattern of a higher proportion of males than of females with other lung conditions.

For persons dying from other causes, a larger proportion of females than of males had high blood pressure, diabetes, or cancer. Smaller proportions of male than of female decedents had experienced one or more heart attacks or had lung conditions other than asthma. This pattern generally applied to black decedents as well as to those who were not black.

Cigarette smoking is another known risk factor for cerebrovascular diseases. Use of cigarettes and length of time the decedent smoked are shown in table 8. An estimated 827,899 ( 45 percent) of the decedents were reported never to have smoked cigarettes. The majority of decedents 25 years of age and over who were reported to have smoked cigarettes had done so for 20 years or more. For all decedents 25 years of age and over, there were differences in smoking status between those dying from stroke and those dying from other causes. Persons dying from stroke were somewhat less likely than those dying from all other causes to have smoked cigarettes. Of those who smoked, sightly smaller proportions of decedents dying from stroke than from
all other causes had smoked for 20 years or more. When the decedent's age was held constant, there were no significant differences in smoking behavior by cause of death for those aged $25-74$ years. At age 75 and over a somewhat smaller proportion of persons dying from stroke than from all other causes had smoked for 20 years or more.

## Summary

The 1,121 persons sampled in the NMFS who died of cerebrovascular diseases represent an estimated 149,699 such deaths, or approximately 7 percent of all persons 25 years of age and over who died in the United States during 1986. Persons who died of stroke tended to be older than those dying of all other causes, and more of them were female. Partly because of their age and sex, adults dying from stroke were more likely than others to be widowed at the time of death and to have resided in an institution during the year prior to death. A larger proportion of decedents dying from stroke than from all other causes were reported to have hypertension, a known risk factor for cerebrovascular disease.

More detailed information from the 1986 NMFS and comparisons of other major causes of death will be
found in subsequent publications from the National Center for Health Statistics (NCHS).

* Figure suppressed to comply with confidentiality requirements

## Technical notes

## Sources of data and sample design

The NMFS sample was selected from the Current Mortality Sample (CMS). The CMS is a systematic 10-percent sample of death certificates received each month in the vital statistics offices of the 50 States, the District of Columbia, and the independent registration area of New York City (4). Although part of the CMS, Oregon was not included in the 1986 NMFS because of respondent consent requirements. Thus, the estimates in this report are representative of deaths in the United States excluding Oregon. Oregon accounts for about 1 percent of all deaths in the United States.

Oversampling of death certificates by race and age permitted the study of race differentials in mortality and yielded the characteristics of persons who died at younger ages. Deaths for persons under 55 years of age were oversampled 3.1 times and deaths for black persons were oversampled 2.9 times. In addition, approximately 2,500 deaths were selected with certainty to permit special studies of certain causes of death or populations. Deaths selected with certainty from the CMS included all women $25-54$ years of age and all men 35-64 years of age who died from ischemic heart disease; all deaths of American Indians, Aleuts, and Eskimos; all deaths from asthma; and all deaths from certain rare cancers (nasopharynx, liver, male breast, lip and oral, nasal, small intestine, and other endocrine cancers). Death certificates in the CMS that were eligible for the 1986 NMFS were sequentially assigned to one of 18 sampling strata. The strata formation was based on the decedents' age, sex, race, and cause of death.

The 1986 NMFS data were obtained through questionnaires mailed to the next of kin or other person listed on the death certificate as providing the personal information on the decedent's death certificate. Questionnaires were mailed by the U.S. Bureau of the Census about 6
months after death occurred. A reminder letter was mailed 10 days after the first mailing, followed by a second mailing 1 month after the initial mailing. Telephone or personal visits were made by Census Bureau interviewers to nonrespondents 1 month after the second mailing.

The overall response rate for the survey was 89 percent, yielding 16,589 completed questionnaires. Eighty-two percent of the respondents who completed the NMFS questionnaire were close relatives of the decedentspouses, parents, siblings, or adult children-and another 12 percent were more distant relatives. Only 6 percent of the respondents were unrelated to the decedent.

Information for each decedent on the underlying cause of death and all other causes contributing to the death was obtained from the Mortality Vital Statistics Multiple Cause-of-Death Statistical File compiled by NCHS. Records from this multiple cause-ofdeath file were matched to the data from the NMFS informant questionnaire for each decedent in the survey. The overall match rate was 99.9 percent.

## Estimation procedures

Statistics produced from the NMFS are derived by a complex estimating procedure. The estimating procedure used to produce essentially unbiased national estimates from the NMFS has three principal components: inflation by reciprocals of the probabilities of sample selection, adjustment for nonresponse, and a ratio adjustment to fixed totals. The ratio adjustment factors make NMFS estimates of decedents in 18 age-racesex categories equal to the number of resident deaths in 1986 for the United States, excluding Oregon. Although the final weights applied to the NMFS adjust for differential sampling by race, sex, and age, no adjustment was made for cause of death. Hence, NMFS counts of death by cause will not necessarily equal counts obtained from the vital statistics file.

## Sampling errors

Because the estimates for this report are based on a sample, they may differ from figures that would have been obtained had a complete census been taken using the same schedules, instructions, and procedures. The standard error is primarily a measure of the variability that occurs by chance because only a sample, rather than the entire population, is surveyed. The standard error also reflects part of the measurement error, but it does not measure any systematic biases in the data. The chances are 95 in 100 that an estimate from the sample differs by less than twice the standard error from the value that would be obtained from a complete census.

The standard errors used in this report were approximated using the balanced-repeated-replication procedure. This method yields the overall variability through observation of variability among random subsamples of the total sample. A description of the development and evaluation of the replication technique for error estimation has been published (5).

It would be impracticable to present exact standard error estimates for all statistics used in this report. Thus, a generalized variance function was produced for aggregated estimates by fitting the data into 18 curves corresponding to the strata using the empirically determined relationship between the size of an estimate $X$ and its relative variance ( $\operatorname{rel} \operatorname{var} X$ ). This relationship is expressed as

$$
\begin{aligned}
\operatorname{rel} \operatorname{var} X & =\frac{\mathrm{S}_{x}^{2}}{X^{2}} \\
& =a+\frac{b}{x}
\end{aligned}
$$

where $a$ and $b$ are regression estimates determined by an iterative procedure. These regression estimates are presented in table $I$.

Table l. Parameters used to approximate the relative standard errors for estimates based on the 1986 National Mortality Followback Survey, by domain of study

| Domain of study | Parameters |  |

In this report, the determination of statistical inference is based on testing differences between two statistics. The standard error of a difference between two statistics is approximately the square root of the sum of the squares of the standard errors of the individual statistics. This formulation of the standard error of the difference of two statistics quite accurately approximates the standard error for the difference between two uncorrelated statistics; however, it only roughly approximates the standard error in most other cases.

Although the exact number of degrees of freedom in the NMFS sampling variance is not known, the number of degrees of freedom may be approximated by the number of pseudostrata used in the balanced-repeated-replication procedure (6). Accordingly, hypotheses about differences between estimates are tested using 18 degrees of freedom for the two-tailed $t$-tests. Terms relating to differences such as "higher" and "less" indicate that the differences are statistically significant at the 0.05 level. Terms such as "similar" and "no difference" mean that no statistically significant difference exists between
the estimates being compared. A lack of comment on the difference between any two estimates does not mean that the difference was tested and found to be not significant.

## Rounding of numbers and percents

Numbers and percents within the tables and text were rounded to the nearest whole number or tenth of a percent. Therefore, the estimates may not add to the totals. In addition, the total estimated number of decedents varies from one table to another because of the exclusion of decedents with "no answer" responses.

NOTE: Nine other Federal agencies signed interagency agreements with NCHS to cosponsor the 1986 NMFS. These agencies are the National Heart, Lung, and Blood Institute; the National Institute of Child Health and Human Development; the National Cancer Institute; the National Institute of Aging, the National Institute of Mental Health; the Health Care Financing Administration; the U.S. Department of Veterans Affairs; the Indian Health Service; and the Office of the Secretary for Planning and Evaluation in the Department of Health and Human Services.

## Vital and Health Statistics series descriptions

SERIES 1. Programs and Collection Procedures-These reports describe the data collection programs of the National Center for Health Statistics. They include descriptions of the methods used to collect and process the data, definitions, and other material necessary for understanding the data.
SERIES 2. Data Evaluation and Methods Research-These reports are studies of new statistical methods and include analytical techniques, objective evaluations of reliability of collected data, and contributions to statistical theory. These studies also include experimental tests of new survey methods and comparisons of U.S. methodology with those of other countries.

SERIES 3. Analytical and Epidemiological Studies-These reports present analytical or interpretive studies based on vital and health statistics. These reports carry the analyses further than the expository types of reports in the other series.
SERIES 4. Documents and Committee Reports-These are final reports of major committees concerned with vital and health statistics and documents such as recommended model vital registration laws and revised birth and death certificates.
SERIES 5. International Vital and Health Statistics Reports-These reports are analytical or descriptive reports that compare U.S. vital and health statistics with those of other countries or present other international data of relevance to the health statistics system of the United States.

SERIES 6. Cognition and Survey Measurement-These reports are from the National Laboratory for Collaborative Research in Cognition and Survey Measurement. They use methods of cognitive science to design, evaluate, and test survey instruments.
SERIES 10. Data From the National Health Interview Survey-These reports contain statistics on illness; unintentional injuries; disability; use of hospital, medical, and other health services; and a wide range of special current health topics covering many aspects of health behaviors, health status, and health care utilization. They are based on data collected in a continuing national household interview survey.
SERIES 11. Data From the National Health Examination Survey, the National Health and Nutrition Examination Surveys, and the Hispanic Health and Nutrition Examination SurveyData from direct examination, testing, and measurement on representative samples of the civilian noninstitutionalized population provide the basis for (1) medically defined total prevalence of specific diseases or conditions in the United States and the distributions of the population with respect to physical, physiological, and psychological characteristics, and (2) analyses of trends and relationships among various measurements and between survey periods.
SERIES 12. Data From the Institutionalized Population SurveysDiscontinued in 1975. Reports from these surveys are included in Series 13.

SERIES 13. Data From the National Health Care Survey-These reports contain statistics on health resources and the public's use of health care resources including ambulatory, hospital, and long-term care services based on data collected directly from health care providers and provider records.

SERIES 14. Data on Health Resources: Manpower and FacilitiesDiscontinued in 1990. Reports on the numbers, geographic distribution, and characteristics of health resources are now included in Series 13.

SERIES 15. Data From Special Surveys-These reports contain statistics on health and health-related topics collected in special surveys that are not part of the continuing data systems of the National Center for Health Statistics.

SERIES 16. Compilations of Advance Data From Vital and Health Statistics-Advance Data Reports provide early release of information from the National Center for Health Statistics' health and demographic surveys. They are compiled in the order in which they are published. Some of these releases may be followed by detailed reports in Series 10-13.

SERIES 20. Data on Mortality-These reports contain statistics on mortality that are not included in regular, annual, or monthly reports. Special analyses by cause of death, age, other demographic variables, and geographic and trend analyses are included.
SERIES 21. Data on Natality, Marriage, and Divorce-These reports contain statistics on natality, marriage, and divorce that are not included in regular, annual, or monthly reports. Special analyses by health and demographic variables and geographic and trend analyses are included.

SERIES 22. Data From the National Mortality and Natality SurveysDiscontinued in 1975. Reports from these sample surveys, based on vital records, are now published in Series 20 or 21.
SERIES 23. Data From the National Survey of Family GrowthThese reports contain statistics on factors that affect birth rates, including contraception, infertility, cohabitation, marriage, divorce, and remarriage; adoption; use of medical care for family planning and infertility; and related maternal and infant health topics. These statistics are based on national surveys of childbearing age.

SERIES 24. Compilations of Data on Natality, Mortality, Marriage, Divorce, and Induced Terminations of PregnancyThese include advance reports of births, deaths, marriages, and divorces based on final data from the National Vital Statistics System that were published as supplements to the Monthly Vital Statistics Report (MVSR). These reports provide highlights and summaries of detailed data subsequently published in Vital Statistics of the United States. Other supplements to the MVSR published here provide selected findings based on final data from the National Vital Statistics System and may be followed by detailed reports in Series 20 or 21.
