# Recent Trends in Adolescent Smoking, Smoking-Uptake Correlates, and Expectations About the Future 

by Abigail J. Moss and Karen F. Allen, M.B.A., Division of Health Interview Statistics, National Center for Health
Statistics, and Gary A. Giovino, Ph.D., Office on Smoking and Health, Centers for Disease Control and Prevention, and Sherry L. Mills, M.D., M.P.H., National Cancer Institute, National Institutes of Health

## Highlights

In 1989, the National Center for Health Statistics (NCHS) conducted the National Health Interview Survey (NHIS) on Teenage Attitudes and Practices (TAPS), a national survey of adolescents interviewed about their use of tobacco. Among the findings are the following highlights:

- About 1.7 million youths had smoked a whole cigarette before their 12th birthday. An estimated 3.7 million U.S. teenagers (16 percent) were current cigarette smokers. An additional 6.8 million teenagers ( 29 percent) had experimented with cigarettes.
- Among 16-18-year-olds, about 60 percent were either currently smoking ( 25 percent) or had experimented with cigarettes (34 percent). About the same proportions of boys and girls reported that they currently smoked.
- Proportionately more black teenagers ( 63 percent) than white teenagers ( 52 percent) said that they had never smoked.
- Teenagers were three times more likely to smoke ( 37 percent) if their parents and at least one older sibling smoked than if no one in the household smoked (12 percent).
- Teenagers with no best friencis of the same sex who smoked seldom smoked (about 3 percent). However, almost half of those with at least two best friends who smoked were smokers themseives.
- About 40 percent of teenagers who smoked reported using cigarettes daily. Proportionately, twice as many white teenage smokers smoked every day (42 percent) as did black adolescent smokers ( 22 percent). About one in five $16-18$-year-olds who smoked averaged at least 20 cigarettes per day.
- About three teenagers in four who were current smokers (2.: million adolescents) had made at least one serious attempt to quit smoking cigarettes. Ninety-two percent of all adolescents did not expect to be smoking 1 year later.

## Background

Over the past 25 years, cigarette smoking practices of U.S. adolescents have undergone a number of marked changes. In 1968, 17 percent of teenage boys and 10 percent of teenage girls 12-18 years of age reported smoking cigarettes regularly or occasionally (1). In 1974, while the proportion of boys who smoked remained virtually unchanged (16.3 percent), there was about a 60 -percent increase in the proportion of teenage girls who smoked (15.9 percent). That year marked the first time the percentages of girls and boys who smoked were about the same. Between 1974 and 1979, a decrease in cigarette smoking rates was observed among both sexes, but, because the rate of decline was greater among teenage boys, the percent of girls who smoked actually exceeded that of boys ( 13 percent compared with 11 percent) (2-5). Throughout most of the 1980's, the percentages of teenagers who smoked remained fairly stable, though, according to some surveys, more

teenage girls smoked than did teenage boys. It now appears, however, that teenage smoking levels are similar for both sexes $(6,7)$.

Even with the vast body of information now available regarding the adverse effects of cigarette smoking and recent efforts to encourage smokers to quit and young people not to start, cigarette smoking continues to appeal to millions of teenagers. In fact, teenagers are beginning to smoke at younger ages, with the age of initiation decreasing especially among girls (6). Furthermore, teenage smoking tends to establish habits leading to subsequent adult addiction, which, in turn, often leads to significant morbidity and premature death.

This report contains estimates of adolescent tobacco-use patterns derived from the National Center for Health Statistics' 1989 Teenage Attitudes and Practices Survey (TAPS).

## Data and Methods

In 1989, the National Center for Health Statistics (NCHS), in collaboration with the Centers for Disease Control Office on Smoking and Health (OSH) and the National Cancer Institute (NCI) and as part of its National Health Interview Survey (NHIS), conducted the Teenage Attitudes and Practices Survey (TAPS). The TAPS was conducted to provide national household-based smoking data on teenagers between the ages of 12 and 18 . In addition to providing updated and detailed estimates of adolescent smoking practices, the TAPS also was designed to provide a data base for collecting longitudinal data on future smoking behaviors of TAPS adolescents.

Prior to the TAPS, the last national household-based survey focused primarily on teenage smoking practices was conducted in 1979 by telephone by Chilton Research Services for the U.S. Department of Health, Education, and Welfare (1). More recent national estimates of teenage smokers are available from school-based sureys from the

National Institute on Drug Abuse (NIDA) (University of Michigan 1991 Monitoring the Future Project) and the Youth Risk Behavior Surveys (YRBS) $(7,8)$. These estimates excluded high school dropouts and teenagers with high absentee records, two population groups at greatest risk to smoke (9). Further, many details about teenage smoking behavior contained in the TAPS were not included in these surveys.

The TAPS sampling frame consisted of all teenagers between the ages of 12 and 18 (on November 1, 1989) who resided in households interviewed for the NHIS during the last two quarters of 1988 and the first two quarters of 1989. The final TAPS-eligible sample contained 12,097 adolescents. Of that number, 9,965 (about 82 percent) were subsequently interviewed. All figures presented in this report were based upon these sample persons and were weighted to produce national estimates.

Data were primarily collected with computer-assisted telephone interviews (CATI). However, mail questionnaires were also used for those teenagers who could not be reached by telephone (that is, those living in homes without telephones, those with unknown telephone numbers, and those whose telephones were not answered). By necessity, the mail questionnaire represented an abbreviated version of the CATI and did not contain all of the questions asked in the telephone interview.

The technical notes in this report contain more detailed descriptions of the sample design, response rates, data collection procedures employed, and the definitions of certain terms.

Methods for constructing approximate standard errors and tests of significance for estimates and percents presented in this report also appear in these notes. Unless otherwise noted, the comparisons made within the text are significant at the .05 level.

Included in this report are estimates of the number and percent distribution of adolescents in the United States according to their
current smoking practices (table 1). The adolescent smoking status categories used to classify adolescents were: "never smoked" (subdivided by future expectations in regard to smoking, that is, "no intention" or "may smoke"), "experimenter," "former smoker," and "current smoker" (characterized as "heavy," "light," and "occasional"), These categories are described more fully in the technical notes. Tables 2, 3, and 5 contain data that characterized current smokers' past and current smoking practices, including number of days they smoked in the past month; average number of cigarettes smoked per day, per weekday, and per weekend day; and number of quit attempts. Table 4 contains figures on predicted future smoking practices of teenagers (that is, whether or not they reported they expected to be smoking 1 year from the interview). Table 6 includes estimates of ages adolescents reported smoking their first whole cigarette. Table 7 contains estimates for several known correlates of adolescent smoking-uptake behavior, including smoking practices of other household members and best friends of the same sex $(3,4,10-20)$, and participation in organized physical activities $(20,21)$. In table 8, data are presented according to several school-related smoking-uptake correlates, including type of student, attitude toward school, and schoolskipping occurrence (14,20-23). In table 9, estimates are presented for four types of risk-taking behavior $(24,25)$ : fighting in the past year, riding a motorcycle or minibike, riding with a drunk driver or someone on drugs, and enjoyment of risktaking activities. Data on several measurements of smoking knowledge and beliefs are presented in table 10.

## Findings

## Prevalence of teenage smokers

Table 1 contains estimates of the number and percent distribution of adolescents in the United States according to their current smoking practices. These estimates are shown
by the following demographic and socioeconomic indicators: sex, age, race, Hispanic origin, family income, poverty status, highest level of education attained by family, geographic region, and place of residence. Results from the Teenage Attitudes and Practices Survey (TAPS), as stated earlier, were representative of all U.S. teenagers 12-18 years of age.

In 1989, an estimated 3.7 million teenagers ( 16 percent) were current cigarette smokers (table 1). About the same proportions of boys and girls reported that they currently smoked. This trend was noted regardless of age. For the TAPS, a "current" smoker was defined as someone who smoked any time within 30 days of the date of the interview. An additional 6.8 million teenagers ( 29 percent) had experimented with cigarettes. "Experimenters" included teenagers who had ever tried cigarette smoking but had smoked fewer than 100 cigarettes and had not smoked any cigarettes in the past 30 days. While only 4 percent of 12 - and 13 -year-olds were current smokers, an additional 21 percent of adolescents at those ages reported having experimented with cigarettes. Among 16-18-year-olds, about 60 percent were either currently smoking ( 25 percent) or had experimented with cigarettes ( 34 percent).

Experimentation with cigarettes among adolescents appears to have occurred with about the same frequency, regardless of gender, race, or ethnicity. However, among the youngest adolescents, more boys reported experimenting with cigarettes than did girls ( 24 percent, compared with 18 percent).

Proportionately more black teenagers ( 63 percent) than white teenagers ( 52 percent) reported that they never smoked at all. Teenagers of Hispanic origin were also somewhat more likely never to have smoked ( 57 percent) than were non-Hispanic adolescents ( 53 percent) ( 0.10 level of significance).

Among the youngest group of teenage smokers, only about one out
of seven was classified as a heavy smoker. By $16-18$ years of age, half of all teenagers who smoked were heavy smokers. A "heavy" smoker, by the TAPS's definition, was someone who had smoked at least 10 days in the past month and averaged 5 or more cigarettes daily during the past 7 days. Differences were also noted in smoking levels of teenage boys and girls, particularly among older teenagers. Overall, a somewhat higher proportion of teenage boys who smoked were heavy smokers (47 percent, compared with 40 percent of girls who smoked). Among smokers $16-18$ years of age, 55 percent of male smokers and 46 percent of female smokers met the TAPS heavy-smoker criteria.

## Smoking practices of current teenage smokers

Table 2 provides details about the teenage smoking practices of current smokers, measured by the number of days smoked in the past month and the average number of cigarettes smoked daily. Distributions of cigarette smoking behavior on weekdays and weekend days are presented in table 3. Estimates in tables 2 and 3 are shown by age, sex, race, and Hispanic origin.

Similar proportions of teenage male and female smokers smoked on about the same number of days a month, but females reported smoking fewer cigarettes on the days that they did smoke (table 2).

About 40 percent of teenagers who smoked reported using cigarettes daily. Daily cigarette smoking was directly proportional to the age of the smoker, from 17 percent among 12 and 13 -year-olds to 48 percent of those $16-18$ years of age. Proportionately, about twice as many white teenage smokers smoked every day as did black teenagers (42 percent, compared with 22 percent). Hispanic youths who smoked were also less likely to be daily smokers ( 26 percent).

As with daily cigarette consumption, the average number of cigarettes smoked by teenagers also increased with age. Proportionately,
about twice as many smokers 12 and 13 years of age averaged fewer than five cigarettes a day as did those between the ages of 16 and 18 ( 64 percent, compared with 32 percent). No teenagers in the youngest age group averaged 20 cigarettes or more a day, but about 1 in 5 teenagers $16-18$ years of age who smoked reported smoking at this level.

Among the youngest smokers, boys and girls smoked at similar levels: about 90 percent of each gender averaged fewer than 10 cigarettes daily on the days they did smoke. However, older adolescent girls who smoked consumed fewer cigarettes on the days they did smoke than did their male counterparts. For example, whereas about one-fourth of male 16 -18-year-olds who smoked averaged 20 cigarettes or more a day, only about 15 percent of females $16-18$ years old reported smoking at this level.

In patterns similar to those seen in adults, black adolescents smoked on fewer days and averaged fewer cigarettes per day than did white adolescent smokers. Proportionately, about twice as many white teenage smokers smoked every day (42 percent) as did black adolescent smokers (22 percent). About half of black female adolescent smokers reported using cigarettes from 1 to 4 days in the past month compared with 23 percent of white female teenagers. Similarly, Hispanic youths also smoked less often and smoked fewer cigarettes on average than did non-Hispanic teenagers who smoked. Almost 60 percent of Hispanic adolescent smokers averaged fewer than five cigarettes a day, compared with about 36 percent of non-Hispanic teenage smokers who reported smoking fewer than five cigarettes a day.

Overall, teenage smokers appear to smoke slightly more on weekend days than on weekdays: 20 percent reported smoking 20 cigarettes or more per weekend day, compared with 16 percent for weekdays (table 3). However, on average, only slight variations are seen between the
estimates presented in this table for teenagers' weekday smoking levels and those for weekends, and some of the observed differences may be due to sampling variation.

## Expected smoking behavior and quit attempts

When adolescents were asked whether they thought they would be smoking 1 year later, 92 percent answered "no" (table 4). Among current smokers, proportionately twice as many adolescents 16-18 years of age predicted future smoking (45 percent) as did adolescents 12-13 years of age ( 20 percent). Black teenagers who currently smoked were more optimistic about smoking cessation than were their white counterparts ( 24 percent and 45 percent, respectively, predicted smoking the next year).

There was also a direct relationship between the percent of smokers expecting still to be smoking in 1 year and the amount currently smoked. Only 16 percent of "occasional" smokers (those who had smoked 1-9 days in the previous 30 days) predicted smoking 1 year later. However, 46 percent of "light" smokers and 66 percent of "heavy" smokers said they would be still smoking in 1 year. For the TAPS definition, both light and heavy smokers had smoked 10 or more days in the previous 30 days; however, light smokers averaged fewer than 5 cigarettes daily in the past week, and heavy smokers averaged 5 cigarettes or more a day. Less than 1 percent of teenagers who had never smoked predicted becoming a smoker within the year.

Table 5 contains estimates of unsuccessful attempts to quit smoking among current adolescent smokers, classified by age, sex, race, and Hispanic origin. About three teenagers in four who currently smoked ( 2.7 million adolescents) had made at least one serious attempt to quit smoking cigarettes. For more than half of these teenagers, the attempt(s) took place in the 6 months preceding the TAPS interview. Furthermore. regardless of age, sex,
or race, estimates revealed that the adolescent smokers who had tried to quit outnumbered those who had not, ranging from 66 percent of black male smokers to 84 percent of 12 and 13 -year-old boys who smoked.

The percent of teenage smokers who made at least one attempt to quit smoking in the previous 6 months decreased from 73 percent of 12 - and 13 -year-olds to 52 percent of 16-18-year-olds. Similarly, proportionately fewer teenagers $16-18$ years of age reported ever attempting to quit ( 73 percent, compared with 82 percent of youngest smokers).

## Smoking initiation

Table 6 presents estimates of adolescents' reported ages for smoking their first whole cigarette by age, sex, race, and Hispanic origin. About 1.7 million youths had smoked a whole cigarette before their 12th birthday. Boys were somewhat more likely to have smoked their first whole cigarette at a younger age. By the age of 14 , however, gender differences had disappeared.

While similar proportions of black, white, and Hispanic adolescent girls reported first smoking at a given age, white and non-Hispanic male adolescent smokers tended to smoke their first cigarette somewhat earlier than did their black and Hispanic male counterparts. For example, 44 percent of white male adolescent smokers between 16 and 18 years of age had smoked by age 13, compared with about 31 percent of black males. Similarly, Hispanic boys were more likely to have had their first whole cigarette at an older age than were non-Hispanic boys. Of teenagers 16-18 years of age, 32 percent of Hispanic males had smoked by 12 years of age, compared with 43 percent of non-Hispanic males.

## Correlates of smoking uptake

Tables 7-9 present estimates of adolescents' current and expected smoking behavior, according to variables that appear to be associated with teenage smoking practices. Estimates for all of the measures in
tables 7-9 described above are shown by age and sex.

Adolescents living in households where no one smoked were the least likely to smoke (table 7). Among this group, about 61 percent of teenagers had never smoked, and only 12 percent currently smoked. Teenagers were three times more likely to smoke ( 37 percent) if their parents and at least one older sibling smoked than if no one in the household smoked (12 percent).

The smoking practices of older brothers or sisters living at home were more closely associated with teenager smoking than was parental smoking. Thirty percent of adolescents reported currently smoking in homes where only older siblings smoked, compared with 15 percent of teenagers from homes where only their parents smoked.

The TAPS included a question to determine the number of best friends of the same sex who smoked. As expected, the smoking patterns for both teenage boys and girls were highly correlated with the smoking practices of their closest friends. Teenagers with no best friends of the same sex who smoked seldom smoked (about 3 percent). However, almost half of adolescents with at least two best friends who smoked were smokers themselves.

The relationship adolescents had with their parents, as measured by whether teenagers talked to them about serious problems, was associated with smoking status. Among teenagers who said that they discussed serious problems with their parents, only 11 percent currently smoked. In contrast, proportionately more than twice as many teenagers who confided only with friends-and not with a parent, other relative, or another adult-were smokers ( 23 percent).

Another correlate of adolescent smoking is the level of involvement in organized activities, including athletics $(20,21)$. Proportionately, almost twice as many teenagers who did not participate in organized team sports currently smoked (21 percent) as did teenagers involved in
competitive sports activities
(12 percent). Involvement in sports was not found to be a determining factor, however, for young adolescents.

Dramatic differences in teenage smoking practices were also found among adolescents through selfreported school performance ratings and attitudes toward school. Of adolescents who classified themselves as "above average" students, only 10 percent currently smoked; in contrast, 44 percent of "below average" students smoked (table 8). Similarly, proportionately about three times as many adolescents who reported not liking school very much were current smokers ( 35 percent) as were teenagers who said that they liked school a lot (11 percent).

There also appeared to be a direct relationship between the number of unsupervised hours adolescents were left at home before and after school and their current smoking behavior. About twice as many teenagers who were left alone for 15 hours or more a week currently smoked as teenagers who were never without adult supervision ( 18 percent, compared with 8 percent).

Several data items were obtained in the TAPS to identify adolescents who might be considered prone to problems. Two items of this type are shown in this report: skipping any full days from school in the previous 2 weeks and physical fighting in the previous year with someone other than a family member. Adolescents who participated in certain kinds of risk-taking behavior were identified in the TAPS, and data for three of these items are also shown: whether they had ridden a motorcycle or minibike in the previous year, if they had ridden with a driver in the past month who had used alcohol or drugs, and if they agreed that "I get a kick out of doing things every now and then that are a little risky or dangerous."

Proportionately, about twice as many adolescents who skipped school were current smokers ( 38 percent) as youths who had not (17 percent). This 2-to-1 ratio was also found for 3
of the 4 risk-taking behaviors mentioned previously. That is, compared with other teenagers, proportionately about twice as many youths who smoked had been in fights, had ridden a motorcycle or minibike, or enjoyed risky activities now and then (table 9). For the fourth measure, proportionately, more than three times as many teenagers who had ridden with a driver who used alcohol or drugs currently smoked (43 percent) as teenagers who did not report this activity ( 12 percent).

## Smoking knowledge and beliefs

The TAPS questionnaire contained a series of questions to assess teenagers' knowledge and beliefs about cigarette addiction, health risks associated with cigarettes, and perceived benefits from smoking. Table 10 contains data for a few of these indicators by age and sex.

The TAPS interview ascertained whether teenagers had ever taken a class or course at school in which the health risks of smoking were discussed. About the same proportion of teenagers who said they had taken a course of this type were currently smoking as were teenagers who had not taken a class where health risks were discussed.

Similarly, TAPS polled teenagers about recent media exposurethrough television, radio, newspapers, or magazines - to information on the health risks of smoking, and the findings parallel those of classroom exposure. Among teenagers the percentage of smokers was the same regardless of whether they had recently seen, heard, or read materials about the adverse effects of smoking ( 16 percent).

While similarities in teenage smoking practices were found regardless of their reported exposure to information on the health risks associated with cigarette smoking, teenagers' perception of derived benefits and some common myths about smoking reveal substantial differences in smoking behavior. These findings were illustrated by the following three TAPS statements with
which respondents agreed or disagreed: 1) "it's safe to smoke for 1 or 2 years," 2) "cigarettes help people relax," and 3) "smoking helps keep weight down."

Teenagers who assigned positive attributes to cigarettes were 2-4 times more likely to be smokers as were other adolescents. For example, about one-third of adolescents who said that cigarettes help people relax were smokers. In contrast, of teenagers who disagreed with this statement, only 9 percent smoked. Among those who said it was safe to smoke for 1 or 2 years, almost half ( 46 percent) smoked, compared with 13 percent of the teenagers who did not agree with this statement.

## Discussion

Even infrequent experimentation with cigarette smoking among adolescents has been found to increase the likelihood of becoming a smoker in adulthood by a factor of 16, compared with adolescents who had never tried smoking (26). According to the Teenage Attitudes and Practices Survey (TAPS), experimentation with cigarettes occurred with about the same frequency among adolescents regardless of gender, race, or ethnicity. However, among the youngest adolescents interviewed, more boys reported experimenting with cigarettes than did girls, a finding that was reported in another study (10). The TAPS results also showed that about the same proportions of boys and girls in each age group reported that they currently smoked, and these findings were similar to those of other recent national and smaller surveys.

With levels of morbidity and mortality as criteria, cigarette smoking has been called the most serious and widespread form of addiction in the world (27). One way to observe the habit-forming properties of cigarette smoking is to compare the smoking levels of preadolescent and older teenage smokers. According to the TAPS, among the youngest group of teenage smokers, only about one out of seven
was a "heavy smoker." By 16-18 years of age, however, half of all teenagers who smoked were "heavy smokers," by the TAPS criteria.

When the smoking habits of teenage smokers were compared with those of adult smokers (that is, frequency of smoking and number of cigarettes smoked), teenage smoking was, by comparison, "light" (28). Even so, about 40 percent of teenagers who smoked reported using cigarettes daily. Daily cigarette smoking was directly proportional to the age of the smoker. As with daily cigarette consumption, the average number of cigarettes smoked by teenagers also increased with age. Whereas virtually no teenagers in the youngest age group averaged 20 cigarettes or more a day, about 1 in 5 smokers $16-18$ years of age reported smoking at these levels. The increases found in the frequency of daily smoking and average numbers of cigarettes smoked daily among teenagers by age group further reflect the addiction known to result from the use of tobacco products over time (6).

The TAPS finding that the vast majority of teenagers ( 92 percent) did not expect to be smoking in 1 year parallels those of other studies conducted in the late 1960's and 1970's in which about 9 out of 10 teenagers did not expect to be cigarette smokers 5 years later (1,5). Given the substantial body of evidence establishing that cigarettes and other forms of tobacco are addictive (6), these expected behaviors about future smoking reveal most adolescent smokers' naivete about difficulties encountered when attempting to quit. Nonetheless, teenagers and adults who smoke are likely to experience similar withdrawal symptoms (29), so cessation is no easier for young smokers than for their older counterparts.

Other studies also have found that the best predictor of adolescents' future smoking was their previous or current smoking behavior ( $11,32,33$ ). The TAPS finding that teenage quit attempts decreased with age
( 73 percent of 12 - and 13 -year-olds had made at least one attempt to quit smoking in the previous 6 months, compared with 52 percent of teenagers $16-18$ years old) may, in part, have reflected a gradual realization that their cessation attempts would be unsuccessful. The TAPS also estimated that only about 342,000 adolescents ( 1.5 percent of U.S. teenagers who ever smoked) had quit successfully. If expected smoking behaviors were to reflect actual future smoking, particularly among teenagers who currently smoked, more than 50 percent of current adolescent smokers would have to have quit.

It is widely recognized that preventing the onset of smoking in adolescence (and early adulthood) is the best means to eliminate smokinginduced illness (32). Furthermore, children who begin to smoke at a young age are more likely to consume more cigarettes daily than those who start later in life (33). Children 4-10 years of age represent the most impressionable age group where appropriately designed and repetitive antismoking campaigns may be especially important (34). Given that the age of smoking initiation has declined over time, particularly among women (6), and that about 1.7 million youths have smoked a whole cigarette before their 12th birthday, these and other TAPS findings support other recent recommendations that antismoking education start before the age of 9 (35).

Consistent with findings from other surveys (6), TAPS results found that, up to the age of 14 , boys were somewhat more likely to smoke their first whole cigarette at an earlier age than were girls. Also, other recent study results were replicated by the TAPS finding that, for the most part, white teenagers were more likely to smoke their first cigarette at an earlier age than were black teenagers (6).

The TAPS also found that black and Hispanic adolescents smoked on fewer days and averaged fewer cigarettes per day than did white and
non-Hispanic adolescent smokers and were more likely never to be smokers. Cigarette advertising campaigns are now targeting these specific minority groups in recognition of this potential "untapped" cigarette-smoking market (36).

The TAPS findings revealed that older adolescent girls who smoked consumed fewer cigarettes on the days they did smoke than did their male counterparts. Another study has suggested that females experience greater social pressures to smoke than do boys but have a higher sensitivity to nicotine, which is resolved by smoking both at lower levels and choosing low nicotine cigarettes (37).

Both current and future smoking practices among teenagers are greatly influenced by the smoking practices of persons with whom these young people are most often in contact: parents, brothers, sisters, and friends ( $3,4,10-20$ ). Findings from previous studies differ somewhat as to which group or combination of groups provides the best predictors of adolescent smoking. However, with few exceptions, studies consistently have found that teen:lgers who smoke are more likely to have friends, siblings, and parents who smoke. The TAPS results parallel these findings. Adolescents who lived in households where no one smoked were the least likely to be smokers themselves. Teenagers were three times more likely to smoke if their parents and at least one older sibling smoked than if no one in the household smoked.

Studies have also found that smoking is positively correlated with the use of alcohol and other drugs, with escalation from cigarettes to alcohol the most prevalent pattern found $(38,39)$. Certain types of risktaking behavior, such as drug and alcohol use, also have been shown to be predictive of smoking uptake $(24,25)$. Findings from a recent study that concluded that problem-prone youths are most likely to smoke (40) were also demonstrated in the TAPS results. Teenage smoking practices varied markedly among adoiescents, based on self-reported school
performance ratings and attitudes toward school. Proportionately, four times as many adolescents who classified themselves as below average students smoked as above average students, those who reported not liking school very much were three times as likely to be current smokers as those who liked school a lot, and twice as many adolescents who skipped school were current smokers as other youths. For three other troublesome behaviors-youths who smoked had been in fights, ridden a motorcycle or minibike, or enjoyed risky activities now and then-this same 2 -to- 1 ratio occurred. Similarly, teenagers who had ridden with a driver who used alcohol or drugs were three times more likely to smoke as were other teenagers.

The TAPS attempted to assess teenagers' knowledge and beliefs about cigarette addiction, health risks associated with cigarettes, and perceived beneficial results from smoking through a series of detailed questions. The TAPS also assessed whether teenagers had ever taken a class or course at school in which the health risks of smoking were discussed or whether they had been exposed recently to the adverse effects of smoking through television, radio, newspapers, or magazines. Unfortunately, the TAPS questionnaire did not obtain details about the school course curriculum or media exposure to enable further analysis of the TAPS result that showed similar estimates of teenage smokers regardless of their exposure to these "smoking education" efforts. Somewhat contradictory results have also been presented in other studies regarding the effectiveness of educational efforts in reducing smoking among youths ( $12,37,38,41$ ).

Other TAPS results showed that teenagers who perceived smoking to be beneficial-helped keep weight down or helped people relax, for example-were 2-4 times more likely to smoke than were adolescents who did not attribute benefits to smoking. Nevertheless, from these and other TAPS findings presented in this report, it appears that continued
educational efforts are still needed to further sensitize teenagers to the health risks associated with smoking.

## Technical notes

## Source and description of data

This report contains data from the 1989 Teenage Attitudes and Practices Survey (TAPS). The TAPS was a targeted population study of U.S. teenagers $12-18$ years of age. The study was conducted by the National Center for Health Statistics' National Health Interview Survey (NHIS) and co-sponsored by the Centers for Disease Control Office on Smoking and Health (OSH) and the National Cancer Institute (NCI).

The TAPS was designed to obtain national household data about current cigarette-smoking behavior and lifetime smoking practices of adolescents and their beliefs about smoking. Selected correlates of smoking uptake were also addressed in the study.

The TAPS sample was derived from NHIS's household interviews conducted during the final two quarters of 1988 and the firs: two quarters of 1989. All teenagers living in housenolds contacted and interviewed during this period that were 12-18 years of age as of November 1, 1989, were included in the sample. The eligible sample for the TAPS was 12,097 persons.

The TAPS utilized two modes of data collection. The primary method consisted of computer-assisted telephone interviewing (CATI) in households where a telephone number was provided during the original NHIS interview. In addition, self-administered questionnaires were mailed to sample teenagers living in households without telephones or an available telephone number. Mail questionnaires were also sent to those teenagers living in households with an original telephone number but who were never reached using the CATI method. Telephone interviews and all other data collection activities were performed by U.S. Bureau of the Census personnel. Data coliection began in August 1989 and, except for late receipt of some mail questionnaires. cnncluded in December 1989.

Unlike the original NHIS interview, all teenagers responded for themselves. However, prior to the initial telephone contact, advance letters were mailed to a responsible related adult and to each eligible teenager in the household explaining the sponsorship and objectives of the upcoming survey and assuring confidentiality.

The total interviewed TAPS sample included 9,965 adolescents, 9.135 from CATI interviews and the remaining 830 cases from completed mail questionnaires. The total combined response rate for the TAPS from these 2 data-collection procedures was 82 percent. Most of the nonresponse resulted from teenagers' failure to return the mail questionnaire. Only 3.7 percent of interviews of adolescents reached by telephone ended in a refusal either because of the parent's or teenager's initial refusal or subsequent termination of the interview. Item nonresponse was less than 1 percent for the questions discussed in this report. More details about nonresponse are available in a recent report (42).

## Sampling errors

Because estimates shown in this report are based on a sample of the population rather than on the entire population, they are subject to sampling error. When an estimate or the numerator or denominator of a percent is small, the sampling error may be relatively high. In addition, the complex sample design of the NHIS has the effect of making the sampling errors larger than they would be had a simple random sample of equal size been used.

The following method for computing sampling errors is presented for the convenience of readers who want a simple method to use in calculating standard errors for estimates in this report. More precise methods, such as that available in the software program SUDAAN (43), which estimates standard errors for complex sample surveys using Taylor linearization, are recommended for detailed analysis of NHIS data.

Approximate standard errors of the estimated numbers $(x)$ in this report (except for age, sex, and race for all teenagers when the standard error is assumed to be 0.0 ) may be calculated using the formula
$\mathrm{SE}(x)=\sqrt{0.0000307(x)^{2}+3,640(x)}$
Except as noted below, approximate standard errors of the estimated percents in this report may be calculated using the formula
$\operatorname{SE}(p)=\sqrt{\frac{3,640(p)(100-p)}{y}}$
where $p$ is the estimated percent and $y$ is the population denominator.

Approximate standard errors for the percents in table 1 by age, sex, and race only and the percents for the "all teenagers" category in table 4 may be calculated by using the formula

$$
\mathrm{SE}(p)=p \sqrt{0.0000307+3,640 / x}
$$

where $p$ is the estimated percent and $x=p y / 100$ with $y=$ the population denominator.

If $x_{1}$ and $x_{2}$ are two estimates, then the approximate standard error of the difference $\left(x_{1}-x_{2}\right)$ can be computed as follows:
$\sqrt{\operatorname{SE}\left(x_{1}\right)^{2}+\operatorname{SE}\left(x_{2}\right)^{2}-2 r \operatorname{SE}\left(x_{1}\right) \operatorname{SE}\left(x_{2}\right)}$
where $\operatorname{SE}\left(x_{1}\right)$ and $\operatorname{SE}\left(x_{2}\right)$ are computed using the appropriate formulas previously presented in this section, and $r$ is the correlation coefficient between $x_{1}$ and $x_{2}$ (assuming $r=0.0$ will result in an accurate standard error if the two estimates are actually uncorrelated and will result in an overestimate of the standard error if the correlation is positive or an underestimate if the correlation is negative).

In this report, unless otherwise noted, a difference was considered statistically significant at the 5 percent level if the difference $\left(x_{1}-x_{2}\right)$ was at least twice as large as its standard error.

## Related documentation

More detailed discussion of the sample design of the NHIS,
estimating procedures, procedures for estimating standard errors, nonsampling errors, and definitions of other sociodemographic terms used in this report has been published in Vital and Health Statistics, Series 10, nos. 160 and 176; Series 1, no. 18; and Series 2, 110 (44-47).

A public use data file based on the 1989 TAPS was released in February 1992. Information regarding the purchase of the public use tape may be obtained by writing to the Division of Health Interview Statistics, National Center for Health Statistics, 6525 Belcrest Road, Hyattsville, Maryland 20782.

## Definition of terms-TAPS smoking status categories

Never smoked - Never smoked a cigarette.

Never smoked, no intention Never smoked a cigarette or tried or experimented with cigarette smoking; will not try a cigarette soon; and definitely will not be smoking in 1 year.

Never smoked, may smoke - Never smoked a cigarette or tried or experimented with cigarette smoking; may try a cigarette soon or may be smoking in 1 year.

Experimenter-Has either smoked a cigarette or tried or experimented with cigarette smoking, but has not smoked 100 cigarettes and has not smoked in the past 30 days.

Former smoker-Has smoked at least 100 cigarettes, but has not smoked in the past 30 days.

Current smoker-Has smoked a cigarette in the past 30 days.

Current light smoker-Has smoked 10 or more days in the past 30 days, and has smoked an average of fewer than 5 cigarettes per day in the past 7 days.

Current heavy smoker-Has smoked 10 or more days in the past 30 days, and has smoked an average of 5 cigarettes or more per day in the past 7 days.

Current occasional smoker-Has smoked 1 to 9 days in the past 30 days.

# Office Visits to Otolaryngologists 1989-90, National Ambulatory Medical Care Survey 

by David A. Woodwell, Division of Health Care Statistics

This report describes visits made to otolaryngologists during the period from March 1989 to December 1990. The information was collected by means of the National Ambulatory Medical Care Survey (NAMCS), an ongoing probability sample survey of the private office-based, non-Federal physicians practicing in the United States. NAMCS excludes physicians who specialize in anesthesiology, pathology, or radiology and physicians who are principally engaged in teaching, research, or administration. This survey excludes those visits made to hospital emergency or outpatient departments. NAMCS was conducted annually from 1973 through 1981, again in 1985, and annually beginning in 1989 by the Division of Health Care Statistics, National Center for Health Statistics, Centers for Disease Control and Prevention.

Data in this report are from the 1989 and 1990 NAMCS, which were conducted in identical fashion using the same survey instrument, definitions, and procedures. The two data sets were combined to obtain more reliable estimates. The figures presented in this report are estimated from a sample, not the entire universe of visits to ambulatory care physicians, and are therefore subject
to sampling variability. All estimates contained in this report, including the number of visits, the number of drug mentions, and the visit rates, have been adjusted to represent annual statistics. The technical notes at the end of the report provide guidelines for judging the precision of the estimates. Definitions of key terms used in the survey are also provided. A facsimile of the patient record form used for data collection in both 1989 and 1990 is shown in figure 1 and will be useful when reading the survey results.

Survey data show that of the visits made to otolaryngologists, more than four-fifths ( 83 percent) were to physicians who reported they were board certified in otolaryngology, approximately 16 percent were to physicians who reported no board certification, and the remaining 1 percent were to physicians who were certified in surgery.

## Data highlights

As shown in table 1, an estimated annual average of $16,957,000$ visits were made to otolaryngologists in 1989 and 1990. These 16.9 million visits represent about 2 percent of all visits to ambulatory care physicians in
the United States and produce a visit rate of 7 visits per 100 persons. In the combined survey years 1975 and 1976, the estimated annual average number of visits to otolaryngologists was $13,596,000$, again representing about 2 percent of all visits made to ambulatory care physicians, not significantly different from 1989 and 1990. The visit rate for the combined years 1975 and 1976 was 7 visits per 100 persons, the same as that for 1989 and 1990 (1).

## Patient characteristics

Table 2 shows the percent distribution of visits by age and sex of the patient. Most of the visits to otolaryngologists were made by patients under 15 years of age and by patients $25-64$ years of age, who together represented about 70 percent of the visits. This relationship held true for both males and females. There were fewer visits made by young adults and elderly patients. The visit rate dropped from 8 visits per 100 persons for those under 15 years of age to 4 visits per 100 persons for patients $15-24$ years of age. The rate then increased by two visits for each age group thereafter.
U.S. DEPARTMENT OF HEALTH AND HUMAN SERVICES

Centers for Disease Control and Prevention National Center for Health Statistics AND PREVENTION

Figure 1. Patient record form

- U.S. GOVERNMENT PRINTING OFFICE:1989-288-197

There were more female visits to otolaryngologists than male visits 55 percent as compared with 45 percent, respectively. Females under 15 years of age were the only age group to have a smaller percent of visits than their male counterparts. The pattern of patients under 15 years of age and of patients 25-64 years making most of the visits was also evident for both males and females. Male and female visit rates are similar for all age groups and are
not statistically different. The higher frequency and percent of female visits to otolaryngologists are due to the fact that there are more females in the general population, explaining the similarity in the visit rates.

As shown in table 3, more visits were made to otolaryngologists by white persons ( 90 percent) than by black persons (about 6 percent), figures that are not statistically different from the corresponding percents for visits made to all
physician specialties. However, there was a significant difference in the visit rate between white and black patients. White males had visit rates that were 2.3 times higher than those for black males, and white females had rates that were 3 times higher than those for black females.

## Expected sources of payment

Patients paid for all or part of the visit (including deductibles and
copayments) in an estimated 28 percent of the visits. Fee-forservice insurance. other than Blue Cross/Blue Shield, was a source of payment in about 24 percent of the visits to otolaryngologists compared with Blue Cross/Blue Shield, which was used in about 18 percent of the visits. Prepaid plans such as health maintenance organizations (HMO's), individual practice associations (IPA's), and preferred provider organizations (PPO's) were used in about 13 percent of the visits. Government insurance, Medicare and Medicaid, represented approximately 16 and 7 percent of the visits, respectively. Except for Blue Cross/ Blue Shield, all expected sources of payment to otolaryngologists were similar to the corresponding percents for all physicians. Blue Cross/Blue Shield was an expected source of payment for about 18 percent of the visits to otolaryngologists as compared with almost 12 percent of visits to all physicians (figure 2).

## Patient status

As shown in table 4 , about 17 percent of patients visiting otolaryngologists in 1989 and 1990 were referred by another physician. This is significantly greater than the referral rate for all physicians (about 6 percent of their visits were referred by another physician).

New patients to otolaryngologists represented nearly 33 percent of the visits, twice the 16 percent of new patient visits to all physicians. Most visits to otolaryngologists, nearly 60 percent, were made by "old patients" (patients who had seen the physician on a prior occasion, with an "old problem" (a problem that had been treated previously by the physician). Old patients with new problems represented about 8 percent of the visits, which is considerably less than the approximately 23 percent for all physicians. No differences were found in these percents for otolaryngologists between 1989-90 and 1975-76.

## Patient's reason for visit

Tables 5 and 6 display the principal reason for visit as expressed

Table 1. Average annual number, percent distribution, and rate of office visits, by physician specialty: United States, 1989-90

| Physician specialty | Average annual number of visits in thousands | Percent distribution | Average annual number of visits per 100 persons |

by the patient. The principal reason for visit is the problem, complaint, or cause listed first on item 9 of the patient record form. These data have been classified and coded according to the Reason for Visit Classification for Ambulatory Care (RVC) (2).

The RVC is divided into eight modules (or groups of reasons), as detailed in table 5. For otolaryn-
gologist visits, the symptom module was most often cited, accounting for about 73 percent of the visits. Within this module, symptoms referable to the eyes and ears and symptoms referable to the respiratory system accounted for almost 34 percent and 24 percent of the visits, respectively. The treatment module, disease module, and the injury and adverse

Figure 2．Expected source of payment to otolaryngologists：United States，1989－90
effects module accounted for around 14,7 ，and 3 percent of the visits． respectively．

Table 6 lists the top 20 reasons for visit to otolaryngologists in 1989－90，which accounted for more than three－quarters of all visits．The
most frequent reason for visit to otolaryngologists in 1989－90 was for an earache or an ear infection， accounting for 11.3 percent of the visits．Patients with hearing dysfunction accounted for 8.1 percent of the $16,957,000$ average annual
visits，the second most frequent reason for visit．Symptoms referable to throat and other symptoms referable to ears represented 6.3 percent and 5.8 percent of the visits，respectively．The 20 most frequent diagnoses are quite similar to the 20 most frequent reasons for visit to otolaryngologists found in the 1975－76 NAMCS．

## Physician＇s diagnosis

Data on the principal diagnosis rendered by otolaryngologists are shown in tables 7 and 8 ．The principal diagnosis is the first－ recorded diagnosis in item 10a of the patient record form and is associated with the principal reason for visit as recorded in item 9a．The principal diagnosis was coded and classified according to the International Classification of Diseases，9th Revision，Clinical Modification （ICD－9－CM）（3）．

As shown on table 7，the ICD－9－ CM is organized into broad categories relating to the major systems of the body．Diseases of the nervous system and sense organs represented the largest percent of diagnosis by the otolaryngologist，about 38 percent， which was followed by diseases of the respiratory system，approximately 30 percent．The three ICD－9－CM classes－supplementary classifications； symptoms，signs，and ill－defined conditions；and injury and poisoning－represented almost 9,6 ， and 4 percent，respectively，of the principal diagnoses．As would be expected，the percent of visits with diagnoses of diseases of the nervous system and sense organs（mostly ear and nose）and diseases of the respiratory system（mostly throat）is more than double the percent for all physicians－approximately 38 percent and 30 percent，respectively，for otolaryngologists as compared with 11.1 percent and 13.9 percent， respectively，for all physicians．The percent of visits for supplementary classifications（including general medical exam and normal pregnancy exams）for otolaryngologists was about half that for
all physicians, nearly 9 percent compared with 15 percent, respectively.

The top 20 principal diagnoses made by otolaryngologists are shown in table 8. The first three diagnoses, accounting for about one-quarter of the visits ( 26.1 percent), are related to problems of the ear: suppurative and unspecified otitis media ( 9.4 percent), disorders of external ear ( 8.5 percent), and nonsuppurative otitis media and eustachian tube disorders ( 8.2 percent). Following the first three diagnoses are two diagnoses involving the respiratory system: allergic rhinitis ( 7.1 percent) and chronic sinusitis ( 5.2 percent). The 20 most frequent diagnoses are quite similar to the 20 most frequent diagnoses found in the 1975-76 NAMCS.

## Medication therapy

As shown in table 9, otolaryngologists prescribed or administered medication in nearly 47 percent of the office visits in 1989-90, significantly less often than most other physicians specialties. All physicians prescribed or administered medication in 60.2 percent of the visits.

A visit in which the patient was administered or prescribed any type of medication by the physician is called a "drug visit." Of the drug visits to otolaryngologists, about 63 percent were visits when one drug was prescribed or administered, 24 percent were visits when two drugs were prescribed or administered, and 13 percent were visits when three drugs or more were prescribed or administered. Of all the drugs prescribed or administered by office-based ambulatory care physicians, otolaryngologists prescribed or administered only 1.9 percent.

Table 10 classifies the drug mentions into therapeutic categories as defined by the 1985 edition of the National Drug Code Directory (4). Antimicrobial agents accounted for approximately one-third of the otolaryngologists' drug mentions, in addition to respiratory tract drugs, which accounted for about 18 percent. Antimicrobial agents included such

| 20 | Head and face . . . . . . . | . 3005 | 144 | 0.9 | 68.2 |

[^7]drugs as penicillin (11.0 percent), cephalosporin (9.3 percent), and erythromycin and lincosamide (4.1 percent). Respiratory tract drugs included such drugs as nasal decongestants ( 7.0 percent); antitussives, expectorants, and mucolytics ( 4.0 percent); and antihistamines ( 6.9 percent). The therapeutic category skin and mucous membrane represented 9.4 percent of the drug mentions and consisted almost completely of dermatalogics, 8.8 percent. The top 20 generic substances prescribed by otolaryngologists are shown in table 11, with amoxicillin being the most utilized, 9.3 percent. The generic substances beclomethasone, neomycin, hydrocortisone, and phenylephrine followed, accounting for 7.7, 6.7, 6.6, and 5.7 percent of the drug mentions, respectively.

## Duration and disposition of visits

Visits to otolaryngologists had a mean duration of roughly 14 minutes, excluding those visits of zero minutes. More than three-quarters ( 77.7 percent) of the visits lasted no longer than 15 minutes, significantly higher than the 68.1 percent of visits to all physicians. The duration of visit does not include time waiting for the physician or time receiving care from someone else on the physician's staff. Visits of zero minutes, in which the patient had no face-to-face contact with the physician, represented almost 3 percent of the visits (table 12).

In addition, table 12 shows that 57 percent of most visits to otolaryngologists resulted in the physician instructing the patient to return at a specific time, and about 27 percent were instructed to return if needed, compared with approximately 50 percent and 27 percent, respectively, in 1975-76.

${ }^{1}$ Mean duration of vist was 13.8 minutes.

## Technical notes

## Sources of data and sample design

The information presented in this report is based on data collected by means of the National Ambulatory Medical Care Survey (NAMCS) from March 20, 1989, through December 30, 1990. The target universe of NAMCS includes office visits made in the United States by ambulatory patients to nonfederally employed physicians who are principally engaged in office practice but not in the specialties of anesthesiology, pathology, or radiology. Telephone contacts and nonoffice visits are excluded.

A multistage probability sample design is used in NAMCS, involving samples of primary sampling units (PSU's), physician practices within PSU's, and patient visits within physician practices. A sample of 2,535 non-Federal, office-based physicians was selected in 1989 and 2,528 non-Federal, office-based physicians were selected in 1990 from master files maintained by the American Medical Association and American Osteopathic Association. The sample included 104 otolaryngologists in both 1989 and 1990, of which 89 were eligible in 1989 and 84 were eligible in 1990. The physician response rate for the 1989 NAMCS was 74 percent; in 1990, it was 75 percent. Otolaryngologists had a response rate of 71 percent in 1989 and 70 percent in 1990. Sample physicians were asked to complete patient records (figure 1) for a systematic random sample of office visits occurring during a randomly assigned 1 -week reporting period. Responding physicians completed 38,384 patient records in 1989 and 43,469 in 1990. Otolaryngologists completed 1,790 patient record forms in 1989 and 2,185 in 1990. Characteristics of the physician's practice, such as primary specialty and type of practice, were obtained from the physicians during an induction interview. The U.S. Bureau of the Census, Housing Surveys Branch, was responsibie for
the survey's data collection. Processing operations and medical coding were performed by the National Center for Health Statistics, Hospital Discharge and Ambulatory Care Survey Section, Research Triangle Park, North Carolina.

## Sampling errors

The standard error is primarily a measure of the sampling variability that occurs by chance when only a sample, rather than an entire universe, is surveyed. The relative standard error of an estimate is obtained by dividing the standard error by the estimate itself; the result is then expressed as a percent of the estimate. Approximate relative standard errors (RSE's) of selected aggregate statistics are shown in table I, and the relative standard errors of the estimated number of drug mentions are shown in table II. All frequencies in this report are average annual figures and must be doubled before a significance test can be performed. Relative standard errors for aggregate visits and drug estimates may be calculated using the following general formula, where $x$ is the aggregate of interest in thousands, and $A$ and $B$ are the appropriate coefficient from table IV.

$$
\operatorname{RSE}(x)=\sqrt{A+\frac{B}{x}} \times 100.0
$$

Approximate relative standard errors for estimates of the percent of visits are shown in table III. The RSE's for percent may be calculated using the following general formula, where $p$ is the percent of interest and $x$ is the denominator of the percent in thousands, using the appropriate coefficient from table IV.

$$
\operatorname{RSE}(p)=\sqrt{\frac{B(1-p)}{p x}} \times 100.0
$$

## Adjustments for nonresponse

Estimates from NAMCS data were adjusted to account for sample physicians who were in scope but did not participate in the study. This adjustment was calculated to minimize the impact of response on final

Table I. Relative standard errors for estimated numbers of office visits: National Ambulatory Medical Care Survey, 1989-90

| Estimated number of office visits in thousands | All specialties | Otolaryngologist |

| 1,400.000 | 0.1 | 0.2 | 0.2 | 0.3 | 0.4 | 0.4 |

Example of use of table: An esturnate of 30 percent based on an aggregate estumate of 10 million vists has a standard error of 4.2 percent or a relative standard error of 14.0 percent (4.2 percent divided by 30 percent).
estimates by imputing to nonresponding physicians data from visits to similar physicians. For this purpose, physicians were judged similar if they had the same specialty designation and practiced in the same PSU.

## Test of significance and rounding

In this report, the determination of statistical inference is based on a two-sided $t$-test. The Bonferroni inequality was used to estimate the critical value for statistically significant differences ( 0.05 level of significance). Terms relating to differences such as "higher," "less," and so forth indicate that the differences are statistically significant. Terms such as "similar" or "no difference" mean that no statistical significance exists between the estimates being compared. In the tables, estimates of office visits have been rounded to the nearest thousand. Consequently, estimates will not always add to totals. Rates and percents were calculated from original unrounded figures and do not necessarily agree with percents calculated from rounded data.

## Definition of terms

Ambulatory patient - An
ambulatory patient is an individual
seeking personal health services who is not currently admitted to any health care institution on the premises.

Drug mention-A drug mention is the physician's entry of a pharmaceutical agent - by any route of administration-for prevention, diagnosis, or treatment. Generic as well as brand-name drugs are included, as are nonprescription and prescription drugs. Along with all new drugs, the physician also records continued medications if the patient was specifically instructed during the visit to continue the medication.

Drug visit-A drug visit is a visit in which medication was prescribed or provided by the physician.

Office-Offices are the premises physicians identify as locations for their ambulatory practice; these customarily include consultation, examination, or treatment spaces that patients associate with the particular physician.

Otolanyngologist-A physician who specializes in the diseases of the ear, nose, and throat.

Physician-A physician is a duly licensed doctor of medicine (M.D.) or doctor of osteopathy (D.O.) who is currently in office-based practice and who spends some time caring for ambulatory patients. Excluded from

Table IV. Coefficients appropriate for determining relative standard errors, by type of estimate and physician specialty: National Ambulatory Medical Care Survey, 1989-90

| Type of estimate <br> and <br> physician specialty | $A$ | $B$ |
| :---: | :---: | :---: |
| Visits | Coefficient |  |
| Overall totals . . . . . | 0.00097549 | 52779.52184 |
| Otolaryngologist . . . | 0.01236777 | 84645.29550 |
| Drug mentions |  |  |
| Overall totals . . . . . | 0.00157151 | 81470.54833 |
| Otolaryngologist . . . | 0.01603845 | 11420.09384 |

NAMCS are physicians who are hospital-based; who specialize in anesthesiology, pathology, or radiology; who are federally employed; who treat only institutionalized patients; or who are employed full time by an institution and spend no time seeing ambulatory patients.

Visit-A visit is a direct personal exchange between an ambulatory patient and a physician (or a staff member working under the physician's supervision), for the purpose of seeking care and rendering personal health services.

# Office Visits to Obstetricians and Gynecologists: United States, 1989-90 

by Susan M. Schappert, M.A., Division of Health Care Statistics

## Introduction

Over the 2 -year period 1989-90, there were approximately 119.6 million visits made to nonfederally employed, office-based physicians in the United States who specialized in the practice of obstetrics and gynecology-an average of about 59.8 million visits per year. This report summarizes data pertaining to these visits in terms of patient characteristics, physician practice characteristics, and visit characteristics. Other reports are available that present data on office visits to obstetricians and gynecologists for previous years (1-3). Some of the findings from these reports will be discussed in light of current survey data.

The information presented in this report is based on data obtained from the National Ambulatory Medical Care Survey (NAMCS), a national probability sample survey conducted by the Division of Health Care Statistics of the National Center for Health Statistics, Centers for Disease Control and Prevention. This survey was conducted annually from 1973 through 1981, and again in 1985. It
resumed an annual schedule with the 1989 survey.

The 1989 and 1990 NAMCS shared identical survey instruments, definitions, and procedures. The resulting two years of data have been combined to provide more reliable estimates, and the reader should be aware that the estimates, percent distributions, and rates presented in this report, unless otherwise indicated, reflect average annual estimates for 1989 and 1990 based on the combined data. The Patient Record, the survey instrument utilized by participating physicians to record information about their patients' office visits, is shown in figure 1.

The reader should keep in mind that the estimates presented in this report are based on a sample, rather than on the entire universe of office visits, and are subject to sampling variability. The sample design, sampling errors, and guidelines for judging the precision of NAMCS estimates are discussed in the technical notes. Several publications are available that discuss overall findings from the 1989 and 1990 NAMCS (4-6), and reports on special
topics are also available (7-10). Additional reports on visits made during 1989 and 1990 to other physician specialties are forthcoming.

## Data Highlights

## Patient characteristics

Approximately 99.4 percent of visits to obstetricians and gynecologists were made by females, ${ }^{\text {a }}$ and, of these, 85.7 percent were made by females between the ages of 15 and 44 years. These percentages reflect the principal reason for visits to this specialty: routine prenatal examination. Visits by females according to age and race are shown in table 1.

[^11]U.S. DEPARTMENT OF HEALTH AND HUMAN SERVICES Public Health Service
Centers for Disease Control and Prevention National Center for Health Statistics AND PREVENTION

- US GOVERNMENT PRINTNG OFFIEE. 1989-Z26-197

Figure 1. 1989 National Ambulatory Medical Care Survey Patient Record

The age distribution of visits by females to obstetricians and gynecologists has shifted over the years. While 32.7 percent of these visits were made by patients 15-24 years of age in 1975-76. only 21.4 percent were made by patients in this age group in 1989-90.
Correspondingly, females aged 25-44 years comprised 51.7 percent of the total in 1975-76, but had increased their share to 64.3 percent by 1989-90 (figure 2).

However, visit rates appeared not to have changed significantly over the years within any of the five age groups analyzed (figure 3). Females in the age group 25-44 years had the highest rate of visits to obstetricians and gynecologists ( 94.5 visits per 100 females in 1989-90). followed by females aged $15-24$ years ( 71.6 visits per 100). Females under age 15 were the least likely to visit this specialty, with only 1.3 visits per 100 females.

White females made 84.7 percent of all female visits to obstetricians and gynecologists during 1989-90, while black females accounted for 8.6 percent, and Asian/Pacific Islanders accounted for 3 percent. The visit rate for white females was higher ( 47.7 visits per 100 ) than the corresponding rate for black females (31.8 visits per 100). Visit rates for white females did not appear to change significantly during the years

Figure 2. Change in age distribution of office visits by females to obstetricians and gynecologists: United States 1975-90
analyzed. Moreover, no significant differences were found in visit rates for black females in 1975-76 compared with 1989-90, although a somewhat lower visit rate was noted in 1980-81.

## Physician practice characteristics

Obstetrics and gynecology was the fourth most visited physician specialty after general and family practice, internal medicine, and pediatrics, and accounted for an average of 8.6 percent of all office visits for 1989 and 1990 (table 2). This percentage did not differ appreciably from figures reported in 1975 and 1980-81.

Of the average number of office visits made by women during 1989 and 1990 to all specialties, about 14.1 percent were made to obstetricians and gynecologists. However, among women aged 15-44 years, this share was 29.1 percent (figure 4). General and family practice physicians received 30.4 percent of the total for this age group, with other specialties receiving significantly smaller percentages.

## Visit characteristics

More than two-thirds of all visits made by females to obstetricians and gynecologists ( 69.6 percent) were made by patients who had seen the physician previously and were returning for care of their condition.

This reffects, to some extent, the ongoing character of prenatal care. Only 4.7 percent of visits were the result of a referral from another physician (table 3).

Private insurance (including commercial insurance and Blue Cross/Blue Shield) was listed as an expected source of payment at nearly half (48.1 percent) of all visits (table 4). Self-payment was the expected source of payment at 26.7 percent of visits, followed by HMO/prepaid plan (14.4 percent). It should be noted that, physicians were allowed to list more than one expected source of payment per visit.

The patient's principal reason for visit is shown in tables 5 and 6 . Data in table 5 are categorized according to the eight reason for visit modules, or groups of reasons, outlined in $A$ Reason for Visit Classification for Ambulatory Care (RVC) (10). The 15 most frequently mentioned principal reasons for visiting obstetricians and gynecologists are listed in table 6.

The principal reason for visit (item 9a on the Patient Record) is the patient's most important complaint(s), symptom(s), or other reason(s) for this visit expressed in the patient's own words. Up to three reasons per visit may be coded based upon the classification system found in the RVC.

More than half ( 59.6 percent) of all visits by females to obstetricians and gynecologists were classified within the diagnostic, screening, and preventive module, reflecting the large percentage of visits ( 32.8 percent) made for the specific reason of routine prenatal examination. Visits made because of a symptomatic problem or complaint accounted for 23.7 percent of the total; symptomatic problems or complaints were most often related to the genitourinary system.

Diagnostic services ordered or provided at the visit are shown in table 7. The vast majority of visits included some type of diagnostic service ( 94.4 percent), and 36.5 percent of visits included four or more diagnostic services, a significantly higher percentage than

Figure 3. Annual visit rates for females to obstetricians and gynecologists by patlent's age: United States, 1975-90
that found at visits to all other specialties.

The most frequently performed service was a blood pressure check ( 72.7 percent of visits), followed by pelvic exam ( 58.5 percent), urinalysis (45.4 percent), pap test
(34.7 percent), and breast palpation (32.1 percent).

Data on principal diagnoses rendered at visits to obstetricians and gynecologists are shown in table 8. Item 10a of the Patient Record requests that the physician record the principal diagnosis associated with the patient's most important reason for visit. Diagnoses are classified and coded according to the International Classification of Diseases, 9th Revision Clinical Modification, (ICD-9-CM)
(12). They are shown according to major ICD-9 coding classes in table 8 and by the 15 most frequently mentioned principal diagnoses in table 9.

Paralleling the principal reason for visit data, the majority (55.6 percent) of visits reported a principal diagnosis in the supplementary classification (ICD-9-CM codes V01-V82), which includes all diagnoses that are not related to illness or injury. About 22.2 percent of visits reported diagnoses classified as diseases of the genitourinary tract (ICD-9-CM codes 580-629).

Normal pregnancy was the most frequently reported principal diagnosis, listed at 31.3 percent of
visits. The most frequently reported morbidity-related principal diagnosis was menopausal and postmenopausal disorders, listed at 3.6 percent of visits. (Morbidity-related diagnoses are those referable to illness or injury.)

Therapeutic services ordered or provided by the physician are shown in table 10. Less than half of the visits ( 47.3 percent) included some form of counseling or advice by the physician; breast self-exam was the specific type of counseling reported most frequently, occurring at 10.6 percent of visits. However, 35.1 percent of visits included a reference to "other" counseling, which may include various forms of medical, social, and family counseling. More detailed data in this area have been collected in the 1991 NAMCS.

Less than half ( 44.0 percent) of visits to obstetricians and gynecologists included a mention of medication therapy, compared with 61.7 percent of visits to all other specialties, again reflecting the predominance of visits made for reasons other than illness and injury. As used in the NAMCS, the term "drug" is interchangeable with the term "medication" and includes all new or continued medications ordered or provided at the visit, including both prescription and nonprescription preparations, immunizing agents, and desensitizing agents. An earlier report is available that describes the method and instruments used in collecting and processing NAMCS drug data (13).

The number of drug mentions by therapeutic classification is shown in table 11. The classification system used here was adapted from the therapeutic categories found in the National Drug Code Directory, 1985 (14). In cases where a particular drug was classifiable to more than one therapeutic category, it was listed under the category for which it was most frequently prescribed.
"Drug mentions" refer to the total number of medications listed in item 15 of the Patient Record. Physicians may record multiple medications per visit, so that the total

Figure 4. Percent distribution of office visits by females $15-44$ years, according to physician specialty: United States, 1989-90.
number of drug mentions may exceed the total number of visits. This was not the case for visits to obstetricians and gynecologists, however, where only about 1.3 drugs were prescribed per drug visit, and where just 6 mentions of medication were made for every 10 visits in general. "Drug visit" refers to visits with at least one mention of medication ordered or provided by the physician.

Of the average yearly estimate of 34.7 million drug mentions at visits to obstetricians and gynecologists for 1989 and 1990, the largest percentage of mentions ( 34.8 percent) was for hormones and agents affecting hormonal mechanisms. This was followed by metabolic and nutrient agents, which accounted for 23.5 percent of all drug mentions.

The 20 most frequently used generic substances occurring in drug mentions by obstetricians and gynecologists are listed in table 12. The most frequently mentioned generic substance was estradiol, listed as an ingredient in 15.5 percent of drug mentions. (It is important to
note that the rank ordering presented in this and other tables in this report may not always be reliable because near estimates may not be significantly different from each other due to sampling variability.) Among the top 20 generic substances were 5 hormonal agents, and 10 metabolic and nutrient agents. The 10 most frequently mentioned medications according to the entry name of the drug, that is, the actual reference made to it by the physician on the Patient Record, whether by brand name, generic name, or therapeutic effect, is shown in table 13.

Data on disposition of visit are displayed in table 14. Most visits to obstetricians and gynecologists by females included an instruction to return at a specified time (76.7 percent).

Duration of visit is shown in table 15. More than half of all visits by females ( 69.3 percent) lasted 15 minutes or less. Average duration of physician-patient contact (excluding visits of zero minutes duration in which no direct face-to-face contact
between physician and patient occurred) was 15.5 minutes for visits to obstetricians and gynecologists.

Selected visit characteristics for obstetricians and gynecologists as compared with all other specialies are shown in tables 16 and 17. Visits to obstetricians and gynecologists were more likely to be made by female patients and by patients aged 15-44 years than were visits to all other specialties (table 16). Other areas of difference involve the greater likelihood of private insurance as an expected source of payment at visits to this specialty, the predominance of diagnostic, screening, and preventive reasons for visit as opposed to symptomatic complaints, the greater likelihood of nonillness and noninjury diagnoses, the higher number as well as the type of diagnostic services performed, the greater likelihood of counseling for breast selfexamination, the lower percentage of visits at which medication therapy was mentioned, and the higher proportion of visits at which a return visit was scheduled.

Data in table 17 represent the distribution of visits by physician specialty for 10 reasons for visit and 10 diagroses selected from those reported most often at visits to obstetricians and gynecologists. Obstetricians and gynecologists received 79.1 percent of all visits for routine prenatal examination compared with 19.1 percent for general and family practitioners. On the other hand, general and family practitioners received about half ( 50.1 percent) of all visits made for the reason of having a pap smear, which is not significantly different than the proportion made to obstetricians and gynecologists (41.3 percent).

For the 10 diagnoses listed in table 17, obstetricians and gynecologists received a significantly greater proportion of visits for each diagnosis listed, with two exceptions-visits having a diagnosis of candidiasis and visits with a diagnosis of inflammatory disease of the cervix, vagina, and vulva. General
and family practitioners received a substantial proportion of visits with these diagnoses ( 35.9 percent and 40.6 percent, respectively).

${ }^{1}$ Frequency of mention combines single-ingredient agents with mentions of the agent as an ingredient in a combination drug. 2Therapeutic classification is based on the standard drug classification used in the National Drug Code Directory, 1985 Edition. In cases where a generic substance had more than one therapeutic classification, it was listed in the classification for which it was most frequently used.

Table 13. Annual number, percent distribution, and therapeutic classification of the 10 drugs most frequently prescribed at visits by females to obstetricians and gynecologists by entry name of drug, averaged over a 2-year period: United States, 1989-90

| Entry name of drug ${ }^{1}$ | Number of drug mentions in thousands | Percent distribution | Therapeutic classification ${ }^{2}$ |
| :---: | :---: | :---: | :---: |
| Total mentions | 34,738 | 100.0 | ... |

## Technical Notes

## Source of data and sample design

The information in this report is based on data collected through the National Ambulatory Medical Care Survey (NAMCS) over the 2 -year period 1989-90. The target universe of NAMCS includes office visits made in the United States by ambulatory patients to nonfederally employed physicians who are principally engaged in office practice, but not in the specialties of anesthesiology, pathology, or radiology. Telephone contacts and nonoffice visits are excluded.

A multistage probability sample design is used in NAMCS, involving samples of primary sampling units (PSU's), physician practices within PSU's, and patient visits within physician practices. Physicians were stratified into 15 specialty groups during the second stage of the survey design. Detailed descriptions of the 1989 and 1990 NAMCS survey design have been published ( $5,15,16$ ), and the reader is urged to consult these sources for further technical information.

The 1989 NAMCS physician sample included 2,535 physicians who were selected from master files maintained by the American Medical Association and the American Osteopathic Association; 164 of these were obstetricians and gynecologists. Physicians were screened at the time of the survey to ensure that they were eligible for survey participation, based upon a set of design criteria. Of those screened, 608 physicians, including 31 obstetricians and gynecologists, were ruled ineligible (out-of-scope) due to reasons such as being retired or employed primarily in teaching, research, or administration. Of the remaining 1,927 physicians, 74 percent responded to the survey, including 133 obstetricians and gynecologists, or 71 percent of those surveyed.

Sample physicians were asked to complete Patient Records (see figure 1) for a systematic random sample of their office visits occurring
during a randomly assigned 1 -week reporting period. Responding physicians completed 38,384 Patient Records, including 2,504 forms completed by obstetricians and gynecologists.

For 1990, a sample of 3,063 non-Federal, office-based physicians was selected from master files maintained by the American Medical Association and American Osteopathic Association. Of this number, 197 were obstetricians and gynecologists. The overall response rate for the 2,269 in-scope physicians was 74 percent; the rate was 73 percent for the 157 in -scope obstetricians and gynecologists. Responding physicians completed 43,469 Patient Records, including 2,969 forms from obstetricians and gynecologists.

Characteristics of the physician's practice, such as primary specialty and type of practice, were obtained from the physicians during an induction interview. The U.S. Bureau of the Census, Housing Surveys Branch, was responsible for collecting the survey data. Processing operations and medical coding were performed by the National Center for Health Statistics, Hospital Discharge and Ambulatory Care Survey Section, Research Triangle Park, North Carolina.

The 1989 and 1990 NAMCS were identical in terms of survey instruments, definitions, and procedures. The resulting two years of data have been combined to provide more reliable estimates. All estimates, percent distributions, and rates, unless otherwise noted, reflect 1989 and 1990 data that were averaged over the 2 -year period.

## Sampling errors

The standard error is primarily a measure of the sampling variability that occurs by chance when only a sample, rather than an entire universe, is surveyed. The relative standard error of an estimate is obtained by dividing the standard error by the estimate. The result is then expressed as a percent of the estimate. Relative standard errors for
estimated numbers of total office visits to obstetricians and gynecologists in 1989-90 are shown in table I, and relative standard errors for estimated numbers of drug mentions are shown in table II. Readers wishing to utilize these tables should keep in mind that the numbers refer to combined years of data rather than average annual estimates. Stañdard errors for

Table I. Relative standard errors for estimated numbers of office visits by selected physician specialties: National Ambulatory Medical Care Survey, 1989-90

| Estimated numbers of office visits in thousands | Physician speciality |  |  |
| :---: | :---: | :---: | :---: |
|  | All | Obstetrics and gynecology² | General and family practice ${ }^{3}$ |
| Relative standard error in percent |  |  |  |
| 100 | 72.7 | 49.2 | 61.4 |
| 200 | 51.5 | 35.3 | 43.7 |
| 500 | 32.6 | 23.3 | 28.1 |
| 1,000 | 23.2 | 17.6 | 20.5 |
| 2,000 | 16.5 | 13.9 | 15.2 |
| 5,000 | 10.7 | 11.1 | 11.0 |
| 10,000 | 7.9 | 9.9 | 9.1 |
| 20,000 | 6.0 | 9.3 | 6.0 |
| 50,000 | 4.5 | 9.0 | 7.3 |
| 100,000. | 3.9 | 8.8 | 7.0 |
| 200,000. | 3.5 | 8.8 | 6.9 |
| 500,000. | 3.9 | 8.7 | 6.8 |
| 1,000,000 | 3.2 | 8.7 | 6.8 |
| 1,400,000 | 3.2 | 8.7 | 6.8 |

${ }^{1}$ For all specaties, the smallest retiable estimate is 593,000 vists. Estumates below this figure have a retative standard error greater than 30 percent.
${ }^{2}$ For obstetres and gynecology, the smallest reliable estimate is 285.000 visits.
${ }^{3}$ For general and family practice, the smallest reliable estimate is 437,000 visits.

Example of use of table: An aggregate estimate of 1 multion vists to obstetricians and gynecologists has a relative stancard error of 17.6 percent or a standard error of 176,000 visits ( 17.6 percent of 1 million).

Table II. Relative standard errors for estimated numbers of drug mentions at visits to obstetricians and gynecologists: National Ambulatory Medical Care Survey, 1989-90

| Estimated number of drug mentions in thousands ${ }^{1}$ | Relative standard error in percent |
| :---: | :---: |
| 100. | 36.1 |
| 200. | 27.0 |
| 500. | 19.7 |
| 1,000 | 16.6 |
| 2,000 | 14.7 |
| 5,000 | 13.5 |
| 10,000. | 13.1 |
| 20,000. | 12.9 |
| 50,000. | 12.8 |
| 100.000 | 12.7 |
| 1,000,000. | 12.7 |
| The smallest reliable estimate is 155,000 mentions. Estimates below this figure have a relative standard error greater than 30 percent. |  |
| Example of use of table: A drug mentions has a relative a standard error of 1,31 10 million). | te estimate of 10 mil error of 13.1 percen tions (13.1 percent |

estimated percents of visits are shown in table III.

Alternatively, relative standard errors for aggregate estimates may be calculated using the following general formula, where $x$ is the aggregate of interest in thousands, and $A$ and $B$ are the appropriate coefficients from table IV.

$$
\operatorname{RSE}(x)=\sqrt{A+\frac{B}{x}} \cdot 100.0
$$

Similarly, relative standard errors for percents may be calculated using the following general formula, where $p$ is the percent of interest and $x$ is the denominator of the percent in
thousands, using the appropriate coefficient from table IV.

$$
\operatorname{RSE}(p)=\sqrt{\frac{B \cdot(1-p)}{p \cdot x}} \cdot 100.0
$$

## Adjustments for non-response

Estimates from NAMCS data were adjusted to account for sample physicians who were in scope but did not participate in the study. This adjustment was calculated to minimize the impact of response on final estimates by imputing to nonresponding physicians data from visits to similar physicians. For this

Table III. Standard errors for percents of estimated numbers of office visits to obstetricians and gynecologists: National Ambulatory Medical Care Survey, 1989-90

| Base of percent (visits in thousands) | Estimated percent |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1 or 99 | 5 or 95 | 10 or 90 | 20 or 80 | 30 or 70 | 50 |
|  | Standard error in percentage points |  |  |  |  |  |
| 100 | 4.8 | 10.6 | 14.5 | 19.4 | 22.2 | 24.2 |
| 200 | 34 | 7.5 | 10.3 | 13.7 | 15.7 | 17.1 |
| 500 | 2.2 | 4.7 | 65 | 8.7 | 9.9 | 10.8 |
| 1.000 | 1.5 | 3.3 | 4.6 | 6.1 | 7.0 | 7.7 |
| 2000. | 1.1 | 2.4 | 3.3 | 4.3 | 5.0 | 5.4 |
| 5.000. | 0.7 | 1.5 | 2.1 | 2.7 | 3.1 | 3.4 |
| 10.000 | 0.5 | 1.1 | 1.5 | 1.9 | 2.2 | 2.4 |
| 20.000 | 0.3 | 0.8 | 1.0 | 1.4 | 1.6 | 1.7 |
| 50.000 | 0.2 | 0.5 | 0.7 | 0.9 | 1.0 | 1.9 |
| 100,000 | 0.2 | 0.3 | 0.5 | 0.6 | 0.7 | 0.8 |
| 200,000 | 0.1 | 0.2 | 0.3 | 0.4 | 0.5 | 0.5 |
| 500,000 | 0.1 | 0.2 | 0.2 | 0.3 | 0.3 | 0.3 |
| 1,000,000 | 0.1 | 0.1 | 0.1 | 0.2 | 0.2 | 0.2 |

Example of use of tabie: An estimate of 20 percent based on an aggregate estumate of 5 million visits has a standard error of 2.7 percent or a relative standard error of 13.5 percent ( 2.7 percent drvided by 20 percent).

Table IV. Coefficients appropriate for determining relative standard errors by type of estimate and physician groups: National Ambulatory Medical Care Survey, 1989-90

| Type of estimate and physician group | Coefficient |  |
| :---: | :---: | :---: |

| Drug mentions |  |  |
| Overall totals | 0.00157151 | 81.47054833 |
| General and family practice, internal medicine | 0.00589721 | 59.72807201 |
| Psychiatry. | 00296738 | 30.9506771 |
| Doctors of osteopathy, general surgery, orthopedic surgery, cardiovascular disease, urological surgery, dermatology, neurology, ophthalmology. otolaryngology, obstetrics and gynecology, pediatrics. | 0.01603845 | 11.42009384 |
| All other . | 0.51877082 | 70.35063675 |

purpose, physicians were judged similar if they had the same specialty designation and practiced in the same PSU.

## Test of significance and rounding

In this report, the determination of statistical inference is based on the t -test. The Bonferroni inequality was used to establish the critical value for statistically significant differences ( 0.05 level of confidence). Terms relating to differences such as "greater than" or "less than" indicate that the difference is statistically significant. No comment about the difference between any two estimates does not mean that the difference was tested and found to be not significant.

In the tables, estimates of office visits have been rounded to the nearest thousand. Consequently, estimates will not always add to totals. Rates and percents were calculated from original unrouncled figures and do not necessarily agree with percents calculated from rounded data.

## Definition of terms

Ambulatory patient-An ambulatory patient is an individual seeking personal health services who is not currently admitted to any health care institution on the premises.

Physician-A physician is a duly licensed doctor of medicine (M.D.) or doctor of osteopathy (D.O.) who is currently in office-based practice and who spends some time caring for ambulatory patients. Excluded from the NAMCS are physicians who are hospital-based; who specialize in anesthesiology, pathology, or radiology; who are federally employed; who treat only institutionalized patients; or who are employed full time by an institution and spend no time seeing ambulatory patients.

Office - An office is the space physicians identify as a location for their ambulatory practice. Offices customarily include consultation,
examination, or treatment spaces that patients associate with the particular physician.

Visit-A visit is a direct personal exchange between an ambulatory patient and a physician (or a staff member working under the physician's supervision), for the purpose of seeking care and rendering personal health services.

Drug mention - A drug mention is the physician's entry of a pharmaceutical agent - by any route of administration - for prevention, diagnosis, or treatment. Generic as well as brand-name drugs are included, as are nonprescription and prescription drugs. Along with all new drugs, the physician also records continued medications if the patient was specifically instructed during the visit to continue the medication.

Drug visit-A drug visit is a visit in which medication was prescribed or provided by the physician.

Obstetrics and gynecology - The physician practice specialty of obstetrics and gynecology includes physicians who report a specialty to the American Medical Association in any of the following areas gynecology, gynecological oncology, maternal and fetal medicine, obstetrics, obstetrics and gynecology, and reproductive endocrinology.

Pierce, Ph.D., University of California at San Diego

## Introduction

Cigarette smoking has been identified as one of the leading preventable causes of disability and premature death in the United States (1). The relationship between smoking and disease has made the reduction in smoking prevalence one of the major public health goals of the Nation. The United States Public Health Service has set a goal that smoking prevalence in the United States be reduced to 15 percent by the year 2000 (2). Achievement of this goal will require a major reduction in the uptake of smoking by young Americans. Rates for adolescent smoking prevalence differ among various surveys (1); however, prevalence as high as 36 percent has been reported (3). Uptake of smoking by adolescents is one of the primary barriers to reducing smoking prevalence. Teenage smoking behavior has remained relatively steady throughout the 1980's, although smoking among the adult population has decreased (1).

In addition, use of smokeless tobacco products, particularly chewing tobacco and snuff, increased substantially during the 1970's and 1980's (4). National estimates indicate that at least 10 million Americans used some form of smokeless tobacco during 1991 ( $\xi$ ), with use increasing especially amcng male adolescents and young male adults (1). The increased use and appeal of these products assume major public health importance because the evidence reveals that smokeless tobacco can cause oral cancer and other oral conditions and can lead to nicotine addiction and dependence. In 1986, two-thirds of men who had ever used smokeless tobacco reported having started before age 21 (1).

Chronic use of tobacco is not an all-or-none behavior. The level of use changes over time. The different levels of use can be described as an uptake continuum. Determining where adolescents are on this continuum is important in planning preventive interventions. The 1989 Teenage Attitudes and Practices

Survey (TAPS), a targeted-population study from the National Health Interview Survey, was undertaken by the National Center for Health Statistics, the Office on Smoking and Health, the National Cancer Institute, and the American Cancer Society to provide data for in-depth analysis of teenage smoking behavior and to describe the uptake continuum for sub-populations of adolescents.

## Methods

The 1989 TAPS was designed with the intention of providing regular surveillance of teenage smoking behavior and attitudes beginning with the collection of baseline data in 1989 and conducting periodic cross-sectional and/or longitudinal surveys every $3-4$ years. The TAPS sample included all 12-18-year-olds living in households contacted and interviewed in the last two quarters of the 1988 and the first two quarters of the 1989 National Health Interview Survey. The TAPS obtained information on prevalence and for classification by smoking
U.S. DEPARTMENT OF HEALTH AND HUMAN SERVICES Public Health Service
status, knowledge of smoking risks, attitudes about smoking, and correlates of smoking uptake - such as attitudes about school, risk-taking behavior, and peer smoking practices.

The primary method of data collection for the TAPS was computer assisted-telephone interviewing (CATI), whereby interviewers conducted a telephone interview by reading questions from a computer screen and recording responses electronically. Teenagers in the TAPS who were not available by telephone were sent a mail questionnaire. Overall, 9,965 interviews were completed either by telephone or mail with a resulting survey response rate of 82 percent. For a description of the survey design, see Allen, Moss, Botman, et al. (6).

This report presents frequencies and/or percent distributions for virtually all the data items from the TAPS questionnaire. It is intended to provide a convenient source of comprehensive data related to the use of tobacco products by adolescents and to encuurage interested readers to undertake further analysis of the
TAPS data. For other reports on the TAPS survey, see references 7-10.

Estimated percentages for the
United States population of noninstitutionalized youths 12-18 years old are presented in this report by age, sex, race, ethnicity, and adolescent smoking status. Generally, except for knowledge questions that accept "don't know" as an appropriate response, "don't know" and other unacceptable responses have been excluded from the denominator in the calculation of the percent estimates. When possible, the actual question wording is shown along with response categories in the tables. However, many of the questions have been paraphrased or combined.

## Selected findings

Table 1 shows respondents' selfperception of peer attitudes regarding various health-risk behaviors. For most behaviors, current teenage smokers reported that their peers
cared less about behaviors that affected their health than did teenagers who had never smoked. Half of the teenagers who had never smoked cared "a lot" about staying away from drugs, compared with one in five teenagers that currently smoked. Of those who never smoked tobacco, 57 percent cared a lot about not using marijuana, compared with 23 percent of current tobacco smokers. Current smokers cared more about keeping their weight down than did those who had never smoked: 79 percent cared a lot or cared somewhat, compared with 73 percent of teenagers who had never smoked. This perception was consistent with current smokers' response to the question "Do you believe smoking helps people keep their weight down?" (table 7); 30 percent of current smokers believed this to be true, and only 13 percent of those who had never smoked reported believing this. The functional utility of smoking was perceived to be much greater by current smokers than by those who had never
smoked-current smokers also perceived their peers as caring more about controlling their weight than teenagers who had never smoked (table 1).

Among all current teenage smokers in 1989, brand preference was overwhelmingly Marlboro: 68 percent of those who usually bought their own cigarettes bought that brand. The most striking difference in brand preference among sociodemographic subgroups is shown in table 2 for race. White teenagers clearly preferred Marlboros ( 70 percent, versus 9 percent of black teenagers). However, black teenagers bought Newports most often (61 percent, compared with 6 percent of white teenagers). Data pertaining to the brand of choice by most adolescent current smokers also indicated a definite increase in the number of adolescents smoking Camels (11).

Regardless of age, sex, race, or ethnicity, adolescent smokers purchased cigarettes more often from small stores, such as convenience
stores, than from vending machines or large stores: 69 percent often bought cigarettes from small stores, 6 percent often bought cigarettes from vending machines, and 26 percent often bought cigarettes from large stores.

Of currently smoking teenagers who had ever seriously thought about quitting smoking, 86 percent reported having tried to quit at least once, and 76 percent of those who had ever tried to quit reported having tried to quit in the past 6 months. When asked the question "Do you think you will be smoking 1 year from now?", more than half of all teenage smokers said they would definitely or probably not be smoking in a year. Considering the percentage of teenagers who had tried to quit and failed, especially in the past 6 months, it is somewhat surprising to note that so many current teenage smokers ( 54 percent) still believed that they would not be smoking in 1 year. These statistics clearly illustrate the naivete of adolescents with regard to the addictiveness of cigarette smoking.

Adolescents who had never smoked a cigarette or never tried or experimented with cigarette smoking reported on all measures of "intention to smoke" that they had no intention to smoke in the future, with very little variation by sociodemographic subgroups. When asked "Do you think you will try a cigarette soon?", adolescents, regardless of age, were consistent in their resolve not to smoke even though their exposure to and the availability of cigarettes is shown by this data to increase with age. More than 97 percent of 16 -18-year-olds, 96 percent of $14-15$-year-olds, and 94 percent of $12-13$-year-olds reported that they would not try a cigarette soon (table 3). At ages $12-13$, only 24 percent of teenagers reported having been offered a cigarette, but more than half ( 54 percent) of the teenagers who had never smoked had been offered a cigarette by the time they were between 16 and 18 years of age. Older teenagers also believed it would be easy for them to get
cigarettes if they wanted some:
89 percent of $16-18$-year-olds said it would be easy to get cigarettes if they wanted some, compared with 67 percent of $14-15$-year-olds and only 39 percent of $12-13$-year-olds.

A strong correlate of smoking uptake among adolescents is the smoking practices of family and peers (1). Of all current teenage smokers, 17 percent reported living with an older sibling who smoked, but only 5 percent of teenagers who had never smoked lived with siblings who smoked (table 4). Teenagers who smoked also reported more frequently having a parent who smoked: 46 percent of current teenage smokers reported that their parents smoked, and 36 percent of teenagers who had never smoked lived with at least one parent who smoked. Current teenage smokers associated more with other smokers than did teenagers who had never smoked. When asked the question "Of your four best male/female friends, how many smoke?", 82 percent of current smokers reported having at least one best male friend, and 78 percent cited at least one best female friend who smoked. In response to this same question, of adolescents who had never smoked, only 20 percent reported having at least one best male friend, and 18 percent reported having at least one best female friend who smoked.

Teenagers who smoked tobacco also reported knowing more people who used chewing tobacco, snuff, marijuana, crack, or cocaine; drank alcohol; and had had sex than did teenagers who had never smoked. In addition, at least half of all current smokers said that most or all of the people they knew who were their age smoked cigarettes, drank alcohol, got drunk at least once a month, or had had sex.

School performance and attitudes about school were also strong correlates of smoking uptake among adolescents. Again, more current smokers than teenagers who had never smoked reported liking school less, doing poorly in school, and perceiving what they learned in
school as less useful to them later in life. Current smokers also missed more time from school in the 2 weeks prior to the interview and reported cutting school more often.

In table 4, a scale to measure depression was adapted for telephone interviewing from a scale originally designed for self-enumeration application (12). Teenagers who currently smoked were tired; had trouble sleeping; were sad or depressed; felt hopeless, tense, or nervous; and worried more often than teenagers who had never smoked.

Adolescents who smoked were more likely to be involved in risky behaviors, another correlate of smoking uptake, than teenagers who have never smoked. Teenage smokers were twice as likely to have been involved in one or more physical fights in the past year and ridden a motorcycle or minibike often or sometimes in the past year. Smokers were almost three times more likely to rarely or never wear seat belts and six times more likely to have ridden in a car driven by someone who had been using drugs or drinking than those teenagers who had never smoked.

Estimates from the TAPS also showed an important difference between teenagers who smoked and those who had never smoked, in terms of social and family functioning. For example:

- Seventy-eight percent of teenagers who had never smoked reported that they strongly disliked being around people who were smoking, and 94 percent preferred to date nonsmokers, but only 19 percent of current smokers strongly disliked being around others who were smoking, and 51 percent preferred to date nonsmokers.
- More than 90 percent of teenagers who smoked, compared with 57 percent who have never smoked, had had a steady boyfriend or girlfriend. Almost half of those teenage smokers reported that their boyfriend or girlfriend also smoked, but only

8 percent of teenagers who had never smoked reported having a boyfriend or girlfriend who smoked (table 4).

- Teenage smokers had more spendable income than teenagers who had never smoked. More than 45 percent of current smokers had more than $\$ 20.00$ a week to spend any way they wanted to, compared with half as many teenagers who had never smoked. Teenage smokers consequently had more money to spend for cigarettes (table 4).
- Teenagers who smoked were likely to go to a friend if they needed help with a serious problem, but teenagers who had never smoked were more likely to confide in a parent (table 4).
- Almost twice as many teenagers who smoked were left alone at home without parental or adult supervision for 10 or more hours a week as were teenagers who had never smoked (table 4).
- More than half the teenagers who smoked attended religious services rarely or never, compared with fewer than a third of teenagers who have never smoked (table 4).
As shown in table 5, prevalence for males who "ever used" and "ever regularly used" smokeless tobacco products, such as chewing tobacco or snuff, increased with age and was more common among white respondents than among black respondents, and more common among non-Hispanics than among Hispanics. When asked the question "How many of the people you know, who are about your age, use chewing tobacco or snuff?", 14 percent of teenagers who had ever used smokeless tobacco reported that most or all of the people they knew used some form of smokeless tobacco, compared with only 3 percent of teenagers who had never used smokeless tobacco (table 6). Twenty-two percent of male teenagers had ever used chewing tobacco or snuff regularly (table 5). More than 29 percent of these teenagers reported that all or most of the
people they knew used smokeless tobacco. More than 95 percent knew that using smokeless tobacco can cause cancer (table 6).

A significant number of teenagers reported having been exposed to information related to the health risks of smoking regardless of adolescent smoking status. More than 80 percent of both current smokers and teenagers who had never smoked said they had heard or seen something in the media recently about the risks of smoking, and more than 70 percent had taken a class or course at school about the health risks of smoking (table 7). More than 80 percent of current smokers and teenagers who had never smoked also believed that almost all doctors are strongly against cigarette smoking. Despite similar knowledge levels about smoking health risks, current smokers were more likely than teenagers who had never smoked to believe that it was safe to smoke for a year or 2 , that there was no harm in having an occasional cigarette, and that they could stop smoking anytime they wanted to (table 7).

What teenagers believed to be true about smoking was clearly influenced by the benefits they perceived from smoking. Current adolescent smokers were significantly more likely to believe that cigarette smoking helps people when they are bored, helps people relax, helps reduce stress, helps people feel more comfortable in social situations, and helps keep their weight down. For current teenage smokers, the perceived functional utility of smoking clearly outweighed the risks of smoking.

## Discussion

These data highlight several areas of concern. For many adolescents, the perceived benefits of smoking outweighed the risks involved. Adolescent smokers appeared to overestimate their ability to quit smoking. As reported, quit attempts
are often met with failure, a symptom of nicotine addiction (13). In addition, the ease of adolescent access to cigarettes, shown in the TAPS and elsewhere $(14,15)$, highlights the need for better control of tobacco sales to minors.

The United States Public Health Service is committed to reducing the initiation of tobacco use among our Nation's youth (2). One national health objective (Objective 3.10) calls for the establishment of tobacco-free environments and the inclusion of tobacco-use prevention in the curricula of all elementary, middle, and secondary schools, preferably as part of quality school health education (2). Another goal (Objective 3.13) is to enact and enforce laws that prohibit the sale of tobacco products to minors in all 50 States and the District of Columbia (2). As of September 1992, 49 States and the District of Columbia had laws in place restricting the sale of tobacco products to minors (CDC, unpublished data). Although there appears to be widespread support for effective minors' access laws (16), such laws are only rarely enforced (17).

Many perceptions of adolescents about cigarette smoking may result from image-based advertisements ( $1,2,11$ ). The national health objectives also call for the elimination or severe restriction of tobaccoproduct advertising and promotion to which youths are likely to be exposed (Objective 3.15) (2). Other effective strategies may include the development of statewide tobaccocontrol plans to reduce tobacco use, especially among youth (Objective 3.14) (2) and raising state excise taxes on tobacco products $(1,18)$. Progress in the reduction of tobacco-use initiation among adolescents will be enhanced by cooperative efforts among local and state health and education officials, parents, physicians and other health care providers, media, legislators, regulatory agencies, and community youth organizations (3).

[^14]Table 4. Number and percent distribution of teenagers by correlates of smoking uptake and risk-taking behaviors, according to smoking status: United States, 1989-Con.

Table 4. Number and percent distribution of teenagers by correlates of smoking uptake and risk-taking behaviors, according to smoking status: United States, 1989-Con.

1 Includes unknown type of smaker.
2Difference in total number of teenagers from table 1 due to Computer-Assisted Telephone Intervewing (CATI) versus CAT1-mail sample size (see Technical notes).
Includes unknown smoking status, correlates of smoking uptake and risk behaviors.
3 One pack contans 20 cigarettes.
${ }^{4}$ Excludes adolescents not enrolled in school at tume of interview
5 Includes only 12-16-year-oids.
NOTE: Sums may not equal totals due to rounding.

Table 5. Number and percent distribution of male teenagers by smokeless tobacco-use status, according to age, race, and Hispanic origin: United States, 1989

| Age, race, and Hispanic origin | Smokeless tobacco-use status |  |  |  |  |  |

## Technical notes

## Source and description of data

This report contains data from the 1989 Teenage Attitudes and Practices Survey (TAPS). The TAPS was a targeted population study of U.S. teenagers $12-18$ years of age. The study was conducted by the National Center for Health Statistic's National Health Interview Survey (NHIS) and co-sponsored by the Centers for Disease Control's Office on Smoking and Health, the National Cancer Institute, and the American Cancer Society.

The TAPS survey was designed to obtain current national household data about current cigarette-smoking behavior and lifetime smoking practices of adolescents and their beliefs about smoking. Selected correlate measures associated with smoking uptake were also addressed in the study.

The TAPS sample was derived from NHIS household interviews conducted during the final two quarters of 1988 and the first two quarters of 1989. Included in the sample were all sample teenagers living in households contacted and interviewed during this period that were 12-18 years of age as of November 1, 1989. The eligible sample for the TAPS was 12,097 persons.

TAPS utilized two modes of data collection. The primary method consisted of computer-assisted telephone interviewing (CATI) in households where a telephone number was provided during the original NHIS interview. In addition, self-administered questionnaires were mailed to sample teenagers living in households without telephones or an available telephone number. Mail questionnaires were also sent to those teenagers that could not be reached using the CATI method. Telephone interviews and all other datacollection activities were performed by U.S. Bureau of the Census personnel. Data collection began in August 1989 and continued through March 1990.

Unlike the original NHIS interview, the TAPS survey design required that all teenagers respond for themselves. However, prior to the initial telephone contact, advance letters were mailed to a parent or guardian and to each eligible teenager in the household explaining the sponsorship and objectives of the upcoming survey and assuring confidentiality.

The total interviewed TAPS sample included 9,965 adolescents- 9,135 responded in CATI interviews and 830 completed mail questionnaires. The total combined response rate for the TAPS from these two data collection procedures was 82.4 percent. Most of the nonresponse resulted from teenagers' failure to return the mail questionnaire. Only 3.1 percent of interviews of adolescents reached by telephone ended in a refusal, either because of the parents or teenagers initial refusal or because of subsequent termination of the interview. Item nonresponse was less than 1 percent for the questions discussed in this report. More details about non-response are available in a recent report (17).

## Sampling errors

Because estimates shown in this report are based on a sample of the population rather than on the entire population, they are subject to sampling error. When an estimate or the numerator or denominator of a percent is small, the sampling error may be relatively high. In addition, the complex sample design of the NHIS has the effect of making the sampling errors larger than they would be had a simple random sample of equal size been used.

The following method for computing sampling errors is presented for the convenience of readers who want a simple method to use in calculating standard errors for estimates in this report. More precise methods, such as that available in the software program SUDAAN (19), which estimates standard errors for
complex surveys using Taylor linearization, are recommended for detailed analysis of NHIS data.

Approximate standard errors of the estimated numbers ( $x$ ) in this report (except for all teenagers, by age, race, and sex when the standard error is assumed to be 0.0 ) may be calculated using the formula

$$
S E(x)=\sqrt{0.0000307(x)^{2}+3,640(x)}
$$

Except as noted, approximate standard errors of the estimated percents in this report may be calculated using the formula

where $p$ is the estimated percent and $y$ is the population denominator.

Approximate standard errors for the percents in table 5, by age and race, may be calculated by using the formula

$$
\mathrm{SE}(p)=\mathrm{p} \sqrt{0.0000307+3,640 / x}
$$

where $p$ is the estimated percent and $x=p y / 100$ with $y=$ the population denominator.

If $x_{1}$ and $x_{2}$ are two estimates, then the approximate standard error of the difference ( $x_{1-x_{2}}$ ) can be computed as follows:
$\sqrt{\operatorname{SE}\left(x_{1}\right)^{2}+\operatorname{SE}\left(x_{2}\right)-2 r \operatorname{SE}\left(x_{1}\right) \operatorname{SE}\left(x_{2}\right)}$
where $\operatorname{SE}\left(x_{1}\right)$ and $\operatorname{SE}\left(x_{2}\right)$ are computed using the appropriate formulas previously presented in this section, and $r$ is the correlation coefficient between $x_{1}$ and $x_{2}$ (assuming $r=0.0$ will result in an accurate standard error if the two estimates are actually uncorrelated and will result in an overestimate of the standard error if the correlation is positive or an underestimate if the correlation is negative).

In this report, unless otherwise noted, a difference was considered statistically significant at the 5 -percent level if the difference $\left(x_{1}-x_{2}\right)$ was at least twice as large as its standard error.

## Related documentation

More detailed discussion of the sample design of the NHIS, estimating procedures, procedures for estimating standard errors, nonsampling errors, and definitions of other sociodemographic terms used in this report have been published in Vital and Health Statistics, Series 10, numbers 160 and 176; Series 1 , number 18; and Series 2, number 110 (20-23).

A public use data file based on the 1989 TAPS was released in February 1992. Information regarding its purchase may be obtained by writing to the Division of Health Interview Statistics, National Center for Health Statistics, 6525 Belcrest Road, Hyattsville, Maryland 20782.

smoked 100 cigarettes and has not smoked in the past 30 days.

Former smoker - Has smoked at least 100 cigarettes but has not smoked in the past 30 days.

Current smoker-Has smoked a cigarette in the past 30 days.

Current light smoker-Has smoked 10 or more days in the past 30 days, and smoked an average of fewer than five cigarettes per day in the past 7 days.

Current heavy smoker-Has smoked 10 or more days in the past 30 days, and smoked an average of five cigarettes or more per day in the past 7 days.

Current occasional smoker-Has smoked 1 to 9 days in the past 30 days.

# AIDS Knowledge and Attitudes for 1991 

## Data From the National Health Interview Survey

by Shella M. Aguilar and Ann M. Hardy, Dr.P.H., Division of Health Interview Statistics

## Highlights

In 1991, levels of knowledge about the major modes of transmission of human immunodeficiency virus (HIV) remained high in all sociodemographic groups examined. Knowledge about other aspects of acquired immunodeficiency syndrome (AIDS) was more variable, with older and less-educated adults generally being less knowledgeable. Several changes in responses to survey items between 1990 and 1991 were noted, including:

- An increase from 19 to 29 percent in the proportion who felt they knew "a lot" about AIDS.
- An increase from 79 to 86 percent in the proportion who had heard the AIDS virus referred to as "HIV."
- An increase of 3-6 percentage points in the percent of adults stating that various forms of casual contact were "very unlikely" or "definitely not possible" ways to transmit HIV.
- A slight increase in the proportion who reported ever having HIV antibody testing - excluding blood donation (from 11 to 15 percent) and testing through all means (from 26 to 29 percent).

In addition, some changes in responses were noted during 1991, particularly in the fourth quarter compared with earlier quarters. Noteworthy changes seen during 1991 included:

- The proportion who received information about AIDS from television programs in the month before the interview increased from 72 to 78 percent.
- The percentage of parents who had ever discussed AIDS with their children rose from 66 percent in the first quarter to 72 percent in the last quarter of 1991.
- The proportion who knew a person can be infected with the AIDS virus and not have the disease AIDS increased by 5 percentage points (from 77 to 82 percent).
- Those planning future testing for HIV antibodies who indicated such testing would be voluntary increased from 65 to 71 percent.
- The proportion who had heard of zidovudine (also known as AZT or azidothymidine and by the brand name "Retrovir") increased from 50 to 55 percent.

## Introduction

The National Center for Health Statistics (NCHS) has included
questions about HIV and AIDS as part of the National Health Interview Survey (NHIS) since 1987. The purpose of these questions is to provide population-based data on adults' knowledge about AIDS and transmission of HIV and on their experience with HIV antibody testing. Such information is used to help plan and monitor various educational and prevention programs. The questionnaire used in 1991 is the fourth version of this survey (1). Although new questions have been introduced in each version to meet changing data needs, many questions have been used repeatedly to allow for examination of trends. NCHS has routinely published results from this survey in Advance Data From Vital and Health Statistics (2-9). In addition, public use data tapes of the 1987-90 surveys are currently available and more detailed exploration of the data is encouraged.

The NHIS AIDS questionnaires have been developed by NCHS and an Interagency Task Force created by the Public Health Service Data Policy Committee. The Task Force includes representatives from other centers within the Centers for Disease Control and Prevention and from the Office of the Assistant Secretary for
U.S. DEPARTMENT OF HEALTH AND HUMAN SERVICES

## Data and methods

This report presents a summary of data for the entire 1991 datacollection year. Thus there is some overlap with the earlier report that described results from the first quarter of 1991 (9). Unless otherwise stated, the results described were consistent throughout 1991. For certain items, some differences were noted for the fourth quarter of 1991, and these are pointed out. While the exact cause of these variations for that particular quarter is not known, most readers are probably aware of the considerable amount of publicity that occurred in the fourth quarter of 1991 after Earvin "Magic" Johnson announced that he was infected with HIV. Further analyses are underway to determine the impact of this announcement on responses to the NHIS and other AIDS surveys. Also, 1990 data cited in this report for comparison refers to data reported from the fourth quarter of 1990 (8). Details about the sample design and the estimation procedure can be found in "Technical notes" at the end of this report.

Table 1 shows percent distributions by response categories to most of the items included in the NHIS AIDS questionnaire for the entire adult population as well as various subgroups defined by age, sex, race and ethnicity, and education. In most cases, the actual questions are reproduced verbatim in the tables along with the response categories. Refusals and other nonresponse categories (generally less than 1 percent of total responses) are excluded from the denominator in the calculation of estimates, but responses of "don't know" are
included. The NHIS AIDS survey uses the phrase "the AIDS virus" rather than "HIV" because it is felt to be more widely recognized; however, in this report the two terms are used synonymously.

When interpreting trend data, revisions in the questionnaire, whether in actual wording or in context and location of questions, must be considered. There were several important changes and additions to the 1991 version of the survey. First, the series of knowledge items that contain selected statements about HIV and AIDS (question 5 in the 1991 survey) had five possible responses in earlier versions of the questionnaire: "definitely true," "probably true," "probably false," "definitely false," and "don't know." In 1991, the distinction between definitely and probably was eliminated leaving "true," "false," and "don't know" as the only possible response choices.

Before 1991, the section on HIV antibody testing began with a question assessing whether persons had heard of the blood test to detect the AIDS virus infection; those who were not aware of the test were skipped past the remainder of this section. In 1991, this lead-in was eliminated because of concern about people attempting to end the survey prematurely. Persons who truly were not familiar with HIV antibody testing still had the option of responding "don't know" to questions in this section.

Several new items were added to the 1991 survey, including the perceived likelihood of becoming infected by receiving care from an infected health care worker or by donating blood. Reasons why persons had not been tested for HIV were examined. Items were added to assess respondents' knowledge about the HIV antibody test, about AZT, and about the proper use of condoms. Finally, in 1991, a distinction was made between having a co-worker with HIV or AIDS and having other friends or relatives with the disease.

## Selected findings

The following highlights describe survey results of the NHIS AIDS Knowledge and Attitudes Survey for 1991. Unless otherwise noted in the text, all measures described remained stable over this period. All differences cited in the text are statistically significant at the .05 level. Table II shows provisional estimates of the standard errors associated with these results.

## Sources of information

In 1991, 86 percent of adults stated that they had received information about AIDS in the past month. This was consistent with the figure reported for 1990 . Of all categories listed, the primary sources of information were television programs ( 73 percent), newspaper articles ( 47 percent), magazine articles ( 40 percent), and radio programs ( 35 percent). From the third to fourth quarter of 1991, there was a notable increase in the proportion receiving AIDS information. During this time the percent of adults hearing or seeing information from any of the sources mentioned above rose from 1 to 6 percentage points.

When specifically asked about exposure to public service announcements (PSA's) in the previous month, 80 percent reported viewing them on television, 45 percent hearing them on radio, and 9 percent seeing posters in airports. For all three sources, those 18-29 years old, and those with more than 12 years of education appeared to have had more exposure to PSA's than had their counterparts.

Of parents of 10-17-year-olds, 69 percent reported ever discussing AIDS with those children. Overall, white and black parents were more likely to talk to their children about AIDS than were Hispanic parents (70 percent, compared with 61 percent). Women and those $30-49$ years old were also more likely to discuss the topic. The percentage of parents discussing AIDS with their children increased with years of
education, from 56 percent for those with less than 12 years of education to 75 percent for those with more than 12 years of education. Seventyfour percent of parents reported that their children received instruction about AIDS at school. This figure is similar to the percent reported for 1990. The percentage of parents who reported talking to their children about AIDS increased in the fourth quarter of 1991 ( 72 percent, compared with the earlier quarters' range of 66-69 percent).

## General knowledge about AIDS

In 1991, of the adults asked to assess their knowledge of AIDS, 29 percent stated they knew "a lot," and 44 percent stated they knew "some." The percentage of those who knew "a lot" had increased 10 percentage points since 1990 , whereas the percent answering "some" remained stable throughout 1991. The percentages decreased for those who answered "a little" ( 25 percent in 1990 to 19 percent in 1991) and "nothing" (10 percent in 1990 to 8 percent in 1991).

Also in 1991, a higher percentage of people reported having heard the AIDS virus called "HIV" -86 percent in 1991, compared with 79 percent in 1990. Awareness was lower among persons with less than 12 years of education, those over 50 years old, and those of Hispanic descent ( 67 percent, 78 percent, and 72 percent, respectively).

In 1991, new sets of responses were used for questions pertaining to knowledge about AIDS. Prior to 1991, four responses were possible, ranging from "definitely true" to "definitely false." In 1991, the response categories were changed to "true" or "false." "Don't know" also remained an acceptable response in the 1991 questionnaire. This decrease in categories may have accounted for the change in proportions with correct responses from 1990.

Ninety-five percent of adults knew that AIDS is transmissible through sexual intercourse, 94 percent believed a pregnant woman infected
with AIDS can give it to her baby, 92 percent knew there is no cure for AIDS at present, 85 percent knew AIDS reduces the body's natural protection against disease, and 81 percent knew it is an infectious disease caused by a virus. Persons who commonly answered incorrectly included those 50 years old and over and those with 12 or fewer years of education. However, more individuals answered "don't know" than provided the incorrect true-false response.

Correct responses to other AIDS-knowledge questions were lower. Eighty percent of adults knew that a person who has the AIDS virus can look and feel healthy, but 78 percent knew that a person can be infected with HIV and not have the disease AIDS. Sixty-seven percent of adults were aware of the availability of drugs that can lengthen the life of a person infected with AIDS. For these items, the proportion with the correct response was $4-5$ percentage points higher in the fourth quarter of 1991 than in previous quarters.

Also in 1991, more than half of all adults knew that early treatment of HIV can reduce symptoms in an infected person and that AIDS can damage the brain. As before, knowledge levels were lower for older individuals and those with less education.

## Misconceptions about HIV transmission

The NHIS AIDS supplement provides information on respondents' perceptions of the likelihood of HIV transmission associated with several forms of contact. There were five response categories, which ranged from "very likely" to "definitely not possible." The proportion of adults who believed the various modes of transmission were "very unlikely" and "definitely not possible" remained stable throughout 1991 but for most were slightly higher than in 1990 . For these two response categories, the highest percentages were reported for questions that assessed transmission by working near someone with AIDS, attending school with a child who has

AIDS, using public toilets, eating in a restaurant where the cook has AIDS, and being coughed or sneezed on.

Although general knowledge levels about AIDS were high, perceived likelihood of transmission persisted for questions evaluating transmission through casual contact with a health care worker ( 27 percent reported "very likely," and 33 percent reported "somewhat likely"); by sharing plates, forks, or glasses ( 10 and 18 percent); and through mosquitoes or other insects ( 9 and 16 percent). As with previous reports, younger persons, those with more education, and white adults were more likely to view these modes as unlikely or impossible factors in HIV transmission.

## Blood donation and blood screening

Patterns of past blood donation were similar in 1991 to those seen in previous years. Overall, 42 percent of adults reported ever having donated blood; 18 percent had donated since March 1985 (when routine screening of donated blood for HIV began); and 6 percent had donated in the past year. In general, men were more likely to have donated than women, and donations increased with years of education.

In 1991, 60 percent of adults knew that a person could not get HIV while donating blood for use by others; 30 percent believed that they could; and 10 percent did not know. Misconceptions about transmission of HIV by donating blood were higher among black adults ( 43 percent believed that AIDS could be transmitted this way, compared with 27 percent of white adults), and those with less than 12 years of education ( 38 percent, compared with 24 percent of those with more than 12 years of schooling). It should be noted that the data did not distinguish between a respondent who believed that such transmission was likely and one who thought it was just a theoretical possibility if standard blood bank practices were not followed. Also, despite attempts to
make the wording clear, some respondents may still have mistakenly believed that the question referred to getting HIV from receiving blood. Further refinement of this question may help clarify the responses being elicited.

Seventy-six percent of adults in 1991 believed that blood donations were routinely tested for the AIDS vizus. This figure remained stable throughout 1991, but it was higher than that reported in the last quarter $c: 1990$ ( 68 percent). Also, the F-oportion who did not know the answer to this question more than doubled between 1990 and 1991 (from 7 to 16 percent). These changes may have been due in part to the elimination in 1991 of the question sequence that first asked if persons were aware of the blood test to detect HIV infection and then proceeded to oiher questions related to HIV testing.

## HIV antibody testing

Considering HIV testing done for all reasons (including blood donation), an estimated 29 percent of adults in the United States reported having been tested for antibodies to HIV. In 1991, the percent of adults ever tested for HIV - apart from blood donation - was 15 percent, up slightly from 11 percent in the last quarter of 1990 . In the remainder of this report, all reference to HIV testing is restricted to testing for reasons other than blood donation.

In 1991, the NHIS asked those adults who had not been tested for HIV why they had not. The most common response, given by $8+$ percent of those never tested, was that they did not consider themselves to be at risk for AIDS. Very few respondents (less than 2 percent) chose recognized barriers to testing - such as fear of discrimination, not knowing where to go for testing, and not trusting the medical community to keep results confidential-as reasons they had not been tested. The remainder listed fear of needles ( 1 percent), chose another unspecified reason
(6 percent), or said they did not know why they had not been tested ( 9 percent). These figures remained essentially the same through all of 1991.

For those who had ever been tested, about two-thirds had been tested once, and one-third had been tested more than once. This pattern was similar in all subgroups examined. About one-half of those who had been tested had had the test in the 12 months before the interview.

The reported reasons for HIV antibody testing were similar in 1991 to those reported in 1990. Twenty-five percent of those tested did so solely to find out if they were infected. Another 6 percent cited referral by their doctor, the health department, or their sex partner. Fourteen percent had been tested in preparation for hospitalization or a surgical procedure, 14 percent to apply for health or life insurance, and 7 percent each for military induction or service and for employment. Although immigration was mentioned by only 6 percent of all adults tested, it was the reason most commonly cited by Hispanic persons (31 percent). As in 1990, most of those in 1991 who reported being tested had had their last test at their doctor's office or health maintenance organization (HMO) (30 percent); at a hospital, emergency room, or outpatient clinic (25 percent); or at a community health clinic ( 7 percent).

As in the past, about threequarters ( 79 percent) of those tested received their results. This figure decreased with age and was higher among Hispanic adults who were tested than among black or white adults who were tested ( 85 percent compared with 81 and 78 percent, respectively). In 1991, 60 percent of those who were tested received their results in person. This figure showed a slight decrease in the second half of 1991 from the first half ( 62 percent compared with 57 percent). In 1991, almost all adults tested said they felt their results were accurate (99 percent) and that their results
were handled properly in terms of confidentiality ( 95 percent).

The proportion who indicated intention to be tested in the next year was 9 percent, similar to that reported previously. The figure was highest arnong black adults (21 percent). Of those who planned to be tested, most ( 67 percent) said they would be tested voluntarily because they wanted to know if they were infected. The proportion of those planning testing who mentioned this as a reason increased slightly from 65 percent in the first quarter of 1991 to 71 percent in the last quarter. In addition to this reason, another 19 percent said they would be tested as part of a blood donation, and 8 percent each indicated it would be to apply for a job or for insurance (health or life). The percentages for the places where respondents said they would go to have their blood tested were similar to those for places cited by those already tested.

Seventy-four percent of adults recognized that "after a person is infected with the AIDS virus, there can be a period of time before the [blood] test shows the infection"; 23 percent responded "don't know" to this statement. The proportion with the correct response to this item increased slightly in 1991 (70 percent correct in the first quarter compared with 76 percent in the last quarter). Persons less likely to be aware of this fact included those with less than 12 years of education ( 55 percent correct), Hispanic adults ( 61 percent correct), and those 50 years and over (64 percent correct).

## Awareness about zidovudine

A new question was added to the 1991 NHIS AIDS supplement to assess an individual's awareness of zidovudine (also known as AZT or azidothymidine and by the brand name "Retrovir"). AZT was the first antiviral drug approved for use in the treatment of HIV. More than one-half of all adults reported that they had heard of this drug. A notable increase in awareness occurred from the third to fourth
quarter of 1991 ( 50 to 55 percent). Persons between the ages of 30 and 49 (59 percent), and those having higher levels of education were more familiar with the drug ( 24 percent for adults with less than 12 years of education compared with 69 percent for those with more than 12 years of education). Hispanic adults were less aware of AZT than white or black adults ( 32 percent compared with 55 and 43 percent, respectively).

Among persons who had heard of AZT, 89 percent were aware that AZT does not cure people with AIDS, 81 percent knew it can delay or slow down the symptoms of HIV infection, and 59 percent knew of the drug's side effects. Thirty-four percent knew AZT is only appropriate for an HIV-infected individual at certain times during the illness. Proportionately more people answered "don't know" to this question ( 55 percent), as opposed to those giving the incorrect response (11 percent). Half of the adults surveyed knew there are other drugs available to treat AIDS-related illnesses. Between the third and fourth quarters, this percentage rose five points (from 49 to 54 percent). However, 35 percent answered "don't know," and 14 percent did not believe other drugs existed. Slight percentage fluctuations across all sociodemographic groups indicated no specific pattern for those who answered "don't know" as opposed to the correct response. For each question, more people answered "don't know" rather than giving the incorrect response.

## Perceptions about condom use

As in previous years, the 1991 NHIS asked respondents to evaluate the efficacy of condom use as a means of preventing sexual transmission of HIV. Overall, since 1990, the percentages responding "very effective" and "don't know" increased ( 25 and 15 percent in 1990 compared with 28 and 17 percent in 1991, respectively), and those who answered "somewhat effective"
decreased from 53 percent in 1990 to 49 percent in 1991.

The proportions of individuals who answered "very effective" stayed consistently below one-third throughout 1991. For the adults who believed condom use to be "somewhat effective" in preventing HIV infection, there was a 2 -percent increase between the third and fourth quarters of 1991 (49 to 51 percent). Persons least likely to believe in the efficacy of condoms were females, black adults, those of Hispanic descent, and those with less than 12 years of education (19, 22, 21, and 32 percent, respectively).

Two new questions in the 1991 AIDS supplement gauged knowledge of correct condom use. These questions evaluated respondents' ability to distinguish the relative effectiveness of latex versus naturalmembrane condoms and whether they knew the dangers of using oil-based lubricants with latex condoms. For both of these questions, more people chose "don't know" than the correct response.

Although 77 percent of adults considered condom use at least somewhat effective in preventing HIV infection, 61 percent of adults did not know if there was a difference between the effectiveness of latex and natural-membrane condoms.
Nineteen percent recognized that there was a difference, and 18 percent felt there was no difference in effectiveness between the two types of condoms. Persons 30-49, white persons, and those with more than 12 years of education were more likely to provide the correct response; however, even in these groups more than half responded "don't know." Similarly, only 27 percent knew that oil-based lubricants cause latex condoms to break, and 65 percent were unsure of this effect. Six percent called the statement "false." Males and younger individuals were more likely to give the correct answer (31 and 36 percent, respectively). Correct responses increased with years of education -16 percent for those with less than 12 years of education up to 34 percent for those with more than

12 years of education. Those more likely to respond "don't know" included females ( 70 percent), those 50 years of age and over ( 76 percent), individuals of Hispanic descent ( 67 percent), and persons with less than 12 years of education (73 percent).

## Risk of HIV infection

In 1991, 80 percent of adults felt they had no chance of being infected with HIV, and 72 percent said they had no chance of getting it in the future. Black adults were somewhat less likely than white or Hispanic persons to rate their chances of having or getting HIV as "none." Also, those 18-29 years of age were less likely than older persons to feel they had no chance of being or becoming infected. Only 1-2 percent of adults felt their chances of having or getting HIV were "high" or "medium" (these proportions varied little among the sociodemographic groups). As in the past, only a small proportion of adults ( 3 percent) reported being in any of the behavior categories associated with an increased risk of HIV infection.

## Knowing someone with AIDS

In the past, the NHIS AIDS survey has asked respondents if they had ever personally known someone with HIV infection or AIDS. In 1991, the distinction was made between having a co-worker with HIV or AIDS and knowing others (friends or relatives) with the infection. Four percent of adults reported having had a co-worker with HIV or AIDS. This figure increased with years of education, from 2 percent of those with less than 12 years to 7 percent for those with more than 12 years. Nine percent of persons reported having a friend or relative with the disease. This also increased with years of education and was higher for those $30-49$ years of age than for younger or older persons. For both situations, the proportion who said they personally knew someone with AIDS was stable throughout 1991.

NOTE: HMO is health maintenance organization. STD is sexually transmitted disease.

## Technical Notes

The National Health Interview Survey (NHIS) is a continuous, cross-sectional household interview survey. Each week, a probability sample of the civilian noninstitutionalized population residing in the United States is interviewed by personnel of the U.S. Bureau of the Census to obtain information on the health and other characteristics of each member of the household. Information on special health topics is collected for all or a sample of
household members. For the 1991 National Health Interview Survey of AIDS Knowledge and Attitudes, one randomly chosen adult 18 years of age or over was interviewed in each family. The estimates in this report are based on completed interviews with 42,726 individuals. In 1991, the response rate to the basic NHIS core questionnaire was 96 percent; for the NHIS AIDS supplement, it was 90 percent. Therefore, the overall response rate to the 1991 AIDS survey was 86 percent.

Table I. Sample sizes for 1991 National Health Interview Survey of AIDS Knowledge and Attitudes and estimated adult population 18 years of age and over, by selected characteristics: United States, 1991.

| Characteristic | Sample size | Estimated population in thousands |
| :---: | :---: | :---: |
| All adults. | 42,726 | 180,271 |
| Age |  |  |
| 18-29 years. | 9,470 | 46,282 |
| 30-49 years. | 17,391 | 71,831 |
| 50 yeas and over. | 15,865 | 61,157 |
| Sex |  |  |
| Male | 17,845 | 85,632 |
| Female | 24,881 | 94,638 |
| Race and ethnicity |  |  |
| Non-Hispanic: |  |  |
| White. | 32,575 | 139,440 |
| Black. | 5,608 | 19,585 |
| Hispanic | 3,079 | 14,118 |
| Education |  |  |
| Less than 12 years | 9,081 | 36,782 |
| 12 years. | 15.712 | 72,418 |
| More than 12 years | 17,848 | 70,036 |

Table I contains the estimated population size of each of the demographic subgroups included in table 1 to allow readers to derive provisional estimates of the number of people in the United States with a given characteristic-for example, the number of women who have had their blood tested for HIV:

## $0.13 \times 94,638,000$ women tested

The population estimates in table I are based on 1989 data from the NHIS inflated to national population controls by age, race, and sex. The population controls are based on the 1980 census carried forward to 1989. These estimates, therefore, may differ from 1990 census results brought forward to the survey date. Population controls incorporating 1990 census results will be used for survey estimation beginning later in the decade.

Table II shows approximate standard errors for most of the estimates presented in table 1. These standard error estimates were derived by applying a design effect of 1.3 to the standard errors that would have been obtained with a simple randomsample design. The reader is cautioned about comparing estimates when the denominator is small (for example, when looking only at those persons who did not receive the results of their HIV antibody test). A final data file covering the entire 1991 data collection period will be available at the end of 1992.

Table II. Standard errors, expressed in percentage points, of estimated percents from the 1991 National Health Interview Survey of AIDS Knowledge and Attitudes, by selected characteristics: United States, 1991

# Office Visits to Cardiovascular Disease Specialists: United States, 1989-90 

by Susan M. Schappert, M.A., Division of Health Care Statistics

## Introduction

An estimated 22.1 million visits were made in the United States during 1989 and 1990 to nonfederally employed, office-based physicians specializing in cardiovascular diseases -an average of about 11 million visits per year. This report summarizes data pertaining to these visits in terms of patient characteristics, physician practice characteristics, and visit characteristics. Two earlier reports provide information on office visits to specialists in cardiovascular diseases for the years 1975-76 and 1985 (1,2).

The information in this report is based on data collected by means of the National Ambulatory Medical Care Survey (NAMCS), a national probability sample survey conducted by the Division of Health Care Statistics of the National Center for Health Statistics, Centers for Disease Control and Prevention. This survey was conducted yearly from 1973 through 1981 and again in 1985. It resumed an annual schedule with the 1989 survey.

The 1989 and 1990 NAMCS shared identical survey instruments, definitions, and procedures. The resulting two years of data have been
combined to provide more reliable estimates, and the reader should note that the estimates, percent distributions, and rates presented in this report reflect average annual estimates based on the combined 1989 and 1990 data. The Patient Record, which is the survey instrument used by participating physicians to record information about their patients' office visits, is shown in figure 1.

The estimates presented in this report are based on a sample, rather than on the entire universe, of office visits, and are subject to sampling variability. The sample design, sampling errors, and guidelines for judging the precision of NAMCS estimates are discussed in the technical notes. Several publications are available that discuss overall findings from the 1989 and 1990 NAMCS ( $3,4,5$ ), and reports on special topics are also available ( $6,7,8,9,10$ ). Additional reports on visits made during 1989 and 1990 to other physician specialties are forthcoming.

## Patient characteristics

Visits to specialists in cardiovascular diseases by patient's
age, sex, and race are displayed in table 1. Overall, this specialty received an average of 4.5 office visits per 100 persons per year for 1989 and 1990. The visit rate increased with age for both sexes and was highest among persons 65 years of age and over, who made an average of 20.3 visits per 100 persons per year. Visit rates were not significantly different for persons 65-74 years and 75 years of age and over. Also, no significant differences were found by sex within any of the five age groups analyzed (figure 2). However, white persons had a significantly higher rate of visits to cardiovascular disease specialists ( 4.8 visits per 100 persons per year) than did black persons ( 2.2 visits per 100 persons per year). In general, visit rates were not significantly different than those noted in 1985.

Patients over the age of 44 years accounted for 88.7 percent of all visits to this specialty during the 2 -year period covered in this report; more than half ( 54.7 percent) of all office visits to cardiovascular disease specialists were made by persons 65 years of age and over. This age distribution is in sharp contrast to that of visits to all other specialists, where, in general, less than half of

Public Health Service
Centers for Disease Control and Prevention National Center for Health Statistics

Figure 1. 1989 National Ambulatory Medical Care Survey Patient Record

- U.S. GOVERNMENT PRINTING OFFICE:1939-228-197
the visits were made by persons over the age of 44 years (figure 3).

No significant difference was found in the percent of visits made by males and females ( 50.2 percent compared with 49.8 percent, respectively). This pattern is strikingly different from that found among visits to all other specialties, where the percent of visits by males was much lower overall ( 39.4 percent) than the percent of visits by females ( 60.6 percent). Among the 13 most visited physician specialties, the percentage
of visits by females exceeded that of visits by males for all but four specialties-pediatrics, urology, orthopedic surgery, and cardiovascular diseases.

White persons made 90.2 percent of all visits to specialists in cardiovascular diseases and black persons accounted for 6.1 percent of the visits. Approximately 2.3 percent of the visits were made by Asians/ Pacific Islanders.

## Physician practice characteristics

Specialists in cardiovascular diseases received an average of 1.6 percent of the office visits made to ambulatory care physicians for 1989-90, making them the 11th most visited physician specialty (table 2). However, cardiovascular specialists received 2.5 percent of all visits made by persons $45-64$ years of age. The share was even higher for visits made by older patients, with cardiovascular specialists receiving 4.0 percent of all

Figure 2. Annual rate of office visits to cardlovascular disease speciallsts, by patient's age and sex: United States, 1989-90
visits made by persons 65 years of age and over, an average of 6 million visits per year by persons in this age group.

Between 1975 and 1990, the number of visits made to cardiovascular disease specialists increased by about 64 percent, from a 2 -year total of 13.5 million for 1975-76 to a 2 -year total of 22.1 million visits for 1989-90. The 1975-76 total represented 1.2 percent of all visits to office-based physicians during that time. This was not significantly different than their 1989-90 share.

## Visit characteristics

## Referral status and prior-visit status

Nearly 10 percent of office visits to specialists in cardiovascular diseases were the result of a referral by another physician, compared with only 5.4 percent of visits to all other specialties. The chronic nature of cardiovascular diseases is underscored by the fact that more than threequarters ( 78.7 percent) of the visits to this specialty were made by patients returning to the physician for care of a previously treated condition. Of the 13 most visited physician specialties, only psychiatry showed a higher percentage of visits of this type. Visits by referral status and prior-visit status are summarized in table 3.

## Expected source of payment

Private insurance (including Blue Cross/Blue Shield and other commercial insurance) and Medicare were the expected sources of payment listed most frequently at visits to specialists in cardiovascular diseases ( 74.8 percent and 50.8 percent of visits, respectively), while selfpayment was recorded at only 17.5 percent of visits. (It should be noted that more than one expected source of payment may be recorded per visit.) The emphasis on Medicare as an expected source of payment reflects the older age distribution of patients visiting this specialty. In contrast, among visits to all other

specialists, Medicare was listed at only 18.5 percent of visits, while self-payment was mentioned at 31.4 percent. Visits to cardiovascular specialists by expected source of payment are shown in table 4.

## Patient's principal reason for visit

The patient's principal reason for visiting the physician, according to the eight reason for visit modules or groups of reasons outlined in $A$

Reason for Visit Classification for Ambulatory Care (RVC) (11), is shown in table 5. The principal reason for visit (item 9a on the Patient Record) is the patient's most important complaint(s), symptom(s), or other reason(s) for this visit expressed in the patient's (or patient surrogate's) own words. Up to three reasons per visit may be coded based upon the classification system found in the RVC.

Nearly half (47.7 percent) of all visits to this specialty were due to a symptomatic problem or complaint, with the largest percentage of symptoms falling into the general category ( 17.7 percent). Also prominent were the disease module (16.8 percent) and the treatment module ( 16.2 percent), followed by the diagnostic, screening, and preventive module ( 12.3 percent of visits).

Specific reasons for visit are listed in table 6 . The single most frequently mentioned principal reason for visiting a cardiovascular specialist was chest pain and related symptoms, recorded at 13.1 percent of visits. Ischemic heart disease and hypertension were the second and third most frequently mentioned reasons ( 5.6 percent and 5.0 percent of visits, respectively). It is important to keep in mind that the rank ordering in this and other tables in this report may not always be reliable because near estimates may not differ from one another because of sampling variability.

It should also be noted that a large number of visits relating to cardiovascular symptoms and diseases were made to primary care physicians. Cardiologists received about 16 percent of all physicians' office visits made for the reason of chest pain during 1989-90. The majority were directed to primary care physicians, with general and family practitioners receiving 37.0 percent and internists receiving 29.2 percent. Similarly, about half of all visits for hypertension (that is, visits at which the patient's principal reason for visiting the physician was recorded as hypertension) were made to general and family practitioners ( 50.1 percent) and an additional one-third were made to internists ( 32.9 percent). Cardiovascular specialists received only 5.4 percent of these visits. However, for visits where patients expressed their principal reason for the current visit as ischemic heart disease, indicating an established diagnosis and ongoing treatment for this condition, cardiovascular specialists received

39.9 percent of the total, compared with internists ( 31.1 percent) and general and family practitioners (23.5 percent).

## Diagnostic services

Visits made to cardiovascular disease specialists were more likely to include diagnostic services ordered or provided by the physician than were visits to all other specialists. About 89.5 percent of the former included at least one diagnostic service, compared with 62.3 percent of the latter. About three-quarters ( 74.0 percent) of the visits included a blood pressure check, compared with 36.1
percent of visits to all other specialties. Other blood test, cholesterol measure, and chest $x$ ray were also performed more often at visits to cardiovascular specialists. Visits by the number and type of diagnostic services ordered or performed at cardiovascular visits are shown in table 7.

## Principal diagnosis rendered by the physician

Data on principal diagnoses made at office visits are obtained from item 10a of the Patient Record, which asks physicians to record the principal diagnosis associated with the patient's
most important reason for visit. Diagnoses are classified and coded according to the International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) (12).

Nearly two-thirds ( 65.4 percent) of all visits to specialists in cardiovascular diseases resulted in a principal diagnosis classifiable to a disease of the circulatory system (table 8). The most frequently listed diagnosis was "other forms of chronic ischemic heart disease" occurring at 20.3 percent of visits, followed by essential hypertension, listed at 13.0 percent of visits (table 9).

The distribution of visits for selected cardiovascular diagnoses by physician specialty is shown in figure 4. Cardiovascular specialists received about 36.9 percent of all visits in which the principal diagnosis was other forms of chronic ischemic heart disease, 35.3 percent of all visits for angina pectoris, and 26.5 percent of all visits for cardiac dysrhythmias. However, following the pattern seen with reasons for visit, cardiovascular disease specialists received only 5.2 percent of all visits with a principal diagnosis of essential hypertension. More than half of visits with a principal diagnosis of essential hypertension were made to general and family practitioners ( 51.2 percent), and nearly one-third were to internists ( 32.0 percent).

## Therapeutic services

Data on therapeutic services ordered or provided at visits to cardiovascular disease specialists are presented in table 10. Medication therapy was mentioned most frequently, at 80.2 percent of visits, compared with 59.9 percent of visits to all other specialists. More than

'Based on A Reason for Vist Classffication for Ambulatory Care (RVC), Vital Health Stat 2(78), Feb. 1979.
half ( 53.9 percent) of the cardiovascular visits included some form of counseling or advice, with weight and cholesterol reduction
being cited at 18.8 percent and 19.7 percent of visits, respectively. In comparison, only 6.1 percent of all other visits included counseling for
weight reduction, and 2.9 percent mentioned counseling for cholesterol reduction.

Data in tables 11,12 , and 13 present additional information pertaining to the utilization of medication therapy at visits to cardiovascular disease specialists. As used in the NAMCS, the term "drug" is interchangeable with the term "medication" and includes all new or continued medications ordered or provided at the visit. This includes both prescription and nonprescription preparations, immunizing agents, and desensitizing agents. "Drug mentions" refer to the total number of medications listed in item 15 of the Patient Record. Because physicians may record more than one medication per visit, the total number of drug mentions may exceed the total number of visits. "Drug visits" refer to visits with at least one mention of medication ordered or provided by the physician. An earlier report (13) describes in detail the method and instruments used in the collection and processing of NAMCS drug data.

Among visits to cardiovascular specialists, there were an average of 25.4 million drug mentions per year for 1989 and 1990, yielding about 2.9 mentions per drug visit and about 2.3 mentions per visit overall. The number of drug mentions by therapeutic classification, adapted from therapeutic categories used in the National Drug Code Directory, 1985 edition (14), is shown in table 11. In cases where a particular drug was classifiable to more than one therapeutic category, it was listed under the category for which it was most frequently prescribed. As expected, cardiovascular-renal drugs were prescribed most frequently ( 55.8 percent of drug mentions). Within this broad category, antianginal agents and antihypertensive drugs represented 31.2 percent of all of the drug mentions.

The generic substances used most frequently in medications ordered or provided at cardiovascular visits are shown in table 12. The first six of these-digoxin, aspirin, nitroglycerin,

| All other diagnoses ${ }^{2}$. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . | 62 | 0.6 |
| Unknown ${ }^{3}$ | 168 | 1.5 |

${ }^{1}$ Based on the international Classification of Diseases, Sth Revision, Clinica Modification (ICD-9-CM).
${ }^{2}$ Includes diseases of the blood and blood-forming organs (280-289); complications of pregnancy, childbith, and the puerpertum ( $630-676$ ); congental anomalies ( $740-759$ ); and certain condrtons originating in the perinatal penod (760-799). ${ }^{3}$ includes blank diagnoses, uncodable diagnoses, and ilegible daagnoses.
diltiazem, furosemide, and hydrochlorothiazide-were found in 32.5 percent of all of the drugs mentioned at cardiovascular visits. It should be noted that drugs containing more than one ingredient are listed in the data for each ingredient. For example, acetaminophen with codeine would be listed both under the count for acetaminophen as well as the count for codeine.
Drug mentions according to entry name, that is, the name recorded by the physician in item 15 of the Patient Record, are shown in table 13. This could be a trade name, generic name, or simply a desired therapeutic effect. Cardizem was the specific entry listed most frequently ( 4.9 percent of mentions), followed by Lanoxin ( 4.7 percent), and Lasix (4.2 percent).

## Disposition of visit

Visits to cardiovascular specialists were more likely to include instructions to return at a specific time ( 80.2 percent) than were visits to all other specialties ( 61.4 percent). Data on disposition of visit are shown in table 14.

## Duration of visit

About half ( 49.2 percent) of the visits to cardiovascular disease specialists lasted more than 15 minutes, compared with less than one-third ( 29.9 percent) of the visits to all other specialists (table 15). Average duration of cardiovascular visits was relatively long-21.8 minutes compared with 16.4 minutes for visits to all other specialists. Average duration is based on the time spent in direct, face-to-face contact between the physician and the patient. It does not include visits of "zero" minutes duration, that is, visits in which the patient did not meet with the physician directly.

Table 12. Number, percent distribution, and therapeutic classification of drug mentlons at office visits to cardiovascular disease speciallists by the 20 most frequently used generic substances, averaged over a 2-year period: United States, 1989-90

| Generic substance | Number of drug mentions in thousands ${ }^{1}$ | Percent distribution | Therapeutic classification ${ }^{2}$ |
| :---: | :---: | :---: | :---: |
| All mentions. | 25.369 | 100.0 | . . |
| Digoxin . | 1,697 | 6.7 | Cardiac glycoside |
| Aspirin | 1,644 | 6.5 | General analgesic |
| Nitroglycerin. | 1,459 | 5.7 | Antianginal agent |
| Diltiazem. | 1,254 | 4.9 | Antianginal agent |
| Furosemide | 1,144 | 4.5 | Diuretic |
| Hydrochlorothiazide | 1,073 | 4.2 | Diuretic |
| Captopril. | 784 | 3.1 | Antihypertensive agent |
| Triamterene | 713 | 2.8 | Diuretic |
| Dipyridamole | 694 | 2.7 | Agent used in peripheral or cerebral vascular disorders |
| Nitedipine | 664 | 2.6 | Antianginal agent |
| Potassium replacement solutions | 633 | 2.5 | Replenisher and regulator of water and electrolytes |
| Verapamil | 631 | 2.5 | Antiarrhythmic agent |
| Isosorbide | 607 | 2.4 | Antianginal agent |
| Atenolol | 566 | 2.2 | Antihypertensive agent |
| Propanolol. | 538 | 2.1 | Antihypertensive agent |
| Lovastatin | 520 | 2.0 | Agent used to treat hyperlipidemia |
| Enalapril | 509 | 2.0 | Antihypertensive agent |
| Warfarin | 434 | 1.7 | Anticoagulant or thrombolytic |
| Glyburide | 342 | 1.3 | Blood glucose regulator |
| Quinidine | 299 | 1.2 | Antiarrhythmic agent |

${ }^{1}$ Frequency of mention combines single-ingredient agents with mentions of the agent as an ingrecient in a combination drug.
${ }^{2}$ Therapeutic classfication is based on the standard drug classification used In the National Drug Code Directory, 1985 Edition. In cases where a generic substance had more than one therapeutic classification, it was listed in the category for which it was most trequently prescribed.

Table 13. Annual number, percent distribution, and therapeutic classification of the 10 drugs most frequently prescribed at office visits to cardiovascular disease specialists, by entry name of drug, averaged over a 2-year period: United States, 1989-90

| Entry name of drug' | Number of drug mentions in thousands | Parcent distribution | Therapeutic classification ${ }^{2}$ |
| :---: | :---: | :---: | :---: |
| All mentions . . . | 25,369 | 100.0 | $\ldots$ |
| Cardizem | 1.254 | 4.9 | Antianginal agent |
| Lanoxin. | 1,204 | 4.7 | Cardiac glycoside |
| Lasix | 1,075 | 4.2 | Diuretic |
| Capoten | 672 | 2.6 | Antihypertensive agent |
| Acetylsalicylic acid (A.S.A.). | 656 | 2.6 | General analgesic |
| Persantine | 598 | 2.4 | Agent used in peripheral or cerebral vascular disorders |
| Aspirin | 570 | 2.2 | General analgesic |
| Procardia. | 540 | 2.1 | Antianginal agent |
| Tenormin. | 524 | 2.1 | Antihypertensive agent |
| Mevacor | 520 | 2.0 | Agent used to treat hyperlipidemia |

| 11-15 minutes | 3,487 | 31.6 | 212,826 | 31.0 |
| 16-30 minutes | 4,160 | 37.7 | 162,107 | 23.6 |
| 31-60 minutes | 1,064 | 9.6 | 40,582 | 5.9 |
| More than 60 minutes. | 208 | 1.9 | 2,985 | 0.4 |

${ }^{1}$ Visits of zero munutes duration are those in which there was no face-to-tace contact between the physician and the patient.

## Technical notes

## Source of data and sample design

This report is based on data collected through the National Ambulatory Medical Care Survey (NAMCS) over the 2 -year period 1989-90. The target universe of NAMCS includes office visits made in the United States by ambulatory patients to nonfederally employed physicians who are principally engaged in office practice, but not in the specialties of anesthesiology, pathology, or radiology. Telephone contacts and nonoffice visits are excluded.

A multistage probability sample design is used in NAMCS, involving samples of primary sampling units (PSU's), physician practices within PSU's, and patient visits within physician practices. The PSU's are counties, groups of counties, county equivalents (such as parishes or independent cities), or towns and townships (for some PSU's in New England). Physicians were stratified into 15 specialty groups during the second stage of the survey design. Detailed descriptions of the 1989 and 1990 NAMCS design have been published $(4,15,16)$, and the reader is urged to consult these sources for further technical information.

The 1989 NAMCS physician sample included 2,535 physicians selected from master files maintained by the American Medical Association and the American Osteopathic Association; 118 of these were specialists in cardiovascular diseases. Physicians were screened at the time of the survey to ensure that they were eligible for survey participation, based upon a set of design criteria. Of those screened, 608 physicians (including 24 cardiovascular disease specialists) were ruled ineligible (out-of-scope) due to reasons such as being retired or employed primarily in teaching, administration, or research. Of the remaining 1,927 physicians, 74 percent responded to the survey, including 61 cardiovascular disease
specialists, or 65 percent of those surveyed.

Sample physicians were asked to complete Patient Records (see figure 1) for a systematic random sample of their office visits occurring during a randomly assigned 1 -week reporting period. Responding physicians completed 38,384 forms, including 1,087 forms completed by cardiovascular specialists.

For 1990, a sample of 3,063 non-Federal, office-based physicians was selected from master files maintained by the American Medical Association and American Osteopathic Association. Of this number, 149 were specialists in cardiovascular diseases. The overall response rate for the $2,269 \mathrm{in}$-scope physicians was 74 percent; the rate was 67 percent for the 114 in-scope cardiovascular disease specialists. Responding physicians completed 43,469 patient records, including 1,243 forms from cardiovascular disease specialists.

Characteristics of the physician's practice, such as primary specialty and type of practice, were obtained from the physicians during an induction interview. The U.S. Bureau of the Census, Housing Surveys Branch, was responsible for the survey's data collection. Processing operations and medical coding were performed by the National Center for Health Statistics, Hospital Discharge and Ambulatory Care Survey Section, Research Triangle Park, North Carolina.

The 1989 and 1990 NAMCS were identical in terms of survey instruments, definitions, and procedures. The resulting 2 years of data have been combined to provide more reliable estimates. All estimates, percent distributions, and rates presented in this report, unless otherwise noted, reflect 1989 and 1990 data that were averaged over the 2 -year period.

## Sampling errors

The standard error is primarily a measure of the sampling variability that occurs by chance when only a

| All other | 0.01877082 | 70.35063675 |

1990 are shown in table I, relative standard errors for estimated numbers of drug mentions are shown in table II, and standard errors for estimated percents of visits are shown in table III. Readers using these tables should keep in mind that they refer to combined years of data rather than average annual estimates.

Alternatively, relative standard errors for aggregate estimates may be calculated using the following general formula, where $x$ is the aggregate of interest in thousands, and $A$ and $B$
are the appropriate coefficients from table IV.

$$
\operatorname{RSE}(x)=\sqrt{A+\frac{B}{x}} \times 100.0
$$

Similarly, relative standard errors for percents may be calculated using the following general formula, where $p$ is the percent of interest and $x$ is the denominator of the percent in thousands, using the appropriate coefficient from table IV:

$$
\operatorname{RSE}(p)=\sqrt{\frac{B(1-p)}{p x}} \times 100.0
$$

## Adjustments for nonresponse

Estimates from NAMCS data were adjusted to account for sample physicians who were in-scope but did not participate in the study. This adjustment was calculated to minimize the impact of response on final estimates by imputing to nonresponding physicians data from visits to similar physicians. For this purpose, physicians were judged similar if they had the same specialty designation and practiced in the same PSU.

## Test of significance and rounding

In this report, the determination of statistical inference is based on the t -test. The Bonferroni inequality was used to establish the critical value for statistically significant differences ( 0.05 level of confidence). Terms relating to differences such as "greater than" or "less than" indicate that the difference is statistically significant. Lack of comment about the difference between any two estimates does not mean that the difference was tested and found to be not significant.

In the tables, estimates of office visits have been rounded to the nearest thousand. Consequently, estimates will not always add to totals. Rates and percents were calculated from original unrounded figures and do not necessarily agree with percents calculated from rounded data.

## Definition of terms

## Ambulatory patient-An

 ambulatory patient is an individual seeking personal health services who is not currently admitted to any health care institution on the premises.Physician-A physician is a duly licensed doctor of medicine (M.D.) or doctor of osteopathy (D.O.) who is currently in office-based practice and who spends some time caring for ambulatory patients. Excluded from the NAMCS are physicians who are hospital-based; who specialize in
anesthesiology, pathology, or radiology; who are federally employed; who treat only institutionalized patients; or who are employed full time by an institution and spend no time seeing ambulatory patients.

Cardiovascular disease
specialist-A cardiovascular disease specialist is a physician who has self-designated the practice specialty of cardiovascular diseases on the American Medical Association's Physicians' Professional Activities Questionnaire. The physician's specialty is also verified during the NAMCS interview. The practice specialty of cardiovascular diseases is defined as a medical specialty by the AMA (other categories include general practice, surgical specialties, and other specialties), and the American Board of Internal Medicine certifies physicians in that specialty. In the 1989 and 1990 NAMCS, 83.8 percent of all visits to cardiovascular disease specialists were made to physicians who were board certified in internal medicine, while 15.8 percent of visits were made to physicians who did not report board certification.

Office-An office is the space that physicians identify as a location for their ambulatory practice. Offices customarily include consultation, examination, or treatment spaces that patients associate with the particular physician.

Visit-A visit is a direct personal exchange between an ambulatory patient and a physician (or a staff member working under the physician's supervision), for the purpose of seeking care and rendering personal health services.

Drug mention-A drug mention is the physician's entry of a pharmaceutical agent (by any route of administration) for prevention, diagnosis, or treatment. Generic as well as brand-name drugs are included, as are nonprescription and prescription drugs. Along with all new drugs, the physician also records continued medications if the patient was specifically instructed during the visit to continue the medication.

Drug visit-A drug visit is a visit in which medication was prescribed or provided by the physician.

# 1991 Summary: National Hospital Discharge Survey 

by Edmund J. Graves, Division of Health Care Statistics

## Introduction

During 1991, an estimated 31.1 million inpatients, excluding newborn infants, were discharged from short-stay non-Federal hospitals in the United States. These patients used 199.1 million days of inpatient hospital care. The discharge rate was 124.1 discharges per 1,000 civilian population and the average length of stay was 6.4 days.

These and other statistics presented in this report are based on data collected by means of the National Hospital Discharge Survey (NHDS), a continuous survey that has been conducted by the National Center for Health Statistics (NCHS) since 1965. In 1991, data were abstracted from the medical records of approximately 274,000 patients discharged from 484 short-stay non-Federal hospitals. Beginning in 1988, a new three-stage stratified
sample design was put in operation. A brief description of the new design, data collection procedures, and estimation process and definitions of terms used in this report can be found in the section entitled "Technical notes." A description of the development and design of the original NHDS, which was in operation from 1965 to 1987, has been published (1). Differences may exist between data for 1988-91 and earlier years because of the redesign of the survey.

Medical data for hospitalized patients are coded according to the International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) (2). Up to seven diagnoses and four procedures are coded for each discharge. Although diagnoses included in the ICD-9-CM section entitled "Supplementary classification of external causes of injury and poisoning" (codes

E800-E999) are used in the NHDS, these diagnoses are excluded from this report. The conditions diagnosed and procedures performed are presented here by chapter of ICD-9-CM. Within these chapters, a few diagnoses and procedures or groups thereof also are shown. These specific categories were selected primarily because of their large estimates or because they are of special interest. More detailed analyses of NHDS data are published in Series 13 of the NCHS Vital and Health Statistics reports.

Starting in 1985, some hospitals participating in the NHDS have submitted machine-readable data tapes. In 1991, approximately 33 percent of the hospitals used this method to submit data. Analysis indicates that a greater number of nonsurgical procedures per patient are recorded from these hospitals

## Acknowledgments

This report was prepared in the Division of Health Care Statistics. Jean Kozak of the Hospital Care Statistics Branch, provided technical assistance in developing the style and content of this report. George Wolfe of the Technical Services Branch, provided assistance in producing estimates of reliability. Dorothy Graham of the Technical Scrvices Branch verificd the estimates in the report and Charles Adams and Malcolm Graham of the Technical Services Branch provided advice on the computer programming aspects of the report. This report was edited by Klaudia Cox and typeset by Jacqueline M. Davis of the Publications Branch, Division of Data Services.

than from hospitals submitting data in the traditional manual mode (see "Technical notes"). A portion of the increases from 1984 to 1991 in the estimates for miscellaneous diagnostic and therapeutic procedures and, therefore, for total procedures may be due to this change in data collection methods.

In addition, the 1991 data were the first for which all ICD-9-CM procedure codes were used in the NHDS. In previous years, selected codes were excluded. These were primarily codes for certain miscellaneous diagnostic and therapeutic procedures.

## Data highlights

## Utilization by patient and hospital characteristics

The number, rate, and average length of stay of patients discharged from short-stay non-Federal hospitals are shown by age, geographic region, and sex in tables 1-3. The 31.1 million patients discharged from short-stay hospitals during 1991 comprised an estimated 12.5 million males and 18.6 million females. The rate per 1,000 population for females was 144 , which was 41 percent higher than the rate of 103 for males. The number and rate of discharges are higher for females than for males largely because of women 15-44 years of age who are hospitalized for deliveries and pregnancy-related conditions.

The average length of stay was 7.0 days for males and 6.0 days for females during 1991. The average length of stay of the 4.0 million women who were hospitalized for deliveries was 2.8 days. The average length of stay was 4.8 days for patients under 15 years of age, 4.6 days for patients 15-44 years of age, 6.5 days for patients $45-64$ years of age, and 8.6 days for patients 65 years of age and over.

The number of discharges from short-stay hospitals by geographic region during 1991 ranged from 11.3 million in the South to 5.3 million in the West. Regional differences in the number of discharges are accounted
for in part by variations in the population sizes. The rates per 1,000 population ranged from 141 in the Northeast Region to 100 in the West. Average lengths of stay by geographic region were 5.4 days in the West, 6.2 days in the South, 6.5 days in the Midwest, and 7.3 days in the Northeast.

## Utilization by diagnosis

Diseases of the circulatory system ranked first in 1991 of the ICD-9-CM diagnostic chapters as a principal or first-listed diagnosis for patients discharged from non-Federal short-stay hospitals. These conditions accounted for an estimated 5.3 million discharges. Other leading ICD-9-CM diagnostic chapters were supplementary classifications (including females with deliveries) ( 4.4 million discharges), diseases of the digestive system ( 3.3 million discharges), and diseases of the respiratory system ( 3.1 million discharges). Approximately 52 percent of the patients discharged from non-Federal short-stay hospitals were included in these four ICD-9-CM diagnostic chapters.

The diagnostic categories presented in this report were selected either because they appear as principal or first-listed diagnoses with high frequency or because the conditions are of special interest. Many of these categories (such as malignant neoplasms, psychoses, and fractures) are groupings of more detailed diagnoses.

The number and rate of discharges and average length of stay for each ICD-9-CM diagnostic chapter and selected categories are shown by sex and age in tables 4-6. The most common diagnostic categories for all patients were deliveries and heart disease. Other leading diagnostic categories were malignant neoplasms, pneumonia, and fractures. Excluding deliveries, these last four diagnostic categories were the leading first-listed diagnoses for both males and females. Some of the more common diagnoses for patients
under 15 years of age were acute respiratory infections, pneumonia, and asthma. For patients 15-44 years of age, frequent diagnoses were deliveries, psychoses, and fractures. For patients 45-64 years of age and 65 years of age and over, heart disease and malignant neoplasms were major causes of hospitalization. The average length of stay for all patients ranged from 1.2 days for chronic disease of tonsils and adenoids to 14.6 days for malignant neoplasm of large intestine and rectum.

## Utilization by procedure

One or more surgical or nonsurgical procedures were performed for an estimated 21.0 million of the 31.1 million inpatients discharged from short-stay hospitals during 1991. A total of 43.9 million procedures, or an average of 2.1 per patient who underwent at least one procedure, were recorded in 1991.

Procedures are grouped in the tables of this report by the ICD-9-CM procedure chapters. Selected procedures within these chapters also are presented by specific categories. Some of these categories (such as cesarean section and hysterectomy) are presented as single categories even though they are divided into more precise subgroups in ICD-9-CM.

More than three-fourths of all the surgical and nonsurgical procedures performed during 1991 are listed in just 5 of the 16 procedure chapters. These were miscellaneous diagnostic and therapeutic procedures (14.8 million), obstetrical procedures (6.9 million), operations on the digestive system ( 5.6 million), operations on the cardiovascular system (4.1 million), and operations on the musculoskeletal system ( 3.3 million).

The number and rate of all-listed procedures in 1991 for each ICD-9-CM procedure chapter and selected procedure categories are shown by sex and age in tables 7 and 8. Of the 43.9 million procedures performed during 1991, 17.3 million were for males and 26.7 million were
for females. The corresponding rates per 100,000 population were $17,529.3$ for both sexes, 14,204.6 for males, and 20,661.0 for females. Frequent procedures for males were arteriography and angiocardiography, computerized axial tomography, and diagnostic ultrasound. Procedures commonly performed on females were episiotomy, fetal EKG and fetal monitoring, and diagnostic ultrasound.

The rate of procedures by age per 100,000 population ranged from $4,054.9$ for patients under 15 years of age to $47,468.0$ for patients 65 years of age and over. Commonly performed procedures for patients under 15 years of age were respiratory therapy, spinal tap, computerized axial tomography, and diagnostic ultrasound; for patients 15-44 years of age, episiotomy, fetal EKG and fetal monitoring, and cesarean section; for patients 45-64 years of age, arteriography and angiocardiography, cardiac catheterization, diagnostic ultrasound, and computerized axial tomography; for patients 65 years of age and over, arteriography and angiocardiography, computerized axial tomography, and diagnostic ultrasound.

## Technical notes

## Survey methodology

## Source of data

The National Hospital Discharge Survey covers discharges from noninstitutional hospitals, exclusive of Federal, military, and Veterans Administration hospitals, located in the 50 States and the District of Columbia. Only short-stay hospitals (hospitals with an average length of stay for all patients of less than 30 days) or those whose specialty is general (medical or surgical) or children's general are included in the survey. These hospitals must also have six beds or more staffed for patient use.

From 1988 through 1990, the NHDS sampling frame consisted of hospitals that were listed in the April 1987 SMG Hospital Market Tape (3), met the above criteria, and began accepting patients by August 1987. In 1991 the sampling frame was updated to include hospitals from the 1991 SMG Hospital Database Tape (4). For 1991, the sample consisted of 528 hospitals. Of the 528 hospitals, 7 were found to be out of scope (ineligible) because they went out of business or otherwise failed to meet the criteria for the NHDS universe. Of the 521 in-scope (eligible) hospitals, 484 responded to the survey.

## Sample design and data collection

The NCHS has conducted the NHDS continuously since 1965. The original sample was selected in 1964 from a frame of short-stay hospitals listed in the National Master Facility Inventory. That sample was updated periodically with samples of hospitals that opened later. Sample hospitals were selected with probabilities ranging from certainty for the largest hospitals to 1 in 40 for the smallest hospitals. Within each sample hospital, a systematic random sample of discharges was selected. A report on the design and development of the original NHDS was published (1).

Beginning in 1988, the NHDS sample includes with certainty all
hospitals with 1,000 beds or more or 40,000 discharges or more annually. The remaining sample of hospitals is based on a stratified three-stage design. The first stage consists of a selection of 112 primary sampling units (PSU's) that comprise a probability subsample of PSU's to be used in the 1985-94 National Health Interview Survey. The second stage consists of a selection of noncertainty hospitals from the sample PSU's. At the third stage, a sample of discharges was selected by a systematic random sampling technique.

Two data collection procedures were used for the survey. The first was a manual system of sample selection and data abstraction. The second was an automated method, used for approximately 33 percent of the respondent hospitals in 1991, that involived the purchase of data tapes from abstracting service organizations, state data systems, or hospitals.

In the manual system, the sample selection and the transcription of information from the hospital records to abstract forms were performed at the hospitals. The completed forms, along with sample selection control sheets, were forwarded to NCHS for coding, editing, and weighting. Of the hospitals using the manual system in 1991, about two-thirds had the work performed by their own medical records staff. In the remaining hospitals using the manual system, personnel of the U.S. Bureau of the Census did the work on behalf of NCHS.

For the automated system, NCHS purchased tapes containing machine-readable medical record data that were systematically sampled by NCHS.

The medical abstract form and the automated data tapes contain items relating to the personal characteristics of the patient, including birth date, sex, race, and marital status but not name and address; administrative information, including admission and discharge dates, discharge status, and medical record number; and medical information, including diagnoses and
surgical and nonsurgical operations or procedures. Since 1977, patient ZIP Code, expected source of payment, and dates of surgery have also been collected. (The medical record number and patient ZIP Code are confidential information and are not available to the public.)

## Presentation of estimates

The relative standard error of the estimate and the number of sample records on which the estimate is based (referred to as the sample size) are used to identify estimates with relatively low reliability.

Because of the complex sample design of the NHDS, estimates of less than 5,000 are not presented; only an asterisk (*) appears in the tables. These estimates generally have a relative standard error of more than 30 percent or are based on a sample of less than 30 cases. Estimates of 5,000 to 9,000 are preceded by an asterisk $\left({ }^{*}\right)$ to indicate that they should not be assumed to be reliable. These estimates are generally based on less than 60 cases.

## Sampling errors and rounding of numbers

The standard error is primarily a measure of sampling variability that occurs by chance because only a sample rather than the entire universe is surveyed. The relative standard error of the estimate is obtained by dividing the standard error by the estimate itself and is expressed as a percent of the estimate. The resulting value is multiplied by 100 , so the relative standard error is expressed as a percent of the estimate.

Estimates of sampling variability were calculated with SESUDAAN software, which computes standard errors by using a first-order Taylor approximation of the deviation of estimates from their expected values. A description of the software and the approach it uses has been
published (5).
The constants for relative standard error curves for the National

Hospital Discharge Survey are presented in table I. The constants for 1990 are shown because 1991 constants were not available at the time of publication and little difference is expected in the constants for the 2 years. The relative standard error [ $\mathrm{RSE}(X)]$ of an estimate $X$ may be estimated from the formula:

$$
\operatorname{RSE}(X)=100(\sqrt{a+b / X})
$$

where $X, a$, and $b$ are as defined in table I.

Estimates have been rounded to the nearest thousand. For this reason, figures within tables do not always add to the totals. Rates and average lengths of stay were calculated from original, unrounded figures and will not necessarily agree precisely with rates or average lengths of stay calculated from rounded data.

## Tests of significance

In this report, statistical inference is based on the two-sided test with a critical value of $1.96(0.05$ level of significance). Terms such as "higher" and "less" indicate that differences are statistically significant. Terms such as "similar" or "no difference" mean that no statistically significant difference exists between the estimates being compared. A lack of comment on the difference between any two estimates does not mean that the difference was tested and found not to be significant.

## Terms relating to hospitalization

Hospitals - All hospitals with an average length of stay for all patients of less than 30 days or hospitals whose specialty is general (medical or surgical) or children's general are eligible for inclusion in the National Hospital Discharge Survey, except Federal hospitals, hospital units of institutions, and hospitals with less than six beds staffed for patients' use.

Patient-A person who is formally admitted to the inpatient service of a short-stay hospital for observation, care, diagnosis, or treatment. The terms "patient" and "inpatient" are used synonymously.

Newborn infant - A patient admitted by birth to a hospital.

Discharge - The formal release of a patient by a hospital; that is, the termination of a period of hospitalization by death or by disposition to place of residence, nursing home, or another hospital. The terms "discharges" and "patients discharged" are used synonymously.

Discharge rate - The ratio of the number of hospital discharges during a year to the number of persons in the civilian population on July 1 of that year.

Days of care-The number of patient days accumulated at time of discharge by a patient. A stay of less than 1 day (patient admission and discharge on the same day) is

Table 1. Estimated parameters for relative standard error equations for National Hospital Discharge Survey statistics, by sex, age, and geographic region: United States, 1990

| Characteristic | Number of discharges or first-listed diagnoses |  | Number of procedures |  |
| :---: | :---: | :---: | :---: | :---: |
|  | a | b | $a$ | $b$ |

| Sex |  |  |  |  |
| Male | 0.00152 | 313.079 | 0.00410 | 89.724 |
| Female. | 0.00125 | 311.632 | 0.00337 | 83.021 |
| Age |  |  |  |  |
| Under 15 years. | 0.01597 | 47.116 | 0.03171 | 44.124 |
| 15-44 years. | 0.00142 | 299.762 | 0.00302 | 139.070 |
| 45-64 years. | 0.00157 | 234.543 | 0.00491 | 68.024 |
| 65 years and over | 0.00161 | 263.223 | 0.00436 | 47.886 |
| Region |  |  |  |  |
| Northeast | 0.00274 | 56.268 | 0.00588 | 108.765 |
| Midwest | 0.00487 | 183.531 | 0.00885 | 107.681 |
| South. | 0.00375 | 343.892 | 0.00781 | 50.919 |
| West | 0.00564 | 318.914 | 0.01235 | 144.582 |

counted as 1 day in the summation of total days of care. For patients admitted and discharged on different days, the number of days of care is computed by counting all days from (and including) the date of admission to (but not including) the date of discharge.

Average length of stay - The number of days of care accumulated by patients discharged during the year divided by the number of these patients.

## Terms relating to diagnoses

Diagnosis-A disease or injury (or factor that influences health status and contact with health services that is not itself a current illness or injury) on the medical record of a patient.

Principal diagnosis - The condition established after study to be chiefly responsible for occasioning the admission of the patient to the hospital for care.

First-listed diagnosis - The coded diagnosis identified as the principal diagnosis or listed first on the face sheet or discharge summary of the medical record if the principal diagnosis cannot be identified. The number of first-listed diagnoses is equivalent to the number of discharges.

## Terms relating to procedures

Procedure-A surgical or nonsurgical operation, diagnostic procedure, or special treatment reported on the medical record of a patient. Beginning with the 1991 data, all ICD-9-CM procedure codes are used in the NHDS. Previously selected codes, primarily codes for miscellaneous diagnostic and therapeutic procedures, were not used.

All-listed procedures - The number of procedures on the face sheet of the medical record. In the NHDS a maximum of four procedures are coded.

Rate of procedures - The ratio of the number of procedures during $a$. year to the number of persons in the civilian population on July 1 of that year determines the rate of
procedures.

## Demographic terms

Population - The U.S. resident population excluding members of the Armed Forces.

Age - Patient's age at birthday prior to admission to the hospital.

Geographic region -Hospitals are classified by location in one of the four geographic regions of the United States that correspond to those used by the U.S. Bureau of the Census.

# Office Visits to General Surgeons 1989-90, National Ambulatory Medical Care Survey 

by David A. Woodwell, Division of Health Care Statistics

This report describes visits made to general surgeons from March 1989 through December 1990. The information was collected by means of the National Ambulatory Medical Care Survey (NAMCS), a continuing probability sample survey of the private office-based, non-Federal physicians practicing in the United States. NAMCS excludes physicians who specialize in anesthesiology, pathology, or radiology and physicians who are principally engaged in teaching, research, or administration. The survey also excludes those visits made to hospital emergency or outpatient departments. NAMCS was conducted annually from 1973 through 1981, again in 1985, and resumed as an annual survey in 1989, by the Division of Health Care Statistics, National Center for Health Statistics, Centers for Disease Control and Prevention. Participation in the NAMCS is voluntary.

Data in this report are from the 1989 and 1990 NAMCS, which were conducted in identical fashion using the same survey instruments, definitions, and procedures. The data were combined in order to obtain more reliable estimates. The figures in this report are estimated from a sample, not the entire universe, of
visits to general surgeons, and are therefore subject to sampling variability. All estimates in this report, including the number of visits, the number of drug mentions, and the visit rates, have been adjusted to represent average annual statistics and do not represent 2 -year totals. The technical notes at the end of the report provide guidelines for judging the precision of the estimates. Definitions of key terms used in the survey are also provided. The patient record form used for data collection in both 1989 and 1990 is shown in figure 1.

## Data highlights

During 1989-90, there was an estimated annual average of 23.9 million visits to general surgeons accounting for 3.4 percent of all office visits to ambulatory care physicians in the United States (table 1). This estimated annual average of 23.9 million visits is a significant decrease from the estimated annual average of 30.5 million visits in 1980-81 (1) and a further decrease from the estimated 41.2 million visits in 1975 (2). As a percent of total visits to all physicians, visits to general surgeons also decreased during this period
from 7.3 percent in 1975 to 5.3 percent in 1980-81 to 3.4 percent in 1989-90. Whereas general surgeons had an average annual visit rate of 20 visits per 100 persons in 1975, their average annual visit rate in 1989-90 was only 10 visits per 100 persons, or half the 1975 rate. The declining trend in the visit rate to general surgeons could be attributed in part to the fact that since 1980 the number of general surgeons, as a percentage of all surgeons, has decreased 14.3 percent. As a percent of all physicians, general surgeons have decreased from 8.3 percent in 1980 to 6.8 percent in 1990-a decrease of 18.1 percent $(3,4)$.

## Patient characteristics

As shown in table 2, seven of every eight patients ( 88 percent) who visited general surgeons were 25 years of age or older. Visits made by patients ages 25-64 years represented over half of all visits to the general surgeon, with those ages 65-74 and 75 years and over accounting for another 30 percent of the visits. The visit rate increased with age from 2 visits per 100 persons for patients under 15 years of age to 27 visits per

Figure 1. Patient record form

100 persons for patients 75 years of age and over.

General surgeons had significantly more visits by females than tisits by males in 1989-90. About 62 percent of the visits were made by females, which was similar to the distribution in 1975 (2). For both males and females, the percent of visits for patients $25-44$ years old increased significantly from the percent of visits for patients 15-24 years old. In addition, females
represented a significantly higher percent of visits in the two age groups $25-44$ and $45-64$, about 37 percent for females compared with about 21 percent for males. The visit rates were not significantly different by consecutive age groups, within or between male and female groups, but was significant from the under 15 age group to the 75 years and older age group.

Most of the visits to the general surgeon were made by white persons, nearly 82 percent, as compared with
black persons, 15 percent (table 3). For both white and black persons, females visited more often than males. There was no significant difference in the visit rate between white and black persons. White persons had an average annual visit rate of 10 visits per 100 persons as compared with black persons who had a visit rate of 12 visits per 100 persons. This similarity in the visit rate indicates that general surgeons had approximately the same

| 75 years and over | 1,882 | 7.9 | 26 |

proportion of visits by race as the proportion in the general population.

## Expected sources of payment

As shown in table 4, Medicare (almost 26 percent) and "other commercial" insurance (almost 25 percent) were the most frequent sources of payment for visits made to general surgeons. For all physicians,

Medicare was used as a source of payment in 19 percent of the visits, a significant difference of approximately 7 percent reflecting the high rate of older patients that visit general surgeons. Patients paid all or part of the visit cost in an estimated 16 percent of the visits to general surgeons, which is significantly lower than the estimated 31 percent for all physicians. The visits in which the
patient was not charged (almost 8 percent) was higher for general surgeons as compared with all physicians (about 2 percent). Medicaid, Blue Cross/Blue Shield, and pre-paid plans (HMO's, IPA's, and PPO's) were a payment source for about 9 percent, 15 percent, and 13 percent of the visits respectively. If a patient used more than one source of payment, all sources were recorded in item 17 of the patient record form.

## Patient status

As illustrated in table 5, of the visits made to general surgeons in 1989-90, about 14 percent were referred, as compared with about 6 percent of the visits for all physicians. Unpublished data from the 1977 and 1980 NAMCS (1977 was the first year referral data were collected) showed that approximately 11 percent of the visits to general surgeons were referred. In 1985, the percent of visits referred was about 14 percent, which is not significantly different than the estimates from 1977, 1980, or 1989-90.

The visit status of the patient (item 11 on the patient record form) shows that most of the visits were made by patients the physician had previously seen for the same condition (about 65 percent). About 15 percent of the visits were made by patients seen before who were presenting a new problem, and about 20 percent of the visits were made by new patients.

## Patient's reason for visit

The principal reason for visit to the general surgeon, as expressed by the patient, is shown in tables 6 and 7. The principal reason for visit is the problem, complaint, or cause listed first on item 9 of the patient record form. These data have been classified and coded according to the Reason for Visit Classification for Ambulatory Care (RVC) (5).

The RVC is divided into eight modules (or groups of reasons) as detailed in table 6. For visits to general surgeons, the symptom module was most often cited,

| Other | 1,620 | 6.8 | 5.5 |
| Unknown. | 409 | 1.7 | 2.0 |

${ }^{1} \mathrm{HMO}$ is health maintenance organization, IPA is individual practice association, and PPO is preferred provider organization. NOTE: Numbers may not add to totals because more than one source was possible.

Table 5. Average annual number and percent distribution of office visits to general surgeons, by patient's referral status and visit status: United States, 1989-90

| Reterral and visit status | Average annual number of visits in thousands | Parcent distribution |
| :---: | :---: | :---: |
| All visits | 23,891 | 100.0 |
| Patient referred |  |  |
| Yes | 3,430 | 14.4 |
| No. | 20,460 | 85.6 |
| Visit status |  |  |
| New patient | 4,735 | 19.8 |
| Old patient, new problem | 3,606 | 15.1 |
| Old patient, old problem | 15,549 | 65.1 |

containing about 51 percent of all the reasons for visit. Within the symptom module, symptoms of the musculoskeletal system and the genitourinary systems were the reason for visit in approximately 11 percent and 10 percent of the visits respectively. The treatment module accounted for about one-fifth or about 21 percent of the reasons for visit, more than double the corresponding percent for all physicians. This high percentage for the treatment module reflects the type of practice the general surgeon has and the procedures performed as compared with the other specialties. The disease module, the diagnostic, screening, and preventive module, and the injury and adverse effects module, accounted for around 15,6 , and 4 percent of the visits respectively.

The 20 most common principal reasons for visit to general surgeons, as expressed by the patient, are listed in table 7. These reasons account for approximately half of all visits to general surgeons. The first listed principal reason for visit was for lump or mass of breast, which accounted for about 4 percent of the average annual 23.9 million visits to general surgeons. Lump or mass of breast represented 4.3 percent of visits in 1989-90, which is not significantly different than the 1980-81 estimate of 3.1 percent (1). An additional 3.8 percent of the principal reasons for visit were related to the breast, including breast examination, other symptoms referable to breast, and pain or soreness of breast resulting in a total of 8.1 percent. The lump or mass of breast was followed by stomach pain, cramps or spasms and hernia of abdominal cavity with about 4 percent and 3 percent respectively. Overall, of the top 20 principal reasons for visit in 1989-90, few have changed significantly since $1980-81$.

## Physician's diagnosis

Data on the principal diagnosis rendered by the general surgeon are shown in tables 8 and 9. The principal diagnosis is listed on itern

${ }^{1}$ Based on A Reason for Visit Classrfication for Ambulatory Care (RVC) (5).

10a of the patient record form and corresponds with the principal reason for visit (item 9a). This information was coded and classified according to the International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) (6).

The categories in table 8 are divided among the major systems of the body as defined by the ICD-9-CM. Diseases of the digestive system was the largest category with nearly 16 percent of the diagnoses. The supplemental classification, neoplasms, and diseases of the
genitourinary system followed with approximately 13,13 , and 11 percent of the visits respectively. The distribution of visits to general surgeons, as compared with all physicians, differ greatly in their diagnoses. For example, diseases of the digestive system accounted for almost 16 percent of the visits to general surgeons compared with around 4 percent of the visits to all physicians. Diseases of the respiratory system accounted for about 4 percent of the principal diagnoses made by general surgeons, which is much
smaller than the 14 percent made by all physicians. Neoplasms accounted for almost 13 percent of the primary diagnoses by general surgeons, which was significantly larger than the about 3 percent for all physicians.

The 20 most frequently diagnosed conditions made by general surgeons in 1989-90 is listed in table 9. Benign mammary dysplasias accounted for about 4 percent of the principal diagnoses; when combined with other disorders of the breast and malignant neoplasms of the female breast, diagnoses related to the breast accounted for almost 11 percent of the diagnoses by general surgeons in 1989-90 as compared with about 7 percent in 1980-81 (1). This is an increase equal to about 47 percent. Inguinal hernia accounted for an estimated 3.9 percent of the diagnoses. A few of the other principal diagnoses have noteworthy changes since 1980-81-acute upper respiratory infection of multiple or unspecified sites in 1980-81 were an estimated 2.4 percent of the visits (1), but in 1989-90 fell to 0.8 percent of the visits; sprains and strains of other and unspecified parts of the back increased from 0.7 percent in 1980-81 (1) to 2.2 percent in 1989-90.

## Diagnostic services and counseling

Most visits made to general surgeons included at least one diagnostic or screening service. As shown in table 10, patients had their blood pressure taken in about 23 percent of the office visits to general surgeons, which is significantly lower than almost 37 percent for all physicians. In addition, the "other blood test" category accounted for about 8 percent of the visits and "urinalysis" accounted for 6 percent of the visits, which are also lower than the approximately 13 percent for both diagnostic services for all physicians. On the other hand, more office visits to general surgeons included a breast palpation and mammogram as compared with all

physicians. A breast palpation occurred in 9 percent of the office visits to general surgeons with a mammogram occurring in 4 percent of the visits, compared with approxi-
mately 6 percent and 2 percent, respectively, for all physicians.

Counseling or advice was provided or ordered by the general surgeon as shown in table 11. Patients
were counseled, advised, or educated on breast self examinations in almost 7 percent of the visits, which is three times higher than the 2.3 percent for all physicians. They counseled, advised, or educated patients on weight reduction during almost 4 percent of the visits, on cholesterol reduction in about 1 percent of the visits, and on smoking cessation around 2 percent of the visits.

## Medication therapy

As shown in table 12 , most of the visits made to general surgeons resulted in no drugs being administered or prescribed. Only about one-third ( 32 percent) of the visits were "drug" visits, that is, visits in which one or more medications. were administered or prescribed. The corresponding percentages for all physicians are much higher, with 60 percent of the visits being "drug" visits. Medication prescribed by general surgeons represent only about 2 percent of all the medications administered or prescribed by office-based ambulatory care physicians in the United States. Of the drug visits, about 58 percent were for visits in which one drug was administered or prescribed, almost. 20 percent were for two drugs, and about 22 percent were for three or more drugs administered or prescribed (table 12).

There was an estimated annual average of $13,923,000$ medications ordered or prescribed during visits to general surgeons in 1989-90. The "drug mentions" are categorized into therapeutic categories as defined by the 1985 edition of the National Drug Code Directory (7) and are shown in table 13. Cardiovascular-renal drugs accounted for almost 21 percent of the drug mentions and included antihypertensive agents (about 6 percent) and diuretics (around 7 percent). Drugs used for the relief of pain accounted for about 15 percent of the drug mentions and included general analgesics (about 8 percent) and antiarthritic agents (almost 7 percent).

Table 10. Average annual number and percent distribution of office visits to general surgeons and percent distribution of office visits for all physicians by diagnostle service ordered or provided: United States, 1989-90

| Diagnostic service ordered or provided | Visits to general surgeons |  | Visits to all physicians |
| :---: | :---: | :---: | :---: |
|  | Average annual number of visits in thousands | Percent đistnbution | Percent distribution |
| Total visits . | 23.891 | 100.0 | 100.0 |
| Blood pressure. | 5.514 | 23.1 | 36.7 |
| Breast palpation | 2,149 | 9.0 | 5.5 |
| Other blood test | 1,986 | 8.3 | 13.0 |

| Mammogram | 952 | 4.0 | 1.6 |
| Chest X-ray | 672 | 2.8 | 2.8 |
| Other. | 4,27\% | 17.9 | 25.2 |

Note: Numbers may not add to totals because more than one diagnostuc service was possible during the patient visit.

Table 11. Average annual number and percent distribution of office visits to general surgeons by type of counseling and/or advice given: United States, 1989-90

| Type of counseling and/or advice | Average annual <br> number of visits <br> in thousands |
| :--- | :--- |

Note: Numbers may not add to totals because more than one type of counsefing or advice may have been given.
The 20 medications most frequently ordered or prescribed by general surgeons according to their generic ingredients are shown in table 14. Of the first five generic ingredients listed, three are for the relief of pain. These are acetaminophen (approximately 6 percent), codeine (almost 4 percent), and ibuprofen ( 3 percent). The other two drugs among the top five are the diuretics hydrochlorothiazide and furosemide, both approximately 4 percent of medications ordered or prescribed.

## Duration and disposition of visit

Visits made to general surgeons in 1989-90 had a mean duration of almost 15 minutes, excluding visits of zero minutes. Specifically, 13 percent of the visits lasted 1 to 5 minutes, almost 30 percent of the visits lasted 6 to 10 minutes, about 29 percent of
the visits lasted 11 to 15 minutes, and nearly 23 percent of the visits lasted 16 to 30 minutes. Only about 3 percent of the visits lasted longer than 30 minutes. The duration of visit does not include time waiting for the physician or time receiving care from someone else on the physician's staff; it includes only time spent in face-toface contact with the physician. Of the visits made to general surgeons, about 3 percent were for zero minutes meaning that the patient had no face-to-face contact with the physician, but instead received treatment from another member of the physician's staff (table 15).

Most of the patient visits (64 percent) made to general surgeons ended with a disposition to return at a specific time while about one-fifth were to return if needed. The patient was admitted to the hospital in about 3 percent of the visits, which is higher than the 1 percent for all physicians (table 15).

## Technical notes

## Sources of data and sample design

The information presented in this report is based on data collected by means of the National Ambulatory Medical Care Survey (NAMCS) from March 20, 1989, through December 30, 1990. The target universe of NAMCS includes office visits made in the United States by ambulatory patients to nonfederally employed physicians who are principally engaged in office practice but not in the specialties of anesthesiology, pathology, or radiology. Telephone contacts and nonoffice visits are excluded.

A multistage probability sample design is used in NAMCS, involving samples of primary sampling units (PSU's), physician practices within PSU's, and patient visits within physician practices. The PSU's are counties, groups of counties, county equivalents (such as parishes or independent cities), or towns and townships (for some PSU's in New England). A sample of 2,535 nonFederal, office-based physicians was selected in 1989 and 2,528 nonFederal, office-based physicians were selected in 1990 from master files maintained by the American Medical Association and American Osteopathic Association. The sample included 236 general surgeons in 1989 and 230 in 1990 of which 179 were eligible in 1989 and 160 were eligible in 1990 for the survey. The physician response rate for the 1989 NAMCS was 74 percent; in 1990, it was 75 percent. General surgeons had a response rate of 77 percent in 1989 and 75 percent in 1990. Sample physicians were asked to complete patient records (figure 1) for a systematic random sample of office visits occurring during a randomly assigned 1 -week reporting period. Responding physicians completed 38,384 patient records in 1989 and 43,469 in 1990. General surgeons completed 2,823 patient record forms in 1989 and 2,897 in 1990.
Characteristics of the physician's
practice, such as primary specialty and type of practice, were obtained from the physicians during an induction interview. The U.S. Bureau of the Census, Housing Surveys Branch, was responsible for the survey's data collection. Processing operations and medical coding were performed by the National Center for Health Statistics, Hospital Discharge and Ambulatory Care Survey Section, Research Triangle Park, North Carolina.

## Sampling errors

The standard error is primarily a measure of the sampling variability that occurs by chance when only a sample, rather than an entire universe, is surveyed. The relative standard error of an estimate is obtained by dividing the standard error by the estimate itself; the result is then expressed as a percent of the estimate. Approximate relative standard errors (RSE's) of selected aggregate statistics are shown in table $I$, and the relative standard errors of the estimated number of drug mentions are shown in table II. All frequencies in this report are average annual figures and must be doubled before a significance test can be performed. Relative standard errors for aggregate visits and drug estimates may be calculated using the following general formula, where $x$ is the aggregate of interest in thousands, and $A$ and $B$ are the appropriate coefficient from table IV.

$$
\operatorname{RSE}(x)=\sqrt{A+\frac{B}{x}} \times 100.0
$$

Approximate relative standard errors for estimates of the percent of visits are shown in table III. The RSE's for percent may be calculated using the following general formula, where $p$ is the percent of interest and $x$ is the denominator of the percent in thousands, using the appropriate coefficient from table IV.

$$
\operatorname{RSE}(p)=\sqrt{\frac{B(1-p)}{p^{x}}} \times 100.0
$$

Table I. Relative standard errors for estimated numbers of office visits: National Ambulatory Medical Care Survey, 1989-90

| Estimated number of office visits in thousands | All specialties | General surgeon |
| :---: | :---: | :---: |
|  | Relative standard error (RSE) in percent |  |
| 100 | 72.7 | 31.1 |
| 200 | 51.5 | 23.4 |
| 300 | 42.1 | 20.1 |
| 400 | 36.5 | 18.3 |
| 500 | 32.6 | 17.1 |
| 700 | 27.6 | 15.6 |
| 1,000 | 23.2 | 14.4 |
| 2,000 | 16.5 | 12.9 |
| 5,000 | 10.7 | 11.9 |
| 7.000 | 9.2 | 11.7 |
| 10,000 | 7.9 | 11.5 |
| 30.000 | 5.2 | 11.2 |
| 50,000 | 4.5 | 11.2 |
| 100,000 | 3.9 | 11.2 |
| 500,000 | 3.3 | 11.1 |
| 700,000 | 3.2 | 11.1 |
| 1,400,000 | 3.2 | ... |

NOTE: Otolaryngologist 30 percent RSE $=110,000$; all speciaties 30 percent RSE $=593.000$.
Example of use of table: An aggregate estimate of 5 million visits to a a general surgeon has a relative standard error of 11.9 percent or a standard error of 595,000 visits (11.9 percent of 5 million).

Table II. Relative standard errors for estimated numbers of drug mentions: National Ambulatory Medical Care Survey, 1989-90

| Estimated number of drug mentions in thousands | All specialties | General surgeon |
| :---: | :---: | :---: |
|  | Relative standard error (RSE) In percent |  |
| 100 | 90.3 | 36.1 |
| 200 | 63.9 | 27.0 |
| 300 | 52.3 | 23.3 |
| 400 | 45.3 | 21.1 . |
| 500 | 40.6 | 19.7 |
| 700 | 34.3 | 18.0 |
| 1,000 | 28.8 | 16.6 |
| 2,000 | 20.6 | 14.7 |
| 5,000 | 13.4 | 13.5 |
| 7,000 | 11.5 | 13.3 |
| 10,000 | 9.9 | 13.1 |
| 30,000 | 6.5 | 12.8 |
| 50,000 | 5.7 | 12.8 |
| 100,000 | 4.9 | 12.7 |
| 500,000 | 4.2 | 12.7 |
| 700,000 | 4.1 | 12.7 |
| 1,400,000 | 4.0 | . $\cdot$ |

NOTE: Otolaryngologist 30 percent RSE $=155,000$; all speciaties 30 percent RSE $=922,000$.

Example of use of table: An aggregate estumate of 2 million drug mentions by a general surgeon has a relative standard error of 14.7 percent or a standard error of 294 thousand drug mentions ( 14.7 percent of 2 milion).

Table III. Standard errors for percents of estimated numbers of office visits for the National Ambulatory Medical Care Survey: United States, 1989-90

| Base of percent (visits in thousands) |  | Estimated percent |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 1 or 99 | 5 or 95 | 10 or 90 | 20 or 80 | 30 or 70 | 50 |
|  |  | Standard error in percentage points |  |  |  |  |  |
| 100 |  | 2.9 | 6.3 | 8.7 | 11.6 | 13.3 | 14.6 |
| 200 |  | 2.1 | 4.5 | 6.2 | 8.2 | 9.4 | 10.3 |
| 500 |  | 1.3 | 2.8 | 3.9 | 5.2 | 6.0 | 6.5 |
| 700 |  | 1.1 | 2.4 | 3.3 | 4.4 | 5.0 | 6.0 |
| 1,000 |  | 0.9 | 2.0 | 2.8 | 3.7 | 4.2 | 4.6 |
| 2,000 |  | 0.6 | 1.4 | 2.0 | 2.6 | 3.0 | 3.3 |
| 5,000 |  | 0.4 | 0.9 | 1.2 | 1.7 | 1.9 | 2.1 |
| 7,000 |  | 0.4 | 0.8 | 1.0 | 1.4 | 1.6 | 1.7 |
| 10,000 |  | 0.3 | 0.6 | 0.9 | 1.2 | 1.3 | 1.5 |
| 20,000 |  | 0.2 | 0.5 | 0.6 | 0.8 | 1.0 | 1.0 |
| 30,000 |  | 0.2 | 0.4 | 0.5 | 0.7 | 0.8 | 0.8 |
| 50,000 |  | 0.1 | 0.3 | 0.4 | 0.5 | 0.6 | 0.7 |
| 80,000 |  | 0.1 | 0.2 | 0.3 | 0.4 | 0.5 | 0.5 |
| 100,000 |  | 0.1 | 0.2 | 0.3 | 0.4 | 0.4 | 0.5 |
| 500,000 |  | 0.0 | 0.1 | 0.1 | 0.2 | 0.2 | 0.2 |
| 1,400,000 |  | 0.0 | 0.1 | 0.1 | 0.1 | 0.1 | 0.1 |

Example of use of table: An estimate of 30 percent based on an aggregate estumate of 10 million visits has a standard error of 4.2 percent or a relative standard error of 14.0 percent ( 4.2 percent divided by 30 percent).

## Adjustments for nonresponse

Estimates from NAMCS data were adjusted to account for sample physicians who were in scope but did not participate in the study. This adjustment was calculated to minimize the impact of response on final estimates by imputing to nonresponding physicians data from visits to similar physicians. For this purpose, physicians were judged similar if they had the same specialty designation and practiced in the same PSU.

## Test of significance and rounding

In this report, the determination of statistical inference is based on a two-sided $t$-test. The Bonferroni inequality was used to estimate the critical value for statistically significant differences ( 0.05 level of significance). Terms relating to differences such as "higher," "less," and so forth indicate that the differences are statistically significant. Terms such as "similar" or "no difference" mean that no statistical significance exists between the estimates being compared. In the tables, estimates of office visits have been rounded to the nearest thousand. Consequently, estimates will not always add to totals. Rates and percents were calculated from
original unrounded figures and do not necessarily agree with percents calculated from rounded data.

## Definition of terms

## Ambulatory patient-An

 ambulatory patient is an individual seeking personal health services who is not currently admitted to any health care institution on the premises.Drug mention-A drug mention is the physician's entry of a pharmaceutical agent-by any route of administration-for prevention, diagnosis, or treatment. Generic as well as brand-name drugs are included, as are nonprescription and prescription drugs. Along with all new drugs, the physician also records continued medications if the patient was specifically instructed during the visit to continue the medication.

Drug visit-A drug visit is a visit in which medication was prescribed or provided by the physician.

General surgeon-A general surgeon is a physician classified as a specialist in general surgery in the master files of the AMA or AOA.

Office-Offices are the premises physicians identify as locations for their ambulatory practice; these customarily include consultation, examination, or treatment spaces that patients associate with the particular physician.

Table IV. Coefficients appropriate for determining relative standard errors, by type of estimate and physiclan specialty: National Ambulatory Medical Care Survey, 1989-90

| Type of estimate <br> and <br> physician speciaty | Coefficient |  |
| :---: | :---: | :---: |
| Visits | $A$ | $B$ |
| Overall totals . . . . . . | 0.00097549 | 52.77952184 |
| General surgeon . . . | 0.01236777 | 8.46452055 |
| Drug mentions |  |  |
| Overall totals . . . . . . | 0.00157151 | 81.47054833 |
| General surgeon . . . | 0.01603845 | 11.42009384 |

Physician-A physician is a duly licensed doctor of medicine (M.D.) or doctor of osteopathy (D.O.) who is currently in office-based practice and who spends some time caring for ambulatory patients. Excluded from NAMCS are physicians who are hospital-based; who specialize in anesthesiology, pathology, or radiology; who are federally employed; who ireat only institutionalized patients; or who are employed full time by an institution and spend no time seeing ambulatory patients.

Visit-A visit is a direct personal exchange between an ambulatory patient and a physician (or a staff member working under the physician's supervision), for the purpose of seeking care and rendering personal health services.

# Long-Stay Patients in Short-Stay Hospitals 

by Margaret Jean Hall, Ph.D., and Lola Jean Kozak, Ph.D., Division of Health Care Statistics

## Introduction

Patients hospitalized for more than 3 weeks made up only 5 percent of discharges from short-stay hospitals in 1980 and 4 percent in 1990. However, in both years these long-stay patients used more than a quarter of the days of care in short-stay hospitals. The large share of days used by long-stay patients make them an important group for analysis. This report examines the characteristics of long-stay patients and compares them with characteristics of all discharges from short-stay hospitals in 1980 and 1990.

The period 1980-90 was chosen for analysis because it was a decade of marked change in the health care system. Concern about rising health care costs led to several developments that were intended to reduce hospital use. In 1983, the method of payment for hospitalized Medicare patients was fundamentally changed with the implementation of a prospective payment system based on diagnosisrelated groups (DRG's). A rapidly growing number of surgical and diagnostic procedures were shifted
from inpatient to outpatient settings during the 1980's. Health maintenance organizations and preferred-provider organizations expanded during the period, and the number and stringency of utilization review programs increased (1-3).

Short-term hospital use declined during the 1980's. The total number of discharges was 19 percent lower, and the number of days of care was reduced 28 percent in 1990 compared with 1980. The number of discharges and days of care declined for patients with hospital stays of 3 weeks or less and for those with stays of more than 3 weeks.

However, despite the pressures to reduce hospital use, long-stay patients hospitalized for more than 3 weeks continued to account for the same disproportionately large share of hospital days in 1990 as they did in 1980. The extent to which the characteristics of long-stay or all patients changed during the 1980's will be examined in this report.

The data were collected by means of the National Hospital Discharge Survey (NHDS), a continuous
voluntary survey conducted by the National Center for Health Statistics since 1965. It is comprised of information on patients discharged from non-Federal short-stay hospitals. In 1980, data for the survey were abstracted from medical records of approximately 224,000 patients discharged from 420 hospitals. In 1990, 474 hospitals participated in the survey supplying approximately 266,000 abstracts of medical records.

A two-stage, stratified sample design was used for the NHDS during the period 1965-87. A three-stage, stratified sample design began in 1988. A brief description of these two designs, data collection procedures, and the estimation process are in the "Technical notes" of this report. A description of the two survey designs and the effects of the design changes on estimates from the survey has been published (4).

Up to seven diagnoses and four procedures were coded for each discharge in the survey. Coding of diagnoses and procedures was performed according to the International Classification of Diseases,

## Acknowledgments

This report was prepared at the Division of Health Care Statistics. Maria Owings, Hospital Care Statistics Branch, calculated relative standard crrors for estimates, and Dorothy Graham, Technical Services Branch, verified the data. The report was edited by Klaudia Cox and typeset by Zung T.N. Le of the Publications Branch, Division of Data Services.
U.S. DEPARTMENT OF HEALTH AND HUMAN SERVICES

9th Revision, Clinical Modification (ICD-9-CM) (5). Although diagnoses included in the ICD-9-CM section, "Supplementary classification of external causes of injury and poisoning" (codes E800-E999), are used in the NHDS, they are excluded from this report.

To interpret data and compare them with available data from other sources on short-stay hospital use, one must become familiar with the definitions used in NHDS. Definitions of the terms in this report are in the "Technical notes."

## Highlights

- More than 50 percent of long-stay patients were diagnosed with diseases of the circulatory system, mental disorders, neoplasms, injury, or poisoning.
- Hospitalizations for septicemia, psychoses, and miscellaneous complications of surgical and medical care were more frequent in 1990 than in 1980 for all patients and long-stay patients.
- Long-stay patients were more likely to have diagnoses such as septicemia, malignant neoplasms, psychoses, cerebrovascular disease, and fractures than were all patients.
- The rate of procedures per 1,000 discharges was 50 percent higher for long-stay patients than for all patients; the rates in 1990 were higher than the rates in 1980 for both groups.
- The majority of long-stay patients had Medicare as their expected principal source of payment in 1980 and 1990. Medicaid covered a larger share and private insurance covered a smaller share of long-stay and all discharges in 1990 than in 1980.
- The proportion of discharges transferred to other health care facilities was higher in 1990 than in 1981 for both long-stay and all patients. Long-stay patients were more likely to be transferred or discharged dead than were all patients.

Table 1. Number of discharges, days of care, and average lengths of stay for patients discharged from short-stay hospitals, by length of stay category: United States, 1980 and 1990

| Length-of-stay category and measure of hospital use | 1980 | 1990 |
| :---: | :---: | :---: |
| All patients |  |  |
| Number of discharges in thousands. | 37,832 | 30,788 |
| Number of days of care in thousands | 274,508 | 197,422 |
| Average length of stay in days | 7.3 | 6.4 |
| Short-stay patients ${ }^{1}$ |  |  |
| Number of discharges in thousands. | 35,897 | 29,486 |
| Number of days of care in thousands | 202,317 | 146,999 |
| Average length of stay in days | 5.6 | 5.0 |
| Long-stay patients ${ }^{2}$ |  |  |
| Number of discharges in thousands. | 1,935 | 1,302 |
| Number of days of care in thousands | 72,191 | 50.423 |
| Average length of stay in days . . | 37.3 | 38.7 |

## Trends

The number of discharges was lower in 1990 than in 1980 (table 1). The total number of discharges decreased 19 percent from 37.8 million in 1980 to 30.8 million in 1990. Discharges for patients hospitalized 3 weeks or less dropped 18 percent; discharges for long-stay patients hospitalized more than 3 weeks decreased by almost a third, declining from 1.9 million in 1980 to 1.3 million in 1990.

Large decreases in numbers of days of care also occurred during this period. The number of days of care for all patients declined 28 percent from 274.5 million in 1980 to 197.4 million in 1990. Patients with stays of 3 weeks or less had a 27 percent decrease in the number of days of care during the period, and long-stay patients had a 30 percent decrease from 72.2 million days of care in 1980 to 50.4 million days in 1990 .

The average length of stay for all patients decreased from 7.3 days in 1980 to 6.4 days in 1990 and the length of stay for short-stay patients declined from 5.6 days in 1980 to 5.0 days in 1990 . The average stay for long-stay patients did not change significantly: 37.3 days in 1980 and 38.7 days in 1990.

The objective of this report is to compare characteristics of long-stay patients to all patients. Therefore no
additional data are presented for short-stay patients. Because short-stay patients comprise such a large percentage of all patients (9596 percent), the data for all and short-stay patients are very similar.

## Age and sex

Over time, the distribution of discharges and days of care by sex has been stable. Among long-stay patients, 54 percent of discharges were female and they used 54 percent of long-stay days of care in both 1980 and 1990 (table 2). Females made up 60 percent of total discharges and 57-58 percent of total days of care in 1980 and 1990. However, if hospitalizations for deliveries are excluded, the distributions of discharges and days of care by sex are almost the same for long-stay and all patients. For example, in 1990 females made up 54 percent of total discharges and days of care, excluding deliveries.

In 1980 and 1990, approximately half of long-stay discharges and days of care were for patients 65 years of age and over. The elderly made up smaller proportions of total discharges and days of care in both years, but the proportions increased over time. In 1980, the elderly accounted for only 26 percent of total discharges and 38 percent of total days of care. By 1990, they were

Table 2. Number and percent distribution of discharges and days of care for patients discharged from short-stay hospitals, by sex and age of patient, according to length-of-stay category: United States, 1980 and 1990
[Discharges from non-Federal hospitais. Excludes newborn infants]

| 65 years and over | 105,358 | 89,552 | 36.133 | 24,707 | 38.4 | 45.4 | 50.1 | 49.0 |

${ }^{1}$ Long-stay patents had lengiths of stay of more than 3 weeks.

34 percent of discharges and used 45 percent of days of care.

Patients $45-64$ years of age made up approximately the same proportion of long-stay and total discharges in 1980 and 1990. The proportion of discharges and days of care in this age category decreased for both long-stay and all patients from 1980 to 1990. When compared with all patients, long-stay patients under 45 years of age were underrepresented. The proportion of long-stay discharges and days of care for patients under 45 years of age were higher in 1990 than in 1980, although the share of total discharges for this age group decreased during the period.

## Source of payment

In 1980 and 1990, the majority of long-stay discharges and days of care were for patients with Medicare as the expected principal source of payment (table 3), which was consistent with the majority being 65 years of age and over. The proportion of discharges and days of care covered by Medicare were not
significantly different in 1980 and 1990 for long-stay patients, although the number of Medicare discharges and days of care decreased for these patients. For all patients, the proportion of Medicare discharges and days of care increased during that period. The number of discharges did not change significantly, and number of days of care decreased for all Medicare patients.

The private insurance category comprised all health insurance provided by nongovernmental sources, including Blue Cross, other insurance companies, private industry, and philanthropic organizations. In 1980 and 1990 , long-stay patients were less likely to be covered by private insurance than all patients, and the number and proportion of discharges and days of care covered by private insurance have been decreasing for long-stay and all patients. In 1980, private insurance was the payment source for more than half of all discharges but less than a third of long-stay discharges. In 1990, only 39 percent of all discharges and

24 percent of long-stay discharges were in the private insurance category.

In contrast, the proportion of discharges and days of care for patients with Medicaid as their expected principal source of payment were higher in 1990 than in 1980 for long-stay and all patients, although the number of Medicaid discharges and days of care did not change significantly. Medicaid was the expected source of payment for 7 percent of long-stay discharges and days of care in 1980 and increased to 11-12 percent in 1990 .

The self-pay category, where payment for hospitalization was expected from the patient, spouse, family, or next of kin, made up 5-6 percent of discharges and days of care for long-stay and all patients in 1990. Neither the number nor the proportion of discharges or days of care in the self-pay category were significantly different in 1980 and 1990.

These trend data show that private insurers were the leaders in reducing hospital use of long-stay and

'Long-stay patients had lengths of stay of more than 3 weeks.
${ }^{2}$ In 1980 a source of payment was umpured for patents who did not indicate one.
all patients. One reason may have been that persons with private insurance were generally younger or healthier than populations covered by Medicare or Medicaid. Medicare covers the aged, disabled, and those afflicted with end-stage renal disease. In 1990, three-fourths of Medicaid benefits were for disabled, aged, and blind persons (6). Thus, hospital stays for the privately-insured population could have been shortened with less risk to patients' health, and they would have been likely candidates for treatment in outpatient settings.

## Disposition

Changes over time in the dispositions of long-stay patients and all patients are shown in table 4. Data for 1981 rather than 1980 are used in table 4 because the disposition categories for the NHDS were the same in 1981 and 1990. In 1980 and earlier years, data were collected for different disposition categories.

Most patients leave short-stay hospitals as routine discharges. However, long-stay patients were less likely to be routine discharges than all patients, and the proportion of
long-stay discharges in this category decreased over time. In 1981, 67 percent of long-stay discharges were classified as routine, but only 59 percent were in this category in 1990. For all patients, the proportion of routine discharges was not significantly different in 1981 and 1990.

The proportion of long-stay and all patients transferred to other institutions increased over time. In 1981, 14 percent of the long-stay discharges were transferred to another facility or institution compared with 20 percent in 1990. For all discharges, 4 percent were transferred to other facilities in 1981 compared with 8 percent in 1990 . In both years, more than three-quarters of the transfers of long-stay patients were to long-term care institutions and two-thirds of all transfers were in this category.

The increase in transfers may indicate that hospitalized patients were more seriously ill in 1990 than in 1981, which is consistent with the findings of other studies ( $1,7,8$ ). Prior research has also found that to reduce lengths of stay, hospitals have
discharged patients in less stable condition in recent years. Hence, patients are now more likely to require further care (1).

A larger proportion of long-stay patients than all patients were discharged dead in 1981 and 1990. However, the proportion discharged dead in 1981 was not significantly different than in 1990 for either group. For long-stay patients, 10-11 percent were discharged dead compared with 3 percent of all patients. If the severity of illness for hospitalized patients has increased, the proportion discharged dead would be expected to grow. However, there is evidence that an increase in the severity of illness was combined with an increased tendency for hospitals to discharge terminally ill patients before their deaths (1). Deaths in short-stay hospitals made up 50 percent of all deaths in 1981, but decreased to 41 percent of all. deaths in $1990(9,10)$.

## Region

The distribution of discharges and days of care, by region, for long-stay and all patients is shown in

Table 4. Number and percent distribution of discharges and days of care for patients discharged from short-stay hospitals, by dlsposition, according to length-of-stay category: United States, 1981 and 1990
[Discharges from non-Federal hospitals. Excludes newborn infants]

${ }^{i}$ Long-stay patients had lengths of stay of more than 3 weeks.
table 5. The Northeast Region had larger proportions of discharges and days of care for long-stay patients than for all patients in 1980 and 1990. In 1990, 33 percent of the discharges for long-stay patients were in the Northeast as compared with 22 percent of all discharges; 35 percent of long-stay days of care were also in the Northeast, but only

27 percent of all days of care were in this region.

The Midwest Region was notable for sizeable decreases in its proportions of long-stay discharges and days of care. In 1980, 32 percent of the discharges and 31 percent of the days of care for long-stay patients were in the Midwest. However, in 1990 the Midwest had only 23 percent
of long-stay discharges and 21 percent of long-stay days. Although the total discharges and days of care also decreased in the Midwest during this period, the proportion of discharges and days of care were smaller in the Midwest for long-stay patients than for all patients in 1990.

The proportions of discharges and days of care in the South Region
were smaller for long-stay patients than for all patients in both 1980 and 1990. In 1990, for example, 36 percent of all discharges, but only 31 percent of long-stay discharges, were in the South. The West, like the South, had proportionately fewer discharges for long-stay patients than for all patients. The West accounted for 11-13 percent of long-stay discharges as compared with $16-17$ percent of all discharges.

## Diagnoses

Four of the diagnostic chapters in the International Classification of Diseases (5) accounted for 62 percent of discharges of long-stay patients in 1980 and 58 percent in 1990 (table 6). These chapters encompass diseases of the circulatory system, mental disorders, neoplasms, and injury and poisoning. They accounted for only 34 percent of the discharges of all patients in 1980 and 37 percent in 1990.

The proportion of long-stay patients with diseases of the circulatory system decreased from 22 percent in 1980 to 19 percent in 1990, but was larger in both years than the proportion of all patients with circulatory diseases ( 14 percent in 1980 and 17 percent in 1990). Heart disease was the diagnosis for a larger proportion of long-stay patients than for all patients in 1980, but in 1990, the proportions were not significantly different for these two groups. In 1980 and 1990, long-stay patients were more likely to have diagnoses of cerebrovascular disease and diseases of arteries, arterioles, and capillaries than all patients. The number and proportion of discharges for ischemic heart disease, other than acute myocardial infarction, were lower in 1990 than in 1980 for long-stay patients.

Mental disorders increased from 13 percent of long-stay diagnoses in 1980 to 19 percent in 1990 . For all patients, mental disorders accounted for approximately 5 percent of discharges in both years. Psychoses was a major and dramatically increasing diagnostic category for
long-stay patients, making up 5 percent of long-stay discharges in 1980 and 12 percent in 1990. The proportion of all patients with diagnoses of psychoses also increased from 1 to 3 percent. The number and proportion of long-stay and all discharges for neurotic and personality disorders were lower in 1990 than in 1980.

Neoplasms made up 15 percent of long-stay discharges in 1980, but decreased to 11 percent in 1990. Most of these hospitalizations were for treatment of malignant neoplasms, which accounted for 14 percent of the long-stay discharges in 1980, but declined to 11 percent in 1990. Among all patients, those with neoplasms were $6-7$ percent of discharges and those with malignant neoplasms were approximately 5 percent of discharges in 1980 and 1990. The number and proportion of discharges with the diagnosis of malignant neoplasm of trachea, bronchus, and lung were lower in 1990 than in 1980 for long-stay patients, but did not change significantly for all patients during this period.

Injury and poisoning was the diagnostic category for 12 percent of long-stay discharges in 1980 and 10 percent in 1990. For all patients, the injury and poisoning category accounted for 10 percent of discharges in 1980 and 9 percent in 1990. In 1980 and 1990, a larger proportion of long-stay patients than of all patients had fractures, including fractures of the neck of the femur (hip fractures). However, the number and proportion of all fractures and hip fractures were lower in 1990 than in 1980 for long-stay patients. For all patients, the number and proportion did not change significantly for all fractures, but increased for hip fractures. For long-stay and all patients, the number and proportion of discharges classified as miscellaneous complications of surgical and medical care were higher in 1990 than in 1980.

Increases in long-stay discharges were also found for other diagnostic categories. For infectious and parasitic diseases, in particular
septicemia, the number and proportion of long-stay discharges in 1990 were two to four times those in 1980. By 1990, septicemia accounted for half of the long-stay discharges in the infectious and parasitic disease category. The 1990 number and proportion of all discharges with septicemia were also more than three times those in 1980.

In 1990, the number of long-stay discharges assigned to the supplementary classifications doubled, and the proportion more than tripled what they had been in 1980. Within this category, care involving use of rehabilitation procedures was rarely reported as a diagnosis in 1980, but in 1990 , it accounted for more than half of the long-stay discharges in the supplementary classification.

The proportion of long-stay discharges for diseases of the respiratory system increased from 6 percent in 1980 to 9 percent in 1990, although the numbers did not change significantly. Pneumonia increased from 2 to 4 percent of long-stay discharges during this period. Both the number and proportion of all discharges for pneumonia were higher in 1990 than in 1980.

Notable decreases were seen in discharges for other diagnostic categories. The number and proportion of discharges for diseases of the musculoskeletal system and connective tissue were lower in 1990 than in 1980 for long-stay and all patients. For long-stay patients, the number of discharges for arthropathies and related disorders decreased by two-thirds, and the proportion dropped 50 percent during this period. Neither the number nor the proportion of all discharges for these disorders changed significantly. Diabetes mellitus was a less common diagnosis in 1990 than in 1980. The number and proportion of discharges with diabetes mellitus declined for long-stay patients and all patients.

The number and percent distribution of days of care for long-stay and all patients are shown by diagnostic categories in table 7 . The pattern and trend in days of care

${ }^{\text {T Long-stay patients had lengens of stay of more than } 3 \text { weers. }}$
for diagnoses were generally similar to those seen in the discharge data. Diseases of the circulatory system, mental disorders, neoplasms, and injury and poisoning together accounted for 63 percent of the days of care for long-stay patients in 1980 and 57 percent in 1990.

As was the case with discharges, the proportion of days of care for diagnostic categories such as septicemia; most malignant neoplasms; mental disorders; cerebrovascular disease; diseases of arteries, arterioles, and capillaries; all fractures; and hip fractures was higher for long-stay patients than for all patients. Unlike discharges, the proportion of days of care for diseases of the circulatory system was lower for long-stay patients than for all patients in 1990.

Days of care for long-stay patients increased for infectious and parasitic diseases (especially septicemia), psychoses, pneumonia, miscellaneous complications of surgical and medical care, and the supplementary classifications (where care involving use of rehabilitation procedures accounted for half of the days in 1990).

Long-stay patients had decreases in days of care for diagnostic categories such as malignant neoplasms of trachea, bronchus, and lung; diabetes mellitus; neurotic and personality disorders; ischemic heart disease (other than acute myocardial infarction); diseases of arteries, arterioles, and capillaries; arthropathies and related disorders; all fractures; and hip fractures.

## Procedures

The rate of procedures per 1,000 discharges for long-stay patients was 1,255 in 1980 and 2,046 in 1990, an increase of 63 percent (table 8). For all patients, the rate of procedures per 1,000 discharges increased by 58 percent-from 830 in 1980 to 1,316 in 1990. In 1980 and 1990, the rate of procedures per 1,000 discharges was more than 50 percent higher for longstay patients than for all patients. Although long-stay patients
accumulated more procedures per hospitalization, they had fewer procedures per hospital day. In 1990, the rate of procedures per 100 hospital days was 5 for long-stay patients compared with 21 for all patients.

In 1990, 31 percent of the procedures performed on long-stay patients were in the category, miscellaneous diagnostic and therapeutic procedures. Operations on the digestive system made up 19 percent of the procedures and operations on the cardiovascular system accounted for 17 percent of procedures on long-stay patients. Thus, more than two-thirds of the procedures performed on long-stay patients were in these three categories. Only 52 percent of the procedures for all patients were in these three categories in 1990. In 1980, the same three categories of procedures made up approximately half of the procedures performed on long-stay patients and a third of the procedures for all patients.

The rate of miscellaneous diagnostic and therapeutic procedures per 1,000 discharges in 1990 was more than double the rate in 1980 for long-stay patients. The rate for all patients more than tripled during this period. Large increases can be seen in the rates for a number of specific procedures in this category. The rate of computerized axial tomography (CAT) scans more than tripled for long-stay patients and increased six-fold for all patients. Long-stay patients had a rate of diagnostic ultrasound per 1,000 discharges in 1990 that was 4.7 times the 1980 rate, and the 1990 rate of diagnostic ultrasound for all patients was more than six times the 1980 rate. Respiratory therapy and insertion of endotracheal tube were reported infrequently for long-stay and all patients in 1980, but were common procedures in 1990. The rate per 1,000 discharges for arteriography and angiocardiography using contrast material was not significantly higher for long-stay patients in 1990 than in 1980, but it more than tripled for all patients. This was one of the few
diagnostic procedures for which all patients had a higher rate per 1,000 discharges than long-stay patients in 1990.

The increases in miscellaneous diagnostic and therapeutic procedures were probably due in part to changes in the methodology of the National Hospital Discharge Survey (see "Technical notes"). Beginning in 1985, some data for the survey have been obtained from abstracting service organizations. Analysis has indicated that a greater number of nonsurgical procedures per patient were reported by hospitals using abstract services than by hospitals submitting data in the traditional manual form. In addition, more complete reporting of relatively minor procedures has been linked to the implementation of the 1983 Medicare prospective payment system, which is based on diagnosis-related groups (DRG's) (11-13).

Like the rate of miscellaneous diagnostic and therapeutic procedures, the rate of operations on the cardiovascular system per 1,000 discharges in 1990 was more than double the 1980 rate for long-stay patients and more than triple the 1980 rate for all patients. A number of cardiovascular procedures contributed to these increases. The rate of coronary artery bypass grafts per 1,000 discharges more than tripled for long-stay and all patients. The cardiac catheterization rate doubled for long-stay patients and more than tripled for all patients. Puncture of vessel was also reported at a much higher rate in 1990 than in 1980 for long-stay and all patients.

The rate of operations on the digestive system was not significantly different in 1980 as compared with 1990 for long-stay or all patients, but rates of several specific digestive system procedures increased during this period. The rates per 1,000 discharges for gastrostomy and endoscopy of the small intestine more than tripled for long-stay patients and all patients. Long-stay patients had an 86 percent higher rate of endoscopy of the large intestine in 1990 than in 1980, and rates for lysis of peritoneal

Table 8. Number of procedures and ratio of procedures to discharges for patients discharged from short-stay hospitals, by procedure and length-of-stay categories: United States, 1980 and 1990

${ }^{1}$ Long-stay patients had iengths of stay of more than 3 weeks.
adhesions increased approximately 75 percent for long-stay and all patients. In contrast, the rates of cholecystectomy per 1,000 discharges were not significantly higher in 1990 as compared with 1980 for long-stay or all patients.

Other significant changes included a 57 -percent-higher rate of
operations on the respiratory system per 1,000 discharges for long-stay patients in 1990 as compared with 1980. Within the respiratory category, the rate for incision of the chest wall and pleura per 1,000 discharges increased $87-90$ percent for long-stay and all patients. Notable in other categories was the change in the rate
for debridement of wound, infection, and burn per 1,000 discharges, which in 1990 was twice the 1980 rate. The rate for spinal tap also doubled for all patients and increased 86 percent for long-stay patients during this period.

Unlike most rates, the rate of operations on the male genital organs per 1,000 discharges was lower for
long-stay patients in 1990 than in 1980. In particular, the rate of prostatectomy per 1,000 discharges decreased for long-stay patients, even though it did not change significantly for all patients during this period. Prostatectonty was performed at a higher rate per 1,000 discharges for long-stay patients in 1980 but at a higher rate for all patients in 1990.

The rate per 1,000 discharges for the "all other procedures" category was higher for all patients than for long-stay patients in 1980 and 1990. This category included obstetrical procedures and operations on the endocrine system, eye, ear, nose, mouth, and pharynx.

## Summary

In 1980 and 1990 , only 4-5 percent of patients in short-stay hospitals were hospitalized for more than 3 weeks. The number of discharges and days of care for these long-stay patients were lower in 1990 as compared with 1980 , but they continued to use more than a quarter of all hospital days in 1990. Long-stay patients were more likely than all patients to be 65 years of age and over and have Medicare as their expected principal source of payment. For long-stay and all patients, private insurance covered smaller proportions of discharges and days of care, and Medicaid covered larger proportions in 1990 than in 1980.

Long-stay patients were more likely than all patients to be discharged dead or transferred to other hospitals or nursing homes. Long-stay and all patients were more likely to be transferred at discharge in 1990 than in 1981. The Northeast Region had a larger proportion of long-stay patients than of all patients, and that proportion increased from 1980 to 1990 . The proportion of long-stay discharges and days of care in the Midwest decreased during this period.

In 1980 and 1990, more than 50 percent of the discharges and days of care for long-stay patients were for diseases of the circulatory system, mental disorders, neoplasms, or injury
and poisoning. Despite the overall decreases in hospital use by long-stay patients, their discharges and days of care increased significantly from 1980 to 1990 for diagnoses such as septicemia, psychoses, and miscellaneous complications of surgical and medical care. Over time, decreases were seen in long-stay discharges and days of care for a variety of diagnostic categories, including malignant neoplasm of trachea, bronchus, and lung; diabetes mellitus; and fracture of the neck of the femur.

Long-stay patients had a higher rate of procedures per 1,000 discharges in 1990 than in 1980, and a higher rate than all patients in both years. Approximately half of all the procedures performed on long-stay patients in 1980 and two-thirds in 1990 were miscellaneous diagnostic and therapeutic procedures, operations on the cardiovascular system, or operations on the digestive system. The rates of numerous procedures, especially diagnostic tests, increased for long-stay and all patients from 1980 to 1990.

## Technical notes

## Survey methodology

## Source of data

The National Hospital Discharge Survey (NHDS) covers discharges from noninstitutional hospitals, except Federal, military, and Veterans' Administration hospitals, that are located in the 50 States and the District of Columbia. Only hospitals with at least six beds and an average length of stay of less than 30 days for all patients were included in the survey from 1965-87. Beginning in 1988, the universe also included hospitals whose specialty was general (medical or surgical) or children's general, even if the hospital's average length of stay for patients was 30 days or more.

The original universe for the survey consisted of 6,965 hospitals listed in the 1963 National Master Facility Inventory (NMFI). The universe was updated periodically using NMFI data and data from the American Hospital Association to reflect new hospitals entering the universe. Beginning in 1988, the universe for the NHDS consisted of hospitals that were listed in the April 1987 SMG Hospital Market Tape, met the above criteria, and began accepting patients by August 1987.

In 1980, the sample consisted of 544 hospitals, of which 52 were found to be out-of-scope because they had gone out of business or failed to meet the criteria for the NHDS universe. Of the 492 in-scope (eligible) hospitals, 420 participated in the survey. In 1990, 542 hospitals were sampled and 23 were found to be out- of- scope. Of the 519 in-scope hospitals, 474 responded to the survey.

## Sample design and data collection

From 1965 to 1987, the NHDS had a stratified, two-stage design. Sample hospitals were selected with probabilities ranging from certainty for the largest hospitals to 1 in 40 for the smallest hospitals. Within each
sample hospital, a systematic random sample was selected.

Beginning in 1988, the NHDS sample included, with certainty, all hospitals with 1,000 beds or more, or 40,000 discharges or more annually. The remaining sample of hospitals was based on a stratified, three-stage design. The first stage consisted of a selection of 112 primary sampling units (PSU's) that were a probability subsample of PSU's to be used in the 1985-94 National Health Interview Survey. The second stage consisted of a selection of noncertainty hospitals from the sample PSU's. At the third stage, a sample of discharges was selected by a systematic randomsampling technique. A detailed description of the old and new survey designs has been published (4).

Two data collection procedures were used for the survey. The first was a manual system of sample selection and data abstraction, which was used for all hospitals in 1980. The second, an automated method used for approximately 34 percent of the respondent hospitals in 1990, involved the purchase of data tapes from abstracting services.

In the manual system, the sample selection and transcription of information from hospital records to abstract forms were performed at the hospitals. The completed forms, along with sample selection control sheets, were forwarded to the National Center for Health Statistics (NCHS) for coding, editing, and weighting. A few of these hospitals have submitted their data via computer printout or tape in recent years. In about 55 percent of the hospitals that participated in the survey in 1980, and about two-thirds of hospitals using this manual system in 1990, the work was performed by their own medical records staff. In the remaining hospitals using the manual system, the U.S. Bureau of the Census personnel, on behalf of NCHS, did the work.

For the automated system, NCHS purchased tapes containing machinereadable medical record data from abstracting services and State data
systems. Records were systematically sampled by NCHS.

The data collected for the survey included items relating to the patient's personal characteristics, including birth date, sex, race, and marital status (but not the patient's name and address); administrative information, including admission and discharge dates, discharge status, and medical record number; and medical information, including diagnoses and surgical and nonsurgical operations or procedures. Beginning in 1977, data pertaining to patient ZIP Code, expected source of payment, and dates of surgery were also collected. (The medical record number and patient ZIP Code are confidential information and are not available to the public.)

## Presentation of estimates

The relative standard error (RSE) of the estimate and the number of sample records that the estimate was based on are used to identify estimates with relatively low reliability. Because of the complex sample design of the NHDS, estimates of less than 5,000 are not presented; only an asterisk (*) appears in the tables. Generally, these estimates have an RSE of more than 30 percent or are based on a sample of less than 30 cases. Estimates of 5,000-9,000 are preceded by an asterisk (*) to indicate they should not be assumed reliable. These estimates are usually based on fewer than 60 cases.

## Sampling errors and rounding of numbers

The standard error is primarily a measure of sampling variability that occurs by chance, because only a sample rather than the entire universe is surveyed. The RSE of the estimate is obtained by dividing the standard error by the estimate itself. The resulting value is multiplied by 100 , so the RSE is expressed as a percent of the estimate.

Estimates of sampling variability for 1980 data were calculated using a customized computer routine based
on an unbiased algebraic estimator of the variance (14). The RSE's for 1980 discharges or first-listed diagnoses, days of care, and procedures are shown in tables I and II.

SESUDAAN software was used to calculate estimates of sampling variability for 1990 data. This software computes standard errors by using a first-order Taylor approximation of the deviation of estimates from their expected values. A description of the software and the approach it uses has been published (15). The constants for RSE curves for 1990 NHDS estimates are presented in table III. The RSE of an

Table 1. Approximate relative standard errors of estimated numbers of discharges or first-listed diagnoses and all-listed procedures by size of estimate: United States, 1980

| Size of estimate | Number of discharges or first-fisted diagnoses | Number of all-listed procedures |
| :---: | :---: | :---: |
| 5,000 | 18.0 | 17.3 |
| 10,000 | 14.9 | 14.7 |
| 50,000 | 10.1 | 10.6 |
| 100,000 | 8.8 | 9.4 |
| 300,000 | 7.1 | 7.9 |
| 500,000 | 6.5 | 7.3 |
| 1,000,000 | 5.8 | 6.7 |
| 3,000,000 | 5.0 | 5.9 |
| 5,000,000 | 4.7 | 5.6 |
| 10,000,000. | 4.3 | 5.2 |
| 20,000,000. | 4.0 | 4.9 |
| 30,000,000. | 3.8 | 4.7 |
| 40,000,000. | 3.7 | $\ldots$ |

Table II. Approximate relative standard errors of estimated numbers of days of care by size of estimate: United States, 1980

| Size of estimate | Number of days of care |
| :---: | :---: |
| 10,000 | 24.7 |
| 30,000 | 18.9 |
| 50,000 | 16.8 |
| 100,000 | 14.3 |
| 300,000 | 11.2 |
| 500,000 | 10.1 |
| 1,000,000 | 8.8 |
| 3,000,000 | 7.1 |
| 5,000,000 | 6.5 |
| 10,000,000. | 5.7 |
| 50,000,000. | 4.4 |
| 100,000,000. | 4.0 |
| 250,000,000 . | 3.5 |

estimate $(X)$ can be estimated from the formula:

$$
\operatorname{RSE}(X)=100(\sqrt{a+b / X})
$$

where $X, a$, and $b$ are as defined in table III.

Estimates have been rounded to the nearest thousand. For this reason, figures within tables do not always add to the totals. Percents and rates were calculated from original, unrounded figures and do not necessarily agree precisely with percents and rates calculated from rounded data.

## Tests of significance

In this report, statistical inference is based on the two-tailed $t$-test for independent samples using the Bonferroni critical values for post-hoc multiple comparisons ( 0.05 level of significance). Critical values were determined for each set of comparisons, that is, within each table. In comparisons of data for all discharges and long-stay discharges, estimates were not from independent samples; therefore, the $t$-test used is conservative. Terms such as "higher" and "less" indicate that differences are statistically significant. Terms such as "similar" and "no difference" mean that no statistically significant difference exists between the estimates being compared. A lack of comment on the difference between any two estimates does not mean that the difference was tested and found insignificant.

## Definitions of terms

Age - Patient's age at birthday prior to admission to the hospital. Average length of stay-The number of days of care accumulated by patients discharged during the year divided by the number of patients.

Days of care-The number of patient days accumulated by a patient at time of discharge. A stay of less than 1 day (patient admission and discharge on the same day) is counted as 1 day in the summation of total days of care. For patients admitted and discharged on different days, the number of days of care is
computed by counting all days from (and including) the date of admission to (but not including) the date of discharge. The terms days of care, patient days, and hospital days are synonymous.

Diagnosis-A disease or injury (or other factor that influences health status and contact with health services) listed on the medical record of a patient.

- Principal diagnosis - The condition established after study to be chiefly responsible for occasioning the admission of the patient to the hospital for care.
- First-listed diagnosis - The coded diagnosis identified as the principal diagnosis or listed first on the face sheet or discharge summary of the medical record if the principal diagnosis cannot be identified. The number of firstlisted diagnoses is equal to the number of discharges.
Discharge - The formal release of a patient by a hospital, that is, the termination of a period of hospitalization by death or disposition to place of residence, nursing home, another hospital, or other location. The terms discharge, patient, and inpatient are synonymous.

Disposition - The disposition of a patient on termination of hospitalization is classified in one of six categories in this report:

- Routine discharge-Patients who returned to their previous place of residence after discharge.
- Transfer to another short-term hospital-Patients who were transferred to another short-term hospital at discharge.
- Transfer to long-term care institution-Patients who entered a nursing home or other long-term care institution upon discharge from the hospital.
- Other live discharges - Patients who left the hospital against medical advice, patients discharged alive with dispositions other than routine discharge or transfer, and patients discharged alive whose dispositions were not stated.

Table III. Estimated parameters for relative standard error equations for National Hospital Discharge Survey statistics by selected characteristics: United States, 1990

| Characteristic | Number of discharges first-listed diagnoses |  | Number of days of care |  |
| :---: | :---: | :---: | :---: | :---: |
|  | $a$ | $b$ | $a$ | $b$ |

| Medicare. | 0.00233 | 147.208 | 0.00773 | 1,118.298 |
| Medicaid, | 0.00542 | 225.144 | 0.07067 | 1,495.250 |
| Self pay . | 0.00571 | 255.679 | 0.03949 | 1,337.799 |
|  | Number of procedures |  |  |  |
| Total | 0.00547 | 92.597 | . $\cdot$ | $\cdots$ |

NOTE: The relative standard error (RSE) for an estumate ( $x$ ) can be determined by using the equation RSE $(x)=100(\sqrt{a+b / x)}$.

- Dead-Patients who died during an inpatient stay.
- Not stated-Patients whose discharge status, that is, alive or dead, was not reported at discharge.
Expected principal source of payment - The expected principal source of payment is reported by the patient or the patient's representative at time of admission and may differ somewhat from the actual source of payment as determined after discharge. In this report, payment sources are grouped as follows:
- Private insurance-Insurance provided by nongovernmental sources, including Blue Cross and other insurance companies, private industry, and philanthropic organizations.
- Medicare - A nationwide program providing health insurance protection to people 65 years of age and over, people eligible for

Social Security disability payments for more than 2 years, and people with end-stage renal disease.

- Medicaid-A joint Federal-State program that provides benefits for people who meet their State's definition of "low income."
- Self-pay-Patients who expect the costs of hospitalization to be paid for primarily by themselves, spouses, parents, or next of kin.
- Other sources - Includes Worker's Compensation and other government programs, such as CHAMPUS (for dependents of military personnel); other nonprofit sources, such as church welfare; hospitalizations for which there was no charge; and sources that could not be assigned to any other category.
- Not stated - In 1990, patients for whom no source of payment was indicated. In 1980, source of payment was imputed for patients who did not indicate one.

Geographic region - Hospitals are classified by location in one of the four geographic regions of the United States that correspond to those used by the U.S. Bureau of the Census.

## Region

## States included

| Northeast | Maine, New Hampshire Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, and Pennsylvania |
| :---: | :---: |
| Midwest | Michigan, Ohio, Illinois, Indiana, Wisconsin, Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, and Kansas |
| South | Delaware, Maryland, District of Columbia, Virginia, West Virginia, North Carolina, South Carolina, Georgia, Florida, Kentucky, |

Tennessee, Alabama,
Mississippi, Arkansas,
Louisiana, Oklahoma,
and Texas
Montana, Idaho,
Wyoming, Colorado,
New Mexico, Arizona,
Utah, Nevada,
Washington, Oregon,
California, Hawaii, and
Alaska
Hospital-Hospitals with an
average length of stay of less than 30
days for all patients. In 1990,
hospitals whose specialty was general
(medical or surgical) were also
included, even if the average length
of stay of all patients was 30 days or
more. Federal hospitals, hospital units
of institutions, and hospitals with less
than six beds staffed for patients' use
were not included.

Long-stay patient-A patient whose length of stay in the hospital was more than 3 weeks.

Patient - A person formally admitted to the inpatient service of a short-stay hospital for observation, care, diagnosis, or treatment. Newborn infants, defined as those admitted by birth to the hospital, are excluded from this report. The terms patient, inpatient, and discharge are synonymous.

Population -The U.S. resident population, excluding members of the Armed Forces. The population estimates are from tabulations provided by the U.S. Bureau of the Census. The 1990 estimates do not include the results of the 1990 Census.

# National Ambulatory Medical Care Survey: 1991 Summary 

by Susan M. Schappert, M.A., Division of Health Care Statistics

## Introduction

During the 12 -month period from January 1991 through December 1991, an estimated 669.7 million visits were made to nonfederally employed, office-based physicians in the United States-about 2.7 visits per person. This rate is not statistically different from office visit rates observed since 1975 (1,2,3).

This report presents data highlights from the 1991 National Ambulatory Medical Care Survey (NAMCS), a national probability sample survey conducted by the Division of Health Care Statistics of the National Center for Health Statistics, Centers for Disease Control and Prevention. The data summarized here should be considered provisional because final editing may result in minor changes in the estimates. Statistics are presented on patient, physician, and visit characteristics.

Because the estimates presented in this report are based on a sample rather than on the entire universe of office visits, they are subject to sampling variability. The technical
notes found at the end of this report include a brief overview of the sample design used in the 1991 NAMCS, an explanation of sampling errors, and guidelines for judging the precision of the estimates.

The Patient Record is used by physicians participating in the NAMCS to record information about their patients' office visits. This form is reproduced in figure 1 and is intended to serve as a reference for readers as they review the survey findings presented in this document.

The 1991 Patient Record included several questions that were new to the National Ambulatory Medical Care Survey. Through these data items, information was collected on whether the current office visit was injury related, whether the patient smoked cigarettes, and whether ambulatory surgery was scheduled or performed at the visit. In addition, revisions were made to some of the existing data items concerned with diagnostic, screening, and therapeutic services. These changes are discussed in detail below.

The physician sample for the NAMCS was selected with the cooperation of the American Medical Association and the American Osteopathic Association. Their contribution to this effort is gratefully acknowledged.

## Patient characteristics

Office visits by patient's age, sex, and race are shown in table 1. Females made 59.8 percent of all office visits during 1991 and accounted for a higher percent of visits than males in all age categories except the youngest (under 15 years). Females also had significantly higher visit rates than males did in each age category with the exception of the youngest group (under 15 years) and the two oldest groups ( $65-74$ years and 75 years and over). These patterns were also observed in the 1990 NAMCS.

Visit rates tended to increase with age after the age of 24 . Persons 75 years of age and over had the highest visit rate of the six age categories analyzed, at 6.0 visits per
U.S. DEPARTMENT OF HEALTH AND HUMAN SERVICES

Figure 1. Patient record
person. The pattern, however, was found to be slightly different for males and females. Among males, rates increased with each age group after the age of 24 , with males 75 years and over having the highest rate of 6.1 visits per person.

Females, despite a general trend toward increasing visit rates with age after the age of 24 , showed no statistical difference in the rates for females aged $25-44$ years compared with those aged 45-64 years, or in the rates for females aged $65-74$ years
compared with those aged 75 years and over.

White persons made 87.8 percent of all office visits during 1991, with black persons and Asian/Pacific Islanders accounting for 8.7 percent and 3.0 percent, respectively. The percent of visits made by white persons was higher than that reported in 1990, but this is probably due to a change in the coding procedure. For survey years before 1989 , unspecified responses to the race item were
randomly imputed a race designation. The 1989 and 1990 NAMCS included an "unspecified" category in the race item, which resulted in a significantly smaller proportion of visits by white persons than in previous survey years. The 1991 NAMCS reverted to the previous method of imputation of unspecified responses in order to maximize comparability across years of survey data. This method yielded a slightly higher proportion of visits by white

persons compared with 1989 and 1990 data. However, visit rates by age, sex, and race were not statistically different from rates observed in the 1989 NAMCS.

## Physician characteristics

The distribution of office visits according to physician specialty for the 13 most visited specialties is presented in table 2. The largest
share of visits ( 24.6 percent) was made to physicians specializing in general and family practice (GFP); this percentage, however, is significantly smaller than the one noted in 1990 (29.8 percent). A significant decrease was also seen in the visit rate to general and family practitioners, from 85.2 visits per 100 persons in 1990 to 66.3 visits per 100 person in 1991. Visit rates to each of the other 12 specialties were not
significantly different from 1990 visit rates. However, provisional data concerning these physician specialties for 1991 indicates increases in the proportion of visits made to internists, orthopedic surgeons, dermatologists, otolaryngologists, and urologists compared with 1990 figures, as well as a slight decrease in the proportion of visits made to psychiatrists. No significant differences were found in the proportion of visits to pediatricians, obstetricians and gynecologists, ophthalmologists, general surgeons, and neurologists.

A slightly higher proportion of visits were made to doctors of osteopathy in 1991 ( 7.0 percent) than in 1990 ( 5.6 percent). Osteopathic physicians received 18.8 visits per 100 persons during the year, compared with 250.5 visits per 100 persons to all other physicians.

## Visit characteristics

## Referral status and prior-visit status

In general, 6.2 percent of office visits in 1991 were made as the result of a referral from another physician, an increase from the 5.5 percent noted in 1990. The majority of office visits ( 83.3 percent) were made by patients who had seen the physician on a previous occasion, and more than half ( 61.8 percent) of all visits were made by persons who were returning to the physician for care of a previously treated problem (table 3). Only 16.7 percent of visits were made by new patients. These percents are not significantly different from those reported in 1990.

## Expected source of payment

This item was revised slightly from the 1990 NAMCS, with the addition of the "private/commercial" and "other government" payment categories. "Private/commercial" replaces the former categories of commercial insurance and Blue Cross/Blue Shield from the 1990 NAMCS. Data on expected source of payment are shown in table 4.

Expected sources of payment were most often private commercial

Table 2. Number, percent distribution, and annual rate of office visits by physician specialty and professional identity: United States, 1991

| Unknown | 13.828 | 2.1 |

iNumber may exceed total number of visits because more than one source of payment may be coded for each vist.
${ }^{2}$ Category is new on the 1991 National Ambutatory Medical Care Survey
insurance ( 35.8 percent of visits) and patient-paid ( 23.6 percent). The patient-paid category includes the patient's contribution toward "copayments" and "deductibles." Medicare was an expected payment source at 21.2 percent of visits overall, a significant increase from the 1990 level of 19.8 percent. For persons 65 years of age and over, Medicare was an expected source of payment at 80.6 percent of visits.
"HMO/other prepaid" was mentioned at 15.1 percent of visits, which was not significantly different from the 1990 level of 14.5 percent. An increase was noted in the percent of visits with Medicaid as an expected payment source, from 8.5 percent in 1990 to 9.5 percent in 1991. Readers should note that physicians were asked to check all of the applicable payment categories for this survey item, with the result that multiple payment sources could be coded for each visit.

## Is this visit injury related?

The 1991 NAMCS included a new item on the Patient Record in which the physician was asked to record whether the visit was injury related. About 66.1 million visits, or 9.9 percent of all office visits, were injury related; more than half of these visits ( 55.3 percent) were made by males, and 41.1 percent were made by persons $25-44$ years old. Males had a higher injury-visit rate tharı females did overall ( 30.3 visits per 100 males compared with 23.1 visits per 100 females), but these differences were evidenced only in the age groups $15-24$ years and 25-44 years. Injury-visit rates for males and females in the age groups under 15, 45-64, 65-74, and 75 years and over were not found to differ significantly.

Among females, injury-visit rates were lowest for those in the age group under 15 years ( 11.4 visits per 100 females under age 15). Visit rates for the other age groups (15-24 years, $25-44$ years, $45-64$ years, $65-74$ years, and 75 years and over) were higher than that of the youngest group, but were not significantly different from each other. For males, injury-visit
rates were not statistically different for the youngest and two oldest age groups (under 15, 65-74, and 75 years and over). Males 15-24 years, 25-44 years, and 45-64 years had higher injury visit rates (37.4, 39.7, and 33.7 visits per 100 males in each age group respectively), but these rates were not statistically different from each other. Injury-related office visits are described in terms of the patient's age and sex in table 5 .

## Does patient smoke cigarettes?

Another new item in the 1991 NAMCS collected data on whether the patient currently smokes cigarettes. Results from the survey showed that 10.1 percent of all office visits, or 67.7 million, were made by patients who smoke cigarettes. However, the patient's smoking status was not known for 27.7 percent of the total, or 185.2 million office visits. Data on visits according to patient's cigarette smoking status are presented in tables 6 and 7.

## Reason for visit

Item 10 of the Patient Record asks the physician to record the patient's (or patient surrogate's) "complaint(s), symptom(s), or other reason(s) for this visit in the patient's own words." Up to three reasons for visit are classified and coded from the survey according to $A$ Reason for Visit Classification for Ambulatory Care (RVC) (4). The principal reason for visit is the problem, complaint, or reason listed in item 9a.

The RVC is divided into the eight modules or groups of reasons displayed in table 8. More than half of all visits were made for reasons classified as symptoms ( 57.6 percent). Respiratory symptoms accounted for 11.5 percent of all visits, and musculoskeletal symptoms accounted for 11.4 percent.

The 20 most frequently mentioned principal reasons for visit, representing 38.2 percent of all visits, are shown in table 9. (It is important to note that the rank ordering presented in this and other tables in this report may not always be reliable

Table 5. Number, percent distribution, and annual rate of injury-related office visits by patient's age and sex: United States, 1991

| All other specialties | 76.341 | 100.0 | 11.7 | 61.3 | 26.9 |

for about 7.1 million visits. Their higher position on the rank-listing for 1991 was due mainly to a small but significant decrease in the number of visits for hypertension and chest pain and related symptoms.

## Diagnostic and screening services

Statistics on diagnostic and screening services ordered or provided by the physician during the office visit are displayed in table 10. The list of diagnostic and screening services appearing on the Patient Record is changed periodically to reflect the changing needs of data users, recommendations of advisors, and anticipated future health data needs. The 1991 NAMCS added a number of services that either had never appeared on the Patient Record or had not been included for several years. New categories for 1991 include the following: EKG - resting, EKG - exercise, allergy testing, spirometry, strep throat test, hearing test, and mental status exam. In addition, the former "other" category was expanded to permit greater specificity with the addition of the "other radiology" and "other lab test" categories.

More than half ( 64.8 percent) of all office visits included one or more diagnostic or screening service. The most frequently mentioned diagnostic
service was blood pressure check, recorded at 43.2 percent of visits. This percent was significantly higher than that recorded in 1990. (The 1990 percent was also bigher than that found in 1989.) Also, blood pressure checks were ordered or provided at a higher percent of visits by females ( 47.9 percent) than visits by males ( 36.1 percent) in 1991, but the percents for both sexes showed an increase over 1990 figures.

Other frequently mentioned diagnostic and screening services included the new category of "other lab test" (17.1 percent of visits), urinalysis ( 12.7 percent), and visual acuity ( 6.0 percent). Pap tests were ordered or performed at 4.2 percent of visits, while cholesterol measures were taken at 4.0 percent of visits.

Also prominent among the new categories for 1991 were visits at which other radiology (that is, radiology other than chest x ray) was mentioned ( 5.5 percent), visits at which a resting EKG was ordered or provided (2.8 percent), and visits with a test for strep throat ( 2.0 percent).

## Ambulatory surgical procedures

The 1991 NAMCS included a new item concerning ambulatory surgical procedures that were scheduled or performed at the current visit. Physicians were asked to
record up to two outpatient diagnostic or therapeutic procedures, and additional data were collected on the type of anesthesia used for the first-listed procedure. Preliminary results indicate that ambulatory surgical procedures were reported at 6.2 percent of all office visits-about 44.4 million procedures scheduled or performed. More detailed data on these procedures will be reported in a forthcoming publication.

## Principal diagnosis

Item 11 of the Patient Record asks the physician to record the principal diagnosis or problem associated with the patient's most important reason for the current visit as well as any other significant current diagnoses. Up to three diagnoses are coded and classified according to the International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) (5).

Displayed in table 11 are office visits by principal diagnosis using the major disease categories specified by the ICD-9-CM. The supplementary classification, used for diagnoses that are not classifiable to injury or illness (for example, general medical examination, routine prenatal examination, and health supervision of an infant or child), accounted for 15.1 percent of all office visits. Diseases of the respiratory system (13.8 percent) and diseases of the nervous system and sense organs ( 11.6 percent) were also prominent on the list.

The 20 most frequently reported principal diagnoses for 1991 are shown in table 12. These are categorized at the three-digit coding level of the ICD-9-CM, and account for 35.2 percent of all office visits made during the year. The most common diagnosis rendered by physicians at office visits in 1991 was essential hypertension, occurring at 3.5 percent of all visits. Essential hypertension has been the most frequently reported morbidity-related diagnosis in every survey year since the NAMCS began in 1973.
(Morbidity-related diagnoses are

${ }^{1}$ Based on A Reason for Vistt Classmination for Ambulatory Care (RVC). (4).
those classifiable to illness or injury. Nonmorbidity-related diagnoses include routine prenatal examination, health supervision of an infant or child, and general medical examination, among others.)

Of the 20 diagnoses shown in table 12,17 also appeared on the list of the 20 most frequent diagnoses for 1990. New on the list for 1991 were
contact dermatitis and other eczema, general symptoms, and special investigations and examinations. The latter is a diagnosis in the supplementary classification and includes routine examinations of specific systems, for example, gynecological, vision, and hearing exams. Dropping out of the top 20 from 1990 were osteoarthrosis and
allied disorders, disorders of refraction and accommodation, and other forms of chronic ischemic heart disease.

In order to assess the significance of some of the changes in physicians' diagnoses over the years, visit rates for selected diagnoses from 1985-91 are compared in table 13. Between 1985 and 1991, increases were seen in office visit rates for chronic sinusitis and glaucoma, while decreases were noted in visit rates for disorders of refraction and accommodation and neurotic disorders. Slight decreases were also noted in visit rates for essential hypertension and normal pregnancy between 1985 and 1991. Additional years of data will help to put these apparent changes into better perspective.

## Physicians' checklist of medical conditions

In addition to the diagnostic data reported in item 11 of the Patient Record, selected information on the patient's current health status was collected in item 13, another addition to the 1991 NAMCS. Physicians were given a list of four common conditions-depression, hypertension, hypercholesterolemia, and obesity - and asked to record whether the patient now had any of them, regardless of what was recorded as the current diagnosis in item 11 of the survey form. Results from item 13 are shown in tables 14 and 15.

Nearly one-quarter (24.1 percent) of the visits were made by patients who were reported to have one or more of the four conditions listed on the survey form. Hypertension was checked most frequently, at 12.7 percent of the total-about 85.3 million visits. This figure is substantially higher than the number of visits in which a first, second, or third diagnosis of essential hypertension (ICD-9-CM code 401) was reported in item 11 of the Patient Record ( 41.9 million visits or 6.3 percent of the total), and suggests

${ }^{3}$ Incluces dlank dragnoses, uncodable diagnoses, and megible diagnoses.
the possibility that physicians tend to underreport chronic conditions in item 11.

## Therapeutic services

Data on therapeutic services ordered or provided by the physician
at the office visit (item 16 on the Patient Record) are shown in table 16. This item underwent substantial revision in the 1991 NAMCS, with an expanded list of therapeutic categories permitting greater specificity in physicians' responses.

About one-third (33.1 percent) of all office visits included some form of counseling, education, or other nonmedication therapy. Diet education or counseling was mentioned most frequently, at 11.4 percent of the total, or 76.5 million visits. Other prominent categories included exercise
( 8.2 percent), drug abuse
(3.8 percent), weight reduction (3.1 percent), and growth/ development (3.1 percent).

## Medication therapy

Data on medication therapy are shown in tables 17-21. Medication therapy was the most commonly mentioned therapeutic service in 1991 , reported at 423.7 million office visits or 63.3 percent of the total (table 17). Physicians were instructed to record all new or continued medications ordered or provided at the visit, including prescription and nonprescription preparations, and immunizing and desensitizing agents. As used in the NAMCS, the term "drug" is interchangeable with the term "medication," and the term "prescribing" is used broadly to mean ordering or providing any medication, whether prescription or over-the-counter. Visits with one or more drug mentions are termed "drug visits" in the NAMCS. As many as five medications, or drug mentions, could be coded per drug visit, resulting in a total of 804.6 million drug mentions during 1991. This yields an average of 1.2 drug mentions per office visit, or 1.9 drug mentions per drug visit.

Data on number of drug visits and drug mentions by physician specialty are shown in table 18. Internists and cardiovascular disease specialists had the highest percentage of drug visits, at 81.6 percent and 80.4 percent, respectively.

Drug mentions are displayed by therapeutic class in table 19. This classification is based on the therapeutic categories used in the National Drug Code Directory, 1985 edition (6). It should be noted that some drugs have more than one therapeutic application. In cases of

1Based on the International Classification of Diseases, Sth Fievision, Clinical Modnication (ICD-9-CM) (5).
this type, each drug was assigned to the category for which it was most frequently prescribed.
Cardiovascular-renal drugs accounted for 15.5 percent of all drug mentions, while antimicrobial agents
(14.9 percent), pain relief drugs (10.6 percent) and respiratory tract drugs ( 10.0 percent) were also prominent.

The 20 most frequently used generic substances for 1991 are shown in table 20. In this table, drug products containing more than one ingredient (combination products) are included in the data for each ingredient. For example, acetaminophen with codeine is included in both the count for acetaminophen and the count for codeine. Amoxicillin was the generic ingredient most frequently used in drugs ordered or provided by the physician at office visits in 1991 (as well as in 1990), occurring in 4.1 percent of drug mentions. Seventeen of the 20 most used generic ingredients for 1991 were also on the list of the top 20 for 1990.

The 20 medications most frequently ordered or supplied by physicians at office visits are shown by entry name of drug in table 21. Entry
name refers to the actual designation used by the physician on the Patient Record form and may be a trade name, a generic name, or simply a desired therapeutic effect. Amoxicillin was the medication most frequently prescribed by physicians, with 18.0 million mentions, or 2.2 percent of the total. It was followed by Amoxil (1.2 percent), Lasix (1.2 percent), and Ceclor (1.2 percent).

The NAMCS drug data base permits classification by a wide range of variables, including specific product name, generic class, entry form chosen by the physician (that is, brand name, generic name, or the desired therapeutic effect), prescription status (that is, whether the product is prescription or nonprescription), federally controlled substance status, composition status (that is, single- or multiple ingredient product), and therapeutic category. A report describing the method and instruments used to collect and process drug information for the NAMCS is available (7).

## Disposition of visit

About two-thirds ( 66.7 percent) of all office visits included a
scheduled follow-up visit or telephone call, while another 21.6 percent included instructions to return if needed. Less than one percent of visits resulted in a hospital admission. These percentages are not statistically different than those reported in 1990. Data on office visit disposition are displayed in table 22.

## Duration of visit

Data on the duration of office visits are presented in table 23. Duration of visit refers to the amount of time spent in face-to-face contact between the physician and the patient. This time is estimated and recorded by the physician and does not include time spent waiting to see the physician, time spent receiving care from someone other than the physician without the presence of the physician, or time spent by the physician in reviewing patient records and/or test results. In cases where the patient received care from a member of the physician's staff, but did not actually see the physician during the visit, duration was recorded as "zero" minutes.

More than two-thirds (68.3 percent) of office visits had a duration of 15 minutes or less in 1991. The mean duration time for all visits was 17.0 minutes.
Corresponding numbers for 1990 were 69.3 percent and 16.7 minutes, respectively.

Additional reports that utilize 1991 NAMCS data are forthcoming in the Advance Data from Vital and Health Statistics series. In addition, survey data will be available on computer tape from the National Technical Information Service at a nominal cost beginning about June 1993. Questions regarding this report, future reports, or the NAMCS may be directed to the Ambulatory Care Statistics Branch by calling (301) 436-7132.

## Technical notes

## Source of data and sample design

The information presented in this report is based on data collected by means of the National Ambulatory Medical Care Survey (NAMCS) from January 1991 through December 1991. The target universe of NAMCS includes office visits made in the United States by ambulatory patients to nonfederally employed physicians who are principally engaged in office practice, but not in the specialties of anesthesiology, pathology, or radiology. Telephone contacts and nonoffice visits are excluded.

A multistage probability sample design is used in NAMCS, involving samples of primary sampling units (PSU's), physician practices within PSU's, and patient visits within physician practices. The PSU's are counties, groups of counties, county equivalents (such as parishes or independent cities), or towns and townships (for some PSU's in New England). For 1991, a sample of 2,540 nonfederal, office-based physicians was selected from master files maintained by the American Medical Association and American Osteopathic Association. Of this group, 1,887 physicians were in scope, or eligible to participate in the survey. The physician response rate for the 1991 NAMCS was 72 percent. Sample physicians were asked to complete Patient Records (see figure 1) for a systematic random sample of office visits occurring during a randomly assigned 1 -week reporting period. Responding physicians completed 33,795 patient records.

Characteristics of the physician's practice, such as primary specialty and type of practice, were obtained from the physicians during an induction interview. The U.S. Bureau of the Census, Housing Surveys Branch, was responsible for the survey's data collection. Processing operations and medical coding were performed by the National Center for Health Statistics, Hospital Discharge and Ambulatory Care Survey Section,

Table I. Relative standard errors for estimated number of office visits: National Ambulatory Medical Care Survey, 1991

| Estimated number of office visits in thousands | Relative standard error in percent |
| :---: | :---: |
| 100. | 72.1 |
| 200. | 51.1 |
| 500 | 32.5 |
| 1,000. | 23.1 |
| 2,000. | 16.6 |
| 5,000. | 11.0 |
| 10,000 | 8.3 |
| 20.000 | 6.6 |
| 50000 | 5.3 |
| 100.000 | 4.8 |
| 200.000 | 4.5 |
| 500,000 | 4.3 |
| 600.000 | 4.3 |
| 700,000 | 4.3 |

NOTE: The smailest reliable estimate for visits to aggregated spectalties is 588,000 visits. Estimates below this figure have a relative standard error greater than 30 percent and are deemed unrelable by NCHS standards.
Example of use of table: An aggregate estmate of 50 million visits has a relative standard error of 5.3 percent or a standard error of $2,650,000$ visits ( 5.3 percent of 50 mullion).

Research Triangle Park, North Carolina.

## Sampling errors

The standard error is primarily a measure of the sampling variability that occurs by chance when only a sample, rather than an entire universe, is surveyed. The relative standard error of an estimate is obtained by dividing the standard error by the estimate itself; the result is then expressed as a percent of the estimate. Relative standard errors for estimated numbers of office visits in 1991 are shown in table I, relative standard errors for estimated numbers of drug mentions are presented in table II, and standard errors for estimated percents of visits are displayed in table III.

Alternatively, relative standard errors for aggregate estimates may be calculated using the following general formula, where $x$ is the aggregate of interest in thousands, and $A$ and $B$ are the appropriate coefficients from table IV.

$$
\operatorname{RSE}(x)=\sqrt{A+\frac{B}{x}} \cdot 100.0
$$

Similarly, relative standard errors for percents may be calculated using the following general formula, where $p$ is the percent of interest and $x$ is the denominator of the percent in

Table II. Relative standard errors for estimated number of drug mentions: National Ambulatory Medical Care Survey, 1991

| Estimated number of drug mentions in thousands | Relative standard error in percent |
| :---: | :---: |
| 100 | 78.1 |
| 200 | 68.8 |
| 500 | 43.7 |
| 1,000 | 31.2 |
| 2,000. | 22.4 |
| 5.000. | 14.8 |
| 10,000 | 11.2 |
| 20,000 | 8.9 |
| 50.000 | 5.8 |
| 100.000 | 6.5 |
| 200.000 | 6.1 |
| 600.000 | 5.8 |
| 800.000 | 5.8 |
| NOTE: The smallest reliable estumate for drug mentions is 1,083,000 mentions. Estumates below this figure have a relative standard error greater than 30 percent and are deemed unreliable by NCHS standards. |  |
| Example of use of table: An aggre drug mentions has a relative stan a standard error of $2,900,000$ me mullion). | estimate of 50 milion error of 5.8 percent or ( 5.8 percent of 50 |

thousands, using the appropriate coefficient from table IV.

$$
\operatorname{RSE}(p)=\sqrt{\frac{B \cdot(1-p)}{p \cdot x}} \cdot 100.0
$$

## Adjustments for nonresponse

Estimates from NAMCS data were adjusted to account for sample physicians who were in scope but did not participate in the study. This adjustment was calculated to minimize the impact of response on final estimates by imputing to nonresponding physicians data from visits to similar physicians. For this purpose, physicians were judged similar if they had the same specialty designation and practiced in the same PSU.

## Test of significance and rounding

In this report, the determination of statistical inference is based on the $t$-test. The Bonferroni inequality was used to establish the critical value for statistically significant differences ( 0.05 level of confidence). Terms relating to differences such as "greater than" or "less than" indicate that the difference is statistically significant. A lack of comment regarding the difference between any

Table III. Standard errors for percents of estimated number of office visits: National Ambulatory Medical Care Survey, 1991

| Base of percent (visits in tmousands) | Estimated percent |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1 or 99 | 50.95 | 10 or 90 | 20 or 80 | 30 or 70 | 50 |
|  | Standard error in percentage points |  |  |  |  |  |
| 100. | 7.2 | 15.7 | 21.6 | 28.8 | 33.0 | 36.0 |
| 200 | 5.1 | 11.1 | 153 | 20.4 | 23.3 | 25.5 |
| 500. | 3.2 | 7.0 | 9.7 | 12.9 | 148 | 16.1 |
| 1.000. | 23 | 5.0 | 6.8 | 9.1 | 104 | 11.4 |
| 2.000 . | 1.6 | 3.5 | 4.8 | 64 | 7.4 | 81 |
| 5.003. | 1.0 | 2.2 | 31 | 4.1 | 4.7 | 5.1 |
| 10.000 | 0.7 | 16 | 22 | 29 | 3.3 | 36 |
| 20.000 | 0.5 | 11 | 15 | 20 | 2.3 | 26 |
| 50.000 | 0.3 | 0.7 | 10 | 1.3 | 1.5 | 1.6 |
| 102.000 | 0.2 | 0.5 | 0.7 | 0.9 | 1.0 | 1.1 |
| 600.000 | 01 | 0.2 | 0.3 | 0.4 | 0.4 | 0.5 |
| 700.000 | 0.1 | 0.2 | 0.3 | 03 | 0.4 | 0.4 |

Example of use of table: An estimate of 30 percent based on an aggregate estrmate 10 millom visits has a standard error of 3.3 percent or a relat ve standard error of 11.0 percent ( 3.3 percent divided by 30 percent).

Table IV. Coefficients appropriate for determining relative standard errors by type of estimate and physician groups: National Ambulatory Medical Care Survey, 1991

| Type of estmate and physician group | Coefficient |  |
| :---: | :---: | :---: |
|  | A | $B$ |
| Vists |  |  |
| Overall totals | 0.001744284 | 51.82697927 |
| General and family practice. | 0.006617364 | 33.29640705 |
| Internal medicine | 001573396 | 45.10067385 |
| Doctors of osteopathy, pediatrics, obstetrics and gynecology, general surgery, orthopedic surgery, cardiovascular diseases, psychiatry, urological surgery. dermatology, neurology, ophthalmology, |  |  |
| otolaryngology . . . . . . . . . . . . . . . . . . . . . . . | 0.0163602 | 10.90230286 |
| All other . . . . . . . . . . | 0.03340709 | 29.631108 |
| Drug mentions |  |  |
| Overall totals | 0.003224617 | 93.92631687 |
| General and farnly practice, internal medicine. | 0.0122584 | 57.64543271 |
| Doctors of osteopathy, general surgery, orthopedic surgery, cardiovascular diseases, urological surgery, dermatology, neurology. ophthalmology, otolaryngology, obstetrics and gynecology, pediatrics, |  |  |
| psychiatry . . . . . . . . | 0.02784109 | 11.55212504 |
| All other. . | 0.0483582 | 46.33697419 |

two estimates does not mean that the difference was tested and found to be not significant.

In the tables, estimates of office visits have been rounded to the nearest thousand. Consequently, estimates will not always add to totals. Rates and percents were calculated from original unrounded figures and do not necessarily agree with percents calculated from rounded data.

## Definition of terms

Ambulator' patient - An
ambulatory patient is an individual
seeking personal health services who is not currently admitted to any health care institution on the premises.

Physician-A physician is a duly licensed doctor of medicine (MD) or doctor of osteopathy (DO) who is currently in office-based practice and who spends some time caring for ambulatory patients. Excluded from the NAMCS are physicians who are hospital based; who specialize in anesthesiology, pathology, or radiology; who are federally employed; who treat only institutionalized patients; or who are
employed full time by an institution and spend no time seeing ambulatory patients.

Office-An office is the space that physicians identify as a location for their ambulatory practice. Offices customarily include consultation, examination, or treatment spaces that patients associate with the particular physician.

Visit-A visit is a direct personal exchange between an ambulatory patient and a physician (or a staff member working under the physician's supervision) for the purpose of seeking care and rendering personal health services.

Drug mention - A drug mention is the physician's entry of a pharmaceutical agent-by any route of administration - for prevention, diagnosis, or treatment. Generic as well as brand-name drugs are included, as are nonprescription and prescription drugs. Along with all new drugs, the physician also records continued medications if the patient was specifically instructed during the visit to continue the medication.

Drug visit-A drug visit is a visit in which medication is prescribed or provided by the physician.

## Trade name disclaimer

The use of trade names is for identification only and does not imply endorsement by the Public Health Service, U.S. Department of Health and Human Services.

# Vital and Health Statistics series descriptions 

SERIES 1. Programs and Collection Procedures-These reports describe the data collection programs of the National Center for Health Statistics. They include descriptions of the methods used to collect and process the data, definitions, and other material necessary for understanding the data.
SERIES 2. Data Evaluation and Methods Research-These reports are studies of new statistical methods and include analytical techniques, objective evaluations of reliability of collected data, and contributions to statistical theory. These studies also include experimental tests of new survey methods and comparisons of U.S. methodology with those of other countries.

SERIES 3. Analytical and Epidemiological Studies-These reports present analytical or interpretive studies based on vital and health statistics. These reports carry the analyses further than the expository types of reports in the other series.

SERIES 4. Documents and Committee Reports-These are final reports of major committees concerned with vital and health statistics and documents such as recommended model vital registration laws and revised birth and death certificates.
SERIES 5. International Vital and Health Statistics Reports-These reports are analytical or descriptive reports that compare U.S. vital and health statistics with those of other countries or present other international data of relevance to the health statistics system of the United States.

SERIES 6. Cognition and Survey Measurement-These reports are from the National Laboratory for Collaborative Research in Cognition and Survey Measurement. They use methods of cognitive science to design, evaluate, and test survey instruments.

SERIES 10. Data From the National Health Interview Survey-These reports contain statistics on illness; unintentional injuries; disability; use of hospital, medical, and other health services; and a wide range of special current health topics covering many aspects of health behaviors, health status, and health care utilization. They are based on data collected in a continuing national household interview survey.

SERIES 11. Data From the National Health Examination Survey, the National Health and Nutrition Examination Surveys, and the Hispanic Health and Nutrition Examination SurveyData from direct examination, testing, and measurement on representative samples of the civilian noninstitutionalized population provide the basis for (1) medically defined total prevalence of specific diseases or conditions in the United States and the distributions of the population with respect to physical, physiological, and psychological characteristics, and (2) analyses of trends and relationships among various measurements and between survey periods.
SERIES 12. Data From the Institutionalized Population SurveysDiscontinued in 1975. Reports from these surveys are included in Series 13.
SERIES 13. Data From the National Health Care Survey-These reports contain statistics on health resources and the public's use of health care resources including ambulatory, hospital, and long-term care services based on data collected directly from health care providers and provider records.

SERIES 14. Data on Health Resources: Manpower and FacilitiesDiscontinued in 1990. Reports on the numbers, geographic distribution, and characteristics of health resources are now included in Series 13.
SERIES 15. Data From Special Surveys-These reports contain statistics on health and health-related topics collected in special surveys that are not part of the continuing data systems of the National Center for Health Statistics.
SERIES 16. Compilations of Advance Data From Vital and Health Statistics-Advance Data Reports provide early release of information from the National Center for Health Statistics' health and demographic surveys. They are compiled in the order in which they are published. Some of these releases may be followed by detailed reports in Series 10-13.
SERIES 20. Data on Mortality-These reports contain statistics on mortality that are not included in regular, annual, or monthly reports. Special analyses by cause of death, age, other demographic variables, and geographic and trend analyses are included.

SERIES 21. Data on Natality, Marriage, and Divorce-These reports contain statistics on natality, marriage, and divorce that are not included in regular, annual, or monthly reports. Special analyses by health and demographic variables and geographic and trend analyses are included.
SERIES 22. Data From the National Mortality and Natality SurveysDiscontinued in 1975. Reports from these sample surveys, based on vital records, are now published in Series 20 or 21.
SERIES 23. Data From the National Survey of Family GrowthThese reports contain statistics on factors that affect birth rates, including contraception, infertility, cohabitation, marriage, divorce, and remarriage; adoption; use of medical care for family planning and infertility; and related maternal and infant health topics. These statistics are based on national surveys of childbearing age.

SERIES 24. Compilations of Data on Natality, Mortality, Marriage, Divorce, and Induced Terminations of PregnancyThese include advance reports of births, deaths, marriages, and divorces based on final data from the National Vital Statistics System that were published as supplements to the Monthly Vital Statistics Report (MVSR). These reports provide highlights and summaries of detailed data subsequently published in Vital Statistics of the United States. Other supplements to the MVSR published here provide selected findings based on final data from the National Vital Statistics System and may be followed by detailed reports in Series 20 or 21.

[^6]:    Includes other and unknown smoking status.

[^7]:    "Based on "A Reason for Visit Classification for Ambulatory Care" (RVC) (2).

[^8]:    'Based on international Classffication of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) (3).

[^9]:    ${ }^{1}$ Therapeutic class based on the standard drug classification used in the National Drug Code Directory, 1985 Edition (4).
    ${ }^{2}$ Includes: Anesthetic drugs, hematologic agents, metabolic and nutrient agents, and neurologic drugs.

[^10]:    NOTE: Otolaryngologist 30 percent RSE $=155,000$ : all speciatties 30 percent RSE $=922,000$.
    Example of use of table: An aggregate estumate of 2 mullion drug mentions by an otolaryngologist has a relative standard estimate of 14.7 percent or a standard error of 294 thousand drug mentions ( 14.7 percent of 2 million).

[^11]:    ${ }^{2}$ This report focuses primarily on visits made to obstetricians and gynccologists by females (an average of $59,475,000$ visits per year for 1989 and 1990). The estimated number of visits by males (an average of 337,000 per year for 1989 and 1990) is too small to be statistically reliable and thus docs not permit meaningful analysis. A gencral discussion of visits made by males to what is cssentially a specialty dealing with women's reproductive health issues can be found in an earlier publication (2).

[^12]:    IVisit rates are based on U.S. Bureau of the Census estimates of the civilan, noninstitutionalized populaton of the United States for July 1 of 1989 and 1990, averaged over the 2 -year period.
    ${ }^{2}$ Rate based on female visits and female populatıon. Females made 99.4 percent of all visits to this specialty durmg 1989-90, for an average annual estumate of $59,475,000$ visits.
