## Mortality Surveillance System: Models From the First Year

Series 20: Data From the National Vital Statistics System<br>No. 21

This report describes the Mortality Surveillance System and presents the statistical charts and text from its first year, as published in the 12 issues of the Monthly Vital Statistics Report, Vol. 38, No. 2 -Vol. 39, No. 1.

# Mortality Surveillance System: Models From the First Year 

by Frances M. Chevarley, Ph.D., A. Elizabeth
Godfrey, M.S., Harry M. Rosenberg, Ph.D., Kenneth D. Kochanek, M.A., Division of Vital
Statistics, Manning Feinleib, M.D., Dr.P.H., National
Center for Health Statistics

## Introduction

This report presents the statistical charts and text from the first year of the Mortality Surveillance System (MSS), as published in 12 issues of the Monthly Vital Statistics Report (MVSR) (Vol. 38, No. 2-Vol. 39, No. 1), and briefly describes the methodology that was used. Also presented are the monthly data used in fitting the models depicted in the published charts and the model statistics for the fitted curves.

According to the Dictionary of Epidemiology edited by John Last (1) surveillance is "Ongoing scrutiny, generally using methods distinguished by their practicability, uniformity, and frequently their rapidity, rather than by complete accuracy. Its main purpose is to detect changes in trend or distribution in order to initiate investigative or control measures." Conceptually, then, the purpose of the MSS is to detect changes in trend or distribution in order to initiate further investigative and control measures in a practical and timely manner.

The National Center for Health Statistics (NCHS) has a data set that, because of its timeliness, can lend itself to surveillance - the provisional mortality data from the Current Mortality Sample (CMS). These data are published

[^0]every month in the $M V S R$, about 4 months after the main month of occurrence of the deaths and continue to be one of the most accessible means of identifying and monitoring health problems. NCHS decided to use the CMS as the data source for the MSS and to apply a traditional time series regression model to the observed monthly CMS data as the methodology. This methodology had been widely and successfully used to describe trends in mortality data and for surveillance including Serfling (2), Collins (3), Choi and Thacker (4), Lui and Kendal (5), and Shumway (6). In the United States other surveillance systems have been applied to mortality, the best known of which is the statistical system of the Centers for Disease Control and Prevention for tracking influenza and pneumonia and all causes of death by age and month (7). In Great Britain a surveillance system uses final rather than provisional mortality data ( 8 ). The MSS was inaugurated with the February 1989 issue of the $M V S R$ (Vol. 38, No. 2).

The MSS consists of a series of charts and text published each month in the $M V S R$, depicting trends in provisional mortality data for selected causes of death and population groups. Emphasis is given to graphic presentation that permits timely identification of departures from mortality trends observed in the recent past. Shown in the MSS charts are observed data with corresponding predicted values and 95 -percent prediction intervals. Similar graphic presentation techniques have been widely used in the past (9).

Topics for the first year of the MSS were selected in consultation with other Public Health Service agencies to shed light on emerging health concerns and foresee possible changes in trend.

## Methods

## Sources of data

The MSS charts are based entirely on monthly provisional data from the Current Mortality Sample (CMS). The CMS is a national 10 -percent systematic sample of death certificates drawn each month after the certificates are counted in the State registration offices. The sample for each of these areas consists of one-tenth of the death certificates received in the office between a given date and the corresponding date of the following month. All death certificates received during the 1 -month period are sampled regardless of the month or year in which the death occurred. As a result, the sample for a given month is not strictly comparable to a sample based on month-ofoccurrence. About two-thirds of the death certificates for a given month are for deaths that actually occurred in the sample month. Because complete information concerning the underlying cause of death is sometimes not available in the State offices when the sample is drawn but is available later when copies of the final death certificates are processed, cause-of-death estimates from the CMS for certain causes are biased estimates of final data. These variations inherent in provisional data from the CMS are not corrected in the MSS. Estimates of deaths and death rates based on the CMS by age, race, sex, and cause are proportionately adjusted to be consistent with estimates based on provisional monthly U.S. totals based on counts of death certificates received in State registration offices $(10,11)$.

## Statistical model

While different types of models were analyzed to determine the type of model to use for the MSS, a time series regression model was selected because similar models had been used successfully in the past for surveillance and because such a model is easy to use and interpret. The following time series regression model with five terms is used:
$Y(t)=A_{0}+A_{1} t+A_{2} t^{2}+C \cos (2 \pi t / 12)$ $+S \sin (2 \pi t / 12)+\epsilon_{t}$
where

$$
\begin{aligned}
Y(t) & =\text { monthly death rate at time } t \\
t & =\text { month number }(t=0 \text { for Jan. 1979) }
\end{aligned}
$$

$$
\begin{aligned}
A_{0}= & \text { coefficient, which, together with } C \text { determines } \\
& \text { the } Y \text {-intercept } \\
A_{1}= & \text { coefficient of } t \\
A_{2}= & \text { coefficient of } t^{2} \\
C, S= & \text { coefficients of the harmonic terms } \\
\epsilon_{t}= & \text { error terms, assumed to be independent and } \\
& \text { normally distributed with means } 0 \text { and con- } \\
& \text { stant variances, }
\end{aligned}
$$

and $\cos (2 \pi t / 12)$ and $\sin (2 \pi t / 12)$ are 12 -month period harmonic functions.

The general form of the statistical model with five terms, as shown, contains an intercept term, a trend term $t$, a quadratic term $t^{2}$, a cosine term, and a sine term (the 2 latter terms are 12 -month harmonic terms designed to capture the main characteristics of seasonal patterns of mortality). Monthly death rates for most causes of death exhibit a 12 -month seasonal pattern with generally higher rates in the winter when health can be compromised by cold weather.

The coefficients of the model for the 72 charts were estimated using provisional monthly death rates for January 1979-December 1987. The graph of the estimated equations and 95 -percent prediction intervals for the monthly rates were shown through 1987 and projected beyond that. This projection period increased as more data became available and as a result varied from month to month. The symbols in each chart represent actual monthly death rates based on the CMS.

Using the model for 72 different charts in the first year of the MSS has been both an exploratory and a learning process. Over time, and with increasing experience with the models, the criteria to decide which of the five terms to keep in the model became more consistent. By the end of the year, the principle that guided model selection was to include all five terms except in extreme cases. These cases include the following: (a) where there was no clear 12 -month seasonal component in the data, the model was fitted without the harmonic terms; and (b) where the usual model yielded negative prediction intervals, the data were transformed by the natural logarithm before fitting the model. In the latter case, for graphical purposes, the data were transformed back to rates by the inverse of the natural logarithm.

## Results

## Summary

During the first year of the MSS, only three age-sexcause groups were identified out of the total of 72 charts where there may have been a change in trend in the most recent time period since 1987: Cerebrovascular diseases for males aged 65-74 years, Septicemia for females aged 75-84 years, and Diabetes mellitus for females aged 65-74 years. Based on the MSS findings, a further investigation of the recent trends for these age-sex-cause groups may be warranted. For the remaining charts there was not enough evidence to suggest a change in trend.

The 72 charts and accompanying text that were published in the 12 successive $M V S R$ issues are shown in figures 1-72. Shown in tables 1-12 are provisional monthly estimates of numbers of deaths and death rates for 1979-89 for each of the specified causes of death and selected demographic groups for the 72 charts. Estimated deaths and death rates in tables 1-12 based on 100 or fewer estimated deaths have relative standard errors of 30 percent or more and are, therefore, considered unreliable. Rates based on 100 or fewer estimated deaths are indicated by an "*" in these tables. The model parameter estimates and selected statistics for each of these 72 charts are given in table 13.

## Example

The following example illustrates the type of data summarized in this report. For the first month of the MSS there were six charts representing All causes of death for females and males for the following three age groups: $45-54$ years, $55-64$ years, and 65-74 years. The charts and text as previously published for these six charts are shown in figures 1-6. The center line in each of these charts denotes the predicted model based on provisional monthly death rates for the period January 1979-December 1987, and then projected for the most recent period for these charts through September 1988. The two outside lines are the 95 -percent prediction intervals; the symbols represent the observed monthly provisional death rates. As shown in these charts and as discussed in the text, monthly provisional death rates for All causes decreased during the period 1979-87 for males in each of the three age groups. For females the trend in the monthly provisional death rates for All causes during this same period was also downward but only for women in the youngest age group,
$45-54$ years; for women in the other two age groups, 55-64 years and 65-74 years, there was no discernible upward or downward trend during this period. Except for 1 month in one of these charts, the observed monthly rates in the projected first 9 months of 1988 for these six charts were within the 95 -percent prediction intervals of the models estimated on the basis of provisional monthly death rates for 1979-87. Also shown in these charts, death rates for All causes for males and females in each of these three age groups showed a seasonal pattern with provisional monthly death rates generally higher during the winter.

Shown in table 1 are the provisional monthly estimates of deaths and death rates for these six charts; that is, for All causes for 1979-89 for females and males aged 45-54, 55-64, and $65-74$ years. These monthly rates were used in producing the published charts and their associated model statistics in table 13. As shown in table 13, the average monthly sample sizes for the first six MSS charts ranged from 378 for All causes for women aged $45-54$ years to 2,315 for All causes for men aged 65-74 years. As indicated by the estimated coefficients of the model parameters and their corresponding probabilities in table 13 , the first 6 MSS charts used the 4 variable model. The adjusted $R^{2}$ values for these first six models for All causes ranged from 0.4347 for women aged $45-54$ years to 0.7377 for men aged 65-74 years, were higher for males than for females, and increased for each succeeding older age group (as the average monthly sample size increased) for both males and females.

## Discussion

As indicated in the charts and also in the statistics in table 13 , the 5 -term model was a good general model for modeling mortality data for most age-sex-cause groups. The entire 5 -term model was used for 50 of the 72 charts. For 19 of the 72 charts, the 2 harmonic terms were dropped because the monthly rates for these age-sexcause groups did not exhibit 12 -month seasonal patterns. Among these 19 charts, 16 represented specified cancers for selected demographic groups, 2 were for Suicide for females aged $15-24$ and $25-34$ years, and 1 was for Homicide for females aged $25-34$ years. The model included only the $Y$-intercept for 4 of the 72 charts where the 5 -term model did not apply. These cases were Malignant neoplasms of genital organs for males aged 55-64 years and 65-74 years, Malignant neoplasms of genital
organs for females aged 65-74 years, and Homicide and legal intervention for females aged $25-34$ years.

Although the objective was to apply the 5 -term model to the actual monthly death rates whenever possible, it was necessary to transform the data by the natural logarithm for 7 of the 72 charts in order to avoid negative prediction intervals for the model. The data were transferred back by the inverse of the natural logarithm in the published charts. As indicated in table 13, the statistics for these 7 charts are based on a model that used data transformed by the natural logarithm.

Also shown in table 13, the adjusted $R^{2}$ statistic was generally higher for those age-sex-cause groups with larger sample sizes. The adjusted $R^{2}$ statistics were negative
(indicating a particularly poor fit of the chosen model) for 2 of the 72 models of the first year: Suicide for females aged 15-24 years and Malignant neoplasms of digestive organs and peritoneum for females aged $55-64$ years.

Since the first year of the MSS, the MSS topics have been re-evaluated and expanded. Thus, for the second year, the topics were expanded to include the cause Human immunodeficiency virus infection, infant mortality rates by age, and selected causes of infant death. For the third year, added to the topics were age-sex-cause groups for the racial groups white and black. Although the same MSS model has been selected for the second and third years of the MSS, alternative models and modeling criteria merit study.

## Mortality Surveillance System

Figure 1. Death rates per 100,000 females $45-54$ years of age by month: United States, 1981-88

For the period shown in the chart through 1987, there has been a slight decline in provisional death rates for females aged 45-54 years for All causes of death combined. The observed rates for the first 9 months of 1988 were consistent with the rates predicted by a model estimated on the basis of provisional monthly death rates from 1979 to 1987. Death rates for these women showed a seasonal pattern of mortality with a tendency for rates to be higher during the winter months. Based on provisional annual death rates for 1987, the rate for females in this age group was slightly more than half the rate for males.

There was a general decline in provisional death rates for men aged 45-54 years for the period shown in the chart. For these men, death rates from January to September of 1988 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates from 1979 to 1987. However, the rates for February to September of 1988 were consistently above the line predicted by the model. Monthly death rates for males in this age group also showed a seasonal pattern with a tendency toward higher death rates during the winter months. According to provisional annual death rates, the rate in 1987 for males aged $45-54$ years was not quite twice the rate for women in this age group.

Figure 3. Death rates per 100,000 females 55-64 years of age by month: United States, 1981-88

Figure 4. Death rates per 100,000 males $55-64$ years of age by month: United States, 1981-88

There was no overall trend upward or downward in death rates for All causes for females $55-64$ years of age during the period shown in the chart through 1987. Rates for the first 9 months of 1988 were consistent with those predicted by a model estimated on the basis of provisional monthly death rates from 1979 to 1987. The death rates for these women were generally higher in the winter months compared with the summer months. According to provisional annual death rates for 1987, the rate for females aged $55-64$ years was slightly more than half the rate for males in the same age group but about two and a half times the rate for females in the younger age group 45-54 years.

The overall trend of death rates for males aged 55-64 years for All causes combined was downward during the period shown in the chart. Rates for January-September 1988 were consistent with those predicted by a model estimated on the basis of provisional monthly death rates from 1979 to 1987. Death rates for men aged 55-64 years also showed a seasonal pattern of mortality. In 1987 the provisional annual death rate for males was not quite twice the rate for females in the same age group and about two and a half times the rate for males in the younger age group 45-54.years.

Figure 5. Death rates per 100,000 females $65-74$ years of age by month: United States, 1981-88

Figure 6. Death rates per 100,000 males 65-74 years of age by month: United States, 1981-88

During the period shown in the chart, there was no overall trend upward or downward in death rates for All causes for females aged 65-74 years. Monthly death rates for JanuarySeptember 1988 were consistent with those predicted by a model estimated on the basis of provisional monthly death rates from 1979 to 1987. Death rates for these women aged 65-74 years showed a seasonal pattern with a tendency toward higher rates in the winter and lower rates in the summer. The annual death rate for 1987 was slightly more than half the rate for males in the same age group and more than twice the rate for females in the younger age group 55-64 years.

For males aged 65-74 years, the overall trend in death rates for All causes was downward during the period shown in the chart. The monthly death rates for the first nine months of 1988 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. The rates for March to September 1988, however, were consistently above the line predicted by the model. As shown in the chart, men in the age group 65-74 had a seasonal pattern of mortality with a clear tendency for rates to be higher during the winter months. In 1987 the provisional annual death rate for men aged 65-74 years was not quite twice the rate for women in the same age group. This ratio of male to female death rates for this age group was about the same as that observed for the age groups 45-54 years and 55-64 years.

Figure 7. Death rates per 100,000 females 35-44 years of age for Malignant neoplasms of respiratory and intrathoracic organs, by month: United States, 1981-88

Figure 8. Death rates per $\mathbf{1 0 0 , 0 0 0}$ males $\mathbf{3 5 - 4 4}$ years of age for Malignant neoplasms of respiratory and intrathoracic organs, by month: United States, 1981-88

For the period shown in the chart through 1987, there has been a slight downward trend in provisional death rates for females 35-44 years of age for Malignant neoplasms of respiratory and intrathoracic organs. The observed rates for the first 9 months of 1988 were consistent with the rates predicted by a model estimated on the basis of 5 provisional monthly death rates from 1979-87. Based on provisional annual death rates for 1987, the rate for fe0 males in this age group was slightly more than half the rate for males.

There was a decline in provisional death rates for Malignant neoplasms of respiratory and intrathoracic organs for men 35-44 years of age for the period shown in the chatt through 1987. For these men, death rates from JanuarySeptember of 1988 were consistent with a model estimated on the basis of provisional monthly death rates from 1979-87. According to provisional annual death rates, the rate in 1987 for men 35-44 years of age was nearly
0 twice the rate for women in this age group.

Figure 9. Death rates per $\mathbf{1 0 0 , 0 0 0}$ females $\mathbf{4 5 - 5 4}$ years of age for Malignant neoplasms of respiratory and intrathoracic organs, by month: United States, 1981-88

Figure 10. Death rates per $\mathbf{1 0 0 , 0 0 0}$ males $\mathbf{4 5 - 5 4}$ years of age for Malignant neoplasms of respiratory and intrathoracic organs, by month: United States, 1981-88

There has been a slight upward trend in death rates for Malignant neoplasms of respiratory and intrathoracic organs for females 45-54 years of age during the period shown in the chart through 1987. The monthly death rates for the first 9 months of 1988 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates from 1979-87. However, the rates for all but one of the first 9 months were below the line predicted by the model. According to provisional annual death rates for 1987, the rate for females 45-54 years of age was slightly more than half the rate for males in the same age group and more than 6 times the rate for females in the younger age group 35-44 years.

The trend of death rates for males 45-54 years of age for Malignant neoplasms of respiratory and intrathoracic organs was downward during the period shown in the chart. For these men, except for 1 month, death rates from January-September of 1988 all fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates from 1979-87; however, all but one of the monthly rates during this period were above the line predicted by the model. In 1987 the provisional annual death rate for these males was almost twice the rate for females in the same age group and more than 6 times the rate for males in the younger age group 35-44 years.

Figure 11. Death rates per 100,000 females 55-64 years of age for Malignant neoplasms of respiratory and intrathoracic organs, by month: United States, 1981-88

Figure 12. Death rates per 100,000 males $55-64$ years of age for Malignant neoplasms of respiratory and intrathoracic organs, by month: United States, 1981-88

The trend of death rates for females 55-64 years of age for Malignant neoplasms of respiratory and intrathoracic organs was upward for the period shown in the chart through 1987. Monthly death rates for January-September 1988 were consistent with those predicted by a model estimated on the basis of provisional monthly death rates from 1979-87. The annual death rate for 1987 was less than half the rate for males in the same age group; this ratio of female to male death rates for this age group, however, has been increasing. The 1987 provisional death rate for females 55-64 years of age was 3 times the rate for females in the younger age group 45-54 years.

For males 55-64 years of age, there was no discernable trend upward or downward in death rates for Malignant neoplasms of respiratory and intrathoracic organs during the period shown in the chart. The monthly death rates for the first 9 months of 1988 were consistent with those predicted from a model estimated on the basis of provisional monthly death rates for 1979-87. In 1987 the provisional annual death rate for men 55-64 years of age was more than twice the rate for women in the same age group. This ratio of male to female death rates for this age group was higher than that observed for the age groups $35-44$ years and 45-54 years.

Figure 13. Death rates per 100,000 females 45-54 years of age for Chronic obstructive pulmonary diseases and allied conditions, by month: United States, 1981-88
[Data transformed by the natural logarithm before fitting model]

For the period shown in the chart through 1987, there has been a slight upward trend in provisional death rates for females 45-54 years of age for Chronic obstructive pulmonary diseases and allied conditions. The observed rates for the first 9 months of 1988 were consistent with the rates predicted by a model estimated on the basis of provisional monthly death rates from 1979-87. Death rates for these women showed a seasonal pattern of mortality with a tendency for rates to be higher during the early months of the year. Based on provisional annual death rates for 1987, the rate for females in this age group was about the same as the rate for males.

There was a slight decline in provisional death rates for Chronic obstructive pulmonary diseases and allied conditions for men 45-54 years of age for the period shown in the chart through 1987. For these men, monthly death rates from January-September of 1988 were consistent with a model estimated on the basis of provisional monthly death rates from 1979-87. According to provisional annual death rates, the rate in 1979 for males 45-54 years of age was about 1.5 times the rate for women in this age group. Because the death rates for this age group for Chronic obstructive pulmonary diseases and allied conditions have decreased slightly for males and increased slightly for females from 1979-87, the death rates for males and females were closer in 1987 than they were in 1979.

Figure 15. Death rates per 100,000 females 55-64 years of age for Chronic obstructive pulmonary diseases and allied conditions, by month: United States, 1981-88

There has been an upward trend in death rates for Chronic obstructive pulmonary diseases and allied conditions for females 55-64 years of age during the period shown in the chart through 1987. The monthly death rates for the first 9 months of 1988 were consistent with the rates predicted by a model estimated on the basis of provisional monthly death rates from 1979-87. Death rates for these women aged 55-64 years showed a seasonal pattern with a tendency toward higher rates in the early months of the year. According to provisional annual death rates for 1987, the rate for females 55-64 years of age was about two thirds the rate for males in the same age group and almost 5 times the rate for females in the younger age group 45-54 years.

There has been no discernable trend upward or downward in provisional death rates for males 55-64 years of age for Chronic obstructive pulmonary diseases and allied conditions for the period shown in the chart through 1987. For these men, except for one month, the monthly death rates from January-September 1988 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates from 1979-87; however, the monthly death rates for the first 9 months of 1988 were all above the line predicted by the model. As shown in the chart, men in the age group 55-64 years had a seasonal pattern of mortality similar to that shown for females in this age group. In 1987 the provisional annual death rate for these males was about 1.5 times the rate for females in the same age group. This ratio decreased from 1979; in 1979 the rate for males was over twice the rate for females in this age group.

Figure 17. Death rates per 100,000 females 65-74 years of age for Chronic obstructive pulmonary diseases and allied conditions, by month: United States, 1981-88

Figure 18. Death rates per 100,000 males 65-74 years of age for Chronic obstructive pulmonary diseases and allied conditions, by month: United States, 1981-88

The overall trend of death rates for females 65-74 years of age for Chronic obstructive pulmonary diseases and allied conditions was upward for the period shown in the chart through 1987. Monthly death rates for January-September 1988 were consistent with those predicted by a model estimated on the basis of provisional monthly death rates from 1979-87. The death rates for these women were also generally higher in the early months of the year. The annual death rate for females in 1987 was about half the rate for males in the same age group; this ratio of female to male death rates for this age group, however, has been increasing. The 1987 provisional death rate for females 65-74 years of age was 2.7 times the rate for females in the age group 55-64 years.

For males 65-74 years of age, there was no discernable trend upward or downward in death rates for Chronic obstructive pulmonary diseases and allied conditions during the period shown in the chart. The monthly death rates for the first 9 months of 1988 were all within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87; however, these monthly rates for 1988 were all above the line predicted by this model. Death rates for men 65-74 years of age also showed a seasonal pattern of mortality. In 1987 the provisional annual death rate for men 65-74 years of age was almost twice the rate for women in the same age group. This ratio of male to female death rates for this age group was higher than that observed for the age groups 45-54 years and 55-64 years.

Figure 19. Death rates per 100,000 females 15-24 years of age for Accidents and adverse effects, by month: United States, 1982-89

Figure 20. Death rates per 100,000 males 15-24 years of age for Accidents and adverse effects, by month: United States, 1982-89

Accidents and adverse effects is the leading cause of death for females 15-24 years of age. It accounted for 45 percent of all deaths to females in this age group in 1986, the latest year for which final data are available. For these women, provisional death rates from Accidents and adverse effects decreased slightly from 1979 to the early 1980's and, as shown in the chart, have increased slightly since then. The observed rates for 1988 and the first 2 months of 1989 were consistent with the rates predicted by a model estimated on the basis of provisional monthly death rates for 1979-87. Death rates for these women showed a seasonal pattern of mortality with a tendency for rates to be higher during the summer. Based on provisional annual death rates for 1988, the death rate for this cause for females was about one third the rate for males.

Accidents and adverse effects is also the leading cause of death for males 15-24 years of age. In 1986 it accounted for 52 percent of all deaths to men in this age group. For these men, provisional death rates for this cause have declined from 1979 to the mid-1980's and have leveled off since then. Monthly death rates for January 1988-February 1989 were consistent with a model estimated on the basis of provisional monthly death rates for 1979-87. The monthly rates for this cause also showed a seasonal pattern with a tendency toward higher death rates during the summer. According to provisional annual death rates, the rate in 1988 for males $15-24$ years of age was almost 3 times the rate for women in this age group.

Figure 21. Death rates per 100,000 females 15-24 years of age for Homicide and legal intervention, by month: United States, 1982-89
[Data transformed by the natural logarithm before fitting model]

Figure 22. Death rates per 100,000 males 15-24 years of age for Homicide and legal intervention, by month: United States, 1982-89

About 12 percent of all deaths to females $15-24$ years of age were due to Homicide and legal intervention in 1986, the latest year for which final data are available; this was the second leading cause of death in 1986. For these women, there has been no discernible trend upward or downward in the provisional death rates for Homicide and legal intervention for the period shown in the chart through 1987. The monthly death rates for 1988 and for the first 2 months of 1989 were consistent with the rates predicted by a model estimated on the basis of provisional monthly death rates for 1979-87. According to provisional annual death rates for 1988, the death rate for Homicide and legal intervention for females $15-24$ years of age was about one fourth the rate for males in the same age group.

According to 1986 final data, Homicide and legal intervention was the second leading cause of death among males 15-24 years of age. In that year it accounted for approximately 15 percent of all deaths for these males. Death rates for males 15-24 years of age for Homicide and legal intervention decreased from 1979 to the mid-1980's and, as shown in the chart, have increased since then. For these men, the monthly death rates for January 1988-February 1989 were consistent with the rates predicted by a model estimated on the basis of provisional monthly death rates for 1979-87. As shown in the chart, men in the age group 15-24 years had a seasonal pattern of mortality for this cause with a tendency for rates to be higher during the summer. In 1988 the provisional annual death rate for this cause for these males was about 4 times the rate for females in the same age group.

Figure 23. Death rates per 100,000 females 15-24 years of age for Suicide, by month: United States, 1982-89
[Data transformed by the natural logarithm before fitting model]

According to final data for 1986, Suicide was the third leading cause of death for females 15-24 years of age. In that year Suicide accounted for approximately 8 percent of all deaths for these females; in comparison, Homicide and legal intervention accounted for approximately 12 percent of the 1986 deaths in this age-sex group. For females $15-24$ years of age, there has been no discernible trend upward or downward in the provisional death rates for Suicide during the period shown in the chart. The monthly death rates for 1988 and the first 2 months of 1989 were all within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. The annual provisional death rate for Suicide for females in 1988 was about one fifth the rate for males in this age group.

Suicide was also the third leading cause of death for males 15-24 years of age according to 1986 final data. About 14 percent of all deaths for males 15-24 years of age were due to Suicide; this percent for Suicide was similar to the corresponding 15 percent for Homicide and legal intervention. For males 15-24 years of age there was no discernible trend in the Suicide death rate during the period shown in the chart. The monthly death rates for 1988 and the first 2 months of 1989 were all within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. Although the fitted model suggests that death rates for Suicide for males 15-24 years of age have a smooth seasonal pattern with a single peak in the first quarter of the year, the observed death rates show a more irregular seasonal pattern. In 1988 the provisional annual death rate for this cause for men 15-24 years of age was about five times the rate for women in the same age group.

Figure 25. Death rates per 100,000 females 55-64 years of age for Accidents and adverse effects, by month: United States, 1982-89

Figure 26. Death rates per 100,000 males 55-64 years of age for Accidents and adverse effects, by month: United States, 1982-89

There were 2,380 deaths due to Accidents and adverse effects for women 55-64 years of age in 1986, the latest year for which final data are available. These deaths accounted for 2 percent of all deaths for these women in 1986. Of the 2,380 deaths, 1,160 , or almost half, were due to Motor vehicle accidents. For these women, provisional death rates from Accidents and adverse effects decreased slightly from 1979 to the mid 1980's and, as shown in the chart, have increased slightly since then. The observed rates for 1988 and the first 2 months of 1989 were consistent with the rates predicted by a model estimated on the basis of provisional monthly death rates for 1979-87. Based on provisional annual death rates for 1988, the death rate for this cause for females was about one half the rate for males.

Accidents and adverse effects accounted for 5,348 deaths, or 3 percent of all deaths for men 55-64 years of age, according to final data for 1986. Of these 5,348 deaths, 2,197 ( 41 percent) were due to Motor vehicle accidents. For the period shown in the chart, provisional death rates for Accidents and adverse effects have declined. Monthly death rates for January 1988-February 1989 were consistent with a model estimated on the basis of provisional monthly death rates for 1979-87. According to provisional annual death rates in 1988, the rate for males 55-64 years of age was about double the rate for women in this age group.

Figure 27. Death rates per 100,000 females 55-64 years of age for Chronic liver disease and cirrhosis, by month: United States, 1982-89

Figure 28. Death rates per 100,000 males 55-64 years of age for Chronic liver disease and cirrhosis, by month: United States, 1982-89

In 1986, the latest year for which final data are available, there were 2,441 deaths due to Chronic liver disease and cirrhosis for females 55-64 years of age. These deaths accounted for 2 percent of all deaths to these women in 1986. The overall trend of death rates for Chronic liver disease and cirrhosis for these women was slightly downward for the period shown in the chart through 1987. The monthly death rates for 1988 and for the first 2 months of 1989 were consistent with the rates predicted by a model estimated on the basis of provisional monthly death rates for 1979-87. According to provisional annual death rates for 1988, the death rate for Chronic liver disease and cirrhosis for females 55-64 years of age was about one half the rate for males in the same age group.

According to 1986 final data, Chronic liver disease and cirrhosis accounted for 4,722 deaths or 3 percent of all deaths for males 55-64 years of age. For the period shown in the chart through 1987, there was a decline in provisional death rates for Chronic liver disease and cirrhosis for males 55-64 years of age. The monthly death rates for January 1988-February 1989 for these men fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. In 1988 the provisional annual death rate for these men was about 2 times the rate for women in the same age group.

Figure 29. Death rates per 100,000 females $55-64$ years of age for Suicide, by month: United States, 1982-89

## [Data transformed by the natural logarithm before fitting model]

According to final data for 1986 , there were 994 suicides for women 55-64 years of age. In that year, Suicide accounted for approximately 1 percent of all deaths to these women. For these women, there has been no discernible trend upward or downward in the provisional Suicide death rates during the period shown in the chart. The monthly death rates for 1988 and the first two months of 1989 were, with the exception of 1 month, within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87.

Figure 30. Death rates per 100,000 males 55-64 years of age for Suicide, by month: United States, 1982-89

For males 55-64 years of age, Suicide accounted for 2,788 deaths or 2 percent of all deaths for these men in 1986. During the period shown in the chart, there was a slight increase in the provisional death rates for Suicide for these men. The monthly death rates for 1988 and the first 2 months of 1989 were all within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. In 1988 the provisional annual death rate for men 55-64 years of age was 3.7 times the rate for women in the same age group.

Figure 31. Death rates per 100,000 females $55-64$ years of age for Malignant neoplasms of digestive organs and peritoneum, by month: United States, 1982-89

Figure 32. Death rates per 100,000 males $55-64$ years of age for Malignant neoplasms of digestive organs and peritoneum, by month: United States, 1982-89

There were 8,502 deaths due to Malignant neoplasms of digestive organs and peritoneum for women 55-64 years of age in 1987, the latest year for which final data are available. For women in this age group this was the third most frequent cause of malignant neoplasm (cancer) deaths in 1987; it accounted for 19 percent of this group's cancer deaths and 8 percent of deaths from all causes. For these women, there has been no discernible trend upward or downward in the provisional death rates for Malignant neoplasms of digestive organs and peritoneum during the period shown in the chart. The observed rates for 1988 and the first 2 months of 1989 , with the exception of 1 month, fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. Based on provisional annual death rates for 1988, the death rate for this cause for females 55-64 years of age was about one half the rate for males in the same age group.

According to final data for 1987, Malignant neoplasms of digestive organs and peritoneum accounted for 13,046 deaths, or 8 percent of all deaths to men 55-64 years of age. Among these men Malignant neoplasms of digestive organs and peritoneum was the second most frequent cause of cancer death in 1987. For the period shown in the chart, provisional death rates for Malignant neoplasms of digestive organs and peritoneum have declined slightly. Monthly death rates for January 1988-February 1989, except for 1 month, fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. According to provisional annual death rates in 1988, the rate for males 55-64 years of age was about double the rate for women in this age group.

Figure 33. Death rates per 100,000 females 65-74 years of age for Malignant neoplasms of digestive organs and peritoneum, by month: United States, 1982-89

Figure 34. Death rates per $\mathbf{1 0 0 , 0 0 0}$ males 65-74 years of age for Malignant neoplasms of digestive organs and peritoneum, by month: United States, 1982-89

In 1987, the latest year for which final data are available, there were 15,584 deaths due to Malignant neoplasms of digestive organs and peritoneum for women 65-74 years of age; this number is slightly more than the number of deaths for these women due to Malignant neoplasms of respiratory and intrathoracic organs $(15,489)$. For women 65-74 years of age, cancer of the digestive organs and peritoneum was the most frequent cause of cancer death in 1987; it accounted for 24 percent of cancer deaths for these women. The overall trend of provisional death rates for cancer of the digestive organs and peritoneum for these women was downward for the period shown in the chart through 1987. The monthly death rates for 1988 and for the first 2 months of 1989 , except for 1 month, fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. According to provisional annual death rates for 1988, the death rate for Malignant neoplasms of digestive organs and peritoneum for females 65-74 years of age was more than double the rate for females 55-64 years of age.

According to final data for 1987, Malignant neoplasms of digestive organs and peritoneum accounted for 20,555 deaths, or 7 percent of all deaths for males 65-74 years of age. For these men it was the second most frequent cause of cancer death in 1987. For the period shown in the chart through 1987, there was a decline in provisional death rates for Malignant neoplasms of digestive organs and peritoneum for males 65-74 years of age. The monthly death rates for January 1988-February 1989 were, with the exception of 1 month, within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. In 1988 the provisional annual death rate for these men was 1.6 times the rate for women in this same age group.

Figure 35. Death rates per 100,000 females 55-64 years of age for Malignant neoplasm of breast, by month: United States, 1982-89

Figure 36. Death rates per 100,000 females 65-74 years of age for Malignant neoplasm of breast, by month: United States, 1982-89

According to final data for 1987, there were 9,407 deaths due to Malignant neoplasm of breast for women $55-64$ years of age, or 9 percent of deaths for all causes for these women. For women in this age group, breast cancer was the second most frequent cause of cancer death in that year behind respiratory cancer. For the period shown in the chart, there was an increase in the provisional death rates with a leveling off of the rates for the most recent years. The monthly death rates for 1988 and the first 2 montlis of 1989 were consistent with a model estimated on the basis of provisional monthly death rates for 1979-87.

Malignant neoplasm of breast accounted for 10,664 deaths, or 5 percent of all deaths for females 65-74 years of age in 1987. For these women, breast cancer was the third most frequent cause of cancer death in 1987 accounting for 17 percent of all cancer deaths. During the period shown in the chart, there was an increase in the provisional death rates for breast cancer for these women with a leveling off of the rates in the most recent years. The monthly death rates for 1988 and the first 2 months of 1989 were, with the exception of 1 month, within the prediction intervals of a model estimated on the basis of provisional montrily death rates for 1979-87. In 1988 the provisional annual death rate for women 65-74 years was one third greater than the rate for women in the 55-64 year age group.

Figure 37. Death rates per 100,000 females 45-54 years of age for Diseases of heart, by month: United States, 1982-89

Figure 38. Death rates per 100,000 males $45-54$ years of age for Diseases of heart, by month: United States, 1982-89

Diseases of heart was the second most frequent cause of death for women 45-54 years of age in 1987, the latest year for which final data are available. It accounted for 8,413 deaths, or 20 percent of all deaths for women in this age group. For the period shown in the chart through 1987, there has been a downward trend in provisional death rates for these women. The observed rates for 1988 and the first 2 months of 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. Death rates for these women showed a seasonal pattern of mortality with a tendency for rates to be higher during the winter. Based on 1988 provisional annual death rates, the death rate for women in this age group was about one-third the rate for men.

According to final data for 1987, Diseases of heart was the most frequent cause of death for males 45-54 years of age. In that year the 24,295 deaths due to this cause for these men represented 33 percent of deaths from all causes for this group. For the period shown in the chart through 1987, provisional death rates for Diseases of heart have declined for males 45-54 years of age. The monthly death rates for January 1988-February 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for $1979-87$. The monthly death rates for these men also showed a seasonal pattern with a tendency for rates to be higher in the winter. According to provisional annual death rates for 1988, the rate for males $45-54$ years of age was about 3 times the rate for women in this age group.

Figure 39. Death rates per 100,000 females 55-64 years of age for Diseases of heart, by month: United States, 1982-89

Figure 40. Death rates per 100,000 males 55-64 years of age for Diseases of heart, by month: United States, 1982-89

According to final data for 1987, Diseases of heart accounted for 27,967 deaths or 27 percent of all deaths for women 55-64 years of age. It was the second most frequent cause of death (behind cancer) for these women. The overall trend in provisional death rates for Diseases of heart for these women was downward for the period shown in the chart through 1987. The monthly death rates for January 1988-February 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. As shown in the chart, women in the age group $55-64$ years had a seasonal pattern of mortality for this cause with a tendency for rates to be higher during the winter. In 1988 the provisional annual death rate for this cause for this age-sex group was about 4 times the rate for women $45-54$ years of age, and less than half the rate for men 55-64 years of age.

Diseases of heart was the most frequent cause of death for males 55-64 years of age. It accounted for 62,050 deaths or 37 percent of all deaths for males 55-64 years of age in 1987, the latest year final data are available. For the period shown in the chart through 1987, there was a decline in provisional death rates for Diseases of heart for males 55-64 years of age. The monthly death rates for January 1988-February 1989, with the exception of 1 month, fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. The monthly rates for this cause and age-sex group also showed a seasonal pattern of mortality with a tendency toward higher rates during the winter. The 1988 provisional annual death rate for these men was about 3 times the rate for men $45-54$ years of age, and about 2.5 times the rate for women $55-64$ years of age.

Figure 41. Death rates per 100,000 females 65-74 years of age for Diseases of heart, by month: United States, 1982-89

Figure 42. Death rates per 100,000 males 65-74 years of age for Diseases of heart, by month: United States, 1982-89

Diseases of heart was the most frequent cause of death for women 65-74 years of age in 1987, the latest year for which final data are available. In that year there were 69,425 deaths due to this cause for women 65-74 years of age, accounting for 34 percent of deaths from all causes for these women. For the period shown in the chart, provisional death rates for Diseases of heart have declined. The monthly death rates for 1988 and the first 2 months of 1989 were consistent with a model estimated on the basis of provisional monthly death rates for 1979-87. As shown in the chart, women in the age group $65-74$ years had a seasonal pattern of mortality with a tendency for higher rates in the winter. For these women the provisional annual death rate for 1988 for Diseases of heart was one-half the rate for men in this age group; the female to male death ratio was larger for this age group than for the other two age groups.

For males 65-74 years of age, Diseases of heart accounted for 108,647 deaths or 38 percent of all deaths for these men in 1987. For these men Diseases of heart was the most frequent cause of death. During the period shown in the chart, there was a decrease in the provisional death rates for Diseases of heart for these men. The monthly death rates for 1988 and the first 2 months of 1989 were, with the exception of 1 month, within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. Death rates for these men also showed a seasonal pattern with a tendency for rates to be higher in the winter. In 1988 the provisional annual death rate for men 65-74 years of age was 2 times the rate for women in the same age group and 2.3 times the rate for men 55-64 years of age.

Figure 43. Death rates per 100,000 females 55-64 years of age for Cerebrovascular diseases, by month: United States, 1982-89

Figure 44. Death rates per 100,000 males 55-64 years of age for Cerebrovascular diseases, by month: United States, 1982-89

In 1987, the latest year for which final data are available, Cerebrovascular diseases was the third most frequent cause of death for women aged 55-64 years. It accounted for 5,304 deaths, or 5 percent of all deaths for women in this age group. For the period shown in the chart through 1987 there has been a downward trend in provisional death rates for these women. The observed monthly rates for 1988 and the first 6 months of 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. Death rates for these women showed a seasonal pattern of mortality, with a tendency for rates to be higher during the winter. Based on 1988 provisional annual death rates, the death rate for women in this age group was three-fourths the rate for men in the same age group.

According to final data. for 1987 Cerebrovascular diseases was the third most frequent cause of death for males aged 55-64 years. It accounted for 6,184 deaths, or 4 percent of all deaths for males in this age group. For the period shown in the chart through 1987, there was a decline in provisional death rates for Cerebrovascular diseases for males aged 55-64 years. The monthly death rates for January 1988-June 1989 were within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. The monthly rates for this cause and age-sex group also showed a seasonal pattern of mortality, with a tendency toward higher rates during the winter. The 1988 provisional annual death rate for these men was 1.3 times the rate for women in the same age group.

Figure 45. Death rates per 100,000 females $65-74$ years of age for Cerebrovascular diseases, by month: United States, 1982-89

Figure 46. Death rates per 100,000 males $65-74$ years of age for Cerebrovascular diseases, by month: United States, 1982-89

According to final data in 1987 Cerebrovascular diseases was the third most frequent cause of death for women aged 65-74 years. It accounted for 13,836 deaths, or 7 percent of all deaths for women in this age group. There has been a downward trend in provisional death rates for these women for the period shown in the chart through 1987. The monthly rates for 1988 and the first 6 months of 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. The monthly rates for this cause for these women showed a seasonal pattern of mortality, with a tendency for rates to be higher during the winter. Based on 1988 provisional annual death rates, the death rate for women in this age group was about 3 times the rate for women aged $55-64$ years and 0.8 times the rate for men aged 65-74 years.

In 1987 Cerebrovascular diseases was the fourth most frequent cause of death for males aged $65-74$ years and accounted for 13,931 deaths, or 5 percent of all deaths for males in this age group. For the period shown in the chart through 1987, there was a decline in provisional death rates for Cerebrovascular diseases for males aged 65-74 years. The monthly death rates for the period January 1988-June 1989 suggest that the downward trend for this age group may be changing unfavorably, that is, the downward trend may be continuing at a slower pace than in the past. Most of the rates for January 1988-June 1989 are above the fitted model estimated on the basis of provisional monthly death rates for 1979-87. Of these, four were above the upper 95 -percent prediction band based on this model; and all of these four rates were within the last 8 months shown on the chart. The monthly rates for this cause and age-sex group also showed a seasonal pattern of mortality, with a tendency toward higher rates during the winter. The 1988 provisional annual death rate for these men was about 3 times the rate for men aged $55-64$ years and 1.2 times the rate for women aged 65-74 years.

Figure 47. Death rates per 100,000 females 75-84 years of age for Septicemia, by month: United States, 1982-89

Figure 48. Death rates per 100,000 males $75-84$ years of age for Septicemia, by month: United States, 1982-89
[Data transformed by the natural logarithm before fitting model]

According to final data for 1987 Septicemia accounted for 3,493 deaths, or 1 percent of all deaths for women aged 75-84 years. The trend in provisional death rates for Septicemia has been upward for the period shown in the chart through 1987. The monthly death rates for the period January 1988-June 1989 suggest that the Septicemia death rates for these women may not be increasing as rapidly as in the past. Most of the rates for this period were below the fitted model estimated on the basis of provisional monthly death rates for 1979-87; four of these consecutive monthly rates (October 1988-January 1989) were below the lower 95 -percent prediction band for this model. As shown in the chart, women in this age group ( $75-84$ years) had a seasonal pattern of mortality, with a tendency for higher rates in the winter. For these women the provisional annual death rate for 1988 for Septicemia was about three-fourths the rate for men in this age group.

In 1987 Septicemia accounted for 2,691 deaths, or 1 percent of all deaths for males aged 75-84 years. During the period shown in the chart through 1987 there was an upward trend in the provisional death rates for Septicemia for these men. For the period January 1988-June 1989, most of the monthly rates fell below the fitted model estimated on the basis of provisional monthly death rates for 1979-87, but all rates for this period were within the 95 -percent prediction bands for this model. In 1988 the provisional annual death rate for men aged 75-84 years was 1.3 times the rate for women in the same age group.

Figure 49. Death rates per 100,000 females 25-34 years of age for Motor vehicle accidents, by month: United States, 1982-89

Figure 50. Death rates per 100,000 males 25-34 years of age for Motor vehicle accidents, by month: United States, 1982-89

In 1987, the latest year for which final data are available, Accidents and adverse effects was the most frequent cause of death for women aged 25-34 years. Within the category of accidental deaths, Motor vehicle accidents accounted for 2,494 deaths, or 71 percent of all accidental deaths and 16 percent of all deaths for women in this age group. For these women provisional death rates from Motor vehicle accidents decreased slightly from 1979 to 1987. The observed monthly rates for 1988 and the first 7 months of 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. Death rates for these women showed a seasonal pattern of mortality, with a tendency for rates to be higher during the late summer. Based on 1988 provisional annual death rates, the death rate for women in this age group was 0.3 times the rate for men in the same age group.

According to final data for 1987, Accidents and adverse effects was the most frequent cause of death for males aged 25-34 years. Motor vehicle accidents accounted for 7,973 deaths, or 61 percent of all accidental deaths and 19 percent of deaths from all causes for men in this age group. For the period shown in the chart through 1987, there was a gradual decline with a possible leveling off in provisional death rates for Motor vehicle accidents for males aged 25-34 years. Monthly death rates for January 1988-July 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. The monthly death rates for this cause and age-sex group also showed a definite seasonal pattern of mortality, with a tendency toward higher rates during the late summer. The 1988 annual provisional death rate for these men was 3 times the rate for women in the same age group.

Figure 51. Death rates per 100,000 females 35-44 years of age for Motor vehicle accidents, by month: United States, 1982-89

Figure 52. Death rates per 100,000 males 35-44 years of age for Motor vehicle accidents, by month: United States, 1982-89

According to final data for 1987, Accidents and adverse effects was the third most frequent cause of death for females aged $35-44$ years. Motor vehicle accidents accounted for 1,616 deaths, or 64 percent of the accidental deaths and 7 percent of all deaths for women in this age group. There has been no discernible upward or downward trend in the provisional death rates during the period shown in the chart. The observed monthly rates for 1988 and the first 7 months of 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. The monthly death rates showed a seasonal pattern of mortality, with a tendency for the peak in death rates to occur from late summer to early fall. Based on 1988 provisional annual death rates, the death rate for women aged 35-44 years was 0.4 times the rate for men in the same age group and 0.8 times the rate for women aged 25-34 years.

In 1987, the latest year for which final data are available, Accidents and adverse effects was the second most frequent cause of death for males aged 35-44 years. Accidents accounted for 8,339 deaths, or 17 percent of all deaths for males in this age group. Motor vehicle accidents accounted for 4,322 deaths, or 52 percent of all accidental deaths and 9 percent of deaths from all causes for men aged $35-44$ years. For the period shown in the chart through 1987, there was a decline in provisional death rates for Motor vehicle accidents for males aged 35-44 years. The monthly death rates for January 1988-July 1989 were within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. The monthly death rates for this cause and age-sex group, like females in this age group, showed a seasonal pattern of mortality, with a tendency toward higher rates from late summer to early fall. The 1988 provisional annual death rate for these men for Motor vehicle accidents was about 3 times the rate for women in this same age group and 0.7 the rate for males aged 25-34 years.

Figure 53. Death rates per 100,000 females $45-54$ years of age for Motor vehicle accidents, by month: United States, 1982-89

Figure 54. Death rates per 100,000 males 45-54 years of age for Motor vehicle accidents, by month: United States, 1982-89

According to final data for 1987, Accidents and adverse effects was the third most frequent cause of death for females aged 45-54 years and accounted for 1,870 deaths, or 4 percent of all deaths for women in this age group. Motor vehicle accidents accounted for 1,106 deaths, or 60 percent of deaths from all accidents and 3 percent of all deaths for women in this age group. For these women provisional death rates from Motor vehicle accidents decreased slightly from 1979 to the mid 1980's and, as shown in the chart, have increased slightly since then. The observed monthly rates for 1988 and the first 7 months of 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. Monthly rates for this cause showed a seasonal pattern of mortality, with a tendency for rates to be higher during the early fall. Based on 1988 provisional annual death rates, the death rate for women in this age group was one-half the rate for men in the same age group and nearly the same as the rate for women aged 35-44 years.

According to final data for 1987, Accidents and adverse effects was the third most frequent cause of death for males aged 45-54 years and accounted for 5,112 deaths, or 7 percent of deaths from all causes for this age-sex group. Motor vehicle accidents accounted for 2,470 deaths, or 48 percent of deaths from all accidents and 3 percent of deaths from all causes for men aged $45-54$ years. For the period shown in the chart, provisional death rates for Motor vehicle accidents have declined slightly. Except for 1 month, monthly death rates for January 1988-July 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. The monthly rates for this cause and age-sex group also showed a seasonal pattern of mortality, with a tendency toward higher rates during the fall. The 1988 provisional annual death rate for these men was twice the rate for women in this same age group and 0.8 times the rate for men aged 35-44 years.

Figure 55. Death rates per $\mathbf{1 0 0 , 0 0 0}$ males $55-64$ years of age for Malignant neoplasms of genital organs, by month: United States, 1982-89

Figure 56. Death rates per 100,000 males 65-74 years of age for Malignant neoplasms of genital organs, by month: United States, 1982-89

In 1987, the latest year for which final mortality data are available, Malignant neoplasms of genital organs (genital cancer) accounted for 2,531 deaths, or 2 percent of deaths from all causes for men aged 55-64 years. For these men, genital cancer was the third most frequent cause of malignant neoplasm (cancer) death in 1987. For the period shown in the chart through 1987, there has been no discernible upward or downward trend in the provisional death rates for genital cancer. The observed rates for 1988 and the first 7 months of 1989 , with the exception of 3 months, fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. Although three monthly rates were above the upper 95 -percent prediction band, it is too early to detect a shift in trend.

According to final data for 1987, genital cancer accounted for 8,694 deaths, or 3 percent of deaths from all causes for men aged 65-74 years. For these men, this was the third most frequent cause of cancer death. For the period shown in the chart through 1987, there has been no discernible upward or downward trend in provisional death rates for this age-sex group. The observed monthly death rates for this cause for 1988 and the first 7 months of 1989, with the exception of 2 months, fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. Based on 1988 provisional annual death rates, the death rate for men in this age group was 5 times the rate for men aged 55-64 years.

Figure 57. Death rates per $\mathbf{1 0 0 , 0 0 0}$ females $55-64$ years of age for Pneumonia and influenza, by month: United States, 1982-89

Figure 58. Death rates per $\mathbf{1 0 0 , 0 0 0}$ males 55-64 years of age for Pneumonia and influenza, by month: United States, 1982-89

In 1987, the latest year for which final data are available, Pneumonia and influenza was the eighth most frequent cause of death for women 55-64 years of age and accounted for 1,421 deaths, or 1 percent of deaths for women in this age group. For the period shown in the chart through 1987, there was no discernible upward or downward trend in the provisional death rates for Pneumonia and influenza for women aged $55-64$ years. The observed monthly death rates for 1988 and the first 7 months of 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. Death rates for these women showed a seasonal pattern of mortality with a tendency for the peak in death rates to be higher during the winter. Based on 1988 provisional annual death rates, the death rate for women in this age group was half the rate for men in the same age group.

According to final data for 1987, Pneumonia and influenza was the ninth most frequent cause of death for men aged 55-64 years. It accounted for 2,458 deaths, or 1 percent of deaths from all causes for men in this age group. For these men, there has been no discernible upward or downward trend in the provisional death rates for Pneumonia and influenza for 1979-87. The observed monthly death rates for 1988 and the first 7 months of 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. Death rates for these men showed a seasonal pattern of mortality with a tendency for rates to be higher during the winter.

Figure 59. Death rates per $\mathbf{1 0 0 , 0 0 0}$ females 65-74 years of age for Pneumonia and influenza, by month: United States, 1982-89

Figure 60. Death rates per 100,000 males 65-74 years of age for Preumonia and influenza, by month: United States, 1982-89

According to final data for 1987, Pneumonia and influenza was the sixth most frequent cause of death for women aged $65-74$ years and accounted for 3,820 deaths, or 2 percent of deaths from all causes for women in this age group. For the period shown in the chart through 1987, there has been a slight upward trend in provisional death rates for Pneumonia and influenza for these women. Monthly death rates from this cause for January 1988-July 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for $1979-87$. The monthly death rates for this cause and age-sex group showed a seasonal pattern of mortality with the tendency for rates to be higher during the winter. Based on 1988 provisional annual death rates, the death rate for women in this age group was almost 3 times the rate for women aged 55-64 years.

In 1987 Pneumonia and influenza was the fifth most frequent cause of death for men aged 65-74 years. It accounted for 6,206 deaths, or 2 percent of all deaths for these men. For the period shown in the chart through 1987, provisional death rates for Pneumonia and influenza increased slightly for these men. The observed monthly rates for January 1988-July 1989 were, with the exception of 1 month, within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. The monthly death rates for this cause and age-sex group showed a seasonal pattern of mortality, with a tendency for the peak to occur in winter. Based on 1988 provisional annual death rates for Pneumonia and influenza, the death rate for men in this age group was more than twice the rate for women in the same age group and more than 3 times the rate for men 55-64 years of age.

Figure 61. Death rates per $\mathbf{1 0 0 , 0 0 0}$ females 55-64 years of age for Malignant neoplasms of genital organs, by month: United States, 1982-89

Figure 62. Death rates per $\mathbf{1 0 0 , 0 0 0}$ females 65-74 years of age for Malignant neoplasms of genital organs, by month: United States, 1982-89

In 1987, the latest year for which final mortality data are available, Malignant neoplasms of genital organs (genital cancer) accounted for 4,689 deaths, or 4 percent of deaths from all causes for women aged 55-64 years. For these women genital cancer was the fourth most frequent cause of malignant neoplasm (cancer) deaths in 1987. For the period shown in the chart through 1987 there has been a slight decrease in the provisional death rates for genital cancer. The observed rates for 1988 and the first 7 months of 1989, except for 1 month, fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87.

According to final data for 1987, genital cancer accounted for 6,901 deaths, or 3 percent of deaths from all causes for women aged 65-74 years. For these women this was the fourth most frequent cause of cancer death. For the period shown in the chart through 1987 there has been no discernible upward or downward trend in provisional death rates for this age-sex group. The observed monthly death rates for this cause for 1988 and the first 7 months of 1989, except for 1 month, fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. Based on 1988 provisional annual death rates, the death rate for women in this age group was almost two times the rate for women aged 55-64 years.

Figure 63. Death rates per 100,000 females 55-64 years of age for Diabetes mellitus, by month: United States, 1982-89

Figure 64. Death rates per $\mathbf{1 0 0 , 0 0 0}$ males 55-64 years of age for Diabetes mellitus, by month: United States, 1982-89

In 1987, the latest year for which final data are available, Diabetes mellitus was the fifth most frequent cause of death for women aged 55-64 years and accounted for 2,992 deaths, or 3 percent of all deaths for women in this age group. For these women provisional death rates from Diabetes mellitus increased slightly from 1979 to the mid-1980's and, as shown in the chart, have decreased slightly since then through 1987. The observed monthly death rates for 1988 and the first 7 months of 1989, except for 1 month, fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87; however, all but four of the monthly rates for January 1988 through July 1989 were above the line predicted by this model. Based on 1988 provisional annual death rates, the death rate for women in this age group was about the same as the rate for men in the same age group.

According to final data for 1987, Diabetes mellitus was the seventh most frequent cause of death for men aged $55-64$ years. It accounted for 2,922 deaths, or 2 percent of deaths from all causes for men in this age group. For these men provisional death rates from Diabetes mellitus decreased slightly from 1979 to the mid-1980's and, as shown in the chart, have increased slightly since then through 1987. The observed monthly death rates for this cause for 1988 and the first 7 months of 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. Death rates for these men showed a seasonal pattern of mortality, with a tendency toward higher rates during the winter.

Figure 65. Death rates per 100,000 females 65-74 years of age for Diabetes mellitus, by month: United States, 1982-89

Figure 66. Death rates per 100,000 males 65-74 years of age for Diabetes mellitus, by month: United States, 1982-89

According to final data for 1987, Diabetes mellitus was the fifth most frequent cause of death for women aged 65-74 years and accounted for 5,877 deaths, or 3 percent of deaths from all causes for women in this age group. For the period shown in the chart through 1987 there has been no discernible upward or downward trend in the provisional death rates for Diabetes mellitus for these women. While the observed monthly death rates from this cause for 1988 fell within the prediction interval of a model estimated on the basis of provisional monthly death rates for 1979-87, six of the seven monthly death rates were close to the upper 95-percent prediction band for 1989. This may suggest a shift in trend. The monthly death rates for this cause and age-sex group showed a seasonal pattern of mortality, with the tendency toward higher rates during the winter.

In 1987 Diabetes mellitus was the seventh most frequent cause of death for men aged 65-74 years. It accounted for 4,912 deaths, or 2 percent of all deaths for these men. For the period shown in the chart through 1987 there has been no discernible upward or downward trend in the provisional death rates for Diabetes mellitus for these men. The observed monthly rates for January 1988 through July 1989 were, except for 1 month, within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87; however, all but two of these rates within the prediction interval were above the line predicted by this model. The monthly death rates for this cause and age-sex group showed a seasonal pattern of mortality, with a tendency for the peak to occur in winter. Based on 1988 provisional annual death rates for Diabetes mellitus, the death rate for men in this age group was about the same as the rate for women in the same age group and more than twice the rate for men 55-64 years of age.

Figure 67. Death rates per $\mathbf{1 0 0}, 000$ females 25-34 years of age for Accidents and adverse effects, by month: United States, 1982-89

Figure 68. Death rates per 100,000 males 25-34 years of age for Accidents and adverse effects, by month: United States, 1982-89

In 1987, the latest year for which final mortality data are available, Accidents and adverse effects accounted for 3,531 deaths, or 22 percent of deaths from all causes for women aged 25-34 years. For these women, Accidents and adverse effects was the most frequent cause of death in 1987. Provisional death rates for Accidents and adverse effects decreased slightly from 1979 to the mid-1980's and have stabilized since then, through 1987. The observed rates for 1988 and the first 8 months of 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. Death rates for these women showed a seasonal pattern of mortality with a tendency for rates to be somewhat higher during the summer.

According to final data for 1987, Accidents and adverse effects accounted for 13,091 deaths, or 31 percent of deaths from all causes for men aged 25-34 years. For these men, this was the most frequent cause of death. For the period shown in the chart through 1987, there has been a decrease in the provisional death rates for Accidents and adverse effects. The observed monthly death rates for this cause for 1988 and the first 8 months of 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. Death rates for these men showed a seasonal pattern of mortality with a tendency for rates to be higher during the summer. Based on 1988 provisional annual death rates, the death rate for men in this age group was almost 4 times the rate for women aged 25-34 years.

Figure 69. Death rates per 100,000 females 25-34 years of age for Suicide, by month: United States, 1982-89

Figure 70. Death rates per $\mathbf{1 0 0 , 0 0 0}$ males 25-34 years of age for Suicide, by month: United States, 1982-89

In 1987, the latest year for which final data are available, Suicide was the fourth most frequent cause of death for women aged 25-34 years after Accidents and adverse effects; Malignant neoplasms, including neoplasms of lymphatic and hematopoietic tissues; and Homicide and legal intervention. For this group Suicide accounted for 1,285 deaths, or 8 percent of all deaths to women 25-34 years. For these women, provisional death rates for Suicide were stable from 1979 through the early 1980's and, as shown in the chart, have decreased slightly since then, through 1987. The observed monthly death rates for 1988 and the first 8 months of 1989, with the exception of 1 month, fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87.

According to final data for 1987, Suicide was the second most frequent cause of death for men aged 25-34 years after Accidents and adverse effects. It accounted for 5,370 deaths, or 13 percent of deaths from all causes for men in this age group. For the period shown in the chart through 1987, there has been no discernible upward or downward trend in provisional death rates for Suicide for this age-sex group. The observed monthly death rates for this cause for 1988 and the first 8 months of 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. Death rates for these men showed a seasonal pattern of mortality with a tendency for the major peak to occur during the spring. Based on 1988 provisional annual death rates, the death rate for men in this age group was almost 5 times the rate for women in this same age group.

Figure 71. Death rates per 100,000 females 25-34 years of age for Homicide and legal intervention, by month: United States, 1982-89

Figure 72. Death rates per 100,000 males 25-34 years of age for Homicide and legal intervention, by month: United States, 1982-89

According to final data for 1987, Homicide and legal intervention was the third most frequent cause of death for women aged 25-34 years and accounted for 1,501 deaths, or 9 percent of deaths from all causes for women in this age group. For the period shown in the chart through 1987, there has been no discernible upward or downward trend in the provisional death rates for Homicide and legal intervention for these women. The observed monthly death rates for this cause for 1988 and the first 8 months of 1989 fell within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87. Based on 1988 provisional annual death rates for Homicide and legal intervention, the death rate for women in this age group was less than half the rate for men in this same age group.

In 1987 Homicide and legal intervention was the third most frequent cause of death for men aged 25-34 years, after Accidents and adverse effects and Suicide. It accounted for 5,045 deaths, or 12 percent of all deaths for these men. For the period shown in the chart through 1987, there has been a decrease in the provisional death rates for Homicide and legal intervention for these men. Although the observed monthly rates for January 1988-August 1989 were within the prediction intervals of a model estimated on the basis of provisional monthly death rates for 1979-87, all but two of the monthly rates were above the fitted model. The monthly death rates for these men showed a seasonal pattern of mortality, with a tendency for rates to be higher in the fall.

NOTE: Data in this table are for figures 37-42. These figures were previously published in the Monthly Vital Statistics Report on births, marriages, divorces, and deaths for August 1989, volume 38, number 8.

Table 8. Estimated number of deaths and death rates for Cerebrovascular diseases and Septicemia, by specified age, sex, and year and month of occurrence: United States, January 1979-December 1989
[Data are provisional, estimated from a 10-percent sample of deaths. Rates on an annual basis per 100,000 estimated population for the specific month]

| Year and month of occurrence | Cerebrovascular diseases |  |  |  |  |  |  |  | Septicemia |  |  |  |

${ }^{1}$ Data transformed by the natural logarithm before fitting model
.. . Parameter not included in model.

SERIES 1. Programs and Collection Procedures - These reports describe the data collection programs of the National Center for Health Statistics. They include descriptions of the methods used to collect and process the data, definitions, and other material necessary for understanding the data.
SERIES 2. Data Evaluation and Methods Research - These reports are studies of new statistical methods and include analytical techniques, objective evaluations of reliability of collected data, and contributions to statistical theory. These studies also include experimental tests of new survey methods and comparisons of U.S. methodology with those of other countries.

SERIES 3. Analytical and Epidemiological Studies - These reports present analytical or interpretive studies based on vital and health statistics. These reports carry the analyses further than the expository types of reports in the other series.
SERIES 4. Documents and Committee Reports - These are final reports of major committees concerned with vital and health statistics and documents such as recommended model vital registration laws and revised birth and death certificates.
SERIES 5. International Vital and Health Statistics Reports - These reports are analytical or descriptive reports that compare U.S. vital and health statistics with those of other countries or present other international data of relevance to the health statistics system of the United States.
SERIES 6. Cognition and Survey Measurement - These reports are from the National Laboratory for Collaborative Research in Cognition and Survey Measurement. They use methods of cognitive science to design, evaluate, and test survey instruments.

SERIES 10. Data From the National Health Interview Survey - These reports contain statistics on illness; unintentional injuries; disability; use of hospital, medical, and other health services; and a wide range of special current health topics covering many aspects of health behaviors, health status, and health care utilization. They are based on data collected in a continuing national household interview survey.
SERIES 11. Data From the National Health Examination Survey, the National Health and Nutrition Examination Surveys, and the Hispanic Health and Nutrition Examination Survey Data from direct examination, testing, and measurement on representative samples of the civilian noninstitutionalized population provide the basis for (1) medically defined total prevalence of specific diseases or conditions in the United States and the distributions of the population with respect to physical, physiological, and psychological characteristics, and (2) analyses of trends and relationships among various measurements and between survey periods.
SERIES 12. Data From the Institutionalized Population Surveys Discontinued in 1975. Reports from these surveys are included in Series 13.
SEAIES 13. Data From the National Health Care Survey - These reports contain statistics on health resources and the public's use of health care resources including ambulatory, hospital, and long-term care services based on data collected directly from health care providers and provider records.

SERIES 14. Data on Health Resources: Manpower and Facilities Discontinued in 1990. Reports on the numbers, geographic distribution, and characteristics of health resources are now included in Series 13.
SERIES 15. Data From Special Surveys - These reports contain statistics on health and health-related topics collected in special surveys that are not part of the continuing data systems of the National Center for Health Statistics.
SERIES 16. Compilations of Advance Data From Vital and Health Statistics - Advance Data Reports provide early release of information from the National Center for Health Statistics. health and demographic surveys. They are compiled in the order in which they are published. Some of these releases may be followed by detailed reports in Series 10-13.
SERIES 20. Data on Mortality - These reports contain statistics on mortality that are not included in regular, annual, or monthly reports. Special analyses by cause of death, age, other demographic variables, and geographic and trend analyses are included.
SERIES 21. Data on Natality, Marriage, and Divorce - These reports contain statistics on natality, marriage, and divorce that are not included in regular, annual, or monthly reports. Special analyses by health and demographic variables and geographic and trend analyses are included.
SERIES 22. Data From the National Mortality and Natality Surveys Discontinued in 1975. Reports from these sample surveys, based on vital records, are now published in Series 20 or 21.
SERIES 23. Data From the National Survey of Family Growth - These reports contain statistics on factors that affect birth rates, including contraception, infertility, cohabitation, marriage, divorce, and remarriage; adoption; use of medical care for family planning and infertility; and related maternal and infant health topics. These statistics are based on national surveys of childbearing age.
SERIES 24. Compilations of Data on Natality, Mortality, Marriaze, Divorce, and Induced Terminations of Pregnancy These include advance reports of births, deaths, marriages, and divorces based on final data from the National Vital Statistics System that were published as supplements to the Monthly Vital Statistics Report (MVSR). These reports provide highlights and summaries of detailed data subsequently published in Vital Statistics of the United States. Other supplements to the MVSR published here provide selected findings based on final data from the National Vital Statistics System and may be followed by detailed reports in Series 20 or 21 .
