19. ABSTRACT (Continue on reverse if necessary and identify by block number)

The purpose of this program is to perform frequency computations of annual maximum hydrologic events necessary to a regional frequency study. Frequency statistics are computed for recorded events at each station and for each duration. Missing events are computed so that complete sets of events are obtained for all years at all stations while preserving all inter-correlations. These are arranged in the order of magnitude for each station and duration and tabulated with median plotting positions. Statistics for each station are then adjusted to the complete period of region record, and frequency curves are computed in accordance with procedures given in "Statistical Methods in Hydrology" by Leo R. Beard, January 1962, using the logarithmic Pearson Type III function and the expected-probability concept.

REGIONAL FREQUENCY COMPUTATION

HYDROLOGIC ENGINEERING CENTER
723-X6-L7350

1. INTRODUCTION

This program was prepared in the Hydrologic Engineering Center. Up-to-date information and copies of source statement cards for various types of computers can be obtained from the Center upon request by Government and cooperating agencies. While every care is taken to validate this program, it is not feasible to anticipate and test all possible applications. Consequently, the Center is interested in problems that arise in application and will assist in resolving deficiencies in the program to the extent feasible.

2. PURPOSE OF PROGRAM

The purpose of this program is to perform frequency computations of annual maximum hydrologic events necessary to a regional frequency study. Frequency statistics are computed for recorded events at each station and for each duration. Missing events are computed so that complete sets of events are obtained for all years at all stations while preserving all inter-correlations. These are arranged in the order of magnitude for each station and duration and tabulated with median plotting positions. Statistics for each station are then adjusted to the complete period of region record, and frequency curves are computed in accordance with procedures given in "Statistical Methods in Hydrology" by Leo R. Beard, January 1962, using the logarithmic Pearson Type III function and the expected-probability concept. The use of all long-record stations instead of only one for the extension of frequency statistics at short-record stations is considered to constitute some advantage over procedures given in "Statistical Methods". As an alternative use of this program, frequency statistics can be supplied and curves will be computed.

3. DESCRIPTION OF EQUIPMENT

A FORTRAN IV compiler, random number generator (function RNGEN included, see Exhibit 2), and large memory are required. The large amounts of computation make high speed desirable. Accordingly, it is virtually necessary to use a computer of the IBM 7094 class for execution of this program. It is desirable to use one input tape and one output tape unit, in addition to card (tape 7) and printer (tape 6) output and standard (tape 5) input.

4. METHODS OF COMPUTATION

a. Flows for those stations with zeros in the data are first incremented by 1/10 percent of their average for each station and duration in order to preclude infinite negative logarithms. This increment, if added, is later subtracted from reconstituted flows and computed frequency curves. The mean, standard deviation and skew coefficient of the logarithms for each station and duration are then computed. Preliminary to estimating missing flows by correlation, each flow is then converted to a standardized variate using an approximation of the Pearson Type III distribution. This involves the following equations:

$$X_{i,m} = \log (Q_{i,m}+q_i) \tag{1}$$

$$\bar{X}_i = \sum_{m=1}^{N} X_{i,m}/N \tag{2}$$

$$S_i = \sqrt{\sum_{m=1}^{N} (X_{i,m}-\bar{X}_i)^2/(N-1)} \tag{3}$$

$$g_i = N \sum_{m=1}^{N} (X_{i,m}-\bar{X}_i)^3/((N-1)(N-2)S_i^3) \tag{4}$$

$$t_{i,m} = (X_{i,m}-\bar{X}_i)/S_i \tag{5}$$

$$K_{i,m} = 6/g_i \left[((g_i t_{i,m}/2)+1)^{1/3} - 1\right] + g_i/6 \tag{6}$$

in which:

X = Logarithm of flow event
Q = Recorded flow event
q = Small increment of flow used to prevent infinite logarithms for events with zero flow
$\bar{X}$ = Mean logarithm of flow events
N = Total years of record
S = Unbiased estimate of population standard deviation
g = Unbiased estimate of population skew coefficient
t = Pearson Type III standard deviate
i = Duration number
m = Year number
K = Normal standard deviate

b. After transforming the flows for all stations and durations to normal, the gross (simple) correlation coefficients R between all pairs of stations for each duration and for adjacent durations at each station are computed by use of the following formula:

$$R_i = \left\{1 - \left[1 - \left(\sum_{m=1}^{N}(x_{i,m}x_{i-1,m})^2/\left(\sum_{m=1}^{N}x_{i,m}^2 \sum_{m=1}^{N}x_{i-1,m}^2\right)\right)\right]\right.$$

$$\left.(N-1)/(N-2)\right\}^{\frac{1}{2}} \qquad (7)$$

c. Inasmuch as not all stations and durations necessarily have the same length of record, correlation matrices obtained in b might not be complete or internally consistent. If not, missing values are estimated, and low values are raised to obtain consistency, inasmuch as low values are least reliable and least influential. Each missing value is estimated by examining its relationship to related pairs of values by use of the following formula, using i, j and k subscripts to indicate variables used in the gross correlation:

$$R_{ij} = R_{ki}R_{kj} \pm \sqrt{(1-R_{ki}^2)(1-R_{kj}^2)} \qquad (8)$$

d. Consistency of each correlation matrix to be used for estimating missing flows is assured by first testing all combinations of triads of correlation coefficients used in that matrix. The test for consistency of each complete matrix is made by computing the multiple correlation coefficient. If this value is greater than 1.0, further adjustment is required. Such further adjustment is obtained by introducing a coefficient, successively smaller by .2, on the radical in equation 8 and repeating all triad consistency tests until all matrices are consistent.

e. Missing flows are estimated by correlation with corresponding flows at other stations and the flow at the same station for the adjacent duration (preceding duration, except that the succeeding duration is used when estimating for the first tabulated duration). Since it is not known which stations might have recorded or previously estimated values, the correlation matrix and regression equation might be different for the same station and duration in different years. The regression equation is computed for each missing value in terms of normal standard variates by selecting required coefficients from the complete (and consistent) correlation matrix and solving by the Crout method explained in Exhibit 1. The missing value is computed from this regression equation,

introducing a random component equal to the non-determination of the equation, in order to preserve the proper variance (standard deviation) of the flows. This is done as follows:

$$k_1 = \beta_2 k_2 + \beta_3 k_3 + \ldots . \beta_n k_n + \sqrt{1-R^2}\ Z \qquad (9)$$

in which:

k = Normal standard deviate
β_2 = Beta coefficient
R^2 = Determination coefficient
Z = Random number normally distributed
n = Number of variables in equation

f. When all flows have been reconstituted, the mean and standard deviation for each station and duration are recomputed. Regression lines of standard deviation and skew coefficient separately versus mean are computed, and "smoothed" values of standard deviation and skew obtained as described in "Statistical Methods". Equivalent record for the recorded and reconstituted flows for each station and duration is estimated by adding the determination coefficient for each year of reconstituted flow to the total years of recorded flows. This equivalent record is used in computing expected probabilities as discussed below. Flows are arranged in descending order of magnitude and median plotting positions are computed as defined in "Statistical Methods". Frequency-curve coordinates for each station and duration are computed from the mean, standard deviation, skew coefficient, flow increment and equivalent record length, using table values of the normal distribution, the transform for the Pearson Type III function shown in Equation 10, and the following approximate transforms for expected probability:

$$P_{.01} = .01\ (1+1600/N^{1.72}) \qquad (10)$$

$$P_{.1} = .1\ (1+280/N^{1.55}) \qquad (11)$$

$$P_1 = 1 + 26/N^{1.16} \qquad (12)$$

$$P_5 = 5\ (1 + 6/N^{1.04}) \qquad (13)$$

$$P_{10} = 10\ (1 + 3/N^{1.04}) \qquad (14)$$

$$P_{30} = 30\ (1 + .46/N^{.925}) \qquad (15)$$

in which:

P = Expected probability in percent, symmetrical about 50 percent
N = Equivalent years of record

5. INPUT

Input is summarized in Exhibits 6 and 7. All data are entered consecutively on each card, using 8 columns (digits, including decimal point, if used) per variable and 10 variables per card unless fewer variables are called for, except that the first column on each card is reserved for identification. The first output title card must have an A in column 1. An example of input is given in Exhibit 2. Certain inadequacies of data will abort the job and waste input cards until the next card with A in column 1 is reached. After a job is finished, a card with A in column 1 followed by 3 blank cards causes the computer to stop.

6. OUTPUT

Printed output includes key input information for job identification and all results of computations. An example of printed output is given in Exhibit 3.

7. OPERATING INSTRUCTIONS

Standard FORTRAN IV instructions and random number generator are required. No sense switches are used.

8. DEFINITIONS OF TERMS

Terms used in the program are defined in Exhibit 4.

9. PROPOSED FUTURE DEVELOPMENT

No specific future development of this program is presently planned. It is requested that any user who finds an inadequacy or desirable addition or modification notify the Hydrologic Engineering Center.

EXHIBIT 1

Crout's Method

One of the best methods for solving systems of linear equations on desk calculating machines was developed by P. D. Crout in 1941. This method is based on the elimination method, with the calculations arranged in systematic order so as to facilitate their accomplishment on a desk calculator. In this method the coefficients and constant terms of the equations are written in the form of a "matrix," which is a rectangular array of quantities arranged in rows and columns.

The method is best explained by an example. Suppose that in a multiple correlation analysis it is required to solve the following system of linear equations to obtain the unknown values of b_2, b_3, b_4 and b_5.

$$\Sigma x_2^2 \; b_2 + \Sigma x_2 x_3 \; b_3 + \Sigma x_2 x_4 \; b_4 + \Sigma x_2 x_5 \; b_5 = \Sigma x_1 x_2$$

$$\Sigma x_2 x_3 \; b_2 + \Sigma x_3^2 \; b_3 + \Sigma x_3 x_4 \; b_4 + \Sigma x_3 x_5 \; b_5 = \Sigma x_1 x_3$$

$$\Sigma x_2 x_4 \; b_2 + \Sigma x_3 x_4 \; b_3 + \Sigma x_4^2 \; b_4 + \Sigma x_4 x_5 \; b_5 = \Sigma x_1 x_4$$

$$\Sigma x_2 x_5 \; b_2 + \Sigma x_3 x_5 \; b_3 + \Sigma x_4 x_5 \; b_4 + \Sigma x_5^2 \; b_5 = \Sigma x_1 x_5$$

For simplicity let us replace the coefficients of the b's by the letters p, q, r and s, and the constant terms by the letter t, using subscripts 1, 2, 3 and 4 to denote the respective equations:

$$p_1 b_2 + q_1 b_3 + r_1 b_4 + s_1 b_5 = t_1$$

$$p_2 b_2 + q_2 b_3 + r_2 b_4 + s_2 b_5 = t_2$$

$$p_3 b_2 + q_3 b_3 + r_3 b_4 + s_3 b_5 = t_3$$

$$p_4 b_2 + q_4 b_3 + r_4 b_4 + s_4 b_5 = t_4$$

A continuous check on the computations as they progress may be obtained by adding to the matrix of the above system a column of u's, such that $u = p + q + r + s + t$. The matrix and check column are written as follows:

$$\begin{vmatrix} p_1 & q_1 & r_1 & s_1 & t_1 & u_1 \\ p_2 & q_2 & r_2 & s_2 & t_2 & u_2 \\ p_3 & q_3 & r_3 & s_3 & t_3 & u_3 \\ p_4 & q_4 & r_4 & s_4 & t_4 & u_4 \end{vmatrix}$$

The elements p_1, q_2, r_3 and s_4 form the "principal diagonal" of the matrix. Examination of the original equations shows that the coefficients are symmetrical about the principal diagonal, i.e., $q_1 = p_2$, $r_1 = p_3$, $r_2 = q_3$, $s_1 = p_4$, $s_2 = q_4$, and $s_3 = r_4$. This is characteristic of the system of equations to be solved in any multiple correlation analysis. Because of this symmetry, the computations are considerably simplified. While the Crout method may be used to solve any system of linear equations, the computational steps given here are applicable only to those with symmetrical coefficients.

The solution consists of two parts, viz., the computation of a "derived matrix" and the "back solution." Let the derived matrix be denoted as follows:

$$\begin{vmatrix} P_1 & Q_1 & R_1 & S_1 & T_1 & U_1 \\ P_2 & Q_2 & R_2 & S_2 & T_2 & U_2 \\ P_3 & Q_3 & R_3 & S_3 & T_3 & U_3 \\ P_4 & Q_4 & R_4 & S_4 & T_4 & U_4 \end{vmatrix}$$

The elements of the derived matrix are computed as follows:

$$P_1 = p_1 \qquad P_2 = p_2 \qquad P_3 = p_3 \qquad P_4 = p_4$$

$$Q_1 = \frac{q_1}{p_1} \qquad R_1 = \frac{r_1}{p_1} \qquad S_1 = \frac{s_1}{p_1} \qquad T_1 = \frac{t_1}{p_1} \qquad U_1 = \frac{u_1}{p_1}$$

$$Q_2 = q_2 - P_2Q_1 \qquad Q_3 = q_3 - P_3Q_1 \qquad R_2 = \frac{Q_3}{Q_2}$$

$$Q_4 = q_4 - P_4Q_1 \qquad S_2 = \frac{Q_4}{Q_2} \qquad T_2 = \frac{t_2 - T_1P_2}{Q_2} \qquad U_2 = \frac{u_2 - U_1P_2}{Q_2}$$

$$R_3 = r_3 - Q_3R_2 - P_3R_1 \qquad R_4 = r_4 - Q_4R_2 - P_4R_1 \qquad S_3 = \frac{R_4}{R_3}$$

$$T_3 = \frac{t_3 - T_2Q_3 - T_1P_3}{R_3} \qquad U_3 = \frac{u_3 - U_2Q_3 - U_1P_3}{R_3}$$

$$S_4 = s_4 - R_4S_3 - Q_4S_2 - P_4S_1$$

$$T_4 = \frac{t_4 - T_3R_4 - T_2Q_4 - T_1P_4}{S_4} \qquad U_4 = \frac{u_4 - U_3R_4 - U_2Q_4 - U_1P_4}{S_4}$$

The general pattern of the above computations, which may be applied to a system containing any number of equations, is as follows:

(1) The first column of the derived matrix is copied from the first column of the given matrix.

(2) The remaining elements in the first row of the derived matrix are computed by dividing the corresponding elements in the first row of the given matrix by the first element in that row.

(3) After completing the $n^{\underline{th}}$ row, the remaining elements in the $(n+1)^{\underline{th}}$ column are computed. Such an element (X) equals the corresponding element of the given matrix minus the product of the element immediately to the left of (X) by the element immediately above the principal diagonal in the same column as (X), minus the product of the second element to the left of (X) by the second element above the principal diagonal in the same column as (X), etc. After each element below the principal diagonal is recorded, and while that element is still in the calculator, it is divided by the element of the principal diagonal which is in the same column. The quotient is the element whose location is symmetrical to (X) with respect to the principal diagonal.

EXHIBIT 1

(4) When the elements in the $(n+1)^{\underline{th}}$ column and their symmetrical counterparts have been recorded, the $(n+1)^{\underline{th}}$ row will be complete except for the last two elements, which are next computed. Such an element (X) equals the corresponding element of the given matrix minus the product of the element immediately above (X) by the element immediately to the left of the principal diagonal in the same row as (X), minus the product of the second element above (X) by the second element to the left of the principal diagonal in the same row as (X), etc., all divided by the element of the principal diagonal in the same row as (X).

The check column (U) of the derived matrix serves as a continuous check on the computations in that each element in the column equals one plus the sum of the elements in the same row to the right of the principal diagonal. That is,

$$U_1 = 1 + Q_1 + R_1 + S_1 + T_1$$

$$U_2 = 1 + R_2 + S_2 + T_2$$

$$U_3 = 1 + S_3 + T_3$$

$$U_4 = 1 + T_4$$

This check should be made after completing each row.

The elements of the derived matrix to the right of the principal diagonal form a system of equations which may now be used to compute the unknown values of b_2, b_3, b_4 and b_5 by successive substitution. This is known as the "back solution." The computations are as follows:

$$b_5 = T_4$$

$$b_4 = T_3 - S_3 b_5$$

$$b_3 = T_2 - S_2 b_5 - R_2 b_4$$

$$b_2 = T_1 - S_1 b_5 - R_1 b_4 - Q_1 b_3$$

It is very important that the computations be carried to a sufficient number of digits, both in computing the coefficients and constant terms of the original equations, and in computing the elements of the derived matrix. It is possible for relatively small errors in the coefficients and constant terms of the original equations to result in relatively large errors in the computed solutions of the unknowns. The

greatest source of error in computing the elements of the derived matrix arises from the loss of leading significant digits by subtraction. This must be guarded against and can be done by carrying the computations to more figures than the data. As a general rule, it is recommended that the coefficients and constant terms of the original equations be carried to a sufficient number of decimals to produce at least five significant digits in the smallest quantity, and that the elements of the derived matrix be carried to one more decimal than this, but to not less than six significant digits.

EXHIBIT 1

EXHIBIT 2

RANDOM NUMBER FUNCTION RNGEN

This random number function is for a binary machine and the constants must be computed according to the number of bits in an integer word. The numbers generated are uniformly distributed in the interval 0 to 1.

The function is called from the main program by a statement similar to the following:

A = RNGEN (IX)

Where A is some floating point variable name and IX is some integer variable name. The argument name IX need not be the same in the main program and the function. The argument must be initialized to zero in the main program. The location of the initializing statement is important and depends on the results desired. If it is desired to have different sets of random numbers for each of several different sets of computations (jobs) that are run sequentially on the same program, then the argument must be initialized at the very beginning of the program and never reinitialized. If it is permissible to use the same sequence of random numbers for each job, the argument must be initialized at the beginning of each job. The advantage of this latter option occurs when one of the jobs must be re-run for some minor reason as the same random numbers will be used and the results will be comparable.

Three constants must be computed by the following equations:

Constant one (C1) = $2^{(B+1)/2} + 3$

Constant two (C2) = $2^{B} - 1$

Constant three (C3) = $1./2.^{B}$

Where: B = number of bits in an integer word

The constants for some of the common computers are listed in the following table:

COMPUTER	SIZE OF INTEGER WORD	CONSTANTS C1	C2	C3
GE 200 Series	19	1027	524287	0.190734863E-05

EXHIBIT 5

DEFINITIONS 723-X6-L7350

AA(I)	- First half of description for duration I
AB(I)	- Second half
ABS	- Computer library function for absolute value of number
ALOG	- Computer library function for natural logarithm
ANYR(I,K)	- Number of years of data for station K and duration I
ANYRS	- Number of years of data in study
AV(I,K)	- Mean logarithm (or sum of logarithms) for station K and duration I
AVGSK	- Average regional skew coefficient
B(K)	- Regression coefficient for variable (K)
BB	- Regression coefficient
BC	- Regression coefficient
BLANK	- Symbol to identify recorded data
CB	- Regression constant
CC	- Regression constant
CROUT	- Program subroutine to solve simultaneous equations
DQ(I,K)	- Increment added to all flows for duration I at station K to preclude infinite negative logarithms
DTRMC	- Multiple determination coefficient
E	- Symbol to identify reconstituted data
I	- Index for duration
IA	- Indicator in column 1 of first card for each job
ICORL	- Indicator, when positive calls for computation of correlation coefficients
ICSE	- Indicator, case number specifing cause for no independent variables in estimation equation +1 indicates no flows found for correlation +2 indicates all correlations were zero
II	- Index associated with I
INCAD	- Indicator, positive value calls for adjustment of increment to reduce skew coefficient
INDC	- Indicator positive when correlation coefficient has been changed
IPCHQ	- Indicator, when positive calls for punching recorded and reconstituted flows
IPCHS	- Indicator, when positive calls for punching statistics
IPREV	- Order number in regression equation of adjacent duration
IRCRD(J)	- Indicator blank when no record at all stations in year J
IRATO	- Indicator, when positive calls for reading conversion ratios
ISKEW	- Indicator when positive calls for reading skew coefficients

ISTA(K) - Identification number for station K
ISTAN - Station number
ISTN - Array of station sequence by length of record; longest record first
ISTY - Array of station record lengths used to build ISTN array
ITEMP - Temporary variable
ITMP - Temporary variable
ITP - Temporary variable
IX - Index associated with I
IXX - Argument for random number function
IYR - Year number
IYRA - Number of earliest year of record
J - Year index
JA - Index associated with J
JX - Index associated with J
K - Station index
KDUR - Dimension limit for durations
KEEP - Number stations to keep from immediately previous job
KEPT(K) - Station numbers kept from immediately previous job
KRCRD - Indicator, when positive a complete record exists for all stations
KSTA - Dimension limit for stations
KX - Index associated with K
KYRS - Dimension limit for years
L - Subordinate station index
LA - Index associated with L
LTRA - Letter A for testing IA
LX - Index associated with L
M - Sequence index
MM - Index associated with M
N - Temporary counter
NCAB(I,K) - Number of cross products for station K and duration I
NDUR - Number of durations in study
NINDP - Number of independent variables in correlation
NLOG(I,K) - Number of values for station K and duration I
NSMTH - Indicator, zero or positive value causes smoothing of statistics
NSTA - Number of stations in study
NSTAT - Number of stations for which statistics (instead of flows) are supplied
NSTAX - Twice NSTA
NSTXX - Number of stations kept from previous job incremented by 1
NVAR - Total number of variables in correlation
NYDIF - Indicator, when positive a difference in record length exists between new data and data from previous job
NYRS - Number of years in study

P(I) - Exceedence frequency coordinate or ratio to convert flows to average rates
PLTT(J) - Plotting position for event number J
Q(M,K) - Flow or logarithm for station K and sequence number M
QM(I) - Flow for current station and year and for duration I
QR(M,K) - Indicator whether Q(M,K) is recorded or reconstituted
R(K,K+1) - Covariance array for multiple regression equation
RA(I,K,L) - Correlation between stations K and L for duration I
RMAX - Maximum consistent correlation coefficient
RMIN - Minimum consistent correlation coefficient
SA - Sum of mean logarithms for various durations
SAA - Sum of squares of mean logarithms
SAB - Sum of cross products of mean logarithm and standard deviation
SAC - Sum of cross products of mean logarithm and skew coefficient
SB - Sum of standard deviations for various durations
SC - Sum of skew coefficients for various durations
SD(I,K) - Standard deviation (or sum of squares) for station K and duration I
SDA - Standard deviation of short record station
SDB - Standard deviation of long record station
SIN - Computer library function for sine
SKEW(I,K) - Skew coefficient (or sum of cubes) for station K and duration I
SKW(I) - Specified skew coefficient for duration I at all stations
SQA(I,K) - Sum of squares of logarithms in correlation for station K and duration I
SQB(I,K) - Sum of squares of logarithms at related station in correlation with station K for duration I
SUMA(I,K) - Sum of logarithms in correlation for station K and duration I
SUMB(I,K) - Sum of logarithms at related station in correlation with station K for duration I
T - Large number denoting missing record
TEMP - Temporary variable
TMP - Temporary variable
TMPA - Temporary variable
TMPB - Temporary variable
TMPP - Temporary variable
TP - Temporary variable
X(K) - Independent variable related to station K
XINCR(I,K) - Increment for DQ in skew coefficient adjustment routine
XPAB(I,K) - Sum of cross products of logarithms for station K with related station for duration I
XQ(I) - Temporary flow array

EXHIBIT 6

EXHIBIT 7

INPUT DATA

A Three title cards, first must have an A in column 1

B Specification card

1. NDUR - Number of durations, dimensioned for 8.
2. IYRA - Earliest year of record at any station, dimensional for 100 years (NYRS) and NYRS times NDUR (B-1) dimensioned for 400.
3. ISKEW - Indicator, positive value calls for reading skew coefficients for region.
4. KEEP - Number of stations to keep from the immediately preceding job, dimensioned for 10.
5. ICONV - Indicator, positive value calls for reading factors to convert volumes to average flow rates.
6. IPCHQ - Indicator, positive value calls for punching recorded and reconstituted flows on cards.
7. IPCHS - Indicator, positive value calls for punching statistics on cards.
8. NSTAT - Number of stations for which statistics are to be read in, leave blank if statistics are to be computed, no limit on number.
9. NSMTH - Indicator, blank or positive value causes smoothing of statistics.
10. INCAD - Indicator, positive value calls for adjustment of increment to reduce skew coefficient. DO NOT use routinely as frequency curves will be biased.

C Duration description card

1. AAAB - Title of duration such as "PEAK" or "1-DAY," NDUR(B1) items

D Skew coefficients, omit if ISKEW (B3) is not positive

1. SKW - Regional skew coefficient for each successive duration, NDUR(B1) items

E Stations kept, omit if KEEP(B4) is not positive

1. KEPT - Station number (ISTA) of station in preceeding job, KEEP(B4) items. Should be listed in same order as appearing in previous job.

F Conversion factor, omit if ICONV(B5) is not positive

1. P - Factor by which flows for each successive duration are divided to convert to average rate of flow, NDUR(B1) items

G Data cards, omit if NSTAT(B8) is positive

1. ISTA - Station number, limited to five digits
2. IYR - Year number
3. QM - Flow, NDUR(B1) items, -1 indicates missing record. If record for entire year is missing, omit card for that year.

H Card blank after Col 1 to indicate end of flow data, omit if NSTAT(B8) is positive.

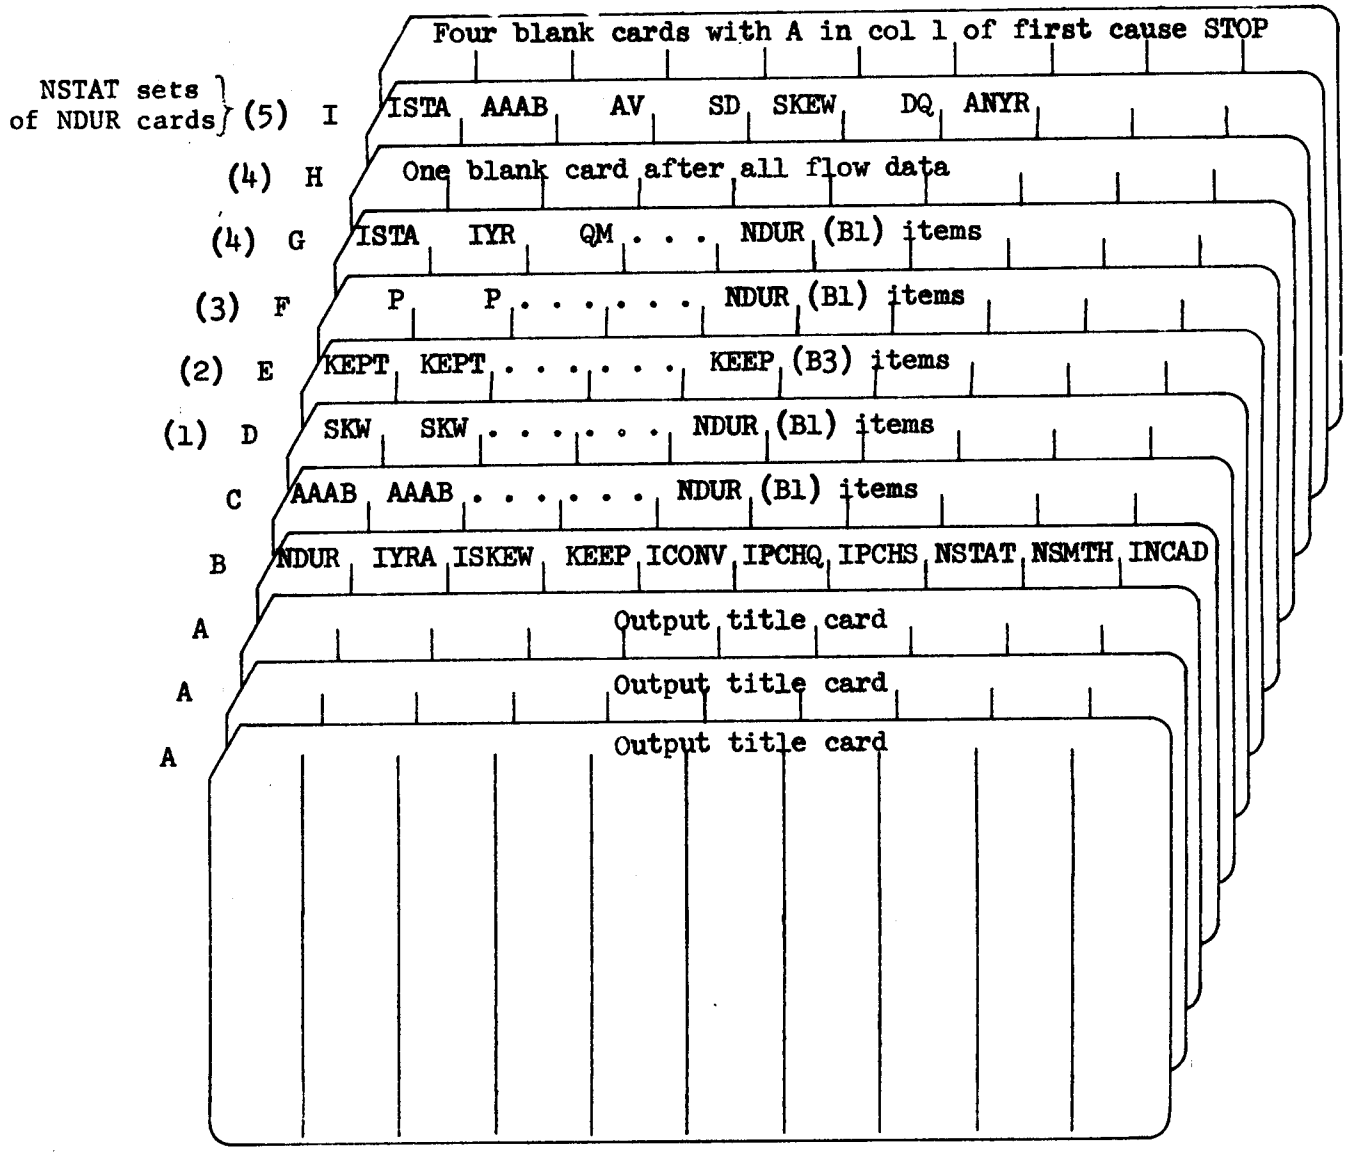
I Input statistics, omit if NSTAT(B8) is not positive. Supply NDUR(B1) cards for each station and data for NSTAT (B8) stations. The order of the durations must be maintained for all stations.

1. ISTA - Station number, limited to five digits.
2. AAAB - Title of duration (see C card.)
3. AV - Mean logarithm for given station and duration
4. SD - Standard deviation of logarithms.
5. SKEW - Skew coefficient of logarithms.
6. DQ - Increment added to flows before statistics were computed.
7. ANYR - Number of years of equivalent record.

Four blank cards with A in Col 1 of the first after the last job will cause a normal stop.

SUMMARY OF REQUIRED CARDS

723-X6-L7350



Notes

(1) Omit if ISKEW (B3) is not positive.
(2) Omit if KEEP (B4) is not positive.
(3) Omit if ICONV (B5) is not positive.
(4) Omit if NSTAT (B8) is positive.
(5) Omit if NSTAT (B8) is not positive.
