169

170 **P.1 MOTIVATION AND GUIDANCE FOR USING THIS SYNTHESIS AND**

171 **ASSESSMENT PRODUCT**

172 The core mission of the U.S. Climate Change Science Program (CCSP) is to “Facilitate

173 the creation and application of knowledge of the Earth’s global environment through

174 research, observations, decision support, and communication”. To accomplish this goal,

175 the CCSP has commissioned 21 Synthesis and Assessment Products to summarize

176 current knowledge and evaluate the extent and development of this knowledge for future

177 scientific explorations and policy planning.

178

179 These Products fall within five goals, namely:

180 1) Improve knowledge of the Earth's past and present climate and environment,

181 including its natural variability, and improve understanding of the causes of

182 observed variability and change;

- 183 2) Improve quantification of the forces bringing about changes in the Earth's climate
184 and related systems;
- 185 3) Reduce uncertainty in projections of how the Earth's climate and environmental
186 systems may change in the future;
- 187 4) Understand the sensitivity and adaptability of different natural and managed
188 ecosystems and human systems to climate and related global changes; and
- 189 5) Explore the uses and identify the limits of evolving knowledge to manage risks
190 and opportunities related to climate variability and change.

191

192 CCSP Synthesis and Assessment Product 5.3 is one of three products to be developed for
193 the final goal.

194

195 This Product directly addresses decision support experiments and evaluations that have
196 used seasonal to interannual forecasts and observational data, and is expected to inform
197 (1) decision makers about the experiences of others who have experimented with these
198 forecasts and data in resource management; (2) climatologists, hydrologists, and social
199 scientists on how to advance the delivery of decision-support resources that use the most
200 recent forecast products, methodologies, and tools; and (3) science and resource
201 managers as they plan for future investments in research related to forecasts and their role
202 in decision support.

203

204 **P.2 BACKGROUND**

205 Gaining a better understanding of how to provide better decision support to decision and

206 policy makers is of prime importance to the CCSP, and it has put considerable effort and
207 resources towards achieving this goal. For example, within its Strategic Plan, the CCSP
208 identifies decision support as one of its four core approaches to achieving its mission¹.
209 The plan endorses the transfer of knowledge gained from science in a format that is
210 usable and understandable, and indicates levels of uncertainty and confidence. CCSP
211 expects that the resulting tools will promote the development of new models, tools, and
212 methods that will improve current economic and policy analyses as well as advance
213 environmental management and decision making.
214
215 CCSP has also encouraged the authors of the 21 Synthesis and Assessment Products to
216 support informed decision making on climate variability and change. Most of the
217 Synthesis and Assessment Products' Prospectuses have outlined efforts to involve
218 decision makers, including a broad group of stakeholders, policy makers, resource
219 managers, media, and the general public, as either writers or as special workshop/meeting
220 participants. Inclusion of decision makers in the Synthesis and Assessment Products also
221 helps to fulfill the requirements of the Global Change Research Act (GCRA) of 1990
222 (P.L. 101-606, section 106), which directs the program to "produce information readily
223 usable by policymakers attempting to formulate effective strategies for preventing,
224 mitigating, and adapting to the effects of global change" and to undertake periodic
225 science "assessments."
226

¹ The four core approaches of CCSP include science, observations, decision support, and communications.

227 In November 2005, the CCSP held a workshop to address the potential of those working
228 in the climate sciences to inform decision and policy makers. The workshop included
229 discussions about decision-maker needs for scientific information on climate variability
230 and change. It also addressed future steps, including the completion of this and other
231 Synthesis and Assessment Products, for research and assessment activities that are
232 necessary for sound resource management, adaptive planning, and policy formulation.
233 The audience included representatives from academia; governments at the state, local,
234 and national levels; non-governmental organizations (NGOs); decision makers, including
235 resource managers and policy developers; members of Congress; and the private sector.
236

237 **P.3 FOCUS OF THIS SYNTHESIS AND ASSESSMENT PRODUCT**

238 In response to the 2003 Strategic Plan for the Climate Change Science Program Office,
239 which recommended the creation of a series of Synthesis and Assessment Product
240 reports, the National Oceanic and Atmospheric Administration (NOAA) took
241 responsibility for this Product. An interagency group comprised of representatives from
242 NOAA, National Aeronautics and Space Administration, U.S. Environmental Protection
243 Agency, U.S. Geological Survey and National Science Foundation wrote the Prospectus²
244 for this Product and recommended that this Synthesis and Assessment Product should
245 concentrate on the water resource management sector. This committee felt that focusing
246 on a single sector would allow for a detailed synthesis of lessons learned in decision-
247 support experiments within that sector. These lessons, in turn, would be relevant,
248 transferable, and essential to other climate-sensitive resource management sectors. Water

² The Prospectus is posted on the Climate Change Science Program website at:
<http://www.climatechange.gov>.

249 resource management was selected, as it was the most relevant of the sectors proposed
 250 and would be of interest to all agencies participating in this process. The group wrote a
 251 Prospectus and posed a series of questions that they felt the CCSP 5.3 Product authors
 252 should address in this Report. Table P.1 lists these questions and provides the location
 253 within the Synthesis and Assessment Product where the authors addressed them.

254

255 **Table P.1 Questions To Be Addressed in Synthesis and Assessment Product 5.3**

Prospectus Question	Product Location where Question is Addressed
What are the seasonal to interannual (e.g., probabilistic) forecast information do decision makers need to manage water resources?	2.1
What are the seasonal to interannual forecast and data products currently available, and how does a product evolve from a scientific prototype to an operational product?	2.2
What is the level of confidence of the product within the scientific community and within the decision-making community? Who establishes these confidence levels, and how are they determined?	2.2
How do forecasters convey information on climate variability and how is the relative skill and level of confidence of the results communicated to resource managers?	2.3
What is the role of probabilistic forecast information in the context of decision support in the water resources sector?	2.3
How is data quality controlled?	2.3
What steps are taken to ensure that this product is needed and will be used in decision support?	2.5
What types of decisions are made that are related to water resources?	3.2
What is the role that seasonal to interannual forecasts play and could play?	3.2
How does climate variability influence water resource management?	3.2
What are the obstacles and challenges decision makers face in translating climate forecasts and hydrology information into integrated resource management?	3.2
What are the barriers that exist in convincing decision makers to consider using risk-based hydrology information (including climate forecasts)?	3.2
What challenges do tool developers have in finding out the needs of decision makers?	3.3
How much involvement do practitioners have in product development?	4.1
What are the measurable indicators of progress in terms of access to information and its effective uses?	4.3
What are the critical components, mechanisms, and pathways that have led to successful utilization of climate information by water	4.4

managers?	
What are the options for improving the use of existing forecasts and data products, and for identifying other user needs and challenges in order to prioritize research for improving forecasts and products?	4.4 and 5
How can these findings can be transferred to other sectors?	5

256

257 **P.4 THE SYNTHESIS AND ASSESSMENT WRITING TEAM**

258 This study required an interdisciplinary team that was able to integrate scientific
 259 understandings about forecast and data products with a working knowledge of the needs
 260 of water resource managers in decision making. As a result, the team included
 261 researchers, decision makers, and federal government employees with varied
 262 backgrounds in the social sciences, physical sciences, and law. The authors were
 263 identified based on a variety of considerations, including their past interests and
 264 involvements with decision-support experiments and their knowledge of the field as
 265 demonstrated by practice and/or involvement in research and/or publications in refereed
 266 journals. In addition, the authors held a public meeting, in January 2007, in which they
 267 invited key stakeholders to discuss their decision support experiments with the
 268 committee. Working with authors and stakeholders with such varied backgrounds
 269 presented some unique challenges including preconceived notions of other disciplines, as
 270 well as the realization that individual words have different meanings in the diverse
 271 disciplines. For example, those with a physical science background understood a more
 272 quantifiable definition for the words ‘confidence’ and ‘uncertainty’ than the more
 273 qualitative (i.e., behavioral) view of the social scientists.

274

275 The author team for this Product was constituted as a Federal Advisory Committee in
 276 accordance with the Federal Advisory Committee Act of 1972 as amended, 5 U.S.C.

277 App.2. The full list of the author team, in addition to a list of lead authors provided at the
278 beginning of each Chapter, is provided on page 3 of this Report. The editorial staff
279 reviewed the scientific and technical input and managed the assembly, formatting, and
280 preparation of the Product.
281

282 **Executive Summary**

283

284 **Convening Lead Author:** Helen Ingram, Univ. of Arizona

285

286 **Lead Authors:** David Feldman, Univ. of California, Irvine; Nathan Mantua, Climate

287 Impacts Group, Univ. of Washington; Katharine L. Jacobs, Arizona Water Institute;

288 Denise Fort, Univ. of New Mexico

289

290 **Contributing Author:** Nancy Beller-Simms, NOAA

291

292 **Editor:** Anne M. Waple, STG, Inc.

293

294 **ES.1 WHAT IS DECISION SUPPORT AND WHY IS IT NECESSARY?**

295 Earth's climate is naturally varying and also changing in response to human activity. Our

296 ability to adapt and respond to climate variability and change depends, in large part, on

297 our understanding of the climate and how to incorporate this understanding into our

298 resource management decisions. Water resources, in particular, are directly dependent on

299 the abundance of rain and snow, and how we store and use the amount of water available.

300 With an increasing population, a changing climate, and the expansion of human activity

301 into semi-arid regions of the United States, water management has unique and evolving

302 challenges. This Product focuses on the connection between the scientific ability to

303 predict climate on seasonal scales and the opportunity to incorporate such understanding

304 into water resource management decisions. Reducing our societal vulnerability to

305 changes in climate depends upon our ability to bridge the gap between climate science
306 and the implementation of scientific understanding in our management of critical
307 resources, arguably the most important of which is water. It is important to note,
308 however, that while the focus of this Product is on the water resources management
309 sector, the findings within this Synthesis and Assessment Product may be directly
310 transferred to other sectors.

311

312 The ability to predict many aspects of climate and hydrologic variability on seasonal to
313 interannual time scales is a significant success in Earth systems science. Connecting the
314 improved understanding of this variability to water resources management is a complex
315 and evolving challenge. While much progress has been made, conveying climate and
316 hydrologic forecasts in a form useful to real world decision making introduces
317 complications that call upon the skills of not only climate scientists, hydrologists, and
318 water resources experts, but also social scientists with the capacity to understand and
319 work within the dynamic boundaries of organizational and social change.

320

321 Up until recent years, the provision of climate and hydrologic forecast products has been
322 a producer-driven rather than a user-driven process. The momentum in product
323 development has been largely skill-based rather than a response to demand from water
324 managers. It is now widely accepted that there is considerable potential for increasing the
325 use and utility of climate information for decision support in water resources
326 management even without improving the skill level of climate and hydrologic forecasts.
327 The outcomes of “experiments” intended to deliver climate-related decision support

328 through “knowledge-to-action networks” in water resource related problems are
329 encouraging.

330

331 Linkages between climate and hydrologic scientists are getting stronger as they now more
332 frequently collaborate to create forecast products. A number of complex factors influence
333 the rate at which seasonal water supply forecasts and climate-driven hydrologic forecasts
334 are improving in terms of skill level. Mismatches between needs and information
335 resources continue to occur at multiple levels and scales. Currently, there is substantial
336 tension between providing tools at the space and time scales useful for water resources
337 decisions that are also scientifically accurate, reliable, and timely.

338

339 The concept of *decision support* has evolved over time. Early in the development of
340 climate information tools, decision support meant the translation and delivery of climate
341 science information into forms believed to be useful to decision makers. With experience,
342 it became clear that climate scientists often did not know what kind of information would
343 be useful to decision makers. Further, decision makers who had never really considered
344 the possibility of using climate information were not yet in a position to articulate what
345 they needed. It became obvious that user groups had to be involved at the point at which
346 climate information began to be developed. Making climate science useful to decision
347 makers involves a process in which climate scientists, hydrologists, and the potential
348 users of their products engage in an interactive dialogue during which trust and
349 confidence is built at the same time that climate information is exchanged.

350

351 The institutional framework in which decision-support experiments are developed has
352 important effects. Currently there is a disconnect between agency-led operational
353 forecasts and experimental hydrologic forecasts being carried out in universities.
354 However, as shown by the experiments highlighted in this Product, it is possible to
355 develop decision-support tools, processes and institutions that are relevant to different
356 geographical scales and are sufficiently flexible to serve a diverse body of users. Such
357 tools and processes can reveal commonalities of interests and shared vulnerabilities that
358 are otherwise obscure. Well-designed tools, institutions, and processes can clarify
359 necessary trade-offs of short- and long-term gains and losses to potentially competing
360 values associated with water allocation and management.

361

362 Evidence suggests that many of the most successful applications of climate information
363 to water resource problems occur when committed leaders are poised and ready to take
364 advantage of unexpected opportunities. In evaluating the ways in which science-based
365 climate information is finding its way to users, it is important to recognize that
366 straightforward, goal-driven processes do not characterize the real world. We usually
367 think of planning and innovation as a linear process, but experience shows us that, in
368 practice, it is a nonlinear, chaotic process with emergent properties. This is particularly
369 true when working with climate impacts and resource management. It is clear that we
370 must address problems in new ways and understand how to encourage diffusion of
371 innovations.

372

373 The building of knowledge networks is a valuable way to provide decision support and
374 pursue strategies to put knowledge to use. Knowledge networks require widespread,
375 sustained human efforts that persist through time. Collaboration and adaptive
376 management efforts among resource managers and forecast producers with different
377 missions show that mutual learning informed by climate information can occur between
378 scientists with different disciplinary backgrounds and between scientists and managers.
379 The benefits of such linkages and relationships are much greater than the costs incurred
380 to create and maintain them, however, the opportunities to build these associations are
381 often neglected or discouraged. Collaborations across organizational, professional,
382 disciplinary, and other boundaries are often not given high priority; incentives and reward
383 structures need to change to take advantage of these opportunities. In addition, the
384 problem of data overload for people at critical junctions of information networks, and for
385 people in decision-making capacity such as those of resource managers and climate
386 scientists, is a serious impediment to innovation.

387

388 Decision-support experiments employing climate related information have had varying
389 levels of success in integrating their findings with the needs of water and other resource
390 managers.

391

392 **ES.2 CLIMATE AND HYDROLOGIC FORECASTS: THE BASIS FOR MAKING**
393 **INFORMED DECISIONS**

394 There are a wide variety of climate and hydrologic data and forecast products currently
395 available for use by decision makers in the water resources sector. However, the use of

396 official seasonal to interannual (SI) climate and hydrologic forecasts generated by federal
397 agencies remains limited in this sector. Forecast skill, while recognized as just one of the
398 barriers to the use of seasonal to interannual climate forecast information, remains a
399 primary concern among forecast producers and users. Simply put, there is no incentive to
400 use SI climate forecasts when they are believed to provide little additional skill to
401 existing hydrologic and water resource forecast approaches (described in Chapter 2). Not
402 surprisingly, there is much interest in improving the skill of hydrologic and water
403 resources forecasts. Such improvements can be realized by pursuing several research
404 pathways, including:

- 405 • Improved monitoring and assimilation of real-time hydrologic observations in
406 land surface hydrologic models that leads to improved estimates for initial
407 hydrologic states in forecast models;
- 408 • Increased accuracy in SI climate forecasts; and
- 409 • Improved bias corrections in existing forecasts.

410

411 Another aspect of forecasts that serves to limit their use and utility is the challenge in
412 interpreting forecast information. For example, from a forecast producer's perspective,
413 confidence levels are explicitly and quantitatively conveyed by the range of possibilities
414 described in probabilistic forecasts. From a forecast user's perspective, probabilistic
415 forecasts are not always well understood or correctly interpreted. Although structured
416 user testing is known to be an effective product development tool, it is rarely done.
417 Evaluation should be an integral part of improving forecasting efforts, but that evaluation
418 should be extended to factors that encompass use and utility of forecast information for

419 stakeholders. In particular, very little research is done on effective seasonal to interannual
420 forecast communication. Instead, users are commonly engaged only near the end of the
421 product development process.

422

423 Other barriers to the use of SI climate forecasts in water resources management have
424 been identified and those that relate to institutional issues and aspects of current forecast
425 products are discussed in Chapters 3 and 4 of this Product.

426

427 Pathways for expanding the use and improving the utility of data and forecast products to
428 support decision making in the water resources sector are currently being pursued at a
429 variety of spatial and jurisdictional scales in the United States. These efforts include:

- 430 • An increased focus on developing forecast evaluation tools that provide users
431 with opportunities to better understand forecast products in terms of their
432 expected skill and applicability;
- 433 • Additional efforts to explicitly and quantitatively link SI climate forecast
434 information with SI hydrologic and water supply forecasting efforts;
- 435 • An increased focus on developing new internet-based tools for accessing and
436 customizing data and forecast products to support hydrologic forecasting and
437 water resources decision making (*e.g.*, the Advanced Hydrologic Prediction
438 Service (AHPS) described in Chapters 2 and 3); and
- 439 • Further improvements in the skill of hydrologic and water supply forecasts.

440

441 Many of these pathways are currently being pursued by the federal agencies charged with
442 producing the official climate and hydrologic forecast and data products for the United
443 States, but there is substantial room for increasing these activities.

444

445 Recent improvements in the use and utility of data and forecast products related to water
446 resources decision making have come with an increased emphasis on these issues in
447 research funding agencies through programs like the National Oceanic and Atmospheric
448 Administration's Regional Integrated Sciences and Assessments (RISA), Sectoral
449 Applications Research Program (SARP), Transition of Research Applications to Climate
450 Services (TRACS) and Climate Prediction Program for the Americas (CPPA) and the
451 World Climate Research Programme's Global Energy and Water Cycle Experiment
452 (GEWEX) programs. Sustaining and accelerating future improvements in the use and
453 utility of official data and forecast products in the water resources sector rests in part on
454 sustaining and expanding federal support for programs focused on improving the skill in
455 forecasts, increasing the access to data and forecast products, identifying processes that
456 influence the creation of knowledge-to-action networks for making climate information
457 useful for decision making, and fostering sustained interactions between forecast
458 producers and consumers.

459

460 **ES.3 DECISION-SUPPORT EXPERIMENTS IN THE WATER RESOURCE**
461 **SECTOR**

462 Decision-support experiments that test the utility of SI information for use by water
463 resource decision makers have resulted in a growing set of successful applications.

464 However, there is significant opportunity for expansion of applications of climate-related
465 data and decision-support tools, and for developing more regional and local tools that
466 support management decisions within watersheds. Among the constraints that limit tool
467 use are:

- 468 • The range and complexity of water resources decisions. This is compounded by
469 the numerous organizations responsible for making these decisions and the shared
470 responsibility for implementing them.
- 471 • Inflexible policies and organizational rules that inhibit innovation. Government
472 agencies historically have been reluctant to change practices, in part because of
473 value differences, risk aversion, fragmentation and sharing of authority. This
474 conservatism impacts how decisions are made as well as whether to use newer,
475 scientifically generated information, including SI forecasts and observational data.
- 476 • Different spatial and temporal frames for decisions. Spatial scales for decision
477 making range from local, state, and national levels to international. Temporal
478 scales range from hours to multiple decades impacting policy, operational
479 planning, operational management, and near real-time operational decisions.
480 Resource managers often make multi-dimensional decisions spanning various
481 spatial and temporal frames.
- 482 • Lack of appreciation of the magnitude of potential vulnerability to climate
483 impacts. Communication of the risks differs among scientific, political, and mass
484 media elites, each systematically selecting aspects of these issues that are most
485 salient to their conception of risk, and thus, socially constructing and
486 communicating its aspects most salient to a particular perspective.

487

488 Decision-support systems are not often well integrated into planning and management
489 activities, making it difficult to realize the full benefits of these tools. Because use of
490 many climate products requires special training or access to data that are not readily
491 available, decision-support products may not equitably reach all audiences. Moreover,
492 over-specialization and narrow disciplinary perspectives make it difficult for information
493 providers, decision makers, and the public to communicate with one another. Three
494 lessons stem from this:

- 495 • Decision makers need to understand the types of predictions that can be made,
496 and the tradeoffs between longer-term predictions of information at the local or
497 regional scale on one hand, and potential decreases in accuracy on the other.
- 498 • Decision makers and scientists need to work together in formulating research
499 questions relevant to the spatial and temporal scale of problems the former
500 manage.
- 501 • Scientists should aim to generate findings that are accessible and viewed as
502 useful, accurate, and trustworthy by stakeholders.

503

504 **ES.4 MAKING DECISION-SUPPORT INFORMATION USEFUL, USEABLE,**
505 **AND RESPONSIVE TO DECISION-MAKER NEEDS**

506 Decision-support experiments that apply SI climate variability information to basin and
507 regional water resource problems serve as test beds that address diverse issues faced by
508 decision makers and scientists. They illustrate how to articulate user needs, overcome

509 communication barriers, and operationalize forecast tools. They also demonstrate how
510 user participation can be incorporated in tool development.

511

512 Five major lessons emerge from these experiments and supporting analytical studies:

- 513 • The effective integration of SI climate information in decisions requires long-term
514 collaborative research and application of decision support through identifying
515 problems of mutual interest. This collaboration will require a critical mass of
516 scientists and decision makers to succeed, and there is currently an insufficient
517 number of “integrators” of climate information for specific applications.
- 518 • Investments in long-term research-based relationships between scientists and
519 decision makers must be adequately funded and supported. In general, progress
520 on developing effective decision-support systems is dependent on additional
521 public and private resources to facilitate better networking among decision
522 makers and scientists at all levels as well as public engagement in the fabric of
523 decision making.
- 524 • Effective decision-support tools must wed national production of data and
525 technologies to ensure efficient, cross-sector usefulness with customized products
526 for local users. This requires that tool developers engage a wide range of
527 participants, including those who generate tools and those who translate them, to
528 ensure that specially-tailored products are widely accessible and are immediately
529 adopted by users insuring relevancy and utility.
- 530 • The process of tool development must be inclusive, interdisciplinary, and provide
531 ample dialogue among researchers and users. To achieve this inclusive process,

532 professional reward systems that recognize people who develop, use, and translate
533 such systems for use by others are needed within management and related
534 agencies, universities, and organizations. Critical to this effort, further progress in
535 boundary spanning—the effort to translate tools to a variety of audiences—
536 requires considerable organizational skills.

537 • Information generated by decision-support tools must be implementable in the
538 short term for users to foresee progress and support further tool development.
539 Thus, efforts must be made to effectively integrate public concerns and elicit
540 public information through dedicated outreach programs.

541

542 **ES.5 LOOKING TOWARD THE FUTURE; RESEARCH PRIORITIES**

543 A few central themes emerge from this Product, and are summarized in this section. Key
544 research priorities are also highlighted.

545

546 **ES.5.1 Key Themes**

547 *1) The “Loading Dock Model” of Information Transfer is Unworkable.*

548 Skill is a necessary ingredient in perceived forecast value, yet more forecast skill by itself
549 does not imply more forecast value. Lack of forecast skill and/or accuracy may be one of
550 the impediments to forecast use, but there are many other barriers as well. Such
551 improvements must be accompanied by better communication and stronger linkages
552 between forecasters and potential users. In this Product, we have stressed that forecasts
553 flow through knowledge networks and across disciplinary and occupational boundaries.

554 Thus, forecasts need to be useful and relevant in the full range from observations to
555 applications, or “end-to-end useful”.

556

557 *2) Decision Support is a Process Rather Than a Product.*

558 As knowledge systems have come to be better understood, providing decision support has
559 come to be understood not as information products but as a communications process that
560 links scientists with users.

561

562 *3) Equity May Not Be Served.*

563 Information is power in global society and, unless it is widely shared, the gaps between
564 the rich and the poor, and the advantaged and disadvantaged may widen.

565

566 *4) Science Citizenship Plays an Important Role in Developing Appropriate Solutions.*

567 A new paradigm in science is emerging, one that emphasizes science-society
568 collaboration and production of knowledge tailored more closely to society’s decision-
569 making needs. Concerns about climate impacts on water resource management are among
570 the most pressing problems that require close collaboration between scientists and
571 decision makers.

572

573 *5) Trends and Reforms in Water Resources Provide New Perspectives.*

574 Some researchers suggest that, since the 1980s, a “new paradigm” or frame for federal
575 water planning has occurred, although no clear change in law has brought this change
576 about. This new paradigm appears to reflect the ascendancy of an environmental

577 protection ethic among the general public. The new paradigm emphasizes greater
578 stakeholder participation in decision making; explicit commitment to environmentally-
579 sound, socially-just outcomes; greater reliance upon drainage basins as planning units;
580 program management via spatial and managerial flexibility, collaboration, participation,
581 and sound, peer-reviewed science; and, embracing of ecological, economic, and equity
582 considerations.

583

584 *6) Useful Evaluation of Applications of Climate Variation Forecasts Requires Innovative*
585 *Approaches.*

586 There can be little argument that SI forecast applications must be evaluated just as most
587 other programs that involve substantial public expenditures are assessed. This Product
588 illustrates many of the difficulties of using standard evaluation techniques.

589

590 **ES.5.2 Research Priorities**

591 As a result of the findings in this Product, we suggest that a number of research priorities
592 should constitute the focus of attention for the foreseeable future. These priorities are:

- 593 • Improved vulnerability assessment;
- 594 • Improved climate and hydrologic forecasts;
- 595 • Enhanced monitoring to better link climate and hydrologic forecasts;
- 596 • Better integration of SI climate science into decision making;
- 597 • Better balance between physical science and social science research related to the
598 use of scientific information in decision making;

- 599 • Better understanding of the implications of small-scale, specially-tailored tools;
- 600 and
- 601 • Sustained long-term scientist-decision-maker interactions and collaborations and
- 602 development of science citizenship and production of knowledge tailored more
- 603 closely to society’s decision-making needs.

604 **Chapter 1. The Changing Context**

605

606 **Convening Lead Author:** Helen Ingram, Univ. of Arizona

607

608 **Lead Authors:** David Feldman, Univ. of California, Irvine; Nathan Mantua, Climate

609 Impacts Group, Univ. of Washington; Katharine L. Jacobs, Arizona Water Institute;

610 Denise Fort, Univ. of New Mexico

611

612 **Contributing Author:** Nancy Beller-Simms, NOAA

613

614 **Edited by:** Anne M. Waple, STG Inc.

615

616 **1.1 INTRODUCTION**

617 Increasingly frequent headlines such as “UN Calls Water Top Priority” (*The Washington*

618 *Post, January 25, 2008*), “Drought-Stricken South Facing Tough Choices” (*The New*

619 *York Times, Oct 15, 2007*), and “The Future is Drying Up” (*The New York Times,*

620 *October 21, 2007*), coupled with the realities of less-available water, have alerted

621 decision makers, from governors and mayors to individual farmers, that climate

622 information is crucial for future planning. Over the past quarter-century, there have been

623 significant advances in the ability to monitor and predict important aspects of seasonal to

624 interannual (SI) variations in climate, especially those associated with variations of the El

625 Niño Southern Oscillation (ENSO) cycle. Predictions of climate variability on SI time

626 scales are now routine and operational, and consideration of these forecasts in making

627 decisions has become more commonplace. Some water resources decision makers have
628 already begun to use seasonal, interseasonal, and even longer time scale climate forecasts
629 and observational data to assess future options, while others are just beginning to realize
630 the potential of these resources. This Product is designed to show how climate and
631 hydrologic forecast and observational data are being used or neglected by water resources
632 decision makers and to suggest future pathways for increased use of this data.

633

634 The Climate Change Science Program (CCSP) included a chapter in its 2003 Strategic
635 Plan that described the critical role of decision support in climate science; previous
636 assessment analyses and case studies have highlighted the importance of assuring that
637 climate information and data would be used by decision makers and not be produced
638 without knowledge of its application. Since that time, there has been increased interest
639 and research in decision-support science focused on organizations using SI forecasts and
640 observational data in future planning. Since the release of the 2003 Strategic Plan, one of
641 the main purposes of CCSP continues to be to “provide information for decision-making
642 through the development of decision-support resources (CCSP, 2008³)”. As a result,
643 CCSP has charged this author group to produce a Synthesis and Assessment Product
644 (SAP) that directly addresses decision-support experiments and evaluations in the water
645 resources sector. This is that Product.

646

647 The authors of this Product concentrated their efforts on discussing SI forecasts and data
648 products. In some cases, however, longer-range forecasts are discussed because they have

³ According to this same document, “Decision-support resources, systems, and activities are climate-related products or processes that directly inform or advise stakeholders to help them make decisions.”

649 become a part of the context for decision-making processes. We provided a range of
650 domestic case study examples, referred to as “experiments and/or evaluations”, and have
651 also provided some international examples, where appropriate.

652

653 **1.2 INCREASING STRESS AND COMPLEXITY IN WATER RESOURCES**

654 Under global warming conditions and an accelerating demand for abundant water
655 supplies, water management may become an increasingly politically charged issue
656 throughout the world in the coming century. Emerging challenges in water quantity,
657 quality, pricing, and water management in relation to seasonal climate fluctuations may
658 increase as the demand for water continues to rise. Though the total volume of water on
659 the planet may be sufficient for societal needs, the largest portion of this water is
660 geographically remote, misallocated, wasted, or degraded by pollution (Whiteley *et al.*,
661 2008). At the same time, there are shifts in water usage, the societal value of natural
662 water systems, and the laws that govern management of this resource. Accordingly, the
663 impact of climate on water resource management has far-reaching implications for
664 everyone, from the farmer who may need to change the timing of crop
665 planting/harvesting or the crop type itself, to citizens who may have to relocate because
666 their potable water supply has disappeared.

667

668 In the United States, water resource decisions are made at multiple levels of government
669 and, increasingly, by the private sector. There is no national water policy, but rather a
670 patchwork of policies, changed to various degrees over decades. Water is controlled,
671 guided, governed, or measured by a gamut of federal agencies that oversee various

672 aspects from quality (*e.g.*, U.S. Environmental Protection Agency [EPA]) to quantity
673 (*e.g.*, U.S. Geological Survey [USGS], Bureau of Reclamation [Reclamation], and U.S.
674 Army Corps of Engineers [USACE]). This is complicated by state, regional, and
675 jurisdictional boundaries and responsibilities. Defining a “decision maker” is equally
676 difficult given the complexity of water’s use and the types of information that can be
677 used to make decisions. Our challenge in writing this Product is to reflect the various
678 models under which water is managed and the diverse character of decisions that
679 comprise water management. To illustrate, the term “water management” encompasses
680 decisions made by: a municipal water entity regarding when to impose outdoor water
681 restrictions; a federal agency regarding how to operate a storage facility; the United
682 States Congress regarding funding of recovery efforts for an endangered species; and by
683 state governments regarding water purchases necessary to ensure compliance with
684 negotiated compacts.

685

686 These types of decisions may be based on multiple factors, such as cost, climate (past
687 trends and future projections), community preferences, political advantage, and strategic
688 concerns for future water decisions. Further, water is associated with many different
689 values including economic security, opportunity, environmental quality, lifestyle, and a
690 sense of place (Blatter and Ingram, 2001). Information about climate variability can be
691 expected to affect some of these decisions and modify some of these values. For other
692 decisions, it may be of remote interest or viewed as entirely irrelevant. For instance, the
693 association of access to water with respect to economic security is relatively fixed while

694 the association of water to lifestyle choices such as a preference for water-based sports
695 may vary with additional information about variability in climate.

696

697 The rapidly-closing gap between usable supplies and rising demand is being narrowed by
698 a myriad of factors, including, but not limited to:

699 • Increasing demand for water with population growth in terms of potable drinking
700 water, agricultural/food requirements, and energy needs.

701 • Greater political power of recreational and environmental interests that insist on
702 minimum instream flows in rivers.

703 • Groundwater reserves where development enabled the expansion of agriculture in
704 the western United States and is the basis for the development of several urban
705 regions. As groundwater reserves are depleted, pressure increases on other water
706 sources.

707 • Water quality problems that persist in many places, despite decades of regulations
708 and planning.

709

710 The best-documented pressure is population growth, which is occurring in the United
711 States as a whole, and especially in the South and Southwest regions where water
712 resources are also among the scarcest. Water rights are afforded to the earliest users in
713 many states, and new users without senior rights often must search for additional
714 supplies. Las Vegas, Nevada is a case study of the measures required to provide water in
715 the desert, but Phoenix, Albuquerque, Denver, Los Angeles and a host of other western
716 cities provide comparable examples. In the southeastern United States, rapid population

717 growth in cities (*e.g.*, Atlanta), combined with poor management and growing
718 environmental concerns that require water to sustain fish and wildlife habitats, have led to
719 serious shortages.

720

721 Recreational and environmental interests also have a direct stake in how waters are
722 managed. For example, fishing and boating have increased in importance in recent
723 decades as recreational uses have expanded and the economic basis of our economy has
724 shifted from manufacturing to service.

725

726 Groundwater mining is a wild card in national water policy. Water resource allocation is
727 generally a matter of state, not federal, control, and states have different policies with
728 respect to groundwater. Some have no regulation; others permit mining (also referred to
729 as groundwater overdrafting). Because groundwater is not visible and its movement is not
730 well understood, its use is less likely to be regulated than surface water use. The effects
731 of groundwater mining become evident not only in dewatering streams, but also impact
732 regions that must search for alternative sources of water when sources diminish or
733 disappear.

734

735 Increasing demands for water are not likely to lead to the development of major
736 additional water sources, although additional storage will probably be developed. The
737 United States engaged in an extended period of big dam and aqueduct construction
738 (Worster, 1985) in which most of the appropriate construction sites were utilized.
739 Further, as rivers are fully appropriated, or over appropriated, there is no longer “surplus”

740 water available for development. Environmental and recreational issues are impacted by
741 further development of rivers, making additional water projects more difficult.

742

743 In response to these challenges, jurisdictions are developing alternatives such as water
744 reuse; utilizing groundwater storage and recovery, which avoids reservoir siting issues;
745 improved efficiency, which has contributed to steady declines in per capita consumption;
746 desalinization of water to expand usable supplies; and conjunctive management of
747 ground and surface water. Issues can arise between jurisdictions, however. For example,
748 pipelines, which have been used for decades, are suggested as the solution to one region's
749 water shortages, only to be met by resistance from the area of origin.

750

751 The most politically appealing water management solutions are often the most modest.
752 Water conservation, which may rely on incentives or regulation, is often the least
753 expensive way of meeting demand but is not always well received. Water pricing has
754 been heralded by generations of economists as the means of ensuring that water choices
755 are made wisely, but regulating demand through higher water rates is not a guaranteed
756 formula for success. Transfers of water from one use to another, from agricultural to
757 urban uses in parts of the western United States for example, are becoming more
758 common as a means of adjusting to changing economic realities. However, these modest
759 solutions that have led to more efficient water allocation have also reduced the ability to
760 adapt to climate variation because wasteful and discretionary uses that are easy to alter
761 have already been changed.

762

763 Water usage may also be examined by the relative flexibility of each demand. Municipal
764 and industrial demands can be moderated through conservation or temporary restrictions,
765 but these demands are less elastic than agricultural use. Agricultural uses, which
766 comprise the largest users by volume, can be restricted in times of drought without major
767 economic dislocations if properly implemented; however, the increasing connection
768 between water and energy may limit this flexibility. Greater reliance on biofuels both
769 increases competition for scarce water supplies and diverts irrigated agriculture from the
770 production of food to the production of oilseeds such as soybeans, corn, rapeseed,
771 sunflower seed, and sugarcane, among other crops used for biofuel. This changes the
772 pattern of agricultural water use in the United States (Whiteley *et al.*, 2008).

773

774 The rationalization of U.S. policies concerning water has been a goal for many decades.
775 Emergent issues of increased climate variability and change may be the agents of
776 transformation for United States water policies as many regions of the country are forced
777 to examine the long term sustainability of water related management decisions (NRC,
778 1999b, Jacobs and Holway, 2004).

779

780 **1.2.1 The Evolving Context: The Importance of Issue Frames**

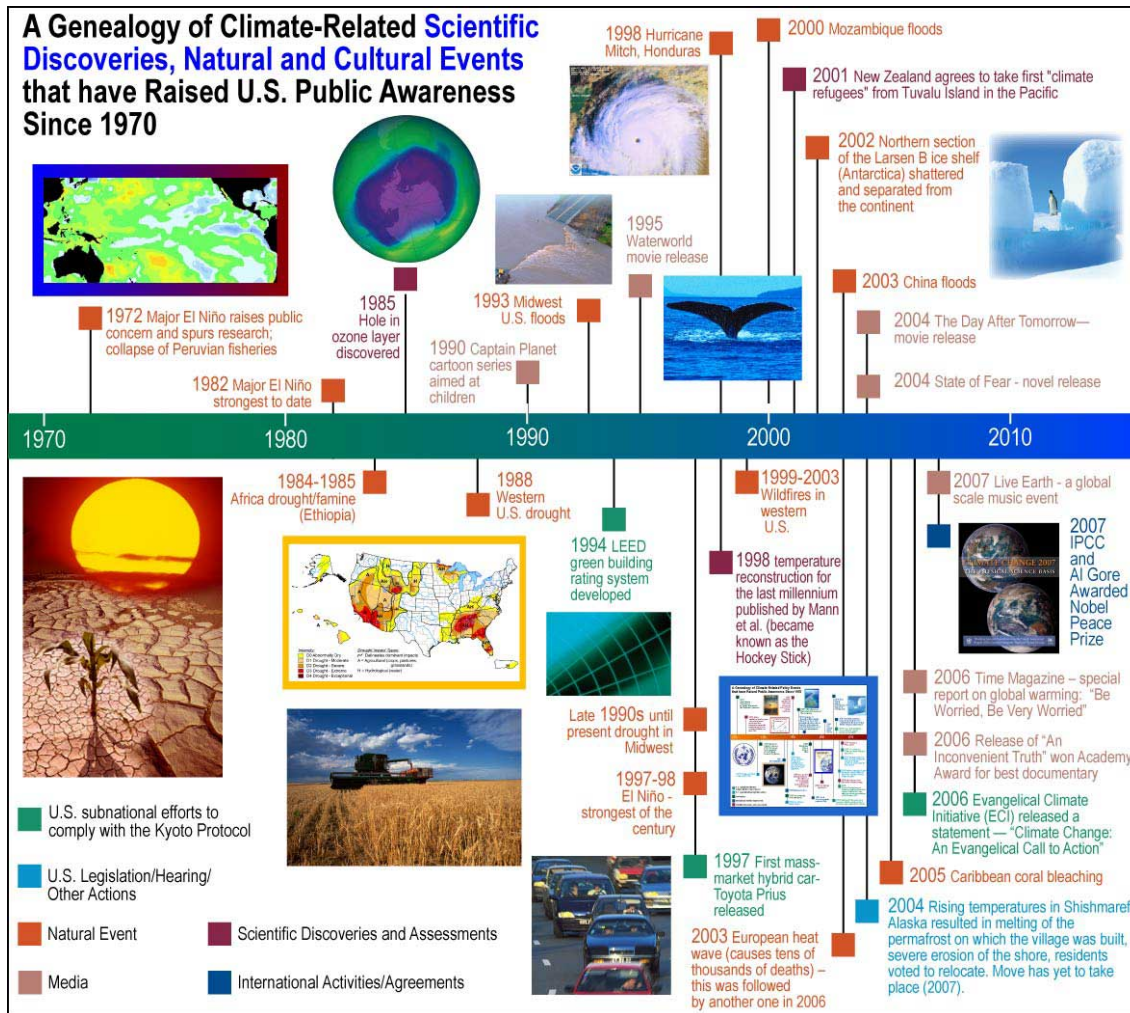

781 In order to fully understand the context in which a decision is made, those in the decision
782 support sciences often look at the “issue frame” or the factors influencing the decision
783 makers, including society’s general frame of mind at the time. A common denominator
784 for conceptualizing a frame is the notion that a problem can be understood or
785 conceptualized in different ways (Dewulf *et al.*, 2005). For the purpose of this Product,

786 an issue frame can be considered a tool that allows us to understand the importance of a
787 problem (Weick, 1995). Thus, salience is an important part of framing. Historically low
788 public engagement in water resource decisions was associated with the widespread
789 perception that the adequate delivery of good quality water is within the realm of experts.
790 Further, the necessary understanding and contribution to decisions takes time,
791 commitment, and knowledge that few possess or seek to acquire as water appears to be
792 plentiful and is available when needed. It was understood that considerable variations in
793 water supply and quality can occur, but it was accepted that water resource managers
794 know how to handle variation.

795

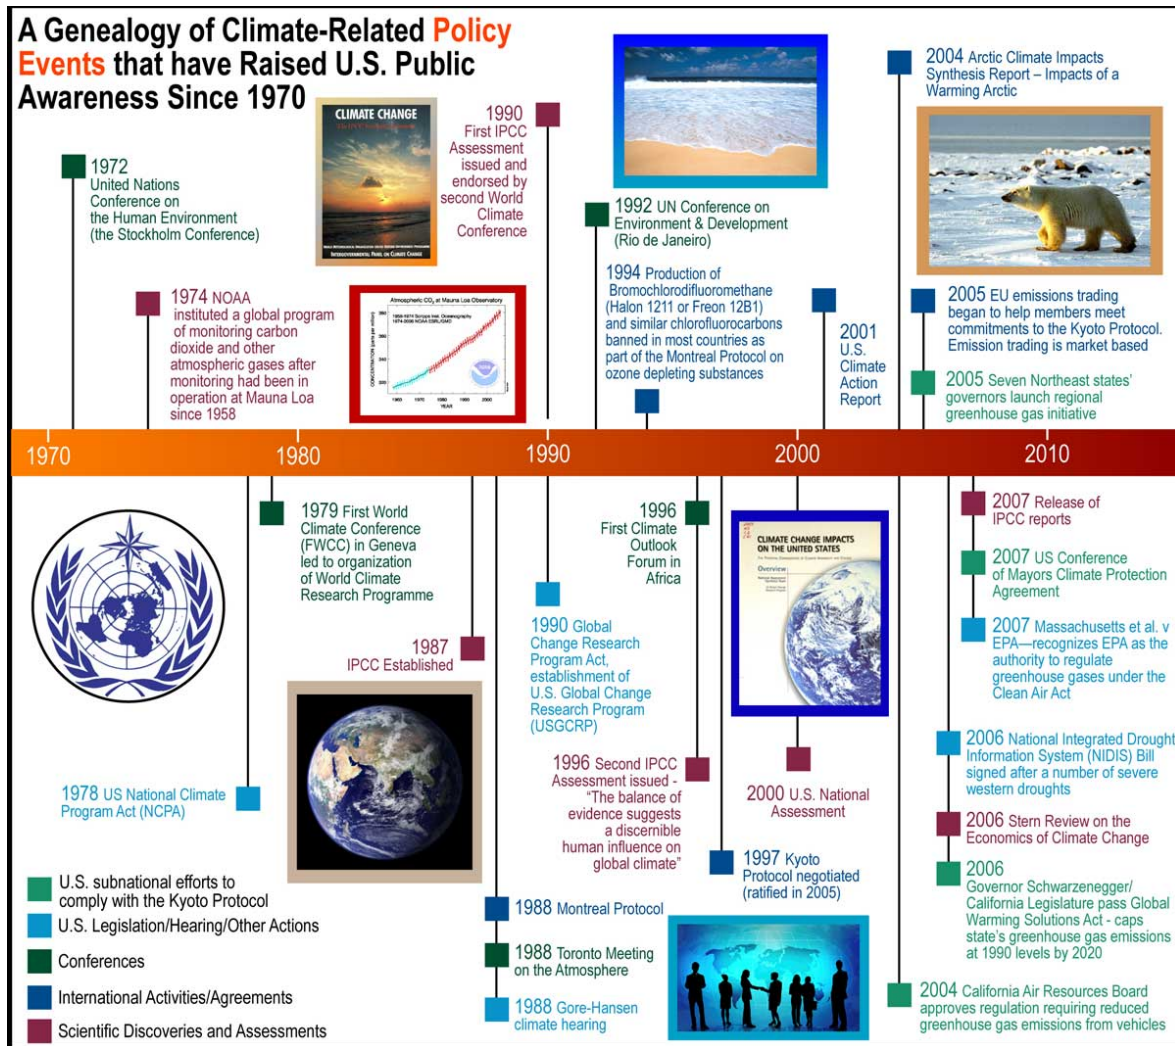

796 A series of events and disclosures of scientific findings have profoundly changed the
797 framing of water issues and the interaction between such framing and climate variability
798 and change. As illustrated in Figure 1.1, natural disasters, including Hurricane Katrina
799 and recent sustained droughts in the United States, have raised awareness of society's
800 vulnerability to flood, drought, and degradation of water quality. Such extreme events
801 occur as mounting evidence indicates that water quantity and quality, fundamental
802 components of ecological sustainability in many geographical areas, are threatened (*e.g.*,
803 deVilliers, 2003). The February 2007 Intergovernmental Panel on Climate Change,
804 Working Group 1, Fourth Assessment Report (IPCC, 2007a) reinforced the high
805 probability of significant future climate change and more extreme climate variation,
806 which is expected to affect many sectors, including water resources. The Report received
807 considerable press coverage and generated increased awareness among the public and
808 policy makers. Instead of being a low visibility issue, the issue frame for water resources

809 has become that of attention-grabbing risk and uncertainty about such matters as rising
 810 sea levels, altered water storage in snow packs, and less favorable habitats for endangered
 811 fish species sensitive to warmer water temperatures. Thus, the effects of global warming
 812 have been an emerging issue-frame for water resources management.

813

814 **Figure 1.1** Timeline from 1970 to present of key natural and cultural events contributing to a widespread
 815 change in context for increasing awareness of climate issues
 816

817

818 **Figure 1.2** Timeline from 1970 to present of key policy events contributing to a widespread change in
 819 context for increasing awareness of climate issues

820

821 Along with greater visibility of water and climate issues has come greater political and
 822 public involvement. At the same time, with an increase in discovery and awareness of
 823 climate impacts, there has been a deluge of policy actions in the form of new reports and
 824 passage of climate-related agreements and legislation (see Figure 1.2). As is the case with
 825 many high profile issues, politicians often try to compete with one another to gain status
 826 as policy leaders who facilitate governmental and private actions to reduce societal
 827 vulnerability to climate related variability. Higher visibility of climate and water

828 variability has put pressure on water managers to be proactive in response to expected
829 negative effects of climate variability and change (Hartmann, *et al.*, 2002; Carbone and
830 Dow, 2005). Specifically, in the case of water managers in the United States, perception
831 of risk has been found to be a critical variable for the adoption of innovative management
832 in the sector (O'Connor *et al.*, 2005).

833

834 Frames encompass expectations about what can happen and what should be done if
835 certain predicted events do occur (Minsky, 1980). The emergent issue frame for water
836 resource management is that new knowledge (about climate change and variability) is
837 being created that warrants management changes. Information and knowledge about
838 climate variability experienced in the recent historical past is no longer as valuable as
839 once it was, and new knowledge must be pursued (Milly *et al.*, 2008). Organizations and
840 individuals face a context today where perceived failure to respond to climate variation
841 and change is more risky than maintaining the status quo.

842

843 **1.2.2 Climate Forecasting Innovations and Opportunities in Water Resources**

844 Only in the last decade or so have climate scientists have become able to predict aspects
845 of future climate variations one to a few seasons in advance with better forecast skill than
846 can be achieved by simply using historical averages for those seasons. This is a
847 fundamentally new scientific advance (NRC, 2008).

848

849 **BOX 1.1 Seasonal to Interannual Climate Forecasts**

850 *Weather forecasts* seek to predict the exact state of the atmosphere for a specific time and place at lead-
851 times ranging from nowcasts (*e.g.*, severe weather warnings) out to a maximum of two weeks.
852 Observations that can be used to accurately characterize the initial state of the atmosphere are crucial to the
853 accuracy of these short-term weather forecasts.. In contrast, seasonal to interannual *climate forecasts* seek

854 to predict the statistics of the atmosphere for a region over a specified window of time, typically from one
855 month to a few seasons in advance.

856
857 Observations of the slowly varying boundary conditions on the atmosphere, including upper ocean
858 temperatures, snow cover, and soil moisture are critical to the accuracy of climate forecasts. Climate
859 forecasts can also address the expected probabilities for extreme events (floods, freezes, blizzards,
860 hurricanes, *etc.*), and the expected range of climate variability. Much of the skill in seasonal to interannual
861 climate forecasts for the United States derives from an ability to monitor and accurately predict the future
862 evolution of ENSO, however, the actual skill demonstrated is not yet high. As a general principle, all
863 climate forecasts are probabilistic. They are probabilistic both in the future state of ENSO and in the
864 consequences of ENSO for remotely influenced regions like the United States. For example, a typical
865 ENSO-related climate forecast for the Pacific Northwest region of the United States might be presented as
866 follows:

867

868 *Based on expectations for continued El Niño conditions in the tropical*
869 *Pacific, we expect increased likelihoods for above average winter and*
870 *spring temperatures with below average precipitation, with small but*
871 *non-zero odds for the opposite conditions (i.e., below average*
872 *likelihoods for below average winter and spring temperatures and*
873 *above average precipitation) in the Pacific Northwest (PNW).*

874

875 At lead times of a few decades to centuries, *climate change scenarios* are based on
876 scenarios for changes in the emissions and concentrations of atmospheric greenhouse
877 gases and aerosols that are important for the Earth's energy budget. Climate change
878 scenarios do not require real-time observations needed to accurately initialize the
879 atmosphere or slowly-evolving boundary conditions (upper ocean temperatures, snow
880 cover, *etc.*). However, a recent study by Keenleyside *et al.* (2008) demonstrates that there
881 is potential for improving the forecast skill in decadal climate predictions made within
882 longer-term climate change scenarios by initializing global climate models with ocean
883 observations.

884 ******END BOX******

885

886 It is important to emphasize that SI climate forecasting skill is still quite limited, and
887 varies considerably depending on lead time, geographic scale, target region, time of year,
888 status of the ENSO cycle, and many other issues that are addressed in Chapter 2. Despite
889 that, the potential usefulness of this new scientific capability is enormous, particularly in
890 the water resources sector. This potential is being harvested through a variety of
891 experiments and evaluations, some of which appear in this Product. For instance,
892 reservoir management changes in the Columbia River Basin in response to SI climate
893 forecast information have the potential to generate an average of \$150 million per year
894 more hydropower with little or no loss to other management objectives (Hamlet *et al.*,

895 2002). Table 1.1 illuminates the potential of SI climate forecasts to influence a wide
 896 range of water-related decisions, potentially providing great economic, security,
 897 environmental quality, and other gains.

898

899 **Table 1.1 Examples of water resource decisions related to seasonal to interannual climate forecasts.**

Decision/topic	Agency/organization Responsible	Activities Affected	Climate Forecast Information Relevance
Dam and reservoir management and reservoir allocation	<ul style="list-style-type: none"> • U.S. Army Corps of Engineers • U.S. DOI*, Bureau of Reclamation • Tennessee Valley Authority • FERC* and its licensed projects • Federal power marketing agencies • State, local, regional water management entities and utilities, irrigation districts 	Distribution of inflows and outflows for: <ul style="list-style-type: none"> • agriculture • public supply • industry • power • flood control • navigation • instream flow maintenance • protecting reserved waters for resources/ other needs 	<ul style="list-style-type: none"> • Total reservoir inflow • Long-range precipitation • Long-range temperature • Flow data • Snow melt data • Flood forecasts • Shifts in “phase” in decadal cycles
Irrigation/water allocation for agriculture/aquaculture	<ul style="list-style-type: none"> • Federal, state and regional facility operators • Irrigation districts • Agricultural cooperatives • Farmers 	How much water and when and where to allocate it	<ul style="list-style-type: none"> • Long/short-range precipitation • Long-range temperature

 901 DOC: Department of Commerce; DOI: Department of the Interior; FERC: Federal Energy Regulatory
 902 Commission; NMFS: National Marine Fisheries Service.
 903

904 Aside from the potential applications suggested in Table 1.1, there are other overarching
 905 opportunities for use of SI climate and hydrologic forecasts recently introduced to the
 906 water resources sector. Adaptive Management and Integrated Water Resources
 907 Management are examples of reforms that are still in relative infancy (discussed in
 908 further detail in Chapters 3 and 4) but could gain considerable momentum through

909 fostering continuous feedback from forecasts to changes in practice and improved
910 performance. Adaptive management embraces the need for continuous monitoring and
911 feedback. Information provided by forecasts can prompt real time adaptations by public
912 and private agencies and water users (NRC 2004). Integrated Water Resources
913 Management provides a more holistic view of water supply or demand and is based
914 around the concepts of flexibility and adaptability, using measures that can be easily
915 reversed or are robust under changing circumstances (IPCC, 2007b). Such potential
916 flexibility and adaptability extends not only to water agencies, but also to the general
917 public. Advances in climate forecast skills and their applications provide an opportunity
918 to give the public a deeper understanding about the relationship of climate variability to
919 increased risk, vulnerability, and uncertainty related to water that now tends to be
920 perceived in terms of a replication of the past. In addition, tuning water management
921 more closely to real time climate prediction allows for reducing the lead time for
922 response to climate variation.

923

924 **1.2.3 Organizational Dynamics and Innovation**

925 The flow of information among agencies and actors in the complex organizational fields
926 of climate forecasting and water resources is not always effective. Even as skill levels of
927 climate and hydrologic forecasts have improved, resistance to their use in water resources
928 management both exists and persists (O'Conner *et al.*, 1999; Rayner *et al.*, 2005; Yarnal
929 *et al.*, 2006). Such resistance to innovation is to be expected, according to organizational
930 and management literature that addresses the management of information across
931 boundaries of various kinds that include organizations, disciplines, fields, and practices

932 (Carlile, 2004; Feldman *et al.*, 2006). The same specialization that makes organizations
933 effective in meeting internal organizational goals can make them resistant to innovation
934 (Weber, 1947). Creating a product or service requires experience, terminologies, tools,
935 and incentives that are embedded in a specific organization. Because knowledge requires
936 time, resource, and opportunity cost investments, it constitutes a kind of “stake,” and
937 therefore significant costs are associated with acquiring new knowledge across
938 boundaries (Carlile, 2002). Further, if the kind of knowledge that needs to be coordinated
939 across boundaries is so different that a bridge of a common language must be created to
940 allow translation, then the barriers are more difficult to overcome. Finally, demands made
941 by sharing information across boundaries may be so novel that an organization must
942 make a fundamental readjustment that challenges everything it knows.

943

944 Figure 1.3, adapted from Carlile (2004), depicts the challenges that must be addressed in
945 order to share knowledge across boundaries, and conveys the challenge of innovation
946 through information sharing across different organizations, levels of government, and
947 public and private sectors. The lowest level of the inverted triangle shows information
948 transfer is relatively simple between climate forecasters from different organizations.
949 Forecasters generally share common knowledge, and know each others’ language and
950 levels of expertise regardless of organizational ties. Because a common lexicon exists,
951 knowledge transfer is relatively simple. The usual barriers to smooth information flow
952 apply, including information overload, availability of storage and retrieval technologies
953 and other information processing challenges. Unfortunately, because agencies tend to
954 prefer their own terminology and trust information that comes from inside the

955 organization more than information from outside, the adoption of SI climate forecast
956 information in the water resource sector rarely fits this simple transfer profile.

957

958 At the second, or translation, level of information management, language issues become
959 problematic and development of shared information is more difficult. This level of
960 information sharing typifies the relationships between climate forecasters and water
961 resource forecasters who have long predicted water futures using data such as snowpack,
962 soil moisture, and basin and watershed models. Efforts to communicate at this level
963 involve a large expenditure of effort that must be justified within the organization and
964 may encounter resistance unless offset by some considerable worthwhile pay-off.

965 Successful efforts for communication could include the creation of a lexicon with
966 common definitions, the development of shared methodologies, the formulation of cross-
967 organizational teams, the engagement in strategies such as collocation of offices, and the
968 employment of individuals who can act as translators or brokers.

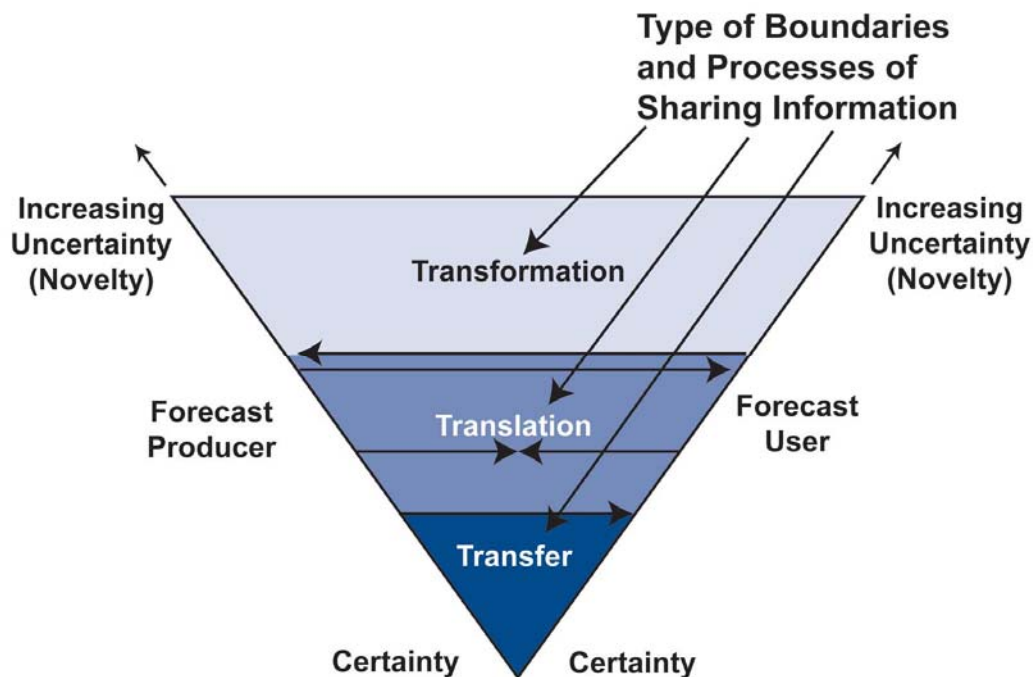

969

970 The third, or transformation, level of managing information requires considerable change
971 in the ways in which organizations presently process and use information. Currently,
972 climate forecasters tend to follow what has been termed the “loading dock” model, or
973 simply issuing forecasts with little notion of whether they will be used by other
974 organizations (Cash *et al.*, 2005). Knowledge at this third level (ultimately at all levels)
975 must be created collaboratively, that is, coproduced with outside organizations, interests
976 and entities, rather than delivered and must be clear, credible and legitimate to all
977 engaged actors. Information is likely to be more salient if it comes from known and

978 trusted sources (NRC, 1984, 1989, 2008). Credibility is not just credibility of scientists,
 979 but also to users; information is more credible if it recognizes and addresses multiple
 980 perspectives. Legitimacy relates to even-handedness and the absence of narrow
 981 organizational or political agendas (Cash *et al.*, 2003; NRC, 2007, 2008). Almost all of
 982 the important applications of SI climate forecasts involve information management at the
 983 third level.

984

985

986

987

988 **Figure 1.3** Illustration of information sharing processes. At the tip of the triangle forecast producers and
 989 forecast users are sharing a common syntax and framework, and therefore knowledge is simply transferred.
 990 As the products and uses become increasingly different and novel, a process of learning has to occur for
 991 information to be translated (middle of inverted triangle). Finally, information will need to be transformed
 992 in order for knowledge to be accessible to very different parties (top of the inverted triangle). Adapted from
 993 Carlile, 2004
 994

995 **1.2.4 Decision Support, Knowledge Networks, Boundary Organizations, and**
996 **Boundary Objects**

997 A recent National Academy of Sciences Report (2008) observed that decision support is
998 widely used but definitions of what constitutes that support vary. Following the lead of
999 this Product, decision support is defined here as creating conditions that foster the
1000 appropriate use of information. This definition presumes that the climate scientists who
1001 generate SI climate forecasts often do not know what type of useful information they
1002 could provide to water resources managers, and that water managers do not necessarily
1003 know how they could apply SI climate forecasts and related information (NAS, 2008).
1004 The primary objective of decision-support activities is to foster transformative
1005 information exchange that will both change the kind of information that is produced and
1006 the way it is used (NRC 1989, 1996, 1999a, 2005, 2006, 2008).

1007

1008 Decision support involves engaging effective two-way communication between the
1009 producers and users of climate information (Jacobs *et al.*, 2005; Lemos and Morehouse,
1010 2005; NRC, 1999a, 2006) rather than just the development of tools and products that may
1011 also be useful though less functional. This conception of decision support brings into
1012 focus human relationships and networks in information utilization. The test of
1013 transformed information is that it is trusted and considered reliable, and is fostered by
1014 familiarity and repeated interaction between information collaborators and the working
1015 and reworking of relationships. A knowledge network is built through such human
1016 interactions across organizational boundaries, creating and conveying information that is
1017 useful for all participants, ranging from scientists to multiple decision makers.

1018

1019 A variety of mechanisms can be employed to foster the creation of knowledge networks
1020 and the coproduction of knowledge that transcends what is already available. Among
1021 such mechanisms are boundary organizations that play an intermediary role between
1022 different organizations, specializations, disciplines, practices, and functions including
1023 science and policy (Cash, 2001; Guston, 2001). These organizations can play a variety of
1024 roles in decision support, such as convening together, collaboration among users and
1025 producers, mediation for the various parties and the production of boundary objects. A
1026 boundary object is a prototype, model or other artifact through which collaboration can
1027 occur across different kinds of boundaries. Collaborative participants may come to
1028 appreciate the contribution of other kinds of knowledge, perspectives, expertise or
1029 practices and how they may augment or modify their own knowledge through
1030 engagement (Star and Griesemer, 1989). For example, a fish ladder is a kind of boundary
1031 object since it is an add-on to a dam structure. It must be integrated into the structural
1032 design, so hydrologists and engineers must collaborate on design decisions. At the same
1033 time, it serves fish species, so the insight of biologists about fish behavior is necessary for
1034 the ladder to work as it is intended.

1035

1036 **1.3 OUTLINE OF THE PRODUCT AND WHERE PROSPECTUS QUESTIONS**
1037 **ARE ADDRESSED**

1038 This chapter addresses the types of SI forecast-related decisions that are made in the
1039 water resources community and the role that such forecasts could play. It describes the

1040 general contextual opportunities and limitations to innovations that could limit the use of
1041 SI forecast information.

1042

1043 Chapter 2 answers the question: What are SI forecast products and how do they evolve
1044 from a scientific prototype to an operational product? It also addresses the issue of
1045 forecast skill, the impediments to progress in improving skill, and the steps necessary to
1046 ensure a product is needed and will be used in decision support. It describes the level of
1047 confidence about SI forecast products in the science and decision-making communities.

1048

1049 Chapter 3 focuses on the obstacles, impediments, and challenges in fostering close
1050 collaboration between scientists and decision makers in terms of theory and observation.
1051 Researchers have documented why and how resource decision makers use information;
1052 Chapter 3 addresses the following kinds of questions: How are hazards and risks related
1053 to climate variability perceived and managed? What are the challenges related to
1054 determining and serving the needs of decision makers, emphasizing the importance of
1055 reliability and trust, and suggesting how decision support could leverage scientific and
1056 technological advances?

1057

1058 Chapter 4 provides examples of a range of decision support experiments in the context of
1059 SI forecast information. It describes the limitations on the kinds of information available
1060 and the need to employ logical inference. It also discusses how decision support tools can
1061 be improved.

1062

1063 Chapter 5 provides a summary of this Product, especially identifying overarching themes.
 1064 It suggests the kinds of research and action needed to improve progress in this area.
 1065 Finally, it addresses how the knowledge gained in water resources might be useful to
 1066 other sectors.

1067

1068 The prospectus for this study contained a series of questions that were to direct this study,
 1069 vetted by the Climate Change Science Program office and by public review. Table 1.2
 1070 summarizes the questions and specifies which Chapter section they are addressed. Table
 1071 1.3 is a summary of the case studies provided in this Product.

1072

1073

1074

1075

1076

Table 1.2 Questions To Be Addressed in Synthesis and Assessment Product 5.3

Question	Product Location where Question is Addressed
What seasonal to interannual (<i>e.g.</i> , probabilistic) forecast information do decision makers need to manage water resources?	2.1
What are the seasonal to interannual forecast/data products currently available and how does a product evolve from a scientific prototype to an operational product?	2.2
What is the level of confidence of the product within the science community and within the decision-making community, who establishes these confidence levels and how are they determined?	2.2
How do forecasters convey information on climate variability and how is the relative skill and level of confidence of the results communicated to resource managers?	2.3
What is the role of probabilistic forecast information in the context of decision support in the water resources sector?	2.3
How is data quality controlled?	2.3
What steps are taken to ensure that this product is needed and will be used in decision support?	2.5
What types of decisions are made related to water resources?	3.2
What is the role that seasonal to interannual forecasts play and could play?	3.2
How does climate variability influence water resource management?	3.2
What are the obstacles and challenges decision makers face in translating climate forecasts and hydrology information into	3.2

integrated resource management?	
What are the barriers that exist in convincing decision makers to consider using risk-based hydrology information (including climate forecasts)?	3.2
What challenges do tool developers have in finding out the needs of decision makers?	3.3
How much involvement do practitioners have in product development?	4.1
What are the measurable indicators of progress in terms of access to information and its effective uses?	4.3
Identify critical components, mechanisms, and pathways that have led to successful utilization of climate information by water managers.	4.4
Discuss options for (a) improving the use of existing forecasts/data products and (b) identify other user needs and challenges in order to prioritize research for improving forecasts and products.	4.4 and 5
Discuss how these findings can be transferred to other sectors.	5

1078

1079

1080

1081

Table 1.3 Summary of Case Studies (i.e., Experiments and Evaluations) presented in this Product.

Study or Experiment	Chapter	Type of Decision Support Information Needed, Used or Delivered	Most Successful Feature(s) or Lesson(s) Learned from Case Study
CPC Seasonal Drought Outlook (DO)	2, Box 2.3	DO is a monthly subjective consensus forecast between several agencies and academic experts, of drought evolution for three months following the forecast date.	Primary drought-related agency forecast produced in US; widely used by drought management and response community from local to regional scales. Research is ongoing for product improvements.
Testbeds	2, Box 2.4	Testbeds are mix of research and operations, serve as conduit between operational, academic and research communities. NOAA currently operates several testbeds (e.g., Hazardous Weather, Climate and Hurricanes).	Testbeds focus on introducing new ideas and data to the existing system and analyzing the results through experimentation and demonstration. Satisfaction with testbeds has been high for operational and research participants alike.
Advanced Hydrologic Prediction Service (AHPS)	2, Box 2.5;3, Section 3.3.1.2	AHPS provides data quicker and at smaller scale (i.e., local watershed) than previous hydrographic models; directly links to local decision makers.	More accurate, detailed, and visually oriented outputs provide longer-range forecasts than current methods. Also includes a survey process and outreach, training, and educational activities.
NWS Local 3-Month Outlook for Temp & Precip (L3MO)	2, Box 2.6	Designed to clarify and downscale the national-scale CPC Climate Outlook temperature forecast product.	Outlook is new; it became operational in January 2007. The corresponding local product for precipitation is still in development as of this writing.
Southwest drought –	3, Section 3.2.3.2	Regional studies of: associations between ENSO	New Mexico and Arizona developed first drought plans; Colorado River Basin water managers have

climate variability, vulnerability & water management		teleconnections, multi-decadal variations in Pacific Ocean-atmosphere system, and regional climate show potential predictability of seasonal climate and hydrology.	commissioned tree-ring reconstructions of streamflow to revise estimates of record droughts, and to improve streamflow forecast performance
Red River of the North – Flooding and Water Management	3, Section 3.2.4	Model outputs to better use seasonal precipitation, snowmelt, etc. are being used in operations decisions; however, the 1997 floods resulted in \$4B in losses. The River crested 5 feet over the flood height predicted by the NCRFC ⁴ ; public blamed NWS for a faulty forecast.	Need for (1) improved forecasts (e.g., using recent data in flood rating curves, real-time forecasting); (2) better forecast communication (e.g., warnings when rating curve may be exceeded and including user feedback in improved forecast communication); and (3) more studies (e.g., reviewing data for future events).
Credibility and the Use of Climate Forecasts: Yakima River Basin /El Niño	3, Section 3.2.4	In 1977, USBR ⁵ issued a faulty forecast for summer runoff to be below an established threshold. Result was increased animosity between water rights holders, loss of confidence in USBR, lawsuits against USBR.	Need for: greater transparency in forecast methods (including issuing forecast confidence limits), better communication between agencies and the public, and consideration of consequences of actions taken by users in the event of a bad forecast.
Credibility and the Use of Climate Forecasts: Colorado Basin Case Studies	3, Section 3.2.4	In 1977, the USBR issued a forecast, based on snowpack, for summer runoff to be below the legally established threshold, resulting in jeopardized water possibilities for junior water rights holders.	Greater transparency in forecast methods (e.g., issuing forecast confidence limits, better communication between agencies and the public, and consideration of users' actions in the event of a bad forecast), would have improved the forecast value and the actions taken by the USBR.
Southeast Drought: Another Perspective on Water Problems in the Southeastern United States	3, Section 3.3.1	A lack of tropical storms/hurricanes and societal influences such as laws, institutions, policies, procedures, precedents and regulations influenced the 2007-2008 Southeast Drought resulting in impacts to agriculture, fisheries, and municipal water supplies.	Impacts exacerbated by (1) little action on river basin compacts between GA, AL, and FL; (2) incompatibility of river usage (e.g., protecting in-stream flow while permitting varied off-stream use), (3) conflicts between up- and down-stream demands (i.e., water supply/wastewater discharge, recreational use), and (4) negotiating process (e.g., compact takes effect only when parties agree to allocation formula).
Policy learning and seasonal climate forecasting application in NE Brazil – integrating information into decisions	3, Section 3.3.1.1	In 1992, in response to a long drought, the State of Ceara created several levels of water management including an interdisciplinary group within the state water management agency to develop and implement reforms.	Inclusion of social and physical scientists and stakeholders resulted in new knowledge (i.e., ideas and technologies) that critically affected water reform, including helping poorer communities better adapt to, and build capacity for managing climate variability impacts on water resources; also helped democratize decision making.
Interpreting	3, Section	The Arizona Salt River Project	SRP managers reduced groundwater pumping in

⁴ NOAA NWS North Central River Forecasting Center

⁵ U.S. Bureau of Reclamation

Climate Forecasts – uncertainties and temporal variability: Use of ENSO based information	3.3.2	(SRP) made a series of decisions based on the 1997/1998 El Nino (EN) forecast plus analysis of how ENs tended to affect their rivers and reservoirs.	1997 in anticipation of a wet winter; storms provided ample water for reservoirs. Success partly due to availability of climate and hydrology research and federal offices in close proximity to managers. Lack of temporal and geographical variability information in climate processes remains a barrier to adoption/use of specific products; decisions based only on forecasts are risky.
How the South Florida Water Management (SFWMD) District Uses Climate Information	4, Exp 1	SFWMD established a regulation schedule for Lake Okeechobee that uses climate outlooks as guidance for regulatory release decisions. A decision tree with a climate outlook is a major advance over traditional hydrologic rule curves used to operate large reservoirs. This experiment is the only one identified which uses decadal climate data in a decision-support context.	To improve basin management, modeling capabilities must: improve ability to differentiate trends in basin flows associated with climate variation and water management; gauge skill gained in using climate information to predict basin hydro-climatology; account for management uncertainties caused by climate; and evaluate how climate projections may affect facility planning and operations. Also, adaptive management is effective in incorporating SI variation into modeling and operations decision-making processes.
Long-Term Municipal Water Management Planning – New York City	4, Exp 2	NYC is adapting strategic and capital planning to include the potential effects of climate change (i.e., sea level rise, higher temperatures, increases in extreme events, and changing precipitation patterns) on the City's water systems. NYC Department of Environmental Protection, in partnership with local universities and private sector consultants, is evaluating climate change projections, impacts, indicators, and adaptation and mitigation strategies to support agency decision making	Shows: (1) plans for regional capital improvements can include measures that reduce vulnerability to sea level rise; (2) the meteorological and hydrology communities need to define and communicate current and increasing risks, with explicit discussion of the inherent uncertainties; (3) more research needed (e.g., to further reduce uncertainties associated with sea-level rise, provide more reliable predictions of changes in frequency / intensity of tropical and extra-tropical storms, etc.); (4) regional climate model simulations and statistical techniques used to predict long-term climate change impacts could be down-scaled to help manage projected SI climate variability; and (5) decision makers need to build support for adaptive action despite uncertainties. The extent and effectiveness of this action will depend on building awareness of these issues among decision makers, fostering processes of interagency interaction and collaboration, and developing common standards.
Integrated Forecast and Reservoir Management (INFORM) - Northern California	4, Exp 3	INFORM aims to demonstrate the value of climate, weather, and hydrology forecasts in reservoir operations. Specific objectives are to: (1) implement a prototype integrated forecast-management system for the Northern California river and reservoir system in close collaboration with operational forecasting and management	INFORM demonstrated key aspects of integrated forecast-decision systems, i.e., (1) seasonal climate and hydrologic forecasts benefit reservoir management, provided that they are used in connection with adaptive dynamic decision methods that can explicitly account for and manage forecast uncertainty; (2) ignoring forecast uncertainty in reservoir regulation and water management decisions leads to costly failures; and. (3) static decision rules cannot take full advantage of and handle forecast uncertainty information. The extent that forecasts help

		agencies, and (2) demonstrate the utility of meteorological/climate and hydrologic forecasts through near-real-time tests of the integrated system with actual data and management input.	depends on their reliability, range, and lead time, in relation to the management systems' ability to regulate flow, water allocation, etc.
How Seattle Public Utility (SPU) District Uses Climate Information to Manage Reservoirs	4. Exp 4	Over the past several years SPU has taken steps to improve incorporation of climate, weather, and hydrologic information into the real-time and SI management of its mountain water supply system. They are receptive to new management approaches due to public pressure and the risk of legal challenges related to the protection of fish populations.	Shows: (1) access to skillful SI forecasts enhances credibility of using climate information in the region; (2) monitoring of snowpack moisture storage and mountain precipitation is essential for effective decision making and for detecting long-term trends that can affect water supply reliability; and (3) SPU has significant capacity to conduct in-house investigations/assessments. This provides confidence in the use of information.
Using Paleo-climate Information to Examine Climate Change Impacts	4, Exp 5	Because of repeated drought, western water managers, through partnerships with researchers in the inter-mountain West considered using paleoclimate records of streamflow and hydroclimatic variability to provide an extended record for assessing the potential impact of a more complete range of natural variability as well as providing a baseline for detecting regional impacts of global climate change.	Partnerships have led to a range of applications evolving from a change in thinking about drought to assessing drought impacts on water systems using tree-ring reconstructed flows. Workshops have expanded applications of the tree-ring based streamflow reconstructions to drought planning and water management. Also, an online resource provides water managers access to gage and reconstruction data and a tutorial on reconstruction methods for gages in Colorado and California.
Climate, Hydrology, and Water Resource Issues in Fire-Prone United States Forests	4, Exp 6	The 2000 experiment, consisting of annual workshops to evaluate the utility of climate information for fire management, was initiated to inform fire managers about climate forecasting tools and to enlighten climate forecasters about the needs of the fire management community.	Workshops are now accepted practice by agencies with an annual assessment of conditions and production of pre-season fire-climate forecasts. Scientists and decision makers continue to explore new questions, as well as involve new participants, disciplines and specialties, to make progress in key areas (e.g., lightning climatologies).
The CALFED – Bay Delta Program: Implications of Climate Variability	4 Exp 7	Delta requirements to export water supplies to southern California also include: managing habitat and water supplies in the region, maintaining endangered fish species, making major long-term decisions about rebuilding flood control levees	A new approach has led to consideration of climate change and sea level rise in infrastructure planning; the time horizon for planning has been extended to 200 years. Because of incremental changes in understanding climate, this experiment shows the importance of using adaptive management strategies.

		and rerouting water supply networks through the region.	
Regional Integrated Science and Assessment Teams (RISAs) – An Opportunity for Boundary Spanning, and a Challenge	Section 4.3.2	The eight RISA teams that are sponsored by NOAA represent a new collaborative paradigm in which decision makers are actively involved in developing research agendas. RISAs explicitly seek to work at the boundary of science and decision making.	RISA teams facilitate engagement with stakeholders and design climate-related decision-support tools for water managers through using: (1) a robust “stakeholder-driven research” approach focusing on both the supply (i.e., information development) and demand side (i.e., the user and her/his needs); (2) an “information broker” approach, both producing new scientific information themselves and providing a conduit for new and old information and facilitating the development of information networks; (3) a “participant/advocacy” or “problem-based” approach, involving a focus on a particular problem or issue and engaging directly in solving it; and (4) a “basic research” approach where researchers recognize gaps in the key knowledge needed in the production of context sensitive, policy-relevant information.
Leadership in the California Department of Water Resources (CDWR)	4, Case Study A	Drought in the Colorado River Basin, prompted water resources managers to use climate data in plans and reservoir forecast models. Following a 2005 workshop on paleohydrologic data use in resource management, RISA and CDWR scientists developed ties to improve the usefulness of hydroclimatic science in water management.	CDWR asked the NAS ⁶ to convene a panel to clarify scientific understanding of Colorado River Basin climatology and hydrology, past variations, projections for the future, and impacts on water resources. NAS issued the report in 2007; a new Memorandum of Agreement now exists to improve cooperation with RISAs and research laboratories.
Cooperative extension services, watershed stewardship: the Southeast Consortium	4, Case Studies B and F	The Southeast Climate Consortium RISA (SECC), a confederation of researchers at six universities in Alabama, Georgia, and Florida, has used a top-down approach to develop stakeholder capacity to use climate information in region’s \$33 billion agricultural sector. Early on, SECC researchers recognized the potential of using ENSO impact on local climate data to provide guidance to farmers, ranchers, and forestry sector stakeholders on yields and changes to risk (e.g., frost occurrence).	SECC determined that (1) benefits from producers use of seasonal forecasts depends on factors that include the flexibility and willingness to adapt farming operations to the forecast, and the effectiveness of communication; (2) success in championing integration of new information requires sustained interactions (e.g., with agricultural producers in collaboration with extension agents; (3) direct engagement with stakeholders provides feedback to improve the design of the tool and to enhance climate forecast communication..
Approaches to building user knowledge and	4, Case Study C	Arizona Water Institute, initiated in 2006, focuses resources of the State of	Institute focuses on: capacity building, training students through engagement in real-world water policy issues, providing better access to

⁶ National Academy of Sciences

enhancing capacity building – Arizona Water Institute		Arizona’s university system on the issue of water sustainability. The Institute was designed as a “boundary organization” to build pathways for innovation between the universities and state agencies, communities, Native American tribal representatives, and the private sector.	hydrologic data for decision makers, assisting in visualizing implications of decisions they make, providing workshops and training programs for tribal entities, jointly defining research agendas between stakeholders and researchers, and building employment pathways to train students for jobs requiring special training (e.g., water and wastewater treatment plant operators).
Murray-Darling Basin – sustainable development and adaptive management	4, Case Study D	1985 Murray-Darling Basin Agreement (MDBA), formed by New South Wales, Victoria, South Australia and Commonwealth, provides for integrated management of water and related land resources of world’s largest catchment system. MDBA encourages use of climate information for planning and management; seeks to integrate quality and quantity concerns within single management framework; has broad mandate to embrace social, economic, environmental and cultural issues in decisions, and authority to supplant other jurisdictions to implement water & development policies.	According to Newson (1997), while the policy of integrated management has “received wide endorsement,” progress towards effective implementation has fallen short – especially in the area of floodplain management. This has been attributed to a “reactive and supportive” attitude as opposed to a proactive one. Despite such criticism, it is hard to find another initiative of this scale and sophistication that has attempted adaptive management based on community involvement.
Adaptive management in Glen Canyon, Arizona and Utah	4, Case Study E	Glen Canyon Dam was constructed in 1963 to provide hydropower, irrigation, flood control, and public water supply – and to ensure adequate storage for upper basin states of Colorado River Compact. When dam’s gates closed, the river above and below Glen Canyon was altered by seasonal variability. In 1996, USBR created an experimental flood to restore the river ecosystem.	Continued drought in Southwest is placing increased stress on land and water resources of region, including agriculture. Efforts to restore the river to conditions more nearly approximating the era before the dam was built will require changes in dam’s operating regime to force a greater balance between instream flow and power generation and offstream water supply. This will require forecast use to ensure that these various needs can be optimized.
Potomac River Basin	4, Case Study G	Interstate Commission on the Potomac River Basin (ICPRB) periodically studies the impact of climate change on the supply reliability to the Washington metropolitan area water’s (WMA) use in residential areas.	2005 study stated that the 2030 demand in the WMA could be 74% to 138% greater than that of 1990. According to the report, with aggressive plans in conservation and operation policies, existing resources should be sufficient through 2030; recommended incorporating potential climate impacts in future planning.
Fire prediction	4, Case	Given strong mutual interests	Emphasis on process, as well as product, may be

workshops as a model for climate science-water management process to improve water resources decisions	Study H	in improving the range of tools available to fire management, with goal of reducing fire related damage and loss of life, fire managers and climate scientists have developed long-term process to: improve fire potential prediction; better estimate costs; most efficiently deploy fire fighting resources.	a model for climate science in support of water resources management decision making. Another key facet in maintaining this collaboration and direct application of climate science to operational decision making has been the development of strong professional relationships between the academic and operational partners.
Incentives to Innovate – Climate Variability and Water Management along San Pedro River	4, Case Study I	Highly politicized issue of water management in upper San Pedro River Basin has led to establishment of Upper San Pedro Partnership, whose primary goal is balancing water demands with supply without compromising region’s economic viability, much of which is tied to Fort Huachuca Army base.	Studies show growing vulnerability to climate impacts. Climatologists, hydrologists, social scientists, and engineers work with partnership to strengthen capacity/interest in using climate forecast products. Decision-support model being developed by U. of Arizona engineer with partnership members integrates climate into local decisions.

1232

1233 **KEY FINDINGS**

1234 There are a wide variety of climate and hydrologic data and forecast products currently
1235 available for use by decision makers in the water resources sector, ranging from seasonal
1236 outlooks for precipitation and surface air temperature to drought intensity, lake levels,
1237 river runoff and water supplies in small to very large river basins. However, the use of
1238 official seasonal to interannual (SI) climate and hydrologic forecasts generated by NOAA
1239 and other agencies remains limited in the water resources sector. Forecast skill, while
1240 recognized as just one of the barriers to the use of SI climate forecast information,

1241 remains a primary concern among forecast producers and users. Simply put, there is no
1242 incentive to use SI climate forecasts when they are believed to provide little additional
1243 skill to existing hydrologic and water resource forecast approaches. Not surprisingly,
1244 there is much interest in improving the skill of hydrologic and water resources forecasts.
1245 Such improvements can be realized by pursuing several research pathways, including:

- 1246 • Improved monitoring and assimilation of real-time hydrologic observations in
1247 land surface hydrologic models that leads to improved estimates for initial
1248 hydrologic states in forecast models;
- 1249 • Increased accuracy in SI climate forecasts; and,
- 1250 • Improved bias corrections in existing forecast.

1251 Because runoff and forecast conditions are projected to gradually and continually trend
1252 towards increasingly warmer temperatures as a consequence of human-caused climate
1253 change, the expected skill in regression-based hydrologic forecasts will always be limited
1254 by having only a brief reservoir of experience with each new degree of warming.

1255 Consequently, we must expect that regression-based forecast equations will tend to be
1256 increasingly and perennially out of date in a world with strong warming trends. This
1257 problem with the statistics of forecast skill in a changing world suggests that
1258 development and deployment of more physically based, less statistically based, forecast
1259 models should be a priority in the foreseeable future.

1260

1261 Another aspect of forecasts that serves to limit their use and utility is the challenge in
1262 interpreting forecast information. For example, from a forecast producer's perspective,
1263 confidence levels are explicitly and quantitatively conveyed by the range of possibilities

1264 described in probabilistic forecasts. From a forecast user's perspective, probabilistic
1265 forecasts are not always well understood or correctly interpreted. Although structured
1266 user testing is known to be an effective product development tool, it is rarely done.
1267 Evaluation should be an integral part of improving forecasting efforts, but that evaluation
1268 should be extended to factors that encompass use and utility of forecast information for
1269 stakeholders. In particular, very little research is done on effective seasonal forecast
1270 communication. Instead, users are commonly engaged only near the end of the product
1271 development process.

1272

1273 Other barriers to the use of SI climate forecasts in water resources management have
1274 been identified and those that relate to institutional issues and aspects of current forecast
1275 products are discussed in Chapters 3 and 4 of this Product.

1276

1277 Pathways for expanding the use and improving the utility of data and forecast products to
1278 support decision making in the water resources sector are currently being pursued at a
1279 variety of spatial and jurisdictional scales in the United States. These efforts include:

- 1280 • An increased focus on developing forecast evaluation tools that provide users
1281 with opportunities to better understand forecast products in terms of their
1282 expected skill and applicability;
- 1283 • Additional efforts to explicitly and quantitatively link SI climate forecast
1284 information with SI hydrologic and water supply forecasting efforts;

- 1285 • An increased focus on developing new internet-based tools for accessing and
1286 customizing data and forecast products to support hydrologic forecasting and
1287 water resources decision making; and,
- 1288 • Further improvements in the skill of hydrologic and water supply forecasts.

1289

1290 Many of these pathways are currently being pursued by the federal agencies charged with
1291 producing the official climate and hydrologic forecast and data products for the United
1292 States, but there is substantial room for increasing these activities.

1293

1294 An additional important finding is that recent improvements in the use and utility of data
1295 and forecast products related to water resources decision-making have come with an
1296 increased emphasis on these issues in research funding agencies through programs like
1297 the Global Energy and Water Cycle Experiment (GEWEX—a program initiated by the
1298 World Climate Research Programme) and NOAA’s Regional Integrated Sciences and
1299 Assessment (RISA), Sectoral Applications Research Program (SARP), Transition of
1300 Research Applications to Climate Services (TRACS) and Climate Prediction Program for
1301 the Americas (CPPA) programs. Sustaining and accelerating future improvements in the
1302 use and utility of official data and forecast products in the water resources sector rests, in
1303 part, on sustaining and expanding federal support for programs focused on improving the
1304 skill in forecasts, increasing the access to data and forecast products, and supporting
1305 sustained interactions between forecast producers and consumers. One strategy is to
1306 support demonstration projects that result in the development of new tools and

1307 applications that can then be transferred to broader communities of forecast producers,
1308 including those in the private sector, and broader communities of forecast consumers.

1309

1310 **2.1 INTRODUCTION**

1311 In the past, water resource managers relied heavily on observed hydrologic conditions
1312 such as snowpack and soil moisture to make seasonal to interannual (SI) water supply
1313 forecasts to support management decisions. Within the last decade, researchers have
1314 begun to link SI climate forecasts with hydrologic models (*e.g.*, Kim *et al.*, 2000;
1315 Kyriakidis *et al.*, 2001) or statistical distributions of hydrologic parameters (*e.g.*,
1316 Dettinger *et al.*, 1999; Sankarasubramanian and Lall, 2003) to improve hydrologic and
1317 water resources forecasts. Efforts to incorporate SI climate forecasts into water resources
1318 forecasts have been prompted, in part, by our growing understanding of the effects of
1319 global-scale climate phenomena, like El Niño Southern Oscillation (ENSO), on U.S.
1320 climate, and the expectation that SI forecasts of hydrologically-significant climate
1321 variables like precipitation and temperature provide a basis for predictability that is not
1322 currently being exploited. To the extent that climate variables like temperature and
1323 precipitation can be forecasted seasons in advance, hydrologic and water-supply forecasts
1324 can also be made skillfully well before the end, or even beginning, of the water year⁷.

1325

1326 More generally speaking, the use of climate data and SI forecast information in support
1327 of water resources decision making has been aided by efforts to develop programs

⁷ The *water year*, or hydrologic year, is October 1st through September 30th. This reflects the natural cycle in many hydrologic parameters such as the seasonal cycle of evaporative demand, and of the snow accumulation, melt, and runoff periods in many parts of the United States.

1328 focused on fostering sustained interactions between data and forecast producers and
1329 consumers in ways that support co-discovery of applications (e.g. see Miles et al., 2007).
1330
1331 This chapter focuses on a description and evaluation of hydrologic and climate forecast
1332 and data products that support decision making for water resource managers. Because the
1333 focus of this CCSP Product is on using SI forecasts and data for decision support in the
1334 water resources sector, we frame this chapter around key forecast and data products that
1335 contribute towards improved hydrologic and water supply forecasts. As a result, this
1336 Product does not contain a comprehensive review and assessment of the entire national SI
1337 climate and hydrologic forecasting effort. In addition, the reader should note that, even
1338 today, hydrologic and water supply forecasting efforts in many places are still not
1339 inherently linked with the SI climate forecasting enterprise.
1340
1341 Surveys identify a variety of barriers to the use of climate forecasts (Pulwarty and
1342 Redmond, 1997; Callahan *et al.*, 1999; Hartmann *et al.*, 2002), but insufficient accuracy
1343 is always mentioned as a barrier. It is also well established that an accurate forecast is a
1344 necessary, but in and of itself, insufficient condition to make it useful or usable for
1345 decision making in management applications (Table 2.1). Chapters 3 and 4 provide
1346 extensive reviews, case studies, and analyses that provide insights into pathways for
1347 lowering or overcoming barriers to the use of SI climate forecasts in water resources
1348 decision making.
1349

1350 It is almost impossible to discuss the perceived value of forecasts without also discussing
1351 issues related to forecast skill. Many different criteria have been used to evaluate forecast
1352 skill (see Wilks, 1995 for a comprehensive review). Some measures focus on aspects of
1353 deterministic skill (*e.g.*, correlations between predicted and observed seasonally averaged
1354 precipitation anomalies), while many others are based on categorical forecasts (*e.g.*,
1355 Heidke skill scores for categorical forecasts of “wet,” “dry,” or “normal” conditions). The
1356 most important measures of skill vary with different perspectives. For example,
1357 Hartmann *et al.* (2002) argue that forecast performance criteria based on “hitting” or
1358 “missing” associated observations offer users conceptually easy entry into discussions of
1359 forecast quality. In contrast, some research scientists and water supply forecasters may be
1360 more interested in correlations between the ensemble average of predictions and observed
1361 measures of water supply like seasonal runoff volume.

1362

1363 Forecast skill remains a primary concern among many forecast producers and users. Skill
1364 in hydrologic forecast systems derives from various sources, including the quality of the
1365 simulation models used in forecasting, the ability to estimate the initial hydrologic state
1366 of the system, and the ability to skillfully predict the statistics of future weather over the
1367 course of the forecast period. Despite the significant resources expended to improve SI
1368 climate forecasts over the past 15 years, few water-resource related agencies have been
1369 making quantitative use of climate forecast information in their water supply forecasting
1370 efforts (Pulwarty and Redmond 1997; Callahan *et al.*, 1999).

1371

1372

1373 **Table 2.1** Barriers to the use of climate forecasts and information for resource managers in the Columbia
 1374 River Basin
 1375 (Reproduced from Pulwarty and Redmond, 1997).

- a. Forecasts not “accurate” enough.
- b. Fluctuation of successive forecasts (“waffling”).
- c. The nature of what a forecast is, and what is being forecast (*e.g.*, types of El Niño and La Niña impacts, non-ENSO events, what are “normal” conditions?).
- d. Non-weather/climate factors are deemed to be more important (*e.g.*, uncertainty in other arenas, such as freshwater and ocean ecology [for salmon productivity]).
- e. Low importance is given to climate forecast information because its role is unclear or impacts are not perceived as important enough to commit resources.
- f. Other constraints deny a flexible response to the information (*e.g.*, meeting flood control or Endangered Species Act requirements).
- g. Procedures for acquiring knowledge and making and implementing decisions, which incorporate climate information, have not been clearly defined.
- h. Events forecast may be too far in the future for a discrete action to be engaged.
- i. Availability and use of locally specific information may be more relevant to a particular decision.
- j. “Value” may not have been demonstrated by a credible reliable organization or competitor.
- k. Desired information not provided (*e.g.*, number of warm days, regional detail).
- l. There may be competing forecasts or other conflicting information.
- m. Lack of “tracking” information; does the forecast appear to be verifying?
- n. History of previous forecasts not available. Validation statistics of previous forecasts not available.

1376

1377 In Section 2.2 of this chapter, we review hydrologic data and forecasts products. Section
 1378 2.3 provides a parallel discussion of the climate data and forecast products that support
 1379 hydrologic and water supply forecasting efforts in the United States. In Section 2.4, we
 1380 provide a more detailed discussion of pathways for improving the skill and utility in
 1381 hydrologic and climate forecasts and data products.

1382

1383 Section 2.5 contains a brief review of operational considerations and efforts to improve
 1384 the utility of forecast and data products through efforts to improve the forecast evaluation
 1385 and development process. These efforts include cases in which forecast providers and
 1386 users have been engaged in sustained interactions to improve the use and utility of
 1387 forecast and data products, and have led to many improvements and innovations in the
 1388 data and forecast products generated by national centers. In recent years, a small number
 1389 of water resource agencies have also developed end-to-end forecasting systems (*i.e.*

1390 forecasting systems that integrate observations and forecast models with decision-support
1391 tools) that utilize climate forecasts to directly inform hydrologic and water resources
1392 forecasts.

1393

1394 **BOX 2.1** Agency Support

1395

1396 Federal support for research supporting improved hydrologic forecasts and applications through the use of
1397 climate forecasts and data has received increasing emphasis since the mid-1990s. The World Climate
1398 Research Program's Global Energy and Water Cycle Experiment (GEWEX) was among the first attempts
1399 to integrate hydrology/land surface and atmosphere models in the context of trying to improve hydrologic
1400 and climate predictability.

1401

1402 There have been two motivations behind this research: understanding scientific issues of land surface
1403 interactions with the climate system, and the development or enhancement of forecast applications, *e.g.*, for
1404 water, energy and hazard management. Early on, these efforts were dominated by the atmospheric (and
1405 related geophysical) sciences.

1406

1407 In the past, only a few U.S. programs have been very relevant to hydrologic prediction: the NOAA Climate
1408 Prediction Program for the Americas (CPPA), NOAA predecessors GEWEX Continental-scale
1409 International Project (GCIP), GEWEX Americas Prediction Project (GAPP) and the NASA Terrestrial
1410 Hydrology Program. The hydrologic prediction and water management focus of NOAA and NASA has
1411 slowly expanded over time. Presently, the NOAA Climate Dynamics and Experimental Prediction (CDEP),
1412 Transition of Research Applications to Climate Services (TRACS) and Sectoral Applications Research
1413 Program (SARP) programs, and the Water Management program within NASA, have put a strong
1414 emphasis on the development of both techniques and community linkages for migrating scientific advances
1415 in climate and hydrologic prediction into applications by agencies and end use sectors. The longer-standing
1416 NOAA Regional Integrated Sciences and Assessments (RISA) program has also contributed to improved
1417 use and understanding of climate data and forecast products in water resources forecasting and decision
1418 making. Likewise, the recently initiated postdoctoral fellowship program under the Predictability,
1419 Predictions, and Applications Interface (PPAI) panel of U.S. CLIVAR aims to grow the pool of scientists
1420 qualified to transfer advances in climate science and climate prediction into climate-related decision
1421 frameworks and decision tools.

1422

1423 Still, these programs are not well funded in comparison to current federally funded science-focused
1424 initiatives, and are only just beginning to make inroads into the vast arena of effectively increasing the use
1425 and utility of climate and hydrologic data and forecast products.

1426

1427 **end BOX 2.1**

1428

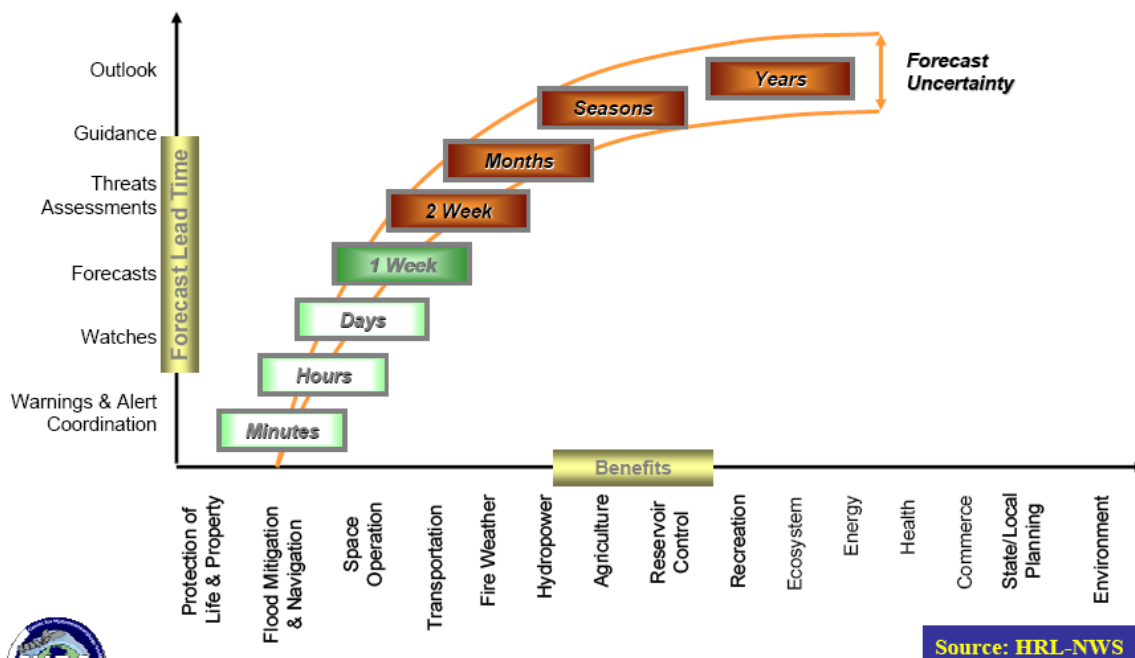

1429 **2.2 HYDROLOGIC AND WATER RESOURCES: MONITORING AND**

1430 **PREDICTION**

1431 The uses of hydrologic monitoring and prediction products, and specifically those that are

1432 relevant for water, hazard and energy management, vary depending on the forecast lead

1433 time (Figure 2.1). The shortest climate and hydrologic lead time forecasts, from minutes
 1434 to hours, are applied to such uses as warnings for floods and extreme weather, wind
 1435 power scheduling, aviation, recreation, and wild fire response management. In contrast, at
 1436 lead times of years to decades, predictions are used for strategic planning purposes rather
 1437 than operational management of resources. At SI lead times, climate and hydrologic
 1438 forecast applications span a wide range that includes the management of water, fisheries,
 1439 hydropower and agricultural production, navigation and recreation. Table 2.2 lists aspects
 1440 of forecast products at these time scales that are relevant to decision makers.
 1441

1442

1443 **Figure 2.1** The correspondence of climate and hydrologic forecast lead time to user sectors in which
 1444 forecast benefits are realized (from National Weather Service Hydrology Research Laboratory). The focus
 1445 of this Product is on climate and hydrologic forecasts with lead times greater than two weeks and up to
 1446 approximately one year.
 1447

1448 **2.2.1 Prediction Approaches**

1449 The primary climate and hydrologic prediction approaches used by operational and
1450 research centers fall into four categories: statistical, dynamical, statistical-dynamical
1451 hybrid, and consensus. The first three approaches are objective in the sense that the inputs
1452 and methods are formalized, outputs are not modified on an *ad hoc* basis, and the
1453 resulting forecasts are potentially reproducible by an independent forecaster using the
1454 same inputs and methods. The fourth major category of approach, which might also be
1455 termed blended knowledge, requires subjective weighting of results from the other
1456 approaches. These types of approaches are discussed in Box 2.2.

1457

1458 BOX 2.2: Forecast Approaches

1459

1460 **Dynamical:** Computer models designed to represent the physical features of the oceans, atmosphere and
1461 land surface, at least to the extent possible given computational constraints, form the basis for dynamical
1462 predictions. These models have, at their core, a set of physical relationships describing the interactions of
1463 the Earth's energy and moisture states. Inputs to the models include estimates of the current moisture and
1464 energy conditions needed to initialize the state variables of the model (such as the moisture content of an
1465 atmospheric or soil layer), and of any physical characteristics (called parameters—one example is the
1466 elevation of the land surface) that must be known to implement the relationships in the model's physical
1467 core. In theory, the main advantage of dynamical models is that influence of any one model variable on
1468 another is guided by the laws of nature as we understand them. As a result, the model will correctly
1469 simulate the behavior of the earth system even under conditions that may not have occurred in the period
1470 during which the model is verified, calibrated and validated. The primary disadvantages of dynamical
1471 models, however, are that their high computational and data input demands require them to approximate
1472 characteristics of the Earth system in ways that may compromise their realism and therefore performance.
1473 For example, the finest computational grid resolution that can be practically achieved in most atmospheric
1474 models (on the order of 100 to 200 km per cell) is still too coarse to support a realistic representation of
1475 orographic effects on surface temperature and precipitation. Dynamical hydrologic models can be
1476 implemented at much finer resolutions (down to ten meters per cell, for catchment-scale models) because
1477 they are typically applied to much smaller geographic domains than are atmospheric models. While there
1478 are many aspects that distinguish one model from another, only a subset of those (listed in Table 1.1) is
1479 appreciated by the forecast user, as opposed to the climate modeler, and is relevant in describing the
1480 dynamical forecast products.

1481

1482 **Statistical:** Statistical forecast models use mathematical models to relate observations of an earth system
1483 variable that is to be predicted to observations of one or more other variables (and/or of the same variable at
1484 a prior time) that serve as predictors. The variables may describe conditions at a point location (*e.g.*, flow
1485 along one reach of a river) or over a large domain, such as sea surface temperatures along the equator. The
1486 mathematical models are commonly linear relationships between the predictors and the predictand, but also
1487 may be formulated as more complex non-linear systems.

1488

1489 Statistical models are often preferred for their computational ease relative to dynamical models. In many
1490 cases, statistical models can give equal or better performance to dynamical models due in part to the
1491 inability of dynamical models to represent fully the physics of the system (often as a result of scale or data

1492 limitations), and in part to the dependence of predictability in many systems on predominantly linear
 1493 dynamics (Penland and Magorian, 1993; van den Dool, 2007). The oft-cited shortcomings of statistical
 1494 models, on the other hand, include their lack of representation of physical causes and effects, which, in
 1495 theory, compromise their ability to respond to unprecedented events in a fashion that is consistent with the
 1496 physical constraints of the system. In addition, statistical models may require a longer observational record
 1497 for “training” than dynamical models, which are helped by their physical structure.
 1498

1499 **Objective hybrids:** Statistical and dynamical tools can be combined using objective approaches. A primary
 1500 example is a weighted merging of the tools’ separate predictions into a single prediction (termed an
 1501 objective consolidation; van den Dool, 2007). A second example is a tool that has dynamical and statistical
 1502 subcomponents, such as a climate prediction model that links a dynamical ocean submodel to a statistical
 1503 atmospheric model. A distinguishing feature of these hybrid approaches is that an objective method exists
 1504 for linking the statistical and dynamical schemes so as to produce a set of outputs that are regarded as
 1505 “optimal” relative to the prediction goals. This objectivity is not preserved in the next consensus approach.
 1506

1507 **Blended Knowledge or Subjective consensus:** Some forecast centers release operational predictions, in
 1508 which expert judgment is subjectively applied to modify or combine outputs from prediction approaches of
 1509 one or more of the first three types, thereby correcting for perceived errors in the objective approaches to
 1510 form a prediction that has skill superior to what can be achieved by objective methods alone. The process
 1511 by which the NOAA Climate Prediction Center (CPC) and International Research Institute for Climate
 1512 and Society (IRI) constructs their monthly and seasonal outlooks for example, includes subjective
 1513 weighting of the guidance provided by different climate forecast tools. The weighting is often highly
 1514 sensitive to recent evolution and current state of the tropical ENSO, but other factors, like decadal trends in
 1515 precipitation and surface temperature, also have the potential to influence the final official climate
 1516 forecasts.
 1517

1518 **end BOX 2.2**
 1519

1520 **Table 2.2** Aspects of forecast products that are relevant to users

Forecast Product Aspect	Description / Examples
Forecast product variables	Precipitation, temperature, humidity, wind speed, atmospheric pressure
Forecast product spatial resolution	Grid cell longitude by latitude, climate division
Domain	Watershed, river basin, regional, national, global
Product time step (temporal resolution)	Hourly, sub-daily, daily, monthly, seasonal
Range of product lead times	1 to 15 days, 1 to 13 months
Frequency of forecast product update	every 12 hours, every month
Lag of forecast product update	The length of time from the forecast initialization time before forecast products are available: e.g., two hours for a medium range forecast, one day for a monthly to seasonal forecast
Existence of historical climatology	Many users require a historical climatology showing forecast model performance to use in bias-correction, downscaling, and/or verification.
Deterministic or probabilistic	Deterministic forecasts have a single prediction for each future lead time. Probabilistic forecasts frame predicted values within a range of uncertainty, and consist either of an ensemble of forecast sequences spanning all lead times, or of a distinct forecast distribution for each future lead time.
Availability of skill/accuracy information	Published or otherwise available information about the performance of forecasts is not always available, particularly for forecasts that are steadily evolving. In principle, the spread of probabilistic forecasts contains such information about the median of the forecast; but the skill characteristics pertaining to the spread of the forecast are not usually available.

1521

1522 Other aspects of dynamical prediction schemes related to model physical and
1523 computational structure are important in distinguishing one model or model version from
1524 another. These aspects are primary indicators of the sophistication of an evolving model,
1525 relative to other models, but are not of much interest to the forecast user community.
1526 Examples include the degree of coupling of model components, model vertical
1527 resolution, cloud microphysics package, nature of data assimilation approaches and of the
1528 data assimilated, and the ensemble generation scheme, among many other forecast
1529 system features.

1530

1531 **2.2.2 Forecast Producers and Products**

1532 Federal, regional, state, and local agencies, as well as private sector companies, such as
1533 utilities, produce hydrologic forecasts. In contrast to climate forecasts, hydrologic
1534 forecast products more directly target end use sectors—*e.g.*, water, energy, natural
1535 resource or hazard management—and are often region-specific. Prediction methods and
1536 forecast products vary from region to region and are governed by many factors, but
1537 depend in no small measure on the hydroclimatology, institutional traditions and sectoral
1538 concerns in each region. A representative sampling of typical forecast producers and
1539 products is given in Appendix A.1. Forecasting activities at the federal, state, regional,
1540 and local scales are discussed in the following subsections.

1541

1542 **2.2.2.1 Federal**

1543 The primary federal streamflow forecasting agencies at SI lead times are the NOAA,
1544 National Weather Service (NWS) and the U.S. Department of Agriculture (USDA)
1545 National Resource Conservation Service (NRCS) National Water and Climate Center
1546 (NWCC). The NWCC's four forecasters produce statistical forecasts of summer runoff
1547 volume in the western United States using multiple linear regression to estimate future
1548 streamflow from current observed snow water equivalent, accumulated water year
1549 precipitation, streamflow, and in some locations, using ENSO indicators such as the
1550 Niño3.4 index (Garen, 1992; Pagano and Garen, 2005). Snowmelt runoff is critical for a
1551 wide variety of uses (water supply, irrigation, navigation, recreation, hydropower,
1552 environmental flows) in the relatively dry summer season. The regression approach has
1553 been central to the NRCS since the mid-1930s, before which similar snow-survey based
1554 forecasting was conducted by a number of smaller groups. Forecasts are available to
1555 users both in the form of tabular summaries (Figure 2.2) that convey the central tendency
1556 of the forecasts and estimates of uncertainty, and maps showing the median forecast
1557 anomaly for each river basin area for which the forecasts are operational (Figure 2.3).
1558 Until 2006, the NWCC's forecasts were released near the first of each month, for summer
1559 flow periods such as April through July or April through September. In 2006, the NWCC
1560 began to develop automated daily updates to these forecasts, and the daily product is
1561 likely to become more prevalent as development and testing matures. The NWCC has
1562 also just begun to explore the use of physically-based hydrologic models as a basis for
1563 forecasting.
1564

1565 NWCC water supply forecasts are coordinated subjectively with a parallel set of forecasts
 1566 produced by the western U.S. NWS River Forecast Centers (RFCs), and with forecasts
 1567 from Environment Canada’s BC Hydro. The NRCS-NWS joint, official forecasts are of
 1568 the subjective consensus type described earlier, so the final forecast products are
 1569 subjective combinations of information from different sources, in this case, objective
 1570 statistical tools (*i.e.*, regression models informed by observed snow water equivalent,
 1571 accumulated water year precipitation, and streamflow) and model based forecast results
 1572 from the RFCs.
 1573

Streamflow Forecasts as of April 1, 2007

Stream and Station	Forecast Period	Forecasts This Year			30 Year '71-'00 Average Runoff kaf
		Most Probable kaf	Reasonable %avg	Max Min %avg	
Alaska					
Gulkana River Sourdough, AK	Apr-Jul	410	86	118 62	475
Kenai River Cooper Landing, AK	Apr-Jul	965	104	122 88	925
Ship Creek Anchorage, AK	Apr-Jul	45	78	102 57	58
Little Susitna River Palmer, AK	Apr-Jul	66	77	100 58	86
Talkeetna River Talkeetna, AK	Apr-Jul	1370	84	99 69	1630

Saskatchewan River Basin					
St. Mary River Babb nr, MT	Apr-Sep	400	89	103 74	450

1574

1575 **Figure 2.2** Example of NRCS tabular summer runoff (streamflow) volume forecast summary, showing
1576 median (“most probable”) forecasts and probabilistic confidence intervals, as well as climatological flow
1577 averages. Flow units are thousand-acre-feet (KAF), a runoff volume for the forecast period. This table was
1578 downloaded from <<http://www.wcc.nrcs.usda.gov/wsf/wsf.html>>.
1579

1580 The NWS surface water supply forecast program began in the 1940s in the Colorado
1581 Basin. It has since expanded to include seasonal forecasts (of volume runoff during the
1582 spring to summer snow melt period) for most of the snowmelt-dominated basins
1583 important to water management in the western United States. These forecasts rely on two
1584 primary tools: Statistical Water Supply (SWS), based on multiple-linear regression, and
1585 Ensemble Streamflow Prediction (ESP), a technique based on hydrologic modeling
1586 (Schaake, 1978; Day, 1985). Results from both approaches are augmented by forecaster
1587 experience and the coordination process with other forecasting entities. In contrast to the
1588 western RFCs, RFCs in the eastern United States are more centrally concerned with short
1589 to medium-range flood risk and drought-related water availability out to about a three
1590 month lead time. At some eastern RFC websites, the seasonal forecast is linked only to
1591 the CPC Drought Outlook rather than an RFC-generated product (Box 2.3).
1592

Spring and Summer Streamflow Forecasts as of April 1, 2007

1593

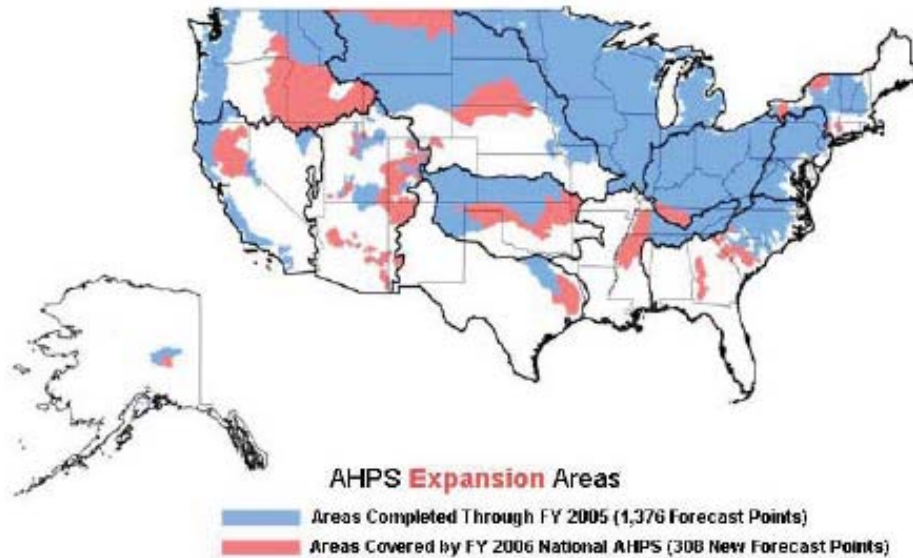

1594 **Figure 2.3** Example of NRCS spatial summer runoff (April-September streamflow) volume forecast
1595 summary, showing median runoff forecasts as an anomaly (percent of average).
1596

1597 The streamflow prediction services of the RFCs have a national presence, and, as such,
1598 are able to leverage a number of common technological elements, including models,
1599 databases and software for handling meteorological and hydrological data, and for
1600 making, assessing and disseminating forecasts (*i.e.*, website structure). Nonetheless, the
1601 RFCs themselves are regional entities with regional concerns.

1602

1603 The NWS's ESP approach warrants further discussion. In the mid 1970s, the NWS
1604 developed the hydrologic modeling, forecasting and analysis system—NWS River
1605 Forecast System (NWSRFS)—the core of which is the Sacramento soil moisture
1606 accounting scheme coupled to the Snow-17 temperature index snow model, for ESP-
1607 based prediction (Anderson, 1972, 1973; Burnash *et al.*, 1973). The ESP approach uses a
1608 deterministic simulation of the hydrologic state during a model spin-up (initialization)
1609 period, leading up to the forecast start date to estimate current hydrologic conditions, and
1610 then uses an ensemble of historical meteorological sequences as model inputs (*e.g.*,
1611 temperature and precipitation) to simulate hydrology in the future (or forecast period).
1612 Until several years ago, the RFC dissemination of ESP-based forecasts for streamflows at
1613 SI lead times was rare, and the statistical forecasts were the accepted standard. Now, as
1614 part of the NWS Advanced Hydrologic Prediction Service (AHPS) initiative, ESP
1615 forecasts are being aggressively implemented for basins across the United States (Figure
1616 2.4) at lead times from hours to SI (McEnery *et al.*, 2005).

1617

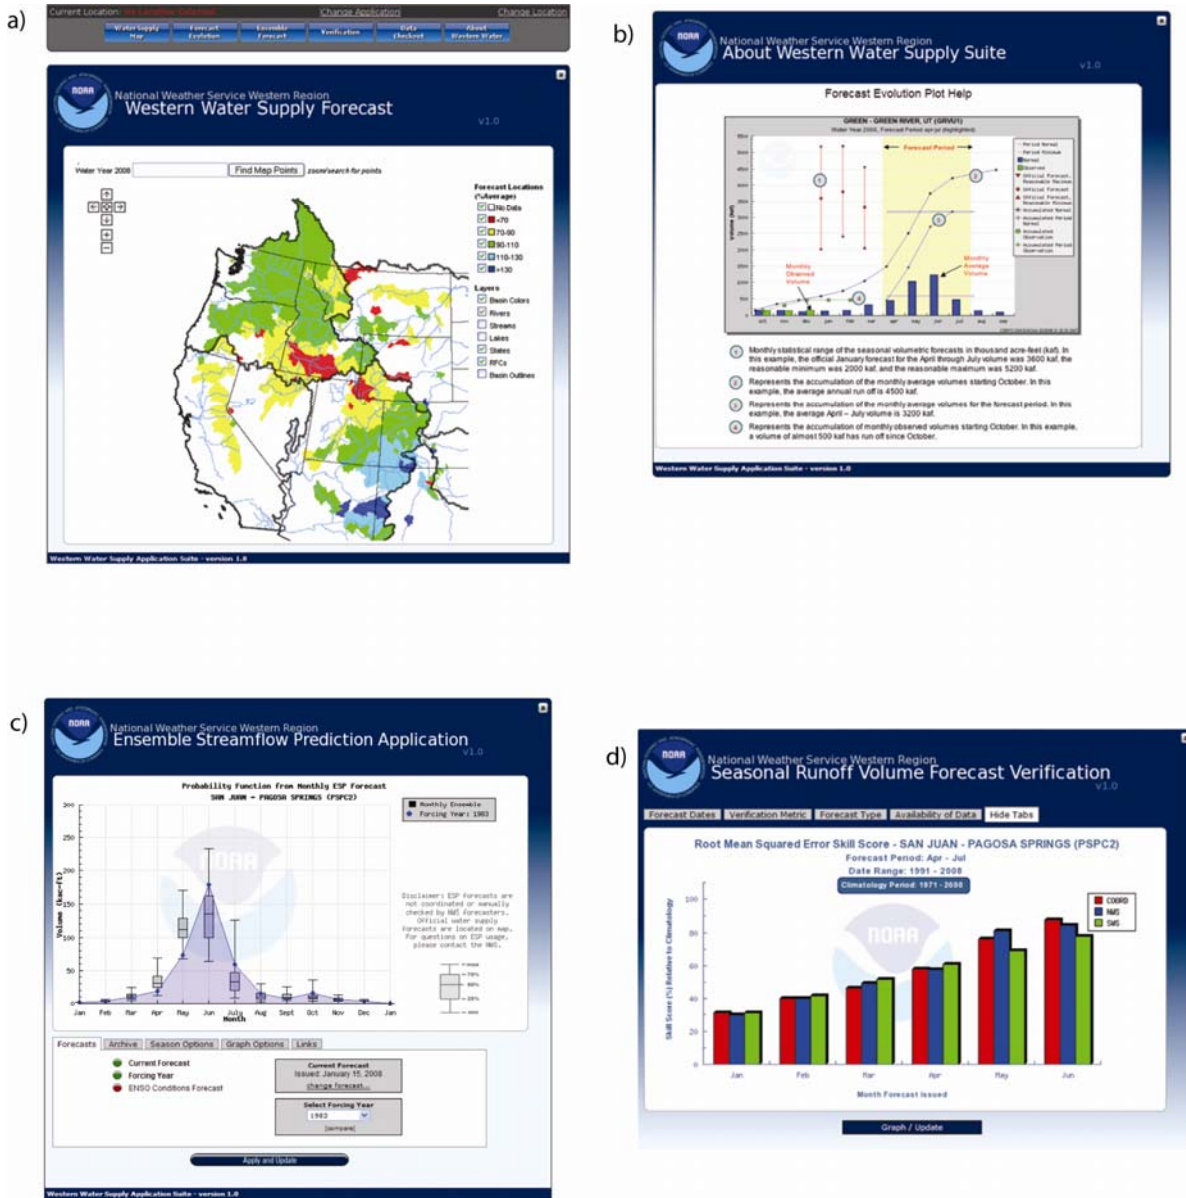

1618

1619 **Figure 2.4** Areas covered by the NWS Advanced Hydrologic Prediction Service (AHPS) initiative
 1620 (McEnery *et al.*, 2005).

1621

1622 At the seasonal lead times, several western RFCs use graphical forecast products for the
 1623 summer period streamflow forecasts that convey the probabilistic uncertainty of the
 1624 forecasts. A unified web based suite of applications that became operational in 2008
 1625 provides forecast users with a number of avenues for exploring the RFC water supply
 1626 forecasts. For example, Figure 2.5 shows (in clockwise order from top left) (a) a western
 1627 United States depiction of the median water supply outlook for the RFC forecast basins,
 1628 (b) a progression of forecasts (median and bounds) during the water year together with
 1629 flow normals and observed flows; (c) monthly forecast distributions, with the option to
 1630 display individual forecast ensemble members (*i.e.*, single past years) and also select
 1631 ENSO-based categorical forecasts (ESP subsets); and (d) various skill measures, such as
 1632 mean absolute error, for the forecasts based on hindcast performance. Access to raw
 1633 ensemble member data is also provided from the same website.

1634

1635

1636 **Figure 2.5** A graphical forecast product from the NWS River Forecast Centers, showing a forecast of
 1637 summer (April through July) period streamflow on the Colorado River, Colorado to Arizona. These figures
 1638 were obtained from <<http://www.nwrfc.noaa.gov/westernwater>>.
 1639

1640 The provision of a service that assists hydrologic forecast users in either customizing a
 1641 selection of ESP possibilities to reflect, perhaps, the users’ interest in data from past years
 1642 that they perceive as analogues to the current year, or the current ENSO state, is a notable
 1643 advance from the use of “climatological” ESP (*i.e.*, using all traces from a historical

1644 period) in the prior ESP-related seasonal forecast products. Some western RFCs have
1645 also experimented with using the CPC seasonal climate outlooks as a basis for adjusting
1646 the precipitation and temperature inputs used in climatological ESP, but it was found that
1647 the CPC outlook anomalies were generally too small to produce a distinct forecast from
1648 the climatological ESP (Hartmann *et al.*, 2002). In some RFCs, NWS statistical water
1649 supply forecasts have also provided perspective (albeit more limited) on the effect of
1650 future climate assumptions on future runoff by including results from projecting 50, 75,
1651 100, 125 and 150 percent of normal precipitation in the remaining water year. At times,
1652 the official NWS statistical forecasts have adopted such assumptions, *e.g.*, that the first
1653 month following the forecast date would contain other than 100 percent of expected
1654 precipitation, based on forecaster judgment and consideration of a range of factors,
1655 including ENSO state and CPC climate predictions.

1656

1657 Figure 2.6 shows the performance of summer streamflow volume forecasts from both the
1658 NWS and NRCS over a recent ten-year period; this example is also part of the suite of
1659 forecast products that the western RFC designed to improve the communication of
1660 forecast performance and provide verification information. Despite recent literature
1661 (Welles *et al.*, 2007) that has underscored a general scarcity of such information from
1662 hydrologic forecast providers, the NWS has recently codified verification approaches and
1663 developed verification tools, and is in the process of disbursing them throughout the RFC
1664 organization (NWS, 2006). The existence in digitized form of the retrospective archive of
1665 seasonal forecasts is critical for the verification of forecast skill. The ten-year record
1666 shown in Figure 2.6, which is longer than the record available (internally or to the public)

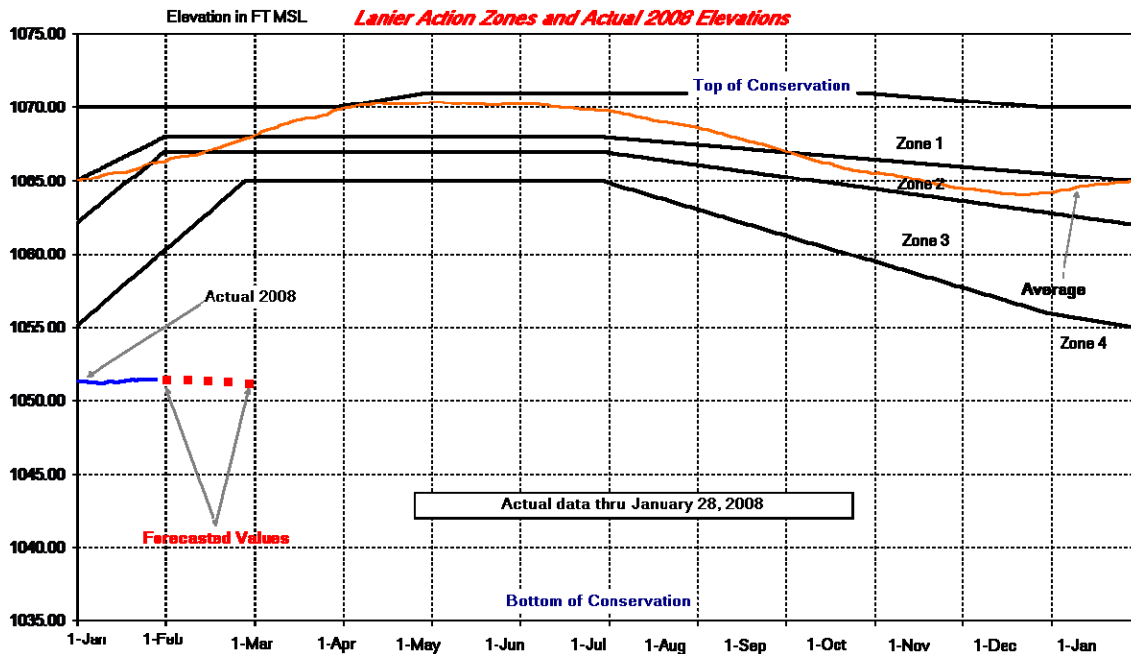

1667 for many public agency forecast variables, is of inadequate length for some types of
 1668 statistical assessment, but is an undeniable advance in forecast communication relative to
 1669 the services that were previously available. Future development priorities include a
 1670 climate change scenario application, which would leverage climate change scenarios
 1671 from IPCC or similar to produce inputs for future water supply planning exercises. In
 1672 addition, forecast calibration procedures (*e.g.*, Seo *et al.*, 2006; Wood and Schaake, 2008)
 1673 are being developed for the ensemble forecasts to remove forecast biases. The current
 1674 NOAA/NWS web service Internet web address is:
 1675 <<http://www.nwrfc.noaa.gov/westernwater>>
 1676

1677
 1678 **Figure 2.6** Comparing ESP and statistical forecasts from the NRCS and NWS for a recent 10-year period.
 1679 The forecasts are for summer (April through July) period streamflow on the Gunnison River, Colorado.
 1680

1681 A contrast to these probabilistic forecasts is the deterministic five-week forecast of lake
 1682 water level in Lake Lanier, GA, produced by the U.S. Army Corps of Engineers
 1683 (USACE) based on probabilistic inflow forecasts from the NWS southeastern RFC.
 1684 Given that the lake is a managed system and the forecast has a sub-seasonal lead time, the
 1685 single-valued outlook may be justified by the planned management strategy. In such a

1686 case, the lake level is a constraint that requires transferring uncertainty in lake inflows to
 1687 a different variable in the reservoir system, such as lake outflow. Alternatively, the
 1688 deterministic depiction may result from an effort to simplify probabilistic information in
 1689 the communication of the lake outlook to the public.

1690

1691 **Figure 2.7** A deterministic five-week forecast of reservoir levels in Lake Lanier, Georgia, produced by
 1692 USACE <<http://water.sam.usace.army.mil/lanfc.htm>>..
 1693

1694 **2.2.2.2 State and regional**

1695 Regionally-focused agencies such as the U.S. Bureau of Reclamation (USBR), the
 1696 Bonneville Power Administration (BPA), the Tennessee Valley Authority (TVA), and the
 1697 Great Lakes Environmental Research Laboratory (GLERL) also produce forecasts
 1698 targeting specific sectors within their priority areas. Figure 2.8 shows an example of an SI
 1699 lead forecast of lake levels produced by GLERL. GLERL was among the first major
 1700 public agencies to incorporate climate forecast information into operational forecasts
 1701 using hydrologic and water management variables. Forecasters use coarse-scale climate

1702 forecast information to adjust climatological probability distribution functions (PDFs) of
1703 precipitation and temperature that are the basis for generating synthetic ensemble inputs
1704 to hydrologic and water management models, the outputs of which include lake level as
1705 shown in the figure. In this case, the climate forecast information is from the CPC
1706 seasonal outlooks (method described in Croley, 1996).

1707

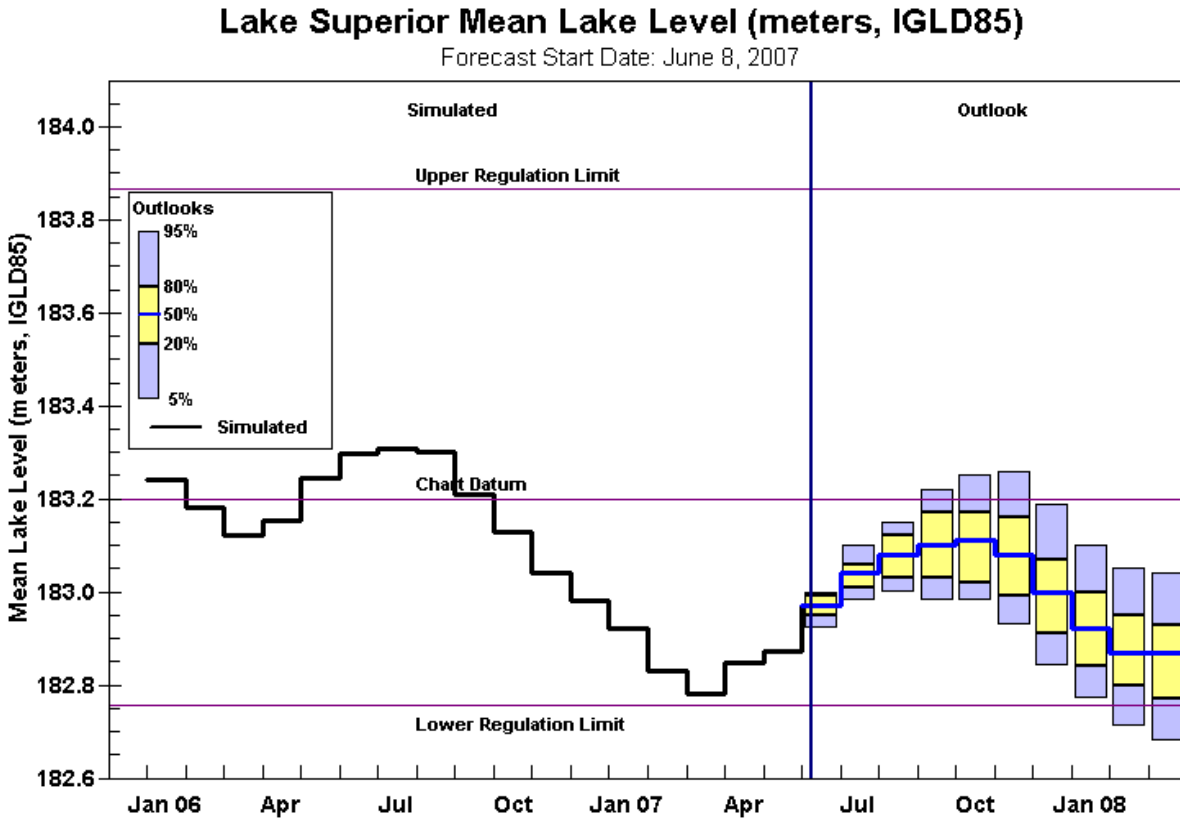

1708 The Bonneville Power Administration (BPA), which helps manage and market power
1709 from the Columbia River reservoir system, is both a consumer and producer of
1710 hydrologic forecast products. The BPA generates their own ENSO-state conditioned ESP
1711 forecasts of reservoir system inflows as input to management decisions, a practice
1712 supported by research into the benefits of ENSO information for water management
1713 (Hamlet and Lettenmaier, 1999).

1714

1715 A number of state agencies responsible for releasing hydrologic and water resources
1716 forecasts also make use of climate forecasts in the process of producing their own
1717 hydrologic forecasts. The South Florida Water Management District (SFWMD) predicts
1718 lake (*e.g.*, Lake Okeechobee) and canal stages, and makes drought assessments, using a
1719 decision tree in which the CPC seasonal outlooks play a role. SFWMD follows GLERL's
1720 lead in using the Croley (1996) method for translating the CPC seasonal outlooks to
1721 variables of interest for their system.

1722

1723

1724

1725 **Figure 2.8** Probabilistic forecasts of future lake levels disseminated by GLERL. From:
 1726 <<http://www.glerl.noaa.gov/wr/ahps/curfcst/>>.
 1727

1728 **2.2.2.3 Local**

1729 At an even smaller scale, some local agencies and private utilities may also produce
 1730 forecasts or at least derive applications-targeted forecasts from the more general climate
 1731 or hydrology forecasts generated at larger agencies or centers. Seattle Public Utilities
 1732 (SPU; see Experiment 4, Section 4.2.1), for example, operates a number of reservoirs for
 1733 use primarily in municipal water supply. SPU makes SI reservoir inflow forecasts using
 1734 statistical methods based on observed conditions in their watersheds (*i.e.*, snow and
 1735 accumulated precipitation), and on the current ENSO state, in addition to consulting the

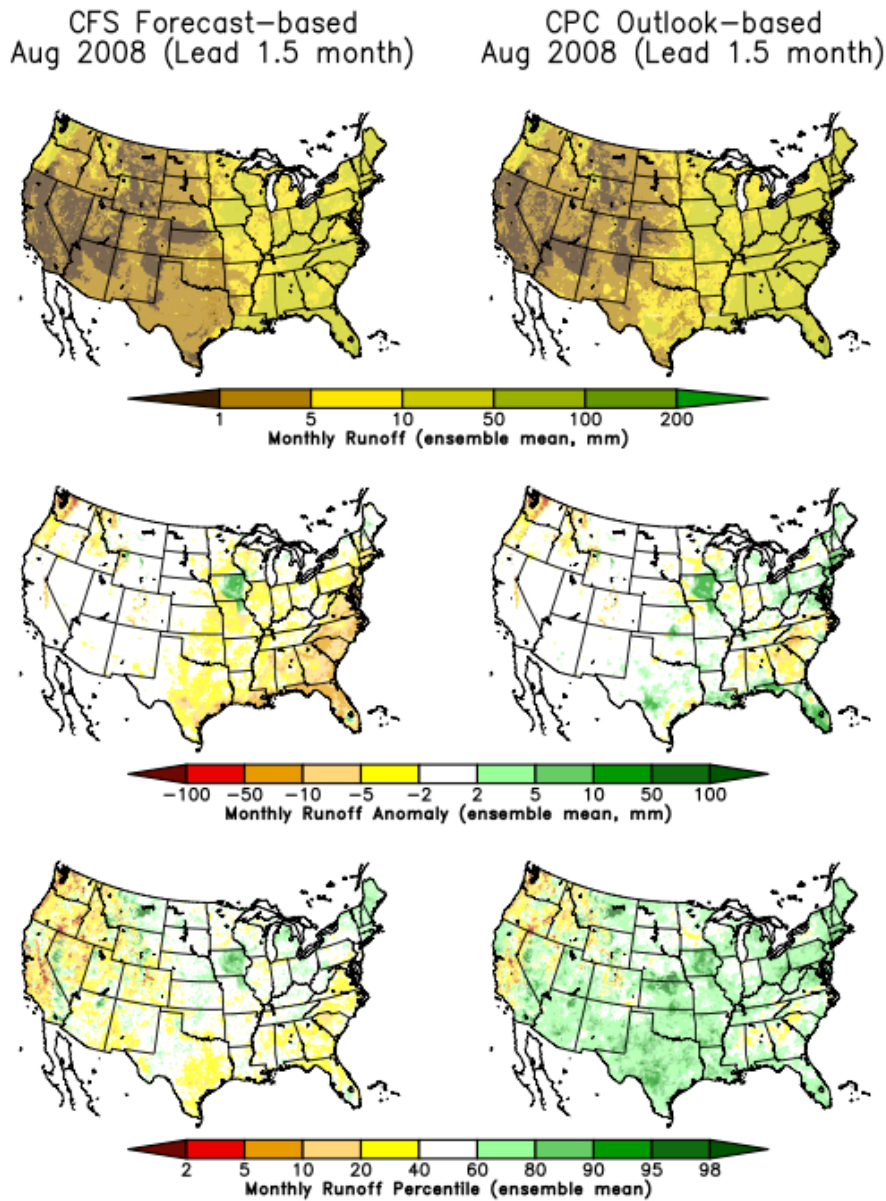

1736 Northwest River Forecast Center (NWRFC) volume runoff forecasts. The SPU forecasts
1737 are made and used internally rather than disseminated to the public.

1738

1739 **2.2.2.4 Research**

1740 Research institutions such as universities also produce hydrologic forecasts of a more
1741 experimental nature. A prime example is the Integrated Forecast and Reservoir
1742 Management (INFORM) project housed at the Hydrologic Research Center (HRC),
1743 which produces not only streamflow forecasts in the State of California, but also reservoir
1744 system forecasts. This project is discussed at greater length in Chapter 4 (Georgakakos *et*
1745 *al.*, 2005). Approximately five years ago, researchers at the University of Washington
1746 and Princeton University launched an effort to produce operational hydrologic and
1747 streamflow predictions using distributed land surface models that were developed by an
1748 interagency effort called the Land Data Assimilation System (LDAS) project (Mitchell *et*
1749 *al.*, 2004). In addition to generating SI streamflow forecasts in the western and eastern
1750 United States, the project also generates real-time forecasts for land surface variables
1751 such as runoff, soil moisture, and snow water equivalent (Wood and Lettenmaier, 2006;
1752 Luo and Wood, 2008), some of which are used in federal drought monitoring and
1753 prediction activities (Wood, 2008; Luo and Wood, 2007). Figure 2.9 shows an example
1754 (a runoff forecast) from this body of work that is based on the use of the Climate Forecast
1755 System (CFS) and CPC climate outlooks. Similar to the NWS ESP predictions, these
1756 hydrologic and streamflow forecasts are physically-based, dynamical and objective. The
1757 effort is supported primarily by NOAA, and like the INFORM project collaborates with
1758 public forecast agencies in developing research-level prediction products. The federal

1759 funding is provided with the intent of migrating operational forecasting advances that
 1760 arise in the course of these efforts into the public agencies, a topic discussed briefly in
 1761 Section 2.1.

1762

1763 **Figure 2.9** Ensemble mean forecasts of monthly runoff at lead 1.5 months created using an LDAS
 1764 hydrologic model driven by CFS and CPS climate outlooks. The hydrologic prediction techniques were
 1765 developed at the University of Washington and Princeton University as part of a real-time streamflow
 1766 forecasting project sponsored by NOAA. Other variables, not shown, include soil moisture, snow water
 1767 equivalent, and streamflow. This map is based on those available from
 1768 <<http://hydrology.princeton.edu/~luo/research/FORECAST/forecast.php>>.
 1769

1770 2.2.3 Skill in SI Hydrologic and Water Resource Forecasts

1771 This section focuses on the skill of hydrologic forecasts; Section 2.5 includes a discussion
1772 of forecast utility. Forecasts are statements about events expected to occur at specific
1773 times and places in the future. They can be either deterministic, single-valued predictions
1774 about specific outcomes, or probabilistic descriptions of likely outcomes that typically
1775 take the form of ensembles, distributions, or weighted scenarios.

1776

1777 The hydrologic and water resources forecasts made for water resources management
1778 reflect three components of predictability: the seasonality of the hydrologic cycle, the
1779 predictability associated with large-scale climate teleconnections, and the persistence of
1780 anomalies in hydrologic initial conditions. Evapotranspiration, runoff (*e.g.*, Pagano *et al.*,
1781 2004) and ground-water recharge (*e.g.*, Earman *et al.*, 2006) all depend on soil moisture
1782 and (where relevant) snowpack conditions one or two seasons prior to the forecast
1783 windows, so that these moisture conditions, directly or indirectly, are key predictors to
1784 many hydrologic forecasts with lead times up to six months. Although hydrologic initial
1785 conditions impart only a few months of predictability to hydrologic systems, during their
1786 peak months of predictability, the skill that they contribute is often paramount. This is
1787 particularly true in the western United States, where much of the year's precipitation falls
1788 during the cool season, as snow, and then accumulates in relatively easily observed form,
1789 as snowpack, until it predictably melts and runs off in the warm season months later.

1790 Information about large-scale climatic influences, like the current and projected state of
1791 ENSO, are valued because some of the predictability that they confer on water resources
1792 has influence even before snow begins to accumulate or soil-recharging fall storms

1793 arrive. ENSO, in particular, is strongly synchronized with the annual cycle so that, in
1794 many instances, the first signs of an impending warm (El Niño) or cold (La Niña) ENSO
1795 event may be discerned toward the end of the summer before the fluctuation reaches its
1796 maturity and peak of influence on the United States climate in winter. This advance
1797 warning for important aspects of water year climate allows forecasters in some locations
1798 to incorporate the expected ENSO influences into hydrologic forecasts before or near the
1799 beginning of the water year (*e.g.*, Hamlet and Lettenmaier, 1999).

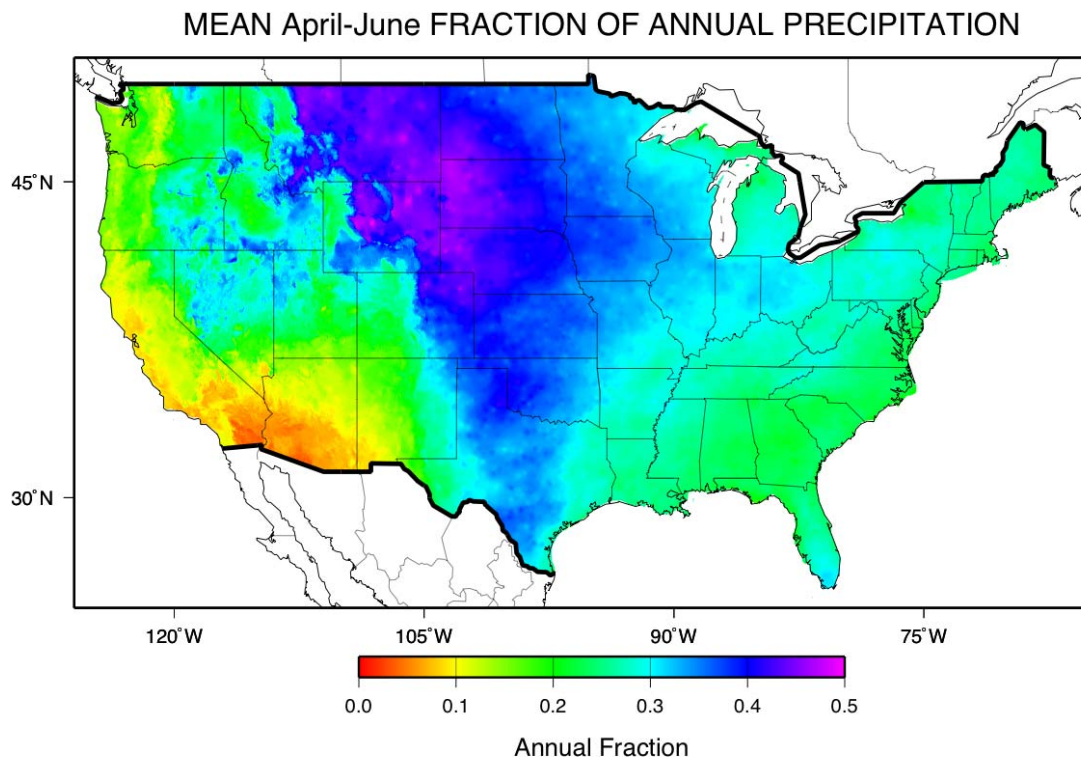

1800

1801 These large-scale climatic influences, however, rarely provide the high level of skill that
1802 can commonly be derived later in the water year from estimates of land surface moisture
1803 state, *i.e.*, from precipitation accumulated during the water year, snow water equivalent or
1804 soil moisture, as estimated indirectly from streamflow. Finally, the unpredictable, random
1805 component of variability remains to limit the skill of all real-world forecasts. The
1806 unpredictable component reflects a mix of uncertainties and errors in the observations
1807 used to initialize forecast models, errors in the models, and the chaotic complexities in
1808 forecast model dynamics and in the real world.

1809

1810 Many studies have shown that the single greatest source of forecast error is unknown
1811 precipitation after the forecast issue date. Schaake and Peck (1985) estimate that for the
1812 1947 to 1984 forecasts for inflow to Lake Powell, almost 80 percent of the January 1st
1813 forecast error is due to unknown future precipitation; by April 1st, Schaake and Peck find
1814 that future precipitation still accounts for 50 percent of the forecast error. Forecasts for a
1815 specific area can perform poorly during years with abnormally high spring precipitation

1816 or they can perform poorly if the spring precipitation in that region is normally a
1817 significant component of the annual cycle. For example, in California, the bulk of the
1818 moisture falls from January to March and it rarely rains in spring (April to June),
1819 meaning that snowpack-based April 1st forecasts of spring-summer streamflow are
1820 generally very accurate. In comparison (see Figure 2.10), in eastern Wyoming and the
1821 front range of Colorado, April through June is the wettest time of year and, by April 1st,
1822 the forecaster can only guess at future precipitation events because of an inability to
1823 skillfully forecast springtime precipitation in this region one season in advance.

1824

1825 **Figure 2.10** Mean percentages of annual precipitation that fell from April through June, 1971 to 2000
1826 (based on 4-km PRISM climatologies). This figure was obtained from
1827 <<http://www.prism.oregonstate.edu/>>.
1828

1829 Pagano *et al.* (2004) determined that the second greatest factor influencing forecasting
1830 skill is how much influence snowmelt has on the hydrology of the basin and how warm

1831 the basin is during the winter. For example, in basins high in the mountains of Colorado,
1832 the temperature remains below freezing for most of the winter. Streamflow is generally
1833 low through April until temperatures rise and the snow starts to melt. The stream then
1834 receives a major pulse of snowmelt over the course of several weeks. Spring precipitation
1835 may supplement the streamflow, but any snow that falls in January is likely to remain in
1836 the basin until April when the forecast target season starts. In comparison, in western
1837 Oregon, warm rain-producing storms can be interspersed with snow-producing winter
1838 storms. Most of the runoff occurs during the winter and it is possible for a large
1839 snowpack in February to be melted and washed away by March rains. For the forecaster,
1840 predicting April-to-July streamflow is difficult, particularly in anticipating the quantity of
1841 water that is going to “escape” before the target season begins. Additional forecast errors
1842 in snowmelt river basins can arise from the inability to accurately predict the sublimation
1843 of snow (sublimation occurs when ice or snow converts directly into atmospheric water
1844 vapor without first passing through the liquid state), a complex process that is influenced
1845 by cloudiness, sequences of meteorological conditions (wind, relative humidity as well as
1846 temperature) affecting crust, internal snow dynamics, and vegetation.

1847

1848 Some element of forecast accuracy depends on the variability of the river itself. It would
1849 be easy to incur a 100 percent forecast error on, for example, the San Francisco River in
1850 Arizona, whose observations vary between 17 percent to more than 750 percent of
1851 average. It would be much more difficult to incur such a high error on a river such as the
1852 Stehekin River in Washington, where the streamflow ranges only between 60 percent and
1853 150 percent of average. A user may be interested in this aspect of accuracy (*e.g.*, percent

1854 of normal error), but most forecasters use skill scores (*e.g.*, correlation) that would
1855 normalize for this effect and make the results from these two basins more comparable. As
1856 noted by Hartmann *et al.* (2002), consumers of forecast information may be more
1857 interested in measures of forecast skill other than correlations.

1858

1859 **2.2.3.1 Skill of current seasonal hydrologic and water-supply forecasts**

1860 As previously indicated, hydrologic and streamflow forecasts that extend to a nine-month
1861 lead time are made for western United States rivers, primarily during the winter and
1862 spring, whereas in other parts of the United States, where seasonality of precipitation is
1863 less pronounced, the forecasts link to CPC drought products, or are qualitative (the NWS
1864 Southeastern RFC, for instance, provides water supply related briefings from their
1865 website), or are in other regards less amenable to skill evaluation. For this reason, the
1866 following discussion of water supply forecast skill focuses mostly on western United
1867 States streamflow forecasting, and in particular water supply (*i.e.*, runoff volume)
1868 forecasts, for which most published material relating to SI forecasts exists.

1869

1870 In the western United States, the skill of operational forecasts generally improves
1871 progressively during the winter and spring months leading up to the period being
1872 forecasted, as increasing information about the year's land surface water budget are
1873 observable (*i.e.*, reflected in snowpack, soil moisture, streamflow and the like). An
1874 example of the long-term average seasonal evolution of NWCC operational forecast skill
1875 at a particular stream gage in Montana is shown in Figure 2.11. The flow rates that are
1876 judged to have a 50 percent chance of not being exceeded (*i.e.*, the 50th percentile or

1877 median) are shown by the blue curve for the early part of 2007. The red curve shows that,
 1878 early in the water year, the April to July forecast has little skill, measured by the
 1879 regression coefficient of determination (r^2 , or correlation squared), with only about ten
 1880 percent of historical variance captured by the forecast equations. By about April 1st, the
 1881 forecast equations predict about 45 percent of the historical variance, and at the end of the
 1882 season, the variance explained is about 80 percent. This measure of skill does not reach
 1883 100 percent because the observations available for use as predictors do not fully explain
 1884 the observed hydrologic variation.
 1885

1886

1887 **Figure 2.11** Recent operational NWCC forecasts of April-July 2007 streamflow volume in Birch Creek at
 1888 Swift Dam near Valier, Montana, showing daily median-forecast values of percentages of long-term
 1889 average streamflow total for summer 2007 (blue) and the long-term estimates of correlation-based forecast
 1890 skill corresponding to each day of the year. Figure obtained from the National Water and Climate Center
 1891 (NWCC) <<http://www.wcc.nrcs.usda.gov/>>.
 1892

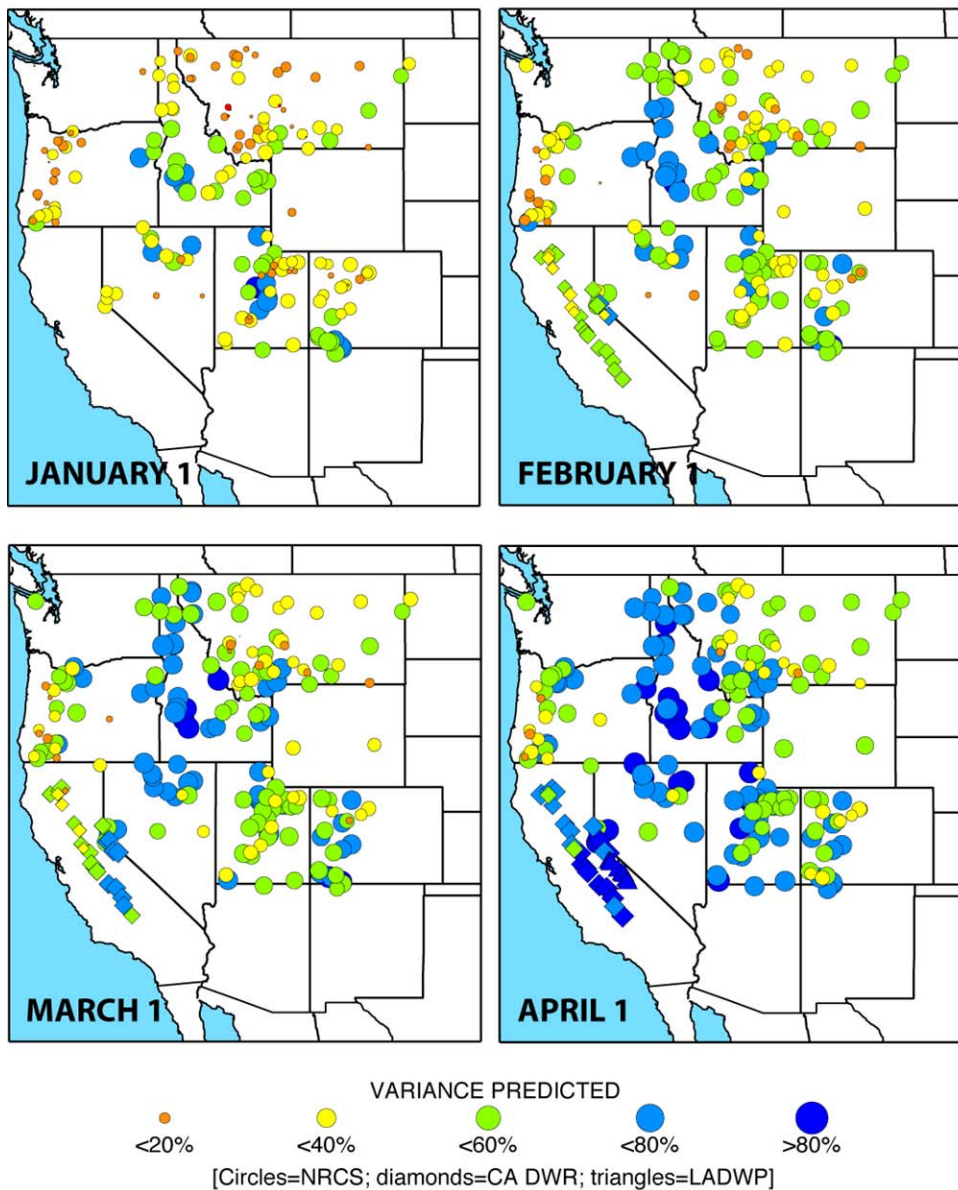

1893 Comparisons of “hindcasts”—seasonal flow estimates generated by applying the
 1894 operational forecast equations to a few decades (lengths of records differ from site to site)
 1895 of historical input variables at each location with observed flows provide estimates of the

1896 expected skill of current operational forecasts. The actual skill of the forecast equations
1897 that are operationally used at as many as 226 western stream gages are illustrated in
1898 Figure 2.12, in which skill is measured by correlation of hindcast median with observed
1899 values.

1900

1901 The symbols in the various panels of Figure 2.12 become larger and bluer in hue as the
1902 hindcast dates approach the start of the April to July seasons being forecasted. They
1903 begin with largely unskillful beginnings each year in the January 1st forecast; by April
1904 1st the forecasts are highly skillful by the correlation measures (predicting as much as 80
1905 percent of the year-to-year fluctuations) for most of the California, Nevada, and Idaho
1906 rivers, and many stations in Utah and Colorado.

**HISTORICAL CORRELATION SKILLS
FOR APRIL-JULY FLOW VOLUMES**

1907

1908 **Figure 2.12** Skills of forecast equations used operationally by NRCS, California Department of Water
 1909 Resources, and Los Angeles Department of Water and Power, for predicting April to July water supplies
 1910 (streamflow volumes) on selected western rivers, as measured by correlations between observed and
 1911 hindcasted flow totals over each station’s period of forecast records. Figure provided by Tom Pagano,
 1912 USDA NRCS.

1913

1914 The general increases in skill and thus in numbers of stations with high (correlation) skill

1915 scores as the April 1st start of the forecast period approaches is shown in Figure 2.13.

1916

1917

1918 **Figure 2.13** Percentages of stations with various correlation skill scores in the various panels (forecast
 1919 dates) of Figure 2.12.

1920

1921 A question not addressed in this Product relates to the probabilistic skill of the forecasts:

1922 How reliable are the confidence limits around the median forecasts that are provided by

1923 the published forecast quantiles (10th and 90th percentiles, for example)? In a reliable

1924 forecast, the frequencies with which the observations fall between various sets of

1925 confidence bounds matches the probability interval set by those bounds. That is, 80

1926 percent of the time, the observed values fall between the 10th and 90th percentiles of the

1927 forecast. Among the few analyses that have been published focusing on the probabilistic

1928 performance of United States operational streamflow forecasts, Franz *et al.* (2003)

1929 evaluated Colorado River basin ESP forecasts using a number of probabilistic measures

1930 and found reliability deficiencies for many of the streamflow locations considered.

1931

1932 **2.2.3.2 The implications of decadal variability and long term change in climate for**
1933 **seasonal hydrologic prediction skill**

1934 In the earlier discussion of sources of water-supply forecast skill, we highlighted the
1935 amounts and sources of skill provided by snow, soil moisture, and antecedent runoff
1936 influences. IPCC projections of global and regional warming, with its expected strong
1937 effects on western United States snowpack (Stewart *et al.*, 2004; Barnett *et al.*, 2008),
1938 raises the concern that prediction methods, such as regression, that depend on a consistent
1939 relationship between these predictors, and future runoff may not perform as expected if
1940 the current climate system is being altered in ways that then alters these hydro-climatic
1941 relationships. Decadal climate variability, particularly in precipitation (*e.g.*, Mantua *et al.*,
1942 1997; McCabe and Dettinger, 1999), may also represent a challenge to such methods,
1943 although some researchers suggest that knowledge of decadal variability can be
1944 beneficial for streamflow forecasting (*e.g.*, Hamlet and Lettenmaier, 1999). One view
1945 (*e.g.*, Wood and Lettenmaier, 2006) is that hydrologic model-based forecasting may be
1946 more robust to the effects of climate change and variability due to the physical constraints
1947 of the land surface models, but this thesis has not been comprehensively explored.

1948

1949 The maps shown in Figure 2.14 are based on hydrologic simulations of a physically-
1950 based hydrologic model, called the Variable Infiltration Capacity (VIC) model (Liang *et*
1951 *al.*, 1994), in which historical temperatures are uniformly increased by 2°C. These figures
1952 show that the losses of snowpack and the tendencies for more precipitation to fall as rain
1953 rather than snow in a warmer world reduce overall forecast skill, shrinking the areas
1954 where snowpack contributes strong predictability and also making antecedent runoff a

1955 less reliable predictor. Thus many areas where warm-season runoff volumes are
1956 accurately predicted historically are likely to lose some forecast skill along with their
1957 snowpack. Overall, the average skill declines by about two percent (out of a historical
1958 average of 35 percent) for the January to March volumes and by about four percent (out
1959 of a historical average of 53 percent) for April to July. More importantly, though, are the
1960 declines in skill at grid cells where historical skills are greatest, nearly halving the
1961 occurrence of high-end (>0.8) January-to-March skills and reducing high-end April-to-
1962 July skills by about 15 percent (Figure 2.15).
1963

CHANGES IN CONTRIBUTIONS OF FORECAST SKILL FOR SEASONAL RUNOFF IN RESPONSE TO +2°C WARMING

JANUARY-MARCH RUNOFF FROM DECEMBER PREDICTORS

APRIL-JULY RUNOFF FROM MARCH PREDICTORS

1964

1965

1966

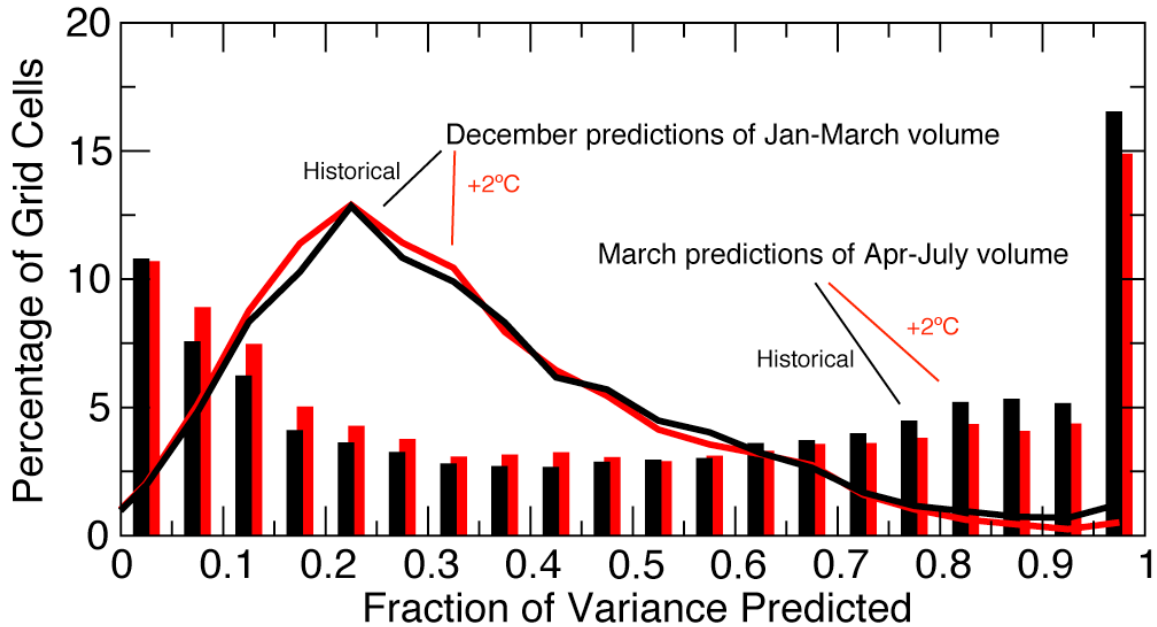

1967

1968

1969

1970

Figure 2.14 Potential contributions of antecedent snowpack conditions, runoff, and Niño 3.4 sea-surface temperatures to seasonal forecast skills in hydrologic simulations under historical, 1950 to 1999, meteorological conditions (left panels) and under those same conditions but with a 2°C uniform warming imposed (Dettinger, 2007).

1971

1972 **Figure 2.15** Distributions of overall fractions of variance predicted, in Figure 2.13, of January to March
 1973 (curves) and April to July (histograms) runoff volumes under historical (black) and +2°C warmer
 1974 conditions (Dettinger, 2007).

1975

1976 This enhanced loss among the most skillful grid cells reflects the strong reliance of those
 1977 grid cells on historical snowpacks for the greater part of their skill, snowpacks which
 1978 decline under the imposed 2°C warmer conditions. Overall, skills associated with
 1979 antecedent runoff are more strongly reduced for the April-to-July runoff volumes, with
 1980 reductions from an average contribution of 24 percent of variance predicted (by
 1981 antecedent runoff) historically to 21 percent under the 2°C warm conditions; for the
 1982 January to March volumes, skill contributed by antecedent runoff only declines from 18.6
 1983 percent to 18.2 percent under the imposed warmer conditions. The relative declines in the
 1984 contributions from snowpack and antecedent runoff make antecedent runoff (or, more
 1985 directly, soil moisture, for which antecedent runoff is serving as a proxy here) a more
 1986 important predictor to monitor in the future (for a more detailed discussion, see Section
 1987 2.4.2).

1988

1989 It is worth noting that the changes in skill contributions illustrated in Figure 2.14 are best-
1990 case scenarios. The skills shown are skills that would be provided by a complete
1991 recalibration of forecast equations to the new (imposed) warmer conditions, based on 50
1992 years of runoff history. In reality, the runoff and forecast conditions are projected to
1993 gradually and continually trend towards increasingly warm conditions, and fitting new,
1994 appropriate forecast equations (and models) will always be limited by having only a brief
1995 reservoir of experience with each new degree of warming. Consequently, we must expect
1996 that regression-based forecast equations will tend to be increasingly and perennially out
1997 of date in a world with strong warming trends. This problem with the statistics of forecast
1998 skill in a changing world suggests development and deployment of more physically
1999 based, less statistically based forecast models should be a priority in the foreseeable
2000 future (Herrmann, 1992; Gleick *et al.*, 2000; Milly *et al.*, 2008).

2001

2002 **2.2.3.3 Skill of climate forecast-driven hydrologic forecasts**

2003 The extent to which the ability to forecast U.S. precipitation and temperature seasons in
2004 advance can be translated into long-lead hydrologic forecasting has been evaluated by
2005 Wood *et al.* (2005). That evaluation compared hydrologic variables in the major river
2006 basins of the western conterminous United States as simulated by the VIC hydrologic
2007 model (Liang *et al.*, 1994), forced by two different sources of temperature and
2008 precipitation data: (1) observed historical meteorology (1979 to 1999); and (2) by
2009 hindcast climate-model-derived six-month-lead climate forecasts.

2010

2011 The Wood *et al.* (2005) assessment quantified and reinforced an important aspect of the
2012 hydrologic forecasting community’s intuition about the current levels of hydrologic
2013 forecast skill using long-lead climate forecasts generated from various sources. The
2014 analysis first underscored the conclusions that, depending on the season, knowledge of
2015 initial hydrologic conditions conveys substantial forecast skill. A second finding was that
2016 the additional skill available from incorporating current (at the time) long-lead climate
2017 model forecasts into hydrologic prediction is limited when all years are considered, but
2018 can improve streamflow forecasts relative to climatological ESP forecasts in extreme
2019 ENSO years. If performance in all years is considered, the skill of current climate
2020 forecasts (particularly of precipitation) is inadequate to provide readily extracted
2021 hydrologic-forecast skill at monthly to seasonal lead times. This result is consistent with
2022 findings for North American climate predictability (Saha *et al.*, 2006). During El Niño
2023 years, however, the climate forecasts have adequate skill for temperatures, and mixed
2024 skill for precipitation, so that hydrologic forecasts for some seasons and some basins
2025 (especially California, the Pacific Northwest and the Great Basin) provide measurable
2026 improvements over the ESP alternative.

2027

2028 The authors of the Wood *et al.* (2005) assessment concluded that “climate model
2029 forecasts presently suffer from a general lack of skill, [but] there may be locations, times
2030 of year and conditions (*e.g.*, during El Niño or La Niña) for which they improve
2031 hydrologic forecasts relative to ESP.” However, their conclusion was that improvements
2032 to hydrologic forecasts based on other forms of climate forecasts, *e.g.*, statistical or
2033 hybrid methods that are not completely reliant on a single climate model, may prove

2034 more useful in the near term in situations where alternative approaches yield better
2035 forecast skill than that which currently exists in climate models.

2036

2037 **2.3 CLIMATE DATA AND FORECAST PRODUCTS**

2038 **2.3.1 A Sampling of SI Climate Forecast Products of Interest to Water Resource**

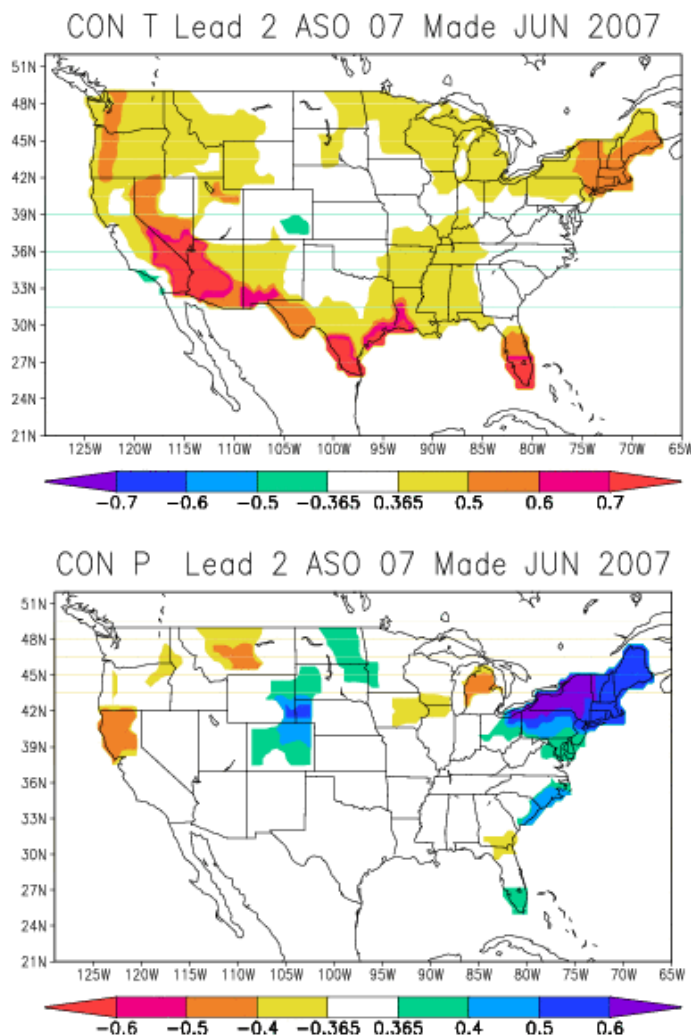

2039 **Managers**

2040 At SI lead times, a wide array of dynamical prediction products exist. A representative
2041 sample of SI climate forecast products is listed in Appendix A.1. The current dynamical
2042 prediction scheme used by NCEP, for example, is a system of models comprising
2043 individual models of the oceans, global atmosphere and continental land surfaces. These
2044 models were developed and originally run for operational forecast purposes in an
2045 uncoupled, sequential mode, an example of which is the so-called “Tier 2” framework in
2046 which the ocean model runs first, producing ocean surface boundary conditions that are
2047 prescribed as inputs for subsequent atmospheric model runs. Since 2004, a “Tier 1”
2048 scheme was introduced in which the models, together called the Coupled Forecast
2049 System (CFS; Saha *et al.*, 2006), were fully coupled to allow dynamic exchanges of
2050 moisture and energy across the interfaces of the model components.

2051

2052 At NCEP, the dynamical tool, CFS, is complemented by a number of statistical forecast
2053 tools, three of which, Screening Multiple Linear Regression (SMLR), Optimal Climate
2054 Normals (OCN), and Canonical Correlation Analysis (CCA), are merged with the CFS to
2055 form an objective consolidation forecast product (Figure 2.16). While the consolidated
2056 forecast exceeds the skill of the individual tools, the official seasonal forecast from CPC

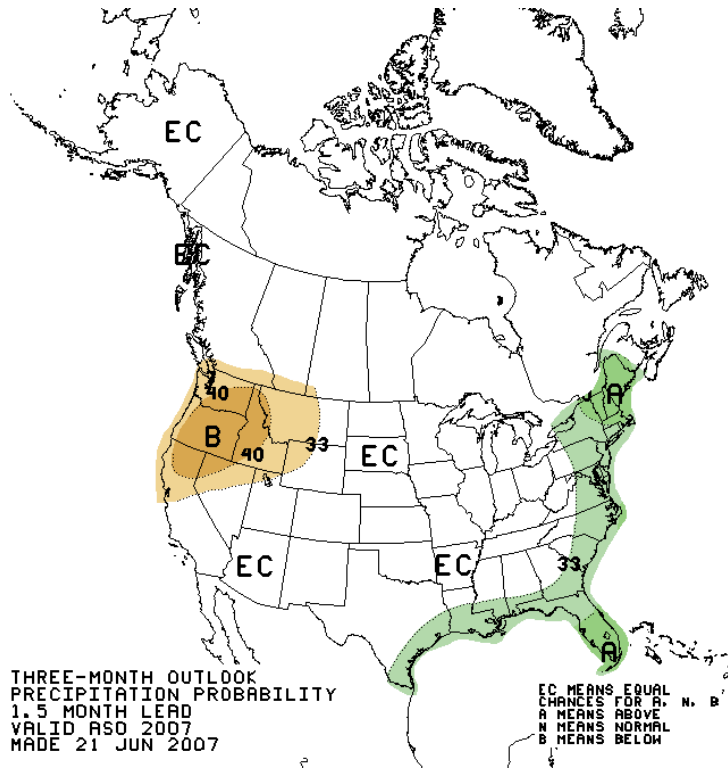

2057 involves a subjective merging of it with forecast and nowcast information sources from a
 2058 number of different sources, all accessible to the public at CPC’s monthly briefing. The
 2059 briefing materials comprise 40 different inputs regarding the past, present and expected
 2060 future state of the land, oceans and atmosphere from sources both internal and external to
 2061 CPC. These materials are posted online at:
 2062 <<http://www.cpc.ncep.noaa.gov/products/predictions/90day/tools/briefing/>>.

2063

2064 **Figure 2.16** CPC objective consolidation forecast made in June 2007 (lead 2 months) for precipitation and
 2065 temperature for the three month period Aug-Sep-Oct 2007. Figure obtained from
 2066 <<http://www.cpc.ncep.noaa.gov>>.
 2067

2068 The resulting official forecast briefing has been the CPC's primary presentation of
2069 climate forecast information each month. Forecast products are accessible directly from
2070 CPC's root level home page in the form of maps of the probability anomalies for
2071 precipitation and temperature in three categories, or "terciles," representing below-
2072 normal, normal and above-normal values; a two-category scheme (above and below
2073 normal) is also available. This framework is used for the longer lead outlooks (Figure
2074 2.17). The seasonal forecasts are also available in the form of maps of climate anomalies
2075 in degrees Celsius for temperature and inches for precipitation (Figure 2.18). The
2076 forecasts are released monthly, have a time-step of three months, and have a spatial unit
2077 of the climate division (Figure 2.19). For users desiring more information about the
2078 probabilistic forecast than is given in the map products, a "probability of exceedence"
2079 (POE) plot, with associated parametric information, is also available for each climate
2080 division (Figure 2.20). The POE plot shows the shift of the forecast probability
2081 distribution from the climatological distribution for each lead-time of the forecast.
2082

2083

2084

2085 **Figure 2.17** NCEP CPC seasonal outlook for precipitation also shown as a tercile probability map.
2086 Tan/brown (green) shading indicates regions where the forecast indicates an increased probability for
2087 precipitation to be in the dry (wet) tercile, and the degree of shift is indicated by the contour labels. EC
2088 means the forecast predicts equal chances for precipitation to be in the A (above normal), B (below
2089 normal), or N (normal) terciles. Figure obtained from
2090 <http://www.cpc.ncep.noaa.gov/products/predictions/multi_season/13_seasonal_outlooks/color/page2.gif>.
2091

Anomaly (Inches) of the Mid-value of the 3-Month Precipitation Outlook Distribution for ASO 2007

Dashed lines are the median 3-month precipitation (inches) based on observations from 1971-2000. Shaded areas indicate whether the anomaly of the mid-value is positive (green) or negative (brown) compared to the 1971-2000 average. Non-shaded regions indicate that the absolute value of the anomaly of the mid-value is less than 0.1. For a given location, the mid-value of the outlook may be found by adding the anomaly value to the 1971-2000 average. There is an equal 50-50 chance that actual conditions will be above or below the mid-value. Please note that this product is a limited representation of the official forecast, showing the anomaly of the mid-value, but not the width of the range of possibilities. For more comprehensive forecast information, please see our additional forecast products.

2092

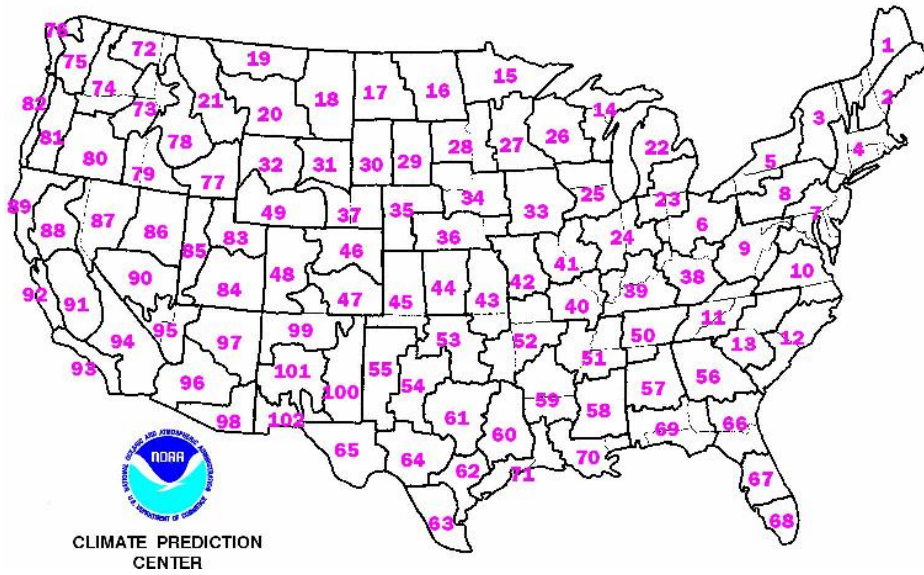

2093 **Figure 2.18** The NCEP CPC seasonal outlook for precipitation shown as inches above or below the total
 2094 normal precipitation amounts for the 3-month target period (compare with the probability of exceedence
 2095 forecast product shown in Figure 2.20). Figure obtained from

2104

PRECIPITATION OUTLOOK FOR ASO 2007
1.5 MONTH LEAD OUTLOOK – MADE June 21 2007
 Climate Division 75 (Seattle Region, Washington)

2105

2106 **Figure 2.20** The NCEP CPC seasonal outlook for precipitation in the Seattle Region Climate Division
 2107 (Division 75 in Figure 2.19) shown as the probability of exceedance for total precipitation for the three-
 2108 month target period
 2109 <[http://www.cpc.ncep.noaa.gov/products/predictions/long_range/poe_graph_index.php?lead=3&climdiv=7](http://www.cpc.ncep.noaa.gov/products/predictions/long_range/poe_graph_index.php?lead=3&climdiv=75&var=p)
 2110 5&var=p.>.
 2111

2112 In addition to NCEP, a few other centers, (e.g., the International Research Institute for
 2113 Climate and Society [IRI]) produce similar consensus forecasts and use a similar map-
 2114 based, tercile-focused framework for exhibiting their results. A larger number of centers
 2115 run dynamical forecast tools, and the NOAA Climate Diagnostics Center, which
 2116 produces monthly climate outlooks internally using statistical tools, also provides
 2117 summaries of climate forecasts from a number of major sources, both in terms of
 2118 probabilities or anomalies, for selected surface and atmospheric variables. Using

2119 dynamical models, the Experimental Climate Prediction Center (ECPC) at Scripps
2120 Institute provides monthly and seasonal time step forecasts of both climate and land
2121 surface variables at a national and global scale. Using these model outputs, ECPC also
2122 generates forecasts for derived variables that target wildfire management—*e.g.*, soil
2123 moisture and the Fireweather Index (see Chapter 4 for a more detailed description of
2124 Water Resource Issues in Fire-Prone U.S. Forests and the use of this index). The CPC has
2125 made similar efforts in the form of the Hazards Assessment, a short- to medium-range
2126 map summary of hazards related to extreme weather (such as flooding and wildfires), and
2127 the CPC Drought Outlook (Box 2.3), a subjective consensus product focusing on the
2128 evolution of large-scale droughts that is released once a month, conveying expectations
2129 for a three-month outlook period.

2130

2131 The foregoing is a brief survey of climate forecast products from major centers in the
2132 United States, and, as such, is far from a comprehensive presentation of the available
2133 sources. It does, however, provide examples from which the following observations about
2134 the general nature of climate prediction in the United States may be drawn. First, that
2135 operational SI climate forecasting is conducted at a relatively small number of federally-
2136 funded centers, and the resulting forecast products are national to global in scale. These
2137 products tend to have a coarse resolution in space and time, and are typically for basic
2138 earth system variables (*e.g.*, temperature, precipitation, atmospheric pressure) that are of
2139 general interest to many sectors. Forecasts are nearly always probabilistic, and the major
2140 products attempt to convey the inherent uncertainty via maps or data detailing forecast

2141 probabilities, although deterministic reductions (such as forecast variable anomalies) are
2142 also available.

2143

2144 **2.3.2 Sources of Climate-Forecast Skill for North America**

2145 Much as with hydrologic forecasts, the skill of forecasts of climate variables (notably,
2146 temperature and precipitation) is not straight forward as it varies from region to region as
2147 well as with the forecast season and lead time; it is also limited by the chaotic and
2148 uncertain character of the climate system and derives from a variety of sources. While
2149 initial conditions are an important source for skill in SI hydrologic forecasts, the initial
2150 conditions of an atmospheric forecast are of little use after about eight to ten days as other
2151 forecast errors and/or disturbances rapidly grow, and therefore have no influence on SI
2152 climate forecast skill (Molteni *et al.*, 1996). SI forecasts are actually forecasts of those
2153 variations of the climate system that reflect predictable changes in boundary conditions,
2154 like sea-surface temperatures (SSTs), or in external ‘forcings,’ disturbances in the
2155 radiative energy budget, of the Earth’s climate system. At time scales of decades to
2156 centuries, potential skill rests in predictions for slowly varying components of the climate
2157 system, like the atmospheric concentrations of carbon dioxide that influence the
2158 greenhouse effect, or slowly evolving changes in ocean circulation that can alter SSTs
2159 and thereby change the boundary conditions for the atmosphere. Not all possible sources
2160 of SI climate-forecast skill have been identified or exploited, but contributors that have
2161 been proposed and pursued include a variety of large-scale air-sea connections (*e.g.*,
2162 Redmond and Koch, 1991; Cayan and Webb, 1992; Mantua *et al.*, 1997; Enfield *et al.*,
2163 2001; Hoerling and Kumar, 2003), snow and sea ice patterns (*e.g.*, Cohen and Entekhabi,

2164 1999; Clark and Serreze, 2000; Lo and Clark, 2002; Liu *et al.*, 2004), and soil moisture
2165 and vegetation regimes (*e.g.*, Koster and Suarez, 1995, 2001; Ni-Meister *et al.*, 2005).
2166
2167 In operational practice, however, most of the forecast skill provided by current forecast
2168 systems (especially including climate models) derives from our ability to predict the
2169 evolution of ENSO events on time scales of 6 to 12 months, coupled with the
2170 “teleconnections” from the events in the tropical Pacific to many areas of the globe.
2171 Barnston *et al.* (1999), in their explanation of the advent of the first operational long-lead
2172 forecasts from the NOAA Climate Prediction Center, stated that “while some
2173 extratropical processes probably develop independently of the Tropics..., much of the
2174 skill of the forecasts for the extratropics comes from anomalies of ENSO-related tropical
2175 sea-surface temperatures.” Except for the changes associated with diurnal cycles,
2176 seasonal cycles, and possibly the (30 to 60 day) Madden-Julian Oscillation of the tropical
2177 ocean-atmosphere system, “ENSO is the most predictable climate fluctuation on the
2178 planet” (McPhaden *et al.*, 2006). Diurnal cycles and seasonal cycles are predictable on
2179 time scales of hours-to-days and months-to-years, respectively, whereas ENSO mostly
2180 provides predictability on SI time scales. Figure 2.21a shows that temperatures over the
2181 tropical oceans and lands and extratropical oceans are more correlated from season to
2182 season than the extratropical continents. To the extent that they can anticipate the slow
2183 evolution of the tropical oceans, indicated by these correlations, SCFs in the extratropics
2184 that derive their skill from an ability to forecast conditions in the tropical oceans are
2185 provided a basis for prediction skill. To the extent that the multi-seasonal long-term
2186 potential predictability of the ENSO episodes (Figure 2.21b) can be drawn upon in

2187 certain regions at certain times of year, the relatively meager predictabilities of North
 2188 American temperatures and precipitation can be extended.
 2189

2190

2191

2192 **Figure 2.21** (a) Map of correlations between surface-air temperatures in each season and the following
 2193 season in 600 years of historical climate simulation by the HadCM3 model (Collins 2002); (b) Potential
 2194 predictability of a common ENSO index (Niño3 SST, the average of SSTs between 150°W and 90W, 5°S
 2195 and 5°N), average temperatures over the United States and Canada, and average precipitation over the
 2196 United States and Canada, with skill measured by anomaly correlations and plotted against the forecast lead
 2197 times; results extracted from Collins (2002), who estimated these skills from the reproducibility among
 2198 multiple simulations of 30 years of climate by the HadCM3 coupled ocean-atmosphere model. Correlations
 2199 below about 0.3 are not statistically significant at the 95 percent level.
 2200

2201 The scattered times between ENSO events drastically limits skillful prediction of events
 2202 until, at least, the first faltering steps towards the initiation of an ENSO event have been

2203 observed. ENSO events, however, are frequently (but not always) phase-locked
2204 (synchronized) with aspects of the seasonal cycle (Neelin *et al.*, 2000), so that (a)
2205 forecasters know when to look most diligently for those “first faltering steps” and (b) the
2206 first signs of the initiation of an event are often witnessed six to nine months prior to
2207 ENSO’s largest expressions in the tropics and Northern Hemisphere (*e.g.*, Penland and
2208 Sardeshmukh, 1995). Thus, ENSO influences, however irregular and unpredictable they
2209 are on multiyear time scales, regularly provide the basis for SI climate forecasts over
2210 North America. ENSO events generally begin their evolution sometime in late (northern)
2211 spring or early summer, growing and maturing until they most often reach full strength
2212 (measured by either their SST expressions in the tropical Pacific or by their influences on
2213 the Northern Hemisphere) by about December – March (*e.g.*, Chen and van den Dool
2214 1997). An ENSO event’s evolution in the tropical ocean and atmosphere during the
2215 interim period is reproducible enough that relatively simple climate indices that track
2216 ENSO-related SST and atmospheric pressure patterns in the tropical Pacific provide
2217 predictability for North American precipitation patterns as much as two seasons in
2218 advance. Late summer values of the Southern Oscillation Index (SOI), for instance, are
2219 significantly correlated with a north-south see-saw pattern of wintertime precipitation
2220 variability in western North America (Redmond and Koch, 1991).

2221

2222 **2.4 IMPROVING WATER RESOURCES FORECAST SKILL AND PRODUCTS**

2223 Although forecast skill is only one measure of the value that forecasts provide to water
2224 resources managers and the public, it is an important measure, and current forecasts are
2225 generally understood to fall short of the maximum possible skill on SI time scales (*e.g.*,

2226 <http://www.clivar.org/organization/wgsip/spw/spw_position.php>). Schaake *et al.*
2227 (2007) describe the SI hydrologic prediction process for model-based prediction in terms
2228 of several components: (1) development, calibration and/or downscaling of SI climate
2229 forecasts; (2) estimation of hydrologic initial conditions, with or without data
2230 assimilation; (3) SI hydrologic forecasting models and methods; and (4) calibration of the
2231 resulting forecasts. Notable opportunities for forecast skill improvement in each area are
2232 discussed here.

2233

2234 **2.4.1 Improving SI Climate Forecast Use for Hydrologic Prediction**

2235 SI climate forecast skill is a function of the skill of climate system models, the efficacy of
2236 model combination strategies if multiple models are used, the accuracy of climate system
2237 conditions from which the forecasts are initiated, and the performance of post-processing
2238 approaches applied to correct systematic errors in numerical model outputs.
2239 Improvements are sought in all of these areas.

2240

2241 **2.4.1.1 Climate forecast use**

2242 Many researchers have found that SI climate forecasts must be downscaled,
2243 disaggregated and statistically calibrated to be suitable as inputs for applied purposes
2244 (*e.g.*, hydrologic prediction, as in Wood *et al.*, 2002). Downscaling is the process of
2245 bridging the spatial scale gap between the climate forecast resolution and the
2246 application's climate input resolution, if they are not the same. If the climate forecasts are
2247 from climate models, for instance, they are likely to be at a grid resolution of several
2248 hundred kilometers, whereas the application may require climate information at a point

2249 (*e.g.*, station location). Disaggregation is similar to downscaling, but in the temporal
2250 dimension—*e.g.*, seasonal climate forecasts may need to be translated into daily or sub-
2251 daily temperature and precipitation inputs for a given application (as described in Kumar,
2252 2008). Forecast calibration is a process by which the statistical properties (such as bias
2253 and spread errors) of a probabilistic forecast are corrected to match their observed error
2254 statistics (*e.g.*, Atger, 2003; Hamill *et al.*, 2006). These procedures may be distinct from
2255 each other, or they may be inherent parts of a single approach (such as the analogue
2256 techniques of Hamill *et al.*, 2006). These steps do not necessarily improve the signal to
2257 noise ratio of the climate forecast, but done properly, they do correct bias and reliability
2258 problems that would otherwise render impossible their use in applications. For shorter
2259 lead predictions, corrections to forecast outputs have long been made based on (past)
2260 model output statistics (MOS; Glahn and Lowry, 1972). MOS are sets of statistical
2261 relations (*e.g.*, multiple linear regression) that effectively convert numerical model
2262 outputs into unbiased, best climate predictions for selected areas or stations, where “best”
2263 relates to past performance of the model in reproducing observations. MOS corrections
2264 are widely used in weather prediction (Dallavalle and Glahn, 2005). Corrections may be
2265 as simple as removal of mean biases indicated by historical runs of the model, with the
2266 resulting forecasted anomalies superimposed on station climatology. More complex
2267 methods specifically address spatial patterns in climate forecasts based on specific
2268 inadequacies of the models in reproducing key teleconnection patterns or topographic
2269 features (*e.g.*, Landman and Goddard, 2002; Tippett *et al.*, 2003).
2270

2271 A primary limitation on calibrating SI forecasts is the relatively small number of
2272 retrospective forecasts available for identifying biases. Weather predictions are made
2273 every day, so even a few years of forecasts provide a large number of examples from
2274 which to learn. SI forecasts, in contrast, are comparatively infrequent and even the
2275 number of forecasts made over several decades may not provide an adequate resource
2276 with which to develop model-output corrections (Kumar, 2007). This limitation is
2277 exacerbated when the predictability and biases themselves vary between years and states
2278 of the global climate system. Thus there is a clear need to expand current “reforecast”
2279 practices for fixed SI climate models over long historical periods to provide both for
2280 quantification (and verification) of the evolution of SI climate forecast skills and for post-
2281 processing calibrations to those forecasts.

2282

2283 **2.4.1.2 Development of objective multi-model ensemble approaches**

2284 The accuracy of SI climate forecasts has been shown to increase when forecasts from
2285 groups of models are combined into multi-model ensembles (*e.g.*, Krishnamurti *et al.*,
2286 2000; Palmer *et al.*, 2004; Tippett *et al.*, 2007). Multi-model forecast ensembles yield
2287 greater overall skill than do any of the individual forecasts included, in principle, as a
2288 result of cancellation of errors between ensemble members. Best results thus appear to
2289 accrue when the individual models are of similar skill and when they exhibit errors and
2290 biases that differ from model to model. In part, these requirements reflect the current
2291 uncertainties about the best strategies for choosing among models for inclusion in the
2292 ensembles used and, especially for weighting and combining the model forecasts within
2293 the ensembles. Many methods have been proposed and implemented (*e.g.*, Rajagopalan *et*

2294 *al.*, 2002; Yun *et al.*, 2005), but strategies for weighting and combining ensemble
2295 members are still an area of active research (*e.g.*, Doblas-Reyes *et al.*, 2005; Coelho *et*
2296 *al.*, 2004). Multi-model ensemble forecast programs are underway in Europe
2297 (DEMETER, Palmer *et al.*, 2004) and in Korea (APEC; *e.g.*, Kang and Park, 2007). In
2298 the United States, IRI forms an experimental multi-model ensemble forecast, updating
2299 monthly, from seasonal forecast ensembles run separately at seven centers, a “simple
2300 multi-model” approach that compares well with centrally organized efforts such as
2301 DEMETER (Doblas-Reyes *et al.*, 2005). The NOAA Climate Test Bed Science Plan also
2302 envisions such a capability for NOAA (Higgins *et al.*, 2006).

2303

2304 **2.4.1.3 Improving climate models, initial conditions, and attributions**

2305 Improvements to climate models used in SI forecasting efforts should be a high priority.

2306 Several groups of climate forecasters have identified the lack of key aspects of the
2307 climate system in current forecast models as important weaknesses, including
2308 underrepresented linkages between the stratosphere and troposphere (Baldwin and
2309 Dunkerton, 1999), limited processes and initial conditions at land surfaces (Beljaars *et*
2310 *al.*, 1996; Dirmeyer *et al.*, 2006; Ferranti and Viterbo, 2006), and lack of key
2311 biogeochemical cycles like carbon dioxide.

2312

2313 Because climate prediction is, by most definitions, a problem determined by boundary
2314 condition rather than an initial condition, specification of atmospheric initial conditions is
2315 not the problem for SI forecasts that it is for weather forecasts. However, SI climate
2316 forecast skill for most regions comes from knowledge of current SSTs or predictions of

2317 future SSTs, especially those in the tropics (Shukla *et al.*, 2000; Goddard and Dilley,
2318 2005; Rosati *et al.*, 1997). Indeed, forecast skill over land (worldwide) increases directly
2319 with the strength of an ENSO event (Goddard and Dilley, 2005). Thus, an important
2320 determinant of recent improvements in SI forecast skill has been the quality and
2321 placement of tropical ocean observations, like the TOGA-TAO (Tropical Atmosphere
2322 Ocean project) network of buoys that monitors the conditions that lead up to and
2323 culminate in El Niño and La Niña events (Trenberth *et al.*, 1998; McPhaden *et al.*, 1998;
2324 Morss and Battisti, 2004). More improvements in all of the world's oceans are expected
2325 from the broader Array for Real-time Geostrophic Oceanography (ARGO) upper-ocean
2326 monitoring arrays and Global Ocean Observing System (GOOS) programs (Nowlin *et al.*,
2327 2001). In many cases, and especially with the new widespread ARGO ocean
2328 observations, ocean data assimilation has improved forecast skill (*e.g.*, Zheng *et al.*,
2329 2006). Data assimilation into coupled ocean-atmosphere-land models is a difficult and
2330 unresolved problem that is an area of active research (*e.g.*, Ploshay and Anderson, 2002;
2331 Zheng *et al.*, 2006). Land-surface and cryospheric conditions also can influence the
2332 seasonal-scale dynamics that lend predictability to SI climate forecasting, but
2333 incorporation of these initial boundary conditions into SI climate forecasts is in an early
2334 stage of development (Koster and Suarez, 2001; Lu and Mitchell, 2004; Mitchell *et al.*,
2335 2004). Both improved observations and improved avenues for including these conditions
2336 into SI climate models, especially with coupled ocean-atmosphere-land models, are
2337 needed. Additionally, education and expertise deficiencies contribute to unresolved
2338 problems in data assimilation for geophysical modeling. OFCM (2007) documents that
2339 there is a need for more students (either undergraduate or graduate) who have sufficient

2340 mathematics and computer science skills to engage in data assimilation work in the
2341 research and/or operational environment.
2342
2343 Finally, a long-standing but little explored approach to improving the value of SI climate
2344 forecasts is the attribution of the causes of climate variations. The rationale for an
2345 attribution effort is that forecasts have greater value if we know why the forecasted event
2346 happened, either before or after the event, and why a forecast succeeded or failed, after
2347 the event. The need to distinguish natural from human-caused trends, and trends from
2348 fluctuations, is likely to become more and more important as climate change progresses.
2349 SI forecasts are likely to fail from time to time or to realize less probable ranges of
2350 probabilistic forecasts. Knowing that forecasters understand the failures (in hindsight)
2351 and have learned from them will help to build increasing confidence through time among
2352 users. Attempts to attribute causes to important climate events began as long ago as the
2353 requests from Congress to explain the 1930s Dust Bowl. Recently NOAA has initiated a
2354 Climate Attribution Service (see: <<http://www.cdc.noaa.gov/CSI/>>) that will combine
2355 historical records, climatic observations, and many climate model simulations to infer the
2356 principal causes of important climate events of the past and present. Forecasters can
2357 benefit from knowledge of causes and effects of specific climatic events as well as
2358 improved feedbacks as to what parts of their forecasts succeed or fail. Users will also
2359 benefit from knowing the reasons for prediction successes and failures.

2360

2361 **2.4.2 Improving Initial Hydrologic Conditions for Hydrologic and Water Resource**
2362 **Forecasts**

2363 Operational hydrologic and water resource forecasts at SI time scales derive much of
2364 their skill from hydrologic initial conditions, with the particular sources of skill
2365 depending on seasons and locations. Better estimation of hydrologic initial conditions
2366 will, in some seasons, lead to improvements in SI hydrologic and consequently, water
2367 resources forecast skill. The four main avenues for progress in this area are: (1)
2368 augmentation of climate and hydrologic observing networks; (2) improvements in
2369 hydrologic models (*i.e.*, physics and resolution); (3) improvements in hydrologic model
2370 calibration approaches; and (4) data assimilation.

2371

2372 **2.4.2.1 Hydrologic observing networks**

2373 As discussed previously (in Section 2.2), hydrologic and hydroclimatic monitoring
2374 networks provide crucial inputs to hydrologic and water resource forecasting models at SI
2375 time scales. Continuous or regular measurements of streamflow, precipitation and snow
2376 water contents provide important indications of the amount of water that entered and left
2377 river basins prior to the forecasts and thus directly or indirectly provide the initial
2378 conditions for model forecasts.

2379

2380 Observed snow water contents are particularly important sources of predictability in most
2381 of the western half of the United States, and have been measured regularly at networks of
2382 snow courses since the 1920s and continually at SNOTELs (automated and telemetered
2383 snow instrumentation sites) since the 1950s. Snow measurements can contribute as much
2384 as three-fourths of the skill achieved by warm-season water supply forecasts in the West
2385 (Dettinger, 2007). However, recent studies have shown that measurements made at most

2386 SNOTELs are not representative of overall basin water budgets, so that their value is
2387 primarily as indices of water availability rather than as true monitors of the overall water
2388 budgets (Molotch and Bales, 2005). The discrepancy arises because most SNOTELs are
2389 located in clearings, on flat terrain, and at moderate altitudes, rather than the more
2390 representative snow courses that historically sampled snow conditions throughout the
2391 complex terrains and micrometeorological conditions found in most river basins. The
2392 discrepancies limit some of the usefulness of SNOTEL measurements as the field of
2393 hydrologic forecasting moves more and more towards physically-based, rather than
2394 empirical-statistical models. To remedy this situation, and to provide more diverse and
2395 more widespread inputs as required by most physically-based models, combinations of
2396 remotely sensed snow conditions (to provide complete areal coverage) and extensions of
2397 at least some SNOTELs to include more types of measurements and measurements at
2398 more nearby locations will likely be required (Bales *et al.*, 2006).

2399

2400 Networks of ground-water level measurements are also important because: (1) these data
2401 support operations and research, and (2) the networks' data may be critical to some
2402 aspects of future hydrologic forecast programs. Ground-water level measurements are
2403 made at thousands of locations around the United States, but they have only recently been
2404 made available for widespread use in near-real time (see:

2405 <<http://ogw01.er.usgs.gov/USGSGWNetworks.asp>>). Few operational surface-water
2406 resource forecasts have been designed to use ground-water measurements. Similarly
2407 climate-driven SI ground-water resource forecasts are rare, if made at all. However,
2408 surface-water and groundwater are interlinked in nearly all cases and, in truth, constitute

2409 a single resource (Winter *et al.*, 1998). With the growing availability of real-time
2410 groundwater data dissemination, opportunities for improving water resource forecasts by
2411 better integration and use of surface- and ground-water data resources may develop.
2412 Groundwater level networks already are contributing to drought monitors and response
2413 plans in many states.
2414
2415 Similarly, long-term soil-moisture measurements have been relatively uncommon until
2416 recently, yet are of potentially high value for many land management activities including
2417 range management, agriculture, and drought forecasting. Soil moisture is an important
2418 control on the partitioning of water between evapotranspiration, groundwater recharge,
2419 and runoff, and plays an important (but largely unaddressed) role in the quantities
2420 addressed by water resource forecasts. Soil moisture varies rapidly from place to place
2421 (Vinnikov *et al.*, 1996; Western *et al.*, 2004) so that networks that will provide
2422 representative measurements have always been difficult to design (Wilson *et al.*, 2004).
2423 Nonetheless, the Illinois State Water Survey has monitored soil moisture at about 20 sites
2424 in Illinois for many years (see:
2425 <<http://www.sws.uiuc.edu/warm/soilmoist/ISWSSoilMoistureSummary.pdf>>), but was
2426 alone in monitoring soil moisture at the state scale for most of that time. As the
2427 technologies for monitoring soil moisture have become less troublesome, more reliable,
2428 and less expensive in recent years, more agencies are beginning to install soil-moisture
2429 monitoring stations (*e.g.*, the NRCS is augmenting many of its SNOTELs with soil-
2430 moisture monitors and has established a national Soil Climate Analysis Network (SCAN;
2431 <<http://www.wcc.nrcs.usda.gov/scan/SCAN-brochure.pdf>>); Oklahoma's Mesonet

2432 micrometeorological network includes soil-moisture measurements at its sites; California
2433 is on the verge of implementing a state-scale network at both high and low altitudes).
2434 With the advent of regular remote sensing of soil-moisture conditions (Wagner *et al.*,
2435 2007), many of these *in situ* networks will be provided context so that their geographic
2436 representativeness can be assessed and calibrated (Famligiotti *et al.*, 1999). As with
2437 ground water, soil moisture has not often been an input to water resource forecasts on the
2438 SI time scale. Instead, if anything, it is being simulated, rather than measured, where
2439 values are required. Increased monitoring of soil moisture, both remotely and *in situ*, will
2440 provide important checks on the models of soil-moisture reservoirs that underlie nearly
2441 all of our water resources and water resource forecasts, making hydrological model
2442 improvements possible.

2443

2444 Augmentation of real-time stream gauging networks is also a priority, a subject discussed
2445 in the Synthesis and Assessment Product 4.3 (CCSP, 2008).

2446

2447 **2.4.2.2 Improvements in hydrologic modeling techniques**

2448 Efforts to improve hydrologic simulation techniques have been pursued in many areas
2449 since the inception of hydrologic modeling in the 1960s and 1970s when the Stanford
2450 Watershed Model (Crawford and Linsley, 1966), the Sacramento Model (Burnash *et al.*,
2451 1973) and others were created. More recently, physically-based, distributed and semi-
2452 distributed hydrologic models have been developed, both at the watershed scale (*e.g.*,
2453 Wigmosta *et al.*, 1994; Boyle *et al.*, 2000) to account for terrain and climate
2454 inhomogeneity, and at the regional scale (Liang *et al.*, 1994 among others). Macroscale

2455 models (like the Sacramento Model and the Stanford Watershed Model) were partly
2456 motivated by the need to improve land surface representation in climate system modeling
2457 approaches (Mitchell *et al.*, 2004), but these models have also been found useful for
2458 hydrologic applications related to water management (*e.g.*, Hamlet and Lettenmaier,
2459 1999; Maurer and Lettenmaier, 2004; Wood and Lettenmaier, 2006). The NOAA North
2460 American Land Data Assimilation Project (Mitchell *et al.*, 2004) and NASA Land
2461 Information System (Kumar *et al.*, 2006) projects are leading agency-sponsored research
2462 efforts that are focused on advancing the development and operational deployments of
2463 the regional/physically based models. These efforts include research to improve the
2464 estimation of observed parameters (*e.g.*, use of satellite remote sensing for vegetation
2465 properties and distribution), the accuracy of meteorological forcings, model algorithms
2466 and computational approaches. Progress in these areas has the potential to improve the
2467 ability of hydrologic models to characterize land surface conditions for forecast
2468 initialization, and to translate future meteorology and climate into future hydrologic
2469 response.

2470

2471 Aside from improving hydrologic models and inputs, strategies for hydrologic model
2472 implementation are also important. Model calibration—*i.e.*, the identification of optimal
2473 parameter sets for simulating particular types of hydrologic output (single or multiple)—
2474 has arguably been the most extensive area of research toward improving hydrologic
2475 modeling techniques (*e.g.* Wagener and Gupta, 2005, among others). This body of work
2476 has yielded advances in the understanding of the model calibration problem from both
2477 practical and theoretical perspectives. The work has been conducted using models at the

2478 watershed scale to a greater extent than the regional scale, and the potential for applying
2479 these techniques to the regional scale models has not been explored in depth.

2480

2481 Data assimilation is another area of active research (*e.g.*, Andreadis and Lettenmaier
2482 2006; Reichle *et al.*, 2002; Vrugt *et al.*, 2005; Seo *et al.*, 2006). It is a process in which
2483 verifying observations of model state or output variables are used to adjust the model
2484 variables as the model is running, thereby correcting simulation errors on the fly. The
2485 primary types of observations that can be assimilated include snow water equivalent and
2486 snow covered area, land surface skin temperature, remotely sensed or *in situ* soil
2487 moisture, and streamflow. NWSRFS has the capability to do objective data assimilation.
2488 In practice, NWS (and other agencies) perform a qualitative data assimilation, in which
2489 forecaster judgment is used to adjust model states and inputs to reproduce variables such
2490 as streamflow, snow line elevation and snow water equivalent prior to initializing an
2491 ensemble forecast.

2492

2493 **2.4.3 Calibration of Hydrologic Model Forecasts**

2494 Even the best real-world hydrologic models have biases and errors when applied to
2495 specific gages or locations. Statistical models often are tuned well enough so that their
2496 biases are relatively small, but physically-based models often exhibit significant biases.
2497 In either case, further improvements in forecast skill can be obtained, in principle, by
2498 post-processing model forecasts to remove or reduce any remaining systematic errors, as
2499 detected in the performance of the models in hindcasts. Very little research has been
2500 performed on the best methods for such post-processing (Schaake *et al.*, 2007), which is

2501 closely related to the calibration corrections regularly made to weather forecasts. Seo *et*
2502 *al.* (2006), however, describe an effort being undertaken by the National Weather Service
2503 for short lead hydrologic forecasts, a practice that is more common than for longer lead
2504 hydrologic forecasts. Other examples include work by Hashino *et al.* (2007) and
2505 Krzysztofowicz (1999). At least one example of an application for SI hydrologic
2506 forecasts is given in Wood and Schaake (2008); but as noted earlier, a major limitation
2507 for such approaches is the limited sample sizes available for developing statistical
2508 corrections.

2509

2510 **2.5 IMPROVING PRODUCTS: FORECAST AND RELATED INFORMATION**
2511 **PACKAGING AND DELIVERY**

2512 The value of SI forecasts can depend on more than their forecast skill. The context that is
2513 provided for understanding or using forecasts can contribute as much or more to their
2514 value to forecast users. Several avenues for re-packaging and providing context for SI
2515 forecasts are discussed in the following paragraphs.

2516

2517 Probabilistic hydrologic forecasts typically represent summaries of collections of
2518 forecasts, forecasts that differ from each other due to various representations of the
2519 uncertainties at the time of forecast or likely levels of climate variation after the forecast
2520 is made, or both (Schaake *et al.*, 2007). For example, the “ensemble streamflow
2521 prediction” methodology begins its forecasts (generally) from a single best estimate of
2522 the initial conditions from which the forecasted quantity will evolve, driven by copies of
2523 the historical meteorological variations from each year in the past (Franz *et al.*, 2003).

2524 This provides ensembles of as many forecasts as there are past years of appropriate
2525 meteorological records, with the ensemble scatter representing likely ranges of weather
2526 variations during the forecast season. Sometimes deterministic forecasts are extended to
2527 represent ranges of possibilities by directly adding various measures of past hydrologic or
2528 climatic variability. More modern probabilistic methods are based on multiple climate
2529 forecasts, multiple initial conditions or multiple parameterizations (including multiple
2530 downscalings) (Clark *et al.*, 2004; Schaake *et al.*, 2007). However accomplished, having
2531 made numerous forecasts that represent ranges of uncertainty or variability, the
2532 probabilistic forecaster summarizes the results in terms of statistics of the forecast
2533 ensemble and presents the probabilistic forecast in terms of selected statistics, like
2534 probabilities of being more or less than normal.

2535

2536 In most applications, it is up to the forecast user to interpret these statistical descriptions
2537 in terms of their own particular data needs, which frequently entails (1) application of
2538 various corrections to make them more representative of their local setting and (2), in
2539 some applications, essentially a deconvolution of the reported probabilities into plausible
2540 examples that might arise during the future described by those probabilities. Forecast
2541 users in some cases may be better served by provision of historical analogs that closely
2542 resemble the forecasted conditions, so that they can analyze their own histories of the
2543 results during the analogous (historical) weather conditions. For example, Wiener (2000)
2544 reports that there is wide support for a comparative and relative "now versus normal
2545 versus last year" form of characterizing hydrologic and climate forecasts. Such
2546 qualitative characterizations would require careful and explicit caveats, but still have

2547 value as reference to historical conditions in which most current managers learned their
2548 craft and in which operations were institutionalized or codified. While “normal” is
2549 increasingly problematic, “last year” may be the best and most accessible analogue for
2550 the wide variety of relevant market conditions in which agricultural water users (and their
2551 competitors), for example, operate.

2552

2553 Alternatively, some forecast users may find that elements from the original ensembles of
2554 forecasts would provide useful examples that could be analyzed or modeled in order to
2555 more clearly represent the probabilistic forecast in concrete terms. The original forecast
2556 ensemble members are the primary source of the probabilistic forecasts and can offer
2557 clear and definite examples of what the forecasted future *could* look like (but not
2558 specifically what it *will* look like). Thus, along with the finished forecasts, which should
2559 remain the primary forecast products, other representations of what the forecasts are and
2560 how they would appear in the real world could be useful and more accessible
2561 complements for some users, and would be a desirable addition to the current array of
2562 forecast products.

2563

2564 Another approach to providing context (and, potentially, examples) for the SI water
2565 resource forecasts involves placing the SI forecasts in the context of paleoclimate
2566 reconstructions for the prior several centuries. The twentieth century has, by and large,
2567 been climatically benign in much of the nation, compared to previous centuries (Hughes
2568 and Brown, 1992; Cook *et al.*, 1999). As a consequence, the true likelihood of various
2569 forecasted, naturally-occurring climate and water resource anomalies may best be

2570 understood in the context of longer records, which paleoclimatic reconstructions can
2571 provide. At present, approaches to incorporating paleoclimatic information into responses
2572 to SI forecasts are uncommon and only beginning to develop, but eventually they may
2573 provide a clearer framework for understanding and perfecting probabilistic SI water
2574 resource forecasts. One approach being investigated is the statistical synthesis of
2575 examples (scenarios) that reflect both the long-term climate variability identified in
2576 paleo-records and time-series-based deterministic long-lead forecasts (Kwon *et al.*,
2577 2007).

2578

2579 **2.6 THE EVOLUTION OF PROTOTYPES TO PRODUCTS AND THE ROLE OF** 2580 **EVALUATION IN PRODUCT DEVELOPMENT**

2581 Studies of what makes forecasts useful have identified a number of common
2582 characteristics in the process by which forecasts are generated, developed, and taught to
2583 and disseminated among users (Cash and Buizer, 2005). These characteristics include:
2584 ensuring that the problems that forecasters address are themselves driven by forecast
2585 users; making certain that knowledge-to-action networks (the process of interaction
2586 between scientists and users which produces forecasts) are end-to-end inclusive;
2587 employing “boundary organizations” (groups or other entities that bridge the
2588 communication void between experts and users) to perform translation and mediation
2589 functions between the producers and consumers of forecasts; fostering a social learning
2590 environment between producers and users (*i.e.*, emphasizing adaptation); and providing
2591 stable funding and other support to keep networks of users and scientists working
2592 together.

2593

2594 This section begins by providing a review of recent processes used to take a prototype
2595 into an operational product, with specific examples from the NWS. Some examples of
2596 interactions between forecast producers and users that have lead to new forecast products
2597 are then reviewed, and finally a vision of how user-centric forecast evaluation could play
2598 a role in setting priorities for improving data and forecast products in the future is
2599 described.

2600

2601 **2.6.1 Transitioning Prototypes to Products**

2602 During testimony for this Product, heads of federal operational forecast groups all painted
2603 a relatively consistent picture of how most in-house innovations currently begin and
2604 evolve. Although formal and quantitative innovation planning methodologies exist (see
2605 Appendix A.3: Transitioning NWS Research into Operations and How the Weather
2606 Service Prioritizes the Development of Improved Hydrologic Forecasts), for the most
2607 part, the operational practice is often relatively *ad hoc* and unstructured except for the
2608 larger and longer-term projects. The Seasonal Drought Outlook is an example of a
2609 product that was developed under a less formal process than that used by the NWS (Box
2610 2.3).

2611

2612 **BOX 2.3: The CPC Seasonal Drought Outlook**

2613

2614 The CPC Drought Outlook (DO) is a categorical prediction of drought evolution for the three months
2615 forward from the forecast date. The product, which is updated once per month, comprises a map that is
2616 accompanied by a text discussion of the rationale for the categories depicted on the map.

2617

2618 The starting conditions for the DO are given by the current Drought Monitor (DM) (a United States map
2619 that is updated weekly showing the status of drought nationwide located:

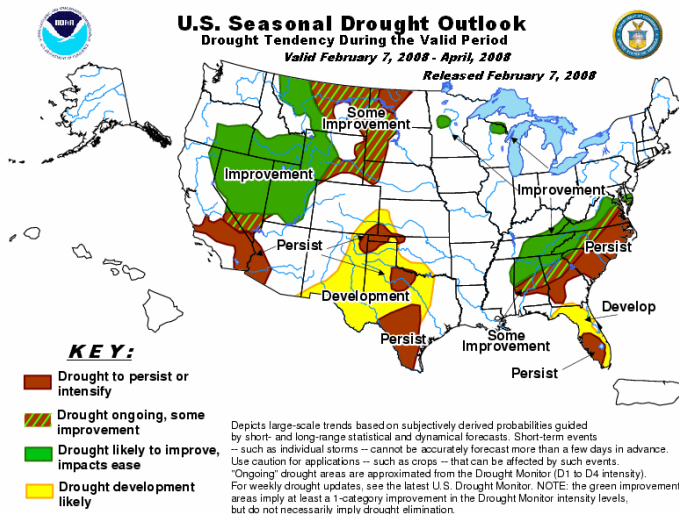

2620 <<http://www.drought.unl.edu/DM/monitor.html>>), and the DO shows likely changes in and adjacent to the
2621 current DM drought areas. The DO is a subjective consensus forecast that is assembled each month by a

2622 single author (rotating between CPC and the National Drought Mitigation Center [NDMC]) with feedback
 2623 from a panel of geographically distributed agency and academic experts. The basis for estimating future
 2624 drought evolution includes a myriad of operational climate forecast products: from short and medium
 2625 range weather forecasts to seasonal predictions from the CPC climate outlooks and the NCEP CFS outputs;
 2626 consideration of climate tendencies for current ENSO state; regional hydroclimatology; and medium-range
 2627 to seasonal soil moisture and runoff forecasts from a variety of sources.
 2628

2629 The DO makes use of the most advanced objective climate and hydrologic prediction products currently
 2630 available, including not only operational, but experimental products, although the merging of the different
 2631 inputs is based on expert judgment rather than an objective system. The DO is verified by comparing the
 2632 DM drought assessments at the start and end of the DO forecast period; verification skill scores have been
 2633 tracked for the last seven years. The DO is the primary drought-related agency forecast produced in the
 2634 United States, and is widely used by the drought management and response community from local to
 2635 regional scales.
 2636

2637 The DO was developed in the context of new drought assessment partnerships between the CPC, USDA
 2638 and the NDMC following the passage of the National Drought Policy Act of 1998. The DM was released as
 2639 an official product in August, 1999, with the expectation that a weekly or seasonal drought forecast

2640

capacity would be added in the future. A drought on the Eastern Seaboard in the fall of 1999 required briefings for the press and the Clinton Administration; internal discussions between DM participants at the CPC led to the formation of the first version of the DO (maps and text) for these briefings. These were released informally to local, state and federal agency personnel throughout the winter of 1999 to 2000, and received positive feedback.

The CPC decided to make the products official, provided public statements and developed product specifications, and made the product operational in March 2000. The initial development process

2658

2659 was informal and lasted about six months. In November 2000, the first Drought Monitor Forum was held,
 2660 at which producers and users (agency, state, private, academic) came together to evaluate the DM in its first
 2661 year and plan for its second, providing, in addition, a venue for discussion of the DO. This forum still meets
 2662 bi-annually, focusing on both DM and DO-relevant issues. Developmental efforts for the DO are internal at
 2663 CPC or within NCEP, and the primary avenues for feedback are the website and at presentations by DO
 2664 authors at workshops and conferences. The DO authors also interact with research efforts funded by the
 2665 NOAA Climate Program Office and other agency funding sources, and with NOAA research group efforts
 2666 (such as at NCEP), as part of the ongoing development effort. URL:

2667 <http://www.cpc.noaa.gov/products/expert_assessment/drought_assessment.shtml>.

2668
 2669 **end BOX 2.3*******
 2670

2671 Climate and water resource forecasters are often aware of small adjustments or “tweaks”
 2672 to forecasts that would make their jobs easier; these are often referred to as “forecasts of

2673 opportunity.” A forecaster may be aware of a new dataset or method or product that
2674 he/she believes could be useful. Based on past experience, production of the forecast may
2675 seem feasible and it could be potentially skillful. In climate forecasting in particular,
2676 where there is very high uncertainty in the forecasts themselves and there is marginal user
2677 adoption of existing products, the operational community often focuses more on potential
2678 forecast skill than likely current use. The belief is that if a product is skillful, a user base
2679 could be cultivated. If there is no skill, even if user demand exists, forecasting would be
2680 futile.

2681

2682 Attractive projects may also develop when a new method comes into use by a colleague
2683 of the forecaster (someone from another agency, alumni, friend or prior collaborator on
2684 other projects). For example, Redmond and Koch (1991) published the first major study
2685 of the impacts of ENSO on western United States streamflow. At the time the study was
2686 being done, a NRCS operational forecaster was one of Koch’s graduate students. The
2687 student put Koch's research to operational practice at the NRCS after realizing that
2688 forecast skill could be improved.

2689

2690 Efficiency is also often the inspiration for an innovation. A forecaster may be looking for
2691 a way to streamline or otherwise automate an existing process. For example, users
2692 frequently call the forecaster with a particular question; if it is possible to automate
2693 answering that question with a new Internet-based product, the forecaster may be freed
2694 up to work on other tasks. While most forecasters can readily list several bottlenecks in

2695 the production process, this knowledge often comes more from personal experience than
2696 any kind of structured system review.

2697

2698 At this stage, many ideas exist for possible innovations, although only some small subset
2699 of them will be pursued. The winnowing process continues with the forecaster and/or
2700 peers evaluating the feasibility of the innovation: Is the method scientifically defensible?
2701 Are the data reliably available to support the product? Are the computers powerful
2702 enough to complete the process in a reasonable time? Can this be done with existing
2703 resources, would it free up more resources than it consumes, or is the added value worth
2704 the added operational expense? In other words, is the total value of the advance worth the
2705 effort? Is it achievable and compatible with legacy systems or better than the total worth
2706 of the technology, installed base and complementary products?

2707

2708 If it is expected to be valuable, some additional questions may be raised by the forecaster
2709 or by management about the appropriateness of the solution. Would it conflict with or
2710 detract from another product, especially the official suite (*i.e.*, destroy competency)?
2711 Would it violate an agency policy? For example, a potential product may be technically
2712 feasible but not allowed to exist because the agency's webpage does not permit
2713 interactivity because of increasingly stringent congressionally-mandated cyber-security
2714 regulations. In this case, to the agency as a whole, the cost of reduced security is greater
2715 than the benefit of increased interactivity. It is important to note that if security and
2716 interactivity in general are not at odds, the issue may be that a particular form of
2717 interactivity is not compatible with the existing security architecture. If a different

2718 security architecture is adopted or a different form of interactivity used (*e.g.*, written in a
2719 different computer language), then both may function together, assuming one has the
2720 flexibility and ability to change.

2721

2722 Additionally, an agency policy issue can sometimes be of broader, multi-organizational
2723 scope and would require policy decisions to settle. For example, no agency currently
2724 produces water quality forecasts. Which federal agency should be responsible for this: the
2725 USDA, Environmental Protection Agency, USGS or NWS? What of soil moisture
2726 forecasts? Should it be the first agency to develop the technical proficiency to make such
2727 forecasts? Or should it be established by a more deliberative process to prevent “mission
2728 creep?” Agencies are also concerned about whether innovations interfere with the
2729 services provided by the private sector.

2730

2731 If appropriate, the forecaster may then move to implement the solution on a limited test
2732 basis, iteratively developing and adapting to any unforeseen challenges. After a
2733 successful functional prototype is developed, it is tested in-house using field personnel
2734 and/or an inner circle of sophisticated customers and gradually made more public as
2735 confidence in the product increases. In these early stages, many of the “kinks” of the
2736 process are smoothed out, developing the product format, and look and feel and adapting
2737 to initial feedback (*e.g.*, “please make the map labels larger”) but, for the most part,
2738 keeping the initial vision intact.

2739

2740 There is no consistent formal procedure across agencies for certifying a new method or
2741 making a new product official. A product may be run and labeled “experimental” for one
2742 to two years in an evaluation period. The objectives and duration of the evaluation period
2743 are sometimes not formalized and one must just assume that if a product has been
2744 running for an extended period of time with no obvious problems, then it succeeds and
2745 the experimental label removed. Creating documentation of the product and process is
2746 often part of the transition from experimental to official, either in the form of an internal
2747 technical memo, conference proceedings or peer-reviewed journal article, if appropriate.

2748

2749 If the innovation involves using a tool or technique that supplements the standard suite of
2750 tools, some of the evaluation may involve running both tools in parallel and comparing
2751 their performance. Presumably, ease of use and low demand on resources are criteria for
2752 success (although the task of running models in parallel can, by itself, be a heavy demand
2753 on resources). Sometimes an agency may temporarily stretch its resources to
2754 accommodate the product for the evaluation period and if additional resources are not
2755 acquired by the end of the evaluation (for one of a number of reasons, some of which
2756 may not be related to the product but, rather, are due to variability in budgets), the
2757 product may be discontinued.

2758

2759 Sometimes skill is used to judge success, but this can be a very inefficient measure. This
2760 is because seasonal forecast skill varies greatly from year to year, primarily due to the
2761 variability of nature. Likewise, individual tools may perform better than other tools in
2762 some years but not others. In the one to two years of an evaluation period the new tool

2763 may be lucky (or unlucky) and artificially appear better (or worse) than the existing
2764 practice.
2765
2766 If the agency recognizes that a tool has not had a fair evaluation, more emphasis is placed
2767 on “hindcasting,” using the new tool to objectively and retrospectively generate realistic
2768 “forecasts” for the last 20 to 30 years and comparing the results to hindcasts of the
2769 existing system and/or official published forecasts. The comparison is much more
2770 realistic and effective, although hindcasting has its own challenges. It can be
2771 operationally demanding to produce the actual forecasts each month (*e.g.*, the agency
2772 may have to compete for the use of several hours of an extremely powerful computer to
2773 run a model), much less do the equivalent of 30 years worth at once. These hindcast
2774 datasets, however, have their own uses and have proven to be very valuable (*e.g.*, Hamill
2775 *et al.*, 2006 for medium range weather forecasting and Franz *et al.*, 2003 for seasonal
2776 hydrologic forecasting). Oftentimes, testbeds are better suited for operationally realistic
2777 hindcasting experiments (Box 2.4).

2778

2779 BOX 2.4 What Role Can a “Testbed” Play in Innovation?

2780

2781 For an innovation to be deemed valuable, it must be able to stand on its own and be better than the entire
2782 existing system, or marginally better than the existing technology, if it is compatible with the rest of the
2783 framework of the existing system. If the innovation is not proven or believed likely to succeed, its adoption
2784 is less likely to be attempted. However, who conducts the experiments to measure this value? And who has
2785 the resources to ensure backwards-compatibility of the new tools in an old system?

2786

2787 This model lacks any direct communication between user and producer and leaves out the necessary
2788 support structure to help users make the most of the product (Cash *et al.*, 2006). Similarly, testbeds are
2789 designed as an alternative to the “loading dock” model of transferring research to operations. A loading
2790 dock model is one in which scientists prepare models, products, forecasts or other types of information for
2791 general dissemination, in somewhat of a vacuum, without consulting with and/or understanding the needs
2792 of the people who will be using that information, with the anticipation that others will find these outputs
2793 useful.

2794

2795 Previously, a researcher might get a short-term grant to develop a methodology, and conduct an idealized,
2796 focused study of marginal operational realism. The results might be presented at research conferences or
2797 published in the scientific literature. While a researcher's career may have a unifying theme, for the most
2798 part, this specific project may be finished when publication is accomplished and the grant finishes.
2799 Meanwhile, the operational forecaster is expected to seek out the methodology and attempt to implement it,
2800 although, often, the forecaster does not have the time, resources or expertise to use the results. Indeed, the
2801 forecaster may not be convinced of the incremental advantage of the technique over existing practices if it
2802 has not endured a realistic operational test and been compared to the results of the official system.

2803
2804 Testbeds are intermediate activities, a hybrid mix of research and operations, serving as a conduit between
2805 the operational, academic and research communities. A testbed activity may have its own resources to
2806 develop a realistic operational environment. However, the testbed would not have real-time operational
2807 responsibilities and instead, would be focused on introducing new ideas and data to the existing system and
2808 analyzing the results through experimentation and demonstration. The old and new system may be run in
2809 parallel and the differences quantified. The operational system may even be deconstructed to identify the
2810 greatest sources of error and use that as the motivation to drive new research to find solutions to operations-
2811 relevant problems. The solutions are designed to be directly integrated into the mock-operational system
2812 and therefore should be much easier to directly transfer to actual production.

2813
2814 NOAA has many testbeds currently in operation: Hydrometeorological (floods), Hazardous Weather
2815 (thunderstorms and tornadoes), Aviation Weather (turbulence and icing for airplanes), Climate (ENSO,
2816 seasonal precipitation and temperature) and Hurricanes. The Joint Center for Satellite Data Assimilation is
2817 also designed to facilitate the operational use of new satellite data. A testbed for seasonal streamflow
2818 forecasting does not exist. Generally, satisfaction with testbeds has been high, rewarding for operational
2819 and research participants alike.

2820
2821 **end BOX 2.4 *******

2822

2823 During the evaluation period, the agency may also attempt to increasingly
2824 “institutionalize” a process by identifying and fixing aspects of a product or process that
2825 do not conform to agency guidelines. For example, if a forecasting model is demonstrated
2826 as promising but the operating system or the computer language it is written in does not
2827 match the language chosen by the agency, a team of contract programmers may rewrite
2828 the model and otherwise develop interfaces that make the product more user-friendly for
2829 operational work. A team of agency personnel may also be assembled to help transfer the
2830 research idea to full operations, from prototype to project. For large projects, many
2831 people may be involved, including external researchers from several other agencies.

2832

2833 During this process of institutionalization, the original innovation may change in
2834 character. There may be uncertainty at the outset and the development team may
2835 consciously postpone certain decisions until more information is available. Similarly,
2836 certain aspects of the original design may not be feasible and an alternative solution must
2837 be found. Occasionally, poor communication between the inventor and the developers
2838 may cause the final product to be different than the original vision. Davidson *et al.* (2002)
2839 found success in developing a hydrologic database using structured, iterative
2840 development involving close communication between users and developers throughout
2841 the life of the project. This model is in direct contrast to that of the inventor generating a
2842 ponderous requirements document at the outset, which is then passed on to a separate
2843 team of developers who execute the plan in isolation until completion.

2844

2845 **2.6.2 Evaluation of Forecast Utility**

2846 As mentioned in Section 2.1, there are many ways to assess the usefulness of forecasts,
2847 one of which is forecast skill. While there are inherent limitations to skill (due to the
2848 chaotic nature of the atmosphere), existing operational systems also fall short of their
2849 potential maximum skill for a variety of reasons. Section 2.4 highlighted ways to improve
2850 operational skill, such as by having better models of the natural system or denser and
2851 more detailed climate and hydrologic monitoring networks. Other factors, such as
2852 improved forecaster training or better visualization tools, also play a role. This section
2853 addresses the role of forecast evaluation in driving the technology development agenda.

2854

2855 Understanding the current skill of forecast products is a key component to ensuring the
2856 effectiveness of programs to improve the skill of these products. There are several
2857 motivations for verifying forecasts including administrative, scientific and economic
2858 (Brier and Allen, 1951). Evaluation of very recent forecasts can also play a role in
2859 helping operational forecasters make mid-course adjustments to different components of
2860 the forecast system before issuing an official product.

2861

2862 Of particular interest to forecasting agencies is administrative evaluation because of its
2863 ability to describe the overall skill and efficiency of the forecast service in order to
2864 inform and guide decisions about resource allocation, research directions and
2865 implementation strategies (Welles, 2005). For example, the development of numerical
2866 weather prediction (NWP) forecasting models is conducted by numerous, unaffiliated
2867 groups following different approaches, with the results compared through objective
2868 measures of performance. In other words, the forecasts are verified, and the research is
2869 driven, not by *ad hoc* opinions postulated by subject matter experts, but by the actual
2870 performance of the forecasts as determined with objective measures (Welles *et al.*, 2007).
2871 The most important sources of error are identified quantitatively and systematically, and
2872 are paired with objective measures of the likely improvement resulting from an
2873 innovation in the system.

2874

2875 Recently, the NWS adopted a broad national-scale administrative initiative of hydrologic
2876 forecast evaluation. This program defines a standard set of evaluation measures,
2877 establishes a formal framework for forecast archival and builds flexible tools for access

2878 to results. It is designed to provide feedback to local forecasters and users on the
2879 performance of the regional results, but also to provide an end-to-end assessment of the
2880 elements of the entire system (HVSRT, 2006). Welles *et al.* (2007) add that these
2881 activities would be best served by cultivating a new discipline of “hydrologic forecast
2882 science” that engages the research community to focus on operational-forecast-specific
2883 issues.

2884

2885 While administrative evaluation is an important tool for directing agency resources,
2886 innovation should ultimately be guided by the anticipated benefit to forecast users. Some
2887 hydrologists would prefer not to issue a forecast that they suspect the user could not use
2888 or would misinterpret (Pielke, Jr., 1999). Additionally, evaluations of forecasts should be
2889 available and understandable to users. For instance, it might be valuable for some users to
2890 know that hydrologic variables in particular regions of interest lack predictability.

2891 Uncertainty about the accuracy of forecasts precludes users from making more effective
2892 use of them (Hartmann *et al.*, 2002). Users want to know how good the forecasts are so
2893 they know how much confidence to place in them. Agencies want to focus on the aspects
2894 of the forecast that are most important to users. Forecast evaluation should be more
2895 broadly defined than skill alone; it should also include measures of communication and
2896 understandability, as well as relevance. In determining these critical aspects, agencies
2897 must make a determination of the key priorities to address given the number and varied
2898 interest of potential forecast users. The agencies can not fully satisfy all users. The
2899 Advanced Hydrologic Prediction System (AHPS) of the NWS provides a nice case study
2900 of product development and refinement in response to user-driven feedback (Box 2.5).

2901

2902 **BOX 2.5 The Advanced Hydrologic Prediction Service**

2903

2904 Short to medium range forecasts (those with lead times of hours to days) of floods are a critical component
2905 of NWS hydrological operations, and these services generate nearly \$2 billion of benefits annually
2906 (NHWC, 2002). In 1997 the NWS Office of Hydrologic Development began the Advanced Hydrologic
2907 Prediction Service (AHPS) program to advance technology for hydrologic products and forecasts. This 16-
2908 year multi-million dollar program seeks to enhance the agency's ability to issue and deliver specific, timely,
2909 and accurate flood forecasts. One of its main foci is the delivery of probabilistic and visual information
2910 through an Internet based interface. One of its seven stated goals is also to "Expand outreach and engage
2911 partners and customers in all aspects of hydrologic product development" (NRC, 2006).

2912

2913 Starting in 2004, the National Research Council reviewed the AHPS program and also analyzed the extent
2914 that users were actually playing in the development of products and setting of the research agenda
2915 (National Research Council, 2006). The study found that AHPS had largely a top-down structure with
2916 technology being developed at a national center to be delivered to regional and local offices. Although
2917 there was a wide range of awareness, understanding and acceptance of AHPS products inside and outside
2918 the NWS, little to no research was being done in early 2004 on effective communication of information,
2919 and some of the needs of primary customers were not being addressed. From the time the NRC team
2920 carried out its interviews, the NWS started acting on the perceived deficiencies, so that, by the time the
2921 report was issued in late 2006, the NWS had already made some measurable progress. This progress
2922 included a rigorous survey process in the form of focus groups, but also a more engaged suite of outreach,
2923 training, and educational activities that have included presentations at the national floodplain and
2924 hydrologic manager's conferences, the development of closer partnerships with key users, committing
2925 personnel to education activities, conducting local training workshops, and awarding a research grant to
2926 social scientists to determine the most effective way to communicate probabilistic forecasts to emergency
2927 and floodplain managers.

2928

2929 **end BOX 2.5**

2930

2931 There is another component to forecast skill beyond the assessment of how the forecast
2932 quantities are better (or worse) than a reference forecast. Thinking of forecast assessment
2933 more broadly, the forecasts should be evaluated for their "skill" at communicating their
2934 information content in ways that can be correctly interpreted both easily and reliably—
2935 *i.e.*, no matter what the quantity (*e.g.*, wet, dry, or neutral tercile) of the forecast, the user
2936 can still correctly interpret it (Hartmann *et al.*, 2002).

2937

2938 Finally, it seems important to stress that agencies should provide for user-centric forecast
2939 assessment as part of the process for moving prototypes to official products. This would
2940 include access to user tools for assessing forecast skill (*i.e.*, the Forecast Evaluation Tool,

2941 which is linked to by the NWS Local 3-month Temperature Outlook [Box 2.6]), and field
2942 testing of the communication effectiveness of the prototype products. Just as new types of
2943 forecasts should show (at least) no degradation in predictive skill, they should also show
2944 no degradation in their communication effectiveness.

2945

2946 **BOX 2.6 NWS Local 3-Month Outlooks for Temperature and Precipitation**

2947

2948 In January 2007, the NWS made operational the first component of a new set of climate forecast products
2949 called Local 3-Month Outlooks (L3MO). Accessible from the NWS Weather Forecast Offices (WFO),
2950 River Forecast Centers (RFC) and other NWS offices, the Local 3-Month Temperature Outlook (L3MTO)
2951 is designed to clarify and downscale the national-scale CPC Climate Outlook temperature forecast product.
2952 The corresponding local product for precipitation is still in development as of the writing of this Product.
2953 The local outlooks were motivated by ongoing NOAA NWS activities focusing on establishing a dialog
2954 with NWS climate product users <<http://www.nws.noaa.gov/directives/>>. In particular, a 2004 NWS
2955 climate product survey (conducted by Claes Fornell International for the NOAA Climate Services Division)
2956 found that a lack of climate product clarity lowered customer satisfaction with NWS CPC climate outlook
2957 products; and presentations and interactions at the annual Climate Prediction Application Science
2958 Workshop (CPASW) highlighted the need for localized CPC climate outlooks in numerous and diverse
2959 applications.

2960

2961 In response to these user-identified issues, CSD collaborated with the NWS Western Region Headquarters,
2962 CPC and the National Climatic Data Center (NCDC) to develop localized outlook products. The
2963 collaboration between the four groups, which linked several line offices of NOAA (*e.g.*, NCDC, NWS),
2964 took place in the context of an effort that began in 2003 to build a climate services infrastructure within
2965 NOAA. The organizations together embarked on a structured process that began with a prototype
2966 development stage, which included identifying resources, identifying and testing methodologies, and
2967 defining the product delivery method. To downscale the CPC climate outlooks (which are at the climate
2968 division scale) to local stations, the CSD and WR development team assessed and built on internal, prior
2969 experimentation at CPC that focused on a limited number of stations. To increase product clarity, the team
2970 added interpretation, background information, and a variety of forecast displays providing different levels
2971 of data density. A NWS products and services team made product mockups that were reviewed by all 102
2972 WFOs, CPC and CSD representatives and a small number of non-agency reviewers. After product
2973 adjustments based on the reviews, CSD moved toward an experimental production stage, providing NWS
2974 staff with training and guidelines, releasing a public statement about the product and writing product
2975 description documentation. Feedback was solicited via the experimental product website beginning in
2976 August 2006, and the products were again adjusted. Finally, the products were finalized, the product
2977 directive was drafted and the product moved to an operational stage with official release. User feedback
2978 continues via links on the official Product website <<http://www.weather.gov/climate/l3mto.php>>.

2979

2980 In general, the L3MO development process exhibited a number of strengths. Several avenues existed for
2981 user needs to reach developers, and user-specified needs determined the objectives of the product
2982 development effort. The development team, spanning several parts of the agency, then drew on internal
2983 expertise and resources to propose and to demonstrate tentative products responding to those needs. The
2984 first review stage of the process gave mostly internal (*i.e.*, agency) reviewers an early opportunity for
2985 feedback, but this was followed by an opportunity for a larger group of users in the experimental stage,
2986 leading to the final product. An avenue for continued review is built into the product dissemination
2987 approach.

3423

3424 **KEY FINDINGS**

3425 Decision-support experiments that test the utility of seasonal to interannual (SI)
3426 information for use by water resource decision makers have resulted in a growing set of
3427 successful applications. However, there is significant opportunity for expansion of
3428 applications of climate-related data and decision-support tools, and for developing more
3429 regional and local tools that support management decisions within watersheds. Among
3430 the constraints that limit tool use are:

- 3431 • The range and complexity of water resources decisions: This is compounded by
3432 the numerous organizations responsible for making these decisions, and the

3433 shared responsibility for implementing them. These organizations include water
3434 utility companies, irrigation management districts and other entities, and
3435 government agencies.

3436 • Inflexible policies and organizational rules that inhibit innovation: Government
3437 agencies historically have been reluctant to change practices in part because of
3438 value differences; risk aversion; fragmentation; the primacy accorded water
3439 rights, which often vary from region to region, and among various users; and
3440 sharing of authority. This conservatism impacts how decisions are made as well
3441 as whether to use newer, scientifically generated information, including SI
3442 forecasts and observational data.

3443 • Different spatial and temporal frames for decisions: Spatial scales for decision
3444 making range from local, state, and national levels to international. Temporal
3445 scales range from hours to multiple decades impacting policy, operational
3446 planning, operational management, and near real-time operational decisions.
3447 Resource managers often make multi-dimensional decisions spanning various
3448 spatial and temporal frames.

3449 • Lack of appreciation of the magnitude of potential vulnerability to climate
3450 impacts: Communication of the risks differs among scientific, political, and mass
3451 media elites, each systematically selecting aspects of these issues that are most
3452 salient to their conception of risk, and thus, socially constructing and
3453 communicating its aspects most salient to a particular perspective.

3454

3455 Decision-support systems are not often well integrated into planning and management
3456 activities, making it difficult to realize the full benefits of these tools. Because use of
3457 many climate products requires special training or access to data that are not easily
3458 available, decision-support products may not equitably reach all audiences. Moreover,
3459 over-specialization and narrow disciplinary perspectives make it difficult for information
3460 providers, decision makers, and the public to communicate with one another. Three
3461 lessons stem from this:

3462

- 3463 • Decision makers need to understand the types of predictions that can be made,
3464 and the trade-offs between longer-term predictions of information at the local or
3465 regional scale on the one hand, and potential decreases in accuracy resulting
3466 from transition to smaller spatial scales on the other.
- 3467 • Decision makers and scientists need to work together in formulating research
3468 questions relevant to the spatial and temporal scale of problems the former
3469 manage that can be supported by current understandings of physical conditions.
- 3470 • Scientists should aim to generate findings that are accessible and viewed as
3471 useful, accurate and trustworthy by stakeholders by working to enhance
3472 transparency of the scientific process.

3473

3474 **3.1 INTRODUCTION**

3475

3476 Over the past century, the United States has built a vast and complex
3477 infrastructure to provide clean water for drinking and for industry, dispose of
3478 wastes, facilitate transportation, generate electricity, irrigate crops, and reduce the
3479 risks of floods and droughts. . . . To the average citizen, the nation's dams,
3480 aqueducts, reservoirs, treatment plants, and pipes are . . . taken for granted. Yet
3481 they help insulate us from wet and dry years and moderate other aspects of our

3482 naturally variable climate. Indeed they have permitted us to almost forget about
3483 our complex dependences on climate. We can no longer ignore these close
3484 connections (Gleick, 2000).
3485

3486 This Chapter synthesizes and distills lessons for the water resources management sector
3487 from efforts to apply decision-support experiments and evaluations using SI forecasts and
3488 observational climate data. Its thesis is that, while there is a growing, theoretically-
3489 grounded body of knowledge on how and why resource decision makers use information,
3490 there is little research on barriers to use of decision-support products in the water
3491 management sector. Much of what we know about these barriers comes from case studies
3492 on the application of SI forecast information and by efforts to span organizational
3493 boundaries dividing scientists and users. Research is needed on factors that can be
3494 generalized beyond these single cases in order to develop a strong, theoretically-grounded
3495 understanding of the processes that facilitate information dissemination, communication,
3496 use, and evaluation, and to predict effective methods of boundary spanning between
3497 decision makers and information generators.

3498

3499 Decision support is a three-fold process that encompasses: (1) the generation of climate
3500 science products; (2) the translation of those products into forms useful for decision
3501 makers (*i.e.*, user-centric information); and, (3) the processes that facilitate the
3502 dissemination, communication, and use of climate science products, information, and
3503 tools (NRC, 2007). As shall be seen, because users include many private and small users,
3504 as well as public and large users serving multiple jurisdictions and entities, effective
3505 decision support is difficult to achieve.

3506

3507 Section 3.2 describes the range of major decisions water users make, their decision-
3508 support needs, and the role decision-support systems can play in meeting them. We
3509 examine the attributes of water resource decisions, their spatial and temporal
3510 characteristics, and the implications of complexity, political fragmentation, and shared
3511 responsibility on forecast use. We also discuss impediments to forecast information use
3512 by decision makers, including mistrust, uncertainty, and lack of agency coordination, and
3513 discuss four cases whose problem foci range from severe drought to flooding, where
3514 efforts to address these impediments are being undertaken with mixed results.

3515

3516 Section 3.3 examines challenges in fostering closer collaboration between scientists and
3517 decision makers in order to communicate, translate, and operationalize climate forecasts
3518 and hydrology information into integrated water management decisions. We review what
3519 the social and decision sciences have learned about barriers in interpreting, deciphering,
3520 and explaining climate forecasts and other meteorological and hydrological models and
3521 forecasts to decision makers, including issues of relevance, accessibility, organizational
3522 constraints on decision makers, and compatibility with users' values and interests. Case
3523 studies reveal how these issues manifest themselves in decision-support applications.

3524 Chapter 4, which is a continuation of these themes in the context of how to surmount
3525 these problems, examines how impediments to effectively implementing decision-support
3526 systems can be overcome in order to make them more useful, useable, and responsive to
3527 decision-maker needs.

3528

3529 **3.2 WHAT DECISIONS DO WATER USERS MAKE, WHAT ARE THEIR**
3530 **DECISION-SUPPORT NEEDS, AND WHAT ROLES CAN DECISION-SUPPORT**
3531 **SYSTEMS PLAY IN MEETING THESE NEEDS?**

3532 This section reviews the range and attributes of water resource decisions, including
3533 complexity, political fragmentation, shared decision making, and varying spatial scale.
3534 We also discuss the needs of water resource managers for climate variability forecast
3535 information, and the multi-temporal and multi-spatial dimensions of these needs. Finally,
3536 we examine how climatic variability affects water supply and quality. Embedded in this
3537 examination is discussion of the risks, hazards, and vulnerability of water resources (and
3538 human activities dependent on them) from climatic variability.

3539

3540 **3.2.1 Range and Attributes of Water Resource Decisions**

3541 As discussed in Chapter 1, and as illustrated in Table 1.1, decisions regarding water
3542 resources in the United States are many and varied, and involve public and private sector
3543 decision makers such as farmers, ranchers, electric power utilities, and eminent domain
3544 landowners who use a large percentage of the country's water. Spatial scales for decision
3545 making range from local, state, and national levels to international political jurisdictions,
3546 the latter with some say in the way United States water resources are managed (Hutson *et*
3547 *al.*, 2004; Sarewitz and Pielke, 2007; Gunaji, 1995; Wagner, 1995). These characteristics
3548 dictate that information must be tailored to the particular roles, responsibilities, and
3549 concerns of different decision makers to be useful. Chapter 1 also suggests that the way
3550 water issues are framed—a process determined partly by organizational commitments
3551 and perceptions, and in part by changing demands imposed by external events and

3552 actors—determines how information must be tailored to optimally impact various
3553 decision-making constituencies and how it will likely be used once tailored. Here we
3554 focus on the implications of this multiple-actor, multi-jurisdictional environment for
3555 delivery of climate variability information.

3556

3557 **3.2.1.1 Institutional complexity, political fragmentation, and shared decision**

3558 **making: impacts on information use**

3559 The range and complexity of water resource decisions, the numerous organizations
3560 responsible for making these decisions, and the shared responsibility for implementing
3561 them affect how water resource decision makers use climate variability information in
3562 five ways:

- 3563 1) a tendency toward institutional conservatism by water agencies;
- 3564 2) a decision-making climate that discourages innovation;
- 3565 3) a lack of national-scale coordination of decisions
- 3566 4) difficulties in providing support for decisions at varying spatial and temporal
3567 scales due to vast variability in “target audiences” for products; and
- 3568 5) growing recognition that rational choice models that attempt to explain
3569 information use as a function of decision-maker needs for “efficiency” are overly
3570 simplistic.

3571 These are discussed in turn in this Section and the following two Sections.

3572

3573 First, institutions that make water resource decisions, particularly government agencies,
3574 operate in domains where they are beholden to powerful constituencies. These
3575 constituencies have historically wanted public works projects for flood control,

3576 hydropower, water supply, navigation, and irrigation. They also have worked hard to
3577 maximize their benefits within current institutional structures, and are often reluctant to
3578 change practices that appear antiquated or inefficient to observers.

3579

3580 The success of these constituencies in leveraging federal resources for river and harbor
3581 improvements, dams, and water delivery systems is in part due to mobilizing regional
3582 development interests. Such interests commonly resist change and place a premium on
3583 engineering predictability and reliability (Feldman, 1995, 2007; Ingram and Fraser, 2006;
3584 Merritt, 1979; Holmes, 1979). This conservatism not only affects how these agencies and
3585 organizations make decisions, it also impacts how they employ, or do not employ,
3586 scientifically generated information, including that related to SI climate variability.
3587 Information that conflicts with their mandates, traditions, or roles may not be warmly
3588 received, as surveys of water resource managers have shown (*e.g.*, O'Connor *et al.*, 1999
3589 and 2005; Yarnal *et al.*, 2006; Dow *et al.*, 2007).

3590

3591 Second, the decision-making culture of United States water resources management has
3592 traditionally *not* embraced innovation. It has long been the case that value differences,
3593 risk aversion, fragmentation, and sharing of authority has produced a decision-making
3594 climate in which innovation is discouraged. This has, on occasion, been exacerbated by
3595 the growth of competitive water markets that sometimes discourage innovation in favor
3596 of short-term economic gain, and has been seen, for instance, in adoption of irrigation
3597 water conserving techniques or even crop rotation. When innovations have occurred, they
3598 have usually resulted from, or been encouraged through, outside influences on the

3599 decision-making process, including extreme climate events or mandates from higher-
3600 level government entities (Hartig *et al.*, 1992; Landre and Knuth, 1993; Cortner and
3601 Moote, 1994; Water in the West, 1998; May *et al.*, 1996; Upendram and Peterson, 2007;
3602 Wiener *et al.*, 2008;).

3603

3604 Third, throughout the history of United States water resources management there have
3605 been various efforts to seek greater synchronization of decisions at the national level, in
3606 part, to better respond to environmental protection, economic development, water supply,
3607 and other goals. These efforts hold many lessons for understanding the role of climate
3608 change information and its use by decision makers, as well as how to bring about
3609 communication between decision makers and climate information producers. While there
3610 has been significant investment of federal resources to provide for water infrastructure
3611 improvements, there has been little national-scale coordination over decisions, or over the
3612 use of information employed in making them (Kundell *et al.*, 2001). The system does not
3613 encourage connectivity between the benefits of the federal investments and those who
3614 actually pay for them, which leaves little incentive for improvements in efficiency and
3615 does not reward innovation (see Wahl, 1989).

3616

3617 **3.2.1.2 Implications of the federal role in water management**

3618 In partial recognition of the need to coordinate across state boundaries to manage
3619 interstate rivers, in the 1960s, groups of northeastern states formed the Delaware River
3620 Basin Commission (DRBC) and the Susquehanna River Basin Commission (SRBC) to
3621 pave the way for conflict resolution. These early federal interstate commissions
3622 functioned as boundary organizations that mediated communication between supply and

3623 demand functions for water and climate information (Sarewitz and Pielke, 2007). They
3624 relied on frequent, intensive, face-to-face negotiations; coordination among politically-
3625 neutral technical staffs; sharing of study findings among partners; willingness to sacrifice
3626 institutional independence when necessary; and commission authority to implement
3627 decisions so as to transcend short-term pressures to act expediently (Cairo, 1997; Weston,
3628 1995)⁸.

3629

3630 An ambitious effort to coordinate federal water policy occurred in 1965 when Congress
3631 established the Water Resources Council (WRC), under the Water Resources Planning
3632 Act, to coordinate federal programs. Due to objections to federal intervention in water
3633 rights issues by some states, and the absence of vocal defenders for the WRC, Congress
3634 de-funded WRC in 1981 (Feldman, 1995). Its demise points out the continued frustration
3635 in creating a national framework to coordinate water management, especially for optimal
3636 management in the context of climate variability. Since termination of the WRC,
3637 coordination of federal programs, when it has occurred, has come variously from the
3638 Office of Management and Budget, White House Council on Environmental Quality, and
3639 *ad hoc* bodies (*e.g.*, Task Force on Floodplain Management)⁹. A lesson in all of this is
3640 that innovation in promoting the use of information requires a concerted effort across

⁸ Compact entities were empowered to allocate interstate waters (including groundwater and inter-basin diversions), regulate water quality, and manage interstate bridges and ports. DRBC includes numerous federal partners such as the Interior Department and Army Corps of Engineers officials (DRBC, 1998; DRBC, 1961; Weston, 1995; Cairo, 1997). One of the forces giving rise to DRBC was periodic *drought* that helped exacerbate conflict between New York City and other political entities in the basin. This led to DRBC's empowerment, as the nation's first federal interstate water commission, in all matters relating to the water resources of its basin, ranging from flooding to fisheries to water quality.

⁹Today the need for policy coordination, according to one source, "stems from the . . . environmental and social crises affecting the nation's rivers" (Water In the West, 1998: xxvii). In nearly every basin in the West, federal agencies are responding to tribal water rights, growing urban demands, endangered species listings, and Clean Water Act lawsuits. Climate change is expected to exacerbate these problems.

3641 agencies and political jurisdictions. Sometimes this may best be facilitated by local
3642 collaboration encouraged by federal government incentives; at other times, federal
3643 coordination of information may be needed, as shown by a number of case studies noted
3644 in Chapter 4.

3645

3646 Fourth, the physical and economic challenge in providing decision support due to the
3647 range of “target audiences” (*e.g.*, Naim, 2003) and the controversial role of the federal
3648 government in such arenas is illustrated by efforts to improve the use of SI climate
3649 change information for managing water resources along the United States-Mexico border,
3650 as well as the United States-Canada border. International cross-boundary water issues in
3651 North America bring multiple additional layers of complexity, in part because the federal
3652 governments of Canada, Mexico and the United States often are ill-equipped to respond
3653 to local water and wastewater issues. Bringing the U.S. State Department into discussions
3654 over management of treatment plants, for example, may not be an effective way to
3655 resolve technical water treatment or supply problems.

3656

3657 In the last decade, climate-related issues that have arisen between Mexico and the United
3658 States regarding water revolve around disagreements among decision makers on how to
3659 define extraordinary drought, allocate shortages, and cooperatively prepare for climate
3660 extremes. These issues have led to renewed efforts to better consider the need for
3661 predictive information and ways to use it to equitably distribute water under drought
3662 conditions. Continuous monitoring of meteorological data, consumptive water uses,
3663 calculation of drought severity, and detection of longer-term climate trends could, under

3664 the conditions of these agreements, prompt improved management of the cross-boundary
3665 systems (Gunaji, 1995; Mumme, 2003, 1995; Higgins *et al.*, 1999). The 1906 Rio Grande
3666 Convention and 1944 Treaty between the United States and Mexico, the latter established
3667 the *International Boundary Water Commission*, contain specific clauses related to
3668 “extraordinary droughts.” These clauses prescribe that the United States government
3669 apprise Mexico of the onset of drought conditions as they develop, and adjust water
3670 deliveries to both United States and Mexican customers accordingly (Gunaji, 1995).
3671 However, there is reluctance to engage in conversations that could result in permanent
3672 reduced water allocations or reallocations of existing water rights.

3673

3674 For the United States and Canada, a legal regime similar to that between the United
3675 States and Mexico has existed since the early 1900s. The anchor of this regime is the
3676 1909 Boundary Waters Treaty that established an *International Joint Commission* with
3677 jurisdiction over threats to water quality, anticipated diversions, and protection of
3678 instream flow and water supply inflow to the Great Lakes. Climate change-related
3679 concerns have continued to grow in the Great Lakes region in recent years due,
3680 especially, to questions arising over calls to treat its water resources as a marketable
3681 commodity, as well as concerns over what criteria to use to resolve disputes over these
3682 and other questions (Wagner, 1995; International Joint Commission, 2000).

3683

3684 **3.2.1.3 Institutions and decision making**

3685 Fifth, there is growing recognition of the limits of so-called *rational choice models* of
3686 information use, which assume that decision makers deliberately focus on optimizing

3687 organizational performance when they use climate variability or other water resource
3688 information. This recognition is shaping our understanding of the impacts of institutional
3689 complexity on the use of climate information. An implicit assumption in much of the
3690 research on probabilistic forecasting of SI variation in climate is that decision makers on
3691 all levels will value and use improved climate predictions, monitoring data, and forecast
3692 tools that can predict changes to conditions affecting water resources (*e.g.*, Nelson and
3693 Winter, 1960). *Rational choice* models of decision making are predicated on the
3694 assumption that decision makers seek to make optimal decisions (and perceive that they
3695 have the flexibility and resources to implement them).

3696

3697 A widely-cited study of four water management agencies in three locations—the
3698 Columbia River system in the Pacific Northwest, the Metropolitan Water District of
3699 Southern California, and the Potomac River Basin and Chesapeake Bay in the greater
3700 Washington, D.C. area—examined the various ways water agencies at different spatial
3701 scales use probabilistic climate forecast information. The study found that not only the
3702 multiple geographic scales at which these agencies operate but also the complexity of
3703 their decision-making systems dramatically influence how, and to what extent, they use
3704 probabilistic climate forecast information. An important lesson is that the complexity of
3705 these systems' sources of supply and infrastructure, and the stakeholders they serve are
3706 important influences on their capacity to use climate information. Decision systems may
3707 rely on multiple sources of data, support the operation of various infrastructure
3708 components, straddle political (and hydrological) boundaries, and serve stakeholders with

3709 vastly different management objectives (Rayner *et al.*, 2005). Thus, science is only one of
3710 an array of potential elements influencing decisions.

3711

3712 The cumulative result of these factors is that water system managers and operations
3713 personnel charged with making day-to-day decisions tend toward an overall institutional
3714 conservatism when it comes to using complex meteorological information for short- to
3715 medium-term decisions. Resistance to using new sources of information is affected by the
3716 complexity of the institutional setting within which managers work, dependency on craft
3717 skills and local knowledge, and a hierarchy of values and processes designed to ensure
3718 their political invisibility. Their goal is to smooth out fluctuations in operations and keep
3719 operational issues out of the public view (Rayner *et al.*, 2005).

3720

3721 In sum, the use of climate change information by decision makers is constrained by a
3722 politically-fragmented environment, a regional economic development tradition that has
3723 inhibited, at least until recently, the use of innovative information (*e.g.*, conservation,
3724 integrated resource planning), and multiple spatial and temporal frames for decisions. All
3725 this makes the target audience for climate information products vast and complex.

3726

3727 The interplay of these factors, particularly the specific needs of target audiences and the
3728 inherently conservative nature of water management, is shown in the case of how
3729 Georgia has come to use drought information to improve long-term water supply
3730 planning. As shall be seen later (Section 3.3.1), while the good news in this case is that
3731 information is beginning to be used by policymakers, the downside is that *some*

3732 information use is being inhibited by institutional impediments, namely, interstate
3733 political conflicts over water.

3734

3735 **BOX 3.1 Georgia Drought**

3750

Two apparent physical causes of the 2007/2008 Southeast drought include a lack of tropical storms and hurricanes, which usually can be counted on to replenish declining reservoirs and soil moisture, and the development of a La Niña episode in the tropical Pacific, which continues to steer storms to the north of the region (Box Figure 3.1). Drought risk is frequently modeled as a function of hazard (*e.g.*, lack of precipitation) and vulnerability (*i.e.*, susceptibility of society to the hazard) using a multiplicative formula, risk = hazard *vulnerability (Hayes *et al.*, 2004). In 2007, Atlanta, Georgia received only 62 percent of its average annual precipitation, the second driest calendar year on record; moreover, streamflows were among the lowest recorded levels on several streams. By June 2007, the National Climatic Data Center reported that December through May precipitation totals for the Southeast were at new lows. Spring wildfires spread throughout southeastern Georgia which also recorded its worst pasture conditions in 12 years. Georgia's Governor Purdue extended a state of emergency through June 30; however, the state's worst drought classification, accompanied by a ban on outdoor water use, was not declared until late September.

3751

3752

3753

3754

3755

3756

3757

While progressive state drought plans, such as Georgia's (which was adopted in March, 2003), emphasize drought preparedness and mitigation of impacts through mandatory restrictions in some water use sectors, they do not commonly factor in the effect of population growth on water supplies. Moreover, conservation measures in a single state cannot address water allocation factors affecting large, multi-state watersheds, such as the Apalachicola-Chattahoochee-Flint (ACF), which encompasses parts of Georgia, Alabama, and Florida.

3758

Institutional barriers and problems

3772

3773

The source of water woes in this Southeastern watershed dates back to a 1987 decision by the Army Corps of Engineers to reallocate 20 percent of power generation flow on the Chattahoochee River to municipal supply for Atlanta, which sits near the headwaters of the river. Alabama and Florida soon demanded an assessment of the environmental and economic effects of that decision, which set off a series of on-again, off-again disputes and negotiations between the three states, known as the "Tri- State Water Wars," that have not been resolved (as of June, 2008). At the heart of the disputes is a classic upstream-downstream water use and water rights dispute, pitting municipal water use for the rapidly expanding Atlanta metropolitan region against navigation, agriculture, fishing, and environmental uses downstream in Alabama and Georgia. The situation is further complicated by water quality concerns, as downstream users suffer degraded water quality, due to polluted urban runoff and agricultural waste, pesticide, and fertilizer leaching. Despite the efforts of the three states and Congress to create water compacts, by engaging in joint water planning and developing and sharing common data bases, the compacts have never been implemented as a result of disagreements over what constitutes equitable water allocation formulae (Feldman, 2007).

3774 Political and sectoral disputes continue to exacerbate lack of coordination on water-use priorities, and there
 3775 is a continuing need to include climate forecast information in these activities, as underscored by
 3776 continuing drought in the Southeast. The result is that water management decision making is constrained,
 3777 and there are few opportunities to insert effective decision-support tools, aside from the kinds of multi-
 3778 stakeholder shared-vision modeling processes developed by the U.S. Army Corps of Engineers Institute for
 3779 Water Resources.

3780 **Box Figure 3.1** Georgia statewide precipitation: 1998 to 2007.

3781
 3782 (end box)
 3783

3784 *Spatial scale of decisions*

3785 In addition to the challenges created by institutional complexity, the spatial scale of
 3786 decisions made by water management organizations ranges from small community water
 3787 systems to large, multi-purpose metropolitan water service and regional water delivery
 3788 systems (Rayner *et al.*, 2005). Differences in spatial scale of management also affect
 3789 information needed—an issue discussed in Chapter 4 when we analyze Regional

3790 Integrated Science Assessment (RISA) experiences. These problems of diverse spatial
3791 scale are further compounded by the fact that most water agency boundaries do not
3792 conform to hydrological units. While some entities manage water resources in ways that
3793 conform to hydrological constraints (*i.e.*, watershed, river basin, aquifer or other drainage
3794 basin, Kenney and Lord, 1994; Cairo, 1997), basin-scale management is not the most
3795 common United States management approach. Because most hydrologic tools focus on
3796 watershed boundaries, there is a disconnect between the available data and the decision
3797 context.

3798

3799 Decision makers often share authority for decisions across local, state, and national
3800 jurisdictions. In fact, the label “decision maker” embraces a vast assortment of elected
3801 and appointed local, state, and national agency officials, as well as public and private
3802 sector managers with policy-making responsibilities in various water management areas
3803 (Sarewitz and Pielke, 2007). Because most officials have different management
3804 objectives while sharing authority for decisions, it is likely that their specific SI climate
3805 variability information needs will vary not only according to spatial scale, but also
3806 according to institutional responsibilities and agency or organization goals.

3807 Identifying who the decision makers are is equally challenging. The Colorado River basin
3808 illustrates the typical array of decision makers on major U.S. streams. A recent study in
3809 Arizona identified an array of potential decision makers affected by water shortages
3810 during drought, including conservation groups, irrigation districts, power providers,
3811 municipal water contractors, state water agencies, several federal agencies, two regional
3812 water project operators (the Central Arizona and Salt River projects), tribal

3813 representatives, land use jurisdictions, and individual communities (Garrick *et al.*, 2008).
3814 This layering of agencies with water management authority is also found at the national
3815 level.

3816

3817 There is no universally agreed-upon classification system for defining *water users*.
3818 Taking as one point of departure the notion that water users occupy various “sectors”
3819 (*i.e.*, activity areas distinguished by particular water uses), the U.S. Geological Survey
3820 (USGS) monitors and assesses water use for eight user categories: public supply,
3821 domestic use, irrigation, livestock, aquaculture, industrial, mining, and thermo-electric
3822 power. These user categories share freshwater supplies withdrawn from streams and/or
3823 aquifers and, occasionally, from saline water sources as well (Hutson *et al.*, 2004).
3824 However, the definitions of these classes of users vary from state to state.

3825

3826 One limitation in this user-driven classification scheme in regards to identifying
3827 information needs for SI climate forecasts is that it inadvertently excludes in-stream
3828 water users, those who do not remove water from streams or aquifers. Instream uses are
3829 extremely important, as they affect aquatic ecosystem health, recreation, navigation, and
3830 public health (Gillilan and Brown, 1997; Trush and McBain, 2000; Rosenberg *et al.*,
3831 2000; Annear *et al.*, 2002). Moreover, instream uses and wetland habitats have been
3832 found to be among the most vulnerable to impacts of climate variability and change
3833 (USGCRP, 2001)¹⁰.

¹⁰In general, federal law protects instream uses only when an endangered species is affected. Protection at the state level varies, but extinction of aquatic species suggests the relatively low priority given to protecting flow and habitat. Organizations with interests in the management of instream flows are diverse,

3834

3835 Finally, decision makers' information needs are also influenced by the time frame for
3836 decisions, and to a greater degree than scientists' needs. For example, while NOAA
3837 researchers commonly distinguish between weather prediction information, produced on
3838 an hours-to-weeks time frame, and climate predictions, which may be on a SI time frame,
3839 many managers make decisions based on annual operating requirements or on shorter
3840 time frames that may not match the products currently produced.

3841

3842 Two important points stem from this. First, as longer-term predictions gain skill, use of
3843 longer-term climate information is likely to expand, particularly in areas with economic
3844 applications. Second, short-term decisions may have long-term consequences. Thus,
3845 identifying the information needed to make better decisions in all time frames is
3846 important, especially since it can be difficult to get political support for research that
3847 focuses on long-term, incremental increases in knowledge that are the key to significant
3848 policy changes (Kirby, 2000). This poses a challenge for decision makers concerned
3849 about adaptation to global change.

3850

3851 Multi-decadal climate-hydrology forecasts and demand forecasts (including population
3852 and economic sector forecasts and forecasts of water and energy demand) are key inputs
3853 for policy decisions. Changes in climate that affect these hydrology and water demand
3854 forecasts are particularly important for policy decisions, as they may alter the anticipated

ranging from federal land management agencies to state natural resource agencies and private conservation groups, and their climate information needs widely vary (Pringle, 2000; Restoring the Waters, 1997).

3855 streams of benefits and impacts of a proposal. Information provided to the policy
3856 planning process is best provided in the form of tradeoffs assessing the relative
3857 implications, hazards, risks, and vulnerabilities associated with each policy option¹¹.

3858

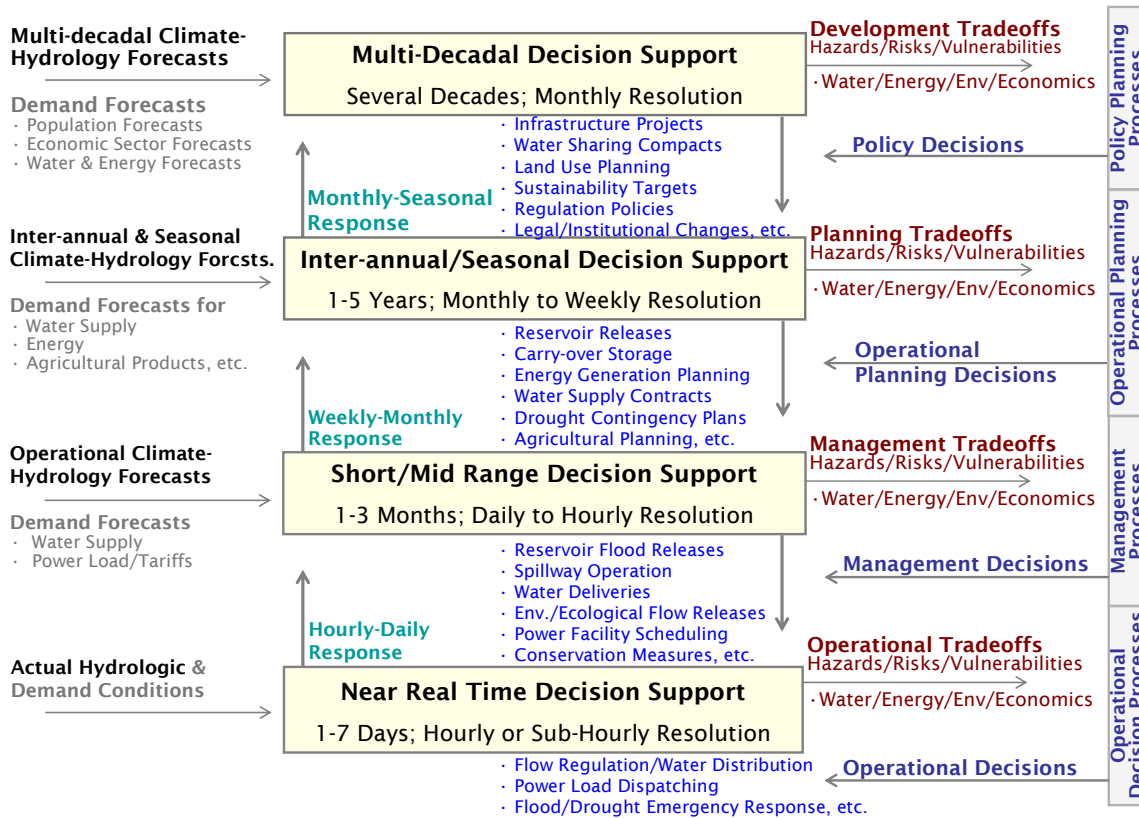

3859 **3.2.2 Decision-support Needs of Water Managers for Climate Information**

3860 As we have noted, the decision-support needs of water resource decision makers for
3861 information on climate variability depend upon the temporal and spatial scale of the
3862 decisions that they make. The complexity of the decision process is graphically illustrated
3863 in Figure 3.1 (Georgakakos, 2006; HRC-GWRI, 2006). This figure includes four
3864 temporal scales ranging from multiple decades to hours. The first decision level includes
3865 *policy decisions* pertaining to multi-decadal time scales and involving infrastructure
3866 changes (*e.g.*, storage projects, levee systems, energy generation facilities, waste water
3867 treatment facilities, inter-basin transfer works, sewer/drainage systems, well fields, and
3868 monitoring networks), as well as water sharing compacts, land use planning, agricultural
3869 investments, environmental sustainability requirements and targets, regulations, and other
3870 legal and institutional requirements (see Wiener *et al.*, 2000). Policy decisions may also
3871 encompass many political entities. Decisions pertaining to trans-boundary water
3872 resources are particularly challenging, as noted in Section 3.2.1.1, because they aim to
3873 reconcile benefits and impacts measured and interpreted by different standards, generated

¹¹ Ideally, the purpose of the participatory planning processes is to formulate policies benefiting stakeholders. The process is highly interactive and iterative with stakeholder groups formulating policy options for assessment by the decision support systems and experts, in turn, interpreting the assessment results for the stakeholders who evaluate and refine them. It is acknowledged, however, that water resource decisions are often contentious, and stakeholder decision processes may fail to reach consensus.

3874 and accrued by stakeholders of different nations, and regulated under different legal and
 3875 institutional regimes (Naim, 2003; Mumme, 2003,1995; Higgins *et al.*, 1999).

3876

3877

3878 **Figure 3.1** Water resources decisions: range and attributes.

3879

3880 The second decision level involves *operational planning decisions pertaining to inter-*
 3881 *annual and seasonal time scales.* These and other lower-level decisions are made within
 3882 the context set by the policy decisions and pertain to interannual and seasonal reservoir
 3883 releases, carry-over storage, hydro-thermal energy generation plans, agreements on
 3884 tentative or final water supply and energy contracts, implementation of drought
 3885 contingency plans, and agricultural planning decisions, among others. The relevant
 3886 spatial scales for operational planning decisions may be as large as those of the policy

3887 decisions, but are usually associated with individual river basins as opposed to political
3888 jurisdictions. Interannual and seasonal hydro-climatic and demand forecasts (for water
3889 supply, energy, and agricultural products) are critical inputs for this decision level.

3890

3891 The third decision level pertains to *operational management decisions associated with*
3892 *short- and mid-range time scales of one to three months*. Typical decisions include
3893 reservoir releases during flood season; spillway operations; water deliveries to urban,
3894 industrial, or agricultural areas; releases to meet environmental and ecological flow
3895 requirements; power facility operation; and drought conservation measures. The benefits
3896 and impacts of these decisions are associated with daily and hourly system response (high
3897 resolution). This decision level requires operational hydro-climatic forecasts and
3898 forecasts of water and power demand and pricing. The decision process is similar to those
3899 of the upper decision layers, although, as a practical matter, general stakeholder
3900 participation is usually limited, with decisions taken by the responsible operational
3901 authorities. This is an issue relevant to several cases discussed in Chapter 4.

3902

3903 The final decision level pertains to *near real time operations* associated with hydrologic
3904 and demand conditions. Typical decisions include regulation of flow control structures,
3905 water distribution to cities, industries, and farms, operation of power generation units,
3906 and implementation of flood and drought emergency response measures. Data from real
3907 time monitoring systems are important inputs for daily to weekly operational decisions.
3908 Because such decisions are made frequently, stakeholder participation may be

3909 impractical, and decisions may be limited to government agencies or public sector
3910 utilities according to established operational principles and guidelines.
3911 While the above illustration addresses water resources complexity (*i.e.*, multiple temporal
3912 and spatial scales, multiple water uses, multiple decision makers), it cannot be
3913 functionally effective (*i.e.*, create the highest possible value) unless it exhibits
3914 consistency and adaptiveness. *Consistency* across the decision levels can be achieved by
3915 ensuring that (1) lower level forecasts, decision support systems, and stakeholder
3916 processes operate within the limits established by upper levels (as represented by the
3917 downward pointing feedback links in Figure 3.1, and (2) upper decision levels capture the
3918 benefits and impacts associated with the high resolution system response (as represented
3919 by the upward pointing feedback links in Figure 3.1). *Adaptiveness*, as a number of
3920 studies indicate, requires that decisions are continually revisited as system conditions
3921 change and new information becomes available, or as institutional frameworks for
3922 decision making are amended (Holling, 1978; Walters, 1986; Lee, 1993).

3923

3924 **3.2.3 How Does Climate Variability Affect Water Management?**

3925 Water availability is essential for human health, economic activity, ecosystem function,
3926 and geophysical processes. Climate variability can have dramatic seasonal and
3927 interannual effects on precipitation, drought, snow-pack, runoff, seasonal vegetation,
3928 water quality, groundwater, and other variables. Much recent research on climate
3929 variability impacts on water resources is linked to studies of long-term climate change,
3930 necessitating some discussion of the latter. In fact, there is a relative paucity of
3931 information on the potential influence of climate change on the underlying patterns of

3932 climate variability (*e.g.*, CCSP, 2007). At the close of this section, we explore one case—
3933 that of drought in the Colorado River basin—exemplifying several dimensions of this
3934 problem, including adaptive capacity, risk perception, and communication of hazard.

3935
3936 According to the Intergovernmental Panel on Climate Change (IPCC), while total annual
3937 precipitation is increasing in the northern latitudes, and average precipitation over the
3938 continental United States has increased, the southwestern United States (and other semi-
3939 tropical areas worldwide) appear to be tending towards reduced precipitation, which in
3940 the context of higher temperatures, results in lower soil moisture and a substantial effect
3941 on runoff in rivers (IPCC, 2007b). The observed trends are expected to worsen due to
3942 continued warming over the next century. Observed impacts on water resources from
3943 changes that are thought to have already occurred include increased surface temperatures
3944 and evaporation rates, increased global precipitation, an increased proportion of
3945 precipitation received as rain rather than snow, reduced snowpack, earlier and shorter
3946 runoff seasons, increased water temperatures and decreased water quality (IPCC, 2007a,
3947 b).

3948
3949 Additional effects on water resources result from sea-level rise of approximately 10 to 20
3950 cm since the 1890s (IPCC, 2007a)¹², an unprecedented rate of mountain glacier melting,
3951 seasonal vegetation emerging earlier in the spring and a longer period of photosynthesis,
3952 and decreasing snow and ice cover with earlier melting. Climate change is also likely to
3953 produce increases in intensity of extreme precipitation events (*e.g.*, floods, droughts, heat
3954 waves, violent storms) that could “exhaust the social buffers that underpin” various

¹² According to the IPCC 2007 Fourth Assessment Report, sea level has risen an average of 1.8 mm per year over the period 1961 to 2003 (IPCC, 2007a).

3955 economic systems such as farming; foster dynamic and interdependent consequences
3956 upon other resource systems (*e.g.*, fisheries, forests); and generate “synergistic” outcomes
3957 due to simultaneous multiple human impacts on environmental systems (*i.e.*, an
3958 agricultural region may be simultaneously stressed by degraded soil and changes in
3959 precipitation caused by climate change) (Rubenstein, 1986; Smith and Reeves, 1988;
3960 Atwood *et al.*, 1988; Homer-Dixon, 1999).

3961

3962 Studies have concluded that changes to runoff and stream flow would have considerable
3963 regional-scale consequences for economies as well as ecosystems, while effects on the
3964 latter are likely to be more severe (Milly *et al.*, 2005). If elevated aridity in the western
3965 United States is a natural response to climate warming, then any trend toward warmer
3966 temperatures in the future could lead to serious long-term increase in droughts,
3967 highlighting both the extreme vulnerability of the semi-arid West to anticipated
3968 precipitation deficits caused by global warming, and the need to better understand long-
3969 term drought variability and its causes (Cook *et al.*, 2004).

3970

3971 The impacts of climate variability are largely regional, making the spatial and temporal
3972 scale of information needs of decision makers likewise regional. This is why we focus
3973 (Section 3.2.3.1) on specific regional hazards, risks, and vulnerabilities of climate
3974 variability on water resources. TOGA and RISA studies focus on the regional scale
3975 consequences of changes to runoff and stream flow on economies as well as ecosystems
3976 (Milly *et al.*, 2005).

3977

3978 **3.2.3.1 Hazards, risks, and vulnerabilities of climate variability**

3979 A major purpose of decision-support tools is to reduce the risks, hazards, and
3980 vulnerabilities to water resources from SI climate variation, as well as to related resource
3981 systems, by generating climate science products and *translating* these products into forms
3982 useful to water resource managers (NRC, 2008). In general, what water managers need
3983 help in translating is *how* changes resulting from weather and SI climate variation can
3984 affect the functioning of the systems they manage. Numerous activities are subject to
3985 risk, hazard, and vulnerability, including fires, navigation, flooding, preservation of
3986 threatened or endangered species, and urban infrastructure. At the end of this section, we
3987 focus on three less visible but nonetheless important challenges: water quality,
3988 groundwater depletion, and energy production.

3989

3990 Despite their importance, hazard, risk, and vulnerability can be confusing concepts. A
3991 *hazard* is an event that is potentially damaging to people or to things they value. Floods
3992 and droughts are two common examples of hazards that affect water resources. *Risk*
3993 indicates the probability of a particular hazardous event occurring. Hence, while the
3994 hazard of drought is a concern to all water managers, drought risk varies considerably
3995 with physical geography, management context, infrastructure type and condition, and
3996 many other factors so that some water resource systems are more at-risk than others
3997 (Stoltman *et al.*, 2004; NRC, 1996; Wilhite, 2004).

3998

3999 A related concept, vulnerability, is more complex and can cause further confusion¹³.
4000 Although experts dispute precisely what the term means, most agree that vulnerability
4001 considers the likelihood of harm to people or things they value and it entails physical as
4002 well as social dimension (*e.g.*, Blaikie *et al.*, 1994; Cutter 1996; Hewitt, 1997; Schröter *et*
4003 *al.*, 2005; Handmer, 2004). Physical vulnerability relates to exposure to harmful events,
4004 while social vulnerability entails the factors affecting a system's sensitivity and capacity
4005 to respond to exposure. Moreover, experts accept some descriptions of vulnerability more
4006 readily than others. One commonly accepted description considers vulnerability to be a
4007 function of exposure, sensitivity, and adaptive capacity (Schneider and Sarukhan, 2001).
4008 Exposure is the degree to which people and the places or things they value, such as their
4009 water supply, are likely to be impacted by a hazardous event, such as a flood. The "things
4010 they value" include not only economic value and wealth but also cultural, spiritual, and
4011 personal values. This concept also refers to physical infrastructure (*e.g.*, water pipelines
4012 and dams) and social infrastructure (*e.g.*, water management associations). Valued
4013 components include intrinsic values like water quality and other outcomes of water
4014 supply availability such as economic vitality.
4015
4016 *Sensitivity* is the degree to which people and the things they value can be harmed by
4017 exposure. Some water resource systems, for example, are more sensitive than others
4018 when exposed to the same hazardous event. All other factors being equal, a water system
4019 with old infrastructure will be more sensitive to a flood or drought than one with new

¹³ Much of this discussion on vulnerability is modified from Yarnal (2007). See also Polsky *et al.* (2007), and Dow *et al.*, (2007) for definitions of vulnerability, especially in relation to water resource management.

4020 state-of-the-art infrastructure; in a century, the newer infrastructure will be considerably
4021 more sensitive to a hazardous event than it is today because of aging.

4022

4023 *Adaptive capacity* is the least explored and most controversial aspect of vulnerability.

4024 The understanding of adaptive capacity favored by the climate change research

4025 community is the degree to which people can mitigate the potential for harm—that is,

4026 reduce vulnerability—by taking action to reduce exposure or sensitivity, both before and

4027 after the hazardous event. The physical, social, economic, spiritual, and other resources

4028 they possess, including such resources as educational level and access to technology,

4029 determine the capacity to adapt. For instance, all things being equal, a community water

4030 system that has trained managers and operators with up-to-date computer technology will

4031 be less vulnerable than a neighboring system with untrained volunteer operators and

4032 limited access to computer technology¹⁴.

4033

4034 Some people or things they value can be highly vulnerable to low-impact events because

4035 of high sensitivity or low adaptive capacity. Others may be less vulnerable to high-impact

4036 events because of low sensitivity or high adaptive capacity. A hazardous event can result

4037 in a patchwork pattern of harm due to variation in vulnerability over short distances

4038 (Rygel *et al.*, 2006). Such variation means that preparing for or recovering from flood or

4039 drought may require different preparation and recovery efforts from system to system.

¹⁴ A slightly different view of adaptive capacity favored by the hazards and disaster research community is that it consists of two subcomponents: coping capacity and resilience. The former is the ability of people and systems to endure the harm; the latter is the ability to bounce back after exposure to harmful events. In both cases, water resource systems can take measures to increase their ability to cope and recover, again depending on the physical, social, economic, spiritual, and other resources they possess or have access to.

4040

4041 **3.2.3.2 Perceptions of risk and vulnerability—Issue frames and risk communication**

4042 Much of the research on vulnerability of water resources to climate variability has
4043 focused on *physical vulnerability* (i.e., the exposure of water resources and water
4044 resource systems to harmful events). Cutter *et al.* (2003) and many others have noted,
4045 however, that *social vulnerability*—the social factors that affect a system’s sensitivity to
4046 exposure, and that influence its capacity to respond and adapt in order to lessen its
4047 exposure or sensitivity—can often be more important than physical vulnerability.
4048 Understanding the social dimensions of vulnerability and related risks is therefore crucial
4049 to determining how climate variation and change will affect water resources.

4050

4051 The perception of risk is perhaps the most-studied of the social factors relating to climate
4052 information and the management of water resources. At least three barriers stemming
4053 from their risk perceptions prevent managers from incorporating weather and climate
4054 information in their planning; each barrier has important implications for communicating
4055 climate information to resource managers and other stakeholders (Yarnal *et al.*, 2005). A
4056 fourth barrier relates to the underlying public perceptions of the severity of climate
4057 variability and change and thus, implicit public support for policies and other actions that
4058 might impel managers to incorporate climate variability into decisions.

4059

4060 The first conceptual problem is that managers who find climate forecasts and projections
4061 to be reliable appear in some cases no more likely to use them than managers who find

4062 them to be unreliable (O'Connor *et al.*, 1999, 2005)¹⁵. Managers most likely to use
4063 weather and climate information may have experienced weather and climate problems in
4064 the recent past—their heightened feelings of vulnerability are the result of negative
4065 experiences with weather or climate. The implication of this finding is that simply
4066 delivering weather and climate information to potential users may be insufficient in those
4067 cases in which the manager does not perceive climate to be a hazard, at least in humid,
4068 water rich regions of the United States that we have studied¹⁶. Purveyors of weather and
4069 climate information may need to convince potential users that, despite the absence of
4070 recent adverse events, their water resources have suffered historically from, and therefore
4071 are vulnerable to, weather and climate.

4072

4073 The second barrier is that managers' perceptions about the usefulness of climate
4074 information varies not only with their exposure to adverse events, but also with the
4075 financial, regulatory, and management contexts of their decisions (Yarnal *et al.*, 2006;
4076 Dow *et al.*, 2007). The implication of this finding is that assessments of weather and
4077 climate vulnerability and of climate information needs must consider the institutional
4078 contexts of the resource systems and their managers. Achieving a better understanding of
4079 these contexts and of the informational needs of resource managers requires working with
4080 them directly.

¹⁵ Based on findings from two surveys of community water system managers (more than 400 surveyed in each study) in Pennsylvania's Susquehanna River Basin. The second survey compared Pennsylvania community water system managers to their counterparts in South Carolina (more than 250 surveyed) and found that managers who find climate forecasts and projections to be reliable are no more likely to use them than are those who find them to be unreliable. Thus, unless managers feel vulnerable (vulnerability being a function of whether they have had adverse experience with weather or climate), they are statistically less likely to use climate forecasts.

¹⁶ Additional research on water system manager perceptions is needed, in regions with varying hydro-meteorological conditions, to discern if this finding holds true in other regions.

4081

4082 The third barrier is that managers expect more difficulties to come from associated
4083 financial and water quality impacts of climate challenges associated with floods and
4084 droughts than from their ability to find water and supply it to their customers (Yarnal *et*
4085 *al.*, 2006; Dow *et al.*, 2007). Combined with the second barrier, the implication is that
4086 managers view weather and climate forecasts as more salient when put into the context of
4087 system operations and management needs. Presenting managers with a climate forecast
4088 for the United States showing the regional probability of below-normal precipitation for
4089 the coming season may not generate much interest; presenting those managers with a
4090 Palmer Drought Severity Index tailored to their state that suggests a possible drought
4091 watch, warning, or emergency will grab their attention (Carbone and Dow, 2005). The
4092 Southwest drought case discussed at the end of this section exemplifies how this salience
4093 worked to prod decision makers to partner closely with water managers, and how the
4094 latter embraced climate knowledge in improving forecasts and demand estimates.

4095

4096 The fourth barrier is the way climate variability and change are framed as public policy
4097 issues, and how their risks are publically communicated. Regardless of the “actual” (if
4098 indeterminate) risks from climate change and variability, communication of the risks
4099 differs among scientific, political, and mass media elites—each systematically selecting
4100 aspects of these issues that are most relevant to their conception of risk, and thus, socially
4101 constructing and communicating its aspects most salient to a particular perspective. Thus,
4102 climate variability can be viewed as: a phenomenon characterized by probabilistic and
4103 consequential uncertainty (science); an issue that imposes fiduciary or legal responsibility

4104 on government (politics); or, a sequence of events that may lead to catastrophe unless
4105 immediate action is taken (Weingart *et al.*, 2000).

4106

4107 Related to this is considerable research that suggests that when risk information, such as
4108 that characteristic of climate change or variability modeling and forecasting, is generated
4109 by select groups of experts who work in isolation from the public (or from decision
4110 makers), the risks presented may sometimes be viewed as untrustworthy or as not
4111 credible and worthy of confidence. This research also suggests that building trust requires
4112 the use of public forums designed to facilitate open risk communication that is clear,
4113 succinct, and jargon-free, and that provide groups ample opportunity for questions,
4114 discussion, feedback, and reaction (*e.g.*, Freudenburg and Rursch, 1994; Papadakis, 1996;
4115 Jasanoff, 1987; Covello *et al.*, 1990; NRC, 1989).

4116

4117 Research on these barriers also shows that personal experience has a powerful influence
4118 on perceptions of risk and vulnerability. They suggest that socioeconomic context is
4119 important in shaping perceptions, and, thus, the perceptions they produce are very
4120 specific. They also show that climate information providers must present their
4121 information in ways salient to potential users, necessitating customizing information for
4122 specific user groups. Finally, they suggest ways that perceptions can be changed.

4123

4124 Research on the influence of climate science on water management in western Australia
4125 (Power *et al.*, 2005) suggests that water resource decision makers can be persuaded to act
4126 on climate variability information if a strategic program of research in support of specific

4127 decisions (*e.g.*, responses to extended drought) can be wedded to a dedicated, timely risk
4128 communication program. In this instance, affected western Australian states formed a
4129 partnership between state agencies representing economic interests affected by drought,
4130 national research institutions engaged in meteorology and hydrology modeling, and water
4131 managers. This partnership succeeded in influencing decision making by: being sensitive
4132 to the needs of water managers for advice that was seen as “independent,” in order to
4133 assure the public that water use restrictions were actually warranted; providing timely
4134 products and services to water users in an accessible way; and, directly involving water
4135 managers in the process of generating forecast information. The Georgia drought case
4136 (Section 3.2.1) also illustrates the need to be sensitive and responsive to decision-maker
4137 needs. As in Australia, ensuring scientific “independence” facilitated the efforts of
4138 managers to consider climate science in their decisions, and helped ensure that climate
4139 forecast information was “localized” through presentation at public meetings and other
4140 forums so that residents could apply it to local decisions (Power *et al.*, 2005). In sum, to
4141 overcome barriers to effective climate information communication, information must be
4142 specific to the sectoral context of managers and enhance their ability to realize
4143 management objectives threatened by weather and climate.

4144

4145 We now examine three particularly vulnerable areas to climate variability: water quality,
4146 groundwater depletion, and energy production. Following this discussion, we feature a
4147 case study on *drought responses in the Southwest United States* which is instructive about
4148 the role that perceived vulnerability has played in adaptive responses.

4149

4150 **Water Quality:** Assessing the vulnerability of water quality to climate variability and
 4151 change is a particularly challenging task, not only because quality is a function (partly)
 4152 of water quantity, but because of the myriad physical, chemical and biological
 4153 transformations that non-persistent pollutants undergo in watersheds and water bodies
 4154 including fire hazards (e.g., Georgia Forestry Commission, 2007). One of the most
 4155 comprehensive literature reviews of the many ways in which water quality can be
 4156 impacted by climate variability and change was undertaken by Murdoch *et al.* (2000). A
 4157 synopsis of their major findings is depicted in Table 3.1.

4158

4159 **Table 3.1 Water Quality, Climate Variability, and Climate Change** (source: Murdoch *et al.*, 2003)

4160

Impacts associated with increases in temperature alone

- Decreased oxygen-holding capacity due to higher surface-water temperatures
- In arctic regions, the melting of ice and permafrost resulting in increased erosion, runoff, and *cooler* stream temperatures.
- Changes in the seasonal timing and degree of stratification of temperate lakes.
- Increased biomass productivity leading to increased rates of nutrient cycling, eutrophication and anoxia.
- Increased rates of chemical transformation and bioaccumulation of toxins.
- Changes in the rates of terrestrial nutrient cycling and the delivery of nutrients to surface waters.

Impacts associated with drought and decreases in streamflow

- Increased concentration of pollutants in streams, but decreased total export of those pollutants to the receiving water body.
- Decreases in the concentration of pollutants that are derived from the flushing of shallow soils and by erosion.
- Increases in the concentration of pollutants that are derived from deeper flow paths and from point sources.
- Decreased stratification and increased mixing in estuaries and other coastal waters, leading to decreased anoxia of bottom waters and decreased nutrient availability (and eutrophication).
- Movement of the freshwater-saltwater boundary up coastal river and intrusion of saltwater into coastal aquifers—impacts which would be exacerbated by sea-level rise.

Impacts associated with flooding and increases in streamflow

- In general, mitigation of the impacts associated with drought and decreases in streamflow
- Increases in the spatial extent of source areas for storm flow, leading to the increased flushing of pollutants from both point and non-point sources of pollution.
- Increased rates of erosion
- Increased rates of leaching of pollutants to groundwater
- Greater dilution of pollutants being countervailed by decreased rates of chemical and biological transformations owing to shorter residence times in soils, groundwater and surface waters.

4161

4162 One conclusion to be drawn from Table 3.1 is that climate variability and change can
4163 have both negative and positive impacts on water quality. In general, warmer surface-
4164 water temperatures and lower flows tend to have a negative impact through decreases in
4165 dissolved oxygen (DO). In contrast, decreased flows to receiving water bodies, especially
4166 estuaries and coastal waters, can improve water quality, while increased flows can
4167 degrade water quality of the receiving water bodies, particularly if they carry increased
4168 total loads of nutrients and sediments. In healthy watersheds that are relatively
4169 unimpacted by disturbances to the natural vegetation cover, increased stream flow may
4170 increase water quality in the given stream by increasing dilution and DO.

4171

4172 Increased runoff and flooding in urbanized areas can lead to increased loads of non-point
4173 source pollutants (Kirshen *et al.*, 2006) such as pesticides and fertilizer from landscaped
4174 areas, and point source pollutants, from the overflow of combined sewer systems
4175 (Furrow, 2006). In addition to increasing pesticide and nutrient loads (Chang *et al.*,
4176 2001), increase in runoff from agricultural lands can lead to greater sediment loads from
4177 erosion and pathogens from animal waste (Dorner *et al.*, 2006). Loads of non-point
4178 pollution may be especially large during flooding if the latter occurs after a prolonged dry
4179 period in which pollutants have accumulated in the watershed.

4180

4181 The natural vegetation cover that is integral to a healthy watershed can be disturbed not
4182 only by land-use but by the stresses of climate extremes directly (*e.g.*, die off during
4183 drought and blow down of trees during tropical storms and hurricanes) and climate-
4184 sensitive disturbances indirectly (*e.g.*, pest infestations and wildfire). Climate change and

4185 variability can also lead to both adaptive human changes in land use and land cover that
4186 can impact water quality (*e.g.* changes in cropping patterns and fertilizer use), as well as
4187 to mitigative ones (*e.g.*, increased planting of low water use native plants). Hence there is
4188 a tight and complex coupling between land use changes and the potential impacts of
4189 climate variability and change on water quality.

4190

4191 Water quality can also be indirectly impacted by climate variability and change through
4192 changes in water use. Withdrawals from streams and reservoirs may increase during a
4193 drought thereby degrading stream water quality through lower in-stream flows, polluted
4194 return flows, or both. Under the water rights system of the western United States, junior
4195 agricultural users may be cut off during drought, thereby actually reducing return flows
4196 from agricultural lands and further lowering in-stream flows.

4197

4198 Perhaps the most common water quality related, climate-sensitive decisions undertaken
4199 by water resource managers in the United States are in relation to the regulation of dams
4200 and reservoirs. Very often, reservoir releases are made to meet low flow requirements or
4201 maintain stream temperatures in downstream river reaches. Releases can also be made to
4202 improve water quality in downstream reservoirs, lakes and estuaries. Any operating
4203 decisions based on water quality usually occur in the context of the purpose(s) for which
4204 the dam and reservoir were constructed—typically some combination of hydropower,
4205 flood control, recreation, and storage for municipal supply and irrigation. Thus, decision-
4206 support systems for reservoir operation that include water quality usually do so in a
4207 multi-objective framework (*e.g.*, Westphal *et al.*, 2003).

4208

4209 Municipal water providers would also be expected to respond to water quality
4210 degradation forecasts. Some decisions they might undertake include stockpiling treatment
4211 chemicals, enhanced treatment levels, *ad hoc* sediment control, preparing to issue water
4212 quality alerts, increasing water quality monitoring, and securing alternative supplies [see
4213 Denver and New York City case studies in Miller and Yates (2005) for specific examples
4214 of climate-sensitive water quality decision making by water utilities]. Managers of
4215 coastal resources such as fisheries and beaches also respond to water-quality forecasts.

4216

4217 Decision making with regards to point sources will necessarily occur within the context
4218 of the permitting process under the National Pollution Discharge Elimination System and
4219 the in-stream water quality standards mandated by the Clean Water Act (Jacoby, 1990).

4220 Regulation of non-point sources falls entirely to the states and is therefore highly variable
4221 across the nation, but is in general done to a lesser degree than the regulation of point
4222 sources. Examples of actions, either voluntary or mandatory, that could be taken in
4223 response to a seasonal forecast of increased likelihood of flooding include: decreased
4224 fertilizer and pesticide application by farmers, measures for greater impoundment of
4225 runoff from feedlots, and protection of treatment ponds of all kinds from overflow.

4226

4227 **Groundwater Depletion:** The vulnerability of groundwater resources to climate
4228 variability and change is very much dependent on the hydrogeologic characteristics of a
4229 given aquifer. In general, the larger and deeper the aquifer, the less interannual climate
4230 variability will impact groundwater supplies. On the other hand, shallow aquifers that are

4231 hydraulically connected to surface waters tend to have shorter residence times and
4232 therefore respond more rapidly to climate variability. The vulnerability of such aquifers
4233 should be evaluated within the context of their conjunctive use with surface waters.
4234

4235 Seasonal and interannual variability in water-table depths are a function of natural
4236 climate variability as well as variations in human exploitation of the resource. During
4237 periods of drought, water tables in unconfined aquifers may drop because of both reduced
4238 recharge and increased rates of pumping. Reduced hydraulic head at well intakes then
4239 decreases the potential yield of the given well or well field and increases the energy
4240 required for pumping. In extreme cases, the water table may drop below the well intake,
4241 resulting in complete drying of the well. Municipal supply and irrigation wells tend to be
4242 developed in larger aquifers and at depths greater than wells supplying individual
4243 domestic users. Therefore, they are in general less vulnerable to interannual climate
4244 variability. In addition to the reduction in the yield of water-supply wells, drops in water
4245 table depths during droughts may result in the drying of springs and worsening of low
4246 flow conditions in streams. Greater withdrawals may result because of the shifting of
4247 usage from depleted surface waters, as well as because of an overall increase in demand
4248 due to lower precipitation and greater evapotranspirative demand from the land surface
4249 and water bodies. Morehouse *et al.* (2002) find this to be the case in southern Arizona. To
4250 the extent that climate change reduces surface water availability in the Southwest United
4251 States, it can be anticipated that pressure on groundwater supplies will increase as a
4252 result.
4253

4254 When long-term average pumping rates exceed recharge rates the aquifer is said to be in
4255 *overdraft*. Zekster *et al.* (2005) identify four major impacts associated with groundwater
4256 extraction and overdraft: (1) reduction of stream flow and lake levels, (2) reduction or
4257 elimination of vegetation, (3) land subsidence, and (4) seawater intrusion. Additional
4258 impacts include changes in water quality due to pumping from different levels in aquifers
4259 and increased pumping costs. The Edwards Aquifer in south-central Texas, which
4260 supplies over two million people in the San Antonio metropolitan area, is identified by
4261 Loáiciga (2003) as particularly vulnerable to climate change and variability because it is
4262 subject to highly variable rates of recharge and has undergone a steady increase in
4263 pumping rates over the last century. While groundwater overdraft is most common in the
4264 arid and semi-arid western United States (Roy *et al.*, 2005; Hurd *et al.*, 1999), it is not
4265 uncommon in the more humid East. Lyon *et al.* (2005) study the causes of the three
4266 drought emergencies that have been declared in Rockland County, New York since 1995.
4267 Seventy-eight percent of the county's public water supply is from small regional aquifers.
4268 Rather than increased frequency or intensity of meteorologic or hydrologic drought, the
4269 authors attribute drought emergencies to development and population growth overtaking
4270 local supplies and to failure of aging water-supply infrastructure. The former is an
4271 example of *demand-driven* drought. The Ipswich River Basin in northeast Massachusetts
4272 is another example in the East where population growth is taxing groundwater resources.
4273 Because of reliance on ground water and in-stream flows for municipal and industrial
4274 supply, summer low flows in the Ipswich frequently reach critical levels (Zarriello and
4275 Ries, 2000).
4276

4277 A few researchers have studied the potential application of SI climate forecasting to
4278 forecasting of groundwater recharge and its implications for water management. For
4279 example, using U.S. Geological Survey recharge estimates for the Edwards Aquifer from
4280 1970 to 1996, Chen *et al.* (2005) find that recharge rates during La Niña years average
4281 about twice those during El Niño years. Using a stochastic dynamic programming model,
4282 they show that optimal water use and allocation decision making based on El Niño-
4283 Southern Oscillation (ENSO)¹⁷ forecasts could result in benefits of \$1.1 to \$3.5 million
4284 per year, mainly to agricultural users as a result of cropping decisions.

4285

4286 Hanson and Dettinger (2005) evaluate the SI predictability of groundwater levels in the
4287 Santa Clara-Calleguas Basin in coastal Southern California using a regional groundwater
4288 model (RGWM) as driven by a general circulation model (GCM). In agreement with
4289 other studies, they find a strong association between groundwater levels and the Pacific
4290 Decadal Oscillation (PDO) and ENSO. Their results led them to conclude that coupled
4291 GCM-RGWM modeling is useful for planning and management purposes, particularly
4292 with regard to conjunctive use of surface and ground water and the prevention of
4293 saltwater intrusion. They also suggest that GCM forecast skill may at times be strong
4294 enough to predict groundwater levels. Forecasts of greater surface water availability may
4295 allow utilities to reduce reliance on over-utilized and expensive groundwater resources.

¹⁷ The Southern Oscillation Index (SOI) is a calculation of monthly or seasonal fluctuations in the air pressure difference between Tahiti and Darwin, Australia. When the air pressure in Tahiti is below normal and the air pressure in Darwin is above normal, the SOI is in a negative phase. Prolonged periods of negative SOI values often occur with abnormally warm ocean waters across the eastern tropical Pacific resulting in a period called an El Niño. Conversely, prolonged periods of positive SOI values (air pressure in Tahiti is above normal and in Darwin it is below normal) coincides with abnormally cold ocean waters across the eastern tropical Pacific and is called a La Niña.

4296 Bales *et al.* (2004) note that a forecast for heavy winter snowpack during the 1997/1998
4297 El Niño led the Salt River Project in Arizona to reducing groundwater pumping in the fall
4298 and winter in favor of greater releases from reservoirs, thereby saving about \$1 million.

4299

4300 **Water Supply and Energy Production:** Adequate water supplies are an essential part of
4301 energy production, from energy resource extraction (mining) to electric-power generation
4302 (DOE, 2006). Water withdrawals for cooling and scrubbing in thermoelectric generation
4303 now exceed those for agriculture in the United States (Hutson *et al.*, 2004), and this
4304 difference becomes much greater when hydropower uses are considered. Emerging
4305 energy sources, such as biofuels, synfuels, and hydrogen, will add to future water
4306 demands. Another new energy-related stress on water resource systems will be the
4307 integration of hydropower with other intermittent renewables, such as wind and solar, at
4308 the power system level. Hydropower is a very flexible, low-cost generating source that
4309 can be used to balance periods when other renewables are not available (*e.g.*, times of
4310 calm winds) and thus maintain electricity transmission reliability. As more non-hydro
4311 renewables are added to transmission grids, calls for fluctuating hydropower operation
4312 may become more frequent and economically valuable, and may compete with other
4313 water demands. If electricity demand increases by 50 percent in the next 25 years, as
4314 predicted by the Energy Information Administration, then energy-related water uses can
4315 also be expected to expand greatly—an ominous trend, especially where available water
4316 resources are already over allocated.

4317

4318 The Climate Change Science Program's Synthesis and Analysis Product 4.5 examined
4319 how climate change will affect the energy sector (CCSP, 2007). Some of the most direct
4320 effects of climate change on the energy sector will occur via water cycle processes
4321 (CCSP, 2007). For instance, changes in precipitation could affect prospects for
4322 hydropower, either positively or negatively, at different times and locations. Increases in
4323 storm intensity could threaten further disruptions of the type experienced in 2005 with
4324 Hurricane Katrina. Also, average warming can be expected to increase energy needs for
4325 cooling and reduce those for warming. Concerns about climate change impacts could
4326 change perceptions and valuations of energy technology alternatives. Any or all of these
4327 types of effects could have very real meaning for energy policies, decisions, and
4328 institutions in the United States, affecting discussions of courses of action and
4329 appropriate strategies for risk management and energy's water demands will change
4330 accordingly.

4331

4332 The energy-related decisions in water management are especially complex because they
4333 usually involve both water quality and quantity aspects, and they often occur in the
4334 context of multiple-use river basins. The Tennessee Valley is a good example of these
4335 complexities. The Tennessee Valley Authority (TVA) operates an integrated power
4336 system of nuclear, coal, and hydropower projects along the full length of the Tennessee
4337 River. TVA's river operations include upstream storage reservoirs and mainstem locks
4338 and dams, most of which include hydropower facilities. Cold water is a valuable resource
4339 that is actively stored in the headwater reservoirs and routed through the river system to
4340 maximize cooling efficiencies of the downstream thermoelectric plants. Reservoir

4341 releases are continuously optimized to produce least-cost power throughout the river
4342 basin, with decision variables of both water quantity and quality.

4343

4344 **Case Study: Southwest drought—climate variability, vulnerability, and water**
4345 **management**

4346 **Introduction**

4347 Climate variability affects water supply and management in the Southwest through
4348 drought, snowpack runoff, groundwater recharge rates, floods, and temperature-driven
4349 water demand. The region sits at a climatic crossroads, at the southern edge of reliable
4350 winter storm tracks and at the northern edge of summer North American monsoon
4351 penetration (Sheppard *et al.*, 2002). This accident of geography, in addition to its
4352 continental location, drives the region's characteristic aridity. Regional geography also
4353 sets the region up for extreme vulnerability to subtle changes in atmospheric circulation
4354 and the impacts of temperature trends on snowmelt, evaporation, moisture stress on
4355 ecosystems, and urban water demands. The instrumental climate record provides ample
4356 evidence of persistent regional drought during the 1950s (Sheppard *et al.*, 2002; Goodrich
4357 and Ellis, 2006), and its influence on Colorado River runoff (USGS, 2004); in addition
4358 the impact of the 1950s drought on regional ecosystems is well documented (Allen and
4359 Breshears, 1998; Swetnam and Betancourt, 1998). Moreover, it has been well known for
4360 close to a decade that interannual and multi-decadal climate variations, forced by
4361 persistent patterns of ocean-atmosphere interaction, lead to sustained wet periods and
4362 severe sustained drought (Andrade and Sellers, 1988; D'Arrigo and Jacoby, 1991; Cayan
4363 and Webb, 1992; Meko *et al.*, 1995; Mantua *et al.*, 1997; Dettinger *et al.*, 1998).

4364

4365 **Sources of vulnerability**

4366 Despite this wealth of information, interest in the effects of climate variability on water
4367 supplies in the Southwest has been limited by dependence on seemingly unlimited
4368 groundwater resources, which are largely buffered from interannual climate fluctuations.
4369 Evidence of extensive groundwater depletion in Arizona and New Mexico, from a
4370 combination of rapid urban expansion and sustained pumping for irrigated agriculture,

4371 has forced changes in water policy, resulting in a greater reliance on renewable surface
4372 water supplies (Holway, 2007; Anderson and Woosley, Jr., 2005; Jacobs and Holway,
4373 2004). The distance between the Southwest's urban water users and the sparsely-
4374 populated mountain sources of their surface water in Wyoming, Utah, and Colorado,
4375 reinforces a lack of interest in the impacts of climate variations on water supplies (Rango,
4376 2006; Redmond, 2003). Until Southwest surface water supplies were substantially
4377 affected by sustained drought, beginning in the late 1990s, water management interest in
4378 climate variability seemed to be focused on the increased potential for flood damage
4379 during El Niño episodes (Rhodes *et al.*, 1984; Pagano *et al.*, 2001).

4380

4381 Observed vulnerability of Colorado River and Rio Grande water supplies to recent
4382 sustained drought, has generated profound interest in the effects of climate variability on
4383 water supplies and management (*e.g.*, Sonnett *et al.*, 2006). In addition, extensive
4384 drought-driven stand-replacing fires in Arizona and New Mexico watersheds have
4385 brought to light indirect impacts of climate variability on water quality and erosion
4386 (Neary *et al.*, 2005; Garcia *et al.*, 2005; Moody and Martin, 2001). Prompted by these
4387 recent dry spells and their impacts, New Mexico and Arizona developed their first
4388 drought plans (NMDTF, 2006; GDTF, 2004); in fact, repeated drought episodes,
4389 combined with lack of effective response, compelled New Mexico to twice revise its
4390 drought plan (NMDTF, 2006; these workshops are discussed in Chapter 4 in Case Study
4391 H). Colorado River Basin water managers have commissioned tree-ring reconstructions
4392 of streamflow, in order to revise estimates of record droughts, and to improve streamflow
4393 forecast performance (Woodhouse and Lukas, 2006; Hirschboeck and Meko, 2005).
4394 These reconstructions and others (Woodhouse *et al.*, 2006; Meko *et al.*, 2007) reinforce
4395 concerns over surface water supply vulnerability, and the effects of climate variability
4396 and trends (*e.g.*, Cayan *et al.*, 2001; Stewart *et al.*, 2005) on streamflow.

4397

4398 **Decision-support tools**

4399 Diagnostic studies of the associations between ENSO teleconnections, multi-decadal
4400 variations in the Pacific Ocean-atmosphere system, and Southwest climate demonstrate
4401 the potential predictability of seasonal climate and hydrology in the Southwest (Cayan *et*

4402 *al.*, 1999; Gutzler, *et al.*, 2002; Hartmann *et al.*, 2002; Hawkins *et al.*, 2002; Clark *et al.*,
4403 2003; Brown and Comrie, 2004; Pool, 2005). ENSO teleconnections currently provide an
4404 additional source of information for ensemble streamflow predictions by the National
4405 Weather Service (NWS) Colorado Basin River Forecast Center (Brandon *et al.*, 2005).
4406 The operational use of ENSO teleconnections as a primary driver in Rio Grande and
4407 Colorado River streamflow forecasting, however, is hampered by high variability
4408 (Dewalle *et al.*, 2003), and poor skill in the headwaters of these rivers (Udall and
4409 Hoerling, 2005; FET, 2008).

4410

4411 **Future prospects**

4412 Current prospects for forecasting beyond ENSO time-scales, using multi-decadal “regime
4413 shifts” (Mantua, 2004) and other information (McCabe *et al.*, 2004) are limited by lack of
4414 spatial resolution, the need for better understanding of land-atmosphere feedbacks, and
4415 global atmosphere-ocean interactions (Dole, 2003; Garfin *et al.*, 2007). Nevertheless,
4416 Colorado River and Rio Grande water managers, as well as managers of state
4417 departments of water resources have embraced the use of climate knowledge in
4418 improving forecasts, preparing for infrastructure enhancements, and estimating demand
4419 (Fulp, 2003; Shamir *et al.*, 2007). Partnerships among water managers, forecasters, and
4420 researchers hold the most promise for reducing water supply vulnerabilities and other
4421 water management risks through the incorporation of climate knowledge (Wallentine and
4422 Matthews, 2003).

4423

4424 **3.2.4 Institutional Factors that Inhibit Information Use in Decision-Support Systems**

4425 In Section 3.1, decision support was defined as a process that generates climate science
4426 products *and* translates them into forms useful for decision makers through dissemination
4427 and communication. This process, when successful, leads to institutional transformation
4428 (NRC, 2008). Five factors are cited as impediments to optimal use of decision-support
4429 systems’ information: (1) lack of integration of systems with expert networks; (2) lack of
4430 institutional coordination; (3) insufficient stakeholder engagement in product

4431 development; (4) insufficient cross-disciplinary interaction; and, (5) expectations that the
4432 expected “payoff” from forecast use may be low. The *Red River flooding and flood*
4433 *management case* following this discussion exemplifies some of these problems, and
4434 describes some promising efforts being expended in overcoming them.

4435

4436 Some researchers (Georgakakos *et al.*, 2005) note that because water management
4437 decisions are subject to gradual as well as rapid changes in data, information, technology,
4438 natural systems, uses, societal preferences, and stakeholder needs, effective decision-
4439 support processes regarding climate variability information must be adaptive and include
4440 self-assessment and improvement mechanisms in order to be kept current (Figure 3.2).

4441

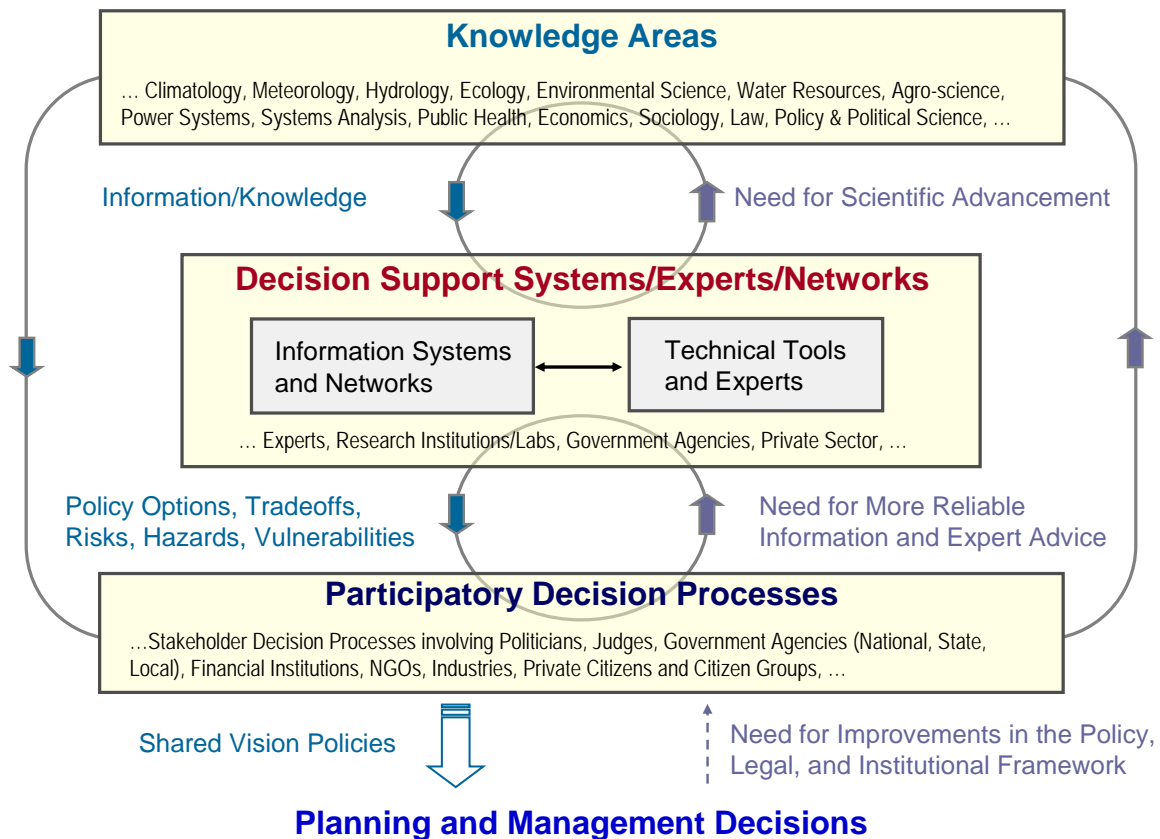

4442 These assessment and improvement mechanisms, which produce transformation, are
4443 denoted by the upward-pointing feedback links shown in Figure 3.2, and begin with
4444 monitoring and evaluating the impacts of previous decisions. These evaluations ideally
4445 identify the need for improvements in the effectiveness of policy outcomes and/or legal
4446 and institutional frameworks. They also embrace assessments of the quality and
4447 completeness of the data and information generated by decision-support systems and the
4448 validity and sufficiency of current knowledge. Using this framework as a point of
4449 departure makes discussing our five barriers to information use easier to comprehend.

4450

4451 First, the lack of integrated decision-support systems and expert networks to support
4452 planning and management decisions means that decision-support experts and relevant
4453 climate information are often not available to decision makers who would otherwise use

4454 this information. This lack of integration is due to several factors, including resources
 4455 (e.g., large agencies can better afford to support modeling efforts, consultants, and large-
 4456 scale data management efforts than can smaller, less-well funded ones), organizational
 4457 design (expert networks and support systems may not be well-integrated administratively
 4458 from the vantage point of connecting information with users’ “decision routines”), and
 4459 opportunities for interaction between expert system designers and managers (the strength
 4460 of communication networks to permit decisions and the information used for them to be
 4461 challenged, adapted, or modified—and even to frame scientific questions). This challenge
 4462 embraces users and producers of climate information, as well as the boundary
 4463 organizations that can serve to translate information (Hartmann, 2001; NRC, 1996;
 4464 Sarewitz and Pielke, 2007; NRC, 2008).

4465

4466

4467 **Figure 3.2** Water resources decision processes.

4468

4469 Second, the lack of coordination of institutions responsible for water resources
4470 management means that information generated by decision-support networks must be
4471 communicated to various audiences in ways relevant to their roles and responsibilities
4472 (Section 3.2.1). Figure 3.2 and discussion of the factors that led to development of better
4473 decision support for flood hazard alleviation on the *Red River of the North* reveal how
4474 extreme environmental conditions compound the challenge in conveying information to
4475 different audiences given the dislocation and conflict that may arise.

4476

4477 Third, limited stakeholder participation and political influence in decision-making
4478 processes means that decision-support products may not equitably penetrate to all
4479 relevant audiences. It also means that because water issues typically have low visibility
4480 for most of the public, the economic and environmental dislocations caused by climate
4481 variability events (*e.g.*, drought, floods), or even climate change, may exacerbate these
4482 inequities and draw sudden, sharp attention to the problems resulting from failure to
4483 properly integrate decision-support models and forecast tools, since disasters often strike
4484 disadvantaged populations disproportionately (*e.g.*, Hurricane Katrina in 2005)
4485 (Hartmann *et al.*, 2002; Carbone and Dow, 2005; Subcommittee on Disaster Reduction,
4486 2005; Leatherman and White, 2005).

4487

4488 Fourth, the lack of adequate cross-disciplinary interaction between science, engineering,
4489 public policy-making, and other knowledge and expertise sectors, as well as across

4490 agencies, academic institutions, and private sector organizations, exacerbates these
4491 problems by making it difficult for decision-support information providers to
4492 communicate with one another. It also exacerbates the problem of information overload
4493 by inhibiting use of incremental additional tools, the sources and benefits of which are
4494 unclear to the user. In short, certain current decision-support services are often narrowly
4495 focused, developed by over-specialized professionals working in a “stovepipe” system of
4496 communication within their organizations. While lack of integration can undermine the
4497 effectiveness of decision-support tools and impede optimal decisions, it may create
4498 opportunities for design, development and use of effective decision-support services.

4499 Box 3.1*****

4500 **Case Study: Red River of the North – Flooding and Water Management**

4501 **Overview**

4502 This case study of climate variability information use focuses on flooding. Model outputs
4503 to better encompass seasonal precipitation, snowmelt and other factors are increasingly
4504 being incorporated into operations decisions. Two questions that this area faced were (1)
4505 How can complex data be translated into useable warning and alert systems for decision
4506 making? and, (2) Are deterministic forecasts an effective mechanism for communicating
4507 information for use in water resource planning and management?

4508 **Background and Context**

4509 Flooding on the Red River of the North in April 1997 resulted in losses estimated to be
4510 four billion dollars. The Red River crested about five feet higher than the maximum flood
4511 height of 49 feet predicted by the NOAA NWS North Central River Forecast Center
4512 (NCRFC) and the public outcry was that the NWS had failed to render a correct forecast
4513 (Pielke, 1999). With snowmelt as the dominant contributor to spring flooding, in
4514 February 1997 the NCRFC had issued an outlook assuming average temperatures and no
4515 additional precipitation for the next few months of 47.5 feet and a second outlook
4516 assuming average temperature and precipitation of 49 feet. In early April 1997, there was
4517 a record snowfall in the region, which neither outlook scenario anticipated. On April 14,

4518 1997, a crest forecast of 50 feet was issued for East Grand Forks to occur in the April
4519 19th through 22nd time period; the river actually crested at 54 feet on April 19, breaching
4520 levees. A critical issue identified in the NOAA Office of Hydrology 1998 report is that
4521 the previous record flood stage height was 48.8 feet and NWS outlooks were based on
4522 extrapolations of the rating curves and there was no way to know that experimental rating
4523 curves being developed by the Army Corps of Engineers would have been more accurate.

4524

4525 The NWS forecasts provided no measure of uncertainty, and were interpreted as either an
4526 exact or maximum estimate of expected river crest height. The communication and
4527 interpretation of these rather precise flood outlooks, with no updates prior to mid-April,
4528 led local officials to assume they were prepared to deal with worst-case flood scenarios.

4529

4530 In fall 2006, the NRC released a report entitled “Completing the Forecast: Characterizing
4531 and Communicating Uncertainty for Better Decisions Using Weather and Climate
4532 Forecasts,” noting that all predictions are inherently uncertain, and that effective
4533 communication of uncertainty information in weather, seasonal climate, and hydrological
4534 forecasts benefits users’ decisions (*e.g.*, Hartmann, 2002). The chaotic character of the
4535 atmosphere, coupled with inevitable inadequacies in observations and computer models,
4536 results in forecasts that always contain uncertainties. These uncertainties generally
4537 increase with forecast lead time and vary with weather situation and location. Uncertainty
4538 is thus a fundamental characteristic of weather, seasonal climate, and hydrological
4539 prediction, and no forecast is complete without a description of its uncertainty.

4540 Nonetheless, for decades, users of weather, seasonal climate, and hydrological
4541 (collectively called “hydrometeorological”) forecasts have not provided complete
4542 information about the certainty or likelihood of a particular event.

4543

4544 Users became comfortable with single-valued forecasts and applied their own experience
4545 in determining how much confidence to place in the forecast. The evolution of the media
4546 as the primary vehicle for conveying weather information in the United States
4547 compounded this trend. The inclusion of uncertainty information in a forecast was
4548 viewed by some as a weakness or disadvantage instead of supporting a more

4549 scientifically sound and useful product.

4550

4551 Most forecast products from the weather and climate enterprise, including those from the
4552 NWS, continue this deterministic legacy. Decisions by users at all levels, but perhaps
4553 most critically those associated directly with protection of life and property, are being
4554 made without the benefit of knowing the uncertainties of the forecasts upon which they
4555 rely.

4556

4557 The complex hydraulic characteristics of the Red River of the North at Grand Forks and
4558 East Grand Forks were difficult to model with the NWS forecast methods in place during
4559 the April 1997 flood. This was the primary reason for the forecast error at that location.

4560

4561 **Lessons learned**

4562 As the NWS RFCs move to improve probabilistic forecasts, making sure that these
4563 climate variability forecasts are of use to decision makers will be critical. In this regard, a
4564 number of useful lessons emanate from this case, including: overriding the rating curves
4565 for flooding to reflect recent data; conducting inter-agency review of available data that
4566 might be applicable to future flooding; moving toward real-time forecasting to the extent
4567 that dynamic routing procedures permit; warning decision makers when a forecast might
4568 exceed the top of the rating curve (so that appropriate risk responses can be better
4569 contemplated); modeling the impact of temporary meltwater storage on flood hazard;
4570 supporting aerial snow cover surveys; incorporating user feedback to improve
4571 communication of forecast information; and conducting post-flooding technical
4572 assessment workshops among relevant agencies to assess how, and how effectively,
4573 climate forecast information was used.

4574 **END Box 3.1*******

4575 **3.2.5 Reliability and Trustworthiness as Problems in Collaboration**

4576 The collaborative process for decision support must be believable and trustworthy, with
4577 benefits to all engaged in it. One of the challenges in ensuring that information is
4578 perceived by decision makers as trustworthy is that trust is the result of an interactive

4579 process of long-term, sustained effort by scientists to respond to, work with, and be
4580 sensitive to the needs of decision makers and users, and of decision makers becoming
4581 sensitive to, and informed about, the process of research. In part, trust is also a matter of
4582 the perceived credibility of the outcomes generated by decision-support systems.

4583

4584 The *Red River Flood warning case* (Section 3.2.4) provides an excellent example of this
4585 problem—users had become comfortable with single-valued forecasts and thus had
4586 applied their own experience in determining how much confidence to place in the
4587 forecasts they received. Coupled with the dependence on media as the tool for conveying
4588 weather information, the inclusion of uncertainty information in a forecast was viewed by
4589 some as a weakness, or disadvantage, in providing adequate warning of impending flood
4590 conditions, instead of an advantage in ensuring a more sound and useful forecast product.

4591

4592 Two other case vignettes featured below, *the Yakima and Upper Colorado River basins*,
4593 reveal the inverse dimensions of this problem. In effect, what happens if forecast
4594 information proves to be incorrect in its predictions, because predictions turned out to be
4595 technically flawed, overly (or not sufficiently) conservative in their estimate of hazards,
4596 contradictory in the face of other information, or simply insufficiently sensitive to the
4597 audiences to whom forecasts were addressed?

4598

4599 As these cases suggest, given the different expectations and roles of scientists and
4600 decision makers, what constitutes credible information to a scientist involved in climate
4601 prediction or evaluation may differ from what is considered credible information by a

4602 decision maker. To a decision maker, forecast credibility is often perceived as hinging
4603 upon its certainty. The more certain and exact a forecast, the more trusted it will be by
4604 decision makers, and the more trustworthy the developers of that information will be
4605 perceived. As shown below, improvements in forecast interpretation and translation,
4606 communication and institutional capacity to adjust to changing information and its
4607 consequences, are essential to addressing this problem. A basic characteristic of much
4608 forecast information is that even the best forecasts rarely approach close to absolute
4609 certainty of prediction—this issue is discussed in Section 3.3.2.

4610 Begin Box 3.2*****

4611 **Case Study: Credibility and the Use of Climate Forecasts: (A) Yakima River**
4612 **Basin/El Niño and (B) Colorado Basin Case Studies**

4613 **(A) Yakima Case**

4614 **Background**

4615 Establishing credibility is essential to fostering the use of climate forecasts in water
4616 management decisions. Although daily weather forecasts, relied upon by millions of
4617 people, can be extremely accurate the majority of the time, the most memorable forecasts
4618 are ones that miss the mark. This is especially true where operational risk tolerance is
4619 low, and the consequences are costly, such as the case of the Yakima River basin in 1977
4620 (Glantz, 1982). At risk in this well-documented case were the livelihoods of hundreds in
4621 a heavily irrigated agricultural region in the lee of Washington’s Cascade Mountains.

4622

4623 **The Problem—Relating Forecast to Allocation Decisions**

4624 Low snowpack in the late winter of 1977 prompted the U.S. Bureau of Reclamation to
4625 issue a forecast for summer runoff below the threshold established in a legal precedent
4626 (U.S. District Court, 1945), with the consequence that junior water rights holders would
4627 receive irrigation allocations as low as six percent of normal. In fact, the forecast issued
4628 by Reclamation was exceedingly conservative, well below runoff estimates by the NWS
4629 and Soil Conservation Service. As noted by Glantz (1982), such low allocations “were

4630 noted by all observers as insufficient to protect perennial plants and trees from drought-
4631 related destruction. The loss of perennial plants and trees could mean a loss of production
4632 for up to eight years...[with] replacement costs...on the order of \$7[,000]-\$8000 per
4633 acre.” Orchardists and others were forced to pursue expensive tactics to protect their
4634 investments, including well digging and deepening, leasing water rights, and
4635 transplanting crops. As it turned out, Reclamation’s forecast suffered from technical
4636 deficiencies: calculations failed to include return flows and treated some reservoir storage
4637 as flow. In addition, changes in operations that differed from Reclamation policy within
4638 memory of Yakima basin farmers, and poor communications left water users and the
4639 public frustrated and uninformed. The aftermath of the forecast, actions taken by
4640 agriculturalists, and subsequent investigations, resulted in animosity between senior and
4641 junior water rights holders, a loss of confidence in Reclamation, and lawsuits against the
4642 agency (Allen Orchards *et al.*, 1980).

4643

4644 **Lessons**

4645 Glantz surmises that greater transparency in forecast methods, including issuing forecast
4646 confidence limits, better communication between agencies and the public, and
4647 consideration of the consequences of potential actions taken by users in the event of an
4648 erroneous forecast, would have improved the value of the forecast and the actions taken
4649 by Reclamation. Twenty years later, NOAA made a similar error when issuing a *perfectly*
4650 *confident* forecast of intensifying drought conditions for the Midwestern United States in
4651 2000 (Changnon, 2002). Based on the forecasts, state water officials took actions they felt
4652 were needed anyway, and were not harmed by the lack of predictive skill and over-
4653 confidence in the forecast; however, agricultural producers may have sustained losses on
4654 the order of \$1 billion, depending on the extent to which they employed particular pricing
4655 strategies. The upshot of this case of a failed forecast, once again, was increased
4656 skepticism in long-term climate forecasts and government institutions (Changnon, 2002).

4657

4658 **(B) El Niño and the Lower Colorado River basin case**

4659 **Background**

4660 Incorporating probabilistic climate forecast information into water management actions is
4661 more difficult than most climate researchers expect. Pagano *et al.* (2001; 2002)
4662 documented Arizona water and emergency management use of climate forecasts during
4663 the 1997/1998 El Niño. Studies determined that issues in interpretation of the NOAA
4664 Climate Prediction Center's three category probabilistic forecasts presented a major
4665 barrier to forecast use (Pagano *et al.*, 2002). Despite the fact that the climate forecasts
4666 expressed a 50 percent probability of seasonal precipitation totals being in the wettest
4667 one-third of the 1961 to 1990 distribution of precipitation, agencies prepared for an array
4668 of outcomes ranging from "business as usual," to 100 percent above normal precipitation.
4669 Some stakeholders, such as the U.S. Bureau of Reclamation, took action, by reducing
4670 reservoir levels, in order to avoid potential structural damage. The 1982/1983 El Niño
4671 events threatened to undermine Glen Canyon dam (Rhodes *et al.*, 1984) and the memory
4672 of nearly losing the dam was still fresh in the Bureau's institutional memory.

4673

4674 **Problem: Conflicting predictions**

4675 Another noteworthy barrier to forecast use was noted in the 1997/1998 ENSO event,
4676 when ENSO-based climate forecasts contradicted historical regression-based water-
4677 supply outlooks, and it became difficult for stakeholders to reconcile differences between
4678 the forecasts. One stakeholder noted "the man with two watches never knows what time it
4679 is" (Pagano *et al.*, 2001). Salt River Project (SRP), the major surface water manager in
4680 the Phoenix metropolitan area, relied upon in-house research and a history of tracking
4681 ENSO in their decision to shift from groundwater to surface water supplies in
4682 anticipation of the 1997/1998 El Niño. However, SRP chose to [correctly] ignore
4683 forecasts for an East Pacific hurricane to track across their region of interest, based on a
4684 greater perceived margin of error in such forecasts (Pagano *et al.*, 2001). These examples
4685 resonate, in part, with the Yakima, 1977, case study, because they demonstrate decision
4686 makers' ability to substitute their own judgment after previously relying on information
4687 with a poor track record or insufficient interpretation of potential outcomes.

4688

4689 **Lessons**

4690 The Arizona examples illustrate the need for capacity building to promote understanding
4691 of uncertainty in forecasts, and to avoid the outcome of "once burned, twice shy,"
4692 identified by Adeel and Glantz (2001), especially where agencies or operations have little
4693 capacity to recover from poor decisions based on "blown" (*i.e.*, failed) forecasts.

4694 End Box 3.2*****

4695 **3.2.5.1 Other reliability and trustworthiness issues: The need for high resolution**
4696 **data**

4697 Research on the information needs of water decision makers has increasingly brought
4698 attention to the fact that use of climate-related decision-support tools is partly a function
4699 of the extent to which they can be made relevant to site-specific conditions and specific
4700 managerial resource needs, such as flow needs of aquatic species; the ability to forecast
4701 the impact of climate variability on orographic precipitation; and, the ability to fill in
4702 gaps in hydrologic monitoring (CDWR, 2007). In effect, proper integration of climate
4703 information into a water resource management context means developing high-resolution
4704 outputs able to be conveyed at the watershed level. It also means predicting changes in
4705 climate forecasts through the season and year, and regularly updating predictions.

4706 Specificity of forecast information can be as important as reliability for decision making
4707 at the basin and watershed level (CDWR, 2007). The Southwest drought case discussed
4708 in Section 3.2.3 illustrates the importance of information specificity in the context of
4709 water managers' responses, particularly within the Colorado River basin.

4710

4711 **3.2.5.2 Uncertainty in the regulatory process**

4712 While uncertainty is an inevitable part of the water resource decision makers' working
4713 environment, one source of lack of trust revolves around multi-level, multi-actor

4714 governance (Section 3.2 1). Shared governance for water management, coupled with the
4715 risk-averse character of traditional public works-type water agencies in particular, leads
4716 to situations where, while parties may act together for purposes of shared governance,
4717 “they may not have common goals or respond to common incentives” (NRC, 2008).
4718 Moreover, governance processes that cross various agencies, jurisdictions, and
4719 stakeholder interests are rarely straightforward, linear, or predictable because different
4720 actors are asked to provide information or resources peripheral to their central functions.
4721 In the absence of clear lines of authority, trust among actors and open lines of
4722 communication are essential (NRC, 2008).

4723

4724 As shown in Chapter 4 in the discussion of the *South Florida water management* case, a
4725 regulatory change introduced to guide water release decisions helped increase certainty
4726 and trust in the water allocation and management process. The South Florida Water
4727 Management District uses a Water Supply and Environment (WSE) schedule for Lake
4728 Okeechobee that employs seasonal and multi-seasonal climate outlooks as guidance for
4729 regulatory releases (Obeysekera *et al.*, 2007). The WSE schedule, in turn, uses ENSO and
4730 Atlantic Multi-decadal Oscillation (AMO; Enfield *et al.*, 2001) to estimate net inflow.
4731 The discussion of this case shows how regulatory changes initially intended to simply
4732 guide water release decisions can also help build greater certainty and trust in the water
4733 allocation and management process by making decisions predictable and transparent.

4734

4735 **3.2.5.3 Data problems**

4736 Lack of information about geographical and temporal variability in climate processes is
4737 one of the primary barriers to adoption and use of specific products. An important
4738 dimension of this lack of information problem, relevant to discussions of reliability and
4739 trust, revolves around how decision makers make decisions when they have poor, no, or
4740 little data. Decision research from the social and behavioral sciences suggests that when
4741 faced with such problems, individual decision makers typically omit or ignore key
4742 elements of good decision processes. This leads to decisions that are often ineffective in
4743 bringing about the results they intended (Slovic *et al.*, 1977). Furthermore, decision
4744 makers, such as water managers responsible for making flow or allocation decisions
4745 based on incomplete forecast data, may respond to complex tasks by employing
4746 professional judgment to simplify them in ways that seem adequate to the problem at
4747 hand, sometimes adopting “heuristic rules” that presume different levels of risk are
4748 acceptable based on their prior familiarity with a similar set of problems (Tversky and
4749 Kahneman, 1974; Payne *et al.*, 1993).

4750

4751 Decision makers and the public also may respond to probabilistic information or
4752 questions involving uncertainty with predictable biases that ignore or distort important
4753 information (Kahneman *et al.*, 1982) or exclude alternative scenarios and possible
4754 decisions (*e.g.*, Keeney, 1992; NRC, 2005). ENSO forecasts illustrate some of these
4755 problems¹⁸. Operational ENSO-based forecasts have only been made since the late 1980s
4756 while ENSO-related products that provide information about which forecasts are likely to

¹⁸ El Niños tend to bring higher-than-average winter precipitation to the U.S. Southwest and Southeast while producing below-average precipitation in the Pacific Northwest. By contrast, La Niñas produce drier-than-average winter conditions in the Southeast and Southwest while increasing precipitation received in the Pacific Northwest.

4757 be most reliable for what time periods and in which areas, have an even shorter history.
4758 Thus, decision-maker experience in their use has been limited. Essential knowledge for
4759 informed use of ENSO forecasts includes understanding of the temporal and geographical
4760 domain of ENSO impacts. Yet, making a decision based only on this information may
4761 expose a manager unnecessarily to consequences from that decision such as having to
4762 having to make costly decisions regarding supplying water to residents when expected
4763 rains from an ENSO event do not materialize.

4764

4765 **3.2.5.4 Changing environmental, social and economic conditions**

4766 Over the past three decades, a combination of economic changes (*e.g.*, reductions in
4767 federal spending for large water projects), environmental conditions (*e.g.*, demands for
4768 more non-structural measures to address water problems, population growth, and
4769 heightened emphasis on environmental restoration practices), and public demands for
4770 greater participation in water resource management have led to new approaches to water
4771 management. In Chapter 4 we address two of these approaches: adaptive management
4772 and integrated resource management. These approaches emphasize explicit commitment
4773 to environmentally-sound, socially-just outcomes; greater reliance upon drainage basins
4774 as planning units; program management via spatial and managerial flexibility,
4775 collaboration, participation, and peer-reviewed science (Hartig *et al.*, 1992; Landre and
4776 Knuth, 1993; Cortner and Moote, 1994; Water in the West, 1998; May *et al.*, 1996;
4777 McGinnis, 1995; Miller *et al.*, 1996; Cody, 1999; Bormann *et al.*, 1993; Lee, 1993). As
4778 shall be seen, these approaches place added demands on water managers regarding use of
4779 climate variability information, including adding new criteria to decision processes such

4780 as managing in-stream flows/low flows, climate variability impacts on runoff, water
4781 quality, fisheries, and water uses.

4782

4783 **3.2.5.5 Public perception and politics may outweigh facts and professional judgment**

4784 Climate variability and its risks are viewed through perceptual frames that affect not only
4785 decision makers and other policy elites, but members of the general public. Socialization
4786 and varying levels of education contribute to a social construction of risk information that
4787 may lead the public to view extreme climate variability as a sequence of events that may
4788 lead to catastrophe unless immediate action is taken (Weingart *et al.*, 2000). Extreme
4789 events may heighten the influence of sensational reporting, impede reliance upon
4790 professional judgment, lead to sensationalized reporting, and affect a sudden rise in
4791 public attention that may even shut off political discussion of the issue (Weingert *et al.*,
4792 2000).

4793

4794 **3.2.5.6 Decision makers may be vulnerable when they use information**

4795 Decision makers can lose their jobs, livelihoods, stature, or reputation by relying on
4796 forecasts that are wrong. Likewise, similar consequences can come about from untoward
4797 outcomes of decisions based on *correct* forecasts. This fact tends to make decision
4798 makers risk averse, and sometimes politically over-sensitive when using information, as
4799 noted in Chapter 4. As Jacobs (2002) notes in her review, much has been written on the
4800 reasons why decision makers and scientists rarely develop the types of relationships and
4801 information flows necessary for full integration of scientific knowledge into the decision-
4802 making process (Kirby, 2000; Pagano *et al.*, 2001; Pulwarty and Melis, 2001 Rayner *et*

4803 *al.*, 2005). The primary reasons are problems with relevance (are the scientists asking and
4804 answering the right questions?), accessibility of findings (are the data and the associated
4805 value-added analysis available to and understandable by the decision makers?),
4806 acceptability (are the findings seen as accurate and trustworthy?) conclusions being
4807 drawn from the data (is the analysis adequate?) and context (are the findings useful given
4808 the constraints in the decision process?).

4809

4810 Scientists have some authority to overcome some of these sources of uncertainty that
4811 result in distrust (*e.g.*, diagnosing problems properly, providing adequate data, updating
4812 forecasts regularly, and drawing correct forecast conclusions). Other constraints on
4813 uncertainty, however, may be largely out of their control. Sensitivity to these sources of
4814 uncertainty, and their influence upon decision makers, is important.

4815

4816 The *Yakima case*, discussed earlier in the context of forecast credibility, further illustrates
4817 how decision makers can become vulnerable by relying on information that turns out to
4818 be inaccurate or a poor predictor of future climate variability events. It underscores the
4819 need for trust-building mechanisms to be built into forecast translation projects, such as
4820 issuing forecast confidence limits, communicating better with the public and agencies,
4821 and considering the consequences of potential actions taken by users in the event of an
4822 erroneous forecast. The next section discusses particular challenges related to translation.

4823

4824 **3.3 WHAT ARE THE CHALLENGES IN FOSTERING COLLABORATION**
4825 **BETWEEN SCIENTISTS AND DECISION MAKERS?**

4826 This section examines problems in translating climate forecasts and hydrology
4827 information into integrated water management decisions, forecast communication, and
4828 operationalizing decision-support systems. This discussion focuses on translation of
4829 scientific information into forms useful and useable by decision makers.

4830

4831 **3.3.1 General Problems in Fostering Collaboration**

4832 The social and decision sciences have learned a great deal about the obstacles,
4833 impediments, and challenges in translating scientific information, especially forecasts, for
4834 decision makers generally, and resource managers in particular. Simply “doing research”
4835 on a problem does not assure in any way that the research results can or will contribute to
4836 solving a societal problem; likewise “more research does not necessarily lead to better
4837 decisions” (*e.g.*, Cash *et al.*, 2003; Jacobs *et al.*, 2005; Sarewitz and Pielke, 2007; Rayner
4838 *et al.*, 2005). Among the principal reasons information may not be used by decision
4839 makers are that they do not fit the setting or timing in which the decision occurs and that
4840 there are external constraints that preclude its use. A further explanation follows.

4841

4842 The information may be viewed as irrelevant to the user or inappropriate to the decision
4843 context: While scientists’ worldviews are strongly influenced and affected by the
4844 boundaries of their own research and disciplines, decision makers’ worldviews are
4845 conditioned by the “decision space” (Jacobs *et al.*, 2005). Decision space refers to the
4846 range of realistic options available to a given decision maker to resolve a particular
4847 problem. While a new scientifically-derived tool or source of information may have

4848 obvious applications when viewed from a theoretical perspective, a decision maker may
4849 be constrained from using a tool or information by external factors.
4850
4851 External constraints such as laws and regulations may limit the range of options available
4852 to the decision maker: Policies, procedures, and precedents relevant to a given
4853 decision—including decisional rules and protocols, expectations imposed by decision
4854 makers through training and by peer and supervisory expectations, sufficiency of
4855 resources (*e.g.*, time and money) within organizations to properly integrate information
4856 and tools into decision making, and the practicality of implementing various options
4857 prescribed by tools and/or information given the key questions the decision maker must
4858 manage on a daily basis—are all factors that limit decision makers’ use of information.
4859 These factors can also limit the range of options available to decision makers.
4860
4861 Political scientists who study administrative organizations cite three principal ways the
4862 rule-making culture of administrative organizations hinders information use, ranging
4863 from the nature of policy “attentiveness” in administrative organizations in which
4864 awareness of alternatives is often driven by demands of elected officials instead of newly
4865 available information (*e.g.*, Kingdon, 1995), to organizational goals and objectives which
4866 often frame or restrict the flow of information and “feedback.” Another set of reasons
4867 revolves around the nature of indirect commands within organizations that evolve
4868 through trial and error. Over time, these commands take the form of rules and protocols
4869 which guide and prescribe appropriate and inappropriate ways of using information in
4870 bureaucracies (Stone, 1997; Torgerson, 2005).

4871

4872 The following case, relating to the translation of drought information in the southeastern
4873 United States, describes the influence of institutional constraints on information use. In
4874 this instance, the problem of drought is nested within a larger regional water dispute
4875 among three states. By describing the challenges in incorporating drought and water
4876 shortage information into basin-wide water planning, this case also helps clarify a
4877 number of salient problems faced by water managers working with complex information
4878 in a contentious political or legal context. In short, information usefulness is determined
4879 in part by social and political context or “robustness.” To be “socially robust,”
4880 information must first be valid outside, as well as inside, the laboratory where it is
4881 developed; and secondly, it must involve an extended group of experts, including lay
4882 ‘experts’ (Gibbons, 1999).

4883

4884 **Case Study: The Southeast Drought: Another Perspective on Water Problems in**
4885 **the Southeastern United States**

4886 **Introduction and context**

4887 As mentioned earlier, drought risk consists of a hazard component (*e.g.*, lack of
4888 precipitation, along with direct and indirect effects on runoff, lake levels and other
4889 relevant parameters) and a vulnerability component. Some aspects of vulnerability
4890 include the condition of physical infrastructure; economics, awareness and preparedness;
4891 institutional capability and flexibility; policy, demography, and access to technology
4892 (Wilhite *et al.*, 2000). Thus, there are clearly non-climatic factors that can enhance or
4893 decrease the likelihood of drought impacts. Laws, institutions, policies, procedures,
4894 precedents and regulations, for instance, may limit the range of options available to the
4895 decision maker, even if he or she is armed with a perfect forecast.

4896

4897 In the case of the ongoing drought in the southeastern United States, the most recent
4898 episode, beginning in 2006 and intensifying in 2007 (see Box Figure 3.1), impacts to
4899 agriculture, fisheries, and municipal water supplies were likely exacerbated by a lack of
4900 action on water resources compacts between Georgia, Alabama, and Florida (Feldman,
4901 2007). The hazard component was continuously monitored at the state, regional, and
4902 national level by a variety of institutions, including state climatologists, the Southeast
4903 Regional Climate Center, the Southeast Climate Consortium, the USGS, the NWS, the
4904 U.S. Drought Monitor and others. In some cases, clear decision points were specified by
4905 state drought plans (Steinemann and Cavalcanti, 2006; Georgia DNR, 2003). (Florida
4906 lacks a state drought plan.) During the spring of 2007 the situation worsened as record
4907 precipitation deficits mounted, water supplies declined, and drought impacts, including
4908 record-setting wildland fires, accumulated (Georgia Forestry Commission, 2007).
4909 Georgia decision makers faced the option of relying on a forecast for above-average
4910 Atlantic hurricane frequency, or taking more cautious, but decisive, action to stanch
4911 potentially critical water shortages. Public officials allowed water compacts to expire,
4912 because they could not agree on water allocation formulae. As a result, unresolved
4913 conflicts regarding the relative priorities of upstream and downstream water users (e.g.,
4914 streamflows intended to preserve endangered species and enrich coastal estuaries vied for
4915 the same water as reservoir holdings intended to drought-proof urban water uses)
4916 impeded the effective application of climate information to mitigate potential impacts.

4917

4918 **The Apalachicola-Chattahoochee-Flint River basin compact negotiations**

4919 The Apalachicola-Chattahoochee-Flint (ACF) River Basin Compact was formed to
4920 address the growing demands for water in the region's largest city, Atlanta, while at the
4921 same time balancing off-stream demands of other users against in-stream needs to
4922 support fisheries and minimum flows for water quality (Hull, 2000). While the basin is
4923 rapidly urbanizing, farming, and the rural communities that depend upon it, remain
4924 important parts of the region's economy. Conflicts between Georgia, Florida, and
4925 Alabama over water rights in the basin began in the late 1800s. Today, metro-Atlanta
4926 daily draws more than 400 million gallons of water from the river and discharges into it
4927 more than 300 million gallons of wastewater.

4928

4929 Following protracted drought in the region in the 1990s, decision makers in Alabama,
4930 Florida, and Georgia dedicated themselves to avoiding lengthy and expensive litigation
4931 that likely would have led to a decision that would have pleased no one. In 1990, the
4932 three states began an 18-month negotiation process that resulted, first, in a *Letter of*
4933 *Agreement* (April, 1991) to address short term issues in the basin and then, in January
4934 1992, a *Memorandum of Agreement* that, among other things, stated that the three states
4935 were in accord on the need for a study of the water needs of the three states. The three
4936 states' governors also agreed to initiate a comprehensive study by the Army Corps of
4937 Engineers (Kundell and Tetens, 1998).

4938

4939 At the conclusion of the 1998 compact summit, chaired by former Representative
4940 Gingrich, the three states agreed to: protect federal regulatory discretion and water
4941 rights; assure public participation in allocation decisions; consider environmental impacts
4942 in allocation; and develop specific allocation numbers—in effect, guaranteeing volumes
4943 “at the state lines.” Water allocation formulas were to be developed and agreed upon by
4944 December 31, 1998. However, negotiators for the three states requested at least a one-
4945 year extension of this deadline in November of 1998, and several extensions and requests
4946 for extensions have subsequently been granted over the past dozen years, often at the
4947 11th hour of stalemated negotiations.

4948

4949 Opportunities for a breakthrough came in 2003. Georgia's chief negotiator claimed that
4950 the formulas posted by Georgia and Florida, while different, were similar enough to
4951 allow the former to accept Florida's numbers and to work to resolve language differences
4952 in the terms and conditions of the formula. Alabama representatives concurred that the
4953 numbers were workable and that differences could be resolved. Nonetheless, within days
4954 of this tentative settlement, negotiations broke off once again (Georgia Environmental
4955 Protection Division, 2002a). In August 2003, Governors Riley, Bush, and Perdue from
4956 Alabama, Florida, and Georgia, respectively, signed a memorandum of understanding
4957 detailing the principles for allocating water for the ACF over the next 40 years; however,
4958 as of this writing, Georgia has lost an appeal in the Appellate Court of the District of

4959 Columbia to withdraw as much water as it had planned to do, lending further uncertainty
4960 to this dispute (Goodman, 2008).

4961

4962 **Policy impasse**

4963 Three issues appear to be paramount in the failure to reach accord. First, various demands
4964 imposed on the river system may be incompatible, such as protecting in-stream flow
4965 while permitting varied off-stream uses. Second, many of the prominent user conflicts
4966 facing the three states are up- versus down-stream disputes. For example, Atlanta is a
4967 major user of the Chattahoochee. However, it is also a “headwaters” metropolis. The
4968 same water used by Atlanta for water supply and wastewater discharge is used by “up-
4969 streamers” for recreation and to provide shoreline amenities such as high lake levels for
4970 homes (true especially along the shoreline of Lake Lanier), and provides downstream
4971 water supply to other communities. Without adequate drawdown from Lanier, for
4972 example, water supplies may be inadequate to provide for all of Atlanta’s needs.

4973 Likewise, water quality may be severely degraded because of the inability to adequately
4974 dilute pollution discharges from point and non-point sources around Atlanta. This is
4975 especially true if in-stream water volumes decline due to growing off-stream demands.

4976

4977 Finally, the compact negotiating process itself lacks robustness; technically, the compact
4978 does not actually take effect until an allocation formula can be agreed upon. Thus, instead
4979 of agreeing on an institutional framework that can collect, analyze, translate, and use
4980 information to reach accord over allocation limits and water uses, the negotiations have
4981 been targeted on first determining a formula for allocation based on need (Feldman,
4982 2007). As we have seen in the previous case on drought management in Georgia, climate
4983 forecast information is being used to enhance drought preparedness and impact
4984 mitigation. Nevertheless, as noted in that case, conservation measures in one state alone
4985 cannot mitigate region-wide problems affecting large, multi-state watersheds. The same
4986 holds true for regional water supply dispute-resolution. Until a cooperative decision-
4987 making platform emerges whereby regional climate forecast data can be used for conjoint
4988 drought planning, water allocation prescriptions, and incorporation of regional population

4989 and economic growth (not currently done on an individual state-level), effective use of
4990 decision-support information (*i.e.*, transformation) will remain an elusive goal.

4991

4992 **3.3.1.1 Researchers often develop products and tools that they believe will be useful,
4993 and make them available for use without verifying whether they are needed:**

4994 This is sometimes referred to as the “loading dock” phenomenon (Cash et al., 2006). It
4995 generally results from one-way communication, without sufficient evaluation of the
4996 needs of stakeholders. The challenge of integrating information and tools into decision
4997 making is a problem endemic to all societies; particularly, as this Product presents, in the
4998 case of climate variability and water management. Developing nations are faced with the
4999 additional impediment of facing these problems without adequate resources. The
5000 following case study of northeast Brazil is one example of this struggle.

5001

5002 **Case Study: Policy learning and seasonal climate forecasting application in
5003 Northeast Brazil—integrating information into decisions**

5004 **Introduction**

5005 The story of climate variability forecast application in the state of Ceará (northeast
5006 Brazil) chronicles a policy process in which managers have deployed seasonal climate
5007 forecasting experimentally for over ten years for water and agriculture, and have slowly
5008 learned different ways in which seasonal forecasting works, does not work, and could be
5009 improved for decision making (Lemos *et al.*, 2002; Lemos, 2003; Lemos and Oliveira,
5010 2004; Taddei 2005; Pfaff *et al.*, 1999).

5011

5012 The *Hora de Plantar* (“Time to Plant”) Program, begun in 1988, aimed at distributing
5013 high-quality, selected seed to poor subsistence farmers in Ceará and at maintaining a
5014 strict planting calendar to decrease rain-fed farmers sensitivity to climate variability
5015 (Lemos, 2003). In exchange for selected seeds, farmers “paid” back the government with
5016 grain harvested during the previous season or received credit to be paid the following

5017 year. The rationale for the program was to provide farmers with high quality seeds (corn,
5018 beans, rice, and cotton), but to distribute them only when planting conditions were
5019 appropriate. Because farmers tend to plant with the first rains (sometimes called the “pre-
5020 season”) and often have to replant, the goal of this program was to use a simplified
5021 soil/climate model, developed by the state meteorology agency (FUNCEME) to orient
5022 farmers with regard to the actual onset of the rainy season (Andrade, 1995).

5023

5024 While the program was deemed a success (Golnaraghi and Kaul, 1995), a closer look
5025 revealed many drawbacks. First, it was plagued by a series of logistical and enforcement
5026 problems (transportation and storage of seed, lack of enough distribution centers, poor
5027 access to information and seeds by those most in need, fraud, outdated client lists)
5028 (Lemos *et al.*, 1999). Second, local and lay knowledge accumulated for years to inform
5029 its design was initially ignored. Instead, the program relied on a model of knowledge use
5030 that privileged the use of technical information imposed on the farmers in an
5031 exclusionary and insulated form that alienated stakeholders and hampered buy-in from
5032 clients (Lemos, 2003). Third, farmers strongly resented *Hora de Plantar's* planting
5033 calendar and its imposition over their own best judgment. Finally, there was the
5034 widespread perception among farmers (and confirmed by a few bank managers) that a
5035 “bad” forecast negatively affected the availability of rural credit (Lemos *et al.*, 1999).
5036 While many of the reasons farmers disliked the program had little to do with climate
5037 forecasting, the overall perception was that FUNCEME was to blame for its negative
5038 impact on their livelihoods (Lemos *et al.*, 2002; Lemos, 2003; Meinke *et al.*, 2006). As a
5039 result, there was both a backlash against the program and a relative discredit of
5040 FUNCEME as a technical agency and of the forecast by association. The program is still
5041 active, although by 2002, the strict coupling of seed distribution and the planting calendar
5042 had been phased out (Lemos, 2003).

5043

5044 In 1992, as part of Ceará’s modernizing government administration, and in response to a
5045 long period of drought, the State enacted Law 11.996 that defined its policy for water
5046 resources management. This new law created several levels of water management,
5047 including watershed Users’ Commissions, Watershed Committees and a state level Water

5048 Resources Council. The law also defined the watershed as the planning unit of action;
5049 spelled out the instruments of allocation of water permits and fees for the use of water
5050 resources; and regulated further construction in the context of the watershed (Lemos and
5051 Oliveira, 2004; Formiga-Johnsson and Kemper, 2005; Pfaff *et al.*, 1999).

5052

5053 **Innovation – Using Information More Effectively**

5054 One of the most innovative aspects of water reform in Ceará was creation of an
5055 interdisciplinary group within the state water management agency (COGERH) to develop
5056 and implement reforms. The inclusion of social and physical scientists within the agency
5057 allowed for the combination of ideas and technologies that critically affected the way the
5058 network of *técnicos* and their supporters went about implementing water reform in the
5059 State. From the start, COGERH sought to engage stakeholders, taking advantage of
5060 previous political and social organization within the different basins to create new water
5061 organizations (Lemos and Oliveira, 2005). In the Lower Jaguaribe-Banabuiú River basin,
5062 for example, the implementation of participatory councils went further than the suggested
5063 framework of River Basin Committees to include the Users Commission to negotiate
5064 water allocation among different users directly (Garjulli, 2001; Lemos and Oliveira,
5065 2004; Taddei, 2005; Pfaff *et al.*, 1999). COGERH *técnicos* specifically created the
5066 Commission independently of the “official” state structure to emphasize their autonomy
5067 *vis-à-vis* the State (Lemos and Oliveira, 2005). This agenda openly challenged a pattern
5068 of exclusionary water policymaking prevalent in Ceará and was a substantial departure
5069 from the top-down, insulated manner of water allocation in the past (Lemos and Oliveira,
5070 2004). The ability of these *técnicos* to implement the most innovative aspects of the
5071 Ceará reform can be explained partly by their insertion into policy networks that were
5072 instrumental in overcoming the opposition of more conservative sectors of the state
5073 apparatus and their supporters in the water user community (Lemos and Oliveira, 2004).

5074

5075 The role of knowledge in building adaptive capacity in the system was also important
5076 because it helped democratize decision making. In Ceará, the organization of stakeholder
5077 councils and the effort to use technical knowledge, especially reservoir scenarios to
5078 inform water release, may have enhanced the system’s adaptive capacity to climate

5079 variability as well as improved water resources sustainability (Formiga-Johnson and
5080 Kemper, 2005; Engle, 2007). In a recent evaluation of the role of governance institutions
5081 in influencing adaptive capacity building in two basins in northeastern Brazil (Lower
5082 Jaguaribe in Ceará and Pirapama in Pernambuco), Engle (2007) found that water reform
5083 played a critical role in increasing adaptive capacity across the two basins. And while the
5084 use of seasonal climate knowledge has been limited so far (the scenarios assume zero
5085 inflows from future rainfall), there is great potential that use of seasonal forecasts could
5086 affect several aspects of water management and use in the region and increase forecast
5087 value.

5088

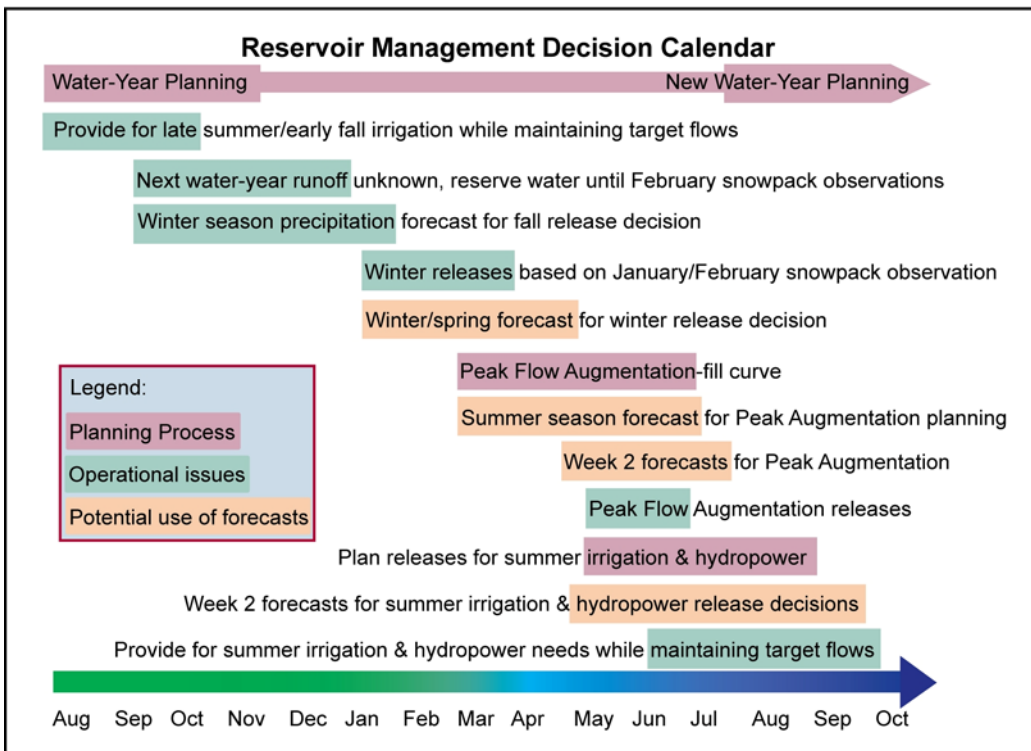

5089 In the context of Ceará's Users Commissions, the advantages are twofold. First, by
5090 making simplified reservoir models available to users, COGERH is not only enhancing
5091 public knowledge about the river basin but also is crystallizing the idea of collective risk.
5092 While individual users may be willing to go along with the status quo, collective
5093 decision-making processes may be much more effective in curbing overuse. Second,
5094 information can play a critical role in democratization of decision making at the river
5095 basin level by training users to make decisions, and dispelling the widespread distrust that
5096 has developed as a result of previous applications of climate information. Finally, the
5097 case suggests that incorporating social science into processes that are being designed to
5098 optimize the use of climate forecast tools in specific water management contexts can
5099 enhance outcomes by helping poorer communities better adapt to, and build capacity for,
5100 managing climate variability impacts on water resources. Building social capital can be
5101 advantageous for other environmental issues as well, including an increasing likelihood
5102 of public attentiveness, participation, awareness, and engagement in monitoring of
5103 impacts.

5104

5105 **3.3.1.2 Information may not be available at the time it could be useful**

5106 It is well established in the climate science community that information must be timely in
5107 order to be useful to decision makers. This requires that researchers understand and be
5108 responsive to the time frames during the year for which specific types of decisions are

5109 made. Pulwarty and Melis (2001), Ray and Webb (2000), and Wiener *et al.* (2000) have
 5110 developed and introduced the concept of “decision calendars” in the context of the
 5111 Western Water Assessment in Boulder, Colorado (Figure 3.3). Failure to provide
 5112 information at a time when it can be inserted into the annual series of decisions made in
 5113 managing water levels in reservoirs, for example, may result in the information losing
 5114 virtually all of its value to the decision maker. Likewise, decision makers need to
 5115 understand the types of predictions that can be made and trade-offs between longer-term
 5116 predictions of information at the local or regional scale and potential decreases in
 5117 accuracy. They also need to help scientists in formulating research questions.
 5118

5119
 5120 **Figure 3.3** An example of a decision calendar for reservoir management planning. Shaded bars indicate
 5121 the timing of information needs for planning and operational issues over the year (Source: Ray and Webb,
 5122 2000).
 5123

5124 The importance of leadership in initiating change cannot be overstated (Chapter 4), and
5125 its importance in facilitating information exchange is also essential; making connections
5126 with on-the-ground operational personnel and data managers in order to facilitate
5127 information exchange is of particular importance. The presence of a “champion” within
5128 stakeholder groups or agencies may make the difference in successful integration of new
5129 information. Identifying people with leadership qualities and working through them will
5130 facilitate adoption of new applications and techniques. Recently-hired water managers
5131 have been found to be more likely to take risks and deviate from precedent and “craft
5132 skills” that are unique to a particular water organization (Rayner *et al.*, 2005).

5133

5134 The following vignette on the Advanced Hydrologic Prediction System (AHPS),
5135 established in 1997, exemplifies a conscious effort by the National Weather Service to
5136 respond to many of these chronic relational problems in a decisional context. AHPS is an
5137 effort to go beyond traditional river stage forecasts which are short-term (one to three
5138 days), and are the product of applied historical weather data, stream gage data, channel
5139 cross-section data, water supply operations information, and hydrologic model
5140 characteristics representing large regions. It is an effort that has worked, in part, because
5141 it has many “champions”; however, questions remain about whether resources for the
5142 initiative have been adequate.

5143

5144 AHPS responds directly to the problem of timely information availability by trying to
5145 provide forecasting information sooner, particularly on potential flooding; linking it
5146 directly to local decision makers, providing the information in a visual format; and,

5147 perhaps most of all, providing a dedicated program within NOAA (and the NWS) that
5148 has the capacity to work directly with the user community and monitor ongoing, evolving
5149 decision-support needs.

5150

5151 **Vignette: AHPS—Advantages over conventional forecasting**

5152 Applying the same hydrologic data used in current methods, AHPS also employs
5153 advanced hydrologic models with characteristics specific to local watersheds and
5154 tributaries. These advanced, localized hydrologic models increase forecast accuracy by
5155 20 percent over existing models. Its outputs are more accurate, detailed, and visually
5156 oriented, and are able to provide decision makers and the public with information on,
5157 among other variables: how high a river will rise, when it will reach its peak, where
5158 properties will be subject to flooding, and how long a flood event will continue. It is
5159 estimated that national implementation of AHPS will save at least \$200 million per year
5160 in reduced flood losses and contribute an additional \$400 million a year in economic
5161 benefits to water resource users (Advanced Hydrologic Prediction Service/
5162 <http://www.state.nj.us/drbc/Flood_Website/AHPS.htm>).

5163

5164 **Benefits and application**

5165 AHPS provides detailed products in an improved format. Because it is visually oriented,
5166 it provides information in a format that is easier to understand and use by the general
5167 public as well as planners and scientists. AHPS depicts the magnitude and probability of
5168 hydrologic events, and gives users an idea of worst case scenario situations. Finally,
5169 AHPS provides forecasts farther in advance of current methods, allowing people
5170 additional time to protect themselves, their families, and their property from floods.

5171

5172 Following the Great Flood of 1993 in the Midwest, the Des Moines River Basin in Iowa
5173 was selected to be a location to test for the first phase toward national implementation of
5174 AHPS. Residents, via the Internet, can now access interactive maps displaying flood
5175 forecast points. Selecting any of the flood forecast points on the map allows Internet
5176 users to obtain river stage forecast information for the point of interest. Available

5177 information includes: river flood stages, flow and volume probabilities, site maps, and
5178 damage tables projecting areas are likely to be subject to flooding.

5179

5180 **Status and assessment**

5181 A 2006 NRC report found AHPS to be an ambitious climate forecast program that
5182 promises to provide services and products that are timely and necessary. However, it
5183 expressed concerns about “human and fiscal resources,” recommending that there is a
5184 need for trained hydrologic scientists to conduct hydrologic work in the NWS. Regarding
5185 fiscal resources, “the budgetary history and current allocation seem misaligned with the
5186 ambitious goals of the program.” Thus, the program’s goals and budget should be
5187 brought into closer alignment (NRC, 2006).

5188

5189 **3.3.2 Scientists Need to Communicate Better and Decision Makers Need a Better**

5190 **Understanding of Uncertainty—it is Embedded in Science**

5191 Discussions of uncertainty are at the center of many debates about forecast information
5192 and its usefulness. Uncertainties result from: the relevance and reliability of data, the
5193 appropriateness of theories used to structure analyses, the completeness of the
5194 specification of the problem, and in the “fit” between a forecast and the social and
5195 political matters of fact on the ground (NRC, 2005). While few would disagree that
5196 uncertainties are inevitable, there is less agreement as to how to improve ways of
5197 describing uncertainties in forecasts to provide widespread benefits (NRC, 2005).

5198 It is important to recognize that expectations of certainty are unrealistic in regards to
5199 climate variability. Weather forecasts are only estimates; the risk tolerance (Section
5200 3.2.3) of the public is often unrealistically low. As we have seen in multiple cases, one
5201 mistaken forecast (*e.g.*, the Yakima basin case) can have an impact out of proportion to
5202 the gravity of its consequences. Some starting points from the literature include helping

5203 decision makers understand that uncertainty does not make a forecast scientifically
5204 flawed, only imperfect. Along these lines, decision makers must understand the types of
5205 predictions that can be made and trade-offs between predictions of information at the
5206 local or regional scale that are less accurate than larger scale predictions (Jacobs *et al.*,
5207 2005). They also need to help scientists formulate research questions that result in
5208 relevant decision-support tools.

5209

5210 Second, uncertainty is not only inevitable, but necessary and desirable. It helps to
5211 advance and motivate scientific efforts to refine data, analysis, and forecaster skills;
5212 replicate research results; and revise previous studies, especially through peer review
5213 (discussed below) and improved observation. As one observer has noted, “(un)certainty is
5214 not the hallmark of bad science, it is the hallmark of honest science (when) we know
5215 enough to act is inherently a policy question, not a scientific one” (Brown, 1997).

5216

5217 Finally, the characterization of uncertainty should consider the decision relevance of
5218 different aspects of the uncertainties. Failure to appreciate such uncertainties results in
5219 poor decisions, misinterpretation of forecasts, and diminished trust of analysts.

5220 Considerable work on uncertainty in environmental assessments and models make this
5221 topic ripe for progress (*e.g.*, NRC, 1999).

5222

5223 **Vignette: Interpreting Climate Forecasts—uncertainties and temporal variability**

5224 **Introduction**

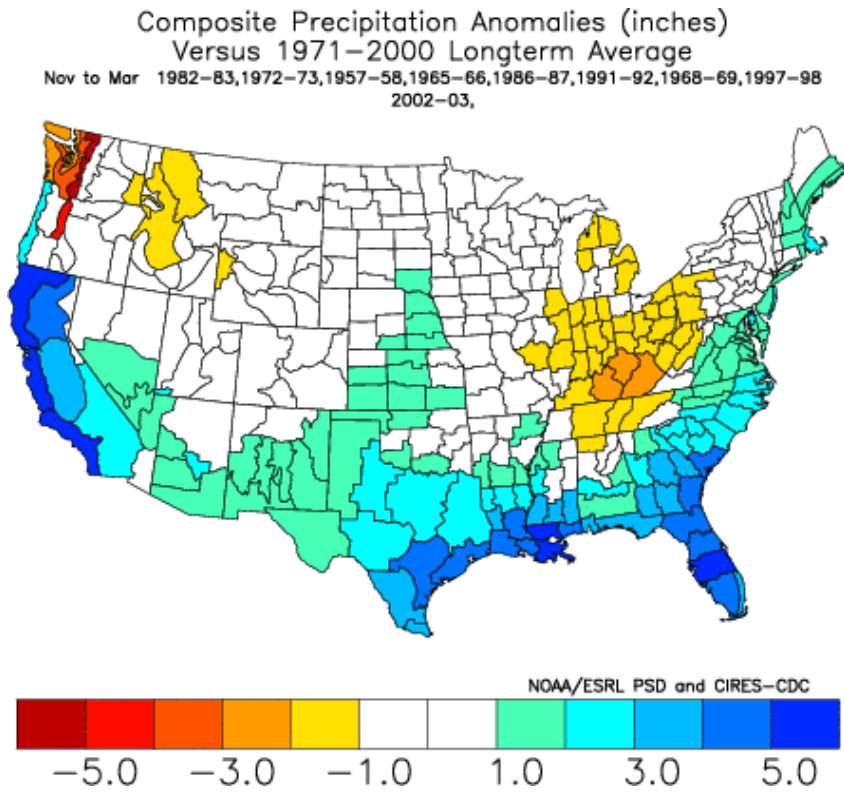

5225 Lack of information about geographical and temporal variability in climate processes is
5226 one of the primary barriers to adoption and use of specific products. ENSO forecasts are

5227 an excellent example of this issue. While today El Niño (EN) and La Niña (LN) are part
5228 of the public vocabulary, operational ENSO-based forecasts have only been made since
5229 the late 1980s. Yet, making a decision based only on the forecasts themselves may
5230 expose a manager to unanticipated consequences. Additional information can mitigate
5231 such risk. ENSO-related ancillary products, such as those illustrated in Figures 3.4 and
5232 3.5, can provide information about which forecasts are likely to be most reliable for what
5233 time periods and in which areas. As Figure 3.4 shows, informed use of ENSO forecasts
5234 requires understanding of the temporal and geographical domain of ENSO impacts. EN
5235 events tend to bring higher than average winter precipitation to the U.S. Southwest and
5236 Southeast while producing below-average precipitation in the Pacific Northwest. LN
5237 events are the converse, producing above-average precipitation in the Pacific Northwest
5238 and drier patterns across the southern parts of the country. Further, not all ENs or LNs are
5239 the same with regard to the amount of precipitation they produce. As illustrated in Figure
5240 3.6, which provides this kind of information for Arizona, the EN phase of ENSO tends to
5241 produce above-average winter precipitation less dependably than the LN phase produces
5242 below-average winter precipitation.

5243

5244 An example of the value of combining ENSO forecasts with information about how
5245 ENSO tended to affect local systems arose during the 1997/1998 ENSO event. In this
5246 case, the Arizona-based Salt River Project (SRP) made a series of decisions based on the
5247 1997/1998 EN forecast plus analysis of how ENs tended to affect their system of rivers
5248 and reservoirs. Knowing that ENs tended to produce larger streamflows late in the winter
5249 season, SRP managers reduced groundwater pumping in August 1997 in anticipation of a
5250 wet winter. Their contingency plan called for resuming groundwater pumping if
5251 increased streamflows did not materialize by March 1, 1998. As the winter progressed, it
5252 became apparent that the EN had produced a wet winter and plentiful water supplies in
5253 SRP's reservoirs. The long-lead decision to defer groundwater pumping in this instance
5254 saved SRP \$1 million (Pagano *et al.*, 2001). SRP was uniquely well positioned to take
5255 this kind of risk because the managers making the decisions had the support of upper-
5256 level administrators and because the organization had unusually straightforward access to
5257 information. First, a NWS office is co-located in the SRP administrative headquarters,

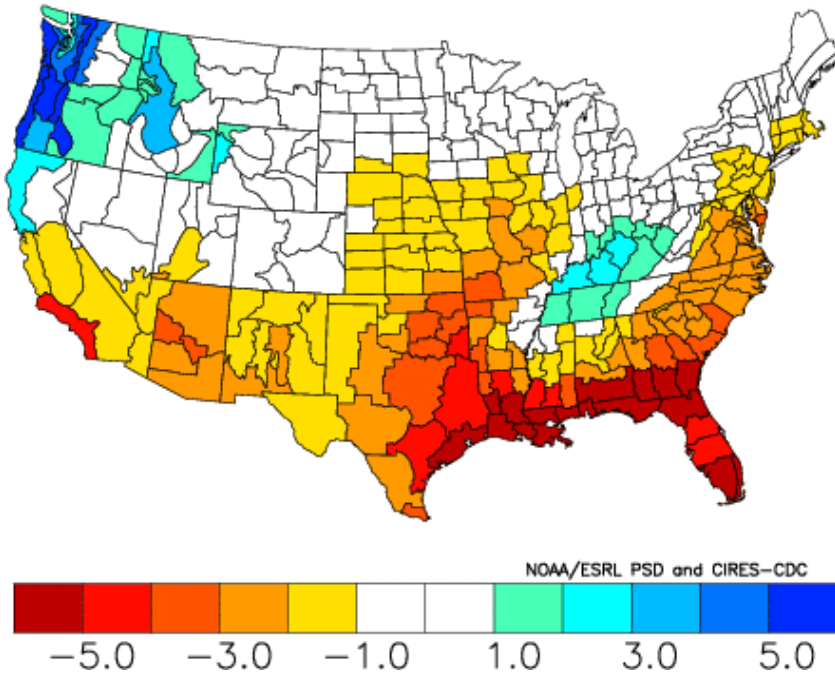

5258 and second, key decision makers had been interacting regularly with climate and
 5259 hydrology experts associated with the NOAA-funded Climate Assessment for the
 5260 Southwest (CLIMAS) project, located at the University of Arizona. Relatively few
 5261 decision makers have this level of support for using climate forecasts and associated
 5262 information. The absence of such support systems may increase managers' exposure to
 5263 risk, in turn generating a strong disincentive to use climate forecasts.

5270

5271

5272

5273 **Figure 3.6** Southern Oscillation Index (SOI) June through November, *versus*. Winter precipitation
 5274 November through April for 1896 to 2001 for three phases of ENSO, El Niño, La Niña, and Neutral, for
 5275 Arizona climate division 6. Note the greater variation in El Niño precipitation (blue) than in La Niña
 5276 precipitation (red).
 5277

5278 3.4 SUMMARY

5279 Decision-support systems are not often well integrated into policy networks to support
 5280 planning and management, making it difficult to convey information. Among the reasons
 5281 for this are a tendency toward institutional conservatism by water agencies, a decision-
 5282 making climate that discourages innovation, lack of national-scale coordination of
 5283 decisions, difficulties in providing support for decisions at varying spatial and temporal
 5284 scales due to vast variability in “target audiences” for products, and growing recognition
 5285 that rational choice models of information transfer are overly simplistic. The case of

5286 information use in response to Georgia’s recent drought brings to light problems that
5287 students of water decision making have long described about resistance to innovation.
5288
5289
5290 Ensuring information relevance requires overcoming the barriers of over-specialization
5291 by encouraging inter-disciplinary collaboration in product and tool development.
5292 Decision makers need to learn to appreciate the inevitability and desirability of forecast
5293 uncertainties at a regional scale on the one hand, and potential decreases in accuracy on
5294 the other. Scientists must understand both internal institutional impediments (agency
5295 rules and regulations) as well as external ones (*e.g.*, political-level conflicts over water
5296 allocation as exemplified in the Southeast United States, asymmetries in information
5297 access in the case of Northeast Brazil) as factors constraining decision-support translation
5298 and decision transformation. While the nine cases discussed here have been useful and
5299 instructive, more generalizable findings are needed in order to develop a strong,
5300 theoretically-grounded understanding of processes that facilitate information
5301 dissemination, communication, use, and evaluation—and to predict effective methods of
5302 boundary spanning between decision makers and information generators. We discuss this
5303 set of problems in Chapter 4.

5962

5963

5964

5965

5966

5967

5968

5969 **KEY FINDINGS**

5970 Decision-support experiments that apply seasonal and interannual climate variability
5971 information to basin and regional water resource problems serve as test beds that address
5972 diverse issues faced by decision makers and scientists. They illustrate how to identify
5973 user needs, overcome communication barriers, and operationalize forecast tools. They
5974 also demonstrate how user participation can be incorporated into tool development.

5975

5976 Five major lessons emerge from these experiments and supporting analytical studies:

- 5977 • The effective integration of seasonal to interannual climate information in
5978 decisions requires long-term collaborative research and application of decision
5979 support through identifying problems of mutual interest. This collaboration will
5980 require a critical mass of scientists and decision makers to succeed and there is
5981 currently an insufficient number of “integrators” of climate information for
5982 specific applications.
- 5983 • Investments in long-term research-based relationships between scientists and
5984 decision makers must be adequately funded and supported. In general, progress
5985 on developing effective decision-support systems is dependent on additional
5986 public and private resources to facilitate better networking among decision
5987 makers and scientists at all levels as well as public engagement in the fabric of
5988 decision making.
- 5989 • Effective decision-support tools must integrate national production of data and
5990 technologies to ensure efficient, cross-sector usefulness with customized products

5991 for local users. This requires that tool developers engage a wide range of
5992 participants, including those who generate tools and those who translate them, to
5993 ensure that specially-tailored products are widely accessible and are immediately
5994 adopted by users insuring relevancy and utility.

5995 • The process of tool development must be inclusive, interdisciplinary, and provide
5996 ample dialogue among researchers and users. To achieve this inclusive process,
5997 professional reward systems that recognize people who develop, use and translate
5998 such systems for use by others are needed within water management and related
5999 agencies, universities and organizations. Critical to this effort, further progress is
6000 needed in boundary spanning—the effort to translate tools to a variety of
6001 audiences across institutional boundaries.

6002 • Information generated by decision-support tools must be implementable in the
6003 short term for users to foresee progress and support further tool development.
6004 Thus, efforts must be made to effectively integrate public concerns and elicit
6005 public information through dedicated outreach programs.

6006

6007 **4.1 INTRODUCTION**

6008 This chapter examines a series of decision-support experiments that explore how
6009 information on seasonal to interannual (SI) climate variability is being used, and how
6010 various water management contexts serve as test beds for implementing decision-support
6011 outputs. We describe how these experiments are implemented and how SI climate
6012 information is used to assess potential impacts of and responses to climate variability and

6013 change. We also examine characteristics of effective decision-support systems, involving
6014 users in forecast and other tool development, and incorporating improvements.

6015

6016 Section 4.2 discusses a series of experiments from across the nation, and in a variety of
6017 contexts. Special attention is paid to the role of key leadership in organizations to
6018 empower employees, take risks, and promote inclusiveness. This section highlights the
6019 role of organizational culture in building pathways for innovation related to boundary-
6020 spanning approaches.

6021

6022 Section 4.3 examines approaches to increasing user knowledge and enhancing capacity
6023 building. We discuss the role of two-way communication among multiple forecast and
6024 water resource sectors, and the importance of translation and integration skills, as well as
6025 operations staff incentives for facilitating such integration.

6026

6027 Section 4.4 discusses the development of measurable indicators of progress in promoting
6028 climate information access and effective use, including process measures such as
6029 consultations between agencies and potential forecast user communities. The role of
6030 efforts to enhance dialogue and exchange among researchers and users is emphasized.

6031

6032 Finally, Section 4.5 summarizes major findings, directions for further research, and
6033 recommendations, including: needs for better understanding of the role of decision-
6034 maker context for tool use, how to assess vulnerability to climate, communicating results
6035 to users, bottom-up as well as top-down approaches to boundary-spanning innovation,

6036 and applicability of lessons from other resource management sectors (*e.g.*, forestry,
6037 coastal zone management, hydropower) on decision-support use and decision
6038 maker/scientist collaboration.

6039

6040 We conclude that, at present, the weak conceptual grounding afforded by cases from the
6041 literature necessitates that we base measures to improve decision support for the water
6042 resources management sector, as it pertains to inclusion of climate forecasts and
6043 information, on best judgment extrapolated from case experience. Additional research is
6044 needed on effective models of boundary spanning in order to develop a strong,
6045 theoretically-grounded understanding of the processes that facilitate information
6046 dissemination, communication, use, and evaluation so that it is possible to generalize
6047 beyond single cases, and to have predictive value.

6048

6049 **4.2 DECISION-SUPPORT TOOLS FOR CLIMATE FORECASTS: SERVING**
6050 **END-USER NEEDS, PROMOTING USER ENGAGEMENT AND**
6051 **ACCESSIBILITY**

6052 This section examines a series of decision-support experiments from across the United
6053 States. Our objective is to learn how the barriers to optimal decision making, including
6054 impediments to trust, user confidence, communication of information, product
6055 translation, operationalization of decision-support tools, and policy transformation
6056 discussed in Chapter 3, can be overcome. As shall be seen, all of these experiments share
6057 one characteristic: users have been involved, to some degree, in tool development—
6058 through active elicitation of their needs, involvement in tool design, evaluation of tool

6059 effectiveness (and feedback into product refinement as a result of tool use), or some
6060 combination of factors.

6061

6062 **4.2.1 Decision-Support Experiments on Seasonal to Interannual Climate Variability**

6063 The following seven cases are important test beds that examine how, and how effectively,
6064 decision-support systems have been used to manage diverse water management needs,
6065 including ecological restoration, riparian flow management, urban water supply,
6066 agricultural water availability, coastal zone issues, and fire management at diverse spatial
6067 scales: from cities and their surrounding urban concentrations (New York, Seattle), to
6068 regions (Northern California, South Florida, Inter-mountain West); a comprehensively-
6069 managed river basin (CALFED); and a resource (forest lands) scattered over parts of the
6070 U.S. West and Southwest. These cases also illustrate efforts to rely on temporally diverse
6071 information (*i.e.*, predictions of future variability in precipitation, sea-level rise, and
6072 drought as well as past variation) in order to validate trends.

6073

6074 Most importantly, these experiments represent the use of different ways of integrating
6075 information into water management to enable better decisions to be made, including
6076 neural networks¹⁹ in combination with El Niño-Southern Oscillation (ENSO) forecasting;
6077 temperature, precipitation and sea-level rise prediction; probabilistic risk assessment;
6078 integrated weather, climate and hydrological models producing short- and longer-term

¹⁹ A neural network or "artificial neural network" is an approach to information processing paradigm that functions like a brain in processing information. The network is composed of a large number of interconnected processing elements (neurons) that work together to solve specific problems and, like the brain, the entire network learns by example.

6079 forecasts; weather and streamflow station outputs; paleoclimate records of streamflow
6080 and hydroclimatic variability; and the use of climate change information on precipitation
6081 and sea-level rise to address shorter-term weather variability.

6082

6083 ***Experiment 1:***

6084 ***How the South Florida Water Management District Uses Climate Information***

6085 ***The Experiment***

6086 In an attempt to restore the Everglades ecosystem of South Florida, a team of state and
6087 federal agencies is engaged in the world's largest restoration program (Florida
6088 Department of Environmental Protection and South Florida Water Management District,
6089 2007). A cornerstone of this effort is the understanding that SI climate variability (as well
6090 as climate change) could have significant impacts on the region's hydrology over the
6091 program's 50-year lifetime. The South Florida Water Management District (SFWMD) is
6092 actively involved in conducting and supporting climate research to improve the
6093 prediction and management of South Florida's complex water system (Obeysekera *et al.*,
6094 2007). The SFWMD is significant because it is one of the few cases in which decade-
6095 scale climate variability information is being used in water resource modeling, planning,
6096 and operation programs.

6097

6098 ***Background/Context***

6099 Research relating climatic indices to South Florida climate started at SFWMD more than
6100 a decade ago (South Florida Water Management District, 1996). Zhang and Trimble
6101 (1996), Trimble *et al.* (1997), and Trimble and Trimble (1998) used neural network
6102 models to develop a better understanding of how ENSO and other climate factors
6103 influence net inflow to Lake Okeechobee. From that knowledge, Trimble *et al.* (1998)
6104 demonstrated the potential for using ENSO and other indices to predict net inflow to
6105 Lake Okeechobee for operational planning. Subsequently, SFWMD was able to apply
6106 climate forecasts to its understanding of climate-water resources relationships in order to
6107 assess risks associated with seasonal and multi-seasonal operations of the water

6108 management system and to communicate the projected outlook to agency partners,
6109 decision makers, and other stakeholders (Cadavid *et al.*, 1999).

6110

6111 *Implementation/Application*

6112 The SFWMD later established the Water Supply and Environment (WSE), a regulation
6113 schedule for Lake Okeechobee that formally uses seasonal and multi-seasonal climate
6114 outlooks as guidance for regulatory release decisions (Obeysekera *et al.*, 2007). The WSE
6115 schedule uses states of ENSO and the Atlantic Multidecadal Oscillation (AMO) (Enfield
6116 *et al.*, 2001) to estimate the Lake Okeechobee net inflow outlook for the next six to 12
6117 months. A decision tree with a climate outlook is a unique component of the WSE
6118 schedule and is considered a major advance over traditional hydrologic rule curves
6119 typically used to operate large reservoirs (Obeysekera *et al.*, 2007). Evaluation of the
6120 application of the WSE schedule revealed that considerable uncertainty in regional
6121 hydrology remains and is attributable to some combination of natural climatic variation,
6122 long-term global climate change, changes in South Florida precipitation patterns
6123 associated with drainage and development, and rainfall-runoff relationships altered by
6124 infrastructure changes (Obeysekera *et al.*, 2007).

6125

6126 *Lessons Learned*

6127 From its experience with climate information and research, SFWMD has learned that to
6128 improve its modeling capabilities and contributions to basin management, it must
6129 improve its ability to: differentiate trends and discontinuities in basin flows associated
6130 with climate variation from those caused by water management; gauge the skill gained in
6131 using climate information to predict basin hydroclimatology; improve management;
6132 account for management uncertainties caused by climate variation and change; and
6133 evaluate how climate change projections may affect facility planning and operation of the
6134 SFWMD (Bras, 2006; Obeysekera *et al.*, 2007).

6135

6136 The district has also learned that, given the decades needed to restore the South Florida
6137 ecosystem, adaptive management is an effective way to incorporate SI climate variation
6138 into its modeling and operations decision-making processes, especially since longer term

6139 climate change is likely to exacerbate operational challenges. As previously stated, this
6140 experiment is also unique in being the only one that has been identified in which decadal
6141 climate status (*e.g.*, state of the AMO) is being used in a decision-support context.

6142

6143 ***Experiment 2:***

6144 ***Long-Term Municipal Water Management Planning – New York City***

6145 ***The Experiment***

6146 Projections of long-term climate change, while characterized by uncertainty, generally
6147 agree that coastal urban areas will, over time, be increasingly threatened by a unique set
6148 of hazards. These include sea-level rise, increased storm surges, and erosion. Two
6149 important questions facing decision makers are: (1) How will long-term climate change
6150 increase these threats, which are already of concern to urban planners? and (2) Can
6151 information on the likely changes in recurrence intervals of extreme events (*e.g.*, tropical
6152 storms) be used in long term municipal water management planning and decision
6153 making?

6154

6155 ***Background and Context***

6156 Water management in coastal urban areas faces unique challenges due to vulnerabilities
6157 of much of the existing water supply and treatment infrastructure to storm surges, coastal
6158 erosion, coastal subsidence, and tsunamis (Jacobs *et al.*, 2007; OFCM, 2004). Not only
6159 are there risks due to extreme events under current and evolving climate conditions, but
6160 many urban areas rely on aging infrastructure that was built in the late nineteenth and
6161 early twentieth centuries. These vulnerabilities will only be amplified by the addition of
6162 global warming-induced sea-level rise due to thermal expansion of ocean water and the
6163 melting of glaciers, mountain ice caps and ice sheets (IPCC, 2007a). For example,
6164 observed global sea-level rise was ~1.8 mm (~0.07 in) per year from 1961 to 2003,
6165 whereas from 1993 to 2003 the rate of sea-level rise was ~3.1 mm (~0.12 in) per year
6166 (IPCC, 2007a). The Intergovernmental Panel on climate Change (IPCC) projections for
6167 the twenty-first century (IPCC, 2007a) are for an “increased incidence of extreme high
6168 sea level” which they define as the highest one percent of hourly values of observed sea
6169 level at a station for a given reference period. The New York City Department of

6170 Environmental Protection (NYCDEP) is one example of an urban agency that is adapting
6171 strategic and capital planning to take into account the potential effects of climate
6172 change—sea-level rise, higher temperature, increases in extreme events, and changing
6173 precipitation patterns—on the city’s water systems. NYCDEP, in partnership with local
6174 universities and private sector consultants, is evaluating climate change projections,
6175 impacts, indicators, and adaptation and mitigation strategies to support agency decision
6176 making (Rosenzweig *et al.*, 2007).

6177

6178 *Implementation/Application*

6179 In New York City (NYC), as in many coastal urban areas, many of the wastewater
6180 treatment plants are at elevations of two to six meters above present sea level and thus
6181 within the range of current surges for tropical storms and hurricanes and extra-tropical
6182 cyclones (or “Nor’easters”) (Rosenzweig and Solecki, 2001; Jacobs, 2001). Like many
6183 U.S. cities along the northern Atlantic Coast, NYC’s vulnerability to storm surges is
6184 predominantly from Nor’easters that occur largely between late November and March,
6185 and tropical storms and hurricanes that typically strike between July and October. Based
6186 on global warming-induced sea-level rise inferred from IPCC studies, the recurrence
6187 interval for the 100-year storm flood (probability of occurring in any given year = 1/100)
6188 may decrease to 60 years or, under extreme changes, a recurrence interval as little as four
6189 years (Rosenzweig and Solecki, 2001; Jacobs *et al.*, 2007).

6190

6191 Increased incidence of high sea levels and heavy rains can cause sewer back-ups and
6192 water treatment plant overflows. Planners have identified activities to address current and
6193 future concerns such as using sea-level rise forecasts as inputs to storm surge and
6194 elevation models to anticipate the impact of flooding on NYC coastal water resource-
6195 related facilities. Other concerns include potential water quality impairment from heavy
6196 rains that can increase pathogen levels and turbidity with the possible effects magnified
6197 by “first-flush” storms: heavy rains after weeks of dry weather. NYC water supply
6198 reservoirs have not been designed for rapid releases and any changes to operations to
6199 limit downstream damage through flood control measures will reduce water supply. In

6200 addition, adding filtration capacity to the water supply system would be a significant
6201 challenge.

6202

6203 Planners in NYC have begun to consider these issues by defining risks through
6204 probabilistic climate scenarios, and categorizing potential adaptations as related to (1)
6205 operations/management; (2) infrastructure; and (3) policy (Rosenzweig *et al.*, 2007). The
6206 NYCDEP is examining the feasibility of relocating critical control systems to higher
6207 floors/ground in low-lying buildings, building protective flood walls, modifying design
6208 criteria to reflect changing hydrologic processes, and reconfiguring outfalls to prevent
6209 sediment build-up and surging. Significant strategic decisions and capital investments for
6210 NYC water management will continue to be challenged by questions such as: How does
6211 the city utilize projections in ways that are robust to uncertainties? and, when designing
6212 infrastructure in the face of future uncertainty, how can these planners make
6213 infrastructure more robust and adaptable to changing climate, regulatory mandates,
6214 zoning, and population distribution?

6215

6216 *Lessons Learned*

6217 When trends and observations clearly point to increasing risks, decision makers need to
6218 build support for adaptive action despite inherent uncertainties. The extent and
6219 effectiveness of adaptive measures will depend on building awareness of these issues
6220 among decision makers, fostering processes of interagency interaction and collaboration,
6221 and developing common standards (Zimmerman and Cusker, 2001).

6222

6223 New plans for regional capital improvements can be designed to include measures that
6224 will reduce vulnerability to the adverse effects of sea-level rise. Wherever plans are
6225 underway for upgrading or constructing new roadways, airport runways, or wastewater
6226 treatment plants, which may already include flood protection; project managers now
6227 recognize the need to consider sea-level rise in planning activities (*i.e.*, OFCM, 2002).

6228

6229 In order to incorporate new sources of risk into engineering analysis, the meteorological
6230 and hydrology communities need to define and communicate current and increasing risks

6231 clearly, and convey them coherently, with explicit consideration of the inherent
 6232 uncertainties. Research needed to support regional stakeholders include: further reducing
 6233 uncertainties associated with sea-level rise, providing more reliable predictions of
 6234 changes in frequency and intensity of tropical and extra-tropical storms, and determining
 6235 how saltwater intrusion will impact freshwater. Finally, regional climate model
 6236 simulations and statistical techniques being used to predict long-term climate change
 6237 impacts could be down-scaled to help manage projected SI climate variability. This could
 6238 be especially useful for adaptation planning (OFCM, 2007a).

6239

6240 **Experiment 3:**

6241 **Integrated Forecast and Reservoir Management (INFORM) - Northern California**

6242 **The Experiment**

6243 The Integrated Forecast and Reservoir Management (INFORM) project aims to
 6244 demonstrate the value of climate, weather, and hydrology forecasts in reservoir
 6245 operations. Specific objectives are to: (1) implement a prototype integrated forecast-
 6246 management system for the Northern California river and reservoir system in close
 6247 collaboration with operational forecasting and management agencies, and (2) demonstrate
 6248 the utility of meteorological/climate and hydrologic forecasts through near-real-time tests
 6249 of the integrated system with actual data and management input.

6250

6251

6252

6253

6254

6255

6256

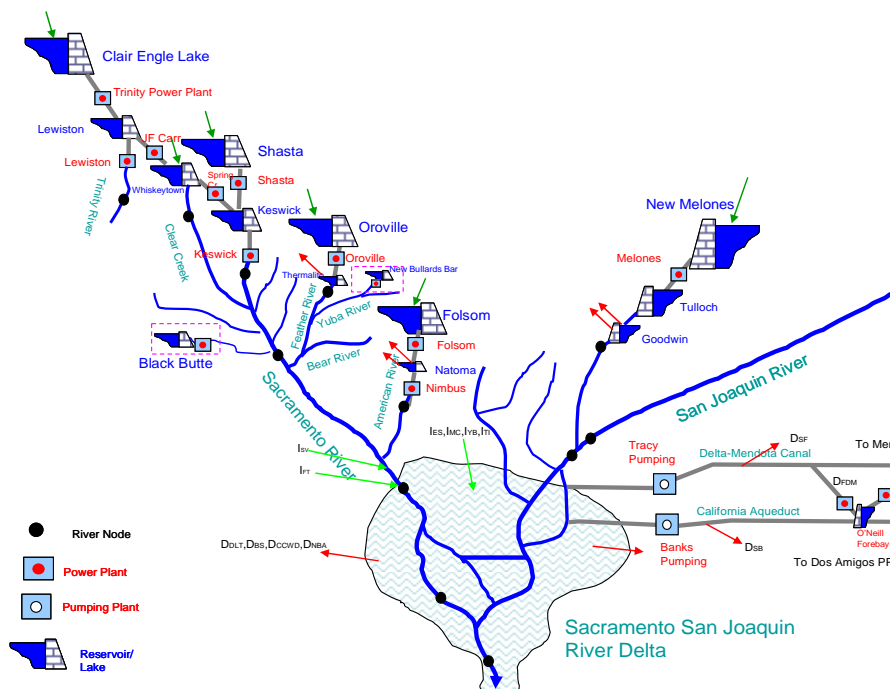

6257

6258

6259

6260

6261

6262

6263

6264

6265 **Figure 4.1** Map of Sacramento and San Joaquin River Delta.

6266

6267 *Background and Context*

6268 The Northern California river system (Figure 4.1) encompasses the Trinity, Sacramento,
6269 Feather, American, and San Joaquin river systems, and the Sacramento-San Joaquin
6270 Delta (see: Experiment 7, CALFED)²⁰. The Sacramento and San Joaquin Rivers join to
6271 form an extensive delta region and eventually flow out into the Pacific Ocean. The
6272 Northern California river and reservoir system serves many vital water uses, including
6273 providing two-thirds of the state's drinking water, irrigating seven million acres of the
6274 world's most productive farmland, and providing habitat to hundreds of species of fish,
6275 birds, and plants. In addition, the system protects Sacramento and other major cities from
6276 flood disasters and contributes significantly to the production of hydroelectric energy.
6277 The Sacramento-San Joaquin Delta provides a unique environment and is California's
6278 most important fishery habitat. Water from the delta is pumped and transported through
6279 canals and aqueducts south and west serving the water needs of many more urban,
6280 agricultural, and industrial users.

6281

6282 An agreement between the U.S. Department of the Interior, U.S. Bureau of Reclamation,
6283 and California Department of Water Resources provides for the coordinated operation of
6284 the federal and state facilities (Agreement of Coordinated Operation-COA). The
6285 agreement aims to ensure that each project obtains its share of water from the San
6286 Joaquin Delta and protects other beneficial uses in the delta and the Sacramento Valley.
6287 Coordination is structured around the necessity to meet in-basin use requirements in the
6288 Sacramento Valley and the San Joaquin Delta, including delta outflow and water quality
6289 requirements.

6290

6291 *Implementation/Application*

²⁰ CA. Gov. Welcome to Calfed Bay-Deltas Program. <http://calwater.ca.gov/index.aspx>

6292 The INFORM Forecast-Decision system consists of a number of diverse elements for
6293 data handling, model runs, and output archiving and presentation. It is a distributed
6294 system with on-line and off-line components. The system routinely captures real-time
6295 National Center for Environmental Predictions (NCEP) ensemble forecasts and uses both
6296 ensemble synoptic forecasts from NCEP's Global Forecast System (GFS) and ensemble
6297 climate forecasts from NCEP's Climate Forecast System (CFS). The former produces
6298 real-time short-term forecasts, and the latter produce longer-term forecasts as needed
6299 (HRC-GWRI, 2006).

6300

6301 The INFORM DSS is designed to support the decision-making process, which includes
6302 multiple decision makers, objectives, and temporal scales. Toward this goal, INFORM
6303 DSS includes a suite of interlinked models that address reservoir planning and
6304 management at multi-decadal, interannual, seasonal, daily, and hourly time scales. The
6305 DSS includes models for each major reservoir in the INFORM region, simulation
6306 components for watersheds, river reaches, and the Bay Delta, and optimization
6307 components suitable for use with ensemble forecasts. The decision software runs off-line,
6308 as forecasts become available, to derive and assess planning and management strategies
6309 for all key system reservoirs. DSS is embedded in a user-friendly, graphical interface that
6310 links models with data and helps visualize and manage results.

6311

6312 Development and implementation of the INFORM Forecast-Decision system was carried
6313 out by the Hydrologic Research Center (in San Diego) and the Georgia Water Resources
6314 Institute (in Atlanta), with funding from NOAA, CALFED, and the California Energy
6315 Commission. Other key participating agencies included U.S. National Weather Service
6316 California-Nevada River Forecast Center, the California Department of Water Resources,
6317 the U.S. Bureau of Reclamation Central Valley Operations, and the Sacramento District
6318 of the U.S. Army Corps of Engineers. Other agencies and regional stakeholders (*e.g.*, the
6319 Sacramento Flood Control Authority, SAFCA, and the California Department of Fish and
6320 Game) participated in project workshops and, indirectly, through comments conveyed to
6321 the INFORM Oversight and Implementation Committee.

6322

6323 *Lessons Learned*

6324 The INFORM approach demonstrates the value of advanced forecast-decision methods
6325 for water resource decision making, attested to by participating agencies who took part in
6326 designing the experiments and who are now proceeding to incorporate the INFORM tools
6327 and products in their decision-making processes.

6328

6329 From a technical standpoint, INFORM served to demonstrate important aspects of
6330 integrated forecast-decision systems, namely that (1) seasonal climate and hydrologic
6331 forecasts benefit reservoir management, provided that they are used in connection with
6332 adaptive dynamic decision methods that can explicitly account for and manage forecast
6333 uncertainty; (2) ignoring forecast uncertainty in reservoir regulation and water
6334 management decisions leads to costly failures; and. (3) static decision rules cannot take
6335 full advantage of and handle forecast uncertainty information. The extent to which
6336 forecasts benefit the management process depends on their reliability, range, and lead
6337 time, in relation to the management systems' ability to regulate flow, water allocation,
6338 and other factors.

6339

6340 ***Experiment 4:***6341 ***How Seattle Public Utility District Uses Climate Information to Manage Reservoirs***6342 *The Experiment*

6343 Seattle Public Utilities (SPU) provides drinking water to 1.4 million people living in the
6344 central Puget Sound region of Washington. SPU also has instream (*i.e.*, river flow),
6345 resource management, flood control management and habitat responsibilities on the
6346 Cedar and South Fork Tolt Rivers, located on the western slopes of the Cascade
6347 Mountains. Over the past several years SPU has taken numerous steps to improve the
6348 incorporation of climate, weather, and hydrologic information into the real-time and SI
6349 management of its mountain water supply system.

6350

6351 *Implementation/Application*

6352 Through cooperative relationships with agencies such as NOAA's National Weather
6353 Service, U.S. Department of Agriculture, Natural Resource Conservation Service, and the

6354 U.S. Geological Survey (USGS), SPU has secured real-time access to numerous Snotel
6355 sites²¹, streamflow gages and weather stations in and around Seattle's watersheds. SPU
6356 continuously monitors weather and climate data across the maritime Pacific derived from
6357 all these above sources. Access to this information has helped to reduce the uncertainty
6358 associated with making real-time and seasonal tactical and strategic operational
6359 decisions, and enhanced the inherent flexibility of management options available to
6360 SPU's water supply managers as they adjust operations for changing weather and
6361 hydrologic conditions, including abnormally low levels of snowpack or precipitation.

6362

6363 Among the important consequences of this synthesis of information has been SPU's
6364 increasing ability to undertake reservoir operations with higher degrees of confidence
6365 than in the past. As an example, SPU was well served by this information infrastructure
6366 during the winter of 2005 when the lowest snowpack on record was realized in its
6367 watersheds. The consequent reduced probability of spring flooding, coupled with their
6368 ongoing understanding of local and regional climate and weather patterns, enabled SPU
6369 water managers to safely capture more water in storage earlier in the season than normal.
6370 As a result of SPU's ability to continuously adapt its operations, Seattle was provided
6371 with enough water to return to normal supply conditions by early summer despite the
6372 record low snowpack.

6373

6374 SPU is also using conclusions from a SPU-sponsored University of Washington study
6375 that examined potential impacts of climate change on SPU's water supply. To increase
6376 the rigor of the study, a set of fixed reservoir operating rules was used and no provisions
6377 were made to adjust these to account for changes projected by the study's climate change
6378 scenarios. From these conclusions, SPU has created two future climate scenarios, one for
6379 2020 and one for 2040, to examine how the potential impacts of climate change may
6380 affect decisions about future supply. While these scenarios indicated a reduction in yield,
6381 SPU's existing sources of supply were found to be sufficient to meet official demand
6382 forecasts through 2053.

6383

²¹ The Snotel network of weather stations is a snowfall depth monitoring network established by the USGS.

6384 *Lessons Learned*

6385 SPU has actually incorporated seasonal climate forecasts into their operations and is
6386 among the leaders in considering climate change. SPU is a ‘receptive audience’ for
6387 climate tools in that it has a wide range of management and long-term capital investment
6388 responsibilities that have clear connections to climate conditions. Further, SPU is
6389 receptive to new management approaches due to public pressure and the risk of legal
6390 challenges related to the protection of fish populations who need to move upstream to
6391 breed.

6392

6393 Specific lessons include: (1) access to skillful seasonal forecasts enhances credibility of
6394 using climate information in the Pacific Northwest, even with relatively long lead times;
6395 (2) monitoring of snowpack moisture storage and mountain precipitation is essential for
6396 effective decision making and for detecting long-term trends that can affect water supply
6397 reliability; and (3) while SPU has worked with the research community and other
6398 agencies, it also has significant capacity to conduct in-house investigations and
6399 assessments. This provides confidence in the use of information.

6400

6401 ***Experiment 5:***6402 ***Using Paleoclimate Information to Examine Climate Change Impacts***6403 *The Experiment*

6404 Can an expanded estimate of the range of natural hydrologic variability from tree-ring
6405 reconstructions of streamflow, a climate change research tool, be used effectively as a
6406 decision-support resource for better understanding SI climate variability and water
6407 resource planning? Incorporation of tree-ring reconstructions of streamflow into decision
6408 making was accomplished through partnerships between researchers and water managers
6409 in the inter-mountain West.

6410

6411 *Background and Context*

6412 Although water supply forecasts in the inter-mountain West have become increasingly
6413 sophisticated in recent years, water management planning and decision making have
6414 generally depended on instrumental gage records of flow, most of which are less than 100

6415 years in length. Drought planning in the inter-mountain West has been based on the
6416 assumption that the 1950s drought, as the most severe drought in the instrumental record,
6417 adequately represents the full range of natural variability and, thus, a likely worst-case
6418 scenario.

6419

6420 The recent prolonged drought in the western United States prompted many water
6421 managers to consider that the observational gage records of the twentieth century do not
6422 contain the full range of natural hydroclimatic variability possible. Gradual shifts in
6423 recent decades to more winter precipitation as rain and less as snow, earlier spring runoff,
6424 higher temperatures, and unprecedented population growth have resulted in an increase in
6425 vulnerability of limited water supplies to a variable and changing climate. The
6426 paleoclimate records of streamflow and hydroclimatic variability provide an extended,
6427 albeit indirect, record (based on more than 1000 years of record from tree rings in some
6428 key watersheds) for assessing the potential impact of a more complete range of natural
6429 variability as well as for providing a baseline for detecting possible regional impacts of
6430 global climate change.

6431

6432 *Implementation/Application*

6433 Several years of collaborations between scientists and water resource partners have
6434 explored possible applications of tree-ring reconstructed flows in water resource
6435 management to assess the potential impacts of drought on water systems. Extended
6436 records of hydroclimatic variability from tree-ring based reconstructions reveal a wider
6437 range of natural variability than in gage records alone, but how to apply this information
6438 in water management planning has not been obvious. The severe western drought that
6439 began in 2000 and peaked in 2002 provided an excellent opportunity to work with water
6440 resource providers and agencies on how to incorporate paleoclimate drought information
6441 in planning and decision making. These partnerships with water resource managers have
6442 led to a range of applications evolving from a basic change in thinking about drought, to
6443 the use of tree-ring reconstructed flows to run a complex water supply model to assess
6444 the impacts of drought on water systems.

6445

6446 The extreme five-year drought that began in 2002 motivated water managers to ask these
6447 questions: How unusual was 2002, or the 2000-2004 drought? How often do years or
6448 droughts like this occur? What is the likelihood of it happening again in the future
6449 (should we plan for it, or is there too low a risk to justify infrastructure investments)?
6450 And, from a long term perspective, is the 20th/21st century record an adequate baseline
6451 for drought planning?

6452

6453 The first three questions could be answered with reconstructed streamflow data for key
6454 gages, but to address planning, a critical step is determining how tree-ring streamflow
6455 reconstruction could be incorporated into water supply modeling efforts. The tree ring
6456 streamflow reconstructions have annual resolution, whereas most water system models
6457 required weekly or daily time steps, and reconstructions are generated for a few gages,
6458 while water supply models typically have multiple input nodes. The challenge has been
6459 spatially and temporally disaggregating the reconstructed flow series into the time steps
6460 and spatial scales needed as input into models. A variety of analogous approaches have
6461 successfully addressed the temporal scale issue, while the spatial challenges have been
6462 addressed statistically using nearest neighbor or other approaches.

6463

6464 Another issue addressed has been that the streamflow reconstructions explain only a
6465 portion of the variance in the gage record, and the most extreme values are often not fully
6466 replicated. Other efforts have focused on characterizing the uncertainty in the
6467 reconstructions, the sources of uncertainty, and the sensitivity of the reconstruction to
6468 modeling choices. In spite of these many challenges, expanded estimates of the range of
6469 natural hydrologic variability from tree-ring reconstructions have been integrated into
6470 water management decision-support and allocation models to evaluate operating policy
6471 alternatives for efficient management and sustainability of water resources, particularly
6472 during droughts in California and Colorado.

6473

6474 *Lessons Learned*

6475 Roadblocks to incorporating tree-ring reconstructions into water management policy and
6476 decision making were overcome through prolonged, sustained partnerships with

6477 researchers working to make their scientific findings relevant, useful, and usable to users
6478 for planning and management, and water managers willing to take risk and invest time to
6479 explore the use of non-traditional information outside of their comfort zone. The
6480 partnerships focused on formulating research questions that led to applications addressing
6481 institutional constraints within a decision process addressing multiple timescales.

6482

6483 Workshops requested by water managers have resulted in expansion of application of the
6484 tree-ring based streamflow reconstructions to drought planning and water management
6485 <<http://wwa.colorado.edu/resources/paleo/>>. In addition, an online resource called
6486 TreeFlow <<http://wwa.colorado.edu/resources/paleo/data.html>> was developed to
6487 provide water managers interested in using tree ring streamflow reconstructions access to
6488 gage and reconstruction data and information, and a tutorial on reconstruction methods
6489 for gages in Colorado and California.

6490

6491 *Experiment 6*

6492 *Climate, Hydrology, and Water Resource Issues in Fire-Prone United States Forests*

6493 *The Experiment*

6494 Improvements in ENSO-based climate forecasting, and research on interactions between
6495 climate and wildland fire occurrence, have generated opportunities for improving use of
6496 seasonal to interannual climate forecasts by fire managers. They can now better anticipate
6497 annual fire risk, including potential damage to watersheds over the course of the year.

6498 The experiment, consisting of annual workshops to evaluate the utility of climate
6499 information for fire management, were initiated in 2000 to inform fire managers about
6500 climate forecasting tools and to enlighten climate forecasters about the needs of the fire
6501 management community. These workshops have evolved into an annual assessment of
6502 conditions and production of pre-season fire-climate forecasts.

6503

6504 *Background and Context*

6505 Large wildfire activity in the U.S. West and Southeast has increased substantially since
6506 the mid-1980s, an increase that has largely been attributed to shifting climate conditions
6507 (Westerling *et al.*, 2006). Recent evidence also suggests that global or regional warming

6508 trends and a positive phase of the AMO are likely to lead to an even greater increase in
6509 risk for ecosystems and communities vulnerable to wildfire in the western United States
6510 (Kitzberger *et al.*, 2007). Aside from the immediate impacts of a wildfire (*e.g.*,
6511 destruction of biomass, substantial altering of ecosystem function), the increased
6512 likelihood of high sediment deposition in streams and flash flood events can present post-
6513 fire management challenges including impacts to soil stability on slopes and mudslides
6514 (*e.g.*, Bisson *et al.*, 2003). While the highly complex nature and substantially different
6515 ecologies of fire-prone systems precludes one-size-fits-all fire management approaches
6516 (Noss *et al.*, 2006), climate information can help managers plan for fire risk in the context
6517 of watershed management and post-fire impacts, including impacts on water resources.
6518 One danger is inundation of water storage and treatment facilities with sediment-rich
6519 water, creating potential for significant expense for pre-treatment of water or for facilities
6520 repair. Post-fire runoff can also raise nitrate concentrations to levels that exceed the
6521 federal drinking water standard (Meixner and Wohlgemuth, 2004).

6522

6523 Work by Kuyumjian (2004), suggests that coordination among fire specialists,
6524 hydrologists, climate specialists, and municipal water managers may produce useful
6525 warnings to downstream water treatment facilities about significant ash- and sediment-
6526 laden flows. For example, in the wake of the 2000 Cerro Grande fire in the vicinity of
6527 Los Alamos, New Mexico, catastrophic floods were feared, due to the fact that 40 percent
6528 of annual precipitation in northern New Mexico is produced by summer monsoon
6529 thunderstorms (*e.g.*, Earles *et al.*, 2004). Concern about water quality and about the
6530 potential for contaminants carried by flood waters from the grounds of Los Alamos
6531 Nuclear Laboratory to enter water supplies prompted a multi-year water quality
6532 monitoring effort (Gallaher and Koch, 2004). In the wake of the 2002 Bullock Fire and
6533 2003 Aspen Fire in the Santa Catalina Mountains adjacent to Tucson, Arizona, heavy
6534 rainfall produced floods that destroyed homes and caused one death in Canada del Oro
6535 Wash in 2003 (Ekwurzel, 2004), destroyed structures in the highly popular Sabino
6536 Canyon recreation area and deposited high sediment loads in Sabino Creek in 2003
6537 (Desilets *et al.*, 2006). A flood in 2006 wrought a major transformation to the upper
6538 reaches of the creek (Kreutz, 2006). Residents of Summerhaven, a small community

6539 located on Mt. Lemmon, continues to be concerned about the impacts of future fires on
6540 their water resources. In all of these situations, climate information can be helpful in
6541 assessing vulnerability to both flooding and water quality issues.

6542

6543 *Implementation/Application*

6544 Little published research specifically targets interactions among climate, fire, and
6545 watershed dynamics (OFCM, 2007b). Publications on fire-climate interactions, however,
6546 provide a useful entry point for examining needs for and uses of climate information in
6547 decision processes involving water resources. A continuing effort to produce fire-climate
6548 outlooks was initiated through a workshop held in Tucson, Arizona, in late winter 2000.
6549 One of the goals of the workshop was to identify the climate information uses and needs
6550 of fire managers, fuel managers, and other decision makers. Another was to actually
6551 produce a fire-climate forecast for the coming fire season. The project was initiated
6552 through collaboration involving researchers at the University of Arizona, the NOAA-
6553 funded Climate Assessment for the Southwest Project (CLIMAS), the Center for
6554 Ecological and Fire Applications (CEFA) at the Desert Research Institute in Reno,
6555 Nevada and the National Interagency Fire Center (NIFC) located in Boise, Idaho
6556 (Morehouse, 2000). Now called the National Seasonal Assessment Workshop (NSAW),
6557 the process continues to produce annual fire-climate outlooks (*e.g.*, Crawford *et al.*,
6558 2006). The seasonal fire-climate forecasts produced by NSAW have been published
6559 through NIFC since 2004. During this same time period, Westerling *et al.* (2002)
6560 developed a long-lead statistical forecast product for areas burned in western wildfires.

6561

6562 *Lessons Learned*

6563 The experimental interactions between climate scientists and fire managers clearly
6564 demonstrated the utility of climate information for managing watershed problems
6565 associated with wildfire. Climate information products used in the most recently
6566 published NSAW Proceedings (Crawford *et al.*, 2006), for example, include the
6567 following: NOAA Climate Prediction Center (CPC) seasonal temperature and
6568 precipitation outlooks, historical temperature and precipitation data, *e.g.*, High Plains
6569 Regional Climate Center, National drought conditions, from National Drought Mitigation

6570 Center, 12-month standardized precipitation index , spring and summer streamflow
6571 forecasts and departure from average greenness.
6572
6573 Based on extensive interactions with fire managers, other products are also used by some
6574 fire ecologists and managers, including climate history data from instrumental and paleo
6575 (especially tree-ring) records and hourly to daily and weekly weather forecasts, (*e.g.*,
6576 temperature, precipitation, wind, relative humidity).
6577
6578 Products identified as potentially improving fire management (*e.g.*, Morehouse, 2000;
6579 Garfin and Morehouse, 2001) include: improved monsoon forecasts and training in how
6580 to use them, annual to decadal (AMO, Pacific Decadal Oscillation) projections, decadal
6581 to centennial climate change model outputs, downscaled to regional/finer scales, and dry
6582 lightning forecasts.
6583
6584 This experiment is one of the most enduring we have studied. It is now part of accepted
6585 practice by agencies, and has produced spin-off activities managed and sustained by the
6586 agencies and new participants. The use of climate forecast information in fire
6587 management began because decision makers within the wildland fire management
6588 community were open to new information, due to legal challenges, public pressure, and a
6589 “landmark” wildfire season in 2000. The National Fire Plan (2000) and its associated 10-
6590 year Comprehensive Strategy reflected a new receptiveness for new ways of coping with
6591 vulnerabilities, calling for a community-based approach to reducing wildland fires that is
6592 proactive and collaborative rather than prior approaches entered on internal agency
6593 activities.
6594
6595 Annual workshops became routine forums for bringing scientists and decision makers
6596 together to continue to explore new questions and opportunities, as well as involve new
6597 participants, new disciplines and specialties, and to make significant progress in
6598 important areas (*e.g.*, lightning climatologies, and contextual assessments of specific
6599 seasons), quickly enough to fulfill the needs of agency personnel (National Fire Plan,
6600 2000).

6601

6602 *Experiment 7:*6603 *The CALFED—Bay Delta Program: Implications of Climate Variability*6604 *The Experiment*

6605 The Sacramento-San Joaquin River Delta, which flows into San Francisco Bay, is the
6606 focus of a broad array of environmental issues relating to endangered fish species, land
6607 use, flood control and water supply. After decades of debate about how to manage the
6608 delta to export water supplies to southern California while managing habitat and water
6609 supplies in the region, and maintaining endangered fish species, decision makers are
6610 involved in making major long-term decisions about rebuilding flood control levees and
6611 rerouting water supply networks through the region. Incorporating the potential for
6612 climate change impacts on sea level rise and other regional changes are important to the
6613 decision-making process (Hayhoe *et al.*, 2004; Knowles *et al.*, 2006; Lund *et al.*, 2007).

6614

6615 *Background and Context*

6616 Climate considerations are critical for the managers of the CALFED program, which
6617 oversees the 700,000 acres in the Sacramento-San Joaquin Delta. 400,000 acres have
6618 been subsiding due to microbial oxidation of peat soils that have been used for
6619 agriculture. A significant number of the islands are below sea level, and protected from
6620 inundation by dikes that are in relatively poor condition. Continuing sea-level rise and
6621 regional climate change are expected to have additional major impacts such as flooding
6622 and changes in seasonal precipitation patterns. There are concerns that multiple islands
6623 would be inundated in a “10-year storm event,” which represents extreme local
6624 vulnerability to flooding.

6625

6626 In the central delta, there are five county governments in addition to multiple federal and
6627 state agencies and non-governmental organizations whose perspectives need to be
6628 integrated into the management process, which is one of the purposes of the CALFED
6629 program. A key decision being faced is whether delta interests should invest in trying to
6630 build up and repair levies to protect subsided soils. What are the implications for other
6631 islands when one island floods? Knowing the likelihood of sea-level rise of various

6632 magnitudes will significantly constrain the answers to these questions. For example, if the
6633 rise is greater than one foot in the next 50 to 100 years, that could end the debate about
6634 whether to use levee improvements to further protect these islands. Smaller amounts of
6635 sea-level rise will make this decision less clear-cut. Answers are needed in order to
6636 support decisions about the delta in the near term.

6637

6638 *Implementation/Application*

6639 Hundreds of millions of dollars of restoration work has been done in the delta and
6640 associated watersheds, and more investment is required. Where should money be
6641 invested for effective long-term impact? There is a need to invest in restoring lands at
6642 intertidal and higher elevations so that wetlands can evolve uphill while tracking rising
6643 sea level (estuarine progression). Protecting only “critical” delta islands (those with major
6644 existing infrastructure) to endure a 100-year flood will cost around \$2.6 billion.

6645

6646 Another way that climate change-related information is critical to delta management is in
6647 estimating volumes and timing of runoff from the Sierra Nevada mountain range
6648 (Knowles *et al.*, 2006). To the extent that snowpack will be diminished and snowmelt
6649 runoff occurs earlier, there are implications for flood control, water supply and
6650 conveyance, and seawater intrusion – all of which affect habitat and land use decisions.

6651 One possible approach to water shortages is more recent aggressive management of
6652 reservoirs to maximize water supply benefits, thereby possibly increasing flood risk. The
6653 State Water Project is now looking at a ten percent failure rate operating guideline at
6654 Oroville rather than a five percent failure rate operating guideline; this would provide
6655 much more water supply flexibility.

6656

6657 *Lessons Learned*

6658 Until recently the implications of climate change and sea-level rise were not considered
6659 in the context of solutions to the Bay Delta problem—particularly in the context of
6660 climate variability. These implications are currently considered to be critical factors in
6661 infrastructure planning, and the time horizon for future planning has been extended to
6662 over 100 years (Delta Vision Blue Ribbon Task Force, 2008). The relatively rapid shift in

6663 perception of the urgency of climate change impacts was not predicted, but does demand
6664 renewed consideration of adaptive management strategies in the context of incremental
6665 changes in understanding (as opposed to gradual increases in accumulation of new facts,
6666 which is the dominant paradigm in adaptive management).

6667

6668 **4.2.2 Organizational and Institutional Dimensions of Decision-Support Experiments**

6669 These seven experiments illuminate the need for effective two-way communication
6670 among tool developers and users, and the importance of organizational culture in
6671 fostering collaboration. An especially important lesson they afford is in underscoring the
6672 significance of boundary-spanning entities to enable decision-support transformation.

6673 Boundary spanning, discussed in section 4.3, refers to the activities of special
6674 scientific/stakeholder committees, agency coordinating bodies, or task forces that
6675 facilitate bringing together tool developers and users to exchange information, promote
6676 communication, propose remedies to problems, foster frequent engagement, and jointly
6677 develop decision-support systems to address user needs. In the process, they provide
6678 incentives for innovation—frequently noted in the literature—that facilitate the use of
6679 climate science information in decisions (*e.g.*, NRC, 2007; Cash and Buizer, 2005;
6680 Sarewitz and Pielke, 2007). Before outlining how these seven experiments illuminate
6681 boundary spanning, it is important to consider problems identified in recent research.

6682

6683 While there is widespread agreement that decision support involves translating the
6684 products of climate science into forms useful for decision makers and disseminating the
6685 translated products, there is disagreement over precisely what constitutes translation
6686 (NRC, 2008). One view is that climate scientists know which products will be useful to

6687 decision makers and that potential users will make appropriate use of decision-relevant
6688 information once it is made available. Adherents of this view typically emphasize the
6689 importance of developing “decision-support tools,” such as models, maps, and other
6690 technical products intended to be relevant to certain classes of decisions that, when
6691 created, complete the task of decision support. This approach, also called a “translation
6692 model,” (NRC, 2008) has not proved useful to many decision makers—underscored by
6693 the fact that, in our seven cases, greater weight was given to “creating conditions that
6694 foster the appropriate use of information” rather than to the information itself (NRC,
6695 2008).

6696

6697 A second view is that decision-support activities should enable climate information
6698 producers and users to jointly develop information that addresses users’ needs—also
6699 called “co-production” of information or reconciling information “supply and demand”
6700 (NRC, 1989, 1996, 1999, 2006; McNie, 2007; Sarewitz and Pielke, 2007; Lemos and
6701 Morehouse, 2005). Our seven cases clearly delineate the presumed advantages of the
6702 second view.

6703

6704 In the SFWMD case, an increase in user trust was a powerful inducement to introduce,
6705 and then continue, experiments leading to development of a Water Supply and
6706 Environment schedule, employing seasonal and multi-seasonal climate outlooks as
6707 guidance for regulatory releases. As this tool began to help reduce operating system
6708 uncertainty, decision-maker confidence in the use of model outputs increased, as did

6709 further cooperation between scientists and users—facilitated by SFWMD’s
6710 communication and agency partnership networks.

6711

6712 In the case of INFORM, participating agencies in California worked in partnership with
6713 scientists to design experiments that would allow the state to integrate forecast methods
6714 into planning for uncertainties in reservoir regulation. Not only did this set of
6715 experiments demonstrate the practical value of such tools, but they built support for
6716 adaptive measures to manage risks, and reinforced the use, by decision makers, of tool
6717 output in their decisions. Similar to the SFWMD case, through demonstrating how
6718 forecast models could reduce operating uncertainties— especially as regards increasing
6719 reliability and lead time for crucial decisions— cooperation among partners seems to
6720 have been strengthened.

6721

6722 Because the New York City and Seattle cases both demonstrate use of decision-support
6723 information in urban settings, they amplify another set of boundary-spanning factors: the
6724 need to incorporate public concerns and develop communication outreach methods,
6725 particularly about risk, that are clear and coherent. While conscientious efforts to support
6726 stakeholder needs for reducing uncertainties associated with sea-level rise and
6727 infrastructure relocation are being made, the New York case highlights the need for
6728 further efforts to refine communication, tool dissemination, and evaluation efforts to
6729 deliver information on potential impacts of climate change more effectively. It also
6730 illustrates the need to incorporate new risk-based analysis into existing decision
6731 structures related to infrastructure construction and maintenance. The Seattle public

6732 utility has had success in conveying the importance of employing SI climate forecasts in
6733 operations, and is considered a national model for doing so, in part because of a higher
6734 degree of established public support due to: (1) litigation over protection of endangered
6735 fish populations and (2) a greater in-house ability to test forecast skill and evaluate
6736 decision tools. Both served as incentives for collaboration. Access to highly-skilled
6737 forecasts in the region also enhanced prospects for forecast use.

6738

6739 Although not an urban case, the CALFED experiment's focus on climate change, sea-
6740 level rise, and infrastructure planning has numerous parallels with the Seattle and New
6741 York City cases. In this instance, the public and decision makers were prominent in these
6742 cases, and their involvement enhanced the visibility and importance of these issues and
6743 probably helped facilitate the incorporation of climate information by water resource
6744 managers in generating adaptation policies.

6745

6746 The other cases represent variations of boundary spanning whose lessons are also worth
6747 noting. The tree-ring reconstruction case documents impediments of a new data source to
6748 incorporation into water planning. These impediments were overcome through prolonged
6749 and sustained partnerships between researchers and users that helped ensure that
6750 scientific findings were relevant, useful, and usable for water resources planning and
6751 management, and water managers who were willing to take some risk. Likewise, the case
6752 of fire-prone forests represented a different set of impediments that also required novel
6753 means of boundary spanning to overcome. In this instance, an initial workshop held
6754 among scientists and decision makers itself constituted an experiment on how to:

6755 identify topics of mutual interest across the climate and wildland fire management
6756 communities at multiple scales; provide a forum for exploring new questions and
6757 opportunities; and constitute a vehicle for inviting diverse agency personnel, disciplinary
6758 representatives, and operation, planning, and management personnel to facilitate new
6759 ways of thinking about an old set of problems. In all cases, the goal is to facilitate
6760 successful outcomes in the use of climate information for decisions, including faster
6761 adaptation to more rapidly changing conditions.

6762

6763 Before turning to analytical studies on the importance of such factors as the role of key
6764 leadership in organizations to empower employees, organizational climate that
6765 encourages risk and promote inclusiveness, and the ways organizations encourage
6766 boundary innovation (Section 4.3), it is important to reemphasize the distinguishing
6767 feature of the above experiments: they underscore the importance of process as well as
6768 product outcomes in developing, disseminating and using information. We return to this
6769 issue when we discuss evaluation in Section 4.4.

6770

6771 **4.3 APPROACHES TO BUILDING USER KNOWLEDGE AND ENHANCING** 6772 **CAPACITY BUILDING**

6773 The previous section demonstrated a variety of contexts where decision-support
6774 innovations are occurring. This section analyzes six factors that are essential for building
6775 user knowledge and enhancing capacity in decision-support systems for integration of SI
6776 climate variability information, and which are highlighted in the seven cases above: (1)
6777 boundary spanning, (2) knowledge-action systems through inclusive organizations, (3)

6778 decision-support needs are user driven, (4) proactive leadership that champions change;
6779 (5) adequate funding and capacity building, and (6) adaptive management.

6780

6781 **4.3.1 Boundary-Spanning Organizations as Intermediaries Between Scientists and**
6782 **Decision Makers**

6783 As noted in Section 4.2.2, boundary spanning organizations link different social and
6784 organizational worlds (*e.g.*, science and policy) in order to foster innovation across
6785 boundaries, provide two-way communication among multiple sectors, and integrate
6786 production of science with user needs. More specifically, these organizations perform
6787 translation and mediation functions between producers of information and their users
6788 (Guston, 2001; Ingram and Bradley, 2006; Jacobs, *et al.*, 2005). Such activities include
6789 convening forums that provide common vehicles for conversations and training, and for
6790 tailoring information to specific applications.

6791

6792 Ingram and Bradley (2006) suggest that boundary organizations span not only disciplines,
6793 but different conceptual and organizational divides (*e.g.*, science and policy),
6794 organizational missions and philosophies, levels of governance, and gaps between
6795 experiential and professional ways of knowing. This is important because effective
6796 knowledge transfer systems cultivate individuals and/or institutions that serve as
6797 intermediaries between nodes in the system, most notably between scientists and decision
6798 makers. In the academic community and within agencies, knowledge, including the
6799 knowledge involved in the production of climate forecast information, is often produced
6800 in “stove-pipes” isolated from neighboring disciplines or applications.

6801

6802 Evidence for the importance of this proposition—and for the importance of boundary
6803 spanning generally—is provided by those cases, particularly in Chapter 3 (*e.g.*, the
6804 Apalachicola-Chattahoochee-Flint River basin dispute), where the absence of a boundary
6805 spanning entity created a void that made the deliberative consideration of various
6806 decision-maker needs all but impossible to negotiate. Because the compact organization
6807 charged with managing water allocation among the states of Alabama, Florida, and
6808 Georgia would not actually take effect until an allocation formula was agreed upon, the
6809 compact could not serve to bridge the divides between decision making and scientific
6810 assessment of flow, meteorology, and riverine hydrology in the region.

6811

6812 Boundary spanning organizations are important to decision-support system development
6813 in three ways. First, they “mediate” communication between supply and demand
6814 functions for particular areas of societal concern. Sarewitz and Pielke (2007) suggest, for
6815 example, that the IPCC serves as a boundary organization for connecting the science of
6816 climate change to its use in society— in effect, satisfying a “demand” for science
6817 implicitly contained in such international processes for negotiating and implementing
6818 climate treaties as the U.N. Framework Convention on Climate Change and Kyoto
6819 Protocol. In the United States, local irrigation district managers and county extension
6820 agents often serve this role in mediating between scientists (hydrological modelers) and
6821 farmers (Cash *et al.*, 2003). In the various cases we explored in section 4.2.1, and in
6822 Chapter 3 (*e.g.*, coordinating committees, post-event “technical sessions” after the Red

6823 River floods, and comparable entities), we saw other boundary spanning entities
6824 performing mediation functions.
6825
6826 Second, boundary organizations enhance communication among stakeholders. Effective
6827 tool development requires that affected stakeholders be included in dialogue, and that
6828 data from local resource managers (blended knowledge) be used to ensure credible
6829 communication. Successful innovation is characterized by two-way communication
6830 between producers and users of knowledge, as well as development of networks that
6831 allow close and ongoing communication among multiple sectors. Likewise, networks
6832 must allow close communication among multiple sectors (Sarewitz and Pielke, 2007).
6833
6834 Third, boundary organizations contribute to tool development by serving the function of
6835 translation more effectively than is conceived in the loading-dock model of climate
6836 products. In relations between experts and decision makers, understanding is often
6837 hindered by jargon, language, experiences, and presumptions; *e.g.*, decision makers often
6838 want deterministic answers about future climate conditions, while scientists can often
6839 only provide probabilistic information, at best. As noted in Chapter 3, decision makers
6840 often mistake probabilistic uncertainty as a kind of failure in the utility and scientific
6841 merit of forecasts, even though uncertainty is a characteristic of science (Brown, 1997).
6842
6843 One place where boundary spanning can be important with respect to translation is in
6844 providing a greater understanding of uncertainty and its source. This includes better
6845 information exchange between scientists and decision makers on, for example, the

6846 decisional relevance of different aspects of uncertainties, and methods of combining
6847 probabilistic estimates of events through simulations, in order to reduce decision-maker
6848 distrust, misinterpretation of forecasts, and mistaken interpretation of models (NRC,
6849 2005).

6850

6851 Effective boundary organizations facilitate the co-production of knowledge—generating
6852 information or technology through the collaboration of scientists/engineers and
6853 nonscientists who incorporate values and criteria from both communities. This is seen,
6854 for example, in the collaboration of scientists and users in producing models, maps, and
6855 forecast products. Boundary organizations have been observed to work best when
6856 accountable to the individuals or interests on both sides of the boundary they bridge, in
6857 order to avoid capture by either side and to align incentives such that interests of actors
6858 on both sides of the boundary are met.

6859

6860 Jacobs (2003) suggests that universities can be good locations for the development of
6861 new ideas and applications, but they may not be ideal for sustained stakeholder
6862 interactions and services, in part because of funding issues and because training cycles
6863 for graduate students, who are key resources at universities, do not always allow a long-
6864 term commitment of staff. Many user groups and stakeholders either have no contact with
6865 universities or may not encourage researchers to participate in or observe decision-
6866 making processes. University reward systems rarely recognize interdisciplinary work,
6867 outreach efforts, and publications outside of academic journals. This limits incentives for

6868 academics to participate in real-world problem solving and collaborative efforts. Despite
6869 these limitations, many successful boundary organizations are located within universities.
6870
6871 In short, boundary organizations serve to make information from science useful and to
6872 keep information flowing (in both directions) between producers and users of the
6873 information. They foster mutual respect and trust between users and producers. Within
6874 such organizations there is a need for individuals simultaneously capable of translating
6875 scientific results for practical use and framing the research questions from the perspective
6876 of the user of the information. These key intermediaries in boundary organizations need
6877 to be capable of integrating disciplines and defining the research question beyond the
6878 focus of the participating individual disciplines. Table 4.1 depicts a number of boundary
6879 organization examples for climate change decision-support tool development. Section
6880 4.3.2 considers the type of organizational leaders who facilitate boundary spanning.

6881

6882 **Table 4.1 Examples of Boundary Organizations for Decision-support Tool Development.**

6883

Cooperative Extension Services: housed in land-grant universities in the United States, they provide large networks of people who interact with local stakeholders and decision makers within certain sectors (not limited to agriculture) on a regular basis. In other countries, this agricultural extension work is often done with great effectiveness by local government (*e.g.*, Department of Primary Industries, Queensland, Australia).

Watershed Councils: in some U.S. states, watershed councils and other local planning groups have developed, and many are focused on resolving environmental conflicts and improved land and water management (particularly successful in the State of Oregon).

Natural Resource Conservation Districts: within the U.S. Department of Agriculture, these districts are highly networked within agriculture, land management, and rural communities.

Non-governmental organizations (NGOs) and public interest groups: focus on information dissemination and environmental management issues within particular communities. They are good contacts for identifying potential stakeholders, and may be in a position to collaborate on particular projects. Internationally, a number of NGOs have stepped forward and are actively engaged in working with stakeholders to advance use of climate information in decision making (*e.g.*, Asian Disaster Preparedness Center (ADPC), in Bangkok, Thailand).

Federal agency and university research activities: expanding the types of research conducted within management institutions and local and state governments is an option to be considered—the stakeholders can then have greater influence on ensuring that the research is relevant to their particular concerns

6884

6885 An oft-cited model of the type of boundary-spanning organization needed for the transfer
6886 and translation of decision-support information on climate variability is the Regional
6887 Integrated Science and Assessment (RISA) teams supported by NOAA. These teams
6888 “represent a new collaborative paradigm in which decision makers are actively involved
6889 in developing research agendas” (Jacobs, 2003). The eight RISA teams, located within
6890 universities and often involving partnerships with NOAA laboratories throughout the
6891 United States, are focused on stakeholder-driven research agendas and long-term
6892 relationships between scientists and decision makers in specific regions. RISA activities
6893 are highlighted in the sidebar below. This is followed by another sidebar on comparative
6894 examples of boundary spanning which emphasizes the “systemic” nature of boundary
6895 spanning— that boundary organizations produce reciprocity of benefits to various
6896 groups.

6897

6898 One final observation can be made at this juncture concerning boundary spanning and the
6899 dissemination of climate information and knowledge. Some suggest a three-pronged
6900 process of outreach consisting of “missionary work,” “co-discovery,” and “persistence.”
6901 Missionary work is directed toward potential users of climate information who do not
6902 fully understand the potential of climate variation and change and the potential of climate
6903 information applications. Such non-users may reject science not because they believe it to
6904 be invalid, but because they do not envision the strategic threat to their water use, or
6905 water rights, through non-application of climate information. Co-discovery, by contrast,

6906 is the process of co-production of knowledge aimed at answering questions of concern to
6907 both managers and scientists, as we have discussed. Overcoming resistance to using
6908 information, in the first case, and ensuring co-production in the second instance— both
6909 depend on persistence: the notion that effective introduction of climate applications may
6910 require long-term efforts to establish useful relationships, particularly where there is
6911 disbelief in the science of climate change or where there is significant asymmetry of
6912 access to information and other resources (*i.e.*, Chambers, 1997; Weiner, 2004).

6913

6914 **4.3.2 Regional Integrated Science and Assessment Teams (RISAs) – An Opportunity** 6915 **for Boundary Spanning, and a Challenge**

6916 A true dialogue between end users of scientific information and those who generate data
6917 and tools is rarely achieved. The eight Regional Integrated Science and Assessment
6918 (RISA) teams that are sponsored by NOAA and activities sponsored by the
6919 Environmental Protection Agency’s Global Change Research Program are among the
6920 leaders of this experimental endeavor, and represent a new collaborative paradigm in
6921 which decision makers are actively involved in developing research agendas. RISAs
6922 explicitly seek to work at the boundary of science and decision making.

6923

6924 There are five principal approaches RISA teams have learned that facilitate engagement
6925 with stakeholders and design of climate-related decision-support tools for water
6926 managers. First, RISAs employ a “stakeholder-driven research” approach that focuses on
6927 performing research on both the supply side (*i.e.*, information development) and demand
6928 side (*i.e.*, the user and her/his needs). Such reconciliation efforts require robust

6929 communication in which each side informs the other with regard to decisions, needs, and
6930 products— this communication cannot be intermittent; it must be robust and ongoing.

6931

6932 Second, some RISAs employ an “information broker” approach. They produce little new
6933 scientific information themselves, due to resource limitations or lack of critical mass in a
6934 particular scientific discipline. Rather, the RISAs’ primary role is providing a conduit for
6935 information and facilitating the development of information networks.

6936

6937 Third, RISAs generally utilize a “participant/advocacy” or “problem-based” approach,
6938 which involves focusing on a particular problem or issue and engaging directly in solving
6939 that problem. They see themselves as part of a learning system and promote the
6940 opportunity for joint learning with a well-defined set of stakeholders who share the
6941 RISA’s perspective on the problem and desired outcomes.

6942

6943 Fourth, some RISAs utilize a “basic research” approach in which the researchers
6944 recognize particular gaps in the fundamental knowledge needed in the production of
6945 context sensitive, policy-relevant information. Any RISA may utilize many or most of
6946 these approaches at different times depending upon the particular context of the problem.
6947 The more well-established RISAs have more formal processes and procedures in place to
6948 identify stakeholder needs and design appropriate responses, as well as to evaluate the
6949 effectiveness of decision-support tools that are developed.

6950

6951 Finally, a critical lesson for climate science policy from RISAs is that, despite knowing
6952 what is needed to produce, package, and disseminate useful climate information—and the
6953 well-recognized success of the regional partnerships with stakeholders, RISAs continue
6954 to struggle for funding while RISA-generated lessons are widely acclaimed. To a large
6955 extent, they have not influenced federal climate science policy community outside of the
6956 RISAs themselves, though progress has been made in recent years. Improving feedback
6957 between RISA programs and the larger research enterprise need to be enhanced so
6958 lessons learned can inform broader climate science policy decisions—not just those
6959 decisions made on the local problem-solving level (McNie *et al.*, 2007).

6960

6961 In April, 2002, the House Science Committee held a hearing to explore the connections
6962 of climate science and the needs of decision makers. One question it posed was the
6963 following: “Are our climate research efforts focused on the right questions?”
6964 (<http://www.house.gov/science/hearings/full02/apr17/full_charter_041702.htm>).

6965 The Science Committee found that the RISA program is a promising means to connect
6966 decision-making needs with the research prioritization process, because “(it) attempts to
6967 build a regional-scale picture of the interaction between climate change and the local
6968 environment from the ground up. By funding research on climate and environmental
6969 science focused on a particular region, [the RISA] program currently supports
6970 interdisciplinary research on climate-sensitive issues in five selected regions around the
6971 country. Each region has its own distinct set of vulnerabilities to climate change, *e.g.*,
6972 water supply, fisheries, agriculture, *etc.*, and RISA's research is focused on questions
6973 specific to each region.”

In Australia, forecast information is actively sought both by large agribusiness and government policymakers planning for drought because “the logistics of handling and trading Australia’s grain commodities, such as wheat, are confounded by huge swings in production associated with climate variability. Advance information on likely production and its geographical distribution is sought by many industries, particularly in the recently deregulated marketing environment” (Hammer, *et al.*, 2001). Forecast producers have adopted a systems approach to the dissemination of seasonal forecast information that includes close interaction with farmers, use of climate scenarios to discuss the incoming rainfall season and automated dissemination of seasonal forecast information through the RAINMAN interactive software.

In the U.S. Southwest, forecast producers organized stakeholder workshops that refined their understanding of potential users and their needs. Because continuous interaction with stakeholder was well funded and encouraged, producers were able to ‘customize’ their product—including the design of user friendly and interactive Internet access to climate information—to local stakeholders with significant success (Hartmann, *et al.*, 2002; Pagano, *et al.*, 2002; Lemos and Morehouse, 2005). Such success stories seem to depend largely on the context in which seasonal climate forecasts were deployed—in well-funded policy systems, with adequate resources to customize and use forecasts, benefits can accrue to the local society as a whole. From these limited cases, it is suggested that where income, status, and access to information are more equitably distributed in a society, the introduction of seasonal forecasts may create winners; in contrast, when pre-existing conditions are unequal, the application of seasonal climate forecasts may create more losers by exacerbating those inequities (Lemos and Dilling, 2007). The consequences can be costly both to users and seasonal forecast credibility.

7000 4.3.3 Developing Knowledge-Action Systems—a Climate for Inclusive Management

7001

7002

7003

7004

7005

7006

7007

7008

7009

7010

Research suggests that decision makers do not always find SI forecast products, and related climate information, to be useful for the management of water resources—this is a theme central to this entire Product (*e.g.*, Weiner, 2004). As our case study experiments suggest, in order to ensure that information is useful, decision makers must be able to affect the substance of climate information production and the method of delivery so that information producers know what are the key questions to respond to in the broad and varied array of decisional needs different constituencies require (Sarewitz and Pielke, 2007; Callahan *et al.*, 1999; NRC, 1999). This is likely the most effective process by which true decision-support activities can be made useful.

7011 Efforts to identify factors that improve the usability of SI climate information have found
7012 that effective “knowledge-action” systems focus on promoting broad, user-driven risk
7013 management objectives (Cash and Buizer, 2005). These objectives, in turn, are shaped by
7014 the decision context, which usually contains multiple stresses and management goals.
7015 Research on water resource decision making suggests that goals are defined very
7016 differently by agencies or organizations dedicated to managing single-issue problems in
7017 particular sectors (*e.g.*, irrigation, public supply) when compared to decision makers
7018 working in political jurisdictions or watershed-based entities designed to
7019 comprehensively manage and coordinate several management objectives simultaneously
7020 (*e.g.*, flood control and irrigation, power generation, and in-stream flow). The latter
7021 entities face the unusual challenge of trying to harmonize competing objectives, are
7022 commonly accountable to numerous users, and require “regionally and locally tailored
7023 solutions” to problems (Water in the West, 1998; Kenney and Lord, 1994; Grigg, 1996).
7024
7025 Effective knowledge-action systems should be designed for learning rather than knowing;
7026 the difference being that the former emphasizes the process of exchange between
7027 decision makers and scientists, constantly evolving in an iterative fashion, rather than
7028 aiming for a one-time-only completed product and structural permanence. Learning
7029 requires that knowledge-action systems have sufficient flexibility of processes and
7030 institutions to effectively produce and apply climate information (Cash and Buizer,
7031 2005), encourage diffusion of boundary-spanning innovation, be self-innovative and
7032 responsive, and develop “operating criteria that measure responsiveness to changing
7033 conditions and external advisory processes” (Cash and Buizer, 2005). Often,

7034 nontraditional institutions that operate outside of “normal” channels, such as
7035 nongovernmental organizations (NGOs) or regional coordinating entities, are less
7036 constrained by tradition or legal mandate and thus more able to innovate.
7037
7038 To encourage climate forecast and information producers and end-users to better
7039 communicate with one another, they need to be engaged in a long-term dialogue about
7040 each others’ needs and capabilities. To achieve this, knowledge producers must be
7041 committed to establishing opportunities for joint learning. When such communication
7042 systems have been established, the result has been the gaining of knowledge by users.
7043 The discovery that climate information must be part of a larger suite of information can
7044 help producers understand the decision context, and better appreciate that users manage a
7045 broad array of risks. Lead innovators within the user community can lay the groundwork
7046 for broader participation of other users and greater connection between producers and
7047 users (Cash and Buizer, 2005).
7048
7049 Such tailoring or conversion of information requires organizational settings that foster
7050 communication and exchange of ideas between users and scientists. For example, a
7051 particular user might require a specific type of precipitation forecast or even a different
7052 type of hydrologic model to generate a credible forecast of water supply volume. This
7053 producer-user dialogue must be long term, it must allow users to independently verify the
7054 utility of forecast information, and finally, must provide opportunities for verification
7055 results to “feed back” into new product development (Cash and Buizer, 2005; Jacobs *et*
7056 *al.*, 2005).

7057

7058 Studies of this connection refer to it as an “end-to-end” system to suggest that knowledge
7059 systems need to engage a range of participants including those who generate scientific
7060 tools and data, those who translate them into predictions for use by decision makers, and
7061 the decision makers themselves. A forecast innovation might combine climate factor
7062 observations, analyses of climate dynamics, and SI forecasts. In turn, users might be
7063 concerned with varying problems and issues such as planting times, instream flows to
7064 support endangered species, and reservoir operations.

7065

7066 As Cash and Buizer note, “Often entire systems have failed because of a missing link
7067 between the climate forecast and these ultimate user actions. Avoiding the missing link
7068 problem varies according to the particular needs of specific users (Cash and Buizer,
7069 2005). Users want useable information more than they want answers—they want an
7070 understanding of things that will help them explain, for example, the role of climate in
7071 determining underlying variation in the resources they manage. This includes a broad
7072 range of information needed for risk management, not just forecasting particular threats.

7073

7074 Organizational measures to hasten, encourage, and sustain these knowledge-action
7075 systems must include practices that empower people to use information through
7076 providing adequate training and outreach, as well as sufficient professional reward and
7077 development opportunities. Three measures are essential. First, organizations must
7078 provide incentives to produce boundary objects, such as decisions or products that reflect
7079 the input of different perspectives. Second, they must involve participation from actors

7080 across boundaries. And finally, they must have lines of accountability to the various
7081 organizations spanned (Guston, 2001).
7082
7083 Introspective evaluations of the organizations' ability to learn and adapt to the
7084 institutional and knowledge-based changes around them should be combined with
7085 mechanisms for feedback and advice from clients, users, and community leaders.
7086 However, it is important that a review process not become an end in itself or be so
7087 burdensome as to affect the ability of the organization to function efficiently. This
7088 orientation is characterized by a mutual recognition on the part of scientists and decision
7089 makers of the importance of social learning—that is, learning by doing or by experiment,
7090 and refinement of forecast products in light of real-world experiences and previous
7091 mistakes or errors—both in forecasts and in their application. This learning environment
7092 also fosters an emphasis on adaptation and diffusion of innovation (*i.e.*, social learning,
7093 learning from past mistakes, long-term funding).

7094

7095 **4.3.4 The Value of User-Driven Decision Support**

7096 Studies of what makes climate forecasts useful have identified a number of common
7097 characteristics in the process by which forecasts are generated, developed, and taught
7098 to—and disseminated among—users (Cash and Buizer, 2005). These characteristics
7099 (some previously described) include:

- 7100 • Ensuring that the problems forecasters address are driven by forecast users;
- 7101 • Making certain that knowledge-action systems (the process of interaction between
7102 scientists and users that produces forecasts) are end-to-end inclusive;

- 7103 • Employing “boundary organizations” (groups or other entities that bridge the
7104 communication void between experts and users) to perform translation and
7105 mediation functions between the producers and consumers of forecasts;
- 7106 • Fostering a social learning environment between producers and users (*i.e.*,
7107 emphasizing adaptation); and
- 7108 • Providing stable funding and other support to keep networks of users and
7109 scientists working together.

7110

7111 As noted earlier, “users” encompass a broad array of individuals and organizations,
7112 including farmers, water managers, and government agencies; while “producers” include
7113 scientists and engineers and those “with relevant expertise derived from practice” (Cash
7114 and Buizer, 2005). Complicating matters is that some “users” may, over time, become
7115 “producers” as they translate, repackage, or analyze climate information for use by
7116 others.

7117

7118 In effective user-driven information environments, the agendas of analysts, forecasters,
7119 and scientists who generate forecast information are at least partly set by the users of the
7120 information. Moreover, the collaborative process is grounded in appreciation for user
7121 perspectives regarding the decision context in which they work, the multiple stresses
7122 under which they labor, and their goals so users can integrate climate knowledge into risk
7123 management. Most important, this user-driven outlook is reinforced by a systematic
7124 effort to link the generation of forecast information with needs of users through soliciting
7125 advice and input from the latter at every step in the generation of information process.

7126

7127 Effective knowledge-action systems do not allow particular research or technology
7128 capabilities (*e.g.*, ENSO forecasting) to drive the dialogue. Instead, effective systems
7129 ground the collaborative process of problem definition in user perspectives regarding the
7130 decision context, the multiple stresses bearing on user decisions, and ultimate goals that
7131 the knowledge-action system seeks to advance. For climate change information, this
7132 means shifting the focus toward “the promotion of broad, user-driven risk-management
7133 objectives, rather than advancing the uptake of particular forecasting technologies” (Cash
7134 and Buizer, 2005; Sarewitz and Pielke, 2007).

7135

7136 In sum, there is an emerging consensus that the utility of information intended to make
7137 possible sustainable environmental decisions depends on the “dynamics of the decision
7138 context and its broader social setting” (Jasanoff and Wynne, 1998; Pielke *et al.*, 2000;
7139 Sarewitz and Pielke, 2007). Usefulness is not inherent in the knowledge generated by
7140 forecasters—the information generated must be “socially robust.” Robustness is
7141 determined by how well it meets three criteria: (1) is it valid outside, as well as inside the
7142 laboratory; (2) is validity achieved through involving an extended group of experts,
7143 including lay “experts;” and 3) is the information (*e.g.*, forecast models) derived from a
7144 process in which society has participated as this ensures that the information is less likely
7145 to be contested (Gibbons, 1999).

7146

7147 Finally, a user-driven information system relies heavily on two-way communication.

7148 Such communication can help bridge gaps between what is produced and what is likely to

7149 be used, thus ensuring that scientists produce products that are recognized by the users,
7150 and not just the producers, as useful. Effective user-oriented two-way communication can
7151 increase users' understanding of how they could use climate information and enable them
7152 to ask questions about information that is uncertain or in dispute. It also affords an
7153 opportunity to produce "decision-relevant" information that might otherwise not be
7154 produced because scientists may not have understood completely what kinds of
7155 information would be most useful to water resource decision makers (NRC, 2008).

7156

7157 In conclusion, user-driven information in regard to SI climate variability for water
7158 resources decision making must be salient (*e.g.*, decision-relevant and timely), credible
7159 (viewed as accurate, valid, and of high quality), and legitimate (uninfluenced by
7160 pressures or other sources of bias) (see NRC, 2008; NRC, 2005). In the words of a recent
7161 National Research Council report, broad involvement of "interested and affected parties"
7162 in framing scientific questions helps ensure that the science produced is useful ("getting
7163 the right science") by ensuring that decision-support tools are explicit about any
7164 simplifying assumptions that may be in dispute among the users, and accessible to the
7165 end-user (NRC, 2008).

7166

7167 **4.3.5 Proactive Leadership—Championing Change**

7168 Organizations—public, private, scientific, and political—have leaders: individuals
7169 charged with authority, and span of control, over important personnel, budgetary, and
7170 strategic planning decisions, among other venues. Boundary organizations require a kind
7171 of leadership called inclusive management practice by its principal theorists (Feldman

7172 and Khademian, 2004). Inclusive management is defined as management that seeks to
7173 incorporate the knowledge, skills, resources, and perspectives of several actors and seeks
7174 to avoid creating “winners and losers” among stakeholders.

7175

7176 While there is an enormous literature on organizational leadership, synthetic studies—
7177 those that take various theories and models about leaders and try to draw practical, even
7178 anecdotal, lessons for organizations—appear to coalesce around the idea that inclusive
7179 leaders have context-specific skills that emerge through a combination of tested
7180 experience within a variety of organizations, and a knack for judgment (Bennis, 2003;
7181 Feldman and Khademan, 2004; Tichy and Bennis, 2007). These skills evolve through
7182 trial and error and social learning. Effective “change-agent” leaders have a guiding vision
7183 that sustains them through difficult times, a passion for their work and an inherent belief
7184 in its importance, and a basic integrity toward the way in which they interact with people
7185 and approach their jobs (Bennis, 2003).

7186

7187 While it is difficult to discuss leadership without focusing on individual leaders (and
7188 difficult to disagree with claims about virtuous leadership), inclusive management also
7189 embraces the notion of “process accountability:” that leadership is embodied in the
7190 methods by which organizations make decisions, and not in charismatic personality
7191 alone. Process accountability comes not from some external elected political principle or
7192 body that is hierarchically superior, but instead infuses through processes of deliberation
7193 and transparency. All of these elements make boundary organizations capable of being

7194 solution focused and integrative and, thus, able to span the domains of climate knowledge
7195 production and climate knowledge for water management use.

7196

7197 Adaptive and inclusive management practices are essential to fulfilling these objectives.

7198 These practices must empower people to use information through providing adequate

7199 training and outreach, as well as sufficient professional reward and development

7200 opportunities; and they must overcome capacity-building problems within organizations

7201 to ensure that these objectives are met, including adequate user support. The cases

7202 discussed below—on the California Department of Water Resources’ role in adopting

7203 climate variability and change into regional water management, and the efforts of the

7204 Southeast consortium and its satellite efforts—are examples of inclusive leadership which

7205 illustrate how scientists as well agency managers can be proactive leaders. In the former

7206 case, decision makers consciously decided to develop relationships with other western

7207 states’ water agencies and partnership (through a Memorandum of Understanding

7208 [MOU]) with NOAA. In the latter, scientists ventured into collaborative efforts—across

7209 universities, agencies, and states—because they shared a commitment to exchanging

7210 information in order to build institutional capacity among the users of the information

7211 themselves.

7212

7213 ***Case Study A:***

7214 ***Leadership in the California Department of Water Resources***

7215 The deep drought in the Colorado River Basin that began with the onset of a La Niña

7216 episode in 1998 has awakened regional water resources managers to the need to

7217 incorporate climate variability and change into their plans and reservoir forecast models.

7218 Paleohydrologic estimates of streamflow, which document extended periods of low flow

7219 and demonstrate greater streamflow variability than the information found in the gage
7220 record, have been particularly persuasive examples of the non-stationary behavior of the
7221 hydroclimate system (Woodhouse *et al.*, 2006; Meko *et al.*, 2007). Following a 2005
7222 scientist-stakeholder workshop on the use of paleohydrologic data in water resource
7223 management
7224 <http://www.climas.arizona.edu/calendar/details.asp?event_id=21>, NOAA RISA and
7225 California Department of Water Resources (CDWR) scientists developed strong
7226 relationships oriented toward improving the usefulness and usability of science in water
7227 management. Since the 2005 workshop, CDWR, whose mission in recent years includes
7228 preparation for potential impacts of climate change on California's water resources, has
7229 led western states' efforts in partnering with climate scientists to co-produce
7230 hydroclimatic science to inform decision making. CDWR led the charge to clarify
7231 scientific understanding of Colorado River Basin climatology and hydrology, past
7232 variations, projections for the future, and impacts on water resources, by calling upon the
7233 National Academy of Sciences to convene a panel to study the aforementioned issues
7234 (NRC, 2007). This occurred, and in 2007, CDWR developed a Memorandum of
7235 Agreement with NOAA, in order to better facilitate cooperation with scientists in
7236 NOAA's RISA program and research laboratories (CDWRa, 2007).

7237

7238 ***Case Study B:***

7239 ***Cooperative extension services, watershed stewardship: the Southeast Consortium***

7240 Developing the capacity to use climate information in resource management decision
7241 making requires both outreach and education, frequently in an iterative fashion that leads
7242 to two-way communication and builds partnerships. The Cooperative Extension Program
7243 has long been a leader in facilitating the integration of scientific information into decision
7244 maker of practice in the agricultural sector. Cash (2001) documents an example of
7245 successful Cooperative Extension leadership in providing useful water resources
7246 information to decision makers confronting policy changes in response to depletion of
7247 groundwater in the High Plains aquifer. Cash notes the Cooperative Extension's history of
7248 facilitating dialogue between scientists and farmers, encouraging the development of
7249 university and agency research agendas that reflect farmers' needs, translating scientific

7250 findings into site-specific guidance, and managing demonstration projects that integrate
7251 farmers into researchers' field experiments.

7252

7253 In the High Plains aquifer example, the Cooperative Extension's boundary-spanning work
7254 was motivated from a bottom-up need of stakeholders for credible information on
7255 whether water management policy changes would affect their operations. By acting as a
7256 liaison between the agriculture and water management decision making communities,
7257 and building bridges between many levels of decision makers, Kansas Cooperative
7258 Extension was able to effectively coordinate information flows between university and
7259 USGS modelers, and decision makers. The result of their effort was collaborative
7260 development of a model with characteristics needed by agriculturalists (at a sufficient
7261 spatial resolution) and that provided credible scientific information to all parties. Kansas
7262 Cooperative Extension effectiveness in addressing groundwater depletion and its impact
7263 on farmers sharply contrasted with the Cooperative Extension efforts in other states
7264 where no effort was made to establish multi-level linkages between water management
7265 and agricultural stakeholders.

7266

7267 The Southeast Climate Consortium RISA (SECC), a confederation of researchers at six
7268 universities in Alabama, Georgia, and Florida, has used more of a top-down approach to
7269 developing stakeholder capacity to use climate information in the Southeast's \$33 billion
7270 agricultural sector (Jagtap *et al.*, 2002). Early in its existence, SECC researchers
7271 recognized the potential to use knowledge of the impact of the El Niño-Southern
7272 Oscillation on local climate to provide guidance to farmers, ranchers, and forestry sector
7273 stakeholders on yields and changes to risk (*e.g.*, frost occurrence). Through a series of
7274 needs and vulnerability assessments (Hildebrand *et al.*, 1999, Jagtap *et al.*, 2002), SECC
7275 researchers determined that the potential for producers to benefit from seasonal forecasts
7276 depends on factors that include the flexibility and willingness to adapt farming operations
7277 to the forecast, and the effectiveness of the communication process—and not merely
7278 documenting the effects of climate variability and providing better forecasts (Jones *et al.*,
7279 2000). Moreover, Fraisse *et al.* (2006) explain that climate information is only valuable
7280 when both the potential response and benefits of using the information are clearly

7281 defined. SECC's success in championing integration of new information is built upon a
7282 foundation of sustained interactions with agricultural producers in collaboration with
7283 extension agents. Extension specialists and faculty are integrated as members of the
7284 SECC research team. SECC engages agricultural stakeholders through planned
7285 communication and outreach, such as monthly video conferences, one-on-one meetings
7286 with extension agents and producers, training workshops designed for extension agents
7287 and resource managers to gain confidence in climate decision tool use and to identify
7288 opportunities for their application, and by attending traditional extension activities (*e.g.*,
7289 commodity meetings, field days) (Fraisie *et al.*, 2005). SECC is able to leverage the trust
7290 engendered by Cooperative Extension's long service to the agricultural community and
7291 Extension's access to local knowledge and experience, in order to build support for its
7292 AgClimate online decision-support tool <<http://www.agclimate.org>> (Fraisie *et al.*,
7293 2006). This direct engagement with stakeholders provides feedback to improve the design
7294 of the tool and to enhance climate forecast communication (Breuer *et al.*, 2007).

7295

7296 Yet another Cooperative Extension approach to integrating scientific information into
7297 decision making is the Extension's Master Watershed Steward (MWS) programs. MWS
7298 was first developed at Oregon State University
7299 <<http://seagrant.oregonstate.edu/wsep/index.html>>. In exchange for 40 hours of training
7300 on aspects of watersheds that range from ecology to water management, interested citizen
7301 volunteers provide service to their local community through projects, such as drought and
7302 water quality monitoring, developing property management plans, and conducting
7303 riparian habitat restoration. Arizona's MWS program includes training in climate and
7304 weather (Garfin and Emanuel, 2006); stewards are encouraged to participate in drought
7305 impact monitoring through Arizona's Local Drought Impact Groups (GDTF, 2004;
7306 Garfin, 2006). MWS enhances the capacity for communities to deploy new climate
7307 information and to build expertise for assimilating scientific information into a range of
7308 watershed management decisions.

7309

7310 **4.3.6 Funding and Long-Term Capacity Investments Must Be Stable and**
7311 **Predictable**

7312 Provision of a stable funding base, as well as other investments, can help to ensure
7313 effective knowledge-action systems for climate change. Stable funding promotes long-
7314 term stability and trust among stakeholders because it allows researchers to focus on user
7315 needs over a period of time, rather than having to train new participants in the process.
7316 Given that these knowledge-action systems produce benefits for entire societies, as well
7317 as for particular stakeholders in a society, it is not uncommon for these systems to be
7318 thought of as producing both public and private goods, and thus, needing both public and
7319 private sources of support (Cash and Buizer, 2005). Private funders could include, for
7320 example, farmers whose risks are reduced by the provision of climate information (as is
7321 done in Queensland, Australia, where the individual benefits of more profitable
7322 production are captured by farmers who partly support drought-warning systems). In less
7323 developed societies, by contrast, it would not be surprising for these systems to be
7324 virtually entirely supported by public sources of revenue (Cash and Buizer, 2005).

7325

7326 Experience suggests that a public-private funding balance should be shaped on the basis
7327 of user needs and capacities to self-tailor knowledge-action systems. More generic
7328 systems that could afterwards be tailored to users' needs might be most suitable for
7329 public support, while co-funding with particular users can then be pursued for developing
7330 a collaborative system that more effectively meets users' needs. Funding continuity is
7331 essential to foster long-term relationship building between users and producers. The key
7332 point here is that—regardless of who pays for these systems, continued funding of the

7333 social and economic investigations of the use of scientific information is essential to
7334 ensure that these systems are used and are useful (Jacobs *et al.*, 2005).
7335
7336 Other long-term capacity investments relate to user training—an important component
7337 that requires drawing upon the expertise of “integrators.” Integrators are commonly self-
7338 selected managers and decision makers with particular aptitude or training in science, or
7339 scientists who are particularly good at communication and applications. Training may
7340 entail curriculum development, career and training development for users as well as
7341 science integrators, and continued mid-career in-stream retraining and re-education.
7342 Many current integrators have evolved as a result of doing interdisciplinary and applied
7343 research in collaborative projects, and some have been encouraged by funding provided
7344 by NOAA’s Climate Programs Office (formerly Office of Global Programs) (Jacobs, *et*
7345 *al.*, 2005).

7346

7347 **4.3.7 Adaptive Management for Water Resources Planning—Implications for**
7348 **Decision Support**

7349 Since the 1970s, an “adaptive management paradigm” has emerged that is characterized
7350 by: greater public and stakeholder participation in decision making; an explicit
7351 commitment to environmentally sound, socially just outcomes; greater reliance upon
7352 drainage basins as planning units; program management via spatial and managerial
7353 flexibility, collaboration, participation, and sound, peer-reviewed science; and finally,
7354 embracing of ecological, economic, and equity considerations (Hartig *et al.*, 1992;
7355 Landre and Knuth, 1993; Cortner and Moote, 1994; Water in the West, 1998; May *et al.*,

7356 1996; McGinnis, 1995; Miller *et al.*, 1996; Cody, 1999; Bormann *et al.*, 1993; Lee,
7357 1993). Adaptive management traces its roots to a convergence of intellectual trends and
7358 disciplines, including industrial relations theory, ecosystems management, ecological
7359 science, economics, and engineering. It also embraces a constellation of concepts such as
7360 social learning, operations research, environmental monitoring, precautionary risk
7361 avoidance, and many others (NRC, 2004).

7362

7363 Adaptive management can be viewed as an alternative decision-making paradigm that
7364 seeks insights into the behavior of ecosystems utilized by humans. In regard to climate
7365 variability and water resources, adaptive management compels consideration of questions
7366 such as the following: What are the decision-support needs related to managing in-
7367 stream flows/low flows? How does climate variability affect runoff? What is the impact
7368 of increased temperatures on water quality or on cold-water fisheries' (e.g., lower
7369 dissolved oxygen levels)? What other environmental quality parameters does a changing
7370 climate impact related to endangered or threatened species? And, what changes to runoff
7371 and flow will occur in the future, and how will these changes affect water uses among
7372 future generations unable to influence the causes of these changes today? What makes
7373 these questions particularly challenging is that they are interdisciplinary in nature²².

7374

²² Underscored by the fact that scholars concur, adaptive management entails a broad range of processes to avoid environmental harm by imposing modest changes on the environment, acknowledging uncertainties in predicting impacts of human activities on natural processes, and embracing social learning (*i.e.*, learning by experiment). In general, it is characterized by managing resources by learning, especially about mistakes, in an effort to make policy improvements using four major strategies that include: (1) modifying policies in the light of experience, (2) permitting such modifications to be introduced in "mid-course, (3) allowing revelation of critical knowledge heretofore missing and analysis of management outcomes, and (4) incorporating outcomes in future decisions through a consensus-based approach that allows government agencies and NGOs to conjointly agree on solutions (Bormann, *et al.*, 1993; Lee, 1993; Definitions of Adaptive Management, 2000).

7375 While a potentially important concept, applying adaptive management to improving
7376 decision support requires that we deftly avoid a number of false and sometimes
7377 uncritically accepted suppositions. For example, adaptive management does not postpone
7378 actions until “enough” is known about a managed ecosystem, but supports actions that
7379 acknowledge the limits of scientific knowledge, “the complexities and stochastic
7380 behavior of large ecosystems,” and the uncertainties in natural systems, economic
7381 demands, political institutions, and ever-changing societal social values (NRC, 2004;
7382 Lee, 1999). In short, an adaptive management approach is one that is flexible and subject
7383 to adjustment in an iterative, social learning process (Lee, 1999). If treated in such a
7384 manner, adaptive management can encourage timely responses by: encouraging
7385 protagonists involved in water management to bound disputes; investigating
7386 environmental uncertainties; continuing to constantly learn and improve the management
7387 and operation of environmental control systems; learning from error; and “reduc(ing)
7388 decision-making gridlock by making it clear ... that there is often no “right” or “wrong”
7389 management decision, and that modifications are expected” (NRC, 2004).

7390

7391 The four cases discussed below illustrate varying applications, and context specific
7392 problems, of adaptive management. The discussion of Integrated Water Resource
7393 Planning stresses the use of adaptive management in a variety of local political contexts
7394 where the emphasis is on reducing water use and dependence on engineered solutions to
7395 provide water supply. The key variables are the economic goals of cost savings coupled
7396 with the ability to flexibly meet water demands. The Arizona Water Institute case
7397 illustrates the use of a dynamic organizational training setting to provide “social learning”

7398 and decisional responsiveness to changing environmental and societal conditions. A key
7399 trait is the use of a boundary-spanning entity to bridge various disciplines.

7400

7401 The Glen Canyon and Murray-Darling Basin cases illustrate operations-level decision
7402 making aimed at addressing a number of water management problems that, over time,
7403 have become exacerbated by climate variability, namely: drought, streamflow, salinity,
7404 and regional water demand. On one hand, adaptive management has been applied to “re-
7405 engineer” a large reservoir system. On the other, a management authority that links
7406 various stakeholders together has attempted to instill a new set of principles into regional
7407 river basin management. It should be borne in mind that transferability of lessons from
7408 these cases depends not on some assumed "randomness" in their character (they are not
7409 random; they were chosen because they are amply studied), but on the similarity between
7410 their context and that of other cases. This is a problem also taken up in Section 4.5.2.

7411

7412 **4.3.8 Integrated Water Resources Planning—Local Water Supply and Adaptive** 7413 **Management**

7414 A significant innovation in water resources management in the United States that affects
7415 climate information use is occurring in the local water supply sector: the growing use of
7416 integrated water resource planning (or IWRP) as an alternative to conventional supply-
7417 side approaches for meeting future demands. IWRP is gaining acceptance in chronically
7418 water-short regions such as the Southwest and portions of the Midwest, including
7419 Southern California, Kansas, Southern Nevada, and New Mexico (*e.g.*, Beecher, 1995;
7420 Warren *et al.*, 1995; Fiske and Dong, 1995; Wade, 2001).

7421

7422 IWRP’s goal is to “balanc(e) water supply and demand management considerations by
7423 identifying feasible planning alternatives that meet the test of least cost without
7424 sacrificing other policy goals” (Beecher, 1995). This can be variously achieved through
7425 depleted aquifer recharge, seasonal groundwater recharge, conservation incentives,
7426 adopting growth management strategies, wastewater reuse, and/or applying least cost
7427 planning principles to large investor-owned water utilities. The latter may encourage
7428 IWRP by demonstrating the relative efficiency of efforts to reduce demand as opposed to
7429 building more supply infrastructure. A particularly challenging alternative is the need to
7430 enhance regional planning among water utilities in order to capitalize on the resources of
7431 every water user, eliminate unnecessary duplication of effort, and avoid the cost of
7432 building new facilities for water supply (Atwater and Blomquist, 2002).

7433

7434 In some cases, short-term applications of least cost planning may increase long-term
7435 project costs, especially when environmental impacts, resource depletion, and energy and
7436 maintenance costs are included. The significance of least cost planning is that it
7437 underscores the importance of long- and short-term costs (in this case, of water) as an
7438 influence on the value of certain kinds of information for decisions. Models and forecasts
7439 that predict water availability under different climate scenarios can be especially useful to
7440 least cost planning and make more credible efforts to reducing demand. Specific
7441 questions IWRP raises for decision support given a changing climate include: How
7442 precise must climate information be to enhance long-term planning? How might
7443 predicted climate change provide an incentive for IWRP strategies? and, What climate

7444 information is needed to optimize decisions on water pricing, re-use, shifting from
7445 surface to groundwater use, and conservation?

7446

7447 *Case Study C:*

7448 *Approaches to building user knowledge and enhancing capacity building—the Arizona*
7449 *Water Institute*

7450 The Arizona Water Institute was initiated in 2006 to focus the resources of the State of
7451 Arizona’s university system on the issue of water sustainability. Because there are 400
7452 faculty and staff members in the three Arizona universities who work on water-related
7453 topics, it is clear that asking them and their students to assist the state in addressing the
7454 major water quantity and quality issues should make a significant contribution to water
7455 sustainability. This is particularly relevant given that the state budget for supporting
7456 water resources related work is exceedingly small by comparison to many other states,
7457 and the fact that Arizona is one of the fastest-growing states in the United States. In
7458 addition to working towards water sustainability, the Institute’s mission includes water-
7459 related technology transfer from the universities to the private sector to create and
7460 develop economic opportunities, as well as build capacity, to enhance the use of scientific
7461 information in decision making.

7462

7463 The Institute was designed from the beginning as a “boundary organization” to build
7464 pathways for innovation between the universities and state agencies, communities, Native
7465 American tribal representatives, and the private sector. In addition, the Institute is
7466 specifically designed as an experiment in how to remove barriers between groups of
7467 researchers in different disciplines and across the universities. The Institute’s projects
7468 involve faculty members from more than one of the universities, and all involve true
7469 engagement with stakeholders. The faculty is provided incentives to engage both through
7470 small grants for collaborative projects and through the visibility of the work that the
7471 Institute supports. Further, the Institute’s structure is unique, in that there are high level
7472 Associate Directors of the Institute whose assignment is to build bridges between the
7473 universities and the three state agencies that are the Institute’s partners: Water

7474 Resources, Environmental Quality, and Commerce. These Associate Directors are
7475 physically located inside the state agencies that they serve. The intent is to build trust
7476 between university researchers (who may be viewed as “out of touch with reality” by
7477 agency employees), and agency or state employees (whom researchers may believe are
7478 not interested in innovative ideas). Physical proximity of workspaces and daily
7479 engagement has been shown to be an ingredient of trust building.

7480

7481 A significant component of the Institute’s effort is focused: on capacity building, on
7482 training students through engagement in real-world water policy issues, on providing
7483 better access to hydrologic data for decision makers, on assisting them in visualizing the
7484 implications of the decisions that they make, on workshops and training programs for
7485 tribal entities, on joint definition of research agendas between stakeholders and
7486 researchers, and on building employment pathways to train students for specific job
7487 categories where there is an insufficient supply of trained workers, such as water and
7488 wastewater treatment plant operators. Capacity-building in interdisciplinary planning
7489 applications such as combining land use planning and water supply planning to focus on
7490 sustainable water supplies for future development is emerging as a key need for many
7491 communities in the state.

7492

7493 The Institute is designed as a “learning organization” in that it will regularly revisit its
7494 structure and function, and redesign itself as needed to maintain effectiveness in the
7495 context of changing institutional and financial conditions.

7496

7497 ***Case Study D:***

7498 ***Murray-Darling Basin—sustainable development and adaptive management***

7499 The Murray-Darling Basin Agreement (MDBA), formed in 1985 by New South Wales,
7500 Victoria, South Australia and the Commonwealth, is an effort to provide for the
7501 integrated and conjoint management of the water and related land resources of the
7502 world’s largest catchment system. The problems initially giving rise to the agreement
7503 included rising salinity and irrigation-induced land salinization that extended across state
7504 boundaries (SSCSE, 1979; Wells, 1994). However, embedded in its charter was a

7505 concern with using climate variability information to more effectively manage drought,
7506 runoff, riverine flow and other factors in order to meet the goal of “effective planning
7507 and management for the equitable, efficient and sustainable use of the water, land and
7508 environmental resources (of the basin)” (MDBC, 2002).

7509

7510 Some of the more notable achievements of the MDBA include programs to promote the
7511 management of point and non-point source pollution; balancing consumptive and in-
7512 stream uses (a decision to place a cap on water diversions was adopted by the
7513 commission in 1995); the ability to increase water allocations – and rates of water flow –
7514 in order to mitigate pollution and protect threatened species (applicable in all states
7515 except Queensland); and an explicit program for “sustainable management.” The latter
7516 hinges on implementation of several strategies, including a novel human dimension
7517 strategy adopted in 1999 that assesses the social, institutional and cultural factors
7518 impeding sustainability; as well as adoption of specific policies to deal with salinity,
7519 better manage wetlands, reduce the frequency and intensity of algal blooms by better
7520 managing the inflow of nutrients, reverse declines in native fisheries populations (a plan
7521 which, like that of many river basins in the United States, institutes changes in dam
7522 operations to permit fish passage), and preparing floodplain management plans.

7523

7524 Moreover, a large-scale environmental monitoring program is underway to collect and
7525 analyze basic data on pressures upon the basin’s resources as well as a “framework for
7526 evaluating and reporting on government and community investment” efforts and their
7527 effectiveness. This self-evaluation program is a unique adaptive management innovation
7528 rarely found in other basin initiatives. To support these activities, the Commission funds
7529 its own research program and engages in biophysical and social science investigations. It
7530 also establishes priorities for investigations based, in part, on the severity of problems,
7531 and the knowledge acquired is integrated directly into commission policies through a
7532 formal review process designed to assure that best management practices are adopted.

7533

7534 From the standpoint of adaptive management, the Murray-Darling Basin Agreement
7535 seeks to integrate quality and quantity concerns in a single management framework; has a

7536 broad mandate to embrace social, economic, environmental and cultural issues in
7537 decisions; and has considerable authority to supplant, and supplement, the authority of
7538 established jurisdictions in implementing environmental and water development policies.
7539 While water quality policies adopted by the Basin Authority are recommended to states
7540 and the federal government for approval, generally, the latter defer to the commission and
7541 its executive arm. The MDBA also promotes an integrated approach to water resources
7542 management. Not only does the Commission have responsibility for functions as widely
7543 varied as floodplain management, drought protection, and water allocation, but for
7544 coordinating them as well. For example, efforts to reduce salinity are linked to strategies
7545 to prevent waterlogging of floodplains and land salinization on the Murray and
7546 Murrumbidgee Valleys (MDBC, 2002). Also, the Basin commission's environmental
7547 policy aims to utilize water allocations not only to control pollution and benefit water
7548 users, but to integrate its water allocation policy with other strategies for capping
7549 diversions, governing in-stream flow, and balancing in-stream needs and consumptive
7550 (*i.e.*, agricultural irrigation) uses. Among the most notable of MDBC's innovations is its
7551 community advisory effort.

7552

7553 In 1990, the ministerial council for the MDBC adopted a Natural Resources Management
7554 Strategy that provides specific guidance for a community-government partnership to
7555 develop plans for integrated management of the Basin's water, land and other
7556 environmental resources on a catchment basis. In 1996, the ministerial council put in
7557 place a Basin Sustainability Plan that provides a planning, evaluation and reporting
7558 framework for the Strategy, and covers all government and community investment for
7559 sustainable resources management in the basin.

7560

7561 According to Newson (1997), while the policy of integrated management has "received
7562 wide endorsement," progress towards effective implementation has fallen short—
7563 especially in the area of floodplain management. This has been attributed to a "reactive
7564 and supportive" attitude as opposed to a proactive one. Despite such criticism, it is hard
7565 to find another initiative of this scale and sophistication that has attempted adaptive
7566 management based on community involvement.

7567

7568 *Case Study E:*7569 *Adaptive management in Glen Canyon, Arizona and Utah*

7570 Glen Canyon Dam was constructed in 1963 to provide hydropower, water for irrigation,
7571 flood control, and public water supply—and to ensure adequate storage for the upper
7572 basin states of the Colorado River Compact (*i.e.*, Utah, Wyoming, New Mexico, and
7573 Colorado). Lake Powell, the reservoir created by Glen Canyon Dam, has a storage
7574 capacity equal to approximately two years flow of the Colorado River. Critics of Glen
7575 Canyon Dam have insisted that its impacts on the upper basin have been injurious almost
7576 from the moment it was completed. The flooding of one of the West's most beautiful
7577 canyons under the waters of Lake Powell increased rates of evapotranspiration and other
7578 forms of water loss (*e.g.*, seepage of water into canyon walls) and eradicated historical
7579 flow regimes. The latter has been the focus of recent debate. Prior to Glen Canyon's
7580 closure, the Colorado River, at this location, was highly variable with flows ranging from
7581 120,000 cubic feet per second (cfs) to less than 1,000 cfs.

7582

7583 When the dam's gates were closed in 1963, the Colorado River above and below Glen
7584 Canyon was altered by changes in seasonal variability. Once characterized by muddy,
7585 raging floods, the river became transformed into a clear, cold stream. Annual flows were
7586 stabilized and replaced by daily fluctuations by as much as 15 feet. A band of exotic
7587 vegetation colonized a river corridor no longer scoured by spring floods; five of eight
7588 native fish species disappeared; and the broad sand beaches of the pre-dam river eroded
7589 away. Utilities and cities within the region came to rely on the dam's low cost power and
7590 water, and in-stream values were ignored (Carothers and Brown, 1991).

7591

7592 Attempts to abate or even reverse these impacts came about in two ways. First, in 1992,
7593 under pressure from environmental organizations, Congress passed the Grand Canyon
7594 Protection Act that mandated Glen Canyon Dam's operations coincide with protection,
7595 migration, and improvement of the natural and cultural resources of the Colorado River.
7596 Second, in 1996, the Bureau of Reclamation undertook an experimental flood to restore
7597 disturbance and dynamics to the river ecosystem. Planners hoped that additional sand

7598 would be deposited on canyon beaches and that backwaters (important rearing areas for
7599 native fish) would be revitalized. They also hoped the new sand deposits would stabilize
7600 eroding cultural sites while high flows would flush some exotic fish species out of the
7601 system (Moody, 1997; Restoring the Waters, 1997). The 1996 flood created over 50 new
7602 sandbars, enhanced existing ones, stabilized cultural sites, and helped to restore some
7603 downstream sport fisheries. What made these changes possible was a consensus
7604 developed through a six-year process led by the Bureau that brought together diverse
7605 stakeholders on a regular basis. This process developed a new operational plan for Lake
7606 Powell, produced an environmental impact statement for the project, and compelled the
7607 Bureau (working with the National Park Service) to implement an adaptive management
7608 approach that encouraged wide discussion over all management decisions.

7609

7610 While some environmental restoration has occurred, improvement to backwaters has
7611 been less successful. Despite efforts to restore native fisheries, the long-term impact of
7612 exotic fish populations on the native biological community, as well as potential for long-
7613 term recovery of native species, remains uncertain (Restoring the Waters, 1997). The
7614 relevance for climate variability decision support in the Glen Canyon case is that
7615 continued drought in the Southwest is placing increasing stress on the land and water
7616 resources of the region, including agriculture lands. Efforts to restore the river to
7617 conditions more nearly approximating the era before the dam was built will require
7618 changes in the dam's operating regime that will force a greater balance between instream
7619 flow considerations and power generation and offstream water supply. This will also
7620 require imaginative uses of forecast information to ensure that these various needs can be
7621 optimized.

7622

7623 **4.3.9 Measurable Indicators of Progress to Promote Information Access and Use**

7624 These cases, and our previous discussion about capacity building, point to four basic
7625 measures that can be used to evaluate progress in providing equitable access to decision-
7626 support-generated information. First, the overall process of tool development should be

7627 inclusive. This could be measured and documented over time by the interest of groups to
7628 continue to participate and to be consulted and involved. Participants should view the
7629 process of collaboration as fair and effective—this could be gauged by elicitation of
7630 feedback from process participants.

7631

7632 Second, there should be progress in developing an interdisciplinary and interagency
7633 environment of collaboration, documented by the presence of dialogue, discussion, and
7634 exchange of ideas and data among different professions—in other words, documented
7635 boundary-spanning progress and building of trusted relationships. One documentable
7636 measure of interdisciplinary, boundary-spanning collaboration is the growth, over time,
7637 of professional reward systems within organizations that reward and recognize people
7638 who develop, use, and translate such systems for use by others.

7639

7640 Third, the collaborative process must be viewed by participants as credible. This means
7641 that participants feel it is believable and trustworthy and that there are benefits to all who
7642 engage in it. Again, this can be documented by elicitation of feedback from participants.

7643 Finally, outcomes of decision-support tools must be implementable in the short term, as
7644 well as longer-term. It is necessary to see progress in assimilating and using such systems
7645 in a short period of time in order to sustain the interest, effort, and participatory
7646 conviction of decision makers in the process. Table 4.2 suggests some specific, discrete
7647 measures that can be used to assess progress toward effective information use.

7648

7649 **Table 4.2 Promoting Access to Information and its Use Between Scientists and Decision Makers – A**
7650 **Checklist (adopted from: Jacobs, 2003).**

7651

Information Integration

- Was information received by stakeholders and integrated into decision-makers' management framework or world view?
- Was capacity built? Did the process lead to a result where institutions, organizations, agencies, officials can use information generated by decision-support experts? Did experts who developed these systems rely upon the knowledge and experience of decision makers—and respond to their needs in a manner that was useful?
- Will stakeholders continue to be invested in the program and participate in it over the long term?

Stakeholder Interaction/Collaboration

- Were contacts/relationships sustained over time and did they extend beyond individuals to institutions?
- Did stakeholders invest staff time or money in the activity?
- Was staff performance evaluated on the basis of quality or quantity of interaction?
- Did the project take on a life of its own, become at least partially self-supporting after the end of the project?
- Did the project result in building capacity and resilience to future events/conditions rather than focus on mitigation?
- Was quality of life or economic conditions improved due to use of information generated or accessed through the project?
- Did the stakeholders claim or accept partial ownership of final product?

Tool Salience/Utility

- Are the tools actually used to make decisions; are they used by high-valued uses and users?
- Is the information generated/provided by these tools accurate/valid?
- Are important decisions made on the basis of the tool?
- Does the use of these tools reduce vulnerabilities, risks, and hazards?

Collaborative Process Efficacy

- Was the process representative (all interests have a voice at the table)?
- Was the process credible (based on facts as the participants knew them)?
- Were the outcomes implementable in a reasonable time frame (political and economic support)?
- Were the outcomes disciplined from a cost perspective (*i.e.*, there is some relationship between total costs and total benefits)?
- Were the costs and benefits equitably distributed, meaning there was a relationship between those who paid and those who benefited?

7652

7653 **4.3.10 Monitoring Progress**

7654 An important element in the evaluation of process outcomes is the ability to monitor
 7655 progress. A recent National Academy report (NRC, 2008) on NOAA's Sectoral
 7656 Applications Research Program (SARP), focusing on climate-related information to
 7657 inform decisions, encourages the identification of process measures that can be recorded
 7658 on a regular basis, and of outcome measures tied to impacts of interest to NOAA and
 7659 others that can also be recorded on a comparable basis.

7660

7661 These metrics can be refined and improved on the basis of research and experience, while
7662 consistency is maintained to permit time-series comparisons of progress (NRC, 2008).
7663 An advantage of such an approach includes the ability to document learning (*e.g.*, Is there
7664 progress on the part of investigators in better project designs? Should there be a
7665 redirection of funding toward projects that show a large payoff in benefits to decision
7666 makers?).

7667

7668 Finally, the ability to consult with agencies, water resource decision makers, and a host of
7669 other potential forecast user communities can be an invaluable means of providing “mid-
7670 course” or interim indicators of progress in integrating forecast use in decisions. The
7671 Transition of Research Applications to Climate Services Program (TRACS), also within
7672 the NOAA Climate Program Office, has a mandate to support users of climate
7673 information and forecasts at multiple spatial and geographical scales—the transitioning of
7674 “experimentally mature climate information tools, methods, and processes, including
7675 computer-related applications (*e.g.* web interfaces, visualization tools), from research
7676 mode into settings where they may be applied in an operational and sustained manner”
7677 (TRACS, 2008). While TRACS primary goal is to deliver useful climate information
7678 products and services to local, regional, national, and even international policy makers, it
7679 is also charged with learning from its partners how to better accomplish technology
7680 transition processes. NOAA’s focus is to infer how effectively transitions of research
7681 applications (*i.e.* experimentally developed and tested, end-user-friendly information to
7682 support decision making), and climate services (*i.e.* the routine and timely delivery of that
7683 information, including via partnerships) are actually occurring.

7684

7685 While it is far too early to conclude how effectively this process of consultation has
7686 advanced, NOAA has established criteria for assessing this learning process, including
7687 clearly identifying decision makers, research, operations and extension partners, and
7688 providing for post-audit evaluation (*e.g.*, validation, verification, refinement,
7689 maintenance) to determine at the end of the project if the transition of information has
7690 been achieved and is sustainable. Effectiveness will be judged in large part by the
7691 partners, and will focus on the developing means of communication and feedback, and on
7692 the deep engagement with the operational and end-user communities (TRACS, 2008).

7693

7694 The Southeast Climate Consortium case discussed below illustrates how a successful
7695 process of ongoing stakeholder engagement can be developed through the entire cycle
7696 (from development, introduction, and use) of decision-support tools. This experiment
7697 affords insights into how to elicit user community responses in order to refine and
7698 improve climate information products, and how to develop a sense of decision-support
7699 ownership through participatory research and modeling. The Potomac River case focuses
7700 on efforts to resolve a long-simmering water dispute and the way collaborative processes
7701 can themselves lead to improved decisions. Finally, the Upper San Pedro Partnership
7702 exemplifies the kind of sustained partnering efforts that are possible when adequate
7703 funding is made available, politicization of water management questions is prevalent, and
7704 climate variability has become an important issue on decision-makers' agenda, while the
7705 series of fire prediction workshops illustrate the importance of a highly-focused

7706 problem—one that requires improvements to information processes, as well as outcomes,
7707 to foster sustained collaboration.

7708

7709 ***Case Study F:***

7710 ***Southeast Climate Consortium capacity building, tool development***

7711 The Southeast Climate Consortium is a multidisciplinary, multi-institutional team, with
7712 members from Florida State University, University of Florida, University of Miami,
7713 University of Georgia, University of Auburn and the University of Alabama-Huntsville.
7714 A major part of the Southeast Climate Consortium's (SECC) effort is directed toward
7715 developing and providing climate and resource management information through
7716 AgClimate <<http://www.agclimate.org/>>, a decision-support system (DSS) introduced for
7717 use by Agricultural Extension, agricultural producers, and resource managers in the
7718 management of agriculture, forests, and water resources. Two keys to SECC's progress in
7719 promoting the effective use of climate information in agricultural sector decision making
7720 are (1) iterative ongoing engagement with stakeholders, from project initiation to
7721 decision-support system completion and beyond (further product refinement,
7722 development of ancillary products, *etc.*) (Breuer *et al.*, 2007; Cabrera *et al.*, 2007), and
7723 (2) co-developing a stakeholder sense of decision-support ownership through
7724 participatory research and modeling (Meinke and Stone, 2005; Breuer *et al.*, 2007;
7725 Cabrera *et al.*, 2007).

7726

7727 The SECC process has begun to build capacity for the use of climate information with a
7728 rapid assessment to understand stakeholder perceptions and needs regarding application
7729 of climate information that may have benefits (*e.g.*, crop yields, nitrogen pollution in
7730 water) (Cabrera *et al.*, 2006). Through a series of engagements, such as focus groups,
7731 individual interviews, research team meetings (including stakeholder advisors), and
7732 prototype demonstrations, the research team assesses which stakeholders are most likely
7733 adopt the decision-support system and communicate their experience with other
7734 stakeholders (Roncoli *et al.*, 2006), as well as stakeholder requirements for decision
7735 support (Cabrera *et al.*, 2007). Among the stakeholder requirements gleaned from more

7736 than six years of stakeholder engagements, are: present information in an uncomplicated
7737 way (often deterministic), but allow the option to view probabilistic information; provide
7738 information timed to allow users to take revised or preventative actions; include an
7739 economic component (because farmer survival, *i.e.* cost of practice adoption, takes
7740 precedence over stewardship concerns); and allow for confidential comparison of model
7741 results with proprietary data.

7742

7743 The participatory modeling approach used in the development of DyNoFlo, a whole-farm
7744 decision-support system to decrease nitrogen leaching while maintaining profitability
7745 under variable climate conditions (Cabrera *et al.*, 2007), engaged federal agencies,
7746 individual producers, cooperative extension specialists, and consultants (who provided
7747 confidential data for model verification). Cabrera *et al.* (2007) report that the dialogue
7748 between these players, as equals, was as important as the scientific underpinning and
7749 accuracy of the model in improving adoption. They emphasize that the process, including
7750 validation (defined as occurring when researchers and stakeholders agree the model fits
7751 real or measured conditions adequately) is a key factor in developing stakeholder sense of
7752 ownership and desire for further engagement and decision-support system enhancement.
7753 These findings concur with recent examples of the adoption of climate data, predictions
7754 and information to improve water supply model performance by Colorado River Basin
7755 water managers (Woodhouse and Lukas, 2006; B. Udall, personal communication).

7756

7757 ***Case Study G:***

7758 ***The Potomac River Basin***

7759 Water wars, traditionally seen in the West, are spreading to the Midwest, East, and South.
7760 The “Water Wars” report (Council of State Governments, 2003) underlines the stress a
7761 growing resident population is imposing on a limited natural resource, and how this stress
7762 is triggering water wars in areas formerly with plentiful water. An additional source of
7763 concern would be the effect on supply and the increase in demand due to climate
7764 variability and change. Although the study by Hurd *et al.* (1999) indicated that the
7765 Northeastern water supply would be less vulnerable to the effect of climate change, the
7766 Interstate Commission on the Potomac River Basin (ICPRB) periodically studies the

7767 impact of climate change on the supply reliability to the Washington metropolitan area
7768 (WMA). (See also: *Restoring the Waters*. 1997, Boulder, CO, Natural Resources Law
7769 Center, the University of Colorado School of Law, May.)

7770

7771 The ICPRB was created in 1940 by the States of Maryland and West Virginia, the
7772 Commonwealths of Virginia and Pennsylvania, and the District of Columbia. The ICPRB
7773 was recognized by the United States Congress, which also provided a presence in the
7774 Commission. The ICPRB's purpose is "regulating, controlling, preventing, or otherwise
7775 rendering unobjectionable and harmless the pollution of the waters of said Potomac
7776 drainage area by sewage and industrial and other wastes."

7777

7778 The Potomac River constitutes the primary source of water for the WMA. Out of the five
7779 reservoirs in the WMA, three are in the Potomac River Basin. Every five years,
7780 beginning in April, 1990, the Commission evaluates the adequacy of the different sources
7781 of water supply to the Metropolitan Washington area. The latest report, (Kame'enui *et*
7782 *al.*, 2005), includes a report of a study by Steiner *et al.* (1997) of the potential effects of
7783 climate variability and change on the reliability of water supply for that area.

7784

7785 The ICPRB inputs temperature, precipitation from five general circulation models
7786 (GCMs), and soil moisture capacity and retention, to a water balance model, to produce
7787 monthly average runoff records. The computed Potential Evapotranspiration (PET) is
7788 also used to estimate seasonal water use in residential areas.

7789

7790 The results of the 2005 study indicated that, depending on the climate change scenario,
7791 the demand in the Washington metropolitan area in 2030 could be 74 to 138 percent
7792 greater than that of 1990. According to the report, "resources were significantly stressed
7793 or deficient" at that point. The water management component of the model helped
7794 determine that, with aggressive plans in conservation and operation policies, existing
7795 resources would be sufficient through 2030. In consequence, the study recommended
7796 "that water management consider the need to plan for mitigation of potential climate
7797 change impacts" (Kame'enui *et al.*, 2005; Steiner *et al.*, 1997).

7798

7799 **Case Study H:**7800 ***Fire prediction workshops as a model for a climate science-water management process***
7801 ***to improve water resources decision support***

7802 Fire suppression costs the United States about \$1 billion each year. Almost two decades
7803 of research into the associations between climate and fire (*e.g.*, Swetnam and Betancourt,
7804 1998), demonstrate a high potential to predict various measures of fire activity, based on
7805 direct influences, such as drought, and indirect influences, such as growth of fire fuels
7806 such as grasses and shrubs (*e.g.*, Westerling *et al.*, 2002; Roads *et al.*, 2005; Preisler and
7807 Westerling, 2007). Given strong mutual interests in improving the range of tools
7808 available to fire management, with the goals of reducing fire related damage and loss of
7809 life, fire managers and climate scientists have developed a long-term process to improve
7810 fire potential prediction (Garfin *et al.*, 2003; Wordell and Ochoa, 2006) and to better
7811 estimate the costs and most efficient deployment of fire fighting resources. The strength
7812 of collaborations between climate scientists, fire ecologists, fire managers, and
7813 operational fire weather forecasters, is based upon mutual learning and meshing of both
7814 complementary knowledge (*e.g.*, atmospheric science and forestry science) and expertise
7815 (*e.g.*, dynamical modeling and command and control operations management) (Garfin,
7816 2005). The emphasis on process, as well as product, may be a model for climate science
7817 in support of water resources management decision making. Another key facet in
7818 maintaining this collaboration and direct application of climate science to operational
7819 decision-making has been the development of strong professional relationships between
7820 the academic and operational partners. Aspects of developing these relationships that are
7821 germane to adoption of this model in the water management sector include:

- 7822 • Inclusion of climate scientists as partners in annual fire management strategic
7823 planning meetings;
- 7824 • Development of knowledge and learning networks in the operational fire
7825 management community;
- 7826 • Inclusion of fire managers and operational meteorologists in academic research
7827 projects and development of verification procedures (Corringham *et al.*, 2008)
- 7828 • Co-location of fire managers at academic institutions (Schlobohm *et al.*, 2003).

7829

7830 *Case Study I:*7831 *Incentives to Innovate—Climate Variability and Water Management along the San*
7832 *Pedro River*

7833 The San Pedro River, though small in size, supports one of the few intact riparian
7834 systems remaining in the Southwest. Originating in Sonora, Mexico, the stream flows
7835 northward into rapidly urbanizing southeastern Arizona, eventually joining with the Gila
7836 River, a tributary of the Lower Colorado River. On the American side of the international
7837 boundary, persistent conflict plagues efforts to manage local water resources in a manner
7838 that supports demands generated at Fort Huachuca Army Base and the nearby city of
7839 Sierra Vista, while at the same time preserving the riparian area. Located along a major
7840 flyway for migratory birds and providing habitat for a wide range of avian and other
7841 species, the river has attracted major interest from an array of environmental groups that
7842 seek its preservation. Studies carried out over the past decade highlight the vulnerability
7843 of the river system to climate variability. Recent data indicate that flows in the San Pedro
7844 have declined significantly due, in part, to ongoing drought. More controversial is the
7845 extent to which intensified groundwater use is depleting water that would otherwise find
7846 its way to the river.

7847

7848 The highly politicized issue of water management in the upper San Pedro River Basin has
7849 led to establishment of the Upper San Pedro Partnership, whose primary goal is balancing
7850 water demands with water supply in a manner that does not compromise the region's
7851 economic viability, much of which is directly or indirectly tied to Fort Huachuca Army
7852 base. Funding from several sources, including, among others, several NOAA programs
7853 and the Netherlands-based Dialogue on Climate and Water, has supported ongoing efforts
7854 to assess vulnerability of local water resources to climate variability on both sides of the
7855 border. These studies, together with experience from recent drought, point toward
7856 escalating vulnerability to climatic impacts, given projected increases in demand and
7857 likely diminution of effective precipitation over time in the face of rising temperatures
7858 and changing patterns of winter versus summer rainfall (IPCC, 2007a). Whether recent
7859 efforts to reinforce growth dynamics by enhancing the available supply through water

7860 reuse or water importation from outside the basin will buffer impacts on the riparian
7861 corridor remains to be seen. In the meantime, climatologists, hydrologists, social
7862 scientists, and engineers continue to work with members of the Partnership and others in
7863 the area to strengthen capacity and interest in using climate forecast products. A
7864 relatively recent decision to include climate variability and change in a decision-support
7865 model being developed by a University of Arizona engineer in collaboration with
7866 members of the Partnership constitutes a significant step forward in integrating climate
7867 into local decision processes.

7868

7869 The incentives for engagement in solving the problems in the San Pedro include both a
7870 “carrot” in the form of federal and state funding for the San Pedro Partnership, and a
7871 newly formed water management district, and a “stick” in the form of threats to the future
7872 of Fort Huachuca. Fort Huachuca represents a significant component of the economy of
7873 southern Arizona, and its existence is somewhat dependent on showing that endangered
7874 species in the river, and the water rights of the San Pedro Riparian Conservation Area,
7875 are protected.

7876

7877 **4.4 SUMMARY FINDINGS AND CONCLUSIONS**

7878 The decision-support experiments discussed here and in Chapter 3, together with the
7879 analytical discussion, have depicted several barriers to use of decision-support
7880 experiment information on SI climate conditions by water resource managers. The
7881 discussion has also pinpointed a number of ways to overcome these barriers and ensure
7882 effective communication, transfer, dissemination, and use of information. Our major
7883 findings are as follows.

7884

7885 Effective integration of climate information in decisions requires identifying topics of
7886 mutual interest to sustain long-term collaborative research and application of decision-

7887 support outcomes: Identifying topics of mutual interest, through forums and other means
7888 of formal collaboration, can lead to information penetration into agency (and stakeholder
7889 group) activities, and produce self-sustaining, participant-managed spin-off activities.
7890 Long-term engagement also allows time for the evolution of scientist/decision-maker
7891 collaborations, ranging from understanding the roles of various players to connecting
7892 climate to a range of decisions, issues, and adaptation strategies—and building trust.

7893

7894 Tools must engage a range of participants, including those who generate them, those who
7895 translate them into predictions for decision-maker use, and the decision makers who
7896 apply the products. Forecast innovations might combine climate factor observations,
7897 analyses of climate dynamics, and SI forecasts. In turn, users are concerned with varying
7898 problems and issues such as planting times, instream flows to support endangered
7899 species, and reservoir operations. While forecasts vary in their skill, multiple forecasts
7900 that examine various factors (*e.g.*, snow pack, precipitation, temperature variability) are
7901 most useful because they provide decision makers more access to data that they can
7902 manipulate themselves.

7903

7904 A critical mass of scientists and decision makers is needed for collaboration to succeed:
7905 Development of successful collaborations requires representation of multiple
7906 perspectives, including diversity of disciplinary and agency-group affiliation. For
7907 example, operations, planning, and management personnel should all be involved in
7908 activities related to integrating climate information into decision systems; and there
7909 should be sound institutional pathways for information flow from researchers to decision

7910 makers, including explicit responsibility for information use. Cooperative relationships
7911 that foster learning and capacity building within and across organizations, including
7912 restructuring organizational dynamics, are important, as is training of “integrators” who
7913 can assist stakeholders with using complex data and tools.

7914

7915 What makes a “critical mass” critical? Research on water resource decision making
7916 suggests that agencies and other organizations define problems differently depending on
7917 whether they are dedicated to managing single-issue problems in particular sectors (*e.g.*,
7918 irrigation, public supply) or working in political jurisdictions or watershed-based entities
7919 designed to comprehensively manage and coordinate several management objectives
7920 simultaneously (*e.g.*, flood control and irrigation, power generation, and in-stream flow).
7921 The latter entities face the unusual challenge of trying to harmonize competing
7922 objectives, are commonly accountable to numerous users, and require “regionally and
7923 locally tailored solutions” to problems (Water in the West, 1998; also, Kenney and Lord,
7924 1994; Grigg, 1996). A lesson that appears to resonate in our cases is that decision makers
7925 representing the affected organizations should be incorporated into collaborative efforts.

7926

7927 Forums and other means of engagement must be adequately funded and supported.

7928 Discussions that are sponsored by boundary organizations and other collaborative
7929 institutions allow for co-production of knowledge, legitimate pathways for climate
7930 information to enter assessment processes, and a platform for building trust.

7931 Collaborative products also give each community something tangible that can be used
7932 within its own system (*i.e.*, information to support decision making, climate service, or

7933 academic research products). Experiments that effectively incorporate seasonal forecasts
7934 into operations generally have long-term financial support, facilitated, in turn, by high
7935 public concern over potential adverse environmental and/or economic impacts. Such
7936 concern helps generate a receptive audience for new tools and ideas. Flexible and
7937 appropriate sources of funding must be found that recognize benefits received by various
7938 constituencies on the one hand, and ability to pay on the other. A combination of
7939 privately-funded, as well as publicly-supported revenue sources may be appropriate in
7940 many cases—both because of the growing demands on all sources of decision-support
7941 development, and because such a balance better satisfies demands that support for these
7942 experiments be equitably borne by all who benefit from them (Cash and Buizer, 2005).
7943 Federal agencies within CCSP can help in this effort by developing a database of possible
7944 funding sources from all sectors, public and private (CDWRb, 2007).

7945

7946 There is a need to balance national decision-support tool production against
7947 customizable, locally specific conditions. Given the diversity of challenges facing
7948 decision makers, the diverse needs and aspirations of stakeholders, and the diversity of
7949 decision-making authorities, there is little likelihood of providing comprehensive climate
7950 services or “one-stop-shop” information systems to support all decision making or risk
7951 assessment. Support for tools to help communities and other self-organizing groups
7952 develop their own capacity and conduct their own assessments within a regional context
7953 is essential.

7954

7955 There is a growing push for smaller scale products that are tailored to specific users, as
7956 well as private sector tailored products (*e.g.*, “Weatherbug”). However, private sector
7957 products are generally available only to specific paying clients, and may not be equitable
7958 to those who lack access to publicly-funded information sources. Private observing
7959 systems also generate issues related to trustworthiness of information and quality control.
7960 What are the implications of this push for proprietary vs. public domain controls and
7961 access? This problem is well-documented in policy studies of risk-based information in
7962 the fields of food labeling, toxic pollutants, medical and pharmaceutical information, and
7963 other forms of public disclosure programs (Graham, 2002).

7964

7965 **4.5 FUTURE RESEARCH NEEDS AND PRIORITIES**

7966 Six major research needs are at the top of our list of priorities for investigations by
7967 government agencies, private sector organizations, universities, and independent
7968 researchers. These are:

- 7969 1) Better understanding the decision context within which decision support tools are
7970 used,
- 7971 2) Understanding decision-maker perceptions of climate risk and vulnerability;
- 7972 3) Improving the generalizability/transferability of case studies on decision-support
7973 experiments,
- 7974 4) Understanding the role of public pressures and networks in generating demands
7975 for climate information,
- 7976 5) Improving the communication of uncertainties, and
- 7977 6) Lessons for collaboration and partnering with other natural resource areas.

7978

7979 Better understanding of the decision-maker context for tool use is needed. While we
7980 know that the institutional, political and economic context has a powerful influence on
7981 the use of tools, we need to learn more about how to promote user interactions with
7982 researchers at all junctures within the tool development process.

7983

7984 The institutional and cultural circumstances of decision makers and scientists are
7985 important to determining the level of collaboration, Among the topics that need to be
7986 addressed are the following:

- 7987 • understanding how organizations engage in transferring and developing climate
7988 variability information,
- 7989 • defining the decision space occupied by decision makers,
- 7990 • determining ways to encourage innovation within institutions, and
- 7991 • understanding the role of economics and chain-of-command in the use of tools.

7992

7993 Access to information is an equity issue: large water management agencies may be able
7994 to afford sophisticated modeling efforts, consultants to provide specialized information,
7995 and a higher quality of data management and analysis, while smaller or less wealthy
7996 stakeholders generally do not have the same access or the consequent ability to respond
7997 (Hartmann, 2001). This is especially true where there are no alternatives to private
7998 competitive markets where asymmetries of economic buying power may affect
7999 information access. Scientific information that is not properly disseminated can
8000 inadvertently result in windfall profits for some and disadvantage others (Pfaff *et al.*,

8001 1999; Broad and Agrawalla, 2000; Broad *et al.*, 2002). Access and equity issues also
8002 need to be explored in more detail.

8003

8004 **4.5.1 Understanding Decision-Makers' Perceptions of Climate Vulnerability**

8005 Much more needs to be known about how to make decision makers aware of their
8006 possible vulnerability from climate variability impacts to water resources. Research on
8007 the influence of climate science on water management in western Australia, for example,
8008 (Power *et al.*, 2005) suggests that water resource decision makers can be persuaded to act
8009 on climate variability information if a strategic program of research in support of specific
8010 decisions (*e.g.*, extended drought) can be wedded to a dedicated, timely risk
8011 communication program.

8012

8013 While we know, based on research in specific applications, that managers who find
8014 climate forecasts and projections to be reliable may be more likely to use them, those
8015 most likely to use weather and climate information are individuals who have experienced
8016 weather and climate problems in the recent past. The implication of this finding is that
8017 simply delivering weather and climate information to potential users may be insufficient
8018 in those cases in which the manager does not perceive climate to be a hazard—at least in
8019 humid, water-rich regions of the United States that we have studied²³.

8020

8021 We also need to know more about how the financial, regulatory, and management
8022 contexts influence perceptions of usefulness (Yarnal *et al.*, 2006; Dow *et al.*, 2007).

²³Additional research on water system manager perceptions is needed, in regions with varying hydro-meteorological conditions, to discern if this finding is universally true.

8023 Experience suggests that individual responses, in the aggregate, may have important
8024 impacts on one's capacity to use, access, and interpret information. Achieving a better
8025 understanding of these factors and of the informational needs of resource managers will
8026 require more investigation of their working environments and intimate understanding of
8027 their organizational constraints, motivations, and institutional rewards.

8028

8029 **4.5.2 Possible Research Methodologies**

8030 Case studies increase understanding of how decisions are made by giving specific
8031 examples of decisions and lessons learned. A unique strength offered by the case study
8032 approach is that “. . .only when we confront specific facts, the raw material on the basis
8033 of which decisions are reached—not general theories or hypotheses—do the limits of
8034 public policy become apparent (Starling, 1989).” In short, case studies put a human face
8035 on environmental decision making by capturing, even if only in a temporal “snapshot,”
8036 the institutional, ethical, economic, scientific, and other constraints and factors that
8037 influence decisions.

8038

8039

8040 **4.5.3 Public Pressures, Social Movements and Innovation**

8041 The extent to which public pressures can compel innovation in decision-support
8042 development and use is an important area of prospective research. As has been discussed
8043 elsewhere in this Product, knowledge networks—which provide linkages between various
8044 individuals and interest groups that allow close, ongoing communication and information
8045 dissemination among multiple sectors of society involved in technological and policy

8046 innovations— can be sources of non-hierarchical movement to impel innovation
8047 (Sarewitz and Pielke, 2007; Jacobs, 2005). Such networks can allow continuous feedback
8048 between academics, scientists, policy-makers, and NGOs in at least two ways: 1) by
8049 cooperating in seeking ways to foster new initiatives, and 2) providing means of
8050 encouraging common evaluative and other assessment criteria to advance the
8051 effectiveness of such initiatives.

8052

8053 Since the late 1980s, there has arisen an extensive collection of local, state (in the case of
8054 the United States) and regional/sub-national climate change-related activities in an array
8055 of developed and developing nations. These activities are wide-ranging and embrace
8056 activities inspired by various policy goals, some of which are only indirectly related to
8057 climate variability. These activities include energy efficiency and conservation programs;
8058 land use and transportation planning; and regional assessment. In some instances, these
8059 activities have been enshrined in the “climate action plans” of so-called Annex I nations
8060 to the UN Framework Convention on Climate Change (UNCED, 1992; Rabe, 2004).

8061

8062 An excellent example of an important network initiative is the International Council of
8063 Local Environmental Initiatives, or ICLEI is a Toronto, Canada-based NGO representing
8064 local governments engaged in sustainable development efforts worldwide. Formed in
8065 1990 at the conclusion of the World Congress of Local Governments involving 160 local
8066 governments, it has completed studies of urban energy use useful for gauging growth in
8067 energy production and consumption in large cities in developing countries (*e.g.*, Kugler,
8068 2007; ICLEI, 2007). ICLEI is helping to provide a framework of cooperation to evaluate

8069 energy, transportation, and related policies and, in the process, may be fostering a form of
8070 “bottom-up” diffusion of innovation processes that function across jurisdictions—and
8071 even entire nation-states (Feldman and Wilt, 1996; 1999). More research is needed on
8072 how,—and how effectively networks actually function and whether their efforts can shed
8073 light on the means by which the diffusion of innovation can be improved and evaluated.

8074

8075 Another source of public pressure is social movements for change—hardly unknown in
8076 water policy (*e.g.*, Donahue and Johnston, 1998). Can public pressures through such
8077 movements actually change the way decision makers look at available sources of
8078 information? Given the anecdotal evidence, much more research is warranted. One of the
8079 most compelling recent accounts of how public pressures can change such perceptions is
8080 that by the historian Norris Hundley on the gradual evolution on the part of city leaders in
8081 Los Angeles, California, as well as members of the public, water agencies, and state and
8082 federal officials—toward diversion of water from the Owens Valley.

8083

8084 After decades of efforts and pressures from interested parties to, at first prevent and then
8085 later, roll back, the amount of water taken from the Owens River, the city of Los Angeles
8086 sought an out-of-court settlement over diversion; in so doing, they were able to study the
8087 reports of environmental degradation caused by the volumes of water transferred, and
8088 question whether to compensate the Valley for associated damages (Hundley, 2001).

8089 While Hundley’s chronicling of resistance has a familiar ring to students of water policy,
8090 remarkably little research has been done to draw lessons using the grounded theory
8091 approach discussed earlier—about the impacts of such social movements.

8092

8093 While uncertainty is an inevitable factor in regards to climate variability and weather
8094 information, the communication of uncertainty—as our discussion has shown—can be
8095 significantly improved. Better understanding of innovative ways to communicate
8096 uncertainty to users should draw on additional literatures from the engineering,
8097 behavioral and social, and natural science communities (*e.g.*, NRC 2005; NRC 2006).
8098 Research efforts are needed by various professional communities involved in the
8099 generation and dissemination of climate information to better establish how to define and
8100 communicate climate variability risks clearly and coherently and in ways that are
8101 meaningful to water managers. Additional research is needed to determine the most
8102 effective communication, dissemination and evaluation tools to deliver information on
8103 potential impacts of climate variability, especially with regards to such factors as further
8104 reducing uncertainties associated with future sea-level rise, more reliable predictions of
8105 changes in frequency and intensity of tropical and extra-tropical storms, and how
8106 saltwater intrusion will impact freshwater resources, and the frequency of drought. Much
8107 can be learned from the growing experience of RISAs and other decision-support
8108 partnerships and networks.

8109

8110 Research on lessons from other resource management sectors on decision-support use
8111 and decision maker/researcher collaboration would be useful. While water issues are
8112 ubiquitous and connect to many other resource areas, a great deal of research has been
8113 done on the impediments to, and opportunities for, collaboration in other resource areas
8114 such as energy, forests, coastal zone and hydropower. This research suggests that there is

8115 much that water managers and those who generate SI information on climate variability
8116 could learn from this literature. Among the questions that need further investigation are
8117 issues surrounding the following subject areas: (1) innovation (Are there resource areas
8118 in which tool development and use is proceeding at a faster pace than in water
8119 management?); (2) organizational culture and leadership (Are some organizations and
8120 agencies more resistant to change, more hierarchical in their decision making, more
8121 formalized in their decisional protocols than is the case in water management?); and (3)
8122 collaborative style (Are some organizations in certain resource areas or science endeavors
8123 better at collaborating with stakeholder groups in the generation of information tools, or
8124 other activities? [*e.g.*, Kaufman, 1967; Bromberg, 2000]). Much can also be learned
8125 about public expectations and the expectations of user groups from their collaborations
8126 with such agencies that could be valuable to the water sector.

8637

8638 **5.1 INTRODUCTION**

8639 The future context for decision support for seasonal to interannual (SI) climate
8640 forecasting-related decisions in water resources and other sectors will evolve in response
8641 to future climate trends and events, advances in monitoring, predicting and
8642 communicating information about hydrologically-significant aspects of climate, and
8643 social action. Climate-related issues have a much higher profile among the public, media,
8644 and policy makers than they did even a few years ago. In water resources and other
8645 sectors, climate is likely to be only one of a number of factors affecting decision making,
8646 and the extent to which it is given priority will depend both on the experiences associated
8647 with “focusing events” such as major droughts, floods, hurricanes and heat waves, and on
8648 how strong knowledge networks have become (Pulwarty and Melis, 2001). The utility of
8649 climate information will depend largely on how salient, credible, valuable and legitimate

8650 it is perceived to be. These qualities are imparted through knowledge networks that can
8651 be fostered and strengthened using decision-support tools. Increasingly, climate
8652 forecasting and data have become integrated with water resources decisions at multiple
8653 levels, and some of the lessons learned in the water sector can improve the application of
8654 SI climate forecasts in other climate sensitive sectors. Better integration of climate
8655 forecasting science into water resources and other sectors will likely save and improve
8656 lives, reduce damages from weather extremes, and lower economic cost related to
8657 adapting to continued climate variability.

8658

8659 Section 5.2 of this Chapter highlights a number of overarching themes that need to be
8660 emphasized as important to understanding the overall challenges facing decision support
8661 and its use. Section 5.3 addresses research priorities that are critical to progress. Section
8662 5.4 discusses other sectors that are likely to be affected by climate variation that could
8663 profit from lessons in the water resources sector.

8664

8665 **5.2 OVERARCHING THEMES AND FINDINGS**

8666 **5.2.1 The “Loading Dock Model” of Information Transfer is Unworkable**

8667 Only recently have climate scientists come to realize that improving the skill and
8668 accuracy of climate forecasting products does not necessarily make them more useful or
8669 more likely to be adopted (*e.g.*, see Chapter 2, Box 2.4). Skill is a necessary ingredient in
8670 perceived forecast value, yet more forecast skill by itself does not imply more forecast
8671 value. Lack of forecast skill and/or accuracy may be one of the impediments to forecast
8672 use, but there are many other barriers to be overcome. Better technical skill must be

8673 accompanied by better communication and stronger linkages between forecasters and
8674 potential users. In this Product, we have stressed that forecasts flow through knowledge
8675 networks and across disciplinary and occupational boundaries. Thus, forecasts need to
8676 support a range of activities including research and applications, and be “end-to-end
8677 useful.” End-to-end useful implies a broad fabric of utility, created by multiple entities
8678 that adopt forecasts for their own reasons and adapt them to their own purposes by
8679 blending forecast knowledge with local know-how, practices, and other sources of
8680 information more familiar to those participants. These network participants then pass the
8681 blended information to other participants who, in turn, engage in the same process. By
8682 the end of the process of transfer, translation and transformation of information, forecast
8683 information may look very different from what scientists initially envisioned.

8684

8685 Skill and accuracy are only two of the values important to the use of climate knowledge;
8686 others might include relevance, timeliness, and credibility. Using climate information and
8687 decision tools can have obvious economic benefits, and these advantages can extend into
8688 the political, organizational, and professional realms as well. Salience is a product of
8689 framing in the larger political community and the professional circles in which different
8690 decision makers travel. Novel ideas are difficult for organizations to adopt, and therefore,
8691 such ideas become more credible if they are consistent with, and tempered by, already
8692 existing information channels and organizational routines.

8693

8694 **5.2.2 Decision Support is a Process Rather Than a Product**

8695 As knowledge systems have become better understood, providing decision support has
8696 evolved into a communications process that links scientists with users rather than a one-
8697 time exchange of information products. While decision tools such as models, scenarios,
8698 and other boundary objects that connect scientific forecasters to various stakeholder
8699 groups can be helpful, the notion of tools insufficiently conveys the relational aspects of
8700 networks. Relevance, credibility, and legitimacy are human perceptions built through
8701 repeated interactions. For this reason, decision support does not result in a product that
8702 can be shelved until needed or reproduced for different audiences. Clearly, lessons from
8703 decision-support experience are portable from one area to another but only as the
8704 differences in context are interpreted, understood, and taken into account.

8705

8706 Governments are not the only producers of climate variability forecasts. Non-
8707 governmental actors, including private businesses, play a critical role in knowledge
8708 networks, particularly in tailoring climate forecast products to fit the needs of particular
8709 sectors and user groups. Nothing in this Product should suggest that knowledge networks
8710 must be wholly or even primarily developed in the public sector. Just as numerous
8711 entrepreneurs have taken National Weather Service forecasts and applied them to
8712 different sectors and user-group needs, SI climate information transfer, translation and
8713 transformation may become functions largely provided by the private sector. However, as
8714 argued in the following section, there is clearly a role for the public sector because
8715 information access is related to economic and social outcomes that must be
8716 acknowledged.

8717

8718 Ensuring that information is accessible and relevant will require paying greater attention
8719 to the role of institutions in furthering the process of decision support; particularly
8720 *boundary spanning* activities that bring together tool developers and users to exchange
8721 information, promote communication, propose remedies to problems, foster stakeholder
8722 engagement, and conjointly develop decision-support systems to address user needs. An
8723 important facet of boundary spanning is that the exchange (including co-production,
8724 transference, communication and dissemination) of climate information to water decision
8725 makers requires partnerships among public and private sector entities. In short, to avoid
8726 the loading-dock model previously discussed, efforts to further boundary-spanning
8727 partnerships is essential to fostering a process of decision support (NRC, 2007; Cash and
8728 Buizer, 2005; Sarewitz and Pielke, 2007).

8729

8730 **5.2.3 Equity May Not Be Served**

8731 Information is power in global society and, unless it is widely shared, the gaps between
8732 the advantaged and the disadvantaged may widen. Lack of resources is one of the causes
8733 of poverty, and resources are required to tap into knowledge networks. Unequal
8734 distribution of knowledge can insulate decision making, facilitate elite capture of
8735 resources, and alienate disenfranchised groups. In contrast, an approach that is open,
8736 interactive and inclusive can go a long way in supporting informed decisions that, in turn,
8737 can yield better outcomes from the perspective of fairness.

8738

8739 While United Nations Millennium Development Goals attract attention to equity in poor
8740 countries, the unequal availability of and access to knowledge and technology, including

8741 SI forecast products, exacerbates inequalities within the United States. The case of
8742 agriculture is especially important because of the high impacts the agricultural sector has
8743 upon the long-term quality of the general environment. The dust bowl of the 1930s and
8744 its broad national impact stand as a reminder of the consequences of poorly informed and
8745 unsustainable practices. Avoiding repetition of such top soil losses, desertification
8746 increases, and social dislocations is more likely if early warning of variations in seasonal
8747 precipitation and runoff are available, trusted, and credible. To build and maintain
8748 networks in the agricultural sector, particularly among smaller, less-advantaged farmers
8749 will require greater efforts (Wiener, 2007).

8750

8751 The emergence of seasonal climate forecasting initially raised great expectations of its
8752 potential role to decrease the vulnerability of poor farmers around the world to climate
8753 variability and the development and dissemination of forecasts have been justified in
8754 equity terms (Glantz, 1996; McPhaden *et al.*, 2006). However, ten years of empirical
8755 research on seasonal forecasting application and effect on agriculture, disaster response
8756 and water management have tempered these expectations (Klopper, 1999; Vogel, 2000;
8757 Valdivia *et al.*, 2000; Letson *et al.*, 2001; Hammer *et al.*, 2001; Lemos *et al.*, 2002; Patt
8758 and Gwata, 2002; Broad *et al.*, 2002; Archer, 2003; Lusenso *et al.*, 2003; Roncoli *et al.*,
8759 2006; Bharwani *et al.*, 2005; Meinke *et al.*, 2006; Klopper *et al.*, 2006). Examples of SI
8760 climate forecast applications show that not only are the most vulnerable often unable to
8761 benefit, but in some situations may even be harmed (Broad *et al.*, 2002; Lemos *et al.*,
8762 2002; Patt and Gwata, 2002; Roncoli *et al.*, 2004). However, some users have been able
8763 to benefit significantly from this new information. For example, many Pacific island

8764 nations respond to El Niño forecasts and avoid potential disasters from water shortages.
8765 Similarly, agricultural producers in Australia have been better able to cope with swings in
8766 their commodity production associated with drought and water managers. In the
8767 Southwest United States, managers have been able to incorporate SI climate forecasts
8768 into their decision-making processes in order to respond to crises—and this is also
8769 beginning to occur in more water-rich regions such as the Southeast United States that are
8770 currently facing prolonged drought (Hammer *et al.*, 2001; Hartmann *et al.*, 2002; Pagano
8771 *et al.*, 2002; Georgia DNR, 2003). But, unless greater effort is expended to rectify the
8772 differential impacts of climate information in contexts where the poor lack resources, SI
8773 climate forecasts will not contribute to global equity.

8774

8775 There are several factors that help to explain when and where equity goals are served in
8776 SI climate forecasting and when they are not (Lemos and Dilling, 2007). Understanding
8777 existing levels of underlying inequities and differential vulnerabilities is critical
8778 (Agrawala *et al.*, 2001). Forecasts are useful only when recipients of information have
8779 sufficient decision space or options to be able to respond to lower vulnerability and risk.
8780 Differential levels in the ability to respond can create winners and losers within the same
8781 policy context. For example, in Zimbabwe and northeastern Brazil, news of poor rainfall
8782 forecasts for the planting season influence bank managers who systematically deny
8783 credit, especially to poor farmers they perceive as high risk (Hammer *et al.*, 2001; Lemos
8784 *et al.*, 2002). In Peru, a forecast of El Niño and the prospect of a weak season gives
8785 fishing companies incentives to accelerate seasonal layoffs of workers (Broad *et al.*,
8786 2002). Some users (bankers, businesses) who were able to act based on forecasted

8787 outcomes (positive or negative) benefited while those who could not (farmers,
8788 fishermen), were harmed. Financial, social and human resources to engage forecast
8789 producers are often out of reach of the poor (Lemos and Dilling, 2007). Even when the
8790 information is available, differences in resources, social status, and empowerment limit
8791 hazard management options. As demonstrated by Hurricane Katrina, for example, the
8792 poor and minorities were reluctant to leave their homes for fear of becoming victims of
8793 crime and looting, and were simply not welcome as immigrants fleeing from disaster
8794 (Hartmann *et al.*, 2002; Carbone and Dow, 2005; Subcommittee on Disaster Reduction,
8795 2005; Leatherman and White, 2005).

8796

8797 Native American farmers who are unable to move their farming enterprises as do
8798 agribusinesses, and cannot lease their water rights strategically to avoid planting during
8799 droughts, are disadvantaged because of their small decision space or lack of alternatives.
8800 Moreover, poorer groups often distrust experts who are in possession of risk information
8801 because the latter are often viewed as elitist; focused more on probabilities rather than on
8802 the consequences of disaster; or unable to communicate in terms comprehensible to the
8803 average person (Jasanoff, 1987; Covello *et al.*, 1990). However, other research has found
8804 that resources, while desirable, are not an absolute constraint to poor people's ability to
8805 benefit from seasonal forecast use. In these cases, farmers have been able to successfully
8806 use seasonal climate forecasts by making small adjustments to their decision-making
8807 process (Eakin, 2000; Patt *et al.*, 2005; Roncoli *et al.*, 2006).

8808

8809 A more positive future in terms of redressing inequity and reducing poverty can take
8810 place if application policies and programs create alternative types of resources, such as
8811 sustained relationships with information providers and web-based tools that can be easily
8812 tailored to specific applications; promotion of inclusionary dissemination practices; and
8813 paying attention to the context of information applications (Valdivia *et al.*, 2000; Archer,
8814 2003; Ziervogel and Calder, 2003; Roncoli *et al.*, 2006). Examples in the literature show
8815 that those who benefit from SI climate forecasts usually have the means to attend
8816 meetings or to access information through the media (at least through the radio). For
8817 example, small farmers in Tamil Nadu, India (Huda *et al.*, 2004) and Zimbabwe (Patt and
8818 Gwata, 2002) benefited from climate information through a close relationship with
8819 forecast “brokers”²⁴ who spent considerable effort in sustaining communication and
8820 providing expert knowledge to farmers. However, the number of farmers targeted in these
8821 projects was very limited. For any real impact, such efforts will need to be scaled up and
8822 sustained beyond research projects.

8823

8824 Equitable communication and access are critical to fairness with respect to potential
8825 benefit from forecast information, but such qualities often do not exist. Factors such as
8826 levels of education, access to electronic media such as the Internet, and expert knowledge
8827 critically affect the ability of different groups to take advantage of seasonal forecasts
8828 (Lemos and Dilling, 2007). While the adoption of participatory processes of
8829 communication and dissemination can defray some of these constraints, the number of
8830 positive cases documented is small (*e.g.*, Patt *et al.*, 2005; Roncoli *et al.*, 2006; O’Brien

²⁴ Researchers in the India case and researchers and extension agents in the Zimbabwe case.

8831 and Vogel, 2003). Also, because forecasts are mostly disseminated in the language of
8832 probabilities, they may be difficult to assimilate by those who do not generally think
8833 probabilistically nor interpret probabilities easily, or those whose framing of
8834 environmental issues is formed through experience with extreme events (Nicholls, 1999;
8835 Yarnal *et al.*, 2006; Dow *et al.*, 2007; Weingert *et al.*, 2000). In a situation where private
8836 enterprise is important for participants in knowledge networks, serving the poor may not
8837 be profitable, and for that reason they become marginalized.

8838

8839 Fostering inclusive, equitable access, therefore, will require a combination of
8840 organizational practices that empower employees, and engage agency clients, outside
8841 stakeholder groups, and the general public through providing training and outreach in
8842 tool use, and the infusion of trust in communication of risks. The latter will require use of
8843 public forums and other vehicles that provide opportunities for open, clear, jargon-free
8844 information as well as opportunity for discussion and public reaction (Freudenburg and
8845 Rursch, 1994; Papadakis, 1996; Jasanoff, 1987; Covello *et al.*, 1990; NRC, 1989). If
8846 climate science applications are to more clearly put vulnerable poor people on an equal
8847 footing or to go further toward reducing inequality, decision support must target the
8848 vulnerable poor specifically. Specific training and a concerted effort to “fit” the available
8849 information to local decision-making patterns and culture can be a first step to enhance its
8850 relevance. Seasonal forecast producers and policy makers need to be aware of the broader
8851 sociopolitical context and the institutional opportunities and constraints presented by
8852 seasonal forecast use and understand potential users and their decision environment. A
8853 better fit between product and client can avoid situations in which forecast use may harm

8854 those it could help. Finally, as some of the most successful examples show, seasonal
8855 forecasting applications should strive to be more transparent, inclusionary, and interactive
8856 as a means to counter power imbalances.

8857

8858 **5.2.4 Science Citizenship Plays an Important Role in Developing Appropriate**

8859 **Solutions**

8860 Some scholars observe that a new paradigm in science is emerging, one that emphasizes
8861 science-society collaboration and production of knowledge tailored more closely to
8862 society's decision-making needs (Gibbons, 1999; Nowotny *et al.*, 2001; Jasanoff, 2004a).
8863 The philosophy is that, through mobilizing both academic and pragmatic knowledge and
8864 experience, better solutions may be produced for pressing problems. Concerns about
8865 climate impacts on water resource management are among the most pressing problems
8866 that require close collaboration between scientists and decision makers. Examples of
8867 projects that are actively pursuing collaborative science to address climate-related water
8868 resource problems include the Sustainability of Semi-Arid Hydrology and Riparian Area
8869 (SAHRA) project <<http://www.sahra.arizona.edu>>, funded by the National Science
8870 Foundation (NSF) and located at the University of Arizona and the NSF-funded Decision
8871 Center for a Desert City, located at Arizona State University <<http://dcdc.asu.edu>>. The
8872 regional focus of NOAA's Regional Integrated Sciences and Assessments (RISA)
8873 program is likewise providing opportunities for collaborations between scientists and
8874 citizens to address climate impacts and information needs in different sectors, including
8875 water resource management. An examination of the Climate Assessment for the
8876 Southwest (CLIMAS), one of the RISA projects, provided insight into some of the ways

8877 in which co-production of science and policy is being pursued in a structured research
8878 setting (Lemos and Morehouse, 2005).

8879

8880 Collaborative efforts to produce knowledge for policy applications not only expand the
8881 envelope of the scientific enterprise, but also change the terms of the relationship
8882 between scientists and citizens. This emergence of new forms of science/society
8883 interactions has been documented from various perspectives, including the place of local,
8884 counter-scientific, and non-scientific knowledge (Eden, 1996; Fischer, 2000), links with
8885 democracy and democratic ideals (Jasanoff, 1996; Harding, 2000; Durodié, 2003), and
8886 environmental governance and decision making (Jasanoff and Wynne, 1998; Bäckstrand,
8887 2003; Brunner *et al.*, 2005). These types of collaboration present opportunities to bridge
8888 the gaps between abstract scientific conceptualizations and knowledge needs generated
8889 by a grounded understanding of the nature and intensity of actual and potential risks, and
8890 the specific vulnerabilities experienced by different populations at different times and in
8891 different places. As we are coming to understand, seasonal and interannual variations of
8892 past climate may be misleading about future variation, and a heightened awareness and
8893 increased observation on the part of citizens in particular contexts is warranted.

8894 Moreover, engaged citizens may well come to think more deeply about the longer-term
8895 environmental impacts of both human activities and the variable climate.

8896

8897 Unlike the more traditional “pipeline” structure of knowledge transfer uni-directionally
8898 from scientists to citizens, multi-directional processes involving coproduction of science
8899 and policy may take a more circuitous form, one that requires experimentation and

8900 iteration (Lemos and Morehouse, 2005; Jasanoff and Wynne, 1998). This model of
8901 science-society interaction has a close affinity to concepts of adaptive management and
8902 adaptive governance (Pulwarty and Melis, 2001; Gunderson, 1999; Holling, 1978;
8903 Brunner *et al.*, 2005), for both of these concepts are founded on notions that institutional
8904 and organizational learning can be facilitated through careful experimentation with
8905 different decision and policy options. Such experimentation is ideally based on best
8906 available knowledge but allows for changes based on lessons learned, emergence of new
8907 knowledge, and/or changing conditions in the physical or social realms. The experiments
8908 described in this Product offer examples of adaptive management and adaptive
8909 governance in practice.

8910

8911 Less extensively documented, but no less essential to bringing science to bear effectively
8912 on climate-related water resource management challenges is the notion of science
8913 citizenship (Jasanoff, 2004b), whereby the fruits of collaboration between scientists and
8914 citizens produces capacity to bring science-informed knowledge into processes of
8915 democratic deliberation, including network building, participation in policy-making,
8916 influencing policy interpretation and implementation processes, and even voting in
8917 elections. Science citizenship might, for example, involve participating in deliberations
8918 about how best to avert or mitigate the impacts of climate variability and change on
8919 populations, economic sectors, and natural systems vulnerable to reduced access to water.
8920 Indeed, water is fundamental to life and livelihood, and, as noted above, climate impacts
8921 research has revealed that deleterious effects of water shortages are unequally
8922 experienced; poorer and more marginalized segments of populations often suffer the most

8923 (Lemos, 2008). Innovative drought planning processes require precisely these kinds of
8924 input, as does planning for long-term reductions in water availability due to reduced
8925 snowpack. Issues such as these require substantial evaluation of how alternative solutions
8926 are likely to affect different entities at different times and in different places. For
8927 example, substantial reduction in snowpack, together with earlier snowmelt and longer
8928 periods before the onset of the following winter, will likely require serious examination
8929 of social values and practices as well as of economic activities throughout a given
8930 watershed and water delivery area. As these examples demonstrate, science citizenship
8931 clearly has a crucial role to play in building bridges between science and societal values
8932 in water resource management. It is likely that this will occur primarily through the types
8933 of knowledge networks and knowledge-to-action networks discussed earlier in this
8934 Chapter.

8935

8936 **5.2.5 Trends and Reforms in Water Resources Provide New Perspectives**

8937 As noted in Chapters 1 and 4, since the 1980s a “new paradigm” or frame for federal
8938 water planning has developed that appears to reflect the ascendancy of an environmental
8939 protection ethic among the general public. The new paradigm emphasizes greater
8940 stakeholder participation in decision making; explicit commitment to environmentally-
8941 sound, socially-just outcomes; greater reliance upon drainage basins as planning units;
8942 program management via spatial and managerial flexibility, collaboration, participation,
8943 and sound, peer-reviewed science; and an embrace of ecological, economic, and equity
8944 considerations (Hartig *et al.*, 1992; Landre and Knuth, 1993; Cortner and Moote, 1994;

8945 Water in the West, 1998; McGinnis, 1995; Miller *et. al.*, 1996; Cody, 1999; Bormann *et*
8946 *al.*, 1994; Lee, 1993).

8947

8948 This “adaptive management” paradigm results in a number of climate-related SI climate
8949 information needs, including questions pertaining to the following: what are the
8950 decision-support needs related to managing in-stream flows/low flows? and, what
8951 changes to water quality, runoff and streamflow will occur in the future, and how will
8952 these changes affect water uses among future generations unable to influence the current
8953 causes of these changes? The most dramatic change in decision support that emerges
8954 from the adaptive management paradigm is the need for real-time monitoring and
8955 ongoing assessment of the effectiveness of management practices, and the possibility that
8956 outcomes recommended by decision-support tools be iterative, incremental and reversible
8957 if they prove unresponsive to critical groups, ineffective in managing problems, or both.
8958 What makes these questions particularly challenging is that they are interdisciplinary in
8959 nature²⁵.

8960

8961 Because so many of the actions necessary to implement either adaptive management or
8962 integrated water resources management rest with private actors who own either land or
8963 property rights, the importance of public involvement can not be overemphasized. At the

²⁵ Underscored by the fact that scholars concur adaptive management entails a broad range of processes to avoid environmental harm by imposing modest changes on the environment, acknowledging uncertainties in predicting impacts of human activities on natural processes, and embracing social learning (*i.e.*, learning by experiment). In general, it is characterized by four major strategies: (1) managing resources by learning, especially about mistakes, in an effort to make policy improvements, (2) modifying policies in the light of experience—and permitting such modifications to be introduced in “mid-course”, (3) allowing revelation of critical knowledge heretofore missing, as feedback to improve decisions, and (4) incorporating outcomes in future decisions through a consensus-based approach that allows government agencies and non-governmental organizations (NGOs) to conjointly agree on solutions (Bormann *et. al.*, 1993; Lee, 1993; Definitions of Adaptive Management, 2000).

8964 same time, the difficulties of implementing these new paradigm approaches should not be
8965 overlooked. The fragmented patchwork of jurisdictions involved and the inflexibility of
8966 laws and other institutions present formidable obstacles that will require both greater
8967 efforts and investments if they are to be overcome.

8968

8969 Another significant innovation in U.S. water resources management that affects climate
8970 information use is occurring in the *local* water supply sector, as discussed in Chapter 4,
8971 the growing use of integrated water resource planning (or IWRP) as an alternative to
8972 conventional supply-side approaches for meeting future demands. IWRP is gaining
8973 acceptance in chronically water-short regions such as the Southwest and portions of the
8974 Midwest—including Southern California, Kansas, Southern Nevada, and New Mexico
8975 (Beecher, 1995; Warren *et al.*, 1995; Fiske and Dong, 1995; Wade, 2001). IWRP
8976 supports the use of multiple sources of water integration of quality and quantity issues
8977 and information like that of SI climate and water supply forecasts as well as feedback
8978 from experience and experiments.

8979

8980 IWRP's goal is to "balance water supply and demand management considerations by
8981 identifying feasible planning alternatives that meet the test of least cost without
8982 sacrificing other policy goals (Beecher, 1995)." This can be variously achieved through
8983 depleted aquifer recharge, seasonal groundwater recharge, conservation incentives,
8984 adopting growth management strategies, wastewater reuse, and applying least-cost
8985 planning principles to large investor-owned water utilities. The latter may encourage
8986 IWRP by demonstrating the relative efficiency of efforts to reduce demand as opposed to

8987 building more supply infrastructure. A particularly challenging alternative is the need to
8988 enhance regional planning among water utilities in order to capitalize on the resources of
8989 every water user, eliminate unnecessary duplication of effort, and avoid the cost of
8990 building new facilities for water supply (Atwater and Blomquist, 2002).

8991

8992 In some cases, short term least cost planning may *increase* long-term project costs,
8993 especially when environmental impacts, resource depletion, and energy and maintenance
8994 costs are included. The significance of least-cost planning is that it underscores the
8995 importance of long- and short-term costs (in this case, of water) as an influence on the
8996 value of certain kinds of information for decisions. The most dramatic change in decision
8997 support that emerges from the adaptive management paradigm is the need for real-time
8998 monitoring and ongoing assessment of the effectiveness of management practices, and
8999 the possibility that outcomes recommended by decision-support tools be iterative,
9000 incremental and reversible if they prove unresponsive to critical groups, ineffective in
9001 managing problems, or both. Models and forecasts that predict water availability under
9002 different climate scenarios can be especially useful to least-cost planning and make more
9003 credible efforts to reducing demand. Specific questions IWRP raises for decision-
9004 support-generated climate information include: how precise must climate information be
9005 to enhance long-term planning? How might predicted climate change provide an
9006 incentive for IWRP strategies? And, what climate information is needed to optimize
9007 decisions on water pricing, re-use, shifting from surface to groundwater use, and
9008 conservation?

9009

9010 **5.2.6 Useful Evaluation of Applications of Climate Variation Forecasts Requires**
9011 **Innovative Approaches**

9012 There can be little argument that SI climate and hydrologic forecast applications must be
9013 evaluated just as are most other programs that involve substantial public expenditures.
9014 This Product has evidenced many of the difficulties in using standard evaluation
9015 techniques. While there have been some program evaluations, mostly from the vantage
9016 point of assessing the influence of RISAs on federal climate science policy (*e.g.*, McNie
9017 *et al.*, 2007; Cash *et al.*, 2006), there has been little formal, systematic, standardized
9018 evaluation as to whether seasonal to interannual climate and hydrologic forecast
9019 applications are optimally designed to learn from experience and incorporate user
9020 feedback. Evaluation works best on programs with a substantial history so that it is
9021 possible to compare present conditions with those that existed some years ago. The effort
9022 to promote the use of SI climate forecasts is relatively new and has been a moving target,
9023 with new elements being regularly introduced, making it difficult to determine what
9024 features of those federal programs charged with collaborating with decision makers in the
9025 development, use, application, and evaluation of climate forecasts have which
9026 consequences. As the effort to promote greater use of SI climate and hydrologic forecasts
9027 accelerates in the future, it is important to foster developments that facilitate evaluation.
9028 It is imperative that those promoting forecast use have a clear implementation chain with
9029 credible rationales or incentives for participants to take desired actions. Setting clear
9030 goals and priorities for allocation of resources among different elements is essential to
9031 any evaluation of program accomplishments (NRC, 2007). It is especially difficult to
9032 measure the accomplishment of some types of goals that are important to adaptive

9033 management, such as organizational learning. For this reason, we believe that consistent
9034 monitoring and regular evaluation of processes and tools at different time and spatial
9035 scales will be required in order to assess progress.

9036

9037 An NRC panel addressing a closely related challenge for standard evaluation
9038 recommended that the need for evaluation should be addressed primarily through
9039 monitoring (NRC, 2007). The language of that report seems entirely applicable here:

9040 Monitoring requires the identification of process measures that
9041 could be recorded on a regular (for instance, annual) basis and of
9042 useful output or outcome measures that are plausibly related to the
9043 eventual effects of interest and can be feasibly and reliably
9044 recorded on a similar regular basis. Over time, the metrics can be
9045 refined and improved on the basis of research, although it is
9046 important to maintain some consistency over extended periods
9047 with regard to at least some of the key metrics that are developed
9048 and used.

9049

9050 There are signals of network building and collaborative forecaster/user interaction and
9051 collaboration that can be monitored. Meetings and workshops held, new contacts made,
9052 new organizations involved in information diffusion, websites, list serves, newsletters
9053 and reports targeted to new audiences are but a few of the many activities that are
9054 indicative of network creation activity.

9055

9056 **5.3 RESEARCH PRIORITIES**

9057 As a result of the findings in this Product, we suggest that a number of research priorities
9058 should constitute the focus of attention for the foreseeable future: (1) improved
9059 vulnerability assessment, (2) improved climate and hydrologic forecasts, (3) enhanced
9060 monitoring and modeling to better link climate and hydrologic forecasts, (4)

9061 identification of pathways for better integration of SI climate science into decision
9062 making, (5) better balance between physical science and social science research related to
9063 the use of scientific information in decision making, (6) better understanding and support
9064 for small-scale, specially-tailored tools, and (7) significant funding for sustained long-
9065 term scientist/decision-maker interactions and collaborations. The following discussion
9066 identifies each priority in detail, and recommends ways to implement them.

9067

9068 **5.3.1 A Better Understanding of Vulnerability is Essential**

9069 Case studies of the use of decision-support tools in water resources planning and
9070 management suggest that the research and policy-making communities need a far more
9071 comprehensive picture of the vulnerability of water and related resources to climate
9072 variability. This assessment must account for vulnerability along several dimensions.

9073

9074 As we have seen, there are many forms of climate vulnerability—ranging from social and
9075 physical vulnerability to ecological fragmentation, economic dislocation, and even
9076 organizational change and turmoil. Vulnerability may also range across numerous
9077 temporal and spatial scales. Spatially, it can affect highly localized resources or spread
9078 over large regions. Temporally, vulnerability can be manifested as an extreme and/or
9079 rapid onset problem that lasts briefly, but imposes considerable impact on society (*e.g.*,
9080 intense tropical storms) or as a prolonged or slow-onset event, such as drought, which
9081 may produce numerous impacts for longer time periods.

9082

9083 In order to encompass these widely varying dimensions of vulnerability, we also need
9084 more research on how decision makers perceive the risks from climate variability and,
9085 thus, what variables incline them to respond proactively to threats and potential hazards.
9086 As in so many other aspects of decision-support information use, previous research
9087 indicates that merely delivering weather and climate information to potential users may
9088 be insufficient in those cases in which the manager does not perceive climate variability
9089 to be a hazard—for example, in humid, water rich regions of the United States that we
9090 have studied (Yarnal *et al.*, 2006; Dow *et al.*, 2007). Are there institutional incentives to
9091 using risk information, or—conversely—not using it? In what decisional contexts (*e.g.*,
9092 protracted drought, sudden onset flooding hazards) are water managers most likely—or
9093 least likely—to be susceptible to employing climate variability hazard potential
9094 information?

9095

9096 More research is needed on the relationship of perceived vulnerability and the credibility
9097 of different sources of information including disinformation. What is the relationship of
9098 sources of funding, and locus of researchers such as government or private enterprise,
9099 and discounting of information?

9100

9101 **5.3.2 Improving Hydrologic and Climate Forecasts**

9102 Within the hydrologic systems, accurate measures and assimilation of the initial state are
9103 crucial for making skillful hydrologic forecasts; therefore, a sustained high-quality
9104 monitoring system tracking stream flow, soil moisture, snowpack, and evaporation,
9105 together with tools for real-time data assimilation, are fundamental to the hydrologic

9106 forecasting effort. In addition, watersheds with sparse monitoring networks, or relatively
9107 short historical data series, are also prone to large forecast errors due to a lack of
9108 historical and real-time data and information about its hydrologic state.

9109

9110 Monitoring and assimilation are also essential for climate forecasting, as well as exercises
9111 of hindcasting to compare present experience with the historical record. Moreover,
9112 monitoring is critical for adaptive and integrated water resources management, and for
9113 the more effective adoption of strategies currently widely embraced by natural resources
9114 planners and managers.

9115

9116 On-going improvements in the skill of climate forecasting will continue to provide
9117 another important avenue for improving the skill in SI hydrologic and water supply
9118 forecasts. For many river basins and in many seasons, the single greatest source of
9119 hydrologic forecast error is unknown precipitation after the forecast issue date. Thus,
9120 improvements in hydrologic forecasting are directly linked with improvements in
9121 forecasts for precipitation and temperature.

9122

9123 In addition, support for coordinated efforts to standardize and quantify the skill in
9124 hydrologic forecasts is needed. While there is a strong culture and tradition of forecast
9125 evaluation in meteorology and climatology, this sort of retrospective analysis of the skill
9126 of seasonal hydrologic forecasts has historically not been commonly disseminated.
9127 Hydrologic forecasts have historically tended to be more often deterministic than
9128 probabilistic with products focused on water supplies (*e.g.*, stream flow, reservoir

9129 inflows). In operational settings, seasonal hydrologic forecasts have generally been taken
9130 with a grain of salt, in part because of limited quantitative assurance of how accurate they
9131 can be expected to be. In contrast, operational climate forecasts and many of today's
9132 experimental and newer operational hydrologic forecasts are probabilistic, and contain
9133 quantitative estimates for the forecast uncertainty.

9134

9135 New efforts are needed to extend "forecasts of opportunity" beyond those years when
9136 anomalous El Niño-Southern Oscillation (ENSO) conditions are underway. At present,
9137 the skill available from combining SI climate forecasts with hydrologic models is limited
9138 when all years are considered, but can provide useful guidance in years having
9139 anomalous ENSO conditions. During years with substantial ENSO effects, the climate
9140 forecasts have high enough skill for temperatures, and mixed skill for precipitation, so
9141 that hydrologic forecasts for some seasons and some basins provide measurable
9142 improvements over approaches that do not take advantage of ENSO information. In
9143 contrast, in years where the state of ENSO is near neutral, most of the skill in U.S.
9144 climate forecasts is due to decadal temperature trends, and this situation leads to
9145 substantially more limited skill in hydrologic forecasts. In order to improve this situation,
9146 additional sources of climate and hydrologic predictability must be exploited; these
9147 sources likely include other patterns of ocean temperature change, sea ice, land cover,
9148 and soil moisture conditions.

9149

9150 Linkages between climate and hydrologic scientists are getting stronger as they
9151 collaboratively create forecast products. A great many complex factors influence the rate

9152 at which seasonal water supply forecasts and climate forecast-driven hydrologic forecasts
9153 are improving in terms of skill level. Mismatches between needs and information
9154 resources continue to occur at multiple levels and scales. There is currently substantial
9155 tension between providing tools at the space and time scales useful for water resources
9156 decisions and ensuring that they are also scientifically defensible, accurate, reliable, and
9157 timely. Further research is needed to identify ways to resolve this tension.

9158

9159 **5.3.3 Better Integration of Climate Information into Decision Making**

9160 It cannot be expected that information that promises to lower costs or improve benefits
9161 for organizations or groups will simply be incorporated into decisions. Scholarly research
9162 on collaboration among organizations indicates that straightforward models of
9163 information transfer are not operative in situations where a common language between
9164 organizations has not been adopted, or more challenging, when organizations must
9165 transform their own perspectives and information channels to adjust to new information.
9166 It is often the case that organizations are path dependent, and will continue with decision
9167 routines even when they are suboptimal. The many case examples provided in this
9168 Product indicate the importance of framing issues; framing climate dependent natural
9169 resources issues that emphasize the sources of uncertainty and variability of climate and
9170 the need for adaptive action helps in integrating forecasting information. What is needed
9171 are not more case studies, however, but better case investigations employing grounded
9172 theory approaches to discerning general characteristics of decision-making contexts and
9173 their factors that impede, or provide better opportunities for collaboration with scientists
9174 and other tool developers. The construction of knowledge networks in which information

9175 is viewed as relevant, credible, and trusted is essential, and much can be learned from
9176 emerging experiences in climate-information networks being formed among local
9177 governments, environmental organizations, scientists, and others worldwide to exchange
9178 information and experiences, influence national policy-making agendas, and leverage
9179 international organization resources on climate variability and water resources—as well
9180 as other resource—vulnerability.

9181

9182 Potential barriers to information use that must be further explored include: the cultural
9183 and organizational context and circumstances of scientists and decision makers; the
9184 decision space allowed to decision makers and their real range of choice; opportunities to
9185 develop—and capacity to exercise—science citizenship; impediments to innovation
9186 within institutions; and solutions to information overload and the numerous conflicting
9187 sources of already available information. As our case studies have shown, there is often a
9188 relatively narrow range of realistic options open to decision makers given their roles,
9189 responsibilities, and the expectations placed upon them.

9190

9191 There are also vast differences in water laws and state-level scientific and regulatory
9192 institutions designed to manage aquifers and stream-flows in the United States and
9193 information can be both transparent and yet opaque simultaneously. While scientific
9194 products can be precise, accurate, and lucid, they may still be inaccessible to those who
9195 most need them because of proprietary issues restricting access except to those who can
9196 pay, or due to agency size or resource base. Larger agencies and organizations, and
9197 wealthier users, can better access information in part because scientific information that

9198 is restricted in its dissemination tends to drive up information costs (Pfaff *et al.*, 1999;
9199 Broad and Agrawalla, 2000; Broad *et al.*, 2002; Hartmann, 2001). Access and equity
9200 issues also need to be explored in more detail. Every facet of tool use juncture needs to be
9201 explored.

9202

9203 Priority in research should be toward focused, solution-oriented, interdisciplinary projects
9204 that involve sufficient numbers and varieties of kinds of knowledge. To this end,
9205 NOAA's Sectoral Applications Research Program is designed to support these types of
9206 interactions between research and development of decision-support tools. Although this
9207 program is small, it is vital for providing knowledge on impacts, adaptation, and
9208 vulnerability and should be supported especially as federal agencies are contemplating a
9209 larger role in adaptation and vulnerability assessments and in light of pending legislation
9210 by Congress.

9211

9212 Regional Integrated Science Assessments are regarded as a successful model of effective
9213 knowledge-to-action networks because they have developed interdisciplinary teams of
9214 scientists working as (and/or between) forecasts producers while being actively engaged
9215 with resource managers. The RISAs have been proposed as a potentially important
9216 component of a National Climate Service (NCS), wherein the NCS engages in
9217 observations, modeling, and research nested in global, national, and regional scales with a
9218 user-centric orientation (Figure 1 of Miles *et al.*, 2006). The potential for further
9219 development of the RISAs and other boundary spanning organizations that facilitate
9220 knowledge-to-action networks deserves study. Further, as they are the most successful

9221 long-term effort by the federal government to integrate climate science in sectors and
9222 regions across the United States, they merit expanded financial and institutional support.

9223

9224 **5.3.4 Better Balance Between Physical Science and Social Science**

9225 Throughout this Product, the absence of systematic research on applications of climate
9226 variation forecasting information has required analysis to be based on numerous case
9227 study materials often written for a different purpose, upon the accumulated knowledge
9228 and wisdom of authors, and logical inference. The dearth of hard data in this area attests
9229 to the very small research effort afforded the study of use-inspired social science
9230 questions. Five years ago a social science review panel recommended that NOAA should
9231 readjust its research priorities by additional investment in a wide variety of use-inspired
9232 social science projects (Anderson *et al.*, 2003). What was once the Human Dimensions of
9233 Climate Change Program within NOAA now exists only in the Sectoral Applications
9234 Research Program, an important and worthy endeavor, but one whose small staff and
9235 budget can hardly address these important research needs. Managers whose
9236 responsibilities may be affected by climate variability need detailed understanding of
9237 relevant social, economic, organizational and behavioral systems—as well as the ethical
9238 dilemmas faced in using, or not using information; including public trust, perceived
9239 competence, social stability and community well-being, and perceived social equity in
9240 information access, provision, and benefit. Much more needs to be known about the
9241 economic and other factors that shape demands for water, roads, and land conversion for
9242 residential and commercial development, and shape social and economic resilience in
9243 face of climate variability.

9244

9245 A recent NRC Report (2007) set out five research topics that have direct relevance to
9246 making climate science information better serve the needs of various sectors: human
9247 influences on vulnerability to climate; communications processes; science produced in
9248 partnership with users; information overload; and innovations at the individual and
9249 organizational level necessary to make use of climate information. The last research topic
9250 is the particular charge of NOAA's Sectoral Applications Research Program and is of
9251 great relevance to the subject of this Product. However, the lack of use of theoretically-
9252 infused social science research is a clear impediment to making investments in physical
9253 sciences useful and used. Committed leadership that is poised to take advantage of
9254 opportunities is fundamental to future innovation, yet not nearly enough research has
9255 been done on the necessary conditions for recruitment, promotion and rewarding
9256 leadership in public organizations, particularly as that leadership serves in networks
9257 involving multiple agencies, both public and private, at different organizational levels.

9258

9259 **5.3.5 Better Understanding of the Implications of Small-Scale, Tailored Decision-**
9260 **Support Tools is Needed**

9261 While there is almost universal agreement that specially tailored, small scale forecast
9262 tools are needed, concern is growing that the implications of such tools for
9263 trustworthiness, quality control, and ensuring an appropriate balance between proprietary
9264 *versus* public domain controls have not been sufficiently explored.

9265

9266 There is a growing push for smaller scale products that are tailored to specific users but
9267 are expensive, as well as private sector tailored products (*e.g.*, “Weatherbug” and many
9268 reservoir operations proprietary forecasts have restrictions on how they share data with
9269 NOAA); this also generates issues related to trustworthiness of information and quality
9270 control. What are the implications of this push for proprietary *versus* public domain
9271 controls and access? This problem is well-documented in policy studies of risk-based
9272 information in the fields of food labeling, toxic pollutants, medical and pharmaceutical
9273 information, and other public disclosure or “right-to-know” programs, but has not been
9274 sufficiently explored in the context of climate forecasting tool development.

9275

9276 Related to this issue of custom-tailoring forecast information is the fact that future
9277 progress in making climatic forecasts useful depends upon advancing our understanding
9278 of the incorporation of available knowledge into decisions in water related sectors, since
9279 there are already many useful applications of climate variation and change forecasts at
9280 present skill levels. Here, the issue is tailoring information to the *type* of user. Research
9281 related to specific river systems, and/or sectors such as energy production, flood plain
9282 and estuary planning and urban areas is important. Customizable products rather than
9283 generic services are the most needed by decision makers. The uptake of information is
9284 more likely when the form of information provided is compatible with existing practice.
9285 It makes sense to identify decision-support experiments where concerted efforts are made
9286 to incorporate climate information into decision making. Such experimentation feeds into
9287 a culture of innovation within agencies that is important to foster at a time when
9288 historically conservative institutions are evolving more slowly than the pace of change in

9289 the natural and social systems, and where, in those instances when evolution is taking
9290 place relatively quickly—there are few analogues that can be used as reference points for
9291 how to accommodate these changes and ensure that organizations can adapt to stress—an
9292 important role of visionary leadership (Bennis, 2003; Tichy and Bennis, 2007)

9293

9294 Given the diversity of challenges facing decision makers, the varied needs and aspirations
9295 of stakeholders, and the diverse array of decision-making authorities, there is little hope
9296 of providing comprehensive climate services or a “one-stop-shop” information system to
9297 support the decision-making or risk-assessment needs of a wide audience of users.

9298 Development of products to help nongovernmental communities and groups develop their
9299 own capacity and conduct their own assessments is essential for future applications of
9300 climate information.

9301

9302 A seasonal hydrologic forecasting and applications testbed program would facilitate the
9303 rapid development of better decision-support tools for water resources planning.

9304 Testbeds, as described in Chapter 2, are intermediate activities, a hybrid mix of research
9305 and operations, serving as a conduit between the operational, academic and research
9306 communities. A testbed activity may have its own resources to develop a realistic
9307 operational environment. However, the testbed would not have real-time operational
9308 responsibilities and instead, would be focused on introducing new ideas and data to the
9309 existing system and analyzing the results through experimentation and demonstration.

9310 The old and new system may be run in parallel and the differences quantified (a good
9311 example of this concept is the INFORM program tested in various reservoir operations in

9312 California described in Chapter 4). Other cases that demonstrate aspects of this same
9313 parallelism are the use of paleoclimate data in the Southwest (tree-ring data being
9314 compared to current hydrology) and the South Florida WMD (using decade-scale data
9315 together with current flow and precipitation information). The operational system may
9316 even be deconstructed to identify the greatest sources of error, and these findings can
9317 serve as the motivation to drive new research to find solutions to operations-relevant
9318 problems. The solutions are designed to be directly integrated into the mock-operational
9319 system and therefore should be much easier to directly transfer to actual production.
9320 While NOAA has many testbeds currently in operation, including testbeds focused on:
9321 Hydrometeorology (floods), Hazardous Weather (thunderstorms and tornadoes), Aviation
9322 Weather (turbulence and icing for airplanes), Climate (El Niño, seasonal precipitation
9323 and temperature) and Hurricanes, a testbed for seasonal stream flow forecasting does not
9324 exist. Generally, satisfaction with testbeds has been high, with the experience rewarding
9325 for operational and research participants alike.

9326

9327 **5.4 THE APPLICATION OF LESSONS LEARNED FROM THIS PRODUCT TO** 9328 **OTHER SECTORS**

9329 Research shows the close interrelationships among climate change, deep sustained
9330 drought, beetle infestations, high fuel load levels, forest fire activity, and the secondary
9331 impacts of fire activity including soil erosion, decreases in recharge, and increases in
9332 water pollution. Serious concern about the risks faced by communities in wildland-urban
9333 interface areas as well as about the long-term viability of the nation's forests is warranted.
9334 It is important to know more about climate-influenced changes in marine environments

9335 that have significant implications for the health of fisheries and for saltwater ecosystems.
9336 Potential changes in the frequency and severity of extreme events such as tropical storms,
9337 floods, droughts, and strong wind episodes threaten urban and rural areas alike and need
9338 to be better understood. Rising temperatures, especially at night, are already driving up
9339 energy use and contributing to urban heat island effects. They also pose alarming
9340 potential for heat wave-related deaths such as those experienced in Europe a few years
9341 ago. The poor and the elderly suffer most from such stresses. Clearly, climate conditions
9342 affect everyone's daily life.

9343

9344 Some of the lessons learned and described in this Product from the water sector are
9345 directly transferable to other sectors. The experiments described in Chapters 2, 3, and 4
9346 are just as relevant to water resource managers as they are to farmers, energy planners or
9347 city planners. Of the overarching lessons described in this Chapter, perhaps the most
9348 important to all sectors is that the climate forecast delivery system in the past, where
9349 climatologists and meteorologists produced forecasts and other data in a vacuum, can be
9350 improved. This Product reiterates in each chapter that the loading dock model of
9351 information transfer (see Chapter 2, Box 2.4) is unworkable. Fortunately, this Product
9352 highlights experiments where interaction between producers and users is successful. A
9353 note of caution is warranted, however, against supposing that lessons from one sector are
9354 directly transferable to others. Contexts vary widely in the severity of problems, the level
9355 of forecasting skill available, and the extent to which networks do not exist or are already
9356 built and only need to be engaged. Rather than diffusion of model practices, we suggest

9357 judicious attention to a wide variety of insights suggested in the case studies and
9358 continued support for experimentation.

9359

9360 This Product has emphasized that decision support is a process rather than a product.
9361 Accordingly, we have learned that communication is key to delivering and using climate
9362 products. One example where communication techniques are being used to relay relevant
9363 climate forecast and other relevant information can be found in the Climate Assessment
9364 for the Southwest (RISA) project where RISA staff are working with the University of
9365 Arizona Cooperative Extension to produce a newsletter that contains official and non-
9366 official forecasts and other information useful to a variety of decision makers in that area,
9367 particularly farmers <<http://www.climas.arizona.edu/forecasts/swoutlook.html>>.

9368

9369 Equity is an issue that arises in other sectors as well. Emergency managers preparing for
9370 an ENSO-influenced season already understand that while some have access to
9371 information and evacuation routes, others, notably the elderly and those with financial
9372 difficulties, might not have the same access. To compound this problem, information may
9373 also not be in a language understood by all citizens. While these managers already realize
9374 the importance of climate forecast information, improved climate forecast and data
9375 delivery and/or understanding will certainly help in assuring that the response to a
9376 potential climate disaster is performed equitably for all of their residents (Beller-Simms,
9377 2004).

9378

9379 Finally, science citizenship is and will be increasingly important in all sectors. Science
9380 citizenship clearly has a crucial role to play in building bridges between science and
9381 societal values in all resource management arenas and increased collaboration and
9382 production of knowledge between scientists and decision makers. The use of SI and
9383 climate forecasts and observational data will continue to be increasingly important in
9384 assuring that resource-management decisions bridge the gap between climate science,
9385 and the implementation of scientific understanding in our management of critical
9386 resources.

9639

9640 (Adapted from the National Weather Service Instruction 10-103, June, 2007, available at:

9641 <<http://www.weather.gov/directives/sym/pd01001003curr.pdf>>)

9642

9643 Because of the operational nature of the National Weather Service's mission, transition of

9644 research into operations is of particular importance. Transition of all major NOAA

9645 research into operations is monitored by the NOAA Transition Board. Within the

9646 National Weather Service (NWS), two structured processes are followed to transition

9647 research into operations, in coordination with the NOAA Transition Board. The

9648 Operations and Service Improvement Process (OSIP) is used to guide all projects,
 9649 including non-hydrology projects, through field deployment within the Advanced
 9650 Weather Interactive System (AWIPS). A similar process called Hydrologic Operations
 9651 and Service Improvement Process (HOSIP), with nearly identical stages and processes as
 9652 OSIP, is used exclusively for the hydrology projects. For those hydrology projects that
 9653 will be part of AWIPS, HOSIP manages the first two stages of hydrologic projects, and,
 9654 upon approval, they are moved to OSIP. The OSIP process is described below.

9655

9656 The Operations and Service Improvement Process consists of five stages (Table A.1). In
 9657 order for a project to advance from one stage to the next, it must pass a review process (a
 9658 “gate”) which determines that the requirements for each gate are met and that the typical
 9659 gate questions are satisfactorily answered.

9660

9661 **Table A.1 National Weather Service Transition of Research to Operations: Operational and Service**
 9662 **Improvement Process, OSIP.**

Stage	Major Activity	Typical Decision Point (Gate) Questions
1	Collection and Validation of Need or Opportunity	Is this valid for the Weather Service? What is to be done next and who will do it?
2	Concept Exploration and Definition	Are the concept and high level requirements adequately defined or is research needed? What is to be done next and who will do it?
3	Applied Research and Analysis	What solutions are feasible, which is best? What is to be done next and who will do it?
4	Operational Development	Does developed solution meet requirements? Is there funding for deployment and subsequent activities? What is to be done next and who will do it?
5	Deploy, Maintain, and Assess	Survey—How well did the solution meet the requirements?

9663

9664 Each gate requires that the project be properly documented up to that point. The first
 9665 stage, *Collection and Validation of Need or Opportunity*, allows people who have a need,
 9666 an idea, or an opportunity (including people external to the NWS) to hold discussions

9667 with an OSIP Submitting Authority to explore the merits of that idea, and to have that
9668 idea evaluated. For this evaluation, the working team prepares two documents:
9669 (1) A Statement of Need or Opportunity Form, which describes the Need or Opportunity
9670 for consideration, and
9671 (2) The OSIP Project Plan, which identifies what is to be done next and what resources
9672 will be needed. For Hydrology projects, the Statement of Need requires the endorsement
9673 of a field office.

9674

9675 The *Concept Exploration and Definition* stage requires the preparation of the following
9676 documents:

9677 (1) The Exploratory Research Results Document which, as required for research projects,
9678 documents the results from exploratory research to determine effectiveness, use, or
9679 concept for associated need or opportunity, and documents the availability of already-
9680 developed solutions that will meet the Statement of Need;

9681 (2) The Concept of Operations and Operational Requirements Document, which
9682 describes how the system operates from the perspective of the user in terms that define
9683 the system capabilities required to satisfy the need; and

9684 (3) An updated OSIP Project Plan.

9685

9686 During the *Applied Research and Analysis* stage, the team conducts applied research,
9687 development, and analysis; identifies possible solutions; defines and documents the
9688 technical requirements; prepares a Business Case Analysis (BCA) to present a detailed
9689 comparison of the potential alternative solutions, with the recommendation of the

9690 working team as to which alternative is preferred. The BCA is a critical element in
9691 demonstrating to NWS, NOAA, and Department of Commerce management that a
9692 program is a prudent investment and will support and enhance the ability of the NWS to
9693 meet current and planned demand for its products and services. This stage requires the
9694 preparation of four documents:

9695 (1) The Applied Research Evaluation, which documents how the research was carried
9696 out, how the processes were validated, and the algorithm description for operational
9697 implementation;

9698 (2) The Technical Requirements document, which states what the operational system
9699 must explicitly address;

9700 (3) The Business case, which collects the business case analysis that describes how the
9701 system will be used; and

9702 (4) An updated OSIP Project Plan.

9703

9704 During the *Operational Development* stage, the team performs the operational
9705 development activities summarized in the approved Project Plan as described in the
9706 Operational Development Plan. The purpose of this stage is to fully implement the
9707 previously selected solution, to verify that the solution meets the operational and
9708 technical requirements, to conduct preparations to deploy the solution to operations, and
9709 to carry out the actions stated in the Training Plan. During this stage, the team prepares:

9710 (1) The Deployment Decision Document, which summarizes the results of the
9711 development and verification activities and presents the results of preparations for
9712 deployment, support, and training;

9713 (2) The Deployment, Maintenance and Assessment Plan, which is the plan for the final
9714 OSIP stage; and

9715 (3) An updated OSIP Project Plan and other documentation as needed.

9716

9717 During the final stage, *Deploy, Maintain and Assess*, the team performs the deployment
9718 activities summarized in the approved Project Plan as described in the Deployment,
9719 Assessment, and Lifecycle Support Plan. The primary purpose of this stage is to fully
9720 deploy the developed and verified solution.

9721

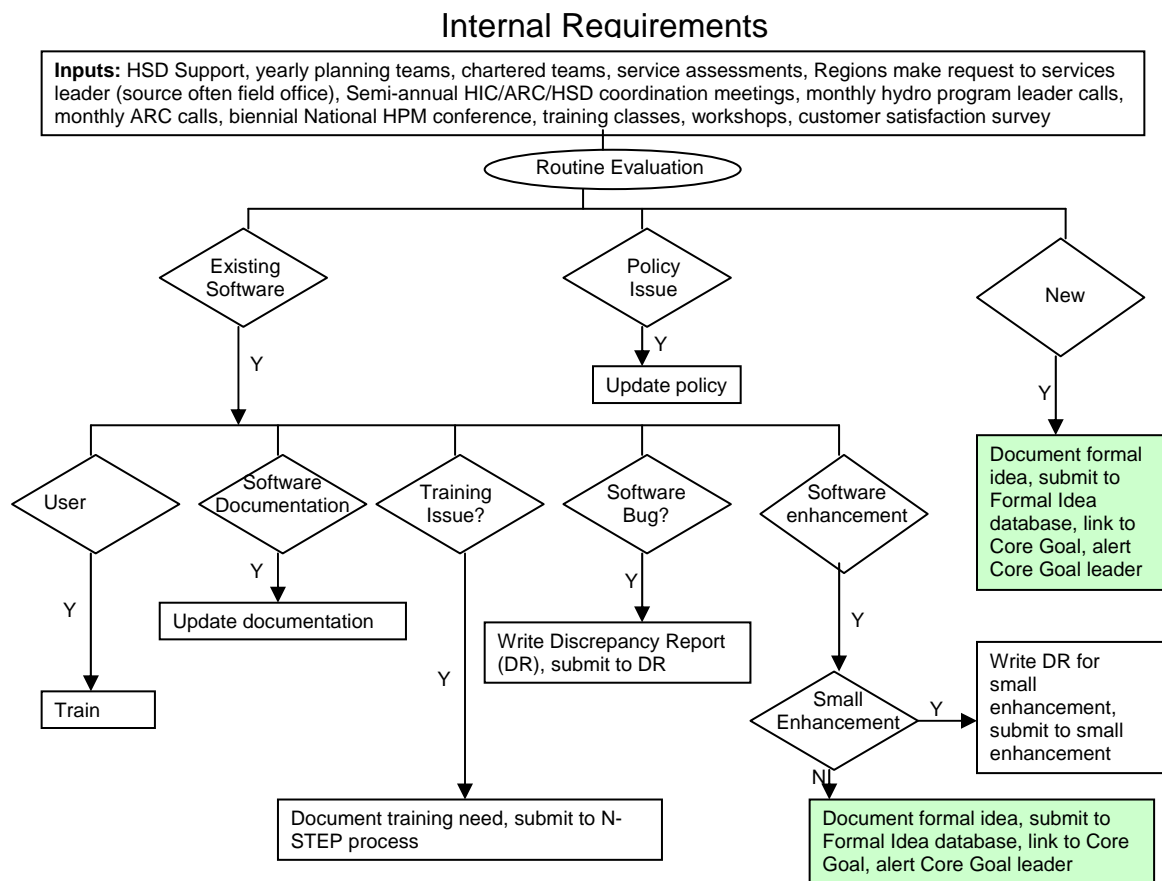

9722

9723 **Appendix B. How the National Weather Service**
9724 **Prioritizes the Development of Improved Hydrologic**
9725 **Forecasts**

9737
9738 (Adapted from Mary Mulluski’s Hydrologic Services Division (HSD) Requirements
9739 Process: How to Solicit, Collect, Refine, and Integrate Formal Ideas into Funded Projects,
9740 NWS internal presentation, 2008).
9741
9742 There are three sources of requirements toward the development of improved hydrologic
9743 forecasts at the National Weather Service: internal and external forecast improvements,

9744 and Web page information improvement. All improvements are coordinated by the
9745 National Weather Service Hydrologic Services Division (HSD).
9746
9747 The internal hydrologic forecast improvement requirements at the National Weather
9748 Service are a result of one of more of these sources:

- 9749 • HSD routine support
- 9750 • Proposed research and research-to-operations projects by annual planning teams,
9751 with the participation of HSD, the Office of Hydrologic Development (OHD),
9752 River Forecast Center and Weather Forecast Offices employees
- 9753 • Teams chartered to address specific topics
- 9754 • The result of service assessments
- 9755 • Solicitation by the National Weather Service (NWS) Regions of improved
9756 forecast requirements to services leaders
- 9757 • Semi-annual Hydrologists-in-charge (HIC), Advanced Hydrologic Prediction
9758 Service (AHPS) Review Committee (ARC), and HSD Chiefs coordination
9759 meetings
- 9760 • Monthly hydro program leader calls
- 9761 • Monthly ARC calls
- 9762 • Biennial National Hydrologic Program Manager's Conference (HPM)
- 9763 • Training classes, workshops, and customer satisfaction surveys
- 9764

9765 A flow diagram of the internal hydrologic forecast process is shown in Figure B.1.

9766

9767 **Figure B.1** Hydrologic forecast improvement: internal requirements process.

9768

9769 The external requirements for hydrologic forecast improvements are the results of:

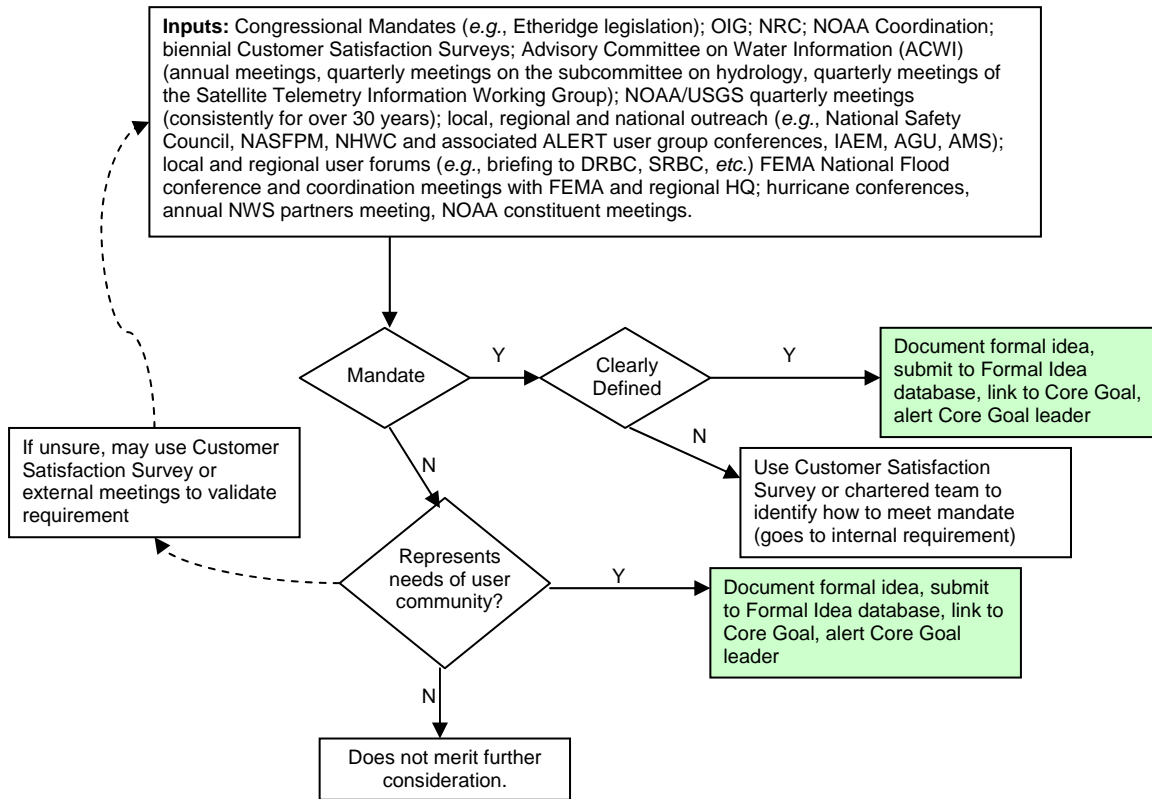

- 9770 • Congressional mandates
- 9771 • Office of Inspector General (OIG) requirements
- 9772 • National Research Council (NRC) recommendations
- 9773 • NOAA Coordination
- 9774 • Biennial customer satisfaction surveys
- 9775 • Annual meetings, quarterly meetings on the subcommittee on hydrology,
- 9776 quarterly meetings of the Satellite Telemetry Information Working Group of the
- 9777 Advisory Committee on Water Information (ACWI)

- 9778 • NOAA/USGS quarterly meetings (consistently for over 30 years)
- 9779 • Local, regional and national outreach such as the National Safety Council,
- 9780 National Association of Flood Plain Managers, (NASFPM), National Hydrologic
- 9781 Warning Council (NHWC) and associated ALERT (Automated Local Evaluation
- 9782 in Real Time) user group conferences, International Association of Emergency
- 9783 Managers, (IAEM), American Geophysical Union (AGU), American
- 9784 Meteorological Society (AMS)
- 9785 • Local and regional user forums (*e.g.*, briefing to the Delaware River Basin
- 9786 Commission (DRBC), and Susquehanna River Basin Commission (SRBC))
- 9787 • Federal Emergency Management Agency (FEMA) National Flood conference
- 9788 and coordination meetings with FEMA and regional headquarters
- 9789 • Hurricane conferences, annual NWS partners meeting, NOAA constituent
- 9790 meetings

9791 A flow diagram of the external hydrologic forecast process is shown in Figure B.2.

9792

External Requirements Process

9793

9794 **Figure B.2** Hydrologic forecast improvement: external requirements process.

9795

9796 A fundamental part of the overall service of issuing hydrologic forecasts is the
 9797 communication of those forecasts to the users, and the Web is an important part of that
 9798 communication process. The requirement process for Web page improvements would
 9799 arise from:

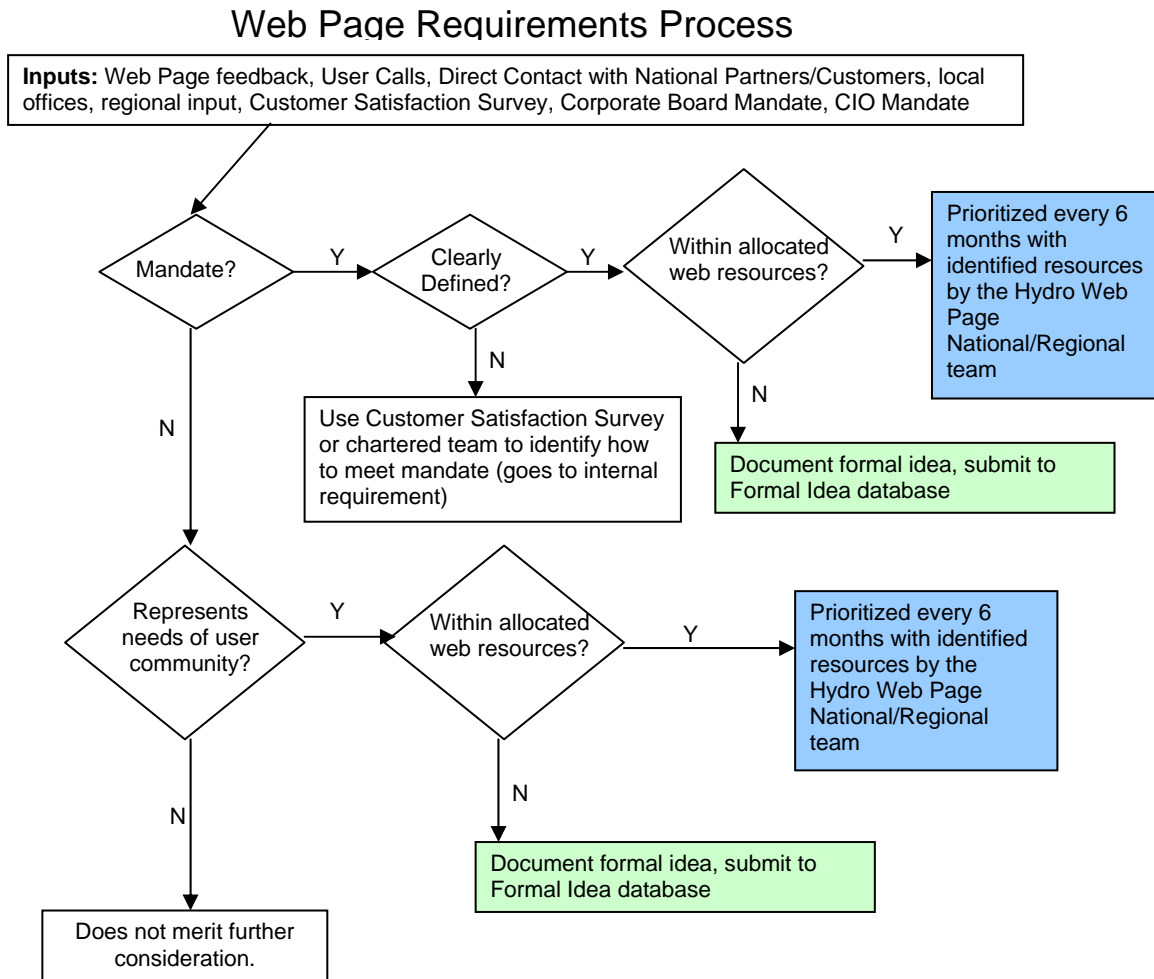

- 9800 • Requests arising from user feedback on the web
- 9801 • User calls
- 9802 • Direct contact with national partners/customers
- 9803 • Local NWS offices and NWS regions input
- 9804 • Customer satisfaction survey
- 9805 • Corporate Board Mandate

- 9806 • Chief Information Office Mandate

9807

9808 Figure B.3 shows the flow diagram for the web-page improvement requirement process.

9809

9810

9811 **Figure B.3** Web-page improvement process.

9812

9813

9814

9815

9816

9817 **Glossary and Acronyms**

9818

9819 **GLOSSARY**

9820

9821 **Adaptive capacity**

9822 The ability of people to mitigate or reduce the potential for harm, or their vulnerability to
9823 various hazards that can cause them harm, by taking action to reduce exposure or
9824 sensitivity, both before and after the hazardous event.

9825

9826 **Adaptive management**

9827 Approach to water resource management that emphasizes stakeholder participation in
9828 decisions; commitment to environmentally sound, socially just outcomes; reliance upon
9829 drainage basins as planning units; program management via spatial and managerial
9830 flexibility, collaboration, participation, and sound, peer-reviewed science; and embracing
9831 ecological, economic, and equity considerations.

9832

9833 **Boundary organizations**

9834 Entities that perform translation and mediation functions between producers (*i.e.*,
9835 scientists) and users (*i.e.*, policy makers) of information. These functions include
9836 convening forums to discuss information needs, providing training, assessing problems in
9837 communication, and tailoring information for specific applications. Individuals within
9838 these organizations who lead these activities are often termed “integrators.”

9839

9840 **Conjunctive use**

9841 The conjoint use of surface and groundwater supplies within a region to supply various
9842 uses and permit comprehensive management of both sources. This requires co-
9843 management of a stream or system of streams and an aquifer system to meet several
9844 objectives such as conserving water supplies, preventing saltwater intrusion into aquifers,
9845 and preventing contamination resulting from one supply source polluting another.

9846

9847 **Decision maker**

9848 In water resources, the term embraces a vast assortment of elected and appointed local,
9849 state, and national agency officials, as well as public and private sector managers with
9850 policy-making responsibilities in various water management areas.

9851

9852 **Decision-support experiments**

9853 Practical exercises where scientists and decision makers explicitly set out to use decision-
9854 support tools – such as climate forecasts, hydrological forecasts, *etc.* – to aid in making
9855 decisions in order to address the impacts of climate variability and change upon various
9856 water issues.

9857

9858 **Disaggregation**

9859 Similar to downscaling, but in the temporal dimension; *e.g.*, seasonal climate forecasts
9860 may need to be translated into daily or subdaily temperature and precipitation inputs for a
9861 given application.

9862

9863 Downscaling

9864 The process of bridging the spatial scale gap between the climate forecast resolution and
9865 the application's climate input resolution, if they are not the same. If the climate
9866 forecasts are from climate models, for instance, they are likely to be at a grid resolution
9867 of several hundred km, whereas the application may require climate information at a
9868 point (*e.g.*, station location).

9869

9870 Dynamical forecasts

9871 Physics-based forecasts that are developed from conservation equations.

9872

9873 Ensemble streamflow prediction (ESP)

9874 Uses an ensemble of historical meteorological sequences as model inputs (*e.g.*,
9875 temperature and precipitation) to simulate hydrology in the future (or forecast) period.

9876

9877 Hindcasts

9878 Simulated forecasts for periods in the past using present day tools and monitoring
9879 systems. Hindcasts are often used to evaluate the potential skill of present day forecast
9880 systems.

9881

9882 Integrated water resource planning

9883 Efforts to manage water by balancing supply and demand considerations through
9884 identifying feasible alternatives that meet the test of least cost without sacrificing other

9885 policy goals – such as depleted aquifer recharge, seasonal groundwater recharge,
9886 conservation, growth management strategies, and wastewater reuse.

9887

9888 **Knowledge-to-action networks**

9889 The interaction among scientists and decision makers that results in decision-support
9890 system development. It begins with basic research, continues through development of
9891 information products, and concludes with end use application of information products.

9892 What makes this process a “system” is that scientists and users discuss what is needed as
9893 well as what can be provided; learn from one another’s perspectives; and try to
9894 understand one another’s roles and professional constraints.

9895

9896 **Objective hybrid forecasts**

9897 Forecasts that objectively use some combination of objective forecast tools (typically, a
9898 combination of dynamical and statistical approaches).

9899

9900 **Physical vulnerability**

9901 The hazard posed to, for example, water resources and water resource systems by
9902 exposure to harmful, natural, or technological events such as pollution, flooding, sea-
9903 level rise, or temperature change.

9904

9905 **Predictand**

9906 Statistical methods usually employing one or more predictors to forecast a target variable,
9907 which is often referred to as the *predictand*.

9908 Sensitivity

9909 The degree to which people and the things they value can be harmed by exposure. Some
9910 water resource systems, for example, are more sensitive than others when exposed to the
9911 same hazardous event. All other factors being equal, a water system with old
9912 infrastructure will be more sensitive to a flood or drought than one with state-of-the-art
9913 infrastructure.

9914

9915 Social vulnerability

9916 The social factors (*e.g.*, level of income, knowledge, institutional capacity, disaster
9917 experience) that affect a system's sensitivity to exposure, and that also influences its
9918 capacity to respond and adapt in order to reduce the effects of exposure.

9919

9920 Statistical forecasts

9921 Objective forecasts based on empirically determined relationships between observed
9922 predictors and predictands.

9923

9924 Subjective consensus forecasts

9925 Forecasts in which expert judgment is subjectively applied to modify or combine outputs
9926 from other forecast approaches.

9927

9928 **Water year** or hydrologic year
9929 October 1st through September 30th. This reflects the natural cycle in many hydrologic
9930 parameters such as the seasonal cycle of evaporative demand, and of the snow
9931 accumulation, melt, and runoff periods in many parts of the United States.
