## **INTRODUCTION**

Sample costs to produce sweetpotato transplants in hotbeds and sweetpotatoes in the San Joaquin Valley are shown in this study. The study is intended as a guide only, and can be used to make production decisions, determine potential returns, prepare budgets and evaluate production loans. The practices described are based on production operations considered typical for this crop and region, but will not apply to every farm. Sample costs for labor, materials, equipment and custom services are based on current figures. "Your Costs" columns in Tables 1, 2, 5 and 6 are provided for entering your farm costs.

The hypothetical farm operations, production practices, overhead, and calculations are described under the assumptions. For additional information or an explanation of the calculations used in the study call the Department of Agricultural and Resource Economics, University of California, Davis, California, (530) 752-3589 or the local UC Cooperative Extension office.

Sample Cost of Production Studies for many commodities can be downloaded at <u>http://coststudies.ucdavis.edu</u>, requested through the Department of Agricultural and Resource Economics, UC Davis, (530) 752-4424 or obtained from the local county UC Cooperative Extension offices. Some archived studies are also available on the website.

The University of California does not discriminate in any of its policies, procedures or practices. The university is an affirmative action/equal opportunity employer. University of California and USDA, Risk Management Cooperating.

## ASSUMPTIONS

The assumptions refer to Tables 1 to 12 and pertain to sample costs to produce sweetpotato transplants and sweetpotatoes in the San Joaquin Valley. The cultural practices described represent production operations and materials considered typical for a farm in the region. Costs, materials, and practices in this study will not apply to all farms. Timing of and types of cultural practices will vary among growers within the region and from season to season due to variables such as weather, soil, and insect and disease pressure. **The use of trade names and cultural practices in this report does not constitute an endorsement or recommendation by the University of California nor is any criticism implied by omission of other similar products or cultural practices.** 

**Farm**. This report is based on a 200 non-contiguous acre farm managed by the grower. The farm is planted to sweetpotatoes and orchards. The farm is located on the valley floor on sandy to sandy loam soil (the preferred soil for sweetpotatoes). The grower owns 120 acres and rents 80 acres of which 75 are planted to sweetpotatoes and 1.25 acres are hotbeds for growing transplants. Each sweetpotato field is 25 planted acres. The remaining rented acreage is roads, irrigation system, and open areas. Roads and buildings occupy approximately five acres of the owned land.

## **Transplant Production (Hotbeds) Operating Costs**

Tables 1 - 4

**Hotbed Location**. Hotbeds are used to grow slips (plant cuttings) for transplanting to the field. They may be placed on both owned and rented ground (rented in this study). In some operations, the grower may grow transplants for others, however this is not common. In this study, it is assumed that the grower is producing transplants only for his own operation. Land for the hotbed area covers 1.25 acres. Hotbed areas must have access to a well, because district water may be unavailable in February. Soils chosen for the beds are generally sandy to loamy sand in texture.

**Hotbed Land Preparation**. In late fall and winter, the area for the hotbeds is prepared by chiseling and disking. The land is then leveled with a triplane, fumigated, amended with fertilizers and/or compost, and beds dug in preparation for planting.

**Fumigation.** The field is fumigated and tarped by a custom operator using a 53% methyl bromide (MeBr) and 47% chloropicrin (Pic) blend for nematode, insect, and weed control. After two to three weeks, the tarp is mechanically cut open to allow the field to air out, then removed and taken to the dump. The field is then disked once to vent the ground. Because of alleys and field borders, the fumigated area is slightly more than double the area planted to the beds. For this study, the total fumigated area is 1.25 acres, and is based on an average hot bed to field acre ratio of 1:62.

Environmental Protection Agency (EPA) requirements to comply with the Montreal protocol may severely restrict or eliminate the use of methyl bromide; this fumigant may be unavailable after 2005. Currently, the sweetpotato industry in California is operating under a Critical Use Exemption permit that allows use of methyl bromide. This permit will expire in 2005, and may not be renewed. Fumigation alternatives include tarped Telone (1,3-D) plus chloropicrin, flood metam sodium (Vapam), or solarization. Telone + Pic product and application costs are similar to MeBr + Pic.

**Plant.** Potatoes are started in hotbeds that can be heated from decomposing cotton gin trash, or they can be started in cold beds without heat. For this study, hot beds are utilized. The hotbeds are planted in February

using seed saved from the previous season (medium grade) and some purchased virus-tested seed. For this study, it is assumed that purchased virus-tested seed comprises 25% of the total seed requirements. The grower produced seed is assumed to have a value of \$0.10 per pound. Common varieties in the region are Diane (red-skinned), Beauregard (copper-skinned), Hanna and Golden Sweet (tan), and Japanese.

Plant beds are 8-feet wide with 10-feet between beds giving a total row width of 18-feet. The beds are plowed out (excavated to a depth of 12 to 14-inches), then gin trash at 1.25 truck loads per acre is placed in the bed by five men with pitchforks working six hours. The gin trash is then packed in two passes with the grower's tractor and roller, irrigated and covered with soil using a tractor and mechanical dirt thrower. Pre-heated sweetpotato roots are hauled from storage and placed in the beds by hand, then covered with more soil. About one-half acre of planted area, or one acre of fumigated area is required to produce transplants for 62 acres of field production.

It takes approximately 500 to 800 pounds of medium-sized potatoes to furnish enough cuttings (sometimes called slips) or transplants (so called when they are pulled from the beds) for one acre of crop, depending on variety. Because of low plant production and a 9-inch in-row field plant spacing, Beauregard usually requires the most space (about 50 feet of bed for each field acre), whereas Hanna requires the least (about 25 feet of bed required). For this study, it is assumed that 35 linear feet of hotbed planted area and 800 pounds of potato seed are needed to produce enough transplants for one acre on a 9-inch spacing (17,500 plants). Planting time is assumed to be 308 man-hours per acre, which includes a 10 man crew and a foreman. The forklift operator drives both the truck and the forklift.

**Tunnels**. After planting, clear plastic tunnels are placed over the beds to protect the plants from frost and encourage rapid growth. Reusable metal rods or hoops are placed every 3 to 4 feet down the bed, and then plastic is pulled over the hoops. One edge is covered with dirt to hold the plastic in place, the other edge is held in place with dirt filled bags placed every six-feet. Depending on the weather, the bags are set aside daily to uncover the plants. It takes 2.75 man-hours per acre each day to uncover the beds and an equal amount of time to re-cover. Typically, tunnels must be used until May.

**Irrigation**. During bed preparation, aluminum pipe is laid to irrigate or moisten the gin trash and is assumed to take four man hours to haul and lay the pipe, irrigate, and remove the pipe. After covering the sweetpotatoes in the beds, the irrigation system is installed (PVC pipe and risers with sprinklers) by the grower's labor. The sprinklers are placed in alternate open areas between the beds so that each line will cover two beds (approximately 36-feet). Risers typically occur every 25 feet. The field is irrigated every three days for about twelve weeks at one hour per acre per irrigation. Because hotbeds typically begin before district water is available, well water is used. Water costs are included in the rent, but the grower pays the pumping or electrical charge. The estimated pumping cost is \$34.25 per acre foot (\$2.85 per acre inch).

**Fertilization**. Pre-plant fertilizer is applied after fumigating. A complete NPK formulation is used in this study (15-15-15 at 800 pounds per broadcast acre), though compost can be utilized as well and is often applied in conjunction with the fertilizer. The hot beds are also topdressed once in the spring by hand to supply the equivalent of about 30 pounds of nitrogen (N) per acre.

**Topping.** Prior to cutting plants for the field, many beds are trimmed using gas-powered "weed whackers" to encourage uniform height in the plants. Plant tops may be trimmed weekly from mid-April to harvest (about 4 weeks). It takes approximately two man-hours per week (4 men x 0.50 hours per acre) to trim the plants.

**Pest Management.** If insects or diseases appear, contact your local farm advisor or pest control adviser (PCA). For information on pesticide use permits, contact the local county agricultural commissioner's office. Adjuvants are recommended for many pesticides for effective control, but are not included in this study. Pesticide costs vary by location and grower volume. Pesticides costs in this study are taken from a single dealer and shown as full retail.

*Weeds*. The fumigation to control nematodes usually provides adequate weed control. Weed escapes are removed using hand labor.

*Insects.* Fumigation usually provides all the insect control needed. Aphids may be a problem in some years, and can be controlled with the registered insecticides Fulfill (pymetrozine), Actara (thiamethoxam) or Provado (imidacloprid), if needed. Armyworms can be controlled with Bt insecticides (Dipel, Xentari) or Intrepid if required. For this study, no insect control in the beds is suggested.

*Diseases.* The transplants are susceptible to many soilborne diseases. Use of fumigation and disease free seed can be an effective control. Scurf and other rots may be suppressed by spraying Botran (dichloran) or Mertect (thiabendizole) on the seed prior to covering with soil. For this study, fungicides are not used in the beds, however, transplants are dipped in fungicide solutions at cutting prior to field planting. Mertect is recommended as a plant dip at the rates of 8 fluid ounces per 7.5 gallons of water. Not all varieties or transplants require treatment, only the sweet and Japanese varieties which account for 30% of the market. In this study 30% of the transplants are treated. The plants are dipped for four minutes.

**Cutting Plants**. The beds may be cut twice for transplants, but in this study they are harvested once. Hot beds are ready to be harvested when the plants are about 12 inches in height. To limit the transfer of diseases or nematodes from the bed to the field, plants should be cut about 1 to 2 inches above the soil line, then gathered and placed into milk crates for transport to the field. Depending on variety, about 13,000 to 17,500 plants will be needed to plant one acre. One man can pull 1,000 to 1,200 plants per hour. Before going to the field, transplants are dipped in a fungicide solution (see above paragraph). In general, the plants cut from the hotbeds are transplanted within 24 hours. In this study, the truck driver operates the forklift in the field and makes two trips each day at one hour per trip to the production field.

**Returns.** It is assumed that all production from the hot beds will be used for planting in the field, with no sales to other growers. Therefore, there are no returns calculated for transplants. Growers using Enterprise Accounting may assign a return to the hotbed transplants.

## **Field Production Operating Costs** Tables 5 - 10

**Field Location.** Field locations chosen for sweetpotato production generally have sandy to loamy sand soils, as these soil types produce the best yield and quality. Additionally, soils need to be well drained and contain low levels of salt with a pH less than 7 and an electrical conductivity (EC) less than 2. Soil samples should be taken in the fall to help determine fertilizer and amendment rates.

**Land Preparation**. In the fall (November), fields are ripped in two directions by a custom operator and disked twice by the grower in preparation for fumigation. Conventionally grown sweetpotatoes are usually fumigated with Telone (1,3-D) at 12 - 14 gallons per acre. Applications are made in the fall or spring by a custom fumigation company (Telone is not applied in January). Telone use is restricted in buffer zones and by a California state mandated cap that limits the total amount of Telone that can be applied within a section of land. In areas where it cannot be used, alternatives include Mocap and Lorsban insecticides. In our scenario,

Telone is applied in the fall by a custom applicator. The grower then disks and rolls the ground in a single operation twice to seal the soil and prevent the loss of fumigant to the air. In the spring beginning in March, the cover crop is disked, compost applied, chiseled once, and springtoothed twice. Shortly before planting, the beds are pulled (listed) by a custom operator. Preplant fertilizers are applied at the same time the beds are made. Depending on plant date, fields may be pre-irrigated before the beds are pulled.

**Cover Crop.** In November or December, Merced Rye at 30 pounds per acre is planted. The rye is disked in March and/or April with two passes to incorporate the material into the soil.

**Transplanting**. The sweetpotato cuttings (slips) are cut from the hotbeds and transplanted in the field from mid-April through mid-June (May in this study). The grower transplants on 80-inch beds, two rows per bed at 9-inch down the row spacing (17,500 plants per acre). Most growers use a four-row planter that pulls a water tank (2,500 gal). Eight persons (two persons per row of potatoes to pick up the plant from a box and place in the machine) are on the planter and one or two following to stick in missed plants. A second tractor pulls a large nurse tank (2,500 gallons) to haul water to the field and fills the tank attached to the planter while on the move. Approximately, 2,000 to 3,000 gallons of water per acre are applied at transplanting. The cost of \$32.97 per thousand plants or \$577 per production acre for the transplants is from the Total Hotbed Cash Costs in Table 1.

**Irrigation**. Most sweetpotato fields are drip irrigated, although some furrow irrigation is still used. Both well and surface water are used; surface water requires the use of sand media filters, whereas the well water only needs screen filters. Pumps are powered by both diesel and electric motors. In this scenario, each field uses surface water with a portable 3-tank sand media filter and diesel motor. The pumps are included under Investments (Non-Cash Overhead) and the operation costs (fuel, lube) and maintenance costs are assumed to be included in Equipment Repairs in the tables under Cash Overhead. Other commonly used systems are surface water with a portable 3-tank sand media filter and electric motor; and well water with a screen filter system and electric motor. Surface water is supplied by the Merced Irrigation District (MID). Water costs are \$14.25 per acre-foot (\$1.18 per acre inch) plus \$27 per acre stand-by (paid by landlord).

The drip tape is laid on the soil surface in the center of the bed soon after planting. Because of root intrusion problems, the drip tape is not buried and used for only one season before being discarded. Drip tape is thin, typically 5 to 6 mil, and low flow (15 gallons per hour per 100 feet). The tape is laid using a drip tape machine with tractor covering three beds at a time, using one tractor driver and two men on the tape machine. Three men lay the lateral line and connect the drip. The field is irrigated according to the planting date and the water requirements of the crop. Initially the field may be irrigated weekly in May, then beginning in June, fields may be irrigated for approximately 8 to 12 hours everyday through August. Irrigation labor calculated from grower data is 0.05 hours per acre per irrigation. Irrigation includes the water costs per irrigation and irrigation labor to maintain the system. The crop uses approximately 30 to 36 acre-inches per season (2.5 to 3 acre ft).

**Fertilizer/Soil Amendments.** Soil samples for nutrient analysis are taken from each field prior to land preparation. Costs are shown for sample analysis, but not for collecting the sample. In this study, the sample is taken by a PCA or person with a similar position. Gypsum at one ton per acre is applied in November prior to chiseling. Composted manure is applied in March after the cover crop is incorporated and prior to chiseling. Phosphorous (P), potassium (K), and zinc (Zn) are applied pre-plant when pulling the beds; rates should be based on a soil test. A portion of the nitrogen (N) is also applied at this time, with the majority applied through the drip tape after transplanting. In this scenario, 80 gallons per acre (about 800 lbs) of 8-8-8 + Zn is applied in a band under each plant row before transplanting. Supplemental nitrogen is applied in-season (June and July) using 20 gallons of UAN32 (60 lbs N per acre) equally divided among the applications. Fertilizer is applied

through the drip tape when irrigating beginning 4 to 6 weeks after transplanting. A total of 120 pounds of fertilizer N is applied to the crop.

**Pest Management.** If insects or diseases appear, contact your local farm advisor or pest control adviser (PCA). For information on pesticide use permits, contact the local county agricultural commissioner's office. Adjuvants are recommended for many pesticides for effective control, but are not included in this study. Pesticide costs vary by location and grower volume. Pesticides costs in this study are taken from a single dealer and shown as full retail.

*Weeds.* Weeds are controlled with mechanical cultivation, hand weeding, and careful use of selective herbicides. Fumigation prior to planting may also provide some weed control. Fields are generally cultivated with a rolling or standard cultivator two weeks after planting (May) followed with two more cultivations at two-week intervals (June). One month to 6 weeks after transplanting, bed middles can be sprayed with a band application of Roundup (glyphosate) to control emerged weeds under the drip tape. Hand weeding is usually needed three times during the season, in June and July. Post-emergence (July) control of grassy weeds is accomplished with broadcast applications of Poast (sethoxydim), Fusilade (fluazifop), or Prism (clethodim) plus a crop oil concentrate.

*Insects and nematodes.* The most problematic insects in California sweetpotato production include armyworms, grubs, and wireworms. Western Yellowstripe Armyworms (*Spodoptera spp.*) may be a problem in some years, though treatment is usually not required in all fields. In this study, Intrepid (methoxyfenozinde) is air applied for worm control in early August on one-half of the acreage. The Morning Glory Leafminer (*Bedellia somulentella*) is sometimes seen each year, but usually arrives too late in the season to require management. Wireworms (*Limonius* spp.) and grubs (Scarab beetles) can be very problematic in certain fields and because of their life cycles, are difficult to control. Previous history of this problem, high organic matter, new ground (from pasture or orchard), and wet zones/over irrigation will increase the likelihood of problems and the need for control measures. Fumigation can provide good suppression of these insects. Lorsban (chlorpyrifos) and Mocap (ethoprop) may be shanked and incorporated into those areas that cannot be fumigated, and may provide some control. Root knot nematodes (*Meloidogyne incognita*) are common in most of the sandy soils where sweetpotatoes are grown and can be very problematic. Nematodes are best controlled with fumigation and resistant varieties. Some varieties, such as Beauregard, are very susceptible. Newer varieties, such as Bienville and Covington, are moderately resistant to root knot nematode and are recommended for organic fields.

*Diseases.* Depending on variety, the transplants are susceptible to many soilborne diseases. Use of disease free seed and cutting transplants above the ground can be an effective way to limit the spread of Scurf (*Monilochaetes infuscans*), Pox (*Streptomyces sp*), and Black Rot (*Ceratocistis fimbriata*). Transplant dips using Benlate (registration inactive) or Mertect will reduce the incidence of Stem Rot (*Fusarium* sp) in susceptible varieties such as Koto Buki and Golden Sweet. Telone fumigation for nematode and insect control will also provide some suppression of field diseases, though efficacy is not sufficient to suppress *Fusarium*. Pre-irrigating late planted fields and maintaining a soil pH less than 5.7 will also help control Soil Pox (*Streptomyces ipomoea*). Soil pH can be adjusted by applying lime or sulfur in the fall. Newer varieties have greater resistance to most field diseases. Plants in this study are treated with Mertect at cutting and the cost is included as a hotbed operation.

Sweetpotato Feathery Mottle Virus causes the disease Russet Crack and can lead to significant losses of yield and quality in the variety Beauregard after only 4 years. Other varieties are also susceptible but may not show symptoms as quickly. This disease is transmitted by aphids and is best controlled by using clean, virus-

tested plants either purchased directly from Foundation Plant Services in Davis, CA or purchasing new seed (G1) from a reliable grower.

**Pickup.** Costs for two 1/2-ton pickups are included in the study. The pickups are used by the grower and/or irrigator to inspect the fields and general ranch business. The calculations in the study are estimated and do not represent results from any collected data.

**Harvest**. Prior to digging the crop, the drip tape and laterals are removed by hand, then the crop canopy is removed using a flail mower followed by a vine cutter. One vine tractor can keep up with 10 diggers. The drip tape is hauled to the landfill and the laterals are stored. The crop is harvested with a tractor drawn potato harvester (PTO digger chain lifts potatoes). The potatoes are removed from the chain by hand, and sorted by size into one of eight bins located on the digger. For this scenario, five people on the digger are sorting into Number 1, Jumbo, and Medium size classes. For the 75 acres, the grower owns and uses two diggers. Costs also include the use of a forklift in the field to lift the boxes on and off the digger and to load them on a truck to haul to the storage warehouse. Another forklift at the warehouse is used to unload and stack the full bins and to reload the truck with empty bins for the field. The truck driver operates both forklifts. Depending on the grade of sweetpotato, a bin weighs 800 to 900 pounds when full. Most of the crop (90%) is stored prior to packing. Curing is no longer a common practice, and is not included as a cost in this study. A water truck makes several trips over the field roads each day to water the roads in order to reduce dust emissions.

*Yields.* Based on the 2000 - 2003 Merced County crop report, the crop yields an average of 13 marketable tons per acre (650 forty pound boxes per acre). The sweetpotatoes are sold by grade size: U.S. No. 1s, Mediums, and Jumbos. The grades are based on size and freedom from defects; U.S. No. 1s bring the highest returns for the grower and usually account for about 60% of the pack-out yield. Yields decline in storage from losses due to postharvest disease and dehydration; typical losses are about 2% per month after the first month. The average yield shown in this study takes the seasonal dehydration into account.

*Returns.* Based on Merced County crop reports, the overall average return for years 1999 to 2003 is \$550 per ton FOB shed (\$11 per 40 pound box). These returns reflect fresh market sales (no processing) and packing costs that have not been deducted. Packing costs are typically \$4.00 per 40 pound box. Prices received vary by variety, grade, and time of year. The Ranging Analysis Table (Table 8) shows production costs over a range of yields as well as net returns over operating costs, cash costs and total costs over the same range of prices and yields. Table 9, Range of Prices Over Percent Shrinkage by Month shows how returns are affected by shrinkage based on the average cost study yield of 650 boxes. For this table, it is assumed the yield at harvest is 706.50 boxes and that the average shrink over the season is 8% based on a shrinkage rate of 2% per month. The Gross Returns table shows Gross Returns FOB packing shed. The Net Returns table, subsections of Table 9 show the net returns based on the production and packing costs for the 650 box yield as shown in Table 8.

*Assessments.* The California Sweetpotato Council helps unite growers and packers for the benefit of the entire industry. The Council distributes promotional material, sponsors a National Meeting, and funds the clean seed program. Membership in the council is voluntary and the cost is \$5.00 per production acre. The cost is included in this study under Cash Overhead.

*Packing Charges.* Packing charges are typically about \$4.00 per 40 pound box, but are not included as a cost in the general study. To calculate net returns in Tables 8 and 9, packing charges are shown and included as a cost.

## Labor, Equipment, and Interest Costs

**Labor.** Labor rates of \$11.82 per hour for machine operators and \$9.73 for general labor includes payroll overhead of 39%. The basic hourly wages are \$8.50 for machine operators and \$7.00 for general labor. The overhead includes the employers' share of federal and California state payroll taxes, workers' compensation insurance for potato crops (code 0041), and a percentage for other possible benefits. Workers' compensation costs will vary among growers, but for this study the cost is based upon the average industry final rate as of January 1, 2005 (California Department of Insurance). Labor for operations involving machinery are 20% higher than the operation time given in Tables 1 and 5 to account for the extra labor involved in equipment set up, moving, maintenance, work breaks, and field repair.

**Equipment Operating Costs.** Repair costs are based on purchase price, annual hours of use, total hours of life, and repair coefficients formulated by American Society of Agricultural Engineers (ASAE). Fuel and lubrication costs are also determined by ASAE equations based on maximum power takeoff (PTO) horsepower, and fuel type. Prices for on-farm delivery of diesel and gasoline are \$2.00 and \$2.55 per gallon, respectively. The cost includes a 2% local sales tax on diesel fuel and 8% sales tax on gasoline. Gasoline also includes federal and state excise tax, which are refundable for on-farm use when filing your income tax. The fuel, lube, and repair cost per acre for each operation in Table 1 and 5 are determined by multiplying the total hourly operating cost in Table 12 for each piece of equipment used for the selected operation by the hours per acre. Tractor time is 10% higher than implement time for a given operation to account for setup, travel and down time.

**Interest On Operating Capital.** Interest on operating capital is based on cash operating costs and is calculated monthly until harvest at a nominal rate of 9.25% per year. A nominal interest rate is the typical market cost of borrowed funds. The interest cost of post harvest operations is discounted back to the last harvest month using a negative interest charge. The rate will vary depending upon various factors, but the rate in this study is considered a typical lending rate by a farm lending agency as of January 2006.

**Risk.** Production risks should not be minimized. While this study makes every effort to model a production system based on typical, real world practices, it cannot fully represent financial, agronomic and market risks, which affect the profitability and economic viability.

## **Cash Overhead**

Table 11

Cash overhead consists of various cash expenses paid out during the year that are assigned to the whole farm and not to a particular operation. These costs include property taxes, interest on operating capital, office expense, liability and property insurance, and investment repairs.

**Property Taxes.** Counties charge a base property tax rate of 1% on the assessed value of the property. In some counties special assessment districts exist and charge additional taxes on property including equipment, buildings, and improvements. For this study, county taxes are calculated as 1% of the average value of the property. Average value equals new cost plus salvage value divided by 2 on a per acre basis.

**Insurance.** Insurance for farm investments varies depending on the assets included and the amount of coverage. Property insurance provides coverage for property loss and is charged at 0.70% of the average value of the assets over their useful life. Liability insurance covers accidents on the farm and costs \$733 for the entire farm.

**Office Expense.** Office and business expenses are estimated at \$100 per acre. These expenses include office supplies, telephones, bookkeeping, accounting, and legal fees for the sweetpotato part of the whole farm. The cost is a general estimate and not based on any actual data.

**Land Rent.** Land rents in Merced County depending on the irrigation district in 2005 (Trends and Leases) ranged from \$100 to \$250 per acre. Land rents according to growers in the area ranged from \$375 to \$400 per acre. For this study, \$375 is the rental value and the landowner pays the basic monthly water service charge and the grower pays the cost for the water used. The hotbeds are planted prior to surface water availability in the canals, so rent is \$475 per acre and includes pump use with the renter paying the pumping or electrical costs.

**Sanitation Rental.** The cost includes double unit toilets with washbasins, delivered and serviced weekly. The toilets are rented for three months beginning in mid-February for the hotbeds and again for six months beginning in April for the production field. The costs are allocated accordingly.

**Investment Repairs.** Annual maintenance on Investments is calculated as 2% of the purchase price, except for the portable pumps. Fuel and maintenance costs are included for the portable pumps and calculated as 15% of the new cost.

## **Non-Cash Overhead** Tables 11 – 12

Non-cash overhead is calculated as the capital recovery cost for equipment and other farm investments.

**Capital Recovery Costs.** Capital recovery cost is the annual depreciation and interest costs for a capital investment. It is the amount of money required each year to recover the difference between the purchase price and salvage value (unrecovered capital). It is equivalent to the annual payment on a loan for the investment with the down payment equal to the discounted salvage value. This is a more complex method of calculating ownership costs than straight-line depreciation and opportunity costs, but more accurately represents the annual costs of ownership because it takes the time value of money into account (Boehlje and Eidman). The formula for the calculation of the annual capital recovery costs is ((Purchase Price – Salvage Value) x Capital Recovery Factor) + (Salvage Value x Interest Rate).

*Salvage Value*. Salvage value is an estimate of the remaining value of an investment at the end of its useful life. For farm machinery (tractors and implements) the remaining value is a percentage of the new cost of the investment (Boehlje and Eidman). The percent remaining value is calculated from equations developed by the American Society of Agricultural Engineers (ASAE) based on equipment type and years of life. The life in years is estimated by dividing the wear out life, as given by ASAE by the annual hours of use in this operation. For other investments including irrigation systems, buildings, and miscellaneous equipment, the value at the end of its useful life is zero. The salvage value for land is the purchase price because land does not depreciate. The purchase price and salvage value for equipment and investments are shown in the tables.

*Capital Recovery Factor.* Capital recovery factor is the amortization factor or annual payment whose present value at compound interest is 1. The amortization factor is a table value that corresponds to the interest rate used and the life of the machine.

*Interest Rate.* The interest rate of 6.25% is used to calculate capital recovery. The rate will vary depending upon size of loan and other lending agency conditions, but is a suggested rate by a farm lending agency in January 2006.

**Building.** The metal building(s) are on a cement slab and total approximately 2,400 square feet. The buildings are used for shops and equipment storage. The buildings are located on the grower owned land.

**Warehouse.** The 9,600 square foot metal insulated building is used for potato storage. It also includes evaporative coolers for maintaining storage temperature. The warehouse is located on the grower owned land.

**Seedhouse/General Warehouse.** The seedhouse is a 500 square foot metal building on a cement slab. Potatoes removed from storage for seed and new seed potatoes purchased are warmed in this building for a couple of weeks prior to planting. The house is heated with a propane heater and the propane costs are assumed to be included in the Investment Repairs under Cash Overhead. During other times of the year the building is used for other storage or use.

Coolers. Five evaporative coolers are installed on the roof of the potato storage warehouse.

**Bins.** The bins are used for crop storage in the warehouse and each holds approximately 800 to 900 pounds of potatoes. Thirty-six hundred bins are owned by the grower -2,400 are wood and 1,200 are plastic. Bins require some annual maintenance and these costs are included in Investment Repairs. Seventy-five bins are used part-time for seed storage and this cost is allocated to the hotbeds.

**Land.** Cropland in the region ranges from \$2,500 per acre to \$15,000 per acre, depending upon irrigation where the land is located. In this study, we assume the land is in the Merced Irrigation District (MID) and is valued between \$5,000 and \$9,000 per acre. The value is not shown for land, because the potatoes are grown on rented land.

**Tools.** This includes shop tools, hand tools, and miscellaneous field tools. The tools are an estimated value and not taken from any specific data.

**Irrigation/Laterals.** The grower purchases drip tape for the beds annually and owns the lateral lines that connect to the drip tape. The drip tape is included in the production costs and the laterals under non-cash overhead. Each field is assumed to be 25 acres with 0.25-mile runs (field length) and require 33 feet of lateral lines per acre for a total of 2,500 linear feet. Drip tape is taken to the landfill for disposal.

**Portable Pumps.** Three 50 horse power (HP) diesel booster pumps with 3-tank sand media filters, one in each field, are used to pump the surface water and supply the water to each field. Annual maintenance and fuel is assumed to cost 15% of the purchase price and is included in Investment repairs under Cash Overhead.

**Equipment.** Farm equipment is purchased new or used, but the study shows the current purchase price for new equipment. The new purchase price is adjusted to 60% to indicate a mix of new and used equipment. Annual ownership costs for equipment and other investments are shown in the Whole Farm Annual Equipment, Investment, and Business Overhead Costs table. Equipment costs are composed of three parts: non-cash overhead, cash overhead, and operating costs. Both of the overhead factors have been discussed in previous sections. The operating costs consist of repairs, fuel, and lubrication and are discussed under operating costs.

Table Values. Due to rounding, the totals may be slightly different from the sum of the components.

#### NET RETURNS ABOVE TOTAL COSTS\*\*

\*See Returns under Production in text. Yield and Returns based on average of 650 boxes or 706.5 boxes at September harvest

\*\*Production costs are from Table 8, "Costs Per Acre at Varying Yields to Produce Sweetpotatoes", 650 boxes per acre column. The appropriate production cost (Table 8) subtracted from the Gross Income (Table 9) = Net Returns
