

Progress In Poultry

"THROUGH RESEARCH"

THE EFFECTS OF CAGE DENSITY, HOUSING AND STRAIN OF CHICKENS ON VARIOUS PERFORMANCE PARAMETERS (REPORT #1)

Donald D. Bell, Poultry Specialist, University of California, Riverside
John Carey, Poultry Specialist, University of North Carolina, Raleigh

Introduction: The effects of floor space allowances and colony size for caged layers has been the subject of hundreds of scientific papers over the last forty or more years. Differences between treatments have ranged from little or none to very large effects on performance. Obviously, the conditions between experiments varied as researchers used different strains, breeds, cage sizes and designs, housing systems, environments, feeding programs and other related management systems.

The North Carolina Random Sample Test began to study these inter-relationships in the early 1980's when new facilities were constructed at the Piedmont Research Station. Three houses were equipped with conventional 12" wide by 18" deep cages and the shallow cage which used the exact reverse dimensions--18" wide by 12" deep.

The researchers were interested in determining the effects of various forms of management and housing on performance in white and brown egg strains of chickens. This research is, without a doubt, the most comprehensive ever attempted to seek answers to this very complex question.

This report is a summarization of results over the last five tests and allows the reader to assess the repeatability of results associated with the factors of strain/breed, housing, and cage density. A second report will emphasize the cage shape aspects of the tests.

Description of the test: The following table describes the five tests included in this review.

NUMBER	I.D.	HATCH DATE	ENDING DATE	WEEKS
23rd	81/82	4/1/81	8/10/82	21-71
24th	82/83	3/31/82	8/9/83	21-71
25th	83/84	3/30/83	8/7/84	21-71
26th	84/85	4/14/84	6/23/85	20-62
27th	85/86	12/17/85	2/24/87	20-62

All groups were reared in cages. Each test group was replicated four times and randomly located within each housing type. Throughout this discussion, LAC refers to light and air controlled housing and curtain refers to an open-sided flush house. Density results reflect the average of both cage shapes.

Tables 1-3 summarize results by chicken type (white vs. brown egg strains). Tables 4-12 summarize results by strain for six major strains of White Leghorns. Table 13 is a summary of the other tables.

Interpretation of these data should emphasize the repeatability of results between strains, breeds and housing types. The reader should pay particular attention to the possibility of

interactions between factors. e.g. Do results appear to change direction with various factors? Does cage shape affect performance in one type of housing differently than in others?

Statistical analyses were not performed on the consistency of results between tests because of the many differences which existed between the tests. We would suggest, though, that the reader should place greatest emphasis on those factors that repeat themselves in at least four of the five tests.

The Babcock results in tables 4-12 have been adjusted to compensate for not being in all five tests in the ratio of the three-test results to the five-test averages.

A brief summary of general conclusions is on page 15.

* Other strains are included besides those listed in Tables 4-12.

General Conclusions: Hen housed egg production consistently favors the lower density. Housing type and strain/breed appear to have very little influence on the differences observed between the two densities. In general the 3 bird cages outperformed the 4 bird cages by about 12 eggs. Feed consumption was 4 to 5 percent more in the three bird cages and about 2 percent higher in the curtain sided housing. All strains/breeds showed similar relationships.

The feed required to produce one dozen eggs is about 4 percent higher in the curtain sided house but is essentially the same in the two densities. All strains perform similarly relative to these factors.

Density appears to have practically no effect on egg size. Egg size, though, is about 4 percent larger in the curtain sided house.

Total egg mass is primarily affected by the hen-housed egg production differences. The 3 bird cages produced about 6 percent more total weight of eggs. This was consistent with all strains. The curtain sided houses produced about 3 percent more egg mass.

The 3 bird cages produced less cracked eggs, 2.75% vs 3.45%. The LAC house also produced less cracked eggs, 2.78% vs 3.43%.

Considerably less mortality was observed in the 3 bird cages. Total mortality for the average test combining housing types was 7.7 percent for the three bird cage compared to 10.7 percent for the four bird cages. Mortality was slightly higher in the LAC house.

The feed requirement to produce a pound of eggs was practically the same between densities and housing types. The

combined results for the two chicken types were practically the same in both types of houses and in both densities.

In conclusion, there is very little evidence that strains perform differ-

ently with respect to cage density or housing. Density advantages or disadvantages seem to be shared equally among the strains tested. Effects of housing are also common to different strains.

Acknowledgements

The authors wish to express their appreciation to the staff at the Piedmont Research Station who were responsible for the daily operations associated with these tests. Also, we wish to acknowledge the contributions of Dr. Grady Martin who served as project director for many years including the period covered by the first three tests included in this discussion. And finally, we appreciate the support of the poultry industry and especially those breeders who have cooperated in this project in past years.

Distribution of PROGRESS IN POULTRY Is made to industry leaders and fellow researchers. Anyone wishing to be placed on the mailing list may send a request to the Editor.
