**Interventions and Regulatory Review**

1  
2  
3 MS. OLIVER: Good morning. I am glad to see our  
4 panel and working group were able to make it here on time.  
5 Not everyone is here, but most.

6 I just want to take a minute to remind you of some  
7 of the things I said yesterday about what we wanted the  
8 Fresh Produce Working Group to consider, and that was the  
9 information that was presented here, and to provide to FDA  
10 some recommended controls or interventions that you believe  
11 we should consider in the near term to enhance the safety of  
12 sprouts.

13 As I said yesterday, we have various avenues  
14 available including voluntary guidance, performance  
15 standards, good manufacturing practices or HACCP, and one of  
16 the questions we had is do we have the science available to  
17 support any or all of these and, if not all, which options,  
18 if any, and the other thing is to look and see are there any  
19 additional specific research areas that we should consider.

20 Yesterday, we heard from a number of groups  
21 including the consumers. We heard a number of people talk  
22 about what controls we should put into place, about  
23 separating the seeds for agriculture from seeds for human  
24 production. We also heard from the industry and individuals  
25 how difficult that actually would be.

1           There were a number of other questions that came  
2 up. We heard a little about the morphology of the seed and  
3 the fact that the way it is harvested, you are probably  
4 going to get cracks in your seeds and have problems, all the  
5 different types of seeds no matter whether it be an alfalfa  
6 seed, a clover seed or whatever, even though all of the  
7 seeds are a bit different.

8           A lot of other questions came up yesterday about  
9 interventions and interventions in the seed process, as well  
10 as interventions during the manufacturing process. In  
11 talking about some of those in the seed process, we talked  
12 about irradiation, we talked about chlorine, sodium  
13 hypochlorite, calcium hypochlorite, ozone, and others.

14           A lot of these come either under EPA's regulations  
15 or under FDA's regulations from our Office of Premarket  
16 Approval. Some even require food additive petitions. We  
17 wanted to take a few minutes this morning to have both EPA  
18 and FDA give a presentation from that standpoint, so that  
19 the panel could understand this and the working group in the  
20 background.

21           The two individuals from EPA who will be making  
22 presentations first can only stay a short time because they  
23 have another meeting to go to, so after their presentations  
24 I would like them to stay and take questions. We can have  
25 three or four questions from the panel and working group if

1 you have any specifically for them, and there will be  
2 somebody available that will stay around later from EPA if  
3 there are questions later in the morning in the general  
4 session.

5 With that, I would like to introduce Dr. Frank  
6 Sanders and Dr. Connie Welch from EPA, who will talk about  
7 EPA considerations.

8 **EPA Considerations**

9 DR. SANDERS: Good morning. Again, my name is  
10 Frank Sanders, and I am the Director of Antimicrobial  
11 Division of the Office of Pesticide Programs in EPA. We are  
12 responsible for the registration of pesticide products  
13 including germicides and other antimicrobial products.

14 I have with me, as was pointed out, Connie Welch,  
15 Chief of the Regulatory Branch II, and Michelle Wingfield,  
16 Chief of the Science Support Branch. Michelle is in the  
17 audience, but she will remain behind in the event that you  
18 have additional questions. Both Connie and Michelle are  
19 critical to our registration process, and they will provide  
20 more details on alfalfa sprout and seed issues in a few  
21 minutes.

22 Let me say we at EPA are prepared to work with the  
23 states and industry to rapidly approve the use of products  
24 that will control E. coli on alfalfa sprout and seeds.  
25 Products that make public health claims, such as kills E.

1 coli or strep, require registration under the provisions of  
2 FIFRA. This process can often be difficult and can also  
3 require several months to complete, and there are basically  
4 three ways in which products can be approved for use by EPA.  
5 They are Section 18, Emergency Use, Section 24(c), Special  
6 Local Needs, and Section 3, Registration.

7           Currently, there are no applications pending with  
8 us for the use of any products for the control of E. coli on  
9 alfalfa sprouts or seeds, however, it is my understanding  
10 that the State of California had issued a special local  
11 needs registration for the use of calcium hypochlorite on  
12 alfalfa seeds. This is a prewash soak in five pounds of  
13 seed and one gallon of 2 percent calcium hypochlorite  
14 solution.

15           We at EPA have not yet received this application  
16 for review. With respect to 24(c), we have disapproval  
17 authority, but the states have the authority to issue that  
18 for 90 days.

19           California has the only 24(c) that I understood,  
20 that I know about, that can be used for control of E. coli  
21 on alfalfa sprouts. Other states may also wish to take  
22 similar actions.

23           Let me say that there are chemicals, such as  
24 calcium hypochlorite, sodium hypochlorite, and hydrogen  
25 peroxide that we will likely be able to reach registration

1 decisions on rather quickly because tolerance exemptions or  
2 tolerances are already established for those chemicals.

3 For chemicals where there is no tolerance or  
4 exemption from tolerance, it would take much longer for us  
5 to reach a registration decision.

6 Connie will briefly outline the process required  
7 to obtain registration under the three categories of Section  
8 18, Special Local Needs, Section 3, and, if necessary,  
9 Michelle will briefly talk about the methodology that will  
10 be needed to determine the product efficacy.

11 If you wish to contact me in the future on any of  
12 these issues, I can be reached on Area Code (703) 308-6435.

13 Connie.

14 DR. WELCH: As Frank mentioned, there are three  
15 options right now for registration. One would be under a  
16 Section 18, the other one is 24(c), which is a Special Local  
17 Need, and what would be a new registration or new use.

18 Under the 24(c), the calcium hypochlorite already  
19 had a tolerance exemption, so that was pretty easy, and as  
20 he mentioned, the only state that we have worked with so far  
21 is the State of California.

22 We have not seen the 24(c) officially. We have  
23 gotten like a fax copy and made a few comments, but we have  
24 not seen it officially. We do have 90 days to approve or  
25 disapprove. We do not foresee disapproving this because it

1 is calcium hypochlorite, we do have a database, we feel  
2 familiar with calcium hypochlorite, that it will be  
3 efficacious.

4 As I mentioned, under all three areas, the  
5 tolerance or tolerance exemption would be required if one  
6 does not already exist, and usually, in our data packages  
7 for tolerances or tolerance exemptions, you are looking at  
8 such data as residue chemistry data and toxicity data to  
9 establish a tolerance or tolerance exemption.

10 Many times the tolerance exemption is based on the  
11 toxicity of the chemical or if there are no residues.

12 As Frank mentioned, time frames vary with each  
13 registration option. A Section 18 obviously will be put  
14 through rather quickly especially if the tolerance already  
15 exists. As far as the 24 (c), like I said, we have a 90-day  
16 approval time to approve or disapprove.

17 Under our FQPA, our Food Quality Protection Act,  
18 we have certain time frames that we must abide by, because  
19 this is a food use, it does not come under that time frame,  
20 however, given the situation, we would certainly give it a  
21 priority as far as moving it through the registration  
22 process.

23 Of course, in all areas, efficacy data would be  
24 needed. This is a public health claim, and so we would need  
25 to see some form of efficacy data. At this point, I would

1 say just in seeking a registration, it would be very helpful  
2 upfront to contact us, so that we can go over the data  
3 requirements.

4           There may be some that may be waived given the  
5 circumstances or the use involved that, you know, it may be  
6 applicable to waive some of the data requirements, so it  
7 would be very helpful in the beginning to contact us, that  
8 we can talk with you and work with you over each of the data  
9 requirements, and, you know, go a little bit more into  
10 detail what would be required for the use that you are  
11 seeking to register.

12           We can take questions right now.

13           DR. BUCHANAN: Do you have an outline of the  
14 efficacy requirements that you need for testing that we can  
15 get our hands on?

16           DR. SANDERS: We do have an outline for most  
17 efficacy testing. Michelle Wingfield will be available to  
18 talk about that in more detail.

19           MS. WINGFIELD: As far as the efficacy data  
20 requirements are concerned, this is a relatively new area  
21 for us, looking at public health related uses on fresh foods  
22 and produce. Given that it is a new area, last September  
23 1997, we presented before our Scientific Advisory Panel the  
24 question on the state of the science for efficacy evaluation  
25 on fresh fruit and produce.

1           We are currently working with groups who are  
2 establishing methodologies for evaluating the efficacy of  
3 fresh fruit and produce. According to the Scientific  
4 Advisory Panel, these methodologies should be simulated in  
5 use, actually using the subject fruit and vegetables as  
6 carriers, if you will, to determine the efficacy of  
7 antimicrobial products.

8           Again, this is a new area. We will be looking at  
9 peer review of these new methodologies and techniques, and  
10 validation processes before we approve any applications in  
11 these areas.

12           Any other questions? Yes.

13           DR. FARRAR: We just want to thank you for your  
14 assistance with Cal/EPA in speeding through our 24(c). One  
15 of the points that we sort of had to compromise on to get  
16 our request pushed through was the 12-hour re-entry issue  
17 that I think you folks had some input on, as well as  
18 Cal/EPA.

19           I would ask you, when the petition comes forward  
20 to you for both our 24(c) and the national application, to  
21 look at that issue again. A 12-hour re-entry is just not  
22 feasible in many of these sprout production facilities. We  
23 think there are other alternatives that we can work out, but  
24 12-hour entry puts kind of a real burden on a lot of these  
25 facilities not designed for a separate area with separate

1 ventilation, and so forth. We just ask that you take a look  
2 at that.

3 MS. WINGFIELD: Agree. In our comments back to I  
4 believe Dr. Jerry Campbell, those were some of our exact  
5 comments. We can work with you on that and possibly lower  
6 that. We don't foresee that as a show-stopper in this  
7 application.

8 DR. KVENBERG: I have a question relative to your  
9 protocols on efficacy and the advice you have received.

10 Do you have any information since pathogens are  
11 quite a rare event and can't be used in actual tests within  
12 food facilities, any information on surrogate pathogens or  
13 indicator organisms that would demonstrate efficacy that you  
14 could give us information on?

15 MS. WINGFIELD: It was the recommendation of the  
16 panel that we focus mainly on the two pathogens most  
17 affecting at this time food safety, which would be E. coli  
18 0157:H7, and the Listeria monocytogenes as at least the  
19 basis for establishing efficacy.

20 If an applicant wishes to list other pathogens on  
21 their label, they would have to test against those other  
22 pathogens also, but as far as the basic baseline, we are  
23 looking at the Listeria and the E. coli 0157:H7.

24 DR. KVENBERG: Let me restate my question. I  
25 understand that efficacy has to be demonstrated of the

1 chemical against the actual pathogens of concern. My  
2 question went to efficacy testing and actual implant  
3 operations.

4 Is there any ancillary data of non-pathogen  
5 bacteria that have the same characteristics that would be  
6 useful to EPA's application for efficacy?

7 MS. WINGFIELD: Not to my knowledge at this time  
8 although we would be willing to talk with several, in fact,  
9 we need to talk with several experts in this area for  
10 answering questions such as this.

11 DR. KVENBERG: Thank you.

12 DR. WELCH: I don't believe I left my phone  
13 number. It is (703) 308-8218. So far, like I say, we have  
14 only worked with one state, and the calcium hypochlorites  
15 and sodium hypochlorites fall within the jurisdiction of my  
16 branch.

17 If there are other chemicals, you can still give  
18 me a call, and if they don't fall within my jurisdiction, we  
19 can direct you to the right person.

20 MR. BERNARD: An additional clarification, if I  
21 could.

22 What are the categories of data that you need?  
23 You mentioned efficacy, you mentioned toxicology.

24 DR. WELCH: Toxicology was the chemistry.

25 MR. BERNARD: Environmental?

1 DR. WELCH: Some environmental depending on the  
2 use, if it would come under an indoor or an outdoor use.

3 MR. BERNARD: So, somebody seeking approval for a  
4 new compound would have to provide data in all three of  
5 those categories.

6 DR. WELCH: Yes. For the tolerance exemption, we  
7 mainly look at the residue data and the toxicology data.  
8 For purposes of a registration, that is where maybe eco or  
9 environmental fate data may or may not come into play.

10 MR. BERNARD: But for efficacy, you still don't  
11 have the protocol that you expect to be followed in place?

12 MS. WINGFIELD: Right. As I said before, this is  
13 a new area for us. Really only one perspective applicant  
14 has come forward thus far seeking a registration, and we are  
15 working with them in development of their efficacy protocol.

16 MR. BERNARD: How long do you think it might be  
17 before you have decided on a protocol, because I think most  
18 of the people here feel some urgency that if there is a  
19 compound that shows good efficacy, that we would like to get  
20 it on line and using to deal with a, "real public health  
21 issue" here.

22 MS. WINGFIELD: Agreed. In fact, one of the  
23 people that we are working with is Dr. Larry Beuchat, and I  
24 believe he will be addressing some of the efficacy issues in  
25 his presentation later this morning.

1 DR. SANDERS: Keep in mind that this is an unusual  
2 situation. To the degree that we can provide some  
3 assistance, we want to do that. We may have to be creative  
4 in some approaches. As long as we maintain good science, I  
5 think we can make some decisions to allow certain uses to  
6 occur, but we will have to keep in mind that we have to have  
7 quality science in reaching these decisions.

8 DR. FARRAR: One more question. There was some  
9 confusion, there is some confusion still regarding the  
10 tolerance exemption. You mentioned that you would still  
11 like to look at residue data even though there is a  
12 tolerance exemption established already. That seems a bit  
13 confusing to a lot of people.

14 DR. WELCH: Okay. I am sorry. Maybe I didn't  
15 state it clearly, but the residue data would only be needed  
16 if there is no tolerance currently on the books. So, it is  
17 only required in seeking a new tolerance or in proposing a  
18 tolerance exemption.

19 MS. OLIVER: Fine. Thank you very much, Dr.  
20 Sanders and Dr. Welch and Michelle. Michelle will be around  
21 later and can take questions during the group questioning at  
22 10:50, correct?

23 MS. WINGFIELD: Yes.

24 MS. OLIVER: Fine.

25 The next presentation will be from FDA, our Office

1 of Premarket Approval, and Laura Tarantino will discuss FDA  
2 considerations. Laura.

3 **FDA Considerations**

4 DR. TARANTINO: I will come up here and try not to  
5 stand behind the podium but where you can see me, but I do  
6 have a couple of overheads, so it might be easier if I came  
7 up.

8 I think, very much like what Frank and Connie just  
9 did, I just want to take a couple minutes to probably just  
10 give you an idea of what the regulatory framework is that  
11 people would need to deal with if they were going to come in  
12 to say, okay, I have got an intervention, it looks pretty  
13 good, what do I need to do to make sure it is lawful.

14 So, just a very quick sort of Food Additives 101,  
15 and there will be a test, but there is really only one  
16 question, and the answer to that is come in early. As  
17 Connie said, I think the bottom line take home is if it  
18 looks like there is something that looks effective and  
19 useful, it would be very helpful if people came in and told  
20 us about it as early as possible in the process. No matter  
21 how good an intervention might be, it is not going to be of  
22 use to anyone if it is not legal.

23 [Slide.]

24 Why would you need to come to us? Of course, if  
25 what you are dealing with turns out to be a food additive,

1 the Food, Drug, and Cosmetic Act does require premarket  
2 approval for new food additives. It also defines what food  
3 additive is, and that is on the next overhead.

4 [Slide.]

5 Food additive, any substance the intended use of  
6 which results or may reasonably be expected to result  
7 directly or indirectly in its becoming a component or  
8 otherwise affecting the characteristics of any food.

9 This is very, very broad. It is applied not only  
10 to ingredients intentionally added, it is applied to  
11 anything that may affect the characteristics, so that given  
12 the definition on its own, it would cover virtually  
13 everything, but on the next overhead, Congress also provided  
14 us with a bunch of exemptions from the definition of food  
15 additive.

16 [Slide.]

17 One of the classes of exemptions were things that  
18 are authorized by other laws, and one of those is  
19 pesticides, so if you have something that falls under EPA  
20 jurisdiction, then, you go to those folks.

21 Color additives, new animal drugs, one that could  
22 go on there now, which wasn't there when we first made this  
23 up, was dietary ingredients and dietary supplements, so that  
24 if it is covered by other laws or other parts of this law,  
25 it is exempt from the food additive definition.

1           Prior sanctioned substances, kind of a very narrow  
2 group. Those are substances that before 1958, when this  
3 whole part of the Act was passed, had gotten a written  
4 specific approval from either the FDA or the USDA for a  
5 particular use of an additive.

6           Then, of course, the last one there, generally  
7 recognized as safe, is a very significant exemption,  
8 important and widely misunderstood. In brief, I think what  
9 is most important about this is a substance is not a food  
10 additive and is exempt from the need for premarket approval  
11 if experts and qualified experts -- and these experts are  
12 not reserved to be necessarily the government -- determine  
13 that a particular use of a substance is safe based on either  
14 a history of wide use and safe use before 1958, or evidence  
15 that is widely available and widely available to experts  
16 that the use is safe, and that widely available evidence is  
17 such that experts can generally agree that the evidence  
18 supports the safety. It is actually a fairly vigorous  
19 burden, but a very important exemption, and one that we  
20 might come back to.

21           So, all of these are things that do not fall under  
22 the food additive definition, but if we go back to the  
23 definition on the next overhead, earlier, I ended the  
24 definition right about here, and then had three dots.

25           [Slide.]

1 Well, more of this definition talks about  
2 including any substance intended for use, producing,  
3 manufacturing, packing, processing, et cetera, and relevant  
4 to this discussion, any source of radiation intended for any  
5 such use.

6 So, this is, I think, where I know ionizing  
7 radiation is one of a number of techniques that is under  
8 active investigation for this, and this is where, as a  
9 matter of law, ionizing radiation and treatment radiation  
10 would be defined as a food additive and thus would be  
11 subject to premarket approval.

12 [Slide.]

13 So, let's say we have determined it is a food  
14 additive, it is not a pesticide, you come to FDA. It is  
15 subject to premarket approval. What then?

16 I just want to mention a couple of characteristics  
17 of the approval process under the food additive and some  
18 things that are perhaps different from EPAs. What is not  
19 different is the burden for establishing the safety is on  
20 the sponsor, and one does that by collecting the data and  
21 submitting it to the Agency in the form of a petition, and  
22 then FDA has the responsibility to review what is I think  
23 worth noting is then we issue a regulation.

24 What is sort of unique about the food additive  
25 process, not quite, EPA has this for registrations, but we

1 do rulemaking, and there are two things about it. The  
2 rulemaking is generic. That is, if we approve an additive,  
3 anyone can use it, not just the petitioner, under the  
4 conditions of use for which it has been approved.

5           The other is I think the sad fact that rulemaking  
6 takes time. It takes time, it's hard, and even if we were  
7 spectacularly efficient -- and sometimes we are not -- it  
8 still take time. I think this comes back to my earlier  
9 stricture that if you have something that looks promising,  
10 the earlier you can come and talk to us about it, and get us  
11 looking at it, the better off folks are going to be.

12           FDA is not permitted to consider possible benefits  
13 in making the safety decision. We can't change the safety  
14 standard, we can't change the standard for review. What we  
15 can do, what we will do, what we do do is make sure that if  
16 there is a thought that something has a potential public  
17 health benefit, to make sure it gets prompt attention, but  
18 that is different from saying that we have different  
19 standards.

20           The other thing we don't have is anything that is  
21 particularly analogous to either the exemption or the local  
22 use. We don't have any codified way of allowing a food  
23 additive on the market, if it is a food additive, prior to  
24 the issuance of a regulation.

25           [Slide.]

1           This just lists, I think, the same kind of  
2 question that Dane had asked. This is the standard  
3 information that is required in a petition in law and  
4 regulations, and, of course, it is very, very broad and much  
5 of it is common sense.

6           What is it? What do you want to use it for? How  
7 much are you going to use? Does it do what it is supposed  
8 to? Sometimes you need method, sometimes you don't. Safety  
9 studies, that is the tox studies. Proposed tolerances if  
10 needed. Most of the time you may not. Environmental  
11 information maybe, largely having to do with sites of  
12 production or ways that the additive itself would be  
13 disposed of and such.

14           These are very generic, and certainly don't give  
15 much help in terms of what would be needed in a particular  
16 case. Once again, I think it does behoove folks to talk to  
17 us because, in particular, for example, in the case of  
18 irradiation, in the case of petitions for irradiation,  
19 obviously, some of these don't really apply. They are very  
20 different beasts indeed.

21           [Slide.]

22           The kinds of things that are on here are just  
23 generic safety issues that we would consider in any  
24 petition. Obviously, toxicity in the case of irradiation,  
25 this might be chemistry really, radiation chemistry data.

1           Nutritional adequacy in the case of radiation  
2 petitions really has to do with are you irradiating and  
3 changing the levels of nutrients in a way that would affect  
4 a major source of a nutrient in the diet. This is possibly  
5 not terribly relevant for sprouts, but would be something.

6           Potential microbiological risk I think is where we  
7 would just look to make sure that you haven't done anything  
8 that would make the food less safe. For example, if you had  
9 very, very sensitive to whatever treatment it was, chemical,  
10 radiation, spoilage organisms, and a very resistant  
11 pathogen, might you be doing it, the process, in a way that  
12 would kill off spoilage organisms and leave the pathogen  
13 without competition.

14           I think when people were talking about efficacy  
15 earlier, and I talked about one of the things we need in the  
16 petition is evidence that it does its intended use, I think  
17 it would be helpful if we tried to separate out the safety  
18 review from efficacy per se, the standard for the food  
19 additives is for it to be safe. It is not like the drug  
20 standard where it is safe and efficacious.

21           If you do have performance standards, it is  
22 something that you are going to want to think about, and you  
23 are going to want to make sure that the conditions of use  
24 that you apply for cover the conditions which will allow you  
25 to reach a performance standard, but on our side in terms of

1 the safety review, we are less concerned about performance  
2 standards, and would need to have you talk to other folks,  
3 but I think that is something we would very much want to  
4 talk about as to how you frame an application and how you  
5 position it in terms of what the technical effect is in any  
6 potential rulemaking.

7           On that, I am going to stop except to reiterate  
8 that we do recognize the importance of some of these things.  
9 We can, we do, we will work with folks on anything that you  
10 might want to come forward, and I guess one thing that I  
11 will go back to is a regulation needs to cover a particular  
12 use of a substance, so quite analogous to some of the things  
13 that EPA said, in some cases we may have food additive  
14 approvals for a substance for some uses, but they may not  
15 cover the particular use you want.

16           That is all I have to say, so, questions.

17           MS. OLIVER: I think I would like to save all the  
18 questions for later, and we will do the questions after the  
19 next panel.

20           The next panel is going to deal with science and  
21 Dr. Peter Feng from FDA, Center for Food Safety and Applied  
22 Nutrition, is going to moderate that.

23           Dr. Feng.

24                           **State of the Science**

25           DR. FENG: Thank you, Janice, and good morning.

1           The next session, we are going to be addressing  
2 the state of science of two main aspects. One, of course,  
3 is detection methodology for these pathogens in seeds and  
4 sprouts. The other one is on preventive measures.

5           We are very fortunate to have a very international  
6 group of experts to address both of these topics. On the  
7 aspect of detection, one thing I want to mention is there is  
8 two aspects that are deficient in detection of sprouts. The  
9 first was mentioned yesterday, and that is our inability to  
10 consistently isolate pathogens from the seeds.

11           The other aspect that nobody has brought up is the  
12 absence of standardized detection methods for Salmonella and  
13 0157:H7 in sprouts and seed products. Hopefully, our  
14 experts will be able to provide answers for those questions.

15           My first speaker today is Greg Inami from the  
16 California State Department of Health. He is a  
17 microbiologist who has been actively involved in all the  
18 outbreaks of pathogens in sprouts in California. He has  
19 been analyzing most of the samples, and on occasion he has  
20 been able to isolate Salmonella from the seeds.

21           Greg is going to share with us his experiences in  
22 analyzing these products.

23           Greg.

24   **Methodology/Salmonella**

25           MR. INAMI: Thank you, Peter.

1 [Slide.]

2 Today, I am going to cover some of the work that  
3 we have done over the last two years in the isolation and  
4 detection of Salmonella in naturally contaminated alfalfa  
5 seeds.

6 There have been a number of outbreaks of  
7 Salmonella gastroenteritis connected to consumption of  
8 sprouts. These are some of the more notable outbreaks, and  
9 I am not going to cover these because a lot of these were  
10 covered yesterday, but what I do like to emphasize here are  
11 some of the lab results some of these investigators got in  
12 isolating Salmonella from sprouts and seeds.

13 The first two outbreaks that we have here, the  
14 investigators were actually able to isolate it from both the  
15 sprouted product and also from the seed. In the latter  
16 outbreak, the Bovismorbificans outbreak, the investigator  
17 was only able to isolate it from the seed after sprouting  
18 and growth, and I am going to be referring to this outbreak  
19 a little bit later.

20 In contrast, in 1995 -- and this has been  
21 mentioned many times yesterday -- the Salmonella Stanley  
22 outbreak. In this case, no Salmonella was isolated from the  
23 sprout or the seed, and the outbreak was determined by epi  
24 data and also by molecular comparison of the patient's  
25 isolates.

1 I want to skip around now. We worked on the  
2 Montevideo, Meleagridis outbreak, and that is a very  
3 interesting case. We did not isolate Montevideo from any of  
4 the sprout product or from the seed, however, with the  
5 Meleagridis, we were able to isolate from several packages  
6 of sprouts, but not the seed.

7 As you can see, in some cases, it seems like it is  
8 really easy to isolate these organisms out of the sprouts  
9 and seeds, and in other cases, as in the Stanley outbreak  
10 and the Montevideo, epi data and molecular testing of the  
11 patient's isolates were required.

12 The distribution of Salmonella and the numbers on  
13 the seeds may vary from lot to lot, and what we have seen,  
14 they may vary from bag to bag.

15 As I said, I am going to discuss some of the work  
16 that we have done over the past couple of years.

17 Our story begins in 1996, when public health  
18 officials in Oregon and British Columbia independently noted  
19 an increase of Salmonella serotype Newport, and this was in  
20 January of 1996. After an epi investigation, alfalfa  
21 sprouts were found to be associated with the illness.

22 Further traceback found a single lot of seeds to  
23 be the common source of these alfalfa sprouts. These seeds  
24 were imported from the Netherlands by a U.S. company, and  
25 they were distributed to sprout growers in California,

1 Oregon, and British Columbia, and actually, 90 percent of  
2 the seeds were shipped to Oregon and British Columbia, and  
3 some of them were shipped to California.

4 As part of our investigation, alfalfa seeds from  
5 the suspect lot were embargoed from a California sprouting  
6 company by the California Department of Health Services,  
7 Food and Drug Branch, and they were submitted to our  
8 laboratory, which is the microbial diseases laboratory of  
9 the California Department of Health Services.

10 They initially submitted 10 sample units to our  
11 laboratory for testing, and each of these sample units  
12 consisted of one bag of seeds weighing approximately 500  
13 grams. Now, we were looking for the best method that would  
14 give us the best recovery of Salmonella, and we searched in  
15 the literature and we found this paper in the Lancet by  
16 Ponka, and others, and they reported an outbreak of  
17 Salmonella Bovismorbificans connected with the consumption  
18 of alfalfa sprouts, and in this report, they were able to  
19 isolate the Bovismorbificans from both the sprout and the  
20 seeds.

21 However, they were only able to isolate it from  
22 the seeds after sprouting and growth, and not from the  
23 germinated seeds, and they have the statement here that our  
24 experience shows the Salmonella cannot be cultured from the  
25 seeds, but only after sprouting.

1           So, we followed their lead and decided to  
2 cultivate the seeds for four days before enriching and  
3 testing for Salmonella.

4           [Slide.]

5           This is our procedure for our sprouting procedure,  
6 and the procedure was done under aseptic conditions. All  
7 material, glassware, and media were properly sterilized  
8 before use. We examined 100 grams of seeds from each sample  
9 unit, and the seeds were soaked in two times sterile  
10 distilled water for 18 to 20 hours at room temperature.

11           The soaked seeds were subsequently planted and  
12 spread out onto moistened sterile gauze in a beaker, and  
13 they were covered loosely with an aluminum foil. These  
14 seeds were incubated for four days at room temperature under  
15 fluorescent lights and these seeds were not watered over the  
16 four-day period.

17           At four days, the seeds had germinated and grew to  
18 about 2 to 3 centimeters, and we tested 100 grams of the  
19 sprouted seed using a modification of the U.S. Food and  
20 Drug's procedure for Salmonella, and this comes out of their  
21 bacteriological analytical manual.

22           This procedure includes a pre-enrichment and a  
23 nonselective lactose broth, and then it goes into two  
24 selective enrichment broth, and we use a selenite and  
25 tetrathionate, and these are added to a post-enrichment M-

1 broth, which isn't labeled here.

2           The modifications of this method is the use of an  
3 enzyme immunoassay for detecting Salmonella, culturing from  
4 the M-broth to hecto and an XLD, and the exclusion of  
5 bismuth sulfite agar due to lack of resources at the time we  
6 were doing this exam.

7           Of the 10 sampled units examined, we were able to  
8 detect 4 using the EIA. Salmonella serotype Newport was  
9 isolated from 4 of the sample units, and salmonella serotype  
10 Albany and Schwarzengrun were isolated from a fifth.

11           One interesting note to point out is sample unit  
12 No. 9, we observed this negative EIA, and we had a positive  
13 culture, and we have observed these previously in our lab  
14 with other EIA's and testing with other food products, and  
15 this may suggest that the low numbers of culturable  
16 organisms may not be detected by EIA.

17           So, we were successful in detecting and isolating  
18 Salmonella from the alfalfa seed after germinating and  
19 growth. Now, as you could see, this procedure was very  
20 time-consuming and labor-intensive. It took over four days  
21 before we can start testing. Testing usually takes an  
22 additional three to four days before we get isolates on  
23 plates.

24           So, what we did is we did further testing using  
25 these five culture-positive sample units in a limited study

1 examining alternative seed processing methods that were  
2 faster and less time-consuming and less labor-intensive.

3           These alternative seed processing methods included  
4 seed shredding, seed soaking, and a washing method before  
5 culturing. The seed shredding was investigated since we  
6 believed that the Salmonella may be contained within the  
7 seed.

8           Shredding was thought to release the Salmonella  
9 into the enrichment broth, and the method involves taking  
10 100 grams of the dried alfalfa seeds, placing them in a  
11 blender jar, and shredding the seeds to a coarse powder,  
12 after which a 1 to 10 or a 900 ml of lactose broth was  
13 added, and the shredded seed was incubated accordingly.

14           We also explored a soaking and washing method to  
15 determine if we could isolate the organisms from the outside  
16 of the seed. The seed soaking method, 900 ml of lactose  
17 broth was added to 100 grams of seeds. These were gently  
18 mixed and incubated accordingly.

19           For the washing method, 100 grams of seeds were  
20 mixed with 200 ml of lactose broth, and these were mixed  
21 over an hour period of time. The lactose broth was decanted  
22 and incubated.

23           The enrichment detection and isolation method that  
24 we used for these alternative seed processing methods is the  
25 same procedure that we used for the sprouting method, and

1 that was the modified FDA-BAM Method. To rapidly identify  
2 any positive sample units, we used the EIA as initial screen  
3 before culturing. However, because one of the sample units  
4 was EIA-negative, culture-positive in our sample unit No. 9,  
5 we cultured sample unit 9 and 10 as a control regardless of  
6 EIA results.

7 [Slide.]

8 Our results shown here show that of the five  
9 culture-positive sample units that we tested, three were  
10 positive by EIA using the shredding method, two were  
11 positive by the soaking, and none was positive by the  
12 washing method.

13 Salmonella serotype Newport was isolated from all  
14 of the EIA-positive samples and also from one EIA-negative  
15 sample unit. The shredding method seems to have given the  
16 best detection out of this limited study that we did,  
17 however, overall, it looks like the sprouting method may  
18 show slightly higher detection with the EIA.

19 Interpreting the culturing, results are difficult  
20 since we had to sample unit No. 10, which showed a negative  
21 EIA, positive culture for Salmonella. Again, I want to  
22 stress that using an EIA to screen out negative samples may  
23 actually underestimate how many sample units contain  
24 Salmonella in low numbers.

25 So of the four methods that we looked at, the two

1 methods that seemed to be the most promising were the  
2 sprouting growth method and the shredding method, and  
3 recently, within the last month, we did some more work, and  
4 we did a little bit better controlled study in which we did  
5 a comparison of sprouting versus shredding for the isolation  
6 of Salmonella from these naturally contaminated seeds, and  
7 in this study we examined 30 sampling units of alfalfa  
8 seeds, and each of these sampling units were about a one-  
9 pound bag or 500 grams of seeds.

10           These were reserve sample unit of seeds from the  
11 1996 Oregon and British Columbia outbreak, and these were  
12 never tested before. The method we followed, that was the  
13 FDA-BAM method for the isolation of Salmonella.

14           We excluded the EIA because of the EIA-negative  
15 culture-positive units we had seen previously, and we tried  
16 to streamline the procedure, and how we did this is we  
17 tested previously positive bags of seeds, and we sprouted  
18 them for three days, and we found we were actually able to  
19 isolate Salmonella, so we shortened our incubation period  
20 from four days to three days, and we tested 100 grams of  
21 seeds from each of the sample units for each of the methods.

22           This is just a diagram of the BAM method that is  
23 listed in the BAM.

24           Our results are very interesting. With the  
25 sprouting method, we were able to isolate 3 out of 30 sample

1 units. With the shredding method, we were able to isolate 2  
2 of the 30 sample units. There is not much difference there,  
3 but it is interesting to note that the two positives that we  
4 got out of the shredding were different than the ones that  
5 we got out of the sprouting.

6 So, in total, we were able to isolate with both of  
7 these methods 5 positive sample units out of the 30.

8 This data may suggest that sprouting may be  
9 slightly better in detection than the shredding, but the  
10 jury is still out on that, but there are two other items  
11 that I want to mention that sort of support the sprouting  
12 and growth of these seeds for detection of Salmonella, and  
13 both of these come out of a paper that Jaquette and Dr.  
14 Beuchat published in 1996, and I think this was mentioned  
15 yesterday.

16 What they did is they seeded Salmonella Stanley  
17 onto the alfalfa seeds and they were able to show a 3 to 4  
18 log increase during a 54-hour germination sprouting period,  
19 so we actually are getting amplification as you are growing  
20 the sprout.

21 They also reported phenol compounds present in the  
22 seed coat which could possibly be toxic to Salmonella, so  
23 this kind of goes against shredding the seeds, these phenol  
24 compounds may be released, may be toxic to the Salmonella.  
25 Results from this study, our study, and the results from

1 Ponka may support sprouting and growth of the alfalfa seeds  
2 before culturing to increase the level of the pathogen for  
3 isolation, however, I think further studies need to be done  
4 to determine the most sensitive method.

5 [Slide.]

6 Very quickly, we did another limited study using  
7 these naturally contaminated seeds and looking at sodium  
8 hypochlorite solutions efficacy in killing Salmonella from  
9 the seeds. Again, this work was prompted by the paper from  
10 Jaquette and Dr. Beuchat.

11 There are just two items I want to point out on  
12 this slide here. One is that we were able to isolate  
13 Salmonella Newport from these seeds after we treated them  
14 with 700 parts per million of a sodium hypochlorite solution  
15 for one minute, and also treating with 270 parts per million  
16 for one minute and five minutes.

17 The other item I would like to point out has to do  
18 with sample size. On the bottom here there are two  
19 distilled water controls that we tested, and when we tested  
20 50 grams of these controls, we were not able to isolate the  
21 Salmonella, however, when we went back to the same lot and  
22 tested 100 grams, we did get isolation of the Salmonella.

23 We have observed this phenomenon twice in our  
24 laboratory again, however, because the number of bags we  
25 tested were limited, further work is needed to determine a

1 proper sample size.

2 [Slide.]

3 So, in summary, the distribution of Salmonella may  
4 vary from lot to lot, and actually may vary from bag to bag  
5 and within a given sample unit. The numbers appear to be  
6 low on these seeds, making isolation very difficult.

7 We are currently testing 100 grams from each  
8 sample unit, and then we follow the FDA sampling plan for  
9 Salmonella. When we can, we routinely test about 60 sample  
10 units per lot.

11 Sprouting gives us better recovery of Salmonella  
12 from the seeds versus the alternative seed processing  
13 methods, and there is a question mark there. I think the  
14 jury is still out, but among the two methods used in tandem,  
15 the sprouting and the shredding method, those two methods  
16 gave us a higher positivity rate from those 30 sample units  
17 that we tested.

18 We are currently sprouting and growing the seeds  
19 for three days before following the FDA BAM method of  
20 Salmonella. We are no longer using an enzyme immunoassay  
21 for detection because using an EIA may be not sensitive  
22 enough in detecting low numbers even after an enrichment  
23 period.

24 Our experience with sodium hypochlorite solution  
25 shows that it does not eliminate Salmonella from the seed,

1 and Dr. Beuchat, I am sure, will be discussing this in more  
2 detail.

3 [Slide.]

4 The last item that is very interesting, these  
5 seeds that we tested are two years old and actually they are  
6 probably even older than that, and we found that Salmonella  
7 is viable in these alfalfa seeds for up to two years or  
8 longer when stored at room temperature in the dark.

9 With that, I would like to thank you for your  
10 attention.

11 DR. FENG: Thank you, Greg.

12 Our next speaker is Mr. Steve Weagant from our FDA  
13 lab in Bothell, Washington. Steve has been very active in  
14 0157:H7 methodology. He is mainly responsible for  
15 developing most of the assays that we use in our FDA BAM  
16 manual. He was involved in the FDA sprout survey that was  
17 done several years ago, and he is also very active currently  
18 in the compliance program for sprouts that is in place right  
19 now.

20 Steve.

21 **Methodology/E. Coli 0157:H7**

22 MR. WEAGANT: Thank you, Peter.

23 As Peter said, I am Steve Weagant from FDA/Seattle  
24 laboratory, and I am going to talk to you about the  
25 development and evaluation of methodology for use in FDA

1 labs for the enrichment and isolation of E. coli 0157 in  
2 foods and particularly in sprouts.

3 Our attempts to isolate E. coli 0157:H7 from  
4 hamburger during the large outbreak in Washington State and  
5 other western states in 1993 was frustratingly unproductive.  
6 We felt that the methods that were currently recommended at  
7 that time needed improvement.

8 Our efforts led to an improved method for  
9 isolation of E. coli 0157:H7 in foods which was published in  
10 the Journal of Food Protection in January of 1995. This  
11 method was adopted in FDA's Eighth Edition of  
12 Bacteriological Analytical Manual.

13 Since then, this method has been used to provide  
14 food isolates from several outbreaks of E. coli 0157:H7  
15 infections. These include an outbreak of home-prepared  
16 hamburgers in 1994 in Washington and Oregon, an outbreak in  
17 several western states associated with salami produced in  
18 California and they produced the isolate for the Odwalla  
19 outbreak recently.

20 Just an overview of the method that we had  
21 developed using enrichment in what we call EEB or EHEC  
22 enrichment broth, which is based on the modified TSB  
23 developed by Dr. Doyle's group, and we did not add the  
24 novobiocin supplement for inhibition of competitors, but  
25 instead used vancomycin, cefsulodin, and cefixime.

1 I will just kind of walk you through this method.  
2 Here is a photo of adding the 25 grams of sprouts to the  
3 enrichment broth, and this homogenized and then incubated at  
4 37 degrees for 6 and 24 hours with agitation, which is  
5 extremely important.

6 Then, after the enrichment period, the enrichment  
7 was diluted and spread plated to sorbitol MacConkey's agar  
8 supplemented with tellurite and cefixime, and that is  
9 referred to as TCSMAC. Some authors refer to it as CTSMAC.  
10 It's the same formulation.

11 These plates were incubated overnight and typical  
12 colonies were picked for purity and screened through spot  
13 indole test, and then typical growth on EMB agar and HCMUG  
14 agar. Then, the presumptive positives were tested for the  
15 O157 and the H7 antigen by latex agglutination kit, and then  
16 subsequently tested for the Shiga-like toxin genes with PCR,  
17 and they are also confirmed as E. coli using either Vitek or  
18 API20E.

19 We also used an alternate technique in this work  
20 using immunomagnetic separation, or IMS, and this is a step  
21 between enrichment and the isolation which involves placing  
22 a ml of the enrichment broth with magnetizable plastic beads  
23 that are coated with the O157 antigen, and these trap the  
24 target bacteria, and we go through this procedure of adding  
25 the enrichment to the beads in a small tube, microcentrifuge

1 tube, and then tumbling them for about half an hour, and  
2 then they are rinsed twice and then they are trapped to the  
3 side of the tube. We remove the enrichment, and then they  
4 are rinsed twice, and the beads are then plated onto the  
5 TCSMAC agar.

6 This is the appearance of a TCSMAC plate through  
7 the enrichment and isolation without IMS. As you can see,  
8 the vast majority of the colonies are the pink colonies,  
9 which are not the target organism.

10 This a typical colony for the E. coli 0157 on this  
11 agar, and with IMS, we can see that the majority of the  
12 colonies present are the target colonies. And here are a  
13 few of the competitors, as well.

14 This methodology was validated in five different  
15 food types. In this study, the results showed overall with  
16 five food types that the direct isolation was about  
17 equivalent in results to the use of the IMS.

18 We had heard from other labs and had observed  
19 ourselves that in pure culture, the EHEC enrichment broth,  
20 the EEB with the cefixime at 0.05 mg/liter was somewhat  
21 inhibitory to some strains of 0157, and we investigated this  
22 and found indeed it was a problem.

23 This is a look at the EEB broth in pure culture  
24 with E. coli 0157 strains, and we found that at the 0.05  
25 mg/liter, all the strains seemed to be at least somewhat

1 inhibited. As we lowered the cefixime level, we found that  
2 the inhibition finally ceased at between 0.025 mg/liter and  
3 0.0125 mg/liter.

4 As a result, we thought it advisable to lower the  
5 level of cefixime in the EEB.

6 Because of the rapidly advancing problems with E.  
7 coli 0157 in sprouts and the upcoming FDA nationwide sprout  
8 assignment, we turned our attention to devising a workable  
9 method for isolating E. coli 0157 in sprouts.

10 I had recalled that from our previous work that in  
11 sprouts particularly, we did have a very good success using  
12 the IMS method, and this is a summary of our data from 1995  
13 that shows as we were using artificially contaminated  
14 sprouts with E. coli 0157, and as we lowered the levels of  
15 contamination down to 0.1 organisms or CFU/gram, in 16  
16 trials, we had 3 positives with straight technique and 10  
17 using the IMS, so it was pretty helpful. That is about 60  
18 percent positive with that method.

19 We began a series of experiments to compare six  
20 different enrichments for the recovery of E. coli 0157 from  
21 artificially contaminated sprouts using TCSMAC agar and with  
22 and without the IMS procedure after 6 and 24 hours of  
23 enrichment.

24 We also looked at detection by immunoprecipitin  
25 tests called VIP from BioControl. As we progressed, we

1 gradually reduced the level of contamination from 1 CFU/gram  
2 in sprouts to 0.12 CFU/gram.

3           We just look at the methods that we used. Three  
4 of our enrichment methods were done at 37 degrees with  
5 shaking. This included the original EEB formulation, EEB  
6 with one-quarter of the cefixime and then the modified EC  
7 broth that is the recommended enrichment for USDA.

8           We also looked at modified TSB with novobiocin,  
9 the original formulation by Doyle, but at 37 degrees without  
10 shaking, which was recommended in the procedure by  
11 BioControl.

12           We also looked at modified buffered peptone water,  
13 which is a formulation that has been proposed by Larry  
14 Ristano in Illinois and also buffered peptone water which we  
15 modified with acriflavine, cefsulodin, and vancomycin.

16           As you can see, the direct plating at six hours  
17 was fairly unproductive. We had some better results with  
18 IMS, but as we increased the enrichment time to 24 hours, we  
19 began to see much more positives, and as we added the IMS  
20 procedure at 24 hours, those positives increased the  
21 modified TSB at static was not as productive.

22           As we lowered the inoculation level from 0.42 to  
23 0.35, we began to see that the six-hour enrichment was  
24 fairly unproductive, and continuing the trends at 24 hours,  
25 I failed to mention the VIP detection was fairly successful

1 at above this level, but began to fail at this level.

2           Then, we got down to 0.12 CFU/gram, again, our  
3 six-hour procedures were fairly unproductive, 24 hours much  
4 better, the static 37 degrees was not productive, and VIP  
5 had failed us on these completely.

6           Just a look at the overall data from four  
7 different experiments, and tried to draw some conclusions  
8 from that.

9           One to six-hour enrichment was not as productive  
10 or as sensitive for sprouts, and we have not extended these  
11 into other food types which we are planning to do. Shaking  
12 seemed to be essential to the enrichment procedure.

13           Several enrichments were fairly comparable, so our  
14 overall results, looking at the EEB and the EEB with one-  
15 quarter cefixime modified BPW, and then with the additives,  
16 and then also the modified EC broth seemed to produce fairly  
17 comparable results.

18           One interesting note is that the reduction of  
19 cefixime in the inoculated food samples was not nearly as  
20 important as in pure cultures. There may be some modifying  
21 effects of the food matrix or the competitive microflora  
22 that seemed to modify the harsh effects of cefixime.

23           We feel that IMS is particularly valuable. It was  
24 the most productive method at 24 hours with TCSMAC, and we  
25 also feel that the VIP at least for this product was not

1 very productive.

2           So, out of this we developed a recommended  
3 procedure that is being used by FDA in its sprout  
4 assignment, and that is, to use the 25 grams of product with  
5 225 ml of the EEB, and we are lowering the cefixime to a  
6 quarter down to 0.0125 mg/liter, homogenized, and then  
7 incubate at 37 degrees C, 24 hours, with shaking, and then  
8 go through the immunomagnetic separation technique, and then  
9 plating onto the TCSMAC agar and overnight incubation of  
10 TCSMAC.

11           Typical colonies were then picked and streaked  
12 onto TSAYE and then screened through EMB, HCMUG, spot indole  
13 test, the Remel 0157:H7 latex agglutination kit identified  
14 as E. coli by Vitek or API20E, and then the STX1 and 2, the  
15 Shiga-like toxin genes were confirmed with PCR.

16           I would like to acknowledge some of the others  
17 involved in the work that has been done. Jim Bryant and  
18 Andy Ballen from the CL District Lab, Karen Geneman from the  
19 Seafood Products Research Center in Seattle, and Dr. Feng at  
20 FDA CFSAN for his guidance and support.

21           DR. FENG: Thank you, Steve.

22           Our next speaker is Dr. Larry Beuchat from the  
23 University of Georgia. Dr. Beuchat has already been quoted  
24 by many speakers on his work in preservatives and  
25 disinfectants, and that is the topic he is going to address.

1 Dr. Beuchat, please.

2 **Disinfectants**

3 DR. BEUCHAT: Thank you, Peter, quoted and  
4 misquoted, but thank you very much for inviting me to come  
5 in to present some of the data, some of the results that we  
6 have generated, some on Salmonella, as well as on E. coli  
7 0157:H7, with, in the case of Salmonella, our observations  
8 on seeds, as well as sprouts, and on E. coli, mostly just  
9 seeds to date.

10 I should also acknowledge before I begin to review  
11 and to share with really a summary of the observations that  
12 we have made, but the Salmonella work was done for the most  
13 part by Cindy Jaquette, who was a Master's degree student  
14 with me in 1996, 1995-1996. The work with E. coli 0157:H7  
15 was done by another Master's degree student, Peter Taramena.  
16 So, those two individuals deserve the credit really for the  
17 data that I will be presenting today.

18 So, I will get started here on the first slide.

19 The first section that I will present is on the  
20 Salmonella work, and I will be a little more brief on these  
21 data because, as a number of people have mentioned, the data  
22 have actually been published and are available for your  
23 observations and whatever you want to draw from them.

24 But the work that we did in the 1995-1996 years  
25 were actually done as a response to the outbreak that was

1 noted earlier or one of the outbreaks with Stanley,  
2 Salmonella Stanley.

3           These are the objectives of that study, and  
4 actually the objectives of this study were very much similar  
5 to the study that we have more recently done with E. coli  
6 0157:H7, and very basically was to test the efficacy of  
7 chlorine at that time, and we did try some other chemicals  
8 subsequently on the behavior of really the inactivation of  
9 Salmonella Stanley on alfalfa seeds to determine the  
10 survival characteristics of this particular Salmonella  
11 isolate on dry seeds as they may be stored in-house at a  
12 processing sprout operation or perhaps in a warehouse, a  
13 seed warehouse; and thirdly, to determine the behavior of  
14 the organism on seeds subjected to conditions that might be  
15 used commercially to grow and market seeds, and there is  
16 such a wide range of techniques that are used to produce  
17 sprouts we used a tray method, not having the drum system  
18 available then or now actually.

19           I am going directly to the data, the observations  
20 that we did make on a number of different chemicals. Of  
21 course, at that time, we were interested largely in the  
22 sodium hypochlorite, the chlorine source, that is, the  
23 hypochlorous acid and its activity on Salmonella.

24           We tried up to, in this particular set of data, up  
25 to 2,000 parts per million. Now, this is active chlorine.

1 We ran the tests at room temperature, about 70 degrees  
2 Fahrenheit, and I don't recall the time, 10 minutes in this  
3 case, but were able to reduce from about 8,000/gram down to  
4 less than 1.

5 On these particular tests, we did not run  
6 enrichment, so we do not know if, in fact, there were any  
7 viable cells, but the limit of detection was 1 CFU/gram, and  
8 with 2,000 ppm, we were not able to measure any viable  
9 counts.

10 We also did germination studies along with all of  
11 these chemical treatment studies, and in no case, in this  
12 particular table, did we find any reduction, at least  
13 significant reduction in terms of statistical significance  
14 with any of the treatments.

15 We also looked at calcium hypochlorite a little  
16 less in terms of concentration, but essentially, the same  
17 type of reduction. I should also mention these letters  
18 here, when you see a different letter -- let me back up --  
19 if a number, a count is not followed by the same letter,  
20 then, they are significantly different at 95 percent  
21 confidence level. In other words, a reduction of 7,900 to  
22 331 is a significant reduction, another significant  
23 reduction, and a third here with the 2,000 ppm.

24 We got the same scenario essentially with the  
25 calcium form of the hypochlorite. Hydrogen peroxide up to 6

1 percent, we got reductions, although in this case, we were  
2 able to count or at least detect a very low number of  
3 colonies. So, hydrogen peroxide also looked promising for  
4 the reduction of Salmonella on seeds.

5           Ethanol at 80 percent, we got a tremendous  
6 reduction. I will get to this later, but with the E. coli,  
7 we also lost germination; with the Salmonella studies we  
8 didn't, at least with this particular lot of seeds, observe  
9 any reduction in germination.

10           Now, we did follow up. I think Dr. Tompkin  
11 questioned yesterday had any work been done on temperature,  
12 that is, heating, and perhaps even heating in conjunction  
13 with chemicals.

14           This is a summary of some information, data that  
15 we did generate. We looked at several different  
16 temperatures in three-degree increments at higher  
17 temperatures. This would be our control of the room  
18 temperature, but also 54 and 57. We also looked at 60, 63,  
19 and somehow we chose three-degree increments.

20           We dipped, that is, submerged the seeds for either  
21 five or 10 minutes in each instance, then, we measured the  
22 population, in this case, of the Salmonella both in the dip  
23 solution, that is, what might be washed off during the dip  
24 process but remained viable, and also in the seeds.

25           We, of course, can pick up viable cells in the dip

1 solution. We also, in this case, reduced populations at 54  
2 degrees, and we did not detect the Salmonella at 57 or  
3 above. The same general trend holds true for the counts on  
4 the seeds, however, I must also mention that we did not do  
5 enrichment on the seeds, nor in the water, so we don't know  
6 quite whether we actually eliminated in terms of any viable  
7 cells the Salmonella from the seeds.

8           This bar graph shows you percent germination  
9 versus various temperatures of treatment, either in the  
10 green for five minutes, or the red for 10 minutes. Room  
11 temperature, not too surprisingly, we didn't reduce the  
12 viability, the germination at all even out to about 60  
13 degrees for five minutes we did not lose germination,  
14 however, for 10 minutes you get a significant reduction  
15 certainly at 60 degrees, and you see it beginning to fall  
16 off even at 57 degrees.

17           So, we have, as somebody mentioned yesterday, a  
18 fairly narrow window here in terms of the temperature that  
19 might be used, an elevated heating process that could be  
20 administered to seeds for the sole purpose of reducing  
21 populations of Salmonella.

22           There is some promise here. There are through  
23 strict controlled conditions the possibility that a  
24 temperature treatment could be, at least in conjunction  
25 perhaps with the chemical treatment, a possible step forward

1 in reducing, eliminating, not only Salmonella, but maybe E.  
2 coli and Listeria and other pathogens from alfalfa seeds.

3           This graph shows you the population of -- again,  
4 this is Salmonella Stanley versus time, and what we tried to  
5 do here was to grow the inoculated -- well, we inoculated  
6 alfalfa seeds, then, we grew sprouts using a system at least  
7 we thought would be within the boundaries of what might be  
8 used in the commercial setting, a six-hour soak time  
9 followed by a 24-hour time in which the seeds would be  
10 germinated, and then a three-day period from 30 hours to 102  
11 for the actual sprout growth and maturation, and then we put  
12 the sprouts into refrigerated storage. This was about 9 to  
13 10 degrees for 10 days, 102 to 342 hours.

14           So, as I believe Peter mentioned, or Gregory  
15 mentioned, we do get amplification during the germination  
16 process. Now, admittedly, the initial inoculum was high,  
17 but still we do get a tremendous increase during that  
18 period, and then an increase to maybe a high  $10^6$ ,  $10^7$ , which  
19 holds incidently through 10 days of storage at refrigeration  
20 temperature.

21           I do not have a graph showing this kind of data  
22 from the E. coli studies. We did that, and it looks very  
23 similar. I don't have a figure or a slide showing that, but  
24 0157 behaves very similar to this during the same treatment,  
25 the same system that we used there for the Salmonella.

1           Now, we did work also with dry seeds. We didn't  
2 go out to the year or two years that was mentioned earlier,  
3 but we did inoculate seeds and then we stored them at 8  
4 degrees Celsius or 21. The 8 degree for nine weeks,  
5 population was reduced by about 5-fold, and this was on dry  
6 seeds.

7           We also did studies at 8 degrees for one week and  
8 then 21 degrees for eight weeks. Now, you might ask why did  
9 you do 8 degrees for one week and 21 for eight weeks. Well,  
10 this was an afterthought. We had all the seeds in 8  
11 degrees. After about one week, we decided, well, maybe we  
12 should store some of these at room temperature, so we pulled  
13 some of them out and actually did the rest of the study  
14 storing them at 21 degrees.

15           But after eight weeks, we had a reduction of about  
16 40-fold at room temperature. So, we don't get a tremendous  
17 reduction at room temperature.

18           Our conclusions from this are that the  
19 concentrations of chlorine at that time that were  
20 traditionally used to sanitize alfalfa seeds were not  
21 effective, and still are not effective in eliminating  
22 Salmonella Stanley. Hydrogen peroxide and ethanol likewise  
23 were not certainly totally effective. Heating at maybe 54  
24 degrees for 10 minutes reduces populations by 100-fold.  
25 Heating at 57 at 135 degrees Fahrenheit for 10 minutes

1 reduces the population by about 300-fold, but does cause  
2 some loss of germinability.

3           The organism survives longer in seeds at 8 than  
4 21. Not too surprisingly, the organism can grow, does grow  
5 on alfalfa seeds during the production of sprouts, and does  
6 not lose viability during subsequent storage at  
7 refrigeration temperatures, 5 degrees for 10 days.

8           Now, to go on to the E. coli work, and this is  
9 more recent work that Peter Taramena has done, and I am  
10 going to go into a little more depth here on the objectives  
11 and the methods that we used, and methods of preparing seeds  
12 and analyzing, as a number of individuals have brought up,  
13 are a dilemma, a challenge, not only for seeds, but in  
14 produce in general.

15           But our objectives here were similar to those that  
16 we had when we began the Salmonella studies, that is, to  
17 determine the efficacy of several chemicals on their  
18 activity to kill E. coli on alfalfa seeds destined for  
19 sprouting and to determine the viability of the organism on  
20 dry seeds during storage.

21           We chose for this particular set of experiments,  
22 five strains. I have listed them here, one of which came  
23 from the Michigan/Virginia outbreak. It is the same strain.  
24 We actually got the one from the Virginia outbreak, and also  
25 one that had been isolated from a patient that was

1 associated with a lettuce outbreak. So, those are the five  
2 strains that we used of E. coli 0157:H7.

3 We would grow the strains under fairly traditional  
4 techniques, tryptic soy broth, 24 hours, 37 degrees, and  
5 then we would actually mix those strains. We, through a lot  
6 of experience, have been able to -- well, we have observed  
7 that we get about the same numbers. If we don't, we add  
8 little different volumes, but we wanted to have about the  
9 same number of each strain in this cocktail of E. coli that  
10 we would actually use to inoculate the seeds.

11 We did inoculate about 1 kilogram of seed at a  
12 time. We mixed for only one minute. We did not want the  
13 seed to take up too much of the moisture of the water from  
14 the dip, and then we would dry those seeds for 48 hours  
15 under a laminar flow hood. The temperature ranged from 22  
16 to 23 degrees, and the final moisture content after about 48  
17 hours was about 5.1 to 5.4 percent.

18 Then, what we would do, we have learned also in  
19 anticipating that some of the cells that might remain viable  
20 at that period of time could die off, those in various  
21 stages of debilitation and stress could die off within the  
22 first week or two, we always store our seeds for several  
23 days before we actually begin these tests.

24 We store them at refrigeration temperature, and I  
25 will show you a slide later that will indicate that we do

1 have die-off during the first week or so at refrigeration  
2 temperature and then it levels off.

3 Well, here are the chemicals listed in no  
4 particular order and the concentrations of these chemicals  
5 that we have evaluated. All of the results that I will show  
6 you are from at least triplicate experiments, triplicate  
7 trials, and then plated in duplicate on the enumeration  
8 media.

9 The pH of the solutions that were used are given  
10 here. We have done a little testing to determine carryover  
11 of residuals. In the case of the two acidified products,  
12 the pH, surface pH of sorbitol MacConkey agar is around 5.7,  
13 maybe a little stressful for already stressed cells, but not  
14 necessarily probably are going to inhibit the recovery  
15 resuscitation and colony formation by most.

16 In the case of the trisodium phosphate, the pH of  
17 the surface of the sorbitol MacConkey agar is about 8, 7.9  
18 to 8.0, so again, not really out of line with what would be  
19 reasonable to expect the colonies to form.

20 Now, the treatment of the seeds. Our system was  
21 to use 10 grams of seed, 40 milliliters of the treatment  
22 solution. If I don't mention otherwise, this was all done  
23 at room temperature.

24 We would have usually two exposure times, and they  
25 may differ, and that will be shown later. We would decant

1 the chemical, we would add 20 milliliters of a 10 percent  
2 peptone water, and then dilute that and plate out on  
3 sorbitol MacConkey agar. We would also remove some seeds  
4 for germination using a standard procedure for germination.

5 This slide and the ones that follow all use the  
6 same format, so I would like to spend a little time just  
7 setting you up on how we are going to show these data.

8 On this axis are the populations, that is, the  
9 number of viable cells of 0157 that we detected using the  
10 system just described. The concentration of the chemical on  
11 this axis and the time of treatment here, the blue in this  
12 case 3 minutes, and the red, 10.

13 All that data that we present on individual slides  
14 were compared for significant differences, statistical  
15 differences. So, we compared time, as well as concentration  
16 in this grid. Again, if you see a bar that does not have  
17 the same letter, then, there is significant difference,  
18 however, in this case, for example, 10-minute treatment down  
19 from zero, that is, the control down to 1,000 parts per  
20 million, well, we did reductions in counts, we got no  
21 significant reduction. Going to 2,000 parts per million, we  
22 did get a significant reduction. The same for three  
23 minutes.

24 Now, you might ask why, if you treat for three  
25 minutes, you get a lower number than you do for 10 minutes.

1 We have seen this on several occasions even with the  
2 Salmonella data.

3 Our thought is that in the case of those chemicals  
4 that are neutralized or in some way inactivated, reduced in  
5 their lethality upon contact with organic material, that  
6 whatever happened in terms of lethality happens early on in  
7 the process.

8 If, in this case, you leave the seeds in the 2,000  
9 ppm chlorinated water for another seven minutes, what we  
10 think is happening is that the cells that had adhered to the  
11 seeds are being removed or at least being loosened and we  
12 then add the peptone water and we vigorously shake that  
13 seed-peptone mixture, that we are actually separating cells  
14 from one another and separating more easily the cells from  
15 the seed in the 10-minute treatment test versus the three.

16 So what we are doing is we are seeing less  
17 colonies formed here at three minutes on our enumeration  
18 medium, but, in fact, there are probably -- well, one would  
19 think -- as many as 10 minutes and maybe even more. But  
20 this is real, this is something we have seen over and over  
21 again, not just for chlorine, but with some of the other  
22 chemicals that we have evaluated, as well.

23 That was the sodium hypochlorite. Here is the  
24 calcium hypochlorite giving you the same setup in terms of  
25 presentation of the data, and similar results in terms of

1 the effectiveness of the two different products. One is not  
2 too surprised because the basic active component is  
3 hypochlorous acid whether it comes from calcium or sodium.

4 Now, I don't have on slides data that we have  
5 generated on 20,000 parts per million. It was mentioned  
6 yesterday and indeed we did observe that at 20,000 parts per  
7 million, that is 2 percent calcium hypochlorite, that 3 out  
8 of 3 replicate trials that we were not able to detect E.  
9 coli 0157 by enrichment.

10 Now, knowing that this is as promising as any  
11 really of the chemicals that we had evaluated, we wanted to  
12 actually follow up with more replications, which we did, and  
13 I don't have those data on slides, but I have them on a  
14 table here, and it is important that I give you the proper  
15 information.

16 We did the test actually six more times, six  
17 additional replicates. Three of these replicates were the  
18 very same as we did when we generated the data indicating  
19 that we could not recover through enrichment in three  
20 replications the organism from seeds that had been treated  
21 with 20,000 parts per million of calcium hypochlorite.

22 The second set of three replicates, we didn't get  
23 the same results. In fact, out of the three replicates, we  
24 could isolate in each of the replications the organism  
25 through enrichment, we could detect E. coli 0157:H7 on the

1 treated seeds.

2 A third series of three replicates, this time at  
3 21 degrees and also at 55 degrees, thinking that the heat  
4 may have some synergistic effect, came a little closer to  
5 eliminating the organism, but in one out of the three sets,  
6 three replications, we would even with a 55-degrees  
7 treatment, 20,000 ppm calcium hypochlorite, isolate the  
8 organism, detect the organism through enrichment.

9 We did a double treatment, that is, treated with  
10 20,000 parts per million for three minutes. This was all  
11 three-minute data now. Then, we analyzed through  
12 enrichment, and then we went back, we treated the very same  
13 seeds again, 55 degrees, 20,000 parts per million, and could  
14 still isolate the organism.

15 So, while we have made I think certainly progress  
16 and have I think through all the chemical treatments that we  
17 have evaluated, this one does look the most promising. We  
18 still cannot say that we can eliminate about -- this, in the  
19 latter case, was a little over 2 log from the initial  
20 population the organism from alfalfa seeds.

21 Now, to go on to the other chemicals that we have  
22 evaluated, acidified -- this is actually chlorine dioxide  
23 acidified product -- we are seeing fairly large and  
24 significant reductions at 500 parts per million. Even at  
25 100 parts per million of chlorine dioxide, acidified

1 chlorine dioxide, we are seeing tremendous reductions even  
2 at three minutes, certainly at five minutes.

3           The other product is essentially I think -- let's  
4 see, chlorine dioxide product -- this is a product from  
5 [Alside] Corporation. It gives us similar results. The  
6 formulations that we were provided and that we used started  
7 with a 500 and then there is 850 and 1,200, there is  
8 actually a process in which you mix two containers of  
9 solution to get the concentrations that are used, in this  
10 case presented here, 500, 850, and 1,200.

11           MS. DeROEVER: Dr. Beuchat, two minutes, please.

12           DR. BEUCHAT: Yes. We got tremendous reductions  
13 at the 500, and this I think follows the observations that  
14 we saw with the other chlorine dioxide product, ethanol does  
15 a pretty good job, unfortunately, ethanol reduces the  
16 viability of this particular lot of seeds.

17           Hydrogen peroxide, I mentioned earlier with  
18 Salmonella, did a fairly good job in reduction. We also saw  
19 that here even at less concentration, 1 percent, we got a  
20 reduction. However, even at 8 percent, through enrichment,  
21 we could isolate 0157 from seeds, treatment for 10 or for 3  
22 minutes, and that was starting out with just a little over 3  
23 log of E. coli 0157:H7.

24           Trisodium phosphate, up to 15 percent, even at 4  
25 percent, a very low count, not being able to detect it by

1 direct to plating, but even at 15 percent, picking it up by  
2 enrichment, 3 out of 3 reps in every case.

3 Two products that are formulated and commercially  
4 marketed by Ecolab, Tsunami, and Vortex -- I don't believe  
5 Vortex is authorized certainly at this point for the use on  
6 produce or seeds, it is another product, but we wanted to  
7 try it -- again, with 80 parts per million, this is a  
8 peroxyacetic acid-based product, as is this one. We did get  
9 large reductions in populations.

10 A product called Vegi-Clean out of Microside in  
11 Troy, Michigan, we got reductions even with, well, 1  
12 percent, 2 percent.

13 These are the data for the storage study  
14 population versus time of storage. This is at 20 weeks.  
15 This is the 5 degree data and the 25 degree and 37. We have  
16 additional data. This is a little less than five months.  
17 We had 8-month data in which we are still picking up by  
18 enrichment the organism at 37, the 5 degrees flattening off.

19 MS. DeROEVER: Time, please.

20 DR. BEUCHAT: Conclusion. Low concentrations of  
21 those chemicals that you see, either peroxide, trisodium  
22 phosphate, or acidified sodium chlorite, chlorine dioxide do  
23 cause significant reductions of the organism on seeds with  
24 little effect on germination, but all the chemical  
25 treatments reduced the numbers of cells recovered on the

1 seeds, but none really eliminated the pathogen in our hands.  
2 An elevated storage reduces the population, but does not  
3 eliminate it. Those are alfalfa seeds up close.

4 Thank you.

5 DR. FENG: Thank you, Dr. Beuchat, for a very  
6 comprehensive, thorough review of disinfectants.

7 Our next speakers are Dr. William Fett and Dr.  
8 Kathleen Rajkowski from ARS, USDA, in Wyndmoor,  
9 Pennsylvania, and they will detail to us their work on  
10 disinfection and controlling pathogens on Sprouts.

11 **Control of Human Pathogens on Sprouts**

12 DR. FETT: I am Bill Fett, and Kathleen and I are  
13 going to share our 15-minute slot here, so we are going to  
14 have to move very quickly, 7 minutes apiece.

15 I wanted to mention one thing. The ARS  
16 information staff has put together a news background on what  
17 we are going to be talking about, and this has been provided  
18 to the panel members here on the stage, and there are some  
19 other copies in the back.

20 If I could have the slides, please.

21 I also want to mention that some of the work on  
22 irradiation that we will be talking about today was also  
23 done by Don Thayer, who is a research leader at the Eastern  
24 Regional Research Center.

25 We are firm believers that to have the best chance

1 of producing a safe sprout that we are going to have to  
2 employ multiple hurdles, multiple techniques along the way  
3 to give us the best change of having safe sprouts.

4           So, the first set of data that I will show you is  
5 some very recent data. I won't go into too much detail on  
6 the methodology because I don't have much time here. I will  
7 just say that Dr. Buchanan has been provided with a detailed  
8 report on these experiments.

9           This is the result of two experiments that were  
10 done fairly recently looking at the effect of calcium  
11 hypochlorite at various high concentrations on the effect of  
12 the viability of E. coli 0157:H7 that was artificially  
13 inoculated onto the seed.

14           We used a cocktail of four strains. One was the  
15 sprout-related strain from 1977, two were cider related  
16 strains, and one was the hamburger strain from a 1993  
17 outbreak. We started out with seed inoculated at about  $10^6$   
18 cells, CFU/gram of seed.

19           The treatment was for 10 minutes at room  
20 temperature, and it was preceded by two rinses of the  
21 inoculated seed with sterile tap water, and also there were  
22 two rinses with sterile tap water following the treatment  
23 with calcium hypochlorite.

24           I should say that the seed that we used for these  
25 experiments was sterile seed produced by very high-dose

1 gamma irradiation 25 kilogray. After treatment and rinsing,  
2 the seeds were pummeled in a sterile peptone water and  
3 plated either onto trypticase soy agar or E. coli/coliform  
4 Petrifilms produced by 3M. The Petrifilm media is selective  
5 and the TSA is not.

6           If we look at the TSA data, we can see that with  
7 the buffer control about  $10^6$  CFU/gram, we look at calcium  
8 hypochlorite, now, this is weight per volume. I think there  
9 is still some confusion when we are talking about calcium  
10 hypochlorite on what the actual concentrations are. In  
11 conversations with the people in California, it is my  
12 understanding that the registration is for 20,000 ppm of  
13 available chlorine.

14           Now, to get 20,000 ppm of available chlorine on a  
15 calculated basis, one has to use about 3 percent on a weight  
16 per volume basis because the commercial calcium hypochlorite  
17 is about 65 to 68 percent available chlorine. So,  
18 initially, we were going to start with just a look at 2  
19 percent and below, but after those conversations, we upped  
20 it to 3 percent to give us about 20,000 ppm of available  
21 chlorine.

22           You can see in our experiments that it did make a  
23 big difference going from 2 to 3 percent even though  
24 statistically with two replications there was no  
25 significance, but I am sure when we replicate this some

1 more, we will probably see a statistically significant  
2 difference between 2 and 3 percent.

3           The other thing I would like to point out is that  
4 on the Petrifilms, we didn't detect any E. coli 0157:H7  
5 survivors at the two highest levels of calcium hypochlorite.  
6 We believe that this is due to injury of population of E.  
7 coli 0157 that will not grow on the selective media, but  
8 will grow on the non-selective media.

9           We also have been looking at various chemicals as  
10 additions to the irrigation water. We use a tray system  
11 shown here, usually employing one tray with smaller trays on  
12 it. You can see a carboy here. That is where we put our  
13 solutions and they are pumped up, and the growing sprouts  
14 are sprayed through a spray nozzle up here.

15           This work was done with alfalfa again, and this  
16 just shows you some control values for total aerobes,  
17 coliforms in use in molds. These experiments were not done  
18 with human pathogens. Here, we have the seed treatments,  
19 sodium hypochlorite, calcium hypochlorite. This is on a  
20 weight per volume basis here.

21           Then, no addition to the irrigation water, and  
22 these are the kind of levels that we are seeing, and you can  
23 notice that at least with these two seed treatments, no  
24 reduction in the final microbial loads on the sprouts.

25           This just lists some of the chemicals that we have

1 tried so far. Unfortunately, we have not come up with a  
2 chemical that we can add to the irrigation water that will  
3 give us even a consistent 1 or 2 log reduction in the  
4 microbial loads.

5           Hydrogen peroxide, when we got up to 1,000 ppm,  
6 caused injury. We had some injury with the sodium  
7 hypochlorite. We have taken EDTA up to I believe 400 ppm  
8 with no effect. Right now we are trying some commercial  
9 sodium chlorite preparations.

10           I think we know the reason that it is very  
11 difficult to reduce the microbial loads on alfalfa sprouts,  
12 and that is due to much of the natural population being  
13 present in the form of byofilms. It is important because  
14 bacterial cells and biofilms are well known to be very  
15 resistant to antimicrobial compounds over free living  
16 bacterial cells, a difference of 1,000- to 5,000-fold.

17           We did some SEM studies on four different types of  
18 sprouts obtained at the retail level, and found that indeed  
19 natural biofilms are very abundant on all four of the types  
20 of sprouts that we looked at on all different plant parts.

21           Also, alfalfa sprouts that we grew up in our own  
22 lab for four days harbored extensive number of biofilms.

23           MS. DeROEVER: You have got two minutes, please.

24           DR. FETT: Okay. The last intervention that I  
25 would like to talk about -- and this is something we are

1 kind of just getting into -- is the area of competitive  
2 exclusion, and that is the use of innocuous or non-harmful  
3 microbes to exclude human pathogens should be from nutrients  
4 and/or colonization sites.

5 I am not going to go over this, but if you can  
6 read quickly, this is our protocol that we used. Here, we  
7 are looking at Salmonella. We had a cocktail of four  
8 Salmonella strains that we inoculated the seed with, and  
9 then we put the potential antagonist into the soak water.  
10 So, we think this could be a very easy technique for growers  
11 to do at the grower's site.

12 This just continues on with our protocol, a seven-  
13 day incubation period. This just shows you the vials that  
14 we use for the bioassay. These are about seven-day-old  
15 alfalfa sprouts and about seven-day old broccoli sprouts. I  
16 can tell you that of the 70 or so plant-associated bacteria  
17 that we have tested so far, that we have come across one  
18 strain that, in two experiments, reduced Salmonella by 5  
19 logs, and actually in the first experiment, it was  
20 undetectable compared to our control which had about  $10^7$   
21 CFU/gram of Salmonella.

22 So, I think this is a very interesting technique  
23 that might be very useful for the growers at the growers'  
24 site.

25 I am going to turn over the microphone now to Dr.

1 Rajkowski.

2 DR. RAJKOWSKI: In order for the irradiation  
3 process to be considered for use in the reduction or  
4 elimination of pathogens on sprouts or seeds, some points  
5 must be considered. On the onset of the work, the first  
6 consideration was would the sprout be a viable product.

7 What I did here is I obtained commercially grown  
8 sprouts and irradiated them at 2 kilogray and kept the  
9 control and the irradiated product in the similar  
10 circumstance, which was in a refrigerated room approximately  
11 8 degrees Celsius for a week, and then we photographed the  
12 results.

13 These were the alfalfa sprouts. As you can see on  
14 the control, there is browning and deterioration  
15 particularly in the root area where the 2 kilogray sprout  
16 looks just like as obtained a week before.

17 The next procedure was to take the sprouts,  
18 artificially inoculate them with both Salmonella and E. coli  
19 0157:H7 to determine a D-radiation value of these pathogens  
20 on the sprouts.

21 Most of the data previously reported in the  
22 literature are from meat, and I used both the meat cocktail  
23 for E. coli and for Salmonella. The strains are located  
24 over here, which are ATCC 35150, 34889, 43894, and two that  
25 were isolated from meat outbreaks, and for the isolates from

1 a sprout isolate, which was F4546.

2 For the Salmonella, they were Dublin Enteritidis,  
3 Newport Seftenberg and typhimurium. These are the ones that  
4 are reported by Dr. Thayer in all of his works. The strains  
5 that we used for the sprout isolates were Anatum Stanley,  
6 which is what was reported today and yesterday, Newport, and  
7 infantalis.

8 The results showed that compared to the meat  
9 strains on sprouts, which is a moist product, there is no  
10 difference in the D-values.

11 Using a similar procedure that Dr. Beuchat  
12 mentioned, we inoculated alfalfa seeds. We inoculated them  
13 to a level of approximately  $10^8$  to  $10^9$  to obtain our D-  
14 radiation values. The seeds being a dry product would have  
15 a slightly higher D-radiation value than any moist product.

16 Using the same strains as was used for the  
17 sprouts, these are the ones that are the meat isolate  
18 strains, we obtained a D-value about 0.6 kilograys. It is  
19 reported in percent inactivation as opposed to log  
20 reduction, so at a 99.99 percent reduction at about 2.5  
21 kilogray, we have reduced the population of 0157:H7.

22 The D-radiation value of the alfalfa seed using  
23 the sprout isolates were similar to those found for the  
24 meat.

25 The D-radiation values for the Salmonella, the

1 meat isolates that we used was slightly higher than had been  
2 anticipated, but again, these were done on a dry product,  
3 and the percent moisture, as you do your radiation, must be  
4 taken into consideration.

5           So, for the Salmonella of the meat isolates, we  
6 were able to obtain a 99.9 percent reduction at about a 2.8  
7 kilogray, with a D-value of close to 1.96 plus or minus  
8 0.05. Using the sprout isolates, we obtained approximately  
9 the same amount or the same D-value of 1.02.

10           Statistical analysis of the D-values has shown  
11 that there is no statistical differences between the meat  
12 isolate or the sprout isolates on the seeds, but they are  
13 much higher than those ever reported for the meat.

14           To show that the seeds are still viable, this is  
15 an experiment that I ran where I controlled all the seeds  
16 received 5 kilogray, and these are alfalfa seeds, of  
17 irradiation. All I varied was the temperature, and the  
18 temperatures ranged from 30 degrees down to zero degrees  
19 Celsius, which is about 32 to about 94 degrees Fahrenheit.

20           The control over has approximately the same mass  
21 weight as those that were irradiated at 5 kilogray. So,  
22 even at 5 kilogray, which would be much higher than used or  
23 would be proposed used the seeds were still viable.

24           In conclusion, competitive exclusion was an  
25 effective hurdle in controlling the growth of Salmonella on

1 sprouts. The shelf life of sprouts is increased at the  
2 irradiation of 2 kilogray. What we would like to do is go  
3 back, repeat this experiment and continuing it longer than  
4 just one week. The irradiation D-value of E. coli and  
5 Salmonella on sprouts are similar to the D-values for meat  
6 products being that these are moist products.

7           Reduction of microbial growth on growing sprouts  
8 will be difficult due to biofilm formation that Dr. Bill  
9 Fett mentioned. The radiation D-value for E. coli and  
10 Salmonella on alfalfa seeds appeared to be higher than the  
11 D-value for meat products, which means that a combination of  
12 irradiation with the chemical treatment is a viable  
13 alternative to the reduction or elimination of the pathogens  
14 on the seeds.

15           Thank you.

16           DR. FENG: Thank you, Dr. Fett and Dr. Rajkowski.

17           We have been going about two hours now, and we are  
18 running a little bit behind, so I have been informed that we  
19 are going to take a break now for about 15 minutes, and we  
20 will pick it up again at 10:05. Thank you.

21           [Recess.]

22           DR. FENG: We are going to continue with the last  
23 two speakers for this session entitled "State of the  
24 Science." We have two speakers from Japan. The first  
25 speaker is Dr. Kenji Isshiki from the National Food Research

1 Institute. He has been working a lot with control measures,  
2 and he is going to be discussing with us some of this work  
3 done using oyster shell calcium in preventing growth of  
4 0157:H7.

5 Dr. Isshiki.

6 **Control Measures**

7 DR. ISSHIKI: Thank you Dr. Feng.

8 Good morning, everybody. I am Kenji Isshiki. I  
9 work for the Japanese Ministry of Agriculture, Forestry, and  
10 Fisheries. Actually, I work in National Food Research  
11 Institute.

12 First of all, I would like to express my sincere  
13 thanks to all of you. After we had the severe E. coli 0157  
14 outbreaks in 1996, we thank you for your kind help. I am  
15 poor in English communication, so please be patient to my  
16 broken English.

17 This photograph shows radish sprouts growing in  
18 Japan. In Japan, we have various kinds of grow foods in  
19 fish and vegetables. Radish sprouts are eaten and grown,  
20 and after the outbreaks of 1996, radish sprouts also eaten  
21 after cooking.

22 Next slide, please.

23 In Japan, we have some kind of sprouts. One is  
24 radish sprouts, and the other is alfalfa, and traditionally  
25 eaten mung bean sprouts, and the new type of sprout is pea

1 sprout. This type of pea sprout and mung bean sprout cooked  
2 and then eaten.

3 Next slide, please.

4 We take quick look at the radish sprout  
5 production. This is a seed. These seeds came from the  
6 U.S.A., and this is making chlorinated water, and this is  
7 washing of the seed.

8 Next slide, please.

9 This is preparing the mat under the seed. It is  
10 put into the corner of the seed.

11 Next slide, please.

12 This is humidifier, hold the sprout for  
13 germinations in dark rooms for about two days. After,  
14 sprout moves to the greenhouse, and about five days after,  
15 are harvested and packaged.

16 Next slide, please.

17 In Japan, Ministry of the Health and Welfare  
18 announced that radish sprout was suspected epidemiologically  
19 as most likely food that cause outbreaks in Japan in 1996,  
20 but no E. coli 0157:H7 was detected from the radish and  
21 others.

22 Ministry of Agriculture, Forestry, and Fisheries  
23 decided to make this guidelines for the growing radish  
24 sprout to improve the safety of the product. A committee  
25 was organized and discussion on hygienic matters related to

1 radish sprouts production was carried out.

2 We make some experiment for these committees.

3 This photograph shows the surface of the stem of the radish  
4 sprout. You can see some bacteriums. This is a normal  
5 flora of the radish.

6 Next slide, please.

7 This is also the normal flora of the radish, maybe  
8 to make biofilms. If the E. coli 0157 attaches to these  
9 stems or leafs, we could not wash out all of the E. coli  
10 0157. We could only 99 percent of E. coli by the washings.

11 Next slide, please.

12 The seed and the E. coli and the water is very  
13 important. If the seed were polluted by E. coli 0157, water  
14 is added, the E. coli was very increased. This seed  
15 intentionally contaminated with E. coli 0157. Chlorinated  
16 water was used for the disinfection of the seed, but small  
17 time is observed, but after then the growth if very rapid.

18 We carried out some experiment. We make polluted  
19 seed and mixed with non-polluted seed. If we mixed one  
20 polluted seed with 1,000 non-polluted seed, the initial  
21 counts of E. coli is less than 300, but one day after adding  
22 water, the E. coli was increased to 12,000. It is very  
23 important. One seed were polluted, and non-polluted 10,000  
24 seed, they were also polluted.

25 Next slide, please.

1           So, we have done various kind of disinfection  
2 experiment for getting the clean seed, but most of them not  
3 successful. Some take care of the 0157, but actually we  
4 cannot use this method because we have food sanitation laws  
5 and other laws.

6           This is one example of disinfection of seed. This  
7 is dry air heating, polluted, intentionally polluted seed  
8 dry air at 75 degrees C. First day, 0157 was detected, six  
9 days or seven days after, 0157 was not detected, but the  
10 seed were put into the water and 20 hours after we took the  
11 E. coli 0157, the product is polluted by the 0157, which is  
12 very important.

13           Next slide, please.

14           This is my laboratory. These are oyster shells,  
15 oyster shells heated by more than 800 degrees Centigrade.  
16 The main component, calcium -- calcium oxide, so it makes a  
17 powder, and then added to the radish sprout, at this point  
18 0157 is added, and results calcinated calcium the 0157 is  
19 rapidly increased, but the addition of the 0.4 percent  
20 calcinated calcium, 0157 is killed and then 0157 is not  
21 detected. Radish sprout is not affected by the calcinated  
22 calcium.

23           Next slide, please.

24           We recommend two-day disinfection method. This is  
25 hot water treatment. The first step, it is dipped in hot

1 water for 55 degrees C. for six minutes, 131 degrees.

2           The second step is cool down with water and dip  
3 into a 2 percent calcinated calcium for five minutes. We  
4 can disinfect. Final product is negative, but heavy  
5 pollution of the E. coli, all of the E. coli was killed, and  
6 final product is positive. It is very important to check  
7 the seed and also check the final product, because the E.  
8 coli 0157 can recover during the cultivation of the radish  
9 sprout.

10           Next slide, please.

11           This is another recommendation of the seed  
12 treatment, hot water and sodium hypochlorite. The first  
13 step is dipped in hot water at 60 degrees C. for 90 seconds,  
14 and cooled down with water, and dip in 200 ppm chlorine  
15 water, and this is needed twice. Heavy pollution, cannot  
16 get final product negative, but slight pollution we can get  
17 the final product negative for E. coli 0157.

18           Next slide, please.

19           So, our committee recommended three treatments.  
20 First, wash with chlorinated water using water containing  
21 more than 0.1 ppm chlorinated water. The second step is  
22 sanitize with hot water and chemicals. The third step is  
23 keep water changing during the germination step. If the  
24 water is not changed, the concentration of the E. coli 0157  
25 is very high.

1           So, the outline of the clean sprout production we  
2 recommend is, first, examination of the seed  
3 microbiologically. We need E. coli is not detected. E.  
4 coli is indicator of bacteriums. If the E. coli is  
5 detected, we need second step, examination of the E. coli  
6 0157. Next step is wash seed well with clean water. The  
7 next step is sanitize seed, hot water and chemical  
8 treatment.

9           The fourth step is keep water changing during the  
10 germination. Fifth step is grow sprouts cleanly. Sixth  
11 step is distribute them under 10 degrees C.

12           Next slide, please.

13           So, our committee make final recommendations,  
14 sanitary guidelines for growth radish sprout. In October  
15 1996, a procedural manual was put forth by the Ministry of  
16 Agriculture. It has been revised in 1998.

17           It is pointed that the water and seed are very  
18 important to obtain the clean radish sprout. It is  
19 recommended to use tap water or disinfected chlorine water.  
20 Every lot of the seed must be checked as free from E. coli.  
21 If the E. coli was detected, it should be necessary for use  
22 the seed to contain free from the Shiga toxin producing the  
23 E. coli and Salmonella.

24           It is recommended that the seed should be  
25 sanitized with hot water. Other issues, such as the

1 sanitation facilities and employees are discussed in  
2 manuals.

3           This photograph shows one product of the radish  
4 sprout. This shows this product was produced under these  
5 guidelines.

6           Next slide, please.

7           So, we need more research. Actually, we have  
8 small amount of the information about the E. coli, so in our  
9 ministry, we start research, making the compost for other  
10 items under research.

11           Next slide, please.

12           Next year, we will make guidelines for clean  
13 production for the hydroponics or hydroculture of  
14 vegetables. We need more research to make the guidelines.

15           This is my presentation. Thank you very much for  
16 your attention.

17           [Applause.]

18           DR. FENG: Thank you, Dr. Isshiki.

19           Our final speaker for this session is Dr. Susumu  
20 Kumagai from the National Institute of Infectious Diseases  
21 in Japan. Dr. Kumagai has recently published a few papers  
22 on artificial contamination of radish sprouts using 0157:H7,  
23 and that is the work he is going to be sharing with us.

24           Dr. Kumagai.

25

#### Control Measures

1 DR. KUMAGAI: Thank you, Dr. Feng, for the kind  
2 introduction and for also inviting me to this very important  
3 meeting.

4 Slide, please.

5 My talk today is our study of experimental  
6 contamination of radish sprouts with E. coli 0157:H7.

7 In 1996, there were several large outbreaks in  
8 Japan, and the largest one among them took place in Sakai  
9 City with more than 6,000 patients and hydroponically grown  
10 radish sprouts were implicated in this outbreak.

11 Radish sprouts are sold in such containers, and  
12 people usually eat them after removing their roots, and  
13 usually eat raw as salad, sushi, and other dishes as was  
14 shown by Dr. Isshiki.

15 A question we had at this time was how can radish  
16 sprouts be contaminated with E. coli 0157:H7, and in order  
17 to see it, we performed a series of experiments of  
18 contamination of radish sprouts with E. coli 0157:H7. Those  
19 were the experiments, contamination of edible parts of  
20 radish sprouts by soaking their roots in E. coli 0157:H7  
21 containing water, and through activation of the organism  
22 during growth of radish sprouts from artificially  
23 contaminated seeds.

24 The location of the organism in artificially  
25 contaminated radish sprouts by immunofluorescence and

1 immunoscanning electron microscopy, and the effects of this  
2 infection and heat treatment on survival of the organism in  
3 artificially contaminated radish sprouts.

4           At first, we started the contamination of edible  
5 parts of retailed packed radish sprouts after contamination  
6 of their roots. Retailled packed radish sprouts, they have a  
7 height of 12 to 14 centimeter, and we made holes at the  
8 bottom of packs, and then these packs were dipped in the  
9 water containing E. coli 0157:H7 at the level of 4 to 7 log  
10 CFU/ml, so that their roots were dipped in the same water.

11           Eighteen hours later, we cut the edible parts off  
12 the sprouts, 4.5 to 5.0 centimeter long, and then determined  
13 the presence of E. coli 0157:H7.

14           The results were expressed as the number of  
15 contaminated packs per quarter number of packs used in this  
16 experiment. In either contamination level, the edible parts  
17 were contaminated with E. coli 0157:H7 for the two strains  
18 used in this experiment.

19           From this result, we thought of the possibility  
20 that E. coli 0157:H7 can be absorbed from the root to the  
21 edible parts of radish sprouts, and in order to see whether  
22 it is true or not, we did the next experiment as shown here.

23           The seeds were placed on the net in the beaker,  
24 and sterile water was given to the seeds, and they were  
25 grown for eight days, and then they were separated to four

1 groups. The first two groups, the roots remained intact,  
2 and for the third group, the roots were cut in half, and for  
3 the last group, the roots were completely cut away, removed.

4 Then, for the first group, the remaining roots  
5 were dipped, half of the remaining roots were dipped in E.  
6 coli 0157:H7-inoculated water, and for the second group, the  
7 whole roots and the lower part or hypocotyl were dipped in  
8 the same water, and for the third group, the roots were also  
9 dipped in this water.

10 For the last group, the robust part of hypocotyls  
11 were dipped in the same water. Eighteen hours later, the  
12 edible parts of sprouts were analyzed for E. coli 0157:H7.  
13 This shows the seeds on the net in the beaker, and this  
14 shows the grown radish sprouts. You can see sprouts were  
15 not so crowded as retailed packed sprouts.

16 This shows the result of this experiment. For the  
17 first two groups in which their roots remained intact, no  
18 edible parts were contaminated with E. coli 0157:H7,  
19 however, for the third group, and last group, the edible  
20 parts were contaminated with the organism.

21 The former experiment using retailed packed radish  
22 sprouts showed the edible parts of them became contaminated.  
23 If the roots were dipped in contaminated water, and this  
24 experiment showed however contamination doesn't spread from  
25 intact roots to the edible part, if sprouts were not so

1 crowded and spaces between sprouts are wide enough, and also  
2 this result showed that the contaminations spreads to the  
3 edible parts if the roots were hypocotyl or injured, and  
4 from all these results we thought that the observed  
5 contamination of the edible parts of the retailed packed  
6 radish sprouts may have been due to possible injury of their  
7 roots were action caused by a crowded condition of sprouts.

8           The next subject was contamination of edible parts  
9 of radish sprouts after contamination of seeds with E. coli  
10 0157:H7. In order to clarify it, we did the following  
11 experiments.

12           The seeds were on the net and dipped in the water  
13 containing 0157:H7 at a level of 3.5 log CFU/ml, and eight  
14 hours later, radish seeds were took away from the water and  
15 analyzed for E. coli 0157:H7, and the other seeds were  
16 transferred into sterile water, and 24 hours later, also  
17 germinating seeds were analyzed for the presence of the  
18 organism.

19           In the other experiments, also, the seeds were  
20 contaminated with the organism in the same manner as these  
21 experiments, and then they were grown for about one week,  
22 and then the edible part were analyzed also for the presence  
23 of E. coli 0157.

24           This shows the seeds in the water containing E.  
25 coli 0157, and this shows the grown radish sprouts. This

1 shows the results of these experiments. At eight hours, the  
2 seeds contained 4 log cells of 0157:H7, and then 24 hours  
3 later, germinating seeds contain more than 8 log cells, and  
4 then at seven days, the edible parts contained nearly about  
5 6 log cells.

6 This result indicates clearly that E. coli 0157:H7  
7 increases very rapidly during the early stages of growth of  
8 sprouts including germination stage, and then after grew,  
9 they contain very high level of 0157:H7 in the edible parts.

10 In order to see the location of E. coli 0157:H7 in  
11 artificially contaminated sprouts, we did microscopic  
12 observations. This shows the method. We prepared  
13 contaminated sprouts as mentioned before from contaminated  
14 seeds, artificially contaminated seeds, and then after grew  
15 are cut a part of hypocotyl was removed and fixed in  
16 formalin, and then treated with anti-E. coli 0157:H7  
17 antibody, and then are treated with fluorescein conjugated  
18 secondary antibody, and observed on the fluorescent  
19 microscopy.

20 The other group was treated for scanning electron  
21 microscopy including treatment with anti-E. coli 0157:H7  
22 antibody, and then with gold-labeled secondary antibody.

23 This shows horizontal cut of hypocotyl of  
24 artificially contaminated sprouts. There were many strong  
25 fluorescence in and on the vessels of the sprouts, and also

1 near to the epidermis of hypocotyl. This shows  
2 uncontaminated control of hypocotyl, showing background  
3 fluorescence.

4 This shows the outer surface of contaminated  
5 hypocotyl by scanning microscopy. There were many bacteria  
6 on the outer surface of hypocotyl, and they were stained,  
7 they were labeled with gold, and this shows the inside  
8 hypocotyl. This is vessel and although far fewer than the  
9 outer surface, there were bacteria, and some of them were  
10 labeled with gold.

11 This shows stroma of hypocotyl, and around the  
12 stroma there were also many bacteria, and they were labeled  
13 with gold.

14 This is the same, but inside of the stroma also  
15 there were some gold-labeled bacteria, and this bacteria is  
16 just dividing to two cells. This is also the same.

17 These are on the outer surface of hypocotyl, and  
18 these were gold-labeled bacteria, and these are not gold  
19 labeled, perhaps the other bacteria than E. coli 0157:H7.

20 Next, our interest was whether the bacteria inside  
21 tissue are viable or not, and in order to see it, we  
22 prepared contaminated sprouts from artificially contaminated  
23 seeds, and then cotyledons and hypocotyl were dipped in  
24 mercury chloride solution for 0.5 to 10 minutes, and mercury  
25 chloride is often used for surface infectant in the field of

1 plant pathology as very strong disinfectant, and sprouts  
2 were dipped in this manner, and then a part of cotyledon was  
3 removed and cut half, longitudinally cut half, and this cut  
4 surface and the outer surface were placed on the others for  
5 detection of E. coli 0157:H7, and then incubated overnight  
6 at 37 degree for colony formation.

7           The results were expressed as positive slices, a  
8 number of positive slices as seen in yellow. E. coli  
9 0157:H7 on the outer surface was killed completely by  
10 mercury chloride treatment for 10 minutes, however, the same  
11 treatment could not completely kill the bacteria inside  
12 tissues.

13           The former experiment indicated that E. coli  
14 0157:H7 exists inside sprouts where mercury chloride cannot  
15 reach in 10 minutes. Next, we examined the heat treatment  
16 of the edible part of artificially contaminated radish  
17 sprouts. As mentioned before, we prepared contaminated  
18 radish sprouts from artificial contamination of seeds, and  
19 then after grew, we took the edible part, 1 to 2 grams, and  
20 then heated in boiling water for 5, 10, or 60 seconds, and  
21 then they were analyzed for E. coli 0157:H7.

22           This shows the result, and the 5-second heating is  
23 very effective to kill the bacteria. The reduction was more  
24 than six orders of magnitude.

25           These are seeds of experiments. We could find

1 contamination of intact roots doesn't spread to the edible  
2 parts if the sprouts are not so crowded and spaces between  
3 sprouts is wide enough, and the edible parts can be heavily  
4 contaminated when they are grown hydroponically from  
5 contaminated seeds.

6 In the experiment, heavily contaminated sprouts, a  
7 large number of the organism exists on the surface of the  
8 plant, but a small number is also inside the plant where  
9 mercury chloride cannot reach in 10 minutes. However, five-  
10 second heating in boiling water is very effective in  
11 reducing viable number of the organism in the plant.

12 Thank you very much for your interest.

13 DR. FENG: Thank you, Dr. Kumagai.

14 This concludes the session on the State of the  
15 Science. I would like to thank all the speakers for  
16 presenting, and I now turn the session back to the panel.

17 DR. KVENBERG: Thank you, Dr. Feng. I am standing  
18 in for Janice Oliver for the moment again on the panel. In  
19 a moment, I would like to bring this morning's speakers up  
20 for questions and answers, but the Chair has received a  
21 request from Mr. Bob Rust who would like to make a very  
22 brief statement.

23 If you could come up to the podium for a few  
24 moments, and then we will ask the speakers for this morning  
25 to come up.

1 MR. RUST: I am Bob Rust with International  
2 Specialty Supply, and we have been selling sprouting seed  
3 for about 18 of the 20 years that we have been in business.  
4 There is a few things to me that are starting to add up.

5 We look at a lot of seed, and I have looked at a  
6 lot of seed at 30 times magnification. I don't recall ever  
7 seeing any chipped seed. I have seen broken seed, and I  
8 have seen cracked seed, but I don't recall ever seeing  
9 chipped seed. Indeed, seed tests, when you purchase seed,  
10 it has the amount of cracked and broken seed listed on the  
11 seed test report. It is generally under 1 percent.

12 I believe -- I could be wrong -- but I very  
13 strongly believe that the slides that we saw from Dr. Wick  
14 today was of scarified seed. Hard seed is seed that won't  
15 readily imbibe water, it has a hard seed coat, and if you  
16 scratch the seed coat, which is called scarifying, it will  
17 imbibe water because the water can get in.

18 Now, we used to buy seed from Italy. In fact, I  
19 contracted about a million pounds from Italy, and this was  
20 maybe 10 years ago. The first about a quarter, maybe  
21 250,000 pounds was good seed, it had a low hard seed count.  
22 All of the rest of it had a high hard seed count, and we  
23 ended up rejecting it.

24 In that period of time, we have got in many  
25 samples from Italy, because it is not very expensive seed,

1 and if we could buy it from Italy, we would, but the hard  
2 seed count has been very high, and there has not been any  
3 acceptable seed to me, and Idaho is another place where  
4 there is a very high hard seed count in the seed. In fact,  
5 we have never bought seed from Idaho.

6           If you scarify that seed, it is then sellable to  
7 sprout growers. Now, some of the contaminated seeds,  
8 contaminated sprouts came from Italy and Idaho, and I also  
9 know the grower in Denmark where the Danish outbreak came  
10 from, and they bought their seed from a company in Italy.  
11 That seed almost certainly was scarified, as well.

12           Seed that is not scarified, which is nearly 100  
13 percent of the seed in a seed lot, is just as smooth as  
14 silk. It is very, very smooth. You look under a microscope  
15 and it looks very smooth. It looks like the portions of the  
16 seed that were not cracked.

17           Now, Dr. Beuchat, when he was doing his research,  
18 he found out that there was one study that he did that  
19 killed all of the Salmonella and E. coli, and another study  
20 that he did, it didn't, even though he did the same study.

21           Now, I spoke to him, and he said that those two  
22 studies were done using two different lots of seed. Now,  
23 they did come from a supplier who does scarify seed, so it  
24 is possible that one of the lots was scarified, and a lot of  
25 bacteria could get in the seed coat, and that the other lot

1 was smooth as silk and basically, when he spiked it, there  
2 was just Salmonella on the outside.

3 I have a strong hunch that intact seed can be  
4 surface sterilized, so what I am proposing is that we take a  
5 very serious look at the problem of scarification and that  
6 for the time being none of the seed companies scarify their  
7 seed and that sprout growers surface sterilize their seed,  
8 and I believe that we will seriously reduce the incidence of  
9 pathogen problems that we have got.

10 DR. KVENBERG: Thank you, Mr. Rust.

11 At this time, could I ask the speakers from this  
12 morning's panel to please come up and find a place where you  
13 will have access to a microphone. We will begin the phase  
14 of this morning's program where we go into questions and  
15 clarification. My watch may be running a little slow. I  
16 have about five after the hour. The panel, please, and  
17 Produce Working Group, take the time you need.

18 Before we break for lunch, which we plan to do at  
19 12:30, I would like to allow sufficient time for public  
20 comment before that period, but let the questions begin and  
21 take the time you need.

22 Dr. Doyle.

23 **Questions of Clarification**

24 DR. DOYLE: Could I ask Mr. Rust a question?

25 MR. RUST: Certainly.

1 DR. DOYLE: How would you perceive the pathogens  
2 contaminating the seeds during this scarification process?

3 MR. RUST: The process of scarification, you take  
4 the seed and you scratch the seed. You put it into a  
5 machine that is designed to scratch the seed. As it  
6 scratches the seed, in the process, it could basically be --  
7 and I am not saying it is -- but it could possibly be  
8 injecting Salmonella into it.

9 If there was feces or something in the scarifier,  
10 and as it scratched it during the process of scratching, it  
11 could basically be injecting it with Salmonella.

12 DR. BUCHANAN: Could I ask a follow-up question?

13 Is there typically any cleaning steps of the seeds  
14 after scarification, or is scarification always post-  
15 cleaning of the seeds?

16 MR. RUST: No, that would be the last step.

17 DR. BUCHANAN: It would be the last step.

18 MR. RUST: Basically, what you have done is you  
19 have taken seed and you have sent it off for germination  
20 tests, and the germination tests shows that is has a high  
21 hard seed count, and then it is not sellable to sprout  
22 growers, it is generally sold into the farm industry.

23 Now, I am not saying, I am not intending to say  
24 this is an unscrupulous practice or anything like that, I am  
25 just saying, I am trying to put some things together, and it

1 is possible that this is what could be the problem in the  
2 industry.

3 DR. KVENBERG: Questions, please. Dr. Troxell.

4 DR. TROXELL: I would like to go to the issue of  
5 the surfactants and Dr. Beuchat's and Dr. Fett's work. With  
6 the treatments you used, were they straight up sodium  
7 hypochlorite and calcium hypochlorite, or did you make any  
8 attempt to use surfactive agents to optimize the wetting and  
9 get into those little grand canyons in the seeds?

10 DR. BEUCHAT: In most of the treatments that we  
11 evaluated, we did not use surfactant, however, in a few we  
12 did, and in those cases we used Tween 80. Just to  
13 give you some numbers on the effectiveness of Tween 80, we  
14 used 1 percent and 2 percent and a control. We used  
15 treatments of 3 and 10 minutes, and this was at room  
16 temperature, 22 degrees Celsius.

17 We were able to reduce populations of E. coli  
18 0157:H7 by less than 1 log even with 2 percent of just Tween  
19 80, so there is some impact of just surfactant without the  
20 chlorine.

21 We did some other studies in which we pretreated  
22 the seed with Tween 80 for three minutes both at 1 percent  
23 and 2 percent, followed by treatment with calcium  
24 hypochlorite -- this is in parts per million -- up to 2,000.

25 In the case where we would pretreat the seeds with

1 1 percent of Tween 80 for three minutes, we were able to  
2 reduce again populations of E. coli 0157, but not by more  
3 than 1.5 logs for 10 minutes.

4           Pretreatment with 2 percent Tween 80 resulted in a  
5 little higher reduction with subsequent treatment with 2,000  
6 parts per million, but in any case, not more than 1.4 logs.  
7 So, the treatment with the Tween 80, then, subsequent  
8 treatment with the calcium hypochlorite had some beneficial  
9 effect, but at least with those relatively few experiments  
10 that we did carry out, was not as beneficial as we had hoped  
11 it would be. But in all of the other experiments, we did  
12 not do pretreatment followed by any of the other chemicals,  
13 just the hypochlorous acid in the form of the calcium  
14 hypochlorite.

15           DR. FETT: No, we did not try surfactants. That  
16 is something that we would like to do, but from a regulatory  
17 standpoint, I don't know how they would view the use of  
18 surfactants, but those are experiments that we plan on doing  
19 in the future.

20           DR. KVENBERG: Dr. Goosby.

21           DR. GOOSBY: Regarding germination and the likely  
22 impact of different chemical treatments, heat treatments,  
23 the use of radiation, is it reasonable to conclude that the  
24 health of the seed and its resistance to those factors might  
25 be influenced by the age and storage conditions of the seed,

1 and has anyone looked at that closely to see that, in fact,  
2 a younger seed in managed storage conditions might be a  
3 factor and still contribute positively to the germination  
4 percentage and its resistance to those kind of treatments?

5 DR. BEUCHAT: In the two series of experiments  
6 that we conducted in which we used in both instances the  
7 20,000 ppm of calcium hypochlorite, the only difference, as  
8 was pointed out by Bob Rust, was the lot of seeds that we  
9 used.

10 In the first instance in which we were not able to  
11 detect through enrichment after the 20,000 ppm treatment E.  
12 coli, we had seeds that were at about a 96, 97 percent  
13 germination level.

14 In the second series of experiments, the  
15 germination level was in the range of 80, 81 percent. Now,  
16 I don't know what the degree of physical damage was in  
17 either case, but I would guess, have to assume that there  
18 was more damage or at least certainly the level of viability  
19 was much lower in the second case, and perhaps the degree of  
20 physical damage through scarification, through whatever  
21 means may have enabled through our inoculation process these  
22 cells to enter the cracks, the crevices, the tissue, and  
23 therefore, be less accessible to the treatment with the  
24 calcium hypochlorite.

25 I do not know. That is speculation, that is

1 theory, but certainly the only difference that occurred, the  
2 only change in these two sets of experiments was the lot of  
3 seeds that we used, the two lots.

4 DR. RAJKOWSKI: We did inoculate Salmonella on two  
5 different seed lots, and statistically, there was no  
6 difference between the seed lots and the D-radiation values  
7 found. So, the seed lots did not make any difference.

8 DR. GOOSBY: Do you have any information about the  
9 age of the different seed lots or their storage conditions  
10 that may impact on the health of the seed?

11 DR. RAJKOWSKI: When those seeds were received in  
12 our building, they were stored in the same room, under the  
13 same conditions, and handled identically. I do have the  
14 information from the seed companies, but I do not have that  
15 with us. That would be a consideration, but I was told that  
16 these were both 96 percent germinable seeds.

17 DR. BUCHANAN: In order to evaluate the  
18 differences between Larry's study on 2,000 parts per million  
19 chlorine and Bill, yours, can I ask two questions, one of  
20 each of you.

21 Larry, in your evaluation methods, your detection  
22 methods, did you go right to a selective medium?

23 DR. BEUCHAT: On the direct plating, yes, we used  
24 sorbitol MacConkey.

25 DR. BUCHANAN: So, you wouldn't detect any injured

1 cells?

2 DR. BEUCHAT: Most likely not.

3 DR. BUCHANAN: Bill, did you have any background  
4 data to indicate whether or not the behavior of seeds  
5 subjected to 25 kilogray of irradiation behaved the same as  
6 seeds that are non-irradiated to such a high dose?

7 DR. FETT: No, I don't have any information on  
8 that. Initially, I was planning on using seed that was not  
9 sterilized, but even with selective media, you run into a  
10 lot of problems, at least we have, with background, natural  
11 microflora on seeds and especially on sprouts, but also with  
12 seeds.

13 We looked at a few different selective media, and  
14 I guess at this point I would have picked rainbow agar with  
15 novobiocin and tellurite if I had to do the experiments with  
16 non-sterile seed or go to antibiotic resistant strains, like  
17 we did with the competitive exclusion experiments, but we  
18 would have to do those experiments to see if there was a  
19 difference between sterile seed and non-sterile seed, but I  
20 kind of doubt there would be, but I am not sure.

21 DR. BUCHANAN: But your data would be consistent  
22 with direct plating on a selective medium overstates the  
23 efficacy of the disinfectant?

24 DR. FETT: That is correct.

25 DR. NEILL: I have a question for Dr. Isshiki. It

1 has to do with the calcinated oyster shell. Two things.

2 I am not all that familiar with this, and I am not  
3 sure everyone else is, so if you could give us a little  
4 information about exactly what that is, and then the second  
5 question that I have is you had a graph, and as I remember  
6 this, the 0.4 percent calcinated experiment has a red line  
7 that is at the bottom of the graph that shows from 0 to 1  
8 for time, there is a marked decrease, and then staying level  
9 in comparison to the controls.

10 This almost looks as though this is directly  
11 bactericidal. Can you tell us about that aspect of this  
12 compound for 0157 and/or any of the other microflora or  
13 whether you think this simply inhibited outgrowth and then  
14 there was die-off?

15 DR. ISSHIKI: Calcinated calcium means heated well  
16 calciums. We use this type of calcium as food additives for  
17 a long period because Japanese people in shortage of calcium  
18 intakes. It is a traditional, new, traditional supplement.

19 For example, the oyster shells, the main component  
20 is calcium carbonate, but after heating it turn to calcium  
21 oxide and mixed with water, it turn to the calcium hydroxide  
22 so the pH is very high, 0.2 or 0.3 in suspension, pH is 12  
23 or 13, so E. coli or Salmonella and other bacterium is  
24 killed by the 0.1 or 0.2 suspension of the calcium.

25 It is not easy to dissolve in water. The maximum

1 point is 0.05 percent. So, we use in suspension state, 0.1  
2 or 0.2. We make examination of the seed treatment. We  
3 attach intentionally E. coli 0157 to the radish seed, and  
4 put into the suspension of 0.2 or 0.3 percent calcinated  
5 calcium, the E. coli was killed. Other type of gram-  
6 negative bacterium was also killed.

7 DR. NEILL: Thank you.

8 DR. KVENBERG: I believe the order of questions is  
9 Dr. Swaminathan and Mr. Bernard. I note Mr. Bernard has got  
10 his placard on end. That is very helpful to the Chair to  
11 maybe expedite time if I can understand, if you have a  
12 question, put it on end, that will cue me, and I will know  
13 how to put it through.

14 DR. SWAMINATHAN: I had a question for Mr. Inami,  
15 but I would like to follow up on that question on the oyster  
16 calcium. If this is simply a pH effect, could one use  
17 sodium hydroxide, and I think with the oyster shell, you  
18 also pointed out that the effect on germination is pretty  
19 minimal. Do you have any data on sodium hydroxide?

20 DR. ISSHIKI: Yes. It is effective to kill the  
21 microorganisms with sodium hydroxide or potassium hydroxide,  
22 but more effectively killed by the calcium hydroxide, much  
23 more killed by the calcinated calciums even though the  
24 eggshell-treated calcium also kills Salmonella and E. coli.

25 DR. SWAMINATHAN: Now, for Mr. Inami, the question

1 was regarding the surfactants. We have had a lot of  
2 discussion of surfactants for its inactivating E. coli 0157  
3 and Salmonella, but I was wondering if a surfactant might be  
4 helpful in allowing your enrichment broth to reach those  
5 organisms that may be trapped inside the seed.

6 Did you try Tergitol 7 or Tween 80 in any of your  
7 experiments?

8 MR. INAMI: Actually, that is an excellent idea.  
9 They do use surfactants for ground beef samples to release  
10 the organisms from the fatty material. We have not used  
11 surfactants on any of our seeds in any of these studies, and  
12 that is something we can take a look at later, though.

13 DR. KVENBERG: Mr. Bernard.

14 MR. BERNARD: Thank you, John. I would like to go  
15 back to the questions I was asking earlier. As my  
16 colleagues on the panel know, I am easily confused and I  
17 think the discussion on approval of additives, while I am  
18 aware of what the law says in terms of certain requirements,  
19 with the passage of the Food Quality and Protection Act and  
20 the changing of responsibilities, I am not sure I understood  
21 from the discussions this morning who makes the decision nor  
22 exactly how that decision is going to be made.

23 So, I guess I, in fact, have two things that I  
24 would like. One is a clarification on how the process works  
25 in terms of if somebody wanted to gain approval for a seed

1 treatment, who should they talk to, and how do we make that  
2 decision, and also, I would like to go back. I did ask a  
3 question that didn't get completely answered, and I  
4 understand we were under some time constraints earlier, but  
5 in terms of the APA protocol, I did ask when we might expect  
6 to have something and to make sure that you understood the  
7 feeling of urgency that many have here.

8 I, quite frankly, find that a bit surprising  
9 because the approval, while it may be new to EPA, is not a  
10 new process. There has to have been some protocol in place  
11 somewhere that has served us up until at least the passage  
12 of FQPA. So, with that, I would like Michelle to maybe help  
13 clarify some of those points.

14 DR. TARANTINO: I will begin and happily pass it  
15 on to Michelle, and gratefully. I think the jurisdictional  
16 issue is a complicated one, there is no question, because of  
17 the changes that are taking place almost as we speak, but  
18 let me give you sort of the easy answers.

19 One, I think, and I will go back and sort of like  
20 a broken record, if you are planning to do something, you  
21 probably ought to call because we are in constant contact  
22 these days about just this issue, and we certainly were at  
23 the time of the calcium hypochlorite, to make sure that we  
24 are both on the same page as to who is doing what.

25 The perhaps straightforward answer at right this

1 moment with the passage of FQPA, is FDA would have approval  
2 for something that was used on a processed food or on wash  
3 water that would contact a processed food in a processing  
4 plant. Just about everything else is EPA's, so that the  
5 calcium hypochlorite and the analogous treatments that were  
6 being talked about by Dr. Beuchat and Dr. Fett right now are  
7 EPA's.

8 I will, and I will regret it immediately, say that  
9 there were some things that FQPA passed, there were some  
10 things that happened kind of accidentally, and there are some  
11 activities now to try to make some adjustments in the  
12 jurisdiction of some things. At least some of those  
13 proposals would imply that some of these kinds of things  
14 could come to FDA in the future.

15 For example, a raw agricultural product in a  
16 processing plant, that this would come back, and I think  
17 probably sprout seeds would be there, might come to FDA. I  
18 shouldn't say come back to FDA, would come to FDA, but right  
19 now if it is not a processed food and if it is not water  
20 contacting a processed food in a processing plant, water  
21 contacting food in the field would be EPA's, water in a  
22 processing plant would be FDA's.

23 Having said that, given that the calcium  
24 hypochlorite and the analogous chemicals are EPA's at the  
25 moment, I will let you talk about the process.

1 MS. WINGFIELD: Thank you.

2 My comments before pertaining specifically to the  
3 efficacy evaluation in this line of products and my  
4 statement that this is a new area for us, traditionally,  
5 fruit and vegetable rinses or washes, as Dr. Tarantino has  
6 stated before, have been evaluated by FDA as indirect food  
7 additives, and some of that information basically funneled  
8 over to EPA without any direct scientific evaluation on the  
9 tolerance or a tolerance exemption level for our particular  
10 office.

11 Where EPA comes into play is that antimicrobial  
12 products used against what we call public health related  
13 pathogens, such as the E. coli 0157:H7, Listeria,  
14 Salmonella, and the like, fall into the jurisdictional area  
15 of the antimicrobials division. Fruit and vegetables  
16 sanitizing rinses, particularly for home owner use, are a  
17 new area for us. It is my understanding that there are  
18 currently no products registered for this particular use  
19 pattern.

20 In that light, we are now evaluating protocols  
21 going through a peer review and a peer validation of new  
22 methods. To give a specific time frame, as Mr. Bernard is  
23 looking for, as far as when we will have a product out on  
24 the market, is somewhat difficult to say at this time,  
25 because the state of the science, we are not really sure.

1 that it is such that you can evaluate these products  
2 totally. We did go before the Scientific Advisory Panel  
3 last year. They gave us some recommendations on perhaps  
4 relaxing our current performance standards, so that a level  
5 of public health benefit will be provided to the consumers.

6 We are working with the Scientific Advisory Panel  
7 for any additional updates. We will also be seeking the  
8 counsel of noted food experts, such as some of the panel  
9 members here, or some of the members in the audience, but  
10 this is really new territory for us and we need to take a  
11 good, strong look at the science itself before we make a  
12 regulatory decision.

13 MR. BERNARD: A follow-up, if I may. Just as  
14 clarification, then, in terms of jurisdiction, there may be  
15 some change in this, I recognize, but if one were to want to  
16 wash a head of lettuce before it is chopped, is that an EPA  
17 approved sin, but once it becomes a salad, then, it's an FDA  
18 item?

19 MS. WINGFIELD: Yes.

20 MR. BERNARD: Okay. I just want to get that  
21 clear.

22 MS. WINGFIELD: That is the state of the  
23 jurisdiction right now.

24 MR. BERNARD: As a further follow-up, I recognize  
25 that benefit can't be considered in the decision, only

1 looking at safety, which seems to run counter to the current  
2 consideration of risk analysis, risk assessment in  
3 regulatory decisionmaking, in other words, if we have a  
4 significant risk reduction, but only an insignificant  
5 increase in risk, you can't consider that, I take it.

6 MS. WINGFIELD: That is not true from an EPA  
7 standpoint. That was an FDA. EPA is a risk-benefit statute  
8 that we operate under FIFRA. If the benefit outweighs the  
9 risk, and there are no unreasonable adverse effects either  
10 to humans or the environment, then, a particular product  
11 would be licensed and registered.

12 MR. BERNARD: I guess the tag line to that  
13 question that I was looking for is there some legislative  
14 change that is needed in either of your opinion, to help us  
15 streamline this process? I know Congress is occupied with  
16 other things these days, but there is still a considerable  
17 focus on food safety on the Hill.

18 DR. TARANTINO: I guess since you are referring to  
19 the Federal Food, Drug, and Cosmetic Act, which is the food  
20 part is not a risk-benefit statute, I am not sure that, you  
21 know, the explicit consideration of benefit is what we would  
22 want, where we would want to go.

23 One of the things that is very different in our  
24 statute, then, the FIFRA, is we have nothing analogous to  
25 the emergency exemption or the local use. That is something

1 that, you know, gives us a little bit of problem in the  
2 sense of if we are going to try to something on an emergency  
3 basis, it is difficult for us to do it.

4 MR. BERNARD: Thank you.

5 DR. TROXELL: I have some other questions, but I  
6 think I would like some more follow-up on what we have just  
7 been talking about. As I understand it -- and I would like  
8 our FDA and EPA people to clarify -- I mean we have two  
9 components you have to deal with. One is the registration  
10 and the other is the additive or tolerance component.

11 So, even if we have a food additive situation, the  
12 sanitizer still needs to have a FIFRA registration, so they  
13 have two applications to deal with, and the second thing --  
14 and if we could clarify that to the extent necessary, please  
15 -- but the second thing is please comment on the role of the  
16 chemical companies that manufactured these sanitizers to get  
17 the registration, it is not necessarily simply a matter of,  
18 say, California/EPA getting their registration, the  
19 emergency registration, but you have to have the buy-in of a  
20 chemical company to carry this.

21 MS. WINGFIELD: For food sanitizers, currently,  
22 the tolerance exemption and registration process basically  
23 go hand in hand. Establishment of a tolerance or exemption  
24 from a tolerance is part of the registration process for  
25 food sanitizers.

1           As far as a Section 24(c), the special local  
2 needs, which is what the State of California instituted, I  
3 am not sure what level of direct buy-in they got from a  
4 particular registrant company or not. Perhaps you could  
5 answer it a little better.

6           DR. KVENBERG: Before we go on with the  
7 discussion, please, can I ask the speakers to identify  
8 themselves for the recording.

9           MS. WINGFIELD: Michelle Wingfield speaking.

10          DR. KVENBERG: Thank you, Michelle.

11          DR. FARRAR: Jeff Farrar. In response to that, we  
12 did get the buy-in from I believe two or three specific  
13 chemical companies. Olan was one of those, I can't remember  
14 the other two.

15          DR. TARANTINO: Let me follow up a little bit on  
16 Terry's question. I think his question in terms of the two  
17 separate hurdles is one of the things that was kind of fixed  
18 by FQPA in the sense that both those processes are now at  
19 EPA and can go hand in hand.

20                 I think one of the struggles that the grower  
21 community is having perhaps is finding folks who have the  
22 wherewithal to come in with the data package for  
23 registration or for a food additive application, and I think  
24 there, you know, the companies that make the chemicals that  
25 are used for agricultural purposes or for processed food are

1 probably in the best position to accumulate that data  
2 package to some extent, but that is probably something that  
3 needs to be worked out because in both cases, for EPA and  
4 for us, it is the sponsor's responsibility to pull together  
5 the data.

6 DR. KVENBERG: Thank you. Another follow-up?

7 DR. TROXELL: Laura, you are saying that if it is  
8 a food additive situation, that is under FDA's jurisdiction,  
9 there is no registration needed, is that what you said?

10 DR. TARANTINO: No, no, no. What I was saying is  
11 the current situation where they are talking about  
12 sanitizers on foods for the seeds and sprouts. This would  
13 all be at EPA and the situation as Michelle had talked  
14 about. Frankly, in fact, now that I think about it,  
15 probably most of the cases where there was an FDA approval  
16 and followed by a registration have been fixed by FQPA.  
17 There may be some out there somewhere, but I don't think so.  
18 I think most of them have been fixed.

19 By the way, I might add, just to go back, although  
20 I said that the calcium hypochlorite and the other chemicals  
21 are all going to be under EPA jurisdiction, at least  
22 traditionally, and I think still, we would hold because of  
23 the way it is written in the statute, that the irradiation  
24 would come to FDA.

25 DR. KVENBERG: Thank you. The questions I have in

1 order that I saw the placards go up, Dr. Sperber, you are  
2 next.

3 DR. SPERBER: I have a few questions for Greg  
4 Inami. As I understood your data, it looks like you had  
5 several positive seed samples that you tested and found  
6 positive two or more times with the different methods you  
7 tested. Did you make any effort to quantify the Salmonella  
8 in those seeds?

9 MR. INAMI: No, all the testing was done under  
10 that two-step enrichment of pre-enrichment and selective  
11 enrichment, so we did not quantify. I must also say when we  
12 did do the enrichments, we would end up on the low end of  
13 about two colonies per a couple plates, and the high end  
14 maybe about 10 or 12, so the numbers on the seeds, to start  
15 with, are very low.

16 DR. SPERBER: Even when you are doing the pre-  
17 enrichment and enrichment, you could do an MPN procedure to  
18 get an estimate of the total count present, and that could  
19 be helpful. I think especially in cases like this if you  
20 are dealing with incriminated lots of seed or any other food  
21 in an outbreak like this, it would be good to get a fix on  
22 the initial number of organisms there. It could be helpful  
23 in a risk assessment for establishing guidelines here or in  
24 even other food categories.

25 So, I would advise all microbiologists, when they

1 run across materials like this, to do two things. One is to  
2 get a fix on the numbers, doing MPN's if you have to, and  
3 then, two, save as much of that material as possible for  
4 your research on disinfecting the seeds and running it  
5 through other protocols to see how these organisms will  
6 grow, how you can keep them from growing.

7 I think it is much more meaningful to do this work  
8 with naturally contaminated materials than it is with  
9 artificially inoculated materials. We have seen a lot of  
10 information presented here in two days, most of it with  
11 artificially inoculated materials, and it might not be that  
12 realistic,

13 MR. INAMI: The one comment I want to make about  
14 the naturally contaminated materials, there is so much  
15 variation in the contamination level. There are points  
16 where we would be sampling 100 grams from a bag where you  
17 get a positive out. We go back, take another 100 grams, and  
18 we get a negative out, go back, take another 100 grams, get  
19 a positive. So, with natural contaminate, you are not going  
20 to have the consistency in your work that you do with the  
21 inoculated seeds.

22 DR. SPERBER: One more point on your work. I  
23 think that -- well, yesterday, many people alluded to the  
24 fact that it is really hard to find Salmonella or E. coli in  
25 seeds, and I was thinking then that perhaps you needed to do

1 something to break the seed coat or liberate the organisms,  
2 and you might have hit upon something there by soaking the  
3 seeds and going through a little sprouting.

4 In your first experiment, you sprouted the seeds  
5 for four days and then later you found out if you sprouted  
6 them for three days, it was just as good. How about  
7 sprouting them for one or two days?

8 MR. INAMI: Actually, that has been brought up  
9 before and we haven't had time to really examine that. The  
10 outbreak of Salmonella Seftenberg, when the San Francisco  
11 District Office isolated that, they isolated out of a one-  
12 day-old sprout sample, it was an in-line sample at the  
13 company, so that has been proposed and that is one thing we  
14 may look into.

15 DR. SPERBER: That may be one area for further  
16 research where if we need to go through some protocol like  
17 this for analyzing seed, that we would want to have the most  
18 efficient method possible.

19 While I have got the microphone, I would like to  
20 make just one comment, and perhaps nobody wants to respond  
21 to it, but something has been bugging for about a year, and  
22 that is the use of 200,000 ppm chlorine for treating seed.  
23 That is just not on this planet in my experience when it  
24 comes to disinfecting process equipment or, you know,  
25 treating water or things like that. To me, that is like

1 deer hunting with a cruise missile. Somehow it just doesn't  
2 connect logically. I don't know how you would need such a  
3 large quantity of material to kill bacteria. Is it simply  
4 because you are overcoming dust in the seed and you are  
5 inactivating so much of the chlorine?

6 DR. KVENBERG: Response to the question from  
7 anyone?

8 DR. BEUCHAT: All I know is that 20,000 parts per  
9 million calcium hypochlorite does not reduce populations of  
10 0157 by more than 2.5 to 3 logs. So, I think we are not  
11 getting the active component to the site of the cell in  
12 these instances.

13 DR. TROXELL: Maybe that is what we have been  
14 dancing around with these questions on surfactants, and so  
15 on, and then I think Dr. Fett had pointed out biofilm  
16 problems, and maybe the issue is not just a concentration,  
17 but optimizing the surfactants and I don't know if it's a  
18 crazy idea to think about other mechanical approaches to  
19 optimize the contact, such as, I don't know, if sonication  
20 at some level would kill the seed or whether it might  
21 actually facilitate breaking up some of the biofilm.  
22 Somebody needs to start thinking about other ways to get  
23 better contact if that is the problem, so, we don't need to  
24 use the cruise missile.

25 DR. KVENBERG: The next placard I have is Dr.

1 Goosby.

2 DR. GOOSBY: A question and a few comments to Dr.  
3 Kumagai. You presented some very interesting work that  
4 talks in terms of the potential for contaminating a product  
5 even if we began with a sterile seed, and again, the concern  
6 for GMPs and some follow up.

7 I am wondering, though, on the artificial  
8 contamination and the 3.5 log CFU/ml was your standard for  
9 the artificial contamination of the radish sprouts, how much  
10 that relates to natural sprouting, growing conditions, and  
11 if other work may be underway that you are aware of,  
12 unpublished or otherwise, that may be looking at some lower  
13 levels that perhaps would relate more to the natural growing  
14 condition to see what our lower end of natural contamination  
15 might be that we need some intervention strategies for.

16 DR. KUMAGAI: We don't have any data on natural  
17 contamination level, and at least as far as we know, we have  
18 done 100 cells per ml. If we use the water containing 100  
19 per ml of E. coli 0157:H7, then, when sprouts grew, then,  
20 the edible parts contained about 7 log cells per gram, and  
21 we don't know the level of natural contamination level of  
22 seeds, we don't know, so perhaps in future, the study using  
23 very low level of contamination of water will be needed, I  
24 think. Is it right to your question?

25 DR. GOOSBY: That is correct, that is what I was

1 asking for. Just to see if, in fact, there is some  
2 understanding that you may have far greater than I on what  
3 the natural sprouted conditions for radish sprouts, to  
4 relate the artificial contamination you have done with the  
5 natural conditions, and as you just indicated, maybe other  
6 levels, other approaches to research in trying to more  
7 narrowly define the question and the answer.

8 Thank you.

9 DR. KVENBERG: Dr. Tompkin.

10 DR. TOMPKIN: With regard to the calcium  
11 hypochlorite, my recollection is that the higher the pH, the  
12 more stable the product, but it is the hypochlorous acid  
13 that is active, and you have to have a neutral or lower pH  
14 for it to be effective, so we are working at the high pH  
15 range where it would probably be least effective. That  
16 might be why it is taking so much.

17 But other than that, I was questioning, would like  
18 to know how much naturally contaminated seed is available  
19 for research, and does anyone know where it is, how much  
20 there is, can it be used. I know the tendency is to bury it  
21 as soon as you can get it or whatever, but I would really  
22 like to see some of that seed subjected to the irradiation  
23 at a 2 kilogray or whatever different levels to see whether  
24 or not irradiation will, in effect, be effective in  
25 naturally contaminated seed.

1 MR. INAMI: Well, we actually have some of the  
2 seed and as Jeff said before, it is going to be auctioned  
3 off after the end of this conference, but I think the  
4 research on looking at irradiation is very important.

5 I don't know if I have the authorization to say  
6 yes, you can have seeds, no, you can't, I mean that really  
7 goes to the chief of our laboratory.

8 DR. FARRAR: A follow-up on that, John. I think  
9 this is a very precious commodity at the moment and perhaps  
10 with the help of the National Advisory Committee, we could  
11 begin to establish some priorities for that remaining small  
12 amount of seed.

13 In addition, we are also convinced we have some  
14 naturally contaminated seed, probably over a ton of it in  
15 storage from our latest Seftenberg and E. coli outbreak that  
16 we have tested repeatedly in different labs across the  
17 country, and been unable to isolate the product, but we are  
18 firmly convinced that it is there.

19 DR. KVENBERG: Thank you. Is this a follow-up on  
20 this, Larry?

21 DR. BEUCHAT: Yes, follow-up to Bruce's point on  
22 the pH. The data that I have shared with you here on the  
23 high levels of calcium hypochlorite, the 2,000 to 20,000  
24 ppm, the pH there was 6.8 to 6.9. We used a mild 0.05 molar  
25 phosphate buffer to keep that hypochlorous acid in at least

1 a range in which it would be active, active component.

2 DR. FETT: We used 500 millimolar of potassium  
3 phosphate buffer, pH 6.8, so our final pH was about 7.0.

4 DR. KVENBERG: Dr. Doyle.

5 DR. DOYLE: I have a labeling question. Perhaps,  
6 Laura, you could answer this. If seeds were irradiated,  
7 would the sprouts resulting from those irradiated seeds have  
8 to be labeled as having been irradiated?

9 DR. TARANTINO: You know, that is a good question.  
10 Probably. The way the reg reads now is a food that has  
11 itself been irradiated needs to be labeled. It would be  
12 hard to me to think of how we would decide that the sprout  
13 itself, because the point of that regulation was that you  
14 don't need to label if it is an ingredient in a multi-  
15 ingredient food where it has been processed and it is  
16 obvious that it has been processed.

17 The point of the labeling of a food that has  
18 itself been irradiated has mainly been applied to produce to  
19 say yeah, this has been processed, something has been done  
20 to it, so consumers can know that, and it would be hard to  
21 see how we could separate the sprouts, but it is a good  
22 question actually. I hadn't thought about it.

23 DR. KVENBERG: Dr. Buchanan.

24 DR. BUCHANAN: I want also to go back to the  
25 regulation a little bit because I have to lead the

1 discussion later this afternoon, and I thought I had a grasp  
2 of it, but then a couple of comments you made during the end  
3 confused me, so let me ask you real two straightforward  
4 questions.

5 My impression was that the seeds' disinfection  
6 would be regulated by EPA, and the sprouts would be  
7 regulated by FDA. That is part 1. The second question is  
8 of all of the treatments that you heard discussed this  
9 morning, are any of them currently approved by both FDA and  
10 EPA for use or whoever?

11 DR. TARANTINO: Your first question was? Try  
12 again. Oh, the seeds and the sprouts.

13 DR. BUCHANAN: The sprouts versus seeds for  
14 regulation.

15 DR. TARANTINO: The sprouts themselves I don't  
16 think we have discussed in the post-FQPA era. My impression  
17 would be it probably would be us, but that is one that I  
18 would want to get on the telephone with those folks, too,  
19 and talk about it. It is the seeds that we have talked  
20 about explicitly, but that would be my guess, as well.

21 Let me say that I think except for irradiation, I  
22 think the things that we have talked about in terms of the  
23 chemical treatments on seeds would be EPA, so take it away.

24 MS. WINGFIELD: Actually, I think some of the  
25 sprout would be EPA also, particularly in home owner. It is

1 very strange at this point particularly for homeowner use.  
2 If an applicant decided to market a product for homeowners  
3 to use on their sprouts once they had been bought from the  
4 store, that would be in EPA.

5 I am sorry, your second question?

6 DR. BUCHANAN: Were any of the technologies that  
7 you heard discussed today, would any of them be approved for  
8 use, are they approved for use, any of them that you heard  
9 discussed today?

10 MS. WINGFIELD: As I said before, we do not  
11 currently have any products specifically registered against  
12 pathogens for fresh fruits and vegetables. The calcium  
13 hypochlorite has an existing tolerance exemption on the  
14 books, one of the reasons why it had not been disapproved  
15 for the 24(c) special local needs, but as far as any of the  
16 other technologies that were discussed, it is my  
17 understanding there is nothing specifically registered.

18 DR. BUCHANAN: And the calcium hypochlorite, at  
19 what level is it approved?

20 MS. WINGFIELD: Both the calcium and sodium  
21 hypochlorite for post-harvest washing, I believe is approved  
22 at 25 ppm.

23 DR. FARRAR: A follow-up, John.

24 DR. KVENBERG: A follow-up from where?

25 DR. FARRAR: This raises another issue I think for

1 the committee to take under advisement, that we are  
2 approaching a very blurry line here, a division.

3           What about pea sprouts grown in a greenhouse or  
4 pea sprouts grown outside, for that matter? We have come  
5 upon the line between agriculture, raw agricultural  
6 commodities, and processed foods, and it is staring us in th  
7 face, and we need to begin making some decisions on those  
8 areas.

9           DR. KVENBERG: I guess it is a prerogative of the  
10 Chair to interject at this point. Perhaps I am not making  
11 the working group's task any easier, but I see what I might  
12 call a parking lot issue for you to come back with a  
13 recommendation to the agencies to settle the matter.

14           I think it is clear from the discussion we have  
15 had up to this particular point in time, further discussions  
16 between agencies are going to be necessary on these points.  
17 My observation -- it is not in the form of a question -- but  
18 just put forth is if you can give us some clarification for  
19 what the tasking for the discussions might be between the  
20 agencies that might be useful, if you can identify the  
21 issues.

22           The next placard I saw up was Dr. Troxell.

23           DR. TROXELL: I will just make one actually follow  
24 up on this, and I have another question, but it is not  
25 necessary. You know, if we view, as we do, the sprouting

1 process, the growing, as being a food manufacturer, it is  
2 not necessary for EPA, with respect to the sanitizers, to  
3 view that as a food. It could still be a raw agricultural  
4 commodity, and we would consider it a food process, so the  
5 lines don't have to be exactly the same for regulating the  
6 sanitizers as they are for our view on jurisdiction of the  
7 setting up the GMPs, and so on.

8 My question was to Dr. Kamagai, who talked about a  
9 pretty dramatic reduction in the levels of E. coli using  
10 five seconds of boiling water, and I assume -- well, I  
11 assume there the quality of that product is not usable for  
12 commercial sale after that. So, would you clarify that, and  
13 secondly, what about internal contamination after that  
14 process? You had described two separate kinds of  
15 contamination, external, and then some internal  
16 contamination. Would that process deal with the internal  
17 contamination also?

18 DR. KUMAGAI: Five-second heating in boiling water  
19 was enough for killing the bacteria even inside of the  
20 tissues. In Japan, Dr. Isshiki showed some people using  
21 radish sprouts by adding to very hot soup, a kind of soup,  
22 but not boiling, but nearly to boiling.

23 At the moment, many facilities preparing school  
24 lunch don't use raw vegetables for their dish, instead, they  
25 are now using the vegetables boiled briefly and perhaps

1 until the safety of raw vegetables can be confirmed, they  
2 continue to use boiling the vegetables.

3 DR. TROXELL: So, the utility here would be just  
4 prior to consumption rather than as a final process step?

5 DR. KUMAGAI: Yes, immediately before serving.

6 DR. KVENBERG: Just so you have an indication of  
7 time and questions, I have four people that have questions.  
8 In order, they are Dr. Swaminathan, Mr. Bernard, Dr.  
9 Slutsker, and Dr. Buchanan. I have received one request for  
10 public comment so far, so we will continue the question  
11 period. We certainly have time allotted to do that.

12 Dr. Swaminathan.

13 DR. SWAMINATHAN: I have a question for Dr.  
14 Tarantino and Mr. Weagant. Can I ask them at the same time?

15 DR. KVENBERG: Certainly.

16 DR. SWAMINATHAN: Dr. Tarantino, I have two  
17 questions. EPA indicated that they usually decide in 90  
18 days whether they approve or disapprove a petition. Can you  
19 give us a time line for petitions if you fast-track them?

20 The second question is a hypothetical situation.  
21 I am just curious. Can a federal public health agency  
22 submit a food additive petition if it deems that it is in  
23 the public interest?

24 DR. TARANTINO: I will answer the second one first  
25 because it is by far the easiest. Absolutely. We would

1 welcome a petition from a sister agency without any problem.  
2 The time line is harder. Obviously it is not fast. I can  
3 see from filing to a petition to publishing something in the  
4 Federal Register including the rulemaking realistically is  
5 unlikely to take less than a year. It could, but it would  
6 be, you know, I would be fooling anyone if I said it would  
7 be a whole lot less than a year, it might be, but that would  
8 truly have to be fast-tracked on, it would have to be a  
9 really good petition coming in.

10 DR. SWAMINATHAN: Thanks.

11 MS. WINGFIELD: Excuse me. I just want to add a  
12 note of clarification to your question. The 90 days is not  
13 for approval of a petition. The 90-day approval or  
14 disapproval is for the 24(c), special local needs. A  
15 petition approval takes much longer than 90 days.

16 DR. TARANTINO: Thank you.

17 DR. SWAMINATHAN: Steve, I have two or three  
18 clarifications from your presentation, two or three  
19 questions. First of all, how were the alfalfa seeds or  
20 sprouts contaminated in your experiments, the artificially  
21 contaminated ones?

22 The second, could you confirm that 37 degrees with  
23 shaking and 42 degrees with shaking gave equivalent results?

24 Third, you mentioned that two of 40 strains of E.  
25 coli 0157 were not inhibited by cefixime at 0.0125 mg/liter,

1 but in your later experiments using these various conditions  
2 of enrichment and shaking and immunomagnetic beads, you  
3 didn't specify as to which strains you used in the  
4 experiments, whether these were cefixime resistant or  
5 cefixime sensitive at that concentration.

6 MR. WEAGANT: First, on how the sprouts were  
7 contaminated, we added the sprouts to the enrichment broth  
8 and immediately added a contaminating liquid to them, and  
9 then proceeded with the blending.

10 As to your question to the efficacy of 37 degrees  
11 and 42 degrees, those were different enrichment matrices or  
12 broths, so a direct comparisons of two temperatures would  
13 take some more experimentation, specifically, just varying  
14 the temperature, and not the composition of the broth.

15 It appears to us that both are effective.  
16 Previous experiments have shown us that 42 degrees is not  
17 inhibitory to the E. coli 0157 and some of the other, STEC,  
18 as well.

19 Your third question, we did in our inoculation  
20 experiments in sprouts use two of the most sensitive strains  
21 that we had encountered in our pure culture work, so that  
22 these strains were two of the most sensitive of the four  
23 that we used, and we did see that effect, that in the  
24 inoculation experiments, the inhibitory effect of the  
25 cefixime seemed to be modified.

1 DR. KVENBERG: We had a follow-up, I think from  
2 Dr. Slutsker.

3 DR. SLUTSKER: Yes, just on the issue of naturally  
4 contaminated seed, there actually have been two outbreaks  
5 that were seed, yielded the pathogen responsible. One was  
6 the Newport, which Greg has described quite well. The other  
7 one is the Infantis/Anatum outbreak in Kansas in 1997.  
8 Those seeds were cultured at the FDA lab in Denver. I don't  
9 know whether any of that seed remains or not, but that could  
10 be another source of naturally contaminated seed.

11 DR. KVENBERG: Dr. Buchanan.

12 DR. BUCHANAN: I actually have two quick  
13 questions. One is for the methods people, and then the  
14 second one for Dr. Isshiki.

15 Methods people, to put this real simply, your  
16 primary limiting factor now in methods is sampling problems,  
17 not detection systems? It is finding the occasional  
18 sporadic contaminant within a lot.

19 MR. WEAGANT: I guess I will start with this. As  
20 far as 0157 in seeds for sprouting, no one that I am aware  
21 of has detected naturally occurring 0157 in seeds for  
22 sprouting. We have not pursued that in our experiments so  
23 far. It is something that needs to be looked at.

24 MR. INAMI: For the Salmonella work, the  
25 Salmonella procedure has been around for a number of years,

1 and it is an AOAC-approved procedure, however, there are a  
2 couple items that you can attach to them.

3           One is the use of a Rappaport vasalis as a  
4 selective enrichment instead of selenite, and growth at 42  
5 and 43 degrees can also be looked at, and we haven't looked  
6 at either of those two methods yet, but the question about  
7 distribution is a big question and in some cases when we  
8 have tested seeds and sprouts from other outbreaks, we are  
9 testing upwards of 150 to 160 bags of seeds, 200 or so  
10 packages of sprouts, and in some cases we don't isolate the  
11 organism, so distribution is a really big problem.

12           DR. BUCHANAN: My second question was for Dr.  
13 Isshiki. In the use of your calcinated oyster shell, I  
14 needed some clarification. Is this used as a treatment of  
15 the seeds only or do you continue to use the calcinated  
16 water as the sprouts germinated, so you have a residual  
17 effect throughout the sprouting process?

18           DR. ISSHIKI: In my laboratory, university  
19 laboratory, it could be used during all stage of growing the  
20 sprout, but actually, we bring to the grower's farm or  
21 factory, it is very difficult to use sprout growing steps,  
22 so we recommend only using the seed treatment..

23           DR. BUCHANAN: What is the limiting factor, why is  
24 it difficult to use in the growing factories while you can  
25 use it in the laboratory?

1 DR. ISSHIKI: It is very alkaline, so training  
2 people to use high alkaline solutions, but training the  
3 people is dangerous for the alkaline solutions.

4 DR. KVENBERG: Dr. Neill, do you have a question?

5 DR. NEILL: Yes, I have another question for Dr.  
6 Isshiki, if I might. If I took this down correctly, this is  
7 from the revised manual, and it was suggesting that seeds be  
8 tested for the presence of E. coli, which I understood would  
9 probably be generic E. coli, and then if a positive were  
10 found, to check to see if it were an STEC.

11 My questions are is such surveillance work being  
12 done, and what do you have at this point in terms of finding  
13 STEC in seeds, and what do you do with those seeds?

14 DR. ISSHIKI: We recommend to discard the seeds.  
15 Firstly, check the E. coli as an indicator. Second step is  
16 detection of the E. coli 0157 STEC and Salmonella. If the  
17 STEC were Salmonella detected, we recommend not to use this  
18 seed, and inform our government and the seed suppliers.

19 DR. NEILL: I think I might be wondering whether  
20 you would have any naturally contaminated seed if something  
21 like that could be discussed perhaps with any of the  
22 authorities, then, if one had found any contaminated seed,  
23 it would probably be something that would be very useful to  
24 the community at large.

25 DR. ISSHIKI: We go direct to ask the seed test

1 people if they find polluted seed, inform the government.  
2 The government or seed supplier inform the sprout growers,  
3 so all sprout growers informed which is very dangerous for  
4 the sproutings, so they discard that seed. So, we recommend  
5 to inform to the government and seed suppliers about seed.

6 DR. KVENBERG: Dr. Swanson, do you have a  
7 question?

8 DR. SWANSON: Actually, I have a question for  
9 perhaps the seed suppliers or sprout growers that may be out  
10 in the audience related to sampling. They previously  
11 indicated that before they purchase seed, they frequently  
12 will test the germination and other properties of those seed  
13 lots, and I am just wondering what size of sample they look  
14 at when they are doing it, is it perhaps greater than 100  
15 grams. I heard 50 pounds. If they sprout 50 pounds,  
16 perhaps we could look at culturing the water that is used to  
17 grow those 50 pounds as a means of enhancing.

18 DR. KVENBERG: One of the ways we may be handle  
19 this question, Dr. Swanson, is when we switch over, in a  
20 moment we will have public comment period, and then maybe we  
21 can get them to come forward and address that at that point.  
22 I have got several people who would like to speak, and I  
23 think the seed suppliers are here.

24 DR. SWANSON: Thank you.

25 DR. KVENBERG: Dr. Nagle.

1 DR. NAGLE: I just wanted to follow up again with  
2 Dr. Isshiki. I guess we are hearing different things. We  
3 are hearing from Dr. Weagant that we can't detect E. coli in  
4 seeds, and yet Dr. Isshiki is saying that they are testing  
5 for E. coli in seeds, and I guess my question is do you find  
6 it, have you found positive E. coli in seeds or especially  
7 E. coli 0157, and if you did, then, could you tell us how  
8 you did that, so that we could find that in other supplies  
9 of seeds?

10 DR. KUMAGAI: E. coli 0157 have never been  
11 detected from sprout seeds in Japan as far as in the form of  
12 culturable living bacteria. Other E. coli, we have found  
13 from Oregon seeds. Is it right?

14 DR. NAGLE: Yes.

15 DR. KVENBERG: Mr. Bernard.

16 MR. BERNARD: Thanks. Just an observation, and  
17 our regulatory colleagues can correct me if I am wrong, but  
18 back in our discussion of cruise missiles and other such  
19 things, there was mention of buffers used to poise pH, so  
20 that calcium hypochlorite was in the most active range, and  
21 I am assuming that anything used as an efficacy enhancer, as  
22 an adjuvant to the process, would also require regulatory  
23 approval. So, if we are using certain buffers, that would  
24 have to also go through a similar review process.

25 So, if one were to petition, for example, for

1 calcium hypochlorite, it would have to be done in the  
2 context of everything that was used to achieve those  
3 results.

4 MS. WINGFIELD: That is correct. My statement  
5 before about the current acceptance for calcium hypochlorite  
6 was calcium hypochlorite in meat or just dissolved in water  
7 without any added surfactants or anything of that nature,  
8 but certainly we would need to evaluate the surfactants in a  
9 tolerance petition, again, their exemption from tolerance  
10 would have to be established in those, as well.

11 **Public Comment**

12 DR. KVENBERG: If there are no other questions  
13 from the working group or the panel, I have received a  
14 request in order from several people to provide public  
15 comment. The first is Frank Shaller, and the second is  
16 Robert Sanderson. Others are also invited to speak at this  
17 point the program if they desire.

18 I would ask for public commenters to please  
19 limited themselves to a five-minute period. Also, we have a  
20 peculiar arrangement here with our microphones, so I would  
21 invite you to the dock, as you would have in an English  
22 court of law in the front, so you can be recorded.

23 Is Frank Shaller available, would you like to make  
24 a comment?

25 MR. SHALLER: First, I would like to point out

1 that if I make any statements about experts or government  
2 agencies, please, don't take it personally. I do not  
3 understand half of what I heard today or yesterday and  
4 today, but what I would like to do is just take for the next  
5 four and a half minutes a step back from all this kind of  
6 information and why are we here.

7           We are here because we are concerned about the  
8 health of the people of this country, and the health of the  
9 people of this country depends on our food supply. The big  
10 picture. Jeffrey Blanda, biochemist, I have heard give an  
11 explanation, a description that the most important thing in  
12 our life is food to our health because we consume about  
13 2,000 pounds a year. That is a lot if you think in terms of  
14 it all in one place at one time, 2,000 pounds a year. In  
15 five years, that is 10,000 pounds. You can do the numbers.

16           Food is important. It has got to be good, clean,  
17 living. It has got to nourish us and our children. The  
18 term quality science was used earlier. There may be some  
19 quality science that we have seen today and yesterday, but  
20 remember, quality science has given us DES, DDT, Olestra.  
21 It has given us the confusion over when to get a mammogram  
22 or whether or not to do a PSA test. 41- 42,000 men are  
23 dying of prostate cancer. Four years ago, 38,000 men were  
24 dying. Quality science, \$30 billion in 30 years, and we are  
25 losing the war with prostate cancer. The numbers are going

1 up, and that is just one example.

2           Where does this quality science come from? The  
3 experts, the people that work with data. Step back from the  
4 data and realize experts can be quoted and misquoted. The  
5 data can be interpreted and misinterpreted. Step back from  
6 the data and say why am I here, why am I on this committee,  
7 why am I working for this government agency, and my analysis  
8 is you are here to do a job of providing good quality food.

9           Now, what scares me, what really concerns me is  
10 when I hear cruise missiles. Chlorine, another expert says  
11 chlorine is a synthetic biocide, halogen-based, that  
12 degrades into carcinogens and depletes ozone layers. I  
13 don't want any more carcinogens being promoted by my  
14 government agencies.

15           Irradiation. We are talking about irradiating  
16 food. Children in grade school are being learned to use a  
17 microwave and get a line of plants, and microwave some water  
18 and don't microwave some water, and then grow these plants.  
19 The obvious conclusion is which is going to grow better. Do  
20 the experiment at home. Have your children do the  
21 experiment. Microwave, yeah, it is great, it is fast, it  
22 satisfies, but there is something missing.

23           What is a molecular effect, and be very careful if  
24 you move in the direction of irradiating our food. It is  
25 really scary. We don't need any more carcinogens. We are

1 losing the war on cancer. You have relatives, I have  
2 relatives, we all have relatives who have already lost the  
3 war on cancer.

4           Disinfectants. They have been around for hundreds  
5 of years, oil of lemon, orange skin, pine oils. I am not an  
6 expert, I don't know what can be done or where to go with  
7 this. I beg of you, look to nature. The pathogens are our  
8 enemy, but they are also our teachers. Learn from the  
9 pathogens. Don't do head to head battle because we will  
10 never win. Just one issue of the antibiotics. We are  
11 losing the war with antibiotics. It is in the press  
12 regularly. The bugs are winning. We have got to learn to  
13 cooperate with nature, learn to cooperate and understand the  
14 pathogens, and not try to blow them away with cruise  
15 missiles.

16           The bottom line is the immune system. We have got  
17 to help support the immune system of the people of this  
18 nation. The standard American diet is not doing it, and the  
19 Food and Drug Administration, the other agencies are  
20 responsible for lowering the quality of our food and for  
21 dumping more carcinogens into our environment.

22           Thank you. Nobody said time up. Thank you very  
23 much for this opportunity, and I ask you, please, step back,  
24 look at the total picture, keep the kids in mind that we  
25 need to work with nature and nourish the body.

1 Thank you.

2 DR. KVENBERG: The next individual who has asked  
3 for comment is Robert Sanderson of Jonathan Sprouts. I  
4 promise I won't start your five minutes until you are  
5 physically at a microphone.

6 MR. SANDERSON: Hi. I am Bob Sanderson. This is  
7 not a comment, it is just a question. I had a confusion  
8 with some slide of Dr. Isshiki. You did some work with dry  
9 heat, and my question is it looked as though perhaps the  
10 seed was held at 75 Centigrade for up to 7 days. Did you  
11 test the germination, the viability of that seed? Thank  
12 you.

13 DR. ISSHIKI: My presentation data is all checked  
14 for the germinations. Germination is not so bad. It is  
15 useful for the commercial sprouting, 99 or 98 percent  
16 germinations.

17 MR. SANDERSON: I think we have been told that  
18 with the hot water soak, temperatures in the same range have  
19 to be within a very, vary small window, and I find that a  
20 little confusing, if you can hold seed dry at 170 degrees  
21 Fahrenheit for a week, and it is still grows, but if you  
22 soak it in hot water for 20 seconds, it won't grow.

23 DR. ISSHIKI: One is dry heating, other is in hot  
24 water. Both, germination is good, more than 99 percent.

25 DR. KVENBERG: Another request I have is from

1 Sally Stanfield from Ellridge Farms, also bearing in mind  
2 Dr. Swanson's request, if I could impose on Bob Rust, if you  
3 are here, and Dan Caudill, she had a question, as well,  
4 going back to the question of what do you do on the seeds,  
5 but let me go first to Sally Stanfield.

6 MS. STANFIELD: Thank you all very much for this  
7 brief opportunity. What I would like to present is the  
8 thought. Obviously, it is a watershed time in terms of  
9 creating regulations, creating a structure that works as we  
10 look at how to keep the food supply safe, specifically  
11 looking at it from the sprout standpoint.

12 We are located in Randallstown, outside of  
13 Baltimore. We have been farmers for years, now we grow  
14 broccoli sprouts. The issue that we have seen, which I now  
15 see coming yet again, is we all have the common goal of a  
16 safe food supply, we have the common goal of the public  
17 health.

18 We also must make very sure that we don't regulate  
19 our producers in such a fashion that they can't produce,  
20 because people, when they go to the grocery stores, they  
21 have an abundant supply of choices in this country, but they  
22 don't understand what goes into the gallon of milk, they  
23 don't understand what comes behind the nice-looking  
24 vegetable, and now, too, they don't know what must come when  
25 one produces a good, healthful sprout.

1           So, what I invite the panel and anyone who is  
2 involved with all the decisions that are now here, the  
3 opportunities that are here, and I know time is precious. I  
4 am a lawyer by trade, I have changed hats and become a  
5 farmer now. Time is real precious, but come see us at our  
6 sites, come learn what we do. Come see us on the job.

7           We want to work with you. We all have the same  
8 goals. We clearly want our consumers to be safe. We live  
9 where we work. We eat the food that we produce. But it is  
10 a practical standpoint that goes with the science, and that  
11 is what I invite you, and all of you collectively, to think  
12 about. It is a time that it is simply we look at it as a  
13 group project, as a common goal, and I think in the long  
14 run, yes, it's hard work, but we end up with a much better  
15 result.

16           Thank you.

17           DR. KVENBERG: We have another commenter. If I  
18 could, I would like to go to the seed question that was  
19 asked. Our next commenter is Rob Carver from Carver  
20 Research.

21           MR. CARVER: Good afternoon. Yesterday, I spoke  
22 about a journey that I took with an indoor farmer who became  
23 a food manufacturer. I would challenge you to closely  
24 examine the semantics of that statement.

25           What we must look at is just by the sheer act of

1 placing a food into a labeled container, use that as a  
2 symbol that this is no longer a raw agricultural product or  
3 that it should be handled as a raw agricultural product

4 I believe that sprout manufacturers can benefit  
5 from the years of practical experience of a lot of common  
6 food manufacturing entities. The milk industry, the meat  
7 industry. Most of the sanitation processes and information  
8 already exists. All we must do is make a conscious choice  
9 to say when it comes to regulating under FIFRA and EPA for  
10 antimicrobials, yes, they are agricultural, but when we  
11 germinate seeds for a finished product that is packaged, let  
12 us say this is food manufacturing, let's apply 21 CFR Part  
13 110, existing current good manufacturing procedures to this  
14 industry, and quit dancing around the idea of I am a farmer.

15 You are not a farmer, you are food manufacturer.

16 Thank you.

17 DR. KVENBERG: I received one final comment before  
18 we close off for lunch from Dr. Wick, who would like to ask  
19 a question, and I also have got a proposal or suggestion to  
20 get to the question that Dr. Swanson asked. Due to the  
21 lateness of the hour, maybe we could, at the chairmanship of  
22 the working group, ask for comment perhaps from the seed  
23 manufacturers or other comments you would want to draw from  
24 at that time. If that would be appropriate, then, I think  
25 we could handle it that way.

1 Dr. Wick, would you like to have the last word  
2 before lunch?

3 DR. WICK: The first one is for you, Dr. Kvenberg.  
4 I want clarification on whether or not your office has  
5 initiated or will initiate -- I don't know if we call it a  
6 Section 18 or not -- but this chlorine issue, and also I  
7 gather that it would take at least a year if it started  
8 today.

9 DR. KVENBERG: My office will not initiate a  
10 request for a Title 18, but we have made contact with or  
11 will make contact with the U.S. Department of Agriculture,  
12 who is dealing with the area of application in support for  
13 the industry. I think we have yet to do that, but I think  
14 on a national basis, it is possible for USDA to work in that  
15 regard, and that is our plan.

16 DR. WICK: My second question is that I am not  
17 sure about calcium hypochlorite, but sodium hypochlorite is  
18 an EPA-registered pesticide, and I wonder if that exempts it  
19 as a food additive.

20 MS. WINGFIELD: I am not sure. I believe there  
21 is, but I am not sure that there is a current tolerance  
22 exemption for sodium hypochlorite. I believe that there is,  
23 but we will have to check on that.

24 DR. KVENBERG: With that, my watch may be somewhat  
25 slower than others, but mine says 12:30 at this point in

1 time, which brings us to the close of this session.

2           Lunch is scheduled for this point in time, and a  
3 reconvening of the Working Group on Fresh Produce is  
4 scheduled for beginning of discussions at 1:30 this  
5 afternoon in this room.

6           [Luncheon recess taken at 12:30 p.m.]

## AFTERNOON SESSION

[1:35 p.m.]

1  
2  
3 DR. BUCHANAN: We are going to try and get  
4 started. We are going to first call on John. You had some  
5 unfinished business from your session this morning. Would  
6 you like to take care of that now?

7 DR. KVENBERG: Thank you. I guess you are  
8 referring to when we were going through the questions of  
9 clarification section, Dr. Swanson asked if we could get  
10 some comment and input from the seed suppliers.

11 DR. SWANSON: The question was when sprouters  
12 obtain samples to determine whether or not they will accept  
13 a lot of seed, how much seed do they obtain and run  
14 germination tests on, for example, as a routine basis. We  
15 heard 50 pounds and 8 pounds.

16 MR. FABRE: Fred Fabre with Cal West Seeds. I can  
17 only generalize and give you the benefit of my experience.  
18 The general understanding as a seedsman is the larger the  
19 sample, the better, so, you know, we always encourage people  
20 to take as large a working sample as they find workable,  
21 almost always a sample large enough to actually do a  
22 production run, so generally, from 20 to 50 pounds from a  
23 carefully composited sample. That is generally the size  
24 that most of our customers require or that we ask them to  
25 test.

1 MR. RUST: Bob Rust with International Specialty  
2 Supply. A lot of growers ask for different things. There  
3 is no standard thing. Some of them will just want enough to  
4 look at, some will want 500 pounds, enough to grow out.  
5 Probably a standard is somewhere around 20 pounds, but there  
6 is a lot of people that don't even ask for any.

7 DR. SWANSON: Thank you.

8 DR. KVENBERG: That concludes any business we had  
9 from this morning.

10 **Fresh Produce Working Group Discussion**

11 DR. BUCHANAN: This afternoon has been devoted to  
12 the Fresh Produce Working Group discussing the information  
13 that we have heard today along with its invited technical  
14 experts and also the members of the panel.

15 We would like to divide the discussion into three  
16 basic parts. I will give you just a time frame, so we can  
17 sort of keep focused on this.

18 Between now and approximately 2:40 to 2:45, we  
19 would like to focus on the questions of currently available  
20 interventions and related activities that could be used to  
21 enhance the safety of sprouted seeds, particularly alfalfa  
22 seeds. The focus here will be evaluating the scientific  
23 information that we heard in the last day and a half.

24 The second half will be from approximately 3  
25 o'clock to 4 o'clock or 3:45, where we would like to

1 identify both the research needs associated with sprouted  
2 seeds and the priority of those research needs.

3 In the last segment, we would like to focus on  
4 other issues associated with the safety of sprouted seeds,  
5 in particular recommendations in relation to food safety  
6 systems, education, and other items that might have an  
7 impact on the safety of sprouted seeds.

8 My job here today as the Chair of the Working  
9 Group is to primarily act as a referee and a timekeeper, and  
10 to try and keep the discussions in an orderly fashion. To  
11 do that, what I would like to do is currently divide the  
12 discussions on the efficacy of potential interventions,  
13 first, on seed treatment, and then subsequently on other  
14 steps within the sprouting process.

15 Kathy, I assume that we have reserved some time at  
16 the end of the day for any additional public comments?

17 MS. DeROEVER: No, there will be no more public  
18 comments.

19 DR. BUCHANAN: Then, we will have the opportunity  
20 of continuing this up until 5 o'clock. I will take a break  
21 at about 2:45 to change subjects. It is a good breaking  
22 point, and to give you 15 minutes to get up and stretch.

23 Let's start focusing on the interventions that  
24 were described here for the treatment of seeds. They  
25 included everything from disinfectants to irradiation. We

1 also have any interventions that might be useful at the seed  
2 mills themselves and at least one recommendation coming from  
3 our speakers on treatment of seeds for scarification that we  
4 also should discuss.

5           Comments, recommendations, and areas of potential  
6 use? Yes.

7           DR. SWAMINATHAN: I actually have a question.  
8 Yesterday, I think in the public comment period, somebody  
9 pointed out that Australia requires treatment of seeds that  
10 are imported into the country, but it was never specified as  
11 to what that treatment is.

12           Could someone amplify on that, please?

13           DR. BUCHANAN: Does anyone know what the treatment  
14 requirements are for the exportation of seeds from the  
15 United States to Australia? It looks like we have a  
16 volunteer.

17           MR. RUST: I am Bob Rust, and I heard that comment  
18 also, and I am not sure whether that was a misunderstanding  
19 or what, but a lot of times they ask the seed to be  
20 [foxtoxined] before it comes to the United States to kill  
21 insects.

22           DR. BUCHANAN: So, it appears that the treatments  
23 required by Australia are not in relation to a foodborne  
24 disease transmission.

25           Yes, Bruce?

1 DR. TOMPKIN: May I comment on that particular  
2 question that you are asking for?

3 DR. BUCHANAN: Yes, please.

4 DR. TOMPKIN: From what I was hearing -- and you  
5 folks correct me if I am wrong -- that the outbreaks that  
6 have occurred in the U.S. have occurred independent of GMP  
7 in a sprouting operation. So, that would suggest that GMP,  
8 important as it is, it alone is not adequate to control this  
9 issue.

10 The available evidence indicates that the seed is  
11 the primary source, thus, in this particular case,  
12 elimination and not reduction is the ultimate long-term goal  
13 for controlling this particular issue or hazard.

14 It appears from what I was hearing that some of  
15 the pathogen is under the seed or in cracks or wherever you  
16 wish, of the seed coat, and there is some issue of that, a  
17 less than 1 percent on cracks and defects of that sort can  
18 naturally occur, and I am sure that must vary, but it seemed  
19 as though some pathogen contamination below the seed coat  
20 may be occurring.

21 It is evident that the pathogen survives for at  
22 least two years at ambient temperature, and that is not  
23 surprising. So, it seems to me that it comes right back  
24 down to some method of decontaminating the seed is what is  
25 needed, and we might consider a short-term and a long-term

1 goal in that regard.

2           Along those lines, it may be possible to actually  
3 come up with some guidance with regard to a performance  
4 criterion for each of those goals, but then relative to the  
5 methods of decontamination, which could fit into a short-  
6 term application, the immersion in a disinfectant certain  
7 does show considerable death, but it in itself is  
8 unreliable, at least based on inoculated product seeds,  
9 whether it would be effective in naturally contaminated is  
10 unknown.

11           The data on irradiation, limited as it was,  
12 certainly would address whatever is under the seed coat, if  
13 that is the problem, so it has an appealing from that  
14 standpoint, it's an appealing means to address the question.

15           Certainly, immersion in hot water is an  
16 alternative to disinfectants, and there is microbiologists,  
17 heat is certainly a preferred method to disinfectants. If  
18 you can come up with the right time temperatures and, in  
19 fact, there were slides or a video showing that a heating  
20 process can be done under commercial conditions. It is a  
21 question of expense, and so on, whether or not that could be  
22 made to be a suitable approach to smaller operations.

23           One area that I didn't hear enough of was  
24 decontamination through dry heat. There was one short  
25 comment actually on that, but there are a lot of examples

1 over the years of needs to eliminate Salmonella, for  
2 example, in gelatin, gums, spices, powdered egg white, and  
3 even now, fresh whole eggs, and so that you still have the  
4 egg with a liquid egg white and yolk, which has now been  
5 demonstrated to be possible.

6           With the switch from ethylene and propylene oxide  
7 for spices, the spice industry is using irradiation, but  
8 they have gone to other means, time, temperature, it is  
9 essentially a dry heating process with control of humidity.  
10 There is quite a bit in the literature, as well as in the  
11 patent literature, of systems designed to reduce Salmonella  
12 in particular in gelatin, rendered animal byproducts, bone  
13 meal, flour, and so on.

14           I haven't heard anyone having considered those  
15 approaches as a means to treat seed. So, it is an area that  
16 should be explored.

17           So, just with that kind of thinking as a  
18 background, there are really those four approaches - liquid  
19 immersion with a disinfectant, hot water, irradiation, and  
20 then this other that I have just described.

21           DR. BUCHANAN: Does anyone have any additional  
22 technologies that they think we ought be considering in  
23 this, that were presented today or which they know is  
24 effective now? I want to keep this away from research. At  
25 this point, we are currently looking at the state of

1 technology now and what could be implemented.

2 Dane.

3 MR. BERNARD: Thanks. There was mention in one of  
4 the presentations -- and it may have been Dr. Davis -- about  
5 vapor phase hydrogen peroxide, but there was only a mention  
6 that it didn't show good results.

7 I am wondering if there has been a significant  
8 amount of work. In our past experience, we have found it to  
9 be a very good and very penetrating means of inactivating  
10 microorganisms, a little bit exotic, but shows some  
11 potential. I am wondering if there has been sufficient  
12 exploration of that technology.

13 DR. BUCHANAN: Anyone on the committee aware of  
14 any research in that area? Yes, John.

15 DR. KVENBERG: Just to clarify your remarks, I  
16 think hydrogen peroxide flushing and aseptic processing has  
17 probably got databases that you were referring to.

18 MR. BERNARD: Our experience with it was in the  
19 aseptic area. There is one piece of packaging equipment  
20 that employs that. Hot hydrogen peroxide is much more  
21 effective than cold peroxide. It needs to be inactivated  
22 or, excuse me, the molecule needs to be activated to get the  
23 hydroxyl radical, so experiments that might use 4, 6, 8  
24 percent at ambient temperature, those are not optimal  
25 conditions for hydrogen peroxide's effectiveness.

1           So, there are a number of things that can be used  
2 to activate it. The vapor phase uses heat to essentially  
3 evaporate a hydrogen peroxide solution, and the vapor phase  
4 is very effective.

5           Other things that could be tried with hydrogen  
6 peroxide, as I said, it needs to be activated to be  
7 effective, the technology has been used for some years in  
8 biotechnology research as a random agent for breaking apart  
9 DNA, and that is typically done by using a metal catalyst in  
10 direct contact with hydrogen peroxide, which causes it to  
11 activate, specifically iron and/or copper can bring a pretty  
12 immediate dissociation of the molecule.

13           I am wondering if anybody has really explored  
14 these other ways of more effectively using hydrogen  
15 peroxide.

16           DR. BUCHANAN: I think if we don't have anyone  
17 that is focusing on some data that they know in this area  
18 already, then, I think we will need to relegate this to  
19 research areas. Bill, I know you made earlier comments  
20 about things that work on food contact surfaces appearing  
21 not to work on sprouts. I wonder if this is another example  
22 of that. Would you care to comment?

23           DR. SPERBER: Well, I don't know about the  
24 peroxide directly, but when it comes to chlorine compounds  
25 like hypochlorite, in the food industry we traditionally use

1 1 to 200 ppm for sanitizing surfaces, and that may be the  
2 key here in the seed discussion is that you can only  
3 sanitize a clean surface. We don't go in and use 2,000 ppm  
4 chlorine to sanitize dirty equipment. First, you have to  
5 clean it. So, there may be an issue here of using the  
6 liquid disinfectants for seeds of the disinfecting material  
7 is being inactivated by the seed itself or by dust or soil  
8 in the seed sample.

9           So, if we are to use -- my comment about deer  
10 hunting with a cruise missile was serious. I think that is  
11 what 20,000 ppm chlorine is like, and if we are going to use  
12 chlorine as a disinfectant for seeds, we ought to figure out  
13 how to first clean the seeds, so that we can use a more  
14 judicious amount of chlorine.

15           DR. BUCHANAN: Bruce has provided us a framework  
16 on how to deal with these questions as we go through at  
17 least in this first phase on seed treatment, and he talked  
18 about an ultimate goal of eliminating foodborne pathogens  
19 from the seed.

20           He talked about then being able to compare the  
21 efficacy of the technologies that he has identified against  
22 that standard, and then identified the need to establish  
23 short-term and long-term goals in terms of their efficacies.  
24 I would like to thank Bruce for providing that framework,  
25 and I think it is a good one for us to deal with.

1 I would like to thank Bruce for providing that  
2 framework, and I think it is a good one for us to deal with.  
3 I would like to give an opportunity to add to this list of  
4 four technologies.

5 Are there any others that we heard during the last  
6 day and a half that should be included in evaluating them in  
7 terms of their effectiveness for eliminating foodborne  
8 pathogens from seeds? To remind you what they are, they are  
9 a liquid immersion with a disinfectant, radiation, hot water  
10 and dry heat.

11 Are there any others that are currently available  
12 that we should add to that list as we go through our  
13 consideration of this aspect of seed decontamination?

14 Larry, as a person that has been doing this for a  
15 while, are there any others that we should be adding to that  
16 list that we could take off the shelf?

17 DR. BEUCHAT: The subject of surfactant and  
18 properties that would be associated with delivery of a  
19 potentially lethal chemical or treatment to the site of the  
20 cell, I think deserves attention.

21 It may be in combination with the liquid immersion  
22 or perhaps one of the other approaches that have been  
23 enumerated. Also, other potentially lethal volatile  
24 materials, gases, these could be from natural sources. We  
25 have some preliminary information and data to indicate, for

1 example, that iso-L-thiocyanate will, in a peer system,  
2 eliminate, kill 0157 rather quickly. This is a component of  
3 a number of plant mustard family, but there are others that  
4 we know are antimicrobial bactericidal, bacteriostatic that  
5 perhaps should deserve attention in terms of a battery of  
6 approaches, and maybe a combination of approaches,  
7 treatments, hurdle approaches that should be looked at.

8 DR. BUCHANAN: I gather at this stage, though,  
9 most of these gases that should be considered are really at  
10 this point at the research stage.

11 Likewise, we have a hot water here. Is anyone  
12 aware of anyone that is doing any work with steam as a  
13 decontaminant? Yes, Bruce.

14 DR. TOMPKIN: Actually, I think some of the  
15 systems or processes that I had in mind do involve  
16 controlled humidity, so that, in fact, you don't have the  
17 product becoming wet, but by controlling the humidity, along  
18 with temperature, you can get a faster kill.

19 DR. BUCHANAN: Yes, John.

20 DR. KVENBERG: Just to point out, I think the body  
21 of literature that is available on inactivation of microbes  
22 with wet heat and dry heat is probably largely known and can  
23 be found in various texts, such as [Elmer Marse] a big  
24 compendium. People are nodding their heads. So, we have a  
25 lot of knowledge about the time/temperature requirements for

1 inactivation are relative to moist heat, at the various  
2 degrees, be in live steam or other elevated temperatures  
3 with moist heat, and I think it is also known that dry heat  
4 is a lot harder to accomplish at kill level temperatures.

5           Obviously, you have to consider the viability of  
6 the sprout. That is one of the things that is different  
7 about this than other foods is you have to maintain a viable  
8 seed in order to have a sprout. That is probably a research  
9 piece.

10           If I could, one of the things that we heard in  
11 this presentation, a remark that has been made is that  
12 pasteurization may not be -- it is nice, but it costs so  
13 much. I am not really sure that has been explored to the  
14 extent. If I heard the presenter correctly, basically,  
15 every particle has to be able to see this, and to me that is  
16 a combination of temperature in immersed hot water and  
17 agitation in order for the seeds to get a uniform  
18 application on a time process that may or may not be a high  
19 cost issue. The question was can the seeds be  
20 "pasteurized," I think that is the simple model.

21           DR. BUCHANAN: What I would like to do now is to  
22 go through each of the four technologies that have been  
23 identified and get some kind of an assessment from the  
24 committee about what expectation do we have in terms of  
25 their efficacy, what kinds of risk reductions we can expect,

1 and are they capable of meeting the overall goal, which  
2 would be the elimination of foodborne pathogens from the  
3 seeds.

4 I would like to start off with liquid immersion,  
5 and I think I am going to direct a real direct question to  
6 Larry, since he did double duty as a member of the panel and  
7 also as a person that has been doing this kind of work.

8 What is our expectation currently in terms of  
9 coming up with disinfectant treatments, water immersion-  
10 based systems that would be effective, and what is the level  
11 of effectiveness we can expect from them?

12 DR. BEUCHAT: The difficulty in part is testing  
13 whatever treatment it may be and expecting a straight line  
14 reduction in counts. We all know, in working in the area of  
15 food microbiology, we get sometimes a shoulder effect,  
16 oftentimes the tail effect. This is the tail effect to the  
17 highest extreme in terms of being able to eliminate a given  
18 population of either Salmonella or 0157 from alfalfa seed.

19 So, I think we should not come up with a certain  
20 log reduction as a goal to obtain, say, whatever it might  
21 be, to zero. We could come up with a target, but with the  
22 expectation of certain percentage of risk associated with  
23 the probability that a viable cell would remain or enough  
24 that through the germination and therefore amplification  
25 process it would have grow and reach fairly large numbers in

1 the sprouting process.

2           The combination of temperature, just heat and  
3 moisture would be one of the most practical ways,  
4 approaches, if that probably fairly delicate balance between  
5 time, temperature, and moisture content can be demonstrated,  
6 can be identified, and if systems can be, and I am sure they  
7 can be, devised to actually process the seeds in a fashion  
8 that upon immediate exit from that system could be contained  
9 in a way that they wouldn't subsequently be contaminated.  
10 That would seem to me to be an area that should deserve  
11 research attention, the balance between moisture,  
12 temperature, time, viability, and also including among all  
13 these experiments different ages of seeds, different  
14 varieties of seeds, if scarified seeds need to be included,  
15 so be it.

16           DR. BUCHANAN: Larry, you had a working assumption  
17 there, and I would like to go back to it, and we will  
18 revisit it again later in another section when I talk about  
19 interventions, is you had the assumption that you would,  
20 after treatment of the seeds, be able to then move them into  
21 a germination and sprouting system that then assured that  
22 they weren't recontaminated.

23           Based on your experience, how likely is that?

24           DR. BEUCHAT: Not likely.

25           DR. BUCHANAN: Because I think that is a very

1 important point that we are going to have to wrestle with  
2 when I come back to this area, is what level of assurances,  
3 if we provide assurances on seeds, what is the likelihood  
4 that they will be recontaminated and you will get the grow-  
5 out problem that we have seen.

6 DR. BEUCHAT: On that point, if, however, a higher  
7 degree of assurance could be made in terms of the seed as it  
8 arrives at the sprouting facility, and then the GMPs and the  
9 other practices and regulatory aspects that would hopefully  
10 improve and maintain a higher level of standard overall in  
11 the processing of sprouts, the preparation and processing of  
12 sprouts, at least there would be perhaps a better chance of  
13 reducing the risk of the end product overall in the industry  
14 of having Salmonella or 0157 as it exited the processing  
15 facility.

16 DR. BUCHANAN: Can I read into this, then, that  
17 you are suggesting that no matter what solution comes  
18 forward, it will have to be a multiple hurdle type of a  
19 system?

20 DR. BEUCHAT: Yes.

21 DR. BUCHANAN: And that implies that no one system  
22 currently available supplies you in your mind with a level  
23 of assurance that you consider needed?

24 DR. BEUCHAT: Correct.

25 DR. BUCHANAN: I throw this out because these are

1 some pretty strong statements, and I would like to bounce it  
2 off the rest of the members.

3 DR. SWANSON: I would like to go back to a point  
4 that Bruce made earlier and tie that with what Larry said.  
5 Bruce pointed out that the source of contamination that  
6 seems to be the primary problem in all the outbreaks that we  
7 have seen to date seems to point to seed, and not  
8 necessarily a GMP issue.

9 I would agree with Larry that there is ample  
10 opportunity for seed to become recontaminated after  
11 disinfection treatment is applied, but with the potential  
12 for amplification that certainly exists in sprouts, if it  
13 was highly likely for that contamination to occur, I would  
14 suggest we would see many more outbreaks than we currently  
15 do.

16 The source of contamination in these processing  
17 facilities, I don't think is inherently there or we would  
18 see many, many sprout outbreaks, and we are not. So, I  
19 agree with the fact that we need a multi-hurdle approach at  
20 each one of the stages, and there isn't one simple solution,  
21 but I think we need to keep in mind that it isn't a high  
22 probability that there is going to be contamination in these  
23 sprouting environments.

24 DR. GOOSBY: Two points that you are working on,  
25 Bob, presently. I would suggest strongly that we look at

1 combinations in addition to the single use of any of these  
2 four, that perhaps some of those used in combination with  
3 another may offer a closer goal of zero of sanitary seed.

4           It has my experience, however, regarding GMPs, in  
5 working with food processing and production facilities, to  
6 pay close attention to the human factors, shall we say, and  
7 the entire environment associated with food production  
8 operations, and not to single California, they are probably  
9 one, if not several, steps ahead of some of the other areas  
10 of the country in that industry, but as I recall, there have  
11 been numerous actions and opportunities taken on the part of  
12 the people in the production area to diminish the likelihood  
13 of the safe product.

14           So, my point is I would encourage consideration of  
15 GMPs in the production area, and in agreeing with the other  
16 concerns and comments made, as well, because we haven't  
17 heard of particular outbreaks to an excessive level in the  
18 minds of some regarding sprouts as a vehicle for foodborne  
19 illness, because they are not recognized or reported or  
20 identified, it may be less than an accurate portrayal of  
21 what is really going on.

22           DR. BUCHANAN: Jeff, in your presentation, you  
23 made some rather strong recommendations in relation to the  
24 GMPs. Would you like to reiterate your position?

25           DR. FARRAR: I think it has been summarized pretty

1 effectively by everyone that we share the belief that GMPs  
2 have to be a vital ingredient in these solutions. They have  
3 to be a given. There can't be any compromise on GMPs, but  
4 to depend on GMPs solely, I am concerned that from what we  
5 have seen in our outbreaks, that may not be sufficient.  
6 Multiple hurdles are needed.

7           Seed disinfection is one step that is available  
8 now, that a lot of sprouters are already doing. A lot of  
9 these other technologies we are talking about, and even  
10 alluding to as readily available, really haven't been that  
11 thoroughly tested yet, dry heat, hot water are two that come  
12 to mind.

13           So, I think we really need to focus our attentions  
14 on what can we do in the next 30, 60 days here to intervene.

15           DR. BUCHANAN: And what do you think we can do in  
16 the next 30 to 60 days?

17           DR. FARRAR: I think we can put forward a  
18 recommendation that USDA and/or FDA submit a petition to EPA  
19 for approval of calcium hypochlorite at the 20,000 ppm level  
20 for disinfection of seeds, and whether we go forward with  
21 other interventions that we have discussed here today, that  
22 is open for discussion, but that is one move we can make  
23 along with strict enforcement and more frequent inspections  
24 for GMPs.

25           DR. BUCHANAN: Discussion on that specific

1 recommendation?

2 DR. SWAMINATHAN: At this point, I am talking  
3 about the 30 to 60-day recommendations. Instead of  
4 immediately the FDA saying that calcium hypochlorite needs  
5 to be approved or petitioning for the approval of calcium  
6 hypochlorite, perhaps the better thing would be to come up  
7 criteria that four process controls that we can achieve at  
8 this point, and this was mentioned actually by Bruce when we  
9 were coming back from lunch, and at this point, there are  
10 three places where one could intervene, at the seed stage,  
11 the sprouting stage, and after the sprouting process.

12 At the disinfection stage, there are at least two  
13 parameters on which criteria need to be established. One is  
14 the degree of kill that one needs to achieve, and I think it  
15 is almost unanimous that we cannot accomplish complete  
16 inactivation of E. coli 0157 and Salmonella, so what is the  
17 best possible control that we can achieve, is it going to be  
18 a 3D or a 2D or a 4D process, if we can come up with  
19 criteria for that, and the second parameter would be  
20 germination, what is acceptable for that, is it over 90  
21 percent, over 95 percent, and so on.

22 I think we need to talk about those a little bit  
23 more and establish the criteria first and then see which of  
24 the treatments we have discussed is practical and also meets  
25 those criteria.

1 DR. BUCHANAN: Additional comments? Terry.

2 DR. TROXELL: I just want to clarify that we have  
3 already been in discussions with USDA to move forward with  
4 an authorization of the 20,000 parts per million calcium  
5 hypochlorite with EPA. I don't know what hurdles there  
6 might be, but it is envisioned that we are going to get  
7 something quick, you know, hopefully, a Section 18 or some  
8 other sort of temporary clearance.

9 I think we all need to look at what the other  
10 treatment, the efficacy is, you know, of the other  
11 treatments, and let's assume for the time being anyway that  
12 calcium hypochlorite is fairly shortly down the road.

13 DR. BUCHANAN: Swami, can I ask a point of  
14 clarification? You came up with three stages - the seed  
15 stage, sprouting stage, and post-sprouting stage.

16 DR. SWAMINATHAN: Yes.

17 DR. BUCHANAN: You eliminated from that list any  
18 consideration of pre-seed stage, that is, seeds before they  
19 got to the sprouter. Are there any interventions that  
20 should be considered pre- the seeds arriving to the  
21 sprouter?

22 DR. SWAMINATHAN: The only one I could think of  
23 was the scarification, which was pointed out by different  
24 people, the hard seed counts and scarification apparently.  
25 What I was hearing was some requirements and standards could

1 be set up in that area. We are talking the short term now,  
2 not research. That is the only thing I could think of.

3 DR. BUCHANAN: Was there sufficient data to make a  
4 case for scarification? I am bouncing around a little bit  
5 on purpose. Yes, John.

6 DR. KVENBERG: Just going back to the conversation  
7 that we heard, if I can go to the pre-seed discussion for a  
8 moment, it seems I recall that climatic conditions and  
9 adaptations of the seed made it a good hot weather sprout or  
10 not a hot weather sprout, and there was also an indication  
11 of origin of where the seed came from, so if you make a  
12 somewhat tenuous connection between what may or may not be  
13 true, the seed that is subject to scarification has a  
14 thicker seed coat and acclimated to a northern climate.

15 Maybe there is some -- I don't know if we have  
16 heard enough to actually make a recommendation, but it seems  
17 that there is some linkage between the origin of the seed  
18 and its need for scarification for sprouting purposes.  
19 That, I think I heard here at the meeting.

20 So, I don't know if there is enough here for the  
21 working group to make a considered opinion of that, but that  
22 is kind of the gist of what I had heard through various  
23 pieces of this was that seed selection source and the  
24 sprouting capability of a hot weather seed made it more  
25 applicable to sprouting without scarification. That is what

1 I heard.

2 DR. BUCHANAN: Bruce, do you no longer have a  
3 comment?

4 DR. TOMPKIN: No, I do.

5 DR. BUCHANAN: Okay. You were next, then Dane.

6 DR. TOMPKIN: I am sure that we wanted to, we  
7 could come up with some good agricultural practices at the  
8 farm level. I would suspect that what you have in place for  
9 growing lettuce, for example, might apply to this, but it is  
10 just a matter of going through that list and sorting out  
11 those that would be appropriate for seeds.

12 DR. BUCHANAN: Can we take that as a  
13 recommendation, that we should emphasize the needs for good  
14 agricultural practices in the production of seeds for  
15 sprouting?

16 DR. TOMPKIN: Yes. However, even with those good  
17 agricultural practices, I think it must be assumed that  
18 certain lots will contain enteric pathogens, because we  
19 cannot control wildlife nor our environment, and so I think  
20 it comes down to a means to decontaminate the seed at the  
21 seed handler level, and essentially, we are thinking of a  
22 pasteurization system. It is just like collecting milk from  
23 a bunch of farmers and then you bring it into a centralized  
24 place and pasteurize it. We are all familiar with that.

25 To move down to that next step, however, we heard

1 that there are 350 approximately sprouters, so in a short  
2 term, what we have been discussing is to use a liquid  
3 disinfection system for use at the sprouter level, and that  
4 would be the calcium hypochlorite or if someone could move  
5 on it, perhaps with hot water or something of that sort,  
6 that would be done at the sprouter level.

7           You have got 350 operators to actually manage and  
8 hope that you can provide them with the tools and the means  
9 to decontaminate the seed to the best that is possible with  
10 that technology, but there is still a question, and so I  
11 could see where we could come up with a short-term goal to  
12 apply a decontamination system at the sprouter level of  
13 whether it is a 4 or 5 log kill, whatever that particular  
14 requirement may be that we could come up with.

15           But then beyond that, I think that a longer term  
16 goal, based on seeds, at the seed distributor level, would  
17 be to come up with a means to provide a pathogen-negative,  
18 that is an enteric pathogen-negative seeds, that perhaps we  
19 could come up with a guidance of, say, start with the seeds  
20 that are inoculated with  $10^4$  per gram, or something of that  
21 sort, and the system must provide a pathogen-negative result  
22 after sprouting, so that you take advantage of the growth  
23 that may occur during sprouting and increase the  
24 sensitivity, and so as you work in that direction as a  
25 longer term goal, to come up with a pathogen-negative seed

1 and then, where possible, verify that or validate that with  
2 naturally contaminated seeds, and maybe we would have more  
3 confidence. Essentially, we are just trying to build  
4 greater confidence into the kill step.

5 DR. BUCHANAN: I get the implication here that a  
6 pathogen-negative seed, is this a seed that is supplied to  
7 the sprouter that is pathogen-negative?

8 DR. TOMPKIN: Yes. If I were a sprouter, in  
9 anything that we would do, we would have to have a negative  
10 product because it is something over which a sprouter has no  
11 control.

12 DR. BUCHANAN: Based on the discussions that took  
13 place at this meeting, are there any steps that the sprouter  
14 could do short term, right now, to provide a pathogen-  
15 negative seed?

16 DR. TOMPKIN: Yes.

17 DR. BUCHANAN: What?

18 DR. TOMPKIN: The individuals providing seeds are,  
19 from what I can see, would have to -- it is going to take  
20 time to do the research, irradiation certainly looks like it  
21 would work, but it is long term in terms of getting  
22 approval.

23 DR. BUCHANAN: Putting approval aside, are there  
24 any barriers here, I mean do we need the research on  
25 irradiation or is there sufficient data to say that it is

1 effective?

2 DR. TOMPKIN: It looks pretty good to me, but I  
3 would like to see it on some naturally contaminated seeds.  
4 So, I think that irradiation is high on the list from my  
5 perspective, but I would not rule out others that are also  
6 possible.

7 Commercially, we used to put powdered egg white  
8 into rooms, large rooms, for a week to 10 days, 130 degrees  
9 is what comes to mind. We also did that with gelatin. When  
10 we had problems with gelatin, it would go into a hot room.  
11 We have done that. We came up with a time, temperature,  
12 humidity controlled system with drums, and as I recall, that  
13 was for gums and stabilizers. There are ways of approaching  
14 a decontamination of dried materials.

15 That really didn't impact on functionality.  
16 Whether it will impact on germination is a question, but  
17 from what I could hear, it looked like you had a pretty good  
18 shot at coming up with something that would work, and not  
19 jeopardize your germination rate.

20 DR. BUCHANAN: Larry, I know you did a little work  
21 on dry heat storage. Did you go up to any temperatures  
22 where you could assure a pathogen-free seed?

23 DR. BEUCHAT: No. The highest temperature in  
24 terms of alfalfa seeds that we have stored is 37 Celsius, so  
25 we really haven't done any temperatures higher than that.

1 DR. BUCHANAN: I was going to say that is a cool  
2 afternoon down in the Imperial Valley.

3 DR. BEUCHAT: But I think it is a bit beyond,  
4 well, certainly, the germination rate is important, but I  
5 have learned a little bit about other things besides just  
6 germination. There is something called vigor, and sprouters  
7 in the audience can help me on this. It is not just  
8 germinating, but it is the rate of growth after germination.

9 When we get into dry or moist heat in terms of a  
10 system to kill pathogens, I know a little bit about the  
11 behavior of other legumes in terms of something called hard  
12 to cook, the problem in the bean industry, and what happens  
13 is, it is accelerated by temperature, elevated temperature,  
14 and moisture, and it comes down to a gelatinization of  
15 carbohydrate, polysaccharide layer, and the difficulty of  
16 taking up water and perhaps in that case difficulty to cook,  
17 but in this case, difficulty to take up water by the seed to  
18 germinate and then carry through processes necessary to be  
19 very vigorous during the sprout growing and maturation  
20 process.

21 So, it is going to be a balancing act here. I  
22 think that definitely we need to know more about it, but it  
23 is not just germination rate in the end, but rather how  
24 quickly it gets to that point where the sprouters can  
25 control spoilage and other factors that impact on sensory

1 quality.

2 DR. BUCHANAN: So far I have heard a lot of  
3 discussion to this point recommending some kind of an active  
4 intervention with the seeds. Do I have anyone that wants to  
5 take the opposite position, that such a step is not  
6 necessary?

7 DR. NAGLE: I am not sure that this is appropriate  
8 now, but I do want to talk about this GAPs that we have just  
9 put down there for the field. Given the discussions that we  
10 have had about the lack of being able to identify these  
11 pathogens in seed, isn't this a bit of an overkill of going  
12 out and trying to tell farmers how to farm when we wouldn't  
13 be able to measure whether they were succeeding or not.

14 I think this is a little bit beyond. I think we  
15 do need to do something with the seed, but I think we have  
16 heard repeatedly over the last two days that this is  
17 probably an event type of contamination, not a gross  
18 contamination caused by processes or by ways of doing  
19 business.

20 It is a deer walking through a field or a bird  
21 flying over a field, it is not just a gross contamination of  
22 the way of agriculture being conducted, and I think we might  
23 be going down the wrong path if we focus too much on this  
24 GAPs for this for alfalfa. I am not talking about lettuce,  
25 I think that was thrown out before, but to put it out for

1 alfalfa now, I think is way premature until we can find  
2 something. I just don't think that this is going to bring  
3 us any increased level of satisfaction that we have done  
4 something about the problem.

5 DR. BUCHANAN: Comments?

6 DR. KVENBERG: Can I just go back to comments I  
7 heard during the meeting, and that had to do with percentage  
8 of damaged seeds, not to harp on the scarification question,  
9 but my earlier point was selection of seed source may have a  
10 bearing on the condition of the seed, whether it comes from  
11 a hot source or not may have a bearing, we just don't know.  
12 Maybe this is a research question, but, you know,  
13 suppositions have been put out that seed source as opposed  
14 to growing condition or good agricultural practices is a  
15 pre-seed condition because it is selection of source that  
16 may reduce the likelihood of occurrence. It was a point I  
17 was trying to make earlier.

18 Maybe that is a research or needs to be delved  
19 into, but the question of the likely contamination of the  
20 seed before it gets to the seed house is a point that has  
21 been discussed at the meeting, it hasn't been discussed  
22 here.

23 DR. BUCHANAN: Additional comments on GAPS?

24 David.

25 DR. GOOSBY: I am really kind of drawn both ways.

1 The complication here is, as I recall from the seed  
2 producers and distributors is that they are producing  
3 primarily seed for agricultural purposes and secondarily for  
4 the sprout industry. Therefore, we are asking a lot of an  
5 agricultural business to entertain GAPs for this small  
6 segment of their work.

7           On the other hand, if there were to be producers  
8 of seeds destined for the sprout industry, and that could be  
9 identified early on, I really think there is value in trying  
10 to create these additional hurdles of protecting the public  
11 health by addressing such concerns as the use of manure,  
12 water, pesticides, those kinds of things at the farm level  
13 to be included in the broad category of GAPs.

14           MR. BERNARD: I have to agree with Nancy on this  
15 one. We have heard repeated testimony to the fact that you  
16 can take lots, even lots which have been implicated in  
17 outbreaks, and test them. Very rarely do you find it, which  
18 tells me this is not a broad contaminant, as something that  
19 might result from an irrigation practice, a fertilization  
20 practice, or a spraying practice. Then, we would expect  
21 more general contamination. We don't see that.

22           These people behind us here know a good deal more  
23 about how seeds are produced, selected for sprouting, et  
24 cetera, and I haven't heard any consensus from them as to  
25 the implications of any of those practices on the resultant

1 problems.

2           To say that there is something, obviously that,  
3 you know, seed for human consumption should be handled such  
4 that it is certainly acceptable for human consumption, but  
5 beyond that, to say that we can come up with any fix on the  
6 good ag practices side that has an implication on the  
7 potential for elimination or prevention of outbreaks is  
8 speculation.

9           There is a long-term research agenda. I would  
10 agree that this is worth looking at, but if we are looking  
11 at some short-term things, I think we have got to go back to  
12 interventions that can be applied either after you have the  
13 seed or in the sprouting and grow-out, and we have got some  
14 priorities that we can talk about there.

15           DR. BUCHANAN: Bill.

16           DR. SPERBER: I think perhaps the seed  
17 distributors do have a bigger role in here than we suspect,  
18 because several times the point was made that only 10 or 15  
19 percent of the alfalfa seed is of sprouting quality, so  
20 somehow the seed distributors are needing to segregate the  
21 sprouting quality seed from the normal agricultural seed,  
22 however that is being done.

23           Another seed person yesterday said that the grow  
24 alfalfa seed by contract, and if you are growing anything by  
25 contract, you can specify where it is grown or you can

1 specify that it not be next to a field lot or places like  
2 that, so you could have small degree of control there.

3 DR. BUCHANAN: I am looking for a consensus to  
4 develop here, and so far I am seeing a consensus not to  
5 recommend anything related to GAPs at this point, but to  
6 regulate it to research. Do I have anyone arguing the  
7 opposite side? Bruce.

8 DR. TOMPKIN: I wouldn't want to tie people's  
9 hands raising alfalfa in the field . I think there is some  
10 very basic things that the application of fresh manure to a  
11 field for fertilizer for this particular crop, I think would  
12 be inappropriate, and you might not have to go any farther  
13 than that.

14 So, when you asked would I agree that GAP should  
15 be on the list, certainly, but to go beyond that, I think  
16 may be inappropriate.

17 DR. BUCHANAN: Why don't we at this point circle  
18 that one with a star or square brackets, cross it out.

19 Let's go back through these real quick on a couple  
20 of the interventions. We had some discussions about  
21 scarification. Do we know enough to make a recommendation  
22 on that now, or do we need to relegate that to research?

23 DR. SWANSON: Research.

24 DR. BUCHANAN: Okay. That gets relegated to  
25 research.

1 DR. BEUCHAT: I don't know of any studies that  
2 have been done to compare, for example, a given lot of  
3 alfalfa seeds, half of which is scarified, the other half  
4 not, inoculate it, and then test disinfectants. So, to  
5 support the point that research needs to be done, yes, I  
6 would do that.

7 On the other hand, I would be very surprised if we  
8 don't see from that type of research that it is much more  
9 difficult to eliminate, to reduce pathogens from the  
10 scarified versus the non-scarified. We will have more  
11 difficulty removing it from the scarified product, but that  
12 the hard data, the scientific data, to my knowledge, has not  
13 been developed.

14 DR. BUCHANAN: I see a consensus there to  
15 recommend scarification as a research area.

16 The other consensus that I have seen to point, and  
17 I haven't yet had anyone argue against it, was that there  
18 should be some positive interventions in decontaminating the  
19 seeds, reducing the risk associated with foodborne  
20 pathogens, that is, some positive intervention step.

21 Do I hear anything from the committee that  
22 surfaces as less than a consensus?

23 [No response.]

24 DR. BUCHANAN: There being none, that there should  
25 be a positive intervention step to reduce the level of

1 microbial contamination of seeds. Lee Ann, you want to put  
2 that up as a recommendation.

3 DR. DOYLE: Mike Doyle. I think when you say a  
4 positive step, that is fairly broad. Maybe if we narrowed  
5 that down and say X number of log reduction or something in  
6 that range.

7 DR. BUCHANAN: That is where we are going now. I  
8 get consensus where I can. If I can get you all to agree  
9 that something needs to be done, then, we can talk about how  
10 much.

11 Let's open the floor. Mike, how much? Then,  
12 after we get how much, then, we will talk about how.

13 DR. DOYLE: I guess I would suggest we might start  
14 out with 4 logs.

15 DR. BUCHANAN: And on what basis do you provide  
16 that estimate of how much we should achieve?

17 DR. DOYLE: Because I think we have a practical  
18 approach that can achieve that with calcium hypochlorite.

19 DR. BUCHANAN: You are talking about the 20,000  
20 parts per million hypochlorite.

21 DR. DOYLE: Right.

22 DR. BUCHANAN: Larry.

23 DR. BEUCHAT: If I could get enough E. coli on the  
24 seed in the first place to get 5 or 6 logs, I think I could  
25 get the 4 log reduction now. It's that very small

1 percentage that lingers behind. If I could get  $10^6$  per  
2 gram, I could probably reduce it to less than  $10^1$ , but it is  
3 that small percentage that remains behind is amplified  
4 during the sprouting process.

5 DR. BUCHANAN: That was a question I asked during  
6 the session this morning, because obviously -- Bill, are you  
7 here in the audience somewhere? I guess Bill Fett left.  
8 They got fairly high numbers. Was that an artifact or was  
9 that -- how did they do it?

10 DR. FARRAR: This whole question, though, gets  
11 back to the point that we don't know at what level these  
12 seeds are naturally contaminated.

13 DR. BUCHANAN: Correct.

14 DR. FARRAR: To assume that they are contaminated  
15 at the  $10^6$  range, I think would be faulty logic at this  
16 point.

17 DR. BUCHANAN: No, that wasn't the logic. It was  
18 whether he would be able to measure whatever he started with  
19 because he starts with such a low level, and I guess the  
20 next question would be is there any indication at all that  
21 the contamination at low levels is different than the  
22 contamination in artificially higher levels.

23 MR. BERNARD: I think the advice given to me ages  
24 ago by one of my mentors when we were talking about how many  
25 logs we needed to achieve a certain target in a product, and

1 he said I don't care how many logs you get it, just kill the  
2 last 10 of the buggers. That is exactly what Larry is  
3 talking about here.

4           You know, what we are seeing with tailing and the  
5 chemical methods is very classic. Somebody comes in to me  
6 and says I have got this stuff, and I can give you a 5 log  
7 kill, I yawn, because that to me means nothing. If you  
8 start out with  $10^7$  artificially inoculated, and do a count o  
9 it, you are down to usually  $10^5$ ,  $10^6$  just because you can't  
10 recover them.

11           So, you know, getting down to 10 is fairly easy  
12 with most chemical treatments, but because of masking,  
13 because attached bacteria are embedded, bacteria are much  
14 hard to kill than the planktonic type. It is exactly what  
15 we went through with biofilms, so it depends on the state of  
16 the organisms.

17           I think the natural contaminants would probably be  
18 very hard to kill even though they are there in very low  
19 numbers with any chemical treatment. That is the problem I  
20 think we are running into.

21           Tailing is a classic problem. It is less of a  
22 problem with heat, even though clumping and other ways of  
23 masking give you some tailing with heat, it is much less of  
24 a problem there. Irradiation is really the only treatment  
25 that gives you pretty much a flat, straight line regardless

1 of whether you artificially inoculate or whether it is a  
2 natural contaminant, because of the hit theory, and so I  
3 think it depends on what intervention you are planning on as  
4 to the importance of natural contaminants versus  
5 artificially inoculate contaminants.

6 I think obviously, if you use high concentrations  
7 of calcium hypochlorite, it is going to reduce your risk,  
8 but as Larry's data has shown, we can't get to a point where  
9 we can have absolute surety with that kind of a system.

10 DR. BUCHANAN: Let me ask you -- we turn the  
11 question around on you -- assuming that you were using a  
12 chemical disinfectant, how effective should that chemical  
13 disinfectant be?

14 MR. BERNARD: As good as you can get it, but you  
15 are still -- it is what do you expect. You know, we are  
16 reducing risk with whatever chemical you can get approved  
17 through the process.

18 DR. BUCHANAN: What should we expect, Dane?

19 MR. BERNARD: What should you expect?

20 DR. BUCHANAN: Right.

21 MR. BERNARD: Mike's number was a good one, but  
22 are you going to get the last 10. No.

23 DR. BUCHANAN: Mike.

24 DR. DOYLE: I think we are looking at the short  
25 term fix, and I think that you hit it on the head, that

1 irradiation would be the most likely long-term fix, but I  
2 haven't seen anything else that looks reasonably practical.

3 DR. BUCHANAN: Jeff did point out that we have a  
4 short-term mount on this one, but 20,000 parts per million  
5 chlorine is not approved yet other than in the State of  
6 California.

7 MS. DeROEVER: You are coming up on quarter of  
8 3:00.

9 DR. BUCHANAN: Okay. Let's talk about very  
10 quickly did we see any interventions that were associated  
11 with the sprouts themselves, the sprouting process, or after  
12 germination that would appear to be effective short term or  
13 long term?

14 DR. TOMPKIN: That calcinated water I thought was  
15 pretty intriguing, and certainly having more information on  
16 it or to understand what was behind it, is it a pH effect,  
17 can something else be used, and if we could take advantage  
18 of that, that would be helpful, because what is unique about  
19 this product is that you will have growth as a result of  
20 sprouting.

21 DR. BUCHANAN: As far as I could tell, I only  
22 heard to technologies. One was the oyster shell technique,  
23 and the other one was radiation of the sprouts after  
24 sprouting.

25 DR. TOMPKIN: But irradiating the sprout when you

1 have 350 sprouters, that is a matter of working that part  
2 out. If you come up with something else that could be used  
3 in-house, it would probably be better.

4 DR. BUCHANAN: What is the importance of coming up  
5 with some kind of intervention either during sprouting or  
6 post-sprouting in terms of the overall safety of this  
7 product?

8 DR. DOYLE: I think it's darn important because we  
9 have a condition which will promote the growth of pathogens  
10 if they should be present.

11 DR. TOMPKIN: There is the possibility of a  
12 competitive exclusion or some sort of prebiotic that we  
13 talked about. There was a little bit about it, and it is a  
14 research idea still, but that would be a third one.

15 DR. BUCHANAN: Additional comments on this  
16 section?

17 MR. BERNARD: Bob, where did we end up with  
18 talking about heat treating either the seeds before sprout,  
19 well, the seeds just before sprouting, is that on the table  
20 at this point in time or not?

21 DR. BUCHANAN: Yes, it is. Do you have some  
22 additional comments on it? I had it identified as a viable  
23 short-term solution.

24 MR. BERNARD: I think that is where I would come  
25 out. Obviously, the death of microorganisms begins about

1 five degrees above their maximum growth temperature, which  
2 opens the door to some low temperature, long-time  
3 treatments. Then, it becomes a race between viability, and  
4 -- what was the other word you used -- vigor of seeds versus  
5 death of microorganisms.

6           If we could be fairly certain that most of the  
7 contaminants were either surface contaminants or very near  
8 surface contaminants, then, that opens the door to high  
9 temperature short time as being probably the most favorable  
10 to the seeds and the most effective in killing, but the  
11 further up in terms of control of time and temperature on  
12 that scale you move, in other words, if you are talking  
13 about 150 degrees for just a few seconds, for example, that  
14 gets a bit on the expensive side in terms of the equipment  
15 to make that kind of thing happen.

16           On the other hand, if you have a possibility of  
17 140 for 10 minutes, that is something that could be done in  
18 a kettle with good temperature control and hand-operated  
19 thermometer. So, those are kind of the range of options,  
20 and I guess there needs to be some research done to kind of  
21 fill in the data gaps as to what we are talking about in  
22 terms of time, temperature profile of seed response versus  
23 the thermal death time data that I am sure the literature  
24 can help us out with.

25           Also, Bruce's discussion earlier about dry heat,

1 not really dry heat, but not adding liquid moisture, but in  
2 a controlled atmosphere, I think is something that could be  
3 explored, as well. Our experience years ago with roast beef  
4 could be utilized. A lot of that data could be used for  
5 that.

6 DR. BUCHANAN: Before we take a quick break, let  
7 me reiterate what I have down in my notes, so that I  
8 understand and we have for the record the consensus that I  
9 think has been developed, that there were four possible  
10 short-term interventions or there is four possible  
11 interventions, two of them that are short term in terms of  
12 they could be applied quickly in a 60- or 90-day period,  
13 would be liquid immersion in a disinfectant, and/or hot  
14 water treatment. The reason I put in "and/or" is that there  
15 was some indication that you could use them in combination.

16 A longer term solution -- and I gather this was  
17 more from the fact that there is some regulatory hurdles  
18 that have to be reached -- was irradiation of the seeds, and  
19 then finally, dry heat, there seems to be not much data  
20 available while it could be applied, there wasn't a lot of  
21 data confirming its efficacy.

22 Have I reached the consensus correctly on those  
23 four technologies? Yes, Bruce.

24 DR. TOMPKIN: With regard to that last one,  
25 actually, there are commercial systems in place, and it

1 should be possible to actually go around and talk to people  
2 who do these things now, such as the spice industry, and so  
3 on, find out what the conditions are, what equipment is  
4 available, and so on.

5 DR. BUCHANAN: You just need to do some validation  
6 studies.

7 DR. TOMPKIN: Right. Textbook information is  
8 helpful, but there is actually ways of going around and  
9 getting such information in a shorter term. I agree with  
10 the four approaches.

11 DR. TROXELL: I just would like to know where the  
12 group came out now with respect to these four on elimination  
13 versus minimized levels, levels of the microbes.

14 DR. BUCHANAN: Unless I am wrong, there was  
15 nothing on eliminating. All of these technologies would  
16 reduce, but not eliminate. Yes, Bruce.

17 DR. TOMPKIN: I would envision that the two short  
18 term, the hot water and the disinfectant, would be to reduce  
19 the risk, but it will not, I don't think we could guarantee  
20 that the disinfectant from what we saw could be relied upon  
21 to eliminate it.

22 Hot water, if you come up with the right system,  
23 and as it was shown on the video, I would have a pretty high  
24 level of confidence in that one as eliminating the pathogen,  
25 but how that would fit in to 350 sprouters is another issue

1 that has got to be dealt with. The one for seeds should be  
2 to eliminate.

3 DR. BUCHANAN: Let's get clarification. I don't  
4 know if Tom Farrar is still here or Kathleen, I didn't see  
5 of the data that they presented today that they were going  
6 for an elimination, they were going for a reduction. They  
7 were going for about a 4 log reduction.

8 DR. SWANSON: 99.9 is what they said.

9 DR. BUCHANAN: 99.9. We will get clarification on  
10 that.

11 DR. DOYLE: I think the goal is to eliminate, but  
12 we just don't have the technology to do that, and that long  
13 term with irradiation.

14 DR. BUCHANAN: Any additional comments on this  
15 section? When you come back, come back with your research  
16 ideas and your priorities and justification for those  
17 priorities.

18 [Recess.]

19 Because of time constraints, and the fact that  
20 some of our board members or panel members have flights to  
21 catch, I would like to change the order that we will be  
22 discussing things.

23 I would like to take things out of order. We are  
24 going to save research needs and priorities for the end, and  
25 I would ask any panel member that has to disappear to please

1 submit their comments on research needs and priorities to us  
2 in writing during the next week, so if you don't have any  
3 opportunity to be here for those discussions, I would ask  
4 you to get that stuff in to us and we will incorporate it.

5           A procedural matter. We are going to take the  
6 draft recommendations we get here, put them together for the  
7 working group members, and then get them back out to you  
8 during the next week, let you review them, see if you are in  
9 agreement, and if not, we will get further discussions on  
10 points of clarification.

11           I would like to now focus on additional approaches  
12 for assuring or improving the safety of sprouted seeds,  
13 particularly alfalfa, but before doing that, I would like to  
14 revisit the good agricultural practices for a moment. Where  
15 is Nagle? I did want Nancy to be here for those  
16 discussions.

17           Do we know enough about good agricultural  
18 practices to make any kind of a recommendation about the use  
19 of manure or the positioning of a field associated with  
20 alfalfa production particularly, but for that matter, seeds  
21 for sprouting across the board, and there has been some  
22 discussions that, that at the end of our discussion that we  
23 had enough information for a general recommendation about  
24 the uses of manure. Comments?

25           DR. FARRAR: Bob, the good agricultural practices

1 are general recommendations in each of the areas including  
2 water, manure, proximity to livestock, and so forth. I have  
3 a little difficulty seeing why they wouldn't apply in this  
4 situation.

5 DR. BUCHANAN: Very honestly, so do I. That is  
6 why it is coming up again. I have a hard time not being  
7 able to figure why you would want to be putting uncomposted  
8 manure on a product that was going to be food.

9 DR. SWANSON: I think that the point was there is  
10 no -- the farmers that are growing the seeds don't  
11 necessarily know if the seeds they are growing are destined  
12 for human consumption or the vast majority of the  
13 agricultural practices that are currently being carried on,  
14 so to suggest that you have to use GAPs is almost fooling  
15 yourself to think that they are going to know that these are  
16 for human consumption.

17 DR. BUCHANAN: Let me turn this around and say  
18 would you as a sprout producer, want to knowingly buy seeds  
19 that had been treated with uncomposted manure?

20 DR. SWANSON: No.

21 DR. BUCHANAN: Why are you, as a sprout producer,  
22 willing to say that at this point? I mean you must be  
23 making an assumption here.

24 DR. NAGLE: Bob, can I comment?

25 DR. BUCHANAN: Please, Nancy.

1 DR. NAGLE: I think we have to look at this, too,  
2 saying okay, when -- remember when we were at the sprouters,  
3 these alfalfa plants are out there for three years, now, are  
4 you going to tell me that it is going to matter to you  
5 whether uncomposted manure was put on there three years ago  
6 if this is the fifth cutting or a sixth cutting of this  
7 stuff?

8 I think we have to be realistic and look at that  
9 and say, you know he may not know three years ago that he  
10 was going to be making sprouts now, but is it even germane?

11 DR. BUCHANAN: I think the current recommendations  
12 from the Organic Board -- and the representatives, if they  
13 are still here, can verify this -- I think the  
14 recommendation is that you shouldn't be using manure with  
15 less than 60 days between its application and harvest.

16 So, those are the good agricultural practices'  
17 recommendation. I see Michelle back there.

18 DR. SMITH: [Off mike]

19 DR. KVENBERG: Bob, they can't hear that, nor was  
20 it recorded, so that is going to get lost.

21 DR. BUCHANAN: Michelle, would you please come up  
22 to a microphone and give us your comment. This isn't an  
23 comment period. This is a person that has supplied  
24 technical information on this issue to the committee.

25 DR. SMITH: The reference to good agricultural

1 practices and the 60-day minimum that the Organic Standards  
2 Board puts in place for the use of raw manure on edible food  
3 crops, that 60-day minimum is not linked to any guarantee of  
4 food safety, so the good agricultural practices that we are  
5 working on right now are focusing more on just maximizing to  
6 the extent possible the time between application of raw  
7 manure and harvest of fresh produce in the case of the  
8 broad-scope document.

9 DR. BUCHANAN: I guess that sounds very reasonable  
10 to me, and I would like to question. I have some concerns  
11 about not even being able to make a statement about the  
12 application of manure.

13 DR. NAGLE: I think we have to be careful what we  
14 are saying. The way the question was posed is would you  
15 accept it if it had had uncomposted manure. I hate to get  
16 into what do you mean by that, is it ever, you know, or  
17 whatever.

18 I mean as long as we have certain reasonable  
19 differences, but to just say not ever treated with composted  
20 manure or uncomposted manure, that raises the question of  
21 what do you mean by ever, you know, in the last two years,  
22 five years, you know, next 10 days, and I think we all  
23 expect to be reasonable in the 60-day number or some  
24 reasonable number is okay.

25 DR. BUCHANAN: I am going to try and draft up

1 something for the final report that comes up with this  
2 reasonable estimate about manure application, because that  
3 was identified as something during the discussion that there  
4 was some concern about. Yes, David.

5 DR. GOOSBY: A couple other comments. In my  
6 interpretation or appreciation of GAPs, they really are  
7 quite general and broad, and we can have them as narrowly or  
8 as broadly defined as might be reasonable, based on common  
9 sense, and dare I say but I think it is appropriate to do  
10 so, that in working with Michelle and others and the GAPs  
11 and GMPs, that we did for other segments of the produce  
12 industry, in most situations, and the concerns we addressed  
13 there were not science based necessarily, but were derived  
14 from good common sense with the cooperation and support to  
15 be embraced by the industry.

16 Because they don't have a regulatory impact, GAPs  
17 that we might recommend here would have that same bearing,  
18 meaning that there would be something in the recommendation  
19 or suggestion, a level of encouragement to be embraced and  
20 adopted by the industry whether we make recommendation only  
21 regarding manure and/or water, and/or pesticides, some of  
22 those main categories that may impact the safety of the  
23 product, and yet are fairly readily controlled by the farm  
24 operations, and this kind of approach be done in balance, so  
25 that we don't impede the farmer's ability to sustain his

1 business operation.

2 DR. BUCHANAN: I am going to switch gears a little  
3 bit and I would like to move into other areas associated  
4 with food safety systems that should be considered and  
5 possibly encouraged by the working group.

6 These can be any of a number of areas. For  
7 example, we heard some discussions about education, we have  
8 heard discussions about HACCP systems, et cetera. So, I  
9 would like to throw this open to the working group  
10 concerning recommendations on other safety assurance systems  
11 and related topics.

12 DR. DOYLE: I would like to raise the question of  
13 testing. I think Katie brought out an interesting point  
14 regarding the water treatment that is used to water sprouts  
15 and testing that water for pathogens.

16 DR. BUCHANAN: I personally found that intriguing.  
17 I have some concern about the capabilities across the board  
18 in terms of sprouters being able to do that technology, but  
19 I think that seems to be a very viable approach to  
20 increasing the safety of the product.

21 Certainly, if I was not wearing my current hat,  
22 but if I was a consultant, I would be recommending that as  
23 certainly a technology that somebody should be looking into.  
24 Do we have additional comments on that?

25 MR. BERNARD: Just a clarification. We are

1 talking about the water that would be used by the sprouter,  
2 applied to the seeds, and continually through the sprouting  
3 process?

4 DR. BUCHANAN: Right, the water that drains off  
5 the sprouts and analyzing that.

6 MR. BERNARD: Oh, okay.

7 DR. BUCHANAN: The water that is drained off of  
8 the sprouts during the germination process, then analyzed to  
9 determine whether or not you are pathogen free for whatever  
10 your indicator organism was.

11 MR. BERNARD: Spent water.

12 DR. BUCHANAN: Spent water.

13 DR. NAGLE: I guess the one thing to think about,  
14 though, we are talking about 350 sprouters as we said. What  
15 would we expect them to look for in this testing, and then  
16 what would the cost of that be, because that would be a cost  
17 to every batch that they make as far as I could tell, the  
18 way we are talking about it now, right?

19 DR. BUCHANAN: Yes.

20 DR. NAGLE: So, we would need, you know, it would  
21 need to be something that wasn't an unreasonable cost to add  
22 to every batch, because that does kind of go in a different  
23 direction. It is almost a hold and release testing that we  
24 are recommending here. Is that what I am hearing?

25 DR. BUCHANAN: I think what we have to consider in

1 any kind of recommendation, are we recommending that we  
2 think every batch should be tested or are we recommending  
3 that that technology be encouraged within the sprout  
4 industry.

5 DR. NAGLE: That is what I am asking because if we  
6 make a recommendation, it may carry more weight than we  
7 thought it was going to have or it may become de facto  
8 regulation almost, so we want to make sure that we have  
9 looked at all of the potential ramifications of this, and  
10 then the windfall that laboratories would be getting.

11 DR. BUCHANAN: Mike and then Bruce.

12 DR. DOYLE: I think there are ways in which you  
13 can composite samples, so that there is not an unusually  
14 large number of samples that would have to be tested on a  
15 daily basis. I would be interested in looking for specific  
16 indicator organisms and/or specific pathogens like Listeria  
17 and Salmonella.

18 DR. BUCHANAN: Bruce.

19 DR. TOMPKIN: Since 1995, from what I understand  
20 from the data that were presented yesterday, there have been  
21 eight outbreaks, recognized outbreaks attributed to sprouts.  
22 There were the six Salmonella and two from 0157. You  
23 consider how many batches or lots that have been produced of  
24 sprouts. I don't think -- yes, the risk to consumer is high  
25 if it does contain a pathogen, however, it would appear that

1 the prevalence or the frequency with which this occurs is  
2 pretty low, and to try and to impose pathogen testing on  
3 this particular industry as a hold and test program, I  
4 wouldn't recommend that, however, it would be very desirable  
5 for the processors to understand their process, know where  
6 the weaknesses are, and then build in some control measures  
7 to address those weaknesses.

8           Just as a beginning, if they could test perhaps  
9 for E. coli as an indicator, which could be done at  
10 relatively lower cost and certainly 350, probably certainly  
11 the larger ones could be using a Petrifilm, it could be done  
12 in-house, you get the results rather quickly, it is low  
13 cost, it provides information that would enable the  
14 processor to understand what the risk is, and to adjust the  
15 process.

16           I don't think that considering what we heard to  
17 test for 0157 or Salmonella in each production lot, the  
18 frequency is just too low to justify that.

19           DR. BUCHANAN: Peggy.

20           DR. NEILL: I just want to mention something  
21 almost I think as a sidebar to Bruce's comment, because it  
22 has come up a couple of times. It has to do with this  
23 concept of how many outbreaks we have seen and what that  
24 means.

25           I think in the past 10 years, there is an

1 increasing appreciation that foodborne outbreaks are more  
2 often low level, sporadic contamination, and widely  
3 dispersed. Our current infectious disease surveillance  
4 networks do not pick those up very well unless the pathogen  
5 is something extremely unusual.

6 We could be having frequent Salmonella  
7 typhimurium, for example, outbreaks associated with sprouts,  
8 and unless they have unusual additional attributes for them  
9 to be caught in the surveillance networks, there is no other  
10 way that you are going to see these.

11 So, I think that we need to probably be somewhat  
12 cautious. We are new even at finding sprout-associated  
13 outbreaks, and I think we should just work forward from  
14 saying that they are occurring and then take it from there.  
15 I am in agreement, however, with Bruce's other comments  
16 regarding the use of testing for other purposes.

17 DR. BUCHANAN: Bruce, i would like to restate my  
18 own personal opinion, which is in agreement with Peggy's, is  
19 that the only reason or one of the major reasons why these  
20 outbreaks were identified is that they were all unusual  
21 serotypes, at least on the Salmonella side.

22 If they weren't unusual serotypes, we probably  
23 would have never identified them except maybe in California  
24 where they do a really good job.

25 Additional comments on testing? Yes, Katie.

1 DR. SWANSON: There is a couple of angles you can  
2 play on this testing scenario. One could say that rather  
3 than testing every batch, you could run a test on every lot  
4 of seed, so you would fill a drum or your trays, or  
5 whatever, just to verify that that particular lot was okay  
6 and once you have done that, you would be fine, because the  
7 amount of seed that they are running through in those drums  
8 are a lot greater than the 100 grams that microbiologists  
9 will sample and run, so it is likely that you would be able  
10 to pick something up that way. So, that is one angle to  
11 consider.

12 Another one is there were comments from the  
13 sprouters saying, well, epidemiological data may implicate  
14 sprouts, but you have had a hard time testing it. They  
15 could view this as an insurance policy if they are testing  
16 their product as it goes out the door, and someone says,  
17 hey, you have had an outbreak, they could say, look, I have  
18 done this testing, and it is not fair, it might be something  
19 else.

20 So, you know there is numerous considerations that  
21 can be given around this testing.

22 DR. BUCHANAN: Bruce, can I ask for one  
23 clarification? Your proposal for testing is to focus on  
24 generic E. coli, and to use this in approximately the same  
25 way that E. coli is used for validation of HACCP systems.

1 DR. TOMPKIN: That is correct. It is to generate  
2 background information to allow the processor to design a  
3 controlled system that would address enteric pathogens.

4 DR. BUCHANAN: This brings me up to the next  
5 question I had is that we have had several comments related  
6 to that this is not a GMP question. We have had some  
7 discussions on whether we have interventions that can be  
8 used in a positive fashion, and we have identified that they  
9 are.

10 The next question I guess is does this need to be  
11 structured in a HACCP system. I would like to bring that up  
12 as the next subject. Mike.

13 DR. DOYLE: Before we get onto that, I would like  
14 to go back to the testing the organisms of interest. I  
15 asked the question do we have enough data to show that E.  
16 coli is a reasonably good indicator of the presence of  
17 Salmonella and other potential pathogens that we are finding  
18 in sprouts.

19 I don't know. I don't think we do, but based on  
20 what we have seen with E. coli as an indicator in poultry,  
21 from what I read it is not necessarily a good indicator of  
22 the presence of pathogens, and so I would suggest even  
23 though the incidence may be low, i would be more interested  
24 in the results of Salmonella testing than I would be E. coli  
25 testing.

1           Secondly, I think it would also be important to  
2 look at the environment in which the sprouts are growing,  
3 and there we tend to look for Listeria as the indicator of  
4 environmental contamination.

5           DR. BUCHANAN: You have brought another dimension  
6 into this, the testing of environmental samples. So, before  
7 we go to environmental samples, let's focus on any kind of a  
8 recommendation we have about potential testing as a possible  
9 intervention tool or possible aid to working in a sprout  
10 operation. Do we know enough about which organism to test  
11 for or is that the recommendation, that we encourage this  
12 type of testing and that would include identifying an  
13 appropriate indicator organism?

14           [No response.]

15           DR. BUCHANAN: Okay. We are working towards a  
16 recommendation that testing of the spent water be evaluated  
17 as a potential intervention. That is basically what it is,  
18 it is intervention be it an indicator organism of process  
19 control or, if you wanted to use it as a batch-by-batch  
20 clearance, it is in essence an intervention we are going to  
21 be using.

22           Do we know enough to make a recommendation about  
23 what should be the organism of choice or does this need to  
24 be evaluated further? Yes, Bruce.

25           DR. TOMPKIN: I think probably we need more to

1 understand its value. The assumption is that we would only  
2 test the water. If I were a processor, I would actually  
3 test some finished product, too, because there are a few  
4 things that happen between the sprouting and the package.

5 DR. SPERBER: Just one quick sidebar. I have  
6 missed some of the previous meetings on this topic, but Mike  
7 opened up another topic, too, by mentioning Listeria testing  
8 in environmental samples. Do we know that LM is not a  
9 hazard in sprouts? It is a refrigerated, perishable food,  
10 and all of the discussion on food safety issues has been  
11 0157.

12 DR. BUCHANAN: I am going to step back because I  
13 am going to give you FDA's policy.

14 MR. BERNARD: I am not sure that we know that it  
15 is not, but in our experience in trying to find it in  
16 various types of establishments, this is a kind of an  
17 environment we wouldn't expect to find it, because it is not  
18 a good competitor. One thing we know is that we are getting  
19 a lot of microorganisms growing. As an example, if you try  
20 to find Listeria, as we have, in fermented meat plants where  
21 you are working with starters and things like that, it is  
22 difficult to find in most of those environments.

23 I wouldn't expect it to be a high yield  
24 microanalysis here, but I don't know enough to say that it  
25 is not a problem.

1 DR. GOOSBY: To underscore what Dane said, in my  
2 opinion we know too little to declare that it is not a  
3 problem, and I recall when Listeria raised its ugly head in  
4 a major way in the food industry, and it was a post-  
5 pasteurization contaminant of dairy products hardly a decade  
6 ago, and I can draw some analogies between the environment  
7 in a dairy processing plant related to the environment in a  
8 sprout producing plant, temperature, humidity, those kinds  
9 of things, and the LM is so ubiquitous, I really think there  
10 is a potential threat there that needs a real close look.

11 DR. NAGLE: Can I ask a question -- back to our  
12 original question --

13 DR. BUCHANAN: I am trying to get closure on one  
14 before I go on to the next.

15 DR. NAGLE: Okay, I will wait.

16 DR. BUCHANAN: I would like to get closure on a  
17 recommendation about testing --

18 DR. NAGLE: That is what I want to ask. In any of  
19 the data that we have, that Jeff has or anyone has, about  
20 outbreak of sprouts, do we have any microdata about the  
21 other organisms that might be there in those foods, were any  
22 of the processors running routine, just total plate counts  
23 or anything, do we know any of the data from there? That  
24 might help us understand this.

25 DR. FARRAR: I can report on a couple outbreaks in

1 California. Unfortunately, the first one is tragic and all  
2 too obvious, our 1996 Montevideo and Meleagridis outbreak  
3 when we finally found the sprout planter and told them why  
4 we were there, the sprouter said, oh, I am not surprised to  
5 see you. Ultimately, he told us that he had been testing  
6 his product recently after Stanley and Newport, he had been  
7 testing his product for Salmonella, and got a positive  
8 Salmonella isolate about two or three weeks before the  
9 outbreak started, and continue to ship his product.

10 Another recent outbreak in 1997, the sprouter was  
11 doing periodic test of his product, total plate counts,  
12 Salmonella and E. coli along with some environmental  
13 monitoring, and that outbreak, we did see some positive  
14 generic E. coli in the environmental monitoring preceding  
15 the outbreak.

16 There were no positives in that product, however.

17 DR. BUCHANAN: Bruce.

18 DR. TOMPKIN: Didn't we hear that FDA is going to  
19 do a survey of sprouts?

20 DR. BUCHANAN: Yes.

21 DR. TOMPKIN: Why not just include E. coli as an  
22 analysis and see what we find.

23 DR. BUCHANAN: I heard a second recommendation  
24 related to microbiological testing that focused on  
25 environmentals. Mike, do you want to further discuss this

1 as a recommendation, and then we will focus on it and then  
2 we will let the rest of the panel respond to it?

3 DR. DOYLE: Well, as Bruce has indicated, we ought  
4 to be looking at the entire process within the plant, and do  
5 testing that would be relevant to get baseline information  
6 as to how well the plant is operating, and the environment  
7 is one of those conditions in which you need to address, and  
8 Listeria has in the past shown to be a good indicator of how  
9 well processes are operating within the plant from an  
10 environmental perspective.

11 DR. BUCHANAN: Does anyone know any available  
12 information on environmental sprout operations?

13 DR. FARRAR: There are a couple private labs in  
14 California that have a fair amount of data from several  
15 sprouters. They could be asked if they would be willing to  
16 share the data by not identifying the sprouter, but there is  
17 substantial data there.

18 DR. BUCHANAN: Since we didn't focus this during  
19 the day and a half, we are probably going to have to come  
20 back to it because as far as I know, we don't have any data.  
21 We would have to go out and acquire it.

22 DR. SWANSON: Wasn't environmental sampling part  
23 of the ISGA recommendation, and perhaps that organization  
24 could poll their members and provide some data?

25 DR. BUCHANAN: That is a good idea. We will

1 approach them.

2 Let's move on to HACCP. We have heard comments  
3 that this is not a GMP problem.

4 DR. TOMPKIN: Not true.

5 DR. BUCHANAN: That this is not just a GMP  
6 problem. That, of course, then begs the question do we need  
7 a system on top of GMPs or would that be helpful. I would  
8 like to throw that around to the panel to get their feel on  
9 the importance of HACCP, are we ready for HACCP, do we have  
10 the scientific data, and what should we be moving towards.  
11 Yes, Mike.

12 DR. DOYLE: I question do we have the critical  
13 control points that are needed to have a reasonably  
14 effective HACCP plant.

15 DR. BUCHANAN: I assume you are using our  
16 committee's definition of a critical control point.

17 DR. DOYLE: As you wish.

18 DR. BUCHANAN: Which is a step or steps that  
19 reduce the level of risk, reduce, eliminate, or control the  
20 level of risk to an acceptable level.

21 DR. SWANSON: And are essential to reduce.

22 DR. BUCHANAN: And are essential to doing it.  
23 Okay. Do we have critical control points, Mike?

24 DR. DOYLE: I am not sure that we have enough. We  
25 may have some, but I am not an expert in the area of sprout

1 growing, so I am not a good one to ask.

2 DR. BUCHANAN: Larry.

3 DR. BEUCHAT: Neither am I an expert in sprout  
4 growing, but from my experiences recently, I would say that  
5 we probably don't know as much as we should about critical  
6 control points or don't have enough of them that could be  
7 identified at this point.

8 DR. BUCHANAN: Wait a second. I want Bruce --

9 DR. TOMPKIN: Maybe I will pull you out of the  
10 hole?

11 DR. BUCHANAN: Right.

12 DR. TOMPKIN: Well, HACCP is a good food safety  
13 management system, and this particular industry should look  
14 at its value and apply the principles of HACCP which may  
15 lead to the development of a HACCP plan. So, going through  
16 the advisory committee's nine principles, and so on, they  
17 may result in a HACCP plan, and I think that we should leave  
18 that process to that group to determine how best to apply  
19 it.

20 On the other hand, GMP, of course, is essential as  
21 the foundation of HACCP, and those principles of GMP should  
22 be applied also. Those should be applied across the board.  
23 HACCP may be built on top of it.

24 DR. NAGLE: I think as we have discussed a little  
25 earlier today, you know, we are talking about a widely

1 disparate industry, we are talking about a group. I think  
2 we need to get to the base level. We all believe that, you  
3 know, GMPs and SSOPs are all important bases for HACCP, and  
4 that you can't really build a good HACCP plan unless you  
5 have all of those things in place.

6 I think we need to keep encouraging the  
7 development of those building blocks for the industry, so  
8 that then we can use -- having those in place, can then go  
9 in and truly identify what appropriate critical control  
10 points can be developed.

11 DR. BUCHANAN: Let me rephrase this another way.  
12 The ISGA recommends in their documentation, encourages the  
13 development of HACCP systems for all sprout growers. Should  
14 we encourage the rest of the sprout growers that are not  
15 members of ISGA to take the lead of this segment of their  
16 industry?

17 DR. NAGLE: I will comment sure, but the other  
18 part is, the other thing we have to do is we heard people  
19 over the last two days reminding them that they are not just  
20 agricultural growers, that they are food processors, and we  
21 need to make sure that they understand CFR Title 21 first  
22 before they develop a HACCP plan, because otherwise it's  
23 like trying to teach somebody how to climb a mountain before  
24 they learn how to walk.

25 DR. GOOSBY: I would comment in concurrence with

1 what Nancy just said. It is an evolutionary process to get  
2 from no real evaluation or agency inspection programs all  
3 the way to a HACCP based system, however, by encouraging the  
4 support of ideas and recommendations by ISGA to be more  
5 broadly embraced by the entire industry toward the ultimate  
6 goal of looking toward a HACCP size based system.

7 DR. BUCHANAN: Nicely put.

8 DR. NAGLE: One more comment. I think we could  
9 also encourage the sprout growing industry to look at the  
10 pre-cut salad industry as an example. Ten years ago, they  
11 were in a similar situation as this, that they were a widely  
12 disparate industry that really didn't have a lot of things  
13 in place, and I think as what we have seen is that the pre-  
14 cut salad industry is doing a lot on their own to make sure  
15 that they haven't had any problems, which if we look at the  
16 data, we notice that pre-cut lettuce salads are not -- pre-  
17 cut, pre-packaged lettuce salads are not on the list of  
18 things that have had significant outbreaks.

19 So, you know, they could take an example from  
20 there because those guys all thought they were just farmers,  
21 too, when they were first cutting lettuce. Well, I am just  
22 chopping it, I am not doing anything else, it's the same old  
23 stuff that it was before. So, I think that is a good way  
24 for them to go.

25 DR. SWANSON: While I fully believe that HACCP

1 must be established on solid GMPs, there is one particular  
2 part about HACCP that is different than implementing GMP  
3 programs, and that is the fact that the producer needs to  
4 understand what their hazards are.

5           If sprout producers understand that they do have  
6 this amplification process that is in there, just the  
7 exercise of going through that, so they fully understand  
8 what is at risk, I think is helpful, and for that matter,  
9 having them address HACCP does seem to make some sense, the  
10 principles of HACCP as Bruce indicated.

11           DR. BUCHANAN: Bruce.

12           DR. TOMPKIN: I am kind of stepping back and  
13 looking at what is going on. I have been through a lot of  
14 issues over the years with trade associations as problems  
15 were identified, whether it was Salmonella and fermented  
16 sausage or cooked meat patties, roast beef, and so on, and  
17 in each of those instances, the industry developed a  
18 guideline that was distributed to all the processors or  
19 members of the trade associations as an educational tool to  
20 bring up the industry.

21           I don't know, I haven't received anything in this  
22 material that has a rough draft, for example, from the  
23 Sprout Growers Association that suggests that they are  
24 essentially developing their own guidelines based on their  
25 knowledge because they know what they are doing.

1 I would hope they are not relying on the Federal  
2 Government and this panel to tell them what to do, because  
3 they will really be in trouble.

4 DR. BUCHANAN: Bruce, the ISGA has provided us --  
5 and I am sorry you didn't get a copy of it with some of the  
6 historical information since we have been at this for a  
7 little longer than you -- they have several documents they  
8 have provided us.

9 But that does bring us up to the next subject,  
10 Terry, I want to make sure we cover before we take a five-  
11 minute break, and that is education. I would like to assess  
12 and then get any recommendations you have about education,  
13 and in this, I am looking for education in its broadest  
14 sense. This is education of consumers, producers,  
15 regulators, whoever.

16 Do we have educational needs and what are they,  
17 and who should they be addressed to? Comments.

18 DR. FARRAR: We certainly have educational needs  
19 in the sprout-growing population, at least in California.  
20 We have severe deficiencies in knowledge and awareness of  
21 SOPs and GMPs, so that is a critical missing link right now  
22 that we hope to remedy in the short term, sprout specific  
23 training, not generic food safety training, but sprout  
24 specific training.

25 DR. BUCHANAN: Lee Ann, do you want to scribble

1 that down on your pad as one of the recommendations. Unless  
2 I hear something to the opposite effect, that sounds like  
3 good solid advice. I see everybody nodding their heads.

4 How about other than the producers? I haven't  
5 heard anything for consumers. Do I gather that you don't  
6 consider that as high a priority or as efficacious, or if  
7 you feel that if you train the sprout producers, you will  
8 largely eliminate the problem?

9 DR. DOYLE: We have already put out an advisory to  
10 the high risk populations. What more would you see needs to  
11 be done in the area of educating consumers?

12 DR. BUCHANAN: Was that sufficient? Do you feel  
13 that that type of a notification was sufficient to meet the  
14 needs for educating the public?

15 DR. NAGLE: We know Caroline does not think it was  
16 sufficient.

17 DR. FARRAR: In the way of consumer notification,  
18 would the committee entertain a recommendation for a minimum  
19 of "keep refrigerated" marking on packaging?

20 DR. BUCHANAN: Is there any indication  
21 scientifically that "keep refrigerated" will help?

22 [No response.]

23 DR. BUCHANAN: I am getting no overwhelming  
24 response. Everyone is looking up at the ceiling.

25 Larry.

1 DR. BEUCHAT: Should we go back in terms of  
2 education to seed handlers, seedsmen, even to growers in  
3 terms of bringing them into this process, the total system  
4 in terms of education, not just beginning with the sprouter?

5 DR. BUCHANAN: That is a good point. Would you  
6 agree with that, Jeff, is the need similar there?

7 DR. FARRAR: We are back to lack of science based  
8 understanding of good agricultural practices, but yes, a  
9 general education in those broad policies wouldn't hurt.  
10 Our situation in California is we have basically one seed  
11 supplier in the entire state. It would be a small audience,  
12 but it is important nonetheless.

13 DR. BUCHANAN: It's really high efficiency, high  
14 attention. That is the kind of student-teacher ratio you  
15 always dreamt of. I guess at that point it is actually  
16 mentoring.

17 I am going to have you take a five-minute break  
18 and then we are going to come back and do research.

19 [Recess.]

20 DR. BUCHANAN: We are going to start the last  
21 section which is going to be the identification of research  
22 needs and then also trying to give some relative priority to  
23 when these things should be done.

24 I just want to re-verify what we are going to be  
25 doing here as the Produce Working Group of the Advisory

1 Committee. Lee Ann and I will go back, take your comments,  
2 and we are going to draft up a working group series of  
3 recommendations which we will submit to both the full  
4 committee in time for its next meeting and we will be also  
5 submitting it as part of the public comment coming from this  
6 meeting to FDA right now. This is just in keeping with the  
7 procedures that we have used before in these kind of public  
8 meetings.

9 So, you will be seeing quickly, after this  
10 meeting, the comments, the draft. We would appreciate that  
11 you get it back to us immediately and then we will be  
12 providing it to the FDA as part of the record of this  
13 meeting.

14 Research. I think we all have come to the  
15 conclusion that there are a number of things associated with  
16 the microbiological safety of sprouted seeds that require  
17 additional research. I would like to get at least some of  
18 the broad areas identified and then determine in which order  
19 we should be addressing them with the resources that are  
20 available, and if you know where research is currently  
21 taking place that we have not identified here, we would also  
22 appreciate you letting us know where this is taking place,  
23 so that we can attempt to obtain any information from them  
24 and also to help coordinate the information, so that we are  
25 getting the most, at least on the federal side, from the

1 public investment into research. That is one of our  
2 objectives is also to make sure that we are doing research  
3 cost efficiently.

4 Research needs. I throw it open to all of you  
5 researchers out there or you people that need researchers,  
6 and maybe that is the place to start. We have got some  
7 people that need research -- I can see Jeff just waiting to  
8 get at that microphone. Jeff.

9 DR. FARRAR: We certainly fall into that category  
10 of people needing research. I think this item falls both  
11 into the future research and thing that can be done short  
12 term, Bob. That is the potential development of a sprout  
13 outbreak investigation questionnaire that all states could  
14 collect similar bits of information in these outbreaks,  
15 information on all aspects of sprouting - sprout facilities  
16 that may be implicated in outbreaks, seeds used, a variety  
17 of seeds, type of seeds, disinfection methods, a generic  
18 template that each state could perhaps add onto with  
19 additional questions, but a minimum amount of information  
20 collected across all states, possibly even going back to  
21 past outbreaks, as well.

22 DR. BUCHANAN: One of the areas that we heard  
23 about today, we had the state of the science on detection  
24 methods, and one of the lessons that I have taken home when  
25 dealing with E. coli 0157 in sprouted seeds or any commodity

1 for that matter, is that it occurs at very low levels and  
2 very sporadically, and current systems for taking samples  
3 tend to focus more and more on smaller and smaller samples,  
4 and I think that we can take a larger sample or to be able  
5 to remove a sample and concentrate it even more than we now  
6 have with the immunomagnetic bead capture systems would be  
7 extremely helpful.

8 I would like to make a note here, and that was  
9 identified as a FDA priority need this past year in our  
10 solicitations for proposals. It was also solicited as a  
11 need by CREES in their proposals, and neither organization  
12 found the submissions really to the point, that we need to  
13 encourage people to be exploring how to concentrate samples  
14 microbiologically or to be able to look at larger and larger  
15 samples, so that we can get better data.

16 Certainly, the sampling techniques for sprouted  
17 seeds and the methods we do have some concerns that they are  
18 not up to the needs we have unless we take them and  
19 literally sprout the seeds at this point.

20 DR. NAGLE: I was going to say, to speak for  
21 Katie, you know, what she was saying before is that that  
22 method of using 50 pounds of seed, you know, whatever,  
23 growing out a whole thing of seed, we may need some work in  
24 that area of trying to find what is the best way to do  
25 something like that, so that you can have a really broad

1 sample.

2 DR. BUCHANAN: Which I might note if you want to  
3 go all the way to sort of the Buck Rogers type approach,  
4 theoretically, the runoff from a sprout operation in  
5 conjunction with a biosensor is like an ideal application  
6 where you could just literally continue to monitor all of  
7 the water all of the time. So, certainly this is an area  
8 that has a lot of potential.

9 Additional areas. Short-term needs. Let's talk  
10 about short-term needs. Bruce.

11 DR. TOMPKIN: It seems like the short term could  
12 be the disinfection of seeds at the sprouter level, and  
13 essentially come up with a procedure, and there is one  
14 already, and that would be helpful. There was concern  
15 expressed yesterday in particular over the discontinuation  
16 of research on chlorine dioxide, I think it was -- or ozone,  
17 excuse me, in Beltsville, and if that really has merit, and  
18 the problem of this nature, it seems to me that it should be  
19 supported rather than -- they should be doing more rather  
20 than less. I don't know who is going to pick that up.

21 DR. BUCHANAN: I might note the immediacy of your  
22 input on this, your list that you come up with will also be  
23 taken out to the meeting that will be held at the National  
24 Center for Food Safety and Technology on the 5th to discuss  
25 research needs. This list is going to go out there. So,

1 there will be some immediacy in your recommendations.

2 DR. TOMPKIN: I think the priority should be given  
3 to a means to decontaminate the seeds where we would have a  
4 high level of confidence that upon sprouting, they would be  
5 negative, that is, the seeds per se would not be a source of  
6 these pathogens.

7 DR. DOYLE: Can I add to that? It is more of a  
8 long-term approach, but it fits with this. I think we need  
9 to better understand how these seeds become contaminated by  
10 pathogens, is it an internal contamination or an external  
11 contamination, learn more about how they locate within these  
12 areas on the seed, and define what surfactants, if at all,  
13 might be best for removal.

14 DR. GOOSBY: Talking about the seed, too, and the  
15 interventions to sanitize it, maybe it is obvious, but to  
16 clarify, the consideration of research for combination  
17 interventions, if, in fact, the liquid sanitizers in  
18 conjunction with radiation or any groups thereof, offer  
19 greater potential for having a sanitary seed than any single  
20 treatment by itself.

21 DR. KVENBERG: I think one area as far as applied  
22 work that ought to be examined further is the quality of the  
23 seed itself. It is being assumed that all seed is equal.  
24 It may not be. We probably ought to look at the seeds  
25 themselves and see if there is variability in addition to

1 the organisms.

2 DR. BUCHANAN: The other one that we had  
3 identified earlier was the effect of scarification.

4 DR. KVENBERG: That is where I was going.

5 DR. BUCHANAN: Right.

6 DR. KVENBERG: Or any other variable differences  
7 that might be adjunct to that.

8 DR. GOOSBY: Along the line John is saying, the  
9 viability of the seed, considerations of such factors as  
10 storage conditions and age of the seed, perhaps attend  
11 somewhat to what it will stand up under as far as treatment  
12 procedures.

13 DR. KVENBERG: That may be a mid- to long-term.  
14 We may have to get into survival. Storage conditions of the  
15 seed came up, cold storage, warm storage, dry heat, all  
16 those things which I think are time studies. Survival is  
17 the issue I guess here.

18 DR. TROXELL: I was going to add on the dry heat  
19 is certainly something that looks like will be done in a  
20 relatively short time to find out what the log reduction and  
21 viability would be.

22 DR. KVENBERG: Just on a practical matter on the  
23 premise on heat, as long as we are on the subject here,  
24 also, is pasteurization, the question came up on the  
25 feasibility and cost. I think the question is what are the

1 operating parameters that really you need to get to  
2 irrespective of current systems that may be out there, what  
3 do you need to do to accomplish it, and then you worry about  
4 cost applications.

5           If you have got either steam applications or high  
6 heat, plus agitation, in a water system, that could explored  
7 probably in the short term, non-chemical treatments.

8           MR. BERNARD: I would agree. I think the short  
9 term application of lower temperature, longer time, which to  
10 me is a relatively inexpensive way of applying a  
11 pasteurization treatment to the seeds.

12           A literature search could look into D-values,  
13 times and temperatures to give us an idea whether it is  
14 feasible or not. You know, we don't need specific data, but  
15 we need general data to see if we are in the ballpark.

16           What I think needs to be done, although in  
17 conjunction with that, and relatively immediately, is the  
18 time and temperature effects on the viability of the seeds  
19 themselves, and if those two don't match, then, you begin to  
20 look at high temperature, short time alternatives, a more  
21 expensive way to do it, but certainly effective.

22           DR. BUCHANAN: So far we have focused on the seeds  
23 themselves. I know Bill is not here. He had to head for  
24 the airport. But I know one of his points was that you have  
25 your primary control at the beginning of the process, is it

1 worthwhile to be exploring technologies for actually  
2 treating the sprouts themselves.

3 For the purposes of the transcript, Nancy Nagle,  
4 who is standing in the back of the room said yes, that it is  
5 very important. Thank you, Nancy. Have a good trip home.

6 DR. DOYLE: Also, in between, if we could develop  
7 approaches where we could control the growth of pathogens  
8 during the sprouting process.

9 DR. BUCHANAN: Right, reduce the amplification.  
10 Are there other research areas that are unique to  
11 sprouts that we need to be considering?

12 DR. KVENBERG: Maybe it is a subset of what Mike  
13 just said, but it would be a review of the process  
14 themselves and equipment and design as it contributes.

15 DR. BUCHANAN: Do you have some specific aspect of  
16 equipment design that you think we should be focusing on?

17 DR. KVENBERG: Well, there is the two processes I  
18 am aware of, and that is the nested tray operations and the  
19 tumblers, which is the only real processing that is going on  
20 is the outgrowth of the sprouts. See if there is an  
21 amplification step or reservoir step, blind spots, or  
22 recontamination, whatever, that would be a subset of  
23 reducing the likelihood of amplification or an intervention  
24 step that could be imposed on existing equipment.

25 DR. BUCHANAN: You say you are looking for better

1 sanitization of the equipment, easier to clean.

2 DR. KVENBERG: Right. Above all, do no harm, but  
3 hopefully there will be something that may be evident in the  
4 equipment that can actually improve the situation that  
5 hasn't been applied.

6 DR. BUCHANAN: Janice just reminded me of  
7 calcinated oyster shells, and to take a look at that under  
8 conditions that are more typical of alfalfa sprout  
9 operations here in the United States and its potential.

10 DR. TOMPKIN: Along those lines, we did have a lot  
11 of questions as to whether or not it would be possible to  
12 control the conditions of sprouting in such a way that we  
13 would essentially control the growth. We talked in terms of  
14 pH, temperature, temperature of sprouting, and so on,  
15 essentially build in some hurdles to limit the growth of  
16 enteric pathogens, and still have an acceptable sprouting  
17 process and product.

18 DR. BUCHANAN: I am losing my panel. I am trying  
19 to do this quickly. Talk about GAPS. I am just going to  
20 start at one end and move my way through in terms of  
21 research needs.

22 Is there any additional identifiable research  
23 needs at the production end of the seed itself, that is, out  
24 on the farm?

25 [No response.]

1 DR. BUCHANAN: In the transport and mill  
2 operations of the seed as they are being cleaned?

3 DR. TOMPKIN: I think they have been expressed.  
4 We have talked about it.

5 DR. BUCHANAN: Anything in how seeds or after they  
6 have come from the mill, are transported, stored, handled,  
7 et cetera?

8 [No response.]

9 DR. BUCHANAN: Anything additional on the  
10 treatment of seeds after they have come into the sprout  
11 operation?

12 DR. GOOSBY: We have identified that as a good  
13 research area.

14 DR. BUCHANAN: Right. We have identified several  
15 issues related to the germination and outgrowth of the  
16 sprouts themselves. Is there anything additional on the  
17 packaging and distribution of the sprouts after they have  
18 been produced?

19 DR. TROXELL: The one thing on the spent water to  
20 identify what good indicator organisms, cheap indicator  
21 organisms, I know we have talked about that, but we haven't  
22 said it again here.

23 DR. BUCHANAN: We have identified that as a  
24 research need and also as a result of our survey.

25 DR. TROXELL: Right.

1 DR. BUCHANAN: Anything that has to deal with the  
2 general environment within the sprout operation? Any  
3 additional needs associated with the distribution and  
4 marketing of sprouts?

5 DR. GOOSBY: We just need a package that  
6 continuously liberates the bactericidal gas all the way from  
7 the final packaging to the consumer.

8 DR. BUCHANAN: David's wish list.

9 DR. GOOSBY: In an idea world.

10 DR. BUCHANAN: Right. Finally, anything  
11 additional that we should talk about on the ability of the  
12 consumer to use these or anything that would help the  
13 consumer use them more effectively?

14 DR. TOMPKIN: I haven't thought it through, but I  
15 think that in terms of your understanding from a risk  
16 assessment standpoint, you would need to know as much as  
17 possible about the consumers, how it is used, so that you  
18 can come up with a better grasp for the exposure assessment.  
19 Isn't that would be what you would go after? What impact  
20 those factors may have.

21 DR. BUCHANAN: We haven't had any discussion at  
22 all that I know of on interventions that can be used in the  
23 home other than the five-second boiling of radish sprouts.

24 Is there any additional information needed to  
25 these types of interventions?

1 DR. TOMPKIN: Is the agency going to undertake a  
2 risk assessment for this product?

3 DR. BUCHANAN: Certainly at this point we are  
4 attempting to gather the scientific information that we  
5 would need to do a risk assessment. That is one the primary  
6 needs that we have in terms of identifying the research.

7 Seeing no additional comments, I am about ready to  
8 turn the meeting back over to Janice Oliver. Do I have any  
9 additional comments or recommendations related to research  
10 or overall recommendations by the panel on this area in  
11 light of the meeting that has taken place here? Terry.

12 DR. TROXELL: Would we benefit from some research  
13 on washington of the sprouts by consumer? We heard a lot  
14 about the relative numbers of bacteria that the Japanese had  
15 in their studies on the external versus internal, but most  
16 of them seem to be external, so if consumers wash them, they  
17 might knock the levels down some and could knock them down  
18 to a level that wasn't infective for some people anyway.  
19 Would that be something to look into?

20 I am posing the question pretty much to the  
21 leftover panel.

22 MR. BERNARD: As a leftover panelist, I think it  
23 is worth a look at what strategies might be able to be used  
24 at that level.

25 DR. BUCHANAN: Certainly anything that empowers

1 the consumer we think is worth the research investment.

2 DR. TOMPKIN: Could we position that in with other  
3 fresh vegetables, and so on, such as lettuce, and so on?  
4 Sprouts have been used for quite some time, and to come up  
5 with a specific recommendation to consumers to treat sprouts  
6 in such and such a way, actually doing the research is worth  
7 doing, what can be accomplished by rinsing, is it of value  
8 and how best to do it, but you might keep it in mind that  
9 this could be applicable to other ready-to-eat materials and  
10 position it in that way so that it has broader application.

11 DR. BUCHANAN: Excellent point.

12 MS. OLIVER: It is also applicable to the retail  
13 industry.

14 DR. BUCHANAN: David.

15 DR. GOOSBY: Memory fails me on this question. I  
16 recall that some concern was raised about labeling "for  
17 refrigeration only," and we I think responded that we  
18 weren't sure what the science says on that.

19 Did we ever reach an answer to that and in the  
20 retail environment, as well as in transit, if that question  
21 was answered and I wasn't listening, good, or if not, I  
22 would suggest that is a research agenda.

23 DR. BUCHANAN: Larry has had his hand up.

24 DR. BEUCHAT: Just to continue along the  
25 discussion of treatment near the end of the system in terms

1 of time between treatment and consumption, either in a food  
2 service setting or in the home, those interventions aren't  
3 necessarily dependent upon the success of those, storage for  
4 any period of time between that treatment and consumption.  
5 That is, if quality is going to be affected, say, in three  
6 or four days, that is not at that point as large a factor to  
7 consider. I guess what I am saying is those interventions I  
8 think should be part of this total system from the seed from  
9 the field to the point of consumption, food service setting  
10 or in the home.

11 DR. BUCHANAN: Dane.

12 MR. BERNARD: As you progress with what ever risk  
13 assessment, whether an extensive one or one to just get  
14 through, that you go through here as part of risk management  
15 strategies that you consider once you get to that point, I  
16 think some research on the effectiveness of messages and on  
17 specifically whether information provided through health  
18 care givers, dietary advice, so to speak, might be an  
19 effective management strategy or part of an overall  
20 management strategy.

21 DR. BUCHANAN: As my panel just started to get  
22 even smaller, I am going to turn the meeting back over the  
23 Janice Oliver.

24 MS. OLIVER: I think the meeting is about over and  
25 the panel has about dissolved, but I would like to thank you

1 all, but what I basically heard was that multiple  
2 interventions are needed and that not one intervention will  
3 do, and that the panel is recommending interventions at  
4 three different steps - pre-seed, seed, and at the sprout,  
5 or in the pre-seed the only thing you are recommending in  
6 good agricultural practices is looking at fresh manure, and  
7 Bob will work on writing up something there, but at the  
8 seed, you are looking at multiple interventions.

9           You are looking at irradiation, but it is not  
10 approved right now, and you are looking at use of calcium  
11 hypochlorite, some type of liquid intervention at the  
12 processor, 20,000 parts per million is what I hear the  
13 recommendation, and applying the principles of HACCP is  
14 important especially so that the sprouters know what is  
15 happening during the sprouting operation, that the  
16 microorganisms are growing at a rapid rate.

17           Education is important for the sprout growers and  
18 for the seed producers, and that GMPs, everything is based  
19 on GMPs and SSOPs, that is a basic assumption that you are  
20 going with, besides the research areas which go from -- I  
21 think the beginning through the end, they are multiple. I  
22 think most of them you have cited here, and some others I  
23 think were cited even during the meeting.

24           I would like to thank all of you for your time.  
25 Bob will draft up the recommendations and pass it by all of

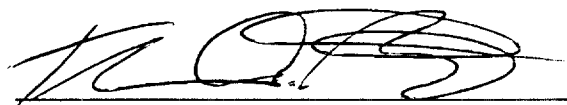

1 you to make sure you agree, and I would also like to thank  
2 all of others who stayed and gave us their advice, their  
3 presentations, and talked to us in between breaks, and all.

4 Thank you.

5 [Whereupon, at 4:42 p.m., the meeting was  
6 concluded.]

**CERTIFICATE**

I, **THOMAS C. BITSKO**, the Official Court Reporter for Miller Reporting Company, Inc., hereby certify that I recorded the foregoing proceedings; that the proceedings have been reduced to typewriting by me, or under my direction and that the foregoing transcript is a correct and accurate record of the proceedings to the best of my knowledge, ability and belief.

A handwritten signature in black ink, appearing to read 'T.C. Bitsko', written over a horizontal line.

**THOMAS C. BITSKO**
