#### Estimates of the Poverty Population Including the Value of Noncash Benefits: 1979 to 1982

#### **SUMMARY**

This is the second exploratory report published by the Bureau of the Census describing methods for assigning dollar values to noncash benefits received by the low-income population. The purpose of this report is to provide estimates of the value of noncash benefits during the period 1979 through 1982 and assess their effect on estimates of the poverty population. The first report provided estimates only for 1979.

The Bureau of the Census is the official source of poverty statistics as indicated by Directive No. 14 issued by the Office of Management and Budget. The current definition of poverty is based on cash or money income alone and therefore, does not include the value of noncash transfers as income.

Growth of the noncash transfer programs during the 1970's led to concerns that although these types of benefits were very important to the well-being of the low-income population they were not taken into account in official measures of poverty. To provide data needed to study this issue, the Bureau of the Census in March 1980 began collecting data on household participation in a selected group of noncash benefit programs. These were the Food Stamp program, the National School Lunch program, public or other subsidized rental housing programs, the Medicare program, and the Medicaid program.

The first exploratory study based on noncash benefit data collected in the March 1980 Current Population Survey was released as Technical Paper No. 50 in March 1982. This research document was authored by Dr. Timothy Smeeding, a recognized expert in this area, during his assignment as an American Statistical Association Research Fellow. The study examined three concepts for valuing noncash benefits. These were the "market value" approach, the "recipient" or "cash equivalent" approach, and the "poverty budget share" approach. Using these methods, and variations on the types of benefits valued, the study produced nine alternative estimates of poverty for 1979. Inclusion of the value of noncash benefits lowered the poverty rate by between 12 and 42 percent overall, depending on the valuation method and types of benefits valued. The report showed that poverty rates for the elderly were reduced by between 6 and 70 percent, the wide range reflecting the important effect of the values for medical benefits.

This new report represents an extension of the exploratory work carried out for 1979. The concepts and procedures followed in making estimates of the noncash benefit values were almost identical to those used initially. The report provides nine alternative estimates of poverty for each year between 1979 and 1982, and in keeping with the research nature of the study, makes no recommendations as to the most appropriate methods for valuing benefits or for including these values in the measure of poverty.

The alternative estimates of the poverty population developed for this report show the extent to which poverty rates are reduced by the inclusion of the value of noncash benefits. In 1979, estimates of the number of poor under the nine alternative procedures ranged from 15.1 million to 22.4 million depending on the technique and benefits valued. The poverty rates for the nine alternative estimates ranged from a low of 6.8 percent to a high of 10.1 percent. In 1982, the alternative estimates of the number of persons below the poverty level ranged from 22.9 million to 31.4 million and the corresponding poverty rates ranged from a low of 10.0 percent to a high of 13.7 percent.

The official poverty statistics have shown that the number of poor increased from 26.1 to 34.4 million between 1979 and 1982, raising the poverty rate by 28 percent. In 1979 the poverty rate was 11.7 percent, but rose to 15.0 percent in 1982, increasing significantly during each year of this 4-year period. The only major group of the population escaping this increase was the elderly. The poverty rate for this group showed no statistically significant change between 1979 and 1982 (15.2 percent in 1979 and 14.6 percent in 1982).

The rate of increase in poverty between 1979 and 1982 was larger, based on estimates of poverty that include noncash benefit values, than that indicated by the official statistics. The increase in the poverty rate after including noncash benefit values ranged from a low of 35 percent to a high of 47 percent. While these rates of increase were significantly higher than the 28-increase in the official poverty rate the absolute increases in the number of poor were, in some cases, lower. The 47-percent increase in poverty based on one of the approaches represented a 7.8 million increase in the number of poor compared to the 8.3 million increase in the official number. This occurred because the alternative estimate of 15.1 million for 1979 was a much smaller base from which to measure change than the official estimate of 26.1 million.

It should be emphasized that the procedures and results presented in this report are experimental and do not represent any official change in the current, official measure of poverty. The Bureau of the Census and the Office of Management and Budget have recently agreed to convene a panel of experts who will review this report and others related to the valuation of noncash benefits and measurement of poverty in order to help establish a basis for integrating the value of

noncash benefits into the measure of poverty.

#### INTRODUCTION

This is the second exploratory report published by the Bureau of the Census describing alternative procedures for valuing noncash benefits received by the low-income population and estimating the effect of these values on the size and composition of the poverty population. The first report, issued in March 1982, focused on the value of these benefits and the effect on poverty estimates for 1979 alone. The purpose of this second report is to provide estimates of the value of noncash benefits and their effect on estimates of the poverty population during the period from 1979 to 1982. The methods used to value noncash benefits in this report are nearly identical to those examined in the previous study. The results, therefore, should be considered an extension of the earlier exploratory work. Modifications of the procedures used in the initial study are described in the technical appendices.

The techniques used to value noncash benefits in this report are subject to the same conceptual and measurement problems as those described in the initial work. Estimates of the poverty population shown in this report based on the combination of money income and values of noncash benefits do not reflect any official change in the methods used for estimating the poverty population

for statistical purposes.

The Bureau of the Census has been the source of the official estimates of the poverty population since 1969 as specified in Directive No. 14 issued by the Office of Management and Budget. Estimates of the poverty population have been published annually since that time based on the cash or money income data collected in the March Current Population Survey (CPS). In March 1980, the Bureau began collecting data on participation in a selected group of noncash benefit programs. Questions covering participation in the National School Lunch Program, Food Stamp Program, public and other subsidized rental housing programs, Medicare, and Medicaid have been a permanent part of the March survey since that time. These serve as the basis for examining procedures for valuing benefits and estimating the effect on poverty for this study.

The Bureau's work in the area of noncash valuation research began in the fall of 1980, following concerns expressed by Congress as outlined in Appendix A. At that time Dr. Timothy Smeeding came to the Census Bureau as a visiting scholar under the American Statistical Association Fellowship Program. Dr. Smeeding, a leading expert in this field, worked closely with the Census Bureau staff to investigate various procedures that might be used to value noncash benefits for 1979.

This investigation resulted in the publication of Technical Paper No. 50, issued in March 1982, showing the effect of including the value of noncash benefits as income for purposes of measuring the poverty population. The report examined three different valuation methods: the market value, the cash equivalent value, and the poverty budget share value. (The conceptual basis of these methods is described later.) The three valuation approaches were applied to three different combinations of food, housing, and medical care benefits, thus producing nine different alternative estimates of poverty for 1979. It was found that the estimated number of persons in poverty would be reduced between 12 and 42 percent in 1979, depending upon the choice of valuation technique and combination of benefits.

There has been considerable interest in more up-to-date estimates of the value of noncash benefits and their effect on poverty. Between 1979 and 1982, the U.S. economy passed through two recessions, the first between January and July 1980 and the second between July 1981 and November 1982, periods of high unemployment, and an increase of about 33 percent in consumer prices. There were also changes in the funding and regulation of some of the noncash benefit programs. While the official poverty statistics based on money income alone indicate that the poverty rate increased from 11.7 to 15.0 percent betwen 1979 and 1982, no estimates had been made indicating the level and change in poverty during this period after valuing noncash benefits. The purpose of

this report is to provide those data.

Although this report presents estimates of the value of noncash benefits and their effect on estimates of poverty for the 1979 to 1982 period, it should be emphasized that these estimates continue to be exploratory in nature. There has been much controversy over the valuation approaches developed in Technical Paper No. 50, since each approach has its own associated strengths and weaknesses. The Bureau of the Census and the Office of Management and Budget plan to convene a special panel of economic experts to review the noncash benefit valuation issues and to make recommendations concerning valuation techniques and methods for integrating these values into the official estimates of poverty. Until a final decision on these matters is reached, the Bureau plans to produce annual estimates similar to those provided in this report. Data will be shown for each of the three valuation approaches and the three combinations of food, housing, and medical benefits.

This report is organized into several sections. Following the introduction are sections covering the growth of noncash benefits programs and a description of the three valuation concepts used in this analysis. Succeeding those are sections on the levels and trends in the poverty population during the 1979 to 1982 period, changes in receipt and average values of noncash benefits, and estimates of poverty before and after inclusion of both cash and noncash benefits. This

material is followed by a discussion of the study's limitations. The section on limitations discusses some of the more important conceptual and empirical problems encountered in the study including the issue of poverty as a relative or absolute measure, difficulties in obtaining all of the data needed to value the benefits, and survey underestimates of income amounts and noncash benefit recipients. Next are the detailed tables, providing data on noncash benefits and their effect on poverty for various demographic and socioeconomic subgroups of the population. Technical appendices are included after the detailed tables. Appendix A describes the U.S. Senate statement that initiated noncash benefit research at the Bureau. Appendix B provides the technical details about the methods used to value noncash benefits under each of the different approaches. Appendix C provides information on the Source and Reliability of the Estimates. Appendix D gives a description of each of the noncash benefit programs. Appendix E is a glossary of standard statistical definitions and explanations. Appendix F discusses problems of underreporting of recipiency and amounts in the March CPS.

#### **GROWTH OF NONCASH BENEFITS**

The majority of Federal expenditures intended to assist the low-income population are now concentrated in programs that provide in-kind or noncash benefits. The market value of these meanstested benefits surpassed that of means-tested cash assistance during the early 1970's and has continued to grow in importance. The growth of both cash and noncash benefit programs is illustrated in table A. This table shows that in 1965, near the time the current poverty definition was developed, the market value of means-tested noncash benefits was about \$5.3 billion (in 1982) constant dollars). About three-fourths of these means-tested benefits were in the form of medical assistance to low-income elderly persons. The means-tested cash assistance in 1965 was about \$17.2 billion, more than three times the expenditure on noncash programs. By 1970, the market value of noncash benefits had risen almost 4-fold to about \$19.7 billion. Expenditures on cash assistance programs increased by only 3 percent to \$17.7 billion. In 1979, the first year for which noncash benefit data were collected in the March CPS, noncash benefits to the low-income population stood at about \$44.0 billion compared to only \$28.6 billion for the means-tested cash

Since the focus of this report is on the 1979 to 1982 period, estimates of cash and noncash benefits for each year of this period are included in table A. Data in this table indicate that the market value (the estimated cost of an equivalent good or service in the private market place as described in detail later) of means-tested noncash benefits continued to increase between 1979 and 1981, then declined in 1982. Means-tested cash benefits declined for each year of this period and were lower in 1982 than in 1975 after adjusting for the change in prices. It is clear from table A that Medicaid is, by far, the largest means-tested noncash benefit program accounting for about 64 percent of the total in 1982. The market value of Medicaid alone, \$29.9 billion, exceeds

the \$25.9 billion in means-tested cash assistance.

The lower portion of table A shows the two nonmeans-tested benefits that were valued in this study. The market value of Medicare has risen rapidly since the program began in 1966. The \$51.1 billion figure for 1982 was the largest of any government noncash benefit program. Over the period from 1979 to 1982 the market value of Medicare increased by 28 percent after adjusting for changes in the price of medical care. This compares to only a slight increase in the market value

for Medicaid benefits during the entire period and a 2-percent decline between 1981 and 1982. The other nonmeans-tested benefit, paid or full-price school lunches, declined in market value during the 1979 to 1982 period, mainly the result of reduced Federal subsidies. The market value of paid school lunch subsidies fell by about 40 percent during this 4-year period.

#### **EXPLANATION OF VALUATION TECHNIQUES**

The valuation of noncash benefits in this report is based on the three valuation methods presented in Technical Paper No. 50. Before examining each valuation technique in detail, it is useful to understand the major conceptual differences between them and their general relationship to one another. "Market value" is the private market cost of the goods and services transferred to the recipient. "Recipient or cash equivalent value" is the cash amount for which recipients would be willing to trade their right to the noncash benefit given their current incomes (including cash and the market value of any noncash benefits received). The "poverty budget share" approach does not attempt to value the noncash benefit directly, but, instead measures the amount by which the poverty threshold could be reduced for the family receiving the benefit. This reduction is equal to the average dollar amount of the good or service consumed by households with money income approximately equal to the poverty level.

Table A. Means-Tested Cash Assistance and the Market Value of Noncash Benefits Valued in This Study: 1965, 1970, 1975, and 1979 to 1982

(In millions of 1982 constant dollars)

Type of benefit	1965	1970	1975	1979	1980	1981	1982

NA Not applicable.

#### Market Value

The market value (MV) of an in-kind transfer is equal to the private market purchasing power of benefits received by the individual. That is, in-kind transfers present beneficiaries with control over some amount of economic resources that can be bought and thus have been explicitly valued in the private market. Because MV is intuitively appealing and relatively easy to compute, it is the measure most often used in studies of the value and distribution of in-kind transfer benefits. All other valuation methods require a good estimate of the MV of the good or service being transferred as a starting place. In some cases, e.g., food stamps, the market value is directly measurable as the dollar value of food coupons in the market. In other cases, MV is not so easily determined. For example, although the annual expenditures for medical care benefits are easily obtained, determining the concept to be used and calculating the MV of these benefits is more difficult. In this study, the market value of medical care is based on an insurance value approach, not on the amount of medical care actually consumed or on the price of a similar good in the private market place. This was done by dividing total medical benefits paid by the program by the number of persons covered. In some cases this procedure assigned values for medical bene-In the case of public fits that were larger than the poverty threshold for the individual. housing, the conceptual measure of MV was defined as the difference between the private market rental value of the unit and the rent paid by the tenants. Estimating MV for public housing is difficult because the private market rental value of public housing units is not available directly from surveys or other sources. Complex statistical procedures were used to link data from the Annual Housing Survey and the March CPS in order to arrive at estimates of MV for this benefit.

#### Recipient or Cash Equivalent Value

The receipt of noncash benefits may distort consumption patterns, and, therefore, add less to a recipient's economic well-being than an equal dollar value cash transfer. If so, the benefits should be discounted from their market value to their recipient value to reflect this lower value. Recipient value (RV) theoretically reflects the program beneficiary's own valuation of the benefit. Theoretically, it would be measured by the amount of cash that would make the recipient feel just as well off as the noncash benefit. In economic theory, the RV is also known as the cash

<sup>&</sup>lt;sup>1</sup>Includes Aid to Families with Dependent Children, General Assistance, Supplemental Security Income, and Means-tested Veteran's pensions.

<sup>&</sup>lt;sup>2</sup>Estimates for 1979 through 1982 were derived directly from the noncash valuation techniques studied in this report.

equivalent value and is formally termed the "Hicksian equivalent variation" after John Hicks (1943). Many economists feel that, in theory, cash equivalent value is the proper measure for economists are in full agreement on this issue, however, since many earlier studies of the effect of noncash benefits on poverty have used MV. The Congressional Budget Office (1977) and Hoagland may be less than the MV.

In theory, the recipient or cash equivalent value can be estimated by assigning a utility function to all recipients. The cash equivalent measure is the amount of cash transfer that leaves the recipient at the same level of well-being or utility as the noncash transfers. Accurate estimates of cash equivalent value necessitate knowledge of all recipients' differing utility a high degree of accuracy, and because of difficulties with current consumption data, a simplified measure of recipient value was developed as a substitute

The cash equivalent value estimates in this study are based on household survey data that allow the calculation of normal (average) expenditures at different income levels. These estimates mal expenditure on that good or service by unsubsidized consumers with similar characteristics itly assumes that there is no difference between the comparable family and the recipient family. Program while the other (the comparison unit) does not, it may be incorrect to infer that the extension of the cash equivalent value approach.

If the recipient normally spends less than the MV of the noncash benefit on the subsidized good or service, the noncash benefit will cause a change in the expenditure pattern. This means not lead to a change in spending habits. If the MV of the benefit exceeds the normal expenditure level, RV can be approximated by the level of normal expenditures. If normal expenditures the MV of the benefit, RV is equal to MV. That is, because the noncash benefit recipient would pattern.

The estimates of RV's was based on data from several sources. The normal expenditures for food were computed using diary data from the new Consumer Expenditure Survey. Those for public and 1981. While none of these data sources is ideal, the data used to compute the RV's for medical benefits are especially weak. They were derived from the 1972-1973 Consumer Expenditure Survey and required the inclusion of persons covered by Medicare and employer-provided health insurance. More details on these problems can be found in Appendix B and Technical Paper No. 50.

#### Poverty Budget Share Value

The third valuation method examined in this study was poverty budget share (PBS). The PBS approach is a different and much more limited valuation technique that links the value of noncash benefits directly to the current concept of poverty. As mentioned earlier, PBS is not strictly a measure of the value of noncash benefits but rather, it is a method for dealing with such benefits the determination of a person's poverty status. The poverty thresholds can be thought of as or single person. The amount of money needed to meet their needs will be reduced if some of the needs are met by noncash benefits. For example, if a low-income person participates in the Medical program, then PBS assumes that his medical needs are met and the amount of money required to duced would be no more than that implied by observed consumption levels for people near the poverty level who were not receiving such benefits.

The derivation of the current poverty definition was based on well-specified food needs and implies certain levels of need for other commodities as well (i.e., some amount of expenditure for each good was budgeted into the poverty levels) even though no well-specified levels of minimum housing or medical care needs exist. The PBS approach assumes that the "value" of these benefits

 $<sup>^{1}</sup>$ A utility function is an economic construct that indicates consumer's relative preferences for various goods and services depending on how consumers substitute these goods and services

for purposes of measuring poverty should be limited to no more than the amounts implied by consumption patterns at the poverty level. This assumption does not presume that benefits above this amount have no worth to the individual; it merely presumes that recipients have little ability to use excess amounts of one noncash benefit to meet different types of needs. To assign a substantially larger value to a particular benefit would require the assumption that recipients can make such substitutions to a significant extent.

Derivation of PBS values were based on data from the Annual Housing Survey and the 1960-61 Consumer Expenditure Survey. Because the poverty levels were developed assuming one-third of income is spent on food, the PBS value limits on food were set at one-third of the poverty levels. The PBS value limits for housing were obtained from the Annual Housing Surveys for 1979 and 1981 by computing the average proportions of income spent on housing by families with incomes near the poverty level not residing in public housing. Values for medical benefits were estimated based on the 1960-61 Consumer Expenditure Survey. Poverty levels were multiplied by the proportions of income spent on medical care during the 1960-61 period to arrive at the PBS limits.

#### **ILLUSTRATION OF VALUATION TECHNIQUES**

Two of the three valuation techniques used in this study, recipient value and poverty budget shares, are difficult for many people to understand. To help provide a clearer picture of these concepts and the relationship between the three approaches examples have been included for food stamp and Medicaid benefits.

#### **Food Stamps**

The market value has been defined as the price of the good or service provided for by the non-cash benefit. A 4-person family with an annual cash income of \$5,000 in 1979 and receiving an annual face value of \$2,600 in food stamps would be assigned \$2,600 as a market value. This value was assigned because the food stamps purchase that amount of the good, in this case food. The total income of the family would then be \$7,600, bringing the family above the poverty level of \$7,386.

The recipient value assigned would, in most cases, be somewhat less than the market value because most recipients would prefer cash and would be willing to exchange the food stamps for an amount which is less than the face value of \$2,600. The normal expenditure approach used in this study assigned recipient values for food stamps that averaged about 96 percent of the market value. Hence, this hypothetical family would have been assigned a value of \$2,496 for the recipient value, an amount that also brings the family income above the poverty level.

The third approach, poverty budget shares, is the most difficult of the three procedures to understand. Under this procedure, an amount, the poverty budget share, is first computed. For food this amount was equal to .333 (the proportion of income required for food, as implied by the official definition of poverty) multiplied by the poverty level, in this case \$7,386. The poverty budget share amount equals \$2,460. This means that the poverty level has \$2,460 budgeted for food. The concept states that the benefit fills a requirement in the budget and amounts in excess of the requirement do not have an effect on determining poverty status. In this example, the poverty budget share value of \$2,460 is \$140 less than the market value and \$36 less than recipient value. The poverty budget share value also raises the family income above the poverty level.

#### Medicaid

An insurance value approach was used to assign the market value of Medicaid benefits. Under this concept total medical benefits paid were divided by the number of persons enrolled in the program. Beneficiaries were grouped into four categories: aged, blind or disabled, nondisabled persons age 21 to 64 years, and nondisabled persons under age 21. Insurance values for persons in these four groups were computed separately by state of residence. For example, an elderly person living alone in New York with money income of \$3,200 in 1979 would have been assigned a market value of \$3,691 if covered by Medicaid. This amount is \$219 higher than the poverty level of \$3,472 for this group.

The normal expenditure approach to assigning recipient value for Medicaid would have used data from the 1972-73 Consumer Expenditure Survey to assign a value of \$385 for the insurance value of Medicaid to this individual. Under this concept, the value of the benefit is limited to the amount spent for the good or service, on average, by persons not covered by the program.

The poverty budget shares for medical care were based on the 1960-61 Consumer Expenditure Survey. This survey showed that aged persons living alone, with money income near the poverty level,

spent about 11.4 percent of their income on medical care. Based on this figure, the poverty budget share value for Medicaid was \$396, 11.4 percent of the \$3,472 poverty level for this aged person in 1979.

#### TRENDS IN THE POVERTY POPULATION BETWEEN 1979 AND 1982

#### **Official Poverty Statistics**

In 1982, about 34.4 million Americans were officially classified as living below the poverty level. This group represented about 15 percent of the U.S. noninstitutional population in that year. Four years earlier, in 1979, the number of persons below the poverty level was estimated to be about 26.1 million, or 11.7 percent of the population.

The number of poor and the poverty rate increased during each year of the 1979 to 1982 period. The number of poor increased by 32 percent and the poverty rate by 28 percent overall. Between 1979 and 1980 the poverty rate rose from 11.7 to 13.0 percent. In 1981 the rate increased to 14.0 percent and finally to 15.0 percent for 1982, the latest year for which official poverty estimates are available.

Higher rates of poverty were evident for most segments of the U.S. population over this 4-year period (see table B). The poverty rates for Whites, Blacks, and persons of Spanish origin were all higher in 1982 than in 1979. The poverty rate for children under 18 years rose from 16.0 to 21.3 percent. In contrast, the poverty rate for the elderly, persons age 65 years old and over, showed no statistically significant change (15.2 percent in 1979 and 14.6 percent in 1982). This

Table B. Number of Persons Below the Poverty Level and Poverty Rates, by Selected Characteristics: 1982 and 1979

		ımber	Poverty rate			
Characteristic	1982	1979	Percent change	1982	1979	Percent change
All persons	34,398	26,072	31.9	15.0	11.7	28.2
White	23,517	17,214	36.6	12.0	9.0	33.3
Black	9,697	8,050	20.5	35.6	31.0	14.8
Spanish origin	4,301	2,921	47.2	29.9	21.8	37.2
Children under 6 years old	4,977	3,521	41.4	23.8	18.2	30.8
Children 6 to 17 years old	8,670	6,856	26.5	20.9	15.6	34.0
Persons age 65 years and over	3,751	3,682	1.9	14.6	15.2	-3.9
Persons in families, total	27,349	_19,964	370	13.6	10.2	33.3
Persons in married-couple families	14,839	10,074	47.3	8.9	6.1	45.9
Persons in families maintained by women, no husband present	11,701	9,400	24.5	40.6	34.9	16.3
Unrelated individuals	6,458	5,743	12.4	23.1	21.9	5.5
Mailes	2 <del>,</del> -347	1,972-	- 19 <del>.</del> 0	18-8-	16.9-	11.2
Females	4,110	3,771	9.0	26.6	26.0	2.3

can, in part, be attributed to two cash programs, Social Security and Supplemental Security Income, both indexed to increase benefit amounts at a rate equal to the increase in consumer prices during the 1979 to 1982 period.

The poverty rate for persons in families rose from 10.2 percent in 1979 to 13.6 percent in 1982, a 33-percent increase. The rate for persons in families maintained by women, no husband present climbed from 34.9 percent to 40.6 percent, a rise of 16 percent. The poverty rate for persons in married-couple families increased from 6.1 percent in 1979 to 8.9 percent in 1982, up

almost 46 percent.

The poverty rate for male unrelated individuals rose by about 11 percent, from 16.9 percent in 1979 to 18.8 percent in 1982 while the rate for female unrelated individuals did not change significantly (26.0 percent in 1979 and 26.6 percent in 1982). The increase in the poverty rates for unrelated individuals as a group was lower than that for all persons because of the high proportion of unrelated individuals over age 65. As noted previously, the elderly experienced no statistically significant change in their poverty rate during this period.

#### **Poverty Statistics After Valuing Noncash Benefits**

Comparisons of estimates of the poverty population before and after inclusion of the value of noncash benefits are summarized in tables C, D, and E. These comparisons reveal the levels and trends in the poverty population over this 4-year period for nine different combinations of the three valuation approaches and three groupings of benefits valued. These nine alternative esti-

mates are identical to those shown in the earlier report.

Three different groupings of the food, housing, and medical benefits were chosen because of the overwhelming importance of medical benefits and concerns over the proper treatment of medical expenditures for the institutionalized in the calculation of insurance values for Medicare and Medicaid. Detailed discussions of these issues are contained in Technical Paper No. 50. The three categories of benefits used were 1) food and housing benefits only, 2) food, housing, and medical benefits including expenditures for institutional care, and 3) food, housing, and medical benefits excluding expenditures for institutional care.

The effect of the value of noncash benefits on estimates of poverty varies significantly for different subgroups of the population since certain subgroups tend to receive larger or smaller amounts than others. The poverty rate for the aged population, persons age 65 years or older, is especially sensitive to the value of medical benefits since such a large proportion of this group

is covered by Medicare.

Market Value. The market value approach assigns the largest values to noncash benefits, and, therefore, counting these values as income for purposes of measuring poverty causes the largest reductions in the estimates of poverty. In 1979, accounting for the market value of food and housing benefits alone reduced the overall poverty rate from 11.7 to 9.7 percent, a 17-percent reduction, and the total number of poor from 26.1 to 21.7 million. A much larger reduction in poverty for the base year 1979 was observed by including the market value of medical benefits. The poverty rate after valuing all medical benefits was 6.8 percent, a 42-percent reduction over the official poverty estimates for 1979. Reductions in the poverty rates can be noted in the detailed tables for various subgroups of the poverty population for each year of this 4-year period. The size of the reductions varies for the different subgroups, reflecting differences in the number and types of benefits received.

The effect of market values for medical benefits is most noticeable on the poverty rates for the aged. Because almost all persons age 65 and over are covered by Medicare and/or Medicaid, most of these persons were assigned market values that averaged \$830 for Medicare and almost \$2,200 for Medicaid for 1979. While the poverty rate for persons age 65 and over declined from 15.2 percent to 13.4 percent for 1979 after including the market value of food and housing benefits alone, the rate declined to only 4.3 percent when all medical benefits were counted at market value. This means that the poverty rate for the aged was 72 percent lower in 1979, under the mar-

ket value approach including the value of all food, housing, and medical benefits.

Adding the market values of noncash benefits to income for purposes of measuring poverty also has a major effect on the poverty rates for children. In 1979 the official poverty rate for children under age 6 was 18.2 percent. This rate compares to 14.8 percent following the valuation of food and housing and 11.3 percent when food, housing, and all medical benefits are included. These represent reductions of 19 and 38 percent, respectively for 1979. The 6 to 17 year age group were poor at a rate of 15.6 percent in the 1979 base year. Market values for food and housing benefits reduced the poverty rate for this group to 12.0 percent, lower by 23 percent. The poverty rate after consideration of medical benefits was 8.7 percent, down by about 44 percent for 1979.

Table C. Comparison of the Number of Poor and Poverty Rates for Persons Using Alternative Income Concepts and Valuation Techniques: 1982 and 1979

(Numbers in thousands)

		9				
Income concept		et value approach	Recipient equivale	or cash ent value approach	Poverty budget share value approach

<sup>&</sup>lt;sup>1</sup>Percent reduction in the poverty rate from the current poverty estimate based on money income alone.

Two groups with higher than average poverty rates are Blacks and persons in female householder families, no husband present. The official poverty rate for Blacks was 31.0 percent in 1979. After valuing noncash benefits for food and housing, the rate declined to 23.5 percent, a 24-percent reduction. Inclusion of the value of medical benefits yielded a 14.9 percent poverty rate for Blacks, a decrease of 52 percent over the official estimate.

The effects of noncash benefit values for persons living in female householder families with no husband present were similar to those for Blacks. The official poverty rate for this group, 34.9 percent for 1979, was lowered to 26.0 percent with market values of food and housing benefits, a 26-percent decline, and 16.6 percent counting all benefits, also a 52-percent reduction in the rate.

The trend in poverty over this 4-year period as measured using the market value approach differs from the trend as indicated through the official poverty statistics. The official statistics show that poverty increased by about 28 percent during the 1979-82 period. After accounting for noncash benefits the poverty rate showed higher rates of increase, about 38 percent if only food and housing are included and 47 percent if food, housing, and all medical benefits are included at market value (see table D). This increase in poverty rates resulted from a steady year-to-year climb over this period as is illustrated in table 1.

Table D. Poverty Rates for Persons, by Valuation Technique and Alternative Income Concept: 1982 and 1979

		Market value			ipient	value	Poverty budget shares			
Income concept	1982	1979	Percent change	1982	1979	Percent change	1982	1979	Percent change	
Money income alone	15.0	11.7	28.2	15.0	11.7	28.2	15.0	11.7	28.2	
Money income plus food and housing	13.4	9.7	38.1	13.7	10.0	37.0	13.6	10.1	34.7	
and medical care (excluding in- stitutional care expenditures) Money income plus food, housing,	10.3	7.0	47.1	12.8	9.2	39.1	12.5	9.1	37.4	
and medical care (including institutional care expenditures)	10.0	6.8	47.1	12.7	9.0	41.1	12.5	9.1	37.4	

The official poverty rates for the aged population and the rates after valuing food and housing benefits showed no statistically significant change between 1979 and 1982. When medical benefits are included, however, the poverty rate for persons 65 years old and over declined from

4.3 percent in 1979 to 3.5 percent in 1982, a 19-percent reduction.

Trends in the poverty rates for children between 1979 and 1982 were significantly altered following the inclusion of noncash benefit values. Between 1979 and 1982, the official poverty rate for children under age 6 rose from 18.2 percent to 23.8 percent, an increase of 31 percent. Based on market valuation techniques for food and housing the poverty rate increased by 45 percent, from 14.8 percent to 21.4 percent. The change in poverty rates after including medical benefits was from 11.3 percent in 1979 to 17.2 percent in 1982, a 52-percent rise. Changes in the poverty rates for the 6 to 17 year age group followed a similar trend.

The upward trend in poverty rates over this period was also accentuated for Blacks and persons in female householder families, no husband present. The increase in the official poverty rate for Blacks was about 15 percent between 1979 and 1982, rising from 31.0 percent to 35.6 percent. The increase in the poverty rates after including food and housing benefits at market value was about 31 percent, rising from 23.5 to 30.7 percent. When all benefits are included, food, housing, and

medical, the poverty rate increased by 44 percent, from 14.9 to 21.5 percent.

For persons in female householder families, no husband present, the official poverty rate rose from 34.9 to 40.6, a 16-percent increase. The rate of increase in poverty was 34 percent during the 4-year period based on the market value of food and housing benefits and 49 percent if all noncash benefits are included.

Recipient or Cash Equivalent Value. Because recipient values for noncash benefits are based on the normal expenditure approach and limited to be no greater than the market value, the recipient value technique has a smaller effect on estimates of the poverty rate than the market value. In 1979, the estimated poverty rate after inclusion of food and housing benefits was 10.0 percent. This was about 15 percent below the official rate of 11.7 percent for that year. This compares with a 17-percent reduction for the market value approach. Inclusion of the medical care benefits at recipient value reduced the poverty rate to 9.0 percent, 23 percent lower than the official level. This reduction is far less than the overall 42-percent reduction in the poverty rate achieved through the market value approach.

Recipient values for food and housing benefits are very similar, on average, to market values; however, recipient values for medical care are much lower than market values. Because the recipient values for medical benefits are lower than market values, reduction in the poverty rate for the elderly was less than that occurring under the market value approach. Using this approach the poverty rate for the elderly after noncash benefits are valued was 9.5 percent for 1979, about

 $<sup>^{1}\</sup>text{No}$  statistically significant difference exists between the 45-percent increase and the 52-percent increase which includes medical benefits.

Table E. Poverty Rates for Persons, by Valuation Technique by Selected Characteristics: 1982 and 1979

Year and characteristic	Official poverty definition	Market value approach <sup>1</sup>	Recipient value approach <sup>1</sup>	Poverty budget share approach <sup>1</sup>
1982

1979				21.0
All persons White Black Spanish origin Children under 6 years old Children 6 to 17 years old Persons age 65 years and over Persons in families, total Persons in married-couple families. Persons in families maintained by women, no husband present Unrelated individuals Males Females	9.0 31.0 21.8	6.8 5.6 14.9 12.0 11.3 8.7 4.3 5.7 3.9 16.6 13.5 12.9 14.0	9.0 7.1 22.2 16.6 14.5 11.8 9.5 7.7 4.8 25.2 18.1 15.1 20.6	9.1 7.2 22.1 16.3 14.2 11.6 9.8 7.7 4.9 24.5 18.5 15.3 21.0

<sup>&</sup>lt;sup>1</sup>Noncash benefit values include all food, housing, and medical benefits with institutional expenditures.

38 percent below the official 15.2 percent rate, but considerably higher than the 4.3 percent ob-

The trend in poverty during 1979 to 1982 as measured using the cash equivalent value approach also differs from the trend indicated by the official poverty statistics. Whereas the official statistics show that poverty increased by 28 percent during this period, after counting noncash benefits the poverty rate showed a higher rate of increase. The rate increased by 37 percent if only food and housing are included, and by 41 percent if food, housing, and all medical benefits are included at cash equivalent value.

Poverty Budget Share Value. The poverty budget share approach to valuing noncash benefits resulted in an overall reduction of 14 percent in the poverty rate for the base year 1070 if food

rate for the elderly was reduced from 15.2 percent to 13.4 percent using the combined value of

food and housing and to 9.8 percent after counting all medical benefits.

Including noncash benefits at their poverty budget share value also shows a different trend in poverty during 1979 to 1982 than indicated by the official statistics. The poverty rate increased by 35 percent during this period if only food and housing benefits are counted and by 37 percent if food, housing, and all medical benefits are counted at their poverty budget share value. As noted earlier, the official poverty rate based on money income alone increased by 28 percent during this period.

#### RECEIPT OF NONCASH BENEFITS AND AVERAGE NONCASH BENEFIT VALUES

An examination of changes in the poverty rate during 1979 to 1982 has shown higher rates of increase after counting the value of noncash benefits than indicated by the official measure. These differences could have been caused by a number of factors. First, the proportion of the poverty population receiving noncash benefits may have declined. Second, the average value of the benefits for this group may have declined relative to changes in the Consumer Price Index, the measure used to adjust the poverty levels annually. Third, the composition of the poverty population may have changed, making noncash benefits less effective in reducing poverty. The data shown in table F provide some insight into these changes.

Overall, the proportions of unrelated individuals below the poverty level receiving noncash benefits were slightly lower in 1982 than 1979, and there is some evidence that the proportion of

families was also slightly less.

Declines in the proportion of two-person families with a householder 65 years old and over (about 3 percentage points) and in the proportion of unrelated individuals age 65 and over (about 5 percentage points) below the poverty level was a second factor affecting the rates of change in

Table F. Percent of Poor Families and Unrelated Individuals Receiving Noncash Benefits and Mean Market Value of Noncash Characteristics: 1979 and 1982

(1982 Constant Dollars)

Not applicable.

poverty rates. Both of these groups had relatively low poverty levels in 1979 (\$3,472 and \$4,364, respectively, compared to \$7,386 for 4-person families) and almost all received noncash benefits in the form of Medicare and/or Medicaid. In 1979, for example, the average market values of medical benefits for these groups were \$1,560 for unrelated individuals 65 years old and over and \$2,430 for the two-person families. Since these values are large in relation to the poverty levels, they tend to have a large effect on estimates of poverty when combined with cash income for purposes of measuring poverty status.

It appears that the most important factor leading to higher rates of increase in poverty after valuation of noncash benefits was the small increases in average noncash benefit values over the 4-year period relative to the 33 percent increase in consumer prices. Overall, the average market value of noncash benefits received by families below the poverty level, \$3,330 in 1982, was 10 percent lower, in real terms, than the average for 1979. Groups shown in table F posting increases in average benefits significantly greater than the rise in prices were families with aged householder, aged unrelated individuals, and total unrelated indivdiuals. This can be attributed to the increases in average market values for Medicare and Medicaid. Table B-5 of Appendix B shows that the average Medicare market value for the aged increased by 61 percent, from \$930 to \$1,500. Average market values for the aged and disabled under Medicaid shown in tables B-6 and B-7, increased by 60 percent and 45 percent, respectively. In contrast, average Medicaid market values for adults, 21 to 64 years old, and for children rose by only 16 and 14 percent,

Average market values for food benefits received by poor families declined slightly from \$1,350 in 1979 to \$1,300 in 1982. The average market value for the public housing subsidy was about 26 percent lower in 1982 than in 1979, dropping from \$2,390 to \$1,760, in real terms.

#### POVERTY BEFORE AND AFTER CASH AND NONCASH BENEFITS

The cumulative effect of cash assistance programs and noncash benefit programs on the poverty population is summarized in table G for families and unrelated individuals for 1979 and 1982. The

detailed tables contain similar data for these two groups by selected characteristics.

If neither cash assistance nor the value of noncash benefits are considered, 10.0 million families, about 16.8 percent, would have been classified as poor in 1979 compared to 12.0 million, 19.6 percent in 1982. After counting Social Security benefits the number of poor families declines to 6.1 million in 1979, 8.0 million in 1982. Means-tested cash benefits lower the number of poor families to the official levels of 5.5 million for 1979 and 7.5 million for 1982. Cash benefits reduced the poverty rate for families from 10.2 to 9.2 percent in 1979 and from 13.0 to 12.2 percent in 1982. Noncash benefit values that include the value of medical care with institutional care expenditures reduced the poverty rate for families by between 25 and 43 percent and the number of poor families to a range between 3.1 and 4.1 million in 1979, depending on the valuation approach used. The reduction in the poverty rate for 1982 ranged from 16 to 34 percent with the number of poor families ranging from 4.9 million to 6.2 million.

The mean poverty deficit for families was \$4,910 (in 1982 constant dollars) before any cash or noncash benefits were counted in 1979. This compares to a mean deficit of \$5,120 for 1982. This amount is a measure of difference between the poverty level and the incomes of families below the poverty level. The mean deficit based on the official poverty definition was \$3,900 in 1982, up 9 percent over 1979, while the deficits after valuing noncash benefits showed no significant change

Also shown in table G are the mean amount of benefits received in excess of the poverty level. This has been computed for poor families whose income rises above the poverty level based on a specified benefit value. The mean amount in excess of the poverty level was \$4,290 for all cash transfers in 1982, virtually unchanged from the 1979 level in real terms. Most of this excess accummulated from Social Security benefits. The mean amount of noncash benefits in excess of the poverty level for families rising above the poverty level based on the value of noncash benefits was between \$1,030 and \$3,030 for 1979 depending on the valuation technique selected. The mean amounts of noncash benefits in excess of poverty were somewhat lower in 1982 than in 1979, between \$840 and \$2,630. It should be noted that neither the cash nor the noncash benefit programs are designed to provide benefits that bring family income from below the poverty line to the poverty line. The table has been included only to show the relative importance and effects of the current benefit and recipient levels.

The lower portion of table G shows similar data for unrelated individuals, 30 percent of whom were age 65 and over in 1979. An analysis of the figures for this group shows that in 1979 Social Security benefits—alone reduced the pretransfer poverty rate by 36 percent, from 36.7 to 23.5 percent. A similar reduction occurred in 1982, from 37.8 to 24.0 percent. Other cash transfers, in this case largely Supplemental Security Income, reduce the rate to the official level of 21.9 percent for 1979, 23.1 percent in 1982. The value of noncash benefits lowered the poverty rate

to between 13.5 and 18.5 percent in 1979 and between 14.7 and 19.7 percent in 1982, depending upon the valuation approach.

#### LIMITATIONS OF THE STUDY

There are many conceptual and empirical problems associated with the procedures used to value noncash benefits and include these values for purposes of measuring the poverty population. Limitations of the valuation techniques themselves are discussed separately in the sections describing each procedure. While Technical Paper No. 50 discussed many of these limitations in detail, nevertheless, it is important to outline some of the major problems here.

The major conceptual issue related directly to the procedures described in this study is the use of poverty thresholds based on relationships between food requirements, cash expenditures for food, and cash income. Some experts have stated that changing the income measure used to determine poverty by adding the value of noncash benefits requires changing the poverty definition as well to reflect both cash income and noncash benefits. They believe that accounting for noncash benefits would alter the food to income ratio and therefore the food multiplier used to establish the current poverty levels. The current definition of poverty was developed in 1964 when noncash benefits were a very small part of low-income assistance programs and a much smaller portion of the "total" income received by households at the middle and upper portions of the income distribution. While the exact effect of these noncash benefits on the food-to-income ratio used to derive the current poverty levels is unknown, most analysts agree that it would be small. Today, the value of noncash benefits received by the poor exceeds that of cash assistance, and the value of fringe benefits paid to employees by employers are much more important than in the mid-1960's. The food-to-income ratio based on the value of cash income and the value of noncash benefits today might be significantly higher or lower; however, such an update of the food-to-income ratio would leave the poverty definition closer to a relative rather than an absolute measure. The current poverty measure has been called relatively absolute because it is based on the average proportion of income spent on food by all families and the expenditures needed to meet minimal nutritional standards. A more detailed discussion of this issue is contained in Chapter 2 of the earlier report.

The major empirical problems that were encountered in this research effort were the lack of a more comprehensive data base from which to launch the study and underreporting of both cash income and noncash benefits in the March CPS survey. First, the March CPS does not collect information on all sources of noncash benefits. Data for some public noncash programs such as free or reduced-price school breakfasts, the Women and Infants Care Program, and several smaller programs for child nutrition, low-income energy assistance, etc., assisting the low-income population were not included. Data covering all noncash benefits received by the low-income population have not been collected because of constraints on interview time and questionnaire size. It should be noted, however, that the value of the benefits covered in the March CPS represent over 90 percent of the noncash benefits to the low-income population. Second, no data were collected on in-kind assistance provided by private charities or other organizations. Third, the questions on the March CPS were not specifically designed for purposes of noncash valuation. The lack of detailed information covering participation in the National School Lunch Program including amounts paid and days of participation probably prevented a more accurate distribution of these benefits. Estimating the value of subsidies for public or other low-rent housing was also difficult. Data from the Annual Housing Survey were used to assign market rents and subsidized rents paid to households

dure tended to distribute benefits evenly, thus overestimating the values for part-year participants and underestimating the values for full-year participants.

The second empirical problem is the underreporting of cash income and noncash benefits. This is a common problem encountered in household surveys that attempt to collect these types of data. The effect of underreporting is downward biased estimates of income and program participation and overestimation of the extent of poverty. The magnitude of this problem is unknown. While income underreporting is a serious problem in household surveys such as the March CPS, its effect on measures of year-to-year change in levels of income and poverty is much less important because year-to-year variations in underreporting are relatively small. Estimates of underreporting are contained in Appendix F.

reporting residence in public and other subsidized rental housing. The lack of data on the "true" market rent of the subsidized unit is probably the most serious problem in this area. As was the case for all benefits except food stamps, no data were available on the number of months of participation. All recipients were assigned amounts that reflect 12-month participation. This proce-

# Appendix A. U.S. Senate Statement, "Data Collection and Poverty Level"

Official poverty statistics published by the Bureau of the Census currently ignore billions of dollars of Government in-kind benefits, such as food stamps, public housing rental subsidies and medical care. The Congresssional Budget Office has estimated that including in-kind benefits in the income statistics would cause the number of people in poverty to decline to about 9 million as compared to official statistics showing nearly 25 million people in poverty. The official statistics show no significant reduction in recent years in the incidence of poverty, although in-kind benefit programs have expanded greatly.

The Committee considers it essential that official poverty statistics reflect, at the earliest possible date, the effects of in-kind benefits. Without such information Congress and the Execu-

tive Branch cannot be certain that Government transfer programs are properly targeted.

The Census Bureau has recognized the need for better data on in-kind benefits. The most recent March Current Population Survey has collected data on some types of in-kind program benefits. In addition, Census has under way an experimental survey-known as the Survey of Income and Program Participation--which collects more extensive data. However, Census has not yet published the data collected thus far and has no current plans for integrating such data with cash income

data now reported routinely.

The Committee has inscribed language in the bill directing the Secretary of Commerce to expedite the program of collecting, through surveys, data on benefits received and data on participation in federally funded, in-kind benefit programs. Programs on which data are to be reported include, but are not necessarily limited to, food stamps, Medicaid, Medicare and subsidies in areas such as housing, nutrition, child care and transportation. The Secretary of Commerce is further directed to continue research and testing of techniques for assigning monetary values to in-kind benefits, and for calculating the impact of such benefits on income and poverty estimates. The Secretary of Commerce is also directed to include in survey reports beginning no later than October 1, 1981, appropriate summaries of data on in-kind benefits and estimates of the effect of in-kind benefits on the number of families and individuals below the poverty level.

Department of State, Justice, and Commerce, The Judiciary and Related Agencies, Appropriation Bill, 1981. U.S. Senate, 96th Congress, 2nd Session. September 16, 1980: 33-34.

# Appendix B. Description of Noncash Valuation Techniques

This appendix contains descriptions of the procedures used to develop and assign values to each of the five types of noncash benefits valued in this study. These benefits are (1) food stamps, (2) school lunches, (3) public or other subsidized rental housing, (4) Medicaid, and (5) Medicare. The first section describes procedures for the market value approach, the second, procedures for the recipient or cash equivalent approach, and the third, procedures for the poverty budget share approach.

#### **MARKET VALUE**

The market value concept values the noncash benefit at the cost of the specific goods or services in the private market place. The procedures used to assign market values to noncash benefits require the identification of analogous goods or services in the private market place and estimation of the cost of the goods or services. Because it is sometimes difficult to find and value goods or services in the private market place that are precisely the same as that provided by the noncash benefit program various assumptions and compromises were made in the estimation process. Details of the market value estimation process are contained in the following subsections for each noncash benefit.

<u>Food stamps</u>. Valuing food stamps was the simplest and most straightforward of the market value procedures. The market value assigned was the annual face value as reported in the survey; i.e., the face value is equal to the purchasing power of the food stamps in the market place.

School lunches. All children eating lunches prepared in schools that participate in the National School Lunch Program receive a subsidy or benefit because the price paid by the student is less than the cost of the meal. The value of the benefit varies depending on how much the student pays for the lunch. In the case of school lunches it is difficult to identify the analogous good in the private market place since such a large proportion of schools participate in the program. It was decided, therefore, to assign market values that were equal to the amount of money and value of commodities contributed by the Department of Agriculture and State governments (excluding contributions directly from student payments for lunches).

Data from the Department of Agriculture allowed the calculation of the amount of contributions per meal served. These contributions differ for each of the three categories of lunches: (1) paid (full price), (2) reduced price, and (3) free. Table B-1 shows the total contributions per meal by type of lunch for 1979 to 1982. These figures were multiplied by 167 days to obtain an annual estimate per child. This assumes an average school year of 180 days and 93 percent attendance. Annual market values per child are also shown in table B-1. These amounts were multiplied by the number of children in each family reporting that they usually ate a hot lunch offered at school.

<u>Public and other subsidized rental housing</u>. The noncash benefit for public or other subsidized rental housing was defined as the difference between the market rent of the housing unit and the subsidized or lower rent paid by the participant. The market value of the benefit is equal to this difference. Data on the market rent of public housing units are not readily available. Since these data are the key to estimating market values, procedures were developed to estimate market rents.

The market rent estimation procedure was based on survey data from the 1979 and 1981 Annual Housing Survey (AHS) national samples conducted by the Bureau of the Census. The AHS was chosen for several reasons. First, it collected relatively current data on monthly amounts paid for rent and utilities. Second, it allowed identification of public or other subsidized housing units.

Table B-1. Contributions Per Meal and Annual Market Value Subsidies for National School Lunch Program Benefits, by Type of Lunch: 1979 to 1982

(Figures in dollars)

;	197	79	198	0	198	1	198	2
Type of lunch	Per meal	Annual	Per meal	Annual	Per meal	Annual	Per meal	Annual
Full price	.31	51.77	.34	56.78	.32	53.44	.23	38.41
Reduced price	.84	140.28	.95	158.65	.99	165.33	.84	140.28
Free	1.04	173.68	1.15	192.05	1.19	198.73	1.24	207.08

Third, the AHS had a relatively large sample size, about 60,000 households. Finally, the survey can provide data needed for future updates.

The first step in the market rent estimation procedure was development of a method to "statistically" match public and private market rental units with similar housing characteristics. In this process each sample public or subsidized housing unit was matched to two nonsubsidized units with similar housing unit characteristics. The average market rent for two matching private market units was assigned as the market rent for each matching public or other subsidized rental unit. The average market rent for two nonsubsidized units was assigned rather than a rental amount from only one unit in order to help stabilize the estimated market rents.

Once the assignment of a market rent had been made to each public or subsidized rental housing unit on the 1979 and 1981 AHS sample files, tabulations of average market rents and average subsidized rents paid were made. An examination of these data indicated that the data for both years should be combined in order to provide larger sample sizes and thus more stable estimates for the market and subsidized rents.

The tabulation and combination of the market rent and subsidized rent data for 1979 and 1981 were followed by the calculation of average market values for the rent subsidy. These averages were simply the difference between the average simulated market rents and the average reported subsidized rents paid. Tables B-2, B-3, and B-4 show the average market rents, average subsidized rents, and average market value subsidies used in the assignment of market values for public housing. The values in these tables are averages derived by combining the 1979 and 1981 data. The averages were replaced by rent to income ratios for purposes of making the actual calculation.

Market value estimates for public housing described here differ somewhat from those used in the original Technical Paper No. 50 work because slightly different procedures were used. The original work covering 1979 used data from the 1979 AHS; however, valuation techniques based on hedonic regression procedures yielded lower estimates of market rent for the public housing units and thus lower market values for the noncash housing benefit.

The rent to income ratios used in the assignment of the market value subsidy were held constant for all years. This meant that the market value subsidy for public housing was fixed as a function of income level based on the combined 1979 and 1981 data. This procedure yielded market value subsidies that changed only slightly over the 4-year period.

Medicare and Medicaid. Procedures used to assign the market value of Medicare and Medicaid coverage are based on an insurance value concept. A major problem in the assignment of market values is the identification of a comparable good in the private market and estimation of the cost of the comparable good. The comparable private market, in the case of Medicare and Medicaid, would be nonprofit insurance companies charging premium amounts that cover the cost of benefits and overhead.

In the absence of a similar private market, the market values of Medicare and Medicaid were determined using program data covering the total amount of medical vendor payments and numbers of persons covered or enrolled in the program, including those covered but not receiving medical care benefits from the program.

The market values for Medicare are shown in table B-5 for 1979 and 1982. These values were obtained by dividing medical benefits paid by the number of enrollees. All calculations of

market value were made separately by State and risk class. As can be seen in the table, the Medicare risk classes were the aged (persons over age 65) and the disabled. Supplemental Medical Insurance (SMI) premiums were assumed to be paid by all enrollees and were, therefore, deducted in the market value calculation process. These amounts of SMI premiums have not been deducted from the values shown in table B-5. The data in these tables include expenditures for the institutionalized population. The market values based on vendor payments that exclude institutional expenditures were estimated to be about 2 percent lower in all States even though this factor differed slightly from State to State. Unlike the earlier study, no adjustment was made to the average value to account for small amounts of program administrative costs. All of the data used in the estimation of the market value of Medicare are readily available from the Health Care Financing Administration, Department of Health and Human Services.

The market values for Medicaid are shown in tables B-6 and B-7 for 1979 and B-8 and B-9 for 1982. Separate market values based on inclusion and exclusion of instituional expenditures have been provided to illustrate the large differences in market values resulting from the exclusion or inclusion of benefits paid on behalf of institutionalized individuals. Four risk classes were defined for estimating the market value of Medicaid. These were aged, blind or disabled, dependent children under age 21, and adults aged 21 to 64. The calculations for the child and adult risk classes were restricted to expenditures and recipients in AFDC units. Calculations excluded the "other Title XIX" recipients and benefits as shown in the annual HCFA tabulation.

The computation of market values for Medicaid was not made based on the "ever enrolled" population. Estimating "ever enrolled" populations within risk class and State for Medicaid is difficult. There are no administrative or survey data available that can be used to develop accurate "ever enrolled" figures and the figures on those receiving benefits are weak for some States, often requiring revision. An examination of estimates of market value based on recipients of Medicaid benefits with market value estimates based on the "ever enrolled" figures derived for the original Technical Paper No. 50 study covering 1979 showed relatively small differences for most States. Some large differences were discovered during this comparison. These apparent problems were traced to major revisions to the HCFA Medicaid data following completion of the original valuation work. Considering the relatively small differences in these comparisons, the problems in obtaining an adequate "ever enrolled" estimate, and the major revisions made to the 1979 Medicaid data, it was decided to compute the market values for Medicaid based on estimated recipient counts readily available from HCFA. Use of this procedure may overstate the value somewhat, but provides a more consistent and stable data base for the examination of the effect of noncash benefits on changes in poverty levels during the 1979 to 1982 period. Administrative costs were also excluded in the calculation of Medicaid benefits.

# RECIPIENT OR CASH EQUIVALENT VALUE

The recipient or cash equivalent concept assigns a value to the noncash benefit that would make the recipient feel just as well off as the noncash benefit itself. This concept reflects

the value the recipient places on the benefit. The recipient or cash equivalent concept assures that the value assigned never exceeds the market value and is, in most cases, less than the market value.

Two procedures have been used by researchers to estimate recipient values. These are the utility function approach and the normal expenditures approach. Both of these approaches have advantages and disadvantages. The major problem in either case, however, is a lack of data needed to adequately estimate recipient value accurately. A more detailed discussion of the recipient value concept and problems of estimation is contained in Technical Paper No. 50.

The normal expenditure approach was used to estimate recipient values in this study. The first step in this technique is to obtain expenditure data for households purchasing the good or service in the private market. In this valuation effort, the general procedure was to tabulate an average annual household expenditure matrix defined by a set of cross-classifying variables. The next step was comparison of the previously assigned market value of the noncash benefit to the average (normal) expenditure in the appropriate cell of this matrix. The recipient value assigned was equal to the average value in the matrix unless this value is greater than the market value. In this situation, the recipient value is constrained, making it equal to the market value.

<u>Food Stamps</u>. The recipient or cash equivalent values for food stamps were based on some of the newly available expenditure data from the Consumer Expenditure Survey (CES) diary sample. The CES is conducted by the Bureau of the Census under the sponsorship of the Bureau of Labor Statistics. Since this survey has a relatively small sample size it was necessary to combine

expenditure data for 1980, 1981, and 1982 in order to improve the stability of the normal expenditure matrix. Table B-10 shows the figures used in the assignment of recipient value for food stamps. These average expenditures include both food consumed at home and 100 percent of the reported expenditures away from home. In practice, the average subsidy amounts were replaced by subsidy-to-income ratios in order to compute recipient values. These ratios are shown in Table B-11 and were used in the estimation process throughout the 1979 to 1982 period.

Since food stamps may have been received for a specified number of months during the year, the calculation of recipient value should be based only on the months during which the stamps were received. Data collected in the March CPS on the number of months received were used to account for these part-year recipients. This was accomplished by transforming the average annual normal food expenditures and market value of food stamps to average monthly figures. In these cases, if the average monthly normal expenditure was less than the average monthly food stamp amount, the annual recipient value was made equal to the average monthly normal expenditure multiplied by the number of months in which food stamps were received. If the monthly normal expenditure was greater than the market value, the annual recipient value equaled the annual market value of food stamps.

<u>School lunches</u>. Estimating normal expenditures for school lunches is difficult since virtually all school children eating lunches prepared at school are participating in the program; i.e., there is no private market from which to estimate normal expenditures. Given this problem and

the relatively small size of the benefits, a decision was made to assign recipient values to school lunch benefits that were equal to the market value of these benefits.

<u>Public or Other Subsidized Rental Housing.</u> Estimates of recipient value for public housing tenants were based on data from the 1979 and 1981 Annual Housing Survey as were the estimates of market value. The first step in the procedure was tabulation of average or normal annual rental expenditures in the private market place—in this case, rental units in nonpublic housing. Data for 1979 and 1981 were combined to increase the sample size in order to stabilize the average rental amounts. The normal expenditure estimates tabulated for the recipient value calculations are shown in table B-12.

The second step, calculation of recipient value for public housing, is somewhat more complicated than for food stamps because the recipients pay a reduced price rather than obtaining the goods at no cost. First, the market rent established as part of the market value procedures (table B-2) was compared to the appropriate normal expenditures figure in table B-12. If the market rent figure was less than the normal expenditure the recipient value was assigned to be equal to the market value of the benefit. If the market rent figure was greater than the normal expenditure the recipient value was determined as the difference between the normal expenditure and the subsidized rental payment (table B-4). In practice, the average figures shown in these tables were replaced by expenditure to income ratios. These ratios were then used in the calculations for each of the four years.

Medical Care Benefits. The procedures used to estimate recipient value of medical care benefits were based on simple updates of the original 1979 techniques. These procedures were used because there are no new data available that would permit revisions and improvements to the procedures.

While reasonably current data were available to estimate the normal expenditures for food and housing, no such data exist for medical care. A nonsubsidized population is, for all practical purposes, nonexistent. The aged population is almost totally covered by the Medicare program and the population under 65 years of age receives widespread coverage from employer-provided group health insurance.

The estimates of normal expenditures for medical care were made using data from the 1972-73 Consumer Expenditure Survey (CES) in spite of the major problems cited above. The normal expenditure tabulation used as the basis for this study is shown in Table B-13. The data for the underage-65 population were derived from CES survey cases reporting partial employer-provided coverage. The expenditure data do not include the amount of the employer's contribution and, therefore, the normal expenditures for this group are probably underestimated. The sample group used to derive the normal expenditures for the 65-and-over population included persons with Medicare coverage but excluded persons covered by Medicaid and those covered by both Medicaid and Medicare. Use of the Medicare population in estimates of normal expenditures is undesirable and probably results in underestimates of recipient value as well.

The normal expenditure data in table B-13 were tabulated from the 1972-73 CES. Adjustments were then made to the 1972-73 average medical expenditures and income classes to account for the increases in consumer prices. The expenditure data were adjusted by the change in the medical component within the overall Consumer Price Index (CPI). The income classes were adjusted by the change in the overall CPI. These same adjustments were made annually to update the 1979 figures in this table to the appropriate year between 1980 and 1982.

Table B-13. Normal Expenditure Values for Medical Care, by Age or Disability Status of the Householder and Size of Household

(In 1979 dollars)

The assignment of recipient values followed the same procedures as outlined for food stamps. Separate estimates of recipient value were made based on the inclusion or exclusion of institutional care expenditures.

# **POVERTY BUDGET SHARES**

The third procedure used to value noncash benefits in this study was the poverty budget share (PBS) approach. The PBS approach is a different and much more limited valuation technique that links the value of the noncash benefit directly to the current money income poverty concept. The PBS approach assumes that, for purposes of measuring poverty, the value assigned to the benefit can be no greater than the amount that is usually spent on the specified good or service by people near the poverty level, since values in excess of this amount cannot always substitute for other needs.

Food benefits. The values of food stamps and school lunch benefits were combined for the calculation of the PBS value for food benefits. The amount spent on food by families near the poverty line was assumed to be one-third of the appropriate poverty level. This reflects directly the food to income ratio used to develop the current poverty definition. The PBS limits for food benefits are shown in table B-14 for 1979 through 1982. The figures in this table are simply the weighted average poverty threshold for the specified family type multiplied by one-third. The PBS value was computed by comparing the combined market value of food stamps and school lunch to the DBS limit.

lunch to the PBS limit. If the market value was greater than the PBS limit, the PBS value was constrained to the PBS limit. If the market value was lower, the PBS value was equal to the market value.

<u>Public or other subsidized-rental housing</u>. The PBS values for public or other subsidized rental housing were computed using the 1979 and 1981 AHS data. Calculation of the PBS limits were based on the housing expenditure to income ratios shown in table B-15. These ratios represent the proportion of income spent on nonsubsidized rental housing by families with incomes within

Table B-14. Poverty Budget Shares for Food, by Year and Size of Family Unit

(Figures in dollars)

9 persons or more	(X)	(X)	6,191	6,566		

<sup>11979</sup> and 1980

 $\pm 25$  percent of the poverty level and are averages of the 1979 and 1981 data from the AHS for non-subsidized housing units.

The calculation of the PBS limit was made by multiplying the appropriate proportion in table B-15 by the family's poverty level. If the previously assigned market rent exceeded the PBS limit, the PBS value for public housing was made equal to the difference between the PBS limit and the amount of subsidized rent paid. If the market rent was less than the PBS limit, the PBS value for public housing was made equal to the market value of the subsidy.

Medical care. The PBS values for noncash medical care benefits were computed using the same expenditure to income ratios at the poverty line as used in the previous study. These ratios which were derived from the 1960-61 Consumer Expenditure Survey are shown in table B-16. The data from the 1960-61 survey were selected originally because they reflect expenditure patterns for medical care that existed prior to the Medicare program and expansion of employer-provided benefits. The PBS value for medical care was computed by comparing the combined market value of Medicare and/or Medicaid for the family with the PBS limit. The PBS value was equal to the PBS limit if the market value exceeded the limit or equal to the market value if the market value was lower.

# Appendix C. Source and Reliability of Estimates

#### SOURCE OF DATA

The estimates in this report are based on data obtained during the month of March in the years 1980 to 1983 from the Current Population Survey (CPS) conducted by the Bureau of the Census and from supplementary questions to the CPS. The monthly CPS deals mainly with labor force data for the civilian noninstitutional population. Questions relating to labor force participation are asked about each member 14 years old and over in every sample household. In addition, each March, supplementary questions are asked about money income, noncash benefits, and work experience for the previous year. In order to obtain more reliable data for the Spanish origin population, the March CPS samples are enlarged to include all households from the previous November sample which contained at least one sample person of Spanish origin. For this report, persons in the Armed Forces living off post or with their families on post are also included.

The present CPS sample was initially selected from the 1970 census files with coverage in all 50 States and the District of Columbia. The sample is continually updated to reflect new construction. The Spanish supplemental sample adds about 2,500 eligible households.

The following table provides a description of some aspects of the CPS sample designs in use during the referenced data collection periods.

### Description of the Current Population Survey (1980-1983)

Time period	Number		Housing units eligible <sup>3</sup>		
	of sample areas <sup>1</sup>	Sample civil divisions <sup>2</sup>	Interviewed	Not interviewed	
May 1981 to March 1983 January 1980 to April 1981.	629 629	1,148 1,133	58,000 63,000	2,500 3,000	

 $<sup>^{1}\</sup>mathrm{These}$  areas were chosen to provide coverage in each State and the District of Columbia.

Each year about 5 percent of occupied units were visited but interviews were not obtained because the occupants were not found at home after repeated calls or were unavailable for some other reason.

 $<sup>^2</sup>$ Includes counties, independent cities and minor civil divisions in the U.S.

<sup>&</sup>lt;sup>3</sup>Monthly averages, excluding supplemental Spanish households.

For a description of the previous CPS sample designs see the detailed reports in the series, Current Population Reports, Series P-60, Bureau of the Census, U.S. Department of Commerce. The estimation procedure used in this survey involved the inflation of the weighted sample results to independent estimates of the total civilian noninstitutional population of the United States by age, race, and sex. The estimation procedure for the data in the report also involved a further adjustment so that husband and wife of a household received the same weight. These independent estimates were based on statistics from the 1980 Decennial Census of Population; statisforces.

# **RELIABILITY OF ESTIMATES**

Since the CPS estimates are based on a sample, they may differ somewhat from the figures that would have been obtained if a complete census had been taken using the same questionnaire, insample survey--sampling and nonsampling. The standard errors provided for this report primarily indicate the magnitude of the sampling error. They also partially measure the effect of some nonsampling errors in response and enumeration, but do not measure any systematic biases in the data. The full extent of nonsampling error is unknown. Consequently, particular care should be exercised in the interpretation of figures based on a relatively small number of cases or on small differences between estimates.

Nonsampling variability. Nonsampling errors can be attributed to many sources, e.g., inability to obtain information about all cases in the sample, definitional difficulties, differences in the interpretation of questions, inability or unwillingness on the part of the respondents to provide correct information, inability to recall information, errors made in collection such as in recording or coding the data, errors made in processing the data, errors made in estimating values for missing data, and failure to represent all units with the sample (undercoverage).

Undercoverage in the CPS results from missed housing units and missed persons within sample households. Overall undercoverage, as compared to the level of the 1980 Decennial Census, is undercoverage is larger for males than for females and larger for Blacks and other races combined than for Whites. Ratio estimation to independent age-sex-race population controls partially corrects for the bias due to survey undercoverage. However, biases exist in the estimates to the extent that missed persons in missed households or missed persons in interviewed households have different characteristics from interviewed persons in the same age-sex-race group. Further, the independent population controls used have not been adjusted for undercoverage in the decennial

The estimates of income and noncash benefits received (as derived from the March CPS) are subject to underreporting. Underreporting in household surveys can be attributed to several factors. These include a failure to report benefits received and misclassification of the source of benefits.

For additional information on nonsampling error including the possible impact on CPS when known, refer to Statistical Policy Working Paper 3, "An Error Profile: Employment as Measured by the Current Population Survey," Office of Federal Statistical Policy and Standards, U.S. Department of Commerce, 1978 and, Technical Paper No. 40, "The Current Populaton Survey: Design and Methodology," Bureau of the Census, U.S. Department of Commerce.

Sampling Variability. The standard errors given in tables C-1 through C-4 are primarily measures of sampling variability, that is, of the variation that occurred by chance because a sample rather than the entire population was surveyed. The sample estimate and its standard error enable one to construct confidence intervals—ranges that would—include the—average result of all possible samples with a known probability. For example, if all possible samples were selected, each of these being surveyed under essentially the same general conditions and using the same sample design, and if an estimate and its standard error were calculated from each sample, then:

- 1. Approximately 68 percent of the intervals from one standard error below the estimate to one standard error above the estimate would include the average result of all possible samples.
- 2. Approximately 90 percent of the intervals from 1.6 standard errors below the estimate to 1.6 standard errors above the estimate would include the average result of all possible samples.
- 3. Approximately 95 percent of the intervals from two standard errors below the estimate to two standard errors above the estimate would include the average result of all possible samples.

The average estimate derived from all possible samples is or is not contained in any particular computed interval. However, for a particular sample, one can say with a specified confidence that the average estimate derived from all possible samples is included in the confidence interval.

Standard errors may also be used to perform hypothesis testing, a procedure for distinguishing between population parameters using sample estimates. The most common types of hypotheses are: 1) the population parameters are identical, versus 2) they are different. An example of this would be comparing the poverty rate for Whites versus the poverty rate for Blacks. Tests may be performed at various levels of significance, where a level of significance is the probability of

concluding that the parameters are different when, in fact, they are identical.

All statements of comparison in the text have passed a hypothesis test at the 0.10 level of significance or better, and most have passed a hypothesis test at the 0.05 level of significance or better. This means that, for most differences cited in the text, the estimated difference between parameters is greater than twice the standard error of the difference. For other differences mentioned, the estimated difference between parameters is between 1.6 and 2.0 times the standard error of the difference. When this is the case, the statement of comparison will be qualified in some way; e.g., by use of the phrase "some evidence."

Note when using small estimates. Summary measures (such as means, medians, and percent distributions) are shown only when the base is 75,000 or greater. Because of the large standard errors involved, there is little chance that summary measures would reveal useful information when computed on a smaller base. Estimated numbers are shown, however, even though the relative standard errors of these numbers are larger than those for corresponding percentages. These smaller estimates are provided primarily to permit such combinations of the categories as serve each user's needs.

## STANDARD ERRORS OF ESTIMATES

Standard error tables and their use. In order to derive standard errors that would be applicable to a large number of estimates and that could be prepared at a moderate cost, a number of approximations were required. Therefore, instead of providing an individual standard error for each estimate, generalized sets of standard errors are provided for various types of characteristics. As a result, the sets of standard errors provided give an indication of the order of magnitude of the standard error of an estimate rather than the precise standard error.

standard error of an estimate rather than the precise standard error.

The figures presented in tables C-1 and C-2 are approximations to standard errors of various estimates for households and persons in the United States. To obtain the approximate standard error for a specific characteristic the appropriate standard error in table C-1 or C-2 must be multiplied by the "f" factor for that characteristic given in tables C-3 or C-4. These factors must be applied to the generalized standard errors in order to adjust for the combined effect of the

sample design and the estimating procedure on the value of the characteristic.

Table C-1. Standard Errors of Estimated Numbers of Households or Persons: 1979 to 1982

(Numbers in thousands)

Size of estimate	Standard error <sup>1</sup>	Size of estimate	Standard error <sup>1</sup>	
75	13 21 29 41 58 71	7,500	127 154 192 247 269 243	

<sup>1</sup>These values must be multiplied by the appropriate "f" factor in tables C-3 and C-4 to obtain the standard error for a specific characteristic.

Table C-2. Standard Errors of Estimated Percentages of Households or Persons: 1979 to 1982

Base of estimated percentage (thousands)	Estimated percentage <sup>1</sup>						
	2 or 98	5 or 95	10 or 90	25 or 75	50		
75 100 250 500 1,000 2,000 3,000 5,000 10,000 15,000 25,000 100,000 100,000 125,000	2.1 1.8 1.2 0.8 0.6 0.4 0.3 0.3 0.2 0.2 0.15 0.12 0.08 0.06 0.05	3.3 2.9 1.8 1.3 0.9 0.6 0.5 0.4 0.3 0.3 0.2 0.2 0.2 0.13 0.09 0.08	4.5 3.9 2.5 1.8 1.2 0.9 0.7 0.6 0.5 0.4 0.3 0.2 0.2 0.12 0.11	6.6 5.7 3.6 2.5 1.8 1.3 1.0 0.8 0.7 0.6 0.5 0.4 0.3 0.2 0.2	7.6 6.6 4.1 2.9 2.1 1.5 1.2 0.9 0.8 0.7 0.5 0.4 0.3 0.2 0.2		

 $<sup>^{1}</sup>$ These values must be multiplied by the appropriate "f" factor in tables C-3 and C-4 to obtain the standard error for a specific characteristic.

Standard errors for intermediate values not shown in the generalized tables of standard errors may be approximated by linear interpolation. Standard errors of estimated means and medians are provided in the detailed tables.

Two parameters (denoted "a" and "b") are used to calculate standard errors for each type of characteristic; they are presented in tables C-3 and C-4. These parameters were used to calculate the standard errors in tables C-1 and C-2 and to calculate the "f" factors in tables C-3 and C-4. They also may be used to calculate directly the standard errors for estimated numbers and percentages. Methods for computation are given in the following sections.

Standard errors of estimated numbers. The approximate standard error,  $\sigma_X$ , of an estimated number shown in this report can be obtained in two ways. It may be obtained by use of the formula

$$\sigma_{\mathsf{X}} = \mathsf{f}_{\sigma}$$
 (1)

where f is the appropriate "f" factor from Table C-3 or C-4, and  $\sigma$  is the standard error on the estimate obtained by interpolation from Table C-1. Alternatively, it may be approximated by the following formula, from which the standard errors in Table C-1 were calculated. Use of this formula will provide more accurate results than the use of formula (1) above.

$$\sigma_{x} = \sqrt{ax^{2} + bx} \tag{2}$$

Here x is the size of the estimate and a and b are the parameters in tables C-3 and C-4 associated with the particular type of characteristic.

 $<sup>^{1}</sup>$ For non-metropolitan residence categories multiply the "a" and "b" parameters by 1.5 and the "f" factor by 1.22.

Standard errors of estimated percentages. The reliability of an estimated percentage, computed using sample data for both numerator and denominator, depends upon both the size of the percentage and the size of the total upon which this percentage is based. Estimated percentages are relatively more reliable than the corresponding estimates of the numerators of the percentages, particularly if the percentages are 50 percent or more. When the numerator and denominator of the percentage are in different categories, use the "f" factor or parameters from table C-3 or C-4 can be obtained by use of the formula

$$^{\sigma}(x,p) = f_{\sigma}$$
 (3)

In this formula, f is the appropriate "f" factor from table C-3 or C-4 and  $\sigma$  is the standard error on the estimate from table C-2. Alternatively, it may be approximated by the following formula, from which the standard errors in table C-2 were calculated. Use of this formula will give more accurate results than use of formula (3) above.

$$\sigma(x,p) = \sqrt{\frac{b}{x} \cdot p (100 - p)}$$
 (4)

Here x is the size of the subclass of persons or households which is the base of the percentage, p is the percentage (0 ), and b is the parameter in table C-3 or C-4 associated with the particular type of characteristic in the numerator of the percentage.

Under 14 years	-0.000052 -0.000019 -0.000077 -0.000098 -0.000134 -0.000070 -0.000139	6057 3017 3017 3017 3017 3017 3017	-0.000052 -0.000178 -0.000542 -0.000939 -0.001253 -0.000765 -0.001683	6057 3017 3017 3017 3017 3017 3017	-0.000052 -0.000032 -0.000122 -0.000169 -0.000230 -0.000117 -0.000153	6057 4520 4520 4520 4520 4520 4520	1.88 1.32 1.32 1.32 1.32 1.32	1.88 1.62 1.62 1.62 1.62 1.62

luse these factors for total or any race.

Illustration of the use of standard error tables. Suppose that in 1979 there were 9,549,000 households below the poverty level. Using table C-1 and the "f" factor of 1.04 show that the standard error of an estimate of this size is approximately 129,000. Alternately, using the parameters in table C-3 in formula (2) gives a more accurate estimate of the standard error of

158,000 = 
$$\sqrt{(0.000076)(9,549,000)^2 + (1876)(9,549,000)}$$

A 90-percent confidence interval as shown by the data is from 9,296,000 to 9,802,000. Therefore, a conclusion that the average estimate derived from all possible samples lies within a range computed in this way would be correct for roughly 90 percent of all possible samples. Similarly, we could conclude with 95-percent confidence that the average estimate derived from all possible samples lies within the interval from 9,233,000 to 9,865,000 (using twice the standard error).

Suppose that of the 8,405,000 Black households in 1979, 29.9 percent were below the poverty level. table C-2 shows the standard error of 29.9 percent on a base of 8,405,000 to be approximately 0.7 percent. (An "f" factor of 1.04 was applied here.)

Alternatively, this standard error could have been derived by using the "b" parameter for Blacks from table C-3 in formula (4).

$$0.7 = \sqrt{\frac{1876}{8,405,000}} (29.9)(70.1)$$

Consequently, a 90-percent confidence interval as shown by these data is from 28.8 to 31.0 percent, and a 95-percent confidence interval is from 28.5 to 31.3 percent.

<sup>2</sup>Use these factors for Spanish origin

<sup>3</sup>Use these parameters for work experience and employment status data for persons.

correct for roughly 68 percent of all possible samples. Thus, we can conclude with 68-percent confidence that the number of persons below the poverty level in 1980 is higher than the figure

<u>Standard error of a ratio</u>. Certain mean values for persons in households listed in the tables of this report were calculated as the ratio of two numbers. For example, the mean number of persons

$$\frac{x}{y} = \frac{\text{total number of persons in households}}{\text{total number of households}}$$

Standard errors for these means may be approximated as shown below. There are two cases to consider. In either case, the denominator y represents a count of households of a certain class, and the numerator x represents a count of persons with the characteristic under consideration who are members of these households.

<u>Case 1</u>: There is at least one person having the characteristic in every household of the class; for example, the mean number of persons per household, or the mean number of persons per household with a male householder. For ratios of this kind, the standard error is approximated by the following formula:

$$\sigma_{x/y} = \sqrt{\frac{\left(\frac{x}{y}\right)^2 \left[\left(\frac{\sigma_y}{y}\right)^2 + \left(\frac{\sigma_x}{x}\right)^2 - 2\rho \left(\frac{\sigma_x}{x}\right) \left(\frac{\sigma_y}{y}\right)\right]}$$
 (6)

The standard error of the estimated number of households,  $\sigma_y$ , and the standard error of the estimated number of persons with the characteristic in those households,  $\sigma_x$ , may be obtained from formula (1) or (2). In formula (6),  $\rho$  represents the correlation coefficient between the numerator and the denominator of the estimate. In the above example, and for other ratios of this kind, use 0.7 as an estimate of  $\rho$ .

Case 2: The number of persons having the characteristic in a given household may be 0, 1, 2, 3, or more; for example, the mean number of persons under 18 years of age per household. For ratios of this kind the standard error is approximated by formula (6) but  $\rho$  is assumed to be zero. If  $\rho$  is actually positive (negative), then this procedure will provide an overestimate (underestimate) of the standard error of the ratio.

NOTE: When computing the approximate standard error of a ratio and the numerator of the ratio is income, use formula (10) for the standard error of an arithmetic mean. If the ratio has persons in the numerator and households in the denominator, then formula (6) with appropriate value of  $\rho$  will give a result preferable to that of formula

Comparisons of alternate poverty estimates for the same population. As discussed in this report, several estimates of poverty may be obtained for any given population by using different income concepts and valuation techniques in determining poverty status. The most meaningful comparisons between two measures of poverty are those in which either the income concept or the valuation technique is fixed, e.g., a comparison between a poverty estimate determined by income and the market value of food and housing benefits and a poverty estimate determined by income and the ket value of food, housing and medical benefits. All comparisons presented in this section make

<u>Standard errors for within-year differences between poverty estimates</u>. In a given year the standard error for the difference of two poverty estimates (numbers or percentages) is given by the

$$(x,y) = {}^{\sigma}d \tag{7}$$

Comparisons of estimates. Estimates are often compared by computing their difference or ratio. The two sections which follow, "Standard Error of a Difference" and "Standard Error of a Ratio" give general procedures for the computation of standard errors when making comparisons. This report also discusses several different estimates of poverty when noncash benefits are included as income. The standard errors needed for the comparison of such estimates are discussed in the section "Comparisons of Alternative Poverty Estimates for the Same Population."

Standard error of a difference. For a difference between two sample estimates, the standard error is approximately equal to

$$\sigma_{(x-y)} = \sqrt{\frac{2}{\sigma_{x}^{2} + \frac{2}{\sigma_{y}^{2}} - 2\rho - \sigma_{x}^{\sigma_{y}}}}$$
 (5)

where  $\sigma_X$  and  $\sigma_Y$  are the standard errors of the estimates x and y (from tables C-1 through C-4). The estimates can be numbers, percents, ratios, etc. The correlation coefficient  $\rho$  can be determined from table C-5 for year-to-year comparisons for poverty estimates and proportions (assuming the same yearly poverty definition); for other comparisons assume that  $\rho$  equals zero. Making this assumption will result in accurate estimates of standard errors for the difference between two estimates of the same characteristic in two different areas, or for the difference between separate and uncorrelated characteristics in the same areas. If, however, there is a high positive (negative) correlation between the two characteristics, the formula will overstate (understate) the true standard error.

Table C-5. Year-to-Year Correlation Coefficients for Poverty Estimates of Households and Persons: 1979 to 19821

Characteristic	Households	Persons
Total White Black and/or other races Spanish origin	0.35 0.30 0.35 0.55	0.45 0.35 0.45 0.65

<sup>&</sup>lt;sup>1</sup>The correlations for estimates two or more years apart are zero.

Illustration of the computation of the standard error of a difference in estimates. Suppose that the number of persons below the poverty level in 1980 was 29,272,000 and in 1979 the figure was 26,072,000. The apparent difference is 3,200,000. As shown above, the standard error on the estimate of 29,272,000 persons below the poverty level is 454,000. The standard error on the 26,072,000 low-income persons computed from (2) is 431,000. From table C-5 we obtain the correlation coefficient,  $\rho = 0.45$ .

The standard error associated with the estimated difference of 3,200,000 is:

$$465,000 = \sqrt{(454,000)^2 + (431,000)^2 - 2(0.45)(454,000)(431,000)}$$

This means that the 68-percent confidence interval around the 3,200,000 difference is from 2,735,000 to 3,665,000, i.e., 3,200,000  $\pm$  465,000. A conclusion that the average estimate of the difference derived from all possible samples lies within a range computed in this way would be

where d = |x-y|, the absolute difference between the two estimates x and y, and  $\sigma_d$  is computed by using formula (1) or (2) using d as the size of the estimate or by using formula (3) or (4) using d as the estimated percentage.

Standard errors for difference of yearly change between poverty estimates. In comparing year-to-year changes between two poverty estimates, (e.g., change in poverty from 1979 to 1980 using cash income alone in determining poverty versus the change in poverty using income and food and housing benefits in determining poverty) the standard error of a difference of differences is needed.

If  $x_1$ ,  $x_2$  ( $y_1$ ,  $y_2$ ) are the x(y) estimates in years 1 and 2, and  $d = (x_1 - x_2) - (y_1 - y_2)$  then

$$\sigma_{\rm d} = \sqrt{\frac{2}{\sigma_{\rm d_1}^2 + \frac{2}{\sigma_{\rm d_2}^2} - 2_{\rho}^{\sigma_{\rm d_1}^2 \sigma_{\rm d_2}^2}}$$
 (8)

where for i=1 and 2,  $d_i = |x_i - y_i|$ , the absolute difference for the estimates in year i, is obtained using formula (7) and  $\rho$  is obtained from table C-5.

Standard error of the ratio of a poverty estimate to the standard poverty estimate. When computing the ratio of the number of persons in poverty using an alternative poverty definition divided by the number of persons in poverty using the current poverty definition (only income included) the standard error of the ratio can be approximated by the formula

$$\sigma_{x/y} = \sqrt{\frac{\sigma_x}{y}} \quad \left[ \left( \frac{\sigma_x}{x} \right)^2 - \left( \frac{\sigma_y}{y} \right)^2 \right] \tag{9}$$

where  $\sigma_X$  and  $\sigma_y$  are the estimates of the standard errors of the estimates x and y as determined by formula (1) or (2).

Illustration of the computation of a standard error when comparing alternate definitions of poverty. Suppose that the number of people below the poverty level as determined by two definitions of poverty are as listed in the following table:

Method			·	Yearly increase	
		1979	1980		
1.	Current definition	26,072,000	29,272,000	3,200,000	
2.	Market valuation including food/housing	21,208,000	25,100,000	3,892,000	

The data show in the period from 1979 to 1980 that the apparent difference in the increase in poverty between the two methods is 692,000.

Using formula (8) we have:

$$d_1 = 4,864,000, \frac{1}{\sigma} d_1 = 195,000, \frac{2}{\sigma} d_2 = 4,172,000, \frac{\sigma}{\sigma} d_2 = 181,000, \frac{2}{\sigma} d_2 = 181,000, \frac$$

$$^{1}d_{1} = 26,072,000 - 21,208,000$$

$$^{2}\sigma_{d_{1}} = \sqrt{(-0.000031)(4,864,000)^{2} + 7946(4,864,000)}$$

and  $\rho = 0.45$  so that the standard error assoicated with 692,000 is

$$198,000 \triangleq \sqrt{(195,000)^2 + (181,000)^2 - 2(0.45)(195,000)(181,000)}$$

A 95-percent confidence interval around 692,000 is from 296,000 to 1,088,000. Thus, we can conclude with 95-percent confidence that between 1979 and 1980 more people have been added to poverty status by using method 2 than by using method 1.

Standard errors of estimated means and medians. Estimated standard errors are provided for the means and medians of the published income distributions and do not need to be calculated by the user. However, because of the approximations used in developing the formula used to estimate the standard error of the mean, the standard error reported for this statistic will generally be an underestimate. Since some users may wish to combine two or more income distributions and compute means and medians for the combined distribution, the following sections have been provided to enable the user to calculate standard errors for these statistics.

Standard error of an arithmetic mean. To obtain a rough estimate of the standard error of a mean, use the following formula:

$$\sigma_{\overline{X}} = \sqrt{\frac{b}{y} \cdot s^2} \tag{10}$$

In this formula, y is the size of the base of the distribution and b is a parameter which depends on the sample size, the sample design, the estimation procedure, and the type of characteristic. Values of b are given in tables C-3 and C-4. The variance,  $s^2$ , is given by the following formula:

$$s^2 = \sum_{i=1}^{C} p_i \overline{x}^2 - \overline{x}^2$$
 (11)

where  $\overline{x}$  is the mean of the distribution defined by  $\sum_{i=1}^{C} p_i \overline{x_i}$ ; c is the number of groups in the distribution; i indicates a specific group, taking on values of 1 through c;  $p_i$  is the proportion

distribution; i indicates a specific group, taking on values of 1 through c;  $p_i$  is the proportion of total cases in the i<sup>th</sup> group; and  $x_i$  is the midpoint of the i<sup>th</sup> group (or discrete value of the i<sup>th</sup> group).

 $\overline{x_i}$  =  $(z_{i-1} + z_i)/2$ , where  $z_{i-1}$  and  $z_i$  are the lower and upper interval boundaries, respectively, for group i. Group c is open-ended; i.e., no upper interval boundary exists. For this group an approximate average value is:

$$\overline{x}_{c'} = \frac{3}{2} z_{c-1}$$

When two or more distributions are combined, the mean of the combined distribution is:

$$\overline{x} = \frac{1}{v} \sum_{j} \overline{x}_{j} y_{j}$$

where  $\overline{x}_j$  is the mean of the  $j^{th}$  distribution,  $y_j$  is the base of  $j^{th}$  distribution, and  $y = \sum_j y_j$ . This mean must be computed by the user.

Estimation of median incomes. Median incomes have been estimated using either Pareto interpolation or linear interpolation. Pareto interpolation assumes a decreasing density of population within an income interval, whereas linear interpolation assumes a constant density of population within an income interval. Estimates of median income and their associated standard errors have been calculated using Pareto interpolation if the width of the income interval containing the

estimate is greater than \$2,500. Otherwise, the computations have been carried out using linear interpolation.

Standard error of a median. The sampling variability of an estimated median depends upon the form of the distribution as well as the size of its base. An approximate method for measuring the reliability of an estimated median is to determine a confidence interval about it. (See the section on sampling variability for a general discussion of confidence intervals.) The following procedure may be used to estimate the 90-percent confidence limits of a median based on sample data.

- Determine, using the standard error tables and factors or formula (4), the standard error of the estimate of 50 percent from the distribution;
- Add to and subtract from 50 percent, 1.6 multiplied by the standard error determined in step
- Using the distribution of the characteristic, calculate the values from the distribution corresponding to the two points established in step 2. These values will be the limits for the confidence interval.

For calculation of the confidence interval use Pareto interpolation for any point in an income interval greater than \$2,500 width; use linear interpolation otherwise.

A 95-percent confidence interval may be determined by finding the values corresponding to 50

percent plus and minus twice the standard error determined in step 1.

The formulas used to implement step 3 for Pareto or linear interpolation are:

$$x_{pN} = A_1 \exp \left[ \ln \left( \frac{pN}{N_1} \right) - \ln \left( \frac{A}{2} \right) \right]$$
  $\ln \left( \frac{N}{2} \right)$  (12)

$$x_{pN} = \frac{N_1 - pN}{N_1 - N_2} \qquad (A_2 - A_1) + A_1 \tag{13}$$

where

N = total number of households or persons in the distribution,

 $x_{pN}$  = estimated upper and lower bounds for the confidence interval (0 $\leq$ p $\leq$ 1). For purposes of calculating the confidence interval, p takes on the values in step 2. Note that  $x_{DN}$  estimates the median when p = .50 is used in the formulas,

 $A_1$  and  $A_2$  = the lower and upper bounds respectively on the interval in which  $x_{pN}$  falls,

 $N_1$  and  $N_2$  = the estimated number of household or persons with incomes greater than  $A_1$  and A<sub>2</sub>, respectively.

exp. is the exponential function,

is the natural logarithm function.

It should be noted that a mathematically equivalent result is obtained by using common logarithms (base 10) and antilogs.

For illustrations of the computations of a confidence interval for a median, see the Source and Reliability section of the Current Population Reports, Series P-60, U.S. Bureau of the Census, Department of Commerce.

### Appendix D. Program Descriptions and Data Collection

Appendix D contains brief descriptions of each public in-kind transfer program covered in the March CPS, a description of the questions used to collect the data, and an evaluation of the data quality. The description of each program begins with a statement of program objectives and is followed by general comments regarding program characteristics, eligibility, and so forth. Next is a review of the survey questions and the limitations associated with the question wording and design.

#### **FOOD STAMPS**

The Food Stamp Act of 1977 defines this Federally funded program as one intended to "permit low-income households to obtain a more nutritious diet." (From title XIII of P.L. 95-113, The Food Stamp Act of 1977, declaration of policy.) Food purchasing power is increased by providing eligible households with coupons which can be used to purchase food. The Food and Nutrition Service (FNS) of the U.S. Department of Agriculture (USDA) administers the Food Stamp program through State and local welfare offices. The Food Stamp program is the major national income support program to which all low-income and low-resource households, regardless of household characteristics, are eligible.

The Food Stamp Act was amended by the 1981 Omnibus Budget Reconciliation Act which changed the criteria used to determine food stamp eligibility (P.L. 97-35, title I, subtitle A). As of October 1, 1981, households without an elderly or disabled member must have gross monthly income below 130 percent of the Federal poverty level. Previously, eligibility was based on "countable" income (gross income less specified deductions for shelter, medical expenses, child care, etc.) so, e.g., a household with a gross income of twice the poverty guideline and substantial specified deductions could have been eligible for food stamps. Therefore, the data for 1982 reflect the new eligibility criteria. The asset (resources) limit was \$1,750 per household until July 1980, when it was changed to \$1.500. For households of two or more persons with at least one member 60 or over, the asset limit was \$3,000. This \$3,000 limit has not changed since 1979. The questions on participation in the Food Stamp program in the March CPS were designed to identify households in which one or more of the current members received food stamps during the calendar year. Once a food stamp household was identified, a question was asked to determine the number of current household members covered by food stamps during the year. Questions were also asked about the number of months food stamps were received and the total face value of all food stamps received during that period.

### **SCHOOL LUNCHES**

The National School Lunch program is designed "to help safeguard the health and well-being of the Nation's children by assisting the States in providing an adequate supply of foods" (P.L. 79-396, the National School Lunch Act of 1946) for all children at moderate cost. Additional assistance is provided for children determined by local school officials to be unable to pay the "full established" price for lunches. Like the Food Stamp program, the National School Lunch program is administered by the Food and Nutrition Service of the U.S. Department of Agriculture through State educational agencies or through regional USDA nutrition services for some nonprofit private schools.

All students eating lunches prepared at participating schools pay less than the total cost of the lunches. Some students pay the "full established" price for lunch (which itself is subsi-

income was between 125 and 195 percent of the poverty guidelines. The term "income" basically followed the Census Bureau definition but excluded certain Federal benefits and specified "hardship" expenses. Effective January 1, 1981, the hardship exclusion was replaced by a standard deduction. (Ref. Federal Register, Vol. 46, No. 11, January 16, 1981.) Beginning August 13, 1981, the income definition was amended to a gross income concept with the standard deduction being eliminated. At the same time, the income eligibility criteria were changed to 130 percent for free lunches and to 185 percent for reduced-price lunches. (Ref. Omnibus Budget Reconciliation Act of 1981, P.L. 97-35, title VIII.)

The questions on the March CPS provide a limited amount of data for the School Lunch program. Questions concerning the program were designed to identify the number of household members 5 to 18 years old who "usually" ate hot lunches during the year. This defined the universe of household members receiving this noncash benefit. This approach was necessary because the majority of children benefit indirectly, i.e., they pay full-established price but are not aware that these lunches are subsidized. A second question identified the number of members receiving free or

# PUBLIC OR OTHER SUBSIDIZED HOUSING

There are numerous programs designed to "remedy the unsafe and unsanitary housing conditions and the acute shortage of decent, safe, and sanitary dwellings for low-income families" (U.S. Housing Act of 1937, declaration of policy). Several Federal, State, and local agencies administer these programs. Some are funded by USDA (for rural families) or largely by State-local agencies but most are administered by the Department of Housing and Urban Development (HUD). Among the most important HUD rental housing programs are Low Rent Public Housing and Sections 8,

236, and 101 (rent supplements) of various U.S. Housing Acts.

Low Rent Public Housing projects are owned, managed, and administered by a local housing authority. Partial financing may be provided by the state or HUD. Participation in public housing is determined by two factors: program eligibility and the availability of housing. Income standards for initial and continuing occupancy vary by local housing authority, although the limits are constrained by Federal guidelines. Rental charges, which, in turn, define net benefits, are set by a Federal statute not to exceed 30 percent of adjusted monthly money income. A recipient household can either be a family or two or more related persons or an individual who is handicapped, elderly, or displaced by urban renewal or natural disaster. Other HUD programs provide similar types of housing assistance to low-income families and individuals.

Two of the more common types of programs in which Federal, State, and local funds are used to subsidize private sector rental housing are rent supplement and interest reduction plans. Under a rent supplement plan (e.g., Sections 8 and 101), the difference between the "fair market" rent and the rent charged to the tenant is paid to the owner by a government agency. Under an interest reduction program (e.g., Section 236), the amount of interest paid on the mortgage by the owner is reduced so that subsequent savings can be passed along to low-income tenants in the form of lower

rent changes.

There were two questions dealing with public and low-cost rental housing on the March CPS supplement questionnaire. The first question identified residence in a housing unit owned by a public agency. The second question identified beneficiaries who were not living in public housing projects but who were paying lower rent because of a government subsidy.

#### **MEDICAID**

The Medicaid program is designed to furnish medical assistance for needy families with dependent children and for aged, blind, or disabled individuals whose incomes and resources are insufficient to meet the costs of necessary medical services. The program is administered by State agencies through grants from the Health Care Financing Administration (HCFA) of the Department of Health and Human Services.

Medicaid is, for the most part, a categorical program with complex eligibility rules which vary from State to State. There are two basic groups of eligible individuals: the categorically eligible and the medically needy. The major categorically eligible groups are all Aid to Families

<sup>&</sup>lt;sup>1</sup>Taken from title XIX of the 1965 Amendments to P.L. 89-97, The Social Security Act, "Grants to States for Medical Assistance Programs," declaration of policy.

with Dependent Children (AFDC) recipients and most Supplemental Security Income (SSI) recipients.<sup>2</sup> Other categorically eligible groups are (1) those who meet basic State cash assistance eligibility rules (the aged, blind, or disabled; needy single parents with children; and, in some States, needy unemployed parents with children who are not currently receiving money payments) and (2) needy persons meeting categorical eligibility standards but are institutionalized for medical reasons (e.g., low-income elderly persons in nursing homes). Institutionalized persons are not included in the CPS universe and, therefore, are not reflected in the CPS recipiency statistics.

In 30 States, Medicaid coverage is also extended to the medically needy: persons meeting categorical age, sex, or disability criteria and having money incomes and assets which exceed eligibility levels for cash assistance but are not sufficient to meet the cost of medical care. Families with large medical expenses relative to their incomes and assets may also meet medically needy eligibility standards by "spending down" (i.e., having high enough medical expenses) to

obtain eligibility.

The Medicaid question on the March CPS attempted to identify all persons 15 years old and over who were covered by Medicaid at any time during the year. The term "covered" means enrolled in the Medicaid program, i.e., had a Medicaid medical assistance card or incurred medical bills which were paid for by Medicaid. In order to be counted, the person did not necessarily have to receive

medical care paid for by Medicaid.

After data collection and creation of an initial microdata file, further refinements were made to assign Medicaid coverage to children. In this procedure, all children under 21 years old in families were assumed to be covered by Medicaid if either the householder or spouse reported being covered by Medicaid. 3 AFDC recipients in all States and SSI recipients living in the 36 States which legally require Medicaid coverage of all SSI recipients were also assigned coverage. The data shown in this report exclude children covered by Medicaid in households where no adult member was covered. Because there are no administrative data which separately identify these recipients, the extent of the bias is unknown.

#### **MEDICARE**

The Medicare program consists of two separate but complementary health plans to provide adequate medical care for the aged and disabled. The Hospital Insurance Plan (Part A) is designed to provide basic protection against the costs of hospital and related post-hospital services. In addition to the elderly, this plan also covers virtually all persons under 65 years old who receive Social Security or Railroad Retirement benefits based on long-term disability. Part A is financed jointly by employers and employees through Social Security payroll deductions. Qualified persons 65 years old and over who are not otherwise eligible for Part A benefits may pay premiums directly to obtain this coverage. The Supplemental Medical Insurance Plan (Part B) is a voluntary plan which builds upon the hospital insurance protection provided by the basic plan and is available to all Medicare Part A beneficiaries. It provides insurance protection covering physicians' and surgeons' services and a variety of medical and other health services received either in hospitals or on an ambulatory basis. It is financed through monthly premium payments (about \$8.50 per month in 1979 and \$11.60 in 1982) by each enrollee and further subsidized by Federal general revenue funds.

The Medicare question on the March CPS attempted to identify all persons 15 years old and over who were covered by Medicare at any time during the year. The term "covered" means enrolled in the Medicare program. In order to be counted, the persons did not necessarily have to receive

medical care paid for by Medicare.

 $<sup>^2</sup>$ In 1981, Public Law 97-35 made several changes in AFDC eligibility determinations under the Medicaid program. Changes in treatment of earnings and other income and resources have resulted in some persons being dropped not only from the AFDC rolls but also off of automatic Medicaid coverage. Some of these individuals may be able to regain coverage if their State offers medically needy protection; however, the range of available benefits may be less.

 $<sup>^3</sup>$ This procedure was required mainly because the Medicaid coverage question was asked only for persons 15 years old and over.

## **Appendix E. Definitions and Explanations**

Population coverage. This report includes the civilian noninstitutional population of the United States (the 50 States and the District of Columbia) and members of the Armed Forces living off post or with their families on post, but excludes all other members of the Armed Forces.

Current poverty definition. Families and unrelated individuals are classified as being above or below the poverty level using the poverty index originated at the Social Security Administration in 1964 and revised by Federal Interagency Committees in 1969 and 1980. The poverty index is based solely on money income and does not reflect the fact that many low-income persons receive noncash benefits such as food stamps, Medicaid, and public housing. The index is based on the Department of Agriculture's 1961 Economy Food Plan and reflects the different consumption requirements of families based on their size and composition. It was determined from the Department of Agriculture's 1955 Survey of Food Consumption that families of three or more persons spend approximately one-third of their income on food; the poverty level for these families was, therefore, set at three times the cost of the economy food plan. For smaller families and persons living alone, the cost of the economy food plan was multiplied by factors that were slightly higher in order to compensate for the relatively larger fixed expenses of these smaller households. The poverty thresholds are updated every year to reflect changes in the Consumer Price Index (CPI). The average weighted poverty thresholds for 1979 to 1982 are shown in table E-1. The average annual Consumer Price Indexes for 1947 through 1982 are shown in table E-2.

The poverty definition was modified slightly in 1981 based on recommendations made by the Federal Interagency Committee. These revisions (1) eliminated distinctions made between families with a female householder, no husband present, and all other families; (2) eliminated the distinctive poverty levels used for nonfarm and farm residence categories; and (3) expanded the matrix of poverty levels to include 8-person families, and 9-or-more person families that previously had been limited to 7 persons or more.

An evaluation of the effect of this change showed that in 1980 the estimated poverty rate was 13.2 percent based on the revised definition compared to 13.0 percent using the definition prior to revision.

Money income. Total money income is the sum of the amounts received from wages and salaries, self-employment income (including losses), Social Security, Supplemental Security Income, public assistance, interest, dividends, rent, royalties, estates or trusts, veterans' payments, unemployment and workers' compensation, private and government retirement and disability pensions, alimony, child support, and any other source of money income which was regularly received. Capital gains (or losses) and lump sum or one-time payments such as life insurance settlements are excluded.

<u>Underreporting</u>. As in most household surveys, estimates from the March CPS of the number of money income recipients and the total amount of money income received are somewhat less than comparable estimates derived from independent sources, such as the Bureau of Economic Analysis, Social Security Administration, and Veterans Administration. The difference between the survey estimate and the independent estimate is generally termed "underreporting." Underreporting tends to be more pronounced for income sources such as public assistance and welfare, unemployment compensation, and property income (interest, dividends, and net rental income). Estimates of income from wages and salaries tend to have less underreporting than most income types. For further details concerning the reporting of cash income and noncash benefits, see appendix F.

In general it should be said that underreporting of money income and of noncash benefits result in the underestimation of money income, and therefore, an overestimate of the size of the

## Appendix F. Underreporting of Cash Income and Noncash Benefits

This appendix discusses some important aspects of underreporting and its measurement, and presents some estimates of underreporting for the base year 1979. The general survey phenomenon that is commonly termed underreporting actually refers to the tendency of household surveys to underestimate the number of income or noncash benefit recipients and/or the amount of income or benefits received. There are three main causes for underreporting. These are failure to report receipt of the income type, underreporting of the amount received, and misclassification of the income type received.

Accurately measuring the extent of underreporting of cash income and noncash benefits is difficult for many of the income types and noncash benefit programs. There are two main components of measuring underreporting: the number of income or noncash benefit recipients and the total amount of income or benefits received. Measuring the survey undercount of recipients for the March CPS is extremely difficult because independent estimates (benchmarks or controls) for the CPS noninstitutional, "ever-received during the year" recipient concept are difficult to validate. In addition, some of the administrative sources required for the derivation of independent estimates. mates have significant errors themselves.

The derivation of accurate underreporting estimates for amounts of income or noncash benefits is easier but still not without similar problems. In general, better administrative data are available on the annual amount of benefits received, or income earned, than recipients. Some of the more important problems associated with development of the independent controls for amounts are adjusting independent estimates to the CPS noninstitutional population, significant differences between alternate sources of independent estimates, especially for self-employment income, interest, dividends, and rents, and periodic revisions to the sources of independent estimates that delay availability of data and significantly alter estimates of underreporting. In the case of noncash benefits, the face value of food stamps was the only noncash benefit amount collected.

Shown in table F-1 are estimates of underreporting for amounts of cash income for 1979. Estimates for the years 1980 through 1982 are not available but are in preparation.

Estimates of the extent of underreporting for most noncash benefits are less well defined. Following are discussions of the underreporting for each benefit type.

Food Stamps. The March CPS estimate for the face value of food stamps received in 1979 was about \$4.9 billion, 79 percent of the independent estimate derived for that year. The 17.5 million recipient (persons covered) estimate for 1979 compares to a 22.8 million independent estimate of recipients. Since this independent estimate was developed using USDA monthly person recipiency counts and average months of participation as reported in the CPS, it is difficult to validate its accuracy.

School lunches. The March CPS data for 1979 show 10.3 million children usually eating free or reduced-price school lunches and 21.7 million usually eating full-price school lunches. Since independent estimates on the "ever-participated" universe are not available for this group, comparisons of the CPS estimates with peak monthly average daily participation have been made. These peak figures were 11.6 million for free or reduced-price lunches and 15.5 million for full-price lunches. The CPS estimate is 89 percent of the peak monthly average for free or reduced-price. The CPS estimate of full-price lunch participants was 140 percent of the peak monthly figure. The obvious conceptual differences between the CPS and USDA figures make these comparisons difficult to interpret.

Public or Other Subsidized Housing. In 1979 the March CPS estimate for the number of households residing in public or other subsidized rental housing was 2,573,000. An independent estimate was derived by summing housing units in (1) low-income public housing, (2) Section 8 (including

Section 202), (3) Rent supplements (Section 101), and (4) Section 236. This summing yielded a figure of 2,688,000. While the CPS estimate was about 96 percent of the independent figure, it is likely that the survey estimate contains some units, such as student or military housing, that were not intended to be counted. The magnitude of this problem is probably small, but unknown.

Medicare. The independent estimate for persons covered by Medicare is probably the most reliable of all independent estimates. In 1979, this figure was 27.1 million persons. This compares to a survey estimate of 26.2 million, 97 percent of the control. The survey count probably contains some persons covered by Medicaid that report coverage under Medicare by mistake. The magnitude of this misreporting problem is not known.

Medicaid. While the previous technical paper contained figures labeled independent estimates, the derivation of these estimates used a combination of administrative counts for persons "ever receiving" benefits and the March CPS "ever covered" figures. Because the derivation of the independent estimates should not be based, even partially, on the survey data, this comparison has not been made here. The CPS estimate of 18.5 million for 1979 was about 87 percent of the "unduplicated" administative figure of 21.5 million persons "ever receiving" benefits available from the Health Care Financing Administation (HCFA). This HCFA figure has not been adjusted for decedents or the institutionalized population and does not include persons who were covered by Medicaid but did not receive benefits in 1979.
