TABLE OF CONTENTS

Figure 9. Vertical section (a) and perspective view (b) of glass and interior shade layers showing variables used in the gap air flow analysis. In (b), the air-flow opening areas A_{bot} , A_{top} , A_l , A_r and A_h are shown schematically. See *Engineering Manual* for definition of thermal variables. 113

Figure 10. Examples of air-flow openings for an interior shade covering glass of height H and width W . Not to scale. (a) Horizontal section through shade with openings on the left and right sides (top view). (b) Vertical section through shade with openings at the top and bottom (side view). In (a) Left-Side Opening Multiplier = $A_l/sH = \min(l/s, 1)$ and Right-Side Opening Multiplier = $A_r/sH = \min(r/s, 1)$. In (b) Top Opening Multiplier = $A_{top}/sW = t/s$ and Bottom Opening Multiplier = $A_{bot}/sW = b/s$ 114

WindowMaterial:Blind..... 116

Figure 11. (a) Side view of a window blind with horizontal slats (or top view of blind with vertical slats) showing slat geometry. The front face of a slat is shown by a heavy line. The slat angle is defined as the angle between the glazing outward normal and the slat outward normal, where the outward normal points away from the front face of the slat. (b) Slat orientations for representative slat angles. The slat angle varies from 0° , when the front of the slat is parallel to the glazing and faces toward the outdoors, to 90° , when the slat is perpendicular to the glazing, to 180° , when the front of the slat is parallel to the glazing and faces toward the indoors. The minimum and maximum slat angles are determined by the slat thickness, width and separation. 123

Guidelines for Daylighting Modeling (Detailed Method)	384
Figure 46. For daylighting purposes the thermal zone enclosed by the dashed boundary line should be modeled as a typical zone (Room-1) with a zone multiplier of 4.	385
Figure 47. Rooms A, B, C and D have different daylighting characteristics. If lumped into a single thermal zone the daylighting calculation will be less accurate because the blockage of direct light by the interior walls between these rooms is modeled with some simplifications (see Interior Obstructions below). To get a good daylighting calculation each room should be input as a separate thermal zone.	385
Figure 48. Two independently-controlled lighting zones, each with 50% of the area of the thermal zone.	386
Figure 49. Wall A (or Wall B) is an interior obstruction that prevents light from directly reaching the daylighting reference point from the window.....	387

TABLE OF CONTENTS

Figure 50. Vertical section through a double-façade building showing daylighting through interior windows. The dashed lines show that (1) reference point RP1 receives direct light from exterior window EW1 via interior window IW1; (2) RP2 receives direct light from EW1 and EW2 via IW2; and (3) RP3 receives direct light from EW2 via IW3.....	388
Figure 51. General configuration of daylighting through interior windows that can be calculated with EnergyPlus. IW = interior window, EW = exterior window.	388

Input-Output Reference

This document is intended to be an encyclopedic reference for the EnergyPlus Input Data Dictionary (IDD), Input Data File (IDF) and potential resultant outputs (various output files).

The following descriptions are “grouped” by the elements in the IDD (ref: Getting Started Document and the IDD Conventions). In some cases, the descriptions of reporting will be done for an object (e.g. Lighting electrical consumption or thermal comfort value for a group of people) and in some cases for the entire group (e.g., ambient condition reports).

What's different about EnergyPlus Input and Output?

The usual procedure for non-interactive programs is to process all the input necessary to “do the job”, perform the actions required by the input, and somewhere along the way produce reports on the actions. Usually, there will be error messages on incorrect input statements and/or incorrect conditions detected during processing. Usually, the input is echoed in its entirety so that the context of errors is shown clearly.

Results are typically output into reports as well as a compilation of various inputs reformatted into different groupings than were originally entered (defaults filled in, etc.)

EnergyPlus does all the above. However, some nuances are different from the usual actions.

EnergyPlus Input Processing

- 1) EnergyPlus reads the data dictionary (Energy+.idd) and the input data file (in.idf) prior to doing anything else. Only after this is done does processing start. HOWEVER, the input processor only knows as much as the data dictionary has told it. It knows which fields should be alpha and which should be numeric. All of this information (including the IDD) is echoed to the audit file (audit.out) in case errors occur. Most of the errors show up (out of context) in the standard error file (eplusout.err) – there might be enough information to decipher where the error is or you may have to look at the more inclusive audit file. Invalid numeric fields are detected during this processing and default numeric fields are filled. For more information on the IDD, its structure and implications, please see the IDD Conventions discussion below.
- 2) The biggest difference between EnergyPlus and more traditional input processing is that EnergyPlus is modular in its actual filling in the details for the simulation. Because of the modular structure of EnergyPlus, each module is responsible for “getting” its own input. It receives this input from the input processor in the form of alpha and numeric fields. Each module typically gets all its input the first time it is called. The implication for the user is that error messages may show up in somewhat peculiar places. A further implication is that no order is needed in the input data file! Data that is not needed by a particular simulation is not processed.
- 3) The data dictionary has the capability to do “automatic” range checking on numeric fields as well as fill in numeric defaults. Both filling in defaults and “automatic” range checking are done when the data is read. Other checks may need a combination of fields and won't be done until the data is “processed” (after the simulation starts).
- 4) A couple of other differences that might not be true in other programs: Blanks are significant in alpha fields **SO** DesignDay is not the same as Design Day (1 space between Design and Day) nor Design Day (2 spaces between Design and Day). Alpha objects, however, *are* case insensitive SO DesignDay is the same as 'designday' or 'SizingPeriod:DesignDay'.

EnergyPlus Output Processing

- 1) Unlike the usual formatted output text formatted reports, EnergyPlus usual output is either at the summary or at the detailed (variable) level. Summary reports exist for many inputs as well as sizing results. The more detailed variable level reporting is produced as “stream of consciousness” (as the simulation happens) and must be post-processed for more sensible viewing.
- 2) Most EnergyPlus reporting can be readily viewed in current spreadsheet programs – or other software that can process “delimited variable” reports. In these kind of reports, each “column” is separated from the next by a “delimiter”. Typical delimiters are “comma” and “tab”. Gradually, EnergyPlus reporting is moving from all comma separated reports to allow the user to select the delimiter via “style” objects.
- 3) Styled reports allow for more selectable output reporting but also increase the number of output files as we have chosen to create the report names with extensions that typify the actual reporting. Depending on the reporting, these can be:
 - ✓ Tab – reports with a .tab extension have tabs as the delimiter. These report files (directly from EnergyPlus) will be named something like “eplus<xxx>.tab” where the <xxx> is a short name of the kind of report (e.g. Zsz for Zone Sizing, Map for Daylighting Map)
 - ✓ Csv – reports with a .csv extension have commas as the delimiter. These are also specially formatted for use in spreadsheets (such as the compilation of results from the eplusout.eso file into the eplusout.csv file using the default post-processor program).
 - ✓ Txt – reports with a .txt extension have spaces as the “delimiter” but only certain of these are really formatted the way you might expect: where multiple spaces make printing with a non-proportional font would produce readable output.
 - ✓ Html – reports with a .html extension are “web-browser” ready.

IDD Conventions

The following is a basic description of the structure of the IDD (it’s actually taken directly from the IDD file). As noted within, ! signifies a comment character as does the \. \ has also been adopted as a convention for including more specific comments about each field in an object. These have been used with success in the IDFEditor and it is hoped the flexibility will provide other interface developers with useful information.

```
!IDD_Version VERSION NUMBER
! *****
! This file is the Input Data Dictionary (IDD) for EnergyPlus.
! The IDD defines the syntax and data model for each type of input "Object."
!
! Object Description
! -----
! To define an object (a record with data), develop a key word that is unique
! Each data item to the object can be A (Alphanumeric string) or N (numeric)
! Number each A and N. This will show how the data items will be put into the
! arrays that are passed to the Input Processor "Get" (GetObjectItem) routines.
! All alpha fields are limited to 100 characters. Numeric fields should be
! valid numerics (can include such as 1.0E+05) and are placed into double
! precision variables.
!
! NOTE: Even though a field may be optional, a comma representing that field
! must be included (unless it is the last field in the object). Since the
! entire input is "field-oriented" and not "keyword-oriented", the EnergyPlus
! Input Processor must have some representation (even if blank) for each
! field.
!
```

```

! Object Documentation
! -----
! In addition, the following special comments appear one per line and
! most are followed by a value. Comments may apply to a field or the object
! or a group of objects.
!
! Field-level comments:
!
! \field      Name of field
!              (should be succinct and readable, blanks are encouraged)
!
! \note      Note describing the field and its valid values
!
! \required-field To flag fields which may not be left blank
!              (this comment has no "value")
!
! \units      Units (must be from EnergyPlus standard units list)
!              EnergyPlus units are standard SI units
!
! \ip-units   IP-Units (for use by input processors with IP units)
!              This is only used if the default conversion is not
!              appropriate.
!
! \minimum    Minimum that includes the following value
!
! \minimum>   Minimum that must be > than the following value
!
! \maximum    Maximum that includes the following value
!
! \maximum<   Maximum that must be < than the following value
!
! \default    Default for the field (if N/A then omit entire line)
!
! \deprecated This field is not really used and will be deleted from the object.
!              The information is gotten internally within the program.
!
! \autosizable Flag to indicate that this field can be used with the Auto
!              Sizing routines to produce calculated results for the
!              field. If a value follows this, then that will be used
!              when the "Autosize" feature is flagged. To trigger
!              autosizing for a field, enter Autosize as the field's
!              value. Only applicable to numeric fields.
!
! \autocalculatable Flag to indicate that this field can be automatically
!              calculated. To trigger auto calculation for a field, enter
!              Autocalculate as the field's value. Only applicable to
!              numeric fields.
!
! \type       Type of data for the field -
!              integer
!              real
!              alpha      (arbitrary string),
!              choice      (alpha with specific list of choices, see
!                          \key)
!              object-list (link to a list of objects defined elsewhere,
!                          see \object-list and \reference)
!
! \retaincase Retains the alphabetic case for alpha type fields
!
! \key        Possible value for "\type choice" (blanks are significant)
!              use multiple \key lines to indicate all valid choices
!
!

```

```

! \object-list      Name of a list of user-provided object names that are valid
entries
!                  for this field (used with "\reference")
!                  see Zone and BuildingSurface:Detailed objects below for
!                  examples.
!                  ** Note that a field may have only one \object-list reference.
!                  ** If it must reference more than one object-list, then a
!                  composite object-list should be created which contains all
!                  valid references.
!
! \reference        Name of a list of names to which this object belongs
!                  used with "\type object-list" and with "\object-list"
!                  see Zone and BuildingSurface:Detailed objects below for
!                  examples:
!
!                  Zone,
!                  A1 , \field Name
!                  \type alpha
!                  \reference ZoneNames
!
!                  BuildingSurface:Detailed,
!                  A4 , \field Zone Name
!                  \note Zone the surface is a part of
!                  \type object-list
!                  \object-list ZoneNames
!
!                  For each zone, the field "Name" may be referenced
!                  by other objects, such as BuildingSurface:Detailed, so it is
!                  commented with "\reference ZoneNames"
!                  Fields that reference a zone name, such as BuildingSurface:Detailed's
!                  "Zone Name", are commented as
!                  "\type object-list" and "\object-list ZoneNames"
!                  ** Note that a field may have multiple \reference commands.
!                  ** This is useful if the object belongs to a small specific
!                  object-list as well as a larger more general object-list.
!
! Object-level comments:
!
! \memo             Memo describing the object
!
! \unique-object    To flag objects which should appear only once in an idf
!                  (this comment has no "value")
!
! \required-object  To flag objects which are required in every idf
!                  (this comment has no "value")
!
! \min-fields       Minimum number of fields that should be included in the
!                  object.  If appropriate, the Input Processor will fill
!                  any missing fields with defaults (for numeric fields).
!                  It will also supply that number of fields to the "get"
!                  routines using blanks for alpha fields (note -- blanks
!                  may not be allowable for some alpha fields).
!
! \obsolete         This object has been replaced though is kept (and is read)
!                  in the current version.  Please refer to documentation as
!                  to the dispersal of the object.  If this object is
!                  encountered in an IDF, the InputProcessor will post an
!                  appropriate message to the error file.
!                  usage: \obsolete New=>[New object name]
!
! \extensible:<#>  This object is dynamically extensible -- meaning, if you
!                  change the IDD appropriately (if the object has a simple list
!                  structure -- just add items to the list arguments (i.e. BRANCH

```

```

! LIST). These will be automatically redimensioned and used during
! the simulation. <#> should be entered by the developer to signify
! how many of the last fields are needed to be extended (and EnergyPlus
! will attempt to auto-extend the object).
!
! \format          The object should have a special format when saved in
!                  the IDF Editor with the special format option enabled.
!                  The options include SingleLine, Vertices, CompactSchedule,
!                  FluidProperties, ViewFactors, and Spectral.
!                  The SingleLine option puts all the fields for the object
!                  on a single line. The Vertices option is used in objects
!                  that use X, Y and Z fields to format those three fields
!                  on a single line.
!                  The CompactSchedule formats that specific object.
!                  The FluidProperty option formats long lists of fluid
!                  properties to ten values per line.
!                  The ViewFactor option formats three fields related to
!                  view factors per line.
!                  The Spectral option formats the four fields related to
!                  window glass spectral data per line.
!
! Group-level comments:
!
! \group          Name for a group of related objects
!
!
! Notes on comments
! -----
!
! 1. If a particular comment is not applicable (such as units, or default)
! then simply omit the comment rather than indicating N/A.
!
! 2. Memos and notes should be brief (recommend 5 lines or less per block).
! More extensive explanations are expected to be in the user documentation

```

IDD – IP Units

In addition, the IDD contains indications of IP (inch-pound) units for the EnergyPlus standard SI (Systems International) units. These may be used by input and output interfaces to display values in the IP system. As noted, if the IP units are “standard” (first block below), then no \ip-units is expected in the field. Note that for some fields – due to their multiple use (for example, schedule values) – there cannot be a ip-unit designation.

```

! Default IP conversions (no \ip-units necessary)
! m => ft 3.281

```

In the descriptions below, you will see IDD snippets for each input object. The Site:Location object will serve as an example.

```

Site:Location,
  \unique-object
  \min-fields 5
A1 , \field Name
  \required-field
  \type alpha
N1 , \field Latitude
  \units deg
  \type real
N2 , \field Longitude
  \units deg
  \type real
N3 , \field Time Zone
  \units hr
  \type real
N4 ; \field Elevation
  \units m
  \type real

```

For the purposes of this example, the IDD snippet above is somewhat abbreviated from the true definition that you will find in the IDD file and below in the more complete description of the Location object.

First, the object name is given. (Site:Location) This is followed by a comma in both the definition (IDD) and in an input file (IDF). In fact, all fields except the terminating field of an

IDD class object and IDF object are followed by commas. The final field in an IDD class object or in an IDF object is terminated by a semi-colon.

Next is an alpha field, the location name. As noted above, for input, spaces are significant in this field. The main inputs for Site:Location are numeric fields. These are numbered (as is the alpha field) for convenience. The \ designations will show various information about the objects as described above in the IDD conventions discussion. Of importance for reading this document are the units and possible minimum and maximum values for a field.

There is automatic processing of the \minimum, \maximum and \default data for numeric fields. Any infractions of the \minimum, \maximum fields are automatically detected and messages will appear in the standard error file. After all the input is checked, infractions will cause program termination (before the bulk of the simulation is completed). Defaults are also enforced if you leave the numeric field blank.

Some objects need all the parameters listed by the definition; some do not. In the descriptions that follow, we will try to indicate which parts are optional. Usually, these will be the last fields in the object input or definition. Even if items are not used for a particular object (e.g. Multiplier in the FenestrationSurface:Detailed and type=Door), the field must be included unless it is the *last field in the object*. So, for this instance, one must include a multiplier field (must be numeric and would need to obey any \minimum, \maximum rules) for doors.

Group – Simulation Parameters

This group of objects influences the simulation in various ways.

Version

Field: Version Identifier

The Version object allows you to enter the proper version that your IDF was created for. This is checked against the current version of EnergyPlus and a Severe error issued (non-terminating) if it does not match the current version string.

```
Version,
  \unique-object
  \format singleLine
A1 ; \field Version Identifier
  \required-field
```

Timestep

Field: Number of Timesteps per Hour

The Timestep object specifies the "basic" timestep for the simulation. The value entered here is usually known as the Zone Timestep. This is used in the Zone Heat Balance Model calculation as the driving timestep for heat transfer and load calculations. The value entered here is the number of timesteps to use within an hour. Longer length timesteps have lower values for Number of Timesteps per Hour. For example a value of 6 entered here directs the program to use a zone timestep of 10 minutes and a value of 60 means a 1 minute timestep. The user's choice for Number of Timesteps per Hour must be evenly divisible into 60; the allowable choices are 1, 2, 3, 4, 5, 6, 10, 12, 15, 20, 30, and 60.

The choice made for this field has important implications for modeling accuracy and the overall time it takes to run a simulation. Here are some considerations when choosing a value:

- The solution technique used in EnergyPlus has been designed to be stable with zone timesteps of up to sixty minutes (Number Timesteps in Hour = 1). However, 60 minutes is considered a "long" timestep and it should only be used in rare occasions where there is no HVAC system, accuracy is not a concern, and short run times are critical. Such long timesteps are not recommended to use because simulation results are more accurate for shorter timesteps, of say 10 minutes or less (Number of

Timesteps per Hour of 6 or more). Shorter zone timesteps improve the numerical solution of the Zone Heat Balance Model because they improve how models for surface temperature and zone air temperature are coupled together. Longer timesteps introduce more lag and lead to more a dampened dynamic response.

- Simulation run time increases with shorter timesteps or larger values for Number of Timesteps per Hour. The effect varies with the nature of the model. The user can test out different values on their particular model to understand the implications for his or her particular case. Sometimes large models with multizone HVAC and Plant systems execute nearly as fast with 15 minute timesteps as with 60 minute timesteps because fewer iterations are required in the system modeling since the prior timestep's results are close to the final outcome of next timestep.
- The weather data files usually have 60-minute data. However, it does not follow that this should be used as the basis for choosing the zone timestep because:
 - EnergyPlus carefully interpolates the weather data between data points for use at shorter timesteps. This is discussed in a later section: Weather Data Hourly Interpolation
 - Many aspects of a model have time scales that differ from the that of the weather data. A goal of the modeling is to predict how the building will respond to the weather. However, the building's response is not *governed* by the time scale that the weather data are available at, but rather the time scales of the dynamic performance of the thermal envelope as well as things like schedules for internal gains, thermostats, and equipment availability.
- If the model will include calculating the cost of electricity, then the user should be aware that many electric utility tariffs base charges on demand windows of a specified length of time. If the choice of Number of Timesteps per Hour is not consistent with the demand window, then unexpected results may be obtained. For reasonable prediction of the maximum rates for electricity use for in calculating demand charges, the length of the zone timestep needs to be consistent with the tariff's demand window. The following table lists what values are consistent with various demand windows.

Demand Window	Applicable Number of Timesteps per Hour
QuarterHour	4, 12, 20, or 60
HalfHour	2, 4, 6, 10, 12, 20, 30, or 60
FullHour, Day, Week	Any

There is also second type of timestep inside EnergyPlus that is known as the System Timestep. This is a variable-length timestep that governs the driving timestep for HVAC and Plant system modeling. The user cannot directly control the system timestep (except by use of the ConvergenceLimits object). When the HVAC portion of the simulation begins it's solution for the current zone timestep, it uses the zone timestep as its maximum length but then can reduce the timestep, as necessary, to improve the solution. The technical details of the approach are explained in the Engineering Documentation under "Integrated Solution Manager".

Users can see the system timestep used if they select the "detailed" frequency option on an HVAC report variable (e.g. Zone/Sys Air Temperature). To contrast, the "Zone" variables will only be reported on the zone timestep (e.g. Zone Mean Air Temperature).

```

Timestep,
  \unique-object
  \format singleLine
N1 ; \field Number of Timesteps per Hour
  \required-field
  \note Number in hour: normal validity 4 to 60: 6 suggested
  \note Must be evenly divisible into 60
  \note Allowable values include 1, 2, 3, 4, 5, 6, 10, 12, 15, 20, 30, and 60
  \note Normal 6 is minimum as lower values may cause inaccuracies
  \note A minimum value of 20 is suggested for both ConductionFiniteDifference
  \note and CombinedHeatAndMoistureFiniteElement surface heat balance algorithms
  \note
  \default 6
  \type integer
  \minimum 1
  \maximum 60

```

And, the IDF example:

```
Timestep, 6; !Suggested default for most system simulations
```

Suggested defaults are 4 for non-HVAC simulations, 6 for simulations with HVAC, 20 is the minimum for ConductionFiniteDifference and HeatAndMoistureFiniteElement simulations.

Note that hourly data (such as outdoor conditions expressed by Design Days or Weather data) are interpolated to the Zone Timestep. This is discussed in a later section: Weather Data Hourly Interpolation

ConvergenceLimits

This item is an “advanced” feature that should be used only with caution. It is specifically included to assist some users “speed up” calculations while not overly compromising accuracy. The user must judge for him/herself whether the reduced run time is useful.

Field: Minimum System Timestep

Usually the minimum system timestep is allowed to vary from the zone timestep (as maximum) to a minimum timestep of 1 minute during certain system calculations. This might be when the system turns on or off, for example. Entering 0 in this field sets the minimum system timestep to be the same as the zone timestep. Otherwise the units of the field are minutes. It’s probably a good idea to have any minimum entered be a divisor of the zone timestep.

Field: Maximum HVAC Iterations

The HVAC Manager will iterate to a solution or up to a set number of iterations. If not “converged”, then a warning error appears:

```
** Warning ** SimHVAC: Maximum iterations (20) exceeded for all HVAC loops, at CHICAGO IL USA TMY2-94846 WMO#=725300, 10/07 14:06 - 14:08
```

In order to reduce time used in simulating your building, you may choose to enter a lesser number than the default of 20 for the maximum number of iterations to be used. Or, you may wish to enter a bigger number for certain buildings. To get more information printed with a “max iteration” message, you need to enter a “Diagnostics, DisplayExtraWarnings;” command (which may also generate other warnings than just this one).

The IDD for the object:

```

ConvergenceLimits,
  \unique-object
N1 , \field Minimum System Timestep
     \units minutes
     \type integer
     \note 0 sets the minimum to the zone timestep (ref: Timestep)
     \note 1 is normal (ratchet down to 1 minute)
     \note setting greater than zone timestep (in minutes) will effectively set to zone timestep
     \minimum 0
     \maximum 60
N2 ; \field Maximum HVAC Iterations
     \type integer
     \default 20
     \minimum 1

```

and in use in an IDF:

```

ConvergenceLimits,
0;           ! Minimum System Timestep (0=same as zone timestep)

```

Building

The Building object describes parameters that are used during the simulation of the building. There are necessary correlations between the entries for this object and some entries in the Site:WeatherStation and Site:HeightVariation objects, specifically the Terrain field.

Field: Building Name

Building name is specified for output convenience.

Field: North Axis

The Building North Axis is specified **relative to true North**. Buildings frequently do not line up with true north. For convenience, one may enter surfaces in a “regular” coordinate system and then shift them via the use of the North Axis. The value is specified in degrees from “true north” (clockwise is positive).

The figure below shows how the building north axis can be rotated to correspond with one of the major axes of an actual building. The relevance of this field is described more completely under “GlobalGeometryRules”; in particular, the value of “North Axis” is *ignored* if a coordinate system other than “relative” is used.

Figure 1. Illustration of Building North Axis

Field: Terrain

The site’s terrain affects how the wind hits the building – as does the building height. In addition, the external conduction method usually has its own parameters for the calculation. Please see the Engineering Documentation, External Conduction section for particulars. The legal values for this field are shown in the following table.

Table 1. Values for "Terrain"

Terrain Type Value	Terrain Description
Country	Flat, Open Country
Suburbs	Rough, Wooded Country, Suburbs
City	Towns, city outskirts, center of large cities
Ocean	Ocean, Bayou flat country
Urban	Urban, Industrial, Forest

Field: Loads Convergence Tolerance Value

This value represents the number at which the loads values must agree before “convergence” is reached. Loads tolerance value is a fraction of the load.

Field: Temperature Convergence Tolerance Value

This value represents the number at which the zone temperatures must agree (from previous iteration) before "convergence" is reached. (Units for this field is delta C).

Convergence of the simultaneous heat balance/HVAC solution is reached when either the loads or temperature criterion is satisfied.

All tolerances have units so the temperature tolerance is in degrees C (or degrees K) and the loads tolerance is in Watts. Both tolerances work the same way, just one looks at temperatures and one looks at heating and cooling loads. After the second warm-up day, the program compares the maximum temperature experienced in a space with the maximum temperature from the previous day. If those two temperatures are within the tolerance, then it has passed the first warm-up check.

It does a similar comparison with lowest temperatures experience within all the zones. If the current simulation day and the previous day values are within the tolerance, then it has passed the second warm-up check. Similar things are done with the loads tolerance and the maximum heating and cooling loads that are experienced within the spaces. Those are compared individually to the values for the previous day. If they are both in tolerance, then the simulation has passed the third and fourth warm-up check. The simulation stays in the warm-up period until ALL FOUR checks have been passed.

Please note--other "convergence tolerance" inputs are required for certain HVAC equipment (unit ventilator, unit heater, window AC, etc.). The purpose and units of these parameters are different from "load convergence tolerance" and "temperature convergence tolerance" in the BUILDING object.

Field: Solar Distribution

Setting this value determines how EnergyPlus treats beam solar radiation and reflectances from exterior surfaces that strike the building and, ultimately, enter the zone. There are five choices: **MinimalShadowing**, **FullExterior** and **FullInteriorAndExterior**, **FullExteriorWithReflections**, **FullInteriorAndExteriorWithReflections**.

MinimalShadowing

In this case, there is no exterior shadowing except from window and door reveals. All beam solar radiation entering the zone is assumed to fall on the floor, where it is absorbed according to the floor's solar absorptance. Any reflected by the floor is added to the transmitted diffuse radiation, which is assumed to be uniformly distributed on all interior surfaces. If no floor is present in the zone, the incident beam solar radiation is absorbed on all interior surfaces according to their absorptances. The zone heat balance is then applied at each surface and on the zone's air with the absorbed radiation being treated as a flux on the surface.

FullExterior, FullExteriorWithReflections

In this case, shadow patterns on exterior surfaces caused by detached shading, wings, overhangs, and exterior surfaces of all zones are computed. As for MinimalShadowing, shadowing by window and door reveals is also calculated. Beam solar radiation entering the zone is treated as for MinimalShadowing -- All beam solar radiation entering the zone is assumed to fall on the floor, where it is absorbed according to the floor's solar absorptance. Any reflected by the floor is added to the transmitted diffuse radiation, which is assumed to be uniformly distributed on all interior surfaces. If no floor is present in the zone, the incident beam solar radiation is absorbed on all interior surfaces according to their absorptances. The zone heat balance is then applied at each surface and on the zone's air with the absorbed radiation being treated as a flux on the surface.

FullInteriorAndExterior, FullInteriorAndExteriorWithReflections

This is the same as FullExterior except that instead of assuming all transmitted beam solar falls on the floor the program calculates the amount of beam radiation falling on each surface in the zone, including floor, walls and windows, by projecting the sun's rays through the

exterior windows, taking into account the effect of exterior shadowing surfaces and window shading devices.

If this option is used, you should be sure that the surfaces of the zone totally enclose a space. This can be determined by viewing the **epplusout.dxf** file with a program like AutoDesk's Volo View Express. You should also be sure that the zone is **convex**. Examples of convex and non-convex zones are shown in Figure 2. The most common non-convex zone is an L-shaped zone. (A formal definition of convex is that any straight line passing through the zone intercepts at most two surfaces.) If the zone's surfaces do not enclose a space or if the zone is not convex you should use Solar Distribution = **FullExterior** instead of **FullInteriorAndExterior**.

If you use **FullInteriorAndExterior** the program will also calculate how much beam radiation falling on the inside of an exterior window (from other windows in the zone) is absorbed by the window, how much is reflected back into the zone, and how much is transmitted to the outside. In this calculation the effect of a shading device, if present, is accounted for.

Figure 2. Illustration of Convex and Non-convex Zones

Reflection calculations

Note: Using the reflection calculations can be very time-consuming. Even error-prone. As a possible alleviation, you can use the Output:Diagnostics,DoNotMirrorDetachedShading; in many cases to get past a fatal error.

If using reflections, the program calculates beam and sky solar radiation that is reflected from exterior surfaces and then strikes the building. These reflecting surfaces fall into three categories:

- (1) **Shadowing surfaces.** These are surfaces like overhangs or neighboring buildings entered with Surface Shading:Site:Detailed, Shading:Building:Detailed, or Shading:Zone:Detailed. See Figure 3.
- (2) These surfaces can have diffuse and/or specular (beam-to-beam) reflectance values that are specified with the Shading Surface Reflectance object (ref: ShadingProperty:Reflectance).
- (3) **Exterior building surfaces.** In this case one section of the building reflects solar radiation onto another section (and vice-versa). See Figure 4.
- (4) The building surfaces are assumed to be diffusely reflecting if they are opaque (walls, for example) and specularly reflecting if they are windows or glass doors. The reflectance values for opaque surfaces are calculated by the program from the Solar Absorptance and Visible Absorptance values of the outer material layer of the surface's

construction (ref: Material properties). The reflectance values for windows and glass doors are calculated by the program from the reflectance properties of the individual glass layers that make up surface's construction assuming no shading device is present and taking into account inter-reflections among the layers (ref: Window Properties).

- (5) **The ground surface.** Reflection from the ground is calculated even if reflections option is not used. But in this case the ground plane is considered unobstructed, i.e., the shadowing of the ground by the building itself or by obstructions such as neighboring buildings is ignored. This shadowing is taken into account if the reflections option is used.¹ This is shown in Figure 5.

Figure 3. Solar reflection from shadowing surfaces. Solid arrows are beam solar radiation; dashed arrows are diffuse solar radiation. (a) Diffuse reflection of beam solar radiation from the top of an overhang. (b) Diffuse reflection of sky solar radiation from the top of an overhang. (c) Beam-to-beam (specular) reflection from the façade of an adjacent highly-glazed building represented by a vertical shadowing surface.

Figure 4. Solar reflection from building surfaces onto other building surfaces. In this example beam solar reflects from a vertical section of the building onto a roof section. The reflection from the window is specular. The reflection from the wall is diffuse.

¹ If reflections option is used for the ground surface then the ground view factor is NOT used.

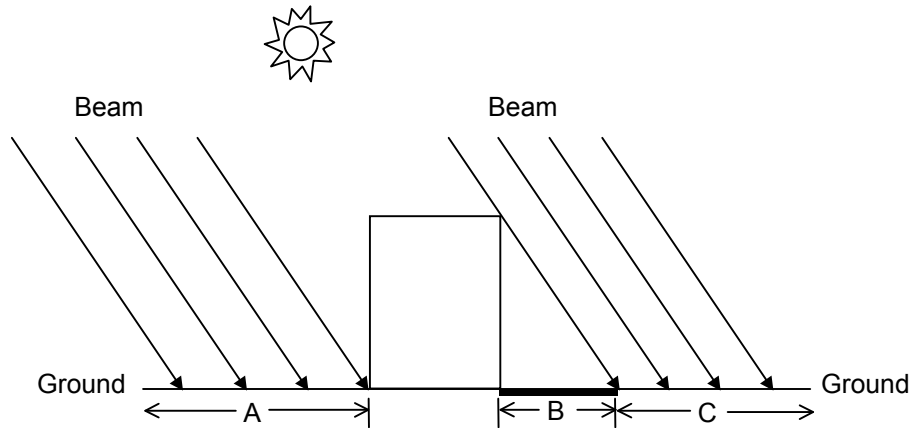

Figure 5. Shadowing from building affects beam solar reflection from the ground. Beam-to-diffuse reflection from the ground onto the building occurs only for sunlit areas, A and C, not from shaded area, B.

Field: Maximum Number of Warmup Days

This field specifies the number of “warmup” days that might be used in the simulation before “convergence” is achieved. The default number, 25, is usually more than sufficient for this task; however, some complex buildings (with complex constructions) may require more days. A warning message will occur when the simulation “runs” out of days:

```
Loads Initialization did not Converge (CheckWarmupConvergence)
```

You may be able to increase the Maximum Number of Warmup Days and get convergence, but some anomalous buildings may still not converge. Simulation proceeds for x warmup days until “convergence” is reached (see the discussion under the Temperature Convergence Tolerance Value field in this object, just above).

SurfaceConvectionAlgorithm:Inside

Three interior convection models may be selected for global use. The simple natural convection model applies constant heat transfer coefficients depending on the surface orientation. The detailed natural convection model correlates the heat transfer coefficient to the temperature difference for various orientations. This model is based on flat plate experiments. The third model is a mixed and forced convection model for ceiling diffuser

configurations. The model correlates the heat transfer coefficient to the air change rate for ceilings, walls and floors. These correlations are based on experiments performed in an isothermal room with a cold ceiling jet.

To avoid discontinuities in surface heat transfer rate calculations, all of correlations have been extrapolated beyond the lower limit of the data set (3 ACH) to a natural convection limit that is applied during the hours when the system is off. These models are explained in detail in the EnergyPlus Engineering Reference Document.

Field: Algorithm

The model specified in this field is the default algorithm for all zones. The optional Zone Inside Convection Algorithm field in the Zone object may be used to selectively override this value on a zone-by-zone basis.

```

IDF Example:

```
SurfaceConvectionAlgorithm:Inside,Detailed;
```

SurfaceConvectionAlgorithm:Outside

Field: Algorithm

Six exterior convection models may be selected in EnergyPlus. The simple convection model applies heat transfer coefficients depending on the roughness and windspeed. This is a combined heat transfer coefficient that includes radiation to sky, ground, and air. The correlation is based on Figure 1, Page 25.1 (Thermal and Water Vapor Transmission Data), 2001 ASHRAE Handbook of Fundamentals.

All other convection models apply heat transfer coefficients depending on the roughness, windspeed, and terrain of the building's location. These are *convection only* heat transfer coefficients; radiation heat transfer coefficients are calculated automatically by the program. All algorithms are described more fully in the Engineering Reference.

Note that when the surface is wet (i.e. it is raining and the surface is exposed to wind) then the convection coefficient appears as a very large number (1000) and the surface is exposed to the Outdoor Wet-bulb Temperature rather than the Outdoor Dry-bulb Temperature.

```

HeatBalanceAlgorithm

The HeatBalanceAlgorithm object provides a way to select what type of heat and moisture transfer algorithm will be used across the building construction calculations.

Field: Algorithm

Four values are allowed to select which solution will be used. The **ConductionTransferFunction** selection is a sensible heat only solution and does not take into account moisture storage or diffusion in the construction elements. The **MoisturePenetrationDepthConductionTransferFunction** selection is a sensible heat diffusion and an inside surface moisture storage algorithm that also needs additional moisture material property information. See the appropriate moisture material property objects for additional information. **Advanced/Research usage: The ConductionFiniteDifference selection is a sensible heat only solution and does not take into account moisture storage or diffusion in the construction elements. This solution technique uses a 1-D finite difference solution in the construction elements.**

Advanced/Research usage: The CombinedHeatAndMoistureFiniteElement is a coupled heat and moisture transfer and storage solution. The solution technique uses a one dimensional finite difference solution in the construction elements and requires further material properties described in the Heat and Moisture Transfer material properties objects.

Field: Surface Temperature Upper Limit

This field is a bit “advanced”. It should only be used when the simulation fails AND you cannot determine a cause for the failure. That is, you receive an error similar to:

```

** Severe  ** Temperature out of bounds (202.91) for surface=Wall11
**   ~~~  ** in Zone=Zone01
**   ~~~  ** Occurrence info=NEW YORK CITY NY SUMMER, 07/21 16:00 - 16:01
**   ~~~  ** A temperature out of bounds problem can be caused by several things. The user
**   ~~~  ** should check the weather environment, the level of internal gains with respect
**   ~~~  ** to the zone, and the thermal properties of their materials among other things.
**   ~~~  ** A common cause is a building with no thermal mass -- all materials with
**   ~~~  ** Regular-R definitions.

```

And, after careful perusal, you cannot find a solution as suggested in the error description. You may then want to enter a higher number than the default for this field.

ShadowCalculation

In order to speed up the calculations, shadowing calculations (sun position, etc) are performed over a period of days. Note that this value may be very important for determining the amount of sun entering your building and by inference the amount of cooling or heating load needed for maintaining the building. Though termed “shadowing” calculations, it in affect determines the sun position for a particular day in a weather file period simulation. (Each design day will use the date of the design day object). Even though weather file data contains the amount of solar radiation, the internal calculation of sun position will govern how that affect various parts of the building. By default, this is every 20 days throughout a weather run period.

Field: Calculation Frequency

This numeric field will cause the shadowing calculations to be done periodically using the number in the field as the number of days in each period. Using this field will allow you to synchronize the shadowing calculations with changes in shading devices. Using the default of 20 days in each period is the average number of days between significant changes in solar position angles.

Field: Maximum Figures in Shadow Overlap Calculations

This numeric field will allow you to increase the number of figures in shadow overlaps. Due to the shadowing algorithm, the number of shadows in a figure may grow quite large even with fairly reasonable looking structures. Of course, the inclusion of more allowed figures will increase calculation time. Likewise, too few figures may not result in as accurate calculations as you desire.

```
ShadowCalculation,
  \unique-object
  N1 , \field Calculation Frequency
      \required-field
      \type integer
      \minimum 1
      \default 20
      \note 0=Use Default Periodic Calculation|<else> calculate every <value> day
      \note only really applicable to RunPeriods
  N2 ; \field Maximum Figures in Shadow Overlap Calculations
      \note Number of allowable figures in shadow overlap calculations
      \type integer
      \minimum 200
      \default 15000
```

If shadowing surfaces are used with the transmittance property, the user should be careful to synchronize this calculation with the scheduled occurrence of the transmittance (if any) (or use 1, which will be the most accurate but will cause more time in the calculations). Example:

```
ShadowCalculation,1;
```

Output:Diagnostics

Sometimes, messages only confuse users – especially new users. Likewise, sometimes certain report variables exist for only a certain condition but some take them at face value/name. Some features may be very important but under certain instances cause problems. Thus, we have added the **diagnostic output** object to be able to turn on or off certain messages, variables, and features depending on conditions.

Both fields of the Output:Diagnostics command can accept all the applicable keys. More than one object may be entered.

Field: *key1*, *key2*

Allowable choices are:

DisplayAllWarnings – use this to get all warnings (except the developer warnings “DisplayZoneAirHeatBalanceOffBalance”). This key sets all other display warning values to on.

DisplayExtraWarnings – use this to get all extra warnings. An example of an extra warning is when a user enters a ceiling height or volume with the Zone object and EnergyPlus calculates something significantly different based on the entered zone geometry.

DisplayUnusedSchedules – use this to have the unused schedules (by name) listed at the end of the simulation.

DisplayUnusedObjects – use this to have unused (orphan) objects (by name) listed at the end of the simulation.

DisplayAdvancedReportVariables – use this to be able to use the “Opaque Surface Inside Face Conduction” – the name may be misleading to some. If you put in this field, then you will be able to report on this variable.

DisplayZoneAirHeatBalanceOffBalance – this is a developer diagnostic which you can turn on, if you desire.

DoNotMirrorDetachedShading – use this to turn off the automatic mirroring of detached shading surfaces. These surfaces are automatically mirrored so that the user does not need to worry about facing direction of the surface and the shading surface will shade the building as appropriate. Note that Shading:Zone:Detailed surfaces are also mirrored and there is no way to turn that “off”.

ReportDuringWarmup – use this to allow reporting during warmup days. This can show you exactly how your facility is converging (or not) during the initial “warmup” days of the simulation. Generally, only developers or expert simulation users would need this kind of detail.

The IDD for the object follows:

```

Output:Diagnostics,
  A1 , \field Key 1
      \type choice
      \key DisplayAllWarnings
      \key DisplayExtraWarnings
      \key DisplayUnusedSchedules
      \key DisplayUnusedObjects
      \key DisplayZoneAirHeatBalanceOffBalance
      \key DisplayAdvancedReportVariables
      \key DoNotMirrorDetachedShading
  A2 ; \field Key 2
      \type choice
      \key DisplayAllWarnings
      \key DisplayExtraWarnings
      \key DisplayUnusedSchedules
      \key DisplayUnusedObjects
      \key DisplayZoneAirHeatBalanceOffBalance
      \key DisplayAdvancedReportVariables
      \key DoNotMirrorDetachedShading

```

In IDF use:

```

Output:Diagnostics,
  DisplayExtraWarnings;

```

Output:PreprocessorMessage

The Output:PreprocessorMessage object can be used by preprocessor programs to EnergyPlus for passing certain conditions/errors that might not be detected by scripts executing the EnergyPlus system of programs. This allows EnergyPlus to intercept problems and terminate gracefully rather than the user having to track down the exact conditions.

There is no reason for a user to enter a Output:PreprocessorMessage object but you should encourage interface developers to use this feature. More than one Output:PreprocessorMessage objects may be entered. Of course, no preprocessor message objects are necessary if there is no error information to be passed.

```

P Output:PreprocessorMessage,
  \memo This object does not come from a user input. This is generated by a pre-processor
  \memo so that various conditions can be gracefully passed on by the InputProcessor.
  A1, \field Preprocessor Name
      \retaincase
  A2, \field Error Severity
      \note Depending on type, InputProcessor may terminate the program.
      \type choice
      \key Information
      \key Warning
      \key Severe
      \key Fatal
      \retaincase
  A3, \field Message Line 1
      \retaincase
<reduced for brevity - 10 lines currently allowed>

```

Field: Preprocessor Name

The preprocessor name (e.g. EPMacro, ExpandObjects) is entered here. Case is retained so that messages from EnergyPlus look very similar to what a preprocessor would produce.

Field: Error Severity

This is the error severity. If Fatal, EnergyPlus will terminate after showing all preprocessor messages.

Fields: Message Line 1 through Message Line 10

Each line is limited to 100 characters and an appropriate message can be composed.

An IDF Example:

```
Output:PreprocessorMessage,
  No Preprocessor Used,      !- preprocessor name
  Information,               !- error severity
  Illustrative Message,     !- message line 1
  No problems for processing; !- message line 2
```

And would appear in output:

```
***** Preprocessor="No Preprocessor Used" has the following Information messages:
**   ~~~   ** Illustrative Message
**   ~~~   ** No problems for processing
```

ZoneCapacitanceMultiplier

ZoneCapacitanceMultiplier = 1.0 is the capacitance of the air in the volume of the specified zone. This multiplier can be increased if the zone air capacitance needs to be increased for stability of the simulation.

```
ZoneCapacitanceMultiplier,
  \unique-object
  \format singleLine
  N1 ; \field Multiplier
  \type real
  \default 1.0
  \minimum 0.0
  \note Used for stability in predictor-corrector step by increasing air heat capacity of the zone air.
```

One of the few EnergyPlus defaulted items. If not defined, ZoneCapacitanceMultiplier defaults to 1.0.

SimulationControl

The input for SimulationControl allows the user to specify what kind of calculations a given EnergyPlus simulation will perform. For instance the user may want to perform one or more of the sizing calculations but not proceed to a annual weather file simulation. Or the user might have all flow rates and equipment sizes already specified and desire an annual weather without any preceding sizing calculations. The SimulationControl input allows all permutations of run selection by means of 5 yes/no inputs.

Only one SimulationControl object is permitted for each EnergyPlus input file. While a SimulationControl is needed to trigger sizing calculations, it is optional for other runs (design days, run periods). The actions will still be shown in the eplusout.eio file (see Output Details and Examples Document).

Field: Do Zone Sizing Calculation

Input is Yes or No. The default is No.

Field: Do System Sizing Calculation

Input is Yes or No. The default is No.

Field: Do Plant Sizing Calculation

Input is Yes or No. The default is No.

Field: Run Simulation for Sizing Periods

Input is Yes or No. The default is Yes. Yes implies that the simulation will be run on all the included SizingPeriod objects (i.e., SizingPeriod:DesignDay, SizingPeriod:WeatherFileDays, and SizingPeriod:WeatherFileConditionType)

Field: Run Simulation for Weather File Run Periods

Input is Yes or No. The default is Yes. Yes implies the simulation will be run on all the included RunPeriod objects.

The full IDD specification follows:

```
SimulationControl,
  \unique-object
  A1, \field Do Zone Sizing Calculation
      \type choice
      \key Yes
      \key No
      \default No
  A2, \field Do System Sizing Calculation
      \type choice
      \key Yes
      \key No
      \default No
  A3, \field Do Plant Sizing Calculation
      \type choice
      \key Yes
      \key No
      \default No
  A4, \field Run Simulation for Sizing Periods
      \type choice
      \key Yes
      \key No
      \default Yes
  A5; \field Run Simulation for Weather File Run Periods
      \type choice
      \key Yes
      \key No
      \default Yes
```

An IDF example:

```
SimulationControl,
  Yes, !zone sizing
  No, ! system sizing
  No, ! plant sizing
  No, ! design day full simulation
  No; ! weather file full simulation
```

MeterCustom

A custom meter allows the user to group variables or meters onto a virtual meter that can be used just like a normal meter created by EnergyPlus. For consistency, the items being grouped must all be similar.

Field: Name

This is a user defined name for the custom meter.

Field: Fuel Type

A fuel type should be specified for the meter. All assignments to this meter will be checked to assure that the same fuel type is used. Additionally, this may be used in other objects (such as the Demand Limiting). Valid choices for this field are:

- Electricity
- NaturalGas
- PropaneGas
- FuelOil#1
- FuelOil#2
- Coal
- Diesel
- Gasoline
- Water

- Generic

Fuel types are generally self-explanatory. Generic is included for convenience when a custom meter is defined that doesn't quite fit the "fuel" categories. See the examples below.

Field: group(s) Key Name-Report Variable/Meter Name

The rest of the object is filled with parameters of the key name/report variable or meter names. When a meter name is used, the key name field is left blank.

Field: Key Name #

A key name field is used when the following field specifies a report variable. If the field is left blank, then all the report variables in the following field are assigned to the meter.

Field: Report Variable or Meter Name #

This field must be a valid report variable name or a valid meter name.

The full IDD specification is:

```

Meter:Custom,
  \extensible:2 - repeat last two fields, remembering to remove ; from "inner" fields.
  \memo Used to allow users to combine specific variables and/or meters into
  \memo "custom" meter configurations.
  A1, \field Name
      \required-field
      \reference CustomMeterNames
  A2, \field Fuel Type
      \type choice
      \key Electricity
      \key NaturalGas
      \key PropaneGas
      \key FuelOil#1
      \key FuelOil#2
      \key Coal
      \key Diesel
      \key Gasoline
      \key Water
      \key Generic
  A3, \field Key Name 1
  A4, \field Report Variable or Meter Name 1
  A5, \field Key Name 2
  A6, \field Report Variable or Meter Name 2
  A7, \field Key Name 3
  A8, \field Report Variable or Meter Name 3
  <reduced for brevity>

```

Meter:CustomDecrement

The decrement custom meter is very similar to the custom meter specification but additionally allows a predefined meter to be used as the "source" meter and the remaining items subtract from that predefined meter.

Field: Name

This is a user defined name for the custom meter.

Field: Fuel Type

A fuel type should be specified for the meter. All assignments to this meter will be checked to assure that the same fuel type is used. Additionally, this may be used in other objects (such as the Demand Limiting). Valid choices for this field are:

- Electricity
- NaturalGas
- PropaneGas
- FuelOil#1

- FuelOil#2
- Coal
- Diesel
- Gasoline
- Water
- Generic

Field: Source Meter Name

This name specifies the meter that will be used as the main source for the decrement custom meter. The remainder of the fields are subtracted from the value of this meter to create the meter value named above. The Source Meter is not changed in any way by including this custom meter.

Field: group(s) Key Name-Report Variable/Meter Name

The rest of the object is filled with parameters of the key name/report variable or meter names. When a meter name is used, the key name field is left blank.

Field: Key Name #

A key name field is used when the following field specifies a report variable. If the field is left blank, then all the report variables in the following field are assigned to the meter.

Field: Report Variable or Meter Name #

This field must be a valid report variable name or a valid meter name. Additionally, it must be contained on the Source Meter. Note that, if an error occurs, only the Variable in error will show – confusing things if what was entered was a meter name.

The full IDD specification is:

```
Meter:CustomDecrement,
  \extensible:2 - repeat last two fields, remembering to remove ; from "inner" fields.
  \memo Used to allow users to combine specific variables and/or meters into
  \memo "custom" meter configurations.
A1, \field Name
    \required-field
    \reference CustomMeterNames
A2, \field Fuel Type
    \type choice
    \key Electricity
    \key NaturalGas
    \key PropaneGas
    \key FuelOil#1
    \key FuelOil#2
    \key Coal
    \key Diesel
    \key Gasoline
    \key Water
    \key Generic
A3, \field Source Meter Name
A4, \field Key Name 1
A5, \field Report Variable or Meter Name 1
A6, \field Key Name 2
A7, \field Report Variable or Meter Name 2
A8, \field Key Name 3
A9, \field Report Variable or Meter Name 3
<reduced for brevity>
```

Details of the Custom Meter/Custom Meter:Decrement are shown on the Meter Details file.
Examples of Custom Meter/Custom Meter:Decrement:

```

! The following custom meters are set up to illustrate the capabilities
! of custom meters.
! Custom Meter "MyGeneralLights" duplicates the InteriorLights:Electricity meter.
! Custom Meter "MyBuildingElectric" duplicates the Electricity:Building meter (by specifying that meter).
! Custom Meter (Decrement) "MyBuildingOther" uses Electricity:Building as its source meter
! and subtracts out the values for MyGeneralLights (aka InteriorLights:Electricity). The
! resultant value for MyBuildingOther should be equal to the value for the meters
! Electricity:Building - InteriorLights:Electricity (aka MyGeneralLights)
Meter:Custom,
  MyGeneralLights,      !- Name
  Electricity,          !- Fuel Type
  SPACE1-1,            !- Key Name 1
  Lights Electric Consumption, !- Report Variable or Meter Name 1
  SPACE2-1,            !- Key Name 2
  Lights Electric Consumption, !- Report Variable or Meter Name 2
  SPACE3-1,            !- Key Name 3
  Lights Electric Consumption, !- Report Variable or Meter Name 3
  SPACE4-1,            !- Key Name 4
  Lights Electric Consumption, !- Report Variable or Meter Name 4
  SPACE5-1,            !- Key Name 5
  Lights Electric Consumption; !- Report Variable or Meter Name 5

```

```

Meter:Custom,
  MyBuildingElectric,  !- Name
  Electricity,         !- Fuel Type
  ,                   !- Key Name #1
  Electricity:Building; !- Report Variable or Meter Name #1

Meter:CustomDecrement,
  MyBuildingOther,    !- Name
  Electricity,         !- Fuel Type
  Electricity:Building, !- Source Meter Name
  ,                   !- Key Name #1
  MyGeneralLights;    !- Report Variable or Meter Name #1

```

For an example of “generic” fuel type, one might put the Building Infiltration Heat Loss & Heat Gain on a set of custom meters:

```

Meter:Custom,
  Building Infiltration Heat Loss, !- Name
  Generic,                        !- Fuel Type
  *,                              !- Key Name 1
  Zone Infiltration Total Heat Loss; !- Report Variable or Meter Name 1

Meter:Custom,
  Building Infiltration Heat Gain, !- Name
  Generic,                        !- Fuel Type
  *,                              !- Key Name 1
  Zone Infiltration Total Heat Gain; !- Report Variable or Meter Name 1

```

One can then report these values the same way one reports other standard meters.

Simulation Parameter Outputs

These appear in the **eplusout.eio** file. For details of the reporting, please see the Output Details and Examples document.

Group – Compliance Objects

Not perhaps related directly to simulation, the Compliance Object group provides a repository for a group of objects that can be used directly or indirectly in reporting compliance (such as ASHRAE 90.1) to building standards.

Compliance:Building

The Compliance:Building object describes parameters related to compliance to building standards, building codes, and beyond energy code programs.

Field: Building Rotation for Appendix G

Building Rotation for Appendix G allows for the building model to be rotated for use with compliance such as ASHRAE 90.1 Appendix G. Appendix G requires the building to be rotated 0, 90, 180 and 270 degrees and the values averaged to establish baseline energy use. This input works with relative or world coordinate systems.

```
Compliance:Building,
    \memo Building level inputs related to compliance to building standards, building codes, and beyond
energy code programs.
    \unique-object
    \min-fields 1
N1; \field Building Rotation for Appendix G
    \note Additional degrees of rotation to be used with the requirement in ASHRAE Standard 90.1
Appendix G
    \note that states that the baseline building should be rotated in four directions.
    \units deg
    \type real
    \default 0.0
```

And example from an IDF:

```
Compliance:Building,
90;          Building Rotation for Appendix G
```

Group – Location – Climate – Weather File Access

This group of objects describes the ambient conditions for the simulation.

Site:Location

The location class describes the parameters for the building's location. Only one location is allowed. Weather data file location, if it exists, will override any location data in the IDF. Thus, for an annual simulation, a Location does not need to be entered.

Field: Name

This alpha field is used as an identifying field in output reports.

Field: Latitude

This field represents the latitude (in degrees) of the facility. By convention, North Latitude is represented as positive; South Latitude as negative. Minutes should be represented in decimal fractions of 60. (15' is 15/60 or .25)

Field: Longitude

This field represents the longitude (in degrees) of the facility. By convention, East Longitude is represented as positive; West Longitude as negative. Minutes should be represented in decimal fractions of 60. (15' is 15/60 or .25)

Field: Time Zone

This field represents the time zone of the facility (relative to Greenwich Mean Time or the 0th meridian). Time zones west of GMT (e.g. North America) are represented as negative; east of GMT as positive. Non-whole hours can be represented in decimal (e.g. 6:30 is 6.5).

Field: Elevation

This field represents the elevation of the facility in meters (relative to sea level).

```

Site:Location,
  \unique-object
  \min-fields 5
  A1 , \field Name
      \required-field
      \type alpha
  N1 , \field Latitude
      \units deg
      \minimum -90.0
      \maximum +90.0
      \default 0.0
      \note + is North, - is South, degree minutes represented in decimal (i.e. 30 minutes is .5)
      \type real
  N2 , \field Longitude
      \units deg
      \minimum -180.0
      \maximum +180.0
      \default 0.0
      \note - is West, + is East, degree minutes represented in decimal (i.e. 30 minutes is .5)
      \type real
  N3 , \field Time Zone
      \note basic these limits on the WorldTimeZone Map (2003)
      \units hr
      \minimum -12.0
      \maximum +14.0
      \default 0.0
      \note Time relative to GMT. Decimal hours.
      \type real
  N4 ; \field Elevation
      \units m
      \minimum -300.0
      \maximum< 6096.0
      \default 0.0
      \type real

```

Units with their abbreviations are shown in Appendix A. And, as shown in an IDF:

```

Site:Location, DENVER COLORADO,      ! Name
  39.75000      ,      ! Latitude {N+ S-}
 -104.8700     ,      ! Longitude {W- E+}
 -7.000000    ,      ! TimeZoneNumber {GMT+/-}
 1610.26;     ! Elevation {m}

```

Most examples in this document include the comment lines that illustrate each data field's value. However, this is not necessary (though it makes the IDF more readable). The previous example could also be:

```

Site:Location, DENVER COLORADO,39.75,-104.87,-7,1610.26;

```

Site:WeatherStation

The **Site:WeatherStation** object is used to specify the measurement conditions for the climatic data listed in the weather file. These conditions indicate the height above ground of the air temperature sensor, the height above ground of the wind speed sensor, as well as coefficients that describe the wind speed profile due to the terrain surrounding the weather station. There are necessary correlations between the entries for this object and some entries in the Building object, specifically the Terrain field.

Weather stations throughout the world (ref: WMO – World Meteorological Organization) take their measurements at standard conditions:

- Air temperature is measured at approximately 1.5 m above ground
- Wind speed is measured at 10 m above ground
- Weather station is in a flat, open field with little protection from the wind.

When using weather data from standard sources (e.g., TMY2, IWEC, TMY, or ASHRAE design day data), it is not necessary to use the **Site:WeatherStation** object. However, if you

are using custom weather data or real-time weather data, you may need to read and understand the concepts in the **Site:WeatherStation** object.

The measurement conditions at the weather station (i.e., the weather file) are used by EnergyPlus in conjunction with the *Terrain* field of the **Building** object, or optionally with the **Site:HeightVariation** object (see below), to calculate the local variation in atmospheric properties as a function of height above ground. Outdoor air temperature decreases with height, while wind speed increases with height. The algorithms for this calculation are in the Engineering Reference.

The **Site:WeatherStation** object is useful when working with a custom weather file that includes data that were not measured at the WMO standard conditions. For example, the weather data could be measured on site, or on the roof top of a nearby building. The wind speed profile coefficients can be estimated from the table below or calculated beforehand using more sophisticated techniques such as CFD modeling of the weather station terrain.

Table 2. Wind Speed Profile Coefficients (ASHRAE Fundamentals 2005).

Terrain Description	Exponent	Boundary Layer Thickness (m)
Flat, open country	0.14	270
Rough, wooded country	0.22	370
Towns and cities	0.33	460
Ocean	0.10	210
Urban, industrial, forest	0.22	370

If the **Site:WeatherStation** object is omitted from the input file, the WMO standard measurement conditions are assumed.

Field: Wind Sensor Height Above Ground

The height [m] above ground for the wind speed sensor.

Field: Wind Speed Profile Exponent

The wind speed profile exponent for the terrain surrounding the weather station. The exponent can be estimated from the table above or calculated beforehand using more sophisticated techniques, such as CFD modeling of the weather station terrain.

Field: Wind Speed Profile Boundary Layer Thickness

The wind speed profile boundary layer thickness [m] for the terrain surrounding the weather station. The boundary layer can be estimated from the table above or calculated beforehand using more sophisticated techniques, such as CFD modeling of the weather station terrain.

Field: Air Temperature Sensor Height Above Ground

The height [m] above ground for the air temperature sensor.

For example, if you are using weather data measured on the top of your building, you should set the *Wind Sensor Height Above Ground* and the *Air Temperature Sensor Height Above Ground* to equal the height of your building (say 30 m). The *Wind Speed Profile Exponent* and *Wind Speed Profile Boundary Layer Thickness* should be set to match the values associated with the *Terrain* field of the **Building** object, or the equivalent fields of the **Site:HeightVariation** object.

Or, in IDF terms, with a building in a town or city:

```
Site:WeatherStation,
  30,  !- Wind Sensor Height Above Ground {m}
  0.33,  !- Wind Speed Profile Exponent {}
  460,  !- Wind Speed Profile Boundary Layer Thickness {m}
  30;  !- Air Temperature Sensor Height Above Ground {m}
```

This would change if you had a different wind speed profile exponent or wind speed profile boundary layer thickness at your site.

The complete IDD definition:

```
Site:WeatherStation,
  \unique-object
  \memo This object is only used for non-standard weather data. Standard weather data
  \memo such as TMY2, IWEC, and ASHRAE design day data are all measured at the
  \memo default conditions and do not require this object to be used.
  N1 , \field Wind Sensor Height Above Ground
    \type real
    \units m
    \default 10.0
    \minimum > 0.0
  N2 , \field Wind Speed Profile Exponent
    \type real
    \default 0.14
    \minimum 0.0
  N3 , \field Wind Speed Profile Boundary Layer Thickness
    \type real
    \units m
    \default 270.0
    \minimum 0.0
  N4 ; \field Air Temperature Sensor Height Above Ground
    \type real
    \units m
    \default 1.5
    \minimum 0.0
```

Site:HeightVariation

The **Site:HeightVariation** object is used to specify the local variation in atmospheric properties at the site and should be used only if you require advanced control over the height-dependent variations for wind speed and temperature. The coefficients set by this object are used by EnergyPlus, in conjunction with the **Site:WeatherStation** object (see above), to calculate the local variation in atmospheric properties as a function of height above ground. Outdoor air temperature decreases with height, while wind speed increases with height. The local outdoor air temperature and wind speed are calculated separately for all zones and surfaces, and optionally for outdoor air nodes for which a height has been specified (see **OutdoorAir:Node** object). With the default inputs, wind speed falls significantly at heights lower than the weather station measurement height, and temperature increases slightly. The algorithms for this calculation are in the Engineering Reference. There are necessary correlations between the entries for this object and some entries in the Building object, specifically the Terrain field.

Table 3. Atmospheric Variables at Two Different Heights Above Ground Level.

Variable	1.5 m	284 m	Absolute Diff	Percent Diff
Air Temperature	15°C	13.15°C	1.85°C	12.3%
Barometric Pressure	101,325 Pa	97,960 Pa	3,365 Pa	3.3%
Wind Speed	2.46 m/s	7.75 m/s	5.29 m/s	215%

Note that using this object overrides the wind speed profile coefficients implied by the *Terrain* field of the **Building** object even if the wind speed profile fields are left blank. The wind speed profile coefficients can be estimated from the table above (see **Site:WeatherStation**) or

calculated beforehand using more sophisticated techniques such as CFD modeling of the site terrain.

```

Site:HeightVariation,
  \unique-object
  \memo This object is used if the user requires advanced control over height-dependent
  \memo variations in wind speed and temperature. When this object is not present, the default model
  \memo for temperature dependence on height is used, and the wind speed is modeled according
  \memo to the Terrain field of the BUILDING object.
N1 , \field Wind Speed Profile Exponent
  \note Set to zero for no wind speed dependence on height.
  \type real
  \default 0.22
  \minimum 0.0
N2 , \field Wind Speed Profile Boundary Layer Thickness
  \type real
  \units m
  \default 370.0
  \minimum> 0.0
N3 ; \field Air Temperature Gradient Coefficient
  \note Set to zero for no air temperature dependence on height.
  \type real
  \units K/m
  \default 0.0065
  \minimum 0.0

```

Field: Wind Speed Profile Exponent

The wind speed profile exponent for the terrain surrounding the site. The exponent can be estimated from the table above (see **Site:WeatherStation**) or calculated beforehand using more sophisticated techniques, such as CFD modeling of the site terrain. Note that using this object overrides the wind speed profile coefficients implied by the *Terrain* field of the **Building** object even if this field is left blank.

Field: Wind Speed Profile Boundary Layer Thickness

The wind speed profile boundary layer thickness [m] for the terrain surrounding the site. The boundary layer can be estimated from the table above (see **Site:WeatherStation**) or calculated beforehand using more sophisticated techniques, such as CFD modeling of the site terrain. Note that using this object overrides the wind speed profile coefficients implied by the *Terrain* field of the **Building** object even if this field is left blank. This field can be set to zero to turn off all wind dependence on height.

Field: Air Temperature Gradient Coefficient

The air temperature gradient coefficient [K/m] is a research option that allows the user to control the variation in outdoor air temperature as a function of height above ground. The real physical value is 0.0065 K/m. This field can be set to zero to turn off all temperature dependence on height. Note that the *Air Temperature Sensor Height* in the **Site:WeatherStation** object should also be set to zero in order to force the local outdoor air temperatures to match the weather file outdoor air temperature. This change is required because the **Site:WeatherStation** object assumes an air temperature gradient of 0.0065 K/m.

```

Site:HeightVariation,
  0.22, !- Wind Speed Profile Exponent
  370, !- Wind Speed Profile Boundary Layer Thickness {m}
  0.0065; !- Air Temperature Gradient Coefficient {deltaC/m}

```

RunPeriod

The RunPeriod object describes the elements necessary to create a weather file simulation. Multiple run periods may be input. EnergyPlus accepts weather files in the special EnergyPlus weather format (described below in this document). These files can describe Daylight Saving Time periods as well as holidays within their definitions. The RunPeriod object allows the user to override the use of both the Daylight Saving Period (i.e. use or

ignore) and holidays that are embedded within the weather file. Note that the weather file also may contain design condition information, typical and extreme period information, ground temperatures based on air temperature calculations.

Field: Begin Month

This numeric field should contain the starting month number (1=January, 2=February, etc.) for the annual run period desired.

Field: Begin Day of Month

This numeric field should contain the starting day of the starting month (must be valid for month) for the annual run period desired.

Field: End Month

This numeric field should contain the ending month number (1=January, 2=February, etc.) for the annual run period desired.

Field: End Day of Month

This numeric field should contain the ending day of the ending month (must be valid for month) for the annual run period desired.

Field: Day of Week for Start Day

For flexibility, the day of week indicated on the weather file can be overridden by this field's value. Valid days of the week (Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday) must be entered in this field.

Field: Use Weather File Holidays and Special Days

Weather files can contain holiday designations or other kinds of special days. These day types cause a corresponding day's schedule (see SCHEDULE definitions below) to be used during that day. This field should contain the word **Yes** if holidays or other special days indicated directly on the weather file should retain their "day type" or **No** if holidays or other special days on the weather file should be ignored. Reference SpecialDayPeriod below to enter your own special days and holidays.

Note that a blank or null field in this field will indicate **Yes**.

Field: Use Weather File Daylight Saving Period

Weather files can contain indicators of Daylight Saving period days. For flexibility, you may want to ignore these designations on the weather file. This field should contain the word **Yes** if you will accept daylight saving period days as contained on the weather file (note: not all weather files may actually have this period) or **No** if you wish to ignore Daylight Saving period days that may be on the weather file.

Note that a blank or null field in this field will indicate **Yes**.

Field: Apply Weekend Holiday Rule

In some countries (notably the US), when holidays fall on weekends, they are often observed on a weekday close to the holiday day. (Usually if the specific day falls on a Saturday, the observed day is Friday; if on a Sunday, the observed day is Monday). EnergyPlus will represent this custom using the value in this field. If the field is **Yes**, then specific date holidays that have a duration of one day, will be "observed" on the Monday after the day. (Specific day holidays are such as January 1 – a day-month combination). If the field is blank or **No**, then the holiday will be shown on the day-month as entered. As this option is listed at the RunPeriod, all applicable special days for the run will use the rule – there is no override for individual special days.

Note that a blank or null field in this field will indicate **No**.

Note: EnergyPlus processed weather files available on the EnergyPlus web site: http://www.energyplus.gov/cfm/weather_data.cfm have neither special days specified nor daylight saving period. However, DDY (Design Day) files produced from the ASHRAE Design Conditions that accompany the EPW files may include a DaylightSavingPeriod object for certain locations.

Field: Use Weather File Rain Indicators

Weather files can contain “rain” indicators. (EPW field “Present Weather Codes” – described in the AuxiliaryPrograms document). In turn, rain indicates wet surfaces which changes the film convection coefficient for the surface. Other models may use rain as well (Ground Heat Exchangers). Entering “**Yes**” in this field allows the weather file conditions to represent “Rain”; entering “**No**” in the field “turns off” the rain indicator for this period. You might use this to be able to compare two “same location” weather files of different years, origins, etc.

Field: Use Weather File Snow Indicators

Weather files can contain “snow” indicators. (EPW field “Snow Depth” > 0 indicates “Snow on the ground”). In turn, snow changes the reflectivity of the ground and cascades changes of this reflectivity. Entering “**Yes**” in this field allows the weather file conditions to represent “Snow”; entering “**No**” in the field “turns off” the snow indicator for this period. You might use this to be able to compare two “same location” weather files of different years, origins, etc.

Field: Number of Times Runperiod to be Repeated

This numeric field represents the number of times (usually years) the simulation has to be carried out in a multi runperiod simulation. The default value is set to 1. The number of years of simulation, in case of a Ground Loop Heat Exchanger (GLHE) simulation, should be equal to the length of simulation field in GLHE object. Note that you can specify a number of simulation years with a shorter run period (e.g. 1 week) and EnergyPlus will repeat the simulation of the shorter run period for that many times.

The IDD for object RunPeriod is shown below:

```

RunPeriod,

SizingPeriod:WeatherFileDays

The SizingPeriod:WeatherFileDays object describes using a selected period from the “attached” weather file to be used in load calculations or sizing equipment. The period selected can be as small as a single day or larger. Multiple periods may be input.

Field: Name

This field allows for an assigned name for this run period so it can be tracked easily in sizing and other outputs.

Field: Begin Month

This numeric field should contain the starting month number (1=January, 2=February, etc.) for the annual run period desired.

Field: Begin Day of Month

This numeric field should contain the starting day of the starting month (must be valid for month) for the annual run period desired.

Field: End Month

This numeric field should contain the ending month number (1=January, 2=February, etc.) for the annual run period desired.

Field: End Day of Month

This numeric field should contain the ending day of the ending month (must be valid for month) for the annual run period desired.

Field: Day of Week for Start Day

For flexibility, the day of week indicated on the weather file can be overridden by this field’s value. Valid days of the week (Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday) can be entered. When weekdays are used, each subsequent day in the period will

be incremented. Also valid values are SummerDesignDay, WinterDesignDay, CustomDay1, CustomDay2 – if these days are used, however, they will be applied for the entire period.

Field: Use Weather File Daylight Saving Period

Weather files can contain indicators of Daylight Saving Period days. For flexibility, you may want to ignore these designations on the weather file. This field should contain the word **Yes** if you will accept daylight saving period days as contained on the weather file (note: not all weather files may actually have this period) or **No** if you wish to ignore Daylight Saving Period days that may be on the weather file.

Note that a blank or null field in this field will indicate **Yes**.

Field: Use Weather File Rain and Snow Indicators

Weather files can contain “rain” and “snow” indicators. (EPW field “Present Weather Codes” – described in the AuxiliaryPrograms document). In turn, rain indicates wet surfaces which changes the film convection coefficient for the surface. Other models may use rain as well (Ground Heat Exchangers). Snow indicators can change the ground reflectance if there is snow on the ground. Entering “**Yes**” in this field allows the weather file conditions to represent “Rain” and “Snow”; entering “**No**” in the field “turns off” the rain/snow indicators for this period. You might use this to be able to compare two “same location” weather files of different years, origins, etc.

The IDD for the object follows:

  WinterDesignDay,                       !- Day type
  No,                                     !- Use Weather File Daylight Saving Period
  No;                                     !- Use Weather File Rain and Snow Indicators

```

SizingPeriod:WeatherFileConditionType

When the EPW files are created, a heuristic procedure identifies extreme and typical periods in the actual weather file. This object will allow one of those periods to be selected for sizing or load calculations (typically).

Field: Name

This field allows for an assigned name for this run period so it can be tracked easily in sizing and other outputs.

Field: Period Selection

This field allows the generic period calculated from the weather file to be selected for this run period. It is not completely generic as there may be extreme cold periods in some weather files but extreme wet periods (tropical) in others. Not all weather files have all of the valid choices. The choices for this field are:

- SummerExtreme
- SummerTypical
- WinterExtreme

- WinterTypical
- AutumnTypical
- SpringTypical
- WetSeason
- DrySeason
- NoDrySeason
- NoWetSeason
- TropicalHot
- TropicalCold

Field: Day of Week for Start Day

For flexibility, the day of week indicated on the weather file can be overridden by this field's value. Valid days of the week (Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday) can be entered. When weekdays are used, each subsequent day in the period will be incremented. Also valid values are SummerDesignDay, WinterDesignDay, CustomDay1, CustomDay2 – if these days are used, however, they will be applied for the entire period.

Field: Use Weather File Daylight Saving Period

Weather files can contain indicators of Daylight Saving Period days. For flexibility, you may want to ignore these designations on the weather file. This field should contain the word **Yes** if you will accept daylight saving period days as contained on the weather file (note: not all weather files may actually have this period) or **No** if you wish to ignore Daylight Saving Period days that may be on the weather file.

Note that a blank or null field in this field will indicate **Yes**.

Field: Use Weather File Rain and Snow Indicators

Weather files can contain “rain” and “snow” indicators. (EPW field “Present Weather Codes” – described in the AuxiliaryPrograms document). In turn, rain indicates wet surfaces which changes the film convection coefficient for the surface. Other models may use rain as well (Ground Heat Exchangers). Snow indicators can change the ground reflectance if there is snow on the ground. Entering “**Yes**” in this field allows the weather file conditions to represent “Rain” and “Snow”; entering “**No**” in the field “turns off” the rain/snow indicators for this period. You might use this to be able to compare two “same location” weather files of different years, origins, etc.

```

SizingPeriod:DesignDay

The design day input describes the parameters to effect a “design day” simulation, often used for load calculations or sizing equipment. Using the values in these fields, EnergyPlus “creates” a complete day’s worth of weather data (air temperatures, solar radiation, etc.)

Normal operation uses the default range multipliers as shown in Figure 6 though users may choose to input their own multiplier schedule. Likewise, normal operation specifies one “humidity indicating temperature” which is used to calculate the humidity ratio at maximum temperature – this is used as the constant humidity ratio for the entire day. Again, this can be overridden by specifying a relative humidity schedule. Multiple design days may be specified.

In the install, the “design day files” are included for the weather file locations that are included (weatherdata folder). All the design day definitions from the ASHRAE 2005 design conditions are included, grouped by WMO region, on the main web site with the weather data. http://www.energyplus.gov/cfm/weather_data.cfm These files are in “macro” form but it is easy to cut and paste the appropriate definition segments. These files include the location information as well as some locations have **RunPeriodControl:DaylightSavingTime** objects.

Field: Name

This field, like the location name, is used simply for reporting and identification. This name must be unique among the SizingPeriod names entered.

Field: Maximum Dry-Bulb Temperature

This numeric field should contain the day’s maximum dry-bulb temperature in degrees Celsius. (Reference Appendix A of this document for EnergyPlus standard units and abbreviations). The MacroDataSets design day files show extreme temperature for locations as indicated in the ASHRAE HOF design condition tables.

Field: Daily Temperature Range

A design day can have a “high” temperature and a “low” temperature (or can be a constant temperature for each hour of the day). If there is a difference between high and low temperatures, this field should contain the difference from the high to the low. EnergyPlus, by default, distributes this range over the 24 hours in the day as shown in the figure below:

Daily Range Multiplier

Figure 6. Default Daily range Multiplier for Design Days

More explicitly, EnergyPlus creates an air temperature for each timestep by using the entered maximum dry-bulb temperature in conjunction with the entered daily range and the above multiplier values. The actual equation used is shown below:

$$T_{current} = T_{Max} - T_{range} \cdot T_{Multiplier}$$

where

T_{current} = Air temperature of current Hour of Day

T_{Max} = User supplied Max Dry-bulb Temperature

T_{range} = User supplied Daily Temperature Range

$T_{\text{Multiplier}}$ = Range multiplier as shown on the above graph

The range multiplier values represent typical conditions of diurnal temperatures (i.e. the low temperature for the day occurring about 5:00 AM and the maximum temperature for the day occurring about 3:00 PM).

Field: Humidity Indicating Conditions at Maximum Dry-Bulb

This numeric field represents the “humidity indicating” conditions that are coincident with the maximum temperature for the day. The value in this field is indicated by the key value in the field **Humidity Indicating Type**. This numeric value, along with the Maximum Dry-bulb Temperature and Barometric Pressure, is used to determine a humidity ratio and then used to calculate relative humidity, wet-bulb and dewpoint temperatures at each timestep. Note that this field is unnecessary when you put in a relative humidity day schedule (described later in this section).

Field: Barometric Pressure

This numeric field is the constant barometric pressure (Pascals) for the entire day.

Field: Wind Speed

This numeric field is the wind speed in meters/second (constant throughout the day) for the day. The MacroDataSets design day files includes wind speed values (99.6% - heating, 1% cooling) as indicated in ASHRAE HOF design condition tables. But, you should be aware that traditional values for these are 6.7056 m/s (15 mph) for heating and 3.3528 m/s (7 mph) for cooling. A reminder is shown in the comments for the wind speed values. The comments also note the extreme wind speeds from the ASHRAE tables.

Field: Wind Direction

This numeric field is the source wind direction in degrees. By convention, winds from the North would have a value of 0., from the East a value of 90.

Field: Sky Clearness

This value represents the “clearness” value for the day. This value, along with the solar position as defined by the Location information and the date entered for the design day, help define the solar radiation values for each hour of the day. Traditionally, one uses 0.0 clearness for Winter Design Days.

Field: Rain Indicator

This numeric field indicates whether or not the building surfaces are wet. If the value is 1, then it is assumed that the building surfaces are wet. Wet surfaces may change the conduction of heat through the surface.

Field: Snow Indicator

This numeric field indicates whether or not there is snow on the ground. If the value is 1, then it is assumed there is snow on the ground. Snow on the ground changes the ground reflectance properties.

Field: Day of Month

This numeric field specifies the day of the month. That, in conjunction with the month and location information, determines the current solar position and solar radiation values for each hour of the day.

Field: Month

This numeric field specifies the month. That, in conjunction with the day of the month and location information, determines the current solar position and solar radiation values for each hour of the day.

Field: Day Type

This alpha field specifies the day type for the design day. This value indicates which day profile to use in schedules. For further information, see the Schedule discussion later in this document {Group -- Schedules}. Note that two of the possible day types are SummerDesignDay and WinterDesignDay – allowing the user to customize schedules for the design conditions.

Field: Daylight Saving Time Indicator

This numeric field specifies whether to consider this day to be a Daylight Saving Day. This essentially adds 1 hour to the scheduling times used in items with schedules.

Field: Humidity Indicating Type

Valid choices here are: **WetBulb**, **DewPoint**, **HumidityRatio**, **Enthalpy**, **Schedule**. Units for the first four choices are Celsius, Celsius, ratio of kg wet air/kg dry air (no units), and kJ/kg. Using one of these choices means that you then put an appropriate value in the Humidity Indicating Conditions at Maximum Dry-Bulb field. The **Schedule** choice uses the day schedule indicated in the next field. That is, if you want to specify your own relative humidity to occur throughout the day, you put schedule in here and put in the name of your day schedule that specifies the relative humidity in the Relative Humidity Day Schedule Name.

Field: Relative Humidity Day Schedule Name

If you want to specify your own relative humidity for the day, put in schedule in the Humidity Indicating Type field and put in the name of a day schedule with relative humidity values (0 to 100 percent) in this field.

Field: Dry-Bulb Temperature Range Modifier Type

If you are happy with lows at 5am and highs at 3pm, you can ignore this field. If you want to specify your own temperature range multipliers (see earlier discussion at the Temperature Range field description), you can specify a type here and create a day schedule which you reference in the next field.

If you specify **MultiplierSchedule** in this field, then you need to create a day schedule that specifies a multiplier applied to the temperature range field (above) to create the proper dry-bulb temperature range profile for your design day.

If you specify **DifferenceSchedule** in this field, then you need to create a day schedule that specifies a number to be **subtracted** from dry-bulb maximum temperature for each timestep in the day. Note that numbers in the delta schedules cannot be negative as that would result in a higher maximum than the maximum previously specified.

If you leave this field blank or enter **DefaultMultipliers**, then the default multipliers will be used as shown in the “temperature range” field above.

Field: Dry-Bulb Temperature Range Modifier Schedule Name

This field is the name of a day schedule with the values as specified in the Dry-Bulb Temperature Range Modifier Type field above.

Field: Solar Model Indicator

This field allows the user to select ASHRAEClearSky, ZhangHuang or Schedule for solar modeling in the calculation of the solar radiation in the design day. Both named models use the Clearness value as part of their calculations. More details on the two models are

described in the Engineering Reference. The Schedule choice allows you to enter schedule values for the day's profile (use the next two fields for the names).

Field: Beam Solar Day Schedule Name

This field allows the option for you to put in your own day profile of beam solar values (wh/m²). These values will replace the calculated values during design day processing.

Field: Diffuse Solar Day Schedule Name

This field allows the option for you to put in your own day profile of diffuse solar values (wh/m²). These values will replace the calculated values during design day processing.

The IDD definition for the object:

Look at the example file 1ZoneUncontrolled_DDChanges.idf for several examples of specifying Design Day inputs.

Longer Design Periods

Some features may benefit by using a longer design weather period for sizing or loads calculations. Longer design periods may be created by using the **SizingPeriod:WeatherFileDays** or **SizingPeriod:WeatherFileType** objects. These two objects allow for selections from an attached weather file to be used in the sizing calculations.

RunPeriodControl:SpecialDays

For weather file run periods, special day run periods can be described. These will always be in effect for the selected days in the run period. Depending on the Use Special Days value in the RunPeriod object, these can augment any special days included on the weather file.

Note: EnergyPlus processed weather files available on the EnergyPlus web site: http://www.energyplus.gov/cfm/weather_data.cfm have neither special days specified nor daylight saving period. However, DDY (Design Day) files produced from the ASHRAE Design Conditions that accompany the EPW files may include a DaylightSavingPeriod object for certain locations.

Field: Name

This alpha field is the title for the special day period. It must be unique among all the special day period objects entered.

Field: Start Date

This field is the starting date for the special day period. Dates in this field can be entered in several ways as shown in the accompanying table:

Table 4. Date Field Interpretation

Field Contents	Interpretation
<number> / <number>	Month / Day
<number> Month	Day and Month
Month <number>	Day and Month
<number> Weekday in Month	Numbered weekday of month
Last Weekday In Month	Last weekday of month

In the table, Month can be one of (January, February, March, April, May, June, July, August, September, October, November, December). Abbreviations of the first three characters are also valid.

In the table, Weekday can be one of (Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday). Abbreviations of the first three characters are also valid.

Field: Duration

This numeric field specifies how long (number of days) the special day period lasts.

Field: Special Day Type

This alpha field designates the “day type” for schedule use during the special period. It must be one of (Holiday, SummerDesignDay, WinterDesignDay, CustomDay1, CustomDay2).

```
RunPeriodControl:SpecialDays,
  \min-fields 4
  \memo This object sets up holidays/special days to be used during weather file
  \memo run periods. (These are not used with DesignDay objects.)
  \memo Depending on the value in the run period, days on the weather file may also
  \memo be used. However, the weather file specification will take precedence over
  \memo any specification shown here. (No error message on duplicate days or overlapping
  \memo days).
A1, \field Name
  \required-field
```

```

A2, \field Start Date
  \required-field
  \note Dates can be several formats:
  \note <number>/<number> (month/day)
  \note <number> <Month>
  \note <Month> <number>
  \note <Nth> <Weekday> in <Month>
  \note Last <WeekDay> in <Month>
  \note <Month> can be January, February, March, April, May, June, July, August, September, October,
November, December
  \note Months can be the first 3 letters of the month
  \note <Weekday> can be Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday
  \note <Nth> can be 1 or 1st, 2 or 2nd, etc. up to 5(?)
N1, \field Duration
  \units days
  \minimum 1
  \maximum 366
  \default 1
A3; \field Special Day Type
  \required-field
  \note Special Day Type selects the schedules appropriate for each day so labeled
  \type choice
  \key Holiday
  \key SummerDesignDay
  \key WinterDesignDay
  \key CustomDay1
  \key CustomDay2
  \default Holiday

```

An example in the IDF would be:

```

RunPeriodControl:SpecialDays, President's Day, 3rd Monday in
February,1,Holiday;
RunPeriodControl:SpecialDays, Thanksgiving, 4th Thursday in November,
1,Holiday;
RunPeriodControl:SpecialDays, Halloween, 10/31, 1, Holiday;
RunPeriodControl:SpecialDays, Vacation, 5/1, 14, CustomDay1;

```

RunPeriodControl:DaylightSavingTime

Similar to a special day period, a daylight saving period may be entered to be applied to weather file run periods. These will always be in effect, regardless of the value entered on the RunPeriod object. Note that this period will always override any daylight saving period specified in a weather file.

Note: EnergyPlus processed weather files available on the EnergyPlus web site: http://www.energyplus.gov/cfm/weather_data.cfm have neither special days specified nor daylight saving period.

Field: Start Date

This is the starting date of the daylight saving period. Note that it can be entered in several formats as shown in Table 4. Date Field Interpretation.

Field: End Date

This is the ending date of the daylight saving period. Note that it can be entered in several formats as shown in Table 4. Date Field Interpretation.

```

RunPeriodControl:DaylightSavingTime,
  \unique-object
  \min-fields 2
  \memo This object sets up the daylight saving time period for any RunPeriod.
  \memo Ignores any daylight saving time period on the weather file and uses this definition.
  \memo These are not used with SizingPeriod:DesignDay objects.
  \memo Use with SizingPeriod:WeatherFileDays object can be controlled in that object.
A1, \field Start Date
  \required-field
A2; \field End Date
  \required-field
  \note Dates can be several formats:
  \note <number>/<number> (month/day)
  \note <number> <Month>
  \note <Month> <number>
  \note <Nth> <Weekday> in <Month>
  \note Last <WeekDay> in <Month>
  \note <Month> can be January, February, March, April, May, June, July, August, September, October,
November, December
  \note Months can be the first 3 letters of the month
  \note <Weekday> can be Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday
  \note <Nth> can be 1 or 1st, 2 or 2nd, etc. up to 5(?)

```

And in the IDF:

```

! U.S. Standard for Daylight Saving
RunPeriodControl:DaylightSavingTime,2nd Sunday in March, 1st Sunday in
November; !2007
! Brazil standard
RunPeriodControl:DaylightSavingTime,1st Sunday in October, Last Sunday in
February;
! European Standard
RunPeriodControl:DaylightSavingTime, Last Sunday in March, Last Sunday in
October;
! Syria Standard
RunPeriodControl:DaylightSavingTime, 4/1, 10/1;

```

Of course, these could not all appear in the same IDF as only one DaylightSavingPeriod object per input file is allowed. More information on Daylight Saving Periods can be seen on the web at: <http://www.webexhibits.org/daylightsaving/> The ASHRAE Handbook of Fundamentals [ASHRAE 2005] also contains information about daylight saving periods and their climatic information now includes start and end dates for many locations.

Site:GroundTemperature:BuildingSurface

Ground temperatures are used for the ground heat transfer model. There can be only one ground temperature object included, and it is used as the outside surface temperature for all surfaces with Outside Boundary Condition=Ground. The outside surface temperature for individual surfaces can be specified using the OtherSideCoefficients (ref: SurfaceProperty:OtherSideCoefficients) object that allows Toutside to be set with a schedule. This permits using any number of different outside face temperatures in addition to the ground temperature.

Caution: The “undisturbed” ground temperatures calculated by the weather converter should not be used in building losses but are appropriate to be used in the Site:GroundTemperature:Shallow and Site:GroundTemperature:Deep objects. The reasoning (for building losses) is that these values are too extreme for the soil under a conditioned building. For best results, use the Slab or Basement program described in this document to calculate custom monthly average ground temperatures (see the Ground Heat Transfer section). This is especially important for residential applications and very small buildings. If one of these ground temperature preprocessors is not used, for typical commercial buildings in the USA, a reasonable default value is 2C less than the average indoor space temperature.

More information about determining appropriate ground temperatures is given in the Auxiliary Programs document.

Field: Month Temperature(s) – 12 fields in all

Each numeric field is the monthly ground temperature (degrees Celsius) used for the indicated month (January=1st field, February=2nd field, etc.)

```
Site:GroundTemperature:BuildingSurface,
  \memo These temperatures are specifically for those surfaces that have the outside environment
  \memo of "Ground". Documentation about what values these should be is located in the
  \memo Auxiliary programs document (Ground Heat Transfer) as well as the InputOutput Reference.
  \memo CAUTION - Do not use the "undisturbed" ground temperatures from the weather data.
  \memo These values are too extreme for the soil under a conditioned building.
  \memo For best results, use the Slab or Basement program to calculate custom monthly
  \memo average ground temperatures (see Auxiliary Programs). For typical commercial
  \memo buildings in the USA, a reasonable default value is 2C less than the average indoor space
temperature.
  \unique-object
  \min-fields 12
  \format singleLine

  \type real
  \default 18
---reduced for brevity ---
N12; \field December Ground Temperature
  \required-field
  \units C
  \type real
  \default 18
```

And, the IDF example:

```
Site:GroundTemperature:BuildingSurface, 1.22222233E+01, 1.27777786E+01, 1.44444447E+01,
1.66666679E+01, 1.94444447E+01, 2.33333340E+01, 2.2222233E+01, 2.00000000E+01, 1.77777786E+01,
1.66666679E+01, 1.44444447E+01, 1.27777786E+01;
```

Site:GroundTemperature:Shallow

Site:GroundTemperature:Shallow are used by the Surface Ground Heat Exchanger (i.e. object: GroundHeatExchanger:Surface). Only one surface ground temperature object can be included.

Note that the ground temperatures included in full year weather files may be suitable of being used for the values in these fields – namely, the .5 m depth temperatures that are calculated for “undisturbed” soil of “typical” conditions. However, you may wish to use some other change effect – based on the weather conditions of the building location.

Field: Month Temperature(s) – 12 fields in all

Each numeric field is the monthly surface ground temperature (degrees Celsius) used for the indicated month (January=1st field, February=2nd field, etc.)

```

Site:GroundTemperature:Shallow,
    \memo These temperatures are specifically for the Surface Ground Heat Exchanger and
    \memo should probably be close to the average outdoor air temperature for the location.
    \unique-object
    \min-fields 12
    \format singleLine
N1 , \field January Surface Ground Temperature
    \required-field
    \units C
    \type real

---reduced for brevity ---
N12; \field December Surface Ground Temperature
    \required-field
    \units C
    \type real
    \default 13

```

And, the IDF example:

```
Site:GroundTemperature:Shallow, 4,4,6,6,10,10,15,15,14,14,8,8;
```

Site:GroundTemperature:Deep

Site:GroundTemperature:Deep are used by the Pond Ground Heat Exchanger and Vertical Ground Heat Exchanger objects (i.e. objects: GroundHeatExchanger:Pond and GroundHeatExchanger:Vertical). Only one deep ground temperature object can be included.

Note that the ground temperatures included in full year weather files may be suitable of being used for the values in these fields – namely, the 4 m depth temperatures that are calculated for “undisturbed” soil of “typical” conditions. However, you may wish to use some other change effect – based on the weather conditions or special knowledge of the building location.

Field: Month Temperature(s) – 12 fields in all

Each numeric field is the monthly deep ground temperature (degrees Celsius) used for the indicated month (January=1st field, February=2nd field, etc.)

```

Site:GroundTemperature:Deep,
    \memo These temperatures are specifically for the ground heat exchangers that would use
    \memo "deep" (3-4 m depth) ground temperatures for their heat source.
    \unique-object
    \min-fields 12
    \format singleLine
N1 , \field January Deep Ground Temperature
    \required-field
    \units C
    \type real
    \default 16
---reduced for brevity ---
N12; \field December Deep Ground Temperature
    \required-field
    \units C
    \type real
    \default 16

```

And, the IDF example:

```
Site:GroundTemperature:Deep, 16,16,16,16,16,16,16,16,16,16,16,16;
```

Site:GroundReflectance

Ground reflectance values are used to calculate the ground reflected solar amount. This fractional amount (entered monthly) is used in this equation:

$\text{GroundReflectedSolar} = (\text{BeamSolar} \cdot \text{COS}(\text{SunZenithAngle}) + \text{DiffuseSolar}) \cdot \text{GroundReflectance}$

Of course, the Ground Reflected Solar is never allowed to be negative. The ground reflectance can be further modified when snow is on the ground by the Snow Ground Reflectance Modifier. To use no ground reflected solar in your simulation, enter 0.0 for each month.

Field: Month Average Ground Reflectance(s) – 12 fields in all

Each numeric field is the monthly average reflectivity of the ground used for the indicated month (January=1st field, February=2nd field, etc.)

The IDD Definition:

```
Site:GroundReflectance,
\unique-object
\min-fields 12
\format singleLine
N1 , \field January Ground Reflectance
    \default 0.2
    \type real
    \minimum 0.0
    \maximum 1.0
    \units dimensionless
---reduced for brevity ---
N12 ; \field December Ground Reflectance
    \default 0.2
    \type real
    \minimum 0.0
    \maximum 1.0
    \units dimensionless
```

And use in an IDF:

```
Site:GroundReflectance,
0.600, !January Ground Reflectance
0.600, !February Ground Reflectance
0.400, !March Ground Reflectance
0.300, !April Ground Reflectance
0.200, !May Ground Reflectance
0.200, !June Ground Reflectance
0.200, !July Ground Reflectance
0.200, !August Ground Reflectance
0.200, !September Ground Reflectance
0.200, !October Ground Reflectance
0.300, !November Ground Reflectance
0.400, !December Ground Reflectance
```

Site:GroundReflectance:SnowModifier

It is generally accepted that snow resident on the ground increases the basic ground reflectance. EnergyPlus allows the user control over the snow ground reflectance for both “normal ground reflected solar” calculations (see above) and snow ground reflected solar modified for daylighting. These are entered under this object and both default to 1 (same as normal ground reflectance – no special case for snow which is a conservative approach).

Field: Ground Reflected Solar Modifier

This field is a decimal number which is used to modified the basic monthly ground reflectance when snow is on the ground (from design day input or weather data values).

$$\text{GroundReflectance}_{\text{used}} = \text{GroundReflectance} \cdot \text{Modifier}_{\text{Snow}}$$

The actual Ground Reflectance is limited to [0.0,1.0].

Field: Daylighting Ground Reflected Solar Modifier

This field is a decimal number which is used to modified the basic monthly ground reflectance when snow is on the ground (from design day input or weather data values).

$$\text{DaylightingGroundReflectance}_{\text{used}} = \text{GroundReflectance} \bullet \text{Modifier}_{\text{Snow}}$$

The actual Ground Reflectance is limited to [0.0,1.0].

```
Site:GroundReflectance:SnowModifier,
N1, \field Ground Reflected Solar Modifier
\minimum 0.0
\default 1.0
\note Value for modifying the "normal" ground reflectance when Snow is on ground
\note when calculating the "Ground Reflected Solar Radiation Value"
\note a value of 1.0 here uses the "normal" ground reflectance
\note Ground Reflected Solar = (BeamSolar*CosSunZenith + DiffuseSolar)*GroundReflectance
\note This would be further modified by the Snow Ground Reflectance Modifier when Snow was on the
ground
\note When Snow on ground, effective GroundReflectance is normal GroundReflectance*"Ground
Reflectance Snow Modifier"
\note Ground Reflectance achieved in this manner will be restricted to [0.0,1.0]
N2; \field Daylighting Ground Reflected Solar Modifier
\minimum 0.0
\default 1.0
\note Value for modifying the "normal" daylighting ground reflectance when Snow is on ground
\note when calculating the "Ground Reflected Solar Radiation Value"
\note a value of 1.0 here uses the "normal" ground reflectance
\note Ground Reflected Solar = (BeamSolar*CosSunZenith + DiffuseSolar)*GroundReflectance
\note This would be further modified by the Snow Ground Reflectance Modifier when Snow was on the
ground
\note When Snow on ground, effective GroundReflectance is normal GroundReflectance*"Daylighting
Ground Reflectance Snow Modifier"
\note Ground Reflectance achieved in this manner will be restricted to [0.0,1.0]
```

Outputs will show both the inputs from the above object as well as monthly values for both Snow Ground Reflectance and Snow Ground Reflectance for Daylighting.

Site:WaterMainsTemperature

The Site:WaterMainsTemperature object is used to calculate water temperatures delivered by underground water main pipes. The mains temperatures are used as default, make-up water temperature inputs for several plant objects, including: **WaterUse:Equipment**, **WaterUse:Connections**, **WaterHeater:Mixed** and **WaterHeater:Stratified**. The mains temperatures are also used in the water systems objects to model the temperature of cold water supplies.

Water mains temperatures are a function of outdoor climate conditions and vary with time of year. A correlation has been formulated to predict water mains temperatures based on two weather inputs:

- average annual outdoor air temperature (dry-bulb)
- maximum difference in monthly average outdoor air temperatures

These values can be easily calculated from annual weather data using a spreadsheet or from the ".stat" file available with the EnergyPlus weather files at www.energyplus.gov. Monthly statistics for dry-bulb temperatures are shown with daily averages. The daily averages are averaged to obtain the annual average. The maximum and minimum daily average are subtracted to obtain the maximum difference. For more information on the water mains temperatures correlation, see the *EnergyPlus Engineering Document*.

Alternatively, the Site:WaterMainsTemperature object can read values from a schedule. This is useful for measured data or when water comes from a source other than buried pipes, e.g., a river or lake.

If there is no Site:WaterMainsTemperature object in the input file, a default constant value of 10 C is assumed.

```
Site:WaterMainsTemperature,

28.1; !- Maximum Difference In Monthly Average Outdoor Air Temperatures {deltaC}
```

Site:Precipitation

The Site:Precipitation object is used to describe the amount of water precipitation at the building site over the course of the simulation run period. Precipitation includes both rain and the equivalent water content of snow. Precipitation is not yet described well enough in the usual building weather data file. So this object is used to provide the data using Schedule objects that define rates of precipitation in meters per hour.

A set of schedules for site precipitation have been developed for USA weather locations and are provided with EnergyPlus in the data set called PrecipitationSchedulesUSA.idf. The user can develop schedules however they want. The schedules in the data set were developed using EnergyPlus' weather file (EPW) observations and the average monthly precipitation for the closest weather site provided by NOAA. EPW files for the USA that were based on TMY or TMY2 include weather observations for Light/Moderate/Heavy rainfall, however most international locations do not include these observations. The values were modeled by taking

the middle of the ranges quoted in the EPW data dictionary. The assumed piecewise function is shown below.

$$Amount (m / hour) = \begin{cases} Light = 0.0125 \\ Moderate = 0.052 \\ Heavy = 0.1 \end{cases}$$

The values were inserted on hour by hour basis for the month based on the observations. Then each month was rescaled to meet the average precipitation for the month based on the 30-year average (1971-2000) provided by the NOAA/NCDC. Therefore, the flags in the EPW file match the precipitation schedules for the USA. Note that summing the average monthly precipitation values will not give you the average yearly precipitation. The resulting value may be lower or higher than the average yearly value.

Once the typical rainfall pattern and rates are scheduled, the Site Precipitation object provides a method of shifting the total rainfall up or down for design purposes. Wetter or drier conditions can be modeled by changing the Design Annual Precipitation although the timing of precipitation throughout the year will not be changed.

IDD specification:

```
Site:Precipitation,
  A1, \field Precipitation Model Type
      \type choice
      \key ScheduleAndDesignLevel
  N1, \field Design Level for Total Annual Precipitation
      \note meters of water per year used for design level
  A2, \field Precipitation Rates Schedule Name
      \type object-list
      \object-list ScheduleNames
      \note Schedule values in meters of water per hour
      \note values should be non-negative
  N2; \field Average Total Annual Precipitation
      \note meters of water per year from average weather statistics
      \minimum 0
```

Field: Precipitation Model Type

Choose rainfall modeling options. Only available option is ScheduleAndDesignLevel.

Field: Design Level for Total Annual Precipitation

Magnitude of total precipitation for an annual period to be used in the model. Value selected by the user to correspond with the amount of precipitation expected or being assumed for design purposes. The units are in meters. This field works with the following two fields to allow easily shifting the amounts without having to generate new schedules.

Field: Precipitation Rate Schedule Name

Name of a schedule defined elsewhere that describes the rate of precipitation. The precipitation rate schedule is analogous to weather file data. However, weather files for building simulation do not currently contain adequate data for such calculations. Therefore, EnergyPlus schedules are used to enter the pattern of precipitation events. The values in this schedule are the average rate of precipitation in meters per hour. The integration of these values over an annual schedule should equal the nominal annual precipitation.

Field: Average Total Annual Precipitation

Magnitude of annual precipitation associated with the rate schedule. This value is used to normalize the precipitation.

IDF example:

```

Site:Precipitation,
  ScheduledAndDesignLevel, !- Precipitation Model Type
  0.75,                    !- Design Level Total Annual Precipitation
  PrecipitationSchd,      !- Schedule Name for Precipitation Rates
  0.80771;                !- Average Total Annual Precipitation

```

RoofIrrigation

The RoofIrrigation object is used to describe the amount of irrigation on the ecoroof surface over the course of the simulation runperiod. This object is used to provide irrigation data using Schedule objects that define rates of irrigation in meters per hour. These schedules can be one of two types: Schedule, or SmartSchedule. The Schedule type is used to force an irrigation schedule regardless of the current moisture state of the soil. The SmartSchedule type allows the precipitation schedule to be overridden if the current moisture state of the soil is greater than 30% saturated.

Field: Irrigation Model Type

Choose irrigation modeling options. Available options are Schedule and SmartSchedule.

Field: Irrigation Rate Schedule Name

Name of a schedule defined elsewhere that describes the rate of irrigation. The values in this schedule are the average rate of irrigation in meters per hour.

IDD specification:

```

RoofIrrigation,
  A1, \field Irrigation Model Type
      \type choice
      \key Schedule
      \key SmartSchedule
      \note SmartSchedule will not allow irrigation when soil is already moist.
      \note Current threshold set at 30% of saturation.
  A2; \field Irrigation Rate Schedule Name
      \type object-list
      \object-list ScheduleNames
      \note Schedule values in meters of water per hour
      \note values should be non-negative

```

IDF example:

```

RoofIrrigation,
  Schedule, !- Irrigation Model Type
  IrrigationSchd, !- Schedule Name for Irrigation Rates

```

Climate Group Outputs

Climate related variables appear in two places for EnergyPlus outputs. Certain objects that are invariant throughout a simulation period have lines appear in the eplusout.eio file. For descriptions of this reporting, please see the Output Details and Examples document.

Weather Data Related Outputs

Variables related to ambient environment data are available at timestep and higher resolutions. Below is a variable dictionary of these variables and subsequent definitions:

```

Zone,Average,Outdoor Dry Bulb [C]
Zone,Average,Outdoor Dew Point [C]
Zone,Average,Outdoor Wet Bulb [C]
Zone,Average,Outdoor Barometric Pressure [Pa]
Zone,Average,Outdoor Relative Humidity [%]
Zone,Average,Outdoor Humidity Ratio [kgWater/kgAir]
Zone,Average,Wind Speed [m/s]
Zone,Average,Wind Direction [degree]
Zone,Average,Sky Temperature [C]
Zone,Average,Diffuse Solar [W/m2]

```

```

Zone,Average,Direct Solar [W/m2]
Zone,Average,Ground Reflected Solar [W/m2]
Zone,Average,Ground Temperature [C]
Zone,Average,Outdoor Enthalpy [J/kg]
Zone,Average,Outdoor Air Density [kg/m3]
Zone,Average,Solar Azimuth Angle [degree]
Zone,Average,Solar Altitude Angle [degree]
Zone,Average,Solar Hour Angle [degree]
Zone,Average,Fraction of Time Raining
Zone,Average,Fraction of Time Snow On Ground
Zone,Average,Daylight Saving Time Indicator []
Zone,Average,DayType Index []
Zone,Average,Water Mains Temperature [C]
HVAC,Average,Site Precipitation Rate [m/s]
HVAC,Sum,Site Precipitation [m]
HVAC,Sum,Roof Irrigation Scheduled Amount [m]
HVAC,Sum,Roof Irrigation Actual Amount [m]

```

Note that these data values may be interpolated from “hour” points (ref: Weather Data Hourly Interpolation). The data values represent the “average” over the reporting resolution period.

Outdoor Dry Bulb [C]

This is the outdoor dry-bulb temperature in degrees C.

Outdoor Dew Point [C]

This is the outdoor dewpoint temperature in degrees C.

Outdoor Wet Bulb [C]

The outdoor wet-bulb temperature is derived (at the timestep) from the values for dry-bulb temperature, humidity ratio and barometric pressure.

Outdoor Barometric Pressure [Pa]

This is the atmospheric/barometric pressure in Pa.

Outdoor Relative Humidity [%]

This is the outdoor relative humidity expressed in percent.

Outdoor Humidity Ratio [kgWater/kgAir]

The outdoor humidity ratio is derived (at the timestep) from the dry-bulb temperature, relative humidity and barometric pressure.

Wind Speed [m/s]

This is the outdoor wind speed in m/s.

Wind Direction [degree]

This is the wind direction (N=0, E=90, S=180, W=270).

Sky Temperature [C]

The sky temperature is derived from horizontal IR. It is expressed in degrees C. Note that Sigma is the Stefan-Boltzmann constant in the following equation:

$$Sky\ Temperature = \left(\frac{Horizontal\ IR}{Sigma} \right)^{\frac{1}{4}} - 273.15_{Conversion\ from\ Kelvin\ to\ Centigrade}$$

Diffuse Solar [W/m2]

Diffuse solar is the amount of solar radiation in W/m² received from the sky (excluding the solar disk) on a horizontal surface.

Direct Solar [W/m2]

Direct solar is amount of solar radiation in W/m² received within a 5.7° field of view centered on the sun. This is also known as Beam Solar.

Ground Reflected Solar [W/m2]

The ground reflected solar amount (W/m²) is derived from the Beam Solar, Diffuse Solar, User specified Ground Reflectance (for month) and Solar Altitude Angle:

$$\text{Groundreflectedsolar} = (\text{Beamsolar} \cdot \text{COS}(\text{SolarAltitudeAngle}) + \text{Diffusesolar}) \cdot \text{Groundreflectance}_{\text{month}}$$

where if the calculation returns a value < 0.0, then 0.0 will be reported.

Ground Temperature [C]

The ground temperature is reported in degrees C – this is a user-specified input by month.

Outdoor Enthalpy [J/kg]

Outdoor enthalpy is derived at each timestep from the Outdoor Dry-bulb and the Outdoor Humidity Ratio. It is reported in J/kg.

Outdoor Air Density [kg/m3]

Outdoor air density is derived at each timestep from the Outdoor Barometric Pressure, the Outdoor Dry-bulb temperature and the Outdoor Humidity Ratio. It is reported in units kg/m³.

Solar Altitude Angle [degree]

The Solar Altitude Angle (β) is the angle of the sun above the horizontal (degrees).

Solar Azimuth Angle [degree]

The Solar Azimuth Angle (ϕ) is measured from the North (clockwise) and is expressed in degrees. This is shown more clearly in the following figure.

Figure 7. Solar Position Illustration

Solar Hour Angle [degree]

The Solar Hour Angle (H) gives the apparent solar time for the current time period (degrees). It is common astronomical practice to express the hour angle in hours, minutes and seconds of time rather than in degrees. You can convert the hour angle displayed from EnergyPlus to time by dividing by 15. (Note that 1 hour is equivalent to 15 degrees; 360° of the Earth’s rotation takes place every 24 hours.) The relationship of angles in degrees to time is shown in the following table:

Table 5. Relationship of Angles (degrees) to Time

Unit of Angle	Equivalent time
1 radian	3.819719 hours
1 degree	4 minutes
1 arcmin	4 seconds
1 arcsec	0.066667 seconds

Solar Position

The sun’s position in the sky is expressed in terms of the solar altitude and the solar azimuth. Further, these angles depend on the local latitude, the solar declination (which is a function of the date) and the apparent solar time (solar hour angle).

Fraction of Time Raining

This field shows whether or not (1=yes, 0=no) the weather shows “raining”. For a Design Day, one can denote rain for the entire day but not timestep by timestep. Weather files may indicate rain for a single time interval. This is an “averaged” field – thus a 1 shown for a time period (e.g. daily reporting) means that it was raining during each timestep of that period.

Fraction of Time Snow On Ground

This field shows whether or not (1=yes, 0=no) the weather shows “snow on the ground”. For a Design Day, one can denote snow for the entire day but not timestep by timestep. Weather files may indicate snow (snow depth) for a single time interval. This is an “averaged” field – thus a 1 shown for a time period (e.g. daily reporting) means that there was snow on the ground during each timestep of that period.

Daylight Saving Time Indicator

This field shows when daylight saving time (1=yes, 0=no) is in effect. Though shown as an average variable, this value is only set on a daily basis.

DayType Index

This field shows what "day type" the current day is. Daytypes are (1=Sunday, 2=Monday, etc.) with Holiday=8, SummerDesignDay=9, WinterDesignDay=10, CustomDay1=11, CustomDay2=12. Though shown as an average variable, this value is only set on a daily basis.

Water Mains Temperature

The value of the Water Mains Temperature is reported in C following the calculation shown in the Water Mains Temperature object.

Site Precipitation Rate [m/s]**Site Precipitation [m]**

The rate and quantity of precipitation at the site. These outputs are only available if a Site Precipitation object is used. Precipitation is measured in meters.

Roof Irrigation Scheduled Amount[m]

This is the scheduled amount of irrigation for the green roof (ecorooft) based on the user input. Amount is measured in meters.

Roof Irrigation Actual Amount[m]

This is the actual amount of irrigation for the green roof (ecorooft) based on the scheduled user input and moisture state/saturation of the soil. Amount is measured in meters.

Outputs for local temperature/wind speed calculations

Local atmospheric properties for outdoor air temperature and wind speed are separately calculated and reported for all zones, surfaces, and outdoor air nodes. The report variables are associated with their respective objects:

```
Zone,Average,Zone Outdoor Dry Bulb [C]
Zone,Average,Zone Outdoor Wet Bulb [C]
Zone,Average,Zone Outdoor Wind Speed [m/s]
Zone,Average,Surface Ext Outdoor Dry Bulb [C]
Zone,Average,Surface Ext Outdoor Wet Bulb [C]
Zone,Average,Surface Ext Wind Speed [m/s]
HVAC,Average,System Node Temp[C]           (for OUTDOOR AIR NODE object)
```

Zone Outdoor Dry Bulb [C]

The outdoor air dry-bulb temperature calculated at the height above ground of the zone centroid.

Zone Outdoor Wet Bulb [C]

The outdoor air wet-bulb temperature calculated at the height above ground of the zone centroid.

Zone Outdoor Wind Speed [m/s]

The outdoor wind speed calculated at the height above ground of the zone centroid.

Surface Ext Outdoor Dry Bulb [C]

The outdoor air dry-bulb temperature calculated at the height above ground of the surface centroid.

Surface Ext Outdoor Wet Bulb [C]

The outdoor air wet-bulb temperature calculated at the height above ground of the surface centroid.

Surface Ext Wind Speed [m/s]

The outdoor wind speed calculated at the height above ground of the surface centroid.

System Node Temp [C]

When reporting for the **OutdoorAir:Node** object, this is the outdoor air dry-bulb temperature calculated at the height above ground of the node, if height is specified in the input.

Group – Schedules

This group of objects allows the user to influence scheduling of many items (such as occupancy density, lighting, thermostatic controls, occupancy activity). In addition, schedules are used to control shading element density on the building.

EnergyPlus schedules consist of three pieces: a day description, a week description, and an annual description. An optional element is the schedule type. Each description level builds off the previous sub-level. The day description is simply a name and the values that span the 24 hours in a day to be associated with that name. The week description also has an identifier (name) and twelve additional names corresponding to previously defined day descriptions. There are names for each individual day of the week plus holiday, summer design day, winter design day and two more custom day designations. Finally, the annual schedule contains an identifier and the names and FROM-THROUGH dates of the week schedules associate with this annual schedule. The annual schedule can have several FROM-THROUGH date pairs. One type of schedule reads the values from an external file to facilitate the incorporation of monitored data or factors that change throughout the year.

Schedules are processed by the EnergyPlus Schedule Manager, stored within the Schedule Manager and are accessed through module routines to get the basic values (timestep, hourly, etc). Values are resolved at the Zone Timestep frequency and carry through any HVAC timesteps.

Day Type

A brief description of “Day Type” which is used in the SizingPeriod objects, RunPeriodControl:SpecialDays object, the Sizing objects and also used by reference in the Schedule:Week:Daily object (discussed later in this section).

Schedules work on days of the week as well as certain specially designated days. Days of the week are the normal – Sunday, Monday, Tuesday, Wednesday, Thursday, Friday and Saturday. Special day types that can be designated are: Holiday, SummerDesignDay, WinterDesignDay, CustomDay1, CustomDay2. These day types can be used at the user’s convenience to designate special scheduling (e.g. lights, electric equipment, set point temperatures) using these days as reference.

For example, a normal office building may have normal “occupancy” rules during the weekdays but significantly different use on weekend. For this, you would set up rules/schedules based on the weekdays (Monday through Friday, in the US) and different rules/schedules for the weekend (Saturday and Sunday, in the US). However, you could also specially designate SummerDesignDay and WinterDesignDay schedules for sizing calculations. These schedules can be activated by setting the Day Type field in the Design Day object to the appropriate season (**SummerDesignDay** for cooling design calculations; **WinterDesignDay** for heating design calculations).

In a different building, such as a theater/playhouse, the building may only have occupancy during certain weeks of the year and/or certain hours of certain days. If it was every week, you could designate the appropriate values during the “regular” days (Sunday through

Saturday). But this would also be an ideal application for the “CustomDay1” and/or “CustomDay2”. Here you would set the significant occupancy, lighting, and other schedules for the custom days and use unoccupied values for the normal weekdays. Then, using a weather file and setting special day periods as appropriate, you will get the “picture” of the building usage during the appropriate periods.

ScheduleTypeLimits

Schedule types can be used to validate portions of the other schedules. Hourly day schedules, for example, are validated by range -- minimum/maximum (if entered) -- as well as numeric type (continuous or discrete). Annual schedules, on the other hand, are only validated for range – as the numeric type validation has already been done.

Field: Name

This alpha field should contain a unique (within the schedule types) designator. It is referenced wherever Schedule Type Limits Names can be referenced.

Field: Range

Since schedule values, in their base descriptions, are all numeric, this field will represent the min and max range for the values. If this field is left blank, then the schedule type is not limited to a minimum/maximum value range.

Field: Numeric Type

This field designates how the range values are validated. Using **Continuous** in this field allows for all numbers, including fractional amounts, within the range to be valid. Using **Discrete** in this field allows only integer values between the minimum and maximum range values to be valid.

```
ScheduleTypeLimits,
  \memo ScheduleTypeLimits specifies the data types and limits for the values contained in schedules
  A1, \field Name
     \required-field
     \reference ScheduleTypeLimitsNames
     \note used to validate schedule types in various schedule objects
  A2, \field Range
     \note put in minimum:maximum here or blank if not a limited value, e.g. 0.0:1.0 for fraction
  A3: \field Numeric Type
     \note Numeric type is either Continuous (all numbers within the min and
     \note max are valid or Discrete (only integer numbers between min and
     \note max are valid. (Could also allow REAL and INTEGER to mean the
     \note same things)
     \type choice
     \key Continuous
     \key Discrete
```

Several IDF Examples will illustrate the use:

```
ScheduleTypeLimits,Any Number; ! Not limited
ScheduleTypeLimits,Fraction, 0.0 : 1.0 ,CONTINUOUS;
ScheduleTypeLimits,Temperature,-60:200,CONTINUOUS;
ScheduleTypeLimits,Control Type,0:4,DISCRETE;
ScheduleTypeLimits,On/Off,0:1,DISCRETE;
```

Day Schedules

The day schedules perform the assignment of pieces of information across a 24 hour day. This can occur in various fashions including a 1-per hour assignment, a user specified interval scheme or a list of values that represent an hour or portion of an hour.

Schedule:Day:Hourly

The Schedule:Day:Hourly contains an hour-by-hour profile for a single simulation day.

Field: Name

This field should contain a unique (within all DaySchedules) designation for this schedule. It is referenced by WeekSchedules to define the appropriate schedule values.

Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

Field: Hour Values (1-24)

These fields contain the hourly values for each of the 24 hours in a day. (Hour field 1 represents clock time 00:00:01 AM to 1:00:00 AM, hour field 2 is 1:00:01 AM to 2:00:00 AM, etc.) The values in these fields will be passed to the simulation as indicated for “scheduled” items.

```
Schedule:Day:Hourly,
  \min-fields 26
  \memo A Schedule:Day:Hourly contains 24 values for each hour of the day.
A1 , \field Name
  \required-field
  \type alpha
  \reference DayScheduleNames
A2 , \field Schedule Type Limits Name
  \type object-list
  \object-list ScheduleTypeLimitsNames
N1 , \field Hour 1
  \type real
  \default 0
N2 , \field Hour 2
  \type real
  \default 0
-- etc to 24 hour values
```

For brevity each of the hour fields is not listed here – see the IDD for complete definition. An IDF example:

```
Schedule:Day:Hourly, Day On Peak, Fraction,
  0.,0.,0.,0.,0.,0.,0.,0.,0.,0.,0.,0.,1.,1.,1.,1.,1.,1.,1.,1.,0.,0.,0.,0.,0.,0.;
```

Schedule:Day:Interval

The Schedule:Day:Interval introduces a slightly different way of entering the schedule values for a day. Using the intervals, you can shorten the “hourly” input of the “Schedule:Day:Hourly” object to 2 fields. And, more importantly, you can enter an interval that represents only a portion of an hour. Schedule values are “given” to the simulation at the zone timestep, so there is also a possibility of “interpolation” from the entries used in this object to the value used in the simulation.

Field: Name

This field should contain a unique (within all DaySchedules) designation for this schedule. It is referenced by WeekSchedules to define the appropriate schedule values.

Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

Field: Interpolate to Timestep

The value contained in this field directs how to apply values that aren't coincident with the given timestep (ref: Timestep) intervals. If "Yes" is entered, then any intervals entered here will be interpolated/averaged and that value will be used at the appropriate minute in the hour. If "No" is entered, then the value that occurs on the appropriate minute in the hour will be used as the schedule value.

For example, if "yes" is entered and the interval is every 15 minutes (say a value of 0 for the first 15 minutes, then .5 for the second 15 minutes) AND there is a 10 minute timestep for the simulation: the value at 10 minutes will be 0 and the value at 20 minutes will be .25. For the same input entries but "no" for this field, the value at 10 minutes will be 0 and the value at 20 minutes will be .5.

Field-Set: Time and Value (extensible object)

To specify each interval, both an "until" time (which includes the designated time) and the value must be given.

Field: Time

The value of each field should represent clock time (standard) in the format "Until: HH:MM". 24 hour clock format (i.e. 1PM is 13:00) is used. Note that Until: 7:00 includes all times up through 07:00 or 7am.

Field: Value

This represents the actual value to be passed to the simulation at the appropriate timestep. (Using interpolation value as shown above). Limits on the values are indicated by the Schedule Type Limits Name field of this object.

The IDD representation for the Schedule:Day:Interval object:

```
Schedule:Day:Interval,
  \extensible:2 - repeat last two fields, remembering to remove ; from "inner" fields.
  \memo A Schedule:Day:Interval contains a full day of values with specified end times for each value
  \memo Currently, is set up to allow for 10 minute intervals for an entire day.
  A1 , \field Name
      \required-field
      \type alpha
      \reference DayScheduleNames
  A2 , \field Schedule Type Limits Name
      \type object-list
      \object-list ScheduleTypeLimitsNames
  A3 , \field Interpolate to Timestep
      \note when the interval does not match the user specified timestep a Yes choice will average
between the intervals request (to
      \note timestep resolution. a No choice will use the interval value at the simulation timestep
without regard to if it matches
      \note the boundary or not.
      \type choice
      \key Yes
      \key No
      \default No
  A4 , \field Time 1
      \note "until" includes the time entered.
      \units hh:mm
  N1 , \field Value Until Time 1
  A5 , \field Time 2
      \note "until" includes the time entered.
      \units hh:mm
  N2 , \field Value Until Time 2
  A6 , \field Time 3
      \note "until" includes the time entered.
      \units hh:mm
  N3 , \field Value Until Time 3
<reduced for brevity - can have up to 24 intervals>
```

And an example of use:

```

Schedule:Day:Interval,
  dd winter rel humidity,  !- Name
  Percent,                 !- Schedule Type Limits Name
  No,                      !- Interpolate to Timestep
  until: 24:00,           !- Time 1
  74;                     !- Value Until Time 1

```

Schedule:Day:List

To facilitate possible matches to externally generated data intervals, this object has been included. In similar fashion to the Schedule:Day:Interval object, this object can also include “sub-hourly” values but must represent a complete day in its list of values.

Field: Name

This field should contain a unique (within all day schedules) designation for this schedule. It is referenced by week schedules to define the appropriate schedule values.

Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

Field: Interpolate to Timestep

The value contained in this field directs how to apply values that aren’t coincident with the given timestep (ref: Timestep) intervals. If “Yes” is entered, then any intervals entered here will be interpolated/averaged and that value will be used at the appropriate minute in the hour. If “No” is entered, then the value that occurs on the appropriate minute in the hour will be used as the schedule value.

For example, if “yes” is entered and the minutes per item is 15 minutes (say a value of 0 for the first 15 minutes, then .5 for the second 15 minutes) AND there is a 10 minute timestep for the simulation: the value at 10 minutes will be 0 and the value at 20 minutes will be .25. For the same input entries but “no” for this field, the value at 10 minutes will be 0 and the value at 20 minutes will be .5.

Field: Minutes Per Item

This field allows the “list” interval to be specified in the number of minutes for each item. The value here must be ≤ 60 and evenly divisible into 60 (same as the timestep limits).

Field Value 1 (same definition for each value – up to 1440 (24*60) allowed)

This is the value to be used for the specified number of minutes.

```

Schedule:Day:List,
  \memo Schedule:Day:List will allow the user to list 24 hours worth of values, which can be sub-
  hourly in nature.
  A1 , \field Name
      \required-field
      \type alpha
      \reference DayScheduleNames
  A2 , \field Schedule Type Limits Name
      \type object-list
      \object-list ScheduleTypeLimitsNames
  A3 , \field Interpolate to Timestep
      \note when the interval does not match the user specified timestep a "Yes" choice will average
      between the intervals request (to
      \note timestep resolution. a "No" choice will use the interval value at the simulation timestep
      without regard to if it matches
      \note the boundary or not.
      \type choice
      \key Yes
      \key No
      \default No
  N1 , \field Minutes Per Item
      \note Must be evenly divisible into 60
      \type integer
      \minimum 1
      \maximum 60
  N2, \field Value 1
<reduced for brevity, up to 1440 (24*60) values may be entered>

```

For example:

```

Schedule:Day:List,
  Myschedule, ! name
  Fraction, ! Schedule type
  No, ! Interpolate value
  30, ! Minutes per item
  0.0, ! from 00:01 to 00:30
  0.5, ! from 00:31 to 01:00
  <etc>

```

Week Schedule(s)

The week schedule object(s) perform the task of assigning the day schedule to day types in the simulation. The basic week schedule is shown next.

Schedule:Week:Daily

Field: Name

This field should contain a unique (within all WeekSchedules) designation for this schedule. It is referenced by Schedules to define the appropriate schedule values.

Field: Schedule Day Name Fields (12 day types – Sunday, Monday, ...)

These fields contain day schedule names for the appropriate day types. Days of the week (or special days as described earlier) will then use the indicated hourly profile as the actual schedule value.

```

Schedule:Week:Daily,
  \min-fields 13
  \memo A Schedule:Week:Daily contains 12 Schedule:Day:Hourly objects, one for each day type.
A1 , \field Name
  \required-field
  \reference WeekScheduleNames
  \type alpha
A2 , \field Sunday Schedule:Day Name

```

An IDF example:

```

Schedule:Week:Daily, Week on Peak,
  Day On Peak,Day On Peak,Day On Peak,
  Day On Peak,Day On Peak,Day On Peak,
  Day On Peak,Day On Peak,Day On Peak,
  Day On Peak,Day On Peak,Day On Peak;

```

Schedule:Week:Compact

Further flexibility can be realized by using the Schedule:Week:Compact object. In this the fields, after the name is given, a “for” field is given for the days to be assigned and then a dayschedule name is used.

Field:Name

This field should contain a unique (within all WeekSchedules) designation for this schedule. It is referenced by Schedules to define the appropriate schedule values.

Field-Set – DayType List#, Schedule:Day Name #

Each assignment is made in a pair-wise fashion. First the “days” assignment and then the dayschedule name to be assigned. The entire set of day types must be assigned or an error will result.

Field: DayType List #

This field can optionally contain the prefix “For” for clarity. Multiple choices may then be combined on the line. Choices are: Weekdays, Weekends, Holidays, Alldays, SummerDesignDay, WinterDesignDay, Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, CustomDay1, CustomDay2. In fields after the first “for”, AllOtherDays may also be used.

Field: Schedule:Day Name #

This field contains the name of the day schedule (any of the Schedule:Day object names) that is to be applied for the days referenced in the prior field.

```

    Day On Peak;
Schedule:Week:Compact, WeekDays on Peak,
    WeekDays,
    Day On Peak,
    AllOtherDays
    Day Off Peak;
```

Schedule:Year

The yearly schedule is used to cover the entire year using references to week schedules (which in turn reference day schedules). If the entered schedule does not cover the entire year, a fatal error will result.

Field: Name

This field should contain a unique (between Schedule:Year, Schedule:Compact, and Schedule:File) designation for the schedule. It is referenced by various "scheduled" items (e.g. Lights, People, Infiltration) to define the appropriate schedule values.

Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

Field Set (WeekSchedule, Start Month and Day, End Month and Day)

Each of the designated fields is used to fully define the schedule values for the indicated time period). Up to 53 sets can be used. An error will be noted and EnergyPlus will be terminated if an incomplete set is entered. Missing time periods will also be noted as warning errors; for these time periods a zero (0.0) value will be returned when a schedule value is requested. Each of the sets has the following 5 fields:

Field: Schedule Week Name #

This field contains the appropriate WeekSchedule name for the designated time period.

Field: Start Month #

This numeric field is the starting month for the schedule time period.

Field: Start Day #

This numeric field is the starting day for the schedule time period.

Field: End Month #

This numeric field is the ending month for the schedule time period.

Field: End Day #

This numeric field is the ending day for the schedule time period.

```

Schedule:Year,

-- etc to 53 weekschedule "field sets"

```

For brevity, the entire definition of week schedules is not included here. See the actual IDD for full definition.

Note that there are many possible periods to be described. An IDF example with a single period:

```

Schedule:Year, On Peak, Fraction,
  Week On Peak, 1,1, 12,31;

```

And a multiple period illustration:

```
Schedule:Year,CoolingCoilAvailSched,Fraction,
FanAndCoilAllOffWeekSched, 1,1, 3,31,
FanAndCoilSummerWeekSched, 4,1, 9,30,
FanAndCoilAllOffWeekSched, 10,1, 12,31;
```

The following definition will generate an error (if any scheduled items are used in the simulation):

```
Schedule:Year,MySchedule,Fraction,4,1,9,30;
```

Schedule:Compact

For flexibility, a schedule can be entered in “one fell swoop”. Using the Schedule:Compact object, all the features of the schedule components are accessed in a single command. Like the “regular” schedule object, each schedule:compact entry must cover all the days for a year. Additionally, the validations for DaySchedule (i.e. must have values for all 24 hours) and WeekSchedule (i.e. must have values for all day types) will apply. Schedule values are “given” to the simulation at the zone timestep, so there is also a possibility of “interpolation” from the entries used in this object to the value used in the simulation.

This object is an unusual object for description. For the data the number of fields and position are not set, they cannot really be described in the usual Field # manner. Thus, the following description will list the fields and order in which they must be used in the object. The name and schedule type are the exceptions:

Field: Name

This field should contain a unique (between Schedule:Year, Schedule:Compact, and Schedule:File) designation for the schedule. It is referenced by various “scheduled” items (e.g. Lights, People, Infiltration) to define the appropriate schedule values.

Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

Field-Set (Through, For, Interpolate, Until, Value)

Each compact schedule must contain the elements Through (date), For (days), Interpolate (optional), Until (time of day) and Value. In general, each of the “titled” fields must include the “title”.

Field: Through

This field starts with “Through:” and contains the ending date for the schedule period (may be more than one). Refer to Table 4. Date Field Interpretation for information on date entry – note that only Month-Day combinations are allowed for this field. Each “through” field generates a new WeekSchedule named “Schedule Name”_wk_# where # is the sequential number for this compact schedule.

Field: For

This field starts with “For:” and contains the applicable days (reference the compact week schedule object above for complete description) for the 24 hour period that must be described. Each “for” field generates a new DaySchedule named “Schedule Name”_dy_# where # is the sequential number for this compact schedule.

Field: Interpolate (optional)

This field, if used, starts with “Interpolate:” and contains the word “Yes” or “No”. If this field is not used, it should not be blank – rather just have the following field appear in this slot. The definition of “Interpolate” in this context is shown in the interval day schedule above.

Field: Until

This field contains the ending time (again, reference the interval day schedule discussion above) for the current days and day schedule being defined.

Field: Value

Finally, the value field is the schedule value for the specified time interval.

The complete IDD definition:

```
Schedule:Compact,
  \extensible:1 - repeat last field, remembering to remove ; from "inner" fields.
  \memo Irregular object. Does not follow the usual definition for fields. Fields A3... are:
  \memo Through: Date
  \memo For: Applicable days (ref: Schedule:Week:Compact)
  \memo Interpolate: Yes/No (ref: Schedule:Day:Interval) -- optional, if not used will be "No"
  \memo Until: <Time> (ref: Schedule:Day:Interval)
  \memo <numeric value>
  \memo words "Through","For","Interpolate","Until" must be included.

  Until: 08:00, 0.0,
  Until: 18:00, 1.0,
  Until: 24:00, 0.0,
  For: Weekends WinterDesignDay,
  Until: 10:00, 0.0,
  Until: 16:00, 1.0,
  Until: 24:00, 0.0,
  For: Holidays AllOtherDays,
  Until: 24:00, 0.0;
```

Schedule:File

At times, data is available from a building being monitored or for factors that change throughout the year. The Schedule:File object allows this type of data to be used in EnergyPlus as a schedule.

The format for the data file referenced is a text file with values separated by commas with one line per hour. The file may contain header lines that are skipped. The file should contain values for an entire year (8760 lines with data) or a warning message will be issued. Multiple schedules may be created using a single external data file or multiple external data files may be used. The file must be located in the same directory as the EnergyPlus application.

The use of Schedule:File along with the FuelFactors object and TDV files in the DataSets directory to compute Time Dependent Valuation based source energy as used by the California Energy Commission's Title 24 Energy Code. See Fuel Factor for more discussion on Time Dependent Valuation.

Field: Name

This field should contain a unique (between Schedule:Year, Schedule:Compact, and Schedule:File) designation for the schedule. It is referenced by various "scheduled" items (e.g. Lights, People, Infiltration, FuelFactors) to define the appropriate schedule values.

Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

Field: File Name

This field contains the name of the file that contains the data for the schedule. The field may include just the simple file name, a full path with file name or a relational path with file name. The field must be <= 100 characters. If just a simple file name, the file must be located in the "run" folder (same folder as the EnergyPlus.exe). If a relational path with file name, the file must be placed in relation to the "run" folder. The file name must not include commas or an exclamation point.

Field: Column Number

The column that contains the value to be used in the schedule. The column can be more easily viewed if the comma delimited file is opened in a spreadsheet program that parses commas. The first column is column one. If no data for a row appears for a referenced column the value of zero is used for the schedule value for that hour.

Field: Rows to Skip at Top

Many times the data in a file contains rows (lines) that are describing the files or contain the names of each column. These rows need to be skipped and the number of skipped rows should be entered for this field.

Field: Number of Hours of Data

The value entered in this field should be either 8760 or 8784 as the number of hours of data. 8760 does not include a leap year (if existant). 8784 will include the possibility of leap year data which can be processed according to leap year indicators in the weather file or elsewhere specified.

```
Schedule:File,
\min-fields 5
  \memo A Schedule:File points to a text computer file that has 8760 hours of data.
A1 , \field Name
  \required-field

  \minimum 0
N3 ; \field Number of Hours of Data
  \note 8760 hours does not account for leap years, 8784 does.
  \note should be either 8760 or 8784
  \default 8760
  \minimum 8760
  \maximum 8784
```

Here is an IDF example:

```
Schedule:File,
  elecTDVfromCZ01res,    !- Name
  Any Number,           !- ScheduleType
  TDV_kBtu_CTZ01.csv,   !- Name of File
  2,                    !- Column Number
  4;                    !- Rows to Skip at Top
```

or with a relational path:

```
Schedule:File,
  elecTDVfromCZ01res,    !- Name
  Any Number,           !- ScheduleType
  DataSets\TDV\TDV_kBtu_CTZ01.csv, !- Name of File
  2,                    !- Column Number
  4;                    !- Rows to Skip at Top
```

Schedule Outputs

An optional report can be used to gain the values described in the previous Schedule objects. This is a condensed reporting that illustrates the full range of schedule values – in the style of input: DaySchedule, WeekSchedule, Annual Schedule.

```
Output:Reports, Schedules, Hourly; ! will give them on hourly increments (day schedule
resolution)
Output:Reports, Schedules, Timestep; ! will give them at the timestep of the simulation
```

This report is placed on the eplusout.eio file. Details of this reporting are shown in the Output Details and Examples document.

Schedule Value Output

```
Zone, Average, Schedule Value []
```

Schedule Value

This is the schedule value (as given to whatever entity that uses it). It has no units in this context because values may be many different units (i.e. temperatures, fractions, watts). For best results, you may want to apply the schedule name when you use this report variable to avoid output proliferation. For example, the following reporting should yield the values shown above, depending on day of week and day type:

```
Output:Variable, People_Shopping_Sch, Schedule Value, hourly;
Output:Variable, Activity_Shopping_Sch, Schedule Value, hourly;
```

Group – Surface Construction Elements

This group of objects describes the physical properties and configuration for the building envelope and interior elements. That is, the walls, roofs, floors, windows, doors for the building.

Specifying the Building Envelope

Building element constructions in EnergyPlus are built from the basic thermal and other material property parameters in physical constructions. Materials are specified by types and named. Constructions are defined by the composition of materials. Finally, surfaces are specified for the building with geometric coordinates as well as referenced constructions.

Material and Material Properties

There are several material “types” which may be used to describe layers within opaque construction elements. The choice of which of these types to use is left up to the user. However, some guidance as to which material type to use is appropriate before describing each in detail. The opaque types are:

- Material
- Material:NoMass
- Material:AirGap
- Material:RoofVegetation
- Material:InfraredTransparent

Material is the “preferred” type of material. This requires knowledge of many of the thermal properties of the material, but it allows EnergyPlus to take into account the thermal mass of the material and thus allows the evaluation of transient conduction effects. Material:NoMass is similar in nature but only requires the thermal resistance (R-value) rather than the thickness, thermal conductivity, density, and specific heat. Note that using a simple R-value only material forces EnergyPlus to assume steady state heat conduction through this material layer. Finally, Material:AirGap should only be used for an air gap between other layers in a construction. This type assumes that air is sufficiently lightweight to require only an R-value. In addition, since it is not exposed to any external environment, surface properties such as absorptance are not necessary. Material:RoofVegetation is used to help model “green roofs”. Material:InfraredTransparent is used similarly to the NoMass materials. Each of these materials is described in more detail below.

There are several material additions that can be made to the basic material properties. These additional material types are:

- MaterialProperty:MoisturePenetrationDepth:Settings
- MaterialProperty:HeatAndMoistureTransfer:SorptionIsotherm

- MaterialProperty:HeatAndMoistureTransfer:Diffusion
- MaterialProperty:HeatAndMoistureTransfer:Settings
- MaterialProperty:HeatAndMoistureTransfer:Redistribution
- MaterialProperty:HeatAndMoistureTransfer:Suction
- MaterialProperty:HeatAndMoistureTransfer:ThermalConductivity
- MaterialProperty:PhaseChange

These material property objects are used in conjunction with the basic material specification and reference back to the name of the basic material type. Without the basic material type specified the program, will give a severe error and terminate. For example, specifying the moisture materials and changing the HeatBalanceAlgorithm to a moisture simulation will allow the moisture simulation to take place.

Material

This definition should be used when the four main thermal properties (thickness, conductivity, density, and specific heat) of the material are known. This syntax is used to describe opaque construction elements only.

Field: Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data (ref: Construction).

Field: Roughness

This alpha field defines the relative roughness of a particular material layer. This parameter only influences the convection coefficients, more specifically the exterior convection coefficient. A special keyword is expected in this field with the options being “VeryRough”, “Rough”, “MediumRough”, “MediumSmooth”, “Smooth”, and “VerySmooth” in order of roughest to smoothest options.

Field: Thickness

This field characterizes the thickness of the material layer in meters. This should be the dimension of the layer in the direction perpendicular to the main path of heat conduction. This value must be a positive.

Field: Conductivity

This field is used to enter the thermal conductivity of the material layer. Units for this parameter are W/(m-K). Thermal conductivity must be greater than zero.

Field: Density

This field is used to enter the density of the material layer in units of kg/m³. Density must be a positive quantity.

Field: Specific Heat

This field represents the specific heat of the material layer in units of J/(kg-K). Note that these units are most likely different than those reported in textbooks and references which tend to use kJ/(kg-K) or J/(g-K). They were chosen for internal consistency within EnergyPlus. Only positive values of specific heat are allowed.

Field: Thermal Absorptance

The thermal absorptance field in the Material input syntax represents the fraction of incident long wavelength radiation that is absorbed by the material. This parameter is used when calculating the long wavelength radiant exchange between various surfaces and affects the surface heat balances (both inside and outside as appropriate). Values for this field must be between 0.0 and 1.0 (with 1.0 representing “black body” conditions).

Field: Solar Absorptance

The solar absorptance field in the Material input syntax represents the fraction of incident solar radiation that is absorbed by the material. Solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the amount of incident solar radiation absorbed by various surfaces and affects the surface heat balances (both inside and outside as appropriate). Values for this field must be between 0.0 and 1.0.

Field: Visible Absorptance

The visible absorptance field in the Material input syntax represents the fraction of incident visible wavelength radiation that is absorbed by the material. Visible wavelength radiation is slightly different than solar radiation in that the visible band of wavelengths is much more narrow while solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the amount of incident visible radiation absorbed by various surfaces and affects the surface heat balances (both inside and outside as appropriate) as well as the daylighting calculations. Values for this field must be between 0.0 and 1.0.

```

Material:NoMass

Use this definition when only the thermal resistance (R value) of the material is known. This object is used to describe opaque construction elements.

Field: Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data (ref: Construction, SurfaceControl:MoveableInsulation).

Field: Roughness

This alpha field defines the relative roughness of a particular material layer. This parameter only influences the convection coefficients, more specifically the exterior convection coefficient. A special keyword is expected in this field with the options being “VeryRough”, “Rough”, “MediumRough”, “MediumSmooth”, “Smooth”, and “VerySmooth” in order of roughest to smoothest options.

Field: Thermal Resistance

This field is used to enter the thermal resistance (R-value) of the material layer. Units for this parameter are (m²-K)/W. Thermal resistance must be greater than zero. Note that most R-values in the USA are calculated in Inch-Pound units and must be converted to the SI equivalent.

Field: Thermal Absorptance

The thermal absorptance field in the Material input syntax represents the fraction of incident long wavelength radiation that is absorbed by the material. This parameter is used when calculating the long wavelength radiant exchange between various surfaces and affects the surface heat balances (both inside and outside as appropriate). Values for this field must be between 0.0 and 1.0 (with 1.0 representing “black body” conditions).

Field: Solar Absorptance

The solar absorptance field in the Material input syntax represents the fraction of incident solar radiation that is absorbed by the material. Solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the

amount of incident solar radiation absorbed by various surfaces and affects the surface heat balances (both inside and outside as appropriate). Values for this field must be between 0.0 and 1.0.

Field: Visible Absorptance

The visible absorptance field in the Material input syntax represents the fraction of incident visible wavelength radiation that is absorbed by the material. Visible wavelength radiation is slightly different than solar radiation in that the visible band of wavelengths is much more narrow while solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the amount of incident visible radiation absorbed by various surfaces and affects the surface heat balances (both inside and outside as appropriate) as well as the daylighting calculations. Values for this field must be between 0.0 and 1.0.

```

Material:InfraredTransparent

A Infrared Transparent surface is similar to a resistance-only surface. The idd object for this type of surface is shown below. The surface will actually participate in the transfer of visible and solar radiation by doing a wavelength transformation and making all short wave length radiation that is incident on the surface into long wave length radiation and having it

participate in the long wavelength radiant exchange. **Note the ConvectionCoefficient instructions that follow the Infrared Transparent construction object below.**

```
Material:InfraredTransparent,
  \memo Special infrared transparent material. Similar to a Material:Nomass with low thermal
  resistance.
  \memo High absorptance in both wavelengths.
  \memo Area will be doubled internally to make internal radiant exchange accurate.
  \memo Should be only material in single layer surface construction.
  \memo All thermal properties are set internally. User needs only to supply name.

```

Field: Name

This field contains the unique name (across all Material objects) for the Infrared Transparent material.

A Infrared Transparent surface should not participate in a convective/conductive exchange between the zones it separates. In order to minimize this effect, the ConvectionCoefficients object must be used for the surfaces referencing the Infrared Transparent (IRT) construction.

An example idf object specification for use with the IRT surface is shown below:

```
Material:InfraredTransparent,
  IRTMaterial1;           !- Name

Construction,
  IRTSurface,           !- Name
  IRTMaterial1;       !- Outside Layer
```

Surfaces are not described in this example.

Material:AirGap

This material is used to describe the air gap in an opaque construction element. Glass elements use a different property (WindowGas) to describe the air between two glass layers.

Field: Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data (ref: Construction).

Field: Thermal Resistance

This field is used to enter the thermal resistance (R-value) of the material layer. Units for this parameter are (m²-K)/W. Thermal resistance must be greater than zero. Note that most R-values in the USA are calculated in Inch-Pound units and must be converted to the SI equivalent.

```

0.1603675 ; ! Resistance {M**2K/W}

```

MaterialProperty:MoisturePenetrationDepth:Settings

This material is used to describe the five moisture material properties that are used in the EMPD (Effective Moisture Penetration Depth) heat balance solution algorithm (known there as MoisturePenetrationDepthConductionTransferFunction). The EMPD algorithm is a simplified, lumped moisture model that simulates moisture storage and release from interior surfaces. The model uses "actual" convective mass transfer coefficients that are determined by existing heat and mass transfer relationships, e.g. the Lewis relation. An effective moisture penetration depth may be determined from either experimental or detailed simulation data by using actual surface areas and moisture sorption isotherms.

This moisture model will be used when the appropriate EMPD moisture materials are specified and the Solution Algorithm parameter is set to EMPD.

Field: Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data (ref: Construction).

Field: Moisture Penetration Depth

This field is used to enter the effective moisture penetration depth of the material layer. Units for this parameter are (m).

Field: Constants to Define Moisture Equilibrium Equation

The next four fields, coefficients “a”, “b”, “c”, and “d”, help define the sorption isotherm curve used for building materials under equilibrium conditions. They are used to define the relationship between the material’s moisture content and the surface air relative humidity (ref: Effective Moisture Penetration Depth (EMPD) Model in the Engineering Reference):

$$U = a\varphi^b + c\varphi^d$$

where

a,b,c,d = Coefficients to define the relationship between the material’s moisture content and the surface air relative humidity

U = Moisture content defined as the mass fraction of [water](#) contained in a material [kg/kg]

φ = Surface air relative humidity [0 to 1]

These four fields are dimensionless coefficients.

Field: Moisture Equation Coefficient a

Field: Moisture Equation Coefficient b

Field: Moisture Equation Coefficient c

Field: Moisture Equation Coefficient d

MaterialProperty:PhaseChange

Advanced/Research Usage: This material is used to describe the temperature dependent material properties that are used in the Conduction Finite Difference solution algorithm. This conduction model is done when the appropriate materials are specified and the Solution Algorithm parameter is set to ConductionFiniteDifference. This permits simulating temperature dependent thermal conductivity and phase change materials (PCM) in EnergyPlus.

Field: Name

This field is a regular material name specifying the material with which this additional temperature dependent property information will be associated.

Field: Temperature Coefficient for Thermal Conductivity

This field is used to enter the temperature dependent coefficient for thermal conductivity of the material. Units for this parameter are $(W/(m \cdot K^2))$. This is the thermal conductivity change per unit temperature excursion from 20 C. The conductivity value at 20 C is the one specified with the basic material properties of the regular material specified in the name field. The thermal conductivity is obtained from:

$$k = k_o + k_1(T_i - 20)$$

where:

k_o is the 20C value of thermal conductivity(normal idf input)

k_1 is the change in conductivity per degree temperature difference from 20C (this field).

Field Set: Temperature-Enthalpy

The temperature – enthalpy set of inputs specify a two column tabular temperature-enthalpy function for the basic material. Sixteen pairs can be specified. Specify only the number of pairs necessary. The tabular function must cover the entire temperature range that will be seen by the material in the simulation. It is suggested that the function start at a low temperature, and extend to 100C. Note that the function has no negative slopes and the lowest slope that will occur is the base material specific heat. Enthalpy contributions of the phase change are always added to the enthalpy that would result from a constant specific heat base material. An example of a simple enthalpy temperature function is shown below.

**Field: Temperature x**

This field is used to specify the temperature of the temperature-enthalpy function for the basic material. Units are C.

Field: Enthalpy x

This field specifies the enthalpy that corresponds to the previous temperature of the temperature-enthalpy function. Units are J/kg.

The IDD object for these values is shown below.

```

MaterialProperty:HeatAndMoistureTransfer:Settings

Advanced/Research Usage. This object is used to describe two of the seven additional material properties needed for the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm. The settings object is used when the solutions algorithm is set to CombinedHeatAndMoistureFiniteElement and the appropriate material properties are

assigned to each material. This permits the simulation of the moisture dependant thermal properties of the material as well as the transfer of moisture through, into and out of the material into the zone or exterior.

In addition to the Porosity and Initial Water content properties described here, five additional properties, described by tabulated relationships between variables, are required. These properties are;

- MaterialProperty:HeatAndMoistureTransfer:SorptionIsotherm
- MaterialProperty:HeatAndMoistureTransfer:Suction
- MaterialProperty:HeatAndMoistureTransfer:Redistribution
- MaterialProperty:HeatAndMoistureTransfer:Diffusion
- MaterialProperty:HeatAndMoistureTransfer:ThermalConductivity

All materials in a construction are required to have all material properties defined for HAMT to work.

Within the MaterialProperty:MoisturePenetrationDepth:Settings object the following fields are defined.

Field: Material Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data.

Field: Porosity

The porosity of a material is the maximum fraction, by volume, of a material that can be taken up with water. The units are [m³/m³].

Field: Initial Water Content Ratio

For this solution algorithm, the initial water content is assumed to be distributed evenly through the depth of the material. The units are [kg/kg].

```
MaterialProperty:HeatAndMoistureTransfer:Settings,
  Concrete,      !- Name
  0.76,         !- Porosity
  0.2;         !- Initial (or typical) Water content
```

MaterialProperty:HeatAndMoistureTransfer:SorptionIsotherm

Advanced/Research Usage. This material property is used in conjunction with the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm.

The Isotherm data relates the moisture, or water content [kg/m³] of a material with the relative humidity (RH). The water content is expected to increase as relative humidity increases, starting at zero content at 0%RH and reaching a maximum, defined by the porosity, at 100% relative humidity. These two extremes are automatically set by the HAMT solution. However, if they are entered they will be used as extra data points. Data should be provided with increasing RH and moisture content up to as high an RH as possible to provide a stable solution. One possible reason for the following error message may be that a material has a very rapid increase in water content for a small change in RH, which can happen if the last entered water content point is at a low RH and the material has a very high porosity.

```
** Warning ** HeatAndMoistureTransfer: Large Latent Heat for Surface ROOF
```

Another potential reason for this error being generated is the use of inappropriate values for Vapor Transfer Coefficients. See the SurfaceProperties:VaporCoefficients object in the Advanced Surface Concepts group.

Field: Material Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data.

Field: Number of data Coordinates

A maximum of 25 coordinates can be specified.

Field Set: Relative Humidity-Moisture Content

Field: Relative Humidity x

The relative humidity of the xth coordinate.

Field: Moisture Content x

The Moisture Content of the xth coordinate. The units are [kg/m³]

MaterialProperty:HeatAndMoistureTransfer:Suction

Advanced/Research Usage. This material property is used in conjunction with the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm.

The suction data relates the liquid transport coefficient, under suction, to the water content of a material. A data point at zero water content is required. The liquid transport coefficient at the highest entered water content value is used for all liquid transport coefficient values above this water content. These coefficients are used by HAMT when the rain flag is set in the weather file.

Field: Material Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data.

Field: Number of Suction points

A maximum of 25 points can be specified.

Field Set: Moisture Content-Liquid Transport Coefficient

Field: Moisture Content x

The moisture content of the x^{th} point. The units are [kg/m³].

Field: Liquid Transport Coefficient x

The Liquid Transport Coefficient of the x^{th} point. The units are [m²/s].

The following shows the Input Data Dictionary description of the HAMT-SUCTION input.

MaterialProperty:HeatAndMoistureTransfer:Redistribution

Advanced/Research Usage. This material property is used in conjunction with the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm.

The redistribution data relates the liquid transport coefficient to the water content of a material under normal conditions. A data point at zero water content is required. The liquid transport coefficient at the highest entered water content value is used for all liquid transport coefficient values above this water content. These coefficients are used by the Heat and Moisture Transfer algorithm when the rain flag is NOT set in the weather file.

Field: Material Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data.

Field: Number of Redistribution points

A maximum of 25 points can be specified.

Field Set: Moisture Content-- Liquid Transport Coefficient**Field: Moisture Content x**

The moisture content of the x^{th} point. The units are [kg/m3].

Field: Liquid Transport Coefficient x

The Liquid Transport Coefficient of the x^{th} point. The units are [m2/s].

The following shows the Input Data Dictionary description of the HAMT-REDISTRIBUTION input.

```

MaterialProperty:HeatAndMoistureTransfer:Diffusion

Advanced/Research Usage. This material property is used in conjunction with the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm.

The MU data relates the vapor diffusion resistance factor to the relative humidity (RH). A data point at zero RH is required. The vapor diffusion resistance factor at the highest entered RH value is used for all vapor diffusion resistance factor values above this RH.

Field: Material Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data.

Field: Number of Data Pairs

A maximum of 25 pairs can be specified.

Field Set: Relative Humidity-Vapor Diffusion Resistance Factor

Field: Relative Humidity #x

The moisture content of the xth pair.

Field: Vapor Diffusion Resistance Factor #x

MaterialProperty:HeatAndMoistureTransfer:ThermalConductivity

Advanced/Research Usage. This material property is used in conjunction with the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm.

The thermal data relates the thermal conductivity [W/m-K] of a material to the moisture or water content [kg/m3]. A data point at zero water content is required. The thermal conductivity at the highest entered water content value is used for all thermal conductivity values above this water content. If this object is not defined for a material then the algorithm will use a constant value entered in the Material object for all water contents.

Materials for Glass Windows and Doors

All the materials for glass windows and doors have the prefix “WindowMaterial”. The following WindowMaterial descriptions (Glazing, Glazing:RefractionExtinctionMethod, Gas, GasMixture, Shade, Screen and Blind) apply to glass windows and doors. The property definitions described herein for Glazing, Gas and GasMixture are supported by the National Fenestration Rating Council as standard.

“Front side” is the side of the layer opposite the zone in which the window is defined. “Back side” is the side closest to the zone in which the window is defined. Therefore, for exterior windows, “front side” is the side closest to the outdoors. For interior windows, “front side” is the side closest to the zone adjacent to the zone in which the window is defined.

The solar radiation transmitted by the window layers enters the zone and is a component of the zone load. The solar radiation absorbed in each solid layer (glass, shade, screen or blind) participates in the window layer heat balance calculation. The visible transmittance and reflectance properties of the window are used in the daylighting calculation.

WindowMaterial:Glazing

In the following, for exterior windows, “front side” is the side of the glass closest to the outside air and “back side” is the side closest to the zone the window is defined in. For interzone windows, “front side” is the side closest to the zone adjacent to the zone the window is defined in and “back side” is the side closest to the zone the window is defined in.

Field: Name

The name of the glass layer. It corresponds to a layer in a window construction.

Field: Optical Data Type

If Optical Data Type = SpectralAverage, the values you enter for solar transmittance and reflectance are assumed to be averaged over the solar spectrum, and the values you enter for visible transmittance and reflectance are assumed to be averaged over the solar spectrum and weighted by the response of the human eye. There is an EnergyPlus Reference Data

Set for WindowMaterial:Glazing that contains spectral average properties for many different types of glass.

If Optical Data Type = Spectral, then, in the following field, you must enter the name of a spectral data set defined with the WindowGlassSpectralData object. In this case, the values of solar and visible transmittance and reflectance in the fields below should be blank.

Field: Window Glass Spectral Data Set Name

If Optical Data Type = Spectral, this is the name of a spectral data set defined with a WindowGlassSpectralData object.

Field: Thickness

The surface-to-surface thickness of the glass (m).

Field: Solar Transmittance at Normal Incidence

Transmittance at normal incidence averaged over the solar spectrum. Used only when Optical Data Type = SpectralAverage.

For uncoated glass, when alternative optical properties are available—such as thickness, solar index of refraction, and solar extinction coefficient—they can be converted to equivalent solar transmittance and reflectance values using the equations given in “Conversion from Alternative Specification of Glass Optical Properties.”)

Field: Front Side Solar Reflectance at Normal Incidence

Front-side reflectance at normal incidence averaged over the solar spectrum. Used only when Optical Data Type = SpectralAverage.

Field: Back Side Solar Reflectance at Normal Incidence

Back-side reflectance at normal incidence averaged over the solar spectrum. Used only when Optical Data Type = SpectralAverage.

Field: Visible Transmittance at Normal Incidence

Transmittance at normal incidence averaged over the solar spectrum and weighted by the response of the human eye. Used only when Optical Data Type = SpectralAverage.

For uncoated glass, when alternative optical properties are available—such as thickness, visible index of refraction, and visible extinction coefficient—they can be converted to equivalent visible transmittance and reflectance values using the equations given in “Conversion from Alternative Specification of Glass Optical Properties.”)

Field: Front Side Visible Reflectance at Normal Incidence

Front-side reflectance at normal incidence averaged over the solar spectrum and weighted by the response of the human eye. Used only when Optical Data Type = SpectralAverage.

Field: Back Side Visible Reflectance at Normal Incidence

Back-side reflectance at normal incidence averaged over the solar spectrum and weighted by the response of the human eye. Used only when Optical Data Type = SpectralAverage.

Field: Infrared Transmittance at Normal Incidence

Long-wave transmittance at normal incidence.

Field: Front Side Infrared Hemispherical Emissivity

Front-side long-wave emissivity.

Field: Back Side Infrared Hemispherical Emissivity

Back-side long-wave emissivity.

Field: Conductivity

Thermal conductivity (W/m-K).

Field: Dirt Correction Factor for Solar and Visible Transmittance

This is a factor that corrects for the presence of dirt on the glass. The program multiplies the fields “Solar Transmittance at Normal Incidence” and “Visible Transmittance at Normal Incidence” by this factor if the material is used as the outer glass layer of an exterior window or glass door.² If the material is used as an inner glass layer (in double glazing, for example), the dirt correction factor is not applied because inner glass layers are assumed to be clean. Using a material with dirt correction factor < 1.0 in the construction for an interior window will result in an error message.

Representative values of the dirt correction factor are shown in Table 6.

Table 6. Dirt Correction Factors

Type of Location	Angle of Glazing		
	Vertical	45 ^o	Horizontal
Non-industrial	0.9	0.8	0.7
Industrial	0.7	0.6	0.5
Very Dirty	0.6	0.5	0.4

From Appendix A, “Daylighting in Sports Halls, Report 2,” SportScotland, Nov. 2002
(www.sportscotland.org.uk)

The default value of the dirt correction factor is 1.0, which means the glass is clean.

It is assumed that dirt, if present, has no effect on the IR properties of the glass.

Field: Solar Diffusing

Takes values No (the default) and Yes. If No, the glass is transparent and beam solar radiation incident on the glass is transmitted as beam radiation with no diffuse component. If Yes, the glass is translucent and beam solar radiation incident on the glass is transmitted as hemispherically diffuse radiation with no beam component.³ See Figure 8. Solar Diffusing = Yes should only be used on the *innermost* pane of glass in an exterior window; it does not apply to interior windows.

For both Solar Diffusing = No and Yes, beam is reflected as beam with no diffuse component (see Figure 8)

If, in the Building object, Solar Distribution = FullInteriorAndExterior, use of Solar Diffusing = Yes for glass in an exterior window will change the distribution of interior solar radiation from the window. The result is that beam solar radiation that would be transmitted by a transparent window and get absorbed by particular interior surfaces will be diffused by a translucent window and be spread over more interior surfaces. This can change the time dependence of heating and cooling loads in the zone.

In a zone with Daylighting:Detailed, translucent glazing---which is often used in skylights---will provide a more uniform daylight illuminance over the zone and will avoid patches of sunlight on the floor.

² If Optical Data Type = Spectral, the program multiplies the solar and visible transmittance *at each wavelength* by the dirt correction factor.

³ EnergyPlus does not model the “partially translucent” case in which beam solar radiation incident on the glass is transmitted as a combination of beam and diffuse.

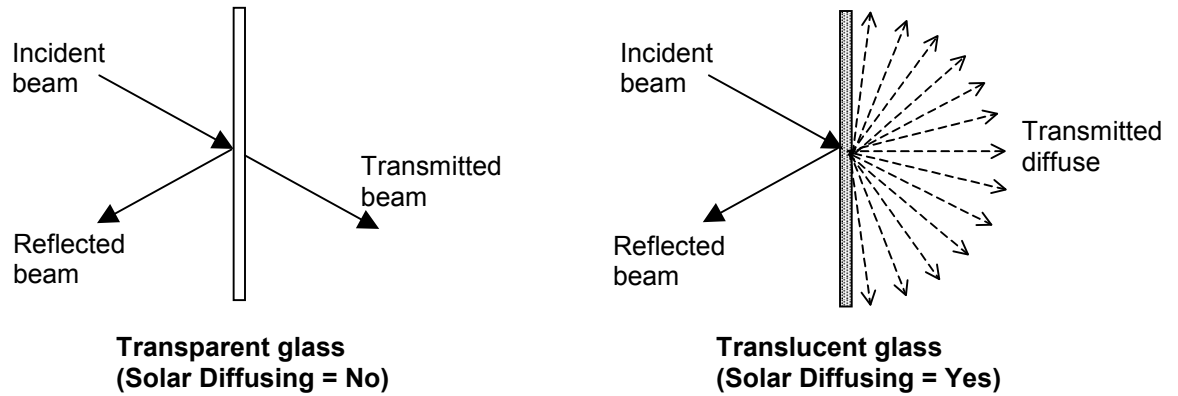

Figure 8. Comparison between transmittance properties of transparent glass (Solar Diffusing = No) and translucent glass (Solar Diffusing = Yes).

WindowMaterial:Glazing:RefractionExtinctionMethod

This is an alternative way of specifying glass properties. [Index of refraction](#) and [extinction coefficient](#) are given instead of the transmittance and reflectance values used in WindowMaterial:Glazing. However, unlike WindowMaterial:Glazing, WindowMaterial:Glazing:RefractionExtinctionMethod is restricted to cases where the front and back optical properties of the glass are the same. This means it cannot be used for glass with a coating on one side. In that case WindowMaterial:Glazing should be used. Also, unlike WindowMaterial:Glazing, WindowMaterial:Glazing:RefractionExtinctionMethod does not allow input of glass wavelength-by-wavelength (spectral) properties.

Field: Name

The name of the glass layer. It corresponds to a layer in a window construction.

Field: Thickness

The surface-to-surface thickness of the glass (m).

Field: Solar Index of Refraction

Index of refraction averaged over the solar spectrum.

Field: Solar Extinction Coefficient

Extinction coefficient averaged over the solar spectrum (m^{-1}).

Field: Visible Index of Refraction

Index of refraction averaged over the solar spectrum and weighted by the response of the human eye.

Field: Visible Extinction Coefficient

Extinction coefficient averaged over the solar spectrum and weighted by the response of the human eye (m^{-1}).

Field: Infrared Transmittance at Normal Incidence

Long-wave transmittance at normal incidence.

Field: Infrared Hemispherical Emissivity

Long-wave hemispherical emissivity, assumed the same on both sides of the glass.

Field: Conductivity

Thermal conductivity (W/m-K).

Field: Dirt Correction Factor for Solar and Visible Transmittance

This is a factor that corrects for the presence of dirt on the glass. It multiplies the solar and visible transmittance at normal Incidence (which the program calculates from the input values

of thickness, solar index of refraction, solar extinction coefficient, etc.) if the material is used as the outer glass layer of an exterior window or glass door. If the material is used as an inner glass layer (in double glazing, for example), the dirt correction factor is not applied because inner glass layers are assumed to be clean. Using a material with dirt correction factor < 1.0 in the construction for an interior window will result in an error message.

Representative values of the direct correction factor are shown in Table 6.

The default value of the dirt correction factor is 1.0, which means the glass is clean. It is assumed that dirt, if present, has no effect on the IR properties of the glass.

Field: Solar Diffusing

Takes values No (the default) and Yes. If No, the glass is transparent. If Yes, the glass is translucent and beam solar radiation incident on the glass is transmitted as hemispherically diffuse radiation with no beam component. Solar Diffusing = Yes should only be used on the innermost pane of glass in an exterior window; it does not apply to interior windows.

If, in the Building object, Solar Distribution = FullInteriorAndExterior, use of Solar Diffusing = Yes for glass in an exterior window will change the distribution of interior solar radiation from the window. The result is that beam solar radiation that would be transmitted by a transparent window and get absorbed by particular interior surfaces will be diffused by a translucent window and be spread over more interior surfaces. This can change the time dependence of heating and cooling loads in the zone.

In a zone with Daylighting:Detailed, translucent glazing, which is often used in skylights, will provide a more uniform daylight illuminance over the zone and will avoid patches of sunlight on the floor.

Glass Optical Properties Conversion

Conversion from Glass Optical Properties Specified as Index of Refraction and Transmittance at Normal Incidence

The optical properties of uncoated glass are sometimes specified by index of refraction, n , and transmittance at normal incidence, T .

The following equations show how to convert from this set of values to the transmittance and reflectance values required by WindowMaterial:Glazing. These equations apply only to uncoated glass, and can be used to convert either spectral-average solar properties or spectral-average visible properties (in general, n and T are different for the solar and visible). Note that since the glass is uncoated, the front and back reflectances are the same and equal to the R that is solved for in the following equations.

Given n and T , find R :

$$r = \left(\frac{n-1}{n+1} \right)^2$$

$$\tau = \frac{\left[(1-r)^4 + 4r^2 T^2 \right]^{1/2} - (1-r)^2}{2r^2 T}$$

$$R = r + \frac{(1-r)^2 r \tau^2}{1-r^2 \tau^2}$$

Example:

$$T = 0.86156$$

$$n = 1.526$$

$$r = \left(\frac{1.526-1}{1.526+1} \right)^2$$

$$\tau = 0.93974$$

$$R = 0.07846$$

WindowMaterial:GlazingGroup:Thermochromic

Thermochromic (TC) materials have active, reversible optical properties that vary with temperature. Thermochromic windows are adaptive window systems for incorporation into building envelopes. Thermochromic windows respond by absorbing sunlight and turning the sunlight energy into heat. As the thermochromic film warms it changes its light transmission level from less absorbing to more absorbing. The more sunlight it absorbs the lower the light level going through it. By using the sun's own energy the window adapts based solely on the directness and amount of sunlight. Thermochromic materials will normally reduce optical transparency by absorption and/or reflection, and are specular (maintaining vision).

A thermochromic window is defined with a Construction object which references a special layer defined with a WindowMaterial:GlazingGroup:Thermochromic object. The WindowMaterial:GlazingGroup:Thermochromic object further references a series of WindowMaterial:Glazing objects corresponding to each specification temperature of the TC layer.

This object specifies a layer of thermochromic glass, part of a thermochromic window. An example file ThermochromicWindow.idf is included in the EnergyPlus installation.

Field: Name

A unique user assigned name for a particular thermochromic glass material.

Field Set (Optical Data Temperature, Window Material Glazing Name) is extensible.

Field: Optical Data Temperature <N>

The temperature of the TC glass layer corresponding to the optical data of the TC layer. Unit is °C.

Field: Window Material Glazing Name <N>

The window glazing (defined with WindowMaterial:Glazing) name that provides the TC glass layer performance at the above specified temperature.

The IDD definition for the object follows:

```

Thermochromic Window Outputs

Window Thermochromic Layer Temperature [C]

The temperature of the TC glass layer of a TC window at each time step.

Window Thermochromic Layer Specification Temperature [C]

The temperature under which the optical data of the TC glass layer are specified.

The overall properties (U-factor/SHGC/VT) of the thermochromic windows at different specification temperatures are reported in the EIO file. These window constructions are created by EnergyPlus during run time. They have similar names with suffix “_TC_XX” where XX represents a specification temperature.

WindowMaterial:Gas

This object specifies the properties of the gas between the panes of a multi-pane window. Gas Type = Custom allows you to specify the properties of gases other than air, Argon, Krypton or Xenon. There is an EnergyPlus Reference Data Set for Material:WindowGas that contains several types of gas of different thicknesses. See Material:WindowGasMixture for the case that the gas fill is a mixture of different gases.

Field: Name

The name of the gas fill. It refers to a layer in a window construction.

Field: Gas Type

The type of gas. The choices are Air, Argon, Krypton, or Xenon. If Gas Type = Custom you can use Conductivity Coefficient A, etc. to specify the properties of a different type of gas.

Field: Thickness

The thickness (m) of the gas layer.

Properties for Custom Gas Types

The following entries are used only if Gas Type = Custom. The A and B coefficients are those in the following expression that gives a property value as a function of temperature in degrees K:

$$Property = Coefficient_A + Coefficient_B * Temperature_K$$

Field: Conductivity Coefficient A

The A coefficient for gas conductivity (W/m-K). Used only if Gas Type = Custom.

Field: Conductivity Coefficient B

The B coefficient for gas conductivity (W/m-K²). Used only if Gas Type = Custom.

Field: Viscosity Coefficient A

The A coefficient for gas viscosity (kg/m-s). Used only if Gas Type = Custom.

Field: Viscosity Coefficient B

The B coefficient for gas viscosity (kg/m-s-K). Used only if Gas Type = Custom.

Field: Specific Heat Coefficient A

The A coefficient for gas specific heat (J/kg-K). Used only if Gas Type = Custom.

Field: Specific Heat Coefficient B

The B coefficient for gas specific heat (J/kg-K²). Used only if Gas Type = Custom.

```

WindowMaterial:GasMixture

This object allows you to specify the fill between the panes of a multi-pane window to be a mixture of two, three or four different gases chosen from air, argon, krypton and xenon. It can also be used if only one type of gas in the fill. In this case you can also use WindowMaterial:Gas. Note that the fractions of gas types in the mixture should add up to 1.0.

Field: Name

The name of the gas mixture. It refers to a layer in a window construction.

Field: Thickness

The thickness (m) of the gas mixture layer.

Field: Number of Gases in Mixture

The number of different types of gas in the mixture (a value from 1 to 4)

Set: Gas Type-Fraction (up to 4)**Field: Gas 1 Type**

The type of the first gas in the mixture. Choices are Air, Argon, Krypton and Xenon.

Field: Gas 1 Fraction

The fraction of the first gas in the mixture.

WindowMaterial:Shade

This object specifies the properties of window shade materials. Reflectance and emissivity properties are assumed to be the same on both sides of the shade. Shades are considered to be perfect diffusers (all transmitted and reflected radiation is hemispherically-diffuse) with transmittance and reflectance independent of angle of incidence. There is an EnergyPlus Reference Data Set for WindowMaterial:Shade that contains properties of generic window shades.

Window shades can be on the inside of the window (“interior shades”), on the outside of the window (“exterior shades”), or between glass layers (“between-glass shades”). When in place, the shade is assumed to cover all of the glazed part of the window, including dividers; it does not cover any of the window frame, if present. The plane of the shade is assumed to be parallel to the glazing.

Note that when locating a window shade between glass layers, the WindowMaterial:Glazing layers in the window construction must all use an Optical Data Type of SpectralAverage. Spectral data for glazing layers is not currently supported for between glass shades.

WindowMaterial:Shade can be used for diffusing materials such as drapery and translucent roller shades. For slat-type shading devices, like Venetian blinds, that have a strong angular dependence of transmission, absorption and reflection, it is better to use WindowMaterial:Blind. WindowMaterial:Screen should be used to model wire mesh insect screens where the solar and visible transmission and reflection properties vary with the angle of incidence of solar radiation.

Transmittance and reflectance values for drapery material with different color and openness of weave can be obtained from manufacturers or determined from 2001 ASHRAE Fundamentals, Chapter 30, Fig. 31.

There are two methods of assigning a shade to a window:

Method 1:

- 1) Define the construction of the window without the shade, the so-called “bare” construction.
- 2) Reference the bare construction in the FenestrationSurface:Detailed for the window.
- 3) Define the WindowMaterial:Shade.
- 4) Define a WindowProperty:ShadingControl for the window in which you (a) specify that this WindowMaterial:Shade is the window’s shading device and (b) specify how the shade is controlled.

Method 2:

- 1) Define the Construction of the window without the shade, the so-called “bare” construction.
- 2) Reference the bare construction in the FenestrationSurface:Detailed for the window.
- 3) Define the WindowMaterial:Shade.
- 4) Define another Construction, called the “shaded construction,” that includes the WindowMaterial:Shade.
- 5) Define a WindowProperty:ShadingControl for the window in which you (a) reference the shaded construction and (b) specify how the shade is controlled.

Note that WindowProperty:ShadingControl has to be used with either method, even if the shade is in place at all times. You will get an error message if you try to reference a shaded construction directly from FenestrationSurface:Detailed.

Field: Name

Name of the shade. It is referenced as an inside or outside layer in a window construction.

Field: Solar Transmittance

Transmittance averaged over the solar spectrum. Assumed independent of incidence angle.

Field: Solar Reflectance

Reflectance averaged over the solar spectrum. Assumed same on both sides of shade and independent of incidence angle.

Field: Visible Transmittance

Transmittance averaged over the solar spectrum and weighted by the response of the human eye. Assumed independent of incidence angle.

Field: Visible Reflectance

Reflectance averaged over the solar spectrum and weighted by the response of the human eye. Assumed same on both side of shade and independent of incidence angle.

Field: Thermal Hemispherical Emissivity

Effective long-wave emissivity. Assumed same on both sides of shade. We can approximate this effective emissivity, ϵ_{eff} , as follows. Let η be the “openness” the shade, i.e., the ratio of the area of openings in the shade to the overall shade area (see Field: Air-Flow Permeability, below). Let the emissivity of the shade material be ϵ . Then

$$\epsilon_{eff} \approx \epsilon(1 - \eta)$$

For most non-metallic materials ϵ is about 0.9.

Field: Thermal Transmittance

Effective long-wave transmittance. Assumed independent of incidence angle. We can approximate this effective long-wave transmittance, T_{eff} , as follows. Let η be the “openness” the shade, i.e., the ratio of the area of openings in the shade to the overall shade area. Let the long-wave transmittance of the shade material be T . Then

$$T_{eff} \approx \eta + T(1 - \eta)$$

For most materials T is very close to zero, which gives

$$T_{eff} \approx \eta$$

Field: Thickness

Thickness of the shade material (m). If the shade is not flat, such as for pleated pull-down shades or folded drapery, the average thickness normal to the plane of the shade should be used.

Field: Conductivity

Shade material conductivity (W/m-K).

Field: Shade to Glass Distance

Distance from shade to adjacent glass (m). This is denoted by s in Figure 9 and Figure 10, below. If the shade is not flat, such as for pleated pull-down shades or folded drapery, the average shade-to-glass distance should be used. (The shade-to-glass distance is used in calculating the natural convective air flow between glass and shade produced by buoyancy effects.). Note used for between-glass shades.

In the following, H is the glazing height and W is the glazing width.

Field: Top Opening Multiplier

Effective area for air flow at the top of the shade divided by sW , the horizontal area between glass and shade (see Figures below).

Field: Bottom Opening Multiplier

Effective area for air flow at the bottom of the shade divided by sW , the horizontal area between glass and shade (see Figures below).

Field: Left-Side Opening Multiplier

Effective area for air flow at the left side of the shade divided by sH , the vertical area between glass and shade (see Figures below).

Field: Right-Side Opening Multiplier

Effective area for air flow at the right side of the shade divided by sH , the vertical area between glass and shade (see Figures below).

Field: Air-Flow Permeability

The fraction of the shade surface that is open to air flow, i.e., the total area of openings (“holes”) in the shade surface divided by the shade area, HW . If air cannot pass through the shade material, Air-Flow Permeability = 0. For drapery fabric and screens the Air-Flow Permeability can be taken as the “openness” of the fabric (see 2001 ASHRAE Fundamentals, Chapter 30, Fig. 31), which is 0.0 to 0.07 for closed weave, 0.07 to 0.25 for semi-open weave, and 0.25 and higher for open weave.

Figure 9. Vertical section (a) and perspective view (b) of glass and interior shade layers showing variables used in the gap air flow analysis. In (b), the air-flow opening areas A_{bot} , A_{top} , A_l , A_r and A_h are shown schematically. See *Engineering Manual* for definition of thermal variables.

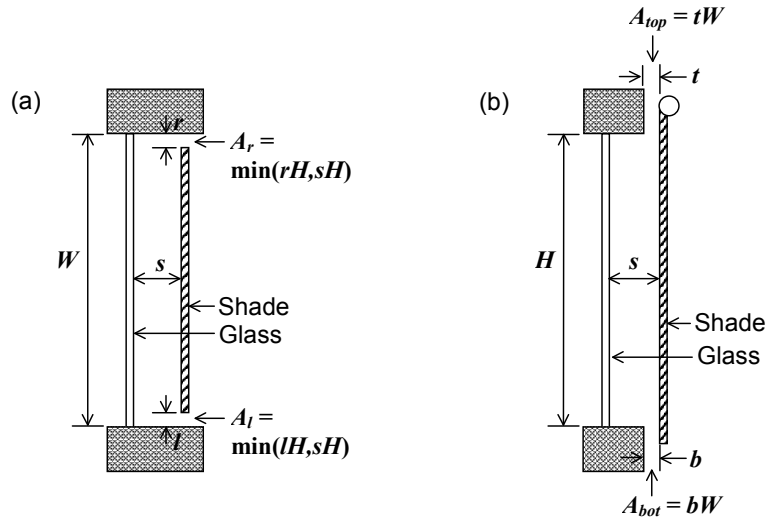

Figure 10. Examples of air-flow openings for an interior shade covering glass of height H and width W . Not to scale. (a) Horizontal section through shade with openings on the left and right sides (top view). (b) Vertical section through shade with openings at the top and bottom (side view). In (a) Left-Side Opening Multiplier = $A_l/sH = \min(l/s, 1)$ and Right-Side Opening Multiplier = $A_r/sH = \min(r/s, 1)$. In (b) Top Opening Multiplier = $A_{top}/sW = t/s$ and Bottom Opening Multiplier = $A_{bot}/sW = b/s$.

WindowMaterial:Blind

This object specifies the properties of a window blind consisting of flat, equally-spaced slats. Unlike window shades, which are modeled as perfect diffusers, window blinds have solar and visible transmission and reflection properties that strongly depend on slat angle and angle of incidence of solar radiation. There is an EnergyPlus Reference Data Set for WindowMaterial:Blind that contains properties of generic window blinds.

Blinds can be located on the inside of the window (“interior blinds”), on the outside of the window (“exterior blinds”), or between two layers of glass (“between-glass blinds”). When in place, the blind is assumed to cover all of the glazed part of the window, including dividers; it does not cover any of the window frame, if present. The plane of the blind is assumed to be parallel to the glazing. When the blind is retracted it is assumed to cover none of the window. The solar and thermal effects of the blind’s support strings, tapes or rods are ignored. Slat curvature, if present, is ignored.

Note that when locating a window blind between glass layers, the WindowMaterial:Glazing layers in the window construction must all use an Optical Data Type of SpectralAverage. Spectral data for glazing layers is not currently supported for between glass blinds.

There are two methods of assigning a blind to a window:

Method 1:

1. Define the construction of the window without the blind, the so-called “bare” construction.
2. Reference the bare construction in the FenestrationSurface:Detailed for the window.
3. Define the WindowMaterial:Blind.
4. Define a WindowProperty:ShadingControl for the window in which you (a) specify that this WindowMaterial:Blind is the window’s shading device and (b) specify how the blind is controlled.

Method 2:

1. Define the Construction of the window without the blind, the so-called “bare” construction.
2. Reference the bare construction in the FenestrationSurface:Detailed for the window.
3. Define the WindowMaterial:Blind.
4. Define another Construction, called the “shaded construction,” that includes the WindowMaterial:Blind.
5. Define a WindowProperty:ShadingControl for the window in which you (a) reference the shaded construction and (b) specify how the blind is controlled.

Note that WindowProperty:ShadingControl has to be used with either method, even if the blind is in place at all times. You will get an error message if you try to reference a construction with a blind directly from Surface:HeatTransfer:Sub.

Note also that WindowProperty:ShadingControl is used to determine not only when the blind is in place, but how its slat angle is controlled.

Field: Name

Name of the blind. It is referenced as a layer in a window construction (ref: Construction) or as a “Material Name of Shading Device” in a WindowProperty:ShadingControl object.

Field: Slat Orientation

The choices are Horizontal and Vertical. “Horizontal” means the slats are parallel to the bottom of the window; this is the same as saying that the slats are parallel to the X-axis of the window. “Vertical” means the slats are parallel to Y-axis of the window.

Field: Slat Width

The width of the slat measured from edge to edge (m). See Figure 11.

Field: Slat Separation

The distance between the front of a slat and the back of the adjacent slat (m). See Figure 11.

Field: Slat Thickness

The distance between the faces of a slat (m). See Figure 11.

Field: Slat Angle

The angle (degrees) between the glazing outward normal and the slat outward normal, where the outward normal points away from the front face of the slat (degrees). See Figure 11.

If the WindowProperty:ShadingControl for the blind has Type of Slat Angle Control for Blinds = FixedSlatAngle, the slat angle is fixed at “Slat Angle.”

If Type of Slat Angle Control for Blinds = BlockBeamSolar, the program automatically adjusts the slat angle so as just block beam solar radiation. In this case the value of “Slat Angle” is used only when the blind is in place and there is no beam solar radiation incident on the blind.

If Type of Slat Angle Control for Blinds = ScheduledSlatAngle, the slat angle is variable. In this case “Slat Angle” is not applicable and the field should be blank.

If Type of Slat Angle Control for Blinds = FixedSlatAngle and “Slat Angle” is less than the minimum or greater than the maximum allowed by Slat Width, Slat Separation and Slat Thickness, the slat angle will be reset to the corresponding minimum or maximum and a warning will be issued.

Field: Slat Conductivity

The thermal conductivity of the slat (W/m-K).

Field: Slat Beam Solar Transmittance

The beam solar transmittance of the slat, assumed to be independent of angle of incidence on the slat. Any transmitted beam radiation is assumed to be 100% diffuse (i.e., slats are translucent).

Field: Front Side Slat Beam Solar Reflectance

The beam solar reflectance of the front side of the slat, assumed to be independent of angle of incidence (matte finish). This means that slats with a large specularly-reflective component (shiny slats) are not well modeled.

Field: Back Side Slat Beam Solar Reflectance

The beam solar reflectance of the back side of the slat, assumed to be independent of angle of incidence (matte finish). This means that slats with a large specularly-reflective component (shiny slats) are not well modeled.

Field: Slat Diffuse Solar Transmittance

The slat transmittance for hemispherically diffuse solar radiation. This value should equal "Slat Beam Solar Transmittance."

Field: Front Side Slat Diffuse Solar Reflectance

The front-side slat reflectance for hemispherically diffuse solar radiation. This value should equal "Front Side Slat Beam Solar Reflectance."

Field: Back Side Slat Diffuse Solar Reflectance

The back-side slat reflectance for hemispherically diffuse solar radiation. This value should equal "Back Side Slat Beam Solar Reflectance."

Field: Slat Beam Visible Transmittance

The beam visible transmittance of the slat, assumed to be independent of angle of incidence on the slat. Any transmitted visible radiation is assumed to be 100% diffuse (i.e., slats are translucent).

Field: Front Side Slat Beam Visible Reflectance

The beam visible reflectance on the front side of the slat, assumed to be independent of angle of incidence (matte finish). This means that slats with a large specularly-reflective component (shiny slats) are not well modeled.

Field: Back Side Slat Beam Visible Reflectance

The beam visible reflectance on the front side of the slat, assumed to be independent of angle of incidence (matte finish). This means that slats with a large specularly-reflective component (shiny slats) are not well modeled.

Field: Slat Diffuse Visible Transmittance

The slat transmittance for hemispherically diffuse visible radiation. This value should equal "Slat Beam Visible Transmittance."

Field: Front Side Slat Diffuse Visible Reflectance

The front-side slat reflectance for hemispherically diffuse visible radiation. This value should equal "Front Side Slat Beam Visible Reflectance."

Field: Back Side Slat Diffuse Visible Reflectance

The back-side slat reflectance for hemispherically diffuse visible radiation. This value should equal "Back Side Slat Beam Visible Reflectance.."

Field: Slat Infrared Hemispherical Transmittance

The slat Infrared transmittance. It is zero for solid metallic, wooden or glass slats, but may be non-zero in some cases (e.g., thin plastic slats).

Field: Front Side Slat Infrared Hemispherical Emissivity

Front-side hemispherical emissivity of the slat. Approximately 0.9 for most materials. The most common exception is bare (unpainted) metal slats or slats finished with a metallic paint.

Field: Back Side Slat Infrared Hemispherical Emissivity

Back-side hemispherical emissivity of the slat. Approximately 0.9 for most materials. The most common exception is bare (unpainted) metal slats or slats finished with a metallic paint.

Field: Blind to Glass Distance

For interior and exterior blinds, the distance from the mid-plane of the blind to the adjacent glass (m). See Figure 11. Not used for between-glass blinds. As for window shades (ref: WindowMaterial:Shade) this distance is used in calculating the natural convective air flow between glass and blind that is produced by buoyancy effects.

Opening Multipliers

The following opening multipliers are defined in the same way as for window shades (see WindowMaterial:Shade, Figure 9 and Figure 10). Note that, unlike window shades, there is no input for Air-Flow Permeability; this is automatically calculated by the program from slat angle, width and separation.

Field: Blind Top Opening Multiplier

Defined as for Material:WindowShade.

Field: Blind Bottom Opening Multiplier

Defined as for Material:WindowShade.

Field: Blind Left-Side Opening Multiplier

Defined as for Material:WindowShade.

Field: Blind Right-Side Opening Multiplier

Defined as for Material:WindowShade.

Field: Minimum Slat Angle

The minimum allowed slat angle (degrees). Used only if WindowProperty:ShadingControl (for the window that incorporates this blind) varies the slat angle (i.e., the WindowProperty:ShadingControl has Type of Slat Angle Control for Blinds = ScheduledSlatAngle or BlockBeamSolar). In this case, if the program tries to select a slat angle less than Minimum Slat Angle it will be reset to Minimum Slat Angle. (Note that if the Minimum Slat Angle itself is less than the minimum allowed by Slat Width, Slat Separation and Slat Thickness, it will be reset to that minimum.)

Field: Maximum Slat Angle

The maximum allowed slat angle (degrees). Used only if WindowProperty:ShadingControl (for the window that incorporates this blind) varies the slat angle (i.e., the WindowProperty:ShadingControl has Type of Slat Angle Control for Blinds = ScheduledSlatAngle or BlockBeamSolar). In this case, if the program tries to select a slat angle greater than Maximum Slat Angle the slat angle will be reset to Maximum Slat Angle. (Note that if the Maximum Slat Angle itself is greater than the maximum allowed by Slat Width, Slat Separation and Slat Thickness, it will be reset to that maximum.)

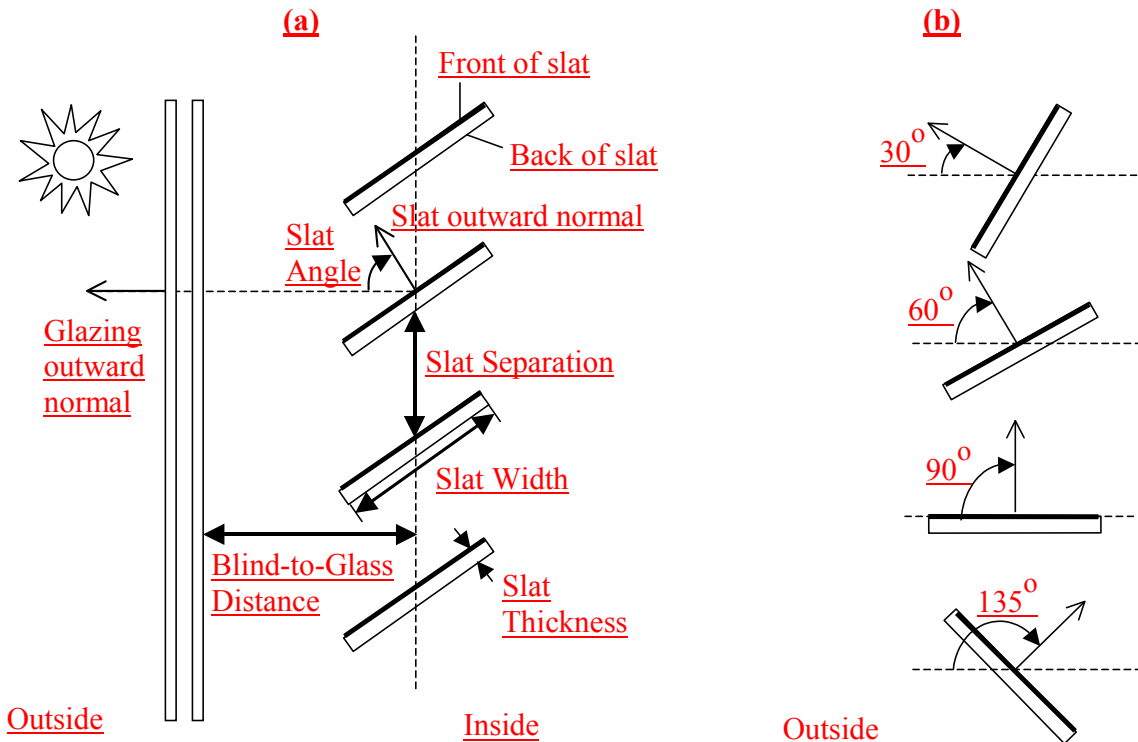

Figure 11. (a) Side view of a window blind with horizontal slats (or top view of blind with vertical slats) showing slat geometry. The front face of a slat is shown by a heavy line. The slat angle is defined as the angle between the glazing outward normal and the slat outward normal, where the outward normal points away from the front face of the slat. (b) Slat orientations for representative slat angles. The slat angle varies from 0°, when the front of the slat is parallel to the glazing and faces toward the outdoors, to 90°,

when the slat is perpendicular to the glazing, to 180° , when the front of the slat is parallel to the glazing and faces toward the indoors. The minimum and maximum slat angles are determined by the slat thickness, width and separation.

WindowMaterial:Screen

This object specifies the properties of exterior window screen materials. The window screen model assumes the screen is made up of intersecting orthogonally-crossed cylinders. The surface of the cylinders is assumed to be diffusely reflecting, having the optical properties of a Lambertian surface.

The beam solar radiation transmitted through a window screen varies with sun angle and is made up of two distinct elements: a direct beam component and a reflected beam component. The direct beam transmittance component is modeled using the geometry of the screen material and the incident angle of the sun to account for shadowing of the window by the screen material. The reflected beam component is an empirical model that accounts for the inward reflection of solar beam off the screen material surface. This component is both highly directional and small in magnitude compared to the direct beam transmittance component (except at higher incident angles, for which case the magnitude of the direct beam component is small or zero and the reflected beam component, though small in absolute terms can be many times larger than the direct beam component). For this reason, the reflected beam transmittance component calculated by the model can be a. disregarded, b. treated as an additive component to direct beam transmittance (and in the same direction), or c. treated as hemispherically-diffuse transmittance based on a user input to the model.

Figure 12. Direct beam and reflected beam transmittance components

The window screen “assembly” properties of overall beam solar reflectance and absorptance (including the screen material ‘cylinders’ and open area) also change with sun angle and are calculated based on the values of the beam solar transmittance components (direct and reflected components described above) and the physical properties of the screen material (i.e., screen material diameter, spacing, and reflectance).

Transmittance, reflectance, and absorptance of diffuse solar radiation are considered constant values and apply to both the front and back surfaces of the screen. These properties are calculated by the model as an average value by integrating the screen’s beam solar properties over a quarter hemisphere of incident radiation. Long-wave emissivity is also assumed to be the same for both sides of the screen.

There is an EnergyPlus Reference Data Set for WindowMaterial:Screen that contains properties for generic window screens. Window screens of this type can only be used on the outside surface of the window (“exterior screens”). When in place, the screen is assumed to cover all of the glazed part of the window, including dividers; it does not cover any of the window frame, if present. The plane of the screen is assumed to be parallel to the glazing.

WindowMaterial:Screen can be used to model wire mesh insect screens where the solar and visible transmission and reflection properties vary with the angle of incidence of solar radiation. For diffusing materials such as drapery and translucent roller shades it is better to use the WindowMaterial:Shade object. For slat-type shading devices like Venetian blinds, which have solar and visible transmission and reflection properties that strongly depend on slat angle and angle of incidence of solar radiation, it is better to use WindowMaterial:Blind.

There are two methods of assigning a screen to a window:

Method 1:

- 1) Define the construction of the window without the screen, the so-called “bare” construction.
- 2) Reference the bare construction in the FenestrationSurface:Detailed for the window.
- 3) Define the WindowMaterial:Screen object.
- 4) Define a WindowProperty:ShadingControl for the window in which you (a) specify that this Material:WindowScreen is the window’s shading device, and (b) specify how the screen is controlled.

Method 2:

1. Define the Construction of the window without the screen, the so-called “bare” construction.
2. Reference the bare construction in the FenestrationSurface:Detailed for the window.
3. Define the WindowMaterial:Screen object.
4. Define another Construction, called the “shaded construction,” that includes the WindowMaterial:Screen.
5. Define a WindowProperty:ShadingControl for the window in which you (a) reference the shaded construction, and (b) specify how the screen is controlled.

Note that WindowProperty:ShadingControl has to be used with either method, even if the screen is in place at all times. You will get an error message if you try to reference a shaded construction directly from a FenestrationSurface:Detailed object.

Field: Name

Enter a unique name for the screen. This name is referenced as an outside layer in a window construction.

Field: Reflected Beam Transmittance Accounting Method

This input specifies the method used to account for screen-reflected beam solar radiation that is transmitted through the window screen (as opposed to being reflected back outside the building). Since this inward reflecting beam solar is highly directional and is not modeled in the direction of the actual reflection, the user is given the option of how to account for the directionality of this component of beam solar transmittance. Valid choices are DoNotModel, ModelAsDirectBeam (i.e., model as an additive component to direct solar beam and in the same direction), or ModelAsDiffuse (i.e., model as hemispherically-diffuse radiation). The default value is ModelAsDiffuse.

Field: Diffuse Solar Reflectance

This input specifies the solar reflectance (beam-to-diffuse) of the screen material itself (not the effective value for the overall screen “assembly” including open spaces between the screen material). The outgoing diffuse radiation is assumed to be Lambertian (distributed

angularly according to Lambert's cosine law). The solar reflectance is assumed to be the same for both sides of the screen. This value must be from 0 to less than 1.0. In the absence of better information, the input value for diffuse solar reflectance should match the input value for diffuse visible reflectance.

Field: Diffuse Visible Reflectance

This input specifies the visible reflectance (beam-to-diffuse) of the screen material itself (not the effective value for the overall screen “assembly” including open spaces between the screen material) averaged over the solar spectrum and weighted by the response of the human eye. The outgoing diffuse radiation is assumed to be Lambertian (distributed angularly according to Lambert's cosine law). The visible reflectance is assumed to be the same for both sides of the screen. This value must be from 0 to less than 1.0.

If diffuse visible reflectance for the screen material is not available, then the following guidelines can be used to estimate this value:

Dark-colored screen (e.g., charcoal):	0.08 – 0.10
Medium-colored screen (e.g., gray):	0.20 – 0.25
Light-colored screen (e.g., bright aluminum):	0.60 – 0.65

Commercially-available gray scale or grayscale reflecting chart references can be purchased for improved accuracy in estimating visible reflectance (by visual comparison of screen reflected brightness with that of various known-reflectance portions of the grayscale).

Field: Thermal Hemispherical Emissivity

Long-wave emissivity ϵ of the screen material itself (not the effective value for the overall screen “assembly” including open spaces between the screen material). The emissivity is assumed to be the same for both sides of the screen.

For most non-metallic materials, ϵ is about 0.9. For metallic materials, ϵ is dependent on material, its surface condition, and temperature. Typical values for metallic materials range from 0.05 – 0.1 with lower values representing a more finished surface (e.g. low oxidation, polished surface). Material emissivities may be found in Table 5 from the 2005 ASHRAE Handbook of Fundamentals, page 3.9. The value for this input field must be between 0 and 1, with a default value of 0.9 if this field is left blank.

Field: Conductivity

Screen material conductivity (W/m-K). This input value must be greater than 0. The default value is 221 W/m-K (aluminum).

Field: Screen Material Spacing

The spacing, S , of the screen material (m) is the distance from the center of one strand of screen to the center of the adjacent one. The spacing of the screen material is assumed to be the same in both directions (e.g., vertical and horizontal). This input value must be greater than the non-zero screen material diameter. If the spacing is different in the two directions, use the average of the two values.

Figure 13. Screen Material Spacing and Diameter

Field: Screen Material Diameter

The diameter, D , of individual strands or wires of the screen material (m). The screen material diameter is assumed to be the same in both directions (e.g., vertical and horizontal). This input value must be greater than 0 and less than the screen material spacing. If the diameter is different in the two directions, use the average of the two values.

Field: Screen to Glass Distance

Distance from the window screen to the adjacent glass surface (m). If the screen is not flat, the average screen to glass distance should be used. The screen-to-glass distance is used in calculating the natural convective air flow between the glass and the screen produced by buoyancy effects. This input value must be from 0.001 m to 1 m, with a default value of 0.025 m if this field is left blank.

Field: Top Opening Multiplier

Effective area for air flow at the top of the screen divided by the horizontal area between the glass and screen (see the same field for the Material:WindowShade object for additional description). The opening multiplier fields can be used to simulate a shading material that is offset from the window frame. Since window screens are typically installed against the window frame, the default value is equal to 0. This input value can range from 0 to 1.

Field: Bottom Opening Multiplier

Effective area for air flow at the bottom of the screen divided the horizontal area between the glass and screen (see the same field for the Material:WindowShade object for additional description). The opening multiplier fields can be used to simulate a shading material that is offset from the window frame. Since window screens are typically installed against the window frame, the default value is equal to 0. This input value can range from 0 to 1.

Field: Left-Side Opening Multiplier

Effective area for air flow at the left side of the screen divided the vertical area between the glass and screen (see the same field for the Material:WindowShade object for additional description). The opening multiplier fields can be used to simulate a shading material that is offset from the window frame. Since window screens are typically installed against the window frame, the default value is equal to 0. This input value can range from 0 to 1.

Field: Right-Side Opening Multiplier

Effective area for air flow at the right side of the screen divided the vertical area between the glass and screen (see the same field for the Material:WindowShade object for additional

description). The opening multiplier fields can be used to simulate a shading material that is offset from the window frame. Since window screens are typically installed against the window frame, the default value is equal to 0. This input value can range from 0 to 1.

Field: Angle of Resolution for Screen Transmittance Output Map

Angle of resolution, in degrees, for the overall screen beam transmittance (direct and reflected) output map. The comma-separated variable file `eplusscreen.csv` (Ref. `OutputDetailsandExamples.pdf`) will contain the direct beam and reflected beam solar radiation that is transmitted through the window screen as a function of incident sun angle (0 to 90 degrees relative solar azimuth and 0 to 90 degrees relative solar altitude) in sun angle increments specified by this input field. The default value is 0, which means no transmittance map is generated. Other valid choice inputs are 1, 2, 3 and 5 degrees.

The input data dictionary (IDD) definition for this object is shown below:

Material:RoofVegetation

This definition must be used in order to simulate the green roof (ecorooft) model. The material becomes the outside layer in a green roof construction (see example below). In the initial release of the green roof model, only one material may be used as a green roof layer though, of course, several constructions using that material may be used. In addition, the model has only been tested with the ConductionTransferFunction solution algorithm – a warning will be issued for other solution algorithm choices.

Field: Name

This field is a unique reference name that the user assigns to a particular ecorooft material. This name can then be referred to by other input data.

Field: Height of Plants

This field defines the height of plants in units of meters. This field is limited to values in the range $0.01 < \text{Height} < 1.00$ m.

Field: Leaf Area Index

This is the projected leaf area per unit area of soil surface. This field is dimensionless and is limited to values in the range of $0.001 < \text{LAI} < 5.0$.

Field: Leaf Reflectivity

This field represents the fraction of incident solar radiation that is reflected by the individual leaf surfaces. Solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. Values for this field must be between 0.1 and 0.4.

Field: Leaf Emissivity

This field is the ratio of thermal radiation emitted from leaf surfaces to that emitted by an ideal black body at the same temperature. This parameter is used when calculating the long wavelength radiant exchange at the leaf surfaces. Values for this field must be between 0.8 and 1.0 (with 1.0 representing “black body” conditions).

Field: Minimum Stomatal Resistance

This field represents the resistance of the plants to moisture transport. It has units of s/m. Plants with low values of stomatal resistance will result in higher evapotranspiration rates than plants with high resistance. Values for this field must be in the range of 50.0 to 300.0.

Field: Soil Layer Name

This field is a unique reference name that the user assigns to the soil layer for a particular ecorooft. This name can then be referred to by other input data.

Field: Roughness

This alpha field defines the relative roughness of a particular material layer. This parameter only influences the convection coefficients, more specifically the exterior convection coefficient. A special keyword is expected in this field with the options being “VeryRough”,

“Rough”, “MediumRough”, “MediumSmooth”, “Smooth”, and “VerySmooth” in order of roughest to smoothest options.

Field: Thickness

This field characterizes the thickness of the material layer in meters. This should be the dimension of the layer in the direction perpendicular to the main path of heat conduction. This value must be a positive.

Field: Conductivity of Dry Soil

This field is used to enter the thermal conductivity of the material layer. Units for this parameter are W/(m-K). Thermal conductivity must be greater than zero.

Field: Density of Dry Soil

This field is used to enter the density of the material layer in units of kg/m³. Density must be a positive quantity.

Field: Specific Heat of Dry Soil

This field represents the specific heat of the material layer in units of J/(kg-K). Note that these units are most likely different than those reported in textbooks and references which tend to use kJ/(kg-K) or J/(g-K). They were chosen for internal consistency within EnergyPlus. Only positive values of specific heat are allowed.

Field: Thermal Absorptance

The thermal absorptance field in the Material input syntax represents the fraction of incident long wavelength radiation that is absorbed by the material. This parameter is used when calculating the long wavelength radiant exchange between various surfaces and affects the surface heat balances (both inside and outside as appropriate). Values for this field must be between 0.0 and 1.0 (with 1.0 representing “black body” conditions).

Field: Solar Absorptance

The solar absorptance field in the Material input syntax represents the fraction of incident solar radiation that is absorbed by the material. Solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the amount of incident solar radiation absorbed by various surfaces and affects the surface heat balances (both inside and outside as appropriate). Values for this field must be between 0.0 and 1.0.

Field: Visible Absorptance

The visible absorptance field in the Material input syntax represents the fraction of incident visible wavelength radiation that is absorbed by the material. Visible wavelength radiation is slightly different than solar radiation in that the visible band of wavelengths is much more narrow while solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the amount of incident visible radiation absorbed by various surfaces and affects the surface heat balances (both inside and outside as appropriate) as well as the daylighting calculations. Values for this field must be between 0.0 and 1.0.

MaterialProperty:GlazingSpectralData

With the MaterialProperty:GlazingSpectralData object, you can specify the wavelength-by-wavelength transmittance and reflectance properties of a glass material. To determine the overall optical properties of a glazing system (solar and visible transmittance and solar absorptance vs. angle of incidence) EnergyPlus first calculates transmittance and absorptance vs. angle of incidence for each wavelength. This is then weighted by a standard solar spectrum to get the solar transmittance and absorptance vs. angle of incidence (for use in the solar heat gain calculations), and further weighted by the response of the human eye to get the visible transmittance vs. angle of incidence (for use in the daylighting calculation).

MaterialProperty:GlazingSpectralData should be used for multi-pane windows when one or more of the glass layers is *spectrally selective*, i.e., the transmittance depends strongly on wavelength. An example is glass with a coating that gives high transmittance in the daylight part of the solar spectrum (roughly 0.4 to 0.7 microns) and low transmittance at longer wavelengths, thus providing better solar heat gain control than uncoated glass. If spectral data is not used in case, the overall optical properties of the glazing system that EnergyPlus calculates will not be correct.

You can input up to 450 sets of values for wavelengths covering the solar spectrum. Each set consists of {wavelength (microns), transmittance, front reflectance, back reflectance}

Spectral data of this kind are routinely measured by glass manufacturers. Data sets for over 800 commercially available products are contained in an Optical Data Library maintained by the Windows Group at Lawrence Berkeley National Laboratory. This library can be downloaded from <http://windows.lbl.gov/>. You will have to edit entries from this library to put them in the format required by the EnergyPlus WindowGlassSpectralData object.

An alternative to using the MaterialProperty:GlazingSpectralData object is to run the WINDOW 5 window analysis program. This program has built-in access to the Optical Data Library and let's you easily create customized, multi-layer glazing systems that can be exported for use in EnergyPlus. For more details, see "StormWindow".

Field: Name

The name of the spectral data set. It is referenced by WindowMaterial:Glazing when Optical Data Type = Spectral.

Fields 1-4 (repeated up to 450 times)

Sets of values for wavelengths covering the solar spectrum (from about 0.25 to 2.5 microns [10^{-6} m]). Each set consists of

{wavelength (microns), transmittance, front reflectance, back reflectance}

The wavelength values must be in ascending order. The transmittance and reflectance values are at normal incidence. “Front reflectance” is the reflectance for radiation striking the glass from the outside, i.e., from the side opposite the zone in which the window is defined. “Back reflectance” is the reflectance for radiation striking the glass from the inside, i.e., from the zone in which the window is defined. Therefore, for exterior windows, “front” is the side closest to the outdoors and “back” is the side closest to the zone in which the window is defined. For interior windows, “front” is the side closest to the adjacent zone and “back” is the side closest to the zone in which the window is defined.

Construction

For walls, roofs, floors, windows, and doors, constructions are “built” from the included materials. Each layer of the construction is a material name listed in order from “outside” to “inside”. Up to ten layers (eight for windows) may be specified (one of the few limitations in EnergyPlus!). “Outside” is the layer furthest away from the Zone air (not necessarily the outside environment). “Inside” is the layer next to the Zone air. In the example floor below, for

example, the outside layer is the acoustic tile below the floor, the next layer is the air space above the tile, and the inside layer is the concrete floor deck.

Figure 14. Example Floor Construction illustration.

Window constructions are similarly built up from items in the Window Materials set using similar layers.. See Figure 15. Illustration for material ordering in windows, which shows the case where an interior shading layer such as a blind is present. The gap between the inside glass layer (layer #3) and the interior shading layer is not entered. Similarly, for an exterior shading layer, the gap between the outside glass layer and the shading layer is not entered.

Figure 15. Illustration for material ordering in windows.

However, for a between-glass shading device the gaps on either side of the shading layer must be entered and they must have the same gas type. In addition, the gap widths with and without the between-glass shading layer must be consistent (see Figure 16).

A maximum of four glass layers and one shading layer is allowed. A gas layer must always separate adjacent glass layers in a multi-pane glazing without a between-glass shading layer.

Figure 16. Window construction with and without a between-glass shading layer. Shown are gap widths g , g_1 and g_2 , and shading layer width, w . An error will result if $g_1 + g_2 + w$ is not equal to g , where w is zero for a blind and greater than zero for a shade.

Outside and inside air film resistances are never given as part of a construction definitions since they are calculated during the EnergyPlus simulation. Note also that constructions are assumed to be one-dimensional in a direction perpendicular to the surface.

Field: Name

This field is a user specified name that will be used as a reference by other input syntax. For example, a heat transfer surface (ref: Building Surfaces) requires a construction name to define what the make-up of the wall is. This name must be identical to one of the Construction definitions in the input data file.

Field: Outside Layer

Each construction must have at least one layer. This field defines the material name associated with the layer on the outside of the construction—outside referring to the side that is not exposed to the zone but rather the opposite side environment, whether this is the outdoor environment or another zone. Material layers are defined based on their thermal properties elsewhere in the input file (ref: Material and Material Properties and Materials for Glass Windows and Doors). As noted above, the outside layer should NOT be a film coefficient since EnergyPlus will calculate outside convection and radiation heat transfer more precisely.

Field(s) 2-10: Layers

The next fields are optional and the number of them showing up in a particular Construction definition depends solely on the number of material layers present in that construction. The data expected is identical to the outside layer field (see previous field description). The order of the remaining layers is important and should be listed in order of occurrence from the one just inside the outside layer until the inside layer is reached. As noted above, the inside layer should NOT be a film coefficient since EnergyPlus will calculate inside convection and radiation heat transfer more precisely.

```

Construction,
  \memo Start with outside layer and work your way to the inside layer
  \memo Up to 10 layers total, 8 for windows
  \memo Enter the material name for each layer

WinAirB1 - AIRSPACE RESISTANCE,
GLASS - CLEAR SHEET 1 / 8 IN;

```

IDF Example (window construction, with interior shade):

```

Construction, DOUBLE PANE WITH ROLL SHADE, !- Material layer names follow:
GLASS - CLEAR SHEET 1 / 8 IN,
WinAirB1 - AIRSPACE RESISTANCE,
GLASS - CLEAR SHEET 1 / 8 IN,
ROLL SHADE - LIGHT

```

Construction:InternalSource

In some cases such as radiant systems, a construction will actually have resistance wires or hydronic tubing embedded within the construction. Heat is then either added or removed from this building element to provide heating or cooling to the zone in question. In the case of building-integrated photovoltaics, the energy removed in the form of electricity will form a sink. It is possible to enter such constructions into EnergyPlus with the syntax described below. The definition is similar to the Construction definition with a few additions related to radiant or other systems that will lead to source/sink terms.

Field: Name

This field is a user specified name that will be used as a reference by other input syntax. For example, a heat transfer surface (ref: Building Surfaces) requires a construction name to define what the make-up of the wall is.

Field: Source Present After Layer Number

This field is an integer that relates the location of the heat source or sink. The integer refers to the list of material layers that follow later in the syntax and determines the layer after which the source is present. If a source is embedded within a single homogenous layer (such as concrete), that layer should be split into two layers and the source added between them. For example, a value of “2” in this field tells EnergyPlus that the source is located between the second and third material layers listed later in the construction description (see layer fields below).

Field: Temperature Calculation Requested After Layer Number

The nature of this field is similar to the source interface parameter (see previous field) in that it is an integer, refers to the list of material layers that follow, and defines a location after the layer number identified by the user-defined number. In this case, the user is specifying the location for a separate temperature calculation rather than the location of the heat source/sink. This feature is intended to allow users to calculate a temperature within the construction. This might be important in a radiant cooling system where condensation could be a problem. This temperature calculation can assist users in making that determination in absence of a full heat and mass balance calculation.

Field: Dimensions for the CTF Calculation

This field is also an integer and refers to the detail level of the calculation. A value of “1” states that the user is only interested in a one-dimensional calculation. This is appropriate for electric resistance heating and for hydronic heating (when boiler/hot water heater performance is not affected by return and supply water temperatures). A value of “2” will trigger a two-dimensional solution for this surface only. This may be necessary for hydronic radiant cooling situations since chiller performance is affected by the water temperatures provided.

A few things should be noted about requesting two-dimensional solutions. First, the calculation of the conduction transfer functions (CTF) is fairly intensive and will require a significant amount of computing time. Second, the solution regime is two-dimensional internally but it has a one-dimensional boundary condition imposed at the inside and outside surface (i.e., surface temperatures are still isothermal as if the surface was one-dimensional).

Field: Tube Spacing

This field defines how far apart in meters the hydronic tubing or electrical resistance wires are spaced in the direction perpendicular to the main direction of heat transfer. Note that this parameter is only used for two-dimensional solutions (see previous field).

Field: Outside Layer

Each construction must have at least one layer. This field defines the material name associated with the layer on the outside of this construction—outside referring to the side that is not exposed to the zone but rather the opposite side environment, whether this is the outdoor environment or another zone. Material layers are defined based on their thermal properties elsewhere in the input file (ref: Material and Material Properties and Materials for Glass Windows and Doors). As noted above, the outside layer should NOT be a film coefficient since EnergyPlus will calculate convection and radiation heat transfer more precisely.

Field(s) 2-10: Layers

The next fields are optional and the number of them showing up in a particular Construction definition depends solely on the number of material layers present in that particular construction. The data expected is identical to the outside layer field (see previous field description). The order of the remaining layers is important and should be listed in order of occurrence from the one just inside the outside layer until the inside layer is reached. As noted above, the inside layer should NOT be a film coefficient since EnergyPlus will calculate convection and radiation heat transfer more precisely.

Composite Wall Constructions

Standard constructions in EnergyPlus are built with the materials and layers described earlier. However, some configurations will not be adequately represented by using this approach. The Reference Data Set CompositeWallConstructions.idf contains constructions and associated materials for a set of **composite** walls. These are walls—such as stud walls—that have complicated heat-flow paths so that the conduction is two- or three-dimensional.

The materials here are **not** real materials but are “equivalent” materials obtained from finite-difference modeling.⁴ EnergyPlus will calculate conduction transfer functions using these materials. The heat transfer based on these conduction transfer functions will then be very close to what would be calculated with a two- or three-dimensional heat transfer calculation.

For stud walls, using these composite constructions will give more accurate heat flow than you would get by manually dividing the wall into a stud section and a non-stud section.

If your wall’s exterior or interior roughness or thermal, solar or visible absorptances are different from those in the data set, you can make the appropriate changes to the first

⁴ The thickness, conductivity, density and specific heat values of the material layers for the different constructions have been taken from the ASHRAE report “Modeling Two- and Three-Dimensional Heat Transfer through Composite Wall and Roof Assemblies in Hourly Energy Simulation Programs (1145-TRP),” by Enermodal Engineering Limited, Oak Ridge National Laboratory, and the Polish Academy of Sciences, January 2001.

material (the outside layer) or the third material (the inside layer). **None of the other values should be changed.**

Complete description of the CompositeWallConstructions data set are found in the OutputDetailsAndExamples document.

Construction:WindowDataFile

The WINDOW 5 program, which does a thermal and optical analysis of a window under different design conditions, writes a data file (“Window5 data file”) containing a description of the window that was analyzed. The Construction:WindowDataFile object allows a window to be read in from the Window5 data file—see “Importing Windows from WINDOW 5.” For information on adding a shading device to the window see “WindowProperty:ShadingControl.”

Field: Name

This is the name of a window on the Window5 data file. An error will result if EnergyPlus cannot find a window of this name on the file, or if the file, called Window5DataFile.dat, is not present. By default, the file Window5DataFile.dat is expected to be in the same folder as the EnergyPlus.exe file (the “run” folder). For details on what is done with the data if a matching window is found on the file see “Importing Windows from WINDOW 5.”

Field: File Name

This is the file name of the Window5 data file that contains the Window referenced in the previous field. You may specify this file name completely, including path, but it must be 60 characters or less. You may also specify it using relative path but that path must be relative to the “run” folder.

The IDD of the object:

```
Construction:WindowDataFile,
    \memo Initiates search of the Window5 data file for a window called Name.
A1 , \field Name
    \required-field
    \type alpha
    \reference ConstructionNames
A2 ; \field File Name
    \retaincase
    \note default file name is "Window5DataFile.dat"
    \note limit on this field is 100 characters.
```

Input Example

```
Construction:WindowDataFile,
DoubleClear;           !- Name of a Window on the Window5 Data File
! Note - Window5DataFile.dat is presumed to be in the "run" folder where EnergyPlus.exe is

FenestrationSurface:Detailed,
Zn001:Wall1001:Win001, !- Name
Window,                !- Class
DoubleClear,         !- Construction Name
Zn001:Wall1001,,       !- Base Surface Name, and Target (if applicable)
0.5,                   !- View Factor to Ground
,                      !- Window Shading Control name
,                      !- Frame/Divider name
1.0,                   !- Multiplier
4,                     !- Number of vertices
0.548, 0.0, 2.5000,    !- X,Y,Z of Vertices
0.548, 0.0, 0.5000,
5.548, 0.0, 0.5000,
5.548, 0.0, 2.5000;
```

An example showing use of specific data file name and relative path location follows:

```
Construction:WindowDataFile,  
  DoubleClear,      !- Name of a Window on the Window5 Data File  
  DataSets\MyWindow5.dat; !- Filename is "MyWindow5.dat" and is in the DataSets folder relative to  
                        !- the "run" folder where EnergyPlus.exe is.
```

Construction Element Outputs

An optional report (contained in **eplusout.eio**) gives calculational elements for the materials and constructions used in the input. These reports are explained fully in the Output Details and Examples document.

Group – Thermal Zone Description/Geometry

Without thermal zones and surfaces, the building can't be simulated. This group of objects (Zone, BuildingSurface) describes the thermal zone characteristics as well as the details of each surface to be modeled. Included here are shading surfaces.

Zone

This element sets up the parameters to simulate each thermal zone of the building.

Field: Direction of Relative North

The Zone North Axis is specified **relative to the Building North Axis**. This value is specified in degrees (clockwise is positive). For more information, see the figure below as well as the description under "GlobalGeometryRules".

Field(s): (X,Y,Z) Origin

The X,Y,Z coordinates of a zone origin can be specified, for convenience in vertice entry. Depending on the values in "GlobalGeometryRules" (see description later in this section), these will be used to completely specify the building coordinates in "world coordinate" or not. Zone Origin coordinates are specified **relative to the Building Origin (which always 0,0,0)**. The following figure illustrates the use of Zone North Axis as well as Zone Origin values.

Figure 17. Illustration of Zone North Axis and Origins

Field: Type

Zone type is currently unused.

Field: Multiplier

Zone Multiplier is designed as a “multiplier” for zone loads. It takes the calculated load for the inputted zone and multiplies it and sends the multiplied load to the attached system to meet the demand. The system will have to be specified to meet the entire multiplied zone load and will report the amount of the load it can meet in the Zone/Sys Sensible Heating or Cooling Energy/Rate report variable. The default is 1.

Field: Ceiling Height

Zone ceiling height is used in several areas within EnergyPlus. Energyplus automatically calculates the zone ceiling height (m) from the average height of the zone. If this field is 0.0, negative or **autocalculate**, then the calculated zone ceiling height will be used in subsequent calculations. If this field is positive, then the calculated zone ceiling height will not be used -- the number entered here will be used as the zone ceiling height. If this number differs significantly from the calculated ceiling height, then a warning message will be issued. If a zone ceiling height is entered, but no Volume is entered, then the floor area (if there is one) times the zone ceiling height will be used as the volume.

Note that the Zone Ceiling Height is the distance from the Floor to the Ceiling in the Zone, not an absolute height from the ground.

Field: Volume

Zone volume is used in several areas within EnergyPlus. EnergyPlus automatically calculates the zone volume (m³) from the zone geometry given by the surfaces that belong to the zone. If this field is 0.0, negative or **autocalculate**, then the calculated zone volume will be used in subsequent calculations. If this field is positive, then it will be used as the zone volume. If this number differs significantly from the calculated zone volume a warning message will be issued. For autocalculate to work properly, the zone must be enclosed by the entered walls. Note that indicating the volume to be calculated but entering a positive ceiling height in the previous field will cause the volume to be calculated as the floor area (if > 0) times the entered ceiling height; else the volume will be calculated from the described surfaces. If this field is positive, any ceiling height positive value will not be used in volume calculations.

Field: Zone Inside Convection Algorithm

The Zone Inside Convection Algorithm field is optional. This field specifies the convection model to be used in the zone. The choices are: **Simple** (constant natural convection - ASHRAE), **Detailed** (variable natural convection based on temperature difference - ASHRAE), **CeilingDiffuser** (ACH based forced and mixed convection correlations for ceiling diffuser configuration with simple natural convection limit), and **TrombeWall** (variable natural convection in an enclosed rectangular cavity). See the Inside Convection Algorithm object for further descriptions of the available models.

If omitted or blank, the algorithm specified in the Inside Convection Algorithm object is the default.

Field: Zone Outside Convection Algorithm

The Zone Outside Convection Algorithm field is optional. This field specifies the convection model to be used in the zone. The choices are: **Simple**, **Detailed**, **BLAST**, **TARP**, **DOE-2**, and **MoWITT**. The simple convection model applies heat transfer coefficients depending on the roughness and windspeed. This is a combined heat transfer coefficient that includes radiation to sky, ground, and air. The correlation is based on Figure 1, Page 25.1 (Thermal and Water Vapor Transmission Data), 2001 ASHRAE Handbook of Fundamentals.

The other convection models apply heat transfer coefficients depending on the roughness, windspeed, and terrain of the building's location. These are *convection only* heat transfer coefficients; radiation heat transfer coefficients are calculated automatically by the program. All algorithms are described more fully in the Engineering Reference.

If omitted or blank, the algorithm specified in the Inside Convection Algorithm object is the default.

Field: Part of Total Floor Area

This optional field defaults to Yes if not specified. The field is used to show when a zone is not part of the Total Floor Area as shown in the Annual Building Utility Performance Summary tables. Specifically, when No is specified, the area is excluded from both the conditioned floor area and the total floor area in the Building Area sub table and the Normalized Metrics sub tables.

Zone Outputs

Each zone command produces zone outputs that echo the input fields above. However, the values to be used for the Zone Ceiling Height and Volume will be displayed if the entered fields are negative or zero. Details on this report are shown in the Output Details and Examples document.

In addition to the invariant outputs for the zone, atmospheric temperature and wind speed due to zone centroid heights are calculated. Rationale and further details on these values is shown in the Weather Station and Site Atmospheric Variation objects. These are described in the Group -- Location – Climate – Weather File Access.

```

Zone,Average,Zone Outdoor Dry Bulb [C]
Zone,Average,Zone Outdoor Wet Bulb [C]
Zone,Average,Zone Outdoor Wind Speed [m/s]

```

Zone Outdoor Dry Bulb [C]

The outdoor air dry-bulb temperature calculated at the height above ground of the zone centroid.

Zone Outdoor Wet Bulb [C]

The outdoor air wet-bulb temperature calculated at the height above ground of the zone centroid.

Zone Outdoor Wind Speed [m/s]

The outdoor wind speed calculated at the height above ground of the zone centroid.

Zone Thermal Output(s)

In addition to the canned Surface reports (view the Reports section later in this document) and surface variables (above), the following variables are available for all zones:

```

Zone,Sum,Zone Total Internal Radiant Heat Gain [J]
Zone,Sum,Zone Total Internal Visible Heat Gain [J]
Zone,Sum,Zone Total Internal Convective Heat Gain [J]

HVAC,Average,Zone Air Relative Humidity[%]

```

Two of these are of particular interest:

Zone, Average, Zone Mean Air Temperature [C] HVAC, Average, Zone/Sys Air Temperature [C]

These two variable outputs are/should be identical. However, note that they can be reported at different time intervals. “Zone Mean Air Temperature” is only available on the Zone/HB timestep (Number of Timesteps per Hour) whereas “Zone/Sys Air Temperature” can be reported at the HVAC timestep (which can vary).

Zone Mean Air Temperature [C]

From the code definition, the zone mean air temperature is the average temperature of the air temperatures at the system timestep. Remember that the zone heat balance represents a “well stirred” model for a zone, therefore there is only one mean air temperature to represent the air temperature for the zone.

Zone/Sys Air Temperature [C]

This is very similar to the mean air temperature in the last field. The “well stirred” model for the zone is the basis, but this temperature is also available at the “detailed” system timestep.

Zone Mean Radiant Temperature [C]

The Mean Radiant Temperature (MRT) in degrees Celsius of a space is really the measure of the combined effects of temperatures of surfaces within that space. The larger the surface area and the closer one is to it, the more effect the surface temperature of that surface has on each other. The MRT is the measure of all these surface areas and temperatures.

Zone Operative Temperature [C]

Zone Operative Temperature (OT) is the average of the Zone Mean Air Temperature (MAT) and Zone Mean Radiant Temperature (MRT), $OT = 0.5 \cdot MAT + 0.5 \cdot MRT$. This report variable is not affected by the type of thermostat controls in the zone, and does not include the direct effect of high temperature radiant systems. See also Zone Thermostat Operative Temperature.

Zone Air Balance Internal Convective Gains Rate [W]

The Zone Air Balance Internal Convective Gains Rate is the sum, in watts, of heat transferred to the zone air from all types of internal gains, including people, lights, equipment etc. This and the following provide results on the load components of the zone air heat balance. This field is not multiplied by zone or group multipliers.

Zone Air Balance Surface Convection Rate [W]

The Zone Air Balance Surface Convection Rate is the sum, in watts, of heat transferred to the zone air from all the surfaces. This field is not multiplied by zone or group multipliers.

Zone Air Balance Interzone Air Transfer Rate [W]

The Zone Air Balance Interzone Air Transfer Rate is the sum, in watts, of heat transferred to the zone air from all the transfers of air from other thermal zones. This field is not multiplied by zone or group multipliers.

Zone Air Balance Outdoor Air Transfer Rate [W]

The Zone Air Balance Outdoor Air Transfer Rate is the sum, in watts, of heat transferred to the zone air from all the transfers of air from the out side, such as infiltration. This field is not multiplied by zone or group multipliers.

Zone Air Balance System Air Transfer Rate [W]

The Zone Air Balance System Air Transfer Rate is the sum, in watts, of heat transferred to the zone air by HVAC air systems. This field is not multiplied by zone or group multipliers.

Zone Air Balance Air Energy Storage Rate [W]

The Zone Air Balance Air Energy Storage Rate is the heat stored, in watts, in the zone air as result of zone air temperature changing from one timestep to the next. This field is not multiplied by zone or group multipliers.

Zone Air Balance Deviation Rate [W]

The Zone Air Balance Deviation Rate is the imbalance, in watts, in the energy balance for zone air. The value should be near zero but will become non-zero if zone conditions are changing rapidly or erratically. This field is not multiplied by zone or group multipliers. (This report variable is only generated if the user has set a computer system environment variable DisplayAdvancedReportVariables equal to "yes".)

Zone/Sys Sensible Heating Energy [J]

This report variable represents the sensible heating energy in Joules that is actually supplied by the system to that zone for the timestep reported. This is the sensible heating rate multiplied by the simulation timestep. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers.

Zone/Sys Sensible Heating (and Cooling) Energy (and Rate) all report the heating or cooling delivered by the HVAC system to a zone. These values are calculated by multiplying the supply air mass flow rate by the difference between the supply air temperature and the zone air temperature. This does not always indicate the operation of heating or cooling coils. For example, cooling will be reported if the supply air is cooled due to the introduction of outside air, even if all coils are off.

Note that these variables are calculated at the system timestep. When reported at the "detailed" reporting frequency, these variable will never show heating and cooling both in the same system timestep. If reported at a frequency less than "Detailed" (for example, Hourly) values may appear in both the heating and cooling variable for the same hour if the system cooled the zone for part of the reporting period and heated the zone for another part of the reporting period.

Zone/Sys Sensible Cooling Energy [J]

This report variable represents the sensible cooling energy in Joules that is actually supplied by the system to that zone for the timestep reported. This is the sensible cooling rate multiplied by the simulation timestep. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers.

Zone/Sys Sensible Heating Rate [W]

This report variable represents the sensible heating rate in Watts that is actually supplied by the system to that zone for the timestep reported. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers.

Zone/Sys Sensible Cooling Rate [W]

This report variable represents the sensible cooling rate in Watts that is actually supplied by the system to that zone for the timestep reported. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers.

Zone Air Humidity Ratio []

This report variable represents the air humidity ratio after the correct step for each zone. The humidity ratio is the mass of water vapor to the mass of dry air contained in the zone in (kg water/kg air) and is unitless.

Zone Air Relative Humidity [%]

This report variable represents the air relative humidity after the correct step for each zone. The relative humidity is in percent and uses the Zone Air Temperature, the Zone Air Humidity Ratio and the Outside Barometric Pressure for calculation.

Zone Total Internal Radiant Heat Gain [J]

This report variable represents the sum of radiant gains from specific internal sources (e.g. equipment) throughout the zone in joules. This includes radiant gain from People, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

Zone-Total Internal Visible Heat Gain [J]

This report variable expresses the sum of heat gain in joules that is the calculated short wavelength radiation gain from lights in the zones. This calculation uses the total energy from lights and the fraction visible to realize this value, summed over the zones in the simulation.

Zone Total Internal Convective Heat Gain [J]

This report variable represents the sum of convective gains from specific sources (e.g. equipment) throughout the zone in joules. This includes convective gain from People, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

Zone Total Internal Latent Gain [J]

This report variable represents the sum of latent gains from specific internal sources (e.g. equipment) throughout the zone in joules. This includes latent gain from People, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

Zone Total Internal Total Heat Gain [J]

This report variable represents the sum of all heat gains throughout the zone in joules. This includes all heat gains from People, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

ZoneList

The ZoneList object defines a list of Zone objects. It is primarily used with the ZoneGroup object to provide a generalized way for doing "Floor Multipliers". (See the ZoneGroup description below.) The associated ZoneList output variables also provide a way to aggregate and organize zone loads.

Zone lists are not exclusive. A zone can be referenced by more than one ZoneList object.

```

ZoneList,
  \min-fields 2
  \extensible:1 - repeat last field, remembering to remove ; from "inner" fields.
A1 , \field Zone List Name
  \required-field
  \type alpha
  \reference ZoneListNames
  \reference ZoneAndZoneListNames
A2 , \field Zone 1 Name
  \required-field
  \type object-list
  \object-list ZoneNames
A3 , \field Zone 2 Name
  \type object-list
  \object-list ZoneNames
--reduced for brevity --
A21; \field Zone 20 Name
  \type object-list
  \object-list ZoneNames

```

Field: Zone List Name

The name of the ZoneList object. Must be unique across ZoneLists.

Field: Zone 1 – 20 Name

Reference to a Zone object. This field is extensible; for greater than 20 zones, edit the IDD to add more *Zone Name* fields.

```

ZoneList,
Mid Floor List,  !- Name
Mid West Zone,  !- Zone 1 Name
Mid Center Zone, !- Zone 2 Name
Mid East Zone;  !- Zone 3 Name

```

ZoneList Outputs

The following output variables are reported by the ZoneList object:

```

HVAC,Average,Zone List Sensible Heating Rate[W]
HVAC,Average,Zone List Sensible Cooling Rate[W]
HVAC,Sum,Zone List Sensible Heating Energy[J]
HVAC,Sum,Zone List Sensible Cooling Energy[J]

```

All ZoneList variables are the sum of the corresponding Zone variables. *Zone Multiplier* fields in the Zone objects are also taken into account.

ZoneGroup

The ZoneGroup object adds a multiplier to a ZoneList. This can be used to reduce the amount of input necessary for simulating repetitive structures, such as the identical floors of a multi-story building. To create a "Floor Multiplier", use the ZoneList object to organize several zones into a typical floor. Then use the *Zone List Multiplier* field in the ZoneGroup object to multiply the system load for the zones in the list will also be multiplied. Zones with a *Multiplier* field greater than one in the Zone object are effectively double-multiplied.

NOTE: Although ZoneLists are not exclusive by themselves, ZoneLists used to form a ZoneGroup are exclusive; the ZoneLists used with a ZoneGroup must not have any zones in common.

Tips for Multi-Story Simulations:

- For floors that are multiplied, connect exterior boundary conditions of the floor to the ceiling and vice versa.
- Since exterior convection coefficients vary with elevation, locate the typical middle floor zones midheight between the lowest and highest middle floors to be modeled.

- Shading must be identical for all multiplied floors or less accurate results may be obtained by using the zone list multiplier.

ZoneGroup and ZoneList can also be used to simulate other repetitive cases, such as clusters of zones on the ground.

```
ZoneGroup,
  \min-fields 2
A1 , \field Zone Group Name
  \required-field
  \type alpha
A2, \field Zone List Name
  \required-field
  \type object-list
  \object-list ZoneListNames
N1; \field Zone List Multiplier
  \type integer
  \default 1
  \minimum 1
```

Field: Zone Group Name

The name of the ZoneGroup object. This must be unique across ZoneGroups.

Field: Zone List Name

Reference to a ZoneList object. The zones in the list constitute the zones in the group.

Field: Zone List Multiplier

An integer multiplier.

```
ZONE GROUP,
Mid Floor,  !- Zone Group Name
Mid Floor List,  !- Zone List Name
8;  !- Zone List Multiplier
```

ZoneGroup Outputs

The following output variables are reported by the ZoneGroup object:

```
HVAC,Average,Zone Group Sensible Heating Rate[W]
HVAC,Average,Zone Group Sensible Cooling Rate[W]
HVAC,Sum,Zone Group Sensible Heating Energy[J]
HVAC,Sum,Zone Group Sensible Cooling Energy[J]
```

All ZoneGroup variables report the associated ZoneList value multiplied by the *Zone List Multiplier*.

Surface(s)

What's a building without surfaces?

EnergyPlus allows for several surface types:

- **BuildingSurface:Detailed**
- **FenestrationSurface:Detailed**
- **Shading:Site:Detailed**
- **Shading:Building:Detailed**
- **Shading:Zone:Detailed**

Each of the preceding surfaces has “correct” geometry specifications. BuildingSurface and Fenestration surfaces (heat transfer surfaces) are used to describe the important elements of the building (walls, roofs, floors, windows, doors) that will determine the interactions of the building surfaces with the outside environment parameters and the internal space requirements. These surfaces are also used to represent “interzone” heat transfer. During specification of surfaces, several “outside” environments may be chosen:

- **Ground** – when the surface is in touch with the ground (e.g. slab floors)

- **Outdoors** – when the surface is an external surface (e.g. walls, roofs, windows directly exposed to the outdoor conditions)
- **Surface** – when the surface is
 - An adiabatic internal zone surface
 - A interzone surface
- **Zone** – when the surface is
 - A interzone surface in which the other surface is not put in the input file.
- **OtherSideCoefficients** – when using a custom profile to describe the external conditions of the surface (advanced concept – covered in subject: SurfaceProperty:OtherSideCoefficients)
- **OtherSideConditionsModel** – when using specially modeled components, such as active solar systems, that cover the outside surface and modify the conditions it experiences.

Surface items must also specify an “outside face object”. This is

- Current surface name – for adiabatic internal surfaces.
- A surface name in another zone – for interzone heat transfer.
- An “opposing” surface name (in the current zone) – for representing “middle” zones.

Zone items must also specify an “outside face object”. This is

- The zone that contains the other surface that is adjacent to this surface but is not entered in input.

Note that heat transfer surfaces are fully represented with each description. As stated earlier in the Construction description, materials in the construction (outside to inside) are included but film coefficients neither inside nor outside are used in the description – these are automatically calculated during the EnergyPlus run. Interzone surfaces which do not have a symmetrical construction (such as a ceiling/floor) require two Construction objects with the layers in reverse order. For example, CEILING with carpet, concrete, ceiling tile and FLOOR with ceiling tile, concrete, carpet. If interzone surfaces have a symmetrical construction, the specification for the two surfaces can reference the same Construction.

Shading surfaces are used to describe aspects of the site which do not directly impact the physical interactions of the environmental parameters but may significantly shade the building during specific hours of the day or time so the year (e.g. trees, bushes, mountains, nearby buildings which aren't being simulated as part of this facility, etc.)

Note that surfaces which are part of the simulated building automatically shade other parts of the building as geometry and time of day dictate – there is no need on the user's part to include surfaces that might be in other zones for shading.

Another surface type:

- **InternalMass**

is used to specify the construction/material parameters and area of items within the space that are important to heat transfer calculations but not necessarily important geometrically. (For example, furniture within the space – particularly for large spaces). Internal mass can also be used for internal walls that are not needed (when FullInteriorAndExterior Solar Distribution is in effect) for solar distribution or to represent many, if not all, interior walls when solar is distributed to the floors only.

Interzone Surfaces

EnergyPlus can quite accurately simulate the surface heat exchange between two zones. However, this accuracy is not always required and using interzonal heat transfer does add to the complexity of the calculations – thus requiring more CPU time to simulate. More information about interzonal heat transfer calculations is contained in the Engineering Reference. Some simple guidelines are presented here – for three cases: adiabatic surfaces, surfaces in “middle” zones, and surfaces where heat transfer is “expected” (e.g. between a residence and an unheated, attached garage).

- **Adiabatic Surfaces** – These surfaces would be represented as common surfaces (between two zones) where both zones are typically the same temperature. Thus, no transfer is expected in the surface from one zone to the next. These surfaces should be described as simply internal surfaces for the zone referencing as their Outside Boundary Condition Object (see later description in individual surface objects) their own surface names.
- **Surfaces in Middle Zones** – Middle zones in a building can be simulated using a judicious use of surfaces and zone multipliers to effect the correct “loads” for the building. Thus, middle zone behavior can be simulated without modeling the adjacent zones. This is done by specifying a surface within the zone. For example, a middle floor zone can be modeled by making the floor the Outside Boundary Condition Object for the ceiling, and the ceiling the Outside Boundary Condition Object for the floor.
- **Surfaces between Zones with differing temperatures** – These zones represent the true use of interzone surfaces. In a residence that has an attached garage, the garage may be unheated/uncooled or at least not conditioned to the same degree as the residence interior. In this case, EnergyPlus can be used to accurately calculate the effects of the differently conditioned space to the other spaces.

Surface View Factors

EnergyPlus uses an area weighted approximation to calculate “view factors” between surfaces within a thermal zone. Each surface uses the total area that it can “see” among the other surfaces. The approximate view factor from this surface to each other surface is then the area of the receiving surface over the sum of areas that is visible to the sending surface.

In order to account in some limited way for the fact that certain surfaces will not see each other, several assumptions have been built into this simple view factor approximation. First, a surface cannot see itself. Second, surfaces with approximately the same azimuth (facing direction) and tilt (“same” being within a built in limit) will not see each other. This means that a window will not see the wall that it is placed on, for example. Third, floors cannot see each other. Fourth, if the surface is a floor, ceiling, roof, or internal mass, the rule for the same azimuth and tilt eliminating radiant exchange between surface is waived when the receiving surface is floor, roof, ceiling, or internal mass as long as both surfaces are not floors.

Note that this does not take into account that surfaces may be “around the corner” from each other and in reality not see each other at all. Rooms are assumed to be convex rather than concave in this method.

To summarize, using the Surface “Class”, the approximate view factors have:

1. No surface sees itself.
2. No Floor sees another floor.
3. All other surface types see Internal Mass.
4. All other surface types see floors.
5. Floors always see ceilings.
6. Floors always see roofs.
7. All other surfaces whose tilt or facing angle differences are greater than 10 degrees see each other.

If geometry is correct, conditions 1,3, and 7 should take care of all surfaces, but the other conditions supply common sense when the geometry is incorrect. More information about the EnergyPlus view factor calculation is contained in the Engineering Reference document.

GlobalGeometryRules

Before the surface objects are explained in detail, a description of geometric parameters used in EnergyPlus will be given. Since the input of surface vertices is common to most of the surface types, it will also be given a separate discussion.

Some flexibility is allowed in specifying surface vertices. This flexibility is embodied in the GlobalGeometryRules class/object in the input file. Note that the parameters specified in this statement are used for all surface vertex inputs – there is no further “flexibility” allowed.

In order to perform shadowing calculations, the building surfaces must be specified. EnergyPlus uses a three dimensional (3D) Cartesian coordinate system for surface vertex specification. This Right Hand coordinate system has the X-axis pointing east, the Y-axis pointing north, and the Z-axis pointing up. See figure below.

```

Field: Starting Vertex Position

The shadowing algorithms in EnergyPlus rely on surfaces having vertices in a certain order and positional structure. Thus, the surface translator needs to know the starting point for each surface entry. The choices are: UpperLeftCorner, LowerLeftCorner, UpperRightCorner, or LowerRightCorner. Since most surfaces will be 4 sided, the convention will specify this position as though each surface were 4 sided. Extrapolate 3 sided figures to this convention. For 5 and more sided figures, again, try to extrapolate the best “corner” starting position.

Field: Vertex Entry Direction

Surfaces are always specified as being viewed from the outside of the zone to which they belong. (Shading surfaces are specified slightly differently and are discussed under the particular types). EnergyPlus needs to know whether the surfaces are being specified in counterclockwise or clockwise order (from the Starting Vertex Position). EnergyPlus uses this to determine the outward facing normal for the surface (which is the *facing angle* of the surface – very important in shading and shadowing calculations).

Field: Coordinate System

Vertices can be specified in two ways: using “Absolute”/“World” coordinates, or a **relative** coordinate specification. Relative coordinates allow flexibility of rapid change to observe changes in building results due to orientation and position. “World” coordinates will facilitate use within a CADD system structure.

Relative coordinates make use of both Building and Zone North Axis values as well as Zone Origin values to locate the surface in 3D coordinate space. **World** coordinates do not use these values.

Typically, all zone origin values for “World” coordinates will be (0,0,0) but Building and Zone North Axis values may be used in certain instances (namely the Daylighting Coordinate Location entries).

Field: Daylighting Reference Point Coordinate System

Daylighting reference points need to be specified as well. Again, there can be two flavors; **relative** and **world**. Daylighting reference points must fit within the zone boundaries.

Relative coordinates make use of both Building and Zone North Axis values as well as Zone Origin values to locate the reference point in 3D coordinate space. **World** coordinates do not use these values.

Field: Rectangular Surface Coordinate System

Simple, rectangular surfaces (Wall:Exterior, Wall:Adiabatic, Wall:Underground, Wall:Interzone, Roof, Ceiling:Adiabatic, Ceiling:Interzone, Floor:GroundContact, Floor:Adiabatic, Floor:Interzone) can be specified with their Lower Left Corner as **relative** or **world**.

Relative (default) corners are specified relative to the Zone Origin for each surface. **World** corners would specify the absolute/world coordinate for this corner.

Surfaces

Surfaces make up the buildings and the elements that shade buildings. There are several methods to inputting surfaces, ranging from simple rectangular surfaces to detailed descriptions that describe each vertex in the order specified in the GlobalGeometryRules object. The simple, rectangular surface objects are described first with the more detailed descriptions following.

Walls

Walls are usually vertical (tilt = 90 degrees). These objects are used to describe exterior walls, interior walls (adiabatic), underground walls, and walls adjacent to other zones.

Wall:Exterior

The Wall:Exterior object is used to describe walls that are exposed to the external environment. They receive sun, wind – all the characteristics of the external world. The IDD definition is shown below:

```

Wall:Exterior,
    \memo Used for exterior walls
    \memo View Factor to Ground is automatically calculated.

Field: Name

This is a unique name associated with the exterior wall. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

Field: Construction Name

This is the name of the construction (ref: Construction) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

Field: Zone Name

This is the zone name to which the surface belongs.

Field: Azimuth Angle

The Azimuth Angle indicates the direction that the wall faces (outward normal). The angle is specified in degrees where East=90, South=180, West=270, North=0.

Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Normally, walls are tilted 90 degrees and that is the default for this field.

Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the GlobalGeometryRules object.

Field: Starting X Coordinate

This field is the X coordinate (in meters).

Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

Field: Length

This field is the length of the wall in meters.

Field: Height

This field is the height of the wall in meters.

Wall:Adiabatic

The Wall:Adiabatic object is used to describe interior walls and partitions. Adiabatic walls are used to describe walls next to zones that have the same thermal conditions (thus, no heat transfer). The IDD definition is shown below:

```

Wall:Adiabatic, \memo used for interior walls

Field: Name

This is a unique name associated with the interior wall. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

Field: Construction Name

This is the name of the construction (ref: Construction) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

Field: Zone Name

This is the zone name to which the surface belongs.

Field: Azimuth Angle

The Azimuth Angle indicates the direction that the wall faces (outward normal). The angle is specified in degrees where East=90, South=180, West=270, North=0.

Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Normally, walls are tilted 90 degrees and that is the default for this field.

Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the GlobalGeometryRules object.

Field: Starting X Coordinate

This field is the X coordinate (in meters).

Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

Field: Length

This field is the length of the wall in meters.

Field: Height

This field is the height of the wall in meters.

Wall:Underground

The Wall:Underground object is used to describe walls with ground contact. The temperature at the outside of the wall is the temperature in the GroundTemperature:BuildingSurface object. The IDD definition is shown below:

```

Wall:Underground, \memo used for interior walls

Field: Name

This is a unique name associated with the underground wall. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

Field: Construction Name

This is the name of the construction (ref: Construction) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

Field: Zone Name

This is the zone name to which the surface belongs.

Field: Azimuth Angle

The Azimuth Angle indicates the direction that the wall faces (outward normal). The angle is specified in degrees where East=90, South=180, West=270, North=0.

Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Normally, walls are tilted 90 degrees and that is the default for this field.

Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the GlobalGeometryRules object.

Field: Starting X Coordinate

This field is the X coordinate (in meters).

Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

Field: Length

This field is the length of the wall in meters.

Field: Height

This field is the height of the wall in meters.

Wall:Interzone

The Wall:Interzone object is used to describe walls adjacent to zones that are significantly different conditions than the zone with this wall.. The IDD definition is shown below:

```

Wall: Interzone, \memo used for interzone walls (walls between zones)

Field: Name

This is a unique name associated with the interzone wall. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

Field: Construction Name

This is the name of the construction (ref: Construction) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

Field: Zone Name

This is the zone name to which the surface belongs.

Field: Outside Boundary Condition Object

The Outside Boundary Condition Object field is the name of a wall in an adjacent zone or the name of the adjacent zone. If the adjacent zone option is used, the adjacent wall is automatically generated in the adjacent zone. If the surface name is used, it must be in the adjacent zone.

Field: Azimuth Angle

The Azimuth Angle indicates the direction that the wall faces (outward normal). The angle is specified in degrees where East=90, South=180, West=270, North=0.

Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Normally, walls are tilted 90 degrees and that is the default for this field.

Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the GlobalGeometryRules object.

Field: Starting X Coordinate

This field is the X coordinate (in meters).

Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

Field: Length

This field is the length of the wall in meters.

Field: Height

This field is the height of the wall in meters.

Roofs/Ceilings

Roofs and ceilings are, by default, flat (tilt = 0 degrees). These objects are used to describe roofs, interior ceilings (adiabatic) and ceilings adjacent to other zones.

Roof

The Roof object is used to describe roofs that are exposed to the external environment. The IDD definition is shown below:

```

Roof,
  \memo Used for exterior roofs
  \memo View Factor to Ground is automatically calculated.

Field: Name

This is a unique name associated with the roof. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

Field: Construction Name

This is the name of the construction (ref: Construction) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

Field: Zone Name

This is the zone name to which the surface belongs.

Field: Azimuth Angle

The Azimuth Angle indicates the direction of the outward normal for the roof. The angle is specified in degrees where East=90, South=180, West=270, North=0.

Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Flat roofs are tilted 0 degrees and that is the default for this field.

Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the GlobalGeometryRules object.

Field: Starting X Coordinate

This field is the X coordinate (in meters).

Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

Field: Length

This field is the length of the roof in meters.

Field: Width

This field is the width of the roof in meters.

Ceiling:Adiabatic

The Ceiling:Adiabatic object is used to describe interior ceilings that separate zones of like conditions. The IDD definition is shown below:

```

Field: Name

This is a unique name associated with the ceiling. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

Field: Construction Name

This is the name of the construction (ref: Construction) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

Field: Zone Name

This is the zone name to which the surface belongs.

Field: Azimuth Angle

The Azimuth Angle indicates the direction of the outward normal for the roof. The angle is specified in degrees where East=90, South=180, West=270, North=0.

Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Flat ceilings are tilted 0 degrees and that is the default for this field.

Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the GlobalGeometryRules object.

Field: Starting X Coordinate

This field is the X coordinate (in meters).

Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

Field: Length

This field is the length of the ceiling in meters.

Field: Width

This field is the width of the ceiling in meters.

Ceiling:Interzone

The Ceiling:Interzone object is used to describe interior ceilings that separate zones of differing conditions (and expect heat transfer through the ceiling from the adjacent zone). The IDD definition is shown below:

```

Ceiling: Interzone,
  \memo used for ceilings using adjacent zone (interzone) heat transfer

Field: Name

This is a unique name associated with the interzone ceiling. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

Field: Construction Name

This is the name of the construction (ref: Construction) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

Field: Zone Name

This is the zone name to which the surface belongs.

Field: Outside Boundary Condition Object

The Outside Boundary Condition Object field is the name of a floor in an adjacent zone or the name of the adjacent zone. If the adjacent zone option is used, the adjacent floor is automatically generated in the adjacent zone. If the surface name is used, it must be in the adjacent zone.

Field: Azimuth Angle

The Azimuth Angle indicates the direction of the outward normal for the roof. The angle is specified in degrees where East=90, South=180, West=270, North=0.

Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Flat ceilings are tilted 0 degrees and that is the default for this field.

Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the GlobalGeometryRules object.

Field: Starting X Coordinate

This field is the X coordinate (in meters).

Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

Field: Length

This field is the length of the ceiling in meters.

Field: Width

This field is the width of the ceiling in meters.

Floors

Floors are, by default, flat (tilt = 180 degrees). These objects are used to describe floors on the ground, interior floors (adiabatic) and floors adjacent to other zones.

Floor:GroundContact

The Floor:GroundContact object is used to describe floors that have ground contact (usually called slabs). The temperature at the outside of the floor is the temperature in the GroundTemperature:BuildingSurface object. The IDD definition is shown below:

```

Floor:GroundContact,
    \memo Used for exterior floors with ground contact
    \memo View Factors to Ground is automatically calculated.

Field: Construction Name

This is the name of the construction (ref: Construction) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior

wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

Field: Zone Name

This is the zone name to which the surface belongs.

Field: Outside Boundary Condition Object

The Outside Boundary Condition Object field is the name of a ceiling in an adjacent zone or the name of the adjacent zone. If the adjacent zone option is used, the adjacent ceiling is automatically generated in the adjacent zone. If the surface name is used, it must be in the adjacent zone.

Field: Azimuth Angle

The Azimuth Angle indicates the direction of the outward normal for the roof. The angle is specified in degrees where East=90, South=180, West=270, North=0.

Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Flat floors are tilted 180 degrees and that is the default for this field.

Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the GlobalGeometryRules object.

Field: Starting X Coordinate

This field is the X coordinate (in meters).

Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

Field: Length

This field is the length of the floor in meters.

Field: Width

This field is the width of the floor in meters.

Windows/Doors

The following window and door objects can be used to specify simple, rectangular doors and windows. In each case, the lower left corner (locator coordinate) of the window or door is specified **relative** to the surface it is on. Viewing the base surface as a planar surface, base the relative location from the lower left corner of the base surface. Vertex entry description as well as provisions for a few other surface types can be entered with the FenestrationSurface:Detailed object.

Window

The Window object is used to place windows on surfaces that can have windows, including exterior walls, interior walls, interzone walls, roofs, floors that are exposed to outdoor

conditions, interzone ceiling/floors. These, of course, can be entered using the simple rectangular objects or the more detailed vertex entry objects. The IDD for the object follows:

```
Window,

    \units m
N4. \field Length
    \units m
N5; \field Height
    \units m
```

Field: Name

This is a unique name associated with the window.

Field: Construction Name

This is the name of the subsurface's construction (ref: Construction and Construction:WindowDataFile).

For windows, if Construction Name is not found among the constructions on the input (.idf) file, the Window5 Data File (default Window5DataFile.dat) will be searched for that Construction Name (see "Importing Windows from WINDOW 5"). If that file is not present or if the Construction Name does not match the name of an entry on the file, an error will result. If

there is a match, a window construction and its corresponding glass and gas materials will be created from the information read from the file.

Field: Building Surface Name

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. For example, a surface in contact with the ground (Outside Boundary Condition = Ground) cannot contain a window. The window assumes the outward facing angle as well as the tilt angle of the base surface.

Field: Shading Control Name

This field, if not blank, is the name of the window shading control (ref: WindowProperty:ShadingControl) for this subsurface. It is used for Surface Type = Window and GlassDoor. To assign a shade to a window or glass door, see WindowMaterial:Shade. To assign a screen, see WindowMaterial:Screen. To assign a blind, see WindowMaterial:Blind. To assign switchable glazing, such as electrochromic glazing, see WindowProperty:ShadingControl.

Field: Frame and Divider Name

This field, if not blank, can be used to specify window frame, divider and reveal-surface data (ref: WindowProperty:FrameAndDivider). It is used only for exterior GlassDoors and rectangular exterior Windows, i.e., those with OutsideFaceEnvironment = Outdoors.

This field should be blank for triangular windows.

Field: Multiplier

This field is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier > 1 can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get if you entered each of the multiple subsurfaces separately.

If Multiplier > 1, you will get

--a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

--an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

Starting Corner for the surface

The rectangular subsurfaces specify the lower left corner of the surface for their starting coordinate. This corner is specified relative to the lower left corner of the base surface by specifying the X and Z values from that corner.

Field: Starting X Coordinate

This field is the X coordinate (in meters).

Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

Field: Length

This field is the length of the window in meters.

Field: Height

This field is the height of the window in meters.

Door

The Door object is used to place opaque doors on surfaces that can have doors, including exterior walls, interior walls, interzone walls, roofs, floors that are exposed to outdoor conditions, interzone ceiling/floors. These, of course, can be entered using the simple rectangular objects or the more detailed vertex entry objects. The IDD for the object follows:

```
Door, \memo used to specify opaque doors

    \units m
N4. \field Length
    \units m
N5; \field Height
    \units m
```

Field: Name

This is a unique name associated with the door.

Field: Construction Name

This is the name of the subsurface's construction (ref: Construction)

Field: Building Surface Name

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. The door assumes the outward facing angle as well as the tilt angle of the base surface.

Field: Multiplier

This field is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier > 1 can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get if you entered each of the multiple subsurfaces separately.

If Multiplier > 1, you will get

--a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

--an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

Starting Corner for the surface

The rectangular subsurfaces specify the lower left corner of the surface for their starting coordinate. This corner is specified relative to the lower left corner of the base surface by specifying the X and Z values from that corner.

Field: Starting X Coordinate

This field is the X coordinate (in meters).

Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

Field: Length

This field is the length of the door in meters.

Field: Height

This field is the height of the door in meters.

GlazedDoor

The GlazedDoor object is used to place doors on surfaces that can have doors, including exterior walls, interior walls, interzone walls, roofs, floors that are exposed to outdoor conditions, interzone ceiling/floors. These, of course, can be entered using the simple rectangular objects or the more detailed vertex entry objects. The IDD for the object follows:

```

Field: Name

This is a unique name associated with the glass door.

Field: Construction Name

This is the name of the subsurface's construction (ref: Construction and Construction:WindowDataFile).

For windows, if Construction Name is not found among the constructions on the input (.idf) file, the Window5 Data File (default Window5DataFile.dat) will be searched for that Construction Name (see "Importing Windows from WINDOW 5"). If that file is not present or if the Construction Name does not match the name of an entry on the file, an error will result. If

there is a match, a window construction and its corresponding glass and gas materials will be created from the information read from the file.

Field: Building Surface Name

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. For example, a surface in contact with the ground (Outside Boundary Condition = Ground) cannot contain a window. The door assumes the outward facing angle as well as the tilt angle of the base surface.

Field: Outside Boundary Condition Object

The Outside Boundary Condition Object field is the name of a glazed (glass) door in an adjacent zone or the name of the adjacent zone. If the adjacent zone option is used, the adjacent ceiling is automatically generated in the adjacent zone. If the surface name is used, it must be in the adjacent zone.

Field: Multiplier

This field is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier > 1 can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get if you entered each of the multiple subsurfaces separately.

If Multiplier > 1, you will get

--a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

--an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

Starting Corner for the surface

The rectangular subsurfaces specify the lower left corner of the surface for their starting coordinate. This corner is specified relative to the lower left corner of the base surface by specifying the X and Z values from that corner.

Field: Starting X Coordinate

This field is the X coordinate (in meters).

Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

Field: Length

This field is the length of the door in meters.

Field: Height

This field is the height of the door in meters.

Surface Vertices

Each of the following surfaces:

BuildingSurface:Detailed

Wall:Detailed

RoofCeiling:Detailed

Floor:Detailed

FenestrationSurface:Detailed

Shading:Site:Detailed

Shading:Building:Detailed

Shading:Zone:Detailed

use the same vertex input. The numeric parameters indicated below are taken from the BuildingSurface:Detailed definition; the others may not be exactly the same but are identical in configuration. They are also “extensible” – so, if you want more vertices for these surfaces, you may add to the IDD definition as indicated in the “extensible” comment or, as EnergyPlus is “auto-extensible” just add the number of vertices into your input file.. Note that FenestrationSurface:Detailed is not extensible and is limited to 4 (max) vertices. If you leave the Number of Surface Vertex groups blank or enter **autocalculate**, EnergyPlus looks at the number of groups entered and figures out how many coordinate groups are entered.

Note that the resolution on the surface vertex input is 1 millimeter (.001 meter). Therefore, using vertices that are very close together (<1 mm) may result in invalid dot product and fatal errors during shading calculations.

```

```

Figure 19. Illustration for Surface Vertices

The figure above will help illustrate Surface Vertex entry. The convention used in “GlobalGeometryRules” dictates the order of the vertices (ref: GlobalGeometryRules). In this example, the conventions used are Starting Vertex Position = UpperLeftCorner and Vertex Entry Direction= CounterClockwise. The surfaces for this single zone are:

```

4,0,0,H, 0,0,0, A,0,0, A,0,H; ! (4 vertices, South Wall)
4,A,0,H,A,0,0,A,B,0,A,B,H; ! (4 vertices, East Wall)
  ignore other walls that are not shown in this figure
4,C,0,J,A,0,H,A,B,H,C,B,J; ! (4 vertices, roof)
3,C,0,J,0,0,H,A,0,H; ! (3 vertices, gable end)
4,0,0,H, 0,0,0, A,0,0, A,0,H; ! (4 vertices, South Wall)

```

Note that in this example, point 1 of the entry is the Upper Left Corner of the rectangular surfaces and the point of the triangle for the 3 sided surface. The east wall shows the order of vertex entry. For horizontal surfaces, any vertex may be chosen as the starting position, but the Vertex Entry Direction convention must be followed. The surface details report (Output: Surfaces:List, Details;) is very useful for reviewing the accuracy of surface geometry inputs (ref: Surface Output Variables/Reports and Variable Dictionary Reports).

Building Surfaces - Detailed

A building surface is necessary for all calculations. There must be at least one building surface per zone. You can use the detailed descriptions as shown below or the simpler, rectangular surface descriptions shown earlier.

Wall:Detailed

The Wall:Detailed object is used to describe walls. The IDD definition, up to the number of surface sides, is shown below:

```

Field: Name

This is a unique name associated with each building surface. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

Field: Construction Name

This is the name of the construction (ref: Construction) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

Field: Zone Name

This is the zone name to which the surface belongs.

Field: Outside Boundary Condition

This value can be one of several things depending on the actual kind of surface.

- 1) **Surface** – if this surface is an internal surface, then this is the choice. The value will either be a surface in the base zone or a surface in another zone. The heat balance between two zones can be accurately simulated by specifying a surface in an adjacent zone. EnergyPlus will simulate a group of zones simultaneously and will include the heat transfer between zones. However, as this increases the complexity of the calculations, it is not necessary to specify the other zone unless the two zones will have a significant temperature difference. If the two zones will not be very different (temperature wise), then the surface should use itself as the outside environment. In either case, the surface name on the “outside” of this surface (adjacent to) is placed in the next field.
- 2) **Adiabatic** – an internal surface in the same Zone. The Outside Boundary Condition Object can be left blank.
- 3) **Zone** – this is similar to Surface but EnergyPlus will automatically create the required surface in the adjacent zone when this is entered for the surface. If there are windows or doors on the surface, EnergyPlus automatically creates appropriate sub-surfaces as well.

- 4) **Outdoors** – if this surface is exposed to outside temperature conditions, then this is the choice. See Sun Exposure and Wind Exposure below for further specifications on this kind of surface.
- 5) **Ground** – if this surface is exposed to the ground, then this is the choice. The temperature on the outside of this surface will be the Ground Temperature.
- 6) **OtherSideCoefficients** – if this surface has a custom, user specified temperature or other parameters (See SurfaceProperty:OtherSideCoefficients specification), then this is the choice. The outside boundary condition will be the name of the SurfaceProperty:OtherSideCoefficients specification.
- 7) **OtherSideConditionsModel** – if this surface has a specially-modeled multi-skin component, such as a transpired collector or vented photovoltaic panel, attached to the outside (See SurfaceProperty:OtherSideConditionsModel specification), then this the choice. The outside face environment will be the name of the SurfaceProperty:OtherSideConditionsModels specification.

Field: Outside Boundary Condition Object

If neither Surface, OtherSideCoefficients, or OtherSideConditionsModel are specified for the Outside Boundary Condition (previous field), then this field should be left blank.

As stated above, if the Outside Boundary Condition is “Surface”, then this field’s value must be the surface name whose inside face temperature will be forced on the outside face of the base surface. This permits heat exchange between adjacent zones (interzone heat transfer) when multiple zones are simulated, but can also be used to simulate middle zone behavior without modeling the adjacent zones. This is done by specifying a surface within the zone. For example, a middle floor zone can be modeled by making the floor the Outside Boundary Condition Object for the ceiling, and the ceiling the Outside Boundary Condition Object for the floor.

If the Outside Boundary Condition is Zone, then this field should contain the zone name of the adjacent zone for the surface.

Note: Zones with interzone heat transfer are not adiabatic and the internal surfaces contribute to gains or losses. Adiabatic surfaces are modeled by specifying the base surface itself in this field. Also, for interzone heat transfer, both surfaces must be represented – for example, if you want interzone heat transfer to an attic space, the ceiling in the lower zone must have a surface object with the outside face environment as the floor in the attic and, likewise, there must be a floor surface object in the attic that references the ceiling surface name in the lower zone.

Equally, if the Outside Boundary Condition is “OtherSideCoefficients”, then this field’s value must be the SurfaceProperty:OtherSideCoefficients name. Or if the Outside Boundary Condition is “OtherSideConditionsModel” then this field’s value must be the SurfaceProperty:OtherSideConditionsModel name.

Field: Sun Exposure

If the surface is exposed to the sun, then “SunExposed” should be entered in this field. Otherwise, “NoSun” should be entered.

Note, a cantilevered floor could have “Outdoors” but “NoSun” exposure.

Field: Wind Exposure

If the surface is exposed to the Wind, then “WindExposed” should be entered in this field. Otherwise, “NoWind” should be entered.

Note: When a surface is specified with “NoWind”, this has several implications. Within the heat balance code, this surface will default to using the simple ASHRAE exterior convection coefficient correlation with a zero wind speed. In addition, since the ASHRAE simple method

does not have a separate value for equivalent long wavelength radiation to the sky and ground, using “NoWind” also eliminates long wavelength radiant exchange from the exterior of the surface to both the sky and the ground. Thus, only simple convection takes place at the exterior face of a surface specified with “NoWind”.

Field: View Factor to Ground

The fraction of the ground plane (assumed horizontal) that is visible from a heat-transfer surface. It is used to calculate the diffuse solar radiation from the ground that is incident on the surface.

For example, if there are no obstructions, a vertical surface sees half of the ground plane and so View Factor to Ground = 0.5. A horizontal downward-facing surface sees the entire ground plane, so View Factor to Ground = 1.0. A horizontal upward-facing surface (horizontal roof) does not see the ground at all, so View Factor to Ground = 0.0.

Unused if reflections option in Solar Distribution field in Building object input unless a DaylightingDevice:Shelf or DaylightingDevice:Tubular has been specified.

If you do not use the reflections option in the Solar Distribution field in your Building object input, you are responsible for entering the View Factor to Ground for each heat-transfer surface. Typical values for a surface that is not shadowed are obtained by the simple equation:

$$\text{View Factor to Ground} = (1 - \cos(\text{SurfTilt})) / 2$$

For example, this gives 0.5 for a wall of tilt 90°. If the tilt of the wall changes, then the View Factor to Ground must also change.

If you enter **autocalculate** in this field, EnergyPlus will automatically calculate the view factor to ground based on the tilt of the surface.

If **you do use the reflections option in the Solar Distribution field** in your Building object input, you do **not** have to enter View Factor to Ground values. In this case the program will automatically calculate the value to use for each exterior surface taking into account solar shadowing (including shadowing of the ground by the building) and reflections from obstructions (ref: Building, Field: Solar Distribution).

However, if you do use the reflections option AND you are modeling a DaylightingDevice:Shelf or DaylightingDevice:Tubular, then you still need to enter some values of View Factor to Ground. For DaylightingDevice:Shelf you need to enter View Factor to Ground for the window associated with the shelf. And for DaylightingDevice:Tubular you need to enter the View Factor to Ground for the FenestrationSurface:Detailed corresponding to the dome of the tubular device.

Note 1: The corresponding view factor to the sky for diffuse solar radiation is not a user input; it is calculated within EnergyPlus based on surface orientation, sky solar radiance distribution, and shadowing surfaces.

Note 2: The view factors to the sky and ground for thermal infrared (long-wave) radiation are not user inputs; they are calculated within EnergyPlus based on surface tilt and shadowing surfaces. Shadowing surfaces are considered to have the same emissivity and temperature as the ground, so they are lumped together with the ground in calculating the ground IR view factor.

Field: Number of Vertices

This field specifies the number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on “Surface Vertices” above.

RoofCeiling:Detailed

The RoofCeiling:Detailed object is used to describe walls. The IDD definition, up to the number of surface sides, is shown below:

Field: Name

This is a unique name associated with each building surface. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

Field: Construction Name

This is the name of the construction (ref: Construction) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

Field: Zone Name

This is the zone name to which the surface belongs.

Field: Outside Boundary Condition

This value can be one of several things depending on the actual kind of surface.

- 1) **Surface** – if this surface is an internal surface, then this is the choice. The value will either be a surface in the base zone or a surface in another zone. The heat balance between two zones can be accurately simulated by specifying a surface in an adjacent zone. EnergyPlus will simulate a group of zones simultaneously and will include the heat transfer between zones. However, as this increases the complexity of the calculations, it is not necessary to specify the other zone unless the two zones will have a significant temperature difference. If the two zones will not be very different (temperature wise), then the surface should use itself as the outside environment. In either case, the surface name on the “outside” of this surface (adjacent to) is placed in the next field.
- 2) **Adiabatic** – an internal surface in the same Zone. The Outside Boundary Condition Object can be left blank.
- 3) **Zone** – this is similar to Surface but EnergyPlus will automatically create the required surface in the adjacent zone when this is entered for the surface. If there are windows or doors on the surface, EnergyPlus automatically creates appropriate sub-surfaces as well.

- 4) **Outdoors** – if this surface is exposed to outside temperature conditions, then this is the choice. See Sun Exposure and Wind Exposure below for further specifications on this kind of surface.
- 5) **Ground** – if this surface is exposed to the ground, then this is the choice. The temperature on the outside of this surface will be the Ground Temperature.
- 6) **OtherSideCoefficients** – if this surface has a custom, user specified temperature or other parameters (See SurfaceProperty:OtherSideCoefficients specification), then this is the choice. The outside boundary condition will be the name of the SurfaceProperty:OtherSideCoefficients specification.
- 7) **OtherSideConditionsModel** – if this surface has a specially-modeled multi-skin component, such as a transpired collector or vented photovoltaic panel, attached to the outside (See SurfaceProperty:OtherSideConditionsModel specification), then this the choice. The outside face environment will be the name of the SurfaceProperty:OtherSideConditionsModels specification.

Field: Outside Boundary Condition Object

If neither Surface, OtherSideCoefficients, or OtherSideConditionsModel are specified for the Outside Boundary Condition (previous field), then this field should be left blank.

As stated above, if the Outside Boundary Condition is “Surface”, then this field’s value must be the surface name whose inside face temperature will be forced on the outside face of the base surface. This permits heat exchange between adjacent zones (interzone heat transfer) when multiple zones are simulated, but can also be used to simulate middle zone behavior without modeling the adjacent zones. This is done by specifying a surface within the zone. For example, a middle floor zone can be modeled by making the floor the Outside Boundary Condition Object for the ceiling, and the ceiling the Outside Boundary Condition Object for the floor.

If the Outside Boundary Condition is Zone, then this field should contain the zone name of the adjacent zone for the surface.

Note: Zones with interzone heat transfer are not adiabatic and the internal surfaces contribute to gains or losses. Adiabatic surfaces are modeled by specifying the base surface itself in this field. Also, for interzone heat transfer, both surfaces must be represented – for example, if you want interzone heat transfer to an attic space, the ceiling in the lower zone must have a surface object with the outside face environment as the floor in the attic and, likewise, there must be a floor surface object in the attic that references the ceiling surface name in the lower zone.

Equally, if the Outside Boundary Condition is “OtherSideCoefficients”, then this field’s value must be the SurfaceProperty:OtherSideCoefficients name. Or if the Outside Boundary Condition is “OtherSideConditionsModel” then this field’s value must be the SurfaceProperty:OtherSideConditionsModel name.

Field: Sun Exposure

If the surface is exposed to the sun, then “SunExposed” should be entered in this field. Otherwise, “NoSun” should be entered.

Note, a cantilevered floor could have “Outdoors” but “NoSun” exposure.

Field: Wind Exposure

If the surface is exposed to the Wind, then “WindExposed” should be entered in this field. Otherwise, “NoWind” should be entered.

Note: When a surface is specified with “NoWind”, this has several implications. Within the heat balance code, this surface will default to using the simple ASHRAE exterior convection coefficient correlation with a zero wind speed. In addition, since the ASHRAE simple method

does not have a separate value for equivalent long wavelength radiation to the sky and ground, using “NoWind” also eliminates long wavelength radiant exchange from the exterior of the surface to both the sky and the ground. Thus, only simple convection takes place at the exterior face of a surface specified with “NoWind”.

Field: View Factor to Ground

The fraction of the ground plane (assumed horizontal) that is visible from a heat-transfer surface. It is used to calculate the diffuse solar radiation from the ground that is incident on the surface.

For example, if there are no obstructions, a vertical surface sees half of the ground plane and so View Factor to Ground = 0.5. A horizontal downward-facing surface sees the entire ground plane, so View Factor to Ground = 1.0. A horizontal upward-facing surface (horizontal roof) does not see the ground at all, so View Factor to Ground = 0.0.

Unused if reflections option in Solar Distribution field in Building object input unless a DaylightingDevice:Shelf or DaylightingDevice:Tubular has been specified.

If you do not use the reflections option in the Solar Distribution field in your Building object input, you are responsible for entering the View Factor to Ground for each heat-transfer surface. Typical values for a surface that is not shadowed are obtained by the simple equation:

$$\text{View Factor to Ground} = (1 - \cos(\text{SurfTilt})) / 2$$

For example, this gives 0.5 for a wall of tilt 90°. If the tilt of the wall changes, then the View Factor to Ground must also change.

If you enter **autocalculate** in this field, EnergyPlus will automatically calculate the view factor to ground based on the tilt of the surface.

If **you do use the reflections option in the Solar Distribution field** in your Building object input, you do **not** have to enter View Factor to Ground values. In this case the program will automatically calculate the value to use for each exterior surface taking into account solar shadowing (including shadowing of the ground by the building) and reflections from obstructions (ref: Building, Field: Solar Distribution).

However, if you do use the reflections option AND you are modeling a DaylightingDevice:Shelf or DaylightingDevice:Tubular, then you still need to enter some values of View Factor to Ground. For DaylightingDevice:Shelf you need to enter View Factor to Ground for the window associated with the shelf. And for DaylightingDevice:Tubular you need to enter the View Factor to Ground for the FenestrationSurface:Detailed corresponding to the dome of the tubular device.

Note 1: The corresponding view factor to the sky for diffuse solar radiation is not a user input; it is calculated within EnergyPlus based on surface orientation, sky solar radiance distribution, and shadowing surfaces.

Note 2: The view factors to the sky and ground for thermal infrared (long-wave) radiation are not user inputs; they are calculated within EnergyPlus based on surface tilt and shadowing surfaces. Shadowing surfaces are considered to have the same emissivity and temperature as the ground, so they are lumped together with the ground in calculating the ground IR view factor.

Field: Number of Vertices

This field specifies the number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on “Surface Vertices” above.

Floor:Detailed

The Floor:Detailed object is used to describe walls. The IDD definition, up to the number of surface sides, is shown below:

Field: Name

This is a unique name associated with each building surface. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

Field: Construction Name

This is the name of the construction (ref: Construction) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

Field: Zone Name

This is the zone name to which the surface belongs.

Field: Outside Boundary Condition

This value can be one of several things depending on the actual kind of surface.

- 1) **Surface** – if this surface is an internal surface, then this is the choice. The value will either be a surface in the base zone or a surface in another zone. The heat balance between two zones can be accurately simulated by specifying a surface in an adjacent zone. EnergyPlus will simulate a group of zones simultaneously and will include the heat transfer between zones. However, as this increases the complexity of the calculations, it is not necessary to specify the other zone unless the two zones will have a significant temperature difference. If the two zones will not be very different (temperature wise), then the surface should use itself as the outside environment. In either case, the surface name on the “outside” of this surface (adjacent to) is placed in the next field.
- 2) **Adiabatic** – an internal surface in the same Zone. The Outside Boundary Condition Object can be left blank.
- 3) **Zone** – this is similar to Surface but EnergyPlus will automatically create the required surface in the adjacent zone when this is entered for the surface. If there are windows or doors on the surface, EnergyPlus automatically creates appropriate sub-surfaces as well.

- 4) **Outdoors** – if this surface is exposed to outside temperature conditions, then this is the choice. See Sun Exposure and Wind Exposure below for further specifications on this kind of surface.
- 5) **Ground** – if this surface is exposed to the ground, then this is the choice. The temperature on the outside of this surface will be the Ground Temperature.
- 6) **OtherSideCoefficients** – if this surface has a custom, user specified temperature or other parameters (See SurfaceProperty:OtherSideCoefficients specification), then this is the choice. The outside boundary condition will be the name of the SurfaceProperty:OtherSideCoefficients specification.
- 7) **OtherSideConditionsModel** – if this surface has a specially-modeled multi-skin component, such as a transpired collector or vented photovoltaic panel, attached to the outside (See SurfaceProperty:OtherSideConditionsModel specification), then this the choice. The outside face environment will be the name of the SurfaceProperty:OtherSideConditionsModels specification.

Field: Outside Boundary Condition Object

If neither Surface, OtherSideCoefficients, or OtherSideConditionsModel are specified for the Outside Boundary Condition (previous field), then this field should be left blank.

As stated above, if the Outside Boundary Condition is “Surface”, then this field’s value must be the surface name whose inside face temperature will be forced on the outside face of the base surface. This permits heat exchange between adjacent zones (interzone heat transfer) when multiple zones are simulated, but can also be used to simulate middle zone behavior without modeling the adjacent zones. This is done by specifying a surface within the zone. For example, a middle floor zone can be modeled by making the floor the Outside Boundary Condition Object for the ceiling, and the ceiling the Outside Boundary Condition Object for the floor.

If the Outside Boundary Condition is Zone, then this field should contain the zone name of the adjacent zone for the surface.

Note: Zones with interzone heat transfer are not adiabatic and the internal surfaces contribute to gains or losses. Adiabatic surfaces are modeled by specifying the base surface itself in this field. Also, for interzone heat transfer, both surfaces must be represented – for example, if you want interzone heat transfer to an attic space, the ceiling in the lower zone must have a surface object with the outside face environment as the floor in the attic and, likewise, there must be a floor surface object in the attic that references the ceiling surface name in the lower zone.

Equally, if the Outside Boundary Condition is “OtherSideCoefficients”, then this field’s value must be the SurfaceProperty:OtherSideCoefficients name. Or if the Outside Boundary Condition is “OtherSideConditionsModel” then this field’s value must be the SurfaceProperty:OtherSideConditionsModel name.

Field: Sun Exposure

If the surface is exposed to the sun, then “SunExposed” should be entered in this field. Otherwise, “NoSun” should be entered.

Note, a cantilevered floor could have “Outdoors” but “NoSun” exposure.

Field: Wind Exposure

If the surface is exposed to the Wind, then “WindExposed” should be entered in this field. Otherwise, “NoWind” should be entered.

Note: When a surface is specified with “NoWind”, this has several implications. Within the heat balance code, this surface will default to using the simple ASHRAE exterior convection coefficient correlation with a zero wind speed. In addition, since the ASHRAE simple method

does not have a separate value for equivalent long wavelength radiation to the sky and ground, using “NoWind” also eliminates long wavelength radiant exchange from the exterior of the surface to both the sky and the ground. Thus, only simple convection takes place at the exterior face of a surface specified with “NoWind”.

Field: View Factor to Ground

The fraction of the ground plane (assumed horizontal) that is visible from a heat-transfer surface. It is used to calculate the diffuse solar radiation from the ground that is incident on the surface.

For example, if there are no obstructions, a vertical surface sees half of the ground plane and so View Factor to Ground = 0.5. A horizontal downward-facing surface sees the entire ground plane, so View Factor to Ground = 1.0. A horizontal upward-facing surface (horizontal roof) does not see the ground at all, so View Factor to Ground = 0.0.

Unused if reflections option in Solar Distribution field in Building object input unless a DaylightingDevice:Shelf or DaylightingDevice:Tubular has been specified.

If you do not use the reflections option in the Solar Distribution field in your Building object input, you are responsible for entering the View Factor to Ground for each heat-transfer surface. Typical values for a surface that is not shadowed are obtained by the simple equation:

$$\text{View Factor to Ground} = (1 - \cos(\text{SurfTilt})) / 2$$

For example, this gives 0.5 for a wall of tilt 90°. If the tilt of the wall changes, then the View Factor to Ground must also change.

If you enter **autocalculate** in this field, EnergyPlus will automatically calculate the view factor to ground based on the tilt of the surface.

If **you do use the reflections option in the Solar Distribution field** in your Building object input, you do **not** have to enter View Factor to Ground values. In this case the program will automatically calculate the value to use for each exterior surface taking into account solar shadowing (including shadowing of the ground by the building) and reflections from obstructions (ref: Building, Field: Solar Distribution).

However, if you do use the reflections option AND you are modeling a DaylightingDevice:Shelf or DaylightingDevice:Tubular, then you still need to enter some values of View Factor to Ground. For DaylightingDevice:Shelf you need to enter View Factor to Ground for the window associated with the shelf. And for DaylightingDevice:Tubular you need to enter the View Factor to Ground for the FenestrationSurface:Detailed corresponding to the dome of the tubular device.

Note 1: The corresponding view factor to the sky for diffuse solar radiation is not a user input; it is calculated within EnergyPlus based on surface orientation, sky solar radiance distribution, and shadowing surfaces.

Note 2: The view factors to the sky and ground for thermal infrared (long-wave) radiation are not user inputs; they are calculated within EnergyPlus based on surface tilt and shadowing surfaces. Shadowing surfaces are considered to have the same emissivity and temperature as the ground, so they are lumped together with the ground in calculating the ground IR view factor.

Field: Number of Vertices

This field specifies the number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on “Surface Vertices” above.

BuildingSurface:Detailed

The BuildingSurface:Detailed object can more generally describe each of the surfaces. The IDD definition, up to the number of surface sides, is shown below:

Field: Name

This is a unique name associated with each building surface. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

Field: Surface Type

Used primarily for convenience, the surface type can be one of the choices illustrated above – Wall, Floor, Ceiling, Roof. Azimuth (facing) and Tilt are determined from the vertex coordinates. Note that “normal” floors will be tilted 180° whereas flat roofs/ceilings will be tilted 0°. EnergyPlus uses this field’s designation, along with the calculated tilt of the surface, to issue warning messages when tilts are “out of range”. Calculations in EnergyPlus use the actual calculated tilt values for the actual heat balance calculations. Note, however, that a floor tilted 0° is really facing “into” the zone and is not what you will desire for the calculations even though the coordinate may appear correct in the viewed DXF display.

“Normal” tilt for walls is 90° -- here you may use the calculated Azimuth to make sure your walls are facing away from the zone’s interior.

Field: Construction Name

This is the name of the construction (ref: Construction) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

Field: Zone Name

This is the zone name to which the surface belongs.

Field: Outside Boundary Condition

This value can be one of several things depending on the actual kind of surface.

- 1) **Surface** – if this surface is an internal surface, then this is the choice. The value will either be a surface in the base zone or a surface in another zone. The heat balance between two zones can be accurately simulated by specifying a surface in an adjacent zone. EnergyPlus will simulate a group of zones simultaneously and will include the heat transfer between zones. However, as this increases the complexity of the calculations, it is not necessary to specify the other zone unless the two zones will have a significant temperature difference. If the two zones will not be very different (temperature wise), then the surface should use itself as the outside environment. In either case, the surface name on the “outside” of this surface (adjacent to) is placed in the next field.
- 2) **Adiabatic** – an internal surface in the same Zone. The Outside Boundary Condition Object can be left blank.
- 3) **Zone** – this is similar to Surface but EnergyPlus will automatically create the required surface in the adjacent zone when this is entered for the surface. If there are windows or doors on the surface, EnergyPlus automatically creates appropriate sub-surfaces as well.
- 4) **Outdoors** – if this surface is exposed to outside temperature conditions, then this is the choice. See Sun Exposure and Wind Exposure below for further specifications on this kind of surface.
- 5) **Ground** – if this surface is exposed to the ground, then this is the choice. The temperature on the outside of this surface will be the Ground Temperature.
- 6) **OtherSideCoefficients** – if this surface has a custom, user specified temperature or other parameters (See SurfaceProperty:OtherSideCoefficients specification), then this is the choice. The outside boundary condition will be the name of the SurfaceProperty:OtherSideCoefficients specification.
- 7) **OtherSideConditionsModel** – if this surface has a specially-modeled multi-skin component, such as a transpired collector or vented photovoltaic panel, attached to the outside (See SurfaceProperty:OtherSideConditionsModel specification), then this the choice. The outside face environment will be the name of the SurfaceProperty:OtherSideConditionsModelspecification.

Field: Outside Boundary Condition Object

If neither Surface, OtherSideCoefficients, or OtherSideConditionsModel are specified for the Outside Boundary Condition (previous field), then this field should be left blank.

As stated above, if the Outside Boundary Condition is “Surface”, then this field’s value must be the surface name whose inside face temperature will be forced on the outside face of the base surface. This permits heat exchange between adjacent zones (interzone heat transfer) when multiple zones are simulated, but can also be used to simulate middle zone behavior without modeling the adjacent zones. This is done by specifying a surface within the zone. For example, a middle floor zone can be modeled by making the floor the Outside Boundary Condition Object for the ceiling, and the ceiling the Outside Boundary Condition Object for the floor.

If the Outside Boundary Condition is Zone, then this field should contain the zone name of the adjacent zone for the surface.

Note: Zones with interzone heat transfer are not adiabatic and the internal surfaces contribute to gains or losses. Adiabatic surfaces are modeled by specifying the base surface itself in this field. Also, for interzone heat transfer, both surfaces must be represented – for example, if you want interzone heat transfer to an attic space, the ceiling in the lower zone must have a surface object with the outside face environment as the floor in the attic and, likewise, there must be a floor surface object in the attic that references the ceiling surface name in the lower zone.

Equally, if the Outside Boundary Condition is “OtherSideCoefficients”, then this field’s value must be the SurfaceProperty:OtherSideCoefficients name. Or if the Outside Boundary Condition is “OtherSideConditionsModel” then this field’s value must be the SurfaceProperty:OtherSideConditionsModel name.

Field: Sun Exposure

If the surface is exposed to the sun, then “SunExposed” should be entered in this field. Otherwise, “NoSun” should be entered.

Note, a cantilevered floor could have “Outdoors” but “NoSun” exposure.

Field: Wind Exposure

If the surface is exposed to the Wind, then “WindExposed” should be entered in this field. Otherwise, “NoWind” should be entered.

Note: When a surface is specified with “NoWind”, this has several implications. Within the heat balance code, this surface will default to using the simple ASHRAE exterior convection coefficient correlation with a zero wind speed. In addition, since the ASHRAE simple method does not have a separate value for equivalent long wavelength radiation to the sky and ground, using “NoWind” also eliminates long wavelength radiant exchange from the exterior of the surface to both the sky and the ground. Thus, only simple convection takes place at the exterior face of a surface specified with “NoWind”.

Field: View Factor to Ground

The fraction of the ground plane (assumed horizontal) that is visible from a heat-transfer surface. It is used to calculate the diffuse solar radiation from the ground that is incident on the surface.

For example, if there are no obstructions, a vertical surface sees half of the ground plane and so View Factor to Ground = 0.5. A horizontal downward-facing surface sees the entire ground plane, so View Factor to Ground = 1.0. A horizontal upward-facing surface (horizontal roof) does not see the ground at all, so View Factor to Ground = 0.0.

Unused if reflections option in Solar Distribution field in Building object input unless a DaylightingDevice:Shelf or DaylightingDevice:Tubular has been specified.

If you do not use the reflections option in the Solar Distribution field in your Building object input, you are responsible for entering the View Factor to Ground for each heat-transfer surface. Typical values for a surface that is not shadowed are obtained by the simple equation:

$$\text{View Factor to Ground} = (1 - \cos(\text{SurfTilt})) / 2$$

For example, this gives 0.5 for a wall of tilt 90°. If the tilt of the wall changes, then the View Factor to Ground must also change.

If you enter **autocalculate** in this field, EnergyPlus will automatically calculate the view factor to ground based on the tilt of the surface.

If **you do use the reflections option in the Solar Distribution field** in your Building object input, you do **not** have to enter View Factor to Ground values. In this case the program will automatically calculate the value to use for each exterior surface taking into account solar shadowing (including shadowing of the ground by the building) and reflections from obstructions (ref: Building, Field: Solar Distribution).

However, if you do use the reflections option AND you are modeling a DaylightingDevice:Shelf or DaylightingDevice:Tubular, then you still need to enter some values of View Factor to Ground. For DaylightingDevice:Shelf you need to enter View Factor to Ground for the window associated with the shelf. And for DaylightingDevice:Tubular you need to enter the View Factor to Ground for the FenestrationSurface:Detailed corresponding to the dome of the tubular device.

Note 1: The corresponding view factor to the sky for diffuse solar radiation is not a user input; it is calculated within EnergyPlus based on surface orientation, sky solar radiance distribution, and shadowing surfaces.

Note 2: The view factors to the sky and ground for thermal infrared (long-wave) radiation are not user inputs; they are calculated within EnergyPlus based on surface tilt and shadowing surfaces. Shadowing surfaces are considered to have the same emissivity and temperature as the ground, so they are lumped together with the ground in calculating the ground IR view factor.

Field: Number of Vertices

This field specifies the number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on “Surface Vertices” above.

An IDF example of three walls (first is an exterior wall, second and third are interzone partitions):

FenestrationSurface:Detailed

This surface class is used for subsurfaces, which can be of five different types: Windows, Doors, GlassDoors, TubularDaylightDomes, and TubularDaylightDiffusers. A subsurface (such as a window) of a base surface (such as a wall) inherits several of the properties (such as Outside Boundary Condition, Sun Exposure, etc.) of the base surface. Windows, GlassDoors, TubularDaylightDomes, and TubularDaylightDiffusers are considered to have one or more glass layers and so transmit solar radiation. Doors are considered to be opaque.

```

Field: Name

This is a unique name associated with the heat transfer subsurface. It may be used in other places as a reference (e.g. as the opposing subsurface of an interzone window or door).

Field: Surface Type

The choices for Surface Type are Window, Door, GlassDoor, TubularDaylightDome, and TubularDaylightDiffuser. Doors are assumed to be opaque (do not transmit solar radiation) whereas the other surface types do transmit solar radiation. Windows and Glass Doors are treated identically in the calculation of conduction heat transfer, solar gain, daylighting, etc. A Window or GlassDoor, but not a Door, can have a movable interior, exterior or between-glass shading device, such as blinds (ref: WindowMaterial:Blind), and can have a frame and/or a divider (ref: WindowProperty:FrameAndDivider). TubularDaylightDomes and TubularDaylightDomes are specialized subsurfaces for use with the DaylightingDevice:Tubular object to simulate Tubular Daylighting Devices (TDDs). TubularDaylightDomes and TubularDaylightDomes cannot have shades, screens or blinds. In the following, the term "window" applies to Window, GlassDoor, TubularDaylightDome, and TubularDaylightDome, if not otherwise explicitly mentioned.

As noted in the description of the BuildingSurface:Detailed, Azimuth (facing angle) and Tilt are calculated from the entered vertices. Tilts of subsurfaces will normally be the same as their base surface. If these are significantly beyond the “normals” for the base surface, warning messages may be issued. If the facing angles are not correct, you may have a window pointing “into” the zone rather than out of it – this would cause problems in the calculations. Note, too, that a “reveal” (inset or outset) may occur if the plane of the subsurface is not coincident with the base surface; the reveal has an effect on shading of the subsurface.

Field: Construction Name

This is the name of the subsurface’s construction (ref: Construction [for Window, GlassDoor and Door] and Construction:WindowDataFile [for Window and GlassDoor]).

For windows, if Construction Name is not found among the constructions on the input (.idf) file, the Window5 Data File (Window5DataFile.dat) will be searched for that Construction Name (see “Importing Windows from WINDOW 5”). If that file is not present or if the Construction Name does not match the name of an entry on the file, an error will result. If there is a match, a window construction and its corresponding glass and gas materials will be created from the information read from the file.

Field: Building Surface Name

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. For example, a surface in contact with the ground (Outside Boundary Condition = Ground) cannot contain a window.

Field: Outside Boundary Condition Object

If the base surface has Outside Boundary Condition = Surface or OtherSideCoefficients, then this field must also be specified for the subsurface. Otherwise, it can be left blank.

If the base surface has Outside Boundary Condition = Zone, then this surface retains that characteristic and uses the same zone of the base surface. It can be entered here for clarity or it can be left blank.

If Outside Boundary Condition for the base surface is Surface, this field should specify the subsurface in the opposing zone that is the counterpart to this subsurface. The constructions of the subsurface and opposing subsurface must match, except that, for multi-layer constructions, the layer order of the opposing subsurface’s construction must be the reverse of that of the subsurface.

If Outside Boundary Condition for the base surface is OtherSideCoefficients, this field could specify the set of SurfaceProperty:OtherSideCoefficients for this subsurface. If this is left blank, then the Other Side Coefficients of the base surface will be used for this subsurface. *Windows and GlassDoors are not allowed to have Other Side Coefficients.*

Field: View Factor to Ground

The fraction of the ground plane (assumed horizontal) that is visible from a heat-transfer surface. It is used to calculate the diffuse solar radiation from the ground that is incident on the surface.

For example, if there are no obstructions, a vertical surface sees half of the ground plane and so View Factor to Ground = 0.5. A horizontal downward-facing surface sees the entire ground plane, so View Factor to Ground = 1.0. A horizontal upward-facing surface (horizontal roof) does not see the ground at all, so View Factor to Ground = 0.0.

Unused if reflections option in Solar Distribution field in Building object input unless a Daylighting Device:Shelf or Daylighting Device:Tubular has been specified.

If you do not use the reflections option in the Solar Distribution field in your Building object input, you are responsible for entering the View Factor to Ground for each heat-transfer surface. Typical values for a surface that is not shadowed are obtained by the simple equation:

$$\text{View Factor to Ground} = (1 - \cos(\text{SurfTilt})) / 2$$

For example, this gives 0.5 for a wall of tilt 90°. If the tilt of the wall changes, then the View Factor to Ground must also change.

If you enter **autocalculate** in this field, EnergyPlus will automatically calculate the view factor to ground based on the tilt of the surface.

If **you do use the reflections option in the Solar Distribution field** in your BUILDING object input, you do **not** have to enter View Factor to Ground values. In this case the program will automatically calculate the value to use for each exterior surface taking into account solar shadowing (including shadowing of the ground by the building) and reflections from obstructions (ref: Building, Field: Solar Distribution).

However, if you do use the reflections option AND you are modeling a DaylightingDevice:Shelf or DaylightingDevice:Tubular, then you still need to enter some values of View Factor to Ground. For DaylightingDevice:Shelf you need to enter View Factor to Ground for the window associated with the shelf. And for DaylightingDevice:Tubular you need to enter the View Factor to Ground for the FenestrationSurface:Detailed corresponding to the dome of the tubular device (ref: NEED CROSS REFERENCE HERE).

Note 1: The corresponding view factor to the sky for diffuse solar radiation is not a user input; it is calculated within EnergyPlus based on surface orientation, sky solar radiance distribution, and shadowing surfaces.

Note 2: The view factors to the sky and ground for thermal infrared (long-wave) radiation are not user inputs; they are calculated within EnergyPlus based on surface tilt and shadowing surfaces. Shadowing surfaces are considered to have the same emissivity and temperature as the ground, so they are lumped together with the ground in calculating the ground infrared view factor.

Field: Shading Control Name

This field, if not blank, is the name of the window shading control (ref: WindowProperty:ShadingControl) for this subsurface. It is used for Surface Type = Window and GlassDoor. To assign a shade to a window or glass door, see WindowMaterial:Shade. To assign a screen, see WindowMaterial:Screen. To assign a blind, see WindowMaterial:Blind. To assign switchable glazing, such as electrochromic glazing, see WindowProperty:ShadingControl.

Field: Frame and Divider Name

This field, if not blank, can be used to specify window frame, divider and reveal-surface data (ref: WindowProperty:FrameAndDivider). It is used only for exterior GlassDoors and rectangular exterior Windows, i.e., those with OutsideFaceEnvironment = Outdoors.

This field should be blank for triangular windows.

Field: Multiplier

Used only for Surface Type = Window, Door or Glass Door. It is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier > 1 can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get if you entered each of the multiple subsurfaces separately.

If Multiplier > 1, you will get

--a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

--an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

Field: Number of Vertices

The number of sides the surface has (number of X,Y,Z vertex groups). For further information, see the discussion on “Surface Vertices” above. Door and GlassDoor subsurfaces are rectangular and therefore have four vertices. Window subsurfaces can be rectangular or triangular and therefore have four or three vertices, respectively.

Fields: Vertex Coordinates

This is a total of twelve fields giving the x,y,z coordinate values of the four vertices of rectangular subsurfaces [m], or a total of nine fields giving the x,y,z coordinate values of the three vertices of triangular windows.

For triangular windows the first vertex listed can be any of the three vertices, but the order of the vertices should be counter-clockwise if VertexEntry is CounterClockWise and clockwise if VertexEntry is ClockWise (ref: GlobalGeometryRules).

An IDF example of a rectangular subsurface (Window):

```

Window Modeling Options

The following table shows what input objects/fields to use to model different window options. It also gives the name of an example input, if available, that demonstrates the option.

Table 7. Window Modeling Options

Option	Object/Field or Output Variable	Input File (distributed with install)
Build up a window from layers	WindowMaterial:Glazing, WindowMaterial:Gas, WindowMaterial:Shade, WindowMaterial:Screen, WindowMaterial:Blind, Construction	WindowTests.idf
Add an overhang	Shading:Zone:Detailed	5ZoneAirCooled.idf
Add a shading device	WindowMaterial:Shade, WindowMaterial:Screen or WindowMaterial:Blind;	WindowTests.idf, PurchAirWindowBlind.idf

	WindowProperty:ShadingControl	
Control a shading device	WindowProperty:ShadingControl	PurchAirWindowBlind.idf
Determine when a shading device is on in a particular timestep	Print the variable “Fraction of Time Shading Device is On”	PurchAirWindowBlind.idf
Control the slat angle of a blind	WindowProperty:ShadingControl	PurchAirWindowBlind.idf
Add a frame	WindowProperty:FrameAndDivider	PurchAirWithDaylighting.idf
Add a divider	WindowProperty:FrameAndDivider	PurchAirWithDaylighting.idf
Allow window to daylight a zone	Daylighting:Controls, Daylighting:DELight:Controls	PurchAirWithDaylighting.idf, DELight-Detailed-Comparison.idf
Find solar reflected onto window from neighboring buildings	Building/SolarDistribution field – uses “WithReflections”	ReflectiveAdjacentBuilding.idf
Model switchable glazing (e.g., electrochromic glass)	WindowProperty:ShadingControl	PurchAirWithDaylighting.idf
Add an interior window	Define two FenestrationSurface:Detailed’s, one for each associated interior wall	PurchAirWithDoubleFacadeDaylighting.idf
Track how beam solar falls on interior surfaces	Building/Solar Distribution = FullInteriorAndExterior	PurchAirWithDoubleFacadeDaylighting.idf
Track beam solar transmitted through interior windows	Building/Solar Distribution = FullInteriorAndExterior	PurchAirWithDoubleFacadeDaylighting.idf
Add a shading device on an interior window	<i>Not allowed</i>	
Model an airflow window (aka, heat extract window)	WindowProperty:AirflowControl	AirflowWindowsAndBetweenGlassBlinds.idf
Add a storm window glass layer	WindowProperty:StormWindow	StormWindow.idf
Add natural ventilation through an open window	Ventilation or AirflowNetwork objects (AirflowNetwork:MultiZone:Surface, AirflowNetwork:MultiZone:Component:DetailedOpening, etc.)	AirflowNetwork3zvent.idf
Add diffusing glass	WindowMaterial:Glazing/Solar Diffusing = Yes	
Add dirt on window	WindowMaterial:Glazing/Dirt Correction Factor for Solar and Visible Transmittance	
Import window (and frame/divider if present) from WINDOW 5 program	See “Importing Windows from WINDOW 5”	
Find daylighting through interior windows	See “Double Facades: Daylighting through Interior Windows”	PurchAirWithDoubleFacadeDaylighting.idf
Determine when condensation	Print the variables “Inside	

occurs	Glass Condensation Flag," "Inside Frame Condensation Flag," "Inside Divider Condensation Flag"	
--------	---	--

InternalMass

Any surface that would logically be described as an interior wall, floor or ceiling can just as easily be described as Internal Mass. Internal Mass surface types only exchange energy with the zone in which they are described; they do not see any other zones. There are two approaches to using internal mass. The first approach is to have several pieces of internal mass with each piece having a different construction type. The other approach is to choose an average construction type and combine all of the interior surfaces into a single internal mass. Note that furniture and other large objects within a zone can be described using internal mass. However, simplifying calculations using internal mass must be used with caution when the "FullInteriorAndExterior" or "FullInteriorAndExteriorWithReflections" Solar Distribution model (see Building parameters) is chosen.

Example

When zoning an office building, five west-facing offices have been combined into one zone. All of the offices have interior walls made of the same materials. As shown in the figure below, this zone may be described with 5 exterior walls and 11 internal walls or 1 exterior wall and 1 internal mass. Note that fewer surfaces will speed up the EnergyPlus calculations.

Figure 20. Representing 11 internal walls as internal mass

Example

A five-story building has the same ceiling/floor construction separating each of the levels. Zones that are on floors 2 through 4 may be described using a single piece of internal mass to represent both the floor and ceiling. The construction for this internal mass would be identical to the ceiling/floor construction that would be used to describe separate surfaces.

```

Field: Name

This is a unique character string associated with the internal mass surface. Though it must be unique from other surface names, it is used primarily for convenience with internal mass surfaces.

Field: Construction Name

This is the name of the construction (ref: Construction) used in the surface.

Field: Zone Name

This is the name of the zone in which the internal mass is represented.

Field: Surface Area

This field is the surface area of the internal mass. The area that is specified must be the entire surface area that is exposed to the zone. If both sides of a wall are completely within the same zone, then the area of both sides must be included when describing that internal wall.

IDF examples of Internal Mass surfaces:

Output variable applicable only to interior windows and glass doors:

```

Zone,Average, Beam Solar Transmitted Through Interior Window [W]

```

Surface Output Variables (all heat transfer surfaces)

Surface Inside Temperature [C]

The inside surface temperature of a heat transfer surface.

Surface Outside Temperature [C]

The outside surface temperature of a heat transfer surface.

Surface Int Adjacent Air Temperature [C]

The effective bulk air temperature used for modeling the inside surface convection heat transfer. This is the same as the zone mean air temperature when using the mixing model for roomair. However, if more advanced roomair models are used, this variable will report the air temperature predicted by the roomair model as it was used in the surface heat balance model calculations.

Surface Int Convection Coeff [W/m2-K]

The inside air film convective conductance for a heat transfer surface.

Surface Ext Convection Coeff [W/m2-K]

The outside air film convective conductance for a heat transfer surface.

Surface Ext Rad To Air Coeff [W/m2-K]

The outside heat transfer coefficient for radiation exchange with the air mass.

Surface Ext Rad To Sky Coeff [W/m2-K]

The outside heat transfer coefficient for radiation exchange with the sky.

Surface Ext Rad To Ground Coeff [W/m2-K]

The outside heat transfer coefficient for radiation exchange with the ground.

Beam Sol Amount from Ext Windows on Inside of Surface [W]

Beam solar radiation from the exterior windows in a zone incident on the inside face of a surface in the zone. If Solar Distribution in the BUILDING object is equal to MinimalShadowing or FullExterior, it is assumed that all beam solar from exterior windows falls on the floor. In this case the value of this report variable can be greater than zero only for floor surfaces. If Solar Distribution equals FullInteriorExterior the program tracks where beam solar from exterior windows falls inside the zone, in which case the value of this variable can be greater than zero for floor as well as wall surfaces.

Beam Sol Intensity from Ext Windows on Inside of Surface [W/m2]

The previous variable divided by the surface's area.

Diff Sol Amount from Ext Windows on Inside of Surface [W]

Diffuse solar radiation from the exterior windows in a zone incident on the inside face of a surface in the zone. It is assumed that this diffuse radiation is uniformly distributed in the inside of the zone.

Diff Sol Intensity from Ext Windows on Inside of Surface [W/m2]

The previous variable divided by the surface's area. Since this diffuse radiation is assumed to be uniformly distributed, the value of this report variable will be the same for all of the heat transfer surfaces in a zone.

Beam Sol Amount from Int Windows on Inside of Surface [W]

Beam solar radiation from the interior (i.e., interzone) windows in a zone incident on the inside face of a surface in the zone. This value is calculated only if Solar Distribution in the BUILDING object is equal to FullInteriorExterior. However, the program does not track where this radiation falls. Instead, it is treated by the program as though it were diffuse radiation uniformly distributed over all of the zone surfaces. See **Figure 21**.

Figure 21. Beam solar radiation entering a zone through an interior window is distributed inside the zone as though it were diffuse radiation.

Beam Sol Intensity from Int Windows on Inside of Surface [W/m2]

The previous variable divided by the surface's area. Since this diffuse radiation is assumed to be uniformly distributed, the value of this report variable will be the same for all of the heat transfer surfaces in a zone.

Initial Transmitted Diffuse Solar Absorbed on Inside of Surface [W]

As of Version 2.1, diffuse solar transmitted through exterior and interior windows is no longer uniformly distributed. Instead, it is distributed according to the approximate view factors between the transmitting window and all other heat transfer surfaces in the zone. This variable is the amount of transmitted diffuse solar that is initially absorbed on the inside of each heat transfer surface. The portion of this diffuse solar that is reflected by all surfaces in the zone is subsequently redistributed uniformly to all heat transfer surfaces in the zone, along with interior reflected beam solar and shortwave radiation from lights. The total absorbed shortwave radiation is given by the next variable.

Total Shortwave Radiation Absorbed on Inside of Surface [W]

As of Version 2.1, the previous variable plus absorbed shortwave radiation from uniformly distributed initially-reflected diffuse solar, reflected beam solar, and shortwave radiation from lights.

Surface Output Variables (exterior heat transfer surfaces)***Surface Ext Outdoor Dry Bulb [C]***

The outdoor air dry-bulb temperature calculated at the height above ground of the surface centroid.

Surface Ext Outdoor Wet Bulb [C]

The outdoor air wet-bulb temperature calculated at the height above ground of the surface centroid.

Surface Ext Wind Speed [m/s]

The outdoor wind speed calculated at the height above ground of the surface centroid.

Surface Ext Sunlit Area [m²]

The outside area of an exterior surface that is illuminated by (unreflected) beam solar radiation.

Surface Ext Sunlit Fraction []

The fraction of the outside area of an exterior surface that is illuminated by (unreflected) beam solar radiation. Equals Surface Ext Sunlit Area divided by total surface area.

Surface Ext Solar Incident [W/m²]

The total solar radiation incident on the outside of an exterior surface. It is the sum of:

- Surface Ext Solar Beam Incident
- Surface Ext Solar Sky Diffuse Incident
- Surface Ext Solar Ground Diffuse Incident
- Surface Ext Solar From Sky Diffuse Refl From Obstructions
- Surface Ext Beam Sol From Bm-To-Bm Refl From Obstructions
- Surface Ext Diff Sol From Bm-To-Diff Refl From Obstructions

Surface Ext Solar Beam Incident [W/m²]

The solar beam radiation incident on the outside of an exterior surface, including the effects of shadowing, if present. The beam here is that directly from the sun; it excludes beam specularly reflected from obstructions.

Surface Ext Solar Sky Diffuse Incident [W/m²]

The solar diffuse radiation from the sky incident on the outside of an exterior surface, including the effects of shadowing, if present.

Surface Ext Solar Ground Diffuse Incident [W/m²]

The solar diffuse radiation incident on the outside of an exterior surface that arises from reflection of beam solar and sky diffuse solar from the ground. This is the sum of the next two output variables, “Surface Ext Diff Sol From Bm-To-Diff Refl From Ground” and “Surface Ext Solar From Sky Diffuse Refl From Ground.” The reflected solar radiation from the ground is assumed to be diffuse and isotropic (there is no specular component).

If “Reflections” option is not chosen in the Solar Distribution Field in the BUILDING object, the effects of shadowing are accounted for by the user-specified value of View Factor to Ground for the surface. If “Reflections” option is chosen, the program determines the effects of shadowing, including time-varying shadowing of the ground plane by the building itself.

Surface Ext Solar From Bm-To-Diff Refl From Ground [W/m²]

The solar diffuse radiation incident on the outside of an exterior surface that arises from beam-to-diffuse reflection from the ground. It is assumed that there is no beam-to-beam (specular) component. The beam here is that directly from the sun; it excludes beam specularly reflected from obstructions.

Surface Ext Solar From Sky Diffuse Refl From Ground [W/m²]

The solar diffuse radiation incident on the outside of an exterior surface that arises from sky diffuse solar reflection from the ground. The sky diffuse here is that directly from the sky; it excludes reflection of sky diffuse from obstructions.

Surface Ext Solar From Sky Diffuse Refl From Obstructions [W/m²]

The solar diffuse radiation incident on the outside of an exterior surface that arises from sky diffuse reflection from one or more obstructions. This value will be non-zero only if “Reflections” option is chosen in the BUILDING object.

Surface Ext Beam Sol From Bm-To-Bm Refl From Obstructions [W/m²]

The solar beam radiation incident on the outside of an exterior surface that arises from beam-to-beam (specular) reflection from one or more obstructions. This value will be non-zero only if “Reflections” option is chosen in the BUILDING object. For windows, the program treats this beam radiation as diffuse radiation in calculating its transmission and absorption.

Surface Ext Diff Sol From Bm-To-Diff Refl From Obstructions [W/m²]

The solar diffuse radiation incident on the outside of an exterior surface that arises from beam-to-diffuse reflection from building shades or building surfaces. This value will be non-zero only if “Reflections” option is chosen in the BUILDING object.

Surface Ext Solar Beam Cosine Of Incidence Angle []

The cosine of the angle of incidence of (unreflected) beam solar radiation on the outside of an exterior surface. The value varies from 0.0 for beam parallel to the surface (incidence angle = 90°) to 1.0 for beam perpendicular to the surface (incidence angle = 0°).

Surface Inside Temperature [C]

The inside surface temperature of a heat transfer surface.

Surface Outside Temperature [C]

The outside surface temperature of a heat transfer surface.

Surface Int Convection Coeff [W/m²-K]

The inside air film convective conductance for a heat transfer surface.

Surface Ext Convection Coeff [W/m²-K]

The outside air film convective conductance for a heat transfer surface.

Opaque Surface Output Variables

The following variables apply only to opaque surfaces, where an opaque surface is considered here to be an exterior or interzone heat transfer surface of class FLOOR, WALL, ROOF or DOOR. **Note – these are advanced variables – you must read the descriptions and understand before use – then you must use the Output:Diagnostics object to allow reporting.**

Opaque Surface Inside Face Conduction [W]

The heat flow by conduction at the inside face of an opaque heat transfer surface. A positive value means that the conduction is from just inside the inside face to the inside face. A negative value means that the conduction is from the inside face into the surface.

Note that Inside Face Conduction, when positive, does **not** indicate the heat flow from the surface to the zone air, which is governed by the inside face convection coefficient and the difference in temperature between the inside face and the zone air.

Opaque Surface Inside Face Conduction Gain [W]

The Opaque Surface Inside Face Conduction when that conduction is positive (see definition of Opaque Surface Inside Face Conduction).

Opaque Surface Inside Face Conduction Loss [W]

The absolute value of the Opaque Surface Inside Face Conduction when that conduction is negative (see definition of Opaque Surface Inside Face Conduction).

Zone Opaque Surface Inside Face Conduction Gain [W]

The sum of the Opaque Surface Inside Face Conduction values for all opaque surfaces in a zone when that sum is positive. For example, assume a zone has six opaque surfaces with Opaque Surface Inside Face Conduction values of 100, -200, 400, 50, 150 and -300 W. Then Zone Opaque Surface Inside Face Conduction Gain = 700 - 500 = 200 W.

Zone Opaque Surface Inside Face Conduction Loss [W]

The absolute value of the sum of the Opaque Surface Inside Face Conduction values for all opaque surfaces in a zone when that sum is negative. For example, assume a zone has six opaque surfaces with Opaque Surface Inside Face Conduction values of -100, -200, 400, -50, 150 and -300W. Then Zone Opaque Surface Inside Face Conduction Loss = $|550 - 650| = |-100| = 100$ W.

Opaque Surface Inside Face Beam Solar Absorbed [W]

Beam solar radiation from exterior windows absorbed on the inside face of an opaque heat transfer surface. For Solar Distribution = FullInteriorAndExterior, this quantity can be non-zero for both floor and wall surfaces. Otherwise, for Solar Distribution = FullExterior or MinimalShadowing, it can be non-zero only for floor surfaces since in this case all entering beam solar is assumed to fall on the floor. Note that this variable will not be operational (have a real value) unless there are exterior windows in the zone.

Window Output Variables

The following output variables apply to subsurfaces that are windows or glass doors. These two subsurface types are called “window” here. “Exterior window” means that the base surface of the window is an exterior wall, floor, roof or ceiling (i.e., the base surface is a BuildingSurface:Detailed with OutsideFaceEnvironment = ExteriorEnvironment). “Interior window” means that the base surface of the window is an inter-zone wall, floor or ceiling. “Glass” means a transparent solid layer, usually glass, but possibly plastic or other transparent material. “Shading device” means an interior, exterior or between-glass shade or blind, or an exterior screen (only exterior windows can have a shading device).

Zone Transmitted Solar [W]**Zone Transmitted Solar Energy [J]**

The total Window Transmitted Solar of all the exterior windows in a zone.

Zone Window Heat Gain [W]**Zone Window Heat Gain Energy [J]**

The sum of the heat flow from all of the exterior windows in a zone when that sum is positive. (See definition of “heat flow” under “Window Heat Gain,” below.)

Zone Window Heat Loss [W]**Zone Window Heat Loss Energy [J]**

The absolute value of the sum of the heat flow from all of the exterior windows in a zone when that sum is negative.

Window Solar Absorbed: All Glass Layers [W]**Window Solar Absorbed: All Glass Layers Energy [J]**

The total exterior beam and diffuse solar radiation absorbed in all of the glass layers of an exterior window.

Window Solar Absorbed: Shading Device [W] and Window Solar Absorbed: Shading Device Energy [J] The exterior beam and diffuse solar radiation absorbed in the shading device, if present, of an exterior window.

Window Transmitted Solar [W] and Window Transmitted Solar Energy [J]

The amount of beam and diffuse solar radiation entering a zone through an exterior window. It is the sum of the following two variables, “Window Transmitted Beam Solar” and “Window Transmitted Diffuse Solar.”

Window Transmitted Beam Solar [W]**Window Transmitted Beam Solar Energy [J]**

The solar radiation transmitted by an exterior window whose source is beam solar incident on the outside of the window. For a bare window, this transmitted radiation consists of beam radiation passing through the glass (assumed transparent) and diffuse radiation from beam reflected from the outside window reveal, if present. For a window with a shade, this transmitted radiation is totally diffuse (shades are assumed to be perfect diffusers). For a window with a blind, this transmitted radiation consists of beam radiation that passes between the slats and diffuse radiation from beam-to-diffuse reflection from the slats. For a window with a screen, this value consists of direct beam radiation that is transmitted through the screen (gaps between the screen material) and diffuse radiation from beam-to-diffuse reflection from the screen material.

Zone Beam Solar from Exterior Windows [W]**Zone Beam Solar from Exterior Windows Energy [J]**

The sum of the Window Transmitted Beam Solar (see definition above) from all exterior windows in a zone.

Zone Beam Solar from Interior Windows [W]**Zone Beam Solar from Interior Windows Energy [J]**

The sum of the Window Transmitted Beam Solar (see definition above) from all interior windows in a zone.

Window Transmitted Diffuse Solar [W]**Window Transmitted Diffuse Solar Energy[J]**

The solar radiation transmitted by an exterior window whose source is diffuse solar incident on the outside of the window. For a bare window, this transmitted radiation consists of diffuse radiation passing through the glass. For a window with a shade, this transmitted radiation is totally diffuse (shades are assumed to be perfect diffusers). For a window with a blind, this transmitted radiation consists of diffuse radiation that passes between the slats and diffuse radiation from diffuse-to-diffuse reflection from the slats. For a window with a screen, this value consists of diffuse radiation transmitted through the screen (gaps between the screen material) and diffuse radiation from diffuse-to-diffuse reflection from the screen material.

Zone Diff Solar from Exterior Windows [W]**Zone Diff Solar from Exterior Windows Energy[J]**

The combined beam and diffuse solar that first entered adjacent zones through exterior windows in the adjacent zones, was subsequently reflected from interior surfaces in those zones (becoming diffuse through that reflection), and was then transmitted through interior windows into the current zone.

Zone Diffuse Solar from Interior Windows [W]**Zone Diffuse Solar from Interior Windows Energy[J]**

The sum of the Window Transmitted Diffuse Solar (see definition above) from all interior windows in a zone.

Window System Solar Transmittance []

Effective solar transmittance of an exterior window, including effect of shading device, if present. Equal to “Window Transmitted Solar” divided by total exterior beam plus diffuse solar radiation incident on the window (excluding frame, if present).

Window System Solar Absorptance []

Effective solar absorptance of an exterior window, including effect of shading device, if present. Equal to “Window Solar Absorbed: All Glass Layers” plus “Window Solar Absorbed: Shading Device” divided by total exterior beam plus diffuse solar radiation incident on window (excluding frame, if present)

Window System Solar Reflectance []

Effective solar reflectance of an exterior window, including effect of shading device, if present. Equal to: $[1.0 - \text{“Window System Solar Transmittance”} - \text{“Window System Solar Absorptance”}]$.

Window Gap Convective Heat Flow [W]**Window Gap Convective Heat Flow Energy[J]**

For an airflow window, the forced convective heat flow from the gap through which airflow occurs. This is the heat gained (or lost) by the air from the glass surfaces (and between-glass shading device surfaces, if present) that the air comes in contact with as it flows through the gap. If the gap airflow goes to the zone indoor air, the gap convective heat flow is added to the zone load. Applicable to exterior windows only.

Window Heat Gain [W]**Window Heat Gain Energy[J]**

The total heat flow to the zone from the glazing, frame and divider of an exterior window when the total heat flow is positive.

For a window *without an interior shading device*, this heat flow is equal to:

- [Window transmitted solar (see definition, above)]
- + [Convective heat flow to the zone from the zone side of the glazing]
- + [Net IR heat flow to the zone from zone side of the glazing]
- [Short-wave radiation from zone transmitted back out the window]
- + [Conduction to zone from window frame and divider, if present]

Here, short-wave radiation is that from lights and diffuse interior solar radiation.

For a window *with an interior shading device*, this heat flow is equal to:

- [Window transmitted solar]
- + [Convective heat flow to the zone from the air flowing through the gap between glazing and shading device]
- + [Convective heat flow to the zone from the zone side of the shading device]
- + [Net IR heat flow to the zone from the zone side of the glazing]
- + [Net IR heat flow to the zone from the zone side of the shading device]
- [Short-wave radiation from zone transmitted back out the window]
- + [Conduction to zone from window frame and divider, if present]

The total window heat flow can also be thought of as the sum of the solar and conductive gain from the window glazing.

Window Heat Loss [W]

Window Heat Loss Energy[J]

The absolute value of the total heat flow through an exterior window when the total heat flow is negative. (See definition of “total heat flow” under “Window Heat Gain,” above.)

Glass Beam-Beam Solar Transmittance []

The fraction of exterior beam solar radiation incident on the glass of an exterior window that is transmitted through the glass assuming that the window has no shading device. Takes into account the angle of incidence of beam solar radiation on the glass. Currently, all glass is considered to be transparent, so that incident beam solar is transmitted only as beam solar with no diffuse solar component.

Glass Diffuse-Diffuse Solar Transmittance []

The fraction of exterior diffuse solar radiation incident on the glass of an exterior window that is transmitted through the glass assuming that the window has no shading device. It is assumed that incident diffuse solar is transmitted only as diffuse with no beam component.

Window Calculation Iterations []

The number of iterations needed by the window-layer heat balance solution to converge.

Solar Horizontal Profile Angle [degrees]

For a vertical exterior window, this is an angle appropriate for calculating beam solar quantities appropriate to horizontal window elements such as horizontal reveal surfaces, horizontal frame and divider elements and horizontal slats of window blinds. It is defined as the angle between the window outward normal and the projection of the sun’s ray on the vertical plane containing the outward normal. See Figure 22.

For an exterior window of arbitrary tilt, it is defined as the angle between the window outward normal the projection of the sun’s ray on the plane that contains the outward normal and is perpendicular to the ground.

If the sun is behind the window, the horizontal profile angle is not defined and is reported as 0.0.

Note that in most texts what we call “horizontal profile angle” is called “vertical profile angle.”

Solar Vertical Profile Angle [degrees]

For a vertical exterior window, this is an angle appropriate for calculating beam solar quantities appropriate to vertical window elements such as vertical reveal surfaces, vertical frame and divider elements and vertical slats of window blinds. It is defined as the angle between the window outward normal and the projection of the sun's ray on the horizontal plane containing the outward normal. See **Figure 22**.

For an exterior window of arbitrary tilt, it is defined as the angle between the window outward normal the projection of the sun's ray on the plane that contains the outward normal and is perpendicular to the plane defined above for Solar Horizontal Profile Angle for a window of arbitrary tilt.

If the sun is behind the window, the vertical profile angle is not defined and is reported as 0.0. Note that in most texts what we call "vertical profile angle" is called "horizontal profile angle."

Figure 22. Vertical exterior window showing solar horizontal profile angle, solar vertical profile angle and solar incidence angle.

Beam Solar Reflected by Outside Reveal Surfaces [W]

Beam solar radiation reflected from the outside reveal surfaces of an exterior window (ref: Reveal Surfaces under WindowProperty:FrameAndDivider).

Beam Solar Reflected by Inside Reveal Surfaces [W]

Beam solar radiation reflected from the inside reveal surfaces of an exterior window (ref: Reveal Surfaces under WindowProperty:FrameAndDivider).

Inside Glass Condensation Flag []

A value of 1 means that moisture condensation will occur on the innermost glass face of an exterior window (i.e., on the glass face in contact with the zone air). Otherwise the value is 0. The condition for condensation is glass inside face temperature < zone air dewpoint temperature.

For airflow exterior windows, in which forced air passes between adjacent glass faces in double- and triple-pane windows, a value of 1 means that condensation will occur on one or both of the glass faces in contact with the airflow. In this case the condition for condensation is:

- For *airflow source = indoorair*, temperature of either face in contact with airflow < zone air dewpoint temperature.
- For *airflow source = outdoorair*, temperature of either face in contact with airflow < outside air dewpoint temperature.

As for regular windows, the value will also be 1 if condensation occurs on the innermost glass face.

Inside Frame Condensation Flag []

If an exterior window has a frame and the value of this flag is 1, condensation will occur on the inside surface of the frame. The condition for condensation is frame inside surface temperature < zone air dewpoint temperature.

Inside Divider Condensation Flag []

If an exterior window has a divider and the value of this flag is 1, condensation will occur on the inside surface of the divider. The condition for condensation is divider inside surface temperature < zone air dewpoint temperature.

Fraction of Time Shading Device Is On []

The fraction of time that a shading device is on an exterior window. For a particular simulation timestep, the value is 0.0 if the shading device is off (or there is no shading device) and the value is 1.0 if the shading device is on. (It is assumed that the shading device, if present, is either on or off for the entire timestep.) If the shading device is switchable glazing, a value of 0.0 means that the glazing is in the unswitched (light colored) state, and a value of 1.0 means that the glazing is in the switched (dark colored) state.

For a time interval longer a timestep, this is the fraction of the time interval that the shading device is on. For example, take the case where the time interval is one hour and the timestep is 10 minutes. Then if the shading device is on for two timesteps in the hour and off for the other four timesteps, then the fraction of time that the shading device is on = $2/6 = 0.3333$.

Window Blind Slat Angle [deg]

For an exterior window with a blind, this is the angle in degrees between the glazing outward normal and the blind slat angle outward normal, where the outward normal points away from the front face of the slat. The slat angle varies from 0 to 180 deg. If the slat angle is 0 deg or 180 deg, the slats are parallel to the glazing and the slats are said to be “closed”. If the slat angle is 90 deg, the slats are perpendicular to the glazing and the slats are said to be “fully open”. See illustrations under WindowMaterial:Blind. For blinds with a fixed slat angle, the value reported here will be constant.

Blind Beam-Beam Solar Transmittance []

For an exterior window with a blind, this is the fraction of exterior beam solar radiation incident on the blind that is transmitted through the blind as beam solar radiation when the blind is isolated (i.e., as though the window glass were not present). Depends on various factors, including slat angle, width, separation, and thickness, and horizontal solar profile angle (for blinds with horizontal slats) or vertical solar profile angle (for blinds with vertical slats). The transmittance value reported here will be non-zero only when some beam solar can pass through the blind without hitting the slats.

Blind Beam-Diffuse Solar Transmittance []

For an exterior window with a blind, the fraction of exterior beam solar radiation incident on the blind that is transmitted through the blind as diffuse solar radiation when the blind is

isolated (i.e., as though the window glass were not present). Depends on various factors, including slat angle, width, separation, thickness and reflectance, and horizontal solar profile angle (for blinds with horizontal slats) or vertical solar profile angle (for blinds with vertical slats).

Blind Diffuse-Diffuse Solar Transmittance []

For an exterior window with a blind, the fraction of exterior diffuse solar radiation incident on the blind that is transmitted through the blind as diffuse solar radiation when the blind is isolated (i.e., as though the window glass were not present). Depends on various factors, including slat angle, width, separation, thickness and reflectance. For blinds with a fixed slat angle the transmittance value reported here will be constant.

Blind/Glass System Beam-Beam Solar Transmittance []

The fraction of exterior beam solar radiation incident on an exterior window with a blind (excluding window frame, if present) that is transmitted through the blind/glass system as beam solar radiation. Depends on various factors, including type of glass; solar incidence angle; slat angle, width, separation, and thickness; and horizontal solar profile angle (for blinds with horizontal slats) or vertical solar profile angle (for blinds with vertical slats).

Blind/Glass System Diffuse-Diffuse Solar Transmittance []

The fraction of exterior diffuse solar radiation incident on an exterior window with a blind (excluding window frame, if present) that is transmitted through the blind/glass system as diffuse solar radiation. Depends on various factors, including type of glass and slat angle, width, separation, thickness and reflectance. For blinds with a fixed slat angle the transmittance value reported here will be constant.

Screen Beam-Beam Solar Transmittance[]

For an exterior window with a screen, this is the fraction of exterior beam solar radiation incident on the screen that is transmitted through the screen as beam solar radiation when the screen is isolated (i.e., as though the window glass were not present). Depends on various factors, including the screen reflectance and the relative angle of the incident beam with respect to the screen. This value will include the amount of inward reflection of solar beam off the screen material surface if the user specifies this modeling option (i.e., Material: WindowScreen, field Reflected Beam Transmittance Accounting Method = Model as Direct Beam).

Screen Beam-Diffuse Solar Transmittance[]

For an exterior window with a screen, the fraction of exterior beam solar radiation incident on the screen that is transmitted through the screen as diffuse solar radiation when the screen is isolated (i.e., as though the window glass were not present). Depends on various factors, including the screen reflectance and the relative angle of the incident beam with respect to the screen. This value is the amount of inward reflection of solar beam off the screen material surface if the user specifies this modeling option (i.e., Material: WindowScreen, field Reflected Beam Transmittance Accounting Method = Model as Diffuse); otherwise, this value will be zero.

Screen Diffuse-Diffuse Solar Transmittance[]

For an exterior window with a screen, the fraction of exterior diffuse solar radiation incident on the screen that is transmitted through the screen as diffuse solar radiation when the screen is isolated (i.e., as though the window glass were not present). Depends on various factors including screen material geometry and reflectance. This value is calculated as an average, constant For a window with a screen, this value consists of diffuse radiation transmitted through the screen (gaps between the screen material) and diffuse radiation from diffuse-to-diffuse reflection from the screen material. For a window with a screen, this value

consists of diffuse radiation transmitted through the screen (gaps between the screen material) and diffuse radiation from diffuse-to-diffuse reflection from the screen material.

Screen/Glass System Beam-Beam Solar Transmittance[]

The fraction of exterior beam solar radiation incident on an exterior window with a screen (excluding window frame, if present) that is transmitted through the screen/glass system as beam solar radiation. Depends on various factors, including the screen reflectance and the relative angle of the incident beam with respect to the screen. This value will include the amount of inward reflection of solar beam off the screen material surface if the user specifies this modeling option (i.e., Material: WindowScreen, field Reflected Beam Transmittance Accounting Method = Model as Direct Beam).

Screen/Glass System Diffuse-Diffuse Solar Transmittance []

The fraction of exterior diffuse solar radiation incident on an exterior window with a screen (excluding window frame, if present) that is transmitted through the screen/glass system as diffuse solar radiation. Depends on various factors including screen material geometry and reflectance.

Beam Solar Transmitted Through Interior Window [W]

The beam solar radiation transmitted through an interior window. Calculated only if Solar Distribution = FullInteriorAndExterior in your Building input. The origin of this radiation is beam solar that enters through an exterior window in a zone and then passes through an interior window into the adjacent zone. The amount of this radiation depends on several factors, including sun position, intensity of beam solar incident on the exterior window (including effects of shadowing, if present), relative position of the exterior and interior window, and the size and transmittance of the windows. Note that if there are two or more exterior windows in a zone, then beam solar from one or more of them may pass through the same interior window. Likewise, if there are more than two or more interior windows in a zone then beam solar from a single exterior window may pass through one or more of the interior windows.

Storm Window On/Off Flag []

Indicates whether a storm window glass layer is present (ref: StormWindow). The value is **0** if the storm window glass layer is off, **1** if it is on, and **-1** if the window does not have an associated storm window. Applicable only to exterior windows and glass doors.

Initial Transmitted Diffuse Solar Transmitted out through Inside of Window Surface [W]

As of Version 2.1, the diffuse solar transmitted through exterior windows that is initially distributed to another window in the zone and transmitted out of the zone through that window. For exterior windows, this transmitted diffuse solar is “lost” to the exterior environment. For interior windows, this transmitted diffuse solar is distributed to heat transfer surfaces in the adjacent zone, and is part of the Initial Transmitted Diffuse Solar Absorbed on Inside of Surface for these adjacent zone surfaces.

Additional Window Outputs (Advanced)

The following output variables for windows or glass doors are available when the user requests to display advanced report variables. These seven reports show the individual components that are combined to determine overall Window Heat Gain and/or Window Heat Loss (described above).

Window Convection Heat Gain from Glazing to Zone [W]

The surface convection heat transfer from the glazing to the zone in watts. This report variable is the term called “[Convective heat flow to the zone from the zone side of the glazing]” under the description above for Window Heat Gain report variable. If the window

has an interior shade or blind, then this is zero and the glazing's convection is included in the report called "Window Convection Heat Gain from Gap between Shade and Glazing to Zone".

Window Net Infrared Heat Gain from Glazing to Zone [W]

The net exchange of infrared radiation heat transfer from the glazing to the zone in watts. This report variable is the term called "[Net IR heat flow to the zone from zone side of the glazing]" under the description above for Window Heat Gain report variable.

Window Shortwave Heat Loss from Zone Back Out Window [W]

This is the short-wave radiation heat transfer from the zone back out the window in watts. This is a measure of the diffuse short-wave light (from reflected solar and electric lighting) that leave the zone through the window. This report variable is the term called "[Short-wave radiation from zone transmitted back out the window]" under the description above for Window Heat Gain report variable.

Window Heat Gain from Frame and Divider to Zone [W]

This is the heat transfer from any frames and/or dividers to the zone in watts. This report variable is the term called "[Conduction to zone from window frame and divider, if present]" under the description above for Window Heat Gain report variable. (The word "conduction" here is used because the models is simplified compared to the complexities of surface convection and radiation.)

Window Convection Heat Gain from Gap between Shade and Glazing to Zone [W]

This is the convection surface heat transfer from the both the glazing and the shade's back face to the zone in Watts. This report variable is the term called "[Convective heat flow to the zone from the air flowing through the gap between glazing and shading device]" under the description above for Window Heat Gain report variable.

Window Convection Heat Gain from Shade to Zone [W]

This is the convection surface heat transfer from the front side of any interior shade or blind to the zone in Watts. This report variable is the term called "[Convective heat flow to the zone from the zone side of the shading device]" under the description above for Window Heat Gain report variable.

Window Net Infrared Heat Gain from Shade to Zone [W]

The net exchange of infrared radiation heat transfer from the shade or blind to the zone in watts. This report variable is the term called "[Net IR heat flow to the zone from the zone side of the shading device]" under the description above for Window Heat Gain report variable.

Thermochromic Window Outputs

Window Thermochromic Layer Temperature [C]

The temperature of the TC glass layer of a TC window at each time step.

Window Thermochromic Layer Specification Temperature [C]

The temperature under which the optical data of the TC glass layer are specified.

The overall properties (U-factor/SHGC/VT) of the thermochromic windows at different specification temperatures are reported in the EIO file. These window constructions are created by EnergyPlus during run time. They have similar names with suffix "_TC_XX" where XX represents a specification temperature.

Other Surface Outputs/Reports

Several reports can be selected for Surfaces. (See Group – Report for details on how to specify). Examples are:

DXF

This report produces a special file (**eplusout.dxf**) in the industry standard DXF (Drawing Interchange Format) for drawings. It is produced and accepted by many popular, commercial CAD programs. Detailed reference can be found on the AutoCAD™ website at: <http://www.autodesk.com/techpubs/autocad/acadr14/dxf/index.htm>

EnergyPlus produces this file from the Report command:

```
Output:Reports, Surfaces, DXF;
```

Details, Vertices, DetailsWithVertices

This version of the report creates lines in the eplusout.eio file for each surface (except internal mass surfaces). Details of this reporting is shown in the Output Details and Examples document.

Shading Surfaces

Shading surfaces are entities outside of the building that may cast shadows on the building's heat transfer surfaces. These entities do not typically have enough thermal mass to be described as part of the building's thermal makeup.

The most important effect of shading surfaces is to reduce solar gain in windows that are shadowed. (However, in some cases, shading surfaces can reflect solar onto a wall or window and increase solar gain.)

There are two kinds of shading surfaces in EnergyPlus: **detached** and **attached**. A **detached** shading surface, such as a tree or neighboring building, is not connected to the building. An **attached** shading surface is typically an overhang or fin that is attached to a particular base surface of the building, usually a wall; attached shading surfaces are usually designed to shade specific windows.

Objects for detached shading surfaces:

Shading:Site

Shading:Building

Shading:Site:Detailed

Shading:Building:Detailed

Similarly to the surfaces, the detailed objects use vertex entry whereas the other objects are limited to rectangular representation.

Objects for attached shading surfaces:

Shading:Overhang

Shading:Overhang:Projection

Shading:Fin

Shading:Fin:Projection

Shading:Zone:Detailed

EnergyPlus creates “bi-directional” shades from each shading surface entered. This means that the shade you input will cast a shadow no matter which side of the shade the sun is on. For example, a vertical fin will cast a shadow whether the sun is on the left side or right side of the fin.⁵

It is important to note that EnergyPlus will automatically account for “self-shading” effects—such as in L-shaped buildings—in which some of the building's wall and roof surfaces shade

⁵ Prior to V1.0.2, a shading surface cast a shadow only in the hemisphere toward which the surface faced. This hemisphere is the one pointed to by the shading surface's outward normal vector, which is the cross product $V23 \times V21$, where $V23$ is the vector from vertex 2 to vertex 3 of the shading surface and $V21$ is the vector from vertex 2 to vertex 1. Beginning with V1.0.2, the shades in EnergyPlus are “bi-directional” so that they can cast shadows in both hemispheres depending on the time-varying position of the sun relative to the shading surface.

other parts of the building, especially windows. This means that you only need to describe shading elements that aren't building heat-transfer surfaces.

Shading surfaces can also **reflect** solar radiation onto the building. This feature is simulated if you choose FullExteriorWithReflections or FullInteriorAndExteriorWithReflections in the Building object (ref: Building - Field: Solar Distribution). In this case, you specify the reflectance properties of a shading surface with the ShadingProperty:Reflectance object .

Shading surfaces also automatically shade diffuse solar radiation (and long-wave radiation) from the sky. And they will automatically shade diffuse solar radiation from the ground if Solar Distribution Field = FullExteriorWithReflections or FullInteriorAndExteriorWithReflections in the Building object.⁶ Otherwise, shading surfaces will not shade diffuse radiation from the ground unless you enter a reduced value for View Factor to Ground for those building surfaces that are shaded (ref: BuildingSurface:Detailed - Field: View Factor to Ground and FenestrationSurface:Detailed - Field: View Factor to Ground).

Detached Shading Surfaces

Shading:Site, Shading:Building

These objects are used to describe rectangular shading elements that are external to the building. Examples are trees, high fences, near-by hills, and neighboring buildings.

If relative coordinates are used (ref: Field: Coordinate System in GlobalGeometryRules), shading surfaces entered with Shading:Site remain stationary if the building is rotated, whereas those entered with Shading:Building rotate with the building. If world coordinates are used Shading:Site and Shading:Building are equivalent.

These shading elements are always opaque. The IDD's for both objects follows:

```

Shading:Site,
  \memo used for shading elements such as trees
  \memo these items are fixed in space and would not move with relative geometry
A1 , \field Name
    \required-field
    \type alpha
    \reference AllShadingAndHTSurfNames
    \reference AllShadingSurfNames
N1, \field Azimuth Angle
    \note Facing direction of outside of shading device (S=180,N=0,E=90,W=270)
    \minimum 0
    \maximum 360
    \units deg
N2, \field Tilt Angle
    \default 90
    \minimum 0
    \maximum 180
    \units deg
N3, \field Starting X Coordinate
    \note Starting coordinate is the Lower Left Corner of the Shade
    \units m
N4, \field Starting Y Coordinate
    \units m
N5, \field Starting Z Coordinate
    \units m
N6. \field Length
    \units m
N7; \field Height
    \units m

```

⁶ If the reflections option for Solar Distribution is used, the program also takes into account the reduction of solar radiation reflected from the ground due to shading of the ground by shading surfaces and by the building itself.

```

```

Field: Name

This is a unique character string associated with the detached shading surface. Though it must be unique from other surface names, it is used primarily for convenience with detached shading surfaces.

Field: Azimuth Angle

Theoretically, this should face to the surface it is shading (i.e. if a south wall, this should be a north facing shade) but since EnergyPlus automatically generates the mirror image, the facing angle per se' is not so important.

Field: Tilt Angle

The tilt angle is the angle (in degrees) that the shade is tilted from horizontal (or the ground). Default for this field is 90 degrees.

Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. See the introductory paragraph for rules on this entry.

Field: Starting X Coordinate

This field is the X coordinate (in meters).

Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

Field: Length

This field is the length of the shade in meters.

Field: Height

This field is the width of the shade in meters.

Shading:Site:Detailed, Shading:Building:Detailed

These objects are used to describe shading elements that are external to the building. Examples are trees, high fences, near-by hills, and neighboring buildings.

If relative coordinates are used (ref: Field: Coordinate System in GlobalGeometryRules), shading surfaces entered with Shading:Site:Detailed remain stationary if the building is rotated, whereas those entered with Shading:Building:Detailed rotate with the building. If world coordinates are used Shading:Site:Detailed and Shading:Building:Detailed are equivalent.

While "detached" implies that shading surfaces are not part of the building, the detached shading sequence can be used to describe attached shading surfaces that may shade heat transfer surfaces in more than one zone. For example, wing A of a building might shade several zones of wing B but wing A (for whatever reason) is not described in the geometry for the simulation so it is represented by a detached shade to get its shadowing effect. The IDD for both objects follows:

```

Shading:Site:Detailed,
  \extensible:3 -- duplicate last set of x,y,z coordinates, renumbering please (and changing z terminator
to , for all but last)

  \note For this object all surface coordinates are relative to the building origin (0,0,0)
  \note and will rotate with the BUILDING north axis.

```

Field: Name

This is a unique character string associated with the detached shading surface. Though it must be unique from other surface names, it is used primarily for convenience with detached shading surfaces.

Field: Transmittance Schedule Name

The name of a schedule of solar transmittance values from 0.0 to 1.0 for the shading surface. If a blank is entered in this field, the transmittance value defaults to 0.0, i.e., the shading surface is opaque at all times. This scheduling can be used to allow for seasonal transmittance change, such as for deciduous trees that have a higher transmittance in winter than in summer. Transmittance based on time of day can also be used—a movable awning, for example, where the transmittance is some value less than 1.0 when the awning is in place and is 1.0 when the awning is retracted.

The following assumptions are made in the shading surface transmittance calculation:

- Both sides of the shading surface have the same transmittance properties.
- The transmittance is the same for both beam and diffuse solar radiation.
- Beam solar transmittance is independent of angle of incidence on the shading surface.
- Beam radiation incident on a shading surface is transmitted as beam radiation with no change in direction, i.e., there is no beam-to-diffuse component.
- If two shading surfaces with non-zero transmittance overlap, the net transmittance is the product of the individual transmittances. Inter-reflection between the shading surfaces (and between the shading surfaces and the building) is ignored.
- For the daylighting calculation (ref: Group – Daylighting) the shading surface's visible transmittance is assumed to be the same as its solar transmittance.
- Shading devices are assumed to be opaque to long-wave radiation no matter what the solar transmittance value is.

Note that shading devices only shade solar radiation when the sun is up, which is automatically determined by EnergyPlus from latitude, time of year, etc. The user need only account for the time-varying transmittance of the shading device in the transmittance schedule, not whether the sun is up or not.

Field: Number Vertices

The number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on “Surface Vertices” above.

IDF example of Detached Shading Surfaces:

```
Shading:Building:Detailed,
EAST SIDE TREE, !- Detached Shading

33.52800 , 13.71600 , 0.9140000 ,
33.52800 , 4.572000 , 0.9140000 ;
Shading:Building:Detailed,
WEST SIDE TREE, !- Detached Shading
ShadingTransmittance:0002, !- Shadowing Transmittance & Schedule
3, !-Triangle
-3.048000 , 7.620000 , 10.05800 ,
-3.048000 , 4.572000 , 0.9140000 ,
-3.048000 , 13.71600 , 0.9140000 ;
```

Attached Shading Surfaces

Overhangs are usually horizontal devices that are used to shade windows. Fins are usually vertical devices that similarly shade windows.

Shading:Overhang

An overhang typically is used to shade a window in a building. The IDD for the object is:

```
Shading:Overhang,
\memo Overhangs are usually flat shading surfaces that reference a window or door.
A1 , \field Name
\required-field
\type alpha

```

Field: Name

This is the name of the overhang. It must be different from other surface names.

Field: Window or Door Name

The name of a window or door that this overhang shades.

Field: Height above Window or Door

This field is the height (meters) above the top of the door for the overhang.

Field Tilt Angle from Window/Door

This field is the tilt angle from the Window/Door. For a flat overhang, this would be 90 (degrees).

Field: Left Extension from Window/Door Width

This field is the width from the left edge of the window/door to the start of the overhang (meters).

Field: Right Extension from Window/Door Width

This field is the width from the right edge of the window/door to the start of the overhang (meters).

Field: Depth

This field is the depth of the overhang (meters) projecting out from the wall.

Shading:Overhang:Projection

An overhang typically is used to shade a window in a building. This object allows for specifying the depth of the overhang as a fraction of the window or door's height. The IDD for the object is:

```
Shading:Overhang:Projection,
  \memo Overhangs are typically flat shading surfaces that reference a window or door.
  A1 , \field Name
      \required-field
      \type alpha
      \reference AttachedShadingSurfNames
      \reference AllShadingAndHTSurfNames
      \reference AllShadingSurfNames

  N5; \field Depth as Fraction of Window/Door Height
      \units m
```

Field: Name

This is the name of the overhang. It must be different from other surface names.

Field: Window or Door Name

The name of a window or door that this overhang shades.

Field: Height above Window or Door

This field is the height (meters) above the top of the door for the overhang.

Field Tilt Angle from Window/Door

This field is the tilt angle from the Window/Door. For a flat overhang, this would be 90 (degrees).

Field: Left Extension from Window/Door Width

This field is the width from the left edge of the window/door to the start of the overhang (meters).

Field: Right Extension from Window/Door Width

This field is the width from the right edge of the window/door to the start of the overhang (meters).

Field: Depth as Fraction of Window/Door Height

This field is the fraction of the window/door height to specify as the depth of the overhang (meters) projecting out from the wall.

Shading:Fin

Fins shade either side of windows/doors in a building. This object allows for specification of both fins for the window. The IDD for the object is:

```

Shading:Fin,
\memo Fins are usually shading surfaces that are perpendicular to a window or door.

```

Field: Name

This is the name of the overhang. It must be different from other surface names.

Field: Window or Door Name

The name of a window or door that this overhang shades.

Field: Left Extension from Window/Door

This field is the width from the left edge of the window/door to the plane of the left fin (meters).

Field: Left Distance Above Top of Window

This field is the distance from the top of the window to the top of the left fin (meters).

Field: Left Distance Below Bottom of Window

This field is the distance from the bottom of the window to the bottom of the left fin (meters).

Field: Left Tilt Angle from Window/Door

This field is the tilt angle from the window / door for the left fin. Typically, a fin is 90 degrees (default) from its associated window/door.

Field: Left Depth

This field is the depth (meters) of the left fin (projecting out from the wall).

Field: Right Extension from Window/Door

This field is the width from the right edge of the window/door to the plane of the right fin (meters).

Field: Right Distance Above Top of Window

This field is the distance from the top of the window to the top of the right fin (meters).

Field: Right Distance Below Bottom of Window

This field is the distance from the bottom of the window to the bottom of the right fin (meters).

Field: Right Tilt Angle from Window/Door

This field is the tilt angle from the window / door for the right fin.. Typically, a fin is 90 degrees (default) from its associated window/door.

Field: Right Depth

This field is the depth (meters) of the right fin (projecting out from the wall).

Shading:Fin:Projection

Fins shade either side of windows/doors in a building. This object allows for specification of both fins for the window. This object allows for specifying the depth of the overhang as a fraction of the window or door's width. The IDD for the object is:

```

Shading:Fin:Projection,
  \memo Fins are usually shading surfaces that are perpendicular to a window or door.

Field: Name

This is the name of the overhang. It must be different from other surface names.

Field: Window or Door Name

The name of a window or door that this overhang shades.

Field: Left Extension from Window/Door

This field is the width from the left edge of the window/door to the plane of the left fin (meters).

Field: Left Distance Above Top of Window

This field is the distance from the top of the window to the top of the left fin (meters).

Field: Left Distance Below Bottom of Window

This field is the distance from the bottom of the window to the bottom of the left fin (meters).

Field: Left Tilt Angle from Window/Door

This field is the tilt angle from the window / door for the left fin. Typically, a fin is 90 degrees (default) from its associated window/door.

Field: Left Depth as Fraction of Window/Door Width

This field is the fraction of the window/door width to specify as the depth of the left fin (meters) projecting out from the wall.

Field: Right Extension from Window/Door

This field is the width from the right edge of the window/door to the plane of the right fin (meters).

Field: Right Distance Above Top of Window

This field is the distance from the top of the window to the top of the right fin (meters).

Field: Right Distance Below Bottom of Window

This field is the distance from the bottom of the window to the bottom of the right fin (meters).

Field: Right Tilt Angle from Window/Door

This field is the tilt angle from the window / door for the right fin.. Typically, a fin is 90 degrees (default) from its associated window/door.

Field: Right Depth as Fraction of Window/Door Width

This field is the fraction of the window/door width to specify as the depth of the right fin (meters) projecting out from the wall.

Shading:Zone:Detailed

This object is used to describe attached “subsurfaces” such as overhangs, wings or fins that project outward from a base surface. This classification is used for convenience; actually, a device of this type can cast shadows on the surface to which it is attached as well as on adjacent surfaces. For example, a fin may shade its parent wall as well as adjacent walls.

Note that a zone surface can cast shadows on other zone surfaces. However, you don’t have to worry about such effects—for example, one wall of an L-shaped building shading another wall--because EnergyPlus will automatically check for this kind of “self shadowing” and do the proper calculations.

Unlike attached (or detached) shading surfaces, building surfaces can only cast shadows in the hemisphere towards which they face. This means, for example, that a roof that faces *upward* will not cast a shadow *downward*. (Thus, specifying an oversized roof in an attempt to account for the shading effects of overhangs will *not* work). Interior surfaces do not cast shadows of any kind.

```

```

Field: Name

This is the name of the attached shading surface. It must be different from other surface names.

Field: Base Surface Name

This is the name of the surface to which this shading device is attached. This surface can be a wall (or roof) but not a window or door.

Field: Transmittance Schedule Name

The name of a schedule of solar transmittance values from 0.0 to 1.0 for the shading surface. If a blank is entered in this field, the transmittance value defaults to 0.0, i.e., the shading surface is opaque at all times. This scheduling can be used to allow for seasonal transmittance change, such as for deciduous trees that have a higher transmittance in winter than in summer. Transmittance based on time of day can also be used—a movable awning, for example, where the transmittance is some value less than 1.0 when the awning is in place and is 1.0 when the awning is retracted.

The following assumptions are made in the shading surface transmittance calculation:

- Both sides of the shading surface have the same transmittance properties.
- The transmittance is the same for both beam and diffuse solar radiation.
- Beam solar transmittance is independent of angle of incidence on the shading surface.
- Beam radiation incident on a shading surface is transmitted as beam radiation with no change in direction, i.e., there is no beam-to-diffuse component.
- If two shading surfaces with non-zero transmittance overlap, the net transmittance is the product of the individual transmittances. Inter-reflection between the shading surfaces (and between the shading surfaces and the building) is ignored.
- For the daylighting calculation (ref: Group – Daylighting) the shading surface's visible transmittance is assumed to be the same as its solar transmittance.

- Shading devices are assumed to be opaque to long-wave radiation no matter what the solar transmittance value is.

Note that shading devices only shade solar radiation when the sun is up, which is automatically determined by EnergyPlus from latitude, time of year, etc. The user need only account for the time-varying transmittance of the shading device in the transmittance schedule, not whether the sun is up or not.

Field: Number Vertices

The number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on “Surface Vertices” above. The example below shows the correct input for an overhang (to shade the appropriate portion of the base wall and window).

Figure 23. Illustration for Attached Shading Surface

Proper specification for this overhang (facing up) is:

4,(C,0,D),(C,-B,D),(C+A,-B,D),(C+A,0,D); () used to illustrate each vertex.

Note that for horizontal surfaces, any corner may be chosen as the starting corner. The order of vertices determines whether the surface is facing up or down. Shading surfaces are mirrored automatically unless the user specifies "DoNotMirrorDetachedShading", so each shading surface need only be described once.

Thus, another shading surface will be created (facing down):

4,(C+A,-B,D),(C+A,0,D),(C,0,D),(C,-B,D);

IDF example of attached shading surfaces (overhang, fin):

```

ShadingProperty:Reflectance

Specifies the reflectance properties of a shading surface when the solar reflection calculation has requested, i.e., when if “Reflections” option is chosen in the Building object (ref: Building - Field: Solar Distribution). It is assumed that shading surfaces are divided into an unglazed, diffusely reflecting portion and a glazed, specularly-reflecting portion, either of which may be zero. The reflectance properties are assumed to be the same on both sides of the shading surface.

Note that a shading transmittance schedule (ref: Shading Surfaces, Field: Transmittance Schedule Name) can be used with a reflective shading surface. However, EnergyPlus assumes that the reflectance properties of the shading surface are constant even if the transmittance varies.

```

Field: Shading Surface Name

The name of the Shading:Site:Detailed, Shading:Building:Detailed, or Shading:Zone:Detailed object to which the following fields apply.

If this ShadingProperty:Reflectance object is not defined for a shading surface the default values listed in each of the following fields will be used in the solar reflection calculation.

Field: Diffuse Solar Reflectance of Unglazed Part of Shading Surface

The diffuse solar reflectance of the unglazed part of the shading surface (default = 0.2). This reflectance is assumed to be the same for beam-to-diffuse and diffuse-to-diffuse reflection. Beam-to-diffuse reflection is assumed to be independent of angle of incidence of beam radiation. Diffuse-to-diffuse reflection is assumed to be independent of angular distribution of the incident of diffuse radiation. The outgoing diffuse radiation is assumed to be isotropic (hemispherically uniform).

The sum of this reflectance and the shading surface transmittance should be less than or equal to 1.0.

Field: Diffuse Visible Reflectance of Unglazed Part of Shading Surface

The diffuse visible reflectance of the unglazed part of the shading surface (default = 0.2). This reflectance is assumed to be the same for beam-to-diffuse and diffuse-to-diffuse reflection. Beam-to-diffuse reflection is assumed to be independent of angle of incidence of beam radiation. Diffuse-to-diffuse reflection is assumed to be independent of angular distribution of the incident of diffuse radiation. The outgoing diffuse radiation is assumed to be isotropic (hemispherically uniform).

This value if used only for the daylighting calculation (ref: Daylighting:Controls). The sum of this reflectance and the shading surface transmittance should be less than or equal to 1.0.

Field: Fraction of Shading Surface That Is Glazed

The fraction of the area of the shading surface that consists of windows (default = 0.0). It is assumed that the windows are evenly distributed over the surface and have the same glazing construction (see following "Name of Glazing Construction"). This might be the case, for example, for reflection from the façade of a neighboring, highly-glazed building. For the reflection calculation the possible presence of shades, screens or blinds on the windows of the shading surface is ignored. Beam-to-beam (specular) reflection is assumed to occur only from the glazed portion of the shading surface. This reflection depends on angle of incidence as determined by the program from the glazing construction. Beam-to-diffuse reflection from the glazed portion is assumed to be zero. The diffuse-to-diffuse reflectance of the glazed portion is determined by the program from the glazing construction.

Field: Glazing Construction Name

The name of the construction of the windows on the shading surface. Required if Fraction of Shading Surface That Is Glazed is greater than 0.0.

WindowProperty:ShadingControl

Window shading with coverings like drapes, blinds, screens or pull-down shades can be used to reduce the amount of solar radiation entering the window or reduce daylighting glare. It can also be used to reduce heat loss through the window (movable insulation). Leaving the window covering open in the winter can maximize solar heat gain and thereby reduce heating loads.

With WindowProperty:ShadingControl—which is referenced by windows and glass doors (ref: FenestrationSurface:Detailed with Type = Window or GlassDoor)—you specify the type and location of the shading device, what variable or combination of variables controls deployment of the shading device, and what the control setpoint is. If the shading device is a blind, you also specify how the slat angle is controlled.

As shown in Figure 24, a shading device can be inside the window (Shading Type = InteriorShade or InteriorBlind), outside the window (Shading Type = ExteriorShade or ExteriorBlind), or between panes of glass (Shading Type = BetweenGlassShade or BetweenGlassBlind). The exception is window screens which can only be outside the window (Shading Type = ExteriorScreen).

Note that when locating a window shade or blind between glass layers, the WindowMaterial:Glazing layers in the window construction must all use an Optical Data Type of SpectralAverage. Spectral data for glazing layers is not currently supported for between glass shades or blinds.

Figure 24. Allowed locations of a window shading device.

When a shading device is present it is either retracted or activated. When it is retracted it covers none of the window. When it is activated it covers the entire glazed part of the window (but not the frame). Whether the shading device is retracted or activated in a particular timestep depends on the control mechanism: see “Shading Control Type,” below. To model a case in which the shading device, when activated, covers only **part** of the window you will have to divide the window into two separate windows, one with the shading device and one without the shading device.

A shading device can also be of a kind in which the optical properties of the glazing switch from one set of values to another in order to increase or decrease solar or visible transmittance (Shading Type = SwitchableGlazing).

There are two ways of specifying the actual shading device:

Specify “Name of Construction with Shading”

This is the name of a window Construction that has the shading device as one of its layers. The thermal and solar-optical properties of the shading device are given by the shading material referenced in that Construction (ref: Construction, WindowMaterial:Shade, WindowMaterial:Screen and WindowMaterial:Blind). To use this method you have to define two Constructions for the window, one without the shading device and one with it. See Example 1, below.

The Construction without the shading device is referenced in the FenestrationSurface:Detailed input for the window (see IDF example, below). The Construction with the shading device is referenced by the window’s WindowProperty:ShadingControl.

For Shading Type = InteriorShade, InteriorBlind, ExteriorShade, ExteriorScreen and ExteriorBlind these two Constructions must be identical except for the presence of the shading layer in the shaded Construction, otherwise you will get an error message. You will also get an error message if the Construction referenced by the window has a shading layer.

Specify the “Material Name of the Shading Device”

This is the name of a WindowMaterial:Shade, WindowMaterial:Screen or WindowMaterial:Blind. This method can be used with Shading Type = InteriorShade, InteriorBlind, ExteriorShade and ExteriorBlind. It cannot be used with Shading Type = BetweenGlassShade, BetweenGlassBlind, or SwitchableGlazing. If Shading Type = InteriorShade or ExteriorShade, then you specify the name of a WindowMaterial:Shade. If Shading Type = InteriorBlind or ExteriorBlind, then you specify the name of a

WindowMaterial:Blind. If Shading Type = ExteriorScreen, then you specify the name of a WindowMaterial:Screen. See Example 2, below. This method is simpler to use since you don't have to specify two Constructions that differ only by the shading layer.

When this method is used, the program will automatically create a shaded window construction by adding a shading layer to the outside or inside of the construction corresponding to the window referencing the WindowProperty:ShadingControl. The name, created by the program, of this shaded construction is composed as follows: if the name of the window construction is CCC and the material name of the shading device is DDD, then the shaded construction name is CCC:DDD:INT for an interior shading device and CCC:DDD:EXT for an exterior shading device.

This method is the required if you want to add a shading device to a construction brought in from a WINDOW5 Data File (ref: Construction:WindowDataFile).

Note that if both "Name of Construction with Shading" and "Material Name of Shading Device" are specified, the former takes precedence.

Most Shading Control Types allow you to specify a schedule that determines when the control is active. One example is a control that is active seasonally. For example, to deploy shading only in the summer when the incident solar is high enough, use Shading Control Type = OnIfHighSolarOnWindow with a schedule that is 1 during the summer months and 0 otherwise and specify Shading Control Is Scheduled = YES.

In addition, most Shading Control Types also allow you to specify that glare control is active in addition to the specified Control Type. For example, you might want to deploy shading when the solar incident on a window is too high OR the glare from the window is too high. This type of joint control requires that the window be in a daylit zone, that the maximum allowed glare be specified in the Daylighting object for the zone, and that Glare Control Is Active = YES in WindowProperty:ShadingControl.

If Shading Type = InteriorBlind, ExteriorBlind or BetweenGlassBlind you can use WindowProperty:ShadingControl to specify how the slat angle of the blind is controlled when the blind is in place.

A special type of WindowProperty:ShadingControl is SwitchableGlazing. An example is electrochromic glazing in which the transmittance and reflectance of the glass is controlled electronically. For example, you could have electrochromic glazing switch from clear (high transmittance) to dark (low transmittance) to control solar gain. If you choose the Shading Type = SwitchableGlazing option for WindowProperty:ShadingControl, the unswitched (clear) state is specified by the Construction referenced by the window and the switched (dark) state is specified by the Construction referenced by WindowProperty:ShadingControl for that window. For example, if you specify Shading Type = SwitchableGlazing and Shading Control Type = OnIfHighSolarOnWindow, then the glazing will switch to the dark state whenever the solar radiation striking the window exceeds the Setpoint value.

For Shading Type = SwitchableGlazing the state of the window is either clear (unswitched) or dark (fully switched) for all Shading Control Types except MeetDaylightIlluminanceSetpoint. In this case, the transmittance of the glazing is adjusted to just meet the daylight illuminance set point at the first daylighting reference point (see Daylighting). This type of control assures that there is just enough solar gain to meet the daylighting requirements in a zone, and no more, thus reducing the cooling load.

Field: Name

Name of the window shading control. It is referenced by a window (ref: Field: Shading Control Name).

Field: Shading Type

The type of shading device. The choices are:

InteriorShade: A diffusing shade is on the inside of the window. (In the shaded Construction the shading layer must be a WindowMaterial:Shade.)

ExteriorShade: A diffusing shade is on the outside of the window. (In the shaded Construction the shading layer must be a WindowMaterial:Shade.)

BetweenGlassShade: A diffusing shade is between two glass layers. (In the shaded Construction the shading layer must be a WindowMaterial:Shade.) This shading type is allowed only for double- and triple-glazing. For triple-glazing the shade must be between the two inner glass layers.

ExteriorScreen: An insect screen is on the outside of the window. (In the shaded Construction the shading layer must be a WindowMaterial:Screen.)

InteriorBlind: A slat-type shading device, such as a Venetian blind, is on the inside of the window. (In the shaded Construction the shading layer must be a WindowMaterial:Blind.)

ExteriorBlind: A slat-type shading device is on the outside of the window. (In the shaded Construction the shading layer must be a WindowMaterial:Blind.)

BetweenGlassBlind: A slat-type shading device is between two glass layers. (In the shaded Construction the shading layer must be a WindowMaterial:Blind.) This shading type is allowed only for double- and triple-glazing. For triple-glazing the blind must be between the two inner glass layers.

SwitchableGlazing: Shading is achieved by changing the characteristics of the window glass, such as by darkening it.

Field: Construction with Shading Name

Name of the window Construction that has the shading in place. The properties of the shading device are given by the shading material referenced in that Construction (ref: Construction, WindowMaterial:Shade, WindowMaterial:Screen and WindowMaterial:Blind). For Shading Type = SwitchableGlazing, this is the name of the Construction that corresponds to the window in its fully-switched (darkest) state.

Specifying “Name of Construction with Shading” is required if Shading Type = BetweenGlassShade, BetweenGlassBlind, or SwitchableGlazing. For other Shading Types, you may alternatively specify “Material Name of Shading Device” (see below).

Field: Shading Control Type

Specifies how the shading device is controlled, i.e., it determines whether the shading device is “on” or “off.” For blinds, screens and shades, when the device is “on” it is assumed to cover all of the window except its frame; when the device is “off” it is assumed to cover none of the window (whether “on” or “off” the shading device is assumed to cover none of the wall that the window is on).

For switchable glazing, “on” means that the glazing is in the fully-switched state and “off” means that it is in the unswitched state; for example, for electrochromic glazing, “on” means the glazing is in its darkest state and “off” means it is in its lightest state.

The choices for Shading Control Type are the following. If SetPoint is applicable its units are shown in parentheses.

AlwaysOn: Shading is always on.

AlwaysOff: Shading is always off.

The following six control types are used primarily to reduce zone cooling load due to window solar gain.

OnIfScheduleAllows: Shading is on if schedule value is non-zero. Requires that Schedule Name be specified and Shading Control Is Scheduled = Yes.

Note: For exterior window screens *AlwaysOn*, *AlwaysOff*, and *OnIfScheduleAllows* are the only valid shading control types.

OnIfHighSolarOnWindow: Shading is on if beam plus diffuse solar radiation incident on the window exceeds SetPoint (W/m^2) and schedule, if specified, allows shading.

OnIfHighHorizontalSolar: Shading is on if total (beam plus diffuse) horizontal solar irradiance exceeds SetPoint (W/m^2) and schedule, if specified, allows shading.

OnIfHighOutdoorAirTemperature: Shading is on if outside air temperature exceeds SetPoint (C) and schedule, if specified, allows shading.

OnIfHighZoneAirTemperature: Shading is on if zone air temperature in the previous timestep exceeds SetPoint (C) and schedule, if specified, allows shading.

OnIfHighZoneCooling: Shading is on if zone cooling rate in the previous timestep exceeds SetPoint (W) and schedule, if specified, allows shading.

OnIfHighGlare: Shading is on if the total daylight glare index at the zone's first daylighting reference point from all of the exterior windows in the zone exceeds the maximum glare index specified in the daylighting input for zone (ref: Group – Daylighting). Applicable only to windows in zones with daylighting.

Note: Unlike other Shading Control Types, glare control is active whether or not a schedule is specified.

MeetDaylightIlluminanceSetpoint: Used only with ShadingType = SwitchableGlazing in zones with daylighting controls. In this case the transmittance of the glazing is adjusted to just meet the daylight illuminance set point at the first daylighting reference point. Note that the daylight illuminance set point is specified in the zone's Daylighting object; it is not specified as a WindowProperty:ShadingControl SetPoint.

The following three control types can be used to reduce zone heating load during the winter by reducing window conductive heat loss at night and leaving the window unshaded during the day to maximize solar gain. They are applicable to any Shading Type except ExteriorScreen but are most appropriate for interior or exterior shades with high insulating value ("movable insulation"). "Night" means the sun is down and "day" means the sun is up.

OnNightIfLowOutdoorTempAndOffDay: Shading is on at night if the outside air temperature is less than SetPoint (C) and schedule, if specified, allows shading. Shading is off during the day.

OnNightIfLowInsideTempAndOffDay: Shading is on at night if the zone air temperature in the previous timestep is less than SetPoint (C) and schedule, if specified, allows shading. Shading is off during the day.

OnNightIfHeatingAndOffDay: Shading is on at night if the zone heating rate in the previous timestep exceeds SetPoint (W) and schedule, if specified, allows shading. Shading is off during the day.

The following two control types can be used to reduce zone heating and cooling load. They are applicable to any Shading Type except ExteriorScreen but are most appropriate for translucent interior or exterior shades with high insulating value ("translucent movable insulation").

OnNightIfLowOutdoorTempAndOnDayIfCooling: Shading is on at night if the outside air temperature is less than SetPoint (C). Shading is on during the day if the zone cooling rate in the previous timestep is non-zero. Night and day shading is subject to schedule, if specified.

OnNightIfHeatingAndOnDayIfCooling: Shading is on at night if the zone heating rate in the previous timestep exceeds SetPoint (W). Shading is on during the day if the zone cooling rate in the previous timestep is non-zero. Night and day shading is subject to schedule, if specified.

The following control types can be used to reduce zone cooling load. They are applicable to any Shading Type except ExteriorScreen but are most appropriate for interior or exterior blinds, interior or exterior shades with low insulating value, or switchable glazing.

OffNightAndOnDayIfCoolingAndHighSolarOnWindow: Shading is off at night. Shading is on during the day if the solar radiation incident on the window exceeds SetPoint (W/m^2) and if the zone cooling rate in the previous timestep is non-zero. Daytime shading is subject to schedule, if specified.

OnNightAndOnDayIfCoolingAndHighSolarOnWindow: Shading is on at night. Shading is on during the day if the solar radiation incident on the window exceeds SetPoint (W/m^2) and if

the zone cooling rate in the previous timestep is non-zero. Day and night shading is subject to schedule, if specified. (This Shading Control Type is the same as the previous one, except the shading is on at night rather than off.)

OnIfHighOutdoorAirTempAndHighSolarOnWindow: Shading is on if the outside air temperature exceeds the Setpoint (C) and if the solar radiation incident on the window exceeds SetPoint 2 (W/m²).

OnIfHighOutdoorAirTempAndHighHorizontalSolar: Shading is on if the outside air temperature exceeds the Setpoint (C) and if the horizontal solar radiation on the window exceeds SetPoint 2 (W/m²).

Field: Schedule Name

Required if Shading Control Is Scheduled = Yes. If schedule value > 0, shading control is active, i.e., shading can be on only if the shading control test passes. If schedule value = 0, shading is off whether or not the control test passes. If Schedule Name is not specified, shading control is assumed to be active at all times.

Field: Setpoint

The setpoint for activating window shading. The units depend on the type of trigger:

- W/m² for solar-based controls
- W for cooling- or heating-based controls
- Degrees C for temperature-based controls

SetPoint is unused for Shading Control Type = OnIfScheduleAllows, OnIfHighGlare and DaylightIlluminance.

Field: Shading Control Is Scheduled

Accepts values YES and NO. The default is NO. Not applicable for Shading Control Type = OnIfHighGlare and should be blank in that case.

If YES, Schedule Name is required and that schedule determines whether the shading control specified by Shading Control Type is active or inactive (see Schedule Name, above).

If NO, Schedule Name is not applicable (should be blank) and the shading control is unscheduled.

Shading Control Is Scheduled = YES is required if Shading Control Type = OnIfScheduleAllows.

Field: Glare Control Is Active

Accepts values YES and NO. The default is NO.

If YES and the window is in a daylit zone, shading is on if the zone's discomfort glare index exceeds the maximum discomfort glare index specified in the Daylighting object referenced by the zone.

The glare test is OR'ed with the test specified by Shading Control Type. For example, if Glare Control Is Active = YES and Shading Control Type = OnIfHighZoneAirTemp, then shading is on if glare is too high OR if the zone air temperature is too high.

Glare Control Is Active = YES is required if Shading Control Type = OnIfHighGlare.

Field: Shading Device Material Name

The name of a WindowMaterial:Shade, WindowMaterial:Screen or WindowMaterial:Blind. Required if "Name of Construction with Shading" is not specified. Not applicable if Shading Type = BetweenGlassShade, BetweenGlassBlind or SwitchableGlazing and should be blank in this case. If both "Name of Construction with Shading" and "Material Name of Shading Device" are entered the former takes precedence.

Field: Type of Slat Angle Control for Blinds

Applies only to Shading Type = InteriorBlind, ExteriorBlind or BetweenGlassBlind. Specifies how the slat angle is controlled. The choices are FixedSlatAngle, ScheduledSlatAngle and BlockBeamSolar.

If FixedSlatAngle (the default), the angle of the slat is fixed at the value input for the WindowMaterial:Blind that is contained in the construction specified by Name of Construction with Shading or is specified by Material Name of Shading Device.

If ScheduledSlatAngle, the slat angle varies according to the schedule specified by Slat Angle Schedule Name, below.

If BlockBeamSolar, the slat angle is set each timestep to just block beam solar radiation. If there is no beam solar on the window the slat angle is set to the value input for the WindowMaterial:Blind that is contained in the construction specified by Name of Construction with Shading or is specified by Material Name of Shading Device. The BlockBeamSolar option prevents beam solar from entering the window and causing possible unwanted glare if the beam falls on work surfaces while at the same time allowing near-optimal indirect radiation for daylighting.

Field: Slat Angle Schedule Name

This is the name of a schedule of slat angles that is used when Type of Slat Angle Control for Blinds = ScheduledSlatAngle. You should be sure that the schedule values fall within the range given by the Minimum Slat Angle and Maximum Slat Angle values entered in the corresponding WindowMaterial:Blind. If not, the program will force them into this range.

Field: Setpoint 2

Used only as the second setpoint for the following two-setpoint control types:
OnIfHighOutdoorAirTempAndHighSolarOnWindow,
OnIfHighOutdoorAirTempAndHighHorizontalSolar,
OnIfHighZoneAirTempAndHighSolarOnWindow,
and OnIfHighZoneAirTempAndHighHorizontalSolar

WindowProperty:FrameAndDivider

The WindowProperty:FrameAndDivider object is referenced by exterior windows that have

- a frame, and/or
- a divider, and/or
- reveal surfaces that reflect beam solar radiation.

A **frame** surrounds the glazing in a window (see Figure 25 and Figure 26). It is assumed that all frame characteristics—such as width, conductance and solar absorptance—are the same for the top, bottom and side elements of the frame. If the frame elements are not the same then you should enter area-weighted average values for the frame characteristics.

The window vertices that you specify in the FenestrationSurface:Detailed object are those of the glazed part of the window, not the frame. EnergyPlus automatically subtracts the area of the frame—determined from the glazing dimensions and the frame width—from the area of the wall containing the window.

A **divider**, as shown in Figure 25, Figure 26 and Figure 27, divides the glazing up into separate lites. It is assumed that all divider elements have the same characteristics. If not, area-weighted average values should be used. EnergyPlus automatically subtracts the divider area from the glazed area of the window.

Reveal surfaces, as shown in Figure 28, are associated with the setback of the glazing from the outside and/or inside surface of the parent wall. If the depth and solar absorptance of these surfaces are specified, the program will calculate the reflection of beam solar radiation from these surfaces. The program also calculates the shadowing (onto the window) of beam and diffuse solar radiation by outside reveal surfaces.

In EnergyPlus, a window can have any combination of frame, divider and reveal surfaces, or none of these.

The best source of frame and divider characteristics is the WINDOW 5 program, which will calculate the values required by EnergyPlus for different frame and divider types. In particular, the THERM program within WINDOW 5 will calculate the effective conductance of frames and dividers; this is the conductance taking 2-D heat transfer effects into account.

Note that a window's frame and divider characteristics, along with other window information, can be read in from the Window 5 Data File (see "Importing Windows from WINDOW 5" and "Construction from Window5 Data File"). In this case the WindowProperty:FrameAndDivider referenced by the window is not applicable and should be blank unless you want to specify reveal surfaces for beam solar reflection.

Figure 25. A window with a frame and divider.

In the illustration above, the divider has two horizontal elements and one vertical element.

Field: Name

The name of the frame/divider object. It is referenced by WindowProperty:FrameAndDivider Name in FenestrationSurface:Detailed.

Frame Fields

Field: Frame Width

The width of the frame elements when projected onto the plane of the window. It is assumed that the top, bottom and side elements of the frame have the same width. If not, an average frame width should be entered such that the projected frame area calculated using the average value equals the sum of the areas of the frame elements.

Field: Frame Outside Projection

The amount by which the frame projects outward from the outside surface of the window glazing. If the outer surface of the frame is flush with the glazing, Frame Outside Projection = 0.0. Used to calculate shadowing of frame onto glass, solar absorbed by frame, IR emitted and absorbed by frame, and convection from frame.

Field: Frame Inside Projection

The amount by which the frame projects inward from the inside surface of the window glazing. If the inner surface of the frame is flush with the glazing, Frame Inside Projection = 0.0. Used to calculate solar absorbed by frame, IR emitted and absorbed by frame, and convection from frame.

Figure 26. Illustration showing frame and divider dimensioning.

Field: Frame Conductance

The effective thermal conductance of the frame measured from inside to outside frame surface (no air films) and taking 2-D conduction effects into account. Obtained from WINDOW 5 or other 2-D calculation.

Field: Ratio of Frame-Edge Glass Conductance to Center-Of-Glass Conductance

The glass conductance near the frame (excluding air films) divided by the glass conductance at the center of the glazing (excluding air films). Used only for multi-pane glazing constructions. This ratio is greater than 1.0 because of thermal bridging from the glazing across the frame and across the spacer that separates the glass panes. Values can be obtained from WINDOW 5 for the user-selected glazing construction and frame characteristics.

Field: Frame Solar Absorptance

The solar absorptance of the frame. The value is assumed to be the same on the inside and outside of the frame and to be independent of angle of incidence of solar radiation.

Field: Frame Visible Absorptance

The visible absorptance of the frame. The value is assumed to be the same on the inside and outside of the frame and to be independent of angle of incidence of solar radiation.

Field: Frame Thermal Hemispherical Emissivity

The thermal emissivity of the frame, assumed the same on the inside and outside.

Divider Fields

Field: Divider Type

The type of divider (see figure below). Divider Type = Suspended is applicable only to multi-pane glazing. It means that the divider is suspended between the panes. (If there are more than two glass layers, the divider is assumed to be placed between the two outermost layers.)

Divider Type = DividedLite means that the divider elements project out from the outside and inside surfaces of the glazing and divide the glazing into individual lites. For multi-pane glazing, this type of divider also has between-glass elements that separate the panes.

Figure 27. Illustration showing divider types.

Field: Divider Width

The width of the divider elements when projected onto the plane of the window. It is assumed that the horizontal and vertical divider elements have the same width. If not, an average divider width should be entered such that the projected divider area calculated using the average value equals the sum of the areas of the divider elements.

Field: Number of Horizontal Dividers

The number of divider elements parallel to the top and bottom of the window.

Field: Number of Vertical Dividers

The number of divider elements parallel to the sides of the window.

Field: Divider Outside Projection

The amount by which the divider projects out from the outside surface of the window glazing. For Divider Type = Suspended, Divider Projection = 0.0. Used to calculate shadowing of divider onto glass, solar absorbed by divider, IR emitted and absorbed by divider, and convection from divider.

Field: Divider Inside Projection

The amount by which the divider projects inward from the inside surface of the window glazing. If the inner surface of the divider is flush with the glazing, Divider Inside Projection = 0.0. Used to calculate solar absorbed by divider, IR emitted and absorbed by divider, and convection from divider.

Field: Divider Conductance

The effective thermal conductance of the divider measured from inside to outside divider surface (no air films) and taking 2-D conduction effects into account. Obtained from WINDOW 5 or other 2-D calculation.

Field: Ratio of Divider-Edge Glass Conductance to Center-Of-Glass Conductance

The glass conductance near the divider (excluding air films) divided by the glass conductance at the center of the glazing (excluding air films). Used only for multi-pane glazing constructions. This ratio is greater than 1.0 because of thermal bridging from the glazing across the divider and across the spacer that separates the glass panes. Values can be obtained from WINDOW 5 for the user-selected glazing construction and divider characteristics.

Field: Divider Solar Absorptance

The solar absorptance of the divider. The value is assumed to be the same on the inside and outside of the divider and to be independent of angle of incidence of solar radiation.

Field: Divider Visible Absorptance

The visible absorptance of the divider. The value is assumed to be the same on the inside and outside of the divider and to be independent of angle of incidence of solar radiation.

Field: Divider Thermal Hemispherical Emissivity

The thermal emissivity of the divider, assumed the same on the inside and outside.

Reveal Surface Fields

The following fields specify the properties of the window reveal surfaces (reveals occur when the window is not in the same plane as the base surface). From this information and from the geometry of the window and the sun position, the program calculates beam solar radiation absorbed and reflected by the top, bottom, right and left sides of outside and inside window reveal surfaces. In doing this calculation, the shadowing on a reveal surface by other reveal surfaces is determined using the orientation of the reveal surfaces and the sun position.

It is assumed that:

- The window is an exterior window and is rectangular.
- The reveal surfaces are perpendicular to the window plane.
- If an exterior shade, screen or blind is in place it shades exterior and interior reveal surfaces so that in this case there is no beam solar on these surfaces.
- If an interior shade or blind is in place it shades the interior reveal surfaces so that in this case there is no beam solar on these surfaces.
- The possible shadowing on inside reveal surfaces by a window divider is ignored.
- The outside reveal surfaces (top, bottom, left, right) have the same solar absorptance and depth. This depth is not input here but is automatically determined by the program— from window and wall vertices—as the distance between the plane of the outside face of the glazing and plane of the outside face of the parent wall.
- The inside reveal surfaces are divided into two categories: (1) the bottom reveal surface, called here the "inside sill;" and (2) the other reveal surfaces (left, right and top).
- The left, right and top inside reveal surfaces have the same depth and solar absorptance. The inside sill is allowed to have depth and solar absorptance values that are different from the corresponding values for the other inside reveal surfaces.
- The inside sill depth is required to be greater than or equal to the depth of the other inside reveal surfaces. If the inside sill depth is greater than zero the depth of the other inside reveal surfaces is required to be greater than zero.

- The reflection of beam solar radiation from all reveal surfaces is assumed to be isotropic diffuse; there is no specular component.
- Half of the beam solar reflected from outside reveal surfaces is goes towards the window; the other half goes back to the exterior environment (i.e., reflection of this outward-going component from other outside reveal surfaces is not considered).
- The half that goes towards the window is added to the other solar radiation incident on the window. Correspondingly, half of the beam solar reflected from inside reveal surfaces goes towards the window, with the other half going into the zone. The portion going towards the window that is not reflected is absorbed in the glazing or is transmitted back out into the exterior environment.
- The beam solar that is absorbed by outside reveal surfaces is added to the solar absorbed by the outside surface of the window's parent wall; similarly, the beam solar absorbed by the inside reveal surfaces is added to the solar absorbed by the inside surface of the parent wall.

The net effect of beam solar reflected from outside reveal surfaces is to increase the heat gain to the zone, whereas the effect of beam solar reflected from inside reveal surfaces is to decrease the heat gain to the zone since part of this reflected solar is transmitted back out the window.

If the window has a frame, the absorption of reflected beam solar by the inside and outside surfaces of the frame is considered. The shadowing of the frame onto interior reveal surfaces is also considered.

Field: Outside Reveal Solar Absorptance

The solar absorptance of outside reveal surfaces.

Field: Inside Sill Depth

The depth of the inside sill, measured from the inside surface of the glazing to the edge of the sill (see Figure 28).

Field: Inside Sill Solar Absorptance

The solar absorptance of the inside sill.

Field: Inside Reveal Depth

The depth of the inside reveal surfaces other than the sill, measured from the inside surface of the glazing to the edge of the reveal surface (see Figure 28).

Field: Inside Reveal Solar Absorptance

The solar absorptance of the inside reveal surfaces other than the sill.

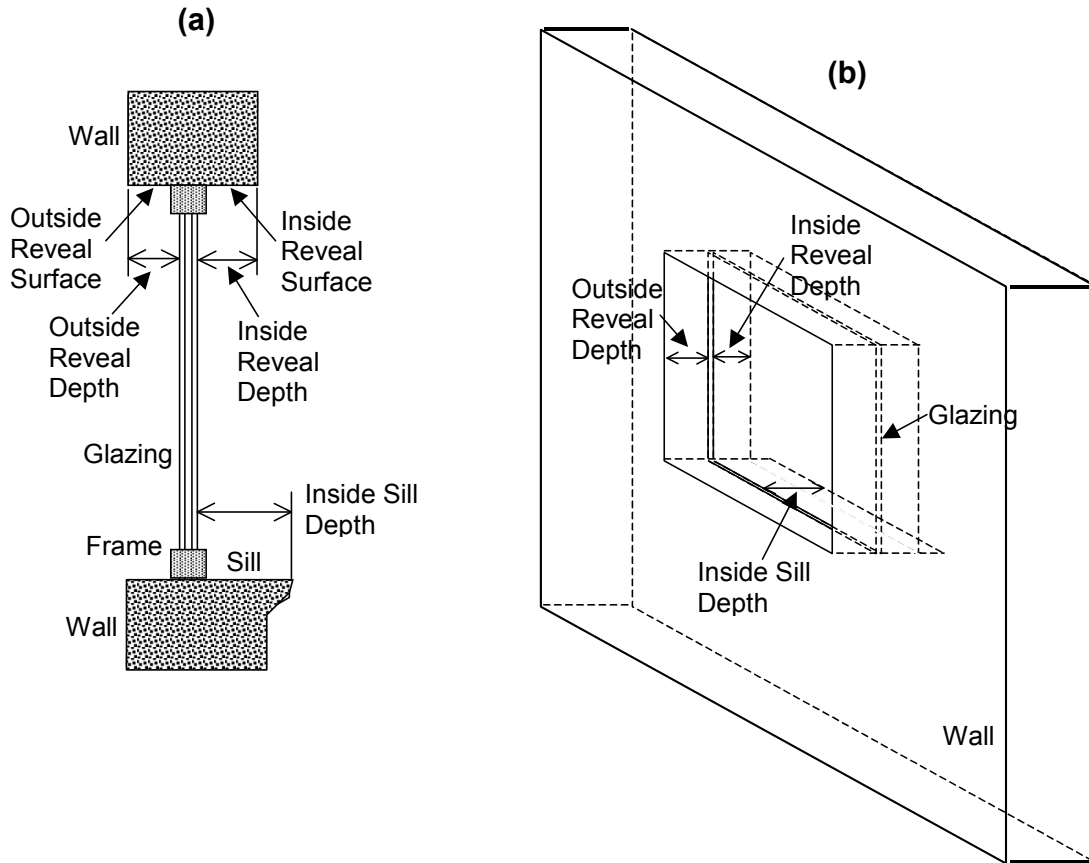

Figure 28. (a) Vertical section through a window (with frame) showing outside and inside reveal surfaces and inside sill. (b) Perspective view looking from the outside of a window (without frame) showing reveal surfaces. Note that “Outside Reveal Depth” is not a user input; it is calculated by the program from the window and wall vertices.

WindowProperty:AirflowControl

This object is used to specify the control mechanism for windows in which forced air flows in the gap between adjacent layers of glass. Such windows are called “airflow windows.” They are also known as “heat-extract windows” or “climate windows.”

A common application is to reduce the zone load by exhausting indoor air through the window. In the cooling season this picks up and expels some of the solar heat absorbed by the window glass (and by the between-glass shade or blind, if present). In the heating season this warms the window, reducing the heat loss from the window. A side benefit is increased thermal comfort. This is because the inside surface of the window will generally be cooler in summer and warmer in winter.

The surface report variable “Window Gap Convective Heat Flow [W]” gives the heat picked up (or lost) by the gap airflow.

Field: Name

Name of the window that this WindowProperty:AirflowControl refers to. It must be a window with two or three glass layers, i.e., double- or triple-glazing. For triple-glazing the airflow is assumed to be between the two inner glass layers.

An error will result if the gas in the airflow gap is other than air (ref: WindowMaterial:GlazingGroup:Thermochromic

Thermochromic (TC) materials have active, reversible optical properties that vary with temperature. Thermochromic windows are adaptive window systems for incorporation into building envelopes. Thermochromic windows respond by absorbing sunlight and turning the sunlight energy into heat. As the thermochromic film warms it changes its light transmission level from less absorbing to more absorbing. The more sunlight it absorbs the lower the light level going through it. By using the sun's own energy the window adapts based solely on the directness and amount of sunlight. Thermochromic materials will normally reduce optical transparency by absorption and/or reflection, and are specular (maintaining vision).

A thermochromic window is defined with a Construction object which references a special layer defined with a WindowMaterial:GlazingGroup:Thermochromic object. The WindowMaterial:GlazingGroup:Thermochromic object further references a series of WindowMaterial:Glazing objects corresponding to each specification temperature of the TC layer.

This object specifies a layer of thermochromic glass, part of a thermochromic window. An example file ThermochromicWindow.idf is included in the EnergyPlus installation.

Field: Name

A unique user assigned name for a particular thermochromic glass material.

Field Set (Optical Data Temperature, Window Material Glazing Name) is extensible.

Field: Optical Data Temperature <N>

The temperature of the TC glass layer corresponding to the optical data of the TC layer. Unit is °C.

Field: Window Material Glazing Name <N>

The window glazing (defined with WindowMaterial:Glazing) name that provides the TC glass layer performance at the above specified temperature.

The IDD definition for the object follows:

```

Thermochromic Window Outputs

Window Thermochromic Layer Temperature [C]

The temperature of the TC glass layer of a TC window at each time step.

Window Thermochromic Layer Specification Temperature [C]

The temperature under which the optical data of the TC glass layer are specified.

The overall properties (U-factor/SHGC/VT) of the thermochromic windows at different specification temperatures are reported in the EIO file. These window constructions are created by EnergyPlus during run time. They have similar names with suffix “_TC_XX” where XX represents a specification temperature.

WindowMaterial:Gas). If an airflow window has a between-glass shade or blind, the gas in the gap on either side of the shade or blind must be air.

Field: Airflow Source

The source of the gap airflow. The choices are:

IndoorAir: Indoor air from the window’s zone is passed through the window.

OutdoorAir: Outdoor air is passed through the window.

Field: Airflow Destination

This is where the gap air goes after passing through the window. The choices are:

IndoorAir: The gap air goes to the indoor air of the window’s zone.

OutdoorAir: The gap air goes to the outside air.

ReturnAir: The gap air goes to the return air for the window’s zone. This choice is allowed only if Airflow Source = InsideAir. If the return air flow is zero, the gap air goes to the indoor air of the window’s zone. If the sum of the gap airflow for all of the windows in a zone with Airflow Destination = ReturnAir exceeds the return airflow, then the difference between this sum and the return airflow goes to the indoor air.

Figure 29 shows the allowed combinations of Airflow Source and Airflow Destination. The allowed combinations of Airflow Source and Airflow Destination are:

IndoorAir → OutdoorAir

IndoorAir → IndoorAir

IndoorAir → ReturnAir

OutdoorAir → IndoorAir

OutdoorAir → OutdoorAir

Field: Maximum Flow Rate

The maximum value of the airflow, in m^3/s per m of glazing width. The value is typically 0.006 to $0.009 \text{ m}^3/\text{s}\cdot\text{m}$ (4 to 6 cfm/ft).

The airflow can be modulated by specifying Airflow Has Multiplier Schedule = Yes and giving the name of the Airflow Multiplier Schedule (see below).

The fan energy used to move the air through the gap is generally very small and so is ignored.

Field: Airflow Control Type

Specifies how the airflow is controlled. The choices are:

AlwaysOnAtMaximumFlow. The airflow is always equal to Maximum Airflow.

AlwaysOff. The airflow is always zero.

ScheduledOnly. The airflow in a particular timestep equals Maximum Airflow times the value of the Airflow Multiplier Schedule for that timestep.

Field: Airflow Is Scheduled

Specifies if the airflow is scheduled. The choices are:

Yes. The airflow is scheduled.

No. The airflow is not scheduled.

If Yes, Airflow Multiplier Schedule Name is required.

Field: Airflow Multiplier Schedule Name

The name of a schedule with values between 0.0 and 1.0. The timestep value of the airflow is Maximum Airflow times the schedule value. Required if Airflow Is Scheduled = Yes. Unused if Airflow Is Scheduled = No. This schedule should have a ScheduleType with Numeric Type = Continuous and Range = 0.0 : 1.0.

Figure 29. Gap airflow configurations for airflow windows. (a) **Air exhaust window:** Airflow Source = InsideAir, Airflow Destination = OutsideAir; (b) **Indoor air curtain window:** Airflow Source = InsideAir, Airflow Destination = InsideAir; (c) **Air supply window:** Airflow Source = OutsideAir, Airflow Destination = InsideAir; (d) **Outdoor air curtain window:** Airflow Source = OutsideAir, Airflow Destination = OutsideAir; (e) **Airflow to Return Air:** Airflow Source = InsideAir, Airflow Destination = ReturnAir. Based on "Active facades," Version no. 1, Belgian Building Research Institute, June 2002.

```

WindowProperty:StormWindow

This object allows you to assign a movable exterior glass layer (“storm window” or “storm glass”) that is usually applied to a window in the winter to reduce heat loss and removed in the summer. A WindowProperty:StormWindow object is required for each window that has an associated storm window. It is assumed that:

- When the storm glass is in place it is the outermost layer of the window, it covers only the glazed part of the window and not the frame, and it forms a tight seal. See Figure 30.
- When the storm glass is not in place it is completely removed and has no effect on window heat transfer.
- The gap between the storm glass and rest of the glazing is filled with air.

Figure 30. Section through a single-glazed window without (left) and with (right) a storm glass layer. Not to scale.

With the addition of a storm window, single glazing effectively becomes double glazing, double glazing becomes triple glazing, etc.

The presence of a storm window is indicated by the report variable “Storm Window On/Off Flag” (see “Window Output Variables”). This flag is **0** if the storm window is off, **1** if it is on, and **-1** if the window does not have an associated storm window.

The program automatically creates a window construction (ref: Construction) that consists of the storm window glass layer and its adjacent air layer added to the original (unshaded, or “bare”) window construction. In the eplusout.eio file this construction is called `BARECONSTRUCTIONWITHSTORMWIN:n`, where *n* is the number of the associated StormWin object. If the window has a shaded construction, the program creates a construction called `SHADEDCONSTRUCTIONWITHSTORMWIN:n` that consists of the storm window glass layer and its adjacent air layer added to the original shaded window construction.

The program also creates a WindowMaterial:Gas layer corresponding to the air layer adjacent to the storm glass. In the eplusout.eio file this layer is called `AIR:STORMWIN:kMM`, where *k* is the thickness of the air layer expressed as an integer number of millimeters.

Field: Window Name

This is the name of a window (or glass door) to which the storm glass is applied. Not all windows can accept WindowProperty:StormWindow. The rules are:

- The window must be an exterior window. WindowProperty:StormWindow is not applicable to interior (interzone) windows.
- The window construction (without the storm glass layer) can have up to three glass layers.
- If the window has an associated shaded construction (ref: WindowProperty:ShadingControl), that construction can have an interior shade or blind and up to three glass layers, or a between-glass shade or blind and two glass layers. The shaded construction cannot have an exterior shade or blind, cannot have a between-glass shade or blind and three glass layers, and cannot be switchable glazing.
- The window cannot be an airflow window, i.e., a window that has an associated WindowProperty:AirflowControl.

Field: Storm Glass Layer Name

This is the name of a window glass material. Storm windows are assumed to consist of a single layer of glass. A storm window frame, if present, is ignored.

Field: Distance Between Storm Glass Layer and Adjacent Glass

The separation between the storm glass and the rest of the window (Figure 30). It is measured from the inside of the storm glass layer to the outside of the adjacent glass layer.

Field: Month that Storm Glass Layer Is Put On

The number of the month (January = 1, February = 2, etc.) during which the storm window is put in place.

Field: Day of Month that Storm Glass Layer Is Put On

The day of the month that the storm window is put in place. It is assumed that the storm window is put in place at the beginning of this day, i.e., during the first simulation timestep of the day, and remains in place until that month and day given by the following two fields.

Field: Month that Storm Glass Layer Is Taken Off

The number of the month (January = 1, February = 2, etc.) during which the storm window is removed.

Field: Day of Month that Storm Glass Layer Is Taken Off

The day of the month that the storm window is removed. It is assumed that the storm window is removed at the beginning of this day, i.e., during the first simulation timestep of the day, and stays off until the month and day given by Month that Storm Glass Layer Is Put On, Day of Month that Storm Glass Layer Is Put On.

In the northern hemisphere, the month the storm window is put on is generally greater than the month it is taken off (for example put on in month 10, when it starts to get cold, and taken off in month 5, when it starts to warm up). In the southern hemisphere this is reversed: month on is less than month off.

Importing Windows from WINDOW 5

The WINDOW 5 program calculates the U-value, Solar Heat Gain Coefficient, solar transmission/absorption characteristics, visible transmission characteristics and other properties of a window under standard indoor and outdoor conditions. WINDOW 5 treats the whole window system—glazing, frame and divider. A sub-program of WINDOW 5 called THERM uses a 2-D finite element calculation to determine the effective conductance of frame, divider and edge-of-glass elements. Another sub-program, OPTICS 5, determines the solar-optical properties of glazing, including laminates and coated glass.

WINDOW 5 writes a data file containing a description of the window that was analyzed. An example is shown below. This file, which can be named by the user, can be read by EnergyPlus. By default, the file name is “Window5DataFile.dat” and is located in the EnergyPlus “run” folder (*the same folder that has the EnergyPlus.exe file*). Or, as illustrated below, you may input the file name (including path or relative path) to the object. For more complete description and examples, see the object description -- Construction:WindowDataFile.

In this way, the same window that was created in WINDOW 5 can be imported into EnergyPlus for annual energy analysis without having to re-input the window data. To obtain WINDOW 5 go to <http://windows.lbl.gov>. A major advantage of using WINDOW 5 to create window input for EnergyPlus is that you will have direct access to WINDOW 5’s expanding database of over 1000 different glass types; and you will be able to browse through this database according to different criteria (color, transmittance, solar heat gain coefficient, etc.) to help you select the best glass type for your application.

Although WINDOW 5 writes only one window entry on the WINDOW 5 data file, EnergyPlus users can combine two or more of these files to end up with a single WINDOW 5 data file

with multiple window entries of different types. In this way a library of windows from WINDOW 5 can be built up if so desired. If you combine files like this you should be sure not to leave out or change any of lines from the original files.

1. There are three methods for inputting window constructions in EnergyPlus:
 - a) input full spectral data for each layer in the IDF,
 - b) input spectral average data for each layer in the IDF,
 - c) import WINDOW 5 report containing layer-by-layer calculated values and overall glazing system angular values.

2. The SHGC calculations in EnergyPlus for window layers input using full spectral data use a spectral weighting data set (derived from Optics5 data file ISO-9845GlobalNorm.std) that is different from the WINDOW 5 default spectral weighting data set (W5_NFRC_2003.std). This difference accounts for most of the variation in SHGC values reported by EnergyPlus and WINDOW 5 for full spectral data window layer input. This variation is more pronounced for window constructions of three glass layers or more.

3. Users intending to select a window construction based on SHGC value for energy code compliance should base their selection on the value reported by WINDOW 5 since this is the officially recognized value.

Please note that there is a bug in WINDOW 5 that causes two of the lines in the EnergyPlus data file to be joined. This bug is fixed in versions of Window 5.02 (and above). To be sure, you can check the data file for a line that looks like:

```
GLAZING SYSTEM OPTICAL DATA Angle 0 10 20 30 40 50 60 70 80 90 Hemis
```

The fixed version of the program will not show the above line; rather, there will be two lines such as shown below. If you have the above condition, with an editor you would break this into two lines:

```
GLAZING SYSTEM OPTICAL DATA
Angle 0 10 20 30 40 50 60 70 80 90 Hemis
```

In EnergyPlus, the Window5 data file is searched for each “Construction from Window5 Data File” object in the EnergyPlus input. This object has a very simple form:

```
Construction:WindowDataFile,
ConstructionName,
FileName; ! Default is Window5DataFile.dat in the "run" folder.
```

If there is a window called ConstructionName on the Window5 data file, the data for that window is read from the file and the following EnergyPlus objects and their names are created. The “W5” prefixed to these names indicates that the object originated in the Window5 data file.

- **WindowMaterial:Glazing** for each of the glass layers. They will be named **W5:ConstructionName:GLASS1**, **W5:ConstructionName:GLASS2**, etc.
- **WindowMaterial:Gas** or **WindowMaterial:GasMixture** for each of the gap layers. They will be named **W5:ConstructionName:GAP1**, **W5:ConstructionName:GAP2**, etc.
- **WindowProperty:FrameAndDivider** (if the window on the Window5 data file has a frame and/or divider). It will be named **W5:ConstructionName**. This WindowProperty:FrameAndDivider will be assigned to any window on the input file that

has a construction called “ConstructionName” *even if that window has referenced another WindowProperty:FrameAndDivider (i.e., if WindowProperty:FrameAndDivider Name for that window is specified)*. In this case a warning will result.

Note that:

An entry on the WINDOW 5 data file usually has just one glazing system. It is also possible to have an entry with two glazing systems separated by a horizontal or vertical mullion. In this case, the two glazing systems can have different dimensions and different properties. For example, one of the two glazing systems could be single glazed and the other could be double glazed. An example of the two glazing system case is given in the sample WINDOW 5 data file shown below (although in this case the properties of the two glazing systems are the same).

EnergyPlus handles the “one glazing system” and “two glazing systems” cases differently. If there is one glazing system, the glazing system height and width from the Window5 data file are not used. Instead, the window dimensions are obtained from the window vertices that have been specified on the IDF file. However, a warning message will result if the height or width calculated from the window’s vertex inputs differs from the corresponding Window5 data file values by more than 10%. This warning is given since the effective frame and edge-of-glass conductances on the WINDOW 5 data file can depend on the window dimensions if the frame is non-uniform, i.e., consists of sections with different values of width, projection, or thermal properties.

If the WINDOW 5 data file entry has two glazing systems, System1 and System2, the following happens, as shown in the figure below. Assume that the original window is called WinOriginal. System1 is assigned to WinOriginal. Then EnergyPlus automatically creates a second window, called WinOriginal:2, and assigns System2 to it. The dimensions of WinOriginal are ignored; the dimensions of System1 on the data file are assigned to it, but the position of the lower left-hand vertex of WinOriginal is retained. The dimensions of System2 on the data file are assigned to WinOriginal:2. The lower left-hand vertex of WinOriginal:2 is determined from the mullion orientation and width.

Note: WinOriginal would have been the IDF window definition – it’s dimensions will be overridden by the systems dimensions from the Window 5 data file. Two windows will be made and called WinOriginal and WinOriginal:2.

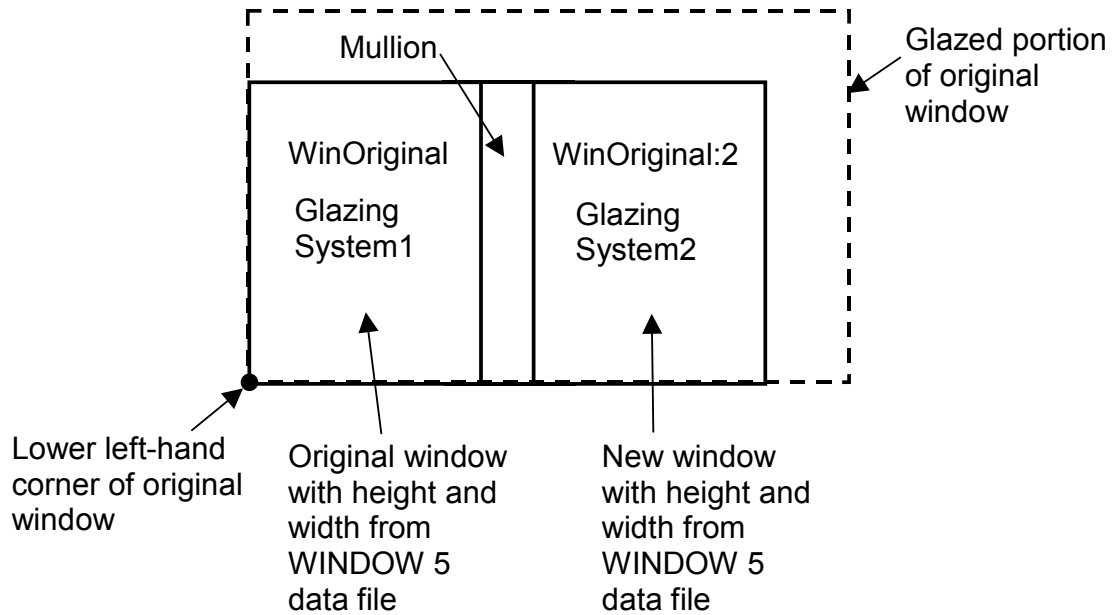

Figure 31. Window5 Glazing system with dual glazing constructions

The Window5 Data File contains no information on shading devices. See “Specify the Material Name of the Shading Device” under WindowProperty:ShadingControl for a method to attach a shading layer to windows read in from this file.

Following is an example WINDOW 5 data file for a slider window with two identical double low-E glazing systems separated by a horizontal mullion. Each system has a frame and divider. Note that all dimensions, such as glazing height and width, are in millimeters; when EnergyPlus reads the file these are converted to meters. Following the data file example is a description of the contents of the file. That data used by EnergyPlus is shown in bold.

```

Description of Contents of Window5 Data File

(Quantities used in EnergyPlus are in bold; others are informative only)

Second line = version of WINDOW5 used to create the data file

Date = date the data file was created

Window name = name of this window; chosen by WINDOW5 user; EnergyPlus user enters the same name in EnergyPlus as name of a "Construction from Window5 Data File" object. EnergyPlus will search the Window5 data file for an entry of this name.

Description = One-line description of the window; this is treated as a comment.

Glazing Systems: 1 or 2; value is usually 1 but can be 2 if window has a horizontal or vertical mullion that separates the window into two glazing systems that may or may not be different.

GLAZING SYSTEM DATA

System1, System2: separate characteristics given if window has a mullion.

Height, *width = height and width of glazed portion (i.e., excluding frame; and, if mullion present, excluding mullion).

nPanels = number of glass layers

Uval-center = center-of-glass U-value (including air films) under standard winter conditions* (W/m²)

SC-center = center-of-glass shading coefficient under standard summer conditions*.

SHCG-center = center-of-glass solar heat gain coefficient under standard summer conditions*.

Tvis-center = center-of-glass visible transmittance at normal incidence

FRAME/MULLION DATA

L,R Sill = left, right sill of frame

L,R Head = left, right header of frame

Top L, Bot L jamb = top-left, bottom-left jamb of frame

Bot L, Bot R jamb = bottom-left, bottom-right jamb of frame

Average frame = average characteristics of frame for use in EnergyPlus calculation. If mullion is present, original window is divided into two separate windows with the same average frame (with the mullion being split lengthwise and included in the average frame).

Width = width (m)

OutsideProj = amount of projection from outside glass (m)

InsideProj = amount of projection from inside glass (m)

Cond = effective surface-to-surface conductance (from THERM calculation) (W/m²)

EdgeCondRatio = ratio of surface-to-surface edge-of-glass conductance to surface-to-surface center-of-glass conductance (from THERM calculation)

SolAbs = solar absorptance

VisAbs = visible absorptance

Emiss = hemispherical thermal emissivity

Orientation = Horizontal or Vertical (mullion only); = None if no mullion.

DIVIDER DATA

Width through **Emiss** are the same as for FRAME/MULLION DATA

#Hor = number of horizontal dividers

#Vert = number of vertical dividers

Type = DividedLite or Suspended

GLASS DATA

System1, System2: separate characteristics are given if window has a mullion.

Cond = conductivity (W/m-K)

Tsol = spectral-average solar transmittance at normal incidence

Rfsol = spectral-average front solar reflectance at normal incidence

Rbsol = spectral-average back solar reflectance at normal incidence

Tvis = spectral-average visible transmittance at normal incidence

Rfvis = spectral-average front visible reflectance at normal incidence

Rbvis = spectral-average back visible reflectance at normal incidence

Tir = hemispherical IR transmittance

EmissF = hemispherical front emissivity

EmissB = hemispherical back emissivity

SpectralDataFile = name of spectral data file with wavelength-dependent transmission and reflection data used by WINDOW 5 to calculate the glazing system optical data. "None" will appear here if spectral-average data for this glass layer were used by WINDOW 5.

GAP DATA

System1, System2: separate characteristics are given if the window has a mullion.

Thick = thickness (m)

nGasses = number of gasses (1, 2 or 3)

GasName = name of the gas

Fraction = fraction of the gas

MolecWeight = molecular weight of the Nth gas

(In the following, conductivity, viscosity and specific heat as a function of temperature, T (deg K), are expressed as $A + B*T + C*T^2$)

ACond = A coeff of conductivity (W/m-K)

BCond = B coeff of conductivity (W/m-K²)

CCond = C coeff of conductivity (W/m-K³)

AVisc = A coeff of viscosity (g/m-s)

BVisc = B coeff of viscosity (g/m-s-K)

CVisc = C coeff of viscosity (g/m-s-K²)

ASpHeat = A coeff of specific heat (J/kg-K)

BSpHeat = B coeff of specific heat (J/kg-K²)

CSpHeat = C coeff of specific heat (J/kg-K³)

GLAZING SYSTEM OPTICAL DATA

System1, System2: separate characteristics are given if the window has a mullion.

Hemisph = hemispherical (i.e., diffuse)

Tsol = solar transmittance vs. angle of incidence

AbsN = solar absorptance of Nth layer vs. angle of incidence

Rfsol = front solar reflectance vs. angle of incidence

Rbsol = back solar reflectance vs. angle of incidence

Tvis = visible transmittance vs. angle of incidence

Rfvis = front visible reflectance vs. angle of incidence

Rbvis = back visible reflectance vs. angle of incidence

*Standard conditions are

Winter:

Indoor air temperature = 21.1C (70F)

Outdoor air temperature = -17.8C (0F)

Wind speed = 6.71 m/s (15 mph)

No solar radiation

Summer:

Indoor air temperature = 23.9C (75F)

Outdoor air temperature = 31.7C (89F)

Wind speed = 3.35 m/s (7.5 mph)

783 W/m² (248 Btu/h-ft²) incident beam solar radiation normal to glazing

Zone Thermal Output(s)

In addition to the canned Surface reports (view the Reports section later in this document) and surface variables (above), the following variables are available for all zones:

```

Zone,Sum,Zone Total Internal Radiant Heat Gain [J]
Zone,Sum,Zone Total Internal Visible Heat Gain [J]
Zone,Sum,Zone Total Internal Convective Heat Gain [J]
Zone,Sum,Zone Total Internal Latent Gain [J]
Zone,Sum,Zone Total Internal Total Heat Gain [J]
Zone,Average,Zone Mean Air Temperature [C]
HVAC,Average,Zone/Sys Air Temperature[C]
Zone,Average,Zone Mean Radiant Temperature [C]
Zone,Average,Zone Operative Temperature [C]
HVAC,Sum,Zone/Sys Sensible Heating Energy[J]
HVAC,Sum,Zone/Sys Sensible Cooling Energy[J]
HVAC,Average,Zone/Sys Sensible Heating Rate[W]
HVAC,Average,Zone/Sys Sensible Cooling Rate[W]
HVAC,Average,Zone Air Humidity Ratio[]
HVAC,Average,Zone Air Relative Humidity[%]

```

Two of these are of particular interest:

```

Zone,Average,Zone Mean Air Temperature [C]
HVAC,Average,Zone/Sys Air Temperature [C]

```

These two variable outputs are/should be identical. However, note that they can be reported at different time intervals. “Zone Mean Air Temperature” is only available on the Zone/HB timestep (Number of Timesteps per Hour) whereas “Zone/Sys Air Temperature” can be reported at the HVAC timestep (which can vary).

Zone Mean Air Temperature [C]

From the code definition, the zone mean air temperature is the average temperature of the air temperatures at the system timestep. Remember that the zone heat balance represents a “well stirred” model for a zone, therefore there is only one mean air temperature to represent the air temperature for the zone.

Zone/Sys Air Temperature[C]

This is very similar to the mean air temperature in the last field. The “well stirred” model for the zone is the basis, but this temperature is also available at the “detailed” system timestep.

Zone Mean Radiant Temperature [C]

The Mean Radiant Temperature (MRT) in degrees Celsius of a space is really the measure of the combined effects of temperatures of surfaces within that space. The larger the surface area and the closer one is to it, the more effect the surface temperature of that surface has on each other. The MRT is the measure of all these surface areas and temperatures.

Zone Operative Temperature [C]

Zone Operative Temperature (OT) is the average of the Zone Mean Air Temperature (MAT) and Zone Mean Radiant Temperature (MRT), $OT = 0.5 \cdot MAT + 0.5 \cdot MRT$. This report variable is not affected by the type of thermostat controls in the zone, and does not include the direct effect of high temperature radiant systems. See also Zone Thermostat Operative Temperature.

Zone/Sys Sensible Heating Energy[J]

This field represents the sensible heating energy in Joules that is actually supplied by the system to that zone for the timestep reported. This is the sensible heating rate multiplied by the simulation timestep. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. . This field is not multiplied by zone or group multipliers.

Zone/Sys Sensible Heating (and Cooling) Energy (and Rate) all report the heating or cooling delivered by the HVAC system to a zone. These values are calculated by multiplying the supply air mass flow rate by the difference between the supply air temperature and the zone air temperature. This does not always

indicate the operation of heating or cooling coils. For example, cooling will be reported if the supply air is cooled due to the introduction of outside air, even if all coils are off.

Note that these variables are calculated at the system timestep. When reported at the "detailed" reporting frequency, these variable will never show heating and cooling both in the same system timestep. If reported at a frequency less than "Detailed" (for example, Hourly) values may appear in both the heating and cooling variable for the same hour if the system cooled the zone for part of the reporting period and heated the zone for another part of the reporting period.

Zone/Sys Sensible Cooling Energy[J]

This field represents the sensible cooling energy in Joules that is actually supplied by the system to that zone for the timestep reported. This is the sensible cooling rate multiplied by the simulation timestep. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers.

Zone/Sys Sensible Heating Rate[W]

This field represents the sensible heating rate in Watts that is actually supplied by the system to that zone for the timestep reported. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers.

Zone/Sys Sensible Cooling Rate[W]

This field represents the sensible cooling rate in Watts that is actually supplied by the system to that zone for the timestep reported. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers.

Zone Air Humidity Ratio[]

This field represents the air humidity ratio after the correct step for each zone. The humidity ratio is the mass of water vapor to the mass of dry air contained in the zone in (kg water/kg air) and is unitless.

Zone Air Relative Humidity[%]

This field represents the air relative humidity ratio after the correct step for each zone. The relative humidity is in percent and uses the Zone Air Temperature, the Zone Air Humidity Ratio and the Outside Barometric Pressure for calculation.

Zone Total Internal Radiant Heat Gain [J]

This field represents the sum of radiant gains from specific internal sources (e.g. equipment) throughout the zone in joules. This includes radiant gain from People, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

Zone-Total Internal Visible Heat Gain [J]

This field expresses the sum of heat gain in joules that is the calculated short wavelength radiation gain from lights in the zones. This calculation uses the total energy from lights and the fraction visible to realize this value, summed over the zones in the simulation.

Zone Total Internal Convective Heat Gain [J]

This field represents the sum of convective gains from specific sources (e.g. equipment) throughout the zone in joules. This includes convective gain from People, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

Zone Total Internal Latent Gain [J]

This field represents the sum of latent gains from specific internal sources (e.g. equipment) throughout the zone in joules. This includes latent gain from People, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

Zone Total Internal Total Heat Gain [J]

This field represents the sum of all heat gains throughout the zone in joules. This includes all heat gains from People, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

Group – Advanced Surface Concepts

This group of objects describe concepts applied to heat transfer surfaces that are of an advanced nature. Careful consideration must be given before using these.

SurfaceControl:MoveableInsulation

Movable insulation can be used/scheduled on any surface regular surface (such as a wall, floor, roof, etc.) but not on a subsurface (such as a window, use WindowProperty:ShadingControl instead). With movable insulation, no reference is made in the surface that is using the insulation – rather the movable insulation statement references the surface to which it is applied.

Exterior movable insulation has undergone some testing and appears to producing expected results. At the modification of this section of the Input/Output Reference (April 2002), interior movable insulation has not yet been tested. The underlying principle has been implemented in EnergyPlus for both interior and exterior movable insulation with the possibility for exterior movable insulation to be transparent (transparent insulation material or TIM). Basically, the addition of movable insulation allows the user to schedule an extra amount of insulation on either the inside or outside surface of a wall (or both). The insulation must be a simple, homogenous material layer (linked to a material definition within the input data file). Note that EnergyPlus allows the exterior movable insulation layer to be transparent to short wavelength radiation (solar). In this case, incident solar is split between the plane between the movable insulation and the surface and the plane between the movable insulation and the surrounding air. This calculation is fairly basic and based on the solar transmittance of the insulation layer (material properties). Using transparent layers for exterior movable insulation allows solar energy to penetrate deeper into a construction where it can be stored for later use in the building (similar in concept to a Trombe Wall).

Field: Insulation Type

This field determines whether the movable insulation is applied to the inside or the outside of the surface by entering “Inside” or “Outside”, respectively.

Field: Surface Name

This field refers the movable insulation back to a particular surface (ref: Building Surfaces) via its user assigned name so that EnergyPlus knows where to apply this extra layer of insulation. This will affect either the inside or outside surface heat balance of this surface depending on the value in the insulation type field (see previous field).

Field: Material Name

This field refers to a material layer (e.g., Material, Material:NoMass, or WindowMaterial:Glazing; transparent layers are only valid for outside movable insulation) via its user assigned name. This provides the program with a full complement of material properties so that the effect of the insulation (R-value and solar transmittance) can be correctly taken into account by EnergyPlus.

Field: Schedule Name

This field is a schedule that theoretically can be any positive real number but was originally intended to be a parameter between 0.0 and 1.0. Its purpose is to act as a fractional modifier on the resistance of the material layer. The actual thermal resistance of the movable insulation is equal to the resistance of the material layer times the current value in the movable insulation schedule. A value of 0.0 simply means that the movable insulation is not present.

The IDD description of movable insulation is as follows:

```
SurfaceControl:MoveableInsulation,
  \memo Exterior or Interior Insulation on surfaces
  A1, \field Insulation Type
      \required-field
      \type choice
      \key Outside
      \key Inside
  A2, \field Surface Name
      \required-field
      \type object-list
      \object-list SurfaceNames
  A3, \field Material Name
      \required-field
  A4; \field Schedule Name
      \required-field
      \type object-list
      \object-list ScheduleNames
```

An example of this syntax implemented in an input file is:

```
SurfaceControl:MoveableInsulation,
  Exterior,                ! Insulation Type
  Zone001:Wall001,        ! Surface Name
  TransparentInsulationMaterial, ! Material Name
  PresentInWinterSchedule; ! Schedule Name
```

SurfaceProperty:OtherSideCoefficients

By referencing the Other Side Coefficients statement in the surface statements (i.e. Outside Boundary Condition), the temperature of the outer plane of a surface (see Figure 32) can be directly controlled. Other side coefficients can also be used to control the exterior convective heat transfer coefficient of a surface and the corresponding exterior air temperature. It should be noted that solar effects are not accounted for when other side coefficients are used. In addition, if other side coefficients are specified for a surface, they also hold for subsurfaces of that surface (though subsurfaces can have their own coefficient set).

Other side coefficients have the same effect on all types of heat transfer surfaces. In other words, an interior surface with other side coefficients specified and an exterior wall with identical other side coefficients specified are simulated exactly the same. A surface that uses other side coefficients should be thought of as a new or separate type of surface. All heat transfer surfaces are simulated in the same manner through conduction transfer functions. The only difference between the various types of heat transfer surfaces is the environment on the other side of the surface. For example, the other side environment of an exterior surface is the outdoor environment. For an interior surface, the temperature of the outer plane of the surface is set equal to the temperature of the inner plane of the surface. Similarly, a surface with other side coefficients specified will allow the user to control the other side environment.

```

Heat transfer through a surface is an extremely important component in the calculation of zone loads. The information to calculate this heat transfer is readily available if the surface is exposed to the outdoor environment or to another zone that is being simulated. Occasionally, a user will want to model the heat transfer through a surface that is adjacent to an area that is not included in the EnergyPlus model. For example, an office area is attached to a warehouse and the user is only interested in simulating the office area. An interior surface with other side coefficients specified could be used to control the environment on the other side of the surface, thereby accounting for the heat transfer through the adjoining surface.

Other Side Coefficients affects the "other side" of a surface as described below. Each coefficient has a special meaning. You may enter a 0 or blank if you are not using a particular coefficient. Note that there are two potential ways to use other side coefficients. Either they

are used to set the temperature of the exterior side surface directly (if the combined convective/radiative coefficient below is less than or equal to zero) or to set both the film coefficient (positive value for the combined convective/radiative coefficient below) and the outside air temperature.

Field: Name

This, of course, is the string referenced in the Surface statement that is using OtherSideCoefficients as the Outside Boundary Condition.

Field: Combined Convective/Radiative Film Coefficient

This is a trigger value. If the value is greater than zero, then it is taken to be the combined convective/radiative film coefficient. In this case (value > 0), the remaining fields are used first to calculate the outside air temperature for the surface and then to calculate the outside surface temperature based on the outside air temperature and the film coefficient. If this field is less than or equal to zero, then the remaining fields are used to calculate the surface temperature (not the outside air temperature). The units for this field are the same as for a convective heat transfer coefficient: $W/(m^2 \cdot K)$. This is referred to as “C1” in the reference below.

Field: Constant Temperature

This field defines a temperature term that is a constant part of the calculation either of the surface or outside air temperature. This parameter is shown as “C5” in the equation below. The units for this parameter are C. If a schedule name is included as the second parameter, the value of this parameter will be overridden by the value from the schedule.

Field: Constant Temperature Coefficient

This field defines a constant coefficient that is applied to the constant temperature (see previous field). This parameter is shown as “C4” in the equation below. This parameter is dimensionless. The value of this parameter should be 1.0 if a schedule is used to set C5.

Field: External Dry-Bulb Temperature Coefficient

This field defines a constant coefficient that is applied to the outside air dry-bulb temperature. This parameter is shown as “C3” in the equation below. This parameter is dimensionless.

Field: Ground Temperature Coefficient

This field defines a constant coefficient that is applied to the ground temperature. This parameter is shown as “C6” in the equation below. This parameter is dimensionless.

Field: Wind Speed Coefficient

This field defines a constant coefficient that is applied to the product of the outside air dry-bulb temperature and the wind speed. This parameter is shown as “C7” in the equation below. This parameter has dimensions of inverse velocity or s/m.

Field: Zone Air Temperature Coefficient

This field defines a constant coefficient that is applied to the temperature of the zone to which this surface belongs. This parameter is shown as “C2” in the equation below. This parameter is dimensionless.

Field: Constant Temperature Schedule Name

This field is used to supply a schedule name. That schedule will supply the “constant” temperature value C5. Note that the value of the C4 field should normally be 1.0 if a schedule is used for C5. Field is alpha. If not blank, it must be a valid schedule name.

Field: Sinusoidal Variation of Constant Temperature Coefficient

This field is optional and can be used to define an alternate method of prescribing the coefficient that is applied to the constant temperature (see the fields Constant Temperature and Constant Temperature Coefficient). This parameter is shown as “C4” in the equation below. If this field is omitted, left blank, or set to “No,” then C4 is a constant (defined in the field Constant Temperature Coefficient). However if this is set to “Yes,” then the value of C4 varies with a unitary sine wave in the following way:

$$C4 = \text{Sin} \left(2\pi \frac{(\text{time of day})}{(\text{period})} \right)$$

The value for “period” is controlled in the following field. The value for “time of day” is based on the zone timestep and is in units of hours. The sine function here uses input as radians. When using this option, the value for C4 will vary between -1.0 and 1.0 and the value put in the field Constant Temperature Coefficient is not used. This option cannot be used at the same time as scheduling a constant temperature with the previous field.

Field: Period of Sinusoidal Variation

This field is used to define the period of the sine wave when using the Sinusoidal Variation of Constant Temperature Coefficient capability selected in the previous field. This field is the time period of the sine wave in units of hours. The default is 24 hours and provides a diurnal sine wave. The value entered here is “period” in the equation in the previous field.

The coefficients listed above are used in the following equation:

$$T = C2 * Tzone + C3 * Toadb + C4 * C5 + C6 * Tgrnd + C7 * Wspd * Toadb$$

where:

T = Outside Air Temperature when N1 (Combined convective/radiative film Coeff) > 0

T = Exterior Surface Temperature when N1 (Combined convective/radiative film Coeff) <= 0

Tzone = Temperature of the zone being simulated (°C)

Toadb = Dry-bulb temperature of the outdoor air (°C)

Tgrnd = Temperature of the ground (°C)

Wspd = Outdoor wind speed (m/sec)

SurfaceProperty:OtherSideConditionsModel

By referencing the Other Side Conditions Model statement in the surface statements (i.e. Outside Boundary Condition), the boundary conditions for the outer plane of the mass wall can be connected to the appropriate model for various multi-skin components. The types of multi-skin components that use this object include systems that are mounted to the outside surface using standoffs that create a small air gap – see Figure 33. This type of modeling allows using the usual heat transfer calculations for the underlying surface with other types of multi-skin component models that are available including: unglazed transpired solar collectors, ventilated photovoltaic panels, and naturally ventilated facades.

The boundary condition values are determined dynamically by the program using internal component models. If you want to define other side surface temperatures or convection conditions, then use SurfaceProperty:OtherSideCoefficients instead of this object.

It should be noted that when other side conditions models are used, solar effects are removed from the surface’s outside face heat balance, but are used in modeling the component adjacent to that surface.

The IDD entry is:

```
SurfaceProperty:OtherSideConditionsModel,
  \memo This object sets up modifying the other side conditions for a surface from other model
  results.
  A1, \field Name
    \required-field

    \note and linearized thermal radiation across a gap or cavity
    \note on the other side of the surface that are modeled sperately.
```

Field: Name

This is the string referenced in the Surface statement that is using OtherSideModel as the Exterior Environment.

Field: Type of Modeling

This is a string key selection used to identify the type of model that will be used to determine boundary conditions. The only available choice is "GapConvectionRadiation."

Figure 33. Illustration for Other Side Conditions Model

An example specification is:

```
SurfaceProperty:OtherSideConditionsModel,
  UTSC OSCM ZN11, ! OtherSideConditionsModel Name
  GapConvectionRadiation; ! Type of Modeling used to determine Boundary Conditions
```

SurfaceProperty:ConvectionCoefficients

The convection coefficients of each surface, both exterior and interior, are automatically calculated during EnergyPlus execution. These calculations are “governed” by other objects such as the Inside Convection Algorithm (overall default) and the Zone Inside Convection Algorithm (Zone Default) and the Outside Convection Algorithm (overall default) and/or the Zone Outside Convection Algorithm (Zone Default). Usually, that will be enough flexibility for most users. However, if you need to match pre-existing convection coefficients (from another program) or are trying to match a test suite of results, you may wish to use the “override” convection coefficients in the following object. This object allows for a single surface to be given specific convection coefficients.

Note that surfaces with “SurfaceProperty:OtherSideCoefficients” cannot use this object with the “outside” coefficient – attempting to do so will cause a severe error; SurfaceProperty:OtherSideCoefficients surfaces can apply an “inside” coefficient. And, surfaces with “Ground” exposure do not use the “outside” coefficient that might be supplied here. Note, too, that some lower boundaries are used regardless by certain surface types (i.e. Window) or certain algorithm types.

Field: Surface Name

This field is the applicable surface name for the user supplied convection coefficient.

Fields (Convection Location, Type, Coefficient & Schedule Name)

For simplicity, the descriptions of these field occur together – however, the fields are used sequentially when put into the IDF file (reference the IDF examples following the descriptions).

Field: Convection Coefficient 1 Location

Field: Convection Coefficient 2 Location

This field contains the word “Outside” or “Inside” depending on which location is being described.

Field: Convection Coefficient 1 Type

Field: Convection Coefficient 2 Type

The entries can be of several types: value (simple value) or schedule (scheduled value) and the usual allowable types for Outside or Inside. The field contains the keys: *Value*, *Schedule*, *Simple*, *Detailed* (all of the preceding are applicable to both “Inside” and “Outside”) and allowable for “Outside”: *BLAST*, *TARP*, *DOE-2*, *MoWitt*. Please see the discussion under SurfaceConvectionAlgorithm:Inside or SurfaceConvectionAlgorithm:Outside for further explanation.

Field: Convection Coefficient 1

Field: Convection Coefficient 2

If the Convection type was “Value”, then this field is filled and contains the simple value to be used. Otherwise, this can be blank.

Field: Convection Coefficient 1 Schedule Name

Field: Convection Coefficient 2 Schedule Name

If the Convection type was “Schedule”, then this field contains the name of a schedule describing the value to be used during the time intervals for the schedule.

The complete IDD definition for the ConvectionCoefficients object follows:

```

SurfaceProperty:ConvectionCoefficients,
  \memo Allow user settable interior and/or exterior convection coefficients.
  \memo Note that some other factors may limit the lower bounds for these values, such as
  \memo for windows, the interior convection coefficient must be >.28,
  \memo for trombe wall algorithm selection (zone), the interior convection coefficient must be >.1
  \memo for detailed interior convection, the lower limit is also .1

SurfaceProperty:ConvectionCoefficients:MultipleSurface

The convection coefficients of each surface, both outside and inside, are automatically calculated during EnergyPlus execution. These calculations are “governed” by other objects such as the Inside Convection Algorithm (overall default) and the Zone Inside Convection Algorithm (Zone Default) and the Outside Convection Algorithm (overall default) and/or the Zone Outside Convection Algorithm (Zone Default). Usually, that will be enough flexibility for most users. However, if you need to match pre-existing convection coefficients (from another program) or are trying to match a test suite of results, you may wish to use the “override” convection coefficients in the following object. This object is similar to the preceding “ConvectionCoefficients” object but allows multiple surfaces to be assigned a type with one object entry.

Note that surfaces with “SurfaceProperty:OtherSideCoefficients” cannot use this object with the “outside” coefficient – attempting to do so will ignore OSC surfaces during a multiple surface “apply”; SurfaceProperty:OtherSideCoefficients surfaces can apply an “inside” coefficient. And, surfaces with “Ground” exposure do not use the “outside” coefficient that might be supplied here. Note, too, that some lower boundaries are used regardless by certain surface types (i.e. Window) or certain algorithm types.

Field: Surface Type

This field is the applicable surface name for the user supplied convection coefficient. The allowable surface types are:

- AllExteriorSurfaces (all surfaces that are “external environment” surfaces)
- AllExteriorWindows (all windows that are “external environment” surfaces)
- AllExteriorWalls
- AllExteriorRoofs
- AllExteriorFloors
- AllInteriorSurface (all surfaces that are “internal” surfaces)
- AllInteriorWindows
- AllInteriorCeilings
- AllInteriorFloors

Fields (Convection Location, Type, Coefficient & Schedule Name)

For simplicity, the descriptions of these field occur together – however, the fields are used sequentially when put into the IDF file (reference the IDF examples following the descriptions).

Field: Convection Coefficient 1 Location

Field: Convection Coefficient 2 Location

This field contains the word “Outside” or “Inside” depending on which location is being described.

Field: Convection Coefficient 1 Type

Field: Convection Coefficient 2 Type

The entries can be of several types: value (simple value) or schedule (scheduled value) and the usual allowable types for Outside or Inside. The field contains the keys: *Value*, *Schedule*, *Simple*, *Detailed* (all of the preceding are applicable to both “Inside” and “Outside”) and allowable for “Outside”: *BLAST*, *TARP*, *DOE-2*, *MoWitt*. Please see the discussion under SurfaceConvectionAlgorithm:Inside or SurfaceConvectionAlgorithm:Outside for further explanation.

Field: Convection Coefficient 1**Field: Convection Coefficient 2**

If the Convection type was “Value”, then this field is filled and contains the simple value to be used. Otherwise, this can be blank.

Field: Convection Coefficient 1 Schedule Name**Field: Convection Coefficient 2 Schedule Name**

If the Convection type was “Schedule”, then this field contains the name of a schedule describing the value to be used during the time intervals for the schedule.

The complete IDD definition for the object follows:

```
SurfaceProperty:ConvectionCoefficients:MultipleSurface,
  \memo Allow user settable interior and/or exterior convection coefficients.
  \memo Note that some other factors may limit the lower bounds for these values, such as
  \memo for windows, the interior convection coefficient must be >.28,
  \memo for trombe wall algorithm selection (zone), the interior convection coefficient must be >.1
  \memo for detailed interior convection, the lower limit is also .1

Convection Coefficients Outputs

Outputs for the User Supplied Convection Coefficients appear as values in the Surface Report Variables (*Surface Int Convection Coeff* and *Surface Ext Convection Coeff*). What the program expects to use is shown in the Surface Details report (*Report, Surfaces, Details*;))

SurfaceProperties:VaporCoefficients

Advanced/Research Usage: The internal and external vapor transfer coefficients that are used by the CombinedHeatAndMoistureFiniteElement model are automatically calculated during EnergyPlus execution using information on the convection coefficients. However it is sometimes useful to be able to “override” the calculation and set fixed values of vapor transfer coefficient for a single surface. These coefficients are only used by the CombinedHeatAndMoistureFiniteElement model and will be ignored by other solution algorithms.

Field: Surface Name

This field is the applicable surface name for the user supplied vapor transfer coefficient.

Field: Constant External Vapor Transfer Coefficient

Select ‘yes’ to use the value supplied as the external vapor transfer coefficient

Field: External Vapor Coefficient Value

HAMT will use this value to calculate the vapour transfer into and out off the external surface of this surface. Units are kg/Pa.s.m².

Field: Constant Internal vapor Transfer Coefficient

Select ‘yes’ to use the value supplied as the internal vapor transfer coefficient

Field: Internal Vapor Coefficient Value

The CombinedHeatAndMoistureFiniteElement algorithm will use this value to calculate the vapor transfer into and out of the internal surface of this surface. Units are kg/Pa.s.m².

```

SurfaceProperties:VaporCoefficients,

SurfaceProperty:ExteriorNaturalVentedCavity

This object is used to model a multi-skin exterior heat transfer surface. This is a special case where the outside face is a slightly detached layer forming a naturally ventilated cavity. The actual outer surface is referred to as the baffle. The modeling here assumes that the heat capacity in the outer baffle can be neglected since it is much lower than the underlying mass surface. This object is used with the `BuildingSurface:Detailed` object where the Heat Transfer surfaces are referred to as the underlying surfaces. The constructions and materials for the `BuildingSurface:Detailed` object should reflect the construction of just the underlying surface. The `Surface:HeatTransfer:ExteriorNaturalVentedCavity` object is used to describe the decoupled layer, or baffle, and the characteristics of the cavity and openings for natural ventilation. This object is also used in conjunction with the `OtherSideConditionsModel`.

The area and orientation are obtained from **BuildingSurface:Detailed** objects, which are referenced by name. This object can be used to model certain types of photovoltaic mounting configurations such as interlocking roof pavers. If the baffle covers only part of a surface, then that surface should be split into separate **BuildingSurface:Detailed** objects where one matches the size of the baffle. A single baffle can be associated with as many **BuildingSurface:Detailed** objects as desired (although if you need to use more than 10 surfaces, then the IDD will need to be extended). The base heat transfer surfaces need not be contiguous nor have the same orientation, but the program will issue warnings if surfaces have widely ranging tilts and azimuths.

Note that the model involves predicting the rates that ambient air moves in and out of the cavity. Accurate modeling of these air flows would be extremely challenging and so the models provided through this object are simplistic engineering models based on discharge coefficients that are sensitive to wind and bouancy effects. The accuracy depends on the

values for, and applicability of, the discharge coefficients and unfortunately little research is available to help characterize these. The models should be considered rudimentary and the user is encouraged to explore different values for the coefficients in attempts to bound the importance of natural ventilation for the cavities. See the Engineering Reference for more details.

Field: Name

This field contains a unique name for the ventilated cavity.

Field: Boundary Conditions Model Name

This field contains the name of an SurfaceProperty:OtherSideConditionsModel object declared elsewhere in the input file. This will connect the baffle and ventilated cavity to the exterior boundary conditions for the underlying heat transfer surface.

Field: Area Fraction of Openings

This field is used to enter an area fraction for what part of the baffle consists of openings. The area of the openings will set to the product of this field and the sum of the area of the underlying surfaces.

Field: Thermal Emissivity of Exterior Baffle Material

This field is used to enter the thermal emissivity of the baffle. This surface property is for longwave infrared radiation. The property is used for both sides of collector. Most painted materials have an emissivity of 0.9.

Field: Solar Absorptivity of Exterior Baffle

This field is used to enter the solar absorptivity of the baffle. This surface property is for shortwave, solar radiation. The property is used for the front side of the baffle that faces the environment. Darker colors have a higher absorptivity. While black is the highest performance, other colors might be used to match the color scheme of the rest of the façade.

Field: Height Scale for Buoyancy-Driven Ventilation

This field is used to enter a nominal height scale for prediction ventilation induced by buoyancy. This value (ΔH_{NPL}) is defined as the height from the midpoint of the lower opening to the neutral pressure level. Increasing the value will increase the ventilation rate due to buoyancy.

Field: Effective Thickness of Cavity Behind Exterior Baffle

This field is used to enter a nominal gap thickness for the collector. This distance value is only used when the collector is near horizontal to determine a length scale in the vertical direction for buoyancy calculations. For example, if the collector is mounted on a flat roof, its tilt-adjusted height is zero and the program will use this gap thickness as a length scale rather than the height from the previous field.

Field: Ratio of Actual Surface Area to Projected Surface Area

This field is used to enter a factor that accounts for the extra surface area resulting from and uneven baffle surface. Corrugations may be present to help stiffen the baffle or ventilated roofing tiles may have more surface area for convection heat transfer than the underlying surface. The projected surface area is obtained by the program from the (flat) underlying surfaces. If the baffle is flat then this ratio is 1.0. If the baffle is corrugated, then this ratio will be greater than one with a typical value might be 1.165.

Field: Roughness of Exterior Surface

This field is used to describe the relative roughness of the baffle material. This field is similar to one in the **Material** object. This parameter only influences the convection coefficients, more specifically the exterior convection coefficient. A special keyword is expected in this

field with the options being “VeryRough”, “Rough”, “MediumRough”, “MediumSmooth”, “Smooth”, and “VerySmooth” in order of roughest to smoothest options.

Field: Effectiveness for Perforations with Respect to Wind

This field is used to enter a value for the coefficient used to determine natural air exchanges from wind. Wind will cause exterior air to move in and out of the cavity. C_v is an arbitrary coefficient used to model the effectiveness of openings and depends on opening geometry and the orientation with respect to the wind. C_v should probably be in the range 0.05 to 0.65. Increasing C_v will increase the amount of natural ventilation. The following equation shows how C_v is used in the program to predict the volumetric flow rate due to wind:

$$\dot{V}_{\text{wind}} = C_v A_{in} U_{\infty}$$

Field: Discharge Coefficient for Openings with Respect to Buoyancy Driven Flow

This field is used to enter a value for the coefficient used to determine natural air exchanges from buoyancy. Stack or buoyancy effects will cause exterior air to move in and out of the cavity. C_d is an arbitrary discharge coefficient that depends on the geometry of the opening. C_d should probably be in the range 0.1 to 1.0. Increasing C_d will increase the amount of natural ventilation. The following equations show how C_d is used in the program to predict the volume flow rate due to buoyancy:

$$\dot{V}_{\text{thermal}} = C_D A_{in} \sqrt{2g\Delta H_{NPL} (T_{a,cav} - T_{amb}) / T_{a,cav}} \quad (\text{if } T_{a,cav} > T_{amb})$$

$$\dot{V}_{\text{thermal}} = C_D A_{in} \sqrt{2g\Delta H_{NPL} (T_{amb} - T_{a,cav}) / T_{amb}} \quad (\text{if } T_{amb} > T_{a,cav} \text{ and baffle is vertical})$$

where ΔH_{NPL} is the value input into the field above for the height scale for buoyancy-driven ventilation.

Field(s): Surface <1 thru x> Name

The remaining fields are used to name the **BuildingSurface:Detailed** objects that are associated with the exterior naturally vented cavity. These are the underlying heat transfer surfaces and are defined elsewhere in the input file. These surfaces should all specify **OtherSideConditionsModel** as their exterior environment. The input object can currently accommodate up to ten surfaces, but it is extensible by modifying the Energy+.idd entry.

The IDD entry for this object is:

SurfaceProperty:ExteriorNaturalVentedCavity Outputs

In addition to related output that can be obtained for all surfaces, these outputs are available for exterior naturally vented cavity configurations:

HVAC,Average, Exterior Cavity Drybulb Temperature[C]
 HVAC,Average, Exterior Baffle Temperature[C]
 HVAC,Average, Exterior Cavity Air Changes per Hour Passive[ACH]
 HVAC,Average, Exterior Cavity Total Natural Vent Mass Flow[kg/s]
 HVAC,Average, Exterior Cavity Total Natural Vent Mass Flow from Wind[kg/s]
 HVAC,Average, Exterior Cavity Total Natural Vent Mass Flow from Bouyancy[kg/s]

Exterior Cavity Drybulb Temperature[C]

The temperature of air inside the cavity behind the baffle.

Exterior Baffle Temperature [C]

The surface temperature of the exterior baffle material itself.

Exterior Cavity Air Changes per Hour Passive[ACH]

The rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive in Air Changes per Hour.

Exterior Cavity Total Natural Vent Mass Flow[kg/s]

The mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive.

Exterior Cavity Total Natural Vent Mass Flow from Wind[kg/s]

The part of mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive due to wind-driven forces.

Exterior Cavity Total Natural Vent Mass Flow from Bouyancy[kg/s]

The part of mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive due to bouyancy-driven forces.

GeometryTransform

This object provides a simple method of altering the footprint geometry of a model. The intent is to provide a single parameter that can be used to reshape the building description contained in the rest of the input file. This object was implemented for use in parametric massing studies and with the optimization program GenOpt. Although building footprint is often constrained in practice, analysts may find this object useful for investigating how building form impacts daylighting and solar gains on the east and west facades with out having to change all of the surface geometry input.

Aspect Ratio is defined as the overall length in the East-West direction divided by the overall length in the North-South direction.

This object should be used with considerable care since it will completely alter the geometry modeled by EnergyPlus and may have unintended side effects. The surface areas of all horizontal surfaces may change radically with corresponding changes in Zone floor areas. The total floor area will not change but individual horizontal surfaces will gain and loose area. Vertical surfaces will have the same height but will gain and lose length. Lighting and electrical equipment design levels for individual zones will likely have a different energy per unit area in the transformed geometry.

The surface geometry must be set to **Relative**, see **GlobalGeometryRules**. Of course, the coordinates must be entered in relative coordinates as well.

Since windows in EnergyPlus need to be rectangular, it is possible to define a horizontal window (skylight) that once transformed is no longer rectangular and will cause EnergyPlus to halt. To avoid this problem, horizontal windows should be defined orthogonal to the

Cardinal directions and building rotation (see **Building**) used to orient the final form with respect to North.

The object doesn't create any specific output, but the results of using it can be understood by viewing DXF output files. Figure 34 shows an example of a building that has been morphed using the Aspect Ratio Transform object. Using this object allowed the same geometry input to generate both of the models represented in by their DXF output files.

Figure 34. Example of Geometry Transform -- Aspect Ratio

The definition from the IDD:

```

GeometryTransform,
  \unique-object
  A1, \field Plane of Transform
      \required-field
      \type choice
      \key XY
      \default XY
      \note only current allowed value is "XY"
  N1, \field Current Aspect Ratio
      \required-field
      \minimum> 0
      \note Aspect ratio of building as described in idf
  N2; \field New Aspect Ratio
      \required-field
      \minimum> 0
      \note Aspect ratio to transform to during run

```

Field: Plane of Transform

This field specifies the plane that the geometry transform should act on. It is currently restricted to altering the horizontal footprint of a building and must be set to "XY."

Field: Current Aspect Ratio

This field specifies the aspect ratio of the building geometry described in the rest of the input file. It is used to scale the new aspect ratio. If this field is set to 1.0, then the altered building will not necessarily have the new aspect ratio defined in the next field.

Field: New Aspect Ratio

This field specifies the aspect ratio that the building described in the rest of the input file will be changed to.

ZoneProperty:UserViewFactors

EnergyPlus has two options for specifying the thermal radiation exchange view factors between surfaces in a zone: the approximate option and the user input option. Because the actual geometric arrangement within a zone is very complex, the approximate method of including thermal mass and other forced exchanges is more realistic than trying to come up with “exact” view factors. However, in some research situations it might be desirable to have control of the view factors used. For this reason, a user input mode has been included in EnergyPlus. The two modes are described in the next sections.

Approximate Option

The first option produces approximate results and uses an area weighted scheme to calculate "view factors" between surfaces within a thermal zone. Each surface uses the total area that it can “see” among the other surfaces. The approximate view factor from this surface to each other surface is then the area of the receiving surface over the sum of areas that are visible to the sending surface.

In order to account in some limited way for the fact that certain surfaces will not see each other, several assumptions have been built into this view factor approximation. First, a surface cannot see itself. Second, surfaces with approximately the same azimuth (facing direction) and tilt ("same" being within a built in limit) will not see each other. This means that a window will not see the wall that it is placed on, for example. Third, floors cannot see each other. Fourth, if the surface is a floor, ceiling, roof, or internal mass, the rule for the same azimuth and tilt eliminating radiant exchange between surfaces is waived when the receiving surface is floor, roof, ceiling, or internal mass as long as both surfaces are not floors.

Note that this does not take into account that surfaces may be "around the corner" from each other and in reality not see each other at all. Rooms are assumed to be convex rather than concave in this method.

To summarize, using the Surface “Class”, the approximate view factors have:

1. No surface sees itself.
2. No Floor sees another floor.
3. All other surface types see Internal Mass.
4. All other surface types see floors.
5. Floors always see ceilings.
6. Floors always see roofs.
7. All other surfaces whose tilt or facing angle differences are greater than 10 degrees see each other.

If geometry is correct, conditions 1,3, and 7 should take care of all surfaces, but the other conditions supply common sense when the geometry is incorrect. More information about the EnergyPlus view factor calculation is contained in the Engineering Reference document.

User Input View Factors

The second option for specifying view factors requires user input values. These should be used with care in research or special situations. The input values are specified in an object named UserViewFactors in the idd and idf. They are identified by their row and column

number in the view factor array. In other words, the view factor is traditionally $F_{i,j}$, and the value along with i and j are specified in the idf . A segment of the idd is shown below.

```
ZoneProperty:UserViewFactors,
  \extensible:3 - copy last three fields, remembering to remove ;
  \format ViewFactor
A1, \field Zone Name
  \type alpha
  \reference ZoneNames
N1, \field i 1
  \note index for following Fij
  \note the view factor numbers are triples in the order i, j, Fij.
  \type integer
N2, \field j 1
  \note index for following Fij
  \note the view factor numbers are triples in the order i, j, Fij.
  \type integer
N3, \field Fij 1
  \type real
  \maximum 1.0
--reduced for brevity --
N70, \field i 24
  \note index for following Fij
  \note the view factor numbers are triples in the order i, j, Fij.
  \type integer
N71, \field j 24
  \note index for following Fij
  \note the view factor numbers are triples in the order i, j, Fij.
  \type integer
N72; \field Fij 24
  \type real
  \maximum 1.0
```

An example idf object is shown below. Note that the alpha field is the zone name for which the view factors apply.

```
ZoneProperty:UserViewFactors,
  ! example with unrealistic view factors that show
  ! a scheme for checking the input.
core,          ! zone name
1,1,.11,      ! triple of i, j, and Fij
1,2,.12,
1,5,.15,
2,2,.22,
2,3,.23,
4,2,.42,
4,5,.45,
5,1,.51,
5,6,.56,
3,6,.36,
4,6,.46,
6,5,.65,
6,4,.64;
```

In order to get user view factors ready for inclusion in an input file, several steps must be taken. First, because EnergyPlus has a data structure for zones that only is defined at initialization, it is necessary to use EnergyPlus to determine the surface numbers (i,j) before a UserViewFactors object can be constructed. This is done by making a run with a special object. This takes the form:

```
Output:Reports,Surfaces,ViewFactorInfo;
```

This will trigger EnergyPlus to produce a special output section in the file `eplusout.eio`. This file, which is csv format, can be opened in Excel, and will show detailed information about the surfaces in all the zones. The example and procedure for using this information is shown in the Output Details and Examples Document.

Group – Room Air Models

Room Air Models

The group of input objects described in this section is used to account for non-uniform room air temperatures that may occur within the interior air volume of a zone. Room air modeling was added to EnergyPlus starting with Version 1.2. Although there are many types of analyses (comfort, indoor air quality, etc) that might benefit from localized modeling of how room air varies across space, only the *temperature* distribution of room air within the zone is currently addressed in EnergyPlus. This allows surface heat transfer and air system heat balance calculations to be made taking into account natural thermal stratification of air and different types of intentional air distribution designs such as under-floor and side-wall displacement ventilation that purport to extract room air at higher-than-mean temperatures. Note that EnergyPlus does **not** have completely general methods of modeling room air that are applicable to every conceivable type of airflow that might occur in a zone. Such models (e.g. RANS-CFD) are too computationally expensive to use with EnergyPlus for the foreseeable future. The models that are available in EnergyPlus offer only limited modeling capabilities for select room airflow configurations. Also note that because the complete mixing model for room air has long been the standard in building energy simulation, there is not currently a consensus on how to best model non-uniform air temperatures in buildings. Therefore, it is up to the user to have a good understanding of when, where, and how to apply the room air models available in EnergyPlus. The rest of this section provides some guidance in the way of examples and further discussion of the models available in EnergyPlus.

EnergyPlus offers the different types of air models listed in the table below along with the input objects associated with the use of that model.

Table 8. Summary of Room Air Models

Air Model Key	Air model Algorithm	Applicability	Input Objects Required
Mixing	Well-Mixed	All zones	None, default
UserDefined	User Defined	All zones	'RoomAirModelType', 'RoomAir:TemperaturePattern:UserDefined', RoomAir:TemperaturePattern:***'
OneNodeDisplacementVentilation	Mundt	displacement ventilation	'RoomAirModelType', 'RoomAirSettings:OneNodeDisplacementVentilation', 'RoomAir:Node'
ThreeNodeDisplacementVentilation	UCSD Displacement Ventilation	displacement ventilation	'RoomAirModelType', 'RoomAirSettings:ThreeNodeDisplacementVentilation'
UnderFloorAirDistributionInterior	UCSD UFAD Interior Model	Interior zones served by a UFAD system	'RoomAirModelType', 'RoomAirSettings:UnderFloorAirDistributionInterior'
UnderFloorAirDistributionExterior	UCSD UFAD Exterior Model	Exterior zones served by a UFAD system	'RoomAirModelType', 'RoomAirSettings:UnderFloorAirDistributionExterior'
CrossVentilation	UCSD Cross Ventilation	cross ventilation	'RoomAirModelType', 'RoomAirSettings:CrossVentilation'

RoomAirModelType

EnergyPlus uses the RoomAirModelType object to determine which air model is available for use in a given zone during the simulation. If no RoomAirModelType object is specified (for each zone or the whole building), then EnergyPlus will run with the conventional, completely mixing air model (for each zone or the whole building). Include a RoomAirModelType for each zone that the user wants modeled using a more detailed method. Currently only a single RoomAirModelType object can be specified for each zone; you cannot switch between models during a simulation. However, the UCSD Displacement, Cross Ventilation and UFAD models switch from displacement to mixing ventilation when the operating conditions do not give rise to unmixed flow. The following parameters are fields required by the RoomAirModelType object.

Field: Name

This alpha field is the air model name selected by user. It is used as an identifier

Field: Zone Name

This alpha field indicates the unique name of a Zone object defined elsewhere in the input file. The type of room air model selected will be applied to this zone.

Field: Room-Air Modeling Type

This alpha field indicates the room-air model used for the specified zone. Currently, there are three options for different air models. Entering the keyword 'Mixing' specifies the conventional complete-mixing air model. Note that Mixing is the default and no RoomAirModelType object would be needed to use the complete-mixing model. Entering the keyword 'UserDefined' specifies the User Defined Room Air Temperature Patterns. Entering the keyword 'OneNodeDisplacementVentilation' specifies the Mundt one node displacement ventilation air model for displacement ventilation. Entering the keyword 'ThreeNodeDisplacementVentilation' specifies the three-node displacement ventilation model developed by the University of California, San Diego (UCSD DV). Entering the keyword 'CrossVentilation' specifies the two-zone cross ventilation model developed by the University of California, San Diego (UCSD CV). Entering the keyword 'UnderFloorAirDistributionInterior' specifies the two-node interior zone under floor air distribution model developed by the University of California, San Diego (UCSD UFI). Entering the keyword 'UnderFloorAirDistributionExterior' specifies the two-node exterior zone under floor air distribution model developed by the University of California, San Diego (UCSD UFE).

Field: Air Temperature Coupling Strategy

This alpha field indicates how air temperatures predicted by the air models are used by the surface heat balance calculation. Two different coupling schemes are available: Direct (also known as *T-couple*) or Indirect (*DT-couple*). In general, indirect coupling is more suited to situations where room air is well controlled and/or the room air model is less robust. Direct coupling is more suited for floating zone air temperatures and/or accurate room air models.

The Mundt model can use either coupling scheme; the UCSD DV, UCSD CV, UCSD UFI, and UCSD UFE models ignore this field and use direct coupling.

Input either *Direct* or *Indirect*

RoomAir:TemperaturePattern:UserDefined

This object is used to explicitly define temperature patterns that are to be applied to the mean air temperature within a thermal zone. This Room Air modeling option is made available for a number of reasons. It allows modeling the consequences of air temperature variations during the design phase when little information is available about the specifics of the air distribution system or positioning of various loads. This option can be used to evaluate the energy implications of different design targets for the temperature patterns. It also provides a method of modeling the annual energy use implications for air temperature distributions determined using separate analyses or measurements. For example, this option could be used to understand the annual energy implications of an air distribution system that has been previously analyzed using Computational Fluid Dynamics.

This approach differs from the other Room Air modeling in that the static temperature pattern is not really *modeled* so that it will respond to conditions that develop during the simulation. More sophisticated dynamic Room Air models will adjust the temperature pattern based on various factors, such as air system flow rate, floor temperature, or rates of internal heat gains. The user-defined temperature distribution patterns are fixed at the beginning and EnergyPlus simply provides results that include the implications of those patterns. This user-defined

distribution option may also be useful for checking dynamic Room Air models by using “bounding” analysis.

Note that using this object carries a certain degree of responsibility. It would be very easy to define a pattern that is non-physical and will lead to erroneous results. The user-defined temperature distributions should (probably) be balanced about the mean so that basic conservation of energy laws are not violated.

Field: Name

This field provides a unique name for this object.

Field: Zone Name

This field provides the unique name of a zone described elsewhere in the file.

Field: Availability Schedule Name

This field provides the name of a schedule that will determine if this model is available. When not available the room air is modeled as completely mixed. When it is available, then a user-defined temperature distribution will be applied. This schedule should be set to “1.0” when model is available and “0.0” when the model is not to be used.

Field: Pattern Control Schedule Name

This field provides the name of schedule that will be used to control which user-defined RoomAir temperature pattern will be applied at any given time. This schedule needs to have integer values that are closely coordinated with those defined as the second field in one of the RoomAir:TemperaturePattern:* objects described below. These schedule values provide the link to the actual patterns to be used throughout the day. This allows controlling which user-defined pattern is used at different times during the simulation. For example, one could use one pattern when the air system is scheduled to be on, and a different pattern when the air system is schedule to be off. Or if the user has knowledge of how the air temperature pattern changes over the course of day in response to changing thermal loads, then this schedule can be used to control when individual patterns are used. For example, a control schedule could use a pattern designated as number 100 from 18:00 to 6:00, pattern number 200 from 6:00 to 12:00, and pattern number 300 from 12:00 to 18:00.

RoomAir:TemperaturePattern:ConstantGradient

This object is used to model room air with a fixed temperature gradient in the vertical direction. This fixed-slope method is about the simplest distribution pattern.

In addition to the vertical temperature gradient, there are three other parameters included in the pattern that are important. The first two might affect how the air system conditioning the room is operated. The first describes the temperature difference between the mean air temperature and the point where the sensor of a drybulb thermostat is situated. The second describes the temperature difference between the mean and the point where system air is being extracted from the zone. This is considered important because the changes in temperature difference between supply and return can affect how an air system is controlled to meet the loads. The third parameter can affect the zone air heat balance by altering the temperature of the air leaving the zone through exhaust fans.

One example of a source of input data for the vertical temperature gradient is ANSI/ASHRAE Standard 55-2004 Thermal Environmental Conditions for Human Occupancy. Table 5.2.4.3 in this Standard specifies an allowable vertical temperature difference between head level and ankle level of 3°C (5°F). If we assume a head to ankle length scale of 1.5 m (5 ft), this leads to a temperature gradient of 3°C/1.5m, or 2.0 °C/m.

Field: Name

This field provides a unique name for this object.

Field: Control Integer for Pattern Control Schedule Name

This field should contain an integer value that is unique among all other RoomAir:TemperaturePattern:* objects. The value used here needs to be in the Pattern Control Schedule for those times when this pattern is to be used for the Room Air Temperature Distribution.

Field: Thermostat Offset

This field specifies the temperature difference between where the thermostat is situated and the mean air temperature.

Field: Return Air Offset

This field specifies the temperature difference between the air leaving the zone and returning to the air system and the mean air temperature.

Field: Exhaust Air Offset

This field specifies the temperature difference between the air leaving the zone and being exhausted out of the building and the mean air temperature.

Field: Temperature Gradient

This field specifies the gradient, or slope, of temperature changes in the vertical direction in °K/m.

```

RoomAir:TemperaturePattern:TwoGradient

This object provides various controls over the value of the gradient used for determining the pattern of room air temperatures. It is similar to previous object RoomAir:TemperaturePattern:ConstantGradient object but simplifies the potentially arduous task of preparing and scheduling a large number of those objects. With this object, two different gradients are entered and user is given several options for controlling how the program will interpolate between the two bounds. The user inputs the height of the location of thermostat, return air, and exhaust air in meters rather than the temperature offset.

Field: Name

This field provides a unique name for this object.

Field: Control Integer for Pattern Control Schedule Name

This field should contain an integer value that is unique among all other RoomAir:TemperaturePattern:* objects. The value used here needs to be in the Pattern Control Schedule for those times when this pattern is to be used for the Room Air Temperature Distribution.

Field: Thermostat Height

This field specifies the distance above the floor where the thermostat is situated. This height is used by the model to determine the thermostat temperature relative to the mean air temperature by applying the gradient.

Field: Return Air Height

This field specifies the distance above the floor where the air leaves the zone and returns to the air system, and the mean air temperature. This height is used by the model to determine the return air temperature relative to the mean air temperature by applying the gradient.

Field: Exhaust Air Height

This field specifies the distance above the floor where the air leaves the zone and enters an exhaust device such as an exhaust fan. This height is used by the model to determine the exhaust air temperature relative to the mean air temperature by applying the gradient.

Field: Temperature Gradient Lower Bound

This field specifies the gradient, or slope, of temperature changes in the vertical direction in °C/m.

Field: Temperature Gradient Upper Bound

This field specifies the gradient, or slope, of temperature changes in the vertical direction in °C/m.

Field: Gradient Interpolation Mode

This field specifies how the program will vary between the two gradients. Select one of the following keywords to choose the simulation data used to scale: 'Outdoor Environment Drybulb Temperature', 'Zone Drybulb Temperature', 'Delta Outdoor and Zone Temperature', 'Sensible Cooling Load', and 'Sensible Heating Load'. These are explained in detail below. All of these options have several things in common. They are essentially hard-coded. There is no support for a general method. The interpolation scheme is based on some variable that might reasonably be expected to correlate with gradient changes. This variable's current value is used to continually adjust the value of the vertical gradient for room air temperature.

OutdoorDryBulbTemperature: This key directs the program to interpolate between upper and lower values of the vertical gradient based on the outdoor air temperature. If the outdoor temperature exceeds the upper limit set in the next field, then the gradient entered in the 'Temperature Gradient Upper Bound' field is used. Similarly if the outdoor air temperature is below the value set in the 'Lower Temperature' field, then the gradient entered in the 'Temperature Gradient Lower Bound' is used. For outdoor temperatures that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.

ZoneDryBulbTemperature: This key directs the program to interpolate between upper and lower values of the vertical gradient based on the mean zone air temperature. If the mean zone air temperature exceeds the upper limit set in the next field, then the gradient entered in the 'Temperature Gradient Upper Bound' field is used. Similarly if the mean zone air temperature is below the value set in the 'Lower Temperature' field, then the gradient entered in the 'Temperature Gradient Lower Bound' is used. For mean zone air temperatures that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.

ZoneAndOutdoorTemperatureDifference: This key directs the program to interpolate between upper and lower values of the vertical gradient based on the difference between the outdoor environment and the mean zone air temperature. If the temperature difference exceeds the upper limit set in the next field, then the gradient entered in the 'Temperature Gradient Upper Bound' field is used. Similarly if the temperature difference is below the value set in the 'Lower Temperature' field, then the gradient entered in the 'Temperature Gradient Lower Bound' is used. For temperature differences that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.

SensibleCoolingLoad: This key directs the program to interpolate between upper and lower values of the vertical gradient based on the sensible cooling load. If the cooling load exceeds the upper limit set in the next field, then the gradient entered in the 'Temperature Gradient Upper Bound' field is used. Similarly if the cooling load is below the value set in the 'Lower

Temperature' field, then the gradient entered in the 'Temperature Gradient Lower Bound' is used. For cooling loads that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.

SensibleHeatingLoad: This key directs the program to interpolate between upper and lower values of the vertical gradient based on the sensible heating load. If the heating load exceeds the upper limit set in the next field, then the gradient entered in the 'Temperature Gradient Upper Bound' field is used. Similarly if the heating load is below the value set in the 'Lower Temperature' field, then the gradient entered in the 'Temperature Gradient Lower Bound' is used. For heating loads that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.

Field: Upper Temperature Bound

This field is used to enter the upper bound on temperature values in Celsius. It is required for the interpolation modes based on temperature.

Field: Lower Temperature Bound

This field is used to enter the lower bound on temperature values in Celsius. It is required for the interpolation modes based on temperature.

Field: Upper Heat Rate Bound

This field is used to enter the upper bound on heat rate values. It is required for the interpolation modes based on load. Both heating and cooling loads are entered as positive numbers (in watts).

Field: Lower Heat Rate Bound

This field is used to enter the lower bound on heat rate values. It is required for the interpolation modes based on load. Both heating and cooling loads are entered as positive numbers (in watts).

An example of this object follows. This pattern will apply no gradient (effectively the mixing model) if zone air temperatures are 22.5 C or lower. It will apply a gradient of 1 degree Celsius per meter if zone temperatures are 26.0 C or higher. For zone air temperatures between 22.5 and 26.0 it will determine the gradient by linear interpolation and use a gradient between 0.0 and 1.0 C/m depending on where the zone air temperature is in the range.

RoomAir:TemperaturePattern:NondimensionalHeight

This object defines a distribution pattern for air temperatures relative to the current mean air temperature as a function of height. The height, referred to as Zeta, is non-dimensional by normalizing with the zone ceiling height. (The actual zone ceiling height can be explicitly entered in the 'Zone' object but if not it is calculated by EnergyPlus from the surfaces attached to the zone.) The temperature differences are not non-dimensional and remain in units of degrees Celsius.

An example of a vertical temperature pattern is shown in the figure below. The pattern itself is treated as a piecewise, linear model of air temperature as a function of height. This Zeta-DeltaTai curve, or lookup table, is then mapped to surfaces defined elsewhere in the file. The centroid of each surface and zone ceiling height are used to automatically assign Zeta values within the program. The zone named in the referencing RoomAir:TemperaturePattern:UserDefined object is used to determine which surfaces will be associated with the pattern when it is applied. A single pattern object can be reused for multiple zones and times.

In addition to the vertical temperature pattern there are three other parameters included in the pattern that are important. The first two might affect how the air system conditioning the room is operated. The first describes the temperature difference between the mean air temperature and the point where the sensor of a drybulb thermostat is situated. The second describes the temperature difference between the mean and the point where system air is being extracted from the zone. This is considered important because the changes in temperature difference between supply and return can affect how an air system is controlled to meet the loads. The third parameter can affect the zone air heat balance by altering the temperature of the air leaving the zone through exhaust fans.

Figure 35. Example of a Vertical Air Temperature Pattern

Field: Name

This field provides a unique name for this object.

Field: Control Integer for Pattern Control Schedule Name

This field should contain an integer value that is unique among all other RoomAir Temperature Pattern objects. The value used here needs to be in the Pattern Control Schedule for those times when this pattern is to be used for the Room Air Temperature Distribution.

Field: Thermostat Offset

This field specifies the temperature difference between where the thermostat is situated and the mean air temperature.

Field: Return Air Offset

This field specifies the temperature difference between the air leaving the zone and returning to the air system and the mean air temperature.

Field: Exhaust Air Offset

This field specifies the temperature difference between the air leaving the zone and being exhausted out of the building and the mean air temperature.

Field Set Zeta and Temperature Difference

The remaining fields contain pairs of values that define a lookup table for the temperature pattern in the vertical direction. The first value is Zeta and the second value is DeltaTai. This object is extensible, by duplicating the last two fields and revising the IDD – note that you will have to replace “inner” semi-colons with commas.

Field: Pair <#> Zeta non-dimensional Height

Zeta is the normalized height and should be a fractional value from 0.0 to 1.0. A value of 0.0 corresponds to the floor and a value of 1.0 corresponds to the ceiling. The Zeta values need to be in increasing value.

Field: Pair <#> Delta Adjacent Air Temperature

DeltaT_{ai} is the temperature difference between the air temperature at the associated Zeta (T_{ai}) and the mean air temperature and is given in degrees Celsius.

The idd entry for this object is:

RoomAir:TemperaturePattern:SurfaceMapping

This object defines a distribution pattern for the air temperatures adjacent to individual surfaces. This object uses the specific names of individual surfaces defined elsewhere in the model. This pattern allows controlling the adjacent air temperature on a surface-by-surface basis rather than by height. This allows modeling different adjacent air temperatures on the opposite sides of the zone.

In addition to the surface mappings there are three other parameters included in the pattern that are important. The first two might affect how the air system conditioning the room is operated. The first describes the temperature difference between the mean air temperature and the point where the sensor of a drybulb thermostat is situated. The second describes the temperature difference between the mean and the point where system air is being extracted from the zone. This is considered important because the changes in temperature difference between supply and return can affect how an air system is controlled to meet the loads. The third parameter can affect the zone air heat balance by altering the temperature of the air leaving the zone through exhaust fans.

Field: Name

This field provides a unique name for this object.

Field: Control Integer for Pattern Control Schedule Name

This field should contain an integer value that is unique among all other RoomAir Temperature Pattern objects. The value used here needs to be in the Pattern Control Schedule for those times when this pattern is to be used for the RoomAir Temperature Distribution.

RoomAir:Node

The RoomAir:Node object is used to define air nodes for a nodal air model. The number of air node objects that need to be specified depends on the nodal air model selected. (However, currently only the Mundt model uses this object). In order to use the Mundt model, the user must specify six or more RoomAir:Node objects of different types for each zone. The exact number of RoomAir:Node in the model will vary based on the resolution of walls. If walls (heat transfer surfaces) are split into separate segments in the vertical direction, then more air nodes of type 'MundtRoom' will be useful. At a minimum, for the Mundt model RoomAir Nodes of the following type are required: 'Inlet', 'Floor', 'Control', 'Ceiling', 'MundtRoom', and 'Return.'

Field: Name

This alpha field is a name for the air node. It should be unique and is used as an identifier

Field: Node Type

This alpha field indicates the type of this air node. The following explains options available for use with the Mundt nodal air model.

Inlet is specified for the air node located where the system air enters the zone.

Floor is specified for the air node located near the floor.

Control is specified for the air node located near the thermostat.

Ceiling is specified for the air node located near the ceiling.

MundtRoom is specified for the air node located adjacent to the wall(s).

Return is specified for the air node located where the system air leaves the zone.

Field: Zone Name

This field indicates the name of the zone (Ref: Zone) that this air node belongs to. This should be the unique name of a zone object defined elsewhere in the input file.

Field: Height of Nodal Control Volume Center

This numeric field indicates the height of the air node center. Air models such as the Mundt model compute the air temperature as a function of height and the value entered here will be used to determine a result for this node. The value should be specified in meters and relative to the floor of the zone.

Field: Surface <#> Name

These remaining alpha fields indicate the names of the surfaces (Ref: Surface) that are interacting convectively with this air node. This field is optional and related to the previous field. Currently, at most 20 surfaces are allowed to interact with a single air node. Only those nodes that interact with the inside faces of surfaces need to specify surface names. Each surface should couple to no more than 1 node.

The idd entry follows.

```

RoomAirSettings:OneNodeDisplacementVentilation

The RoomAirSettings:OneNodeDisplacementVentilation object is used to specify additional input parameters required by the Mundt model that are not available in other input objects in EnergyPlus. A single object will be used for the zone.

Field: Zone Name

This alpha field indicates the name of the zone (Ref: Zone) for the required input parameters as specified in the following fields.

Field: Fraction of Convective Internal Loads Added to Floor Air

This numeric field indicates what fraction of the convective part of the internal gains is added to the air near the floor in the zone specified.

Field: Fraction of Infiltration Internal Loads Added to Floor Air

This numeric field indicates what fraction of the infiltration air enters near the floor in the zone specified.

The idd entry follows:

RoomAirSettings:ThreeNodeDisplacementVentilation

This model is applicable to spaces that are served by a low velocity floor-level displacement ventilation air distribution system. Furthermore, the dominant sources of heat gain should be from people and other localized sources located in the occupied part of the room. The model should be used with caution in zones which have large heat gains or losses through exterior walls or windows or which have considerable direct solar gain. The model predicts three temperatures in the room:

- A foot level temperature (T_{FLOOR}). The floor region is 0.2 meters deep and T_{FLOOR} represents the temperature at the mid-point of the region.
- An occupied subzone temperature (T_{OC}), representing the temperature in the region between the floor layer and the upper, mixed layer.
- An upper node representing the mixed-layer/outflow temperature (T_{MX}) essential for overall energy budget calculations and for modeling comfort effects of the upper layer temperature.

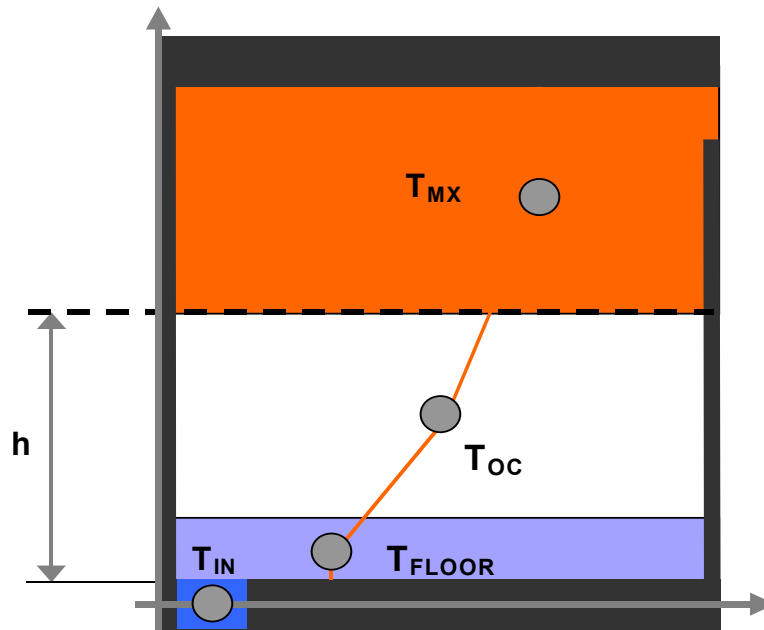

Figure 36. Schematic representation of the three temperature points and temperature gradients

The following fields are used to define an instance of the 'UCSD Displacement Ventilation Model Controls' object.

Field: Zone Name

This field provides the unique name of a zone described elsewhere in the file. A single instance of the 'UCSD Displacement Ventilation Model Controls' object is needed for each zone that is to be modeled using this method.

Field: Gain Distribution Schedule Name

This field specifies the unique name of schedule defined elsewhere in the input file. The schedule values are the fractions of the convective portion of the internal gains in the occupied subzone that remain in the occupied subzone. The remainder of the convective portion of the internal gains in the occupied subzone enters the plumes and is carried to the upper subzone. The types of internal gains that are assumed to be located in the occupied subzone are:

- people
- task lights
- electric equipment
- gas equipment
- hot water equipment
- steam equipment
- other equipment
- baseboard heat

Types of internal gains that are assumed to be in the upper subzone are:

- general lights
- tubular daylighting devices
- high temperature radiant heaters

The schedule values should be between 0 and 1. A value of 1 means that all the convection gains from equipment, task lights and people are dispersed in the lower occupied subzone. Conversely a value of 0 puts all the lower subzone convective gains into the plumes rising into the upper well-mixed subzone.

Field: Number of Plumes per Occupant

This field specifies number of plumes per occupant. Plumes are associated with localized sources of convective heat gain from people and equipment. For example, a value of 2.0 would be used if each occupant has a computer that generates a separate plume that does not merge with the plume from the occupant in the lower, occupied, subzone.

Field: Thermostat Height

This field is the height in meters of the thermostat/temperature control sensor above the floor.

Field: Comfort Height

The height in meters above the floor at which air temperature is calculated for comfort purposes. The air temperature at this height is used in calculating the available measures of comfort: Fanger, Pierce or KSU. The default is 1.1 meters.

Field: Temperature Difference Threshold for Reporting

This field specifies a minimum temperature difference between the upper mixed subzone and the occupied subzone that will be used to trigger whether or not the displacement ventilation auxiliary outputs will be calculated. These outputs are *DV Transition Height*, *DV Fraction Min Recommended Flow Rate*, *DV Average Temp Gradient* and *DV Maximum Temp Gradient*. They are set to negative values when the temperature difference is less than the threshold and the output *DV Zone Is Mixed* is set to 1.

The value should be greater than or equal to zero and is in units of degrees Centigrade. The default value is 0.4 degrees C.

The idd for this object follows.

RoomAirSettings:CrossVentilation

This UCSD Cross Ventilation Room Air Model provides a simple model for heat transfer and vertical temperature profile prediction in cross ventilated rooms. The model distinguishes two regions in the room, the main jet region and the recirculations, and predicts characteristic airflow velocities and average air temperatures. Cross Ventilation (CV) is common in many naturally ventilated buildings, with air flowing through windows, open doorways and large internal apertures across rooms and corridors in the building.

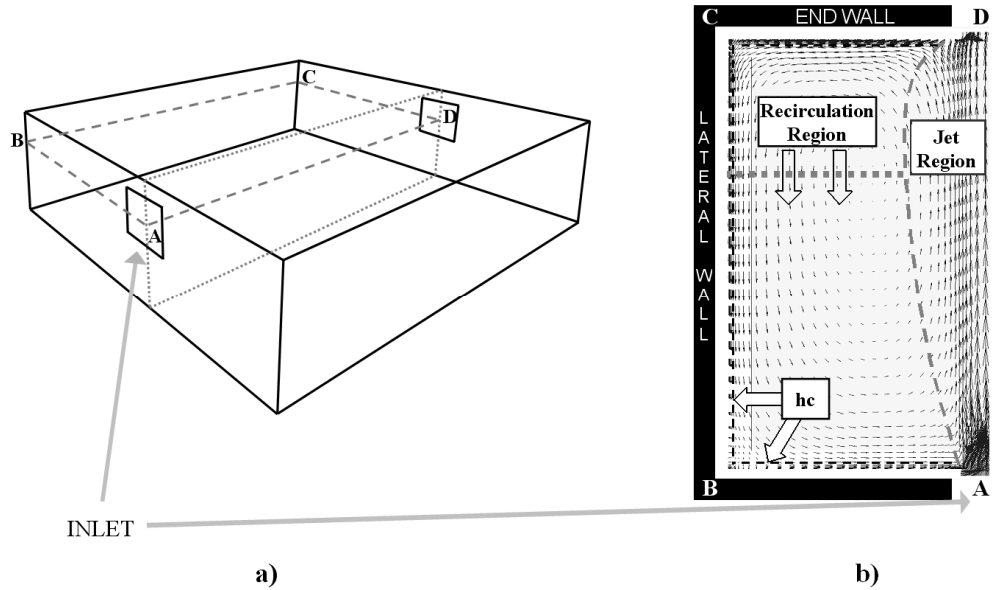

Figure 37. Schematic representation of room air geometry a) schematic representation of a room geometry that generates cross ventilation airflow. b) the proposed model distinguishes two regions in the flow: jet and recirculation (shown here in a CFD simulation of one half of a symmetrical room).

Figure 38. Schematic top view –possible airflow patterns in cross-ventilation.

The following fields are used to define an instance of the 'UCSD Cross Ventilation Model Controls' object.

Field: Zone Name

This field provides the unique name of a zone described elsewhere in the file. A single instance of the 'UCSD Cross Ventilation Model Controls' object is needed for each zone that is to be modeled using this method.

Field: Gain Distribution Schedule Name

This field specifies the unique name of schedule defined elsewhere in the input file. The schedule values are the fractions of the convective portion of the internal gains in the jet and recirculation regions.

The schedule values should be between 0 and 1. A value of 1 means that all the convective gains are dispersed in the jet region. Conversely a value of 0 puts all the convective gains into the recirculation region.

Field: Airflow Region Used for Thermal Comfort Evaluation

Required field whenever thermal comfort is predicted defines air temperature and mean airflow velocity that will be used in the Fanger model conditions must refer to one of the two regions defined in the model: jet or recirculation. Possible choices: **Jet** or **Recirculation**.

```

RoomAirSettings:UnderFloorAirDistributionInterior

This model is applicable to interior spaces that are served by an underfloor air distribution system. The dominant sources of heat gain should be from people, equipment, and other localized sources located in the occupied part of the room. The model should be used with caution in zones which have large heat gains or losses through exterior walls or windows or which have considerable direct solar gain. The model predicts two temperatures in the room:

- An occupied subzone temperature (T_{OC}), representing the temperature in the region between the floor and the boundary of the upper subzone..
- An upper subzone temperature (T_{MX}) essential for overall energy budget calculations and for modeling comfort effects of the upper layer temperature.

The following fields are used to define an instance of the 'UCSD UFAD Interior Model Controls' object.

Field: Zone Name

This field provides the unique name of a zone described elsewhere in the file. A single instance of the 'RoomAirSettings:UnderFloorAirDistributionInterior' object is needed for each zone that is to be modeled using this method.

Field: Number of Diffusers

The total number of diffusers in this zone. This field can be allowed to Autocalculate (in which case it is set to the design occupancy level; i.e., number of people). If the design occupancy is low or zero but there are still heat sources that could generate buoyancy driven plumes, the user should input a value based on the design supply air flow rate of the zone and the design flow rate of an individual diffuser. In the absence of any other information, divide the zone area by 100 ft². The default for this field is Autocalculate.

Field: Power per Plume

The power in watts incorporated in a buoyancy driven thermal plume. Normally we assume all the loads of a workstation create a single plume so that this represents the convective heat gain from a workstation – 1 person, 1 computer terminal, plus any task lighting. A typical value would be 220 watts. However, the model assumes an “equivalent” plume derived from the zone extraction rate normalized to the number of workstations/occupants. This field should be allowed to default – the program will calculate a value based upon the occupancy and the extraction rate. The default is Autocalculate.

Field: Design Effective Area of Diffuser

This is the design air flow opening area in square meters of a single diffuser. The default value depends on the diffuser type. For swirl diffusers it is 0.075 m², for variable area diffusers 0.035 m², for horizontal swirl diffusers 0.006 m², and for linear bar grilles 0.03 m². The default is *Autocalculate*.

Field: Diffuser Slot Angle from Vertical

This input describes the angle at which air emerges from the diffusers. It should be the angle in degrees between the vertical and the diffuser slots. The defaults depend on the diffuser type: for swirl diffusers it is 28 degrees, for variable area diffusers 45 degrees, for DV diffusers 73 degrees, and for linear bar grilles 15 degrees.

Field: Thermostat Height

This field is the height in meters of the thermostat/temperature control sensor above the floor. The default is 1.2 meters.

Field: Comfort Height

The height in meters above the floor at which air temperature is calculated for comfort purposes. The air temperature at this height is used in calculating the available measures of comfort: Fanger, Pierce or KSU. The default is 1.1 meters.

Field: Temperature Difference Threshold for Reporting

This field specifies a minimum temperature difference between the upper subzone and the occupied subzone that will be used to trigger whether or not the UFAD auxiliary outputs will be calculated. These outputs are *UF Transition Height* and *UF Average Temp Gradient*. They are set to zero when the temperature difference is less than the threshold and the output *UF Zone Is Mixed* is set to 1.

The value should be greater than or equal to zero and is in units of degrees Centigrade. The default value is 0.4 degrees C.

Field: Diffuser Type

The choices for this alpha field are **Swirl** | **VariableArea** | **HorizontalSwirl** | **LinearBarGrille** | **Custom**. The swirl and displacement diffusers are fixed area diffusers. The variable area diffusers maintain an approximately constant exit velocity. Linear bar grilles are normally used in exterior zones and are fixed area diffusers. Custom is used to signify that the user intends to input the coefficients A – E (see below) rather than let the program set the coefficients based on diffuser type. The default is *Swirl*.

Field: Transition Height

An optional field to allow the user to specify the transition height (meters above floor) rather than have the program calculate it. The default is 1.7 meters.

Field: Coefficient A

The coefficient A in the formula: $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$. Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalulate*.

Field: Coefficient B

The coefficient B in the formula: $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$. Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalulate*.

Field: Coefficient C

The coefficient C in the formula: $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$. Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalulate*.

Field: Coefficient D

The coefficient D in the formula: $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$. Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalulate*.

Field: Coefficient E

The coefficient E in the formula: $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$. Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalulate*.

RoomAirSettings:UnderFloorAirDistributionExterior

This model is applicable to exterior spaces that are served by an underfloor air distribution system. The dominant sources of heat gain should be from people, equipment, and other localized sources located in the occupied part of the room, as well as convective gain coming from a warm window. The model predicts two temperatures in the room:

- An occupied subzone temperature (T_{OC}), representing the temperature in the region between the floor and the boundary of the upper subzone..
- An upper subzone temperature (T_{MX}) essential for overall energy budget calculations and for modeling comfort effects of the upper layer temperature.

The following fields are used to define an instance of the 'UCSD UFAD Exterior Model Controls' object.

Field: Zone Name

This field provides the unique name of a zone described elsewhere in the file. A single instance of the 'RoomAirSettings:UnderFloorAirDistributionExterior' object is needed for each zone that is to be modeled using this method.

Field: Number of Diffusers

The total number of diffusers in this zone. This field can allowed to Autocalculate (in which case it is set to the design occupancy level; i.e., number of people). If the design occupancy is low or zero but there are still heat sources that could generate buoyancy driven plumes, the user should input a value based on the design supply air flow rate of the zone and the design flow rate of an individual diffuser. In the absence of any other information, divide the zone area by 100 ft². The default for this field is Autocalculate.

Field: Power per Plume

The power in watts incorporated in a buoyancy driven thermal plume. Normally we assume all the loads of a workstation create a single plume so that this represents the convective heat gain from a workstation – 1 person, 1 computer terminal, plus any task lighting. A typical value would be 220 watts. However, the model assumes an "equivalent" plume derived from the zone extraction rate normalized to the number of workstations/occupants. This field should be allowed to default – the program will calculate a value based upon the occupancy and the extraction rate. The default is Autocalculate.

Field: Design Effective Area of Diffuser

This is the design air flow opening area in square meters of a single diffuser. The default value depends on the diffuser type. For swirl diffusers it is 0.075 m², for variable area diffusers 0.035 m², for horizontal swirl diffusers 0.006 m², and for linear bar grilles 0.03 m². The default is *Autocalculate*.

Field: Diffuser Slot Angle from Vertical

This input describes the angle at which air emerges from the diffusers. It should be the angle in degrees between the vertical and the diffuser slots. The defaults depend on the diffuser type: for swirl diffusers it is 28 degrees, for variable area diffusers 45 degrees, for DV diffusers 73 degrees, and for linear bar grilles 15 degrees.

Field: Thermostat Height

This field is the height in meters of the thermostat/temperature control sensor above the floor. The default is 1.2 meters.

Field: Comfort Height

The height in meters above the floor at which air temperature is calculated for comfort purposes. The air temperature at this height is used in calculating the available measures of comfort: Fanger, Pierce or KSU. The default is 1.1 meters.

Field: Temperature Difference Threshold for Reporting

This field specifies a minimum temperature difference between the upper subzone and the occupied subzone that will be used to trigger whether or not the UFAD auxiliary outputs will be calculated. These outputs are *UF Transition Height* and *UF Average Temp Gradient*. They are set to zero when the temperature difference is less than the threshold and the output *UF Zone Is Mixed* is set to 1.

The value should be greater than or equal to zero and is in units of degrees Centigrade. The default value is 0.4 degrees C.

Field: Diffuser Type

The choices for this alpha field are **Swirl** | **VariableArea** | **HorizontalSwirl** | **LinearBarGrille** | **Custom**. The swirl and displacement diffusers are fixed area diffusers. The variable area diffusers maintain an approximately constant exit velocity. Linear bar grilles are normally used in exterior zones and are fixed area diffusers. Custom is used to signify that the user intends to input the coefficients A – E (see below) rather than let the program set the coefficients based on diffuser type. The default is *Swirl*.

Field: Transition Height

An optional field to allow the user to specify the transition height (meters above floor) rather than have the program calculate it. The default is 1.7 meters.

Field: Coefficient A

The coefficient A in the formula: $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$. Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalulate*.

Field: Coefficient B

The coefficient B in the formula: $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$. Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalulate*.

Field: Coefficient C

The coefficient C in the formula: $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$. Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalulate*.

Field: Coefficient D

The coefficient D in the formula: $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$. Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalulate*.

Field: Coefficient E

The coefficient E in the formula: $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$. Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalulate*.

Room Air Model Outputs

Each room air model sets up outputs specific to that model. The effect of room air modeling is usually to adjust the adjacent air temperature along the inside surface of heat transfer surfaces. The output report “Surface Int Adjacent Air Temperature [C]” is provided for this and described under Surfaces:HeatTransfer .

Mundt Model / OneNodeDisplacementVentilation Outputs

The following output is available for the Mundt model.

```
Mundt RoomAir Model Air Node Temp [C]
```

Mundt RoomAir Model Air Node Temp [C]

This report variable provides the drybulb air temperature used in, or calculated by, the Mundt model. The selection key is the name of an air node defined in a ROOMAIR Node object.

ThreeNodeDisplacementVentilation Outputs

```

HVAC,Average,DV Mixed Subzone Temperature[C]
HVAC,Average,DV Occupied Subzone Temperature[C]
HVAC,Average,DV Floor Subzone Temperature[C]

 HVAC,Average,DV Maximum Temp Gradient [K/m]
 HVAC,Average,DV Effective Air Temperature for Comfort [C]
 HVAC,Average,DV Thermostat Temperature [C]

DV Mixed Subzone Temperature[C]

The temperature of the upper well-mixed subzone in degrees C.

DV Occupied Subzone Temperature[C]

The average temperature of the lower, stratified, occupied subzone in degrees C.

DV Floor Subzone Temperature[C]

The temperature of the region near the floor in degrees C.

DV Transition Height [m]

The height above the floor, in meters, of the boundary between the lower occupied subzone and the upper well-mixed subzone.

DV Fraction Min Recommended Flow Rate

The ratio of the minimum recommended flow rate to the actual flow rate. Here flow rate means the sum of infiltration, ventilation, mixing and system air flow rates. The minimum flow is the flow needed to establish the boundary between the occupied and mixed subzones at 1.5 meters.

DV Zone Is Mixed [0-No 1-Yes]

An integer flag that indicates whether the zone is mixed (single node well-mixed zone model used) or stratified (UCSD DV model used). The value 1 means well-mixed; 0 means stratified.

DV Average Temp Gradient [K/m]

The temperature gradient between the middle of the floor region and the middle of the well-mixed upper subzone in degrees Kelvin per meter.

DV Maximum Temp Gradient [K/m]

The maximum of the temperature gradient between the middle of the floor region and the middle of the occupied subzone and the temperature gradient between the middle of the occupied subzone and the middle of the well-mixed subzone. The gradient is in degrees Kelvin per meter.

DV Effective Air Temperature for Comfort [C]

The temperature at the user specified comfort height in degrees C.

DV Thermostat Temperature [C]

The temperature at the height of the thermostat (specified by user input) in degrees C.

CrossVentilation Model Outputs

Zone,Average,CV Jet Region Temperature[C]
 Zone,Average,CV Recirculation Region Temperature[C]

```
Zone,Average,CV Zone Air is Mixing [1-Yes 0-No]
Zone,Average,CV Recirculations Occur In The Flow [1-Yes 0-No]
```

CV Jet Region Temperature[C]

Average air temperature in the jet region of the flow in degrees C.

CV Recirculation Region Temperature[C]

Average air temperature in the recirculation region of the flow in degrees C.

CV Jet Region Average Velocity[m/s]

Average airflow velocity in the jet region of the flow in meters per second.

CV Recirculation Region Average Velocity[m/s]

Average airflow velocity in the recirculation region of the flow in meters per second.

CV Inflow Aperture Area[m2]

Area of the inflow aperture in square meters. This area can change due to variation in wind direction (as inflow aperture changes) or variations in the opening schedule.

CV Room Length[m]

Length of the room along the cross ventilation direction, in meters.

CV Ratio Between Recirculation And Inflow Rate

Ration between airflow rate in the recirculation region and inflow rate, non-dimensional.

CV Zone Air is Mixing [1-Yes 0-No]

An integer flag that indicates whether the zone is mixed (single node well-mixed zone model used) or significant momentum conservation is occurring (UCSD CV model used). The value 1 means well-mixed; 0 means cross ventilation is present. Transition to mixed flow can occur due to three mechanism: reduction in inflow velocity, reduction in inflow aperture area and dominance of buoyancy effects.

CV Recirculations Occur In The Flow [1-Yes 0-No]

An integer flag that indicates whether recirculations are present in the flow. A cross ventilation flow does not have recirculations whenever the inflow area is similar to the room cross section area (such as airflow in a typical corridor).

HVAC,Average,UF Power In Plumes [W]
HVAC,Average,Phi
HVAC,Average,UF Plume Power from Windows [W]UCSD Supply Air Temp
HVAC,Average,Phi
```

UF Mixed Subzone Temperature[C]

The temperature of the upper subzone in degrees C.

UF Occupied Subzone Temperature[C]

The temperature of the lower, occupied subzone in degrees C.

UF Transition Height [m]

The height above the floor, in meters, of the boundary between the lower occupied subzone and the upper subzone..

UF Zone Is Mixed [0-No 1-Yes]

An integer flag that indicates whether the zone is mixed (single node well-mixed zone model used) or stratified (UCSD UFI model used). The value 1 means well-mixed; 0 means stratified.

UF Average Temp Gradient [K/m]

The temperature gradient between the middle of the occupied subzone and the middle of the upper subzone in degrees Kelvin per meter.

UF Effective Air Temperature for Comfort [C]

The temperature at the user specified comfort height in degrees C.

UF Thermostat Temperature [C]

The temperature at the height of the thermostat (specified by user input) in degrees C.

UF Gamma

Value of gamma – a dimensionless “height” used in calculating the transition height. Lower values of gamma indicate increased stratification, higher values less. Generally the values should be between 2 and 30.

UF Power In Plumes [W]

The heat in watts driving the plumes in the occupied subzone.

UF Plume Power from Windows [W]

The convective heat gain from windows in an UnderFloorAirDistributionExterior zone.

Phi

Phi is a measure of temperature stratification in the space. It is the difference between the occupied subzone temperature and the supply temperature divided by difference between the return temperature and the supply temperature. Technically it is equal to Kc. As phi approaches 1, the space is fully mixed. As phi approaches 0, the space becomes fully stratified. Expressed as an equation:

$$(T_{occ} - T_{sup}) / (T_{ret} - T_{sup})$$

Group – Internal Gains (People, Lights, Other internal zone equipment)

Not all the influence for energy consumption in the building is due to envelope and ambient conditions. This group of objects describes other internal gains that may come into play (People, Lights, Various Equipment Types).

People

The people statement is used to model the occupant's affect on the space conditions. The following definition addresses the basic affects as well as providing information that can be used to report the thermal comfort of a group of occupants. The Fanger, Pierce Two-Node, and Kansas State UniversityTwo-Node thermal comfort models are available in EnergyPlus. A user may select any of these models for each People statement by simply adding the appropriate choice keyword after the air velocity schedule name. Thermal comfort calculations will only be made for people statements that include specific requests for these thermal comfort models.

Field: Name

The name of the People object. Must be unique across all People objects.

Field: Zone Name

This field is the name of the zone (ref: Zone) and links a particular people statement to a thermal zone in the building.

Field: Number of People Schedule Name

This field is the name of the schedule (ref: Group -- Schedules) that modifies the number of people parameter (see previous field). The schedule values can be any positive number. The actual number of people in a zone as defined by this statement is the product of the number of people field and the value of the schedule specified by name in this field.

Field: Number of People Calculation Method

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal number of occupants (people) in the Zone. The key/choices are:

- People

With this choice, the method used will be a straight insertion of the number of occupants (people). (The Number of People field should be filled.)

- People/Area

With this choice, the method used will be a factor per floor area of the zone. (The People per Zone Floor Area field should be filled).

- Area/Person

With this choice, the method used will be a factor of floor area per person. (The Zone Floor Area per Person field should be filled).

Field: Number of People

This field is used to represent the maximum number of people in a zone that is then multiplied by a schedule fraction (see schedule field). In EnergyPlus, this is slightly more flexible in that the number of people could be a “diversity factor” applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour, the number of people field is constant for all simulation environments.

Field: People per Zone Floor Area

This factor (person/m²) is used, along with the Zone Floor Area to determine the maximum number of people as described in the Number of People field. The choice from the method field should be “people/area”.

Field: Zone Floor Area per Person

This factor (m²/person) is used, along with the Zone Floor Area to determine the maximum number of people as described in the Number of People field. The choice from the method field should be “area/person”.

Field: Fraction Radiant

This field is a decimal number between 0.0 and 1.0 and is used to characterize the type of heat being given off by people in a zone. The number specified in this field will be multiplied by the total sensible energy emitted by people to give the amount of long wavelength radiation gain from human beings in a zone. The remainder of the sensible load is assumed to be convective heat gain. Note that latent gains from people are not included in either the radiant or convective heat gains. See the Engineering Reference document for more details.

Field: Sensible Heat Fraction

The user can use this field to specify a fixed sensible fraction for the heat gain due to this PEOPLE object. Normally the program calculates the sensible/latent split; this field gives the user control over this split. This field is autocalculated: if the field is blank or **autocalculate**, the program will calculate the sensible/latent split; if a value is entered, it will be used as the sensible fraction of the current total heat gain.

Field: Activity Level Schedule Name

This field is the name of the schedule that determines the amount of heat gain per person in the zone under design conditions. This value is modified somewhat based on a correlation to account for variations in space temperature. The schedule values may be any positive number and the units for this parameter is Watts per person. This schedule represents the total heat gain per person including convective, radiant, and latent. An internal algorithm is used to determine what fraction of the total is sensible and what fraction is latent. Then, the sensible portion is divided into radiant and convective portions using the value specified for Fraction Radiant (above). See the Engineering Reference document for more details.

Values for activity level can range anywhere from approximately 100-150 Watts per person for most office activities up to over 900 Watts per person for strenuous physical activities such as competitive wrestling. The following table (Table 9) is based on Table 4 from the 2005 ASHRAE Handbook of Fundamentals, page 8.6. In addition to the information from the ASHRAE HOF, there is an added column of values in W/Person such as necessary for the activity level schedule values. This column uses the standard adult body surface area of 1.8 m² to multiply the activity levels in W/m² that are used in the table.

Field: Enable ASHRAE 55 comfort warnings

This field accepts either “Yes” or “No” as values. When “Yes” is specified, warnings are generated when the space conditions are outside of the ASHRAE 55 comfort range as discussed in the sections that follow titled “Simplified ASHRAE 55-2004 Graph Related Outputs” and “Simplified ASHRAE 55 Warnings.” The default is not to provide these warnings so if you want to know if your space is outside this comfort range you must set this field to Yes.

Table 9. Metabolic Rates for Various Activities

Activity	Activity Level W/Person EnergyPlus Schedule Value	Activity Level W/m²	met*
<i>Resting</i>			
Sleeping	72	40	0.7
Reclining	81	45	0.8

Tennis, singles	378 to 486	210 to 270	3.6 to 4.0
Basketball	522 to 792	290 to 440	5.0 to 7.6
Wrestling, competitive	738 to 909	410 to 505	7.0 to 8.7

***Note that one met = 58.1 W/m²**

Field: Mean Radiant Temperature Calculation Type

This field specifies the type of Mean Radiant Temperature (MRT) calculation the user wishes to use for the thermal comfort model. At the present time, there are two options for MRT calculation type: zone averaged and surface weighted. The default calculation is "ZoneAveraged". In the zone averaged MRT calculation, the MRT used for the thermal comfort calculations is for an "average" point in the zone. MRT is calculated based on an area-emissivity weighted average of all of the surfaces in the zone. In cases where the emissivity of all of the surfaces are sufficiently small (near zero), the mean radiant temperature will be set to the mean air temperature of the space to avoid divide by zero errors. The other MRT calculation type is "SurfaceWeighted". The goal of this calculation type is to estimate a person in the space close to a particular surface without having to define exact view factors for all of the surfaces and the location of the person in the space. The MRT used in the thermal comfort calculations when the "surface weighted" calculation type is selected is actually the average of the temperature of the surface to which the person is closest (defined by the next field "Surface Name") and the zone averaged MRT (defined above). The surface temperature alone is not used because in theory the maximum view factor from a person to any flat surface is roughly 0.5. In the "surfaceweighted" calculation, the surface in question actually gets slightly more weighting than 50% since the surface selected is still a part of the zone average MRT calculation. Again, this simplification was made to avoid the specification of view factors and the exact location of the person.

A third option is to use "angelfactor". This option allows for more explicit positioning of the person within the space by defining the angle factors from the person to the various surfaces in the zone. This option requires the user to list the surfaces that the person can see from a radiation standpoint and also define the angle (or view) factor for each surface. The

AngleFactorList object (see next object description) is intended to give the user this opportunity.

Field: Surface Name/Angle Factor List Name

This field is only valid when the user selects “surfaceweighted” for the MRT calculation type (see the previous input field description). In this case, the field is the name of a surface within the zone the people are residing. This surface will be used in the MRT calculation as defined above to come up with a more representative MRT for a person near a particular surface. The MRT used for thermal comfort calculations using the “surface weighted” MRT calculation method is the average of the temperature of the surface specified in this field and the “zone averaged” MRT (see the Mean Radiant Temperature calculation type field above).

Field: Work Efficiency Schedule Name

This field is the name of the schedule that determines the efficiency of energy usage within the human body that will be used for thermal comfort calculations. Note that all energy produced by the body is assumed to be converted to heat for the zone heat balance calculation. A value of zero corresponds to all of the energy produced in the body being converted to heat. A value of unity corresponds to all of the energy produced in the body being converted to mechanical energy. The values for this parameter defined in the schedule must be between 0.0 and 1.0. Any value greater than zero will result in a reduction of heat that impacts the thermal comfort energy balance of a person within the space.

Field: Clothing Insulation Schedule Name

This field is the name of the schedule that defines the amount of clothing being worn by a typical zone occupant during various times in the simulation period. This parameter must be a positive real number and has units of Clo. Typical values for Clo can be seen in the ASHRAE 2005 HOF Table 7, page 8.8 (for clothing ensembles) and Table 8, page 8.9 (for garment values).

Field: Air Velocity Schedule Name

This field is the name of the schedule that approximates the amount of air movement in the space as a function of time throughout the simulation period. The user has control over this parameter through the schedule that requires the individual numbers in the schedule to be positive real numbers having units of meters per second.

Field: Thermal Comfort Model Type (up to 3 allowed)

The final one to three fields are optional and are intended to trigger various thermal comfort models within EnergyPlus. By entering the keywords Fanger, Pierce or KSU, the user signifies that either the Fanger, Pierce Two-Node or Kansas State UniversityTwo-Node Thermal Comfort Model results are requested from EnergyPlus for this particular people statement. Note that since up to three models may be specified, the user may opt to have EnergyPlus calculate the thermal comfort for people identified with this people statement using all three models if desired. Note that the KSU model is computationally intensive and may noticeably increase the execution time of the simulation. For descriptions of the thermal comfort calculations, see the Engineering Reference document.

Zone,Average,PierceTSENS
Zone,Average,KsuTSV

```

People Number Of Occupants []

This field is the number of people for this PEOPLE object during the timestep in question.

People Radiant Heat Gain [J]

This field is the amount of radiant heat gain for this PEOPLE object in Joules. This is determined by the current sensible heat gain from people to the zone and the “Fraction Radiant” specified in the input. The radiant gains from people are distributed to the surfaces using an area weighting scheme.

People Convective Heat Gain [J]

This field is the amount of convective heat gain for this PEOPLE object in Joules. This is determined by the current sensible heat gain from people to the zone and the “Fraction Radiant” specified in input. Note that the radiant and convective gains should add up to the sensible heat gain from people. The convective heat gain from people is added to the zone air heat balance directly.

People Latent Heat Gain [J]

This field is the amount of latent heat gain for this PEOPLE object in Joules. This amount is based on the number of people in the space as well as the total amount of energy produced by a typical person defined by the activity schedule in the input. An internal algorithm is used to determine what fraction of the total is sensible and what fraction is latent. Details about this split are included in the Engineering Reference document.

People Sensible Heat Gain [J]

This field is the amount of sensible heat gain for this PEOPLE object in Joules. This amount is based on the number of people in the space as well as the total amount of energy produced by a typical person defined by the activity schedule in the input. An internal algorithm (described in the Engineering Reference document) is used to determine what fraction of the total is sensible and what fraction is latent. The sensible plus the latent heat gain from people equals the total gain specified in the input.

People Total Heat Gain [J]

This field is the total amount of heat gain for this PEOPLE object in Joules. This is derived from the activity level times the number of occupants.

Zone People Number Of Occupants []

This field is the total number of people within the zone during the timestep in question.

Zone People Radiant Heat Gain [J]

This field is the amount of radiant heat gain from people within the zone in Joules. This is determined by the current sensible heat gain from people to the zone and the “Fraction Radiant” specified in the input. The radiant gains from people are distributed to the surfaces using an area weighting scheme.

Zone People Convective Heat Gain [J]

This field is the amount of convective heat gain from people within the zone in Joules. This is determined by the current sensible heat gain from people to the zone and the “Fraction Radiant” specified in input. Note that the radiant and convective gains should add up to the sensible heat gain from people. The convective heat gain from people is added to the zone air heat balance directly.

Zone People Latent Heat Gain [J]

This field is the amount of latent heat gain from people within the zone in Joules. This amount is based on the number of people in the space as well as the total amount of energy produced by a typical person defined by the activity schedule in the input. An internal algorithm is used to determine what fraction of the total is sensible and what fraction is latent. Details about this split are included in the Engineering Reference document.

Zone People Sensible Heat Gain [J]

This field is the amount of sensible heat gain from people within the zone in Joules. This amount is based on the number of people in the space as well as the total amount of energy produced by a typical person defined by the activity schedule in the input. An internal algorithm (described in the Engineering Reference document) is used to determine what fraction of the total is sensible and what fraction is latent. The sensible plus the latent heat gain from people equals the total gain specified in the input.

Zone People Total Heat Gain [J]

This field is the total amount of heat gain from people within the zone in Joules. Derived from the activity level times the number of occupants, this is summed for each people object within a zone.

ThermalComfortMRT [C]

This report variable is the mean radiant temperature used in the thermal comfort calculations. This value is computed according to the "MRT Calculation Type" specified in the PEOPLE object. If a high temperature radiant system is present in the zone, this value will be adjusted according to the current heater operation and the "Fraction of radiant energy incident on people" specified in the HIGH TEMP RADIANT SYSTEM object.

Note for all Thermal Comfort reporting: Though the published values for thermal comfort "vote" have a discrete scale (e.g. -3 to +3 or -4 to +4), the calculations in EnergyPlus are carried out on a continuous scale and, thus, reporting may be "off the scale" with specific conditions encountered in the space. This is not necessarily an error in EnergyPlus – rather a different approach that does not take the "limits" of the discrete scale values into account.

FangerPMV

This field is the "predicted mean vote" (PMV) calculated using the Fanger thermal comfort model.

PiercePMVET

This field is the "predicted mean vote" (PMV) calculated using the effective temperature and the Pierce two-node thermal comfort model.

PiercePMVSET

This field is the "predicted mean vote" (PMV) calculated using the "standard" effective temperature and the Pierce two-node thermal comfort model.

PierceDISC

This field is the "discomfort index" calculated using the the Pierce two-node thermal comfort model.

PierceTSENS

This field is the "thermal sensation index" (PMV) calculated using the Pierce two-node thermal comfort model.

KsuTSV

This field is the "thermal sensation vote" (TSV) calculated using the KSU two-node thermal comfort model.

Simplified ASHRAE 55-2004 Graph Related Outputs

The following output variables are all based on whether the humidity ratio and the operative temperature is within the region shown in ASHRAE Standard 55-2004 in Figure 5.2.1.1. For these outputs the operative temperature is simplified to be the average of the air temperature and the mean radiant temperature. For summer, the 0.5 Clo level is used and, for winter, the 1.0 Clo level is used. The graphs below are based on the following tables which extend the ASHRAE values to zero humidity ratio.

Table 10. Winter Clothes (1.0 Clo)

Operative Temp(degC)	Humidity Ratio
19.6	0.012
23.9	0.012
26.3	0.000
21.7	0.000

Figure 39. Winter Comfort Range

Table 11. Summer Clothes (0.5 Clo)

Operative Temp(degC)	Humidity Ratio
23.6	0.012
26.8	0.012
28.3	0.000
25.1	0.000

Figure 40. Summer Comfort Range

Time Not Comfortable Summer Clothes[hr]

The time when the zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 summer clothes region (see above)

Time Not Comfortable Winter Clothes[hr]

The time when the zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 winter clothes region (see above)

Time Not Comfortable Summer or Winter Clothes[hr]

The time when the zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 summer or winter clothes region (see above)

Time Not Comfortable Summer Clothes Any Zone[hr]

The time when any zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 summer clothes region (see above)

Time Not Comfortable Winter Clothes Any Zone [hr]

The time when any zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 winter clothes region (see above)

Time Not Comfortable Summer or Winter Clothes Any Zone [hr]

The time when any zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 summer or winter clothes region (see above)

Simplified ASHRAE 55 Warnings

The simplified ASHRAE 55 calculations may be computed for occupied zones and, possibly, warnings are shown on the .err file at the end of each simulated environment. To enable this option set the “Enable ASHRAE 55 comfort warnings” field of the People object to Yes. These warnings will not be generated by default.

If you enable the warnings, the simplified ASHRAE 55 calculations are done for occupied zones and, possibly, warnings are shown on the .err file at the end of each simulated environment.

```

** Warning ** More than 4% of time (350.4 hours) uncomfortable in zone ZSF1
**   ~~~   ** 553.0 hours were uncomfortable based on ASHRAE 55-2004 graph (Section 5.2.1.1)
**   ~~~   ** During Environment [10/01 - 09/30]: CHICAGO IL USA TMY2-94846 WMO#=725300
** Warning ** More than 4% of time (350.4 hours) uncomfortable in zone ZNF1
**   ~~~   ** 827.8 hours were uncomfortable based on ASHRAE 55-2004 graph (Section 5.2.1.1)
**   ~~~   ** During Environment [10/01 - 09/30]: CHICAGO IL USA TMY2-94846 WMO#=725300
** Warning ** More than 4% of time (350.4 hours) uncomfortable in zone ZSF2
**   ~~~   ** 593.5 hours were uncomfortable based on ASHRAE 55-2004 graph (Section 5.2.1.1)
**   ~~~   ** During Environment [10/01 - 09/30]: CHICAGO IL USA TMY2-94846 WMO#=725300
** Warning ** More than 4% of time (350.4 hours) uncomfortable in zone ZNF2
**   ~~~   ** 875.8 hours were uncomfortable based on ASHRAE 55-2004 graph (Section 5.2.1.1)
**   ~~~   ** During Environment [10/01 - 09/30]: CHICAGO IL USA TMY2-94846 WMO#=725300

```

You may decide if you need to change parameters to reduce these “uncomfortable” hours. The individual report variables shown previously may help you get more details on when these are occurring.

Following are some suggestions that might be applicable:

- Eliminate occupancy when conditioning equipment is off.
- Note that the ASHRAE graph lower limit is (19.6C to 21.7C) – heating setpoints may need to be nearer 22.2C (72F) than 21.1C (70F).
- Unoccupied heating setpoint should be nearer 16.7C (62F) rather than 12.8C (55F) to reduce the start up recovery.
- Start the occupied setpoint schedule, fan availability schedule, cooling pump availability schedule, reheat coil availability, one hour before occupancy. Seasonal turn on and off of equipment may cause more warnings (but potentially more energy consumption).
- Unoccupied cooling setpoint should be nearer 29.4C (85F) rather than 40.0 (104F) to reduce the start up recovery.

ComfortViewFactorAngles

When requesting EnergyPlus to do a thermal comfort calculation, the program user has three options for defining how the mean radiant temperature will be calculated. The user may select “zoneaveraged” which results in a mean radiant temperature that is characteristic of an “average” location near the center of the zone. The user may also elect to place the person near a particular surface by selecting “surfaceweighted” in the People statement. This takes the average of the zone mean radiant temperature and the temperature of the surface that the person is near and uses this value as the mean radiant temperature when calculating thermal comfort.

The third option is for the user to more explicitly position the person within the space by defining the angle factors from the person to the various surfaces in the zone. This option requires the user to list the surfaces that the person can see from a radiation standpoint and also define the angle (or view) factor for each surface. The AngleFactorList input line is intended to give the user this opportunity.

Field: Name

This field is an unique user assigned name for the list of surfaces that can be seen radiantly by the person for whom thermal comfort is to be evaluated. Any reference to this list by a People statement will use this name.

Field: Zone Name

Zone Name for this surface list. Each of the surfaces listed must be in this zone.

Field: Surface <#> Name

This field is the name of a surface in the zone seen by the person.

Field: Angle Factor <#>

This field is the fraction that this surface contributes to the total mean radiant temperature. This can be thought of as a weighting factor for this surface and the actual mean radiant temperature used in the thermal comfort model is simply the sum of all angle factors multiplied by the corresponding inside surface temperature. Note that the Surface Name/Angle Factor pair can be repeated up to 20 times. The sum of all angle factors within any angle factor list must equal unity, otherwise the program will not accept the input as valid.

The IDD Definition for this object:

```

Lights

The Lights statement allows you to specify information about a zone's electric lighting system, including design power level and operation schedule, and how the heat from lights is distributed thermally.

A zone may have multiple Lights statements. For example, one statement may describe the general lighting in the zone and another the task lighting. Or you can use multiple Lights statements for a zone that has two or more general lighting systems that differ in design level, schedule, etc.

Field: Name

The name of the LIGHTS object.

Field: Zone Name

The name of the thermal zone (ref: Zone) that this Lights statement refers to.

Field: Schedule Name

The name of the schedule that modifies the lighting power design level (see next field). The schedule values can be any positive number. The electrical input for lighting in a particular timestep is the product of the design level and the value of this schedule in that timestep. If the design level is the maximum lighting power input the schedule should contain values between 0.0 and 1.0.

Field: Design Level Calculation Method

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal lighting level in the Zone. The key/choices are:

- LightingLevel

With this choice, the method used will be a straight insertion of the lighting level (Watts) for the Zone. (The Lighting Level field should be filled.)

- Watts/Area

With this choice, the method used will be a factor per floor area of the zone. (The Watts per Zone Floor Area field should be filled).

- Watts/Person

With this choice, the method used will be a factor of lighting level (watts) per person. (The Watts per person field should be filled).

Field: Lighting Level

This is typically the maximum electrical power input (in Watts) to lighting in a zone, including ballasts, if present. This value is multiplied by a schedule fraction (see previous field) to get the lighting power in a particular timestep. In EnergyPlus, this is slightly more flexible in that the lighting design level could be a “diversity factor” applied to a schedule of real numbers.

Field: Watts per Zone Floor Area

This factor (watts/m²) is used, along with the Zone Floor Area to determine the maximum lighting level as described in the Lighting Level field. The choice from the method field should be “watts/area”.

Field: Watts per Person

This factor (watts/person) is used, along with the number of occupants (people) to determine the maximum lighting level as described in the Lighting Level field. The choice from the method field should be “watts/person”.

Heat Gains from Lights:

The electrical input to lighting ultimately appears as heat that contributes to zone loads or to return air heat gains. In EnergyPlus this heat is divided into four different fractions. Three of these are given by the input fields Return Air Fraction, Fraction Radiant and Fraction Visible. A fourth, defined as the fraction of the heat from lights convected to the zone air, is calculated by the program as:

$$f_{\text{convected}} = 1.0 - (\text{Return Air Fraction} + \text{Fraction Radiant} + \text{Fraction Visible})$$

You will get an error message if Return Air Fraction + Fraction Radiant + Fraction Visible exceeds 1.0.

These fractions depend on the type of lamp and luminaire, whether the luminaire is vented to the return air, etc.

Field: Return Air Fraction

The fraction of the heat from lights that goes into the zone return air (i.e., into the zone outlet node). If the return air flow is zero or the zone has no return air system, the program will put this fraction into the zone air. Return Air Fraction should be non-zero only for luminaires that are return-air ducted (see Table 12 and Figure 41). (However, see the field “Return Air Fraction Is Calculated from Plenum Temperature,” below, for an approach to modeling the case where Return Air Fraction is caused by *conduction* between a luminaire that is in contact with a return-air plenum.)

Field: Fraction Radiant

The fraction of heat from lights that goes into the zone as long-wave (thermal) radiation. The program calculates how much of this radiation is absorbed by the inside surfaces of the zone according the area times thermal absorptance product of these surfaces.

Field: Fraction Visible

The fraction of heat from lights that goes into the zone as visible (short-wave) radiation. The program calculates how much of this radiation is absorbed by the inside surfaces of the zone according the area times solar absorptance product of these surfaces.

Approximate values of Return Air Fraction, Fraction Radiant and Fraction Visible are given in Table 12 for overhead fluorescent lighting for the luminaire configurations shown in Figure 41.

Table 12. Approximate values of Return Air Fraction, Fraction Radiant and Fraction Visible for overhead fluorescent lighting for different luminaire configurations. These values assume that no light heat goes into an adjacent zone. Source: *Lighting Handbook: Reference & Application*, 8th Edition, Illuminating Engineering Society of North America, New York, 1993, p. 355.

Field Name	Luminaire Configuration, Fluorescent Lighting				
	Suspended	Surface mount	Recessed	Luminous and louvered ceiling	Return-air ducted
Return Air Fraction	0.0	0.0	0.0	0.0	0.54
Fraction Radiant	0.42	0.72	0.37	0.37	0.18
Fraction Visible	0.18	0.18	0.18	0.18	0.18
$f_{convected}$	0.40	0.10	0.45	0.45	0.10

Figure 41. Overhead fluorescent luminaire configurations.

Field: Fraction Replaceable

This field defines the daylighting control for the LIGHTS object.

If **Daylighting:Controls** or **Daylighting:DELight:Controls** is specified for the zone, this field is used as an on/off flag for dimming controls. If set to 0.0, the lights are not dimmed by the daylighting controls. If set to 1.0, the lights are allowed to be dimmed by the daylighting controls.

Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Task Lights", "Hall Lights", etc. A new meter for reporting is created for each unique subcategory (ref: Output:Meter and). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the lights will be assigned to the "General" end-use subcategory.

Field: Return Air Fraction Calculated from Plenum Temperature

Accepts values Yes or No (the default). Yes is for advanced used only. In this case the program will calculate the return air fraction by assuming that it is due to conduction of some of the light heat into the zone's return air plenum and that the amount of the conduction depends on the plenum air temperature. A Yes value should only be used for luminaires that are recessed and non-vented, as shown in Figure 42.

The value you enter for the Return Air Fraction field will be ignored and you can enter, for fluorescent lighting, Fraction Radiant = 0.37 and Fraction Visible = 0.18, as indicated in Table 12.

This feature requires that the coefficients described below be determined from measurements or detailed calculations since they are very sensitive to the luminaire type, lamp type, thermal resistance between fixture and plenum, etc.

If "Return Air Fraction Is Calculated from Plenum Temperature" = Yes, the return air fraction is calculated *each timestep* from the following empirical correlation:

$$(\text{Return Air Fraction})_{\text{calculated}} = C_1 - C_2 \times T_{\text{plenum}}$$

where T_{plenum} is the previous-time-step value of the return plenum air temperature (deg C), and C_1 and C_2 are the values of the coefficients entered in the next two fields.

To compensate for the change in the return air fraction relative to its input value, the program modifies Fraction Radiant and $f_{\text{convected}}$ by a scale factor such that

$$(\text{Return Air Fraction})_{\text{calculated}} + (\text{Fraction Radiant})_{\text{modified}} + (f_{\text{convected}})_{\text{modified}} + (\text{Fraction Visible})_{\text{input}} = 1.0$$

It is assumed that Fraction Visible is a constant equal to its input value.

Field: Return Air Fraction Function of Plenum Temperature Coefficient 1

The coefficient C_1 in the equation for $(\text{Return Air Fraction})_{\text{calculated}}$.

Field: Return Air Fraction Function of Plenum Temperature Coefficient 2

The coefficient C_2 in the equation for $(\text{Return Air Fraction})_{\text{calculated}}$. Its units are $1/^\circ\text{C}$.

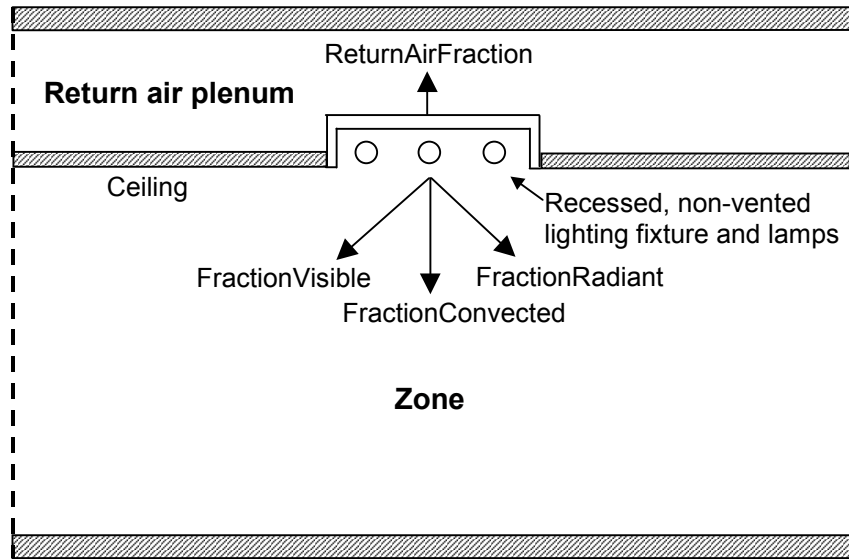

Figure 42. Vertical section through a zone and its return air plenum showing recessed lighting (not to scale). The heat from lights is divided into four fractions, three of which—ReturnAirFraction, FractionRadiant and FractionConvected—depend on plenum air temperature.

Lights Report Outputs

If daylighting controls are operating in the zone, all of the Lights objects with a Fraction Replaceable greater than zero will be reduced by a multiplicative factor that accounts for how much the electric lighting is lowered due to daylighting.

Lights objects have output variables for individual objects and for zone totals.

```

Zone,Average,Lights Electric Power [W]
Zone,Sum,Lights Radiant Heat Gain [J]

Zone,Sum,Zone Lights Total Heat Gain [J]
Zone,Sum,Zone Lights Electric Consumption [J]

```

Lights Electric Power [W]

The electric power input for the lights.

Lights Radiant Heat Gain [J]

The amount of heat gain from lights that is in the form of long-wave (thermal) radiation entering the zone. This heat is absorbed by the inside surfaces of the zone according to an area times long-wave absorptance weighting scheme.

Lights Visible Heat Gain [J]

The amount of heat gain from lights that is in the form of visible (short-wave) radiation entering the zone. This heat is absorbed by the inside surfaces of the zone according to an area times short-wave absorptance weighting scheme.

Lights Convective Heat Gain [J]

The amount of heat gain from lights that is convected to the zone air.

Lights Return Air Heat Gain [J]

The amount of heat gain from lights that goes into the zone's return air (and, therefore, does not directly contribute to the zone load). If the zone has no return air system or the zone's air system is off, this heat will be added to the zone air.

Lights Total Heat Gain [J]

The total heat gain from lights. It is the sum of the following four outputs, i.e., Total Heat Gain = Return Air Heat Gain + Radiant Heat Gain + Visible Heat Gain + Convective Heat Gain. It is also equal to the electrical input to the lights.

Lights Electric Consumption [J]

The lighting electrical consumption including ballasts, if present. These will have the same value as Lights Total Heat Gain (above).

Zone Lights Electric Power [W]

The electric power input for all lights in the zone.

Zone Lights Radiant Heat Gain [J]

The amount of heat gain from all lights in the zone that is in the form of long-wave (thermal) radiation entering the zone. This heat is absorbed by the inside surfaces of the zone according to an area times long-wave absorptance weighting scheme.

Zone Lights Visible Heat Gain [J]

The amount of heat gain from all lights in the zone that is in the form of visible (short-wave) radiation entering the zone. This heat is absorbed by the inside surfaces of the zone according to an area times short-wave absorptance weighting scheme.

Zone Lights Convective Heat Gain [J]

The amount of heat gain from all lights in the zone that is convected to the zone air.

Zone Lights Return Air Heat Gain [J]

The amount of heat gain from all lights in the zone that goes into the zone's return air (and, therefore, does not directly contribute to the zone load). If the zone has no return air system or the zone's air system is off, this heat will be added to the zone air.

Zone Lights Total Heat Gain [J]

The total heat gain from all lights in the zone. It is the sum of the following four outputs, i.e., Total Heat Gain = Return Air Heat Gain + Radiant Heat Gain + Visible Heat Gain + Convective Heat Gain. It is also equal to the electrical input to the lights.

Zone Lights Electric Consumption [J]

The lighting electrical consumption for all lights in the zone including ballasts, if present. This will have the same value as Zone Lights Total Heat Gain (above). However, this amount is also shown in the Electricity meters that are associated with the zone:

- Electricity:Facility,
- Electricity:Building,
- Electricity:Zone:<Zone Name>.

In addition, depending on use, it will be shown in:

- InteriorLights: Electricity and
- InteriorLights:Electricity:Zone :<Zone Name>.

Meters for Lights Outputs

As described in the Lights Outputs, values for lights will show up on the following meters:

Table 13. Distribution of Lights to Meters

Meter Name	Scope	Lights Specifics
Electricity:Facility	Entire Facility	All
Electricity:Building	All Zones	All
Electricity:Zone:<Zone Name>	Specific Zone	All
InteriorLights:Electricity	All Zones	Lights Use
InteriorLights:Electricity:Zone:<Zone Name>	Specific Zone	Lights Use
<End-Use Subcategory>:InteriorLights:Electricity	Specific Subcategory	Lights Use

ElectricEquipment

Field: Name

The name of the ElectricEquipment object.

Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a particular electric equipment statement to a thermal zone in the building.

Field: Schedule Name

This field is the name of the schedule that modifies the design level parameter for electric equipment (see next field). The schedule values can be any positive number. The actual electrical input for equipment in a zone as defined by this statement is the product of the design level field and the value of the schedule specified by name in this field.

Field: Design Level Calculation Method

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal electric equipment level in the Zone. The key/choices are:

- EquipmentLevel

With this choice, the method used will be a straight insertion of the electric equipment level (Watts) for the Zone. (The Design Level field should be filled.)

- Watts/Area

With this choice, the method used will be a factor per floor area of the zone. (The Watts per Zone Floor Area field should be filled).

- Watts/Person

With this choice, the method used will be a factor of equipment level (watts) per person. (The Watts per Person field should be filled).

Field: Design Level

This field (in Watts) is typically used to represent the maximum electrical input to equipment in a zone that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the electric equipment design level could be a “diversity factor” applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour, the design level field is constant for all simulation environments.

Field: Watts per Zone Floor Area

This factor (watts/m²) is used, along with the Zone Area to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be “Watts/Area”.

Field: Watts per Person

This factor (watts/person) is used, along with the number of occupants (people) to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be “Watts/Person”.

Heat Gains from Electric Equipment:

The electrical input to the equipment ultimately appears as heat that contributes to zone loads. In EnergyPlus this heat is divided into four different fractions. Three of these are given by the input fields Fraction Latent, Fraction Radiant and Fraction Lost. A fourth, defined as the fraction of the heat from electric equipment convected to the zone air, is calculated by the program as:

$$f_{\text{convected}} = 1.0 - (\text{Fraction Latent} + \text{Fraction Radiant} + \text{Fraction Lost})$$

You will get an error message if Fraction Latent + Fraction Radiant + Fraction Lost exceeds 1.0.

Field: Fraction Latent

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of latent heat given off by electric equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by electric equipment to give the amount of latent energy produced by the electric equipment. This energy affects the moisture balance within the zone.

Field: Fraction Radiant

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of long-wave radiant heat being given off by electric equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by electric equipment to give the amount of long wavelength radiation gain from electric equipment in a zone.

Field: Fraction Lost

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of "lost" heat being given off by electric equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by electric equipment to give the amount of heat which is "lost" and does not impact the zone energy balances. This might correspond to electrical energy converted to mechanical work or heat that is vented to the atmosphere.

Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Computers", "Copy Machines", etc. A new meter for reporting is created for each unique subcategory (ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the equipment will be assigned to the "General" end-use subcategory.

GasEquipment

Field: Name

The name of the GasEquipment object.

Field: Zone Name

This field is the name of the zone and attaches a particular gas equipment statement to a thermal zone in the building.

Field: Schedule Name

This field is the name of the schedule that modifies the design level parameter for gas equipment (see next field). The schedule values can be any positive number. The actual energy input for gas equipment in a zone as defined by this statement is the product of the design level field and the value of the schedule specified by name in this field.

Field: Design Level Calculation Method

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal gas equipment level in the Zone. The key/choices are:

- EquipmentLevel

With this choice, the method used will be a straight insertion of the gas equipment level (Watts) for the Zone. (The Design Level field should be filled.)

- Watts/Area

With this choice, the method used will be a factor per floor area of the zone. (The Watts per Zone Floor Area field should be filled).

- Watts/Person

With this choice, the method used will be a factor of equipment level (watts) per person. (The Watts per person field should be filled).

Field: Design Level

This field (in Watts) is typically used to represent the maximum energy input to gas equipment in a zone that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the gas equipment design level could be a “diversity factor” applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour, the design level field is constant for all simulation environments.

Field: Watts per Zone Floor Area

This factor (watts/m²) is used, along with the Zone Area to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be “Watts/Area”.

Field: Watts per Person

This factor (watts/person) is used, along with the number of occupants (people) to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be “Watts/Person”.

Heat Gains from Gas Equipment:

The fuel input to the equipment ultimately appears as heat that contributes to zone loads. In EnergyPlus this heat is divided into four different fractions. Three of these are given by the input fields Fraction Latent, Fraction Radiant and Fraction Lost. A fourth, defined as the fraction of the heat from gas equipment convected to the zone air, is calculated by the program as:

$$f_{\text{convected}} = 1.0 - (\text{Fraction Latent} + \text{Fraction Radiant} + \text{Fraction Lost})$$

You will get an error message if Fraction Latent + Fraction Radiant + Fraction Lost exceeds 1.0.

Field: Fraction Latent

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of latent heat given off by gas equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by gas equipment to give the amount of latent energy produced by the gas equipment. This energy affects the moisture balance within the zone.

Field: Fraction Radiant

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of long-wave radiant heat being given off by gas equipment in a zone. The number specified in

this field will be multiplied by the total energy consumed by gas equipment to give the amount of long wavelength radiation gain from gas equipment in a zone.

Field: Fraction Lost

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of "lost" heat being given off by gas equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by gas equipment to give the amount of heat which is "lost" and does not impact the zone energy balances. This might correspond to input energy converted to mechanical work or heat that is vented to the atmosphere.

Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Cooking", "Clothes Drying", etc. A new meter for reporting is created for each unique subcategory (ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the equipment will be assigned to the "General" end-use subcategory.

Electric Equipment Electric Power [W]

Gas Equipment Gas Consumption Rate [W]

Hot Water Equipment Purchased Heating Consumption Rate [W]

Steam Equipment Purchased Heating Consumption Rate [W]

This field is the energy consumption rate for the equipment object in Watts.

Electric Equipment Radiant Heat Gain [J]

Gas Equipment Radiant Heat Gain [J]

Hot Water Equipment Radiant Heat Gain [J]

Steam Equipment Radiant Heat Gain [J]

Other Equipment Radiant Heat Gain [J]

This field is the amount of radiant heat gain for the equipment object in Joules. This is determined by the current heat gain from the equipment to the zone and the “Fraction Radiant” specified in the input. The radiant gains (long wavelength) are distributed to the surfaces using an area weighting scheme.

Electric Equipment Convective Heat Gain [J]***Gas Equipment Convective Heat Gain [J]******Hot Water Equipment Convective Heat Gain [J]******Steam Equipment Convective Heat Gain [J]******Other Equipment Convective Heat Gain [J]***

This field is the amount of convective heat gain for the equipment object in Joules. This is determined by the current heat gain from the equipment to the zone and the “Fraction Radiant”, “Fraction Lost”, “Fraction Latent” specified in input (1-FractionRadiant-FractionLost-FractionLatent = FractionConvected). The convective heat gain is added to the zone air heat balance directly.

Electric Equipment Latent Heat Gain [J]***Gas Equipment Latent Heat Gain [J]******Hot Water Equipment Latent Heat Gain [J]******Steam Equipment Latent Heat Gain [J]******Other Equipment Latent Heat Gain [J]***

This field is the amount of latent heat gain for the equipment object in Joules. This is determined by the current heat gain from the equipment to the zone and the “Fraction Latent” specified in the input.

Electric Equipment Lost Heat Gain [J]***Gas Equipment Lost Heat Gain [J]******Hot Water Equipment Lost Heat Gain [J]******Steam Equipment Lost Heat Gain [J]******Other Equipment Lost Heat Gain [J]***

This field is the amount of “lost” heat gain for the equipment object in Joules. This is determined by the current heat gain from the equipment to the zone and the “Fraction Lost” specified in the input. This amount does not affect the energy heat balance in the zone.

Electric Equipment Total Heat Gain [J]***Gas Equipment Total Heat Gain [J]******Hot Water Equipment Total Heat Gain [J]******Steam Equipment Total Heat Gain [J]******Other Equipment Total Heat Gain [J]***

The total heat gain field is sum of several other fields (radiant, latent, convective). This field is expressed in joules.

Electric Equipment Electric Consumption [J]

The electric equipment consumption field is sum of the other fields (radiant, latent, convective, lost). This field is expressed in joules.

Gas Equipment Gas Consumption [J]

The gas equipment consumption field is sum of the other fields (radiant, latent, convective, lost). This field is expressed in joules.

Hot Water Equipment Purchased Heating Consumption [J]***Steam Equipment Purchased Heating Consumption [J]***

The equipment consumption field is sum of the other fields (radiant, latent, convective, lost). This field is expressed in joules.

Zone Electric Equipment Electric Power [W]***Zone Gas Equipment Gas Consumption Rate [W]******Zone Hot Water Equipment Purchased Heating Consumption Rate [W]******Zone Steam Equipment Purchased Heating Consumption Rate [W]***

This field is the energy consumption rate for all equipment within the zone in Watts.

Zone Electric Equipment Radiant Heat Gain [J]***Zone Gas Equipment Radiant Heat Gain [J]******Zone Hot Water Equipment Radiant Heat Gain [J]******Zone Steam Equipment Radiant Heat Gain [J]******Zone Other Equipment Radiant Heat Gain [J]***

This field is the amount of radiant heat gain for all equipment within the zone in Joules. This is determined by the current heat gain from the equipment to the zone and the “Fraction Radiant” specified in the input. The radiant gains (long wavelength) are distributed to the surfaces using an area weighting scheme.

Zone Electric Equipment Convective Heat Gain [J]***Zone Gas Equipment Convective Heat Gain [J]******Zone Hot Water Equipment Convective Heat Gain [J]******Zone Steam Equipment Convective Heat Gain [J]******Zone Other Equipment Convective Heat Gain [J]***

This field is the amount of convective heat gain for all equipment within the zone in Joules. This is determined by the current heat gain from the equipment to the zone and the “Fraction Radiant”, “Fraction Lost”, “Fraction Latent” specified in input ($1 - \text{FractionRadiant} - \text{FractionLost} - \text{FractionLatent} = \text{FractionConvected}$). The convective heat gain is added to the zone air heat balance directly.

Zone Electric Equipment Latent Heat Gain [J]***Zone Gas Equipment Latent Heat Gain [J]******Zone Hot Water Equipment Latent Heat Gain [J]******Zone Steam Equipment Latent Heat Gain [J]******Zone Other Equipment Latent Heat Gain [J]***

This field is the amount of latent heat gain for all equipment within the zone in Joules. This is determined by the current heat gain from the equipment to the zone and the “Fraction Latent” specified in the input.

Zone Electric Equipment Lost Heat Gain [J]***Zone Gas Equipment Lost Heat Gain [J]******Zone Hot Water Equipment Lost Heat Gain [J]******Zone Steam Equipment Lost Heat Gain [J]******Zone Other Equipment Lost Heat Gain [J]***

This field is the amount of “lost” heat gain for all equipment within the zone in Joules. This is determined by the current heat gain from the equipment to the zone and the “Fraction Lost” specified in the input. This amount does not affect the energy heat balance in the zone.

Zone Electric Equipment Total Heat Gain [J]***Zone Gas Equipment Total Heat Gain [J]******Zone Hot Water Equipment Total Heat Gain [J]******Zone Steam Equipment Total Heat Gain [J]******Zone Other Equipment Total Heat Gain [J]***

The total heat gain field is sum of several other fields (radiant, latent, convective) for all equipment in the zone. This field is expressed in joules.

Zone Electric Equipment Electric Consumption [J]

The electric equipment consumption field is sum of the other fields (radiant, latent, convective, lost) for all equipment in the zone. This field is expressed in joules. This amount is also shown in the Electricity meters that are associated with the zone – Electricity:Facility, Electricity:Building, Electricity:Zone:<Zone Name>, and InteriorEquipment:Electricity.

Zone Gas Equipment Gas Consumption [J]

The gas equipment consumption field is sum of the other fields (radiant, latent, convective, lost) for all equipment in the zone. This field is expressed in joules. This amount is also shown in the Gas meters that are associated with the zone – Gas:Facility, Gas:Building, Gas:Zone:<Zone Name>, and InteriorEquipment:Gas. Gas, here, refers to “Natural Gas” fuel.

Zone Hot Water Equipment Purchased Heating Consumption [J]***Zone Steam Equipment Purchased Heating Consumption [J]***

The equipment consumption field is sum of the other fields (radiant, latent, convective, lost) for all equipment in the zone. This field is expressed in joules. These amounts are shown on the PurchasedHeating meters.

Note that zone energy consumption is not reported for OTHER EQUIPMENT and does not go on any meter.

ZoneBaseboard:OutdoorTemperatureControlled

This object specifies outside temperature-controlled (OTC) baseboard heating. The capacities (high and low) are specified in W at the temperatures specified. The schedule allows both capacities to change hourly on a proportional basis. This baseboard heater does not operate if the outdoor dry-bulb is above the high temperature limit. Between the high temperature and the low temperature, the capacity is interpolated (linear) between the high and the low capacity values. Below the low temperature, the capacity is set at the low

capacity value. This allows the user to add baseboard heat to a perimeter zone starting at a prescribed temperature and then slowly increases this capacity to a max value.

Example:

Temperature High = 10 C Capacity High = 100,000 W

Temperature Low = 0 C Capacity Low = 500,000 W

Table 14. Outdoor Temperature Controlled Baseboard Heat Temperature vs. Capacity

Outdoor Dry-bulb(C)	Baseboard Output
>10	0
10	100,000
8	180,000
6	260,000
4	340,000
2	420,000
0	500,000
< 0	500,000

Field: Name

The name of the ZoneBaseboard:OutdoorTemperatureControlled object.

Field: Zone Name

This field is the name of the zone and attaches the baseboard heat equipment statement to a thermal zone in the building.

Field: Schedule Name

This field is the name of the schedule that modifies the capacities (high and low) for baseboard heat equipment (see next field). The schedule values can be any positive number. The actual energy input for the baseboard equipment in a zone as defined by this statement depends on the actual outdoor temperature and where that temperature is in the range of Low Temperature to High Temperature..

Field: Capacity at Low Temperature

This is the baseboard equipment capacity (Watts) at the low temperature limit.

Field: Low Temperature

If the outdoor dry-bulb temperature (degrees Celsius) is at or below the low temperature the baseboard heater operates at the low temperature capacity.

Field: Capacity at High Temperature

This is the baseboard equipment capacity (Watts) at the high temperature limit.

Field: High Temperature

If the outdoor dry-bulb temperature (degrees Celsius) is greater than the high temperature the baseboard heater will not operate.

Field: Fraction Radiant

This field is a decimal number between 0.0 and 1.0 and is used to characterize the type of heat being given off by baseboard heat equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by the baseboard heat equipment to give the amount of long wavelength radiation gain to the zone.

Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Perimeter Baseboards", etc. A new meter for reporting is created for each unique subcategory (ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the baseboard equipment will be assigned to the "General" end-use subcategory.

ZoneBaseboard:OutdoorTemperatureControlled Output

ZoneBaseboard:OutdoorTemperatureControlled objects have output variables for individual objects and for zone totals. The following outputs are available:

```

Zone,Average,Baseboard Heat Electric Power [W]
Zone,Sum,Baseboard Heat Radiant Heat Gain [J]

```

Zone, Sum, Baseboard Heat Convective Heat Gain [J]
Zone, Sum, Baseboard Heat Total Heat Gain [J]
Zone, Sum, Baseboard Heat Electric Consumption [J]
Zone, Average, Zone Baseboard Heat Electric Power [W]
Zone, Sum, Zone Baseboard Heat Radiant Heat Gain [J]
Zone, Sum, Zone Baseboard Heat Convective Heat Gain [J]
Zone, Sum, Zone Baseboard Heat Total Heat Gain [J]
Zone, Sum, Zone Baseboard Heat Electric Consumption [J]

Baseboard Heat Electric Power [W]

This field is the electric power for the BASEBOARD HEAT object in Watts.

Baseboard Heat Radiant Heat Gain [J]

This field is the amount of radiant heat gain for the BASEBOARD HEAT object in Joules. This is determined by the current heat gain from the heater to the zone and the “Fraction Radiant” specified in the input. The radiant gains (long wavelength) are distributed to the surfaces using an area weighting scheme.

Baseboard Heat Convective Heat Gain [J]

This field is the amount of convective heat gain for the BASEBOARD HEAT object in Joules. This is determined by the current heat gain from the heater to the zone and the “Fraction Radiant” specified in input ($1 - \text{FractionRadiant} = \text{FractionConvected}$). The convective heat gain is added to the zone air heat balance directly.

Baseboard Heat Total Heat Gain [J]

This field is the total amount of heat gain for the BASEBOARD HEAT object in Joules. This is determined by the sum of the radiant and convective heat gains from the baseboard heat.

Baseboard Heat Electric Consumption [J]

The outdoor temperature controlled baseboard heat option is assumed to be fueled by electricity. This field is the same as the Baseboard Heat Total Heat Gain (above) in joules.

Zone Baseboard Heat Electric Power [W]

This field is the electric power for all BASEBOARD HEAT objects within the zone in Watts.

Zone Baseboard Heat Radiant Heat Gain [J]

This field is the amount of radiant heat gain for all BASEBOARD HEAT objects within the zone in Joules. This is determined by the current heat gain from the heater to the zone and the “Fraction Radiant” specified in the input. The radiant gains (long wavelength) are distributed to the surfaces using an area weighting scheme.

Zone Baseboard Heat Convective Heat Gain [J]

This field is the amount of convective heat gain for all BASEBOARD HEAT objects within the zone in Joules. This is determined by the current heat gain from the heater to the zone and the “Fraction Radiant” specified in input ($1 - \text{FractionRadiant} = \text{FractionConvected}$). The convective heat gain is added to the zone air heat balance directly.

Zone Baseboard Heat Total Heat Gain [J]

This field is the total amount of heat gain for all BASEBOARD HEAT objects within the zone in Joules. This is determined by the sum of the radiant and convective heat gains from the baseboard heat.

Zone Baseboard Heat Electric Consumption [J]

The outdoor temperature controlled baseboard heat option is assumed to be fueled by electricity. This field is the same as the Baseboard Heat Total Heat Gain (above) in joules. However, this amount is also shown in the Electricity meters that are associated with the

zone – Electricity:Facility, Electricity:Building, Electricity:Zone:<Zone Name>, and InteriorEquipment:Electricity.

Meters for Equipment Outputs

As described in each of the equipment sections, values for specific equipments will show up on the following meters:

Table 15. Distribution of Equipment to Meters

Meter Name	Scope	Equipment Specifics
Electricity:Facility	Entire Facility	Electric Equipment, OTC Baseboard Heat
Electricity:Building	All Zones	Electric Equipment, OTC Baseboard Heat
Electricity:Zone:<Zone Name>	Specific Zone	Electric Equipment, OTC Baseboard Heat
InteriorEquipment:Electricity	AllZones	Electric Equipment, OTC Baseboard Heat
<End-Use Subcategory>:InteriorEquipment:Electricity	Specific Subcategory	Electric Equipment, OTC Baseboard Heat
Gas:Facility	Entire Facility	Gas Equipment
Gas:Building	All Zones	Gas Equipment
Gas:Zone:<Zone Name>	Specific Zone	Gas Equipment
InteriorEquipment:Gas	AllZones	Gas Equipment
<End-Use Subcategory>:InteriorEquipment:Gas	Specific Subcategory	Gas Equipment

Group – Daylighting

Daylighting can be invoked in EnergyPlus by the use of two objects: **Daylighting:Controls** and **Daylighting:DELight:Controls**. These are described in the following object descriptions.

```

Daylighting dimming controls for the Lights object are activated by setting the Fraction Replaceable field to 1. Setting the field to 0 turns off the dimming controls.
Lights,
  Office Lights 1,          !- Name
  Main Office,             !- Zone Name
  Office Lights Schedule, !- Schedule Name
  LightingLevel,          !- Design Level calculation method
  1039.706, ,,            !- Lighting Level {W}
  0.0,                    !- Return Air Fraction
  0.35,                    !- Fraction Radiant
  0.25,                    !- Fraction Visible
  1.0,                    !- Fraction Replaceable -- activates dimming control by DAYLIGHTING objects
  Ambient Lighting;       !- End-Use Subcategory
    
```

Prior to version 1.3, dimming control was activated by setting the End-Use Subcategory (formerly called LightsEndUseKey) to "GeneralLights" when desired, and deactivated by setting to "TaskLights" when not desired.

Note that Daylighting:Controls and Daylighting:DELight:Controls objects may be intermixed in a single IDF but may not be used in the same zone.

Daylighting:Controls

In this method daylighting illuminance levels are calculated and then used to determine how much the electric lighting can be reduced. The daylight illuminance level in a zone depends on many factors, including sky condition; sun position; calculation point; location, size, and glass transmittance of windows; window shading devices; and reflectance of interior surfaces. Reduction of electric lighting depends on daylight illuminance level, illuminance set point, fraction of zone controlled and type of lighting control.

Field: Zone name

The name of the zone to which the following daylighting-related input applies.

Field: Total Daylighting Reference Points

Allowed values are 1 or 2. This is the number of reference points in the zone at which horizontal daylighting illuminance will be calculated based on input for the following fields. It is assumed that the photocells that control the overhead electric lighting respond to the light levels at the specified reference points.

Fields: (X,Y,Z) of First Reference Point

Required if Total Daylighting Reference Points = 1 or 2. These three fields are the X, Y and Z values of the First Reference point in the coordinate system you specified for daylighting reference points in the GlobalGeometryRules object. Figure 43 shows an example using the relative coordinate (to zone) system. Z is typically at desk height (0.8 m).

If you want to divide a thermal zone into two independently-controlled lighting zones, then Total Daylighting Reference Points should be set to 2 and (X,Y,Z) of the Second Reference Point (see following input fields) should also be specified.

Fields: (X,Y,Z) of Second Reference Point

The X, Y, and Z coordinates, in the same coordinate system, of the second daylighting reference point. Required if Total Daylighting Reference Points = 2. See Figure 43 for an example.

Figure 43. Example showing location of daylighting reference points in the zone coordinate system (relative) of a rectangular zone with three windows. (a) Perspective view, (b) plan view, (c) elevation view. All dimensions are in meters.

Field: Fraction of Zone Controlled by First Reference Point

The fraction of the zone’s floor-area whose electric lighting is controlled by the daylight illuminance at the First Reference Point. If there is only one reference point then a fraction equal to

$$1.0 - (\text{Fraction of Zone Controlled by First Reference Point})$$

is assumed to have no lighting control.

Field: Fraction of Zone Controlled by Second Reference Point

The fraction of the zone’s floor-area whose electric lighting is controlled by the daylight illuminance at the Second Reference Point. Required if Total Daylighting Reference Points = 2. A fraction equal to

$$1.0 - ([\text{Fraction of Zone Controlled by First Reference Point}] + [\text{Fraction of Zone Controlled by Second Reference Point}])$$

is assumed to have no lighting control.

Field: Illuminance SetPoint at First Reference Point

The desired lighting level (in lux) at the First Reference Point. This is the lighting level that would be produced at this reference point at night if the overhead electric lighting were operating at full input power. Recommended values depend on type of activity; they may be found, for example, in the Lighting Handbook of the Illuminating Engineering Society of North America. A typical value for general office work (excluding computer terminals) is 500 lux.

Field: Illuminance SetPoint at Second Reference Point

The desired lighting level (in lux) at the Second Reference Point. Required if Total Daylighting Reference Points = 2. This is the lighting level that would be produced at this reference point at night if the overhead electric lighting were operating at full input power.

Field: Lighting Control Type

The type of overhead electric lighting control. All reference points specified are assumed to have this type of control.

For Lighting Control Type = 1 (continuous), the overhead lights dim continuously and linearly from (maximum electric power, maximum light output) to (minimum electric power, minimum light output) as the daylight illuminance increases. The lights stay on at the minimum point with further increase in the daylight illuminance.

For Lighting Control Type = 2 (stepped), the electric power input and light output vary in discrete, equally spaced steps. The number of steps is given by Number of Steps (Excluding Off) of Stepped Control. For example, if Number of Steps = 3 and Illuminance Setpoint = 600, then the following table shows the fraction of the lights that are on vs. daylight illuminance.

Table 16. Stepped Lighting Control Example

Example of a Stepped Lighting Control System with Three Steps	
Daylight illuminance	Fraction of lights that are on
0-200	1.0
200-400	2/3
400-600	1/3
600 and above	0.0

Lighting Control Type = 3 (continuous/off) is the same as Lighting Control Type = 1 except that the lights switch off completely when the minimum dimming point is reached.

Field: Glare Calculation Azimuth Angle of View Direction Clockwise from Zone y-Axis

Daylight glare from a window depends on occupant view direction. It is highest when you look directly at a window and decreases as you look away from a window. This field specifies the view direction for calculating glare. It is the angle, measured clockwise in the horizontal plane, between the zone y-axis and the occupant view direction.

Field: Maximum Allowable Discomfort Glare Index

If a daylit zone has windows with shading devices (except exterior screens), the shades will be deployed if the daylight glare at the First Reference Point exceeds the value of this field. To get this type of glare control you have to specify Trigger = Glare, GlareOrSolarOnWindow, GlareOrHorizontalSolar, GlareOrOutsideAirTemp, GlareOrZoneAirTemp or GlareOrZoneLoad in WindowProperty:ShadingControl for one or more windows in the zone (see WindowProperty:ShadingControl).

If a zone has two or more windows with glare control, the shading devices will be deployed one by one in the order in which the windows are input until the glare level at each reference point falls below Maximum Allowable Discomfort Glare Index or is as close as possible to it.

The following table gives recommended values of Maximum Allowable Discomfort Glare Index.

Table 17. Recommended Values -- Discomfort Glare Index

Field: Minimum Input Power Fraction for Continuous Dimming Control

For Lighting Control Type = 1 (continuous), the lowest power the lighting system can dim down to, expressed as a fraction of maximum input power (see figure, below). For Lighting Control Type = 3 (continuous/off) this is the power fraction reached just before the lights switch off completely.

Figure 44. Illustration of continuous dimming relationship

The figure above shows the relationship between electric light output and electrical input.

Field: Minimum Light Output Fraction for Continuous Dimming Control

For Lighting Control Type = 1 (continuous), the lowest lighting output the lighting system can dim down to, expressed as a fraction of maximum light output (see figure, above). This is the

fractional light output that the system produces at minimum input power. For Lighting Control Type = 3 (continuous/off) this is the power fraction reached just before the lights switch off completely.

Field: Number of Stepped Control Steps

The number of steps, excluding off, in a stepped lighting control system (see figure, below). Required and must be >0 if Lighting Control Type = 2. The steps are assumed to be equally spaced.

Figure 45. Stepped lighting control with Number of Steps = 3.

Field: Probability Lighting will be Reset When Needed in Manual Stepped Control

May be specified if a stepped lighting control system (Lighting Control Type = 2) is manually operated, such as in a simple, one-step (on-off) system. Gives the probability the occupants of a daylit zone will set the electric lights to the correct level to obtain the required illuminance. The rest of the time the lights are assumed to be set one step too high. For example, consider an on-off lighting system (Number of Steps = 1) with a set point of 600 lux and 0.7 reset probability. Then, when daylighting exceeds 600 lux, the electric lights will be off 70% of the time and on 30% of the time.

Guidelines for Daylighting Modeling (Detailed Method)

Following are some guidelines for preparing EnergyPlus input to model the effects of daylighting. Before studying these guidelines, however, you should read the description of each input field under Daylighting:Controls, and review the IDF example, above, and the sample daylighting input, PurchAirWithDaylighting.idf.

Use of Window Multipliers

If an exterior wall in a daylit zone has a number of identical windows, the windows should be entered separately rather than using a window multiplier (ref: FenestrationSurface:Detailed). Using a multiplier would give an incorrect illuminance calculation since individual windows would not be positioned correctly on the wall.

Use of Zone Multipliers

A zone multiplier should not be used on a daylit zone if the windows in the zone are shadowed by exterior obstructions like trees or neighboring buildings, or by obstructions caused by other parts of building. The reason for this is that the shadowing on the windows of the multiplied zone may be different from zone to zone depending on exactly how the shadows fall on the zones. However, a zone multiplier may be used on a daylit zone if the shadowing is by overhangs, fins and/or window setback.

Thermal Zoning for Daylighting

To correctly calculate both direct and inter-reflected daylight illuminance you should try to model a thermal zone consisting of several similar rooms separated by interior walls as a representative room with a zone multiplier (ref: Zone). An example of this is shown in Figure 46. Room-1 is the representative room, with a zone multiplier = 4.

Interior walls IW-1, IW-2 and IW-3 should be treated as adiabatic, i.e., they should have Outside Boundary Condition = Surface and Outside Boundary Condition Object = IW-1, IW-2,

or IW-3, respectively (ref: BuildingSurface:Detailed). Similarly, if the ceiling and floor of Room-1 are interior surfaces, they should be treated as adiabatic.

Figure 46. For daylighting purposes the thermal zone enclosed by the dashed boundary line should be modeled as a typical zone (Room-1) with a zone multiplier of 4.

Sometimes a representative room cannot be found. Figure 47 shows a section of a building with four rooms having different daylighting characteristics because of different floor area, orientation and/or window size. In this case lumping the rooms into a single thermal zone would give nonsensical daylighting illuminance values because of the presence of the interior walls, which EnergyPlus ignores when calculating illuminance reaching a reference point directly from a window (i.e., without reflection). The solution in this case is to describe each room as a separate thermal zone with its own daylighting reference points, and input the interior walls because these will participate in the calculation of inter-reflected illuminance.

Figure 47. Rooms A, B, C and D have different daylighting characteristics. If lumped into a single thermal zone the daylighting calculation will be less accurate because the blockage of direct light by the interior walls between these rooms is modeled with some simplifications (see Interior Obstructions below). To get a good daylighting calculation each room should be input as a separate thermal zone.

Multiple Lighting Zones

The detailed daylighting calculation allows a thermal zone to be divided into two independently-controlled lighting zones. (See the fields: Fraction of Zone Controlled by First Reference Point, Fraction of Zone Controlled by Second Reference Point, Illuminance SetPoint at First Reference Point, and Illuminance SetPoint at Second Reference Point.) An example is shown in Figure 48, where a relatively deep thermal zone has two lighting zones of equal area.

Figure 48. Two independently-controlled lighting zones, each with 50% of the area of the thermal zone.

Fins, Overhangs and Other Exterior Obstructions

The daylighting calculation accounts for the presence of exterior obstructions in determining the amount of light that strikes the windows. For daylighting purposes exterior obstructions fall into three categories:

- (1) Fins, overhangs, trees, neighboring buildings, etc., entered with the objects Shading:Zone:Detailed, Shading:Site:Detailed, or Shading:Building:Detailed.
- (2) Building surfaces like walls and roofs (in an L-shaped building, for example).
- (3) Surfaces associated with window setback.

Category (1) obstructions can have an associated solar transmittance schedule (see description of the field Transmittance Schedule Name for these shading surfaces). If this schedule is not specified, the surface is opaque (has zero transmittance).

The daylighting calculation takes the transmittance into account in determining, for example, how much light enters a window through a translucent awning. It is assumed that the solar and visible transmittance is the same and that the surfaces are non-diffusing, i.e., they do not change the direction of transmitted light. Ref:Daylighting:Controls.

Category (2) and (3) surfaces are assumed to be opaque.

Surfaces in all three categories are assumed to be black, i.e., they do not reflect light, unless you set if “Reflections” option is chosen in the Building object. Then obstructions can reflect light, such as the top of an overhang reflecting light onto the window above. Ref: Building, Field: Solar Distribution (with reflections options).

Interior Obstructions

The daylighting calculation accounts for the presence of interior obstructions that lie between a window and a reference point. Unlike exterior obstructions, which can be light transmitting, interior obstructions are assumed to be opaque. Interior obstructions can reduce or eliminate the light directly reaching the reference point through a window.

However, interior obstructions that are walls, ceilings or floors are reflecting so they contribute to the inter-reflected component of daylight illuminance as do the non-obstructing zone surfaces.

Interior obstructions can belong to the Shading object series. This type of obstruction is assumed to be non-reflecting so does not contribute to the inter-reflected component of daylight illuminance.

An example of an interior obstruction that is a wall in an L-shaped room is shown in Figure 49. Here, wall A (or, equivalently, Wall B) prevents light from directly getting to the Reference Point from the window.

Figure 49. Wall A (or Wall B) is an interior obstruction that prevents light from directly reaching the daylighting reference point from the window.

Double Façades: Daylighting through Interior Windows

The Daylighting:Controls method, with no additional user input, calculates the contribution of daylight that passes into a target zone through interior windows.⁷ The origin of this daylight is exterior windows in adjacent zones that share interior windows with the target zone. This capability is aimed at daylighting through a **double façade** (also called “double envelope” or “double skin.”)

This is illustrated in Figure 50, which shows a double-façade buffer zone, Z0, with exterior windows EW1 and EW2. Z0 shares interior windows IW1, IW2 and IW3 with daylit occupied zones ZD1, ZD2 and ZD3, respectively (“daylit” here means the zone has an associated Daylighting:Controls object). The daylight illuminance at reference points RP1, RP2 and RP3 comes from the interior windows and has two main sources:

1. Daylight that passes through both an exterior window and an interior window in Z0 and reaches a reference point without reflection. This is called “direct illuminance.”
2. Daylight from Z0 that passes through an interior window and reaches a reference point by inter-reflection in the daylit zone. Because the program calculates this source from the interior solar distribution in Z0 it is recommended that the most accurate calculation of this distribution be made, which occurs if Solar Distribution = FullInteriorAndExterior in the Building object.

A third possible source is neglected because it is generally small in double-façade cases. This is daylight that is reflected from the surfaces of Z0, passes through an interior window and then reaches a reference point without inter-reflection in the daylit zone.

PurchAirWithDoubleFacadeDaylighting.idf is an input example of daylighting through an interior window.

⁷ Formerly, only the exterior windows in a zone could provide daylight to that zone.

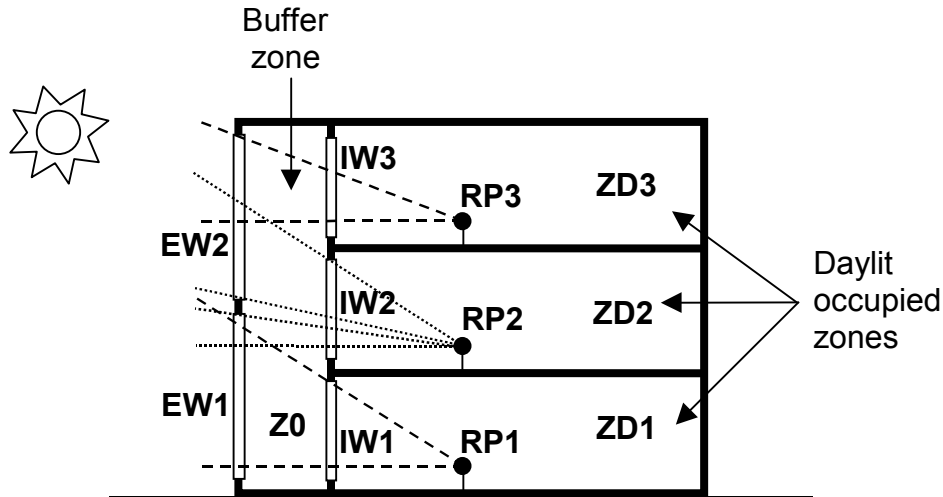

Figure 50. Vertical section through a double-façade building showing daylighting through interior windows. The dashed lines show that (1) reference point RP1 receives direct light from exterior window EW1 via interior window IW1; (2) RP2 receives direct light from EW1 and EW2 via IW2; and (3) RP3 receives direct light from EW2 via IW3.

Interior Window Daylighting Configurations that EnergyPlus Can Calculate

Figure 51 shows schematically the general configuration of daylighting through interior windows that can be calculated with EnergyPlus. Here, daylit zone ZD has one or more interior windows that are adjacent to other zones, each of which has one or more exterior windows. ZD itself may or may not have exterior windows. If it does, then the daylight illuminance from its exterior and interior windows will be additive. The zones adjacent to ZD may or may not be daylit and may or may not have other interior windows that are not adjacent to ZD. (The program does not consider the illuminance in ZD from electric lighting in adjacent zones.)

Figure 51. General configuration of daylighting through interior windows that can be calculated with EnergyPlus. IW = interior window, EW = exterior window.

Interior Window Daylighting Configurations that EnergyPlus Cannot Calculate

Figure 52 shows schematically a configuration of daylighting through interior windows that cannot be calculated with EnergyPlus. Here, zone Z has an interior window that is adjacent to zone Z1 which in turn has an interior window adjacent to zone Z2. However, the daylight from the exterior window in Z2 that enters Z after passing through Z1 is not calculated because Z2 is not adjacent to Z.

Figure 52. Configuration in which daylighting of zone Z through its interior window cannot be calculated with EnergyPlus. IW = interior window, EW = exterior window.

Restrictions on Shading Devices

There are two restrictions on the use of exterior-window shading devices when a daylight zone has interior windows:

- 1) If two daylight zones share an interior window, neither zone can have an exterior window whose shading device does glare control (i.e., the WindowProperty:ShadingControl for the exterior window has Glare Control Is Active = Yes).
- 2) If two daylight zones share an interior window, neither zone can have an exterior window with a WindowProperty:ShadingControl that has Shading Control Type = MeetDaylightIlluminanceSetpoint.

DElight Daylighting Method

The DElight method of analyzing daylighting in buildings is very similar to that used in the Detailed method. For each point in time, DElight calculates the interior daylighting illuminance at specified reference points and then determines how much the electric lighting can be reduced while still achieving a combined daylighting and electric lighting illuminance target. The daylight illuminance level in a zone depends on many factors, including exterior light sources; location, size, and visible light transmittance of simple and complex fenestration systems; reflectance of interior surfaces; and location of calculation reference points. The subsequent reduction of electric lighting depends on daylight illuminance level, illuminance set point, fraction of zone controlled, and type of lighting control.

There are two primary differences between the Detailed and DElight methods of calculating interior illuminance levels. The first is that DElight includes the capability of analyzing complex fenestration systems that include geometrically complicated shading systems (e.g., roof monitors) and/or optically complicated glazings (e.g., prismatic or holographic glass). The second key difference is that DElight uses a radiosity method to calculate the effects of light reflection inside a zone. These methods are discussed in more detail in the engineering documentation.

There are other important differences between the two methods. One is the inability of DElight to perform the type of dynamic shading controls possible using the Detailed method at each point in time during the thermal simulation (e.g., changes in electrochromic glazing transmittances and blind slat angles). Another is the DElight ability to include more than two reference points in its interior illuminance and electric lighting reduction calculations. A third is the current lack of visual quality (e.g., glare) calculations performed by DElight. Fourth, the modeling of interior obstructions is different in the two methods. In the DElight method interior obstructions block interreflections but do not block the initial direct illuminance. In the Detailed method, interior obstructions block the initial direct illuminance but do not block interreflections. See the engineering documentation for more details.

Input for invoking the DElight method involves three object types: **Daylighting:DElight:Controls**, **Daylighting:DElight:ReferencePoint**, and **Daylighting:DElight:ComplexFenestration**. Each of these objects is described below.

Daylighting:DELight:Controls

The first input object required for invoking the DELight method is the Daylighting:DELight:Controls object, which defines the parameters of each daylighting zone within a building. This object must be associated with a specific thermal zone within the building for which the reduction in electric lighting due to daylight illuminance will be accounted.

Field: Name

User name of the DELight daylighting zone to which the following input applies.

Field: Zone Name

The name of the thermal Zone hosting this DELight daylighting zone. This must be a valid name that has been associated with a thermal Zone contained in the same EnergyPlus input data file.

Field: Lighting Control Type

The type of overhead electric lighting control. All reference points specified are assumed to have this type of control.

For Lighting Control Type = 1 (continuous), the overhead lights dim continuously and linearly from (maximum electric power, maximum light output) to (minimum electric power, minimum light output) as the daylight illuminance increases. The lights stay on at the minimum point with further increase in the daylight illuminance.

For Lighting Control Type = 2 (stepped), the electric power input and light output vary in discrete, equally spaced steps. The number of steps is given by Number of Steps (Excluding Off) of Stepped Control. For example, if Number of Steps = 3 and Illuminance Setpoint = 600, then the following table shows the fraction of the lights that are on vs. daylight illuminance.

Table 18. Stepped Lighting Control Example

Example of a Stepped Lighting Control System with Three Steps	
Daylight illuminance	Fraction of lights that are on
0-200	1.0
200-400	2/3
400-600	1/3
600 and above	0.0

Lighting Control Type = 3 (continuous/off) is the same as Lighting Control Type = 1 except that the lights switch off completely when the minimum dimming point is reached.

Field: Minimum Input Power Fraction for Continuous Dimming Control

For Lighting Control Type = 1 (continuous), the lowest power the lighting system can dim down to, expressed as a fraction of maximum input power (see figure, below). For Lighting Control Type = 3 (continuous/off) this is the power fraction reached just before the lights switch off completely.

Figure 53. Illustration of continuous dimming relationship

The figure above shows the relationship between electric light output and electrical input.

Field: Minimum Light Output Fraction for Continuous Dimming Control

For Lighting Control Type = 1 (continuous), the lowest lighting output the lighting system can dim down to, expressed as a fraction of maximum light output (see figure, above). This is the fractional light output that the system produces at minimum input power. For Lighting Control Type = 3 (continuous/off) this is the power fraction reached just before the lights switch off completely.

Field: Number of Steps (Excluding Off) for Stepped Control

The number of steps, excluding off, in a stepped lighting control system (see figure, below). Required and must be >0 if Lighting Control Type = 2. The steps are assumed to be equally spaced.

Figure 54. Stepped lighting control with Number of Steps = 3.

Field: Probability Lighting Will Be Reset When Needed in Manual Stepped Control

May be specified if a stepped lighting control system (Lighting Control Type = 2) is manually operated, such as in a simple, one-step (on-off) system. Gives the probability the occupants of a daylit zone will set the electric lights to the correct level to obtain the required illuminance. The rest of the time the lights are assumed to be set one step too high. For

example, consider an on-off lighting system (Number of Steps = 1) with a set point of 600 lux and 0.7 reset probability. Then, when daylighting exceeds 600 lux, the electric lights will be off 70% of the time and on 30% of the time.

Field: Gridding Resolution

The maximum surface area for nodes in gridding (subdividing) all surfaces in the DElight zone. All reflective and transmitting surfaces will be subdivided into approximately square nodes that do not exceed this maximum. Higher resolution subdivisions require greater calculation times, but generally produce more accurate results. This same gridding resolution is also used to subdivide any Complex Fenestration System surfaces. It is advisable to perform at least one simulation of new input using a small gridding resolution such as 0.1m2 to compare these results against simulation runs at lower resolution (i.e., higher maximum area nodal grids) to get a sense of possible levels of error.

```

Daylighting:DELight:ReferencePoint

The second input object required for invoking the DELight method is the Daylighting:DELight:ReferencePoint object, which defines the parameters of each Reference Point within the associated DELight daylighting zone. This object must be associated with a specific Daylighting:DELight:Controls object instance. There may be up to a maximum of 100 Reference Points for each DELight daylighting zone. Each Reference Point that is input does NOT need to be included in the control of the electric lighting system within the zone. This is determined by the fraction of the zone controlled by each Reference Point, which can be input as 0. Note that the sum of all Reference Point control fractions must equal 1 to obtain correct overall results.

Field: Name

User name of the DELight daylighting Reference Point to which the following input applies.

Field: DELight Name

The name of the Daylighting:DELight:Controls object instance hosting this Reference Point. This must be a valid name that has been associated with a DELight daylighting Zone contained in the same EnergyPlus input data file.

Fields: (X,Y,Z) of Reference Point

These three fields are the X, Y and Z values of the Reference point in the coordinate system you specified for daylighting reference points in the GlobalGeometryRules object. Figure 55 shows an example using the relative coordinate (to zone) system. Z is typically at work surface height (e.g., 0.8m for a desk).

Figure 55. Example showing location of two daylighting reference points in the zone coordinate system (relative) of a rectangular zone with three windows. (a) Perspective view, (b) plan view, (c) elevation view. All dimensions are in meters.

Field: Fraction of Zone Controlled by Reference Point

The zone floor-area fraction of the electric lighting that is controlled by the daylight illuminance at this Reference Point. If the sum of the values for this field for all Reference Points input for a given daylighting zone is less than 1.0, then the remaining fraction (i.e., 1.0 – Sum) is assumed to not have lighting control.

Note that Reference Points may be input with a 0.0 value for this fraction. In this case, daylight factors and interior illuminance values will be calculated for the Reference Point, but it will play no role in controlling the electric lighting within the daylighting zone to which it belongs.

Field: Illuminance Setpoint at Reference Point

The desired lighting level (in lux) at this Reference Point. This is assumed to be the lighting level that would be produced at this reference point at night if the overhead electric lighting were operating at full input power. Recommended values depend on the type of activity and may be found, for example, in the Lighting Handbook of the Illuminating Engineering Society of North America. A typical value for general office work (excluding computer terminals) is 500 lux.

Daylighting:DELight:ComplexFenestration

The third input object related to the DElight method is the Daylighting:DElight: Complex Fenestration object. The DElight daylighting analysis method can be applied to daylighting zones that contain only simple fenestration systems such as windows and skylights that are

standard EnergyPlus sub-surfaces. In this situation, no Daylighting:DElight: Complex Fenestration object would be input.

In addition to analyzing simple fenestration systems, DElight includes the capability of analyzing complex fenestration systems such as geometrically complicated static shading systems (e.g., roof monitors) and/or optically complicated glazings (e.g., prismatic or holographic glass). This capability is based on characterizing these complex fenestration systems (CFS) using bi-directional transmittance distribution functions (BTDF). In general, BTDF data for a specific CFS must be either measured or simulated (e.g., using ray-tracing techniques) prior to employing DElight to analyze it within EnergyPlus. The current implementation of DElight CFS calculations within EnergyPlus supports two approaches to the input of BTDF, an analytical approach and a file-based approach. The details of inputting these two approaches are described below under the User Complex Fenestration Type field.

Two analytical CFS BTDF types are currently supported, window and light shelf. The file-based approach requires that a user has access to a data file containing raw BTDF data that DElight reads as additional input during its analysis calculations. BTDF data files are described separately since it is anticipated that individual EnergyPlus users will not create these data files themselves.

The methods related to characterizing and analyzing CFS using BTDF are still evolving. DElight is an early implementation of CFS analysis methods. These methods, and the input associated with them here, will likely change in the future.

Field: User Name

User name of the DElight daylighting Complex Fenestration to which the following input applies.

Field: Complex Fenestration Type

Type name of the DElight daylighting Complex Fenestration system to be analyzed. This type name must take one of the following two forms.

```
BTDF^GEN^Analytical Type^Normal Visible Transmittance^Dispersion Angle
```

```
BTDF^FILE^Filename
```

The first form above is for supported analytical CFS types which currently include WINDOW and LIGHTSHELF. While these analytical types are relatively simple, they represent flexible ways to explore diffusing CFS systems and the impact of light shelves in redirecting light through an aperture. Each of these types also requires the visible transmittance of the CFS at normal incidence angle, and a dispersion angle (in degrees) that represents the “spread” of transmitted light. A small dispersion angle of 10 corresponds to clear glazing while a large angle of 90 corresponds to perfectly diffusing glazing. The “^” symbol must be used as a delimiter between sub-fields within this Complex Fenestration type name string as shown in the IDF example for WINDOW below, and in the DElight sample input data files.

The second form above is for CFS types for which there is pre-measured or pre-simulated BTDF data. In this case the Filename sub-field must be a valid data file name that is associated with an existing BTDF dataset that DElight can use in its calculations.

Field: Building Surface Name

The name of the heat transfer surface object instance hosting this Complex Fenestration, analogous to the Building Surface Name field for subsurfaces such as Windows. This must be a valid name that has been associated with a heat transfer surface contained in the same EnergyPlus input data file.

Field: Window Name

The name of the Window (ref: FenestrationSurface:Detailed object) instance that will be used to account for the geometry, and the solar/thermal gains/losses, of the Complex Fenestration system surface. This must be a valid name that has been associated with a Window contained in the same EnergyPlus input data file. The geometry for the Complex Fenestration is taken from the geometry input for this standard EnergyPlus subsurface, hence the term “Doppelganger.”

Note that DELight only deals with the visible spectrum of light transmitted through a Complex Fenestration. To account for the solar/thermal influences of a Complex Fenestration, a geometrically coincident subsurface that will be accounted for by methods already within EnergyPlus must be defined in the input data file. This is an interim solution to the issue of accounting for solar/thermal influences that will likely change as techniques analogous to the daylighting analysis of BTDF are developed.

Field: Fenestration Rotation

The in-plane counter-clockwise rotation angle between the Complex Fenestration optical reference direction and the base edge of the Doppelganger Surface geometry. The Complex Fenestration optical reference direction is the direction of the zero azimuth angle for the BDTF dataset. This Rotation angle will typically be zero when the Doppelganger surface is rectangular and its width edge is aligned with the Complex Fenestration optical reference direction.

DElight Output

In addition to the daylighting-specific outputs for DElight listed below, two ASCII text files are created during an EnergyPlus run that includes DElight analysis. Following completion of an EnergyPlus run, these files are given names that consist of the project name appended with DElight.in and DElight.out. The format of these files is described in the Output Details and Examples document.

The following daylighting-specific outputs are available for Daylighting:DELight:Controls within the standard EnergyPlus output environment:

```

Zone,Average,DElight Reference Point Daylight Illuminance [lux]
Zone,Average,Ltg Power Multiplier from Daylighting []

```

DElight Reference Point Daylight Illuminance [lux]

The total daylight illuminance at a DElight reference point from all of the exterior windows in a daylit zone.

Ltg Power Multiplier from Daylighting []

The amount by which the overhead electric lighting power in a zone is multiplied due to usage of DElight calculated daylighting to dim or switch electric lights. For example, if the multiplier is M and the electric power without dimming is P, then the electric power with dimming is M*P. The multiplier varies from 0.0, which corresponds to maximum dimming (zero electric lighting), to 1.0, which corresponds to no dimming.

Daylighting Output

The following daylighting-specific outputs are available for Daylighting:Controls:

```

Zone,Average,Exterior Beam Normal Illuminance [lux]
Zone,Average,Exterior Horizontal Beam Illuminance [lux]
Zone,Average,Exterior Horizontal Illuminance From Sky [lux]
Zone,Average,Luminous Efficacy of Beam Solar Radiation [lum/W]
Zone,Average,Luminous Efficacy of Sky Diffuse Solar Radiation [lum/W]

Surface,Average,Daylight Luminance of Window As Viewed From Ref Point 2
[cd/m2]
Surface,Average,Daylight Illum at Ref Point 2 from Window [lux]
Zone,Average,Daylight Illum at Ref Point 2 [lux], if applicable
Zone,Average,Glare Index at Ref Point 2 [], if applicable
Zone,Average,Ltg Power Multiplier from Daylighting []

```

Exterior Beam Normal Illuminance [lux]

Beam normal illuminance of the sun at the earth's surface, measured in lux (lumens/m²)

Exterior Horizontal Beam Illuminance [lux]

Beam illuminance on an unobstructed horizontal plane at the earth's surface. Equals "Exterior Beam Normal Illuminance" times sine of solar altitude.

Exterior Horizontal Illuminance From Sky [lux]

Illuminance from sky solar radiation on an unobstructed horizontal plane at the earth's surface. The total exterior horizontal illuminance is the sum of "Exterior Horizontal Beam Illuminance" and "Exterior Horizontal Illuminance From Sky."

Luminous Efficacy of Beam Solar Radiation [lum/W]

A measure of the visible light content of beam solar radiation; equal to the number of lumens per watt of beam solar radiation. Depends on atmospheric conditions (moisture, turbidity, cloudiness) and solar altitude.

Luminous Efficacy of Sky Diffuse Solar Radiation [lum/W]

A measure of the visible light content of sky diffuse solar radiation; equal to the number of lumens per watt of sky diffuse solar radiation. Depends on atmospheric conditions (moisture, turbidity, cloudiness) and solar altitude.

Sky Clearness for Daylighting Calculation []

Clearness of sky. One of the factors used to determine sky type and luminous efficacy of solar radiation (see *EnergyPlus Engineering Document*). Sky Clearness close to 1.0 corresponds to an overcast sky. Sky Clearness > 6 is a clear sky.

Sky Brightness for Daylighting Calculation []

Brightness of sky. One of the factors used to determine sky type and luminous efficacy of solar radiation (see *EnergyPlus Engineering Document*).

Daylight Luminance of Window As Viewed From Ref Point 1 [cd/m²]

The area-averaged luminance of an exterior window as viewed from the first reference point in the daylit zone containing the window. In general, higher window luminance values are associated with higher daylight glare values. (Printed only for exterior windows in daylit zones without interior windows.)

Daylight Illum at Ref Point 1 from Window [lux]

The contribution from a particular exterior window to the daylight illuminance at the first reference point in the daylit zone containing the window. (Not printed for exterior windows in daylit zones with interior windows.)

Daylight Illum at Ref Point 1 [lux]

The total daylight illuminance at the first reference point from all of the exterior windows in a daylit zone.

Glare Index at Ref Point 1 []

The daylight glare index at the first reference point in a daylit zone.

Daylight Luminance of Window As Viewed From Ref Point 2 [cd/m²]

The area-averaged luminance of an exterior window as viewed from the second reference point, if present, in the daylit zone containing the window. Note that, for a bare window, this value can be different from the corresponding value at the first reference point since different regions of the sky and ground will be visible from the two reference points, and different ranges of angles of incidence and associated glass transmittance values will be involved. (Not printed for exterior windows in daylit zones with interior windows.)

Daylight Illum at Ref Point 2 from Window [lux]

The contribution from a particular exterior window to the daylight illuminance at the second reference point, if present, in the daylit zone containing the window. (Not printed for exterior windows in daylit zones with interior windows.)

Glare Index at Ref Point 2 []

The daylight glare index at the second reference point, if present, in a daylit zone.

Ltg Power Multiplier from Daylighting []

The amount by which the overhead electric lighting power in a zone is multiplied due to usage of daylighting to dim or switch electric lights. For example, if the multiplier is M and the electric power without dimming is P, then the electric power with dimming is M*P. The multiplier varies from 0.0, which corresponds to maximum dimming (zero electric lighting), to 1.0, which corresponds to no dimming.

Output:IlluminanceMap

The Output:IlluminanceMap object expands on the reporting capabilities of the daylighting simulation. For any zone simulated with Daylighting:Controls, the illuminance map can generate up to a 10 x 10 grid of additional daylighting reference points. The resulting map is output as a comma delimited text file that can be imported into a spreadsheet program for rapid visualization of the daylighting illuminance patterns in a zone.

```

Field: Name

The name of the map object.

Field: Zone Name

Reference to a zone with Daylighting:Controls.

Field: Z Height

The height or elevation of the grid of daylighting points.

Field: X Minimum Coordinate

The minimum X coordinate boundary for the map.

Field: X Maximum Coordinate

The maximum X coordinate boundary for the map.

Field: Number of X Grid Points

The number of daylighting reference points in the X direction from the minimum to the maximum boundaries. (Maximum of 10.)

Field: Y Minimum Coordinate

The minimum Y coordinate boundary for the map.

Field: Y Maximum Coordinate

The maximum Y coordinate boundary for the map.

Field: Number of Y Grid Points

The number of daylighting reference points in the Y direction from the minimum to the maximum boundaries. (Maximum of 10.)

Note: Daylighting factors cannot be accurately calculated for reference points that are very close to a wall or window (less than 0.15 m or 6 inches). An error is reported for a reference point that is too close to a window, but no error is reported for a point that is too close to a wall.

```
Output:IlluminanceMap,

```

Since not all zones are rectangular, it is possible to have map points that are outside the zone. Any illuminance registered at these points is inaccurate and, additionally, a “*” marks these values for easy observance.

OutputControl:IlluminanceMap:Style

This object specifies the “style” for the illuminance map output (described in the Output Details and Examples document). As described above (see: EnergyPlus Output Processing), the user may select the “style” for the daylighting illuminance map output file (eplusmap.<ext>).

Field: Column Separator

For this field, the desired separator for columns is entered. “Comma” creates comma separated fields/columns in the outputs (eplusmap.csv file is created). “Tab” creates tab separated fields/columns in the outputs (eplusmap.tab file is created). “Fixed” creates space

separated fields/columns in the outputs (eplusmap.txt file is created) but these are not necessarily lined up for easy printing.

Note that both tab and comma separated files easily import into Excel™ or other spreadsheet programs. The tab delimited files can also be viewed by text editors, word processing programs and easily converted to “tables” within those programs.

```
OutputControl:IlluminanceMap:Style,
  \memo default style for the Daylighting Illuminance Map is comma -- this works well for
  \memo importing into spreadsheet programs such as Excel(tm) but not so well for word
  \memo processing programs -- there tab may be a better choice. fixed puts spaces between
  \memo the "columns"

```

Daylighting Devices

Daylighting devices work in conjunction with the Daylighting:Controls object to simulate components that can improve daylighting in a zone.

Daylighting devices are also tightly integrated into the zone heat balance. The thermal effects of these devices are simulated with or without the use of a Daylighting:Controls object.

There are two types of daylighting device in EnergyPlus: tubular daylighting devices and daylighting shelves.

DaylightingDevice:Tubular

Tubular daylighting devices (TDDs), also known as tubular skylights or light pipes, are used to bring natural exterior daylight into the hard-to-reach, interior spaces of a building.

TDDs consist of three components: a dome, a pipe, and a diffuser.

Figure 56. Tubular daylighting device diagram.

In EnergyPlus each of these components corresponds to an object in the input file.

The dome and diffuser are defined in the same way as windows using the FenestrationSurface:Detailed object. The *Surface Type* field must be specified as TubularDaylightDome or TubularDaylightDiffuser accordingly.

The location and orientation of the dome surface affect the total amount of daylight collected. The *Base Surface* of the diffuser object determines to which zone the daylighting is delivered. The location and orientation of the diffuser surface affect the amount of daylight received at the Daylighting:Controls reference points.

Although the object definition is the same as for a window, there are several restrictions on TubularDaylightDome and TubularDaylightDiffuser objects:

- Shading control devices are not allowed.
- Frames and dividers are not allowed.
- Multipliers must be 1.0.
- Dome, diffuser, and pipe areas (as given by diameter) must be approximately equal.
- Outside face environment objects are not allowed.
- Dome and diffuser constructions cannot be more than one layer.

Since commercial TDDs are assumed to be cylindrical in shape, it is recommended that the circular areas of the actual dome and diffuser be approximated with a square of equivalent area for the TubularDaylightDome and TubularDaylightDiffuser objects. Although it is possible to use a triangular surface instead, a square is a much better geometric approximation of a circle.

Note that the TubularDaylightDome surface is allowed to have a different position and tilt from the roof base surface. If the actual TDD projects some height above the roof surface, the TubularDaylightDome coordinates should be located accordingly.

Figure 57. Tubular daylighting device DXF output.

The TubularDaylightDome surface automatically casts a shadow on the roof base surface. However, since the pipe is not represented by a surface, it will not cast a shadow. If this effect must be simulated, one or more SURFACE:SHADING objects can be used.

The dome and diffuser objects are connected by the DAYLIGHTING DEVICE:TUBULAR object:

```

Field: Name

The name of the TDD object.

Field: Dome Name

Reference to a FenestrationSurface:Detailed object with *Surface Type* TubularDaylightDome.

Field: Diffuser Name

Reference to a FenestrationSurface:Detailed object with *Surface Type* TubularDaylightDiffuser.

Field: Construction Name

The construction of the TDD pipe. The visible and solar absorptance of the inside material layer determines the reflectivity of the inner mirrored surface of the TDD. This is very important for the overall transmittance of the TDD.

Field: Diameter

The diameter [m] of the TDD pipe. The area of the pipe must match the areas of the dome and diffuser.

Field: Total Length

The total length [m] of the TDD pipe between the dome and the diffuser, including the exterior part above the roof. The exterior length is determined internally by subtracting the transition zone lengths from the total length.

Field: Effective Thermal Resistance

The effective thermal resistance [$\text{m}^2\text{-K/W}$], i.e. R-value, of the TDD between the exterior dome surface and the interior diffuser surface.

Field: Transition Zone<#> Name

Name of zone that the TDD pipe passes through before reaching the delivery zone.

Field: Transition Zone <#> Length

Length of pipe [m] in the transition zone. This is used for determining heat gains due to solar absorbed by the pipe in each transition zone. The distribution of absorbed solar gains can be customized by adjusting the length of pipe in each transition zone. The transition zone gain is proportional to the length of pipe in the zone. If no transition zones are specified, all solar absorbed by the pipe is lost to the exterior environment.

The *Transition Zone Name* and *Transition Zone Length* fields can be repeated for additional transition zones.

Tubular Daylighting Device Output

The following output variables are specific to the DaylightingDevice:Tubular object:

```

Zone,Average,TDD Transmitted Solar [W]
Zone,Average,TDD Pipe Absorbed Solar [W]
Zone,Average,TDD Heat Gain [W]
Zone,Average,TDD Heat Loss [W]
Zone,Average,TDD Beam Solar Transmittance []
Zone,Average,TDD Beam Visible Transmittance []
Zone,Average,TDD Diffuse Solar Transmittance []
Zone,Average,TDD Diffuse Visible Transmittance []

```

In addition, several surface and window variables are also reported for the TubularDaylightDome and TubularDaylightDiffuser objects. For the TubularDaylightDome:

```

Zone,Average,Surface Ext Sunlit Area [m2]
Zone,Average,Surface Ext Sunlit Fraction []
Zone,Average,Surface Ext Solar Incident[W/m2]
Zone,Average,Surface Ext Solar Beam Incident[W/m2]
Zone,Average,Surface Ext Solar Sky Diffuse Incident[W/m2]
Zone,Average,Surface Ext Solar Ground Diffuse Incident[W/m2]
Zone,Average,Surface Ext Solar Beam Cosine Of Incidence Angle[]
Zone,Average,Window Transmitted Solar[W]
Zone,Average,Window Solar Absorbed:All Glass Layers[W]

```

For the TubularDaylightDiffuser:

Zone,Average,Surface Ext Solar Incident[W/m2] (*incident inside of pipe*)
 Zone,Average,Window Transmitted Solar[W] (*same as TDD Transmitted Solar*)
 Zone,Average,Window Solar Absorbed:All Glass Layers[W]

DaylightingDevice:Shelf

Daylighting shelves, or simply light shelves, are another device for bringing more daylight into a building. Installed as an accessory to a window, daylighting shelves work by reflecting exterior light onto the ceiling of a room. Daylighting shelves can have an inside shelf, an outside shelf, or both.

Figure 58. Daylighting shelf diagram.

The inside shelf redistributes light that would have entered the zone anyway. Instead of entering as a beam, all light is reflected onto the zone ceiling and is converted to diffuse shortwave radiation.

The outside shelf changes the amount of light entering the zone. If the shelf surface is more reflective than the ground, it can increase the amount of light incident on the upper part of the window. However, the shading effect of the outside shelf on the lower part of the window must also be considered as it can easily negate any gain achieved in the upper part of the window. All light reflected from the outside shelf that enters the upper window is assumed to strike the ceiling.

Figure 59. Daylighting shelf DXF output.

In EnergyPlus a daylighting shelf is simulated using a DaylightingDevice:Shelf object in combination with up to three other objects: a window, a heat transfer surface, and an attached shading surface.

The window must be divided into two window surfaces: an upper window and a lower window. The upper window interacts directly with the daylighting shelf object and is not allowed to have any shading control devices or frames or dividers. The lower window does not interact with the daylighting shelf object, but does receive shading from the outside shelf. There are no restrictions on the lower window.

The inside shelf is defined as a regular heat transfer surface in the zone. However, the surface must have the *Outside Boundary Condition* field set to Surface with itself as the other zone surface. Shading and thermal mass effects are taken into account.

The outside shelf is defined as a Shading:Zone:Detailed object. The visible and solar absorptance of the outside material layer determines the reflectivity of the shelf.

NOTE: Unlike a regular Shading:Zone:Detailed object, the vertices of the outside shelf surface must be ordered so that the outward normal vector points *upward*, i.e. toward the upper window. This is necessary in order for the outside shelf to properly receive sunlight and shading from other surfaces. A mirror shading surface with the outward normal vector pointing in the opposite direction is automatically created by the program to shade the lower window.

The inside shelf and outside shelf are both optional. However, if neither shelf is specified, the daylighting shelf object has no effect on the simulation.

```

Field: Name

The name of the daylighting shelf object.

Field: Window Name

Reference to a FenestrationSurface:Detailed object with *Surface Type* WINDOW.

Field: Inside Shelf Name

Reference to a BuildingSurface:Detailed object. This field is optional. If used, this surface must have OTHERZONESURFACE specified for the *Outside Face Environment* field and the referenced other zone surface must be itself. The number of vertices of this surface object must be 4.

Field: Outside Shelf Name

Reference to a Shading:Zone:Detailed object. This field is optional. If used, the number of vertices of this surface object must be 4.

Field: Outside Shelf Construction Name

Reference to a CONSTRUCTION object. This field is required if an outside shelf is specified. The visible and solar absorptance of the outside material layer determines the shelf reflectivity.

Field: View Factor To Outside Shelf

User defined value for the view factor from the window to the outside shelf. This field is optional. If not specified, an exact view factor is calculated for two perpendicular rectangles of the same width having a shared edge. If the given surfaces do not meet these geometric requirements, it is necessary to specify a value here.

NOTE: It is up to the user to adjust the view factor to ground of the upper window to account for the part of the view blocked by the outside shelf. The calculated *View Factor To Outside Shelf* is reported in the eio file for this purpose. For the typical case where the shelf is parallel to the ground and the upper window is perpendicular to the ground, the view factor to ground is simply: $0.5 - \text{View Factor To Outside Shelf}$.

```

Shelf Daylighting Device Output

The view factor to outside shelf calculation shows up in the .eio file along with the associated window and window view factors to sky and ground:

```

! <Shelf Details>,Name,View Factor to Outside Shelf,Window Name,Window View
Factor to Sky,Window View Factor to Ground
SHELF,0.29,DAYLIT UPPER WINDOW,0.50,0.21

```

This variable reports the calculated *View Factor To Outside Shelf* so that the user can correctly adjust the view factor to ground of the upper window.

The usual window and surface variables are relevant for the upper window:

```

Zone,Average,Surface Ext Sunlit Area [m2]
Zone,Average,Surface Ext Sunlit Fraction []
Zone,Average,Surface Ext Solar Incident[W/m2]

Zone,Average,Surface Ext Solar Ground Diffuse Incident[W/m2]
Zone,Average,Surface Ext Solar Beam Cosine Of Incidence Angle[]
```

DaylightingDevice:LightWell

This object specifies the properties of a “light well,” which is an opening often found underneath skylights (see Figure 46). The well attenuates the light transmitted by the skylight. The attenuation is characterized by the **well efficiency**, which is the ratio of the amount of light leaving the well to the amount of light entering the well. The well efficiency varies from close to 1.0 to close to zero if there is high attenuation. The well efficiency is used only in the EnergyPlus detailed daylighting calculation, where it multiplies the beam and diffuse light transmitted by the skylight. (The well efficiency is not used in calculating the solar gain through the skylight.)

Figure 60. Skylight with light well: (a) perspective view, (b) vertical section.

If the bottom of the light well is a rectangle of side lengths c and d, as shown in (a), then the perimeter of the bottom of the well = 2(c+d) and the area = cd (see description of field names for the Light Well object).

The well efficiency depends on the visible reflectance of well’s side walls and on the well cavity ratio, WCR, which is given by:

$$WCR = \frac{2.5 \times \text{Well Height} \times \text{Well Perimeter}}{\text{Well Area}}$$

Well Height, Well Perimeter and Well Area are shown or discussed in Figure 46 and described below in the field definitions for the Light Well object.

Figure 47 is a graph that shows well efficiency vs. WCR for different side wall reflectances. For use in the EnergyPlus calculation, a fit has been made to this graph that gives the

following mathematical expression, where “Reflectance” is the user input value of the well-wall reflectance expressed as a fraction:

$$\text{Well efficiency} = e^{-WCR*(0.16368-0.144678*\text{Reflectance})}$$

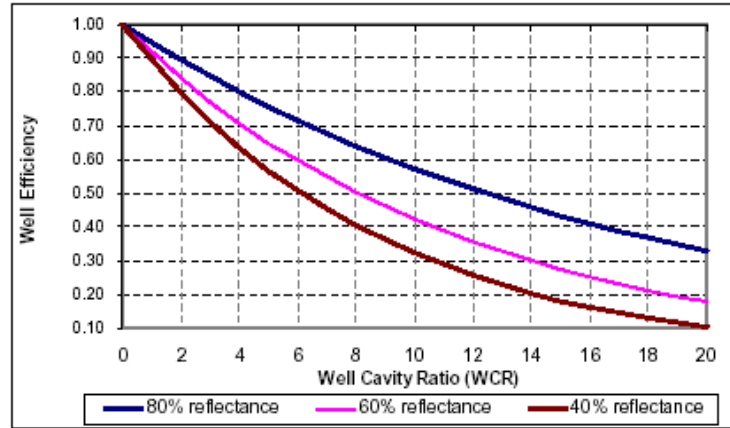

Figure 61. Graph showing light well efficiency vs. well cavity ratio (WCR) for well-wall visible reflectances of 80% (upper curve), 60% (middle curve) and 40% (lower curve). Based on Fig. 8-21 of the Lighting Handbook: Reference and Application, 8th Edition, 1993, Illuminating Engineering Society of North America.

Field: Exterior Window Name

The name of the exterior window that this Light Well is associated with. Generally this is a skylight in a roof. However, light wells can be applied to an exterior window of any slope. Light wells can be assigned to both rectangular and triangular exterior windows, but they should not be assigned to interior windows. Note that the sides of the light well can be sloped and the bottom of the light well can be any shape, not just rectangular.

Field: Height of Well

The distance from the bottom of the skylight to the bottom of the well. If the skylight and well bottom are not coplanar, this is the distance from the center of the bottom of the skylight to center of the bottom of the well. See Figure 46.

Field: Perimeter of Bottom of Well

The perimeter of the bottom opening of the well. See Figure 46.

Field: Area of Bottom of Well

The area of the bottom opening of the well. A warning will be issued if this area is less than the area of the skylight, including frame if present. See Figure 46.

Field: Visible Reflectance of Well Walls

The visible reflectance of the side walls of the well. If the walls do not all have the same reflectance, an area-weighted average value can be used.

```

Group – Exterior Energy Use Equipment

To facilitate the reporting of exterior consumption (to the building’s heat balance/loads considerations), several objects have been included. The consumption related to these items will appear on meters specific to the items.

Exterior:Lights

Field: Name

This descriptive name allows the values of exterior lights consumption to appear in the “normal” output variable list as well as the meters. It cannot be blank nor can it be duplicated by other Exterior:Lights statements.

Field: Schedule Name

A schedule will allow the exterior lights consumption to be operationally different, hour to hour as well as seasonally. Fractional values in the basic schedule will be applied to the design level field below.

Field: Design Level

This field (in Watts) is typically used to represent the maximum electrical input to exterior lighting fixtures that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the lighting design level could be a “diversity factor” applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour and seasonally, the design level field is constant for all simulation environments.

Field: Control Option

This field is used to determine how the exterior lights are controlled. There are currently two options, ‘ScheduleNameOnly’ and ‘AstronomicalClock.’ If this field is omitted or left blank then the program will default to Schedule Name Only mode. The ‘ScheduleNameOnly’ mode

dictates that the exterior lights always follow the schedule named in the field above. The 'AstronomicalClock' mode dictates that despite what the schedule indicates, the exterior lights will not run when the sun is up. Using the Astronomical Clock mode makes it simple to model exterior lights that are controlled by a photocell or other controller that ensures that outdoor lights will not run during the daytime. However, the Astronomical Clock control works off of the position of the sun and therefore does not operate exactly like a photocell. During the night, the schedule values are still applied in the usual way.

Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Grounds Lights", "Facade Lights", etc. A new meter for reporting is created for each unique subcategory (ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the lights will be assigned to the "General" end-use subcategory.

Exterior Lights Outputs

Output for exterior lights appears in three possible places. It will appear on two meters (Electricity:Facility and ExteriorLights:Electricity) as well as in its own designated value in the standard output file.

```
Zone,Meter,Electricity:Facility [J]
Zone,Meter,ExteriorLights:Electricity [J]
Zone,Sum,Exterior Lights-Electric Consumption [J]
```

Exterior:FuelEquipment**Field: Name**

This descriptive name allows the values of exterior equipment consumption to appear in the “normal” output variable list as well as the meters. It cannot be blank nor can it be duplicated by other Exterior:FuelEquipment or Exterior:WaterEquipment statements.

Field: Fuel Use Type

This field designates the appropriate meter for the exterior fuel equipment. Valid fuel types are: Electricity, NaturalGas, PropaneGas, FuelOil#1, FuelOil#2, Diesel, Gasoline, Coal, Steam, DistrictHeating, and DistrictCooling. The fuel type triggers the application of consumption amounts to the appropriate energy meters.

Field: Schedule Name

A schedule will allow the exterior lights consumption to be operationally different, hour to hour as well as seasonally. Fractional values in the basic schedule will be applied to the design level field below.

Field: Design Level

This field (Watts) is typically used to represent the maximum input to exterior fixtures that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the design level could be a “diversity factor” applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour and seasonally, the design level field is constant for all simulation environments.

Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Fountains", etc. A new meter for reporting is created for each unique subcategory (ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the equipment will be assigned to the "General" end-use subcategory.

```

Exterior:WaterEquipment

Field: Name

This descriptive name allows the values of exterior equipment consumption to appear in the “normal” output variable list as well as the meters. It cannot be blank nor can it be duplicated by other Exterior:FuelEquipment or Exterior:WaterEquipment statements.

Field: FuelUseType

For Exterior:WaterEquipment, only “Water” is current allowed for this field.

Field: Schedule Name

A schedule will allow the exterior water consumption to be operationally different, hour to hour as well as seasonally. Fractional values in the basic schedule will be applied to the design level field below.

Field: Design Level

This field (in m3/s) is typically used to represent the maximum volumetric flow for water fixtures that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the exterior water equipment design level could be a “diversity

factor” applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour and seasonally, the design level field is constant for all simulation environments.

Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Landscaping", etc. A new meter for reporting is created for each unique subcategory (ref: Report Meter). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the equipment will be assigned to the "General" end-use subcategory.

Group – Airflow

An important characteristic of energy consumption in buildings is the airflow between zones and airflow due to natural ventilation (e.g., open windows) or mechanically-induced ventilation (e.g., exhaust air fans). This group of objects describes those elements.

The AirflowNetwork model can also be used to model infiltration and mixing (zone-to-zone air flow) with or without the HVAC air distribution system operating (see Group – Airflow Network).

ZoneInfiltration:DesignFlowRate

Infiltration is the unintended flow of air from the outdoor environment directly into a thermal zone. Infiltration is generally caused by the opening and closing of exterior doors, cracks around windows, and even in very small amounts through building elements. The basic equation used to calculate infiltration with this object is:

$$Infiltration = (I_{design})(F_{schedule}) \left[A + B|(T_{zone} - T_{odb})| + C(WindSpeed) + D(WindSpeed^2) \right]$$

More advanced infiltration calculations are possible using the EnergyPlus AirflowNetwork model for natural infiltration driven by wind and/or by forced air. Infiltration described by the equation shown above is entered into EnergyPlus using the following syntax. Exfiltration (the leakage of zone air to the outside) is generally handled better as zone exhaust air in the zone equipment description.

The question of typical values for these coefficients is subject to debate. Ideally, one should do a detailed analysis of the infiltration situation and then determine a custom set of coefficients using methods such as those laid out in Chapter 26 of the ASHRAE Handbook of Fundamentals. The EnergyPlus defaults are 1,0,0,0 which give a constant volume flow of infiltration under all conditions.

BLAST (one of the EnergyPlus predecessors) used the following values as defaults: 0.606, 0.03636, 0.1177, 0. These coefficients produce a value of 1.0 at 0C deltaT and 3.35 m/s (7.5 mph) windspeed, which corresponds to a typical summer condition. At a winter condition of 40C deltaT and 6 m/s (13.4 mph) windspeed, these coefficients would increase the infiltration rate by a factor of 2.75.

In DOE-2 (the other EnergyPlus predecessor), the air change method defaults are (adjusted to SI units) 0, 0, 0.224 (windspeed), 0. With these coefficients, the summer conditions above would give a factor of 0.75, and the winter conditions would give 1.34. A windspeed of 4.47 m/s (10 mph) gives a factor of 1.0.

The source of the BLAST defaults is noted in the BLAST documentation as:

"Empirical equation and the coefficient default were determined from ASHRAE journal articles and other data on the effects of outdoor weather conditions."

The source of the DOE-2 defaults is based on examining the infiltration relationships described in the ASHRAE Handbook of Fundamentals.

The EnergyPlus example files use all of the above, the BLAST defaults in some (e.g., GeometryTest), the DOE-2 defaults in some (e.g., 5ZoneAirCooled), and the EnergyPlus defaults in some (e.g., LgOffVAVDetCoil).

The local outdoor dry-bulb temperature used in the above basic equation (T_{odb}) is typically a function of the height of the zone centroid above ground. The corresponding zone name is given in the second field. The local outdoor dry-bulb temperature calculation procedure is given in the section of "Local Outdoor Air Temperature Calculation" in the Engineering Reference.

The local outdoor wind speed used in the above basic equation (WindSpeed) is also a function of the height of the zone centroid above ground. The corresponding zone name is given in the second field. The local outdoor wind speed calculation procedure is given in the section of "Local Wind Speed Calculation" in the Engineering Reference.

Note: When the value of the Wind Speed Profile Exponent field in the Site:HeightVariation is equal to 0.0. The local wind speed is always equal to the wind speed given in the weather data and will not be dependent on zone centroid height. Similarly, if the value of the Air Temperature Gradient Coefficient is set equal to 0 the local air dry-bulb temperature is also always equal to the air dry-bulb temperature given in the weather data and will not be dependent on zone centroid height.

One or more infiltration objects can be defined for each zone, and the resulting infiltration rate for the zone will simply be the summation of the flow rates specified by the infiltration objects.

Field: Name

The name of the ZoneInfiltration:DesignFlowRate object. This needs to be unique across all different ZoneInfiltration objects.

Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a particular infiltration statement to a thermal zone in the building.

Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design volume flow rate (I_{design}). This fraction between 0.0 and 1.0 is noted as F_{schedule} in the above equation.

Field: Design Flow Rate Calculation Method

This field is a key/choice field that tells which of the next four fields are filled and is descriptive of the method for calculating the design volume flow rate. The key/choices are:

- Flow/Zone

With this choice, the method used will be a straight insertion of the design volume flow rate. (The Design Flow Rate field should be filled.)

- Flow/Area

With this choice, the method used will be a factor per floor area of the zone. (The flow per Zone Area field should be filled).

- Flow/ExteriorArea

With this choice, the method used will be a factor per exterior surface area of the zone. (The flow per Exterior Surface Area field should be filled).

- Flow/ExteriorWallArea

With this choice, the method used will be a factor per exterior wall surface area of the zone. (The flow per Exterior Surface Area field should be filled).

- AirChanges/Hour

With this choice, the method used will be the number of air changes per hour for the infiltration amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. (The Air Changes per Hour field should be filled).

Field: Design Flow Rate

This field denotes the full design volume flow rate (m^3/s). The previous field should choose “flow/zone” as the choice. The design volume flow rate (noted as I_{design} in the above equation) is the maximum amount of infiltration expected at design conditions. The flow rate is expressed in units of . The design value is modified by the schedule fraction (see Field:Schedule Name) and user specified coefficients (see “coefficient” fields below).

Field: Flow per Zone Floor Area

This factor ($\text{m}^3/\text{s}\cdot\text{m}^2$) is used, along with the Zone Area to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “Flow/Area”.

Field: Flow per Exterior Surface Area

This factor ($\text{m}^3/\text{s}\cdot\text{m}^2$) is used, along with the Exterior Surface Area in the Zone to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “Flow/Exteriorarea” or “Flow/ExteriorWallArea”.

Field: Air Changes per Hour

This factor is used, along with the Zone Volume to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “AirChanges/Hour”.

Field: Constant Term Coefficient

This number is the “A” parameter in the above infiltration equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter, however, is a constant under all conditions and is not modified by any environmental effect. As a result, it is dimensionless.

Field: Temperature Term Coefficient

This number is the “B” parameter in the above infiltration equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the temperature difference between the outdoor and indoor air dry-bulb temperatures. The units for this parameter are inverse Celsius.

Field: Velocity Term Coefficient

This number is the “C” parameter in the above infiltration equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the speed of wind being experienced outside the building. The units for this parameter are s/m.

Field: Velocity Squared Term Coefficient

This number is the “D” parameter in the above infiltration equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by square of the speed of wind being experienced outside the building. The units for this parameter are s^2/m^2 .

ZoneInfiltration:EffectiveLeakageArea

ZoneInfiltration:EffectiveLeakageArea model is similar to the other infiltration objects but uses a different equation to model the unintended flow of air from the outdoor environment directly into a thermal zone. Infiltration is generally caused by the opening and closing of exterior doors, cracks around windows, and even in very small amounts through building elements. This model is based on work by Sherman and Grimsrud (1980) and is appropriate for smaller, residential-type buildings. The equation used to calculate infiltration in the effective leakage area model is:

$$Infiltration = (F_{Schedule}) \frac{A_L}{1000} \sqrt{C_s \Delta T + C_w (WindSpeed)^2}$$

where ΔT is the average difference between zone air temperature and the outdoor air temperature and the other coefficients are described below.

Note that the coefficients for the “EffectiveLeakageArea” model are not interchangeable with the similarly named coefficients in the “FlowCoefficient” model (see ZoneInfiltration:FlowCoefficient object).

One or more infiltration objects of different types can be defined for each zone, and the resulting infiltration rate for the zone will simply be the summation of the flow rates specified by the infiltration objects.

Field: Name

The name of the ZoneInfiltration:EffectiveLeakageArea object. This needs to be unique across all different ZoneInfiltration objects.

Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a particular infiltration statement to a thermal zone in the building.

Field: Schedule Name

This field is the name of a schedule (ref: Schedule) that modifies the volume flow rate calculated by the model. This fraction between 0.0 and 1.0 is noted as $F_{Schedule}$ in the above equation.

Field: Effective Air Leakage Area

This field is the effective air leakage area, in cm^2 , at 4 Pa. This is the value A_L in the equation above. Effective leakage area data can be obtained from a whole-building pressure test (eg. blower door test). ASHRAE Handbook of Fundamentals also lists typical values component leakage areas for low-rise residential (e.g. Table 1 in Chapter 26 of HoF 2001). The value should correspond to a pressure difference of 4 Pa.

Field: Stack Coefficient

This field is the value of the stack coefficient, C_s in the equation above. The coefficient has units of $(L/s)^2/(cm^4 \cdot K)$. Values for the “Basic Model Stack Coefficient” listed in the ASHRAE Handbook of Fundamentals (2005 and 2001) are:

One story house	Two story house	Three story house
0.000145	0.000290	0.000435

Field: Wind Coefficient

This field is the value of the wind coefficient, C_w in the equation above. The coefficient has units of $(L/s)^2/(cm^4 \cdot (m/s)^2)$. Values for the “Basic Model Wind Coefficient” listed in the ASHRAE Handbook of Fundamentals (2005 chapter 27; 2001, Chapter 26) depend on the type of shelter and are listed in the following tables.

Shelter class	One story house	Two story house	Three story house
1	0.000319	0.000420	0.000494
2	0.000246	0.000325	0.000382
3	0.000174	0.000231	0.000271
4	0.000104	0.000137	0.000161
5	0.000032	0.000042	0.000049

Shelter class	Description
1	No obstructions or local shielding
2	Typical shelter for an isolated rural house
3	Typical shelter caused by other buildings across the street
4	Typical shelter for urban buildings on larger lots
5	Typical shelter produced by buildings that are immediately adjacent.

ZoneInfiltration:FlowCoefficient

ZoneInfiltration:FlowCoefficient model is similar to the other infiltration objects but uses a different equation to model the unintended flow of air from the outdoor environment directly into a thermal zone. Infiltration is generally caused by the opening and closing of exterior doors, cracks around windows, and even in very small amounts through building elements. This reformulated model is based on the AIM-2 model by Walker and Wilson (1998) and is appropriate for smaller, residential-type buildings. The equation used to calculate infiltration in the flow coefficient model is:

$$Infiltration = (F_{Schedule}) \sqrt{(c C_s \Delta T^n)^2 + (c C_w (s * WindSpeed)^{2n})^2}$$

Where ΔT is the average difference between zone air temperature and the outdoor air temperature and the other coefficients are described below.

Note that the coefficients for the “Flow Coefficient” model are not interchangeable with the similarly named coefficients in the “Effective Leakage Area” model (see ZoneInfiltration:EffectiveLeakageArea object).

One or more infiltration objects of different types can be defined for each zone, and the resulting infiltration rate for the zone will simply be the summation of the flow rates specified by the infiltration objects.

Field: Name

The name of the ZoneInfiltration:FlowCoefficient object. This needs to be unique across all different ZoneInfiltration objects.

Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a particular infiltration statement to a thermal zone in the building.

Field: Schedule Name

This field is the name of a schedule (ref: Schedule) that modifies the volume flow rate calculated by the model. This fraction between 0.0 and 1.0 is noted as F_{schedule} in the above equation.

Field: Flow Coefficient

This field is the flow coefficient in $\text{m}^3/(\text{s}\cdot\text{Pa}^n)$. This is the value c in the equation above. The flow coefficient can be determined from the effective leakage area and whole-building pressure tests (eg. blower door test).

Field: Stack Coefficient

This field is the value of the stack coefficient, C_s in the equation above. The coefficient has units of $(\text{Pa}/\text{K})^n$. Values for the “Enhanced Model Stack Coefficient” listed in the ASHRAE Handbook of Fundamentals (2005 and 2001) are:

	One story house	Two story house	Three story house
With Flue	0.069	0.089	0.107
No Flue	0.054	0.078	0.098

Field: Pressure Exponent

This field is the value of the pressure exponent, n in the equation above. The pressure exponent generally lies between 0.6 and 0.7 with a typical value of $n = 0.67$ for the enhanced model.

Field: Wind Coefficient

This field is the value of the wind coefficient, C_w in the equation above. The coefficient has units of $(\text{Pa}\cdot\text{s}^2/\text{m}^2)^n$. Values for the “Enhanced Model Wind Coefficient” listed in the ASHRAE Handbook of Fundamentals (2005 and 2001) are:

	One story house	Two story house	Three story house
Basement/slab; With Flue	0.142	0.156	0.167
Basement/slab; No Flue	0.156	0.170	0.170
Crawlspace; With Flue	0.128	0.142	0.154
Crawlspace; No Flue	0.128	0.142	0.151

Field: Shelter Factor

This field is the value of the wind coefficient, s in the equation above. The coefficient is dimensionless. Values for the “Enhanced Model Shelter Factor” listed in the ASHRAE Handbook of Fundamentals (2005 and 2001) are:

Shelter class	No Flue	One story house with flue	Two story house with flue	Three story house with flue
1	1.00	1.10	1.07	1.06
2	0.90	1.02	0.98	0.97
3	0.70	0.86	0.81	0.79
4	0.50	0.70	0.64	0.61
5	0.30	0.54	0.47	0.43

Shelter class	Description
1	No obstructions or local shielding
2	Typical shelter for an isolated rural house
3	Typical shelter caused by other buildings across the street
4	Typical shelter for urban buildings on larger lots
5	Typical shelter produced by buildings that are immediately adjacent.

HVAC,Sum,Zone Infiltration Volume [m3]
HVAC,Sum,Zone Infiltration Mass [kg]
HVAC,Average,Zone Infiltration Air Change Rate [ach]

```

Zone Infiltration Sensible Heat Loss [J]

The sensible (temperature) heat loss that occurs when the infiltration air temperature (outdoor) < zone air temperature.

Zone Infiltration Sensible Heat Gain [J]

The sensible (temperature) heat gain that occurs when the infiltration air temperature (outdoor) >= zone air temperature.

Zone Infiltration Latent Heat Loss [J]

The latent heat loss that occurs when the infiltration air humidity ratio (outdoor) < zone air humidity ratio.

Zone Infiltration Latent Heat Gain [J]

The latent heat gain that occurs when the infiltration air humidity ratio (outdoor) >= zone air humidity ratio.

Zone Infiltration Total Heat Loss [J]

The total heat loss that occurs when the sum of Zone Infiltration Sensible Heat Gain and Zone Infiltration Latent Heat Gain < the sum of Zone Infiltration Sensible Heat Loss and Zone Infiltration Latent Heat Loss.

Zone Infiltration Total Heat Gain [J]

The total heat gain that occurs when the sum of Zone Infiltration Sensible Heat Gain and Zone Infiltration Latent Heat Gain >= the sum of Zone Infiltration Sensible Heat Loss and Zone Infiltration Latent Heat Loss.

Zone Infiltration Volume [m3]

The volume flow of the Infiltration air.

Zone Infiltration Mass [kg]

The mass flow of the Infiltration air.

Zone Infiltration Air Change Rate [ach]

The rate of infiltration in air changes per hour.

ZoneVentilation

ZoneVentilation is the purposeful flow of air from the outdoor environment directly into a thermal zone in order to provide some amount of non-mechanical cooling. Ventilation as specified by this input syntax is intended to model “simple” ventilation as opposed to the more detailed ventilation investigations that can be performed with the AirflowNetwork model or with air systems that have outdoor air mixers. Simple ventilation in EnergyPlus can be controlled by a schedule and through the specification of minimum, maximum and delta temperatures as described below. The temperatures can be either single constant values for the entire simulation or schedules which can vary over time. As with infiltration, the actual flow rate of ventilation air can be modified by the temperature difference between the inside

and outside environment and the wind speed. The basic equation used to calculate ventilation in EnergyPlus is:

$$Ventilation = (V_{design})(F_{schedule}) \left[A + B|T_{zone} - T_{odb}| + C(WindSpeed) + D(WindSpeed^2) \right]$$

The local outdoor dry-bulb temperature used in the above basic equation (T_{odb}) is typically a function of the height of the zone centroid above ground. The corresponding zone name is given in the second field. The local outdoor dry-bulb temperature calculation procedure is given in the section of “Local Outdoor Air Temperature Calculation” in the Engineering Reference.

The local outdoor wind speed used in the above basic equation ($WindSpeed$) is also a function of the height of the zone centroid above ground. The corresponding zone name is given in the second field. The local outdoor wind speed calculation procedure is given in the section of “Local Wind Speed Calculation” in the Engineering Reference.

Note: When the value of the Wind Speed Profile Exponent field in the Site:HeightVariation is equal to 0.0. The local wind speed is always equal to the wind speed given in the weather data and will not be dependent on zone centroid height. Similarly, if the value of the Air Temperature Gradient Coefficient is set equal to 0 the local air dry-bulb temperature is also always equal to the air dry-bulb temperature given in the weather data and will not be dependent on zone centroid height.

One or more ventilation objects can be defined for each zone, and the resulting ventilation rate for the zone will simply be the summation of the flow rates specified by the ventilation objects.

More advanced ventilation calculations are possible using the EnergyPlus AirflowNetwork model.

Field: Name

The name of the ZoneVentilation object.

Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a particular ventilation statement to a thermal zone in the building.

Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design volume flow rate (V_{design}). This fraction between 0.0 and 1.0 is noted as $F_{schedule}$ in the above equation.

Field: Design Flow Rate Calculation Method

This field is a key/choice field that tells which of the next four fields are filled and is descriptive of the method for calculating the design volume flow rate. The key/choices are:

■ Flow/Zone

With this choice, the method used will be a straight insertion of the design volume flow rate. (The Design Flow Rate field should be filled.)

■ Flow/Area

With this choice, the method used will be a factor per floor area of the zone. (The Flow per Zone Floor Area field should be filled).

■ Flow/Person

With this choice, the method used will be a factor per nominal number of people in the zone. (The Flow per Person field should be filled).

■ AirChanges/Hour

With this choice, the method used will be the number of air changes per hour for the infiltration amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. (The Air Changes per Hour field should be filled).

Field: Design Flow Rate

This field denotes the full design volume flow rate (m^3/s). The previous field should choose “flow/zone” as the choice. The design volume flow rate (noted as V_{design} in the above equation) is the maximum amount of ventilation expected at design conditions. The design value is modified by the schedule fraction (see Field: Schedule Name) and user specified coefficients (see four “coefficient” fields below).

Field: Flow Rate per Zone Floor Area

This factor ($\text{m}^3/\text{s}\cdot\text{m}^2$) is used, along with the Zone Area to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “flow/area”.

Field: Flow Rate per Person

This factor ($\text{m}^3/\text{s}\cdot\text{person}$) is used, along with the nominal (maximum) number of occupants (people) in the Zone to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “flow/person”.

Field: Air Changes per Hour

With this choice, the method used will be the number of air changes per hour for the ventilation amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. The choice from the method field should be “AirChanges/Hour”.

Field: Ventilation Type

This alpha character string defines the type of ventilation as one of the following options: Natural, Exhaust, or Intake.. Natural ventilation is assumed to be air movement/exchange a result of openings in the building façade and will not consume any fan energy. Values for fan pressure and efficiency for natural ventilation are ignored. For either Exhaust or Intake, values for fan pressure and efficiency define the fan electric consumption. For Natural and Exhaust ventilation, the conditions of the air entering the space are assumed to be equivalent to outside air conditions. For Intake ventilation, an appropriate amount of fan heat is added to the air stream.

Field: Fan Pressure Rise

This is the pressure rise experienced across the fan in Pascals (N/m^2). This is a function of the fan and plays a role in determining the amount of energy consumed by the fan.

Field: Fan Total Efficiency

This is the total fan efficiency (a decimal number between 0.0 and 1.0). This is a function of the fan and plays a role in determining the amount of energy consumed by the fan.

Field: Constant Term Coefficient

This number is the “A” parameter in the above ventilation equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter, however, is a constant under all conditions and is not modified by any environmental effect. As a result, it is dimensionless.

Field: Temperature Term Coefficient

This number is the “B” parameter in the above ventilation equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is

modified by the temperature difference between the outdoor and indoor air dry-bulb temperatures. The units for this parameter are inverse Celsius.

Field: Velocity Term Coefficient

This number is the “C” parameter in the above ventilation equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the speed of wind being experienced outside the building. The units for this parameter are s/m.

Field: Velocity Squared Term Coefficient

This number is the “D” parameter in the above ventilation equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by square of the speed of wind being experienced outside the building. The units for this parameter are s^2/m^2 .

Field: Minimum Indoor Temperature

This is the indoor temperature (in Celsius) below which ventilation is shutoff. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is -100.0°C if the field is left blank. This lower temperature limit is intended to avoid overcooling a space and thus result in a heating load. For example, if the user specifies a minimum temperature of 20°C, ventilation is assumed to be available if the zone air temperature is above 20°C. If the zone air temperature drops below 20°C, then ventilation is automatically turned off.

Field: Minimum Indoor Temperature Schedule Name

This alpha field defines the name of a schedule (ref. Schedule) which contains the minimum indoor temperature (in Celsius) below which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Minimum Indoor Temperature field. If the user enters a valid schedule name, the minimum temperature values specified in this schedule will supersede the constant value specified in the Minimum Indoor Temperature field.

Field: Maximum Indoor Temperature

This is the indoor temperature (in Celsius) above which ventilation is shutoff. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is 100.0°C if the field is left blank. This upper temperature limit is intended to avoid overheating a space and thus result in a cooling load. For example, if the user specifies a maximum temperature of 28°C, ventilation is assumed to be available if the zone air temperature is below 28°C. If the zone air temperature increases to 28°C, then ventilation is automatically turned off.

Field: Maximum Indoor Temperature Schedule Name

This alpha field defines the name of a schedule (ref. Schedule) which contains the maximum indoor temperature (in Celsius) above which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Maximum Indoor Temperature field. If the user enters a valid schedule name, the maximum temperature values specified in this schedule will supersede the constant value specified in the Maximum Indoor Temperature field.

Field: Delta Temperature

This is the temperature difference (in Celsius) between the indoor and outdoor air dry-bulb temperatures below which ventilation is shutoff. The minimum value for this field is -100.0°C

and the default value is also -100.0°C if the field is left blank. This field allows ventilation to be stopped if the temperature outside is too warm and could potentially heat the space. For example, if the user specifies a delta temperature of 2°C, ventilation is assumed to be available if the outside air temperature is at least 2°C cooler than the zone air temperature. If the outside air dry-bulb temperature is less than 2°C cooler than the indoor dry-bulb temperature, then ventilation is automatically turned off.

The values for this field can include negative numbers. This allows ventilation to occur even if the outdoor temperature is above the indoor temperature. The Delta Temperature is used in the code in the following way:

IF ((IndoorTemp - OutdoorTemp) < DeltaTemperature) Then ventilation is not allowed.

Thus, if a large negative number is input for DeltaTemperature, the ventilation can be kept on even if the outdoor temperature is greater than the indoor temperature. This is useful for uncontrolled natural ventilation (open windows) or as a way to estimate the effect of required ventilation air for load calculations.

Field: Delta Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule) which contains the temperature difference (in Celsius) between the indoor and outdoor air dry-bulb temperatures below which ventilation is shutoff as a function of time. The minimum temperature difference value in the schedule can be -100°C. This field is an optional field and has the same functionality as the Delta Temperature field. If the user enters a valid schedule name, the delta temperature values specified in this schedule will supersede the constant value specified in the Delta Temperature field.

Field: Minimum Outdoor Temperature

This is the outdoor temperature (in Celsius) below which ventilation is shut off. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is -100.0°C if the field is left blank. This lower temperature limit is intended to avoid overcooling a space, which could result in a heating load.

Field: Minimum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule) which contains the minimum outdoor temperature (in Celsius) below which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Minimum Outdoor Temperature field. If the user enters a valid schedule name, the temperature values in this schedule will supersede the constant value specified in the Minimum Outdoor Temperature field.

Field: Maximum Outdoor Temperature

This is the outdoor temperature (in Celsius) above which ventilation is shut off. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is 100.0°C if the field is left blank. This upper temperature limit is intended to avoid overheating a space, which could result in a cooling load.

Field: Maximum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule) which contains the minimum outdoor temperature (in Celsius) above which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Maximum Outdoor Temperature field. If the user enters a valid schedule name, the temperature values in this schedule will supersede the constant value specified in the Maximum Outdoor Temperature field.

Field: Maximum Wind Speed

This is the wind speed (m/s) above which ventilation is shut off. This can help simulate conditions where one would normally close windows to avoid chaos in a space (papers blowing around, etc).

ZoneVentilation Outputs

Current ventilation output variables:

```

HVAC,Sum,Zone Ventilation Sensible Heat Loss [J]
HVAC,Sum,Zone Ventilation Sensible Heat Gain [J]
HVAC,Sum,Zone Ventilation Latent Heat Loss [J]
HVAC,Sum,Zone Ventilation Latent Heat Gain [J]
HVAC,Sum,Zone Ventilation Total Heat Loss [J]
HVAC,Sum,Zone Ventilation Total Heat Gain [J]
HVAC,Sum,Zone Ventilation Volume [m3]
HVAC,Sum,Zone Ventilation Mass [kg]
HVAC,Sum,Zone Ventilation Fan Electric Consumption [J]
HVAC,Average,Zone Ventilation Inlet Air Temperature [C]

```

Zone Ventilation Sensible Heat Loss [J]

The sensible (temperature) heat loss that occurs when the ventilation inlet air temperature < zone air temperature. If multiple ventilation objects are specified for a particular zone, the ventilation inlet air temperature is from each ventilation object for the zone.

Zone Ventilation Sensible Heat Gain [J]

The sensible (temperature) heat gain that occurs when the ventilation inlet air temperature >= zone air temperature. If multiple ventilation objects are specified for a particular zone, the ventilation inlet air temperature is from each ventilation object for the zone.

Zone Ventilation Latent Heat Loss [J]

The latent heat loss that occurs when the Ventilation air humidity ratio (outdoor) < zone air humidity ratio.

Zone Ventilation Latent Heat Gain [J]

The latent heat gain that occurs when the Ventilation air humidity ratio (outdoor) >= zone air humidity ratio.

Zone Ventilation Total Heat Loss [J]

The total heat loss that occurs when the sum of Zone Ventilation Sensible Heat Gain and Zone Ventilation Latent Heat Gain < the sum of Zone Ventilation Sensible Heat Loss and Zone Ventilation Latent Heat Loss.

Zone Ventilation Total Heat Gain [J]

The total heat gain that occurs when the sum of Zone Ventilation Sensible Heat Gain and Zone Ventilation Latent Heat Gain >= the sum of Zone Ventilation Sensible Heat Loss and Zone Ventilation Latent Heat Loss.

Zone Ventilation Volume [m3]

The volume flow of the ventilation air.

Zone Ventilation Mass [kg]

The mass flow of the ventilation air.

Zone Ventilation Air Change Rate [ach]

The volume flow rate of the ventilation air in air changes per hour.

Zone Ventilation Fan Electric Consumption [J]

The fan electrical consumption for Intake or Exhaust ventilation types.

Zone Ventilation Inlet Air Temperature [C]

This is equal to the outdoor air temperature except when INTAKE fan power is included. When intake fan power is used, then the additional heat due to the fan is added to the outdoor temperature and this will be reported as the inlet air temperature. If multiple ventilation objects are specified for a particular zone, the reported value is the mass flow weighted temperature for the multiple ventilation objects specified for this zone.

ZoneMixing

In EnergyPlus, the ZoneMixing syntax is intended to allow simplified treatment of air exchange between zones. Note that this statement only affects the energy balance of the “receiving” zone and that this statement will not produce any effect on the “source” zone. Mixing statements can be complementary and include multiple zones, but the balancing of flows between zones is left to the user’s discretion. The use of the Cross Mixing syntax (ref: Cross Mixing) can allow for automatic balancing of flows and energy flow rates between zones but is hindered by the limitation of only a single cross mixing statement per zone. More advanced mixing calculations are possible using the EnergyPlus AirflowNetwork model for multi-zone airflow with or without HVAC system operation. Mixing is entered using the following syntax.

Field: Name

The name of the ZoneMixing object.

Field: Zone Name

This field is the name of the zone (ref: Zone) receiving the amount of air being exchanged and attaches a particular mixing statement to a thermal zone in the building.

Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design volume flow rate parameter (see next field). This fraction between 0.0 and 1.0 modifies the design level parameter.

Field: Design Flow Rate Calculation Method

This field is a key/choice field that tells which of the next four fields are filled and is descriptive of the method for calculating the design volume flow rate. The key/choices are:

- Flow/Zone

With this choice, the method used will be a straight insertion of the design volume flow rate. (The Design Flow Rate field should be filled.)

- Flow/Area

With this choice, the method used will be a factor per floor area of the zone. (The Flow per Zone Floor Area field should be filled).

- Flow/Person

With this choice, the method used will be a factor per nominal number of people in the zone. (The Flow per Person field should be filled).

- AirChanges/Hour

With this choice, the method used will be the number of air changes per hour for the infiltration amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. (The Air Changes per Hour field should be filled).

Field: Design Flow Rate

This field denotes the full design volume flow rate (m^3/s). The previous field should choose “flow/zone” as the choice. The design volume flow rate is the maximum amount of mixing air expected. The design value is modified by the schedule fraction (see Field: Schedule Name) and user specified coefficients (see four “coefficient” fields below).

Field: Flow Rate per Zone Floor Area

This factor ($\text{m}^3/\text{s}\cdot\text{m}^2$) is used, along with the Zone Area to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “Flow/Area”.

Field: Flow Rate per Person

This factor ($\text{m}^3/\text{s}\cdot\text{person}$) is used, along with the nominal (maximum) number of occupants (people) in the Zone to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “Flow/Person”.

Field: Air Changes per Hour

With this choice, the method used will be the number of air changes per hour for the mixing amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. The choice from the method field should be “AirChanges/Hour”.

Field: Source Zone Name

This field is the name of the “source” zone (ref: Zone) that exhausts the amount of air specified by the design level and schedule fields to the zone named in the zone name field.

Field: Delta Temperature

This number controls when mixing air from the source zone is sent to the receiving zone. This parameter is a temperature and is expressed in units of Celsius. If this field is positive, the temperature of the zone from which the air is being drawn (source zone) must be “Delta Temperature” warmer than the receiving zone air or else no mixing occurs. If this field is negative, the temperature of the source zone must be “Delta Temperature” cooler than the receiving zone air or else no mixing occurs. If this parameter is zero, mixing occurs regardless of the relative zone temperatures.

Field: Delta Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule) which contains the temperature difference (in Celsius) between the source zone and receiving zone air dry-bulb temperatures as a function of time. This field is an optional field and has the same functionality as the Delta Temperature field. If the user enters a valid schedule name, the delta temperature values specified in this schedule will supersede the constant value specified in the Delta Temperature field.

Field: Minimum Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule) which contains the minimum receiving zone temperature (in Celsius) below which mixing is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the minimum zone temperature control is not applied.

Field: Maximum Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule) which contains the maximum receiving zone temperature (in Celsius) above which mixing is shutoff as a function of time. The maximum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the maximum zone temperature control is not applied.

Note: The maximum zone temperature when mixing is shutoff must be greater than or equal to the minimum zone temperature when mixing is shutoff at any given time. Otherwise, warnings will be issued and the maximum zone shutoff temperature will be set to the minimum zone shutoff temperature.

Field: Minimum Source Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule) which contains the minimum source zone temperature (in Celsius) below which mixing is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the minimum source zone temperature control is not applied.

Field: Maximum Source Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule) which contains the maximum source zone temperature (in Celsius) above which mixing is shutoff as a function of time. The maximum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the maximum source zone temperature control is not applied.

Note: The maximum source zone temperature when mixing is shutoff must be greater than or equal to the minimum source zone temperature when mixing is shutoff at any given time. Otherwise, warnings will be issued and the maximum source zone shutoff temperature will be set to the minimum source zone shutoff temperature.

Field: Minimum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule) which contains the minimum outdoor temperature (in Celsius) below which mixing is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be

100°C. This field is an optional field. If this field is not entered, the minimum outdoor temperature control is not applied.

Field: Maximum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule) which contains the maximum outdoor temperature (in Celsius) above which mixing is shutoff as a function of time. The maximum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the maximum outdoor temperature control is not applied.

Note: The maximum outdoor temperature when mixing is shutoff must be greater than or equal to the minimum outdoor temperature which mixing is shutoff at any given time. Otherwise, a warning will be issued and the maximum outdoor shutoff temperature will be set to the minimum outdoor shutoff temperature.

```

```

HVAC,Sum,Zone Mixing Latent Heat Loss [J]
HVAC,Sum,Zone Mixing Latent Heat Gain [J]
HVAC,Sum,Zone Mixing Total Heat Loss [J]
HVAC,Sum,Zone Mixing Total Heat Gain [J]

```

Zone Mixing Volume [m3]

The air volume in m³ entering the zone due to mixing during the hour or timestep.

Zone Mixing Mass [kg]

The air mass in kg entering the zone due to mixing during the hour or timestep. The air mass is calculated using the air volume flow from each “source” zone and the density of air calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones.

Zone Mixing Sensible Heat Loss [J]

Zone Mixing Sensible Heat Gain [J]

The sensible (temperature) heat transfer due to mixing in the host (receiving) zone is the sum of all the incoming air mass flow rates multiplied by the elapsed time, the specific heat (calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones) and the temperature differences between the host zone and corresponding source zones. If the heat transfer is negative, the heat transfer is considered to be a zone mixing sensible heat loss. If the heat transfer is positive, the heat transfer is considered to be a zone mixing sensible heat gain.

Zone Mixing Latent Heat Loss [J]

Zone Mixing Latent Heat Gain [J]

The latent heat transfer due to mixing in the host (receiving) zone is the sum of all the incoming air mass flow rates multiplied by the elapsed time, the heat of vaporization (calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones) and the humidity ratio differences between the host zone and corresponding source zones. If the heat transfer is negative, the heat transfer is considered to be a zone mixing latent heat loss. If the heat transfer is positive, the heat transfer is considered to be a zone mixing latent heat gain.

Zone Mixing Total Heat Loss [J]

The total heat loss due to mixing that occurs when the sum of Zone Mixing Sensible Heat Gain and Zone Mixing Latent Heat Gain < the sum of Zone Mixing Sensible Heat Loss and Zone Mixing Latent Heat Loss.

Zone Mixing Total Heat Gain [J]

The total heat gain due to mixing that occurs when the sum of Zone Mixing Sensible Heat Gain and Zone Mixing Latent Heat Gain >= the sum of Zone Mixing Sensible Heat Loss and Zone Mixing Latent Heat Loss.

ZoneCrossMixing

The ZoneCrossMixing syntax is ideally suited for two zones that exchange an equal amount of air between each other and do not have any air exchange with other zones. As with Mixing (ref: Mixing), this is a simplified view of interzone airflow in EnergyPlus. The main difference between Mixing and Cross Mixing is that Cross Mixing has an energy effect on both the source and the receiving zone, thus maintaining both the air mass and energy balances in the two zones.

Cross Mixing can be entered once, in one of the mixing zones; or twice, once for each zone. The object should be entered once if Delta Temperature > 0.0 and it is desirable to have

mixing only when the source zone is warmer than the receiving zone. This might be the case when the warmer zone is below the colder zone and the mixing is buoyancy driven. If the zones are next to each other, separated by an open doorway, it would be more suitable to input a cross mixing object for each zone. Then mixing would occur if the zone temperatures differed by Delta Temperature or greater regardless of which is the warmer zone.

If Delta Temperature = 0.0, Cross Mixing can be entered either once or twice: the effect is exactly the same.

Cross Mixing is entered using the following syntax.

Field: Name

The name of the ZoneCrossMixing object.

Field: Zone Name

This field is the name of the zone (ref: Zone) receiving the amount of air being exchanged and attaches a particular cross mixing statement to a thermal zone in the building.

Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design volume flow rate parameter (see next field). This fraction between 0.0 and 1.0 modifies the design level parameter.

Field: Design Flow Rate Calculation Method

This field is a key/choice field that tells which of the next four fields are filled and is descriptive of the method for calculating the design volume flow rate. The key/choices are:

■ Flow/Zone

With this choice, the method used will be a straight insertion of the design volume flow rate. (The Design Flow Rate field should be filled.)

■ Flow/Area

With this choice, the method used will be a factor per floor area of the zone. (The Flow per Zone Floor Area field should be filled).

■ Flow/Person

With this choice, the method used will be a factor per nominal number of people in the zone. (The flow per person field should be filled).

■ AirChanges/Hour

With this choice, the method used will be the number of air changes per hour for the infiltration amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. (The Air Changes per Hour field should be filled).

Field: Design Flow Rate

This field denotes the full design volume flow rate (m^3/s). The previous field should choose “flow/zone” as the choice. The design volume flow rate is the maximum amount of mixing air expected. The design value is modified by the schedule fraction (see Field: Schedule Name) and user specified coefficients (see four “coefficient” fields below).

Field: Flow Rate per Zone Floor Area

This factor ($m^3/s-m^2$) is used, along with the Zone Area to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “Flow/Area”.

Field: Flow Rate per Person

This factor ($m^3/s-person$) is used, along with the nominal (maximum) number of occupants (people) in the Zone to determine the maximum Design Volume Flow Rate as described in

the Design Volume Flow Rate field. The choice from the method field should be “Flow/Person”.

Field: Air Changes per Hour

With this choice, the method used will be the number of air changes per hour for the mixing amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. The choice from the method field should be “AirChanges/Hour”.

Field: Source Zone Name

This field is the name of the “source” zone (ref: Zone) that exhausts the amount of air specified by the design level and schedule fields to the zone named in the zone name field. In reality, the “source” and “receiving” zones are interchangeable since the cross-mixed air affects both zones.

Field: Delta Temperature

This number controls when mixing air from the source zone is sent to the receiving zone. This parameter is a temperature and is expressed in units of Celsius. If this field is positive, the temperature of the zone from which air is being drawn (“source zone”) must be “Delta Temperature” warmer than the zone air or no mixing occurs. If this field is zero, mixing occurs regardless of the relative air temperatures. Negative values for “Delta Temperature” are not permitted.

Field: Delta Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule) which contains the temperature difference (in Celsius) between the source zone and receiving zone air dry-bulb temperatures as a function of time. This field is an optional field and has the same functionality as the Delta Temperature field. If the user enters a valid schedule name, the delta temperature values specified in this schedule will supersede the constant value specified in the Delta Temperature field.

Field: Minimum Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule) which contains the minimum receiving zone temperature (in Celsius) below which cross mixing is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the minimum zone temperature control is not applied.

Field: Maximum Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule) which contains the maximum receiving zone temperature (in Celsius) above which cross mixing is shutoff as a function of time. The maximum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the maximum zone temperature control is not applied.

Note: The maximum zone temperature when cross mixing is shutoff must be greater than or equal to the minimum zone temperature when cross mixing is shutoff at any given time. Otherwise, warnings will be issued and the maximum zone shutoff temperature will be set to the minimum zone shutoff temperature.

Field: Minimum Source Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule) which contains the minimum source zone temperature (in Celsius) below which cross mixing is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum

value can be 100°C. This field is an optional field. If this field is not entered, the minimum source zone temperature control is not applied.

Field: Maximum Source Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule) which contains the maximum source zone temperature (in Celsius) above which cross mixing is shutoff as a function of time. The maximum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the maximum source zone temperature control is not applied.

Note: The maximum source zone temperature when cross mixing is shutoff must be greater than or equal to the minimum source zone temperature when cross mixing is shutoff at any given time. Otherwise, warnings will be issued and the maximum source zone shutoff temperature will be set to the minimum source zone shutoff temperature.

Field: Minimum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule) which contains the minimum outdoor temperature (in Celsius) below which cross mixing is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the minimum outdoor temperature control is not applied.

Field: Maximum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule) which contains the maximum outdoor temperature (in Celsius) above which cross mixing is shutoff as a function of time. The maximum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the maximum outdoor temperature control is not applied.

Note: The maximum outdoor temperature when cross mixing is shutoff must be greater than or equal to the minimum outdoor temperature which cross mixing is shutoff at any given time. Otherwise, a warning will be issued and the maximum outdoor shutoff temperature will be set to the minimum outdoor shutoff temperature.

```

Zone Mixing Volume [m3]

The air volume in m³ entering the zone due to cross mixing during the hour or timestep.

Zone Mixing Mass [kg]

The air mass in kg entering the zone due to cross mixing during the hour or timestep. The air mass is calculated using the air volume flow from each “source” zone and the density of air calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones.

Zone Mixing Sensible Heat Loss [J]

Zone Mixing Sensible Heat Gain [J]

The sensible (temperature) heat transfer due to cross mixing in the host (receiving) zone is the sum of all the incoming air mass flow rates multiplied by the elapsed time, the specific heat (calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones) and the temperature differences between the host zone and

corresponding source zones. If the heat transfer is negative, the heat transfer is considered to be a zone mixing sensible heat loss. If the heat transfer is positive, the heat transfer is considered to be a zone mixing sensible heat gain.

Zone Mixing Latent Heat Loss [J]

Zone Mixing Latent Heat Gain [J]

The latent heat transfer due to cross mixing in the host (receiving) zone is the sum of all the incoming air mass flow rates multiplied by the elapsed time, the heat of vaporization (calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones) and the humidity ratio differences between the host zone and corresponding source zones. If the heat transfer is negative, the heat transfer is considered to be a zone mixing latent heat loss. If the heat transfer is positive, the heat transfer is considered to be a zone mixing latent heat gain.

Zone Mixing Total Heat Loss [J]

The total heat loss due to cross mixing that occurs when the sum of Zone Mixing Sensible Heat Gain and Zone Mixing Latent Heat Gain < the sum of Zone Mixing Sensible Heat Loss and Zone Mixing Latent Heat Loss.

Zone Mixing Total Heat Gain [J]

The total heat gain due to cross mixing that occurs when the sum of Zone Mixing Sensible Heat Gain and Zone Mixing Latent Heat Gain >= the sum of Zone Mixing Sensible Heat Loss and Zone Mixing Latent Heat Loss.

ZoneEarthtube (Earth Tube)

An earth tube is a long, underground metal or plastic pipe through which air is drawn. During cooling season, as air travels through the pipe, it gives up some of its heat to the surrounding soil and enters the room as cooler air. Similarly, during heating season, as air travels through the pipe, it receives some of its heat from the soil and enters the room as warmer air. Simple earth tubes in EnergyPlus can be controlled by a schedule and through the specification of minimum, maximum, and delta temperatures as described below. As with infiltration and ventilation, the actual flow rate of air through the earth tube can be modified by the temperature difference between the inside and outside environment and the wind speed. The basic equation used to calculate air flow rate of earth tube in EnergyPlus is:

$$EarthTubeFlowRate = (E_{design})(F_{schedule}) \left[A + B |T_{zone} - T_{odb}| + C (WindSpeed) + D (WindSpeed^2) \right]$$

For the simulation of the earth tube, a weather data file is required and, therefore, the earth tube can not run without weather data file. The required input fields to simulate the earth tube include the average soil surface temperature, the amplitude of soil surface temperature, and the phase constant of soil surface temperature. These fields should be calculated in advance by using a separate stand-alone program (CalcSoilSurfTemp) and should be input into earth tube.

CalcSoilSurfTemp – Auxiliary Programs Document

The CalcSoilSurfTemp program is simple and requires only two input fields : soil condition and soil surface condition in addition to a valid weather file. For soil condition, the user should select the number corresponding to the actual condition of the soil surrounding the earth tube from the four following options: 1. HEAVY AND SATURATED, 2. HEAVY AND DAMP, 3. HEAVY AND DRY and 4. LIGHT AND DRY. This determines the thermal diffusivity and thermal conductivity of the surrounding soil. For soil surface conditions, the user should select the number corresponding to the actual condition of the ground surface above the earth tube from the eight following options: 1. BARE AND WET, 2. BARE AND MOIST, 3. BARE AND ARID, 4. BARE AND DRY, 5. COVERED AND WET, 6. COVERED AND MOIST,

7. COVERED AND ARID and 8. COVERED AND DRY. This determines the absorption coefficient and the fraction of evaporation rate of the ground surface.

From this information and an analysis of the weather for the location selected, the CalcSoilSurfTemp program (ref. Auxiliary Programs document) calculates the three parameters listed above. The user must then add these parameters as input into EnergyPlus. The full input description of an earth tube in EnergyPlus is given below.

Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a particular earth tube statement to a thermal zone in the building.

Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design volume flow rate parameter (see next field). This fraction between 0.0 and 1.0 is noted as F_{schedule} in the above equation.

Field: Design Flow Rate

This number (noted as E_{design} in the above equation) is the maximum amount of air mass flow rate of the earth tube expected at design conditions. The flow rate is expressed in units of m^3/s . The design value is modified by the schedule fraction (see previous field) and user specified coefficients (see last four fields).

Field: Minimum Zone Temperature when Cooling

This is the indoor temperature (in Celsius) below which the earth tube is shut off. This lower temperature limit is intended to avoid overcooling a space and thus result in a heating load. For example, if the user specifies a minimum temperature of 20°C , earth tube is assumed to be available if the zone air temperature is above 20°C . If the zone air temperature drops below 20°C , then earth tube is automatically turned off.

Field: Maximum Zone Temperature when Heating

This is the indoor temperature (in Celsius) above which the earth tube is shut off. This higher temperature limit is intended to avoid overheating a space and thus result in a cooling load. For example, if the user specifies a maximum temperature of 20°C , earth tube is assumed to be available if the zone air temperature is below 20°C . If the zone air temperature rises above 20°C , then earth tube is automatically turned off.

Field: Delta Temperature

This is the temperature difference (in Celsius) between the indoor and outdoor air dry-bulb temperatures below which the earth tube is shut off. This is to allow the earth tube to be stopped either if the temperature outside is too warm and could potentially heat the space or if the temperature outside is too cold and could potentially cool the space. For example, if the user specifies a delta temperature of 2°C , earth tube is assumed to be available if the temperature difference between indoor and outdoor temperature is at least 2°C . If the outside air dry-bulb temperature is less than 2°C cooler or warmer than the indoor dry-bulb temperature, then the earth tube is automatically turned off.

Field: Earthtube Type

This alpha character string defines the type of earth tube as one of the following options: Natural, Exhaust, or Intake. A natural earth tube is assumed to be air movement/exchange that will not consume any fan energy or is the result of natural air flow through the tube and into the building. Values for fan pressure and efficiency for a natural flow earth tube are ignored. For either EXHAUST or Intake, values for fan pressure and efficiency define the fan electric consumption. For Natural and Exhaustearth tubes, the conditions of the air entering

the space are assumed to be equivalent to the air which is cooled or heated by passing along the pipe. For Intake earth tubes, an appropriate amount of fan heat is added to the air stream.

Field: Fan Pressure Rise

This is the pressure rise experienced across the fan in Pascals (N/m²). This is a function of the fan and plays a role in determining the amount of energy consumed by the fan.

Field: Fan Total Efficiency

This is the total fan efficiency (a decimal number between 0.0 and 1.0). This is a function of the fan and plays a role in determining the amount of energy consumed by the fan.

Field: Pipe Radius

This is the radius of the earth tube/pipe (in meters). This plays a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe. If the pipe has non-circular cross section, user can use the concept of hydraulic diameter as follows.

$$D = 4 \times \text{Area} / \text{Perimeter}$$

However, since this field requires the pipe radius, hydraulic diameter should be divided by two.

Field: Pipe Thickness

This is the thickness of the pipe wall (in meters). This plays a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe.

Field: Pipe Length

This is the total length of the pipe (in meters). This plays a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe. As the length of the pipe becomes longer, the amount of the heat transfer becomes larger.

Field: Pipe Thermal Conductivity

This is the thermal conductivity of the pipe (in W/m°C). This plays a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe.

Field: Pipe Depth Under Ground Surface

This is the depth of the pipe under the ground surface (in meters). This plays a role in determining the temperature of the soil surrounding the pipe.

Field: Soil Condition

This alpha character string defines the actual condition of the soil surrounding the earth tube and can be one of any of the following options: HeavyAndSaturated, HeavyAndDamp, HeavyAndDry or LightAndDry. This determines the thermal diffusivity and thermal conductivity of the surrounding soil, which play a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe.

Field: Average Soil Surface Temperature

This is the annual average soil surface temperature straight above the earth tube, which plays a role in determining the temperature of the soil surrounding the pipe. This field should be calculated in advance using the separate CalcSoilSurfTemp program.

Field: Amplitude of Soil Surface Temperature

This is the amplitude of soil surface temperature above the earth tube, which plays a role in determining the temperature of the soil surrounding the pipe. This is the difference between

the maximum and minimum soil surface temperature for the whole year divided by two. This field should be calculated in advance using the separate CalcSoilSurfTemp program.

Field: Phase Constant of Soil Surface Temperature

This is the phase constant of the soil surface temperature straight above the earth tube, which play a role in determining the temperature of the soil surrounding the pipe at particular time. This is the time elapsed from the beginning of the year until the soil surface temperature reaches the minimum value of the year. This field should be calculated in advance using the separate CalcSoilSurfTemp program.

Field: Constant Term Flow Coefficient

This number is the “A” parameter in the above earth tube equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter, however, is a constant under all conditions and is not modified by any environmental effect. As a result, it is dimensionless.

Field: Temperature Term Flow Coefficient

This number is the “B” parameter in the above earth tube equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the temperature difference between the outdoor and indoor air dry-bulb temperatures. The units for this parameter are inverse Celsius.

Field: Velocity Term Flow Coefficient

This number is the “C” parameter in the above earth tube equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the speed of wind being experienced outside the building. The units for this parameter are s/m.

Field: Velocity Squared Term Flow Coefficient

This number is the “D” parameter in the above earth tube equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by square of the speed of wind being experienced outside the building. The units for this parameter are s^2/m^2 .

The IDD is shown next. The highlighted field names can be obtained from the extra CalcSoilSurfTemp program.

EarthTube Outputs

Current EarthTube output variables:

```

Zone, Sum, Zone EarthTube Sensible Heat Loss [J]
Zone, Sum, Zone EarthTube Sensible Heat Gain [J]
Zone, Sum, Zone EarthTube Volume [m3]
Zone, Sum, Zone EarthTube Mass [kg]
Zone, Sum, Zone EarthTube Fan Electric Consumption [J]
Zone, Average, Zone EarthTube Inlet Air Temperature [C]

```

Zone EarthTube Sensible Heat Loss [J]

The sensible (temperature) heat loss that occurs when the earth tube air temperature (outdoor) < zone air temperature

Zone EarthTube Sensible heat gain [J]

The sensible (temperature) heat gain that occurs when the earth tube air temperature (outdoor) >= zone air temperature

Zone EarthTube Volume [m3]

The volume flow of the earth tube air

Zone EarthTube Mass [kg]

The mass flow of the earth tube air

Zone EarthTube Fan Electric Consumption [J]

The fan electrical consumption for intake or exhaust earth tube types

Zone EarthTube Inlet Air Temperature [C]

This is equal to the temperature of the air which is cooled or heated by passing along the pipe except when INTAKE fan power is included. When intake fan power is used, then the additional heat due to the fan is added and this will be reported as the inlet air temperature.

ZoneCoolTower:Shower

A cooltower (which is sometimes referred to as a wind tower or a shower cooling tower) is a component that is intended to model a passive downdraught evaporative cooling (PDEC) that is designed to capture the wind at the top of a tower and cool the outside air using water evaporation before delivering it to a space. The air flow in these systems is natural as the

evaporation process increases the density of the air causing it to fall through the tower and into the space without the aid of a fan. A cooltower typically consists of a water spray or an evaporative pad, a shaft, and a water tank or reservoir. Wind catchers to improve the wind-driven performance at the top of the tower are optional. Water is pumped over an evaporative device by water pump which is the only component consumed power for this system. This water cools and humidifies incoming air and then the cool, dense air naturally falls down through shaft and leaves through large openings at the bottom of cooltowers.

The shower cooling tower can be controlled by a schedule and the specification of maximum water flow rate and volume flow rate as well as minimum indoor temperature. The actual flow rate of water and air can be controlled as users specify the fractions of water loss and flow schedule. The required input fields include effective tower height and exit area to obtain the temperature and flow rate of the air exiting the tower. A schedule and rated power for the water pump are also required to determine the power consumed. The component typically has a stand alone water system that is not added to the water consumption from mains. However, users are required to specify the water source through an optional field, the name of water supply storage tank, in case any water comes from a water main. The model is described more fully in the Engineering Reference document.

This model requires weather information obtained from either design day or weather file specifications. The control is accomplished by either specifying the water flow rate or obtaining the velocity at the outlet with inputs and weather conditions when the water flow rate is unknown. As with infiltration, ventilation, and earth tubes, the component is treated in a similar fashion to “natural ventilation” in EnergyPlus. The input data dictionary definition of a shower cooling tower is as follows.

Field: Name

This field is a unique user assigned name for each cooltower. Any reference to this unit by another object will use this name.

Field: Available Schedule Name

This field is the name of the schedule that denotes whether the cooltower can run during a given hour.

Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a particular cooltower statement to a thermal zone in the building.

Field: Water Supply Storage Tank Name

This field is optional. It is used to describe where the cooltower obtains water used for evaporative cooling. If blank or omitted, then the cooltower will obtain water directly from local water main. If the name of a Water Storage Tank object is used here, then the cooltower will obtain its water from that tank. If a tank is specified, the cooltower will attempt to obtain all the water it uses from the tank. However, if the tank cannot provide all the water the cooltower needs, then the cooltower will still operate and obtain the rest of the water it needs from the mains (referred to as ‘Starved’ water).

Field: Flow Control Type

This field specifies how the user wishes to control the cooltower. The air flow from the cooltower may be controlled by either the water flow rate along with the water pump schedule or naturally driven by wind flow. The user must select from the following options: **WaterFlowSchedule** and **WindDrivenFlow**. If the user either wishes to control the water flow rate or has information about the water flow rate, **WaterFlowSchedule** must be selected. **WindDrivenFlow** for cooltower flow control must be selected when the water flow rate is unknown and the user wishes to have the flow rate of both air and water controlled by the external weather conditions (wind speed). If the user does not select a control type, **WindDrivenFlow** is assumed as a flow control type.

Field: Pump Flow Rate Schedule Name

This field modifies the maximum flow rate of water through the cooltower in m³/sec. This input is “optional.” If the user does not enter a schedule, the flow rate through the cooltower is assumed to be constant during all hours that it is operating based on the value entered in the previous input field. Note that the values for this schedule must be between zero and one.

Field: Maximum Water Flow Rate

This field is the maximum water flow rate distributed to the tower in m³/s. This limit is intended to avoid over estimation of water flow rate, which leads higher air flow rate and exit temperature of the air.

Field: Effective Tower Height

This field is the effective tower height for evaporative cooling, from the water spray to the top of the exit in m.

Field: Airflow Outlet Area

This field is the area at the exit of the tower in m². This field is used to determine the air flow rate leaving the tower with the velocity of the air flow.

Field: Maximum Air Flow Rate

This field is the maximum volumetric flow rate of the air leaving the tower in m³/s. This airflow maximum allows the cooltower performance to be limited if the outside wind speed and the tower height are relatively high and thus result in high airflow supplied to the space.

Field: Minimum Indoor Temperature

This field is the minimum indoor temperature in Celsius below which cooltower is shutoff. This lower temperature limit is intended to avoid overcooling a space and thus result in a heating load. For example, if the user specifies a minimum temperature of 20°C, cooltower is assumed to be available if the zone air temperature is above 20°C. If the zone air temperature drops below 20°C, then cooltower is automatically turned off.

Field: Fraction of Water Loss

This field specifies the fraction of the loss of water during either operation or transient operation. If the user does not enter a fraction, no loss of water is assumed and the cooltower water consumption includes only evaporation. Note that the fraction must be between zero and one.

Field: Fraction of Flow Schedule

This field specifies the fraction of the airflow that actually goes to the outside. The user who wishes to control the actual flow to the inside of the building must specify the value of the fraction. If the user does not enter a fraction, the calculated flow rate is the “zone cooltower volume flow rate.” Note that the fraction must be between zero and one.

Field: Rated Power Consumption

This field is the pump’s rated power consumption in Watts.

Zone Cooltower Exit Temperature [C]

The temperature at the exit of the cooltower.

Zone Cooltower Exit Humidity Ratio [C]

The humidity ratio of the air at the exit of the cooltower.

Cooltower Water Consumption [m3]

The water consumption includes not only the direct thermodynamics of water evaporation but also other sources of consumption such as drift or concentration blow down specified by users throughout all processes during the operation.

Cooltower Mains Water Mains Draw [m3]

This is the water consumed by the cooltower that actually be met by the mains water. This report variable appears only when the water comes from mains.

Cooltower Tank Water Consumption [m3]

This is the water consumed by the cooltower that actually be met by the water storage tank. If any amount of the water is starved from mains, this water consumption is the difference between the cooltower water consumption and the following output. This report variable appears only when the water comes from storage tank waters.

Cooltower Starved Water Consumption [m3]

This is the source (mains) of water consumed by the cooltower that could not actually be met by the storage tank. This report variable appears only when the water comes from storage tank waters.

Zone Cooltower Pump Electric Consumption [W]

The power consumed by the recirculating pump in Watts.

Zone Cooltower Pump Electric Energy [J]

The energy consumed by the recirculating pump in Joule.

ZoneThermalChimney (Thermal Chimney)

A thermal chimney is a vertical shaft utilizing solar radiation to enhance the natural ventilation in buildings. It consists of a absorber wall, air gap and glass cover with high solar transmissivity. For the high solar absorption, it is usually south facing.

The key output parameter in the thermal chimney model is the enhanced amount of natural ventilation rate caused by the presence of a thermal chimney. In order to determine the enhanced ventilation, the discharge air temperature from a thermal chimney should be calculated, which, in turn, should be computed based on the information on the absorber wall temperature, glass cover temperature and the vertical air temperature distribution within the thermal chimney. Among them, energy balances for the absorber wall and the glass cover are carried out using the existing algorithm currently available in EnergyPlus, which has the similar approach to the Trombe wall. As stated in the Trombe wall object as well, this approach allows the flexibility for users to specify the various wall parameters and to explore unusual configurations. On the other hand, the vertical air temperature distribution and the resultant discharge air temperature of the thermal chimney are computed using the separate thermal chimney algorithm described in the Engineering Reference document.

Similar to the Trombe wall model, a zone is coupled to the desired surface via an interzone partition. To simulate the thermal chimney, the Solar Distribution field in the Building object should be set to FullInteriorAndExterior so that the majority of the solar flux is directed on the

absorber wall. For a normal sized thermal chimney zone, the user can set the Zone Inside Convection Algorithm to “Detailed”, which takes into account natural convection effects intended for a normal zone. For a narrow cavity zone having high aspect ratios, there is no built-in algorithm for calculating the correct convection coefficients on the inside of thermal chimney zone walls. One option is to use the “Detailed” convection algorithm similar to the Trombe wall model. However, some error may be incurred when used with a narrow zone. Another option is to use the SurfaceProperty:ConvectionCoefficients object to schedule coefficients that have been determined beforehand by the user. In addition, the wall construction of the adjoining zone must be the mirror image of the wall construction in the thermal chimney zone.

The full input description of a thermal chimney in EnergyPlus is given below.

Field: Name

This field is a unique user assigned name for an instance of the thermal chimney system.

Field: Zone Name

This field is the name of the thermal chimney zone (ref: Zone). Since the thermal chimney is not only a system component but also a zone itself, this field is also necessary. It should be differentiated from the *Zone name* field described later.

Field: Availability Schedule Name

This field is the name of the schedule (ref: Schedule) that denotes whether the thermal chimney can operate during a given hour. A schedule value greater than 0 (usually 1 is used) indicates that the system is available and can be on during the hour. A value less than or equal to 0 (usually 0 is used) denotes that the system is not available and must be off for the hour.

Field: Width of the Absorber Wall

This number is the width of the absorber wall in the thermal chimney. The width is expressed in units of m. Even though this value is specified in Surface objects as well, this value is used to compute the discharge air temperature and the enhanced ventilation rate caused by the thermal chimney.

Field: Cross Sectional Area of Air Channel Outlet

This number is the cross sectional area of air channel outlet. The area is expressed in units of m². The enhanced air flow rate by the thermal chimney is dependent on cross sectional areas of air channel inlet and outlet. Cross sectional areas of air channel inlet will be described later in conjunction with the distance from the top of thermal chimney to each inlet and relative ratios of air flow rates passing through each inlet.

Field: Discharge Coefficient

This dimensionless number is the discharge coefficient of the thermal chimney. The ventilation rate enhanced by the thermal chimney is also dependent on the discharge coefficient.

Field: Zone <#> Name

This field is the name of the zone (ref: Zone) to which the thermal chimney is attached. It is used in conjunction with the next three fields. Note that up to 20 sets of zone name, distance from the top of the thermal chimney to each inlet, relative ratios of air flow rates passing through each zone and cross sectional areas of each air channel inlet may be entered for a single thermal chimney if multiple zones share the common thermal chimney.

Field: Distance from Top of Thermal Chimney to Inlet <#>

This field is the distance from the top of the thermal chimney to each inlet corresponding to each zone. It is used in conjunction with the zone name, relative ratios of air flow rates

passing through each zone and cross sectional areas of each air channel inlet. The distance is expressed in units of m. The air flow rate enhanced by the thermal chimney is dependent on the distance between the thermal chimney outlet and inlet.

Field: Relative Ratios of Air Flow Rates Passing through Zone <#>

This dimensionless number is the relative ratio of air flow rates enhanced by the thermal chimney passing through each zone. The total air flow rate enhanced by the thermal chimney is distributed to each zone based on this number if multiple zones share the common thermal chimney. It is used in conjunction with the zone name, the distance from the top of the thermal chimney to each inlet and cross sectional areas of each air channel inlet. Not that the sum of all ratios must be equal to 1.0.

Field: Cross Sectional Areas of Air Channel Inlet <#>

This field is the cross sectional areas of each air channel inlet corresponding to each zone. It is used in conjunction with the zone name, the distance from the top of the thermal chimney to each inlet and relative ratios of air flow rates passing through each zone. The area is expressed in units of m². The air flow rate enhanced by the thermal chimney is dependent on cross sectional areas of air channel inlet and outlet.

System, Average, Thermal Chimney Total Mass Flow Rate [kg/s]
System, Average, Thermal Chimney Air Outlet Temperature [C]

```

Zone ThermalChimney-Heat Loss [J]

The sensible (temperature) heat loss of each zone that occurs when the thermal chimney cools the zone air

Zone ThermalChimney-Heat Gain [J]

The sensible (temperature) heat gain of each zone that occurs when the thermal chimney heats the zone air

Zone ThermalChimney-Volume [m3]

The air volumetric flow of each zone enhanced by the thermal chimney

Zone ThermalChimney-Mass [kg]

The air mass flow of each zone enhanced by the thermal chimney

Thermal Chimney Total Volumetric Flow Rate [m³/s]

The total air volumetric flow rate caused by the thermal chimney

Thermal Chimney Total Mass Flow Rate [kg/s]

The total air mass flow rate caused by the thermal chimney

Thermal Chimney Air Outlet Temperature [C]

The temperature of the air which is discharged from the thermal chimney through the outlet

Group – Design Objects**Input for Design Calculations and Component Autosizing****Overview**

In order for EnergyPlus to successfully calculate zone design heating and cooling loads and air flow rates and for the program to use these results to automatically size the HVAC components a number of input objects must be present and certain object input fields must be entered.

- The input file should contain a SimulationControl object. The 1st field *Do Zone Sizing Calculation* should be entered as *Yes*. This will cause a zone sizing simulation to be done using all the design days in the input file as weather. If there are no air or water loops in the HVAC input fields 2 and 3 can be set to *No*. If there are one or more air loops (i.e., there is at least one AirLoopHVAC object in the input file) then the 2nd field *Do System Sizing Calculation* should be entered as *Yes*. If there are one or more water loops (Plant Loop objects) then the 3rd field *Do Plant Sizing Calculation* should be set to *Yes*. Finally either the 4th field (*Run Simulation for Sizing Periods*) or the 5th field (*Run Simulation for Weather File Run Periods*) should be set to *Yes* in order to autosize the components and do a real simulation using the autosized components. The component autosizing calculations are done on the first pass through the HVAC system in the real simulation.
- There must be at least 2 (up to any number) SizingPeriod objects present. Normally one will be for summer conditions and one for winter. The summer day should normally have the field *Day Type* set to *SummerDesignDay*. The winter design day should normally have *Day Type* set to *WinterDesignDay*.
- To apply a global sizing factor include the Sizing:Parameters object.
- For each controlled zone in the input file there should be a corresponding Sizing:Zone object. Similarly for each AirLoopHVAC there should be a Sizing:System object. And for each Plant or Condenser Loop there should be a Sizing:Plant object. Note however that if a controlled zone has no corresponding Zone Sizing object the data from the first Zone Sizing object will be used. Thus if all the zone sizing information is the same only one Zone Sizing object need be entered.
- Only controlled zones are included in the zone and system sizing calculations. Thus for a design air flow rate to be calculated for a zone, it must contain a thermostat *even though it might not need or have a thermostat in the full simulation*. An illustration would be a three zone building with a packaged single zone system and a thermostat in one of the zones. In order for the two slave zones to be included in the design air flow calculations they must be treated as if they have a thermostat: there must be a ZoneControl:Thermostat for each of the slave zones.
- Some attention should be paid to schedules. In a weekly schedule object the 9th and 10th day schedules are for summer and winter design days respectively. This means that if a DesignDay object has field *Day Type* set to *SummerDesignDay* the day schedule for summer design days will be in effect. Similarly if a DesignDay object has field *Day Type* set to *WinterDesignDay* the day schedule for winter design days will be in effect. Some possible applications of this capability are:

- 1) setting internal loads (lights, equipment, occupancy) to maximum all day for cooling and to zero all day for heating;
- 2) setting heating and cooling thermostat set points to constant values (no set up or set back);
- 3) setting heating and cooling equipment to be always on.

None of these applications are necessarily recommended but these and other uses of the special design day schedules may prove useful for specific situations.

Component Autosizing

For autosizing to occur at the component level the user must enter the special value *autosize* in the numeric fields for which autosizing is available. Those fields can be found by looking at the Energy+.idd data dictionary file or under individual object details in this document. Fields that can be autosized are denoted with the comment *\autosizable*. An example of a few components and fields that are autosizable are listed in the following table.

Table 20. Example Details of Autosizable Objects/Fields

Component / Object	Field(s)
AirLoopHVAC:Unitary:Furnace:HeatOnly	Maximum Supply Air Temperature
	Supply Air Flow Rate
	Fraction of Supply Air Flow That Goes Through the Controlling Zone
AirLoopHVAC:UnitaryHeatCool:VAVChangeoverBypass	System Air Flow Rate During Cooling Operation
	System Air Flow Rate During Heating Operation
	System Air Flow Rate When No Cooling or Heating is Needed
	Outdoor Air Flow Rate During Cooling Operation
	Outdoor Air Flow Rate During Heating Operation
	Outdoor Air Flow Rate When No Cooling or Heating is Needed

Sizing Factors

There are 3 places in the input where the user can impose sizing factors.

1. In Sizing Parameters (object: Sizing:Parameters), the user can specify an over-all sizing factor. This factor is applied to all the zone design loads and air flow rates resulting from the zone sizing calculations.
2. In Zone Sizing (object: Sizing:Zone), the user can specify a sizing factor for a specific zone. The factor is applied to the calculated zone design loads and air flow rates for the zone named in the Sizing:Zone object. This sizing factor overrides the global sizing factor. That is, a zone sizing factor, if specified, replaces the global sizing factor for the named zone.
3. For some plant components (basically all central chillers, boilers and cooling towers) the user can specify a sizing factor that modifies the autosized component capacity and flow rates. These factors are applied after the application of global or zone sizing factors. They are primarily used to split the design load between multiple components. These sizing factors can change the autosizing of the associated loops and pumps. The following rules are followed the effect of plant component sizing factors on loops and pumps.

- a. For supply side branches, the sizing factors of all components in series on the branch are summed and the result becomes the branch sizing factor. If there is a branch pump its autosized design flow rate is multiplied by the branch sizing factor.
- b. For each loop, if the average of the branch sizing factors is less than 1, the loop sizing factor is set equal to the sum of the branch sizing factors. If the average is greater than 1, the loop sizing factor is set equal to the maximum of the branch sizing factors. The loop sizing factor is applied to the loop design flow rate (if autosized) and to the loop pump flow rate (if autosized).

Mixing User-Specified and Autosized Inputs

Mixed user-specified and autosized inputs can be successfully used if the following points and suggestions are followed.

1. Each component is autosized independently. Thus user input for a flow rate in one component will have no effect on other components’ autosized flow rates. For instance, specifying the chilled water loop pump’s rated flow rate will have no effect on the autosizing of the chiller’s design evaporator flow rate or on the plant loop’s autosized maximum loop flow rate.
2. Within a component it is OK to mix user-specified and autosized inputs. In the Chiller:Electric, for example, it is fine to specify the nominal capacity and autosize the other input fields.
3. If the user wants to specify a zone or system air flow rate it should be done using the Sizing:Zone and Sizing:System objects rather than done in the individual components.
4. The plant loop flow rates are sized from the total design demand of the components connected to each loop. The components demanding water need not be autosized for the plant loop autosizing to work successfully. So the user could specify all the air side components and autosize all the plant loops and plant components. Or specify the chilled water loop flow rate, chilled water pump inputs and chiller inputs and let the condenser loop and tower autosize.

Component Sizing Output

The results of the component autosizing calculations are reported on the *eplusout.eio* file. For each component field that has been autosized the object type, object name, field description with unit, and value are printed out as comma separated data on a line beginning with *Component Sizing*. Examples of this are shown in the Output Details and Examples document.

The complete list of objects that have autosized fields is shown in the following table.

Table 21. Complete list of Objects with autosized Fields

User or External Zone Design Flow Rate Inputs

In EnergyPlus the autosizing calculations start with a calculation of the zone design air flow rates using zone by zone design day simulations. The resulting zone design air flow rates and daily air flow sequences are used in the subsequent HVAC and central plant air and fluid flow design calculations and in the component autosizing calculations. The user can override or change the calculated zone design air flow rates in several ways.

- 1) The user can enter a value for *Sizing Factor* in the *Sizing:Parameters* object (see description below).
- 2) The user can specify a zone level *Zone Sizing Factor* in each *Sizing:Zone* object.
- 3) For each zone the user can input a *Cooling Design Air Flow Rate* and/or a *Heating Design Air Flow Rate* (and specify *Cooling Design Air Flow Method = Flow/Zone* and *Heating Design Air Flow Method = Flow/Zone*). These user inputs override the calculated values. The program divides the user input cooling or heating design air flow rate by the calculated values and uses the result as a zone sizing factor to multiply all the elements in the design heating and cooling air flow and load sequences. From this point the design calculations proceed as usual.

User or External System Design Flow Rate Inputs

Using the results of the zone design air flow rate calculation (including any user input or altered flow rates) EnergyPlus proceeds to calculate central air system flow rates and cooling and heating loads. The results of this calculation can be overridden in the following way.

For each system (AirLoopHVAC), in the corresponding *Sizing:System* object, specify *Cooling Design Air Flow Method* to be *Flow/System* and input a value for *Cooling Design Air Flow Rate*. Similarly for heating specify *Heating Design Air Flow Method* to be *Flow/System* and input a value for *Heating Design Air Flow Rate*.

Sizing:Parameters

This object allows the user to specify a global sizing ratio. This ratio will be applied at the zone level to all of the zone heating and cooling loads and air flow rates. These new loads and air flow rates are then used to calculate the system level flow rates and capacities and are used in all of the component sizing calculations.

The user can also specify the width (in load timesteps) of a moving average window which can be used to smooth the calculated zone design flow sequences. The use of this parameter is described below.

Field: Sizing Factor

The global sizing ratio applied to all of the zone design load and air flow rates.

Field: Timesteps in Averaging Window

The number of load timesteps in the zone design flow sequence averaging window. The default is 1, in which case the calculated zone design flow rates are averaged over the load timestep.

The zone design air flow rate calculation is performed assuming a potentially infinite supply of heating or cooling air at a fixed temperature. Thus the calculated design air flow rate will always be able to meet any load or change in load no matter how large or abrupt. In reality air flow rates are limited by duct sizes and fan capacities. The idealized zone design flow calculation may result in unrealistically large flow rates, especially if the user is performing the sizing calculations using thermostat schedules with night setup or setback. The calculated zone design flow rates are always averaged over the load timestep. The user may want to perform a broader average to mitigate the effect of thermostat setup and setback and prevent the warm up or cool down flow rates from dominating the design flow rate calculation.. Specifying the width of the averaging window allows the user to do this.

For example, if the load calculation timestep is 15 minutes and the user specifies the *Timesteps in Averaging Window* to be 4, the zone design air flows will be averaged over a time period of 1 hour. Specifying 8 would result in averaging over a 2 hour period.

```
Sizing:Parameters,
  \unique-object
  \min-fields 1
  N1; \field Sizing Factor
      \type real
      \minimum> 0.0
      \default 1.0
  N2; \field Timesteps in Averaging Window
      \note blank => set the timesteps in averaging window to Number of Timesteps per Hour resulting in a
1 hour averaging window
      \type integer
      \minimum 1
```

Sizing Parameters Outputs

The sizing factor and the averaging window size are reported out on the *eplusout.eio* file. An example is:

```
! <Load Timesteps in Zone Design Calculation Averaging Window>, Value
Timesteps in Averaging Window, 1
! <Sizing Factor Information>, Sizing Factor ID, Value
Sizing Factor, Global, 1.3000
Sizing Factor, Zone SPACE1-1, 1.3000
Sizing Factor, Zone SPACE2-1, 1.3000
Sizing Factor, Zone SPACE3-1, 1.3000
Sizing Factor, Zone SPACE4-1, 1.3000
Sizing Factor, Zone SPACE5-1, 1.3000
```

OutputControl:Sizing:Style

As described above (see: EnergyPlus Output Processing), the user may select the “style” for the sizing result files (*epluszsz.<ext>*, *eplussz.<ext>*). This object applies to all sizing output files.

```
OutputControl:Sizing:Style,
  \memo default style for the Sizing output files is comma -- this works well for
  \memo importing into spreadsheet programs such as Excel(tm) but not so well for word
  \memo processing programs -- there tab may be a better choice. fixed puts spaces between
  \memo the "columns"
  \unique-object
  A1; \field Column Separator
      \required-field
      \type choice
      \key Comma
      \key Tab
      \key Fixed
```

Field: Column Separator

For this field, the desired separator for columns is entered. “Comma” creates comma separated fields/columns in the outputs (*eplus<sizing type>.csv* files are created). “Tab” creates tab separated fields/columns in the outputs (*eplus<sizing type>.tab* files are created). “Fixed” creates space separated fields/columns in the outputs (*eplus<sizing type>.txt* files are created) but these are not necessarily lined up for easy printing.

Note that both tab and comma separated files easily import into Excel™ or other spreadsheet programs. The tab delimited files can also be viewed by text editors, word processing programs and easily converted to “tables” within those programs.

Sizing:Zone

The Sizing:Zone object provides the data needed to perform a zone design air flow calculation for a single zone. This calculation assumes a variable amount of supply air at a fixed temperature and humidity. The information needed consists of the zone inlet supply air

conditions: temperature and humidity ratio for heating and cooling. The calculation is done for every design day included in the input. The maximum cooling load and air flow and the maximum heating load and air flow are then saved for the system level design calculations and for the component automatic sizing calculations.

The Sizing:Zone object is also the place where the user can input the design outdoor air flow rate. This can be specified in a number of ways as is described below under *outside air flow method*. This data is saved for use in the system sizing calculation of for sizing zone components that use outside air.

The user can also place limits on the heating and design cooling air flow rates. See *Heating Design Air Flow Method* and *cooling design air flow method* below and the explanations of the various heating and cooling flow input fields.

Field: Zone Name

The name of the Zone corresponding to this Sizing:Zone object. This is the zone for which the design air flow calculation will be made using the input data of this Sizing:Zone Object.

Field: Zone Cooling Design Supply Air Temperature

The supply air temperature in degrees Celsius for the zone cooling design air flow rate calculation. Air is supplied to the zone at this temperature during the cooling design day simulation, The zone load is met by varying the zone air flow rate. The maximum zone flow rate is saved as the zone cooling design air flow rate.

Field: Zone Heating Design Supply Air Temperature

The supply air temperature in degrees Celsius for the zone heating design air flow rate calculation. Air is supplied to the zone at this temperature during the heating design day simulation, The zone load is met by varying the zone air flow rate. The maximum zone flow rate is saved as the zone heating design air flow rate.

Field: Zone Cooling Design Supply Air Humidity Ratio

The humidity ratio in kilograms of water per kilogram of dry air of the supply air in the zone cooling design air flow rate calculation.

Field: Zone Heating Design Supply Air Humidity Ratio

The humidity ratio in kilograms of water per kilogram of dry air of the supply air in the zone heating design air flow rate calculation.

Field: Outdoor Air Method

The input must be either *Flow/Zone*, or *Flow/Person*, *Flow/Area*, *Sum*, or *Maximum*. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow* as the zone design outdoor air flow rate. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the maximum occupancy to calculate a zone design outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be added to obtain the zone design outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area* and *Outdoor Air Flow per Zone* will be used for the zone design outdoor air flow rate. The default is *Flow/Person*.

Field: Outdoor Air Flow per Person

The design outdoor air flow rate per person for this zone in cubic meters per second. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all People statements assigned to the zone. Occupancy schedule values are not applied. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*, or *Maximum*.

Field: Outdoor Air Flow per Zone Floor Area

The design outside air volumetric flow rate per square meter of floor area (units are $\text{m}^3/\text{s}\cdot\text{m}^2$). This input is multiplied by the zone area to obtain a flow rate. This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*.

Field: Outdoor Air Flow per Zone

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*.

Field: Zone Sizing Factor

This input is a zone level sizing ratio. The zone design heating and cooling air flow rates and loads will be multiplied by the number input in this field. This input overrides the building level sizing factor input in the Sizing:Parameters object.

Field: Cooling Design Air Flow Method

The input must be either *Flow/Zone*, *DesignDay*, or *DesignDayWithLimit*. *Flow/Zone* means that the program will use the input of the field *Cooling Design Air Flow Rate* as the zone design cooling air flow rate. *DesignDay* means the program will calculate the zone design cooling air flow rate using the Sizing:Zone input data and a design day simulation without imposing any limits other than those set by the minimum outside air requirements. *DesignDayWithLimit* means that the maximum from *Cooling Minimum Air Flow per Zone Floor Area* and *Cooling Minimum Air Flow* will set a lower limit on the design maximum cooling air flow rate. The default method is *DesignDay*: i.e., the program uses the calculated design values subject to ventilation requirements.

Field: Cooling Design Air Flow Rate

The design zone cooling air flow rate in cubic meters per second. This input is used if *Cooling Design Air Flow Method* is specified as *Flow/Zone*. The applicable zone or building level sizing factor is applied to this value.

Field: Cooling Minimum Air Flow per Zone Floor Area

The minimum zone cooling volumetric flow rate per square meter (units are $\text{m}^3/\text{s}\cdot\text{m}^2$). This field is used when *Cooling Design Air Flow Method* is specified as *DesignDayWithLimit*. In this case it sets a lower bound on the zone design cooling air flow rate. In all cases the maximum flow derived from *Cooling Minimum Air Flow per Zone Floor Area*, *Cooling Minimum Air Flow*, and *Cooling Minimum Air Flow Fraction* is used to set a minimum supply air flow rate for the zone for VAV systems. The default is .000762, corresponding to .15 cfm/ft^2 . The applicable sizing factor is not applied to this value.

Field: Cooling min air flow

The minimum zone cooling volumetric flow rate in m^3/s . This field is used when *Cooling Design Air Flow Method* is specified as *DesignDayWithLimit*. In this case it sets a lower bound on the zone design cooling air flow rate. In all cases the maximum flow derived from *Cooling Minimum Air Flow per Zone Floor Area*, *Cooling Minimum Air Flow*, and *Cooling Minimum Air Flow Fraction* is used to set a minimum supply air flow rate for the zone for VAV systems. The default is zero. The applicable sizing factor is not applied to this value.

Field: Cooling min air flow fraction

The minimum zone design cooling volumetric flow rate expressed as a fraction of the zone design cooling volumetric flow rate. . In all cases the maximum flow derived from *Cooling Minimum Air Flow per Zone Floor Area*, *Cooling Minimum Air Flow*, and *Cooling Minimum Air Flow Fraction* is used to set a minimum supply air flow rate for the zone for VAV systems. The default is zero. This input is currently used in sizing the fan minimum flow rate. It does not currently affect other component autosizing.

Field: Heating Design Air Flow Method

The input must be either *Flow/Zone*, *DesignDay*, or *DesignDayWithLimit*. *Flow/Zone* means that the program will use the input of the field *Heating Design Air Flow Rate* as the zone design heating air flow rate. *DesignDay* means the program will calculate the zone design heating air flow rate using the *Sizing:Zone* input data and a design day simulation without imposing any limits other than those set by the minimum outside air requirements. *DesignDayWithLimit* means that the maximum from *Heating Minimum Air Flow per Zone Floor Area* and *Heating Minimum Air Flow* will set a lower limit on the design maximum cooling air flow rate. The default method is *DesignDay*: i.e., the program uses the calculated design values subject to ventilation requirements.

Field: Heating Design Air Flow Rate

The design zone heating air flow rate in cubic meters per second. This input is used if *Heating Design Air Flow Method* is specified as *Flow/Zone*.

Field: Heating Maximum Air Flow per Zone Floor Area

The maximum zone heating volumetric flow rate per square meter (units are $\text{m}^3/\text{s}\cdot\text{m}^2$). This field is used when *Heating Design Air Flow Method* is specified as *DesignDayWithLimit*. In this case it sets an upper bound on the zone design heating air flow rate. In all cases the maximum flow derived from *Heating Maximum Air Flow per Zone Floor Area*, *Heating Maximum Air Flow*, and *Heating Maximum Air Flow Fraction* is used to set a maximum heating supply air flow rate for the zone for VAV systems. The default is .002032, corresponding to .40 cfm/ft². This input is not currently used for autosizing any of the components.

Field: Heating Maximum Air Flow

The maximum zone heating volumetric flow rate in m^3/s . This field is used when *Heating Design Air Flow Method* is specified as *DesignDayWithLimit*. In this case it sets an upper bound on the zone design heating air flow rate. In all cases the maximum flow derived from *Heating Maximum Air Flow per Zone Floor Area*, *Heating Maximum Air Flow*, and *Heating Maximum Air Flow Fraction* is used to set a maximum heating supply air flow rate for the zone for VAV systems. The default is .1415762, corresponding to 300 cfm. This input is not currently used for autosizing any of the components.

Field: Heating Maximum Air Flow Fraction

The maximum zone design heating volumetric flow rate expressed as a fraction of the zone design cooling volumetric flow rate. In all cases the maximum flow derived from *Heating Maximum Air Flow per Zone Floor Area*, *Heating Maximum Air Flow*, and *Heating Maximum Air Flow Fraction* is used to set a maximum heating supply air flow rate for the zone for VAV systems. The default is 0.3. This input is not currently used for autosizing any of the components.

Zone Sizing Outputs

The zone design air flow rates and loads are output onto the local file “epluszsz.<ext>” where <ext> is the extension from the sizing style object (default is csv – a comma separated file *epluszsz.csv*). The columns are clearly labeled. It will easily import into Excel or other spreadsheet program that accepts delimited files. All of these values are design air flow rates and loads *calculated by the program*. No sizing factors have been applied.

The calculated zone design air flow rates and the user input or altered zone design air flow rates are also reported on the *eplusout.eio* file. The values are printed out for each zone as comma separated records beginning with *Zone Sizing*. Items output on the *eio* file are: zone name, load type (heating or cooling), design load, calculated design air flow rate, user design

air flow rate, design day name, time of peak, outside temperature at peak, outside humidity ratio at peak.

Sizing:System

The Sizing:System object contains the input needed to perform a central forced air system design air flow, heating capacity, and cooling capacity calculation for a system serving one or more zones. The information needed consists of the outside environmental conditions and the design supply air temperatures, outdoor air flow rate, and minimum system air flow ratio.

The outside conditions come from the design days in the input. A system sizing calculation is performed for every design day in the input file and the resulting maximum heating and cooling air flow rates and capacities are saved for use in the component sizing calculations.

Supply air conditions are specified by inputting a supply air temperature for cooling, a supply air temperature for heating, and a preheat temperature.

The system sizing calculation sums the zone design air flow rates to obtain a system supply air flow rate. The design conditions and the outdoor air flow rate are used to calculate a design mixed air temperature. The temperature plus the design supply air temperatures allows the calculation of system design heating and cooling capacities.

Field: AirLoop Name

The name of the AirLoopHVAC corresponding to this Sizing:System object. This is the air system for which the design calculation will be made using the input data of this Sizing:System Object.

Field: Type of Load to Size On

The user specified type of load on which to size the central system. The choices are *sensible*, *latent*, or *total*. Only *sensible* is operational.

Field: Design Outdoor Air Flow Rate

The design outdoor air flow rate in cubic meters per second. Generally this should be the minimum outdoor air flow. It is used for both heating and cooling design calculations. The assumption for cooling is that any outdoor air economizer will be closed. If *Autosize* is input the outdoor air flow rate will be taken from the sum of the zone outdoor air flow rates.

Field: Minimum System Air Flow Ratio

The design minimum central air flow ratio. This ratio is the minimum system air flow rate divided by the maximum system air flow rate. The value must be between 0 and 1. For constant volume systems the ratio should be set to 1. Note that this ratio should be set to reflect what the user expects the system flow rate to be when maximum heating demand occurs. This ratio is used in calculating the central system heating capacity. Thus if the system is VAV with the zone VAV dampers held at minimum flow when there is a zone heating demand, this ratio should be set to the minimum flow ratio. If the zone VAV dampers are reverse action and can open to full flow to meet heating demand, this ratio should be set to 1.

Field: Preheat Design Temperature

The design air temperature exiting the preheat coil (if any) in degrees Celsius.

Field: Preheat Design Humidity Ratio

The design humidity ratio exiting the preheat coil (if any) in kilograms of water per kilogram of dry air.

Field: Precool Design Temperature

The design air temperature exiting the precooling coil (if any) in degrees Celsius.

Field: Precool Design Humidity Ratio

The design humidity ratio exiting the precooling coil (if any) in kilograms of water per kilogram of dry air.

Field: Central Cooling Design Supply Air Temperature

The design supply air temperature for cooling in degrees Celsius. This should be the temperature of the air exiting the central cooling coil.

Field: Central Heating Design Supply Air Temperature

The design supply air temperature for heating in degrees Celsius. This can be either the reset temperature for a single duct system or the actual hot duct supply air temperature for dual duct systems. It should be the temperature at the exit of the main heating coil.

Field: Sizing Option

If the input is *coincident* the central system air flow rate will be sized on the sum of the coincident zone air flow rates. If the input is *noncoincident* the central system air flow rate will be sized on the sum of the noncoincident zone air flow rates. The default is noncoincident.

Field: 100% Outdoor Air in Cooling

Entering Yes means the system will be sized for cooling using 100% outdoor air. Entering No means the system will be sized for cooling using minimum outside air (the default).

Field: 100% Outdoor Air in Heating

Entering Yes means the system will be sized for heating using 100% outdoor air. Entering No means the system will be sized for heating using minimum outside air (the default).

Field: Central Cooling Design Supply Air Humidity Ratio

The design humidity ratio in kilograms of water per kilogram of dry air at the exit of the central cooling coil. The default is .008.

Field: Central Heating Design Supply Air Humidity Ratio

The design humidity ratio in kilograms of water per kilogram of dry air at the exit of the central heating coil. The default is .008.

Field: Cooling Design Air Flow Method

The input must be either *DesignDay* or *Flow/System*. *DesignDay* means the program will calculate the system design cooling air flow rate using the System Sizing input data and a design day simulation. *Flow/System* means that the program will use the input of the field *Cooling Design Air Flow Rate* as the system design cooling air flow rate. The default method is *DesignDay*: i.e., the program uses the calculated design values.

Field: Cooling Design Air Flow Rate

The design system cooling air flow rate in cubic meters per second. This input is an alternative to using the program calculated value.

Field: Heating Design Air Flow Method

The input must be either *DesignDay* or *Flow/System*. *DesignDay* means the program will calculate the system design heating air flow rate using the System Sizing input data and a design day simulation. *Flow/System* means that the program will use the input of the field *Heating Design Air Flow Rate* as the system design heating air flow rate. . The default method is *DesignDay*: i.e., the program uses the calculated design values.

Field: Heating Design Air Flow Rate

The design system heating air flow rate in cubic meters per second. This input is an alternative to using the program calculated value.

System Sizing Outputs

The system design air flow rates and heating and cooling capacities are output onto the local file “eplussz.<ext>” where <ext> is the extension from the sizing style object (default is csv – a comma separated file *eplussz.csv*). The columns are clearly labeled. It will easily import

into Excel or other spreadsheet program that accepts delimited files. The results are calculated values and do not include any user input system flow rates.

The calculated system design air flow rates and the user input system design air flow rates are also reported on the *eplusout.eio* file. The values are printed out for each system as comma separated records beginning with *System Sizing*. An example is:

```
! <System Sizing Information>, System Name, Field Description, Value
System Sizing, VAV SYS 1, Calculated Cooling Design Air Flow Rate [m3/s], 1.3194
System Sizing, VAV SYS 1, User Cooling Design Air Flow Rate [m3/s], 1.5000
System Sizing, VAV SYS 1, Calculated Heating Design Air Flow Rate [m3/s], 0.90363
System Sizing, VAV SYS 1, User Heating Design Air Flow Rate [m3/s], 1.0000
```

Plant Sizing

The Plant Sizing object contains the input needed for the program to calculate the heating, cooling, and condenser loop flow rates. This information is initially used by components that use water for heating or cooling such as hot or chilled water coils to calculate their maximum water flow rates. These flow rates are then summed for use in calculating the Plant Loop flow rates.

The program will size any number of chilled water, hot water, and condenser loops. There should be one Plant Sizing object for each plant loop that is to be autosized.

Field: Plant or Condenser Loop Name

The name of a Plant Loop or Condenser Loop object corresponding to this Plant Sizing object. This is the plant loop for which this data will be used for calculating the loop flow rate.

Field: Loop Type

The possible inputs are *Heating*, *Steam*, *Cooling*, or *Condenser*.

Field: Design Loop Exit Temperature

The water temperature in degrees Celsius at the exit of the supply side of the plant loop. Thus this is the temperature of the water supplied to the inlet of chilled or hot water coils.

Field: Loop Design Temperature Difference

The design temperature rise (for cooling or condenser loops) or fall (for heating loops) in degrees Celsius across the demand side of a plant loop.

The full IDD specification is:

```
Sizing:Plant,
  \min-fields 4
  A1, \field Plant or Condenser Loop Name
      \note Enter the name of a PlantLoop or a CondenserLoop object

  7.22,              ! chilled water supply temperature  
  6.67;              ! chilled water delta T
```

Plant Sizing Outputs

The loop flow rates are reported on the *eplusout.eio* file along with the component sizing results.

HVAC: Primary and Secondary Systems

The HVAC and equipment section of the EnergyPlus input data dictionary and input data file are slightly more complex than the description of building geometry, internal gains, etc. because of the interconnections of the various parts of an HVAC system. In EnergyPlus, there are several portions to the HVAC simulation. All of these parts must be correctly specified in order to arrive at a valid simulation model. The goal of this section is to provide the interface developer with guidelines on what input is expected and also provide some background on basic EnergyPlus simulation methodology.

An EnergyPlus HVAC simulation consists of various components that are connected physically in the actual system by ducts, piping, etc. Every component in an HVAC system must have an inlet and outlet "node". In the actual system, a node might be a point in the system at which fluid properties can be measured. In an EnergyPlus simulation, the nodes are points at which fluid properties are evaluated and passed on to subsequent equipment.

Components are linked together to form various loops within the simulation. Thus, the output node from one component also serves as the inlet node to the next component. Loops are constructed by defining these loops and also defining the components on the loops. The figure below shows a generic example of the loop-node concept.

Loop nodes are a key defining feature in EnergyPlus. As a result, it is recommended that one of the first steps taken in defining an HVAC system in EnergyPlus be the definition of a node diagram or map. This is helpful for visualization of the entire system. Such a map could be created electronically within an interface or could be kept in the background out of the sight of the user.

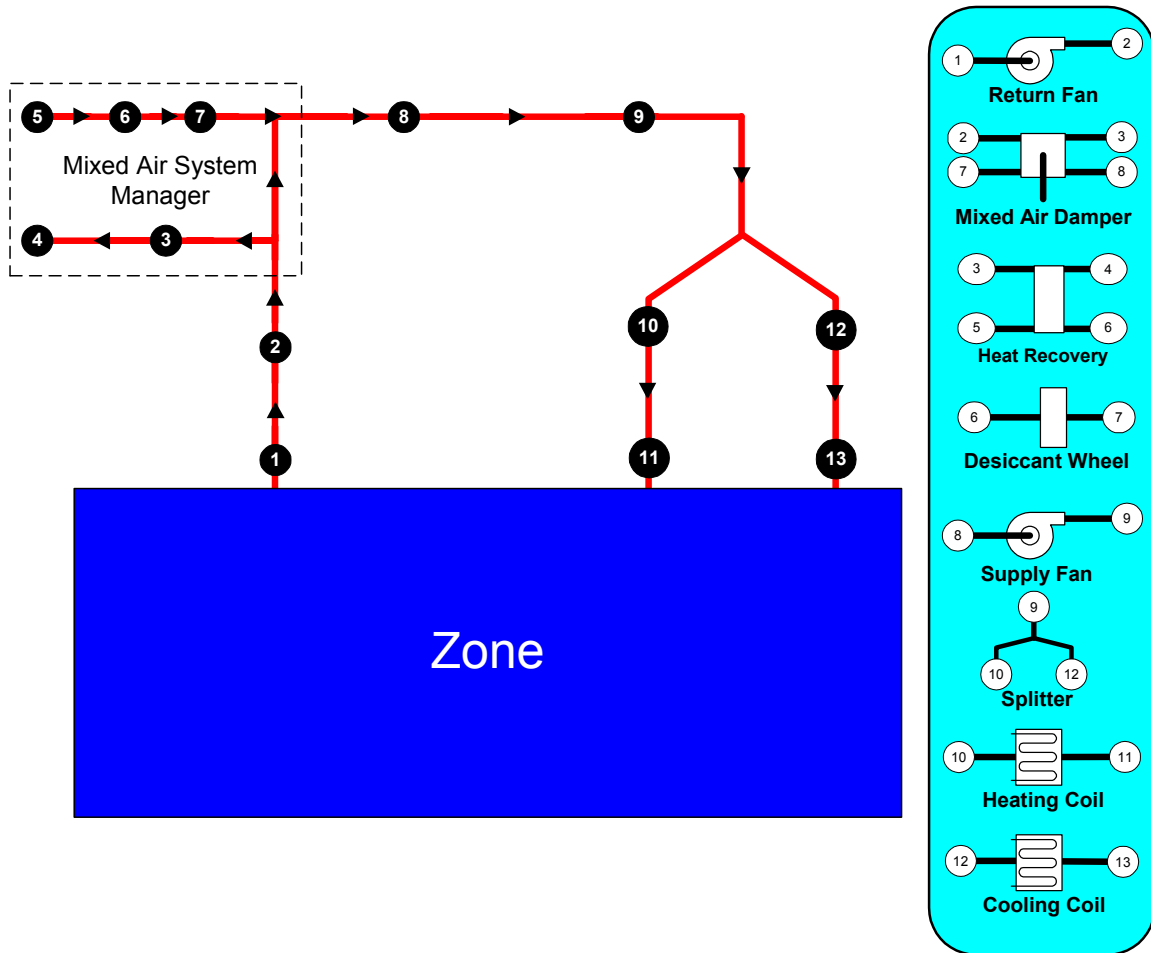

Figure 62. Example Node Diagram

So that these loops are manageable and more clearly defined both in the input and in the simulation, six different loop sections can be defined in an EnergyPlus input file. In general, these six types are in essence three pairs of loop sections that make up three distinct loops: a zone/air loop, a plant loop, and a condenser loop. The six loop section types are defined below.

Air Loop: The air loop is defined by the section of the zone/air loop that starts after the zone return streams are combined and continues on until just before any air stream(s) are branched off to individual zones. The starting point of the air loop is fairly straightforward. The ending point is slightly more complex but can be understood with some examples. For instance, in a terminal reheat system, the end of the air loop would typically be considered the node following the cooling coil. In a dual duct system, the air loop would have two ending points that would correspond to the nodes after the cooling coil and after the heating coil/humidifier. In most cases, the air loop has a single starting point and up to three ending points (for a 3 deck system).

Zone Equipment: The zone equipment section of the input file is defined as more or less the rest of the zone/air loop (outside air is handled separately as a subset of the air loop). This includes everything from where the ducts are split to serve various zones up through where the return ducts from various zones are mixed into a single return duct. Zone equipment can include dampers and reheat coils as well as zone specific conditioning systems such as thermostatic baseboard or a window air conditioner. Most control issues are typically dealt with in the zone equipment section of the simulation.

Plant Loop Demand Side: One side of the plant is where energy is “demanded” by various components that make up the air loop or zone equipment. Typically, this is the water side of equipment such as coils, baseboard, radiant heating and cooling, etc. The demand side of this loop can also include mixers, flow splitters, and a bypass.

Plant Loop Supply Side: The other side of the plant loop is where energy is “supplied” by various components. The components typically found on the supply side include pumps, boilers, chillers, purchased heating and cooling, ice storage, etc. As with the demand side, this loop can also include mixers, flow splitters, and a bypass.

Condenser Loop Demand Side: The condenser loop demand side is analogous to the plant loop demand side. In fact, much of the code and structures are similar. In the case of the condenser loop, energy is typically “demanded” by a chiller condenser. Note that coils, radiant systems, etc. could also be a part of the demand side in the case of free cooling chillers, well water condensers, ground loops, etc.

Condenser Loop Supply Side: This side of the condenser loop consists of the cooling tower, well water, etc. type components. It supplies (rejects) energy that would then be used at the chiller condensers on the other side of the loop.

The section of the input file for describing the HVAC system tends to follow this structure presented above. Both plant and condenser loops are defined with a master description and then branch off into supply and demand side details. Linkage between the two sides is done using node numbers in the master statement. The air loop and zone equipment descriptions are slightly more complex due to the wide range of potential systems that are anticipated. Note that in every section controls become a key element and must be addressed. Each of the following sections details either a loop, a portion of a loop, or controls.

Group – Node-Branch Management

Nodes, Branch Lists and **Branches** define the topography of the HVAC connections.

NodeList

For convenience, the NodeList object can be used to identify all the nodes before use. It is not required for this purpose. The advantage of listing all the nodes in this manner would allow any “node” output variables to be grouped according to user wishes.

There are other lines of input syntax that require the use of a NodeList as part of the input. These syntax items include: OutdoorAir:NodeList and the SetpointManager objects. In these two cases, the use of a NodeList statement is mandatory if there is more than one node in this particular “list”. For example, if the outside air only has a single inlet node, then the name of that node can replace the node list name in the input syntax. As a result of this mandatory specification of node lists for certain types of input, nodes can, obviously, and may be members of more than one list.

Field: Name

This alpha designation must be unique among all the Node List Names. It is used as reference in various objects (e.g. OutdoorAir:NodeList).

Field: Node <#> Name (up to 25 allowed)

Each unique Node identifier creates a Node structure with various attributes depending on the type of node. Typical values include Temperature, Mass Flow Rate, and Temperature Set Point. The alpha designators are associated with a particular node.

```

NodeList,
  \min-fields 2
  \memo This object is used in places where lists of nodes may be
  \memo needed, e.g. ZoneHVAC:EquipmentConnections field Zone Air Inlet Node or NodeList Name
A1 , \field Name
  \required-field
  \type alpha
  \reference NodeLists
A2 , \field Node 1 Name
  \required-field
  \type alpha
A3 , \field Node 2 Name
  \type alpha
A4 , \field Node 3 Name
  \type alpha
-- etc to 25 Node names per NodeList

```

Though each NodeList is limited to 25 nodes, several node lists may be entered if you choose to identify all the nodes up front. For example:

```

NodeList, Nodes1-25,
NODE_1,NODE_2,NODE_3,NODE_4,NODE_5,NODE_6,NODE_7,NODE_8,NODE_9,NODE_10,
NODE_11,NODE_12,NODE_13,NODE_14,NODE_15,NODE_16,NODE_17,NODE_18,NODE_19,NODE_20,
NODE_21,NODE_22,NODE_23,NODE_24,NODE_25;
NodeList, Nodes26-49,NODE_26,NODE_27,NODE_28,NODE_29,NODE_30,
NODE_31,NODE_32,NODE_33,NODE_34,NODE_35,NODE_36,NODE_37,NODE_38,NODE_39,NODE_40,
NODE_41,NODE_42,NODE_43,NODE_44,NODE_45,NODE_46,NODE_47,NODE_48,NODE_49;

```

Node List Outputs

A simple detail of Nodes and numbers assigned appears in the `eplusout.bnd` file:

```

! <Node>,<NodeNumber>,<Node Name>,<Node Fluid Type>,<# Times Node Referenced After Definition>
Node,1,OUTSIDE AIR INLET NODE 1,Air,2
Node,2,VAV SYS 1 INLET NODE,Air,3
Node,3,MIXED AIR NODE 1,Air,5
Node,4,MAIN COOLING COIL 1 OUTLET NODE,Air,3
Node,5,MAIN HEATING COIL 1 OUTLET NODE,Air,4
Node,6,VAV SYS 1 OUTLET NODE,Air,7...

```

In addition, properties of each node is available during the simulation:

```

HVAC,Average,System Node Temp[C]
HVAC,Average,System Node MassFlowRate[kg/s]
HVAC,Average,System Node Humidity Ratio[]
HVAC,Average,System Node Setpoint Temp[C]
HVAC,Average,System Node Setpoint Temp Hi[C]
HVAC,Average,System Node Setpoint Temp Lo[C]
HVAC,Average,System Node Setpoint Humidity Ratio[]
HVAC,Average,System Node Setpoint Humidity Ratio Min[]
HVAC,Average,System Node Setpoint Humidity Ratio Max[]
HVAC,Average,System Node Relative Humidity[%]
HVAC,Average,System Node Pressure[Pa]
HVAC,Average,System Node VolFlowRate[m3/s]
HVAC,Average,System Node Enthalpy[J/kg]
HVAC,Average,System Node Wetbulb Temp[C]
HVAC,Average,System Node Quality[]
HVAC,Average,System Node Height[m]

```

The following node variables are "advanced" and normally used for debugging unusual cases:

```

HVAC,Average,System Node TempMin[C]
HVAC,Average,System Node TempMax[C]
HVAC,Average,System Node MassFlowRateMin[kg/s]
HVAC,Average,System Node MassFlowRateMax[kg/s]
HVAC,Average,System Node MassFlowRateMinAvail[kg/s]

```

HVAC, Average, System Node MassFlowRateMaxAvail[kg/s]
 HVAC, Average, System Node MassFlowRateSetPoint[kg/s]

System Node Temp[C]

The current temperature at a system node in degrees C. For air nodes, this is the dry-bulb temperature.

System Node MassFlowRate[kg/s]

The current mass flow rate at a system node in kg/s.

System Node Humidity Ratio

The current humidity ratio at a system node in kg-water/kg-dry-air. Not applicable for liquid nodes.

System Node Setpoint Temp[C]

The current setpoint temperature at a system node in degrees C. Some controllers and equipment types sense this single setpoint.

System Node Setpoint Temp Hi[C]

The current upper setpoint temperature at a system node in degrees C. Some controllers and equipment types use dual setpoints at a single node.

System Node Setpoint Temp Lo[C]

The current lower setpoint temperature at a system node in degrees C. Some controllers and equipment types use dual setpoints at a single node.

System Node Setpoint Humidity Ratio

The current humidity ratio setpoint at a system node in kg-water/kg-dry-air. Some controllers and equipment types sense this single setpoint. Not applicable for liquid nodes.

System Node Setpoint Humidity Ratio Min[]

The current minimum desired humidity ratio at a system node in kg-water/kg-dry-air. Some controllers and equipment types use the min/max values as dual setpoints at a single node. Not applicable for liquid nodes.

System Node Setpoint Humidity Ratio Max[]

The current maximum desired humidity ratio at a system node in kg-water/kg-dry-air. Some controllers and equipment types use the min/max values as dual setpoints at a single node. Not applicable for liquid nodes.

System Node Relative Humidity [%]

The current relative humidity (calculated from the node temperature, node humidity ratio and standard barometric pressure for the location). Not applicable for liquid nodes.

System Node Pressure[Pa]

The current pressure at a system node in Pa.

System Node VolFlowRate[m3/s]

The current volume flow rate at a system node in m3/s.

System Node Enthalpy[J/kg]

The current enthalpy at a system node in J/kg.

System Node Wetbulb Temp[C]

The current wet-bulb temperature at a system node in degrees C. Not applicable for liquid nodes.

System Node Quality[]

The current system node vapor fraction/percent {0.0-1.0}.

System Node Height[]

The current system node height {m}. Only applicable to outdoor air nodes.

Advanced Node Reporting

The following system node variables are available when you request “Diagnostics, DisplayAdvancedReportVariable;”. They are normally used for debugging unusual system cases and may not be available for all systems. Also, their definitions may change based on the usage in the system.

System Node TempMin[C]**System Node TempMax[C]**

These node variables represent the min/max of loops or branches.

System Node MassFlowRateMin[kg/s]**System Node MassFlowRateMax[kg/s]**

These node variables hold the maximum possible and the minimum allowable flow rates for a particular component. As such, they represent the “hardware limit” on the flow rate for the component. By convention, these variables are stored at the component outlet node. Since components share their nodes (the outlet node of one component is the inlet node of the next component), the protocol must be strictly followed. These variables are set by each component at the beginning of the simulation and are never reset thereafter.

System Node MassFlowRateMinAvail[kg/s]**System Node MassFlowRateMaxAvail[kg/s]**

These node variables represent the *loop* maximum and minimum flow rate for the current configuration of the loop on which the component resides. All components should change the max/min available values so that they lie within the max/min flow rate range for the component. The component simulation reads the current loop min/max available flow rate from its inlet node (“Init” routine) and writes the updated min/max available flow rate to its outlet node (“Update” routine).

System Node MassFlowRateSetPoint[kg/s]**BranchList**

A branch list is intended to define the branches or portions of a particular loop that are present on an individual loop such as a plant or condenser loop. Thus, the BranchList syntax simply provides a list of branch names (see Branch syntax) that then refer to more detailed syntax in another part of the input file. The syntax for describing a list of branches is given below.

Branches in BranchList objects MUST be listed in flow order: inlet branch, then parallel branches, then outlet branch. Branches are simulated in the order listed.

```

BranchList,
\extensible:1 Just duplicate last field and \ comments (changing numbering, please)
\memo Branches MUST be listed in Flow order: Inlet branch, then parallel branches, then Outlet branch.
\memo Branches are simulated in the order listed. Branch names cannot be duplicated within a single
branch list.
  A1, \field Name
      \required-field
      \reference BranchLists
  A2, \field Branch 1 Name
      \required-field
      \type object-list
      \object-list Branches
  A3, \field Branch 2 Name
      \type object-list
      \object-list Branches
  A4, \field Branch 3 Name
      \type object-list
      \object-list Branches
<reduced for brevity>
  A100, \field Branch 49 Name
        \type object-list
        \object-list Branches
  A101; \field Branch 50 Name
        \type object-list
        \object-list Branches

```

Field: Name

A unique name to identify the branch list.

Field: Branch <#> Name

Branch name in the list. As noted above, Branches in BranchList objects MUST be listed in flow order: inlet branch, then parallel branches, then outlet branch. Branches are simulated in the order listed.

An example of this statement in an IDF is:

```

BranchList, Cooling Supply Side Branches,
  CW Pump Branch,
  Little Chiller Branch,
  Big Chiller Branch,
  Purchased Cooling Branch,
  Supply Bypass Branch,
  Cooling Supply Outlet;

```

Branch List Output

No output directly related to Branch Lists current is presented.

Branch

Branches can be considered the mid-level grouping of items in the EnergyPlus HVAC loop scheme. Components are the lowest level of information. A collection of components in series forms a branch. Every branch must have at least one component, but it may have several components in series. The **branch** defines the order that components appear on the branch. Moreover, a collection of branches and their connecting information form a loop. Therefore, a branch is a collection of components while a loop is a collection of branches. Thus, components are specified for particular HVAC loops by assigning them to branches and then connecting those branches together to form a loop. It should be noted that each component also has at least two nodes associated with it—an inlet node and an outlet node. These nodes, by default, are also part of the branch to which their components are assigned. It should be noted that each branch must have at least one component on it. A “null” branch

such as one where the first component on the loop is in reality a splitter or mixer should be defined as a single PIPE component.

Field: Name

This alpha field is the identifying name that allows the branch to be referenced by other elements such as the PlantLoop and CondenserLoop statements.

Field: Maximum Flow Rate

This field is the maximum flow rate (m³/sec) allowed on a particular branch. This number will set an absolute maximum flow rate for all components on the loop. Even if components are defined with a higher flow rate, EnergyPlus will limit the flow on this particular branch to the value entered here by the user. Currently this is used in the Air Loop and is not a required field in the Plant and Condenser Loop. The example files for the Plant and Condenser Loops leave this field blank to simplify flow input.

Field Set (Branch Specifications) – up to 11 allowed

Following the two introductory items, there are up to eleven groups of 5 repeated items: a type, a name, inlet and outlet node names, and a branch control type. All of these items refer to a particular component on the branch. The first component defined by these items will be the first component on this branch, etc. through the end of the list.

Field: Component <#> Object Type

This field is the component object type (object name). The component type refers to other elements within the input file and specifies what kind of component this is. The objects in the “Group – Plant Equipment” section are valid here when the Branch is used in Plant specifications. Fans, coils and Outside Air Systems are also valid component types for the Branch object. Pipes are also valid for this field.

Field: Component <#> Name

The component name is a reference name to distinguish between potentially multiple occurrences of a particular component type in an input file. The set of component type and component name must be unique. (You can only have 1 Boiler object with name MYBOILER).

Field: Component <#> Inlet Node Name

This field references an inlet node name that will be found in the actual component specification.

Field: Component <#> Outlet Node Name

This field references an outlet node name that will be found in the actual component specification.

Field: Component <#> Branch Control Type

The final item in each field-set is the component flow control and how this component relates to the overall flow of the branch. If the field value is **Active**, then this component will try to control the flow through this branch within the limits of the other components on the branch. An ON/OFF status of the Active component in the branch would determine if the branch is completely ON or OFF. A slightly different control type is **SeriesActive**. When one component on a branch is SeriesActive, all other components on that branch also have to be SeriesActive. This type of component tries to set the flow when it is ON, just like an Active component does. However, when this component is OFF, it will just pass the inlet mass flow rate instead of turning the branch OFF. A **Passive** component will simply take whatever amount of flow has been passed to it. The **Bypass** designation should only be used for a branch that has a single component (usually a Pipe). A bypass is used to handle excess flow

when a pump or fan cannot throttle down to send only the amount of flow requested by other components on the loop.

```
Branch,
  \extensible:5 Just duplicate last 5 fields and \ comments (changing numbering, please)
  \memo List components on the branch in simulation and connection order
  \memo Note: this should NOT include splitters or mixers which define
  \memo endpoints of branches
A1, \field Name

  \key Passive
  \key SeriesActive
  \key Bypass
  \note for ACTIVE, Component tries to set branch flow and turns off branch if the component is off
  \note for PASSIVE, Component does not try to set branch flow
  \note for SERIESACTIVE, component is active but does not turn off branch when the component is off
  \note for BYPASS, Component designates a loop bypass
-- reduced for brevity, up to 11 components allowed per branch
```

An example of this statement in an IDF is:

```
Branch,
  Air Loop Main Branch,      !- Branch Name
  1.75,                      !- Maximum Branch Flow Rate {m3/s}
  UNITARYSYSTEM:VAV:CHANGEVERBYPASS, !- Comp1 Type
  GasHeat CBVAV System,     !- Comp1 Name
  Air Loop Inlet Node,      !- Comp1 Inlet Node Name
  Air Loop Outlet Node,     !- Comp1 Outlet Node Name
  Active;                   !- Comp1 Branch Control Type
```

And a more complex one:

```

BRANCH,
  Air Loop Main Branch,      !- Branch Name
  1.3,                      !- Maximum Branch Flow Rate {m3/s}
  FAN:SIMPLE:ConstVolume,   !- Comp1 Type
  Supply Fan 1,             !- Comp1 Name
  Air Loop Inlet Node,      !- Comp1 Inlet Node Name
  Cooling Coil Air Inlet Node, !- Comp1 Outlet Node Name
  Active,                   !- Comp1 Branch Control Type
  COIL:Water:DetailedFlatCooling, !- Comp2 Type
  Detailed Cooling Coil,    !- Comp2 Name
  Cooling Coil Air Inlet Node, !- Comp2 Inlet Node Name
  Air Loop Outlet Node,     !- Comp2 Outlet Node Name
  Passive;                  !- Comp2 Branch Control Type

```

Branch Output

The components on a branch are in series and that list is in simulation and connection order. Each branch must obey the rules: the outlet for component 1 has to have the same node name as the inlet for component 2, and so forth.

Eplusout.err contains the test for “individual branch integrity”:

```

***** Testing Individual Branch Integrity
***** Testing Branch=AIR LOOP MAIN BRANCH
***** ...passed
***** Testing Branch=COOLING DEMAND INLET
***** ...passed
***** Testing Branch=COOLING COIL BRANCH
***** ...passed
***** Testing Branch=DEMAND BYPASS BRANCH
***** ...passed
***** Testing Branch=COOLING DEMAND OUTLET
***** ...passed
***** Testing Branch=COOLING SUPPLY OUTLET
***** ...passed

```

ConnectorList

A connector list is a collection of either one or two connection devices (Connector:Mixer or Connector:Splitter). Due to the definition of a loop in EnergyPlus, there is a maximum of one mixer and one splitter allowed for each loop segment. This limitation still allows a tremendous amount of flexibility to the user and can also still be solved within a reasonable amount of time and without a complex solver routine. The connection list simply allows the specification of the types and names of these devices. This allows the main loop statements to have the flexibility to have multiple lists that can have one or more item.

Field: Name

This field is an identifying name that will be referenced to main loop statements using this connector list. The name must be unique among connector list names.

Field-Set: Connection Object Type and Identifying Name (up to 2 allowed)

Depending on the loop, either one or two of the connectors will be specified. If this particular loop only has a single connector (either Connector:Mixer or Connector:Splitter), then only the first two items (type of connection and identifying name of connector) are included. If both a mixer and splitter are present, the additional type of connection and identifying name must be included. Note that the order that the items appear is inconsequential—either the Connector:Mixer or the Connector:Splitter may appear first. This will not affect the simulation.

Field: Connector 1 Object Type

This field contains the connector type **Connector:Mixer** or **Connector:Splitter**.

Field: Connector 1 Name

This field is an identifying name for the connector. It will be used by other objects in the input file.

Field: Connector 2 Object Type (optional)

This field contains the connector type **Connector:Mixer** or **Connector:Splitter**.

Field: Connector 2 Name (optional)

This field is an identifying name for the connector. It will be used by other objects in the input file.

```
ConnectorList,
  \memo only two connectors allowed per loop
  \memo if two entered, one must be Connector:Splitter and one must be Connector:Mixer
A1, \field Name
  \required-field
  \reference ConnectorLists
A2, \field Connector 1 Object Type
  \required-field
  \key Connector:Splitter
  \key Connector:Mixer
A3, \field Connector 1 Name
  \required-field
A4, \field Connector 2 Object Type
  \key Connector:Splitter
  \key Connector:Mixer
A5; \field Connector 2 Name
```

An example of this statement in an IDF is:

```
ConnectorList LIST, Cooling Supply Side Connectors,
  Connector:Splitter, CW Loop Splitter,
  Connector:Mixer, CW Loop Mixer;
```

Connector List Outputs

No output directly related to Connector Lists is currently presented.

Pipe:Adiabatic

In reality, every component is connected to its closest neighbors via a pipe or a duct. At the current time, such detail is not needed in EnergyPlus. Thus, the Pipe:Adiabatic component is currently used more as a connection device (for branches that really do not have any components associated with them) or as a bypass than anything else. As such, its input is very simple and its algorithm is equally simple. The current algorithm for a pipe is simply to pass the inlet conditions to the outlet of the pipe component. In the future, when pressure simulations and friction tabulation capabilities are added to EnergyPlus, a pipe may be a required element between components.

Field: Name

This alpha field is used as an identifying field for the pipe.

Field: Inlet Node Name

This alpha field is used as an identifying field for the pipe inlet node.

Field: Outlet Node Name

This alpha field is used as an identifying field for the pipe outlet node.

```
Pipe:Adiabatic,
  \memo Passes Inlet Node state variables to Outlet Node state variables
  A1, \field Name
      \required-field
  A2, \field Inlet Node Name
      \required-field
  A3; \field Outlet Node Name
      \required-field
```

An example of this statement in an IDF is:

```
Pipe:Adiabatic,
  Demand Side Inlet Pipe,
  CW Demand Inlet Node,
  CW Demand Entrance Pipe Outlet Node;
```

Pipe Outputs

There are no outputs directly related to Pipes.

Pipe:Adiabatic:Steam

To connect the various components in a steam system regardless of it being the condensate or the steam side of the loop steam pipe needs to be used. In reality, every component is connected to its closest neighbors via a pipe or a duct. At the current time, such detail is not needed in EnergyPlus. Thus, the Pipe:Adiabatic:Steam component is currently used more as a connection device (for branches that really do not have any components associated with them). As such, its input is very simple and its algorithm is equally simple. The current algorithm for a pipe is simply to pass the inlet conditions to the outlet of the pipe component.

Field: Name

This alpha field is used as an identifying field for the steam pipe.

Field: Inlet Node Name

This alpha field is used as an identifying field for the steam pipe inlet node.

Field: Outlet Node Name

This alpha field is used as an identifying field for the steampipe outlet node.

```
Pipe:Adiabatic:Steam,
  \memo Passes Inlet Node state variables to Outlet Node state variables
  A1, \field Name
      \required-field
  A2, \field Inlet Node Name
      \required-field
  A3; \field Outlet Node Name
      \required-field
```

An example of this statement in an IDF is:

```
Pipe:Adiabatic:Steam,
  Steam Demand 1 Steam Inlet Pipe,           !- PipeName
  Steam Demand 1 Steam Demand Inlet Node,    !- Inlet Node Name
  Steam Demand 1 Steam Demand Entrance Pipe Outlet Node; !- Outlet Node Name
```

Steam Pipe Outputs

There are no outputs directly related to Steam Pipes.

Pipe:Indoor

This object specifies inputs which are used to simulate the heat transfer from a plant loop pipe placed in a zone or when a user schedule is used to specify an environment.

Currently, Pipe Heat Transfer (Pipe:Indoor, Pipe:Outdoor, Pipe:Underground) objects are allowed on the supply side of plant loops or condenser loops. Due to simulation restrictions, pipe heat transfer objects are not allowed on the demand side of a loop.

The data definition for object is shown below.

```
Pipe:Indoor,
  \memo Pipe model with transport delay and heat transfer to the environment.
  \memo Heat transfer pipes only allowed on loop supply sides

```

Field: Name

This alpha field is used as an identifying field for the pipe.

Field: Construction Name

This alpha field references a 'wall' construction object that gives a layer-by-layer description of the pipe wall and its insulation. The construction object follows standard conventions, describing material properties for each layer beginning with the outermost insulation layer and ending with the pipe wall layer.

Field: Fluid Inlet Node Name

This alpha field contains the name of the pipe fluid inlet node.

Field: Fluid Outlet Node Name

This alpha field contains the name of the pipe fluid outlet node.

Field: Fluid Name

This alpha field contains the fluid name. This name will be validated against Fluid Names (ref: Fluid Properties section below) in the input file.

Field: Environment Type

Environment type is the environment in which the pipe is placed. It can be either **Zone** or **Schedule**. If specified as Zone, a zone name must be specified in the next field. If specified as Schedule, the Ambient Temperature Zone can be left blank, while a schedule must be specified for the temperature and air velocity.

Field: Ambient Temperature Zone Name

If **Zone** is specified as the environment type, this field is used to specify the name of the zone in which the pipe is located. The zone temperature is used to calculate the heat transfer rate from the pipe.

Field: Ambient Temperature Schedule Name

If **Schedule** is specified as the environment type, this field is used to specify the name of the temperature schedule that gives the ambient air temperature surrounding the pipe. This temperature is used as the outside boundary condition to calculate heat transfer from the pipe.

Field: Ambient Air Velocity Schedule Name

If **Schedule** is specified as the environment type, this field is used to specify the name of the velocity schedule that gives the air velocity near the pipe. This velocity is used to calculate the convection heat transfer coefficient used in the pipe heat transfer calculation.

Field: Pipe Inside Diameter

This field is used to enter the inside diameter of the pipe in units of m. Pipe inside diameter must be a positive number.

Field: Pipe Length

This field is used to enter the length of the pipe in units of m. Pipe length must be a positive number.

An example of this object in an IDF is:

```
Pipe:Indoor,
  Pipe Heat Transfer Towers,      !- name of outside panel heat exchanger
  Insulated Pipe,                !- Construction name
  Condenser Tower Outlet Node,    !- Compl Inlet Node Name

HVAC,Average, Pipe Heat Transfer Fluid Volume Flow Rate [m3/s]
```

Pipe Heat Transfer Fluid Heat Transfer rate [W]

The output provides the total amount of heat loss/gain in the fluid from pipe inlet to outlet.

Pipe Heat Transfer Environmental Heat Transfer rate [W]

The output provides the amount of heat loss/gain from pipe wall to the environment.

Pipe Heat Transfer Fluid Heat Transfer Energy [J]

Total energy fluid has lost/gained between pipe inlet and outlet. It is metered on EnergyTransfer with an end use of Pipes.

Pipe Heat Transfer Environmental Heat Transfer Energy [J]

Total energy lost from the external pipe surface.

Pipe Heat Transfer Fluid Mass Flow Rate [kg/s]

Mass flow rate of the fluid in the pipe.

Pipe Heat Transfer Fluid Inlet Temperature [C]**Pipe Heat Transfer Fluid Outlet Temperature [C]**

Temperature of fluid at entering and exiting of pipe.

Pipe Heat Transfer Fluid Volume Flow Rate [m3/s]

Fluid volumetric flow rate, (mass flow rate / density)

Pipe:Outdoor

This object specifies inputs which are used to simulate the heat transfer from a plant loop pipe placed in an outdoor environment.

Currently, Pipe Heat Transfer (Pipe:Indoor, Pipe:Outdoor, Pipe:Underground) objects are allowed on the supply side of plant loops or condenser loops. Due to simulation restrictions, pipe heat transfer objects are not allowed on the demand side of a loop.

The data definition for object is shown below.

```
Pipe:Outdoor,
  \memo Pipe model with transport delay and heat transfer to the environment.
  \memo Heat transfer pipes only allowed on loop supply sides

Field: Name

This alpha field is used as an identifying field for the pipe.

Field: Construction Name

This alpha field references a 'wall' construction object that gives a layer-by-layer description of the pipe wall and its insulation. The construction object follows standard conventions, describing material properties for each layer beginning with the outermost insulation layer and ending with the pipe wall layer.

Field: Fluid Inlet Node Name

This alpha field contains the name of the pipe fluid inlet node.

Field: Fluid Outlet Node Name

This alpha field contains the name of the pipe fluid outlet node.

Field: Fluid Name

This alpha field contains the fluid name. This name will be validated against Fluid Names (ref: Fluid Properties section below) in the input file.

Field: Ambient Temperature Outside Air Node Name

Ambient temperature outdoor air node is a node representing outdoor air with which pipe transfers heat. The node should be included in an outdoor air node list.

Field: Pipe Inside Diameter

This field is used to enter the inside diameter of the pipe in units of m. Pipe inside diameter must be a positive quantity.

Field: Pipe Length

This field is used to enter the length of the pipe in units of m. Pipe length must be a positive quantity.

An example of this statement in an IDF is:

```

Pipe:Outdoor,
  Pipe Heat Transfer Towers,      !- name of outside panel heat exchanger
  Insulated Pipe,                !- Construction name
  Condenser Tower Outlet Node,    !- Compl Inlet Node Name

HVAC,Average, Pipe Heat Transfer Fluid Volume Flow Rate [m3/s]

```

Pipe Heat Transfer Fluid Heat Transfer rate [W]

The output provides the total amount of heat loss/gain in the fluid from pipe inlet to outlet.

Pipe Heat Transfer Fluid Heat Transfer Energy [J]

Total energy fluid has lost/gained between pipe inlet and outlet. It is metered on EnergyTransfer with an end use of Pipes.

Pipe Heat Transfer Mass Flow Rate [kg/s]

Mass flow rate of the fluid in the pipe.

Pipe Heat Transfer Inlet Temperature [C]**Pipe Heat Transfer Outlet Temperature [C]**

Temperature of fluid at entering and exiting of pipe.

Pipe Heat Transfer Fluid Volume Flow Rate [m3/s]

Fluid volumetric flow rate, (mass flow rate / density)

Pipe:Underground

This object specifies inputs which are used to simulate the heat transfer from a plant loop pipe placed underground.

Currently, Pipe Heat Transfer (Pipe:Indoor, Pipe:Outdoor, Pipe:Underground) objects are allowed on the supply side of plant loops or condenser loops. Due to simulation restrictions, pipe heat transfer objects are not allowed on the demand side of a loop.

The data definition for the object is shown below.

```

Field: Name

This alpha field is used as an identifying field for the pipe.

Field: Construction Name

This alpha field references a basic construction object that gives a layer-by-layer description of the pipe wall and insulation. The construction object follows standard conventions, describing material properties for each layer beginning with the outermost layer, the insulation, if it exists, and ending with the pipe wall layer. The construction object may have either one or two layers. If only one, then the material must be the pipe wall. If two, then insulation is utilized.

Field: Fluid Inlet Node Name

This alpha field contains the name of the pipe fluid inlet node.

Field: Fluid Outlet Node Name

This alpha field contains the name of the pipe fluid outlet node.

Field: Fluid Name

This alpha field contains the fluid name. This name will be validated against a set of fluid names in the input file. Water and glycol mixtures are typically used for these cases.

Field: Sun Exposure

This alpha field allows the user to specify one of two options: NoSun or SunExposed. For SunExposed, the simulation includes diffuse and beam solar effects on the ground surface. For NoSun, no solar effects are included.

Field: Pipe Inside Diameter

This field is used to enter the inside diameter of the pipe in units of m. Pipe inside diameter must be a positive quantity.

Field: Pipe Length

This field is used to enter the length of the pipe in units of {m}. Pipe length must be a positive quantity.

Field: Soil Material Name

This references a Material object that contains the soil properties and thickness. Note that when defining the soil layer, the thickness should be the thickness of soil between the pipe wall and the ground surface.

Field: Average Soil Surface Temperature

If a GroundTemperatures:Surface object is not given in the input, this is #1 of 3 inputs that must be given directly. This represents the annual average soil temperature above the pipe. This field can be calculated in advance using the separate CalcSoilSurfTemp program.

Field: Amplitude of Soil Surface Temperature

If a GroundTemperatures:Surface object is not given in the input, this is #2 of 3 inputs that must be given directly. This represents the annual average soil temperature variation from the average temperature itself. For example, if this were represented as a sine wave, this would simply be the amplitude of the curve. This field can be calculated in advance using the separate CalcSoilSurfTemp program.

Field: Phase Constant of Soil Surface Temperature

If a GroundTemperatures:Surface object is not given in the input, this is #3 of 3 inputs that must be given directly. This represents the time elapsed from the beginning of the year to the date of minimum surface temperature. For example, if this were represented as a sine wave, this would simply be the phase shift of the curve. This field can be calculated in advance using the separate CalcSoilSurfTemp program

In order to avoid having to run the preprocessor program to generate soil temperature, the user may choose to simply input a GroundTemperatures:Surface object. This object inputs average monthly surface temperatures. These temperatures are then used within the model to develop average ground surface data. This ground surface data can then be used as part of the model boundary condition set. Without a set of surface ground temperatures, the model will require user input of the three last input fields.

An example of this object in an IDF is:

```

HVAC, Average, Pipe Heat Transfer Fluid Volume Flow Rate [m3/s]
HVAC, Average, Pipe Heat Transfer Fluid Inlet Temperature [C]
HVAC, Average, Pipe Heat Transfer Fluid Outlet Temperature [C]

```

Pipe Heat Transfer Fluid Heat Transfer rate [W]

The output provides the total amount of heat loss/gain in the fluid from pipe inlet to outlet.

Pipe Heat Transfer Fluid Heat Transfer Energy [J]

Total energy fluid has lost/gained between pipe inlet and outlet. It is metered on EnergyTransfer with an end use of Pipes.

Pipe Heat Transfer Fluid Mass Flow Rate [kg/s]

Mass flow rate of the fluid in the pipe.

Pipe Heat Transfer Fluid Volume Flow Rate [m3/s]

Fluid volumetric flow rate, (mass flow rate / density)

Pipe Heat Transfer Fluid Inlet Temperature [C]

Pipe Heat Transfer Fluid Outlet Temperature [C]

Temperature of fluid at entrance and exit of pipe.

Group – Plant-Condenser Loops

PlantLoop

The main elements of the PlantLoop syntax are described in further detail below. A map of how the input for this portion of the HVAC input fits together is provided in the following diagram.

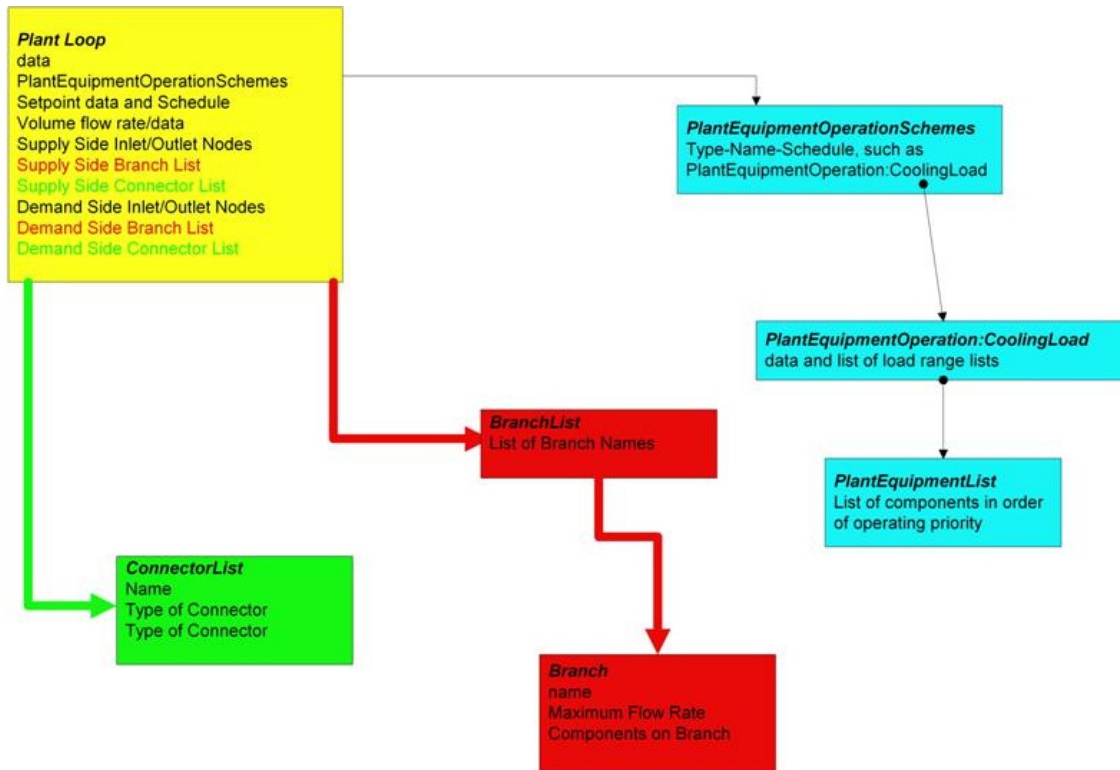

Figure 63. Plant Loop Input Syntax Map

Field: Name

This alpha field is used as an identifying field for the plant loop.

Field: Fluid Type

This alpha field must be a keyword selected from the list of available fluids for an EnergyPlus plant loop. Either “Water” or “Steam” may be used..

Field: Plant Equipment Operation Scheme Name

This alpha field is used as an identifying field for the plant operation scheme. This field ties to the PlantEquipmentOperationSchemes input structure, which must also be defined.

Field: Loop Temperature Setpoint Node Name

This alpha field is used to identify the node which the Loop Manager will access the temperature setpoint that it will try to maintain. This is typically the Plant Loop Supply Side Outlet Node so that it will not interfere with component temperature setpoints. An associated temperature setpoint manager will need to be defined.

Field: Maximum Loop Temperature

This numeric field contains the maximum allowable temperature in Celsius for this loop.

Field: Minimum Loop Temperature

This numeric field contains the minimum allowable temperature in Celsius for this loop.

Field: Maximum Loop Flow Rate

This numeric field contains the maximum loop flow rate in cubic meters per second. This parameter is also used when the user chooses to autocalculate the loop volume. See Volume of the Plant Loop below and the Engineering Manual for more details.

Field: Minimum Loop Flow Rate

This numeric field contains the minimum loop flow rate in cubic meters per second.

Field: Plant Loop Volume

Volume of the plant loop in m³. This numeric field contains the loop volume for the entire loop, ie. both the demand side the the supply side. This is used for the loop capacitance calculation which updates the loop temperature from one timestep to the next and introduces some time delay between the supply and demand sides of the loop. Loop volume (m³) could be calculated from pipe size data but this is not usually known. If zero volume is specified the demand inlet temperature is set to the supply outlet temperature at the previous system timestep. If a very large capacitance is specified unrealistic time delay may result and there may be poor response to changes in loop setpoint temperature. The loop capacitance **autocalculate** option gives reasonable values for most system sizes. This calculation is described in the Engineering Reference manual.

Field: Plant Side Inlet Node Name

This required alpha field contains the identifying name given to the Plant Side Inlet Node.

Field: Plant Side Outlet Node Name

This required alpha field contains the identifying name given to the Plant Side Outlet Node.

Field: Plant Side Branch List Name

This required alpha field contains the identifying name given to the Plant Side Branch List.

Field: Plant Side Connector List Name

This alpha field contains the identifying name given to the Plant Side Connector List.

Field: Demand Side Inlet Node Name

This required alpha field contains the identifying name given to the Demand Side Inlet Node.

Field: Demand Side Outlet Node Name

This required alpha field contains the identifying name given to the Demand Side Outlet Node.

Field: Demand Side Branch List Name

This required alpha field contains the identifying name given to the Demand Side Branch List.

Field: Demand Side Connector List Name

This alpha field contains the identifying name given to the Demand Side Connector List.

Field: Load Distribution Scheme

This alpha field contains the Load Distribution Scheme Keyword. The Load Distribution Scheme selects the algorithm used to sequence equipment operation in order to meet the plant loop demand. Currently, two schemes are functional. **Sequential** uses each piece of equipment to its maximum part load ratio and will operate the last required piece of equipment between its minimum and maximum part load ratio in order to meet the loop

demand. **Optimal** operates each piece of equipment at its optimal part load ratio and will operate the last component between its minimum and maximum part load ratio in order to meet the loop demand. **Uniform** evenly distributes the loop demand amongst all available components on the equipment list for a given load range.

The complete IDD for the Plant Loop is shown below:

Field: Availability Manager List Name

This alpha field contains the identifying name given to the System Availability Manager List.

Field: Plant Loop Demand Calculation Scheme

There are two plant loop demand calculations schemes in EnergyPlus. There is a SingleSetPoint and a DualSetPointDeadband; the SingleSetPoint is the default if this field is left blank. In the SingleSetPoint scheme the Plant Loop requires that a Set Point Manager set a single setpoint value on Node%TempSetPoint. Examples of this set Point manager would be: Set Point Manager:Scheduled, Set Point Manager:Outside Air, etc. For the DualSetPointDeadband scheme the Plant Loop requires that a Set Point Manager set the high and low setpoint values for Node%TempSetPointHi and Node%TempSetPointLo. Examples of this Set Point manager would be: SetpointManager:Scheduled:DualSetpoint.

The Plant Loop Demand Calculation Scheme determines the amount of heating or cooling necessary to bring the temperature of the Plant Loop to its setpoint(s). When this value is determined then the Load Distribution scheme explained in the previous section takes this value and distributes the load to the appropriate equipment. The demand calculation scheme determines how the load is calculated. See more information in the Engineering Document.

Field: Common Pipe Simulation

This field lets user to choose if a common pipe simulation needs to be performed or not. EnergyPlus allows user two different common pipe options. The two options are “**CommonPipe**” and “**TwoWayCommonPipe**”. In Simple “CommonPipe” case no temperature control is possible, while a “TwoWayCommonPipe” has to be used if the user wishes to control the inlet node of either primary or secondary loop. If not specified the field will default to NONE. If the field is set to NONE and the program finds a pump on the demand side it will result in a fatal error. The common pipe simulation is currently limited to simulating loop-placed pumps, i.e. pumps should be placed on the inlet branch of the loop.

```

HVAC, Average, Plant Loop System Cycle On/Off Status
--

Plant Loop Cooling Demand [W]

This is the value of the net demand required to meet the cooling setpoint of the loop. If the loop setpoint is met for the current HVAC timestep, Plant Loop Cooling Demand will equal sum of the total cooling demand from the demand side coils on the loop. It will also equal the cooling output of all chillers (or other cooling equipment) on the loop less any pump heat added to the fluid. For example, for a chilled water loop with one chiller and one pump serving one chilled water coil: Plant Loop Cooling Demand will equal the chiller evaporator heat transfer less the pump heat to fluid, and it will also equal the chilled water coil total cooling output.

If the plant loop setpoint is not met, Plant Loop Cooling Demand will equal the sum of the total cooling demand from the demand side coils on the loop plus the additional cooling required to bring the loop flow to setpoint. If the loop remains off setpoint for successive timesteps, the demand required to return to setpoint will repeat in each timestep until the loop reaches setpoint. For this reason, Plant Loop Cooling Demand should not be summed over time, because it will overstate the demand whenever the loop is off setpoint.

Plant Loop Heating Demand [W]

This is the value of the net demand required to meet the heating setpoint of the loop. If the loop setpoint is met for the current HVAC timestep, Plant Loop Heating Demand will equal sum of the total heating demand from the demand side coils on the loop. It will also equal the heating output of all boilers (or other heating equipment) on the loop plus any pump heat added to the fluid. For example, for a hot water loop with one boiler and one pump serving one hot water coil: Plant Loop Heating Demand will equal the boiler heat transfer plus the pump heat to fluid, and it will also equal the hot water coil total heating output.

If the plant loop setpoint is not met, Plant Loop Heating Demand will equal the sum of the total heating demand from the demand side coils on the loop plus the additional heating required to bring the loop flow to setpoint. If the loop remains off setpoint for successive timesteps, the demand required to return to setpoint will repeat in each timestep until the loop reaches setpoint. For this reason, Plant Loop Heating Demand should not be summed over time, because it will overstate the demand whenever the loop is off setpoint.

Plant Loop InletNode Flowrate [kg/s]

This is the value of the mass flow rate at the Inlet to Plant Loop on the supply side. There is not an associated Plant Loop outlet node flow rate since continuity must be maintained in the loop and the inlet must be the same.

Plant Loop InletNode Temperature[C]

This is the value of the temperature at the Inlet to the plant loop on the supply side.

Plant Loop OutletNode Temperature[C]

This is the value of the temperature at the outlet to the plant loop on the supply side.

Plant Loop Unmet Demand [W]

This is the value of the demand NOT provided by the plant equipment to meet the heating or cooling setpoint of the loop. The value is positive when the plant equipment cannot meet the setpoint, and the value is negative when the plant equipment provides more than enough heating or cooling to meet the setpoint. A negative value can happen when the amount of demand is smaller than the minimum capacity of the equipment using the minimum part load ratio.

Common Pipe Mass Flow Rate [Kg/s]

This output gives the magnitude of the flow through common pipe. The value is averaged over the reporting interval.

Common Pipe Flow Temperature [C]

This output gives the value of the temperature of the fluid flowing through common pipe. This value is averaged over the reporting interval.

Common Pipe Flow Direction []

This output gives the direction of flow in common pipe. The value is an integer and can be 0, 1 or 2. Since the output value is averaged over reporting interval, a non-integer value may be shown as an output when the reporting interval is not detailed. An output value of 0 means that there was no flow in common pipe. An output value of 1 means that the secondary flow is greater than primary flow, whereas a value of 2 means that primary flow is greater than secondary flow.

Primary Side Common Pipe Mass Flow Rate [Kg/s]

This report variable gives the mass flow in the primary side common pipe leg in a Two-Way common pipe simulation. Value is averaged over the reporting interval.

Secondary Side Common Pipe Mass Flow Rate [Kg/s]

This report variable gives the mass flow in the secondary side common pipe leg in a Two-Way common pipe simulation. Value is averaged over the reporting interval.

Primary Side Common Pipe Flow Direction []

This report variable gives the direction of flow in a primary side common pipe leg in a Two-Way Common Pipe Simulation. A value of zero means there was no flow in the pipe. A value of 1 means the flow was from top to bottom in EnergyPlus loop schematic. So for primary side, a value of 1 means the flow is from Primary side inlet to Primary side outlet and a value of 2 means flow is from Primary side outlet to Primary side inlet.

Secondary Side Common Pipe Flow Direction []

This report variable gives the direction of flow in a Secondary side common pipe leg in a Two-Way Common Pipe Simulation. A value of zero means there was no flow in the pipe. A value of 1 means the flow was from top to bottom in EnergyPlus loop schematic. So for Secondary side, a value of 1 means the flow is from Secondary side outlet to Secondary side inlet and a value of 2 means flow is from Secondary side inlet to Secondary side outlet. Note that this is opposite to the primary side common pipe.

Primary to Secondary Mass Flow Rate [Kg/s]

This report variable gives the mass flow from primary to secondary side in a Two-Way common pipe simulation. Value is averaged over the reporting interval.

Secondary to Primary Mass Flow Rate [Kg/s]

This report variable gives the mass flow from secondary to primary side in a Two-Way common pipe simulation. Value is averaged over the reporting interval.

Plant Loop System Cycle On/Off Status

This field is the availability status of a Plant Loop. This status flag is a result of the calculations made by the System Availability Manager(s) listed in a System Availability Manager List. When a single availability manager is used in a System Availability Manager List, this is also the availability status reported by the specific availability manager (Ref. System Availability Manager Outputs). When multiple availability managers are used in a System Availability Manager List, the loop availability status is determined by the rules associated with Plant Loops (see rules described for Group – System Availability Managers).

The control status outputs are represented using integers 0 through 2.. These integers represent *NoAction* (0), *ForceOff* (1), and *CycleOn* (2). Since the status output is averaged, the output result may not correspond to the values described here when report variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Report Variable) to view the availability status at each simulation timestep.

CondenserLoop

The map for condenser loop input is very similar to that for the plant loop. The main differences are some keywords and applicable components. This is depicted in the following diagram.

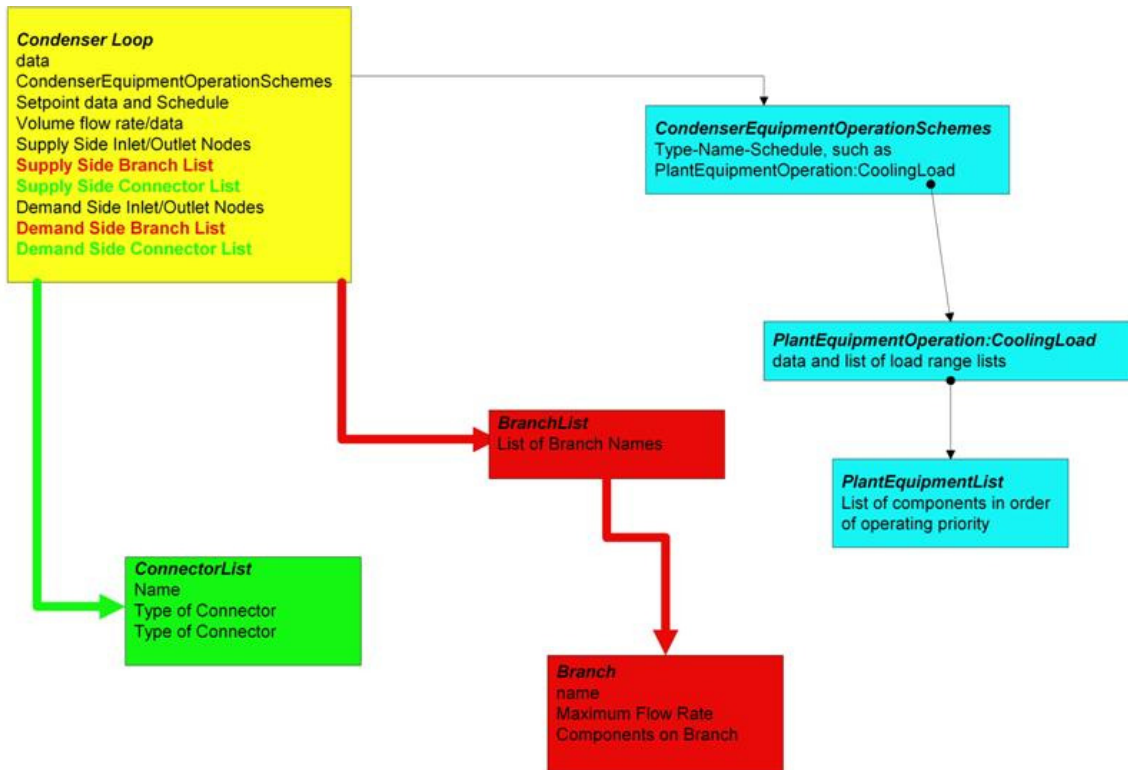

Figure 64. Condenser Loop Input Syntax Map

Field: Name

This alpha field is used as an identifying field for the condenser loop.

Field: Fluid Type

This alpha field must be a keyword selected from the list of available fluids for an EnergyPlus plant loop. Note from the IDD specification that the only currently acceptable one is “Water”.

Field: Condenser Equipment Operation Scheme Name

This alpha field is used as an identifying field for the condenser operation scheme. This field ties to the Condenser Operation Schemes input structure, which must also be defined.

Field: Condenser Loop Temperature Setpoint Node Name or Reference

This alpha field is used to identify the node which the Loop Manager will access the temperature setpoint that it will try to maintain. This is typically the Plant Loop Supply Side Outlet Node so that it will not interfere with component temperature setpoints. An associated temperature setpoint manager will need to be defined.

Another use can be to specify a reference for a condenser type ie. cooling tower or ground heat exchanger. Therefore two additional references can be specified:

Air to use the outdoor air wet-bulb as the setpoint, or

Ground to use the ground temperature as the setpoint.

These conditions vary as the outdoor wet-bulb and ground temperatures vary with the weather file or ground temperature specification.

Field: Maximum Loop Temperature

This numeric field contains the maximum allowable temperature in Celsius for this loop.

Field: Minimum Loop Temperature

This numeric field contains the minimum allowable temperature in Celsius for this loop. This minimum loop temperature is used by the cooling towers to make sure that the minimum is not violated to keep the equipment safe. The minimum is also used to trigger the minimum temperature warning and will notify the user if it gets too low.

Field: Maximum Loop Flow Rate

This numeric field contains the maximum loop flow rate in cubic meters per second.

Field: Minimum Loop Flow Rate

This numeric field contains the minimum loop flow rate in cubic meters per second.

Field: Condenser Loop Volume

Volume of the condenser loop in m³. This numeric field contains the loop volume for the entire loop, i.e., both the demand side and the supply side. This is used for the loop capacitance calculation which updates the loop temperature from one timestep to the next and introduces some time delay between the supply and demand sides of the loop. Loop volume (m³) could be calculated from pipe size data but this is not usually known. If zero volume is specified the demand inlet temperature is set to the supply outlet temperature at the previous system timestep. If a very large capacitance is specified unrealistic time delay may result and there may be poor response to changes in loop setpoint temperature. The loop capacitance **autocalculate** option gives reasonable values for most system sizes. This calculation is described in the Engineering Reference manual.

Field: Condenser Side Inlet Node Name

This required alpha field contains the identifying name given to the Condenser Side Inlet Node.

Field: Condenser Side Outlet Node Name

This required alpha field contains the identifying name given to the Condenser Side Outlet Node.

Field: Condenser Side Branch List Name

This required alpha field contains the identifying name given to the Condenser Side Branch List.

Field: Condenser Side Connector List Name

This required alpha field contains the identifying name given to the Condenser Side Connector List.

Field: Demand Side Inlet Node Name

This required alpha field contains the identifying name given to the Demand Side Inlet Node.

Field: Demand Side Outlet Nodes Name

This required alpha field contains the identifying name given to the Demand Side Outlet Node.

Field: Condenser Demand Side Branch List Name

This required alpha field contains the identifying name given to the Demand Side Branch List.

Field: Condenser Demand Side Connector List Name

This required alpha field contains the identifying name given to the Demand Side Connector List.

Field: Load Distribution Scheme

This alpha field contains the Load Distribution Scheme Keyword. The Load Distribution Scheme selects the algorithm used to sequence equipment operation in order to meet the plant loop demand. Currently, two schemes are functional. **Sequential** uses each piece of equipment to its maximum part load ratio and will operate the last required piece of equipment between its minimum and maximum part load ratio in order to meet the loop demand. **Optimal** operates each piece of equipment at its optimal part load ratio and will operate the last component between its minimum and maximum part load ratio in order to meet the loop demand.

PlantLoopConnection

This component is used to connect 2 plant loops together typically to create a Primary-Secondary plant loop system. This system is typically multiple chillers on the primary constant volume loop, with a variable volume flow system to provide flow to multiple cooling coils. This component is simulated on the Supply Side of the Secondary Loop and the results are provided to the Demand Side of the Primary Loop. Look in the Engineering Document for more explanation of the Primary-Secondary Loop Systems.

This object is OBSOLETE. Use the commonpipe options on the PlantLoop to connect two plant loops.

```

Field: Name

This alpha field contains the identifying name for the Connection Component.

Field: Primary Side Inlet Node Name

This alpha field contains the identifying name for the primary side inlet node.

Field: Primary Side Outlet Node Name

This alpha field contains the identifying name for the primary side outlet node.

Field: Secondary Side Inlet Node Name

This alpha field contains the identifying name for the secondary side inlet node.

Field: Secondary Side Outlet Node Name

This alpha field contains the identifying name for the secondary side outlet node.

Field: Primary Side Design Maximum Flow Rate

Primary Side Design Max Flow Rate is a required field that initializes the primary side of the flow component and has input units of m3/s. This field needs to be set to the same value as the associated Plant Loop.

Field: Primary Side Flow Mode

This alpha field determines if the Primary Side is either a VariableFlow or ConstantFlow Simulation. The default, if not specified, is ConstantFlow.

Field Secondary Side Design Maximum Flow Rate

Secondary Side Design Max Flow Rate is a required field that initializes the secondary side of the flow component and has input units of m3/s. This field needs to be set to the same value as the associated Plant Loop.

Field Secondary Side Flow Mode

This alpha field determines if the Secondary Side is either a VariableFlow or ConstantFlow Simulation. The default, if not specified, is VariableFlow.

An example of this statement in an IDF is:

```

PlantLoopConnection,
  PriSec Loop Connection,
    CW Pri ConnComp Inlet Node, ! Primary_Side_Inlet_Node
    CW Pri ConnComp Outlet Node, ! Primary_Side_Outlet_Node

PlantLoopConnection:Controlled

This component is used to connect 2 plant loops together typically to create a Primary-Secondary plant loop system, and includes an implied 3-way valve to control the leaving temperature on the secondary side. This component is simulated on the Supply Side of the Secondary Loop and the results are provided to the Demand Side of the Primary Loop. The primary and secondary sides may be either constant flow or variable flow. This component will take the flows set by the respective loops and mix primary supply with secondary return to supply the specified secondary setpoint temperature if possible. Look in the Engineering Document for more explanation of the Primary-Secondary Loop Systems.

This object is OBSOLETE. Use the commonpipe options on the PlantLoop to connect two plant loops.

```

PlantLoopConnection:Controlled,
  \obsolete New=>Use Transition Program or Document
  \memo This component is used to connect to Plant Loops together.

Group – Plant-Condenser Control

Operation Schemes (Plant and Condenser)

Plants and condenser loops must have some mechanism for controlling the operation of the loop and which equipment is available under what conditions. Since there may be multiple control schemes that are assigned various priorities associated with each loop, an overall operation scheme must be defined. The overall scheme consists of the object name, an identifying name that is referenced in the main plant or condenser loop statement, and a list of operation schemes. Each operation scheme must have the type of operation scheme, its identifying name, and the schedule that defines its availability. Note that the order in which the individual operation schemes appear in this list defines its priority versus the others with the same scheduled availability. The first scheme appearing in the list is given the highest priority, the second scheme has second highest priority, etc. In other words, if according to its schedule, the first operation scheme is available, then it is used by the simulation to define how the plant or condenser loop operates. If it is not available, the second operation scheme in the list is checked to see if it is available until the highest priority scheme that is also available is found. To allow for simultaneous heating and cooling, there is one configuration where multiple operation schemes are available at a given timestep. This is allowed if a user inputs both a heating range based operation and a cooling range based operation with overlapping schedules. The simulation will look at the current loop demand to determine if the cooling scheme should be used or the heating scheme. In other cases, if two schemes overlap (are available at the same time), a fatal error will be encountered.

PlantEquipmentOperationSchemes

Field: Name

This alpha field contains the identifying name given to the Plant Operation Scheme. This name is placed in the Plant Loop object to select this scheme.

Field Set: (Component Object Type, Name, Schedule) up to 8

Operation schemes are listed in "priority" order. Note that each scheme must address the entire load and/or condition ranges for the simulation. The actual one selected for use will be the first that is "Scheduled" on. That is, if control scheme 1 is not "on" and control scheme 2 is -- then control scheme 2 is selected. Only plant equipment should be listed on a Control Scheme for this item.

Field: Control Scheme <#> Object Type

This alpha field contains the keyword for the type of control scheme used. The options for plant control schemes are:

- PlantEquipmentOperation:Uncontrolled
- PlantEquipmentOperation:CoolingLoad
- PlantEquipmentOperation:HeatingLoad
- PlantEquipmentOperation:ComponentSetpoint

Field: Control Scheme <#> Name

This alpha field contains the identifying name given to the control scheme. These must be the named versions of the referenced Control Scheme (e.g.. a Uncontrolled Loop Operation with this name or a Cooling or Heating Load Range Based Operation with this name).

Field: Control Scheme <#> Schedule

This alpha field contains the schedule name for the control scheme. This schedule consists of weeks and days, with the days containing "0 or 1" for each hour of the day. This binary schedule (0 for off, 1 for on) determines if the control scheme is operating for that hour of day or not.

The IDD for the object is:

```
PlantEquipmentOperationSchemes,
  \memo Operation schemes are listed in "priority" order. Note that each scheme
  \memo must address the entire load and/or condition ranges for the simulation.
  \memo The actual one selected for use will be the first that is "Scheduled"
  \memo on. That is, if control scheme 1 is not "on" and control scheme 2
  \memo is -- then control scheme 2 is selected.
  \memo Only plant equipment should be listed on a Control Scheme for this item.
A1 , \field Name
     \required-field

     \object-list ScheduleNames
A5 , \field Control Scheme 2 Object Type
     \type choice
     \key PlantEquipmentOperation:CoolingLoad
     \key PlantEquipmentOperation:HeatingLoad
     \key PlantEquipmentOperation:Uncontrolled
     \key PlantEquipmentOperation:ComponentSetpoint
A6 , \field Control Scheme 2 Name
     \type object-list
     \object-list ControlSchemeList
A7 , \field Control Scheme 2 Schedule Name
     \type object-list
     \object-list ScheduleNames
-- reduced for brevity --
```

Examples of this statement in two different IDFs:

```

PlantEquipmentOperationSchemes,
  CW Loop Operation,      !- Name
  PlantEquipmentOperation:CoolingLoad, ! Control Scheme 1 Object Type
  Peak Operation,        !- Control Scheme 1 Name
  On Peak,               !- Control Scheme 1 Schedule
  PlantEquipmentOperation:CoolingLoad, ! Control Scheme 2 Object Type
  Off Peak Operation,    !- Control Scheme 2 Name
  Off Peak;              !- Control Scheme 2 Schedule

PlantEquipmentOperationSchemes,
  CW Loop Operation,      !- Name
  PlantEquipmentOperation:CoolingLoad, ! Control Scheme 1 Object Type
  Central Chiller Only,   !- Control Scheme 1 Name
  PlantOnSched;          !- Control Scheme 1 Schedule

```

In the first IDF example, “PlantEquipmentOperation:CoolingLoad” is the type of control scheme. “Peak Operation” and “Off Peak Operation” are the names of two different load range based controls defined separately (see below --). “On Peak” and “Off Peak” are schedules defined elsewhere in the input file.

The load range based operation scheme has two statements associated with it: a main statement that defines the ranges that individual priority settings are valid and the lists of equipment that may be used for each range.

CondenserEquipmentOperationSchemes

Field: Name

This alpha field contains the identifying name given to the Condenser Operation Scheme.

Field Set: (Component Object Type, Name, Schedule) up to 8

Operation schemes are listed in "priority" order. Note that each scheme must address the entire load and/or condition ranges for the simulation. The actual one selected for use will be the first that is "Scheduled" on. That is, if control scheme 1 is not "on" and control scheme 2 is -- then control scheme 2 is selected. Only condenser equipment should be listed on a Control Scheme for this item.

Field: Control Scheme <#> Object Type

This alpha field contains the keyword for the type of control scheme used. The options for plant control schemes are:

This alpha field contains the keyword for the type of control scheme used. Currently, the available options are:

- PlantEquipmentOperation:Uncontrolled
- PlantEquipmentOperation:CoolingLoad
- PlantEquipmentOperation:HeatingLoad
- PlantEquipmentOperation:OutdoorDryBulb
- PlantEquipmentOperation:OutdoorWetBulb
- PlantEquipmentOperation:OutdoorDewpoint
- PlantEquipmentOperation:OutdoorRelativeHumidity
- PlantEquipmentOperation:OutdoorDryBulbDifference
- PlantEquipmentOperation:OutdoorWetBulbDifference
- PlantEquipmentOperation:OutdoorDewpointDifference

The condenser operation schemes apply to the equipment on the ‘supply side’ of the condenser loop—pumps, cooling towers, ground coupled heat exchangers, etc. The keywords select the algorithm that will be used to determine which equipment is available for each timestep. The Load Schemes schemes select a user specified set of equipment for each user specified range of a particular simulation variable. Load schemes compare the demand on the condenser supply side with specified load ranges and associated equipment

lists. Outdoor schemes compare the current value of an environmental parameter with user specified ranges of that parameter.

Field: Control Scheme <#> Name

This alpha field contains the identifying name given to the control scheme.

Field: Control Scheme <#> Schedule

This alpha field contains the schedule name for the control scheme. This schedule consists of weeks and days, with the days containing "0 or 1" for each hour of the day. This binary schedule (0 for off, 1 for on) determines which control scheme is operating for a particular hour. The schedule facilitates daily or seasonal changes in control schemes to meet demand side management or energy conservation goals.

Scheduling conflicts are handled by selecting the first available scheme in order of appearance in the list.

```
CondenserEquipmentOperationSchemes,
  \memo Operation schemes are listed in "priority" order. Note that each scheme
  \memo must address the entire load and/or condition ranges for the simulation.
  \memo The actual one selected for use will be the first that is "Scheduled"
  \memo on. That is, if control scheme 1 is not "on" and control scheme 2
  \memo is -- then control scheme 2 is selected.
  \memo Only condenser equipment should be listed on a Control Scheme for this item.

  \type object-list
  \object-list ScheduleNames
-- reduced for brevity --
```

Examples of this statement in two IDFs:

```
CondenserEquipmentOperationSchemes,
  Tower Loop Operation,      !- CondenserOperationSchemeName
  PlantEquipmentOperation:CoolingLoad, Control Scheme 1 Object Type
  Year Round Tower Operation, !- Control Scheme 1 Name
  PlantOnSched;              !- Control Scheme 1 Schedule

CondenserEquipmentOperationSchemes,Tower Loop Operation,
  PlantEquipmentOperation:CoolingLoad, Peak Load Operation, AFTERNOONSCHEDULE,
  PlantEquipmentOperation:CoolingLoad, OffPeak Load Operation, MORNINGSCHEDULE,
  PlantEquipmentOperation:OutdoorWetBulb, NightOperation, NIGHTSCHEDULE;
```

Each schedule (AFTERNOONSCHEDULE, MORNINGSCHEDULE, NIGHTSCHEDULE) invokes its associated operation scheme (Peak Load Operation, OffPeak Load Operation, NightOperation). The type of operation scheme and its name references the input syntax associated with the range specification and the associated equipment.

PlantEquipmentOperation:Uncontrolled

Uncontrolled loop operation simply specifies a group of equipment that runs ‘uncontrolled’. If the loop runs, this equipment will run also, unless turned off by the loop flow resolver to maintain continuity in the fluid loop.

Field: Name

This alpha field contains the identifying name for the control scheme.

Field: Equipment List Name

This alpha field contains the identifying name for the Equipment List. This field ties to the Load Range Equipment List input structure, which must also be defined.

PlantEquipmentOperation:CoolingLoad**PlantEquipmentOperation:HeatingLoad**

The PlantEquipmentOperation:CoolingLoad and PlantEquipmentOperation:HeatingLoad objects define the different ranges and which equipment list is valid for each range. After the keyword and the identifying name, a series of data trios is expected. In each trio, there is a lower limit for the load range, an upper limit for the load range, and a name that links to an equipment availability list (the PlantEquipmentList or CondenserEquipmentList objects).

Field: Name

This alpha field contains the identifying name for the control scheme.

Field Set: (Lower limit, Upper Limit, Equip List name) up to 10**Field: Load Range <#> Lower Limit**

This numeric field contains the lower demand range (W) for the equipment list. If demand is below this value, then this equipment list will not turn on to meet the demand.

Field: Load Range <#> Upper Limit

This numeric field contains the upper demand range (W) for the equipment list. If demand is above this value, then this equipment list will not turn on to meet the demand.

Field: Priority Control <#> Equipment List Name

This alpha field contains the identifying name for the Equipment List. This field ties to the Load Range Equipment List input structure, which must also be defined.

Below is the data description for the objects.

```
PlantEquipmentOperation:CoolingLoad,
A1 ,\field Name
  \required-field
  \reference ControlSchemeList
N1 ,\field Load Range 1 Lower Limit
  \required-field
  \type real
  \units W
  \minimum 0.0
N2 ,\field Load Range 1 Upper Limit
  \required-field
  \type real
  \units W
  \minimum 0.0
A2 ,\field Priority Control 1 Equipment List Name
  \required-field
  \type object-list
  \object-list PlantAndCondenserEquipmentLists
--reduced for brevity --
```

```

PlantEquipmentOperation:HeatingLoad,
  A1 ,\field Name
      \required-field
      \reference ControlSchemeList
  N1 ,\field Load Range 1 Lower Limit
      \required-field
      \type real
      \units W
      \minimum 0.0
  N2 ,\field Load Range 1 Upper Limit
      \required-field
      \type real
      \units W
      \minimum 0.0
  A2 ,\field Priority Control 1 Equipment List Name
      \required-field
      \type object-list
      \object-list PlantAndCondenserEquipmentLists
--reduced for brevity -

```

An example of these statements in an IDF is:

```

PlantEquipmentOperation:CoolingLoad, Peak Operation,
  0,7000, Chiller Plant,
  7000,24500, Chiller Plant and Purchased,
  24500,500000, Purchased Only;

```

This particular load based operation scheme has three different ranges. “Chiller Plant”, “Chiller Plant and Purchased”, and “Purchased Only” are names which link to various PlantEquipmentList or CondenserEquipmentList objects as described below. Gaps may be left in the operation scheme, but to operate equipment over the entire range, the upper limit of a given range must equal the lower limit of the next range as shown in the example.

PlantEquipmentOperation:OutdoorDryBulb

PlantEquipmentOperation:OutdoorWetBulb

PlantEquipmentOperation:OutdoorRelativeHumidity

PlantEquipmentOperation:OutdoorDewpoint

The outdoor operation objects define the different ranges of the various environmental parameters and which equipment list is valid for each range. After the keyword and the identifying name, a series of data trios is expected. In each trio, there is a lower limit for the load range, an upper limit for the load range, and a name that links to an equipment availability list (the CondenserEquipmentList). IDD excerpts are shown below:

```

PlantEquipmentOperation:OutdoorDryBulb,

```

The fields for each of these are:

Field: Name

This alpha field contains the identifying name for the control scheme.

Field Set: (Lower limit, Upper Limit, Equip List name) up to 10

Field: <specific type> Range <#> Lower Limit

This numeric field contains the lower limit (C for temperature operations, Percent for relative humidity operations) for the equipment list. If specific value is below this value, then this equipment list will not turn on to meet the demand.

Field: <specific type> Range <#> Upper Limit

This numeric field contains the lower limit (C for temperature operations, Percent for relative humidity operations) for the equipment list. If specific value is above this value, then this equipment list will not turn on to meet the demand.

Field: Priority Control Equipment List <#> Name

This alpha field contains the identifying name for the Equipment List. This field ties to the Load Range Equipment List input structure, which must also be defined.

PlantEquipmentOperation:OutdoorDryBulbDifference

PlantEquipmentOperation:OutdoorWetBulbDifference

PlantEquipmentOperation:OutdoorDewpointDifference

The Delta Temperature based control strategies help to control any condenser equipment based on the difference between a reference node temperature and any environmental temperature. For example a cooling tower can be controlled by a strategy, which looks at the difference between the tower inlet temperature and wet-bulb temperature. A difference range is specified for each equipment list. IDD excerpts are shown below:

```
PlantEquipmentOperation:OutdoorDryBulbDifference,

--reduced for brevity--

```

Field: Name

This Alpha value contains the identifying name of the control strategy. This name appears as 'control scheme name' in Condenser Operation Scheme object.

Field: Reference Temperature Node Name

This Alpha value specifies the reference node for the operation scheme identified in the first field.

Field Set: (Lower limit, Upper limit, Switch Type, Equipment List)**Field: <specific type> Range <#> Lower Limit**

This numeric field specifies the minimum temperature difference required for the equipment specified in the equipment list to operate.

Field: <specific type> Range <#> Upper Limit

This numeric field specifies the maximum temperature difference below which the equipment specified in the equipment list is available.

Field: <specific type> Switch<#> Type.

This Alpha field specifies whether the equipment list specified for this range should be **On/Off**, for the limits set by the range. If the Switch type is OFF, all applicable equipment is turned OFF in the range. If the switch is ON, the equipment is turned ON in the range. This field allows the user to switch between equipment lists and provides additional flexibility in the control scheme.

Field: Priority Control <#> Equipment List Name

This alpha field specifies a single/group of objects, which are controlled by a particular scheme and is available for ranges specified.

PlantEquipmentOperation:ComponentSetpoint

In addition to load range based control on the plant loop, sequencing the plant components based on the outlet temperature of individual equipment is allowed. This scheme is common to many present-day Energy Management Systems sequencing. In this scheme, the sequencing is done based on the order specified in the control object described below.

Field: Name

This field specifies the name of the operation scheme.

Field Set: Equipment Object Type, Name, Demand Calculation Node, Setpoint Node, Flow Rate, Operation Type)

Field: Equipment <#> Object Type

This field specifies the type of equipment controlled by scheme.

Field: Equipment <#> Name

This field specifies the name of the controlled equipment.

Field: Demand Calculation <#> Node Name

The component demand will be calculated using the difference between the temperature at the demand node and the component set point temperature.

Field: Setpoint <#> Node Name

Each component controlled under temperature based control will have its own set point different from the loop set point. This field specifies component set point node (Generally its outlet temperatures). This node is acted upon by a SetpointManager in order to obtain the setpoint at any simulation timestep.

Field: Component <#> Flow Rate

This numeric field specifies the design flow rate for the component specified in earlier fields. This flow rate is used to calculate the component demand. The field can be set to autosize, if the user wants the program to calculate the design flow. This would generally be set to autosize when the user does not know the component flow rate and does a sizing calculation for the corresponding component.

Field: Operation<#> Type

This alpha field specifies the operation mode for the equipment. The equipment can be in any of the three modes viz. Cooling, Heating and Dual. Dual is used when the components both as heating and cooling equipment (for example heat pumps).

The IDD for the object is listed below:

```

PlantEquipmentOperation:ComponentSetpoint,
  A1, \field Name
      \required-field
      \reference ControlSchemeList
  A2, \field Equipment 1 Object Type
      \required-field
      \type alpha
  A3, \field Equipment 1 Name
      \required-field
      \type alpha
  A4, \field Demand Calculation 1 Node Name
      \required-field
      \type alpha
  A5, \field Setpoint 1 Node Name
      \required-field
      \type alpha
  N1, \field Component 1 Flow Rate
      \required-field
      \type real
      \units m3/s
      \autosizable
  A6, \field Operation 1 Type
      \required-field
      \type choice
      \key Heating
      \key Cooling
      \key Dual
<reduced for brevity>

```

And, as an example in an IDF:

```

PlantEquipmentOperationSchemes,

```

PlantEquipmentList

CondenserEquipmentList

The **PlantEquipmentList** and **CondenserEquipmentList** specify available plant and condenser loop equipment respectively for any loop operation scheme. Each statement contains the object name, an identifying name (which links the definition back to one of the operation scheme statements and a variable length of data pairs. These pairs refer to a plant equipment type and an identifying name. The type in this list of pairs must correspond to a valid plant object as described in the next subsection.

Field: Name

This alpha field contains the identifying name for the Equipment List.

Field Set: (Object Type, Name) up to 10

Remember the order of equipment on this list determines operation priority. Equipment on the list first will try to meet demand first. These fields tie to the Equipment Definition input structure, which must also be defined.

Field: Equipment <#> Object Type

This alpha field contains the keyword for the type of equipment in operation. Example: (Chiller:Electric, DistrictCooling). The full list of allowable plant equipment is again found as the objects in the section (Group – Plant Equipment).

Field: Equipment <#> Name

This alpha field contains the identifying name for the equipment in operation. This distinguishes between two different pieces of equipment of the same type.

```
PlantEquipmentList,
  \memo List plant equipment in order of operating priority, 1st in list will be used 1st, etc
  \memo Use only plant equipment in this list.
A1 , \field Name
      \required-field

A3 , \field Equipment 1 Name
      \required-field
--reduced for brevity --

CondenserEquipmentList,
  \memo List condenser equipment in order of operating priority, 1st in list will be used 1st, etc
  \memo Use only condenser equipment in this list.
A1 , \field Name
      \required-field
      \reference PlantAndCondenserEquipmentLists
      \reference CondenserEquipmentLists
A2 , \field Equipment 1 Object Type
      \required-field
A3 , \field Equipment 1 Name
      \required-field
--reduced for brevity --
```

An example of this statement in an IDF is:

```
PlantEquipmentList, Chiller Plant and Purchased,
  Chiller:Electric, Big Chiller,
  DistrictCooling, Purchased Cooling;
```

Note that this list is the middle range defined in the PlantEquipmentOperation:CoolingLoad statement named “Peak Operation” above. This defines the equipment available when the load encountered by the plant (chiller water demand, for example) is between 7000 W and 24500 W. EnergyPlus will run the “Big Chiller” first up to its capacity and then attempt to meet the remaining load (while in that range) with the next piece of equipment (in this case, “Purchased:Cooling”) in the list.

Group – Plant Equipment**Equipment Types**

In each **PlantEquipmentList** described using the above syntax, various equipment types and names must be given. Each type-name pair must then have a corresponding equipment definition. This subsection lists the various equipment types that are available and examples from an IDF. Where appropriate, notes and comments on the input structure are provided.

Generic Chiller Outputs

Many output variable names are common across all chiller types. These generic chiller output names all begin with the word "Chiller". Certain chiller types have additional output variables which are specific to that type of chiller. Specific chiller output names begin with the chiller type, for example, "Gas Absorption Chiller Heating Energy [J]." Chiller energy use is added to the appropriate plant-level meters as a cooling end-use.

```
HVAC,Average,Chiller Electric Power [W]
HVAC,Sum,Chiller Electric Consumption [J]
Zone,Meter,Electricity:Plant [J]
Zone,Meter,Cooling:Electricity [J]

HVAC,Average,Chiller Evap Heat Trans Rate [W]
HVAC,Sum,Chiller Evap Heat Trans [J]

```

For steam absorption chillers:

HVAC,Average,Chiller Steam Consumption Rate [W]
 HVAC,Sum,Chiller Steam Consumption [J]
 Zone,Meter,Steam:Plant [J]
 Zone,Meter,Cooling:Steam [J]
 HVAC,Average,Chiller Steam Mass Flow Rate [kg/s]

For hot water absorption chillers:

HVAC,Average,Chiller Hot Water Consumption Rate [W]
 HVAC,Sum,Chiller Hot Water Consumption [J]
 Zone,Meter,Steam:Plant [J]
 Zone,Meter,Cooling:EnergyTransfer [J]
 HVAC,Average,Chiller Hot Water Mass Flow Rate [kg/s]

The following output is applicable only for indirect absorption chillers

HVAC,Average,Chiller Part-Load Ratio
 HVAC,Average,Chiller Cycling Fraction

HVAC,Average,Chiller Propane Consumption Rate [W]
 HVAC,Sum,Chiller Propane Consumption [J]
 Zone,Meter,Propane:Plant [J]
 Zone,Meter,Cooling:Propane [J]
 HVAC,Average,Chiller Propane Mass Flow Rate [kg/s]

HVAC,Average,Chiller Diesel Consumption Rate [W]
 HVAC,Sum,Chiller Diesel Consumption [J]
 Zone,Meter,Diesel:Plant [J]
 Zone,Meter,Cooling:Diesel [J]
 HVAC,Average,Chiller Diesel Mass Flow Rate [kg/s]

HVAC,Average,Chiller Gasoline Consumption Rate [W]
 HVAC,Sum,Chiller Gasoline Consumption [J]
 Zone,Meter,Gasoline:Plant [J]
 Zone,Meter,Cooling:Gasoline [J]
 HVAC,Average,Chiller Gasoline Mass Flow Rate [kg/s]

HVAC,Average,Chiller FuelOil#1 Consumption Rate [W]
 HVAC,Sum,Chiller FuelOil#1 Consumption [J]
 Zone,Meter,FuelOil#1:Plant [J]
 Zone,Meter,Cooling:FuelOil#1 [J]
 HVAC,Average,Chiller FuelOil#1 Mass Flow Rate [kg/s]

HVAC,Average,Chiller FuelOil#2 Consumption Rate [W]
 HVAC,Sum,Chiller FuelOil#2 Consumption [J]
 Zone,Meter,FuelOil#2:Plant [J]
 Zone,Meter,Cooling:FuelOil#2 [J]
 HVAC,Average,Chiller FuelOil#2 Mass Flow Rate [kg/s]

Chiller Electric Power [W]***Chiller Electric Consumption [J]***

These outputs are the electric power input to the chiller. In the case of steam or fuel-powered chillers, this represents the internal chiller pumps and other electric power consumption. Consumption is metered on Cooling:Electricity, Electricity:Plant, and Electricity:Facility.

Chiller Evap Heat Trans Rate [W]***Chiller Evap Heat Trans [J]***

These outputs are the evaporator heat transfer which is the cooling delivered by the chiller. Chiller Evap Heat Trans is metered on Chillers:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

Chiller Evap Water Inlet Temp [C]**Chiller Evap Water Outlet Temp [C]****Chiller Evap Water Mass Flow Rate [kg/s]**

These outputs are the evaporator (chilled water) inlet and outlet temperatures and flow rate.

Chiller COP [W/W]

This output is the coefficient of performance for the chiller during cooling operation. It is calculated as the evaporator heat transfer rate (Chiller Evap Heat Trans Rate) divided by the “fuel” consumption rate by the chiller. For the constant COP and electric chillers, the “fuel” is electricity so the divisor is Chiller Electric Power [W]. For the absorption chiller, the “fuel” is steam so the divisor is Steam Consumption Rate [W].

For the engine driven chiller and combustion turbine chiller, the output variable is renamed as Chiller Fuel COP to clarify that the primary energy input to the chiller is a gaseous or liquid fuel (natural gas, diesel, gasoline, etc.). The divisor is the appropriate fuel consumption rate (Chiller [fuel type] Consumption Rate).

For the direct fired absorption chiller, this variable is renamed as Direct Fired Absorption Chiller Cooling Fuel COP and the divisor is Direct Fired Absorption Chiller Cooling Gas Consumption Rate.

Note that this variable is reported as zero when the chiller is not operating. When reported for frequencies longer than "detailed" (such as timestep, hourly, daily, monthly or environment), this output will only be meaningful when the chiller is operating for the entire reporting period. To determine an average COP for a longer time period, compute the COP based on total evaporator heat transfer divided by total electric or fuel input over the desired period.

Chiller Part-Load Ratio

This output is the operating part-load ratio of the indirect absorption chiller. This output may fall below the minimum part-load ratio specified in the input. For this case, the Chiller Cycling Fraction is used to further define the performance of the indirect absorption chiller.

Chiller Cycling Fraction

This output is the fraction of the timestep the indirect absorption chiller operates. When the chiller operates above the minimum part-load ratio, a chiller cycling fraction of 1 is reported. When the chiller operates below the minimum part-load ratio, the chiller cycling fraction reports the fraction of the timestep the indirect absorption chiller operates.

Chiller Cond Heat Trans Rate [W]**Chiller Cond Heat Trans [J]**

These outputs are the condenser heat transfer which is the heat rejected from the chiller to either a condenser water loop or through an air-cooled condenser. Chiller Cond Heat Trans is metered on HeatRejection:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

Chiller Cond Air Inlet Temp [C]

This output is the condenser (heat rejection) inlet temperature for air-cooled or evap-cooled chillers. For an air-cooled chiller, this output would be the dry-bulb temperature of the air entering the condenser coil. For an evap-cooled chiller, this output would be the wet-bulb temperature of the air entering the evaporatively-cooled condenser coil.

Chiller Cond Water Inlet Temp [C]**Chiller Cond Water Outlet Temp [C]****Chiller Cond Water Mass Flow Rate [kg/s]**

These outputs are the condenser (heat rejection) inlet and outlet temperatures and flow rate for water-cooled chillers.

Chiller Shaft Power [W]**Chiller Shaft Energy [J]**

For engine-driven and turbine-driven chillers, these outputs are the shaft power produced by the prime mover and transferred to the chiller compressor.

Chiller Lube Heat Recovery Rate [W]**Chiller Lube Heat Recovery [J]****Chiller Jacket Heat Recovery Rate [W]****Chiller Jacket Heat Recovery [J]****Chiller Exhaust Heat Recovery Rate [W]****Chiller Exhaust Heat Recovery [J]****Chiller Total Heat Recovery Rate [W]****Chiller Total Heat Recovery [J]**

For chillers with heat recovery, such as engine-driven chillers, these outputs are the components of recoverable energy available. For a given chiller type, one or more of the following components may be applicable: Lube (engine lubricant), Jacket (engine coolant), Exhaust (engine exhaust), and Total. Chiller Lube Heat Recovery, Chiller Jacket Heat Recovery, and Chiller Exhaust Heat Recovery are metered on HeatRecovery:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

Chiller Exhaust Stack Temp [C]

This is the exhaust temperature leaving an engine chiller.

Chiller Heat Recovery Inlet Temp [C]**Chiller Heat Recovery Outlet Temp [C]****Chiller Heat Recovery Mass Flow Rate [kg/s]**

These outputs are the heat recovery inlet and outlet temperatures and flow rate for chillers with heat recovery such as engine-driven and gas turbine chillers.

Chiller <FuelType> Consumption Rate [W]**Chiller <FuelType> Consumption [J]****Chiller <FuelType> Mass Flow Rate [kg/s]****Chiller Gas Mass Consumption [kg] (Gas Turbine Chiller only)**

These outputs are the steam or fuel input for steam or fuel-fired chillers. Valid fuel types depend on the type of chiller. <FuelType> may be one of: Gas (natural gas), Steam, Propane, Diesel, Gasoline, FuelOil#1, and FuelOil#2. Consumption is metered on Cooling:<FuelType>, <FuelType>:Plant, and <FuelType>:Facility.

Chiller:Absorption**Field: Name**

This alpha field contains the identifying name for the absorption chiller.

Field: Nominal Capacity

This numeric field contains the nominal cooling capability of the chiller in Watts.

Field: Nominal Pumping Power

This numeric field contains the nominal pumping power of the absorber in Watts.

Field: Chilled Water Inlet Node Name

This required alpha field contains the identifying name for the absorption chiller plant side inlet node.

Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the absorption chiller plant side outlet node.

Field: Condenser Inlet Node Name

This required alpha field contains the identifying name for the absorption chiller condenser side inlet node.

Field: Condenser Outlet Node Name

This required alpha field contains the identifying name given to the Heat Recovery Loop Component Outlet Node.

Field: Minimum Part Load Ratio

This numeric field contains the absorption chiller's minimum part load ratio. The expected range is between 0 and 1. The minimum part load is not the load where the machine shuts off, but where the amount of power remains constant to produce smaller loads than this fraction.

Field: Maximum Part Load Ratio

This numeric field contains the absorption chiller's maximum part load ratio. This value may exceed 1, but the normal range is between 0 and 1.1.

Field: Optimum Part Load Ratio

This numeric field contains the absorption chiller's optimum part load ratio. This is the part load ratio at which the chiller performs at its maximum COP.

Field: Design Condenser Inlet Temperature

This numeric field contains the absorption chiller's condenser inlet design temperature in Celsius.

Field: Design Chilled Water Flow Rate

For variable volume chiller this is the maximum flow and for constant flow chiller this is the design flow rate. The units are in cubic meters per second.

Field: Design Condenser Water Flow Rate

This numeric field contains the absorption chiller's design condenser water flow rate in cubic meters per second.

Generator Heat Input Part Load Ratio Curve

The Generator Heat Input Part Load Ratio Curve is a quadratic equation that determines the Ratio of the generator load on the absorber to the demand on the chiller. The defining equation is:

$$\text{SteamInputRatio} = \frac{C1}{PLR} + C2 + C3 * PLR$$

The following three fields contain the coefficients for the equation.

Field: Coefficient 1 of the Steam Use Part Load Ratio Curve

C1 in the Generator Heat Input Part Load Ratio Curve. This value is obtained by fitting manufacturers' performance data to the curve.

Field: Coefficient 2 of the Steam Use Part Load Ratio Curve

C2 in the Generator Heat Input Part Load Ratio Curve. This value is obtained by fitting manufacturers' performance data to the curve.

Field: Coefficient 3 of the Steam Use Part Load Ratio Curve

C3 in the Generator Heat Input Part Load Ratio Curve. This value is obtained by fitting manufacturers' performance data to the curve.

Pump Electric Use Part Load Ratio Curve

The Pump Electric Use Part Load Ratio Curve is a quadratic equation that determines the Ratio of the actual absorber pumping power to the nominal pumping power. The defining equation is:

$$\text{ElectricInputRatio} = C1 + C2 * PLR + C3 * PLR^2$$

The following three fields contain the coefficients for the equation.

Field: Coefficient 1 of the Pump Electric Use Part Load Ratio Curve

C1 in the Pump Electric Use Part Load Ratio Curve. This value is obtained by fitting manufacturers' performance data to the curve.

Field: Coefficient 2 of the Pump Electric Use Part Load Ratio Curve

C2 in the Pump Electric Use Part Load Ratio Curve. This value is obtained by fitting manufacturers' performance data to the curve.

Field: Coefficient 3 of the Pump Electric Use Part Load Ratio Curve

C3 in the Pump Electric Use Part Load Ratio Curve. This value is obtained by fitting manufacturers' performance data to the curve.

Field: Chilled Water Outlet Temperature Lower Limit

This numeric field contains the lower limit for the evaporator outlet temperature. This temperature acts as a cut off for heat transfer in the evaporator, so that the fluid doesn't get too cold.

Field: Generator Inlet Node Name

This alpha field contains the identifying name given to the Generator Inlet Node. A steam or hot water loop is not required to simulate an absorption chiller. If a steam/hot water loop is used, enter the name of the generator inlet node.

Field: Generator Outlet Node Name

This alpha field contains the identifying name given to the Generator Outlet Node. A steam or hot water loop is not required to simulate an absorption chiller. If a steam/hot water loop is used, enter the name of the generator outlet node.

Field: Chiller Flow Mode

This alpha field determines if the Chiller is either a VariableFlow or ConstantFlow Chiller Simulation. The default, if not specified, is VariableFlow.

Field: Generator Fluid Type

This choice field specifies the type of fluid used to heat the generator solution. The valid choices are **HotWater** or **Steam**. This field should be specified as Steam or left blank if the generator inlet/outlet nodes are not specified.

Field: Design Generator Fluid Flow Rate

This numeric field contains the absorption chiller's design condenser fluid flow rate in cubic meters per second.

Field: Degree of Subcooling in Steam Generator

Ideally, the steam trap located at the outlet of the generator should remove all the condensate immediately, however, there is a delay in this process in actual systems which causes the condensate to SubCool by a certain amount before leaving the generator. This amount of subcooling is included in the heat transferred to the solution in the generator. The minimum value is 0° Celsius and default is 5° Celsius. This field is not used when the generator inlet/outlet node are not specified or the generator is connected to a hot water loop.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Capacity, Nominal Pumping Power, Design Chilled Water Flow Rate, Design Condenser Water Flow Rate and Design Generator Fluid Flow Rate. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

These chiller output variables are defined above under "Generic Chiller Outputs."

Chiller:Absorption:Indirect

The Chiller:Absorption:Indirect object is an enhanced version of the absorption chiller model found in the Building Loads and System Thermodynamics (BLAST) program. This enhanced model is nearly identical to the existing absorption chiller model (Ref. Chiller:Absorption) with the exceptions that: 1) the enhanced indirect absorption chiller model provides more flexible performance curves and 2) chiller performance now includes the impact of varying evaporator, condenser, and generator temperatures. Since these absorption chiller models are nearly identical (i.e., the performance curves of the enhanced model can be manipulated to produce similar results to the previous model), it is quite probable that the Chiller:Absorption model will be deprecated in a future release of EnergyPlus.

Field: Name

This required alpha field contains the identifying name for the indirect absorption chiller.

Field: Nominal Capacity

This required numeric field contains the nominal cooling capability of the chiller in Watts. This field must be greater than 0 and is autosizable.

Field: Nominal Pumping Power

This required numeric field contains the nominal pumping power of the chiller in Watts. The minimum value for this field is 0 and is autosizable.

Field: Chilled Water Inlet Node Name

This required alpha field contains the identifying name for the chiller chilled water inlet node.

Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the chiller chilled water outlet node.

Field: Condenser Inlet Node Name

This required alpha field contains the identifying name for the chiller condenser inlet node.

Field: Condenser Outlet Node Name

This required alpha field contains the identifying name given to the chiller outlet node.

Field: Minimum Part Load Ratio

This numeric field contains the chiller's minimum part-load ratio. The expected range is between 0 and 1. The minimum part load is not the load where the machine shuts off, but where the amount of power remains constant to produce smaller loads than this fraction.

Field: Maximum Part Load Ratio

This numeric field contains the chiller's maximum part-load ratio. This value may exceed 1, but the normal range is between 0 and 1.1.

Field: Optimum Part Load Ratio

This numeric field contains the chiller's optimum part-load ratio. This is the part-load ratio at which the chiller performs at its maximum COP.

Field: Design Condenser Inlet Temperature

This numeric field contains the chiller's condenser inlet design temperature in Celsius. The default value for this field is 30° C and is only used when the Design Chilled Water Flow Rate is autosized.

Field: Condenser Inlet Temperature Lower Limit

This numeric field contains the chiller's lower limit for the condenser entering water temperature in Celsius. The default value for this field is 15° C. If this limit is exceeded, a warning message will report the incident. No correction to chiller capacity is made for low condenser entering water temperatures.

Field: Chilled Water Outlet Temperature Lower Limit

This numeric field contains the chiller's lower limit for the evaporator leaving water temperature in Celsius. The default value for this field is 5° C. If this limit is exceeded, a warning message will report the incident. No correction to chiller capacity is made for low evaporator leaving water temperatures.

Field: Design Chilled Water Flow Rate

This numeric input specifies the design evaporator volumetric flow rate in cubic meters per second. The value specified must be greater than 0 or this field is autosizable. For variable volume chiller this is the maximum flow and for constant flow chiller this is the design flow rate.

Field: Design Condenser Water Flow Rate

This numeric field specifies the chiller's design condenser water flow rate in cubic meters per second. The value specified must be greater than 0 or this field is autosizable.

Field: Chiller Flow Mode

This choice field determines if the chiller is a VariableFlow or ConstantFlow chiller. The default value is VariableFlow.

Field: Generator Heat Input Function of Part Load Ratio Curve Name

This required alpha field specifies the name of the curve used to determine the heat input to the chiller. The curve is a quadratic or cubic curve which characterizes the heat input as a function of chiller part-load ratio. The curve output is multiplied by the chiller's nominal capacity and operating part-load ratio or minimum part-load ratio, whichever is greater, to determine the amount of heat input required for the given operating conditions.

Field: Pump Electric Input Function of Part Load Ratio Curve Name

This alpha field specifies the name of the curve used to determine the pump electrical input to the chiller. The curve is a quadratic or cubic curve which characterizes the pump electrical power as a function of chiller part-load ratio. The curve output is multiplied by the chiller's nominal pumping power and operating part-load ratio or minimum part-load ratio, whichever is greater, to determine the amount of pumping power required for the given operating conditions.

Field: Generator Inlet Node Name

This alpha field contains the identifying name given to the Generator Inlet Node. A steam or hot water loop is not required to simulate an indirect absorption chiller. If a steam/hot water loop is used, enter the name of the generator inlet node.

Field: Generator Outlet Node Name

This alpha field contains the identifying name given to the Generator Outlet Node. A steam or hot water loop is not required to simulate an indirect absorption chiller. If a steam/hot water loop is used, enter the name of the generator outlet node.

Field: Capacity Correction Function of Condenser Temperature Curve Name

This alpha field specifies the name of a quadratic or cubic curve which correlates the chiller's evaporator capacity as a function of condenser entering water temperature. This curve is used to correct nominal capacity at off-design condensing temperatures.

Field: Capacity Correction Function of Chilled Water Temperature Curve Name

This alpha field specifies the name of a quadratic or cubic curve which correlates the chiller's evaporator capacity as a function of evaporator leaving water temperature. This curve is used to correct nominal capacity at off-design evaporator temperatures.

Field: Capacity Correction Function of Generator Temperature Curve Name

This alpha field specifies the name of a quadratic or cubic curve which correlates the chiller's evaporator capacity as a function of generator entering water temperature. This curve is used to correct nominal capacity at off-design evaporator temperatures and is only used when the Generator Fluid Type is specified as Hot Water.

Field: Generator Heat Input Correction Function of Condenser Temperature Curve Name

This alpha field specifies the name of a quadratic or cubic curve which correlates the chiller's heat input as a function of condenser entering water temperature. This curve is used to correct generator heat input at off-design condensing temperatures.

Field: Generator Heat Input Correction Function of Chilled Water Temperature Curve Name

This alpha field specifies the name of a quadratic or cubic curve which correlates the chiller's heat input as a function of evaporator leaving water temperature. This curve is used to correct generator heat input at off-design evaporator temperatures.

Field: Generator Heat Source Type

This choice field specifies the type of fluid used to heat the generator solution. The valid choices are **HotWater** or **Steam**. This input is used to identify the method used to calculate the generator mass flow rate. This field is not used if the generator inlet/outlet nodes are not specified. The default value is Steam.

Field: Design Generator Fluid Flow Rate

This numeric field specifies the chiller's design generator *fluid* flow rate in cubic meters per second. The value specified must be greater than 0 or this field is autosizable. For variable flow chillers this is the maximum generator flow rate, for constant flow chillers this is the flow rate.

Field: Temperature Lower Limit Generator Inlet

This numeric field specifies the lower limit of the generator's entering water temperature. This field is not used if the Generator Fluid Type is specified as steam.

Field: Degree of Subcooling in Steam Generator

Ideally the steam trap located at the outlet of generator should remove all the condensate immediately, however there is a delay in this process in actual systems which causes the condensate to SubCool by a certain degree before leaving the generator. This amount of subcooling is included in the heat transferred to the solution in the generator. The minimum value is 0° Celsius, the maximum value is 20° Celsius, and the default is 1° Celsius.

Field: Degree of Subcooling in Steam Condensate Loop

This essentially represents the heat loss to the atmosphere due to uninsulated condensate return piping to the boiler. Condensate return piping operates at atmospheric pressure and is not insulated. The condensate sub cools to certain degree before it is pumped back to the boiler. The minimum value is 0° Celsius and the default is 0° Celsius.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Capacity, Nominal Pumping Power, Design Chilled Water Flow Rate, Design Condenser Water Flow Rate and Design Generator Fluid Flow Rate. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

These chiller output variables are defined above under "Generic Chiller Outputs."

Chiller:ConstantCOP

This chiller model is based on a simple, constant COP simulation of the chiller. In this case, performance does not vary with chilled water temperature or condenser conditions.

Such a model is useful when the user does not have access to detailed performance data.

```

Field: Name

This alpha field contains the identifying name for the constant COP chiller.

Field: Nominal Capacity

This numeric field contains the nominal cooling capability of the chiller in Watts.

Field: Nominal COP

This numeric field contains the Chiller's coefficient of performance.

Field: Design Chilled Water Flow Rate

For variable volume chiller this is the maximum flow and for constant flow chiller this is the design flow rate. The units are in cubic meters per second.

Field: Design Condenser Water Flow Rate

This numeric field contains the electric chiller's design condenser water flow rate in cubic meters per second.

Field: Chilled Water Inlet Node Name

This required alpha field contains the identifying name for the constant COP chiller plant side inlet node.

Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the constant COP chiller plant side outlet node.

Field: Condenser Inlet Node Name

This alpha field contains the identifying name for the constant COP chiller condenser side inlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and a condenser inlet node name is specified here, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates an outdoor air node and the air temperature information on this node is taken directly from the weather file (no node height adjustment).

Field: Condenser Outlet Node Name

This alpha field contains the identifying name for the constant COP chiller condenser side outlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates a condenser side outlet air node.

Field: Condenser Type

This alpha field determines what type of condenser will be modeled with this chiller. The 3 type of condensers are AirCooled, WaterCooled, and EvaporativelyCooled with the default being AirCooled if not specified. AirCooled and EvaporativelyCooled do not require a CondenserLoop to be specified, whereas the WaterCooled option requires the full specification of the CondenserLoop and its associated equipment.

Field: Chiller Flow Mode

This alpha field determines if the Chiller is either a VariableFlow or ConstantFlow Chiller Simulation. The default, if not specified, is VariableFlow.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Capacity, Design Chilled Water Flow Rate and Design Condenser Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

An example of this statement in an IDF is:

```

Chiller:ConstantCOP, Little Chiller,
    25000,          ! Nominal Capacity [W]
    2.5,           ! COP
    0.0011,        ! Design Chilled Water Flow Rate [m3/s]
    0.0011,        ! Design Condenser Water Flow Rate [m3/s]
    Little Chiller Inlet Node, Little Chiller Outlet Node,

```

These chiller output variables are defined above under "Generic Chiller Outputs."

Chiller:Electric

This chiller model is the empirical model from the Building Loads and System Thermodynamics (BLAST) program. Capacity, power, and full load are each defined by a set of performance curves (quadratics). Chiller performance curves are generated by fitting catalog data to third order polynomial equations. The nominal inputs and curves described below are combined as follows to calculate the chiller power:

$$\text{Power} = \text{FracFullLoadPower} \cdot \text{FullLoadPowerRat} \cdot \text{AvailToNominalCapacityRatio} \cdot \frac{\text{NominalCapacity}}{\text{COP}}$$

where:

NominalCapacity = Nominal Capacity field

COP = COP field

AvailToNominalCapacityRatio = the result of the Capacity Ratio Curve

FullLoadPowerRat = the result of the Power Ratio Curve

FracFullLoadPower = the result of the Full Load Ratio Curve

Field: Name

This alpha field contains the identifying name for the electric chiller.

Field: Condenser Type

This alpha field determines what type of condenser will be modeled with this chiller. The 3 type of condensers are AirCooled, WaterCooled, and EvaporativelyCooled with the default being AirCooled if not specified. AirCooled and EvaporativelyCooled do not require a Condenser Loop to be specified, where the WaterCooled option requires the full specification of the Condenser Loop and its associated equipment.

Field: Nominal Capacity

This numeric field contains the nominal cooling capability of the chiller in Watts.

Field: Nominal COP

This numeric field contains the chiller's coefficient of performance. For a water-cooled chiller, this number does not include energy use due to condenser pumps and/or fans. For an air-cooled or evap-cooled chiller, this number includes condenser fan power.

Field: Chilled Water Inlet Node Name

This required alpha field contains the identifying name for the electric chiller plant side inlet node.

Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the electric chiller plant side outlet node.

Field: Condenser Inlet Node Name

This alpha field contains the identifying name for the electric chiller condenser side inlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and a condenser inlet node name is specified here, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates an outdoor air node and the air temperature information on this node is taken directly from the weather file (no node height adjustment).

Field: Condenser Outlet Node Name

This alpha field contains the identifying name for the electric chiller condenser side outlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates a condenser side outlet air node.

Field: Minimum Part Load Ratio

This numeric field contains the electric chiller's minimum part load ratio. The expected range is between 0 and 1. The minimum part load is not the load where the machine shuts off, but where the amount of power remains constant to produce smaller loads than this fraction.

Field: Maximum Part Load Ratio

This numeric field contains the electric chiller's maximum part load ratio. This value may exceed 1, but the normal range is between 0 and 1.1.

Field: Optimum Part Load Ratio

This numeric field contains the electric chiller's optimum part load ratio. This is the part load ratio at which the chiller performs at its maximum COP.

Field: Design Condenser Inlet Temperature

This numeric field contains the electric chiller's condenser inlet design temperature in Celsius.

Field: Temperature Rise Coefficient

This numeric field contains the electric chiller's temperature rise coefficient which is defined as the ratio of the required change in condenser water temperature to a given change in chilled water temperature, which maintains the capacity at the nominal value. This is calculated as the following ratio:

$$\frac{TCEnt_{required} - TCEnt_{rated}}{TELV_{required} - TELV_{rated}}$$

where:

$TCEnt_{required}$ = Required entering condenser air or water temperature to maintain rated capacity.

$TCEnt_{rated}$ = Rated entering condenser air or water temperature at rated capacity.

$TELV_{required}$ = Required leaving evaporator water outlet temperature to maintain rated capacity.

$TELV_{rated}$ = Rated leaving evaporator water outlet temperature at rated capacity.

Field: Design Chilled Water Outlet Temperature

This numeric field contains the electric chiller's evaporator outlet design temperature in Celsius.

Field: Design Chilled Water Flow Rate

For variable volume chiller this is the maximum flow and for constant flow chiller this is the design flow rate. The units are in cubic meters per second.

Field: Design Condenser Water Flow Rate

This numeric field contains the electric chiller's design condenser water flow rate in cubic meters per second. For an air-cooled chiller, any number (> 0.0) is a valid entry as this entry is not used within the program when modeling the air-cooled electric chiller.

Capacity Ratio Curve

The Capacity Ratio Curve is a quadratic equation that determines the Ratio of Available Capacity to Nominal Capacity. The defining equation is:

$$AvailToNominalCapacityRatio = C_1 + C_2\Delta_{temp} + C_3\Delta_{temp}^2$$

Where the Delta Temperature is defined as:

$$\Delta_{Temp} = \frac{TempCondIn - TempCondInDesign}{TempRiseCoefficient} - (TempEvapOut - TempEvapOutDesign)$$

$TempCondIn$ = Temperature entering the condenser (water or air temperature depending on condenser type).

$TempCondInDesign$ = Design Condenser Inlet Temperature from User input above.

$TempEvapOut$ = Temperature leaving the evaporator.

$TempEvapOutDesign$ = Design Chilled Water Outlet Temperature from User input above.

$TempRiseCoefficient$ = User Input from above.

The following three fields contain the coefficients for the quadratic equation.

Field: Coefficient 1 of Capacity Ratio Curve

This numeric field contains the first coefficient for the capacity ratio curve.

Field: Coefficient 2 of Capacity Ratio Curve

This numeric field contains the second coefficient for the capacity ratio curve.

Field: Coefficient 3 of Capacity Ratio Curve

This numeric field contains the third coefficient for the capacity ratio curve.

Power Ratio Curve

The Power Ratio Curve is a quadratic equation that determines the Ratio of Full Load Power at Available Capacity to Full Load Power at Nominal Capacity. The defining equation is:

$$FullLoadPowerRatio = C_1 + C_2 AvailToNominalCapRatio + C_3 AvailToNominalCapRatio^2$$

The following three fields contain the coefficients for the quadratic equation.

Field: Coefficient1 of the power ratio curve

This numeric field contains the first coefficient for the power ratio curve.

Field: Coefficient 2 of Power Ratio Curve

This numeric field contains the second coefficient for the power ratio curve.

Field: Coefficient 3 of Power Ratio Curve

This numeric field contains the third coefficient for the power ratio curve.

Full Load Ratio Curve

The Full Load Ratio Curve is a quadratic equation that determines the fraction of full load power. The defining equation is:

$$FracFullLoadPower = C_1 + C_2 PartLoadRatio + C_3 PartLoadRatio^2$$

The following three fields contain the coefficients for the quadratic equation.

Field: Coefficient 1 of Full Load Ratio Curve

This numeric field contains the first coefficient for the full load ratio curve.

Field: Coefficient 2 of Full Load Ratio Curve

This numeric field contains the second coefficient for the full load ratio curve.

Field: Coefficient 3 of Full Load Ratio Curve

This numeric field contains the third coefficient for the full load ratio curve.

Field: Chilled Water Outlet Temperature Lower Limit

This numeric field contains the lower limit for the evaporator outlet temperature. This temperature acts as a cut off for heat transfer in the evaporator, so that the fluid doesn't get too cold.

Field: Chiller Flow Mode

This alpha field determines if the Chiller is either a VariableFlow or ConstantFlow Chiller Simulation. The default, if not specified, is VariableFlow.

Field: Design Heat Recovery Water Flow Rate

This is the design flow rate used if the heat recovery option is being simulated. If this value is greater than 0.0 then a heat recovery loop must be specified and attached to the chiller using the next 2 node fields. To determine how the heat recovery algorithm works look at the

Engineering Manual at the Chiller:Electric with Heat Recovery section. The units are in cubic meters per second.

Field: Heat Recovery Inlet Node Name

This alpha field contains the identifying name for the electric chiller heat recovery side inlet node. A heat recovery loop must be specified and it can only be used with a water-cooled condenser.

Field: Heat Recovery Outlet Node Name(Optional for Heat Recovery)

This alpha field contains the identifying name for the electric chiller heat recovery side outlet node. A heat recovery loop must be specified and it can only be used with a water-cooled condenser.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Capacity, Design Chilled Water Flow Rate and Design Condenser Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

These chiller output variables are defined above under "Generic Chiller Outputs."

Chiller:Electric:EIR

This chiller model is the empirical model used in the DOE-2.1 building energy simulation program. The model uses performance information at reference conditions along with three curve fits for cooling capacity and efficiency to determine chiller operation at off-reference conditions. Chiller performance curves can be generated by fitting manufacturer's catalog data or measured data. Performance curves for more than 160 chillers, including the default DOE-2.1E reciprocating and centrifugal chillers, are provided in the EnergyPlus Reference DataSets (Chillers.idf and AllDataSets.idf).

Note: Chiller:Electric:EIR objects and their associated performance curve objects are developed using performance information for a specific chiller and should normally be used together for an EnergyPlus simulation. Changing the object input values, or swapping performance curves between chillers, should be done with caution.

Field: Name

This alpha field contains the identifying name for the electric EIR chiller.

Field: Reference Capacity

This numeric field contains the reference cooling capacity of the chiller in Watts. This should be the capacity of the chiller at the reference temperatures and water flow rates defined below. Alternately, this field can be autosized.

Field: Reference COP

This numeric field contains the chiller's coefficient of performance. This value should **not** include energy use due to pumps, evap-cooled or air-cooled condenser fans, or cooling tower fans. This COP should be at the reference temperatures and water flow rates defined below.

Field: Reference Leaving Chilled Water Temperature

This numeric field contains the chiller's reference leaving chilled water temperature in Celsius. The default value is 6.67°C.

Field: Reference Entering Condenser Fluid Temperature

This numeric field contains the chiller's reference entering condenser fluid temperature in Celsius. The default value is 29.4°C. For water-cooled chillers this is the water temperature entering the condenser (e.g., leaving the cooling tower). For air- or evap-cooled condensers this is the entering outdoor air dry-bulb or wet-bulb temperature, respectively.

Field: Reference Chilled Water Flow Rate

For a variable flow chiller this is the maximum water flow rate and for a constant flow chiller this is the operating water flow rate through the chiller's evaporator. The units are in cubic meters per second. The minimum value for this numeric input field must be greater than zero, or this field can be autosized.

Field: Reference Condenser Water Flow Rate

This numeric field contains the chiller's operating condenser water flow rate in cubic meters per second. For an air- or evaporatively-cooled chiller, any number (> 0.0) is a valid entry since it is disregarded within the program for these condenser types. Alternately, this field can also be autosized.

Field: Cooling Capacity Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the cooling capacity as a function of the leaving chilled water temperature and the entering condenser fluid temperature. The output of this curve is multiplied by the reference capacity to give the cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the reference temperatures). The curve should have a value of 1.0 at the reference temperatures and flow rates specified above. The biquadratic curve should be valid for the range of water temperatures anticipated for the simulation.

Field: Electric Input to Cooling Output Ratio Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input to cooling output ratio (EIR) as a function of the leaving chilled water temperature and the entering condenser fluid temperature. The EIR is the inverse of the COP. The output of this curve is multiplied by the reference EIR (inverse of the reference COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the reference temperatures). The curve should have a value of 1.0 at the reference temperatures and flow rates specified above. The biquadratic curve should be valid for the range of water temperatures anticipated for the simulation.

Field: Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve Name

The name of a quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the part-load ratio. The EIR is the inverse of the COP, and the part-load ratio is the actual cooling load divided by the chiller's available cooling capacity. The output of this curve is multiplied by the reference EIR (inverse of the reference COP) and the Energy Input to Cooling Output Ratio Function of Temperature Curve to give the EIR at the specific temperatures and part-load ratio at which the chiller is operating. This curve should have a value of 1.0 when the part-load ratio equals 1.0. The quadratic curve should be valid for the range of part-load ratios anticipated for the simulation.

Field: Minimum Part Load Ratio

This numeric field contains the chiller's minimum part-load ratio. The expected range is between 0 and 1. Below this part-load ratio, the compressor cycles on and off to meet the cooling load. The Minimum Part Load Ratio must be less than or equal to the Maximum Part Load Ratio. The default value is 0.1.

Field: Maximum Part Load Ratio

This numeric field contains the chiller's maximum part-load ratio. This value may exceed 1, but the normal range is between 0 and 1.0. The Maximum Part Load Ratio must be greater than or equal to the Minimum Part Load Ratio. The default value is 1.0.

Field: Optimum Part Load Ratio

This numeric field contains the chiller's optimum part-load ratio. This is the part-load ratio at which the chiller performs at its maximum COP. The optimum part-load ratio must be greater than or equal to the Minimum Part Load Ratio, and less than or equal to the Maximum Part Load Ratio. The default value is 1.0.

Field: Minimum Unloading Ratio

This numeric field contains the chiller's minimum unloading ratio. The expected range is between 0 and 1. The minimum unloading ratio is where the chiller capacity can no longer be reduced by unloading and must be false loaded to meet smaller cooling loads. A typical false loading strategy is hot-gas bypass. The minimum unloading ratio must be greater than or equal to the Minimum Part Load Ratio, and less than or equal to the Maximum Part Load Ratio. The default value is 0.2.

Field: Chilled Water Side Inlet Node

This required alpha field contains the identifying name for the chiller plant side (chilled water) inlet node.

Field: Chilled Water Side Outlet Node

This required alpha field contains the identifying name for the chiller plant side (chilled water) outlet node.

Field: Condenser Inlet Node Name

This alpha field contains the identifying name for the chiller condenser side inlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and a condenser inlet node name is specified here, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates an outdoor air node and the air temperature information on this node is taken directly from the weather file (no node height adjustment).

Field: Condenser Outlet Node Name

This alpha field contains the identifying name for the chiller condenser side outlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates a condenser side outlet air node.

Field: Condenser Type

This alpha field determines what type of condenser will be modeled with this chiller. Valid condenser types are AirCooled, WaterCooled, and EvaporativelyCooled with the default being WaterCooled if not specified. AirCooled and EvaporativelyCooled do not require a Condenser Loop to be specified, whereas the WaterCooled option requires the full specification of the Condenser Loop and its associated equipment.

Field: Condenser Fan Power Ratio

This field is used to model condenser fan power associated with air-cooled or evaporatively-cooled condensers (for cooling towers, refer to Group - Condenser Equipment). Enter the ratio of the condenser fan power to the reference chiller cooling capacity in W/W.

Field: Compressor Motor Efficiency

This numeric input represents the fraction of compressor electrical energy consumption that must be rejected by the condenser. Enter a value of 1.0 when modeling hermetic chillers. This value must be between 0.0 and 1.0, with a default value of 1.0.

Field: Leaving Chilled Water Lower Temperature Limit

This numeric field contains the lower limit for the leaving chilled water temperature in Celsius. This temperature acts as a cut off for heat transfer in the evaporator, so that the fluid doesn't get too cold. This input field is currently unused. The default value is 2°C.

Field: Chiller Flow Mode

This alpha field determines if the chiller is modeled with constant or variable water flow through the evaporator. Valid choices are ConstantFlow or VariableFlow, with the default being ConstantFlow.

Field: Design Heat Recovery Water Flow Rate

This is the design heat recovery water flow rate if the heat recovery option is being simulated. If this value is greater than 0.0, a heat recovery loop must be specified and attached to the chiller using the next two node fields. The units are in cubic meters per second.

Field: Heat Recovery Side Inlet Node

This alpha field contains the identifying name for the chiller heat recovery side inlet node. If the user wants to model chiller heat recovery, a heat recovery loop must be specified and it can only be used with a water-cooled condenser.

Field: Heat Recovery Side Outlet Node

This alpha field contains the identifying name for the chiller heat recovery side outlet node. If the user wants to model chiller heat recovery, a heat recovery loop must be specified and it can only be used with a water-cooled condenser.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Reference Capacity, Reference Chilled Water Flow Rate and Reference Condenser Water Flow Rate. Sizing

Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

Most of these chiller output variables are defined above under "Generic Chiller Outputs." Report variables not described above are discussed here.

Chiller Condenser Fan Electric Power [W]

Chiller Condenser Fan Electric Consumption [J]

These outputs are for the electric power consumption of the chiller condenser fan and are applicable to air- or evaporatively-cooled chillers. This output is also added to a report meter with Resource Type = Electricity, End Use Key = Chillers, Group Key = Plant (Ref. Report Meter).

ChillerCapFTemp

This is the output of the curve object Cooling Capacity Function of Temperature Curve.

ChillerEIRFTemp

This is the output of the curve object Electric Input to Cooling Output Ratio Function of Temperature Curve.

ChillerEIRFPLR

This is the output of the curve object Electric Input to Cooling Output Ratio Function of Part Load Curve.

Chiller Part Load Ratio

This output is the ratio of the evaporator heat transfer rate plus the false load heat transfer rate (if applicable) to the available chiller capacity. This value is used to determine ChillerEIRFPLR.

Chiller Cycling Ratio

The cycling ratio is the amount of time the chiller operates during each simulation timestep. If the chiller part-load ratio falls below the minimum part-load ratio, the chiller cycles on and off to meet the cooling load.

Chiller False Load Heat Trans Rate**Chiller False Load Heat Trans**

These outputs are the heat transfer rate and total heat transfer due to false loading of the chiller. When the chiller part-load ratio is below the minimum unloading ratio, the chiller false loads (e.g. hot-gas bypass) to further reduce capacity. The false load heat transfer report variable is not metered.

Chiller:Electric:ReformulatedEIR

This chiller model, developed through the CoolTools™ project sponsored by Pacific Gas and Electric Company (PG&E), is an empirical model similar to EnergyPlus' Chiller:Electric:EIR model. The model uses performance information at reference conditions along with three curve fits for cooling capacity and efficiency to determine chiller operation at off-reference conditions. The model has the same capabilities as the Chiller:Electric:EIR model, but can potentially provide significant accuracy improvement over the Chiller:Electric:EIR model for variable-speed compressor drive and variable condenser water flow applications. Chiller performance curves can be generated by fitting manufacturer's catalog data or measured data. Performance curves developed from manufacturer's performance data are provided in the EnergyPlus Reference DataSets (Chillers.idf and AllDataSets.idf). This chiller model can be used to predict the performance of various chiller types (e.g., reciprocating, screw, scroll, and centrifugal) with water-cooled condensers.

The main difference between this model and the Chiller:Electric:EIR model is the condenser fluid temperature used in the associated performance curves: the Chiller:Electric:ReformulatedEIR model uses the LEAVING condenser water temperature while the Chiller:Electric:EIR model uses the ENTERING condenser water temperature.

Note: Chiller:Electric:Reformulated EIR objects and their associated performance curve objects are developed using performance information for a specific chiller and should almost always be used together for an EnergyPlus simulation. Changing the object input values, or swapping performance curves between chillers, should be done with extreme caution. For example, if the user wishes to model a chiller size that is different from the reference capacity, it is highly recommended that the reference flow rates be scaled proportionately to the change in reference capacity. Although this model can provide more accurate prediction than the Chiller:Electric:EIR model, it requires more performance data to develop the associated performance curves (at least 12 points from full-load performance and 7 points from part-load performance).

Field: Chiller Name

This alpha field contains the identifying name for this chiller.

Field: Reference Capacity

This numeric field contains the reference cooling capacity of the chiller in Watts. This should be the capacity of the chiller at the reference temperatures and water flow rates defined below. Alternately, this field can be autosized.

Field: Reference COP

This numeric field contains the chiller's coefficient of performance. This value should **not** include energy use due to pumps or cooling tower fans. This COP should be at the reference temperatures and water flow rates defined below.

Field: Reference Leaving Chilled Water Temperature

This numeric field contains the chiller's reference leaving chilled water temperature in Celsius. The default value is 6.67°C.

Field: Reference Leaving Condenser Water Temperature

This numeric field contains the chiller's reference leaving condenser water temperature in Celsius. The default value is 35°C.

Field: Reference Chilled Water Flow Rate

For a variable flow chiller this is the maximum water flow rate and for a constant flow chiller this is the operating water flow rate through the chiller's evaporator. The units are in cubic meters per second. The minimum value for this numeric input field must be greater than zero, or this field can be autosized.

Field: Reference Condenser Water Flow Rate

This numeric field contains the chiller's operating condenser water flow rate in cubic meters per second. The units are in cubic meters per second. The minimum value for this numeric input field must be greater than zero, or this field can be autosized.

Field: Cooling Capacity Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the cooling capacity as a function of the leaving chilled water temperature and the leaving condenser water temperature. The output of this curve is multiplied by the reference capacity to give the cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the reference temperatures). The curve should have a value of 1.0 at the reference temperatures and flow rates specified above. The biquadratic curve should be valid for the range of water temperatures anticipated for the simulation (otherwise the program issues warning messages).

Field: Electric Input to Cooling Output Ratio Function of Temperature Curve Name

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input to cooling output ratio (EIR) as a function of the leaving chilled water temperature and the leaving condenser water temperature. The EIR is the inverse of the COP. The output of this curve is multiplied by the reference EIR (inverse of the reference COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the reference temperatures). The curve should have a value of 1.0 at the reference temperatures and flow rates specified above. The biquadratic curve should be valid for the range of water temperatures anticipated for the simulation (otherwise the program issues warning messages).

Field: Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve Name

The name of a bicubic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the leaving condenser water temperature and the part-load ratio. The EIR is the inverse of the COP, and the part-load ratio is the actual cooling load divided by the chiller's available cooling capacity. The output of this curve is multiplied by the reference EIR (inverse of the reference COP) and the Energy Input to Cooling Output Ratio Function of Temperature Curve to give the EIR at the specific temperatures and part-load ratio at which the chiller is operating. This curve should have a value of 1.0 at the reference leaving condenser water temperature with the part-load ratio equal to 1.0. The bicubic curve should be valid for the range of condenser water temperatures and part-load ratios anticipated for the simulation (otherwise the program issues warning messages).

Note: Although a bicubic curve requires 10 coefficients (ref. Curve:Bicubic), coefficients 7, 9 and 10 are typically not used in the performance curve described here and should be entered as 0 unless sufficient performance data and regression accuracy exist to justify the use of these coefficients.

Field: Minimum Part Load Ratio

This numeric field contains the chiller's minimum part-load ratio. The expected range is between 0 and 1. Below this part-load ratio, the compressor cycles on and off to meet the cooling load. The Minimum Part Load Ratio must be less than or equal to the Maximum Part Load Ratio. The default value is 0.1.

Field: Maximum Part Load Ratio

This numeric field contains the chiller's maximum part-load ratio. This value may exceed 1, but the normal range is between 0 and 1.0. The Maximum Part Load Ratio must be greater than or equal to the Minimum Part Load Ratio. The default value is 1.0.

Field: Optimum Part Load Ratio

This numeric field contains the chiller's optimum part-load ratio. This is the part-load ratio at which the chiller performs at its maximum COP. The optimum part-load ratio must be greater than or equal to the Minimum Part Load Ratio, and less than or equal to the Maximum Part Load Ratio. The default value is 1.0.

Field: Minimum Unloading Ratio

This numeric field contains the chiller's minimum unloading ratio. The expected range is between 0 and 1. The minimum unloading ratio is where the chiller capacity can no longer be reduced by unloading and must be false loaded to meet smaller cooling loads. A typical false loading strategy is hot-gas bypass. The minimum unloading ratio must be greater than or equal to the Minimum Part Load Ratio, and less than or equal to the Maximum Part Load Ratio. The default value is 0.2.

Field: Chilled Water Side Inlet Node

This required alpha field contains the identifying name for the chiller plant side (chilled water) inlet node.

Field: Chilled Water Side Outlet Node

This required alpha field contains the identifying name for the chiller plant side (chilled water) outlet node.

Field: Condenser Side Inlet Node

This required alpha field contains the identifying name for the chiller condenser side inlet node.

Field: Condenser Side Outlet Node

This required alpha field contains the identifying name for the chiller condenser side outlet node.

Field: Compressor Motor Efficiency

This numeric input represents the fraction of compressor electrical energy consumption that must be rejected by the condenser. Enter a value of 1.0 when modeling hermetic chillers. This value must be between 0.0 and 1.0, with a default value of 1.0.

Field: Leaving Chilled Water Lower Temperature Limit

This numeric field contains the lower limit for the leaving chilled water temperature in Celsius. This temperature acts as a cut off for heat transfer in the evaporator, so that the water doesn't get too cold. This input field is currently unused. The default value is 2°C.

Field: Chiller Flow Mode Type

This alpha field determines if the chiller is modeled with constant or variable water flow through the evaporator. Valid choices are ConstantFlow or VariableFlow, with the default being ConstantFlow.

Field: Design Heat Recovery Water Flow Rate

This is the design heat recovery water flow rate if the heat recovery option is being simulated. If this value is greater than 0.0, a heat recovery loop must be specified and attached to the chiller using the next two node fields. The units are in cubic meters per second.

Field: Heat Recovery Side Inlet Node

This alpha field contains the identifying name for the chiller heat recovery side inlet node. If the user wants to model chiller heat recovery, a heat recovery loop must be specified and it can only be used with a water-cooled condenser.

Field: Heat Recovery Side Outlet Node

This alpha field contains the identifying name for the chiller heat recovery side outlet node. If the user wants to model chiller heat recovery, a heat recovery loop must be specified and it can only be used with a water-cooled condenser.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Reference Capacity, Reference Chilled Water Flow Rate and Reference Condenser Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

Electric Reformulated EIR Chiller Outputs

The output variables for Chiller:Electric:ReformulatedEIR are the same as the output variables for Chiller:Electric:EIR (ref. Electric EIR Chiller Outputs).

Chiller:EngineDriven**Field: Name**

This alpha field contains the identifying name for the engine driven chiller.

Field: Condenser Type

This alpha field determines what type of condenser will be modeled with this chiller. The 3 type of condensers are AirCooled, WaterCooled, and EvaporativelyCooled with the default being AirCooled if not specified. AirCooled and EvaporativelyCooled do not require a Condenser Loop to be specified, where the WaterCooled option requires the full specification of the Condenser Loop and its associated equipment.

Field: Nominal Capacity

This numeric field contains the nominal cooling capability of the chiller in Watts.

Field: Nominal COP

This numeric field contains the chiller's coefficient of performance (COP).

Field: Chilled Water Inlet Node Name

This required alpha field contains the identifying name for the chiller plant side inlet node.

Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the chiller plant side outlet node.

Field: Condenser Inlet Node Name

This alpha field contains the identifying name for the chiller condenser side inlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and a condenser inlet node name is specified here, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates an outdoor air node and the air temperature information on this node is taken directly from the weather file (no node height adjustment).

Field: Condenser Outlet Node Name

This alpha field contains the identifying name for the chiller condenser side outlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates a condenser side outlet air node.

Field: Minimum Part Load Ratio

This numeric field contains the chiller's minimum part load ratio. The expected range is between 0 and 1. The minimum part load is not the load where the machine shuts off, but where the amount of power remains constant to produce smaller loads than this fraction.

Field: Maximum Part Load Ratio

This numeric field contains the chiller's maximum part load ratio. This value may exceed 1, but the normal range is between 0 and 1.1.

Field: Optimum Part Load Ratio

This numeric field contains the chiller's optimum part load ratio. This is the part load ratio at which the chiller performs at its maximum COP.

Field: Design Condenser Inlet Temperature

This numeric field contains the chiller's condenser inlet design temperature in Celsius.

Field: Temperature Rise Coefficient

This numeric field contains the electric chiller's temperature rise coefficient which is defined as the ratio of the required change in condenser water temperature to a given change in chilled water temperature, which maintains the capacity at the nominal value. This is calculated as the following ratio:

$$\frac{TCEnt_{required} - TCEnt_{rated}}{TELv_{required} - TELv_{rated}}$$

where:

$TCEnt_{required}$ = Required entering condenser air or water temperature to maintain rated capacity.

$TCEnt_{rated}$ = Rated entering condenser air or water temperature at rated capacity.

$TELv_{required}$ = Required leaving evaporator water outlet temperature to maintain rated capacity.

$TELv_{rated}$ = Rated leaving evaporator water outlet temperature at rated capacity.

Field: Design Chilled Water Outlet Temperature

This numeric field contains the chiller's evaporator outlet design temperature in Celsius.

Field: Design Chilled Water Flow Rate

For variable volume chiller this is the maximum flow and for constant flow chiller this is the design flow rate. The units are in cubic meters per second.

Field: Design Condenser Water Flow Rate

This numeric field contains the chiller's design condenser water flow rate in cubic meters per second.

Capacity Ratio Curve

The Capacity Ratio Curve is a quadratic equation that determines the Ratio of Available Capacity to Nominal Capacity. The defining equation is:

$$AvailToNominalCapacityRatio = C_1 + C_2\Delta_{temp} + C_3\Delta_{temp}^2$$

Where the Delta Temperature is defined as:

$$\Delta_{Temp} = \frac{TempCondIn - TempCondInDesign}{TempRiseCoefficient} - (TempEvapOut - TempEvapOutDesign)$$

$TempCondIn$ = Temperature entering the condenser (water or air temperature depending on condenser type).

$TempCondInDesign$ = Design Condenser Inlet Temperature from User input above.

$TempEvapOut$ = Temperature leaving the evaporator.

$TempEvapOutDesign$ = Design Chilled Water Outlet Temperature from User input above.

$TempRiseCoefficient$ = User Input from above.

The following three fields contain the coefficients for the quadratic equation.

Field: Coefficient 1 of Capacity Ratio Curve

This numeric field contains the first coefficient for the capacity ratio curve.

Field: Coefficient 2 of Capacity Ratio Curve

This numeric field contains the second coefficient for the capacity ratio curve.

Field: Coefficient 3 of Capacity Ratio Curve

This numeric field contains the third coefficient for the capacity ratio curve.

Power Ratio Curve

The Power Ratio Curve is a quadratic equation that determines the Ratio of Full Load to Power. The defining equation is:

$$FullLoadtoPowerRatio = C_1 + C_2 AvailToNominalCapRatio + C_3 AvailToNominalCapRatio^2$$

The following three fields contain the coefficients for the quadratic equation.

Field: Coefficient 1 of Power Ratio Curve

This numeric field contains the first coefficient for the power ratio curve.

Field: Coefficient 2 of Power Ratio Curve

This numeric field contains the second coefficient for the power ratio curve.

Field: Coefficient 3 of Power Ratio Curve

This numeric field contains the third coefficient for the power ratio curve.

Full Load Ratio Curve

The Full Load Ratio Curve is a quadratic equation that determines the fraction of full load power. The defining equation is:

$$FracFullLoadPower = C_1 + C_2 PartLoadRatio + C_3 PartLoadRatio^2$$

The following three fields contain the coefficients for the quadratic equation.

Field: Coefficient 1 of Full Load Ratio Curve

This numeric field contains the first coefficient for the full load ratio curve.

Field: Coefficient 2 of Full Load Ratio Curve

This numeric field contains the second coefficient for the full load ratio curve.

Field: Coefficient 3 of Full Load Ratio Curve

This numeric field contains the third coefficient for the full load ratio curve.

Field Chilled Water Outlet Temperature Lower Limit

This numeric field contains the lower limit for the evaporator outlet temperature. This temperature acts as a cut off for heat transfer in the evaporator, so that the fluid doesn't get too cold.

Field: Fuel Use Curve Name

This alpha field contains the name of the Cooling Load to Fuel Use curve. The curve itself is specified separately using the EnergyPlus Curve Manager. The Fuel Use Curve is a quadratic equation that determines the ratio of Cooling Load to Fuel Energy. The defining equation is:

$$CoolingLoadtoFuelCurve = C_1 + C_2 * PLR + C_3 * PLR^2$$

where PLR is the Part Load Ratio from the Chiller. The Part Load Based Fuel Input Curve determines the ratio of fuel energy per unit time (J/s) / cooling load (W). This is illustrated by the logic block in the Engine Driven Chiller algorithm.

```

IF (PartLoadRat == 0) THEN
  EngineDrivenFuelEnergy = 0
ELSE
  ClnLoadFuelRat =
CurveValue (EngineDrivenChiller (ChillerNum) %ClnLoadtoFuelCurve, PartLoadRat )
  EngineDrivenFuelEnergy = QEvaporator / ClnLoadFuelRat
END IF

```

Field: Jacket Heat Recovery Curve Name

This alpha field contains the name of the Recovery Jacket Heat curve. The curve itself is specified separately using the EnergyPlus Curve Manager. The Recovery Jacket Heat Curve is a quadratic equation that determines the ratio of recovery jacket heat to fuel energy. The defining equation is:

$$\text{RecoveryJacketHeatToFuelRatio} = C_1 + C_2RL + C_3RL^2$$

where RL is the Ratio of Load to Diesel Engine Capacity

Field: Lube Heat Recovery Curve Name

This alpha field contains the name of the Recovery Lube Heat curve. The curve itself is specified separately using the EnergyPlus Curve Manager. The Recovery Lubricant Heat Curve is a quadratic equation that determines the ratio of recovery lube heat to fuel energy. The defining equation is:

$$\text{RecoveryLubeHeatToFuelRatio} = C_1 + C_2RL + C_3RL^2$$

where RL is the Ratio of Load to Diesel Engine Capacity

Field: Total Exhaust Energy Curve Name

This alpha field contains the name of the Total Exhaust Energy curve. The curve itself is specified separately using the EnergyPlus Curve Manager. The Total Exhaust Energy Curve is a quadratic equation that determines the ratio of total exhaust energy to fuel energy. The defining equation is:

$$\text{TotalExhaustToFuelRatio} = C_1 + C_2RL + C_3RL^2$$

where RL is the Ratio of Load to Diesel Engine Capacity

Field: Exhaust Temperature Curve Name

This alpha field contains the name of the Exhaust Temperature curve. The curve itself is specified separately using the EnergyPlus Curve Manager. The Exhaust Temperature Curve is a quadratic equation that determines the absolute exhaust temperature. The defining equation is:

$$\text{AbsoluteExhaustTemperature} = C_1 + C_2RL + C_3RL^2$$

where RL is the Ratio of Load to Diesel Engine Capacity

U-Factor Times Area Curve

The U-Factor Times Area (UA) is an equation that determines the overall heat transfer coefficient for the exhaust gasses with the stack. The heat transfer coefficient ultimately helps determine the exhaust stack temperature. The defining equation is:

$$UA\text{ToCapacityRatio} = C_1\text{EngineCapacity}^{C_2}$$

The following two fields contain the coefficients for the equation.

Field: Coefficient 1 of U-Factor Times Area Curve

This numeric field contains the first coefficient for the overall heat transfer coefficient curve.

Field: Coefficient 2 of U-Factor Times Area Curve

This numeric field contains the second (exponential) coefficient for the overall heat transfer coefficient curve.

Field: Maximum Exhaust Flow per Unit of Power Output

This numeric field contains the maximum exhaust gas mass flow rate per watt of cooling provided by the engine driven chiller

Field: Design Minimum Exhaust Temperature

This numeric field contains the steam saturation temperature in Celsius that would be used to determine the energy recovered from a water jacket heat exchanger on the engine.

Field: Fuel Type

This alpha value specifies the type of fuel used in the engine. The fuel type can be NaturalGas, PropaneGas, Diesel, Gasoline, FuelOil#1, or FuelOil#2.

Field: Fuel Higher Heating Value

This numeric field contains the higher heating value of the fuel used in kJ/kg.

Field: Design Heat Recovery Water Flow Rate

This numeric field specifies the heat recovery volumetric flow rate through the engine in m³/sec. The heat recovery loop manager and hot water tan must also be specified if heat energy is to be recovered from the engine driven chiller.

Field: Heat Recovery Inlet Node Name

This alpha field contains the identifying name for the heat recovery side inlet. If a loop is connected, then the jacket and lubricant heat will be recovered. There is no need for an effectiveness term, since the jacket and lubricant recovered heat energies are the actual recovered energies.

Field: Heat Recovery Outlet Node Name

This alpha field contains the identifying name for the heat recovery side outlet.

Field: Chiller Flow Mode

This alpha field determines if the Chiller is either a Variable or Constant Flow Chiller Simulation. The default, if not specified, is Variable Flow.

Field: Maximum Temperature for Heat Recovery at Heat Recovery Outlet Node

This field sets the maximum temperature that this piece of equipment can produce for heat recovery. The idea behind this field is that the current models do not take temperatures into account for availability and they just pass Q's around the loop without a temperature limit.

This temperature limit puts an upper bound on the recovered heat and limits the maximum temperatures leaving the component.

As temperatures in the loop approach the maximum temperature, the temperature difference between the entering water and the surfaces in the piece of equipment becomes smaller. For the given heat recovery flow rate and that temperature difference the amount of heat recovered will be reduced, and eventually there will be no heat recovered when the entering water temperature is equal to the maximum temperature specified by the user in this field. The reduced amount of heat recovered will diminish if the temperature of the loop approach is the maximum temperature, and this will show up in the reporting. This allows the user to set the availability or the quality of the heat recovered for usage in other parts of the system or to heat domestic hot water supply. The temperature is specified in degrees C.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Capacity, Design Chilled Water Flow Rate and Design Condenser Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

These chiller output variables are defined above under "Generic Chiller Outputs."

Chiller:CombustionTurbine

This chiller model is the empirical model from the Building Loads and System Thermodynamics (BLAST) program. Chiller performance curves are generated by fitting catalog data to third order polynomial equations. Three sets of coefficients are required.

Field: Name

This alpha field contains the identifying name for the combustion turbine chiller.

Field: Condenser Type

This alpha field determines what type of condenser will be modeled with this chiller. The 3 type of condensers are AirCooled, WaterCooled, and EvaporativelyCooled with the default being AirCooled if not specified. AirCooled and EvaporativelyCooled do not require a Condenser Loop to be specified, where the WaterCooled option requires the full specification of the Condenser Loop and its associated equipment.

Field: Nominal Capacity

This numeric field contains the nominal cooling capability of the chiller in Watts.

Field: Nominal COP

This numeric field contains the chiller's coefficient of performance (COP).

Field: Chilled Water Inlet Node Name

This alpha field contains the identifying name for the combustion turbine chiller plant side inlet node.

Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the combustion turbine chiller plant side inlet node.

Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the combustion turbine chiller plant side outlet node.

Field: Condenser Inlet Node Name

This alpha field contains the identifying name for the combustion turbine chiller condenser side inlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and a condenser inlet node name is specified here, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates an outdoor air node and the air temperature information on this node is taken directly from the weather file (no node height adjustment).

Field: Condenser Outlet Node Name

This alpha field contains the identifying name for the combustion turbine chiller condenser side outlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates a condenser side outlet air node.

Field: Minimum Part Load Ratio

This numeric field contains the combustion turbine chiller's minimum part load ratio. The expected range is between 0 and 1. The minimum part load is not the load where the machine shuts off, but where the amount of power remains constant to produce smaller loads than this fraction.

Field: Maximum Part Load Ratio

This numeric field contains the combustion turbine chiller's maximum part load ratio. This value may exceed 1, but the normal range is between 0 and 1.1.

Field: Optimum Part Load Ratio

This numeric field contains the combustion turbine chiller's optimum part load ratio. This is the part load ratio at which the chiller performs at its maximum COP.

Field: Design Condenser Inlet Temperature

This numeric field contains the combustion turbine chiller's condenser inlet design temperature in Celsius.

Field: Temperature Rise Coefficient

This numeric field contains the electric chiller's temperature rise coefficient which is defined as the ratio of the required change in condenser water temperature to a given change in chilled water temperature, which maintains the capacity at the nominal value. This is calculated as the following ratio:

$$\frac{TCEnt_{required} - TCEnt_{rated}}{TELV_{required} - TELV_{rated}}$$

where:

$TCEnt_{required}$ = Required entering condenser air or water temperature to maintain rated capacity.

$TCEnt_{rated}$ = Rated entering condenser air or water temperature at rated capacity.

$TELV_{required}$ = Required leaving evaporator water outlet temperature to maintain rated capacity.

$TELV_{rated}$ = Rated leaving evaporator water outlet temperature at rated capacity.

Field: Design Chilled Water Outlet Temperature

This numeric field contains the combustion turbine chiller's evaporator outlet design temperature in Celsius.

Field: Design Chilled Water Flow Rate

For variable volume chiller this is the maximum flow and for constant flow chiller this is the design flow rate. The units are in cubic meters per second.

Field: Design Condenser Water Flow Rate

This numeric field contains the combustion turbine chiller's design condenser water flow rate in cubic meters per second.

Capacity Ratio Curve

The Capacity Ratio Curve is a quadratic equation that determines the Ratio of Available Capacity to Nominal Capacity. The defining equation is:

$$AvailToNominalCapacityRatio = C_1 + C_2\Delta_{temp} + C_3\Delta_{temp}^2$$

Where the Delta Temperature is defined as:

$$\Delta_{Temp} = \frac{TempCondIn - TempCondInDesign}{TempRiseCoefficient} - (TempEvapOut - TempEvapOutDesign)$$

$TempCondIn$ = Temperature entering the condenser (water or air temperature depending on condenser type).

$TempCondInDesign$ = Design Condenser Inlet Temperature from User input above.

$TempEvapOut$ = Temperature leaving the evaporator.

$TempEvapOutDesign$ = Design Chilled Water Outlet Temperature from User input above.

$TempRiseCoefficient$ = User Input from above.

The following three fields contain the coefficients for the quadratic equation.

Field: Coefficient 1 of Capacity Ratio Curve

This numeric field contains the first coefficient for the capacity ratio curve.

Field: Coefficient 2 of Capacity Ratio Curve

This numeric field contains the second coefficient for the capacity ratio curve.

Field: Coefficient 3 of Capacity Ratio Curve

This numeric field contains the third coefficient for the capacity ratio curve.

Power Ratio Curve

The Power Ratio Curve is a quadratic equation that determines the Ratio of Full Load to Power. The defining equation is:

$$FullLoadtoPowerRatio = C_1 + C_2 AvailToNominalCapRatio + C_3 AvailToNominalCapRatio^2$$

The following three fields contain the coefficients for the quadratic equation.

Field: Coefficient 1 of Power Ratio Curve

This numeric field contains the first coefficient for the power ratio curve.

Field: Coefficient 2 of Power Ratio Curve

This numeric field contains the second coefficient for the power ratio curve.

Field: Coefficient 3 of Power Ratio Curve

This numeric field contains the third coefficient for the power ratio curve.

Full Load Ratio Curve

The Full Load Ratio Curve is a quadratic equation that determines the fraction of full load power. The defining equation is:

$$FracFullLoadPower = C_1 + C_2 PartLoadRatio + C_3 PartLoadRatio^2$$

The following three fields contain the coefficients for the quadratic equation.

Field: Coefficient 1 of Full Load Ratio Curve

This numeric field contains the first coefficient for the full load ratio curve.

Field: Coefficient 2 of Full Load Ratio Curve

This numeric field contains the second coefficient for the full load ratio curve.

Field: Coefficient 3 of Full Load Ratio Curve

This numeric field contains the third coefficient for the full load ratio curve.

Field: Chilled Water Outlet Temperature Lower Limit

This numeric field contains the lower limit for the evaporator outlet temperature. This temperature acts as a cut off for heat transfer in the evaporator, so that the fluid doesn't get too cold.

Fuel Input Curve

The Fuel Input Curve is a polynomial equation that determines the Ratio of Fuel Input to Energy Output. The equation combines both the Fuel Input Curve Coefficients and the Temperature Based Fuel Input Curve Coefficients. The defining equation is:

$$FuelEnergyInput = PLoad * (FIC_1 + FIC_2 RLoad + FIC_3 RLoad^2) * (TBFIC_1 + TBFIC_2 AT_{air} + TBFIC_3 AT_{air}^2)$$

where FIC represents the Fuel Input Curve Coefficients, TBFIC represents the Temperature Based Fuel Input Curve Coefficients, Rload is the Ratio of Load to Combustion Turbine Engine Capacity, and AT_{air} is the difference between the current ambient and design ambient temperatures.

The following three fields contain the coefficients for the fuel input curve.

Field: Coefficient 1 of Fuel Input Curve

This numeric field contains the first coefficient for the Fuel Input Curve.

Field: Coefficient 2 of Fuel Input Curve

This numeric field contains the second coefficient for the Fuel Input Curve.

Field: Coefficient 3 of Fuel Input Curve

This numeric field contains the third coefficient for the Fuel Input Curve.

The following three fields contain the coefficients for the temperature based fuel input curve.

Field: Coefficient 1 of Temperature Based Fuel Input Curve

This numeric field contains the first coefficient for the Temperature Based Fuel Input Curve.

Field: Coefficient 2 of Temperature Based Fuel Input Curve

This numeric field contains the second coefficient for the Temperature Based Fuel Input Curve.

Field: Coefficient 3 of Temperature Based Fuel Input Curve

This numeric field contains the third coefficient for the Temperature Based Fuel Input Curve.

Exhaust Flow Curve

The Exhaust Flow Curve is a quadratic equation that determines the Ratio of Exhaust Gas Flow Rate to Engine Capacity. The defining equation is:

$$ExhaustFlowRate = GTCapacity * (C_1 + C_2 AT_{air} + C_3 AT_{air}^2)$$

where GTCapacity is the Combustion Turbine Engine Capacity, and AT_{air} is the difference between the current ambient and design ambient temperatures.

Field: Coefficient 1 of Exhaust Flow Curve

This numeric field contains the first coefficient for the Exhaust Flow Curve.

Field: Coefficient 2 of Exhaust Flow Curve

This numeric field contains the second coefficient for the Exhaust Flow Curve.

Field: Coefficient 3 of Exhaust Flow Curve

This numeric field contains the third coefficient for the Exhaust Flow Curve.

Exhaust Gas Temperature Curve

The Exhaust Gas Temperature Curve is a polynomial equation that determines the Exhaust Gas Temperature. The equation combines both the Exhaust Gas Temperature Curve Coefficients (Based on the Part Load Ratio) and the (Ambient) Temperature Based Exhaust Gas Temperature Curve Coefficients. The defining equation is:

$$ExhaustTemperature = (C_1 + C_2 RLoad + C_3 RLoad^2) * (TBC_1 + TBC_2 AT_{air} + TBC_3 AT_{air}^2) - 273.15$$

where C represents the Exhaust Gas Temperature Curve Coefficients, TBC are the Temperature Based Exhaust Gas Temperature Curve Coefficients, RLoad is the Ratio of Load to Combustion Turbine Engine Capacity, and AT_{air} is the difference between the actual ambient and design ambient temperatures.

Field: Coefficient 1 of Exhaust Gas Temperature Curve

This numeric field contains the first coefficient for the Exhaust Gas Temperature Curve.

Field: Coefficient 2 of Exhaust Gas Temperature Curve

This numeric field contains the second coefficient for the Exhaust Gas Temperature Curve.

Field: Coefficient 3 of Exhaust Gas Temperature Curve

This numeric field contains the third coefficient for the Exhaust Gas Temperature Curve.

Field: Coefficient 1 of Temperature Based Exhaust Gas Temperature Curve

This numeric field contains the first coefficient for the Temperature Based Exhaust Gas Temperature Curve.

Field: Coefficient 2 of Temperature Based Exhaust Gas Temperature Curve

This numeric field contains the second coefficient for the Temperature Based Exhaust Gas Temperature Curve.

Field: Coefficient 3 of Temperature Based Exhaust Gas Temperature Curve

This numeric field contains the third coefficient for the Temperature Based Exhaust Gas Temperature Curve.

Recovery Lubricant Heat Curve

The Recovery Lubricant Heat Curve is a quadratic equation that determines the recovery lube energy. The defining equation is:

$$\text{RecoveryLubeEnergy} = \text{PLoad} * (C_1 + C_2 \text{RL} + C_3 \text{RL}^2)$$

where Pload is the engine load and RL is the Ratio of Load to Combustion Turbine Engine Capacity

The following three fields contain the coefficients for the quadratic equation.

Field: Coefficient 1 of Recovery Lube Heat Curve

This numeric field contains the first coefficient for the Recovery Lube Heat curve.

Field: Coefficient 2 of Recovery Lube Heat Curve

This numeric field contains the second coefficient for the Recovery Lube Heat curve.

Field: Coefficient 3 of Recovery Lube Heat Curve

This numeric field contains the third coefficient for the Recovery Lube Heat curve.

U-Factor Times Area Curve Curve

The U-Factor Times Area Curve (UA) is an equation that determines the overall heat transfer coefficient for the exhaust gasses with the stack. The heat transfer coefficient ultimately helps determine the exhaust stack temperature. The defining equation is:

$$\text{UAToCapacityRatio} = C_1 \text{GasTurbineEngineCapacity}^{C_2}$$

The following two fields contain the coefficients for the equation.

Field: Coefficient 1 of U-Factor Times Area Curve

This numeric field contains the first coefficient for the overall heat transfer coefficient curve.

Field: Coefficient 2 of U-Factor Times Area Curve

This numeric field contains the second (exponential) coefficient for the overall heat transfer coefficient curve.

Field: Gas Turbine Engine Capacity

This numeric field contains the capacity of the gas turbine engine in watts.

Field: Maximum Exhaust Flow per Unit of Power Output

This numeric field contains the maximum exhaust gas mass flow rate per kilowatt of power out.

Field: Design Steam Saturation Temperature

This numeric field contains the design steam saturation temperature in Celsius.

Field: Fuel Higher Heating Value

This numeric field contains the higher heating value of the fuel used in kJ/kg.

Field: Design Heat Recovery Water Flow Rate

This is the design heat recovery water flow rate if the heat recovery option is being simulated. If this value is greater than 0.0, a heat recovery loop must be specified and attached to the chiller using the next two node fields. The units are in cubic meters per second.

Field: Heat Recovery Inlet Node Name

This alpha field contains the identifying name for the heat recovery side inlet. If a loop is connected, then the jacket and lubricant heat will be recovered. There is no need for an effectiveness term, since the jacket and lubricant recovered heat energies are the actual recovered energies.

Field: Heat Recovery Outlet Node Name

This alpha field contains the identifying name for the heat recovery side outlet.

Field: Chiller Flow Mode

This alpha field determines if the Chiller is either a VariableFlow or ConstantFlow Chiller Simulation. The default, if not specified, is VariableFlow.

Field: Fuel Type

This alpha field determines the type of fuel that the chiller uses. The default is Natural Gas.

Field: Heat Recovery Maximum Temperature

This field sets the maximum temperature that this piece of equipment can produce for heat recovery. The idea behind this field is that the current models do not take temperatures into account for availability and they just pass Q's around the loop without a temperature limit. This temperature limit puts an upper bound on the recovered heat and limits the max temperatures leaving the component.

As temperatures in the loop approach the maximum temperature, the temperature difference between the entering water and the surfaces in the piece of equipment becomes smaller. For the given heat recovery flow rate and that temperature difference the amount of heat recovered will be reduced, and eventually there will be no heat recovered when the entering water temperature is equal to the maximum temperature specified by the user in this field. The reduced amount of heat recovered will diminish if the temperature of the loop approach is the maximum temperature, and this will show up in the reporting. This allows the user to set the availability or the quality of the heat recovered for usage in other parts of the system or to heat domestic hot water supply.

The temperature is specified in degrees C.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Capacity, Design Chilled Water Flow Rate and Design Condenser Water Flow Rate. Sizing Factor

allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

These chiller output variables are defined above under "Generic Chiller Outputs." The Fuel Type input will determine which fuel type is displayed in the output. In this example with the user choice of Natural Gas, you will have Gas Consumption.

ChillerHeater:Absorption:DirectFired

This chiller is a direct fired absorption chiller-heater which is modeled using performance curves similar to the equivalent chiller in DOE-2.1E. This type of chiller is unusual for EnergyPlus, because it may be used in the same plant on both a chilled water supply branch and a hot water supply branch. The chiller has six node connections for chilled water, condenser water, and hot water, and can provide simultaneous heating and cooling. During simultaneous operation, the heating capacity is reduced as the cooling load increases (for more details see below).

Field: Name

This alpha field contains the identifying name for the chiller.

Field: Nominal Cooling Capacity

This numeric field contains the nominal cooling capability of the chiller in Watts.

Field: Heating to Cooling Capacity Ratio

A positive fraction that represents the ratio of the heating capacity divided by the cooling capacity at rated conditions. The default is 0.8.

Field: Fuel Input to Cooling Output Ratio

A positive fraction that represents the ratio of the instantaneous cooling fuel used divided by the cooling capacity at rated conditions. The default is 0.97.

Field: Fuel Input to Heating Output Ratio

A positive fraction that represents the ratio of the instantaneous heating fuel used divided by the nominal heating capacity. The default is 1.25.

Field: Electric Input to Cooling Output Ratio

A positive fraction that represents the ratio of the instantaneous electricity used divided by the cooling capacity at rated conditions. If the chiller is both heating and cooling only the greater of the computed cooling and heating electricity is used. The default is 0.01.

Field: Electric Input to Heating Output Ratio

A positive fraction that represents the ratio of the instantaneous electricity used divided by the nominal heating capacity. If the chiller is both heating and cooling, the greater of the cooling electricity and heating electricity is used. The default is 0.0.

Field: Chilled Water Inlet Node Name

This required alpha field contains the identifying name for the chiller chilled water side inlet node. This node name must be the same as the inlet node name for the chilled water supply branch on which this chiller is placed.

Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the chiller chilled water side outlet node.

Field: Condenser Inlet Node Name

This required alpha field contains the identifying name for the chiller condenser side inlet node. If the Chiller is AirCooled, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air dry-bulb temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air dry-bulb temperature is taken directly from the weather data.

Field: Condenser Outlet Node Name

This required alpha field contains the identifying name for the chiller condenser side outlet node.

Field: Hot Water Inlet Node Name

This required alpha field contains the identifying name for the chiller-heater hot water side inlet node. This node name must be the same as the inlet node name for the hot water supply branch on which this chiller-heater is placed.

Field: Hot Water Outlet Node Name

This required alpha field contains the identifying name for the chiller-heater hot water side outlet node.

Field: Minimum Part Load Ratio

A positive fraction that represents the minimum cooling or heating output possible when operated continually at rated temperature conditions divided by the available cooling or heating capacity at those same conditions. If the load on the chiller is below this fraction, the chiller will cycle. If the chiller is simultaneously heating and cooling, the greater part load ratio will be used. The default is 0.1.

Field: Maximum Part Load Ratio

A positive fraction that represents the maximum cooling or heating output possible when operated continually at rated temperature conditions divided by the available cooling or heating capacity at those same conditions. If greater than 1.0, the chiller is typically thought of as capable of being overloaded. The default is 1.0.

Field: Optimum Part Load Ratio

A positive fraction that represents the optimum cooling or heating output possible when operated continually at rated temperature conditions divided by the available cooling or heating capacity at those same conditions. It represents the most desirable operating point for the chiller. The default is 1.0.

Field: Design Entering Condenser Water Temperature

The temperature in degrees C of the water entering the condenser of the chiller when operating at design conditions. This is usually based on the temperature delivered by the cooling tower in a water cooled application. The default is 29C

Field: Design Leaving Chilled Water Temperature

The temperature in degrees C of the water leaving the evaporator of the chiller when operating at design conditions; also called the chilled water supply temperature or leaving chilled water temperature. The default is 7C.

Field: Design Chilled Water Flow Rate

For variable volume this is the max flow and for constant flow this is the flow.

Field: Design Condenser Water Flow Rate

The water flow rate at design conditions through the condenser in m³/s.

Field: Design Hot Water Flow Rate

The water flow rate at design conditions through the heater side.

Field: Cooling Capacity Function of Temperature Curve

The CoolCapfT curve represents the fraction of the cooling capacity of the chiller as it varies by temperature. The curve is normalized so that at design conditions the value of the curve should be 1.0. The curve is usually a biquadratic or bilinear curve with the input variables being the leaving chilled water temperature and either the entering or leaving condenser water temperature (see *Temperature Curve Input Variable* below). The available cooling capacity is computed as follows:

$$\text{AvailableCoolingCapacity} = \text{NominalCoolingCapacity} * \text{CoolCapFTCurve}(\text{LeavingChilledWaterTemp}, \text{SpecifiedCondenserTemp})$$

Field: Fuel-Input-to Cooling Output Ratio Function of Temperature Curve

The CFIRfT curve represents the fraction of the fuel input to the chiller at full load as it varies by temperature. The curve is normalized so that at design conditions the value of the curve should be 1.0. The curve is usually a biquadratic or bilinear curve with the input variables being the leaving chilled water temperature and either the entering or leaving condenser water temperature (see *Temperature Curve Input Variable* below).

Field: Fuel-Input-to Cooling Output Ratio Function of Part Load Ratio Curve

The CFIRfPLR curve represents the fraction of the fuel input to the chiller as the load the chiller varies but the operating temperatures remain at the design values. The curve is normalized so that at full load the value of the curve should be 1.0. The curve is usually linear or quadratic. The cooling fuel input to the chiller is computed as follows:

$$\text{CoolFuelInput} = \text{AvailableCoolingCapacity} * \text{FuelInputToCoolingOutputRatio} * \\ \text{FuelCoolFTCurve}(\text{LeavingChilledWaterTemp}, \text{SpecifiedCondenserTemp}) * \\ \text{FuelCoolFPLRCurve}(\text{CoolPartLoadRatio})$$

Field: Electric Input to Cooling Output Ratio Function of Temperature Curve Name

The ElecCoolFT curve represents the fraction of the electricity to the chiller at full load as it varies by temperature. The curve is normalized so that at design conditions the of the curve should be 1.0. The curve is usually a biquadratic or bilinear curve with the input variables being the leaving chilled water temperature and either the entering or leaving condenser water temperature (see *Temperature Curve Input Variable* below).

Field: Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve Name

The ElecCoolFPLR curve represents the fraction of the electricity to the chiller as the load on the chiller varies but This operating temperatures remain at the design values. The curve is normalized so that at full load the value of the curve should be 1.0. The curve is usually linear or quadratic. The cooling electric input to the chiller is computed as follows:

$$\text{CoolElectricPower} = \text{NominalCoolingCapacity} * \text{ElectricInputToCoolingOutputRatio} * \\ \text{OnTimeFraction} * \\ \text{ElecCoolFTCurve}(\text{LeavingChilledWaterTemp}, \text{SpecifiedCondenserTemp}) * \\ \text{ElecCoolFPLRCurve}(\text{CoolPartLoadRatio})$$

Field: Heating Capacity Function of Cooling Capacity Curve Name

The HeatCapFCool curve represents how the heating capacity of the chiller varies with cooling capacity when the chiller is simultaneous heating and cooling. The curve is normalized so an input of 1.0 represents the nominal cooling capacity and an output of 1.0 represents the full heating capacity (see the Heating to cooling capacity ratio input) The curve is usually linear or quadratic. The available heating capacity is computed as follows:

$$\text{AvailableHeatingCapacity} = \text{NominalCoolingCapacity} * \text{HeatToCoolCapacityRatio} * \\ \text{HeatCapFCoolCurve}(\text{CoolPartLoadRatio})$$

Field: Fuel Input to Heat Output Ratio During Heating Only Operation

When the chiller is operating as only a heater, the curve is used to represent the fraction of fuel used as the heating load varies. It is normalized so that a value of 1.0 is the full available heating capacity. The curve is usually linear or quadratic and will probably be similar to a boiler curve for most chillers.

$$\text{HeatFuelUseRate} = \text{AvailableHeatingCapacity} * \text{FuelInputToCoolingOutputRatio} * \\ \text{IFuelHeatFHPLRCurve}(\text{HeatPartLoadRatio})$$

Field: Temperature Curve Input Variable

This field sets the second independent variable in the three temperature dependent performance curves to either the leaving or entering condenser water temperature. Manufacturers express the performance of their chillers using either the leaving condenser water temperature (to the tower) or the entering condenser water temperature (from the tower). Valid choices for this field are: LeavingCondenser or EnteringCondenser. It is important that the performance curves and this field are consistent with each other. The default is EnteringCondenser.

Field: Condenser Type

The condenser can either be air cooled or connected to a cooling tower. This alpha field contains the keyword for the type of condenser, either AirCooled, or WaterCooled. The default is WaterCooled.

Field: Chilled Water Temperature Lower Limit

The chilled water supply temperature in degrees C below which the chiller will shut off. The default is 2C

Field: Fuel Higher Heating Value

The fuel higher heating value in kJ/kg. *This field is not currently used.*

Field: Chiller Flow Mode

This alpha field determines if the Chiller is either a Variable or Constant Flow Chiller Simulation. The default, if not specified, is Variable Flow.

Field: Fuel Type

This alpha field determines the type of fuel that the chiller uses. The default is Natural Gas.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Cooling Capacity, Design Chilled Water Flow Rate, Design Condenser Water Flow Rate and Design Hot Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

      \default Autosize
      \units m3/s
      \ip-units gal/min
A8 , \field Cooling Capacity Function of Temperature Curve Name
     \note The CoolCapFT curve represents the fraction of the cooling capacity of the chiller as it
     \note varies by temperature. The curve is normalized so that at design conditions the
     \note value of the curve should be 1.0. The curve is usually a biquadratic or bilinear
     \note curve with the input variables being the leaving chilled water temperature and either
     \note the entering or leaving condenser water temperature.
A9 , \field Fuel Input to Cooling Output Ratio Function of Temperature Curve Name
     \note The curve represents the fraction of the fuel input to the chiller at full load as
     \note it varies by temperature. The curve is normalized so that at design conditions the
     \note value of the curve should be 1.0. The curve is usually a biquadratic or bilinear
     \note curve with the input variables being the leaving chilled water temperature and either
     \note the entering or leaving condenser water temperature.
A10 , \field Fuel Input to Cooling Output Ratio Function of Part Load Ratio Curve Name
      \note The curve represents the fraction of the fuel input to the chiller as the load on
      \note the chiller varies but the operating temperatures remain at the design values.
      \note The curve is normalized so that at full load the value of the curve should be 1.0.
      \note The curve is usually linear or quadratic.
A11 , \field Electric Input to Cooling Output Ratio Function of Temperature Curve Name
      \note The curve represents the fraction of the electricity to the chiller at full load as
      \note it varies by temperature. The curve is normalized so that at design conditions the
      \note value of the curve should be 1.0. The curve is usually a biquadratic or bilinear
      \note curve with the input variables being the leaving chilled water temperature and either
      \note the entering or leaving condenser water temperature.
A12 , \field Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve Name
      \note The curve represents the fraction of the electricity to the chiller as the load on
      \note the chiller varies but the operating temperatures remain at the design values.
      \note The curve is normalized so that at full load the value of the curve should be 1.0.
      \note The curve is usually linear or quadratic.
A13 , \field Heating Capacity Function of Cooling Capacity Curve Name
      \note The curve represents how the heating capacity of the chiller varies with cooling
      \note capacity when the chiller is simultaneous heating and cooling. The curve is normalized
      \note so an input of 1.0 represents the nominal cooling capacity and an output of 1.0
      \note represents the full heating capacity (see the Heating to cooling capacity ratio input)
      \note The curve is usually linear or quadratic.
A14 , \field Fuel Input to Heat Output Ratio During Heating Only Operation
      \note When the chiller is operating as only a heater, this curve is used to represent the
      \note fraction of fuel used as the heating load varies. It is normalized so that a value
      \note of 1.0 is the full heating capacity. The curve is usually linear or quadratic and
      \note will probably be similar to a boiler curve for most chillers.

The "Chiller" output variables are defined above under "Generic Chiller Outputs." The specific "Direct Fired Absorption Chiller" output variables and exceptions to the generic outputs are defined below.

Chiller Electric Power [W]**Chiller Electric Consumption [J]**

These outputs are the electric power input to the chiller when operating in cooling mode, heating mode, or both. This value is not metered, but the separate cooling and heating electric consumption are metered (see below).

Chiller Gas Consumption Rate [W]**Chiller Gas Consumption [J]**

These outputs are the natural gas input to the chiller when operating in cooling mode, heating mode, or both depending on the fuel type entered. This value is not metered, but the separate cooling and heating electric consumption are metered (see below).

Direct Fired Absorption Chiller Fraction of Period Running

This is the average fraction of the time period during which the direct fired absorption chiller-heater was operating in either cooling mode, heating mode, or both.

Direct Fired Absorption Chiller Cooling Gas Consumption Rate [W]**Direct Fired Absorption Chiller Cooling Gas Consumption [J]**

These outputs are the natural gas input to the direct fired absorption chiller to serve cooling operation. Consumption is metered on Cooling:Gas, Gas:Plant, and Gas:Facility.

Direct Fired Absorption Chiller Cooling Electric Power [W]**Direct Fired Absorption Chiller Cooling Electric Consumption [J]**

These outputs are the electricity input to the direct fired absorption chiller to serve cooling operation. Consumption is metered on Cooling:Electricity, Electricity:Plant, and Electricity:Facility.

Direct Fired Absorption Chiller Cooling Capacity [W]

This is the average available cooling capacity for the reported time period.

Direct Fired Absorption Chiller Cooling Part Load Ratio

This is the average cooling load (Chiller Evap Heat Trans Rate [W]) divided by the average available cooling capacity (Direct Fired Absorption Chiller Cooling Capacity [W]) for the reported time period.

Direct Fired Absorption Chiller Cooling Fuel COP

This is the average coefficient of performance for the chiller in cooling operation, calculated as the average cooling load (Chiller Evap Heat Trans Rate [W]) divided by the average gas consumption during cooling (Direct Fired Absorption Chiller Cooling Gas Consumption Rate [W]) for the reported time period. If the chiller cooling gas consumption rate (denominator) is zero, then this output variable is set to zero.

Direct Fired Absorption Chiller Heating Rate [W]**Direct Fired Absorption Chiller Heating Energy [J]**

These outputs are the heating delivered by the direct fired absorption chiller-heater to serve heating operation. Energy is metered on Boilers:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

Direct Fired Absorption Chiller Heating Gas Consumption Rate [W]***Direct Fired Absorption Chiller Heating Gas Consumption [J]***

These outputs are the natural gas input to the direct fired absorption chiller-heater to serve heating operation. Consumption is metered on Heating:Gas, Gas:Plant, and Gas:Facility.

Direct Fired Absorption Chiller Heating Electric Power [W]***Direct Fired Absorption Chiller Heating Electric Consumption [J]***

These outputs are the electric power input to the direct fired absorption chiller to serve heating operation. Consumption is metered on Heating:Electricity, Electricity:Plant, and Electricity:Facility.

Direct Fired Absorption Chiller Heating Capacity [W]

This is the average available heating capacity for the reported time period.

Direct Fired Absorption Chiller Heating Part Load Ratio

This is the average heating load (Direct Fired Absorption Chiller Heating Rate [W]) divided by the average available heating capacity (Direct Fired Absorption Chiller Heating Capacity [W]) for the reported time period.

Direct Fired Absorption Chiller Hot Water Inlet Temp [C]***Direct Fired Absorption Chiller Hot Water Outlet Temp [C]******Direct Fired Absorption Chiller Hot Water Mass Flow Rate [kg/s]***

These outputs are the hot water inlet and outlet temperatures and flow rate for the direct fired absorption chiller-heater during heating mode operation.

Boiler:HotWater

The boiler model calculates the performance of fuel oil, gas and electric boilers. Boiler performance is based on nominal thermal efficiency. A normalized efficiency performance curve may be used to more accurately represent the performance of non-electric boilers but is not considered a required input. When using the normalized efficiency performance curve, if all coefficients are not required simply set the unused coefficients to 0. For example, an electric boiler could be modeled by setting the nominal thermal efficiency to a value in the range of 0.96 to 1.0. Coefficient A0 in the normalized efficiency performance curve would equal 1 and all other coefficients would be set to 0. Coefficients for other types of non-electric boilers would set a combination of the available coefficients to non-zero values.

Field: Name

This required alpha field contains the identifying name for the boiler.

Field: Fuel Type

This required choice field specifies the type of fuel used by the boiler. The fuel type can be Electricity, NaturalGas, PropaneGas, FuelOil#1, FuelOil#2, Coal, Diesel, or Gasoline.

Field: Nominal capacity

This numeric field contains the nominal operating capacity (W) of the boiler. The boiler may be autosized and would require a heating plant sizing object.

Fuel Use Equation

The model is based the following two equations:

$$\textit{TheoreticalFuelUse} = \frac{\textit{BoilerLoad}}{\textit{NominalThermalEfficiency}}$$

$$\textit{FuelUsed} = \frac{\textit{TheoreticalFuelUse}}{\textit{NormalizedBoilerEfficiencyCurveOutput}}$$

Field: Nominal Thermal Efficiency

This required numeric field contains the heating efficiency (as a fraction between 0 and 1) of the boiler's burner. This is the efficiency relative to the higher heating value (HHV) of fuel at a part load ratio of 1.0 and the temperature entered for the Design Boiler Water Outlet Temp. Manufacturers typically specify the efficiency of a boiler using the higher heating value of the fuel. For the rare occurrences when a manufacturers (or particular data set) thermal efficiency is based on the lower heating value (LHV) of the fuel, multiply the thermal efficiency by the lower-to-higher heating value ratio. For example, assume a fuel's lower and higher heating values are approximately 45,450 and 50,000 kJ/kg, respectively. For a manufacturers thermal efficiency rating of 0.90 (based on the LHV), the nominal thermal efficiency entered here is 0.82 (i.e. 0.9 multiplied by 45,450/50,000).

Field: Normalized Boiler Efficiency Curve Name

This alpha field contains the curve name which describes the normalized heating efficiency (as a fraction of nominal thermal efficiency) of the boiler's burner. If this field is left blank, the nominal thermal efficiency is assumed to be constant (i.e., Fuel Used is equal to the Theoretical Fuel Use in the equation above). When a boiler efficiency curve is used, the curve may be any valid curve object with 1 (PLR) or 2 (PLR and boiler outlet water temperature) independent variables. A tri-quadratic curve object is not allowed since it uses 3 independent variables. The linear, quadratic, and cubic curve types may be used when the boiler efficiency is solely a function of boiler part-load ratio (PLR). When this type of curve is used, the boiler should operate at (or very near) the design boiler water outlet temperature. Other curve types may be used when the boiler efficiency is a function of both PLR and boiler water temperature. Examples of valid single and dual independent variable equations are shown below. For all curve types PLR is always the x independent variable. When using 2 independent variables, the boiler outlet water temperature (T_{outlet}) is always the y independent variable.

Linear: $Eff = A0 + A1*PLR$

Quadratic: $Eff = A0 + A1*PLR + A2*PLR^2$

Cubic: $Eff = A0 + A1*PLR + A2*PLR^2 + A3*PLR^3$

BiQuadratic: $Eff = A0 + A1*PLR + A2*PLR^2 + A3*T_w + A4*T_w^2 + A5*PLR*T_w$

QuadraticLinear: $Eff = A0 + A1*PLR + A2*PLR^2 + A3*T_w + A4*PLR*T_w + A5*PLR^2*T_w$

BiCubic: $Eff = A0 + A1*PLR + A2*PLR^2 + A3*T_w + A4*T_w^2 + A5*PLR^2 + A6*T_w^3 + A7*PLR^2*T_w + A8*PLR*T_w^2$

where

Eff = normalized boiler efficiency

PLR = boiler part-load ratio

T_w = boiler (outlet) water temperature [°C]

Field: Design Water Outlet Temperature

This numeric field contains the desired boiler water outlet temperature in Celsius.

Field: Design Water Flow Rate

This numeric field contains the maximum design water volumetric flow rate in m³/sec. This should be the largest flow rate that can be heated to the design outlet temperature. This field is autosizable.

Field: Minimum Part Load Ratio

This numeric field contains the minimum part load ratio. If the ratio of demand to boiler nominal capacity is less than the minimum part load ratio, then the Min PLR will determine the operating PLR. The expected range is between 0 and 1. If this field is left blank, the default value is 0.0.

Field: Maximum Part Load Ratio

This numeric field contains the maximum part load ratio. If the ratio of demand to boiler nominal capacity is greater than the maximum part load ratio, then the Max PLR will determine the operating PLR. This value may exceed 1, but the normal range is between 0 and 1.1. If this field is left blank, the default value is 1.0.

Field: Optimum Part Load Ratio

This numeric field contains the optimum part load ratio. This is the part load ratio at which the boiler performs at its maximum efficiency. If this field is left blank, the default value is 1.0.

Field: Boiler Water Inlet Node Name

This required alpha field contains the water inlet node name.

Field: Boiler Water Outlet Node Name

This required alpha field contains the water outlet node name.

Field: Water Outlet Upper Temperature Limit

This numeric field contains the outlet temperature upper limit. If this field is left blank, the default value is 99.9°C.

Field: Boiler Flow Mode

This choice field determines if the boiler is VariableFlow or ConstantFlow. The default, if not specified, is VariableFlow.

Field: Parasitic Electric Load

This optional numeric field contains the parasitic electric power (W) consumed by a forced draft fan or other electrical device associated with the boiler. This parasitic electric load is consumed whenever the boiler is operating, and the model assumes that this parasitic power does not contribute to heating the water. The minimum value for this field is 0.0, and the default value is also 0.0 if the field is left blank.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Capacity and Design Water Flow Rate. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

Boiler Heating Output Rate [W]

Boiler Heating Output Energy [J]

These outputs are the heating output (load) of the boiler. Energy is metered on Boilers:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

Boiler Water Inlet Temp [C]**Boiler Water Outlet Temp [C]****Boiler Water Mass Flow Rate [kg/s]**

These outputs are the hot water inlet and outlet temperatures and flow rate for the boiler.

Boiler Part-Load Ratio

This output is the operating part-load ratio of the boiler. The part-load ratio is calculated as the boiler load divided by the boiler nominal capacity. The part-load ratio is limited by the minimum and maximum part-load ratio inputs specified by the user.

Boiler <FuelType> Consumption Rate [W]**Boiler <FuelType> Consumption [J]**

These outputs are the energy input to the boiler. Valid fuel types are: Electric, Gas (natural gas), Propane, FuelOil#1, FuelOil#2, Coal, Diesel, and Gasoline. Consumption is metered on Heating:<FuelType>, <FuelType>:Plant, and <FuelType>:Facility.

Boiler Parasitic Electric Power [W]**Boiler Parasitic Electric Consumption [J]**

These outputs are the parasitic electric power and parasitic electric consumption associated with the boiler. Used when simulating a forced draft fan or other electric component. Consumption is metered on Heating:Electricity and Electricity:Plant.

Boiler:Steam

The steam boiler model provides a first order approximation of performance for fuel oil, gas and electric boilers. Boiler performance is based on a “theoretical” boiler efficiency (overall efficiency at design operating conditions) and a single quadratic fuel use/ part load ratio curve. This single curve accounts for all combustion inefficiencies and stack losses.

```
Boiler:Steam,
  \memo This boiler model is an adaptation of the empirical model from the Building
  \memo Loads and System Thermodynamics (BLAST) program. Boiler performance
  \memo curves are generated by fitting catalog data to third order
  \memo polynomial equations. A constant efficiency boiler is modeled by setting
  \memo the fuel use coefficients as follows: N9=1, N10=0, N11=0
A1 , \field Name

```

Field: Name

This alpha field contains the identifying name for the Steam Boiler.

Field: Fuel Type

This alpha value specifies the type of fuel used by the boiler. The fuel type can be Electricity, NaturalGas, PropaneGas, FuelOil#1, FuelOil#2, Coal, Diesel, or Gasoline.

Field: Maximum Operating Pressure

This numeric field contains the maximum value of pressure up to which the boiler would operate, or the maximum design pressure. (Pascal)

Field: Theoretical Efficiency

This numeric field contains the heating efficiency (as a fraction between 0 and 1) of the boiler's burner

Field: Design Outlet Steam Temperature

The maximum value of steam temperature the boiler can provide. (Celcius)

Field: Nominal Capacity

This numeric field contains the nominal operating capacity (W) of the boiler.

Field: Minimum Part Load Ratio

This numeric field contains the minimum part load ratio. If the ratio of demand to boiler nominal capacity is less than the minimum part load ratio, then the Min PLR will determine the operating PLR. The expected range is between 0 and 1.

Field: Maximum Part Load Ratio

This numeric field contains the maximum part load ratio. If the ratio of demand to boiler nominal capacity is greater than the maximum part load ratio, then the Max PLR will determine the operating PLR. This value may exceed 1, but the normal range is between 0 and 1.1.

Field: Optimum Part Load Ratio

This numeric field contains the optimum part load ratio. This is the part load ratio at which the boiler performs at its maximum efficiency.

Field: Coefficient 1 of Fuel Use Function of Part Load Ratio Curve

This numeric field contains the fuel use / PLR coefficient1.

Field: Coefficient 2 of Fuel Use Function of Part Load Ratio Curve

This numeric field contains the fuel use / PLR coefficient2.

Field: Coefficient 3 of Fuel Use Function of Part Load Ratio Curve

This numeric field contains the fuel use / PLR coefficient3.

Field: Water Inlet Node Name

This alpha field contains the water inlet node name.

Field: Steam Outlet Node Name

This alpha field contains the steam outlet node name.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Capacity. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

More information on the technical aspects of steam boiler can be found in the Engineering Reference Document.

An example of a Steam Boiler input statement from an IDF is:

 Zone,Meter,Heating:Diesel [J]

HVAC,Average,Boiler Gasoline Consumption Rate [W]
 HVAC,Sum,Boiler Gasoline Consumption [J]
 Zone,Meter,Gasoline:Plant [J]
 Zone,Meter,Heating:Gasoline [J]

Boiler Heating Output Rate [W]

Boiler Heating Output Energy [J]

These outputs are the heating output (load) of the boiler. Energy is metered on Boilers:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

Boiler Condensate Inlet Temp [C]**Boiler Steam Outlet Temp [C]****Boiler Steam Mass Flow Rate [kg/s]**

These outputs are the hot water inlet and Steam outlet temperatures and steam flow rate for the boiler.

Boiler <FuelType> Consumption Rate [W]**Boiler <FuelType> Consumption [J]**

These outputs are the energy input to the boiler. Valid fuel types are: Electric, Gas (natural gas), Propane, FuelOil#1, FuelOil#2, Coal, Diesel, and Gasoline. Consumption is metered on Heating:<FuelType>, <FuelType>:Plant, and <FuelType>:Facility.

Water to Water Heat Pumps

The EnergyPlus has two water-to-water heat pump models, parameter estimation and equation fit, to choose from:

HeatPump:WaterToWater:EquationFit:Cooling**HeatPump:WaterToWater:EquationFit:Heating**

This model is an equation-fit model from the catalog data which resembles a black box with no usage of heat transfer equations. The performance of the heat pump is modeled using curves fitted from the catalog data.

HeatPump:WaterToWater:ParameterEstimation:Cooling**HeatPump:WaterToWater:ParameterEstimation:Heating**

This model is a parameter estimation based model that uses physical parameters generated from the catalog data. The physical parameters are then used to predict the performance of the heat pump using thermodynamic laws and heat transfer equations. The heat pump has a reciprocating compressor that serves both the hot water and the chilled water loop. Note that this model is currently “hardwired” to fluid property R22.

Descriptions and strength of each respective model is available in the following references:

Jin, Hui. 2002. Parameter Estimation Based Models of Water Source Heat Pumps. Phd. Thesis, Department of Mechanical and Aerospace Engineering, Oklahoma State University. (downloadable from <http://www.hvac.okstate.edu/>)

Tang, C. C. 2005. Modeling Packaged Heat Pumps in Quasi-Steady State Energy Simulation Program. M.S. Thesis. Department of Mechanical and Aerospace Engineering, Oklahoma State University. (downloadable from <http://www.hvac.okstate.edu/>)

The Supply side of the heat pump is usually connected to a Ground Heat Exchanger. The figure below shows the layout and piping diagram of the water-to-water heat pump.

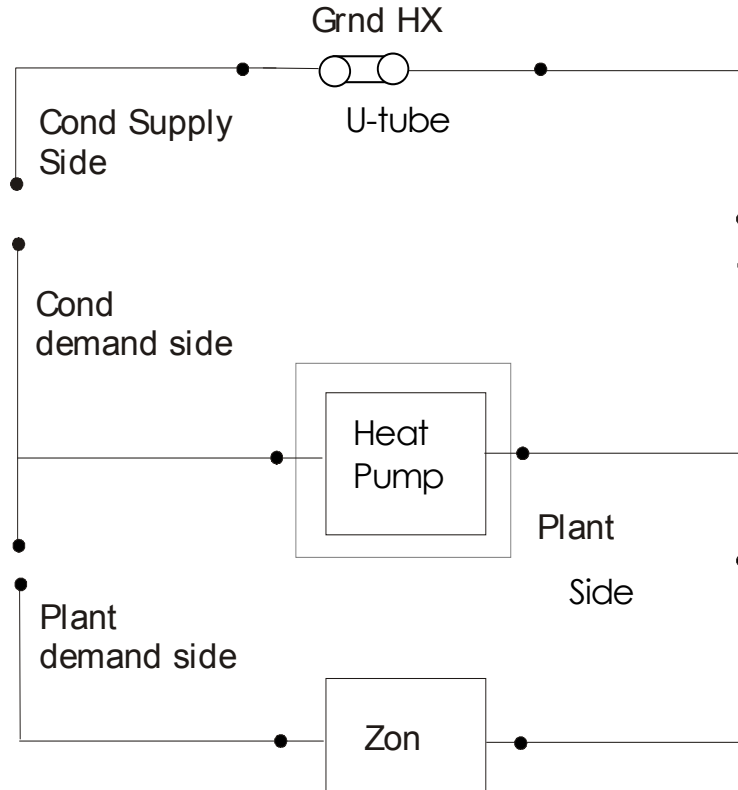

Figure 65. Schematic of EnergyPlus Ground Loop Heat Exchanger

First, the equation fit model objects are described. This model has two sets of coefficients, one for the heating mode and other for the cooling mode.

HeatPump:WaterToWater:EquationFit:Cooling

Field: Name

This alpha field contains the identifying name for the ground source heat pump.

Field: Source Side Inlet Node Name

This alpha field contains the heat pump's source side inlet node name.

Field: Source Side Outlet Node Name

This alpha field contains the heat pump's source side outlet node name.

Field: Load Side Inlet Node Name

This alpha field contains the heat pump's load side inlet node name.

Field: Load Side Outlet Node Name

This alpha field contains the heat pump's load side outlet node name.

Field: Rated Load Side Flow Rate

This numeric field contains the rated volumetric flow rate on the load side of the heat pump in m³/s.

Field: Rated Source Side Flow Rate

This numeric field contains the rated volumetric flow rate on the source side of the heat pump in m³/s.

Field: Rated Cooling Capacity

This numeric field contains the rated cooling capacity of the heat pump in W.

Field: Rated Cooling Power Consumption

This numeric field contains the rated power consumption of the heat pump in W.

Fields: Cooling Capacity Coefficients

Five fields are used to describe the coefficients for the Cooling Capacity curve. More details on how these coefficients are used are described in the Engineering Reference.

Field: Cooling Capacity Coefficient 1-5

These numeric fields contain the five coefficients for the heat pump capacity.

Field: Cooling Compressor Power Coefficients

Five fields are used to describe the coefficients for the Cooling Compressor Power consumption curve. More details on how these coefficients are used are described in the Engineering Reference.

Field: Cooling Compressor Power Coefficient 1-5

These numeric fields contain the five coefficients for the heat pump power consumption.

Field: Cycle Time

This numeric field contains the full on and off cycle time of the heat pump unit in Hour.

Next, the parameter estimation model objects are described. This model has two sets of parameters, one for the heating mode and other for the cooling mode.

HeatPump:WaterToWater:ParameterEstimation:Cooling

Field: Name

This alpha field contains the identifying name for the ground source heat pump.

Field: Source Side Inlet Node Name

This alpha field contains the heat pump's source side inlet node name.

Field: Source Side Outlet Node Name

This alpha field contains the heat pump's source side outlet node name.

Field: Load Side Inlet Node Name

This alpha field contains the heat pump's load side inlet node name.

Field: Load Side Outlet Node Name

This alpha field contains the heat pump's load side outlet node name.

Field: Nominal COP

This numeric field contains the nominal coefficient of performance of the heat pump.

Field: Nominal Capacity

This numeric field contains the nominal capacity of the heat pump in Watts.

Field: Minimum Part Load Ratio

This numeric field contains the minimum part load ratio of the heat pump usually set to 0.

Field: Maximum Part Load Ratio

This numeric field contains the maximum part load ratio of the heat pump usually set to 1.

Field: Optimum Part Load Ratio

This numeric field contains the optimal part load ratio of the heat pump usually set to 1.

Field: Load Side Flow Rate

This numeric field contains the volumetric flow rate on the load side of the heat pump in m3/s

Field: Source Side Flow Rate

This numeric field contains the volumetric flow rate on the source side of the heat pump in m³/s

Field: Load Side Heat Transfer Coefficient

This numeric field contains Estimated parameter load side heat transfer coefficient W/K.

Field: Source Side Heat Transfer Coefficient

This numeric field contains Estimated parameter source side heat transfer coefficient W/K.

Field: Piston Displacement

This numeric field contains the Estimated parameter displacement of the reciprocating compressor in m³/s.

Field: Compressor Clearance Factor

This numeric field contains the Estimated parameter clearance factor of the reciprocating compressor.

Field: Compressor Suction and Discharge Pressure Drop

This numeric field contains the estimated parameter the pressure drop at compressor suction and discharge in Pascals (N/m²).

Field: Superheating

This numeric field contains the estimated parameter superheat at the evaporator outlet in °C.

Field: Constant Part of Electromechanical Power Losses

This numeric field contains the estimated parameter power loss, which accounts for the loss of work due mechanical and electrical losses in the compressor in Watts.

Field: Loss Factor

This numeric field contains the factor of electromechanical loss that is proportional to the theoretical power percentage.

Field: High Pressure Cut Off

This numeric field contains the design pressure limit of the compressor in Pascals (N/m²).

Field: Low Pressure Cut Off

This numeric field contains the design low-pressure limit of the compressor in Pascals (N/m²).

Field: Cycle Time

This numeric field contains the full on and off cycle time of the heat pump unit in Hour.

HeatPump:WaterToWater:ParameterEstimation:Heating

Field: Name

This alpha field contains the identifying name for the ground source heat pump.

Field: Source Side Inlet Node Name

This alpha field contains the heat pump's source side inlet node name.

Field: Source Side Outlet Node Name

This alpha field contains the heat pump's source side outlet node name.

Field: Load Side Inlet Node Name

This alpha field contains the heat pump's load side inlet node name.

Field: Load Side Outlet Node Name

This alpha field contains the heat pump's load side outlet node name.

Field: Nominal COP

This numeric field contains the nominal coefficient of performance of the heat pump.

Field: Nominal Capacity

This numeric field contains the nominal capacity of the heat pump in Watts.

Field: Minimum Part Load Ratio

This numeric field contains the minimum part load ratio of the heat pump usually set to 0.

Field: Maximum Part Load Ratio

This numeric field contains the maximum part load ratio of the heat pump usually set to 1.

Field: Optimum Part Load Ratio

This numeric field contains the optimal part load ratio of the heat pump usually set to 1.

Field: Load Side Flow Rate

This numeric field contains the volumetric flow rate on the load side of the heat pump in m3/s

Field: Source Side Flow Rate

This numeric field contains the volumetric flow rate on the source side of the heat pump in m³/s

Field: Load Side Heat Transfer Coefficient

This numeric field contains Estimated parameter load side heat transfer coefficient W/K.

Field: Source Side Heat Transfer Coefficient

This numeric field contains Estimated parameter source side heat transfer coefficient W/K.

Field: Piston Displacement

This numeric field contains the Estimated parameter displacement of the reciprocating compressor in m³/s.

Field: Compressor Clearance Factor

This numeric field contains the Estimated parameter clearance factor of the reciprocating compressor.

Field: Compressor Suction and Discharge Pressure Drop

This numeric field contains the estimated parameter the pressure drop at compressor suction and discharge in Pascals (N/m²).

Field: Superheating

This numeric field contains the estimated parameter superheat at the evaporator outlet in °C.

Field: Constant Part of Electromechanical Power Losses

This numeric field contains the estimated parameter power loss, which accounts for the loss of work due mechanical and electrical losses in the compressor in Watts.

Field: Loss Factor

This numeric field contains the factor of electromechanical loss that is proportional to the theoretical power percentage.

Field: High Pressure Cut Off

This numeric field contains the design pressure limit of the compressor in Pascals (N/m²).

Field: Low Pressure Cut Off

This numeric field contains the design low-pressure limit of the compressor in Pascals (N/m²).

Field: Cycle Time

This numeric field contains the full on and off cycle time of the heat pump unit in Hour.

```

Since the heat pump is defined with two separate objects (one for heating, one for cooling), the connections to the condenser has to be done carefully. The example below shows the configuration for parameter estimation objects. The same specifications and configuration also applies to the equation fit model.

Steps to specify the Ground Source Heat Pump

For the heating mode:

- 1) Specify a branch for the Heat pump in hot water loop .
- 2) Include the branch name in the splitter and mixer branches.
- 3) Add a branch in condenser loop and include its name in the respective splitter and mixer.

```

! in hot water loop
BRANCH, Heating GshpHeating Branch,
,
HeatPump:WatertoWater:ParameterEstimatinon:Heating,
GshpHeating,
GshpHeating LoadSide Inlet Node,
GshpHeating LoadSide Outlet Node,
ACTIVE;

!in condenser loop
BRANCH, GshpHeating SourceSide Branch,
,
HeatPump:WatertoWater:ParameterEstimatinon:Heating,
GshpHeating,
GshpHeating SourceSide Inlet Node,
GshpHeating SourceSide Outlet Node,
ACTIVE;

```

Example of Heat Pump Links

For the cooling mode:

- 1) Specify a branch for the Heat pump in chilled water loop .
- 2) Include the branch name in the splitter and mixer branches.

3) Add a branch in condenser loop and include its name in the respective splitter and mixer.

```

! in chilled water loop

GSHP COOLING Electric Power [W]

GSHP HEATING Electric Power [W]

These output variables represent the compressor power required to run the heat pump. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

GSHP COOLING Electric Consumption [J]

GSHP HEATING Electric Consumption [J]

These output variables represent the cumulative energy used by the compressor. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period.

GSHP COOLING Load Side Heat Transfer Rate [W]***GSHP HEATING Load Side Heat Transfer Rate [W]***

These output variables represent the heat transfer across the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

GSHP COOLING Load Side Heat Transferred [J]***GSHP HEATING Load Side Heat Transferred [J]***

These output variables represent the cumulative heat transfer across the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period.

GSHP COOLING Source Side Heat Transfer Rate [W]***GSHP HEATING Source Side Heat Transfer Rate [W]***

These output variables represent the heat transfer across the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

GSHP COOLING Source Side Heat Transferred [J]***GSHP HEATING Source Side Heat Transferred [J]***

These output variables represent the cumulative heat transfer across the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period.

GSHP COOLING Load Side Outlet Temperature [C]***GSHP HEATING Load Side Outlet Temperature [C]***

These output variables represent the average fluid temperature leaving the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

GSHP COOLING Load Side Inlet Temperature [C]***GSHP HEATING Load Side Inlet Temperature [C]***

These output variables represent the average fluid temperature entering the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

GSHP COOLING Source Side Outlet Temperature [C]***GSHP HEATING Source Side Outlet Temperature °C]***

These output variables represent the average fluid temperature leaving the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

GSHP COOLING Source Side Inlet Temperature [C]***GSHP HEATING Source Side Inlet Temperature [C]***

These output variables represent the average fluid temperature entering the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

GSHP COOLING Load Side Water Mass Flow Rate[kg/s]**GSHP HEATING Load Side Water Mass Flow Rate[kg/s]**

These output variables represent the average fluid flow rate through the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

GSHP COOLING Source Side Water Mass Flow Rate[kg/s]**GSHP HEATING Source Side Water Mass Flow Rate[kg/s]**

These output variables represent the average fluid flow rate through the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

Water to Water Heat Pump Equation Fit Outputs

This section describes the outputs available for the water to water heat pump, equation fit model; both cooling and heating.

```

GSHP Electric Consumption [J]

This output variable represents the cumulative energy used by the compressor. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period.

GSHP Load Side Heat Transferred [J]

This output variable represents the cumulative heat transfer across the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period.

GSHP Source Side Heat Transferred [J]

This output variable represents the cumulative heat transfer across the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period.

GSHP Electric Power [W]

This output variable represents the compressor power required to run the heat pump. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

GSHP Load Side Heat Transfer Rate [W]

This output variable represents the heat transfer across the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

GSHP Source Side Heat Transfer Rate [W]

This output variable represents the heat transfer across the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

GSHP Load Side Outlet Temperature [C]

This output variable represents the average fluid temperature leaving the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

GSHP Load Side Inlet Temperature [C]

This output variable represents the average fluid temperature entering the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

GSHP Source Side Outlet Temperature [C]

This output variable represents the average fluid temperature leaving the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

GSHP Source Side Inlet Temperature [C]

This output variable represents the average fluid temperature entering the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

GSHP Load Side Water Mass Flow Rate [kg/s]

This output variable represents the average fluid flow rate through the load side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

GSHP Source Side Water Mass Flow Rate [kg/s]

This output variable represents the average fluid flow rate through the source side coil. The values are calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

DistrictCooling

When the user is not interested in a plant simulation or there is some centralized source of chilled water, the following object can be used in the input.

```
DistrictCooling,
  A1 , \field Name
      \required-field
  A2 , \field Chilled Water Inlet Node Name
      \required-field
  A3 , \field Chilled Water Outlet Node Name
      \required-field
  N1 ; \field Nominal Capacity
      \required-field
      \units W
      \minimum 0.0
```

Field: Name

This alpha field contains the identifying name for the district cooling (i.e., purchased chilled water).

Field: Chilled Water Inlet Node Name

This alpha field contains the identifying name for the district cooling inlet node.

Field: Chilled Water Outlet Node Name

This alpha field contains the identifying name for the district cooling outlet node.

Field: Nominal Capacity

This numeric field contains the nominal demand (W) that the district cooling will meet.

An example of this statement in an IDF is:

```
DistrictCooling, Purchased Cooling,
  NODE_35,NODE_49,
  68000;
```

DistrictCooling Outputs

```
HVAC,Average, District Chilled Water Rate [W]
HVAC,Sum, District Chilled Water Energy [J]
Zone,Meter, DistrictCooling:Plant [J]
Zone,Meter,Cooling: DistrictCooling [J]

HVAC,Average,District Cooling Rate [W]

HVAC,Average,District Cooling Inlet Temp [C]
HVAC,Average,District Cooling Outlet Temp [C]
HVAC,Average,District Cooling Mass Flow Rate[kg/s]
```

District Chilled Water Rate [W]**District Chilled Water Energy [J]**

These outputs are the energy taken from purchased chilled water. Consumption is metered on Cooling:DistrictCooling, DistrictCooling:Plant, and DistrictCooling:Facility.

District Cooling Rate [W]

This is the useful cooling energy from purchased chilled water. For the current algorithm, this is the same as District Chilled Water Rate.

District Cooling Inlet Temp[C]**District Cooling Outlet Temp[C]****District Cooling Mass Flow Rate[kg/s]**

These outputs are the supply-side plant loop chilled water inlet and outlet temperatures and mass flow rate.

DistrictHeating

When the user is not interested in a plant simulation or there is some centralized source of hot water (district heating), the following object can be used in the input.

```

DistrictHeating,
A1 , \field Name
    \required-field
A2 , \field Hot Water Inlet Node Name
    \required-field
A3 , \field Hot Water Outlet Node Name
    \required-field
N1 ; \field Nominal Capacity
    \required-field
    \units W
    \minimum 0.0

```

Field: Name

This alpha field contains the identifying name for the district heating (i.e., purchased hot water).

Field: Hot Water Inlet Node Name

This alpha field contains the identifying name for the district heating inlet node.

Field: Hot Water Outlet Node Name

This alpha field contains the identifying name for the district heating outlet node.

Field: Nominal Capacity

This numeric field contains the nominal demand (W) that the district heating will meet.

An example of this statement in an IDF is:

```

DistrictHeating,Purchased Heating,
NODE_30,NODE_29,
1000000;

```

DistrictHeating Outputs

```

HVAC,Average,District Hot Water Rate [W]
HVAC,Sum,District Hot Water Energy[J]
Zone,Meter,DistrictHeating:Plant [J]
Zone,Meter,Heating:DistrictHeating [J]

HVAC,Average,District Heating Rate[W]

HVAC,Average,District Heating Inlet Temp[C]
HVAC,Average,District Heating Outlet Temp[C]
HVAC,Average,District Heating Mass Flow Rate[kg/s]

```

District Hot Water Rate [W]**District Hot Water Energy [J]**

These outputs are the energy taken from purchased hot water. Consumption is metered on Heating:DistrictHeating, DistrictHeating:Plant, and DistrictHeating:Facility.

District Heating Rate [W]

This is the useful heating energy from purchased hot water. For the current algorithm, this is the same as Purchased Hot Water Rate.

District Heating Inlet Temp[C]**District Heating Outlet Temp[C]****District Heating Mass Flow Rate[kg/s]**

These outputs are the supply-side plant loop hot water inlet and outlet temperatures and mass flow rate.

Thermal Storage Objects

There are four types of cold thermal storage objects:

- ThermalStorage:Ice:Simple
- ThermalStorage:Ice:Detailed
- ThermalStorage:ChilledWater:Mixed
- ThermalStorage:ChilledWater:Stratified

These objects are typically placed on the supply side of a primary chilled water loop in series or in parallel with one or more chillers. Using the the component set point (PlantEquipmentOperation:ComponentSetpoint) plant operation scheme type, the chiller and storage tank setpoints are used to control operation. Using a SetpointManager:Scheduled object (or other appropriate type of set point manager), the setpoints on the chiller outlet node and the ice storage outlet node can be used to control how the cooling load is shared and when charging of storage occurs. Example setpoints to use for various modes of operation are shown in the table below:

Mode	Chiller Setpoint	Storage Setpoint
Charging ice storage tank	-5C	7C
Cooling with chiller only	7C	99C
Cooling with chiller and storage (fully load chiller before using storage))	7C	7C
Cooling with chiller and storage (chiller carries portion of load, valid if chiller is upstream of storage)	10C	7C

Example files have been developed for three common storage configurations:

- 1) Series – Chiller Upstream: In this configuration, a chiller is placed first on the same branch as the storage unit and both use the **SeriesActive** branch control type.
- 2) Series – Chiller Downstream: In this configuration, a chiller is placed second on the same branch as the storage unit and both use the **SeriesActive** branch control type.
- 3) Parallel: In this configuration, the chiller is on a branch parallel to the storage unit branch when it is not charging. During charging mode, valves will be changed so that the chiller is in series upstream of the storage. To accomplish this in EnergyPlus, the chiller must be modeled using two different chiller objects to represent the same chiller. One chiller object on a parallel branch operates only when storage is not being charged. The other chiller object, in series upstream of the storage unit operates only during charging mode.

Other considerations for applying cold thermal storage objects include:

- In the PlantLoop object, the "Minimum Loop Temperature" must be set equal to or less than the lowest setpoint to be used anywhere in the loop.
- To end the storage charging cycle, use a AvailabilityManager:LowTemperatureTurnOff to shut off the primary chilled water loop when the temperature leaving the storage tank nears the charging mode chiller setpoint indicating that the tank is fully charged. For example, if the chiller is set to provide –5C chilled water during charging, then charging can be shut down when the water temperature leaving the storage unit reaches –4C. When using a primary-secondary loop arrangement, it may be necessary to schedule this availability manager to be active only when the HVAC systems are off to avoid fighting between the demand controls and the availability manager.

ThermalStorage:Ice:Simple

This thermal storage model is based on a simple simulation of an ice storage tank with a fixed capacity. The tank is charged, or frozen, in an ice-on-coil configuration where ice builds up on the outside of the tubes carrying the brine or glycol solution from the chiller. There are two discharge (melt) options, internal or external. Internal melt uses the same fluid tubes for charging and discharging. External melt uses a separate fluid path for discharge such that the outer layers of ice melt first. The ice storage model includes an implied 3-way valve to control the amount of charge/discharge based on the incoming water temperature and the outlet node setpoint temperature. The storage tank is assumed to be fully charged (full of ice) at the beginning of each environment. The tank is then allowed to charge and discharge during the warmup days of the environment. The tank is best controlled using the PlantEquipmentOperation:ComponentSetpoint plant operation scheme, and requires that a setpoint be placed by a set point manager on the ice storage Plant Outlet Node.

The input fields for the object are described in detail below:

Field: Name

This alpha field contains the identifying name for the ice storage tank.

Field: Ice Storage Type

This alpha field specifies the type of ice storage tank to be modeled. There are two options: "IceOnCoilInternal" models ice-on-coil, internal melt. "IceOnCoilExternal" models ice-on-coil, external melt.

Field: Capacity

This numeric field contains the nominal capacity of the ice storage in GJ (Giga is 10^9).

Field: Inlet Node Name

This alpha field specifies the name of the chilled water inlet node.

Field: Outlet Node Name

This alpha field specifies the name of the chilled water outlet node.

Below is the IDD Definition for the object.

```

ThermalStorage:Ice:Simple,
  \min-fields 5

The following outputs are available for THERMAL STORAGE:ICE:SIMPLE:

```

HVAC,Average,Ice Thermal Storage Load Requested [W]
Zone,Average,Ice Thermal Storage End Fraction[Frac]
HVAC,Average,Ice Thermal Storage Water mass flow rate[kg/s]
HVAC,Average,Ice Thermal Storage Water Inlet Temp[C]
HVAC,Average,Ice Thermal Storage Water Outlet Temp[C]
HVAC,Average,Ice Thermal Storage Cooling Rate[W]
HVAC,Sum,Ice Thermal Storage Cooling Energy[J]
HVAC,Average,Ice Thermal Storage Charging Rate[W]
HVAC,Sum,Ice Thermal Storage Charging Energy[J]
    
```

Ice Thermal Storage Load Requested [W]

The load requested by the plant control scheme. A positive value indicates a cooling load or a request to discharge (melt) the tank. A negative value indicates a request to charge (freeze) the tank.

Ice Thermal Storage End Fraction[Frac]

The fraction of full ice storage which is present at the end of the current HVAC timestep. When reported at a frequency less than detailed, this value is averaged over the reporting period.

Ice Thermal Storage Water mass flow rate[kg/s]

The total water mass flow rate through the ice storage component. Because the component includes an implied 3-way valve, this flow may be all through the tank, all bypassed through the valve, or a mixture of both.

Ice Thermal Storage Water Inlet Temp[C]

The water temperature entering the ice storage component.

Ice Thermal Storage Water Outlet Temp[C]

The water temperature leaving the ice storage component.

Ice Thermal Storage Cooling Rate[W]

The rate of cooling delivered by the ice storage component. A positive value indicates the ice tank is discharging (melting). A zero value indicates the tank is charging or dormant.

Ice Thermal Storage Cooling Energy[J]

The cooling energy delivered by the ice storage component. A positive value indicates the ice tank is discharging (melting). A zero value indicates the tank is charging or dormant.

Ice Thermal Storage Charging Rate[W]

The rate of charging delivered to the ice storage component. A positive value indicates the ice tank is charging (freezing). A zero value indicates the tank is discharging or dormant.

Ice Thermal Storage Charging Energy[J]

The charging energy delivered to the ice storage component. A positive value indicates the ice tank is charging (freezing). A zero value indicates the tank is discharging or dormant.

ThermalStorage:Ice:Detailed

The detailed ice storage model allows the users of EnergyPlus to model more closely specific manufacturers' ice storage units. This is possible due to the use of curve fits to simulate the performance of the ice storage unit during charging and discharging. In this implementation, both charging and discharging are a function of the fraction charged/discharged as well as the log mean temperature difference across the storage unit. More information on the model is provided in the Engineering Reference for EnergyPlus. The remainder of this section describes the input required for the detailed ice storage model and the output that it can produce.

Field: Name

This field is the name of the detailed ice storage system given to it by the user.

Field: Availability Schedule Name

This field is the name of the schedule (ref: Schedule) that determines whether or not the ice storage system is available during a particular time period. This allows the system to be turned off during a particular season. A value of less than or equal to zero indicates that the ice storage system is not available. Any value greater than zero indicates that the system is available.

Field: Capacity

This number is the maximum amount of latent thermal storage available in the ice storage system. This model does not allow the removal or addition of sensible energy from the tank. Thus, it is always assumed to be at the freezing temperature of the storage material. The capacity is expressed in units of GJ.

Field: Inlet Node Name

This is the name of the node that connects the ice storage system to the plant loop. It is the inlet node to the ice storage component. The next field defines the outlet node. Due to presence of an internal bypass in this model, there are other “nodes” that are handled internally within the program. Users do not need to define any nodes other than the inlet and outlet nodes.

Field: Outlet Node Name

This is the name of the other node that connects the ice storage system to the plant loop. It is the outlet node to the ice storage component.

Field: Discharging Curve Object Type

The detailed ice storage model in EnergyPlus takes advantage of the Curve feature of the program. Currently, the only allowed curve fit type for the detailed ice storage model is the QuadraticLinear curve. More information on this curve can be found in the section on Curves.

Field: Discharging Curve Name

This field specifies the name of the actual curve fit to be used to model the discharging process of the detailed ice storage system.

Field: Charging Curve Object Type

The detailed ice storage model in EnergyPlus takes advantage of the Curve feature of the program. Currently, the only allowed curve fit type for the detailed ice storage model is the QuadraticLinear curve. More information on this curve can be found in the section on Curves.

Field: Charging Curve Name

This field specifies the name of the actual curve fit to be used to model the charging process of the detailed ice storage system.

Field: Timestep of the Curve Data

This field defines what timestep was used to produce the curve fits named in the previous inputs. This parameter is important because the curve fit is non-dimensional. Thus, the data used to develop the curve fits were based on a specific length of time. In many cases, this is probably one hour or 1.0. The units for this parameter are hours.

Field: Parasitic Electric Load During Discharging

This field defines the amount of parasitic electric consumption (for controls or other miscellaneous electric consumption associate with the ice storage unit itself) during the discharge phase. This parameter is dimensionless and gets multiplied by the current load on the tank.

Field: Parasitic Electric Load During Charging

This field defines the amount of parasitic electric consumption (for controls or other miscellaneous electric consumption associate with the ice storage unit itself) during the charge phase. This parameter is dimensionless and gets multiplied by the current load on the tank.

Field: Tank Loss Coefficient

This field defines the loss of ice stored during a particular hour. This field is dimensionless (per hour). It is not multiplied by any temperature difference between the tank and the environment in which it might be located.

Field: Freezing Temperature of Storage Medium

This parameter defines the freezing/melting temperature of the ice storage medium in degrees Celsius. For most tanks, this is simply 0.0C (the default value). However, some tanks may use other materials or salts which would change the freezing temperature. This can be changed using this parameter.

Detailed Ice Storage Output

Current detailed ice storage output variables are:

System, Average, Detailed Ice Thermal Storage Load Requested [W]
System, Average, Detailed Ice Thermal Storage Fraction Change [Frac]
System, Average, Detailed Ice Thermal Storage End Fraction [Frac]
System, Average, Detailed Ice Thermal Storage Mass Flow Rate [kg/s]
System, Average, Detailed Ice Thermal Storage Bypass Mass Flow Rate [kg/s]
System, Average, Detailed Ice Thermal Storage Tank Mass Flow Rate [kg/s]
System, Average, Detailed Ice Thermal Storage Fluid Inlet Temp [C]
System, Average, Detailed Ice Thermal Storage Blended Outlet Temp [C]
System, Average, Detailed Ice Thermal Storage Tank Outlet Temp [C]
System, Average, Detailed Ice Thermal Storage Cooling/Discharge Rate [W]
System, Sum, Detailed Ice Thermal Storage Cooling/Discharge Energy [J]
System, Average, Detailed Ice Thermal Storage Charging Rate [W]
System, Sum, Detailed Ice Thermal Storage Charging Energy [J]
System, Average, Detailed Ice Thermal Storage Parasitic Electric Power [W]
System, Sum, Detailed Ice Thermal Storage Parasitic Electric Consumption [J]

Detailed Ice Thermal Storage Load Requested [W]

The actual load (absolute value) on the ice storage system during the current timestep

Detailed Ice Thermal Storage Fraction Change [Frac]

The change in the fraction charged during the current timestep (positive for charging, negative for discharging).

Detailed Ice Thermal Storage End Fraction [Frac]

The fraction charge of the ice storage system at the end of the timestep

Detailed Ice Thermal Storage Mass Flow Rate [kg/s]

The mass flow through the ice storage component

Detailed Ice Thermal Storage Bypass Mass Flow Rate [kg/s]

The mass flow through the ice storage component bypass (bypasses the actual unit)

Detailed Ice Thermal Storage Tank Mass Flow Rate [kg/s]

The mass flow through the ice storage unit itself

Detailed Ice Thermal Storage Fluid Inlet Temp [C]

The inlet temperature to the ice storage component

Detailed Ice Thermal Storage Blended Outlet Temp [C]

The outlet temperature of the component after mixing any bypass flow with flow through the ice storage unit

Detailed Ice Thermal Storage Tank Outlet Temp [C]

The outlet temperature of the ice storage unit itself below mixing with any bypass flow

Detailed Ice Thermal Storage Cooling/Discharge Rate [W]

The cooling done (as a rate) by the ice storage unit or its discharge rate

Detailed Ice Thermal Storage Cooling/Discharge Energy [J]

The total cooling done by the ice storage unit or its discharge rate

Detailed Ice Thermal Storage Charging Rate [W]

The charging done (as a rate) to the ice storage unit

Detailed Ice Thermal Storage Charging Energy [J]

The total charging done to the ice storage unit

Detailed Ice Thermal Storage Parasitic Electric Power [W]

The electric power as a result of parasitic loads on the ice storage unit for things like controls or other miscellaneous parts of the ice storage unit itself

Detailed Ice Thermal Storage Parasitic Electric Consumption [J]

The electric consumption as a result of parasitic loads on the ice storage unit for things like controls or other miscellaneous parts of the ice storage unit itself

ThermalStorage:ChilledWater:Mixed

The ThermalStorage:ChilledWater:Mixed object analytically solves the differential equation governing the energy balance of the water tank. The chilled water is “used” by drawing from the “Use Side” of the water tank. The tank is indirectly charged by circulating cold water through the “Source Side” of the water tank.

Control is based on cycling flow through the source side. When the tank temperature rises above a “cut-in” temperature, source side flow is requested. Source side flow will continue until the tank is cooled to below the tank set point or “cut-out” temperature.

For heat gains from the ambient environment, the ambient air temperature can be taken from a schedule, a zone, or the exterior. When used with a zone, the skin gains are removed from the zone heat balance as negative internal heat gains.

Field: Name

The unique name of the ThermalStorage:ChilledWater:Mixed object.

Field: Tank Volume

The volume of the thermal storage tank [m³].

Field: Setpoint Temperature Schedule Name

The reference to the schedule object specifying the chilled water temperature setpoint [°C]. Also known as the “cut-out” temperature.

Field: Deadband Temperature Difference

The delta temperature difference [Δ°C] between the setpoint and the “cut-in” temperature at which the storage tank will request cooling. In other words, the “cut-in” temperature is Setpoint + Deadband.

Field: Minimum Temperature Limit

The temperature [°C] at which the tank water becomes too cold. No source side flow is allowed when the tank temperature is below this limit. The minimum temperature must be lower than the setpoint temperature at all times.

Field: Nominal Cooling Capacity

This field describes the typical cooling capacity that the chilled water tank will provide. Since this is a passive device, the actual cooling capacity depends on water temperatures and flow rates. However, this field is used to describe the chilled water tank’s nominal cooling capacity for supervisory control where plant operation schemes require a cooling capacity to model how equipment is dispatched.

Field: Ambient Temperature Indicator

The Ambient Temperature Indicator specifies how the ambient air temperature will be indicated. The field can be “Schedule”, “Zone”, or “Exterior.” If *Schedule* is used, the Ambient Temperature Schedule Name field provides the values for ambient temperature. If *Zone* is used, the zone air temperature of the zone specified in the Ambient Temperature Zone field provides the ambient temperature. If *Exterior* is used, the outdoor dry-bulb air temperature provides the ambient temperature.

Field: Ambient Temperature Schedule Name

The field contains the name of a schedule object specifying the ambient air temperature around the tank for skin gains. This field is only used if Ambient Temperature Indicator is *Schedule*.

Field: Ambient Temperature Zone Name

The reference to the zone object specifying the ambient air temperature around the tank for skin gains. This field is only used if Ambient Temperature Indicator is *Zone*.

Field: Ambient Temperature Outdoor Air Node Name

This optional alpha field specifies the outdoor air node (OutdoorAir:Node) name used to define the ambient conditions surrounding the chilled water tank. This field is applicable only when the Ambient Temperature Indicator is specified as *Exterior*, otherwise this field should be left blank. The node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air conditions are taken directly from the weather data.

Field: Heat Gain Coefficient from Ambient Temperature

The gain coefficient [W/K] from the ambient air temperature. This coefficient is often referred to as the "UA" for the overall tank thermal performance with respect to heat gains from the tank's skin..

Field: Use Side Inlet Node Name

The inlet node connection to the plant loop for the use side of the chilled water storage tank. Typically the use side draws chilled water from the tank and returns warmer water.

Field: Use Side Outlet Node Name

The outlet node connection to the plant loop for the use side of the chilled water storage tank. Typically the use side chilled water from the tank and returns warmer water.

Field: Use Side Heat Transfer Effectiveness

This field specifies the heat transfer effectiveness between the use side water and the tank water. If the effectiveness is set to 1 then complete heat transfer occurs, simulating perfect mixing of the use side water and the tank water. If the effectiveness is lower, then the use side outlet water temperature will not be as cold as the tank water, simulating a heat exchanger.

Field: Use Side Availability Schedule Name

This field contains the name of an availability schedule for the use side of the water tank. If the schedule's value is 0.0, then the use side is not available and flow will not be requested.

Field: Use Side Design Flow Rate

This field is used to specify the design flow rate through the Use Side of the chilled water tank. The volumetric design flow rate is specified in m³/s. The field can be autosized. If autosized, then the input file should include a Plant Sizing object for the plant loop connected to the Use side. Sizing results are reported in the EIO file.

Field: Source Side Inlet Node Name

The inlet node connection to the plant loop for the source side of the chilled water storage tank. Typically the source side draws somewhat warm water from the tank and returns colder water. The source side volume flow rate is obtained from the plant loop. The magnitude of the flow rates through the source side can be controlled by setting the Maximum Branch Flow Rate field in the BRANCH object that connects the source inlet node.

Field: Source Side Outlet Node Name

The outlet node connection to the plant loop for the source side of the chilled water storage tank. Typically the source side draws somewhat warm water from the tank and returns colder water.

Field: Source Side Heat Transfer Effectiveness

This field specifies the heat transfer effectiveness between the source side water and the tank water. If the effectiveness is set to 1 then complete heat transfer occurs, simulating perfect mixing of the source side water and the tank water. If the effectiveness is lower, then the source side outlet water temperature will not be as cold as the tank water, simulating a heat exchanger.

Field: Source Side Availability Schedule Name

This field contains the name of an availability schedule for the source side of the water tank. If the schedule's value is 0.0, then the source side is not available and flow will not be requested.

Field: Source Side Design Flow Rate

This field is used to specify the design flow rate through the Source Side of the chilled water tank. The volumetric design flow rate is specified in m^3/s . The field can be autosized. If autosized, then the input file should include a Plant Sizing object for the plant loop. Sizing results are reported in the EIO file.

Field: Tank Recovery Time

This field is used to autosize the Source Side Design Flow Rate. The field is used if the previous field is set to autosize and the water tank's source side is on the demand side of a plant loop. This is the time, in hours, that the chilled water tank is to be indirectly cooled from 14.4°C to 9.0°C using the exit temperature of in the associated Plant Sizing object.

The IDD entry for this object follows.

ThermalStorage:ChilledWater:Mixed Outputs

The following output variables are reported for chilled water thermal storage tanks.

Chilled Water Tank Temperature	!- HVAC Average [C]
Chilled Water Final Tank Temperature	!- HVAC Average [C]
Chilled Water Tank Gain Rate	!- HVAC Average [W]
Chilled Water Tank Gain Energy	!- HVAC Sum [J]
Chilled Water Tank Use Flow Rate	!- HVAC Average [kg/s]
Chilled Water Tank Use Inlet Temperature	!- HVAC Average [C]
Chilled Water Tank Use Outlet Temperature	!- HVAC Average [C]
Chilled Water Tank Use Rate	!- HVAC Average [W]
Chilled Water Tank Use Energy	!- HVAC Sum [J]
Chilled Water Tank Source Flow Rate	!- HVAC Average [kg/s]
Chilled Water Tank Source Inlet Temperature	!- HVAC Average [C]
Chilled Water Tank Source Outlet Temperature	!- HVAC Average [C]
Chilled Water Tank Source Rate	!- HVAC Average [W]
Chilled Water Tank Source Energy	!- HVAC Sum [J]

Chilled Water Tank Temperature [C]

The average water tank temperature.

Chilled Water Tank Final Temperature [C]

The final water tank temperature at the end of the system timestep. If reported at the "Detailed" interval, this report variable can be used to verify an exact energy balance on the water storage tank.

Chilled Water Tank Gain Rate [W]

The average heat exchange rate to the storage tank from the surrounding ambient. This is usually positive with surrounding ambient heating the storage tank.

Chilled Water Tank Gain Energy [J]

The energy exchange to the storage tank from the surrounding ambient. This is usually positive with surrounding ambient heating the storage tank.

Chilled Water Tank Use Flow Rate [kg/s]

The use side mass flow rate.

Chilled Water Tank Use Inlet Temperature [C]

The inlet temperature on the use side.

Chilled Water Tank Use Outlet Temperature [C]

The outlet temperature on the use side.

Chilled Water Tank Use Rate [W]

The average heat transfer rate between the use side water and the tank water.

Chilled Water Tank Use Energy [J]

The heat transfer energy between the use side water and the tank water.

Chilled Water Tank Source Flow Rate [kg/s]

The source side mass flow rate.

Chilled Water Tank Source Inlet Temperature [C]

The inlet temperature on the source side.

Chilled Water Tank Source Outlet Temperature [C]

The outlet temperature on the source side.

Chilled Water Tank Source Rate [W]

The average heat transfer rate between the source side water and the tank water.

Chilled Water Tank Source Energy [J]

The heat transfer energy between the source side water and the tank water.

ThermalStorage:ChilledWater:Stratified

The ThermalStorage:ChilledWater:Stratified object divides the water tank into multiple nodes of equal volume. The nodes are coupled by vertical conduction effects, internode fluid flow, and temperature inversion mixing. The object simultaneously solves the differential equations governing the energy balances on the nodes using a numerical method. The system timestep is divided into many small substeps that allow the simulation to capture events that occur on a very short time scale. The chilled water is "used" by drawing from the "Use Side" of the

water tank. The tank is indirectly charged by circulating cold water through the “Source Side” of the water tank.

Control is based on cycling flow through the source side. When the tank temperature rises above a “cut-in” temperature, source side flow is requested. Source side flow will continue until the tank is cooled to below the tank set point or “cut-out” temperature.

For heat gains from the ambient environment, the ambient air temperature can be taken from a schedule, a zone, or the exterior. When used with a zone, the skin gains are removed from the zone heat balance as negative internal heat gains.

Field: Name

The unique name of the ThermalStorage:ChilledWater:Stratified object.

Field: Tank Volume

The volume of the thermal storage tank [m³].

Field: Tank Height

The height [m] of the tank. For the HorizontalCylinder shape (see below) the height of the tank is the measure in the axial direction, i.e., the height if you were to stand the cylinder up on its end.

Field: Tank Shape

The tank shape determines the size and skin losses of the stratified nodes. There are three options: “VerticalCylinder,” “HorizontalCylinder,” and “Other.”

VerticalCylinder describes most upright cylindrical water tanks.

HorizontalCylinder describes a few specialty water tanks and some large commercial storage tanks. *HorizontalCylinder* implies that the tank is divided into nodes of equal mass, but not equal height.

Other describes water storage tanks that have a uniform horizontal cross-section, but are not cylinders, e.g., a cuboid or other shape. The length of the perimeter is then specified by the Tank Perimeter field.

If blank, the default shape is *VerticalCylinder*.

Field: Tank Perimeter

The length of the tank perimeter [m]. This field is only used if Tank Shape is *Other*.

Field: Setpoint Temperature Schedule Name

The reference to the schedule object specifying the chilled water temperature setpoint [°C]. Also known as the “cut-out” temperature.

Field: Deadband Temperature Difference

The delta temperature difference [Δ°C] between the setpoint and the “cut-in” temperature at which the storage tank will request cooling. In other words, the “cut-in” temperature is Setpoint + Deadband.

Field: Temperature Sensor Height

This field is used to describe the location in the tank where the temperature is sensed for control decisions. The program will associate one of the nodes with this height and use that node’s temperature for control decisions. The location is described in meters from the bottom of the tank.

Field: Minimum Temperature Limit

The temperature [°C] at which the tank water becomes too cold. No source side flow is allowed when the tank temperature is below this limit. The minimum temperature must be lower than the setpoint temperature at all times.

Field: Nominal Cooling Capacity

This field describes the typical cooling capacity that the chilled water tank will provide. Since this is a passive device, the actual cooling capacity depends on water temperatures and flow rates. However, this field is used to describe the chilled water tank's nominal cooling capacity for supervisory control where plant operation schemes require a cooling capacity to model how equipment is dispatched.

Field: Ambient Temperature Indicator

The Ambient Temperature Indicator specifies how the ambient air temperature will be indicated. The field can be "Schedule", "Zone", or "Exterior." If *Schedule* is used, the Ambient Temperature Schedule Name field provides the values for ambient temperature. If *Zone* is used, the zone air temperature of the zone specified in the Ambient Temperature Zone field provides the ambient temperature. If *Exterior* is used, the outdoor dry-bulb air temperature provides the ambient temperature.

Field: Ambient Temperature Schedule Name

The field contains the name of a schedule object specifying the ambient air temperature around the tank for skin gains. This field is only used if Ambient Temperature Indicator is *Schedule*.

Field: Ambient Temperature Zone Name

The reference to the zone object specifying the ambient air temperature around the tank for skin gains. This field is only used if Ambient Temperature Indicator is *Zone*.

Field: Ambient Temperature Outside Air Node Name

This optional alpha field specifies the outdoor air node name used to define the ambient conditions surrounding the chilled water tank. This field is applicable only when the Ambient Temperature Indicator is specified as *Exterior*, otherwise this field should be left blank. The node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air conditions are taken directly from the weather data.

Field: Uniform Skin Loss Coefficient per Unit Area to Ambient Temperature

The uniform skin loss coefficient [W/m^2-K] or U-Value of the tank to the ambient air temperature. The uniform skin loss accounts for the tank insulation. The overall losses at any particular tank node can be further modified using the Additional Loss Coefficient fields to account for thermal shorting due to pipe penetrations, tank feet, and any other loss effects.

Field: Use Side Inlet Node Name

The inlet node connection to the plant loop for the use side of the chilled water storage tank. Typically the use side draws chilled water from the tank and returns warmer water.

Field: Use Side Outlet Node Name

The outlet node connection to the plant loop for the use side of the chilled water storage tank. Typically the use side chilled water from the tank and returns warmer water.

Field: Use Side Heat Transfer Effectiveness

This field specifies the heat transfer effectiveness between the use side water and the tank water. If the effectiveness is set to 1 then complete heat transfer occurs, simulating perfect mixing of the use side water and the tank water. If the effectiveness is lower, then the use side outlet water temperature will not be as cold as the tank water, simulating a heat exchanger.

Field: Use Side Availability Schedule Name

This field contains the name of an availability schedule for the use side of the water tank. If the schedule's value is 0.0, then the use side is not available and flow will not be requested.

Field: Use Side Inlet Height

The height of the use side inlet to the tank. If blank, the inlet defaults to the top of the tank. The inlet height cannot be higher than the tank height.

Field: Use Side Outlet Height

The height of the use side outlet from the tank. If blank or **autocalculate**, the inlet defaults to the bottom of the tank. The outlet height cannot be higher than the tank height.

Field: Use Side Design Flow Rate

This field is used to specify the design flow rate through the Use Side of the water tank. The volumetric design flow rate is specified in m^3/s . The field is needed when the Use Side is connected to a plant loop. The field can be autosized. If autosized, then the input file should include a Plant Sizing object for the plant loop. Sizing results are reported in the EIO file.

Field: Source Side Inlet Node Name

The inlet node connection to the plant loop for the source side of the chilled water storage tank. Typically the source side draws somewhat warm water from the tank and returns colder water. The source side volume flow rate is obtained from the plant loop. The magnitude of the flow rates through the source side can be controlled by setting the Maximum Branch Flow Rate field in the BRANCH object that connects the source inlet node.

Field: Source Side Outlet Node Name

The outlet node connection to the plant loop for the source side of the chilled water storage tank. Typically the source side draws somewhat warm water from the tank and returns colder water.

Field: Source Side Heat Transfer Effectiveness

This field specifies the heat transfer effectiveness between the source side water and the tank water. If the effectiveness is set to 1 then complete heat transfer occurs, simulating perfect mixing of the source side water and the tank water. If the effectiveness is lower, then the source side outlet water temperature will not be as cold as the tank water, simulating a heat exchanger.

Field: Source Side Availability Schedule Name

This field contains the name of an availability schedule for the source side of the water tank. If the schedule's value is 0.0, then the source side is not available and flow will not be requested.

Field: Source Side Inlet Height

The height of the source side inlet to the tank. If blank or **autocalculate**, the inlet defaults to the bottom of the tank. The inlet height cannot be higher than the tank height.

Field: Source Side Outlet Height

The height of the source side outlet from the tank. If blank, the inlet defaults to the top of the tank. The outlet height cannot be higher than the tank height.

Field: Source Side Design Flow Rate

This field is optional and is used to specify the design flow rate through the Source Side of the water heater. The volumetric design flow rate is specified in m^3/s . The field is needed when the Source Side is connected to a plant loop. The field can be autosized. If autosized,

then the input file should include a Plant Sizing object for the plant loop. Sizing results are reported in the EIO file.

Field: Tank Recovery Time

This field is used to autosize the Source Side Design Flow Rate. The field is used if the previous field is set to autosize and the water tank's source side is on the demand side of a plant loop. This is the time, in hours, that the chilled water tank is to be indirectly cooled from 14.4C to 9.0C using the exit temperature of in the associated Plant Sizing object.

Field: Inlet Mode

The inlet mode of entering fluid from the use and source sides. There are two options: "Fixed" or "Seeking." In *Fixed* mode, the fluid enters at the fixed heights specified above. In *Seeking* mode, the fluid "seeks out" the stratified node that is closest to the inlet temperature and adds all flow to that node. The *Seeking* mode provides maximum stratification.

Field: Number of Nodes

The number of stratified nodes in the tank. There must be at least one node. The maximum number of nodes is 10, although this limit can be increased by editing the IDD.

Field: Additional Destratification Conductivity

An additional destratification conductivity [W/m-K] is added to the fluid conductivity of water (0.6 W/m-K) to account for vertical conduction effects along the inside of the tank wall, and perhaps other vertical components such as a dip tube pipe or anode rod.

Field: Node 1-10 Additional Loss Coefficient

An additional heat gain coefficient [W/m-K] added to the skin gains for a given node to account for thermal shorting due to pipe penetrations, tank feet, and any other loss effects.

ThermalStorage:ChilledWater:Stratified Outputs

The following output variables are reported for stratified chilled water thermal storage tanks.

Chilled Water Tank Temperature	!- HVAC Average [C]
Chilled Water Final Tank Temperature	!- HVAC Average [C]
Chilled Water Tank Gain Rate	!- HVAC Average [W]
Chilled Water Tank Gain Energy	!- HVAC Sum [J]
Chilled Water Tank Use Flow Rate	!- HVAC Average [kg/s]
Chilled Water Tank Use Inlet Temperature	!- HVAC Average [C]
Chilled Water Tank Use Outlet Temperature	!- HVAC Average [C]
Chilled Water Tank Use Rate	!- HVAC Average [W]
Chilled Water Tank Use Energy	!- HVAC Sum [J]
Chilled Water Tank Source Flow Rate	!- HVAC Average [kg/s]
Chilled Water Tank Source Inlet Temperature	!- HVAC Average [C]
Chilled Water Tank Source Outlet Temperature	!- HVAC Average [C]
Chilled Water Tank Source Rate	!- HVAC Average [W]
Chilled Water Tank Source Energy	!- HVAC Sum [J]
Chilled Water Tank Node <x> Temperature	!- HVAC Average [C]
Chilled Water Tank Final Node <x> Temperature	!- HVAC Average [C]

Chilled Water Tank Temperature [C]

The average water tank temperature, i.e., the average of all of the node average temperatures.

Chilled Water Tank Final Temperature [C]

The final water tank temperature at the end of the system timestep, i.e., the average of all of the final node temperatures at the end of the system timestep. If reported at the "Detailed" interval, this report variable can be used to verify an exact energy balance on the water storage tank.

Chilled Water Tank Gain Rate [W]

The average heat exchange rate to the storage tank from the surrounding ambient. This is usually positive with surrounding ambient heating the storage tank.

Chilled Water Tank Gain Energy [J]

The energy exchange to the storage tank from the surrounding ambient. This is usually positive with surrounding ambient heating the storage tank.

Chilled Water Tank Use Flow Rate [kg/s]

The use side mass flow rate.

Chilled Water Tank Use Inlet Temperature [C]

The inlet temperature on the use side.

Chilled Water Tank Use Outlet Temperature [C]

The outlet temperature on the use side.

Chilled Water Tank Use Rate [W]

The average heat transfer rate between the use side water and the tank water.

Chilled Water Tank Use Energy [J]

The heat transfer energy between the use side water and the tank water.

Chilled Water Tank Source Flow Rate [kg/s]

The source side mass flow rate.

Chilled Water Tank Source Inlet Temperature [C]

The inlet temperature on the source side.

Chilled Water Tank Source Outlet Temperature [C]

The outlet temperature on the source side.

Chilled Water Tank Source Rate [W]

The average heat transfer rate between the source side water and the tank water.

Chilled Water Tank Source Energy [J]

The heat transfer energy between the source side water and the tank water.

Water Heater Node 1-10 Temperature [C]

The average node temperature.

Water Heater Final Node 1-10 Temperature [C]

The final node temperature at the end of the system timestep.

Group – Water Heaters

Water heater objects are components for storing and heating water. They can be coupled to a plant loop simulation or used stand-alone. Typical water heater applications are for domestic hot water heating, low-temperature radiant space heating, and energy storage for solar hot water systems or waste heat recovery.

When coupled to the plant loop, the water heater has an inlet node and outlet node on the "source side" and an inlet node and outlet node on the "use side". The source side typically draws cold water from the tank and returns warmer water, for instance, from solar hot water systems or waste heat recovery systems. The use side typically draws hot water from the tank and returns cooler water from the cold water supply mains or from the outlet of a heating system. The distinction between source and use sides is merely a convenience for reporting. They can actually be used interchangeably. If so desired, either source side or use side can be used by itself, without the other side being connected to the plant loop.

However, for a water heater that is indirectly heated (e.g. with a separate boiler), the source side can be used to provide remotely heated water to the tank. The source side is configured to operate as a component on the demand side of a plant loop. The design flow rate through the source side can be set by the user or autosized. If autosized, then a Plant Sizing object is needed elsewhere in the input file for the Plant Loop serving the source side. The water heater input includes an additional design parameter that describes how rapidly the tank can recover. The water heaters's Source Side should be on a BRANCH object that is set to "ACTIVE" so that it can request heat from the remote boiler when needed.

Figure 66. Water Heater Configuration

If the use side only consists of domestic hot water usage, a simple scheduled use flow rate can be specified in lieu of the full plant loop connections. The scheduled use flow rate can be used simultaneously with source side plant connections, but cannot be used with use side plant connections.

For stand-alone operation, there are no node connections to the plant loop on either source or use sides. The scheduled use flow rate determines all fluid exchange with the water tank.

There are currently two water heater objects in EnergyPlus:

- WaterHeater:Mixed
- WaterHeater:Stratified

There is also a compound object that uses the WaterHeater:Mixed as part of its strategy:

- WaterHeater:HeatPump

The WaterHeater:Mixed object simulates a well-mixed, single-node water tank. The WaterHeater:Stratified object simulates a stratified, multi-node water tank. Both water heater objects can be appropriate for simulating many types of water heaters and storage tanks, including gas and electric residential water heaters, and a variety of large commercial water heaters. Both objects share similar features, such as stand-alone operation, on- and off-cycle parasitic loads, and thermal losses to the zone. However, each object has its advantages which may make one water heater object more appropriate than the other depending on the application.

Advantages of **WaterHeater:Mixed**:

- can simulate instantaneous/tankless water heaters
- requires less input than the stratified tank
- faster execution time than the stratified tank
- adequate for modeling gas water heaters with no source connections.

Advantages of **WaterHeater:Stratified**:

- better modeling of electric water heaters with two heating elements
- better modeling of thermal storage applications which rely on stratification to improve heat transfer performance.

Standard Ratings

The EIO file reports the industry standard ratings of Recovery Efficiency and Energy Factor for water heater objects. The rating method is based on the GAMA and 10CFR430 test

procedures. Under certain input parameters, the rating method will not succeed and a warning message will be generated. Problems occur when inputs do not allow the tank to recover to the setpoint temperature within the test period. This can occur if the maximum heater capacity is undersized, or if the deadband temperature difference is large enough that the first draw of the test does not trigger the heater to come on. In either case, the Recovery Efficiency test will not compute properly because recovery to the setpoint was not achieved.

Standard ratings for storage-only water tanks (Heater Maximum Capacity = 0) cannot be calculated and do not report anything in the EIO file.

Water Heater:Mixed

The WaterHeater:Mixed object analytically solves the differential equation governing the energy balance of the water tank. Within a timestep, conditions are solved separately for when the heater element or burner is "on" (on-cycle) and when it is "off" (off-cycle). This approach allows ambient losses and parasitic loads to be divided into on-cycle and off-cycle effects and accounted for in detail.

For losses to the ambient environment, the ambient air temperature can be taken from a schedule, a zone, or the exterior. When used with a zone, a fraction of the skin losses can be added to the zone heat balance as internal heat gains.

Control options allow the heater to cycle or modulate to meet the load. When cycling, the heater element or burner is either on or off. The heater remains fully on while heating the tank up to the setpoint temperature. When the setpoint is reached, the heater turns off. The heater remains off until the tank temperature falls below the "cut-in" temperature, i.e., the setpoint temperature minus the deadband temperature difference. The heater continuously cycles on and off to maintain the tank temperature within the deadband. Most storage-tank water heaters cycle.

When modulating, the heater power varies between the maximum and minimum heater capacities. The heater stays on as long as the required total demand is above the minimum capacity. Below the minimum capacity, the heater will begin to cycle on and off based on the deadband temperature difference. Equipment is usually designed and rated to avoid this condition. Most tankless/instantaneous water heaters modulate.

```

Field: Name

The name of the WaterHeater:Mixed object.

Field: Tank Volume

The volume of the storage tank [m³]. This field is autosizable if used with a Water Heater:Sizing object. Although this field is allowed to go down to zero, even so-called "tankless" water heaters have some volume of water that is maintained around the heating elements or in the heat exchanger, typically around 0.00379 m³ (1 gallon).

Field: Setpoint Temperature Schedule Name

The reference to the schedule object specifying the hot water temperature setpoint [°C]. Also known as the "cut-out" temperature.

Field: Deadband Temperature Difference

The delta temperature difference [Δ°C] between the setpoint and the "cut-in" temperature at which the heater will turn on. In other words, the "cut-in" temperature is Setpoint – Deadband.

Field: Maximum Temperature Limit

The temperature [°C] at which the tank water becomes dangerously hot and is vented through boiling or an automatic safety. The tank temperature will never exceed the maximum. Any extra heat added to the tank is immediately vented. Note: The maximum temperature must be greater than the setpoint temperature at all times.

Field: Heater Control Type

The control type can be **Cycle** or **Modulate**. Cycle is appropriate for most storage tank-type water heaters. Modulate is appropriate for most instantaneous/tankless water heaters.

Field: Heater Maximum Capacity

The maximum heat rate [W] that can be supplied to the water, probably the same as the "nominal" capacity. This field is autosizable if used with a Water Heater:Sizing object.

Field: Heater Minimum Capacity

The minimum heat rate [W] that can be supplied to the water. This field is only used when the Heater Control Type is **Modulate**. If the total demand rate for heating is less than the minimum, even a modulating water heater will begin to cycle.

Field: Heater Ignition Minimum Flow Rate

NOT YET IMPLEMENTED.

Field: Heater Ignition Delay

NOT YET IMPLEMENTED.

Field: Heater Fuel Type

The type of fuel used for heating. The fuel type can be Electricity, NaturalGas, PropaneGas, FuelOil#1, FuelOil#2, Coal, Diesel, Gasoline, Steam, or DistrictHeating.

Field: Heater Thermal Efficiency

The thermal conversion efficiency from fuel energy to heat energy for the heater element or burner. This is not the same as the overall efficiency of the water heater.

Field: Part Load Factor Curve Name

The reference to the curve object that relates the overall efficiency of the water heater to the Runtime Fraction (if Control Type **Cycle**) or Part Load Ratio (if Control Type **Modulate**). This is an additional multiplier applied to the Heater Thermal Efficiency to compute fuel energy use. The Part Load Factor Curve should not have a value less than 0.1 in the domain from 0 to 1. If the Part Load Factor Curve accounts for ambient losses and/or parasitic fuel consumption, these effects should not also be input into the related fields in this object as that would result in double-counting.

Field: Off-Cycle Parasitic Fuel Consumption Rate

Off-cycle parasitics include parts of the water heater that consume fuel when the heater is off, for example, a pilot light, or stand-by electronic control circuits. The fuel consumption rate [W] is strictly the total fuel that is consumed by all of the off-cycle parasitics.

Field: Off-Cycle Parasitic Fuel Type

The type of fuel used by the off-cycle parasitics. The fuel type can be Electricity, NaturalGas, PropaneGas, FuelOil#1, FuelOil#2, Coal, Diesel, Gasoline, Steam, or DistrictHeating. The fuel type can be the same or different from the Heater Fuel Type.

Field: Off-Cycle Parasitic Heat Fraction to Tank

The fraction of off-cycle parasitic fuel energy that is converted to heat energy that ends up in the tank water. For example, a pilot light would deliver most of its heat to the tank water, as long as the thermal conversion efficiency must be taken into account, so perhaps 0.80 is reasonable. Electronic control circuits, on the other hand, do not add any heat to the tank and should be 0.

Field: On-Cycle Parasitic Fuel Consumption Rate

On-cycle parasitics include parts of the water heater that consume fuel when the heater is on, for example, an induction fan, or stand-by electronic control circuits. The fuel consumption rate [W] is strictly the total fuel that is consumed by all of the on-cycle parasitics.

Field: On-Cycle Parasitic Fuel Type

The type of fuel used by the on-cycle parasitics. The fuel type can be Electricity, NaturalGas, PropaneGas, FuelOil#1, FuelOil#2, Coal, Diesel, Gasoline, Steam, or DistrictHeating. The fuel type can be the same or different from the Heater Fuel Type.

Field: On-Cycle Parasitic Heat Fraction to Tank

The fraction of on-cycle parasitic fuel energy that is converted to heat energy that ends up in the tank water. For example, an induction fan might (maybe) deliver a small fraction of its energy to the tank water for a value of 0.05. Electronic control circuits, on the other hand, do not add any heat to the tank and should be 0.

Field: Ambient Temperature Indicator

The Ambient Temperature Indicator specifies how the ambient air temperature will be indicated. The field can be **Schedule**, **Zone**, or **Outdoors**. If Schedule is used, the Ambient Temperature Schedule field provides the ambient temperature. If ZONE is used, the zone air temperature of the zone specified in the Ambient Temperature Zone field provides the ambient temperature. If EXTERIOR is used, the outdoor dry-bulb air temperature provides the ambient temperature.

Field: Ambient Temperature Schedule Name

The reference to the schedule object specifying the ambient air temperature around the tank for skin losses. This field is only used if Ambient Temperature Indicator is **Schedule**.

Field: Ambient Temperature Zone Name

The reference to the zone object specifying the ambient air temperature around the tank for skin losses. This field is only used if Ambient Temperature Indicator is **Zone**.

Field: Ambient Temperature Outdoor Air Node Name

This optional alpha field specifies the outdoor air node name used to define the ambient conditions surrounding the water heater tank. This field is applicable only when the Ambient Temperature Indicator is specified as OutdoorAir:Node, otherwise this field should be left blank. The node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air conditions are taken directly from the weather data.

Field: Off-Cycle Loss Coefficient to Ambient Temperature

The loss coefficient [W/K] to the ambient air temperature. Often this coefficient is identical to the "UA" for skin losses. However, it can also be used to model the loss effects of the flue in a combustion water heater, in addition to the skin losses.

Field: Off-Cycle Loss Fraction to Zone

If the Ambient Temperature Indicator is **Zone**, this field adds the specified fraction of the off-cycle losses to the zone heat balance as an internal gain.

Field: On-Cycle Loss Coefficient to Ambient Temperature

The loss coefficient [W/K] to the ambient air temperature. Often this coefficient is identical to the "UA" for skin losses. If the loss effects of the flue are being modeled in the Off-Cycle Loss Coefficient, then this field would have a different value accounting only for the skin losses.

Field: On-Cycle Loss Fraction to Zone

If the Ambient Temperature Indicator is **Zone**, this field adds the specified fraction of the on-cycle losses to the zone heat balance as an internal gain.

Field: Peak Use Flow Rate

The peak flow rate [m³/s] of domestic hot water usage for stand-alone operation, i.e., without plant loop node connections. The peak value is multiplied by the Use Flow Rate Fraction Schedule. If there are node connections, this field is not used.

Field: Use Flow Rate Fraction Schedule Name

The reference to the schedule object specifying the current fraction of Peak Volumetric Use Flow Rate of domestic hot water usage for stand-alone operation.

Field: Cold Water Supply Temperature Schedule Name

The reference to the schedule object specifying the cold water temperature [°C] from the supply mains that makes up for the hot water lost down the drain. If blank, water temperatures are calculated by the Site:WaterMainsTemperature object. This field is for stand-alone operation only. If there are node connections, this field is not used.

Field: Use Side Inlet Node Name

The inlet node connection to the plant loop for the use side of the water heater. Typically the use side draws hot water from the tank and returns cooler water.

Field: Use Side Outlet Node Name

The outlet node connection to the plant loop for the use side of the water heater. Typically the use side draws hot water from the tank and returns cooler water.

Field: Use Side Effectiveness

This field specifies the heat transfer effectiveness between the use side water and the tank water. If the effectiveness is set to 1 then complete heat transfer occurs, simulating perfect mixing of the use side water and the tank water. If the effectiveness is lower, then the use side outlet water temperature will not be as hot as the tank water, simulating a heat exchanger.

Field: Source Side Inlet Node Name

The inlet node connection to the plant loop for the source side of the water heater. Typically the source side draws cold water from the tank and returns warmer water. The source side volume flow rate is obtained from the plant loop. The magnitude of the flow rates through the source side can be controlled by setting the Maximum Branch Flow Rate field in the **Branch** object that connects the source inlet node.

Field: Source Side Outlet Node Name

The outlet node connection to the plant loop for the source side of the water heater. Typically the source side draws cold water from the tank and returns warmer water.

Field: Source Side Effectiveness

This field specifies the heat transfer effectiveness between the source side water and the tank water. If the effectiveness is set to 1 then complete heat transfer occurs, simulating perfect mixing of the source side water and the tank water. If the effectiveness is lower, then the source side outlet water temperature will not be as hot as the tank water, simulating a heat exchanger.

Field: Use Side Design Flow Rate

This field is optional and is used to specify the design flow rate through the Use Side of the water heater. The volumetric design flow rate is specified in m^3/s . The field is needed when the Use Side is connected to a plant loop. The field can be autosized. If autosized, then the input file should include a Plant Sizing object for the plant loop. Sizing results are reported in the EIO file.

Field: Source Side Design Flow Rate

This field is optional and is used to specify the design flow rate through the Source Side of the water heater. The volumetric design flow rate is specified in m^3/s . The field is needed when the Source Side is connected to a plant loop. The field can be autosized. If autosized, then the input file should include a Plant Sizing object for the plant loop. Sizing results are reported in the EIO file.

Field: Indirect Water Heating Recovery Time

This field is optional and is used to provide a design parameter for autosizing design flow rates when the water heater is connected to the demand side of a plant loop. The recovery time is expressed in hours. This is the time that the entire volume of the tank can be heated from 14.4°C to 57.2°C (58°F to 135°F) with an inlet temperature defined as the exit temperature in the associated Plant Sizing object. The default is 1.5 hours. The calculation is based on log-mean temperature difference (LMTD) and includes the heat transfer effectiveness factor entered above.

Water Heater Tank Temperature [C]

The average water tank temperature.

Water Heater Final Tank Temperature [C]

The final water tank temperature at the end of the system timestep. If reported at the "Detailed" interval, this report variable can be used to verify an exact energy balance on the water heater. Also see the report variable: Water Heater Net Heat Transfer Energy.

Water Heater Loss Rate [W]

The average heat loss rate due to the off- and on-cycle loss coefficients to the ambient temperature.

Water Heater Loss Energy [J]

The heat loss energy due to the off- and on-cycle loss coefficients to the ambient temperature.

Water Heater Use Flow Rate [kg/s]

The use side mass flow rate. If stand-alone, this is the scheduled use flow rate.

Water Heater Use Inlet Temperature [C]

The inlet temperature on the use side.

Water Heater Use Outlet Temperature [C]

The outlet temperature on the use side.

Water Heater Use Rate [W]

The average heat transfer rate between the use side water and the tank water.

Water Heater Use Energy [J]

The heat transfer energy between the use side water and the tank water.

Water Heater Source Flow Rate [kg/s]

The source side mass flow rate. If in stand-alone operation, this is 0.

Water Heater Source Inlet Temperature [C]

The inlet temperature on the source side.

Water Heater Source Outlet Temperature [C]

The outlet temperature on the source side.

Water Heater Source Rate [W]

The average heat transfer rate between the source side water and the tank water.

Water Heater Source Energy [J]

The heat transfer energy between the source side water and the tank water.

Water Heater Off-Cycle Parasitic Heat Rate To Tank [W]

The average heat gain rate to the tank water due to off-cycle parasitics.

Water Heater Off-Cycle Parasitic Heat Energy To Tank [J]

The heat gain energy to the tank water due to off-cycle parasitics.

Water Heater On-Cycle Parasitic Heat Rate To Tank [W]

The average heat gain rate to the tank water due to on-cycle parasitics.

Water Heater On-Cycle Parasitic Heat Energy To Tank [J]

The heat gain energy to the tank water due to on-cycle parasitics.

Water Heater Total Demand Rate [W]

The average heating rate demanded to maintain the setpoint temperature.

Water Heater Total Demand Energy [J]

The heating energy demanded to maintain the setpoint temperature.

Water Heater Heating Rate [W]

The average heating rate supplied by the heater element or burner.

Water Heater Heating Energy [J]

The heating energy supplied by the heater element or burner.

Water Heater Unmet Demand Rate [W]

The average heating rate unmet by the heater element or burner. The difference between the Total Demand Rate and the Heating Rate.

Water Heater Unmet Demand Energy [J]

The heating energy unmet by the heater element or burner. The difference between the Total Demand Energy and the Heating Energy.

Water Heater Venting Rate [W]

The average venting rate to keep the tank below the Maximum Temperature Limit.

Water Heater Venting Energy [J]

The venting energy to keep the tank below the Maximum Temperature Limit.

Water Heater Net Heat Transfer Rate [W]

The average net heat transfer rate when considering all losses and gains.

Water Heater Net Heat Transfer Energy [J]

The net heat transfer energy when considering all losses and gains.

Water Heater Cycle On Count []

The number of times that the heater turned on in the time period.

Water Heater Runtime Fraction []

The fraction of the time period that the heater was running.

Water Heater Part Load Ratio []

The fraction of the Heater Maximum Capacity.

Water Heater <Fuel Type> Consumption Rate [W]

The average fuel consumption rate for the heater element or burner.

Water Heater <Fuel Type> Consumption Energy [J]

The fuel consumption energy for the heater element or burner.

Water Heater Off-Cycle <Fuel Type> Consumption Rate [W]

The average fuel consumption rate for the off-cycle parasitics.

Water Heater Off-Cycle <Fuel Type> Consumption Energy [J]

The fuel consumption energy for the off-cycle parasitics.

Water Heater On-Cycle <Fuel Type> Consumption Rate [W]

The average fuel consumption rate for the on-cycle parasitics.

Water Heater On-Cycle <Fuel Type> Consumption Energy [J]

The fuel consumption energy for the on-cycle parasitics.

Water Heater Water Consumption Rate [m³/s]

The water consumption rate for the use side, if in stand-alone operation.

Water Heater Water Consumption [m³]

The water consumption for the use side, if in stand-alone operation.

Water Heater:Stratified

The WaterHeater:Stratified object divides the water tank into multiple nodes of equal volume. The nodes are coupled by vertical conduction effects, internode fluid flow, and temperature inversion mixing. The object simultaneously solves the differential equations governing the energy balances on the nodes using a numerical method. The system timestep is divided into many small substeps that allow the simulation to capture events that occur on a very short time scale. This approach allows ambient losses and parasitic loads to be divided into on-cycle and off-cycle effects and accounted for in detail.

For losses to the ambient environment, the ambient air temperature can be taken from a schedule, a zone, or the exterior. When used with a zone, a fraction of the skin losses can be added to the zone heat balance as internal heat gains.

The WaterHeater:Stratified object allows two heating elements to be simulated. The two elements can cycle on and off to maintain the node temperature within the deadband. The Heater Priority Control field determines how the heaters work together. There are two options: MasterSlave or Simultaneous. In the MasterSlave option, Heater 1 is the master and Heater 2 is the slave. That is, both heaters are not allowed to turn on at the same time. If the thermostats ask for heat at both Heater 1 and 2, only Heater 1 will turn on. Once Heater 1 has met the set point, it turns off and Heater 2 can turn on, if necessary. In the Simultaneous option, Heater 1 and Heater 2 can turn on and off independently. Autosizing is available for only Heater 1.

Field: Name

The name of the WaterHeater:Stratified object.

Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Laundry", "Dish Washing", etc. A new meter for reporting is created for each unique subcategory (ref: Report Meter). Subcategories are also reported in the ABUPS table under the "Water Systems" end-use category. If this field is omitted or blank, the water use will be assigned to the "General" end-use subcategory.

Field: Tank Volume

The actual volume [m3] of fluid in the tank. This field is autosizable if used with a Water Heater:Sizing object. The actual volume is typically not equal to the nominal volume specified by the manufacturer. Actual volume is almost always 10% lower for electric water heaters, and 5% lower for gas water heaters (Burch and Erickson 2004).

Burch, J., and P. Erickson. 2004. "Using Ratings Data to Derive Simulation-Model Inputs for Storage-Tank Water Heaters". *Proceedings of the Solar 2004 Conference, 11-14 July 2004, Portland, Oregon*, American Solar Energy Society (ASES), pp. 393-398.

Field: Tank Height

The height [m] of the tank. For the **HorizontalCylinder** shape (see below) the height of the tank is the measure in the axial direction, i.e., the height if you were to stand the cylinder up on its end. This field is autosizable if used with a Water Heater:Sizing object.

Field: Tank Shape

The tank shape determines the size and skin losses of the stratified nodes. There are three options: **VerticalCylinder**, **HorizontalCylinder**, and **Other**.

VerticalCylinder describes most upright residential water heaters.

HorizontalCylinder describes a few specialty water heaters and large commercial storage tanks. **HorizontalCylinder** can also be used to model an outdoor storage tank located above a solar collector in a thermosiphon configuration. **HorizontalCylinder** implies that the tank is divided into nodes of equal mass, but not equal height.

Other describes water heaters or storage tanks that have a uniform horizontal cross-section, but are not cylinders, e.g., a cuboid or other shape. The length of the perimeter is then specified by the Tank Perimeter field.

If blank, the default shape is **VerticalCylinder**.

Field: Tank Perimeter

The length of the tank perimeter [m]. This field is only used if Tank Shape is **Other**.

Field: Maximum Temperature Limit

The temperature [°C] at which the tank water becomes dangerously hot and is vented through boiling or an automatic safety. The tank temperature will never exceed the maximum. Any extra heat added to the tank is immediately vented. Note: The maximum temperature must be greater than the setpoint temperature at all times.

Field: Heater Priority Control

The heater priority control determines how Heater 1 and Heater 2 work together. There are two options: **MasterSlave** or **Simultaneous**. In the MasterSlave option, Heater 1 is the master and Heater 2 is the slave. In most residential electric water heaters, the heaters operate in a MasterSlave relationship. That is, both heaters are not allowed to turn on at the same time. If the thermostats ask for heat at both Heater 1 and 2, only Heater 1 will turn on. Once Heater 1 has met the set point, it turns off and Heater 2 can turn on, if necessary. In other words, only one heater can be on at any time, and Heater 1 is always has priority over Heater 2.

In the Simultaneous option, Heater 1 and Heater 2 can turn on and off independently.

If blank, the default is **MasterSlave**.

Field: Heater 1 Set Point Temperature Schedule Name

The reference to the schedule object specifying the hot water temperature set point [°C] for Heater 1. Also known as the "cut-out" temperature.

Field: Heater 1 Deadband Temperature Difference

The delta temperature difference [Δ °C] between the set point and the "cut-in" temperature at which Heater 1 will turn on. In other words, the "cut-in" temperature is Set Point – Deadband.

Field: Heater 1 Capacity

The heat rate [W] supplied to the water for Heater 1, probably the same as the "nominal" capacity. For residential electric water heaters, heating elements are usually 4500 W. This field is autosizable if used with a Water Heater:Sizing object.

Field: Heater 1 Height

The height [m] of Heater 1 in the tank.

Field: Heater 2 Set Point Temperature Schedule Name

The reference to the schedule object specifying the hot water temperature set point [°C] for Heater 2. Also known as the "cut-out" temperature.

Field: Heater 2 Deadband Temperature Difference

The delta temperature difference [Δ °C] between the set point and the "cut-in" temperature at which Heater 2 will turn on. In other words, the "cut-in" temperature is Set Point – Deadband.

Field: Heater 2 Capacity

The heat rate [W] supplied to the water for Heater 1, probably the same as the "nominal" capacity. For residential electric water heaters, heating elements are usually 4500 W.

Field: Heater 2 Height

The height [m] of Heater 2 in the tank.

Field: Heater Fuel Type

The type of fuel used for both Heaters 1 and 2. The fuel type can be Electricity, NaturalGas, PropaneGas, FuelOil#1, FuelOil#2, Coal, Diesel, Gasoline, Steam, or DistrictHeating.

Field: Heater Thermal Efficiency

The thermal conversion efficiency from fuel energy to heat energy for the heater element or burner (for both Heaters 1 and 2). This is not the same as the overall efficiency of the water heater.

Field: Off-Cycle Parasitic Fuel Consumption Rate

Off-cycle parasitics include parts of the water heater that consume fuel when the heater is off, for example, a pilot light, or stand-by electronic control circuits. The fuel consumption rate [W] is strictly the total fuel that is consumed by all of the off-cycle parasitics.

Field: Off-Cycle Parasitic Fuel Type

The type of fuel used by the off-cycle parasitics. The fuel type can be Electricity, NaturalGas, PropaneGas, FuelOil#1, FuelOil#2, Coal, Diesel, Gasoline, Steam, or DistrictHeating. The fuel type can be the same or different from the Heater Fuel Type.

Field: Off-Cycle Parasitic Heat Fraction to Tank

The fraction of off-cycle parasitic fuel energy that is converted to heat energy that ends up in the tank water. For example, a pilot light would deliver most of its heat to the tank water, as long as the thermal conversion efficiency must be taken into account, so perhaps 0.80 is reasonable. Electronic control circuits, on the other hand, do not add any heat to the tank and should be 0.

Field: Off-Cycle Parasitic Height

The height [m] where any off-cycle parasitic heat gains are added to the tank.

Field: On-Cycle Parasitic Fuel Consumption Rate

On-cycle parasitics include parts of the water heater that consume fuel when the heater is on, for example, an induction fan, or stand-by electronic control circuits. The fuel consumption rate [W] is strictly the total fuel that is consumed by all of the on-cycle parasitics.

Field: On-Cycle Parasitic Fuel Type

The type of fuel used by the on-cycle parasitics. The fuel type can be Electricity, NaturalGas, PropaneGas, FuelOil#1, FuelOil#2, Coal, Diesel, Gasoline, Steam, or DistrictHeating. The fuel type can be the same or different from the Heater Fuel Type.

Field: On-Cycle Parasitic Heat Fraction to Tank

The fraction of on-cycle parasitic fuel energy that is converted to heat energy that ends up in the tank water. For example, an induction fan might (maybe) deliver a small fraction of its energy to the tank water for a value of 0.05. Electronic control circuits, on the other hand, do not add any heat to the tank and should be 0.

Field: On-Cycle Parasitic Height

The height [m] where any on-cycle parasitic heat gains are added to the tank.

Field: Ambient Temperature Indicator

The Ambient Temperature Indicator specifies how the ambient air temperature will be indicated. The field can be **Schedule**, **Zone**, or **Outdoors**. If Schedule is used, the Ambient

Temperature Schedule value provides the ambient temperature. If Zone is used, the zone air temperature of the zone specified in the Ambient Temperature Zone field provides the ambient temperature. If Outdoors is used, the outdoor dry-bulb air temperature of the outdoor air node specified in the Ambient Temperature OutdoorAir:Node field provides the ambient temperature.

Field: Ambient Temperature Schedule Name

The reference to the schedule object specifying the ambient air temperature around the tank for skin losses. This field is only used if Ambient Temperature Indicator is **Schedule**.

Field: Ambient Temperature Zone

The reference to the zone object specifying the ambient air temperature around the tank for skin losses. This field is only used if Ambient Temperature Indicator is **Zone**.

Field: Ambient Temperature Outdoor Air Node

The reference to the outdoor air node specifying the ambient air temperature around the tank for skin losses. An outdoor air node can be defined by an OutdoorAir:Node object or OutdoorAir:NodeList object. This field is only used if Ambient Temperature Indicator is **Outdoors**.

Field: Uniform Skin Loss Coefficient Per Unit Area to Ambient Temperature

The uniform skin loss coefficient [W/m²-K] or U-Value of the tank to the ambient air temperature. The uniform skin loss accounts for the tank insulation and applies during both off- and on-cycle operation. The overall losses at any particular node can be further modified using the Additional Loss Coefficient fields to account for thermal shorting due to pipe penetrations, water heater feet, and any other loss effects.

Field: Skin Loss Fraction to Zone

If the Ambient Temperature Indicator is **Zone**, this field adds the specified fraction of the skin losses to the zone heat balance as an internal gain.

Field: Off-Cycle Flue Loss Coefficient to Ambient Temperature

The off-cycle flue loss coefficient [W/K] to the ambient air temperature. This field mainly applies to gas water heaters that have a flue.

Field: Off-Cycle Flue Loss Fraction to Zone

If the Ambient Temperature Indicator is **Zone**, this field adds the specified fraction of the off-cycle flue losses to the zone heat balance as an internal gain.

Field: Peak Use Flow Rate

The peak flow rate [m³/s] of domestic hot water usage for stand-alone operation, i.e., without plant loop node connections. The peak value is multiplied by the Use Flow Rate Fraction Schedule. If there are node connections, this field is not used.

Field: Use Flow Rate Fraction Schedule Name

The reference to the schedule object specifying the current fraction of Peak Volumetric Use Flow Rate of domestic hot water usage for stand-alone operation. If blank, the fraction defaults to 1.0 at all times.

Field: Cold Water Supply Temperature Schedule Name

The reference to the schedule object specifying the cold water temperature [°C] from the supply mains that makes up for the hot water lost down the drain. If blank, water temperatures are calculated by the Site:WaterMainsTemperature object. This field is for stand-alone operation only. If there are node connections, this field is not used.

Field: Use Side Inlet Node Name

The inlet node connection to the plant loop for the use side of the water heater. Typically the use side draws hot water from the tank and returns cooler water.

Field: Use Side Outlet Node Name

The outlet node connection to the plant loop for the use side of the water heater. Typically the use side draws hot water from the tank and returns cooler water.

Field: Use Side Effectiveness

This field specifies the heat transfer effectiveness between the use side water and the tank water. If the effectiveness is set to 1 then complete heat transfer occurs, simulating perfect mixing of the use side water and the tank water. If the effectiveness is lower, then the use side outlet water temperature will not be as hot as the tank water, simulating an external heat exchanger that is indirectly coupled to the water heater tank.

Field: Use Side Inlet Height

The height of the use side inlet to the tank. If blank, the inlet defaults to the bottom of the tank. The inlet height cannot be higher than the tank height.

Field: Use Side Outlet Height

The height of the use side outlet from the tank. If blank or **autocalculate**, the inlet defaults to the top of the tank. The outlet height cannot be higher than the tank height.

Field: Source Side Inlet Node

The inlet node connection to the plant loop for the source side of the water heater. Typically the source side draws cold water from the tank and returns warmer water.

Field: Source Side Outlet Node

The outlet node connection to the plant loop for the source side of the water heater. Typically the source side draws cold water from the tank and returns warmer water.

Field: Source Side Effectiveness

This field specifies the heat transfer effectiveness between the source side water and the tank water. If the effectiveness is set to 1 then complete heat transfer occurs, simulating perfect mixing of the source side water and the tank water. If the effectiveness is lower, then the source side outlet water temperature will not be as hot as the tank water, simulating an external heat exchanger that is indirectly coupled to the water heater tank.

Field: Source Side Inlet Height

The height of the source side inlet to the tank. If blank or **autocalculate**, the inlet defaults to the top of the tank. The inlet height cannot be higher than the tank height.

Field: Source Side Outlet Height

The height of the source side outlet from the tank. If blank, the inlet defaults to the bottom of the tank. The outlet height cannot be higher than the tank height.

Field: Inlet Mode

The inlet mode of entering fluid from the use and source sides. There are two options: **Fixed** or **Seeking**. In Fixed mode, the fluid enters at the fixed heights specified above. In Seeking mode, the fluid "seeks out" the stratified node that is closest to the inlet temperature and adds all flow to that node. The Seeking mode provides maximum stratification. The default is **Fixed**.

Field: Use Side Design Flow Rate

This field is optional and is used to specify the design flow rate through the Use Side of the water heater. The volumetric design flow rate is specified in m³/s. The field is needed when the Use Side is connected to a plant loop. The field can be autosized. If autosized, then the input file should include a Plant Sizing object for the plant loop. Sizing results are reported in the EIO file.

Field: Source Side Design Flow Rate

This field is optional and is used to specify the design flow rate through the Source Side of the water heater. The volumetric design flow rate is specified in m³/s. The field is needed when the Source Side is connected to a plant loop. The field can be autosized. If autosized, then the input file should include a Plant Sizing object for the plant loop. Sizing results are reported in the EIO file.

Field: Indirect Water Heating Recovery Time

This field is optional and is used to provide a design parameter for autosizing design flow rates when the water heater is connected to the demand side of a plant loop. The recovery time is expressed in hours. This is the time that the entire volume of the tank can be heated from 14.4°C to 57.2°C (58°F to 135°F) with an inlet temperature defined as the exit temperature in the associated Plant Sizing object. The default is 1.5 hours. The calculation is based on log-mean temperature difference (LMTD) and includes the heat transfer effectiveness factor entered above.

Field: Number Of Nodes

The number of stratified nodes in the tank. There must be at least one node. The maximum number of nodes is 10, although this limit can be increased by editing the IDD.

Field: Additional Destratification Conductivity

An additional destratification conductivity [W/m-K] is added to the fluid conductivity of water (0.6 W/m-K) to account for vertical conduction effects along the inside of the tank wall, and perhaps other vertical components such as the flue, the cold water inlet pipe (dip tube), and the anode rod.

Field: Node 1-10 Additional Loss Coefficient

An additional loss coefficient [W/m-K] added to the skin losses for a given node to account for thermal shorting due to pipe penetrations, water heater feet, and any other loss effects.

Water Heater:Stratified Outputs

All of the output variables reported for the WaterHeater:Mixed object also apply to the WaterHeater:Stratified object, with several qualifications noted below:

Water Heater Tank Temperature [C]

The average water tank temperature, i.e., the average of all of the node average temperatures.

Water Heater Final Tank Temperature [C]

The final water tank temperature at the end of the system timestep, i.e., the average of all of the final node temperatures at the end of the system timestep. If reported at the "Detailed" interval, this report variable can be used to verify an exact energy balance on the water heater.

Water Heater Heating Rate [W]

The total average heating rate supplied by Heater 1 plus Heater 2.

Water Heater Heating Energy [J]

The total heating energy supplied by Heater 1 plus Heater 2.

Water Heater Cycle On Count []

The number of times that either Heater 1 or Heater 2 turned on in the time period.

Water Heater Runtime Fraction []

The fraction of the time period that either Heater 1 or Heater 2 was running.

In addition, the WaterHeater:Stratified object also reports the following output variables:

```
HVAC,Average,Water Heater Heating Rate 1 [W]
HVAC,Average,Water Heater Heating Rate 2 [W]
HVAC,Sum,Water Heater Heating Energy 1 [J]
HVAC,Sum,Water Heater Heating Energy 2 [J]
HVAC,Sum,Water Heater Cycle On Count 1 []
HVAC,Sum,Water Heater Cycle On Count 2 []
HVAC,Average,Water Heater Runtime Fraction 1 []
HVAC,Average,Water Heater Runtime Fraction 2 []
HVAC,Average,Water Heater Node <x> Temperature [C]
HVAC,Average,Water Heater Final Node <x> Temperature [C]
```

Water Heater Heating Rate 1 [W]

The average heating rate supplied by Heater 1.

Water Heater Heating Rate 2 [W]

The average heating rate supplied by Heater 2.

Water Heater Heating Energy 1 [J]

The heating energy supplied by Heater 1.

Water Heater Heating Energy 2 [J]

The heating energy supplied by Heater 2.

Water Heater Cycle On Count 1 []

The number of times that Heater 1 turned on in the time period.

Water Heater Cycle On Count 2 []

The number of times that Heater 2 turned on in the time period.

Water Heater Runtime Fraction 1 []

The fraction of the time period that Heater 1 was running.

Water Heater Runtime Fraction 2 []

The fraction of the time period that Heater 2 was running.

Water Heater Node 1-10 Temperature [C]

The average node temperature.

Water Heater Final Node 1-10 Temperature [C]

The final node temperature at the end of the system timestep.

WaterHeater:Sizing

The WaterHeater:Sizing object is used to provide additional input data needed for designing tank volume and/or heater capacity for either the Mixed or Stratified water heaters. This object is only needed if volume or capacity is being automatically sized. There are no output variable associated with this object -- sizing results are reported to the EIO output file and some predefined summary reports.

A source of design input data for use with this object can be found in the current ASHRAE Handbook HVAC Applications chapter on Service Water Heating.

The idd entry for this object follows.

Field: WaterHeater Name

This field contains the unique name of the water heater being sized. This name should match the name of a Water Heater:Mixed or a Water Heater:Stratified input object defined elsewhere in the input file.

Field: Design Mode

This field describes which of several methods are to be used for sizing the water heater. There are six possible choices and one of the following should be selected:

- **PeakDraw**. This design method uses the design flow rates of all the different demands placed on the water heater. The tank size is based on how long it can meet the demand and how quickly it can recover. The user enters the time in hours that the water heater can meet the demands. Only the hot water uses connected to an individual water heater are included in that water heater's peak draw.
- **ResidentialHUD-FHAMinimum** This design method is based on minimum permissible water heater sizes (established by HUD-FHA in its Minimum Property Standards for One- and Two-Family Living Units, No. 4900.1-1982). The user enters the number of bathrooms and bedrooms in this input object. The smallest allowable water heater sizes are used.
- **PerPerson** This design method scales sizes based on the total number of people in all zones in the building. Each water heater in the model will be sized using the total (peak, design) number of people for the entire model. The number of people is determined from People objects defined elsewhere in the input file
- **PerFloorArea** This design method scales sizes based on the total floor area in all the zones in the building. Each water heater in the model will be sized using all the floor area in the model. The floor areas are determined from the geometry input elsewhere in the input file.
- **PerUnit** This design method scales sizes based on an arbitrary number of units. This can be used, for example, to size based on the number of rooms in a lodging building. The user provides the number of units in an input field in this object.
- **PerSolarCollectorArea** This design method scales tank volume based on the collector area for a solar hot water collector. The collector area is summed for all the collectors in the model and each tank is sized for the total. The collector area is determined from input for Solar Collectors defined elsewhere in the input file.

Field: Time Storage Can Meet Peak Draw

This field provides the time, in hours, that the tank's volume can sustain a peak draw. It is used to size the tank's volume which is the simple product of peak draw volume flow rate and

the draw time. There is no assurance that the water will be at the desired temperature for the entire draw. This field is only used if the Design Mode is “**PeakDraw**.” The water heater must be connected to a full plant loop, be on the supply side, and the plant loop needs a Plant Sizing object.

Field: Time for Tank Recovery

This field provides the the time, in hours, that tank’s heater needs to recover the volume of the tank. The temperatures used to define recovery are a starting temperature of 14.4°C (58°F) and a final temperature of 57.2°C (135°F). This field is only used if the Design Mode is “**PeakDraw**.”

Field: Nominal Tank Volume for Autosizing Plant Connections

This field is used in case the water heater is indirectly heated by its source side connections and they are also autosized. Because of the complexity of such a water heater and the timing for when sizing calculation happen inside EnergyPlus, the Source side connection flow rates need to be reported before the tank’s volume can be sized to meet Peak Draw. This input field is used to provide a nominal tank volume to use temporarily while the flow connections are sized. This field is only used if the Design Mode is “**PeakDraw**” and the water heater has autosized plant connections on the demand side.

Field: Number of Bedrooms

This field is used to enter the numer of bedrooms in the model. This field is only used if the Design Mode is “**ResidentialHUD-FHAMinimum**.”

Field: Number of Bathrooms

This field is used to enter the number of bathrooms in the model. This field is only used if the Design Mode is “**ResidentialHUD-FHAMinimum**.”

Field: Storage Capacity per Person

This field is used to enter the tank’s storage volume on per-person basis. The units are m³/person. This field is only used if the Design Mode is “**PerPerson**.”

Field: Recovery Capacity per Person

This field is used to enter the recovery capacity per person in units of m³/person/hr. This is the volume of water the heater can recover in one hour per person. Recovery is heating water from a starting temperature of 14.4°C (58°F) to a final temperature of 57.2°C (135°F). This field is only used if the Design Mode is “**PerPerson**.”

Field: Storage Capacity per Floor Area

This field is used to enter the tank’s storage volume on a per-floor-area basis. The units are m³ /m² (water/floor area). This field is only used if the Design Mode is “**PerFloorArea**.”

Field: Recovery Capacity per Floor Area

This field is used to enter the recovery capacity per floor area in units of m³/m²/hr. This is the volume water the heater can recover in an hour per floor area. Recovery is heating water from a starting temperature of 14.4°C (58°F) to a final temperature of 57.2°C (135°F). This field is only used if the Design Mode is “**PerFloorArea**.”

Field: Number of Units

This field is used to enter the number of Units for use in sizing on per-Unit basis with the next two fields. This field is only used if the Design Mode is “**PerUnit**.” This can be used to account for any arbitrary item such as lodging rooms, desks, water fixtures, restrooms, etc.

Field: Storage Capacity per Unit

This field is used to enter the tanks' storage volume on per-Unit basis. The units are m³/Unit. The number of Units is entered in the previous field. This field is only used if the Design Mode is "PerUnit."

Field: Recovery Capacity per Unit

This field is used to enter the recover capacity per Unit in units of m³/Unit/hr. This is the volume of water the heater can recover in an hour per Unit. Recovery is heating water from a starting temperature of 14.4°C (58°F) to a final temperature of 57.2°C (135°F). This field is only used if the Design Mode is "PerUnit."

Field: Storage Capacity per Collector Area

This field is used to enter the tank's storage volume on per-solar-collector-area basis. The units are m³/m². This field is only used if the Design Mode is "PerSolarCollectorArea."

Field: Height Aspect Ratio

This field is used to scale the height of a stratified tank to preserve relative geometry for different size tanks. The Height Aspect Ratio is defined as the length scale in the vertical direction (height) divided by the length scale in the horizontal direction (diameter). This field is only used if the water heater being sized is a Water Heater:Stratified, the tank height has been set to Autosize, and the tank shape is set to **VerticalCylinder**. This field can be used with any Design Mode.

WaterHeater:HeatPump

The heat pump water heater (HPWH) is a compound object consisting of a water heater tank (e.g., WaterHeater:Mixed), a direct expansion (DX) "coil" (i.e., an air-to-water DX compression system which includes a water heating coil, air coil, compressor, and water pump), and a fan to provide air flow across the air coil associated with the DX compression system. These objects work together to model a system which heats water using zone air, outdoor air, or a combination of zone and outdoor air as the primary heat source. Numerous configurations of tank location, inlet air source, and DX coil compressor location can be modeled, with one common configuration shown below.

Figure 67. Schematic diagram for a heat pump water heater located in a zone

In this model, the heat pump water heater's DX coil is considered the primary heat source and the water tank's heater (element or burner) provides supplemental heat as necessary. The model also assumes that the heat pump's fan and water pump cycle on and off with the compressor.

To model a heat pump water heater, the input data file must include some combination of the following objects depending on the configuration to be modeled:

- WaterHeater:HeatPump (required)
- WaterHeater:Mixed (required)
- Coil:WaterHeating:AirToWaterHeatPump (required)
- Fan:OnOff (required)
- ZoneHVAC:EquipmentList (when the HPWH draws some or all of its air from the zone, the heat pump water heater type and name must be in this list)
- ZoneHVAC:EquipmentConnections (when the HPWH draws some or all of its air from the zone, the HPWH air inlet and outlet node names must be provided in this object)
- OutdoorAir:NodeList (for HPWHs that use outdoor air as all or part of the heat source, the HPWH outdoor air node name must be provided in this list)

The input fields for the compound object are described in detail below:

Field: Name

This alpha field contains a unique user-assigned name for an instance of a heat pump water heater. Any reference to this heat pump water heater by another object will use this name.

Field: Availability Schedule Name

This alpha field contains the name of the schedule (ref: Schedule) that denotes whether the heat pump compressor is available to operate during a given time period. A schedule value equal to 0 denotes that the heat pump compressor is off for that time period. A value other than 0 denotes that the heat pump compressor is available to operate during that time period. During times when the heat pump compressor is scheduled off, the heater (element or

burner) in the water tank object operates based on its tank set point temperature schedule and the heat pump's parasitic electric power is also off for that time period.

Field: Compressor Setpoint Temperature Schedule Name

This alpha field contains the name of the schedule (ref: Schedule) that specifies the set point (or "cut-out") temperature for the heat pump compressor. Temperature values used in this schedule should be in degrees Celsius. The heat pump compressor cycles off when the tank water reaches this set point temperature. Once the heat pump compressor cycles off, the tank water temperature floats downward until it falls below the set point temperature minus the dead band temperature difference defined below (i.e., the "cut-in" temperature). At this point, the heat pump compressor cycles on and remains on until the heat pump compressor set point temperature is reached.

Field: Dead Band Temperature Difference

This numeric field contains the dead band temperature difference in degrees Celsius. The heat pump compressor "cut-in" temperature is defined as the compressor set point temperature defined above minus this dead band temperature difference. The heat pump compressor cycles on when the water temperature in the tank falls below the "cut-in" temperature. The heat pump compressor remains on until the water temperature in the tank rises above the compressor set point ("cut-out") temperature defined above. The dead band temperature difference must be greater than 0°C and less than or equal to 20°C. If this field is left blank, the default value is 5°C.

In this model, the heat pump water heater's DX compression system is considered the primary heat source and the water tank's heater (element or burner) provides supplemental heat as necessary. Therefore, the cut-in temperature for the heat pump compressor (set point minus dead band temperature difference) is usually higher than the set point temperature for the heater (element or burner) in the associated water heater tank object. At times when the water heater tank set point temperature is greater than the cut-in temperature of the heat pump compressor, the heat pump compressor is disabled and the tank's heater is used to heat the water.

Field: Condenser Water Inlet Node Name

This alpha field contains the name of the inlet water node for the heat pump's water heating coil (condenser). This node name must also be specified in the water heater tank object as the source outlet node name, and in the DX coil object as the condenser water inlet node name.

Field: Condenser Water Outlet Node Name

This alpha field contains the name of the outlet water node for the heat pump's water heating coil (condenser). This node name must also be specified in the water heater tank object as the source inlet node name, and in the DX coil object as the condenser water outlet node name.

Field: Condenser Water Flow Rate

This numeric field contains the heat pump's condenser water flow rate in cubic meters per second. It is the actual condenser water flow rate to be simulated, which may differ from the rated condenser water volumetric flow rate specified for the heat pump's DX coil (Ref. Coil:WaterHeating:AirToWaterHeatPump). This water flow rate must be greater than 0 or this field is autocalculatable. If autocalculated (field value = **autocalculate**), the condenser water flow rate is set equal to the rated heating capacity of the heat pump's DX coil multiplied by $4.487E-8$ m³/s/W. When this flow rate is different from the Rated Condenser Water Volumetric Flow Rate specified in the heat pump's DX coil object (Ref. Coil:WaterHeating:AirToWaterHeatPump), the user should also specify a Total Heating

Capacity Modifier Curve Name (function of water flow fraction) and a Heating COP Modifier Curve Name (function of water flow fraction) in the associated DX coil object to account for differences in capacity and power consumption at the off-rated water flow rate.

Field: Evaporator Air Flow Rate

This numeric field contains the air flow rate across the heat pump's air coil (evaporator) in cubic meters per second. It is the actual air flow rate to be simulated, which may differ from the rated evaporator air volumetric flow rate specified for the heat pump's DX coil (Ref. Coil:WaterHeating:AirToWaterHeatPump). Values must be greater than 0 or this field is autocalculatable. If autocalculated (field value = **autocalculate**), the evaporator air flow rate is set equal to the rated heating capacity of the heat pump's DX coil multiplied by $5.035E-5$ m³/s/W. When this flow rate is different from the Rated Evaporator Air Volumetric Flow Rate specified in the heat pump's DX coil object (Ref. Coil:WaterHeating:AirToWaterHeatPump), the user should also specify a Total Heating Capacity Modifier Curve Name (function of air flow fraction) and a Heating COP Modifier Curve Name (function of air flow fraction) in the associated DX coil object to account for differences in capacity and power consumption at the off-rated air flow rate.

Field: Inlet Air Configuration

This choice field defines the configuration of the air flow path through the heat pump air coil (evaporator) and fan section. Valid entries are **Schedule**, **ZoneAirOnly**, **OutdoorAirOnly**, or **ZoneAndOutdoorAir**. If 'Schedule' is selected, names for an inlet air temperature schedule and an inlet air humidity schedule must be defined in the fields below. If 'ZoneAirOnly' is selected, the corresponding zone name must be entered in the Inlet Air Zone Name field below. If 'ZoneAndOutdoorAir' is selected, the corresponding Inlet Air Zone Name, Inlet Air Mixer Node Name, Outlet Air Splitter Node Name, and an Inlet Air Mixer Schedule Name must be entered in the corresponding fields below.

Field: Air Inlet Node Name

This alpha field contains the name of the node from which the heat pump water heater draws its inlet air. If the Inlet Air Configuration field defined above is set to 'ZoneAirOnly' or 'ZoneAndOutdoorAir', then this node name should be the name of a zone air exhaust node (Ref. ZoneHVAC:EquipmentConnections). If the Inlet Air Configuration field is set to 'OutdoorAirOnly', this node name should be left blank. If the Inlet Air Configuration field is set to 'Schedule', this node name should simply be a unique name that allows the user to receive output on conditions at this node for verification purposes.

Field: Air Outlet Node Name

This alpha field contains the name of the node to which the heat pump water heater sends its outlet air. If the Inlet Air Configuration field defined above is set to 'ZoneAirOnly' or 'ZoneAndOutdoorAir', then this node name should be the name of a zone air inlet node (Ref. ZoneHVAC:EquipmentConnections). If the Inlet Air Configuration field is set to 'OutdoorAirOnly', this node name should be left blank. If the Inlet Air Configuration field is set to 'Schedule', this node name should simply be a unique name that allows the user to receive output on conditions at this node for verification purposes.

Field: Outdoor Air Node Name

This alpha field contains the name of the node from which the heat pump water heater draws its outdoor air. If the Inlet Air Configuration field defined above is set to 'ZoneAirOnly' or 'Schedule', this node name should be left blank. If the Inlet Air Configuration field is set to 'ZoneAndOutdoorAir' or 'OutdoorAirOnly', this node name should be the name of an outdoor air node (Ref. OutdoorAir:NodeList).

Field: Exhaust Air Node Name

This alpha field contains the name of the node to which the heat pump water heater sends its exhaust air. If the Inlet Air Configuration field defined above is set to 'ZoneAirOnly' or 'Schedule', this node name should be left blank. If the Inlet Air Configuration field is set to 'ZoneAndOutdoorAir' or 'OutdoorAirOnly', then this node name should be a unique name that allows the user to receive output on conditions at this node for verification purposes.

Field: Inlet Air Temperature Schedule Name

This alpha field contains the name of a schedule used to define the dry-bulb temperature of the inlet air to the heat pump air coil (evaporator) and fan section. Schedule values should be in degrees Celsius. This field is only used when the Inlet Air Configuration defined above is specified as 'Schedule', otherwise leave this field blank.

Field: Inlet Air Humidity Schedule Name

This alpha field contains the name of a schedule used to define the humidity of the inlet air to the heat pump evaporator and fan section. Schedule values must be entered as relative humidity fraction from 0 to 1 (e.g., a schedule value of 0.5 means 50%RH). This field is only used when the Inlet Air Configuration defined above is specified as 'Schedule', otherwise leave this field blank.

Field: Inlet Air Zone Name

This alpha field contains the name of the zone from which the heat pump evaporator and fan section draws some or all of its inlet air. This field is only used when the Inlet Air Configuration defined above is specified as 'ZoneAirOnly' or 'ZoneAndOutdoorAir'.

Field: Tank Object Type

This alpha (choice) field contains the type of water heater tank used by this heat pump water heater. Currently, the only valid choice is WaterHeater:Mixed.

Field: Tank Name

This alpha field contains the name of the specific water heater tank (WaterHeater:Mixed object) used by this heat pump water heater.

Field: Tank Use Side Inlet Node Name

This alpha field contains the name of the use side inlet node of the water heater tank used by this heat pump water heater. This name must match the Use Side Inlet Node Name in the water heater tank object (Ref. WaterHeater:Mixed). This field is required if the water heater tank use side nodes are connected to a plant loop, otherwise leave this field blank.

Field: Tank Use Side Outlet Node Name

This alpha field contains the name of the use side outlet node of the water heater tank used by this heat pump water heater. This name must match the Use Side Outlet Node Name in the water heater tank object (Ref. WaterHeater:Mixed). This field is required if the water heater tank use side nodes are connected to a plant loop, otherwise leave this field blank.

Field: DX Coil Object Type

This alpha (choice) field contains the type of DX coil used by this heat pump water heater. Currently, the only valid choice is Coil:WaterHeating:AirToWaterHeatPump.

Field: DX Coil Name

This alpha field contains the name of the specific DX coil (Coil:WaterHeating:AirToWaterHeatPump object) used by this heat pump water heater.

Field: Minimum Inlet Air Temperature for Compressor Operation

This numeric field contains the minimum inlet air dry-bulb temperature entering the air coil (evaporator) and fan section, in degrees Celsius, below which the heat pump compressor does not operate. The minimum inlet air dry-bulb temperature should be greater than or equal to 5°C. If this field is left blank, the default value is 10°C.

Field: Compressor Location

This alpha (choice) field contains the location of the heat pump compressor and the air temperature for this location is used to control operation of the compressor's crankcase heater in the Coil:WaterHeating:AirToWaterHeatPump object. Valid entries are **Schedule**, **Zone**, or **Outdoors**. If 'Schedule' is selected, a compressor ambient temperature schedule name must be defined in the field below; otherwise, the field below should be left blank. If 'Zone' is selected, the crankcase heater operation is controlled based on the air temperature in the zone defined in the field Inlet Air Zone Name, and the Inlet Air Configuration must be 'ZoneAirOnly' or 'ZoneAndOutdoorAir'. If 'Outdoors' is selected, crankcase heater operation is controlled based on the outdoor air temperature.

Field: Compressor Ambient Temperature Schedule Name

This alpha field contains the name of a schedule that defines the ambient air temperature surrounding the heat pump compressor, which is used to control the compressor's crankcase heater operation. This field is only used when the compressor location field defined above is specified as 'Schedule', otherwise it should be left blank.

Field: Fan Object Type

This alpha (choice) field contains the type of fan used by this heat pump water heater. Currently, the only valid choice is Fan: OnOff.

Field: Fan Name

This alpha field contains the name of the specific fan (Fan:OnOff object) used by this heat pump water heater.

Field: Fan Placement

This alpha (choice) field defines the placement of the fan in the heat pump water heater. Valid choices are **BlowThrough** (fan upstream of the air coil) and **DrawThrough** (fan downstream of the air coil). If this field is left blank, the default value is DrawThrough.

Field: On Cycle Parasitic Electric Load

This numeric field contains the on-cycle parasitic electric power in Watts. This is the parasitic electric power consumed by controls or other electrical devices associated with the heat pump water heater. This parasitic electric load is consumed whenever the heat pump compressor is operating and the model assumes that this parasitic power does not contribute to heating the water. This parasitic load does, however, affect the zone air heat balance when the heat pump water heater sends some or all of its outlet air to a zone (i.e., Inlet Air Configuration field specified as 'ZoneAirOnly' or 'ZoneAndOutdoorAir') and the Parasitic Heat Rejection Location field is specified as 'Zone'. The minimum value for this field is 0.0, and the default value is also 0.0 if this field is left blank.

Field: Off Cycle Parasitic Electric Load

This numeric field contains the off-cycle parasitic electric power in Watts. This is the parasitic electric power consumed by controls or other electrical devices associated with the heat pump compressor. This parasitic electric load is consumed whenever the heat pump water heater is available but the compressor is not operating, and the model assumes that this parasitic power does not contribute to heating the water. This parasitic load does, however, affect the zone air heat balance when the heat pump water heater sends some or all of its outlet air to a zone (i.e., Inlet Air Configuration field specified as 'ZoneAirOnly' or

'ZoneAndOutdoorAir') and the Parasitic Heat Rejection Location field is specified as 'Zone'. The minimum value for this field is 0.0, and the default value is also 0.0 if this field is left blank.

Field: Parasitic Heat Rejection Location

This alpha (choice) field determines where the on-cycle and off-cycle parasitic heat is rejected. Valid choices are Zone and Exterior. If 'Zone' is selected, both the on-cycle and off-cycle parasitic heat is rejected to the zone defined in the field Inlet Air Zone Name, and the Inlet Air Configuration must be 'ZoneAirOnly' or 'ZoneAndOutdoorAir'. If 'Outdoors' is selected, this parasitic heat is rejected outdoors (does not impact the zone air heat balance) regardless of the specified Inlet Air Configuration. If this field is left blank, the default value is 'Outdoors'.

Field: Inlet Air Mixer Node Name

This optional alpha field defines the name of the HVAC node which represents the mixture of outdoor air and zone air that enters the heat pump air coil (evaporator) and fan section. The model mixes outdoor air with zone air and places the result on this inlet air mixer node based on the Inlet Air Mixer Schedule defined below. When the schedule value is equal to 0, 100% zone air enters the evaporator coil and fan section of the heat pump water heater. When the schedule value is equal to 1, 100% outdoor air enters the evaporator coil and fan section. This node name must be provided if the Inlet Air Configuration field above is specified as 'ZoneAndOutdoor Air', otherwise this field should be left blank.

Field: Outlet Air Splitter Node Name

This alpha field defines the name of the air node to which the heat pump air coil (evaporator) and fan sends all of its outlet air. The supply air flow downstream of this node is split between the zone and outdoors based on the Inlet Air Mixer schedule defined below. When the schedule value is equal to 0, the entire outlet air stream is diverted to the zone. When the schedule value is equal to 1, the entire outlet air stream is exhausted to outdoors. This node name must be provided if the Inlet Air Configuration field above is specified as 'Zone and Outdoor Air', otherwise this field should be left blank.

Field: Inlet Air Mixer Schedule Name

This alpha field defines the name of the schedule (ref: Schedule) that denotes whether the heat pump draws its inlet air from the zone, outdoors, or a combination of zone and outdoor air. A schedule value equal to 0 indicates that the heat pump draws its inlet air from the zone. A schedule value equal to 1 denotes that the heat pump draws its inlet air from outdoors. Values between 0 and 1 denote a mixture of zone and outdoor air proportional to the schedule value. The Inlet Air Mixer schedule controls both the inlet air mixer and outlet air splitter nodes in unison to ensure that the operation of the heat pump does not contribute to zone pressurization or depressurization. For example if the Inlet Air Mixer schedule value is 0.4, then the inlet air mixer node is composed of 40% outdoor air and 60% zone air. For this same case, the outlet air splitter directs 60% of the HPWH outlet air back to the zone and 40% of the outlet air flow is exhausted outdoors. This schedule name must be provided if the Inlet Air Configuration field is specified as 'Zone and Outdoor Air', otherwise this field should be left blank.

Below is the IDD Definition for the WaterHeater:HeatPump compound object.

```

WaterHeater:HeatPump Outputs

HVAC,Average,Heat Pump Water Heater Compressor Part-Load Ratio
HVAC,Average,Heat Pump Water Heater On-Cycle Parasitic Electric Power [W]
HVAC,Sum,Heat Pump Water Heater On-Cycle Parasitic Elec Consumption [J]
HVAC,Average,Heat Pump Water Heater Off-Cycle Parasitic Electric Power [W]
HVAC,Sum,Heat Pump Water Heater Off-Cycle Parasitic Elec Consumption [J]

Heat Pump Water Heater Compressor Part-Load Ratio

This output is the average part-load ratio of the heat pump water heater's compressor (as well as its water pump and fan) for the timestep being reported. This output is independent of the "Water Heater Part Load Ratio" (Ref. Water Heater Outputs) which represents the part-load ratio of the supplemental heater (element or burner) in the water tank. When the water tank's (supplemental) heater set point temperature is higher than the cut-in temperature of the heat pump water heater's compressor, the heat pump compressor is disabled and the water tank's heater (element or burner) is used to heat the water. During these times the Heat Pump Water Heater Compressor Part-Load Ratio is equal to 0.

Heat Pump Water Heater On-Cycle Parasitic Electric Power [W]

Heat Pump Water Heater On-Cycle Parasitic Elec Consumption [J]

Heat Pump Water Heater Off-Cycle Parasitic Electric Power [W]

Heat Pump Water Heater Off-Cycle Parasitic Elec Consumption [J]

These outputs are the parasitic electric power and consumption associated with the heat pump water heater. Specific outputs represent parasitic electrical usage during the compressor/fan on and off cycles. These outputs represent electronic controls or other electric component. The model assumes that the parasitic power does not contribute to heating the water, but it can impact the zone air heat balance depending on user inputs. The parasitic electric consumption outputs are also added to a report meter with Resource Type = Electricity, End Use Key = DHW, Group Key = Plant (ref. Report Meter).

Group – Condenser Equipment

Equipment Types

In each CondenserEquipmentList, various equipment types and names must be given. Each type-name pair must then have a corresponding equipment definition. This subsection lists the various equipment types that are available and examples from an IDF. Where appropriate, notes and comments on the input structure are provided.

CoolingTower:SingleSpeed

Cooling towers are components that may be assigned to condenser loops. The cooling tower is modeled as a counterflow heat exchanger with a single-speed fan (induced draft configuration) based on Merkel's theory. The user must define tower performance via one of two methods: design heat transfer coefficient-area product (UA) and design water flow rate,

or nominal tower capacity at a specific rating point. Regardless of which method is chosen, the design airflow rate and corresponding fan power must be specified. The model will also account for tower performance in the “free convection” regime, when the tower fan is off but the water pump remains on and heat transfer still occurs (albeit at a low level). If the user wants the model to account for “free convection”, they must specify the corresponding airflow rate and heat transfer coefficient-area product (UA), or the nominal tower capacity during this mode of operation.

The cooling tower seeks to maintain the temperature of the water exiting the cooling tower at (or below) a set point. The set point schedule value is defined by the field “Condenser Loop Temperature Setpoint Node Name or Reference” for the CondenserLoop object. The model first checks to determine the impact of “free convection”, if specified by the user, on the tower exiting water temperature. If the exiting water temperature based on “free convection” is at or below the set point, then the tower fan is not turned on. If the exiting water temperature based on “free convection” is below the set point, the tower will operate in FluidBypass mode – portion of the water goes through the tower media and gets cooled while the remaining water flow gets bypassed, two water flows then mix together trying to meet the water setpoint temperature. If the exiting water temperature remains above the set point after “free convection” is modeled, then the tower fan is turned on to reduce the exiting water temperature to the set point. If the capacity control is FanCycling, the model assumes that part-load operation is represented by a simple linear interpolation between two steady-state regimes (i.e., tower fan on for the entire simulation timestep and tower fan off for the entire simulation timestep). Cyclic losses are not taken into account. If the capacity control is FluidBypass, the model determines the fraction of water flow to be bypassed while the remaining water goes through the tower cooling media and gets cooled, then the two water flows mix to meet the setpoint temperature. In this case, the fan runs at full speed for the entire timestep.

Cooling towers here are “wet” and consume water through evaporation, drift, and blowdown. The model can be used to predict water consumed by the towers. The last six input fields are optional and provide methods of controlling details of the water consumption calculations. The user can specify connections to the rest of the buildings water system by providing the name of a water storage tanks (i.e. WaterUse:Storage objects).

The IDD specification for the single-speed cooling tower is given below.

```

CoolingTower:SingleSpeed,
  \min-fields 9
  \memo This tower model is based on Merkel's theory, which is also the basis
  \memo for the tower model in ASHRAE's HVAC1 Toolkit. The closed-circuit cooling tower
  \memo is modeled as a counter flow heat exchanger with a single-speed fan drawing air
  \memo through the tower (induced-draft configuration).
  \memo Added fluid bypass as an additional capacity control. 8/2008.

Field: Name

This alpha field contains the identifying name for the cooling tower.

Field: Water Inlet Node Name

This alpha field contains the identifying name for the cooling tower's water inlet node.

Field: Water Outlet Node Name

This alpha field contains the identifying name for the cooling tower's water outlet node.

Field: Design Water Flow Rate

This numeric field contains the design water flow rate through the tower in m³/s. This value is the flow rate of the condenser loop water being cooled by the tower (not the flow rate of water being sprayed on the outside of the heat exchange coil). If the input field "Performance Input Method" is specified as "UFactorTimesAreaAndDesignWaterFlowRate", then a water flow rate greater than zero must be defined or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design water flow rate is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Plant Sizing and Input for Design Calculations and Component Autosizing). If "Performance Input Method" is specified as "NominalCapacity", then this field must be left blank since the model

automatically assumes a water flow rate of 5.382E-8 m³/s per watt (3 gpm/ton) of tower capacity specified in the field “Nominal Capacity”.

Field: Design Air Flow Rate

This numeric field contains the design air flow rate induced by the tower fan in m³/s. A value greater than zero must be defined regardless of the tower performance input method. Alternately, this field can be autosized. If autosized, the design air flow rate is calculated as follows:

$$\text{Design Air Flow Rate} = \frac{0.5 \rho_{\text{air}} (\text{Fan power at Design Air Flow Rate})}{190}$$

where a fan pressure rise of 190 Pascals and total fan efficiency of 0.5 are assumed.

Field: Fan Power at Design Air Flow Rate

This numeric field contains the fan power (in watts) at the design air flow rate specified in the previous field. A value greater than zero must be specified regardless of the tower performance input method, or this field can be autosized. If autosized, the fan power is calculated as follows:

If “Performance Input Method” is specified as “*UFactorTimesAreaAndDesignWaterFlowRate*”, then

$$\text{Fan power} = 0.0105 \cdot \rho_{\text{water}} \cdot C_{p,\text{water}} \cdot \text{Design Water Flow Rate} \cdot \text{Design Loop } \Delta T$$

is used.

If “Performance Input Method” is specified as “*NominalCapacity*”, then

$$\text{Fan power} = 0.0105 \cdot \text{Tower Nominal Capacity}$$

is used.

Field: U-Factor Times Area Value at Design Air Flow Rate

This numeric field contains the heat transfer coefficient-area product (UA) in watts per degree Celsius corresponding to the design air and water flow rates specified above. If the input field “Performance Input Method” is specified as “*UFactorTimesAreaAndDesignWaterFlowRate*”, then a UA value greater than zero but less than or equal to 300,000 must be defined, or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design tower UA value is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Plant Sizing and Input for Design Calculations and Component Autosizing), assuming a tower water inlet temperature of 35C and tower inlet air at 35C drybulb/25.6C wetbulb. If “Performance Input Method” is specified as “*NominalCapacity*”, then this field must be left blank since the model automatically calculates the tower UA based on the tower capacity specified in the field “Nominal Capacity”.

Field: Air Flow Rate in Free Convection Regime

This numeric field contains the air flow rate (m³/s) when the tower is in the “free convection” regime (water flow exists but tower fan is turned off). This value must be less than the value specified for the field “Design Air Flow Rate”. This field may be autosized, in which case it is set to 10% of the “Design Air Flow Rate”. If the user does not wish to model “free convection” and is using the Performance Input Method “*UFactorTimesAreaAndDesignWaterFlowRate*”, then this field should be set to 0.0. If the user specifies the U-Factor Times Area Value at Free Convection Air Flow Rate or Free Convection Capacity as a value greater than zero, then the free convection air flow rate must be specified greater than 0.0.

Field: U-Factor Times Area Value at Free Convection Air Flow Rate

This numeric field contains the heat transfer coefficient-area product ($W/^\circ C$) when the tower is in the “free convection” regime (water flow exists but tower fan is turned off). This value must be less than the value specified for the field “U-Factor Times Area Value at Design Air Flow Rate”. This field may be autosized, in which case it is set to 10% of the “U-Factor Times Area Value at Design Air Flow Rate”. If the user does not wish to model “free convection” and is using the Performance Input Method “UFactorTimesAreaAndDesignWaterFlowRate”, then this field should be set to 0.0. If “Performance Input Method” is specified as “NominalCapacity”, then this field must be left blank since the model automatically calculates the tower UA based on the tower capacity specified in the field “Free Convection Capacity”.

Field: Performance Input Method

This alpha field contains the method by which the user will specify tower performance: “UFactorTimesAreaAndDesignWaterFlowRate” or “NominalCapacity”. If this field is left blank in the input data file, the default input method is assumed to be “NominalCapacity”. If the method “” is selected, then the user must enter design UA values, design water flow rates and air flow rates as described for the previous input fields. If the method “NominalCapacity” is selected then the fields “Design Water Flow Rate”, “U-Factor Times Area Value at Design Air Flow Rate” and “U-Factor Times Area Value at Free Convection Air Flow Rate” must be left blank, but the fields “Nominal Capacity” and “Free Convection Capacity” must be entered as described below.

Field: Nominal Capacity

This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts, with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be $5.382E-8$ m³/s per watt of nominal capacity (3 gpm/ton). 125% of this nominal tower capacity gives the actual tower heat rejection at these operating conditions (based on historical assumption that the tower must dissipate 0.25W of compressor heat for every watt of heat removed by the evaporator).

Field: Free Convection Capacity

This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts when the tower is in the “free convection” regime (water flow exists but tower fan is turned off), with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be $5.382E-8$ m³/s per watt of nominal tower capacity (input field above). 125% of this free convection tower capacity gives the actual tower heat rejection at these operating conditions (based on historical assumption that the tower must dissipate 0.25W of compressor heat for every watt of heat removed by the evaporator). The value specified for this field must be less than the value specified for the field “Tower Nominal Capacity”. If the user does not wish to model “free convection”, then this field should be set to 0.0. If the user specifies a value greater than zero, then the “Air Flow Rate in Free Convection Regime” field must contain a value greater than zero.

Field: Evaporation Loss Mode

This field is used to choose which method is used to model the amount of water evaporated by the cooling tower. There are two options: **LossFactor** or **SaturatedExit**. The default is SaturatedExit. The user-defined loss factor is entered in the following field. By assuming that the air leaving the tower is saturated, the evaporation can be directly calculated using moist air engineering calculations with data available within the cooling tower model (and does not require additional user input).

Field: Evaporation Loss Factor

This field is used to specify the rate of water evaporated from the cooling tower and lost to the outside air [percent/K]. This field is only used if the Evaporation Calculation Mode is set to **LossFactor**. The evaporation loss is then calculated as a fraction of the circulating condenser water flow and varies with the temperature change in the condenser water. The value entered here is in units of percent-per-degree Kelvin. The evaporation rate will equal this value times each degree Kelvin of temperature drop in the condenser water. Typical values are from 0.15 to 0.27 [percent/K]. The default is 0.2.

Field: Drift Loss Percent

This field is used to specify the rate of water lost to the exiting air as entrained droplets [%]. The drift loss is a percent of the condenser water flow. Typical values for towers with efficient drift eliminators are between 0.002 and 0.2% of the condenser water flow rate. The default value is 0.008%.

Field: Blowdown Calculation Mode

This field specifies which method is used to determine blowdown rates. There two options **ConcentrationRatio** or **ScheduledRate**. The choice will determine which of the two models below is used. The default is ConcentrationRatio.

Field: Blowdown Concentration Ratio

This field is used to dynamically adjust the rate of blowdown in the cooling tower as a function of the rate of evaporation. Blowdown is water intentionally drained from the tower in order to offset the build up of solids in the water that would otherwise occur because of evaporation. The value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Typical values for tower operation are 3 to 5. The default value is 3.

Field: Blowdown Makeup Water Usage Schedule Name

This alpha field contains the name of the schedule used to define the amount of water (m^3/s) flushed from the basin on a periodic basis to purge the tower of mineral scale build-up and other contaminants. This schedule is only used if the Blowdown Calculation Mode is set to ScheduledRate. The amount of water use due to blowdown depends on the makeup water quality and is specific to each geographical location. Typical values range from 0.0002 to 0.0013 m^3/s (17.3 to 112.3 m^3/day). This water usage is in addition to the amount of water lost to the atmosphere due to evaporation and/or drift. Since blowdown occurs when the basin water contaminant concentration is high, blowdown only occurs when the cooling tower is active and water is flowing through the tower (regardless of the water usage defined by this schedule).

Field: Supply Water Storage Tank Name

This field is optional. It is used to describe where the tower obtains water used for evaporative cooling. If blank or omitted, then the tower will obtain water directly from the mains. If the name of a WaterUse:Storage object is used here, then the tower will obtain its water from that tank. If a tank is specified, the tower will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the tower needs, then the tower will still operate and obtain the rest of the water it needs from the mains (referred to as 'Starved' water).

Field: Outdoor Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the cooling tower. If this field is left blank, the outdoor air conditions entering the cooling tower are taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather

data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air conditions are taken directly from the weather data.

Field: Capacity Control

This alpha field contains the cooling capacity control for the cooling tower. Two choices are available: **FanCycling** and **FluidBypass**. During part-load conditions, there are two ways to maintain the exiting water temperature at the setpoint: either cycling the tower fan, or bypassing portion of the tower water with a three-way valve. For FluidBypass, the tower fan still runs at full speed for the entire timestep, but only portion of the water flow goes through the cooling tower media to get cooled while the remaining portion of the water flow gets bypassed. Two water flows then mix at the common water sump to meet the setpoint temperature.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature. For this component the inputs that would be altered by the sizing factor are:

1. Design Water Flow Rate;
2. Design Air Flow Rate;
3. Fan Power at Design Air Flow Rate;
4. U-Factor Times Area Value at Design Air Flow Rate;
5. Air Flow Rate in Free Convection Regime;
6. U-Factor Times Area Value at Free Convection Air Flow Rate.

Note that the U-Factor Times Area Value at Design Air Flow Rate is not *multiplied* by the Sizing Factor. Instead the design tower load is multiplied by the sizing factor and the design UA then calculated as usual. The U-Factor Times Area Value at Free Convection Air Flow Rate is set to 10% of the new design Tower UA.

Three examples of an IDF specification for this object are shown below:

CoolingTower:SingleSpeed Outputs

```

HVAC,Average,Tower Fan Electric Power [W]
HVAC,Sum,Tower Fan Electric Consumption [J]
Zone,Meter,HeatRejection:Electricity [J]

HVAC,Average,Tower Heat Transfer [W]
HVAC,Average,Tower Water Inlet Temp [C]
HVAC,Average,Tower Water Outlet Temp [C]
HVAC,Average,Tower Water Mass Flow Rate [kg/s]
HVAC,Average,Tower External Water Use Rate [m3/s]
HVAC,Average,Tower Fluid Bypass Fraction

```

Tower Fan Electric Power [W]

Tower Fan Electric Consumption [J]

These outputs are the electric power input to the tower fans. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

Tower Heat Transfer [W]

This is the rate at which heat is removed from the condenser water loop by the tower.

Tower Water Inlet Temp [C]***Tower Water Outlet Temp [C]******Tower Water Mass Flow Rate [kg/s]***

These outputs are the tower water inlet and outlet temperatures, and mass flow rate of the circulating condenser water loop.

Tower Water Make Up Rate [m3/s]***Tower Water Make Up [m3]***

These outputs are the water consumed by the wet cooling tower for external water sprays used to augment heat transfer. This is the total of evaporation, drift, and blowdown.

Tower Water Evaporation Rate [m3/s]***Tower Water Evaporation [m3]******Tower Water Drift Rate [m3/s]******Tower Water Drift [m3]******Tower Water Blowdown Rate [m3/s]******Tower Water Blowdown [m3]***

These outputs provide the breakdown of the different components of water use during cooling tower operation.

If a water storage tank is used to provide water to the tower, then the following output variables will also be available.

Tower Water From Storage Tank Rate [m3/s]***Tower Water From Storage Tank [m3]***

These are the rate and volume of water provided by the Water Storage Tank.

Tower Water Starved By Storage Tank Rate [m3/s]***Tower Water Starved By Storage Tank [m3]***

These are the rate and volume of water the Storage Tank connections was not able to provide. The starved water is assumed to come from the mains. The tower's operation is not affected by a lack of storage tank water.

CoolingTower:TwoSpeed

The two-speed cooling tower is modeled in a similar fashion to the single-speed tower. The cooling tower is modeled as a counterflow heat exchanger with a two-speed fan (induced draft configuration) based on Merkel's theory. The user must define tower performance via one of two methods: heat transfer coefficient-area product (UA) and design water flow rate, or nominal tower capacity at a specific rating point. Regardless of which method is chosen, the airflow rate and corresponding fan power at both high and low fan speed must be specified. The model will also account for tower performance in the "free convection" regime, when the tower fan is off but the water pump remains on and heat transfer still occurs (albeit at a low level). If the user wants the model to account for "free convection", they must specify the corresponding air flow rate and heat transfer coefficient-area product (UA), or the nominal tower capacity during this mode of operation.

The cooling tower seeks to maintain the temperature of the water exiting the cooling tower at (or below) a set point. The set point schedule value is defined by the field "Condenser Loop Temperature Setpoint Node Name or Reference" for the CondenserLoop object. The model first checks to determine the impact of "free convection", if specified by the user, on the tower

exiting water temperature. If the exiting water temperature based on “free convection” is at or below the set point, then the tower fan is not turned on. If the exiting water temperature remains above the set point after “free convection” is modeled, then the tower fan is turned on at low speed to reduce the exiting water temperature. If operating the tower fan at low speed does not reduce the exiting water temperature to the set point, then the tower fan is increased to its high speed.

The model assumes that part-load operation is represented by a simple linear interpolation between two steady-state regimes (i.e., tower fan at high speed for the entire simulation timestep and tower fan at low speed for the entire simulation timestep, or tower fan at low speed for the entire simulation timestep and tower fan off for the entire simulation timestep). Cyclic losses are not taken into account.

Cooling towers here are “wet” and consume water through evaporation, drift, and blowdown. The model can be used to predict water consumed by the towers. The last six input fields are optional and provide methods of controlling details of the water consumption calculations. The user can specify connections to the rest of the buildings water system by providing the name of a WaterUse:Storage object.

The IDD specification for the two-speed cooling tower is given below.

```

CoolingTower:TwoSpeed,

```

Field: Name

This alpha field contains the identifying name for the cooling tower.

Field: Water Inlet Node Name

This alpha field contains the identifying name for the cooling tower's water inlet node.

Field: Water Outlet Node Name

This alpha field contains the identifying name for the cooling tower's water outlet node.

Field: Design Water Flow Rate

This numeric field contains the design water flow rate through the tower in m³/s. This value is the flow rate of the condenser loop water being cooled by the tower (not the flow rate of water being sprayed on the outside of the heat exchange coil). If the input field “Performance Input Method” is specified as “UFactorTimesAreaAndDesignWaterFlowRate”, then a water flow rate greater than zero must be defined or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design water flow rate is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Plant Sizing and Input for Design Calculations and Component Autosizing). If “Performance Input Method” is specified as “NominalCapacity”, then this field must be left blank since the model automatically assumes a design water flow rate of 5.382E-8 m³/s per watt (3 gpm/ton) of tower capacity specified in the field “Tower High-Speed Nominal Capacity”.

Field: Air Flow Rate at High Fan Speed

This numeric field contains the tower air flow rate at high fan speed in m³/s. A value greater than zero must be defined regardless of the tower performance input method. Alternately, this field can be autosized. If autosized, the design air flow rate is calculated as follows:

$$\text{Air Flow Rate at High Fan Speed} = \frac{0.5 \rho_{\text{air}} (\text{Fan Power at High Fan Speed})}{190}$$

where a fan pressure rise of 190 Pascals and total fan efficiency of 0.5 are assumed.

Field: Fan Power at High Fan Speed

This numeric field contains the fan power (in Watts) at the high-speed air flow rate specified in the previous field. A value greater than zero must be specified regardless of the tower performance input method, or this field can be autosized. If autosized, the fan power is calculated as follows:

If “Performance Input Method” is specified as “UFactorTimesAreaAndDesignWaterFlowRate”, then

$$\text{Fan power}_{\text{High Fan Speed}} = 0.0105 \cdot \rho_{\text{water}} \cdot C_{p,\text{water}} \cdot \text{Design Water Flow Rate} \cdot \text{Design Loop } \Delta T$$

is used.

If “Performance Input Method” is specified as “NominalCapacity”, then

$$\text{Fan power}_{\text{High Fan Speed}} = 0.0105 \cdot \text{Tower High – Speed Nominal Capacity}$$

is used.

Field: U-Factor Times Area Value at High Fan Speed

This numeric field contains the heat transfer coefficient-area product (UA) in watts per degree Celsius corresponding to the high-speed air flow rate and design water flow rate specified above. If the input field “Performance Input Method” is specified as “UFactorTimesAreaAndDesignWaterFlowRate”, then a UA value greater than zero but less than or equal to 300,000 must be defined, or the field can be autosized. If autosized, a Plant Sizing object must be defined and the tower UA value at high fan speed is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Plant Sizing and Input for Design Calculations and Component Autosizing), assuming a tower water inlet temperature of 35C and tower inlet air at 35C drybulb/25.6C wetbulb. If “Performance Input Method” is specified as “NominalCapacity”, then this field must be left blank since the model automatically calculates the tower UA based on the capacity specified in the field “High-Speed Nominal Capacity”.

Field: Air Flow Rate at Low Fan Speed

This numeric field contains the tower air flow rate at low fan speed in m^3/s . This value must be greater than zero, less than the value specified for the field “Air Flow Rate at High Fan Speed”, and greater than the value specified for the field “Air Flow Rate in Free Convection Regime”. This field may be autosized, in which case it is set to 50% of the “Air Flow Rate at High Fan Speed”.

Field: Fan Power at Low Fan Speed

This numeric field contains the fan power (in Watts) at the low-speed air flow rate specified in the previous field. This value must be specified greater than zero or the field may be autosized, in which case it is set to 16% of the “Fan Power at High Fan Speed”.

Field: U-Factor Times Area Value at Low Fan Speed

This numeric field contains the heat transfer coefficient-area product (UA) in watts per degree Celsius corresponding to the design water flow rate and low-speed air flow rate specified above. If the input field “Performance Input Method” is specified as “UFactorTimesAreaAndDesignWaterFlowRate”, this value must be greater than zero but less than or equal to 300,000, less than the value specified for the field “U-Factor Times Area Value at High Fan Speed”, and greater than the value specified for the field “U-Factor Times Area Value at Free Convection Air Flow Rate”. This field may be autosized, in which case it is set to 60% of the “U-Factor Times Area Value at High Fan Speed”. If “Performance Input Method” is specified as “NominalCapacity”, then this field must be left blank since the model automatically calculates the tower UA based on the tower capacity specified in the field “Low Speed Nominal Capacity”.

Field: Air Flow Rate in Free Convection Regime

This numeric field contains the air flow rate (m^3/s) when the tower is in the “free convection” regime (water flow exists but tower fan is turned off). This value must be less than the value specified for the field “Air Flow Rate at Low Fan Speed”. This field may be autosized, in which case it is set to 10% of the “Air Flow Rate at High Fan Speed”. If the user does not wish to model “free convection” and is using the Performance Input Method “UFactorTimesAreaAndDesignWaterFlowRate”, then this field should be set to 0.0. If the user specifies the U-Factor Times Area Value at Free Convection Air Flow Rate or Free Convection Capacity as a value greater than zero, then the free convection air flow rate must be specified greater than 0.0.

Field: U-Factor Times Area Value at Free Convection Air Flow Rate

This numeric field contains the heat transfer coefficient-area product ($\text{W}/^\circ\text{C}$) when the tower is in the “free convection” regime (water flow exists but tower fan is turned off). This value must be less than the value specified for the field “U-Factor Times Area Value at Low Fan Speed”. This field may be autosized, in which case it is set to 10% of the “U-Factor Times Area Value at High Fan Speed”. If the user does not wish to model “free convection” and is using the Performance Input Method “UFactorTimesAreaAndDesignWaterFlowRate”, then this field should be set to 0.0. If “Performance Input Method” is specified as “NominalCapacity”, then this field must be left blank since the model automatically calculates the tower UA based on the tower capacity specified in the field “Free Convection Capacity”.

Field: Performance Input Method

This alpha field contains the method by which the user will specify tower performance: “UFactorTimesAreaAndDesignWaterFlowRate” or “NominalCapacity”. If this field is left blank in the input data file, the default input method is assumed to be “NominalCapacity”. If the method “UFactorTimesAreaAndDesignWaterFlowRate” is selected, then the user must enter UA values, design water flow rate and air flow rates as described for the previous input fields. If the method “NominalCapacity” is selected then the fields “Design Water Flow Rate”, “U-Factor Times Area Value at High Fan Speed”, “U-Factor Times Area Value at Low Fan

Speed” and “U-Factor Times Area Value at Free Convection Air Flow Rate” must be left blank, but the fields “High Speed Nominal Capacity”, “Low Speed Nominal Capacity” and “Free Convection Capacity” must be entered as described below.

Field: High Speed Nominal Capacity

This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts under high-speed fan operation, with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be $5.382E-8$ m³/s per watt of high-speed nominal capacity (3 gpm/ton). 125% of this nominal tower capacity gives the actual tower heat rejection at these operating conditions (based on historical assumption that the tower must dissipate 0.25W of compressor heat for every watt of heat removed by the evaporator).

Field: Low Speed Nominal Capacity

This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts under low-speed fan operation, with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be $5.382E-8$ m³/s per watt of high-speed nominal tower capacity (input field above). 125% of this nominal tower capacity gives the actual tower heat rejection at these operating conditions (based on historical assumption that the tower must dissipate 0.25W of compressor heat for every watt of heat removed by the evaporator). The value specified for this field must be greater than zero but less than the value specified for the field “High-Speed Nominal Capacity”.

Field: Free Convection Capacity

This numeric input field contains the “nominal” heat rejection capacity of the cooling tower in watts when the tower is in the “free convection” regime (water flow exists but tower fan is turned off), with entering water at 35C (95F), leaving water at 29.4C (85F), entering air at 25.6C (78F) wetbulb and 35C (95F) drybulb temperatures. The design water flow rate is assumed to be $5.382E-8$ m³/s per watt of high-speed nominal tower capacity (input field above). 125% of this free convection tower capacity gives the actual tower heat rejection at these operating conditions (based on historical assumption that the tower must dissipate 0.25W of compressor heat for every watt of heat removed by the evaporator). The value specified for this field must be less than the value specified for the field “Tower Low-Speed Nominal Capacity”. If the user does not wish to model “free convection”, then this field should be set to 0.0. If the user specifies a value greater than zero, then the “Air Flow Rate in Free Convection Regime” field must contain a value greater than zero.

Field: Evaporation Loss Mode

This field is used to choose which method is used to model the amount of water evaporated by the cooling tower. There are two options: ‘LossFactor’ or ‘SaturatedExit’. The default is SaturatedExit. The user-defined loss factor is entered in the following field. By assuming that the air leaving the tower is saturated, the evaporation can be directly calculated using moist air engineering calculations with data available within the cooling tower model (and does not require additional user input).

Field: Evaporation Loss Factor

This field is used to specify the rate of water evaporated from the cooling tower and lost to the outside air [percent/K]. This field is only used if the Evaporation Calculation Mode is set to LossFactor. The evaporation loss is then calculated as a fraction of the circulating condenser water flow and varies with the temperature change in the condenser water. The value entered here is in units of percent-per-degree Kelvin. The evaporation rate will equal this value times each degree Kelvin of temperature drop in the condenser water. Typical values are from 0.15 to 0.27 [percent/K]. The default is 0.2.

Field: Drift Loss Percent

This field is used to specify the rate of water lost to the exiting air as entrained droplets [%]. The drift loss is a percent of the condenser water flow. Typical values for towers with efficient drift eliminators are between 0.002 and 0.2% of the condenser water flow rate. The default value is 0.008%.

Field: Blowdown Calculation Mode

This field specifies which method is used to determine blowdown rates. There two options ConcentrationRatio or ScheduledRate. The choice will determine which of the two models below is used. The default is ConcentrationRatio

Field: Blowdown Concentration Ratio

This field is used to dynamically adjust the rate of blowdown in the cooling tower as a function of the rate of evaporation. Blowdown is water intentionally drained from the tower in order to offset the build up of solids in the water that would otherwise occur because of evaporation. The value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Typical values for tower operation are 3 to 5. The default value is 3.

Field: Blowdown Makeup Water Usage Schedule Name

This alpha field contains the name of the schedule used to define the amount of water (m^3/s) flushed from the basin on a periodic basis to purge the tower of mineral scale build-up and other contaminants. This schedule is only used if the Blowdown Calculation mode is set to ScheduledRate. The amount of water use due to blowdown depends on the makeup water quality and is specific to each geographical location. Typical values range from 0.0002 to 0.0013 m^3/s (17.3 to 112.3 m^3/day). This water usage is in addition to the amount of water lost to the atmosphere due to evaporation and/or drift. Since blowdown occurs when the basin water contaminant concentration is high, blowdown only occurs when the cooling tower is active and water is flowing through the tower (regardless of the water usage defined by this schedule).

Field: Supply Water Storage Tank Name

This field is optional. It is used to describe where the tower obtains water used for evaporative cooling. If blank or omitted, then the tower will obtain water directly from the mains. If the name of a WaterUse:Storage object is used here, then the tower will obtain its water from that tank. If a tank is specified, the tower will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the tower needs, then the tower will still operate and obtain the rest of the water it needs from the mains (referred to as 'Starved' water).

Field: Outdoor Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the cooling tower. If this field is left blank, the outdoor air conditions entering the cooling tower are taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air conditions are taken directly from the weather data.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. Sizing factor allows the user to size a component to meet part of the design load while continuing to

use the autosizing feature. For this component the inputs that would be altered by the sizing factor are:

1. Design Water Flow Rate;
2. Air Flow Rate at High Fan Speed;
3. Fan Power at High Fan Speed;
4. U-Factor Times Area Value at High Fan Speed;
5. Air Flow Rate at Low Fan Speed;
6. Fan Power at Low Fan Speed;
7. U-Factor Times Area Value at Low Fan Speed;
8. Air Flow Rate in Free Convection Regime;
9. U-Factor Times Area Value at Free Convection Air Flow Rate.

Note that the U-Factor Times Area Value at High Fan Speed is not *multiplied* by the Sizing Factor. Instead the design tower load is multiplied by the sizing factor and the design UA then calculated as usual. The U-Factor Times Area Value at Low Fan Speed is set to 60% of the full load design UA. The U-Factor Times Area Value at Free Convection Air Flow Rate is set to 10% of the design Tower UA.

Three examples of an IDF specification for this object are shown below:

Cooling Tower:Two Speed Outputs

```

HVAC,Average,Tower Fan Electric Power [W]
HVAC,Sum,Tower Fan Electric Consumption [J]
Zone,Meter,HeatRejection:Electricity [J]

HVAC,Average,Tower Heat Transfer [W]

HVAC,Average,Tower Water Inlet Temp [C]
HVAC,Average,Tower Water Outlet Temp [C]
HVAC,Average,Tower Water Mass Flow Rate [kg/s]

```

Tower Fan Electric Power [W]

Tower Fan Electric Consumption [J]

These outputs are the electric power input to the tower fans. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

Tower Heat Transfer [W]

This is the rate at which heat is removed from the condenser water loop by the tower.

Tower Water Inlet Temp [C]

Tower Water Outlet Temp [C]

Tower Water Mass Flow Rate [kg/s]

These outputs are the tower water inlet and outlet temperatures, and mass flow rate.

Tower Water Make Up Rate [m3/s]

Tower Water Make Up [m3]

These outputs are the water consumed by the wet cooling tower for external water sprays used to augment heat transfer. This is the total of evaporation, drift, and blowdown.

Tower Water Evaporation Rate [m3/s]***Tower Water Evaporation [m3]******Tower Water Drift Rate [m3/s]******Tower Water Drift [m3]******Tower Water Blowdown Rate [m3/s]******Tower Water Blowdown [m3]***

These outputs provide the breakdown of the different components of water use during cooling tower operation.

If a water storage tank is used to provide water to the tower, then the following output variables will also be available.

Tower Water From Storage Tank Rate [m3/s]***Tower Water From Storage Tank [m3]***

These are the rate and volume of water provided by the Water Storage Tank.

Tower Water Starved By Storage Tank Rate [m3/s]***Tower Water Starved By Storage Tank [m3]***

These are the rate and volume of water the Storage Tank connections was not able to provide. The starved water is assumed to come from the mains. The tower's operation is not affected by a lack of storage tank water.

Cooling Tower:Variable Speed

The variable speed tower model is based on empirical curve fits of manufacturer's performance data or field measurements. The user specifies tower performance at design conditions, and empirical curves are used to determine the approach temperature and fan power at off-design conditions. The user defines tower performance by entering the inlet air wet-bulb temperature, tower range, and tower approach temperature at the design conditions. The corresponding water flow rate (within $\pm 25\%$ of the tower's rated water mass flow rate), air flow rate, and fan power must also be specified. The model will account for tower performance in the "free convection" regime, when the tower fan is off but the water pump remains on and heat transfer still occurs (albeit at a low level). Basin heater operation and makeup water usage (due to evaporation, drift, and blowdown) are also modeled.

The cooling tower seeks to maintain the temperature of the water exiting the cooling tower at (or below) a set point. The set point schedule is defined by the field "Condenser Loop Temperature Setpoint Node Name or Reference" for the CondenserLoop object. The model first checks to determine the impact of "free convection" on the tower exiting water temperature. If the exiting water temperature based on "free convection" is at or below the set point, then the variable-speed tower fan is not turned on. If the exiting water temperature is above the set point after "free convection" is modeled, then the variable-speed tower fan is turned on to reduce the exiting water temperature. Tower fan power is calculated based on the tower air flow rate required to achieve the exiting water set point temperature.

Cooling towers here are "wet" and consume water through evaporation, drift, and blowdown. The model can be used to predict water consumed by the towers. The last six input fields are optional and provide methods of controlling details of the water consumption calculations. The user can specify connections to the rest of the buildings water system by providing the name of a WaterUse:Storage object.

The IDD specification for the variable speed cooling tower is given below.

```

```

Field: Name

This alpha field contains the identifying name for the variable speed cooling tower.

Field: Water Inlet Node Name

This alpha field contains the identifying name for the cooling tower's water inlet node.

Field: Water Outlet Node Name

This alpha field contains the identifying name for the cooling tower's water outlet node.

Field: Model Type

This alpha field contains the type of empirical model used to simulate the tower's thermal performance (approach temperature). Valid choices for this field are "CoolToolsCrossFlow", "CoolToolsUserDefined", "YorkCalc", or "YorkCalcUserDefined". "CoolToolsCrossFlow" and "YorkCalc" are empirical models with the equation form and model coefficients already defined within EnergyPlus. If "CoolToolsUserDefined" or "YorkCalcUserDefined" is selected, the user must specify a valid Model Coefficient Name in the next input field to reference an appropriate CoolingTowerPerformance:CoolTools or CoolingTowerPerformance:YorkCalc object. If a user-defined model type is selected and the specified Model Coefficient Name is not found in the input data file (idf), then a severe message is issued and the simulation will terminate.

Field: Model Coefficient Name

This alpha field contains the identifying name for the object(s) CoolingTowerPerformance:CoolTools or CoolingTowerPerformance:YorkCalc . A single model coefficient object may be used to define coefficients for multiple variable speed cooling tower objects (i.e., the same name may be used in this input field for more than one variable

speed tower). This field is only used when the field Tower Model Type described above is set to “CoolToolsUserDefined” or “YorkCalcUserDefined”, and should be left blank otherwise.

Field: Design Inlet Air Wet-Bulb Temperature

This numeric field specifies the inlet air wet-bulb temperature (°C) at design conditions. This design temperature should correspond with the design values for range temperature, approach temperature, water flow rate, and air flow rate specified in the following fields. The minimum value for this field is 20°C and the default value is 25.6°C if this field is left blank.

Field: Design Approach Temperature

This numeric field specifies the tower approach temperature (°C) at design conditions. The approach temperature is the outlet water temperature minus the inlet air wet-bulb temperature. The design approach temperature should correspond with the design values for inlet air wet-bulb temperature, range temperature, water flow rate, and air flow rate specified for this tower. The value for this field must be greater than 0°C and the default value is 3.9°C if this field is left blank.

Field: Design Range Temperature

This numeric field specifies the range temperature (°C) at design conditions. The range temperature is defined as the inlet water temperature minus the outlet water temperature. The design range temperature should correspond with the design values for inlet air wet-bulb temperature, approach temperature, water flow rate, and air flow rate specified for this tower. The value for this field must be greater than 0°C and the default value is 5.6°C if this field is left blank.

Field: Design Water Flow Rate

This numeric field contains the design water flow rate through the tower in m³/s. The value entered should be within ±25% of the tower’s rated water mass flow rate as specified by the manufacturer if Model Type is “CoolToolsCrossFlow” or “YorkCalc”. This constraint may be different for Model Type “CoolToolsUserDefined” or “YorkCalcUserDefined” (ref. CoolingTowerPerformance:CoolTools or CoolingTowerPerformance:YorkCalc).

This value is the flow rate of the condenser loop water being cooled by the tower. A value greater than zero must be specified or this field can be autosized. A Plant Sizing object must be defined if the field is autosized and the design water flow rate is then derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Plant Sizing and Input for Design Calculations and Component Autosizing). The design water flow rate should correspond with the design values specified for the inlet air wet-bulb temperature, approach temperature, range temperature, and air flow rate. When this field is not autosized, the condenser loop flow rate specified in other objects should be within ±25% of the tower’s rated water flow rate (different range is permissible if Model Type is “User Defined”).

Field: Design Air Flow Rate

This numeric field contains the design (maximum) air flow rate through the tower in m³/s. A value greater than zero must be specified or this field can be autosized. Autosizing of this field does not require a Plant Sizing object since the design air flow rate is assumed to be the design fan power multiplied by a total fan efficiency of 0.5 and divided by a fan pressure rise of 190 Pascals. A correction for altitude is also included as follows:

$$\text{Design Air Flow Rate} = \frac{0.5(\text{Fan power at Design Air Flow Rate})}{190} \left(\frac{101325}{P_{atm}} \right)$$

Field: Design Fan Power

This numeric field contains the fan power in watts at the design (maximum) air flow rate through the tower. A value greater than zero must be specified or this field can be autosized. If autosized, a Plant Sizing object must be defined and the fan power is calculated as follows:

$$\text{Design fan power} = 0.0105 \cdot \rho_{\text{water}} \cdot C_{p,\text{water}} \cdot \text{Design Water Flow Rate} \cdot \text{Design Loop } \Delta T$$

Field: Fan Power Ratio Function of Air Flow Rate Ratio Curve Name

This alpha field contains the curve object name for fan power ratio (fan power/design fan power) as a function of air flow rate ratio (air flow rate/design air flow rate) [ref. Performance Curves]. The curve object must be a cubic curve and should be normalized to 1.0 at an air flow rate ratio of 1.0. If this field is left blank, a theoretical fan curve is assumed where fan power ratio is directly proportional to the air flow rate ratio cubed.

Field: Minimum Air Flow Rate Ratio

This numeric field contains the minimum air flow rate ratio. The tower fan is allowed to operate between the ratio defined here and a maximum air flow rate ratio of 1.0 (which corresponds to the design [maximum] tower air flow rate). Below this value, the tower is assumed to operate either in the “free convection” regime with the tower fan off, or the tower fan is cycled on/off to maintain the exiting water set point temperature. The minimum air flow rate ratio must be greater than or equal to 0.2 and less than or equal to 0.5, with a default value of 0.2 if the field is left blank.

Field: Fraction of Tower Capacity in Free Convection Regime

This numeric field contains the fraction of tower capacity available in the free convection regime (i.e., when the tower fan is off but water continues to flow through the tower). The tower fan does not operate when the free convection tower capacity is able to meet or exceed the exiting water set point temperature. The air flow rate through the tower in the free convection regime is assumed to be this same fraction of the tower design air flow rate. The fraction of tower capacity in free convection regime must be greater than or equal to 0 and less than or equal to 0.2, with a default value of 0.125 if this field is left blank.

Field: Basin Heater Capacity

This numeric field contains the capacity of the tower’s electric basin heater in watts per degree Kelvin. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the tower fan is off and water is not flowing through the tower, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

Field: Basin Heater Setpoint Temperature

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the tower fan is off and water is not flowing through the tower. This set point temperature must be greater than or equal to 2°C, and the default value is 2°C if this field is left blank.

Field: Basin Heater Operating Schedule Name

This alpha field contains the name of the basin heater operating schedule. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature

described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the cooling tower fan is off and water is not flowing through the tower.

Field: Evaporation Loss Mode

This field is used to choose which method is used to model the amount of water evaporated by the cooling tower. There are two options: 'LossFactor' or 'SaturatedExit'. The default is SaturatedExit. The user-defined loss factor is entered in the following field. By assuming that the air leaving the tower is saturated, the evaporation can be directly calculated using moist air engineering calculations with data available within the cooling tower model (and does not require additional user input).

Field: Evaporation Loss Factor

This field is used to specify the rate of water evaporated from the cooling tower and lost to the outside air [percent/K]. This field is only used if the Evaporation Calculation Mode is set to LossFactor. The evaporation loss is then calculated as a fraction of the circulating condenser water flow and varies with the temperature change in the condenser water. The value entered here is in units of percent-per-degree Kelvin. The evaporation rate will equal this value times each degree Kelvin of temperature drop in the condenser water. Typical values are from 0.15 to 0.27 [percent/K]. The default is 0.2.

Field: Drift Loss Percent

This numeric field contains the percent (%) of design water flow rate lost to the atmosphere at the design air flow rate due to drift, which is water droplets that are entrained in the airstream as it passes through the tower. Drift is assumed to vary directly with tower air flow rate ratio, and is in addition to the amount of water lost to the atmosphere due to evaporation and/or blowdown. Typical values for water usage due to drift are from 0.05 to 0.2% of the total water circulation rate with currently-available drift eliminators from tower manufacturers. The value entered in this field must be greater than or equal to zero, and the default is zero if the field is left blank.

Field: Blowdown Calculation Mode

This field specifies which method is used to determine blowdown rates. There two options 'ConcentrationRatio' or 'ScheduledRate'. The choice will determine which of the two models below is used. The default is ConcentrationRatio.

Field: Blowdown Concentration Ratio

This field is used to dynamically adjust the rate of blowdown in the cooling tower as a function of the rate of evaporation. Blowdown is water intentionally drained from the tower in order to offset the build up of solids in the water that would otherwise occur because of evaporation. The value entered here is dimensionless. It can be characterized as the ratio of solids in the blowdown water to solids in the make up water. Typical values for tower operation are 3 to 5. The default value is 3.

Field: Blowdown Makeup Water Usage Schedule Name

This alpha field contains the name of the schedule used to define the amount of water (m^3/s) flushed from the basin on a periodic basis to purge the condenser loop of mineral scale build-up and other contaminants. The amount of water use due to blowdown depends on the makeup water quality and is specific to each geographical location. Typical values range from 0.0002 to 0.0013 m^3/s (17.3 to 112.3 m^3/day). This water usage is in addition to the amount of water lost to the atmosphere due to evaporation and/or drift. Since blowdown occurs when the basin water contaminant concentration is high, blowdown only occurs when the cooling tower is active and water is flowing through the tower (regardless of the water usage defined by this schedule).

Field: Supply Water Storage Tank Name

This field is optional. It is used to describe where the tower obtains water used for evaporative cooling. If blank or omitted, then the tower will obtain water directly from the mains. If the name of a WaterUser:Storage object is used here, then the tower will obtain its water from that tank. If a tank is specified, the tower will attempt to obtain all the water it uses from the tank. However if the tank cannot provide all the water the tower needs, then the tower will still operate and obtain the rest of the water it needs from the mains (referred to as 'Starved' water).

Field: Outdoor Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the cooling tower. If this field is left blank, the outdoor air conditions entering the cooling tower are taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air conditions are taken directly from the weather data.

Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature. For this component the inputs that would be altered by the sizing factor are:

1. Design Water Flow Rate;
2. Design Air Flow Rate;
3. Design Fan Power.

Tower Fan Electric Power [W]***Tower Fan Electric Consumption [J]***

These outputs are the electric power input to the tower fan. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

Tower Fan Part-Load Ratio

This is the on/off cycling rate of the tower fan when free convection cannot meet the set point temperature and the tower capacity at the minimum air flow rate ratio drives the tower exiting water temperature below the set point temperature. The fan part-load ratio is calculated as the ratio of the exiting water temperature in the free convection regime minus the exiting water temperature set point divided by the exiting water temperature in the free convection regime minus the exiting water temperature at the minimum air flow rate ratio. If tower air flow is at or above the minimum air flow rate ratio, then the tower fan part-load ratio is 1.0.

Tower Heat Transfer [W]

This is the rate at which heat is removed from the condenser water loop by the tower.

Tower Water Inlet Temp [C]***Tower Water Outlet Temp [C]******Tower Water Mass Flow Rate [kg/s]***

These outputs are the tower water inlet and outlet temperatures, and mass flow rate of the circulating condenser water loop.

Tower Air Flow Rate Ratio

This is the ratio of air flow through the tower to the design air flow rate. During times when the tower can maintain the condenser loop set point temperature using free convection (when the fan is not operating), the air flow rate ratio is assumed to be equal to the field Fraction of Tower Capacity in Free Convection Regime. During times when the fan cycles on/off to maintain the outlet water set point temperature, the air flow rate ratio is calculated as the

summation of Fan Part-Load Ratio multiplied by the Minimum Air Flow Rate Ratio and (1.0 - Fan Part-Load Ratio) multiplied by the fraction of Tower Capacity in Free Convection Regime.

Tower Basin Heater Electric Power [W]

Tower Basin Heater Electric Consumption [J]

These outputs are the electric power input to the tower basin heater. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

Tower Water Make Up Rate [m3/s]

Tower Water Make Up [m3]

These outputs are the water consumed by the wet cooling tower for external water sprays used to augment heat transfer. This is the total of evaporation, drift, and blowdown.

Tower Water Evaporation Rate [m3/s]

Tower Water Evaporation [m3]

Tower Water Drift Rate [m3/s]

Tower Water Drift [m3]

Tower Water Blowdown Rate [m3/s]

Tower Water Blowdown [m3]

These outputs provide the breakdown of the different components of water use during cooling tower operation.

If a water storage tank is used to provide water to the tower, then the following output variables will also be available.

Tower Water From Storage Tank Rate [m3/s]

Tower Water From Storage Tank [m3]

These are the rate and volume of water provided by the Water Storage Tank.

Tower Water Starved By Storage Tank Rate [m3/s]

Tower Water Starved By Storage Tank [m3]

These are the rate and volume of water the Storage Tank connections was not able to provide. The starved water is assumed to come from the mains. The tower's operation is not affected by a lack of storage tank water.

CoolingTowerPerformance:CoolTools

Variable speed cooling towers can be modeled by EnergyPlus with user-selectable performance based on the CoolTools correlation, YorkCalc correlation, or user-defined coefficients for either the CoolTools or YorkCalc correlations. The empirical CoolTools tower correlation uses a set of 35 coefficients to model the thermal performance (approach temperature) of a cooling tower based on four independent variables. If the user specifies Model Type = CoolToolsCrossFlow in the CoolingTower:VariableSpeed object, then the 35 coefficients derived for the CoolTools simulation model are used and these coefficients are already defined within EnergyPlus. If the user specifies Model Type = CoolToolsUserDefined, then the user must enter a CoolingTowerPerformance:CoolTools object to define the 35 coefficients that will be used by the CoolTools correlation.

The user must specify a name for the model coefficient object, and this name must be used in the CoolingTower:VariableSpeed object (field Model Coefficient Name) to tell the program to use these coefficients. Next, the user enters the minimum and maximum values for inlet air wet-bulb temperature, range temperature, approach temperature, and water mass flow rate

ratio to specify the valid range for which the model coefficients were derived. For all of these variables, the program issues warnings if the actual values are beyond the minimum/maximum values specified. For inlet air wet-bulb temperature and water mass flow rate ratio, the values of these variables used in the calculation of approach temperature are limited to be within the valid minimum/maximum range specified. For approach and range, the warnings are issued if the values are beyond the specified minimum/maximum range but the actual values are still used.

The CoolTools correlation has four independent variables: inlet air wet-bulb temperature (Twb), tower range temperature (Tr), water flow rate ratio (FRwater), and air flow rate ratio (FRair). Temperatures are in units of °C and flow rate ratios are dimensionless (actual flow rate divided by design flow rate). Using these independent variables, tower approach temperature (°C) is calculated as follows:

$$\begin{aligned} \text{Approach} = & \text{Coeff}(1) + \text{Coeff}(2) \cdot \text{FRair} + \text{Coeff}(3) \cdot (\text{FRair})^2 + \\ & \text{Coeff}(4) \cdot (\text{FRair})^3 + \text{Coeff}(5) \cdot \text{FRwater} + \\ & \text{Coeff}(6) \cdot \text{FRair} \cdot \text{FRwater} + \text{Coeff}(7) \cdot (\text{FRair})^2 \cdot \text{FRwater} + \\ & \text{Coeff}(8) \cdot (\text{FRwater})^2 + \text{Coeff}(9) \cdot \text{FRair} \cdot (\text{FRwater})^2 + \\ & \text{Coeff}(10) \cdot (\text{FRwater})^3 + \text{Coeff}(11) \cdot \text{Twb} + \text{Coeff}(12) \cdot \text{FRair} \cdot \text{Twb} + \\ & \text{Coeff}(13) \cdot (\text{FRair})^2 \cdot \text{Twb} + \text{Coeff}(14) \cdot \text{FRwater} \cdot \text{Twb} + \\ & \text{Coeff}(15) \cdot \text{FRair} \cdot \text{FRwater} \cdot \text{Twb} + \text{Coeff}(16) \cdot (\text{FRwater})^2 \cdot \text{Twb} + \\ & \text{Coeff}(17) \cdot (\text{Twb})^2 + \text{Coeff}(18) \cdot \text{FRair} \cdot (\text{Twb})^2 + \\ & \text{Coeff}(19) \cdot \text{FRwater} \cdot (\text{Twb})^2 + \text{Coeff}(20) \cdot (\text{Twb})^3 + \text{Coeff}(21) \cdot \text{Tr} + \\ & \text{Coeff}(22) \cdot \text{FRair} \cdot \text{Tr} + \text{Coeff}(23) \cdot \text{FRair} \cdot \text{FRair} \cdot \text{Tr} + \\ & \text{Coeff}(24) \cdot \text{FRwater} \cdot \text{Tr} + \text{Coeff}(25) \cdot \text{FRair} \cdot \text{FRwater} \cdot \text{Tr} + \\ & \text{Coeff}(26) \cdot (\text{FRwater})^2 \cdot \text{Tr} + \text{Coeff}(27) \cdot \text{Twb} \cdot \text{Tr} + \\ & \text{Coeff}(28) \cdot \text{FRair} \cdot \text{Twb} \cdot \text{Tr} + \text{Coeff}(29) \cdot \text{FRwater} \cdot \text{Twb} \cdot \text{Tr} + \\ & \text{Coeff}(30) \cdot (\text{Twb})^2 \cdot \text{Tr} + \text{Coeff}(31) \cdot (\text{Tr})^2 + \text{Coeff}(32) \cdot \text{FRair} \cdot (\text{Tr})^2 + \\ & \text{Coeff}(33) \cdot \text{FRwater} \cdot (\text{Tr})^2 + \text{Coeff}(34) \cdot \text{Twb} \cdot (\text{Tr})^2 + \text{Coeff}(35) \cdot (\text{Tr})^3 \end{aligned}$$

This object allows the user to specify model coefficients for use with the CoolTools correlation shown above. It is recommended that a broad set of cooling tower performance data be used to generate these model coefficients. The data set used to create the model coefficients should cover the entire range of water and air flow rate ratios and inlet air wet-bulb, range, and approach temperatures expected during the simulation.

The IDD definition is shown below:

-- ALL 35 coefficient fields are required --

Field: Name

This alpha field contains the identifying name for the variable speed cooling tower model coefficients.

Field: Minimum Inlet Air Wet-Bulb Temperature

This numeric field contains the minimum inlet air wet-bulb temperature to be used by the model (approach temperature correlation). Inlet air wet-bulb temperatures less than this value will not be used; instead, the minimum inlet air wet-bulb temperature specified here will be used by the correlation and a warning will be issued.

Field: Maximum Inlet Air Wet-Bulb Temperature

This numeric field contains the maximum inlet air wet-bulb temperature to be used by the model (approach temperature correlation). Inlet air wet-bulb temperatures greater than this value will not be used; instead, the maximum inlet air wet-bulb temperature specified here will be used by the correlation and a warning will be issued.

Field: Minimum Range Temperature

This numeric field contains the minimum range temperature (inlet water temperature minus outlet water temperature) to be used by the empirical model. If the range temperature is less than this value the actual range temperature is still passed to the empirical model but a warning will be issued.

Field: Maximum Range Temperature

This numeric field contains the maximum range temperature (inlet water temperature minus outlet water temperature) to be used by the empirical model. If the range temperature is

greater than this value the actual range temperature is still passed to the empirical model but a warning will be issued.

Field: Minimum Approach Temperature

This numeric field contains the minimum approach temperature (outlet water temperature minus inlet air wet-bulb temperature) to be used by the empirical model. If the calculated approach temperature is less than this value then the calculated value is still used but a warning will be issued.

Field: Maximum Approach Temperature

This numeric field contains the maximum approach temperature (outlet water temperature minus inlet air wet-bulb temperature) to be used by the empirical model. If the calculated approach temperature is greater than this value then the calculated value is still used but a warning will be issued.

Field: Minimum Water Flow Rate Ratio

This numeric field contains the minimum water flow rate ratio (ratio of actual water flow rate to rated water flow rate) to be used by the empirical model. Water flow rate ratios less than this value will not be used; instead, the minimum water flow rate ratio specified here will be used by the model and a warning will be issued.

Field: Maximum Water Flow Rate Ratio

This numeric field contains the maximum water flow rate ratio (ratio of actual water flow rate to rated water flow rate) to be used by the empirical model. Water flow rate ratios greater than this value will not be used; instead, the maximum water flow rate ratio specified here will be used by the model and a warning will be issued.

Field: Coefficient 1 to 35

These numeric fields contain the coefficients to be used by the CoolTools approach temperature correlation shown above.

CoolingTowerPerformance:CoolTools

No additional cooling tower report variables are output when this object is used.

CoolingTowerPerformance:YorkCalc

Variable speed cooling towers can be modeled by EnergyPlus with user-selectable performance based on the CoolTools correlation, YorkCalc correlation, or user-defined coefficients for either the CoolTools or YorkCalc correlations. The empirical YorkCalc tower correlation uses a set of 27 coefficients to model the thermal performance (approach temperature) of a variable speed cooling tower based on three independent variables. If the user specifies Tower Model Type = YorkCalc in the CoolingTower:VariableSpeed object, then the 27 coefficients derived for the YorkCalc simulation model are used and these coefficients are already defined within EnergyPlus. If the user specifies Tower Model Type = YorkCalcUserDefined, then the user must enter a CoolingTowerPerformance:YorkCalc object to define the 27 coefficients that will be used by the YorkCalc correlation.

The user must specify a name for the model coefficient object, and this name must be used in the CoolingTower:VariableSpeed object (field Model Coefficient Name) to tell the program to use these coefficients. Next, the user enters the minimum and maximum values for inlet air wet-bulb temperature, range temperature, approach temperature, and water mass flow rate ratio to specify the valid range for which the model coefficients were derived. The user also specifies the maximum valid liquid-to-gas ratio. For all of these variables, the program issues warnings if the actual values are beyond the minimum/maximum values specified. For inlet air wet-bulb temperature and water mass flow rate ratio, the values of these variables used in the calculation of approach temperature are limited to be within the valid minimum/maximum range specified. For approach, range, and liquid-to-gas ratio the warnings are issued if the values are beyond the specified minimum/maximum range but the actual values are still used.

The YorkCalc correlation has three independent variables: inlet air wet-bulb temperature (Twb), tower range temperature (Tr), and the liquid-to-gas ratio (ratio of water flow rate ratio to air flow rate ratio = LGRatio). Temperatures are in units of °C and liquid-to-gas ratio is dimensionless. Using these independent variables, an approach temperature (°C) is calculated as follows:

$$\begin{aligned} \text{Approach} = & \text{Coeff}(1) + \text{Coeff}(2) \cdot \text{Twb} + \text{Coeff}(3) \cdot \text{Twb}^2 + \text{Coeff}(4) \cdot \text{Tr} + \\ & \text{Coeff}(5) \cdot \text{Twb} \cdot \text{Tr} + \text{Coeff}(6) \cdot \text{Twb}^2 \cdot \text{Tr} + \text{Coeff}(7) \cdot \text{Tr}^2 + \\ & \text{Coeff}(8) \cdot \text{Twb} \cdot \text{Tr}^2 + \text{Coeff}(9) \cdot \text{Twb}^2 \cdot \text{Tr}^2 + \text{Coeff}(10) \cdot \text{LGRatio} + \end{aligned}$$

$$\begin{aligned}
& \text{Coeff}(11) \cdot \text{Twb} \cdot \text{LGRatio} + \text{Coeff}(12) \cdot \text{Twb}^2 \cdot \text{LGRatio} + \\
& \text{Coeff}(13) \cdot \text{Tr} \cdot \text{LGRatio} + \text{Coeff}(14) \cdot \text{Twb} \cdot \text{Tr} \cdot \text{LGRatio} + \\
& \text{Coeff}(15) \cdot \text{Twb}^2 \cdot \text{Tr} \cdot \text{LGRatio} + \text{Coeff}(16) \cdot \text{Tr}^2 \cdot \text{LGRatio} + \\
& \text{Coeff}(17) \cdot \text{Twb} \cdot \text{Tr}^2 \cdot \text{LGRatio} + \text{Coeff}(18) \cdot \text{Twb}^2 \cdot \text{Tr}^2 \cdot \text{LGRatio} + \\
& \text{Coeff}(19) \cdot \text{LGRatio}^2 + \text{Coeff}(20) \cdot \text{Twb} \cdot \text{LGRatio}^2 + \\
& \text{Coeff}(21) \cdot \text{Twb}^2 \cdot \text{LGRatio}^2 + \text{Coeff}(22) \cdot \text{Tr} \cdot \text{LGRatio}^2 + \\
& \text{Coeff}(23) \cdot \text{Twb} \cdot \text{Tr} \cdot \text{LGRatio}^2 + \text{Coeff}(24) \cdot \text{Twb}^2 \cdot \text{Tr} \cdot \text{LGRatio}^2 + \\
& \text{Coeff}(25) \cdot \text{Tr}^2 \cdot \text{LGRatio}^2 + \text{Coeff}(26) \cdot \text{Twb} \cdot \text{Tr}^2 \cdot \text{LGRatio}^2 + \\
& \text{Coeff}(27) \cdot \text{Twb}^2 \cdot \text{Tr}^2 \cdot \text{LGRatio}^2
\end{aligned}$$

This object allows the user to specify model coefficients for use with the YorkCalc correlation shown above. It is recommended that a broad set of cooling tower performance data be used to generate these model coefficients. The data set used to create the model coefficients should cover the entire range of water and air flow rate ratios and inlet air wet-bulb, range, and approach temperatures expected during the simulation.

The IDD definition is shown below:

Field: Name

This alpha field contains the identifying name for the variable speed cooling tower model coefficients.

Field: Minimum Inlet Air Wet-Bulb Temperature

This numeric field contains the minimum inlet air wet-bulb temperature to be used by the model (approach temperature correlation). Inlet air wet-bulb temperatures less than this value will not be used; instead, the minimum inlet air wet-bulb temperature specified here will be used by the correlation and a warning will be issued.

Field: Maximum Inlet Air Wet-Bulb Temperature

This numeric field contains the maximum inlet air wet-bulb temperature to be used by the model (approach temperature correlation). Inlet air wet-bulb temperatures greater than this value will not be used; instead, the maximum inlet air wet-bulb temperature specified here will be used by the model and a warning will be issued.

Field: Minimum Range Temperature

This numeric field contains the minimum range temperature (inlet water temperature minus outlet water temperature) to be used by the empirical model. If the range temperature is less than this value the actual range temperature is still passed to the empirical model but a warning will be issued.

Field: Maximum Range Temperature

This numeric field contains the maximum range temperature (inlet water temperature minus outlet water temperature) to be used by the empirical model. If the range temperature is greater than this value the actual range temperature is still passed to the empirical model but a warning will be issued.

Field: Minimum Approach Temperature

This numeric field contains the minimum approach temperature (outlet water temperature minus inlet air wet-bulb temperature) to be used by the empirical model. If the calculated approach temperature is less than this value then the calculated value is still used but a warning will be issued.

Field: Maximum Approach Temperature

This numeric field contains the maximum approach temperature (outlet water temperature minus inlet air wet-bulb temperature) to be used by the empirical model. If the calculated approach temperature is greater than this value then the calculated value is still used but a warning will be issued.

Field: Minimum Water Flow Rate Ratio

This numeric field contains the minimum water flow rate ratio (ratio of actual water flow rate to rated water flow rate) to be used by the empirical model. Water flow rate ratios less than this value will not be used; instead, the minimum water flow rate ratio specified here will be used by the model and a warning will be issued.

Field: Maximum Water Flow Rate Ratio

This numeric field contains the maximum water flow rate ratio (ratio of actual water flow rate to rated water flow rate) to be used by the empirical model. Water flow rate ratios greater than this value will not be used; instead, the maximum water flow rate ratio specified here will be used by the model and a warning will be issued.

Field: Maximum Liquid to Gas Ratio

This numeric field contains the maximum liquid-to-gas ratio (ratio of actual water flow rate ratio [capped to be within the minimum/maximum water flow rate ratio defined above as necessary] to actual air flow rate ratio) to be used by the empirical model. If the liquid-to-gas ratio is greater than this value the actual liquid to gas ratio is still passed to the empirical model but a warning will be issued.

Field: Coefficient 1 to 27

These numeric fields contain the coefficients to be used by the YorkCalc approach temperature correlation shown above.

An example IDF specification for this object is shown below:

CoolingTowerPerformance:YorkCalc Outputs

No additional cooling tower report variables are output when this object is used.

FluidCooler: SingleSpeed

Fluid coolers are components that may be assigned to condenser loops. The Fluid cooler is modeled as a cross flow heat exchanger (both streams unmixed) with single-speed fans (induced draft configuration). The user must define fluid cooler performance via one of the two methods: design heat transfer coefficient-area product (UA) and design water flow rate, or nominal fluid cooler capacity at a specific rating point. Regardless of which method is chosen, the design airflow rate and corresponding fan power must be specified.

The fluid cooler seeks to maintain the temperature of the water exiting the fluid cooler at (or below) a set point. The set point schedule value is defined by the field “Condenser Loop Temperature Setpoint Node Name or Reference” for the CondenserLoop object. The model assumes that part-load operation is represented by a simple linear interpolation between two steady-state regimes (i.e., fluid cooler fan on for the entire simulation timestep and fluid cooler fan off for the entire simulation timestep). Cyclic losses are not taken into account.

Field: Name

This alpha field contains the identifying name for the Fluid Cooler.

Field: Water Inlet Node Name

This alpha field contains the identifying name for the Fluid Cooler’s water inlet node.

Field: Water Outlet Node Name

This alpha field contains the identifying name for the Fluid Cooler’s water outlet node.

Field: Performance Input Method

This alpha field contains the method by which the user will specify fluid cooler performance: “UFactorTimesAreaAndDesignWaterFlowRate” or “NominalCapacity”.

Field: U-factor Times Area Value at Design Air Flow Rate

This numeric field contains the heat transfer coefficient-area product (UA) in watts per degree Celsius corresponding to the design air and water flow rates specified above. If the input field “Performance Input Method” is specified as “UFactorTimesAreaAndDesignWaterFlowRate”, then a UA value greater than zero but less than or equal to 300,000 must be defined, or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design fluid cooler UA value is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Plant Sizing and Input for Design Calculations and Component Autosizing), the fluid cooler inlet air dry-bulb and wetbulb temperature are taken from the input. If “Performance Input Method” is specified as “NominalCapacity”, then this field must be left blank since the model automatically calculates the fluid cooler UA based on the fluid cooler capacity and nominal conditions specified in input file.

Field: Nominal Capacity

This numeric input field contains the “nominal” heat rejection capacity of the fluid cooler in watts, Nominal conditions i.e. entering air dry-bulb temperature, entering air wet-bulb temperature, Entering water temperature and leaving water temperature should be provided in the input.

Field: Design Entering Water Temperature

This numeric field contains entering water temperature at nominal conditions.

Field: Design Entering Air Temperature

This numeric field contains entering air dry-bulb temperature at nominal conditions.

Field: Design Entering Air Wet-bulb Temperature

This numeric field contains entering air wetbulb temperature at nominal conditions.

Field: Design Water Flow Rate

This numeric field contains the design water flow rate through the fluid cooler in m^3/s . This value is the flow rate of the condenser loop water being cooled by the fluid cooler. If the input field “Performance Input Method” is specified as “UFactorTimesAreaAndDesignWaterFlowRate”, then a water flow rate greater than zero must be defined or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design water flow rate is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Plant Sizing and Input for Design Calculations and Component Autosizing). If “Performance Input Method” is specified as “NominalCapacity”, then this field must be specified as the flow rate for which the nominal capacity is given.

Field: Design Air Flow Rate

This numeric field contains the design air flow rate induced by the fluid cooler fan in m^3/s . A value greater than zero must be defined regardless of the fluid cooler performance input method. Alternately, this field can be autosized. See Engineering ref. for fluid cooler autosizing.

Field: Fan Power at Design Air Flow Rate

This numeric field contains the fan power (in watts) at the design air flow rate specified in the previous field. A value greater than zero must be specified regardless of the performance input method, or this field can be autosized. See Engineering ref. for fluid cooler autosizing.

Field: Fluid Name

This alpha field contains the fluid name. This name will be validated against Fluid Names (ref: Fluid Properties section below) in the input file.

Field: Fluid Glycol Concentration

This numeric field contains the fluid glycol concentration in percentage.

Field: Outdoor Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the fluid cooler. If this field is left blank, the outdoor air conditions entering the fluid cooler are taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air conditions are taken directly from the weather data.

The IDD specification for the single-speed Fluid Cooler is given below.

```

```

Fluid Cooler Fan Electric Power [W]

The electric power consumption of the fluid cooler fans.

Fluid Cooler Fan Electric Consumption [J]

Fan energy use. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

Fluid Cooler Heat Transfer [W]

This is the rate at which heat is removed from the condenser water loop by the fluid cooler.

Fluid Cooler Water Inlet Temperature [C]

The loop temperature at the fluid cooler inlet.

Fluid Cooler Water Outlet Temperature [C]

The loop temperature at the fluid cooler outlet.

Fluid Cooler Water Mass Flow Rate [kg/s]

The loop mass flow rate of the circulating condenser water loop.

Fluidcooler:TwoSpeed

The two-speed fluid cooler is modeled in a similar fashion to the single-speed fluid cooler. The fluid cooler is modeled as a cross flow heat exchanger (both stream unmixed) with two-speed fans (induced draft configuration). The user must define fluid cooler performance via one of two methods: heat transfer coefficient-area product (UA) and design water flow rate, or nominal fluid cooler capacity at a specific rating point. Regardless of which method is chosen, the airflow rate and corresponding fan power at both high and low fan speed must be specified. The Fluid Cooler seeks to maintain the temperature of the water exiting the Fluid Cooler at (or below) a set point. The set point schedule is defined by the field “Condenser Loop Temperature Setpoint Node Name or Reference” for the CondenserLoop object. The model first runs at low speed and calculates the fluid cooler exiting water temperature. If the exiting water temperature based on “low speed” is at or below the set point, then the fluid cooler fan runs at this speed or below this speed. If the exiting water temperature remains above the set point after “low speed” is modeled, then the fluid cooler fan runs at high speed to reduce the exiting water temperature.

The model assumes that part-load operation is represented by a simple linear interpolation between two steady-state regimes (i.e., fluid cooler fan at high speed for the entire simulation timestep and fluid cooler fan at low speed for the entire simulation timestep.). Cyclic losses are not taken into account.

Field: Name

This alpha field contains the identifying name for the fluid cooler.

Field: Water Inlet Node Name

This alpha field contains the identifying name for the fluid cooler’s water inlet node.

Field: Water Outlet Node Name

This alpha field contains the identifying name for the fluid cooler’s water outlet node.

Field: Performance Input Method

This alpha field contains the method by which the user will specify fluid cooler performance: “UFactorTimesAreaAndDesignWaterFlowRate” or “NominalCapacity”.

Field: U-factor Times Area Value at High Fan Speed

This numeric field contains the heat transfer coefficient-area product (UA) in watts per degree Celsius corresponding to the high-speed air flow rate and design water flow rate specified above. If the input field “Performance Input Method” is specified as “UFactorTimesAreaAndDesignWaterFlowRate”, then a UA value greater than zero but less than or equal to 300,000 must be defined, or the field can be autosized. If autosized, a Plant Sizing object must be defined and the fluid cooler UA value at high fan speed is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Plant Sizing and Input for Design Calculations and Component Autosizing), fluid cooler water inlet temperature, fluid cooler inlet air drybulb and wetbulb are provided in the input. If “Performance Input Method” is specified as “NominalCapacity”, then this field must be left blank since the model automatically calculates the fluid cooler UA based on the capacity specified in the field “High Speed Nominal Capacity” and nominal conditions.

Field: U-factor Times Area Value at Low Fan Speed

This numeric field contains the heat transfer coefficient-area product (UA) in watts per degree Celsius corresponding to the design water flow rate and low-speed air flow rate specified above. If the input field “Performance Input Method” is specified as “UFactorTimesAreaAndDesignWaterFlowRate”, this value must be greater than zero but less than or equal to 300,000, less than the value specified for the field “U-factor Times Area Value at High Fan Speed”. This field may be autosized, in which case it is set to 60% of the

“U-factor Times Area Value at High Fan Speed”. If “Performance Input Method” is specified as “NominalCapacity”, then this field must be left blank since the model automatically calculates the fluid cooler UA based on the fluid cooler capacity specified in the field “Low Speed Nominal Capacity”.

Field: High Speed Nominal Capacity

This numeric input field contains the “nominal” heat rejection capacity of the fluid cooler in watts under high-speed fan operation, with nominal (design) inputs entering water temperature, leaving water temperature, entering air temperature and entering air wet-bulb temperature. The design water flow rate is also provided in the input.

Field: Low Speed Nominal Capacity

This numeric input field contains the “nominal” heat rejection capacity of the Fluid Cooler in watts under low-speed fan operation, with nominal (design) inputs entering water temperature, leaving water temperature, entering air temperature and entering air wet-bulb temperature. The design water flow rate is also provided in the input. The value specified for this field must be greater than zero but less than the value specified for the field “High Speed Nominal Capacity”.

Field: Design Entering Water Temperature

This numeric field contains entering water temperature at nominal conditions.

Field: Design Entering Air Temperature

This numeric field contains entering air dry-bulb temperature at nominal conditions.

Field: Design Entering Air Wet-bulb temperature

This numeric field contains entering air wet-bulb temperature at nominal conditions.

Field: Design Water Flow Rate

This numeric field contains the design water flow rate through the fluid cooler in m^3/s . This value is the flow rate of the condenser loop water being cooled by the fluid cooler. If the input field “Performance Input Method” is specified as “UFactorTimesAreaAndDesignWaterFlowRate”, then a water flow rate greater than zero must be defined or the field can be autosized. If autosized, a Plant Sizing object must be defined and the design water flow rate is derived from the design load to be rejected by the condenser loop and the design loop delta T (Ref. Plant Sizing and Input for Design Calculations and Component Autosizing). If “Performance Input Method” is specified as “NominalCapacity”, then this field must be specified as the flow rate for which the nominal capacity is given.

Field: Air Flow Rate at High Fan Speed

This numeric field contains the fluid cooler air flow rate at high fan speed in m^3/s . A value greater than zero must be defined regardless of the fluid cooler performance input method. Alternately, this field can be autosized. See Engineering ref. for fluid cooler autosizing.

Field: Fan Power at High Fan Speed

This numeric field contains the fan power (in Watts) at the high-speed air flow rate specified in the previous field. A value greater than zero must be specified regardless of the fluid cooler performance input method, or this field can be autosized. See Engineering ref. for fluid cooler autosizing.

Field: Air Flow Rate at Low Fan Speed

This numeric field contains the fluid cooler air flow rate at low fan speed in m^3/s . This value must be greater than zero, less than the value specified for the field “Air Flow Rate at High

Fan Speed”. This field may be autosized, in which case it is set to 50% of the “Air Flow Rate at High Fan Speed”.

Field: Fan Power at Low Fan Speed

This numeric field contains the fan power (in Watts) at the low-speed air flow rate specified in the previous field. This value must be specified greater than zero or the field may be autosized, in which case it is set to 16% of the “Fan Power at High Fan Speed”.

Field: Fluid Name

This alpha field contains the fluid name. This name will be validated against Fluid Names (ref: Fluid Properties section below) in the input file.

Field: Fluid Glycol Concentration

This numeric field contains the fluid/glycol concentration in percentage.

Field: Outdoor Air Inlet Node Name

This optional alpha field specifies the outdoor air node name used to define the conditions of the air entering the Fluid Cooler. If this field is left blank, the outdoor air conditions entering the Fluid Cooler are taken directly from the weather data. If this field is not blank, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air conditions from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air conditions are taken directly from the weather data.

The IDD specification for the two-speed Fluid Cooler is given below.

```
Fluidcooler:TwoSpeed,
  \min-fields 12
  \memo This fluidcooler model is based on Merkel's theory, which is also the basis
  \memo for the fluidcooler model in ASHRAE's HVAC1 Toolkit. The closed-circuit FLUID COOLER
  \memo is modeled as a counterflow heat exchanger with a two-speed fan drawing air
  \memo through the fluidcooler (induced-draft configuration).

Fluid Cooler Fan Electric Power [W]

Average fan electric power consumed.

Fluid Cooler Fan Electric Consumption [J]

Total energy used by the fan. Consumption is metered on HeatRejection:Electricity, Electricity:Plant, and Electricity:Facility.

Fluid Cooler Heat Transfer [W]

This is the rate at which heat is removed from the condenser water loop by the fluid cooler.

Fluid Cooler Water Inlet Temperature [C]

Loop temperature at the fluid cooler inlet.

Fluid Cooler Water Outlet Temperature [C]

Loop temperature at the fluid cooler outlet.

Fluid Cooler Water Mass Flow Rate [kg/s]

Loop mass flow rate through the fluid cooler.

GroundHeatExchanger:Vertical

The Energy Plus Ground loop heat exchanger is a condenser component. This serves the condenser supply side in addition to the cooling towers and other condensing components. The following figure shows the Ground Heat Exchanger in the Energy Plus simulation environment.

The heat exchanger response is defined by a G-function. This is a non-dimensional function that is used to calculate the response to square heat pulses of different duration. (This function is not the same as 'G-factors' referred to in the ASHRAE Applications Handbook). This continuous function is specified by a series of data pairs (LNTTS_i, GFNC_i) where,

- LNTTS_i is the non-dimensional time: $\ln(T/T_s)$
- GFNC_i is the G-function value

The G-function is different for each borehole field configuration (i.e. a 4x4 field has a different response than a 80x80 field) and the borehole thermal resistance. It is also dependant on the ratio of borehole spacing to depth. G-function values, for accurate simulation, have to be calculated for each specific heat exchanger design. This can be done using some commercial ground loop heat exchanger design tool and the like. A reference data set, containing examples input data for 1x2, 4x4 and 8x8 configurations and for both standard and thermally enhanced grout, have also been provided. These data are provided as examples only.

Further details of the implementation of this model can be found in:

Murugappan, A. *Implementing Ground Source Heat Pump and Ground Loop Heat Exchanger Models in the EnergyPlus Simulation Environment*. M.S. Thesis, Oklahoma State University, December 2002.

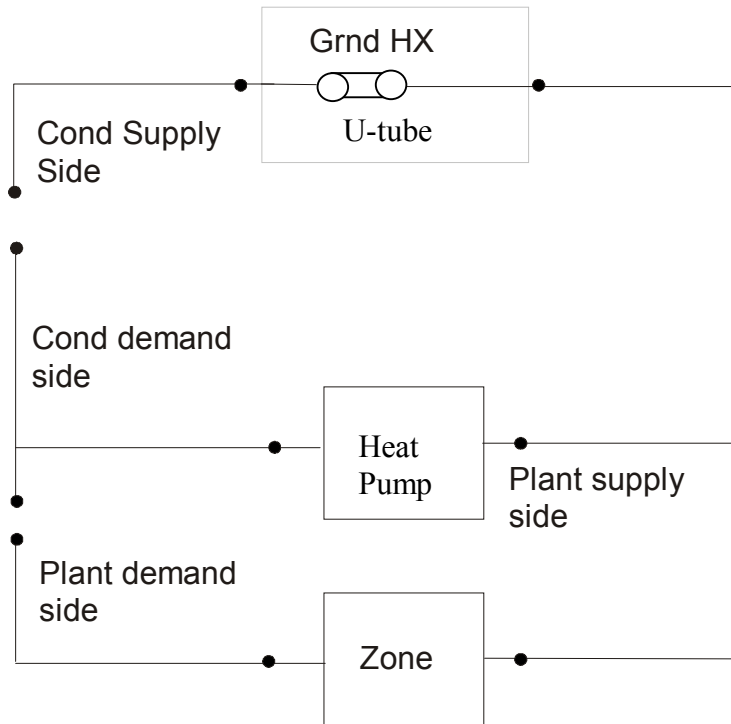

Figure 68. Schematic of EnergyPlus Ground Loop Heat Exchanger

The data definition for the ground loop heat exchanger from the Energy+.idd is shown below. The syntax to the specification of Borehole, U-tube and ground are illustrated in the example following.

Field: Name

This alpha field contains the identifying name for the ground heat exchanger (GHE).

Field: Inlet Node Name

This alpha field contains the ground heat exchanger inlet node name.

Field: Outlet Node Name

This alpha field contains the ground heat exchanger outlet node name.

Field: Maximum Flow Rate

This numeric field contains the GHE maximum design flow rate in cubic meters per seconds.

Field: Number of Bore Holes

This numeric field contains the number of bore holes in the GHE installation.

Field: Bore Hole Length

This numeric field contains the length of the borehole in meters.

Field: Bore Hole Radius

This numeric field contains the radius of the borehole in meters.

Field: Ground Thermal Conductivity

This numeric field contains the thermal conductivity of the ground in W/m-K.

FieldSet: Ground Thermal Heat Capacity

This numeric field contains the thermal heat capacity of the Ground. J/m³-K

Field: Fluid Thermal Heat Capacity

This numeric field contains the specific heat capacity of the U-tube fluid in J/kg-K.

Field: Ground Temperature

This numeric field contains the far field temperature of the ground in °C

Field: Design Flow Rate

This numeric field contains the design volumetric flow rate of the GHE.

Field: Grout Thermal Conductivity

This numeric field contains the thermal conductivity of the filler material in W/m-K.

Field: Pipe Thermal Conductivity

This numeric field contains the thermal conductivity of the pipe in W/m-K.

Field: Fluid Thermal Conductivity

This numeric field contains the thermal conductivity of the U-tube fluid in W/m-K.

Field: Fluid Density

This numeric field contains the density of the U-tube fluid in kilograms per cubic meter.

Field: Fluid Viscosity

This numeric field contains the viscosity of the U-tube fluid in N.s/m².

Field: Pipe Out Diameter

This numeric field contains the outer diameter of the U-tube (pipe) in meters.

Field: U-Tube Distance

This numeric field contains the distance between the two legs of the U-tube in meters.

Field: Pipe Thickness

This numeric field contains the outer diameter of the U-tube (pipe) in meters.

Field: Maximum Length of Simulation

This numeric field contains the maximum number of years of simulation to be carried out.

Field: Number of Data Pairs of the G Function

The borehole response is defined by a non-dimensional 'G-function'. This is specified as a series of data points giving values of non-dimensional time vs G-function value (LNTTS1, GFUNC1), (LNTTS2, GFUNC2), (LNTTS3, GFUNC3) (LNTTS_n, GFUNC_n), This numeric field contains the number of data pairs to be read in (*n*).

Field: G-Function $\ln(T/T_s)$ Value <x>

This numeric field contains the natural log of time/steady state time: $\ln(T/T_s)$

Field: G-Function 'G' Value <x>

This numeric field contains the G-function value of the corresponding LNTTS.

GroundHeatExchanger:Pond

The pond heat exchanger model represents a shallow pond with submerged hydronic tubes through which the heat transfer fluid is circulated. The model represents a 'shallow' pond in that no attempt is made to model any stratification effects that may be present in deeper ponds.

This type of heat exchanger is intended to be connected to the supply side of a condenser loop, and can be used with any type of plant loop. The pond may be specified as the only heat exchanger on the condenser loop (as shown in Figure 69) or it may be connected in parallel with other condenser loop heat exchangers (such as cooling towers, ground surface heat exchangers) as shown in the second figure below.

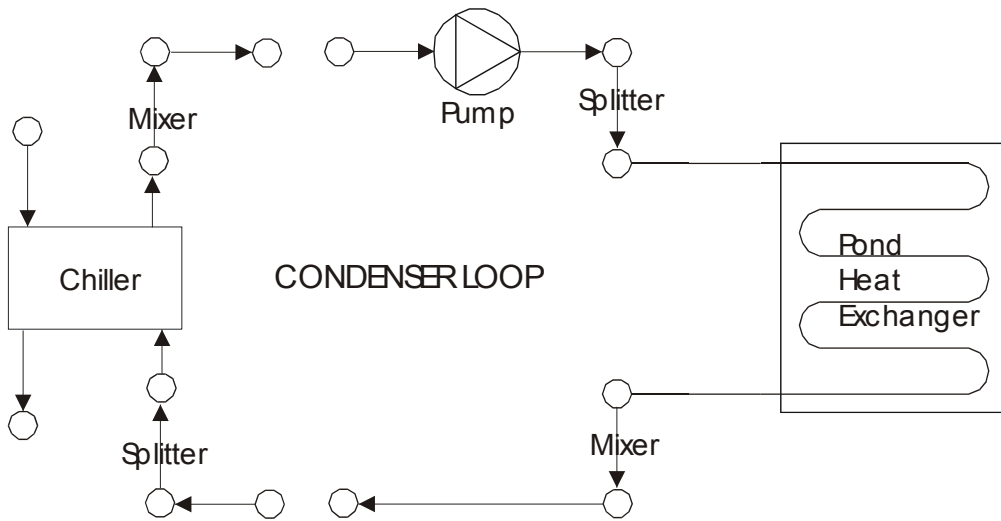

Figure 69. Example of Pond Ground Heat Exchanger as only heat exchanger on condenser loop

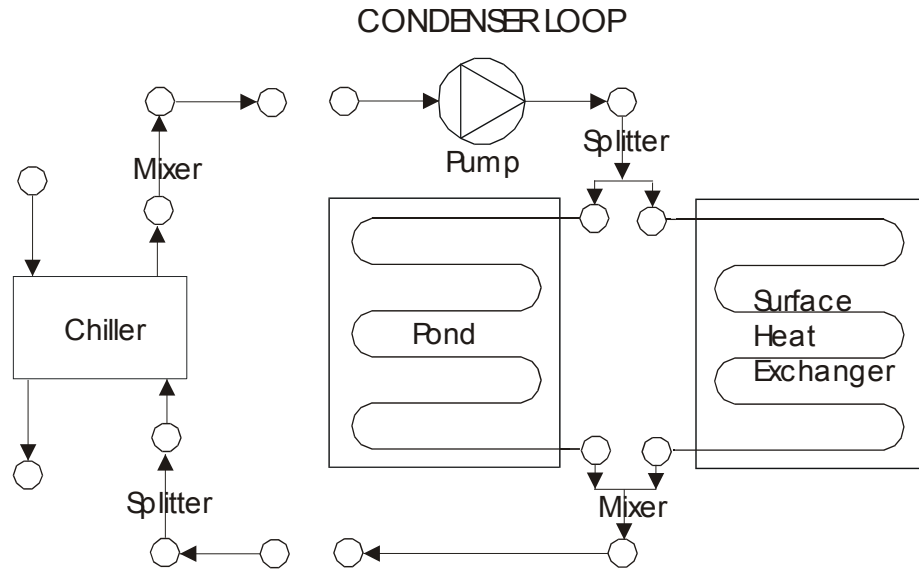

Figure 70. Pond Ground Heat Exchanger with other heat exchangers on condenser loop

Field: Name

This alpha field contains the identifying name for the outside pond heat exchanger.

Field: Fluid Inlet Node Name

This alpha field contains the fluid inlet node name.

Field: Fluid Outlet Node Name

This alpha field contains the fluid outlet node name.

Field: Fluid Name

This alpha field contains the fluid name. This name will be validated against Fluid Names (ref: Fluid Properties section below) in the input file.

Field: Fluid Glycol Concentration

This numeric field contains the fluid/glycol concentration in percentage.

Field: Pond Depth

This numeric field contains the pond depth {m}.

Field: Pond Area

This numeric field contains the pond area {m²}.

Field: Hydronic Tubing Inside Diameter

This numeric field contains the hydronic tubing inside diameter {m}.

Field: Hydronic Tubing Outside Diameter

This numeric field contains the hydronic tubing outside diameter {m}.

Field: Hydronic Tubing Thermal Conductivity

This numeric field contains the hydronic tubing thermal conductivity in W/mK.

Field: Ground Thermal Conductivity

This numeric field contains the ground thermal conductivity in W/m²K.

Field: Number of Tubing Circuits

This numeric field contains the number of hydronic tubing circuits, total in parallel in this pond..

Field: Length of Each Tubing Circuit

This numeric field contains length {m} of each hydronic tubing circuit.

```

```

Pond Ground Heat Exchanger Heat Transfer Rate [W]

Pond Ground Heat Exchanger Energy [J]

These outputs are the pond ground heat exchanger heat transfer rate and total energy exchange for the timestep.

Pond Ground Heat Exchanger Mass Flow Rate [kg/s]

Pond Ground Heat Exchanger Inlet Temp [C]

Pond Ground Heat Exchanger Outlet Temp [C]

These outputs are the pond fluid inlet and outlet temperatures and mass flow rate.

Pond Ground Heat Exchanger Bulk Temp [C]

This output is the pond bulk temperature.

GroundHeatExchanger:Surface

The surface heat exchanger model is to simulate hydronic surface ground heat exchangers. This includes pavement surfaces with embedded pipes for snow-melting or heat rejection from hybrid ground source heat pump systems.

The heat exchanger may be ground coupled or not. In the latter case the bottom surface is exposed to the wind but not solar gains. This type of heat exchanger is intended to be connected to the supply side of a condenser loop, and can be used with any type of plant loop. The surface heat exchanger may be specified as the only heat exchanger on the condenser loop (as shown in the first figure below) or it may be connected in parallel with other condenser loop heat exchangers (such as cooling towers, ground surface heat exchangers) as shown in the second figure below.

Figure 71. Example of Surface Ground Heat Exchanger as only heat exchanger on condenser loop

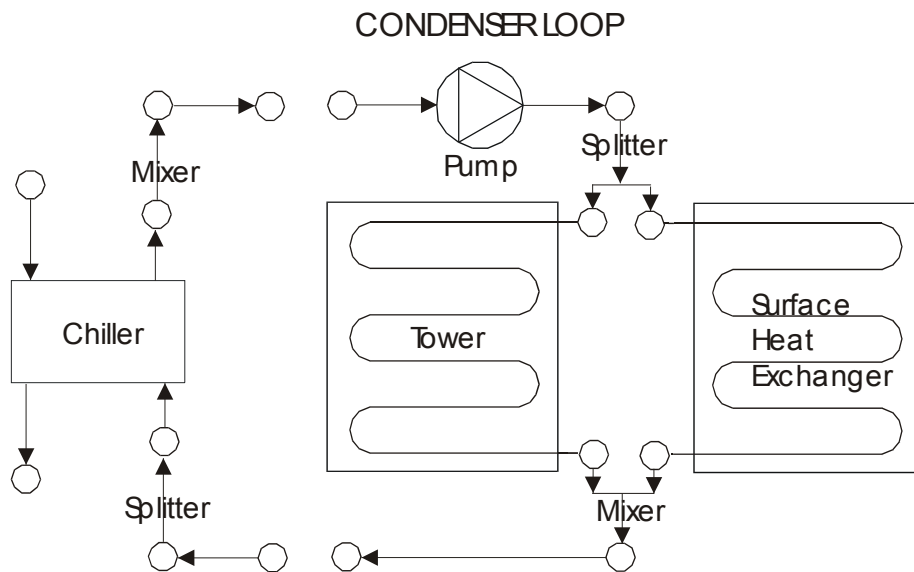

Figure 72. Surface Ground Heat Exchanger with other heat exchangers on condenser loop

Field: Name

This alpha field contains the identifying name for the outside panel heat exchanger.

Field: Construction Name

This alpha field contains the construction name. It must contain a valid "Construction" name that is usual for Surfaces. (Ref: Group – Surface Construction Elements).

Field: Fluid Inlet Node Name

This alpha field contains the fluid inlet node name.

Field: Fluid Outlet Node Name

This alpha field contains the fluid outlet node name.

Field: Fluid Name

This alpha field contains the fluid name. This name will be validated against Fluid Names (ref: Fluid Properties section below) in the input file.

Field: Hydronic Tubing Inside Diameter

This numeric field contains the hydronic tubing inside diameter in m.

Field: Number of Tubing Circuits

This numeric field contains the number of hydronic tubing circuits.

Field: Hydronic Tube Spacing

This numeric field contains the hydronic tube spacing in m.

Field: Surface Length

This numeric field contains the surface length in m.

Field: Surface Width

This numeric field contains the surface width in m.

Field: Lower Surface Environment

This alpha field expresses the lower surface exposure: Exposed or Ground.

Surface Ground Heat Exchanger Surface Energy [J]

This is the total surface energy exchange for the timestep.

Surface Ground Heat Exchanger Source Temp [C]

This is the surface heat exchanger source temperature.

HeatExchanger:Hydronic

This component is intended to be used in a condenser loop to simulate the effect of coupling the condenser and plant loops directly. For example, to bypass a chiller and couple the chilled water loop to the condenser loop so that the chilled water loop uses a cooling tower as its cooling source. This component is accordingly connected to both plant and condenser water loops (in a similar way to a chiller). The component acts to switch on and off the specified chiller/heat pump according to specified criteria (either a setpoint schedule, outside drybulb or wetbulb temperatures). The heat exchanger may be operated either in ideal or UA-effectiveness mode. In the UA-effectiveness mode the actual heat transfer between loops is calculated according to the UA-effectiveness method assuming counter flow. In ideal mode the maximum possible heat transfer is calculated. In this case, if both fluids are the same type and the loop flow rates are the same, operation is if the loops are directly coupled.

The specified plant component (chiller) is switched off and coupling enabled when either the drybulb, wetbulb or condenser loop temperature falls below the scheduled temperature. Any setpoint schedule can be specified. The usual way to operate a chiller would be to specify the schedule the same as the chilled water loop temperature and operate in 'loop' mode. In this way the loops would be connected when condenser water was available at or below the chilled water temperature.

The data definition for the free cooling heat exchanger from the Energy+.idd is shown below.

```
HeatExchanger:Hydronic,
    \memo A fluid/fluid heat exchanger designed to couple the plant loop to the condenser loop.
    \memo May be set as an ideal heat exchanger to emulate complete coupling of the loops.
    \memo May also be used as a 'real' heat exchanger using an U-Factor Times Area-Effectiveness
model.
    \memo For controlled free cooling a component on another branch (e.g. chiller) can
    \memo be switched on/off.

Field: Name

This alpha field contains the unique identifying name of this component.

Field: Controlled Component Name

This alpha field contains the unique identifying name of the component under the control of the heat exchanger (e.g. the corresponding chiller).

Field: Controlled Component Object Type

This alpha field contains the 'type' of the component under the control of the heat exchanger (e.g. Chiller:ConstantCOP).

Field: Setpoint Schedule Name

This alpha field contains the name of the setpoint schedule that is being used to control the heat exchanger.

Field: Condenser Inlet Node Name

This alpha field contains the name of the inlet node on the condenser loop.

Field: Condenser Outlet Node Name

This alpha field contains the name of the outlet node on the condenser loop.

Field: Plant Inlet Node Name

This alpha field contains the name of the inlet node on the plant loop.

Field: Plant Outlet Node Name

This alpha field contains the name of the outlet node on the plant loop.

Field: Condenser Loop Fluid Name

This alpha field contains the name of the fluid used in the condenser loop. The default is **Water**. This fluid name must be the same as defined in the loop specification and its data must be available from the input file.

Field: Plant Loop Fluid Name

This alpha field contains the name of the fluid used in the plant loop. The default is **Water**. This fluid name must be the same as defined in the loop specification and its data must be available from the input file.

Field: Free Cooling Control Mode

This alpha field determines the control mode. Free cooling (coupling) is enabled depending on the comparison of the scheduled temperature with the temperature defined here (drybulb, wetbulb or condenser loop). For example, specifying outside wetbulb here, free cooling would be enabled if the wetbulb temperature fell below the scheduled temperature. Options are: **DryBulbTemperature**, **WetBulbTemperature**, **Schedule**, or **Loop**. The default is Loop.

Field: Heat Exchanger Setpoint Schedule Name

This alpha field contains the name of the setpoint schedule for the heat exchanger.

Field: Heat Exchange Mode

The heat exchanger can operate as either an ideal heat exchanger (the max possible energy is transferred across the loops) or as specified by the UA and effectiveness. The options are correspondingly **Ideal** and **UFactorTimesAreaEffectiveness**. Effectiveness is calculated assuming counter-flow. The default is Ideal.

Field: U-Factor Times Area Value

This numerical field is used to specify the overall UA {W/K} for use in the calculation of actual heat transfer when in UFactorTimesAreaEffectiveness mode.

Field: Condenser Side Flow Rate

This numerical field is used to specify the design flow rate {m³/s} of this component on the condenser side. This would normally be the same as the loop/cooling tower flow rate.

Field: Plant Side Flow Rate

This numerical field is used to specify the design flow rate {m³/s} of this component on the plant side. This would normally be the same as the loop/chiller flow rate.

Field: Controlled Component Condenser Inlet Node Name

This alpha field contains the name of the inlet node on the condenser loop for the component being controlled by the heat exchanger.

Field: Controlled Component Condenser Outlet Node Name

This alpha field contains the name of the outlet node on the condenser loop for the component being controlled by the heat exchanger.

Field: Controlled Component Plant Inlet Node Name

This alpha field contains the name of the inlet node on the plant loop for the component being controlled by the heat exchanger.

Field: Controlled Component Plant Outlet Node Name

This alpha field contains the name of the outlet node on the plant loop for the component being controlled by the heat exchanger.

An example of the model's input from an idf file is shown below.

HeatExchanger:Plate

This component is intended to couple two condenser loops, so that the effect of connecting heating/cooling equipments in series in a branch can be achieved, as is the case required by some hybrid systems. The component is connected to the supply side of one condenser loop and to the demand side of the second condenser loop. The coupling and uncoupling of two loops is achieved based on control equipment defined in the input file. The heat exchanger can be a single component on a branch or can be connected to any other condenser equipment. The heat transfer is calculated as in the case of hydronic free cooling heat exchanger. The figure below shows a typical hybrid system, which uses a Plate heat exchanger to couple two condenser loops.

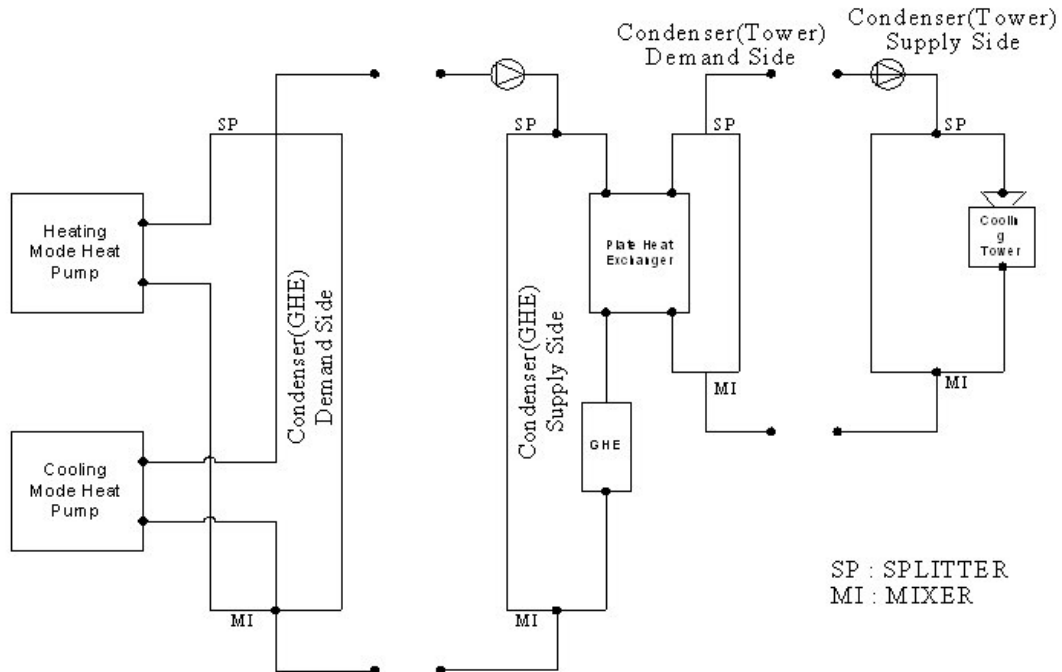

Figure 73. Plate Heat Exchanger (hybrid)

The data definition for the plate cooling heat exchanger from the Energy+.idd is shown below.

```
HeatExchanger:Plate,

Field: Name

This alpha field contains the unique identifying name of this component.

Field: Controlled Component Name

This alpha field is the name of the component, which allows the plate heat exchanger to decide whether the loops have to be coupled or not. If this component is ON, the loops are coupled else the loops are uncoupled.

Field: Controlled Component Object Type

This alpha field tells the type of the component with the name given in the previous field.

Field: Demand Side Inlet Node Name

This alpha field contains the name of the inlet node on the condenser demand side connected to the heat exchanger.

Field: Demand Side Outlet Node Name

This alpha field contains the name of the outlet node on the condenser demand side connected to the heat exchanger.

Field: Supply Side Inlet Node Name

This alpha field contains the name of the inlet node on the Condenser supply side connected to the heat exchanger.

Field: Supply Side Outlet Node Name

This alpha field contains the name of the outlet node on the Condenser supply side connected to the heat exchanger.

Field: Demand Side Loop Fluid Name

This alpha field contains the name of the fluid used in the Demand side of heat exchanger. The default is **Water**. This fluid name must be the same as defined in the loop specification and its data must be available from the input file.

Field: Supply Side Loop Fluid Name

This alpha field contains the name of the fluid used in the Supply side of heat exchanger. The default is **Water**. This fluid name must be the same as defined in the loop specification and its data must be available from the input file.

Field: Heat Exchange Mode

The heat exchanger can operate as either an ideal heat exchanger (the max possible energy is transferred across the loops) or as specified by the UA and effectiveness. The options are correspondingly **Ideal** and **UFactorTimesAreaEffectiveness**. Effectiveness is calculated assuming counter-flow. The default is Ideal.

Field: U-Factor Times Area Value

This numerical field is used to specify the overall UA for use in the calculation of actual heat transfer when in UFactorTimesAreaEffectiveness mode.

Field: Demand Side Flow Rate

This numerical field is used to specify the design flow rate of this component on the Demand side. This would normally be the same as the loop/cooling tower flow rate.

Field: Supply Side Flow Rate

This numerical field is used to specify the design flow rate of this component on the Supply side. This would normally be the same as the loop flow rate.

An example of the model's input from an idf file is shown below.

```

HeatExchanger:WatersideEconomizer

The heat exchanger model designed primarily to support the simulation of plant waterside economizers, but is also suitable for other plant applications. Three types of heat exchangers can be selected: 1.) Plate frame, 2.) Single pass counter-flow and 3.) Single pass parallel-flow. The heat transfer rate is calculated using the UA-effectiveness method. An appropriate effectiveness-NTU correlation is used for each type of heat exchanger. The maximum possible heat transfer rate can be used in the simulation by specifying an **Ideal** heat exchanger. For this case an effectiveness of 1.0 is used.

The data definition for the water-to-water heat exchanger is shown below.

```

Field: Name

This alpha field contains the unique identifying name of this component.

Field: Heat Exchanger Type

This alpha field identifies the type of heat exchanger. Heat exchanger type is specified by one of the following key words:

PlateFrame: specifies a plate-frame heat exchanger. The effectiveness will be calculated using a plate frame heat exchanger correlation. Currently this type of heat exchanger is approximated as cross flow with both streams unmixed

CounterFlow: specifies a counter-flow shell and tube heat exchanger. The effectiveness will be calculated using a counter-flow shell and tube heat exchanger correlation.

ParallelFlow: specifies a parallel-flow shell and tube heat exchanger. The effectiveness will be calculated using a parallel-flow shell and tube heat exchanger correlation.

Ideal: specifies an ideal heat exchanger. The effectiveness will be set to '1.0' and the specified UA will be ignored. The heat transfer rate will be calculated as the maximum possible heat transfer rate.

Field: Availability Schedule Name

Name of the availability schedule for this heat exchanger.

Field: Chilled Water Inlet Node Name

This alpha field contains the name of the heat exchanger inlet node connected to chilled water . In typical water side economizer applications this is the Plant loop.

Field: Chilled Water Outlet Node Name

This alpha field contains the name of the heat exchanger outlet node connected to chilled water . In typical water side economizer applications this is the Plant loop.

Field: Condenser Inlet Node Name

This alpha field contains the name of the heat exchanger inlet node connected to the condenser . In typical water side economizer applications this is the Condenser loop.

Field: Condenser Outlet Node Name

This alpha field contains the name of the heat exchanger outlet node connected to the condenser . In typical water side economizer applications this is the Condenser loop.

Field: Chilled Water Loop Fluid Name

This alpha field contains the Fluid circulating in Chilled Water Loop. The default is Water.

Field: Condenser Loop Fluid Name

This alpha field contains the Fluid circulating in the Condenser Loop. For air cooled condenser this field has to be set to Air. The default is Water.

Field: Chilled Water Side Maximum Flow Rate

This numerical field is used to specify the design (maximum) flow rate {m³/s} for the side of the heat exchanger connected to chilled water loop.

Field: Condenser Side Maximum Flow Rate

This numerical field is used to specify the design (maximum) flow rate {m³/s} for the side of the heat exchanger connected to the Condenser Loop.

Field: Heat Exchanger U-Factor Times Area Value

This numerical field is used to specify the overall U-Factor Times Area (UA) {W/K} for use in the calculation of the heat exchanger effectiveness using the appropriate Δ-NTU correlation. If **Ideal** is specified as the heat exchanger type, the effectiveness will be set to 1.0. When set to autosize Heat Exchanger U-Factor Times Area Value is calculated based on an effectiveness of 1.0

Field: Minimum Temperature Difference to Activate Heat Exchanger

This numerical field is the minimum temperature difference between chilled water side heat exchanger inlet and condenser side heat exchanger inlet required to turn on heat exchanger.

An example of the model's input from an idf file is shown below.

The inlet and outlet temperatures on each side of the component.

Group – Plant-Condenser Flow Control

The connector list described earlier determines how the branches of a particular loop will be hooked together. These connections can be classified either as a separation of a single stream into several outlet streams (splitter) or the merging of several streams into a single outlet stream (mixer). Due to the limitation per branch of a single splitter and a single mixer, the connector list can only have two pieces of equipment as a maximum. The names defined for either/both the splitter or/and the mixer refer then to “component” definitions as described below.

Connector:Splitter, Connector:Mixer

```
Connector:Splitter,
\min-fields 3
  \extensible:1 Just duplicate last field and \ comments (changing numbering, please)
  \memo Split one air/water stream into N outlet streams. Branch names cannot be duplicated
  \memo within a single Splitter list.

    \object-list Branches
reduced for brevity, object is extensible
```

```

Connector:Mixer,
  \min-fields 3
  \extensible:1 Just duplicate last field and \ comments (changing numbering, please)
  \memo Mix N inlet air/water streams into one. Branch names cannot be duplicated within
  \memo a single mixer list.
A1 , \field Name
  \required-field
A2 , \field Outlet Branch Name
  \required-field
  \type object-list
  \object-list Branches
A3 , \field Inlet Branch 1 Name
  \required-field
  \type object-list
  \object-list Branches
A4 , \field Inlet Branch 2 Name
  \type object-list
  \object-list Branches
reduced for brevity, object is extensible

```

The format of both the **Connector:Splitter** and **Connector:Mixer** statements is similar. Both begin with an identifying name followed by the branch name of the “single side” of the component. In the case of the splitter, this is the inlet since the inlet stream is broken into several outlet streams. In the case of the mixer, this is the outlet since several streams are mixed together to form a single outlet. The remaining list of up to 50 names is simply the branch names of the outlet legs in the case of the splitter and inlet legs in the case of the mixer. No control logic is assume in these components—a determination of how much air to split in which direction using the splitter must be defined by other components.

Connector:Splitter

Field: Name

This alpha field contains the identifying name for the Splitter.

Field: Inlet Branch Name

This alpha field contains the identifying name for the Splitter Inlet Branch.

Field: Outlet Branch <x> Name

This alpha field contains the identifying names for the Splitter Outlet Branches and you enter as many outlet branches as needed.

Connector:Mixer

Field: Name

This alpha field contains the identifying name for the Mixer.

Field: Outlet Branch Name

This alpha field contains the identifying name for the Mixer Outlet Branch.

Field: Inlet Branch <x> Name

This alpha field contains the identifying names for the Mixer Inlet Branches and you enter as many inlet branch names as needed..

An example of these statements in an IDF is:

```
Connector:Splitter,  
    CW Loop Splitter,  
    CW Pump Branch,  
    Little Chiller Branch,  
    Big Chiller Branch,  
    Purchased Cooling Branch,  
    Supply Bypass Branch;  
Connector:Mixer,  
    CW Loop Mixer,  
    Cooling Supply Outlet,  
    Little Chiller Branch,  
    Big Chiller Branch,  
    Purchased Cooling Branch,  
    Supply Bypass Branch;
```

TemperingValve

This object is used for special cases where plant flow control is needed to make efficient use of thermal storage. In certain solar hot water and heat recovery situations, a thermal storage tank may become warmer than is necessary or allowable for safe use of the hot water. Although real installations of a tempering, or anti-scald valve, would more commonly mix a new stream of mains water with the hot water to achieve a desired outlet temperature, this is difficult to model directly within EnergyPlus because plant loops need to be closed circuits. For many installations where the water entering the splitter is directly from the mains, such as make up water entering a water heater tank, the modeling provided with this object should be thermodynamically equivalent.

The TemperingValve object models a temperature-controlled diversion valve. It models a valve on a bypass pipe that can open to divert flow around one or more plant components. It can only be used on one of two branches between a Splitter and a Mixer. The figure below shows the use of the tempering valve with a Water Heater:Mixed component on "Stream 2." The tempering valve acts to divert flow through the branch it is on in order to adjust the temperature at the outlet of the mixer. If the temperature at Stream 2 Source Node is warmer than the setpoint and the inlet flow is cooler than the setpoint, then a controller determines how much flow should bypass the storagew tank to achieve the desired setpoint.

Figure 74. Tempering Valve Schematic

The TemperingValve is an **Active** component and the other path should have only **Passive** components. Only two paths in the splitter/mixer can be used; bypasses are not allowed. No other Connector:Splitter and Connector:Mixer pair can be used on the supply side of the plant loop.

Field: Name

This field should contain an unique name for each TemperingValve object

Field: Inlet Node Name

This field should contain the name of node which is the inlet for the valve.

Field: Outlet Node Name

This field should contain the name of node which is the outlet for the valve

Field: Stream 2 Source Node Name

This field should contain the name of node that is the inlet to the Mixer object for the second stream containing the component whose flow is being diverted.

Field: Temperature Setpoint Node Name

This field should contain the name of a node that has a temperature setpoint assigned to it. A separate set point manager object is needed to provide a set point on the node listed here.

Field: Pump Outlet Node Name

This field should contain the name of the node that is the outlet for the pump that is one the same plant loop. This is node is used to sense the total flow rate.

The idd entry for this object is:

```

TemperingValve,
  A1, \field Name
      \required-field
      \type alpha
  A2, \field Inlet Node Name
      \required-field

    DHW Use Side Pump Outlet; ! pump outlet node

```

Tempering Valve Outputs

Use report variables for System Nodes for flow and temperature results.

Group – Air Distribution

AirLoopHVAC

Air loops along with zone equipment form the entire forced air heating and cooling system (air side). The main statement for defining an air loop is the *AirLoopHVAC* object described here. As with the main plant and condenser statements, several of the items in the *AirLoopHVAC* object definition are actually names that refer to other objects in the input file. After the *AirLoopHVAC* object name, four such list pointers are encountered: for controllers, system availability, branches, and connectors. The Controller List defines how the air loop will respond due to various inputs (control signals). The Availability Manager List refers to methods for controlling when a system is operational. This may be as simple as a schedule to define when the system is shutdown. The Branch List lists the branches that comprise the primary air system. Finally, the Connector List lists the connections between the branches. The branches and connections together define the primary air system topology.

The only numeric input is the design primary air flow rate. This item is input just before the BranchList name.

The next series of names refer to nodes for the various inlet and outlet points of the air loop. The air loop starts where the zone equipment ends. This is a single point consisting of the return air duct once all of the zone return air streams have been collected. While in reality, there is really only one point, for clarity within the simulation components and consistency with the other HVAC loop sections, this point in the systems is defined as two points: one that resides with the zone equipment simulation and one that is acted upon by the air loop simulation. Both node names must be entered into the input file, and both nodes must have

unique names. Similarly, the end points of the air loop that also correspond to the beginning points of the zone equipment loop must also be defined. These consist of names referencing lists of up to three pairs of node names as shown below. Up to three air loop outlets are allowed to accommodate the simulation of three deck systems.

Field: Name

This field is a unique, user assigned name for a single instance of an AirLoopHVAC object. Any other object referencing this AirLoopHVAC will use this name.

Field: Controller List Name

This field is the name of a ControllerList object. A Controller List is simply a list of controllers giving both controller name and type. This Controller List specifies all the controllers that will act on this primary air loop. The order of the controllers in the list is significant: controllers are simulated sequentially in the order given in the Controller List.

Field: Availability Manager List Name

This field is the name of a AvailabilityManagerList object. A Availability Manager List is a list of Availability Managers giving both Availability Manager type and name. The availability managers in the list apply to this primary air loop. That is, they determine when and if this air loop is on or off, overriding the control provided by the central fan on/off schedule.

Field: Design Supply Air Flow Rate

This is the system primary air design volumetric flow rate in cubic meters per second.

Field: Branch List Name

This field is the object name of a BranchList object (see BranchList and Branch). The BranchList named here specifies all the branches composing the primary air system. These branches, together with the Connectors listed in the ConnectorList, define the primary air system topology.

Field: Connector List Name

This field is the name of ConnectorList object. This ConnectorList object lists all the Connectors (by type and name) that are included in this primary air system. These Connectors, together with the Branches in the BranchList, define the topology of the primary air system.

Field: Supply Side Inlet Node Name

The name of the air entrance node of this primary air system. This is the inlet node for return air for this air system.

Field: Demand Side Outlet Node Name

The name of the air outlet node for the zone equipment group (ZoneHVAC:EquipmentConnections objects) attached to the primary air system. This should be the outlet node of a AirLoopHVAC:ZoneMixer in the AirLoopHVAC:ReturnPath for the zone equipment group attached to this primary air system.

Field: Demand Side Inlet Node Names

This field can be the name of a node which is the air inlet node for the zone equipment group (see ZoneHVAC:EquipmentConnections objects) attached to this primary air system. Or, this field can be the name of a node list containing one or more nodes (up to 3). These nodes should be the inlet nodes to the AirLoopHVAC:ZoneSplitter or AirLoopHVAC:SupplyPlenum in each of the AirLoopHVAC:SupplyPaths for the zone equipment groups attached to this primary air system. For single duct systems, there is only one node name in this list. For two and three duct systems, the order of the nodes in this list must correspond with the order of the nodes in the Supply Side Outlet Node Names list.

Field: Supply Side Outlet Node Names

This field can be the name of a node which is the air outlet node for each supply duct of this primary air system. Or, this field can be the name of a node list containing one or more nodes (up to 3). The list can contain the names of up to three nodes. For single duct systems, there is only one node name in this list. For two and three duct systems, the order of the nodes in this list must correspond with the order of the nodes in the Demand Side Inlet Node Names list.

The IDD specification:

```
AirLoopHVAC,
  \min-fields 10
  \memo Defines a central forced air system

```

AirLoopHVAC Outputs

```
HVAC,Average,Air Loop System Cycle On/Off Status
```

Air Loop System Cycle On/Off Status

This field is the availability status of an AirLoopHVAC. This status flag is a result of the calculations made by the System Availability Manager(s) listed in a System Availability Manager List. When a single availability manager is used in a System Availability Manager List, this is also the availability status reported by the specific availability manager (Ref. System Availability Manager Outputs). When multiple availability managers are used in a System Availability Manager List, the loop availability status is determine by the rules associated with AirLoopHVACs (see rules described for Group – System Availability Managers). The control status outputs are represented using integers 0 through 3.. These integers represent *NoAction* (0), *ForceOff* (1), *CycleOn* (2), and *CycleOnZoneFansOnly* (3). Since the status output is averaged, the output result may not correspond to the values described here when report variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Report Variable) to view the availability status at each simulation timestep.

A map for Air Loop input syntax is shown in the following diagram.

Air Loop Input Structure/Map

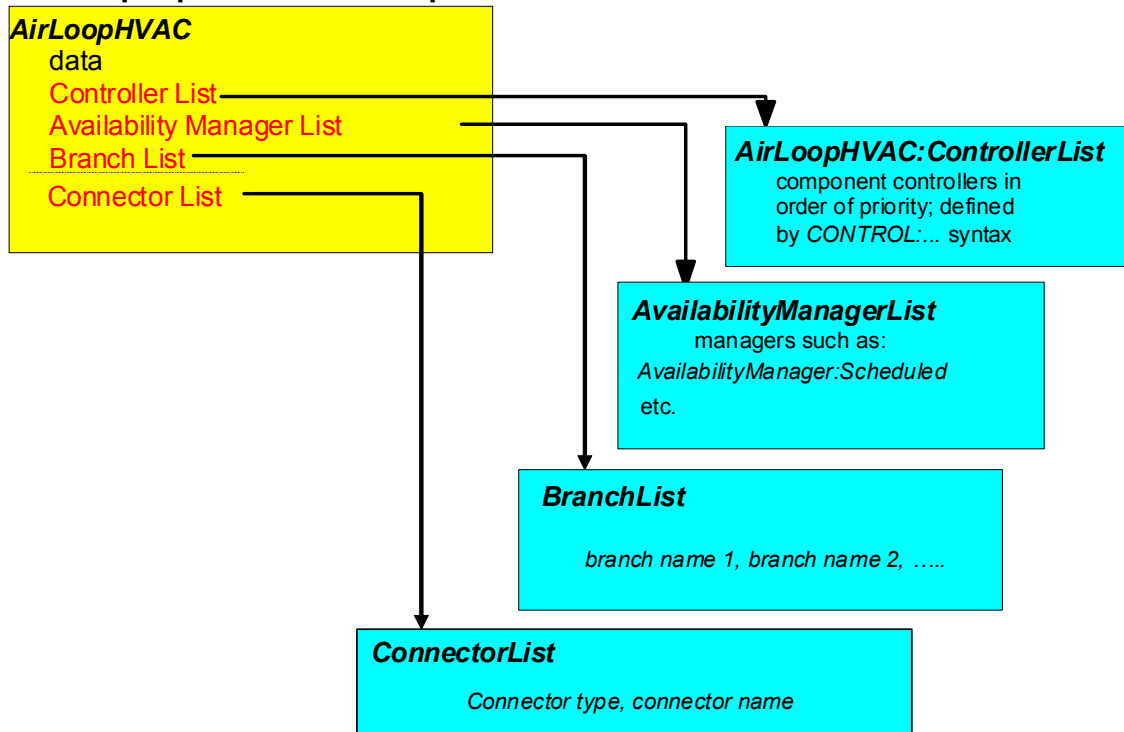

Figure 75. Air Loop Input Syntax Map

AirLoopHVAC:ControllerList

The syntax for the AirLoopHVAC:ControllerList definition is shown below. As with other lists in EnergyPlus input, the object title and identifying name are followed by type-name pairs. In this case, the types are controller types. The order in which controllers appear on this list also define the priority as described below. The identifying name refers back to the name recorded in the AirLoopHVAC statement.

Field: Name

The user designated unique name of an instance of a Controller List. Any object referencing this Controller List will do so using this name.

Field Set (Object Type, Controller Name) up to 8

After the identifying name, input for the controller list consists of up to 8 pairs of data items: a controller type and a controller name. The first controller listed has the highest priority, the second the second highest priority, and so forth.

Field: Controller <x> Object Type

The type of controller. This should be a key word defining a class of controllers such as Controller:WaterCoil.

Field: Controller <x> Name

The name of a controller object (such as a Controller:WaterCoil) defined elsewhere in the input file.

The IDD specification:

```
AirLoopHVAC:ControllerList,
  \memo List controllers in order of control sequence
A1 , \field Name
    \required-field
    \type alpha
    \reference ControllerLists
A2 , \field Controller 1 Object Type
    \required-field
    \type choice
    \key Controller:WaterCoil
    \key Controller:OutdoorAir
A3 , \field Controller 1 Name
    \required-field
    \type object-list
    \object-list AirLoopControllers
A4 , \field Controller 2 Object Type
    \type choice
    \key Controller:WaterCoil
    \key Controller:OutdoorAir
-- etc to # of controller sets entered
```

An example of this statement in an IDF is:

```
AirLoopHVAC:ControllerList,
  Dual Duct System 1 Controllers,
  Controller:WaterCoil, Main Cooling Coil Controller,
  Controller:WaterCoil, Main Heating Coil Controller;
```

The AvailabilityManagerAssignmentList defines the applicable managers used for an AirLoopHVAC or PlantLoop. The priority of availability managers is based on a set of rules and are specific to the type of loop. The output from each Availability Manager is an availability status flag. This flag can have the values *NoAction*, *ForceOff*, *CycleOn*, or *CycleOnZoneFansOnly* (used only for air loops). The availability status flags for the Availability Managers referenced by an air or plant loop are used to set the availability status flag for each loop. For the air loops, *ForceOff* takes precedence: if any of the loop's availability managers are showing status *ForceOff*, the loop status will be *ForceOff*. Next in precedence is *CycleOnZoneFansOnly*, followed by *CycleOn*, and *NoAction*. For the plant loops, there is no precedence among the Availability Manager status flag values. Instead, the first availability manager giving a status flag value other than *NoAction* sets the status for the loop. The Availability Managers are executed in Availability Manager List order.

Special rules also apply for which managers may be listed in a Availability Manager list. The Hybrid Ventilation Control Manager (object: AvailabilityManager:HybridVentilation) is a special type of manager and is never specified in a Availability Manager List (it is used stand-alone for a specific air loop). All other types of availability managers may be listed in the Availability Manager List used for AirLoopHVACs. For Plant Loops, the Night Cycle and Night

Ventilation managers (objects: AvailabilityManager:NightCycle and AvailabilityManager:NightVentilation) are not allowed in the Availability Manager List.

Field: Name

The name of the AvailabilityManagerAssignmentList object. This is referenced by AirLoopHVAC and PlantLoop objects.

Field Set (Availability Manager Object Type, Name)
